Poster Session

#0001 Synapse.org as a foundational platform supporting multicenter cancer data coordination, benchmarking, and broad community reuse.

Adam Taylor, Gaia Andreoletti, Robert Allaway, Jineta Banerjee, Orion Banks, Angie Bowen, Kevin Boske, Aditi Gopalan, Ashley Clayton, Xindi Guo, Savitha Sangameswaran, Amber Nelson, Aditya Nath, Milen Nikolov, Anh Nguyet Vu, Ziwei Pan, Alex Paynter, Chelsea Nayan, Thomas Yu, Bishoy Kamel, Serghei Mangul, Alberto Pepe, Luca Foschini, Susheel Varma

Sage Bionetworks, Seattle, WA

Collaborative cancer research requires a shared data infrastructure that functions across institutions, modalities, and funders. Synapse.org, developed by Sage Bionetworks, is a versatile public data platform used by research consortia, real-world data efforts, and computational challenges. We describe the use of Synapse to support diverse cancer research communities.
Synapse provides tools for validated metadata, provenance, versioning, and fine-grained access control. For supported communities we provide curation and validation apps, domain-specific portals, dashboards, and challenge frameworks. APIs and clients connect Synapse to local compute and trusted research environments (Cavatica, Terra, Pluto, SevenBridges CGC) via GA4GH DRS. Recent enhancements include human-guided, AI-powered curation, OpenSearch-based discovery, and natural-language data search. Data arrive through contributor uploads (web, CLI, APIs), programmatic ETL pipelines, and indexing of external repositories (GEO, dbGaP).. Curated datasets are indexed for discovery and surfaced through program portals. Community use and feedback guide curation priorities, maintaining a continuous improvement cycle.
The Synapse platform hosts >3.6 PB data used by >6,000 monthly users. The Cancer Complexity Knowledge Portal links 160 grants, 4,178 publications, 1,039 datasets, and 321 tools focused on cancer biology. The Human Tumor Atlas Network DCC manages 334 TB of harmonized omics data (0.23M files from 2,372 cases and 11,378 biospecimens across >60 diseases and 25 assays), with >2,500 annual users. The NF Data Portal integrates over 200 TB data from 312 neurology and oncology studies, and catalogues >1,100 tools spanning NF1, NF2, and schwannomatosis. As part of the coordinating center for AACR Project GENIE we have supported the ETL and sharing of clinico-genomic data from 19 centers, including 211,527 patients and 250,018 samples. DREAM cancer challenges run on Synapse have established benchmarks including in AML subtyping, prostate cancer survival, immunotherapy response and digital mammography. Independent Synapse users have contributed >1.2M public files (>95 TB) across 400+ cancer-related projects.
A user-friendly generalist data platform and a set of proven data coordination and challenge operations lower the activation energy for new cancer collaborations, from independent projects to large, multi-institutional networks. We invite researchers to explore Synapse.org and our data portals.
AI was used to summarize metrics and refine wording Authors reviewed and approved all content.

#0002 Variant interpretation web services for precision oncology: Genome Nexus and reVUE.

Xiang Li[1], Alexandria Dymun[1], Benjamin Preiser[1], Reshma Ramaiah[1], Allison Richards[1], Walid Chatila[1], Moriah Nissan[1], Amanda Dhaneshwar[2], Sara E. DiNapoli[3], Erika Gedvilaite[1], Thomas Y. Cong[4], Hongxin Zhang[5], Bryan Lai[1], Selcuk Onur Sumer[1], Aditi Gopalan[6], Tonatiuh Gonzalez[7], Madelaine Rangel[8], Trevor J. Pugh[9], Rose Brannon[1], Michael Berger[1], Debyani Chakravarty[1], Nikolaus Schultz[1], Jianjiong Gao[1], Ino de Bruijn[1]

[1]Memorial Sloan Kettering Cancer Center, New York, NY,[2]St. John's University, New York, NY,[3]Melanoma Research Alliance, New York, NY,[4]Massachusetts Institute of Technology, Cambridge, MA,[5]Oracle, New York, NY,[6]Sage Bionetworks, New York, NY,[7]Weill Cornell Grad. School of Medical Sci., New York, NY,[8]University of Rochester Medical Center, Rochester, NY,[9]UHN Princess Margaret Cancer Centre, Toronto, ON, Canada

Accurate interpretation of genomic alterations is essential for precision oncology, yet variant information remains dispersed across heterogeneous resources. To streamline access to high-quality annotations, we present recent advancements to Genome Nexus (genomenexus.org) and reVUE (cancerrevue.org), two complementary open-source web services that together provide an integrated ecosystem for interpreting both canonical and atypical cancer variants.

Genome Nexus aggregates functional, structural, population, and clinical evidence from a broad collection of cancer- and genome-focused databases. Through a unified API and intuitive interface, it harmonizes variant effect predictions, protein annotations, variant population frequencies, mutational hotspot and driver information, and clinical actionability from resources such as VEP, UniProt, Pfam, gnomAD, Cancer Hotspots, CIViC, OncoKB, and ClinVar. Recent enhancements include improved selection of canonical transcripts for routine clinical cancer care, expanded handling of transcript versioning, and optimized annotation performance. Genome Nexus enables high-throughput variant annotation, supports interactive browsing, and is integrated into cBioPortal and used by AACR Project GENIE.

A subset of genomic alterations exhibit variants with unexpected effects (VUEs), whose molecular consequences diverge from those predicted by standard annotation rules. These variants are frequently mis-annotated despite documented functional evidence in the literature. To address this gap, we developed reVUE, an open-source curated repository and API cataloging experimentally validated VUEs, including therapeutically relevant alterations in genes such as KIT, MET, ATM, EGFR, and BRCA1/2. The resource continues to expand, with several newly curated VUEs added across multiple cancer-associated genes. reVUE is fully integrated into Genome Nexus, ensuring that both predictable and atypical variant effects are captured within a unified interpretation workflow.

Together, Genome Nexus and reVUE advance the accuracy and completeness of cancer variant interpretation by consolidating diverse evidence sources, incorporating expert-curated annotations for complex variant classes, and providing scalable programmatic access. As open-source resources, they support transparent, reproducible, and extensible workflows that enhance precision oncology research and clinical reporting.

#0003 Evaluation of an agentic LLM chatbot for clinico-genomic analysis of AACR GENIE BPC data.

Likhita Thiriveedi, Kenneth L. Kehl

Dana-Farber Cancer Institute, Boston, MA

Purpose
The significant volume and complexity of genomic and clinical data can hinder efficient research based on clinico-genomic datasets, requiring manual effort and specialized expertise. Agentic large language model (LLM) workflows may help accelerate data processing, but the performance of existing LLMs for this task is not well-characterized.
Methods
An agentic large language model-based chatbot was developed to leverage the Gemini-2.5-pro LLM to interpret oncology research queries and autonomously execute sequential analytic tasks based on the AACR GENIE BPC NSCLC cohort (version 2.0 public). The LLM's performance was assessed against a curated benchmark set of 125 expert-reviewed clinical and genomic questions derived from a published study (https://pubmed.ncbi.nlm.nih.gov/37223888/), with accuracy defined as numerical concordance within ±10% of manuscript-reported reference values.
Results
The chatbot was used to ask 118 questions manually extracted from the publication, including questions broadly categorized as quantifying cohort sizes (n=92) or conducting statistical analyses (n=26). The overall accuracy rate was 42.37%. Inaccurate responses were manually reviewed and assigned to the following categories: no obvious source of error or discrepancy (33.8%), where 39.1% of these deviated < 20% from the reference value; chatbot reasoning faulty (36.8%); chatbot failed to clarify a concept in the user question (22.1%); reference publication analysis insufficiently specified to replicate (7.4%); user error in response to chatbot (4.4%); chatbot did not interpret analysis question as intended (1.5%); and unclear/other (1.5%).
Conclusion
Agentic LLM data analysis workflows hold potential for automating components of oncology data interpretation, but current performance limitations, attributable to inconsistent reasoning, incomplete clarification of clinical concepts, and a need for clear specification of published analysis plans for reproducibility and evaluation, highlight the need for further model refinement in these specific areas before these systems can be reliably integrated into real-world clinical research pipelines.

#0004 A multi-agent conversational artificial intelligence ecosystem for real-time integration of clinical, genomic, and social determinants of health data in colorectal cancer precision oncology.

Enrique Velazquez-Villarreal[1], Brigette Waldrup[2]

[1]Integrative Transaltional Sciences, City of Hope Comprehensive Cancer Ctr., Duarte, CA,[2]Integrative Translational Sciences, Beckman Research Institute, City of Hope, Duarte, CA

Introduction: The rapid expansion of clinical, genomic, and social determinants of health (SDoH) data has outpaced traditional analytic approaches, creating an urgent need for intelligent systems capable of integrating and interpreting complex oncology datasets at scale. To address this challenge, our team developed a suite of domain-specific conversational AI agents that enable real-time, natural language-driven exploration of multi-omic colorectal cancer (CRC) data. These agents facilitate discovery of population-specific molecular alterations and treatment-response patterns.

Methods: Each agent leverages fine-tuned biomedical LLaMA-3 models, a natural language-to-code interpreter, and a backend statistical engine linked to harmonized datasets from TCGA, AACR Project GENIE, and cBioPortal. The platform automates cohort creation, mutation profiling, survival analysis, odds ratio testing, and integration of clinical and SDoH variables. Specialized agents include AI-HOPE-PI3K, TGFβ, TP53, RTK-RAS, JAK-STAT, MAPK, WNT, and AI-HOPE-PM, the latter uniquely integrating clinical, genomic, and SDoH features. A core agent maintains data interoperability across the ecosystem. All analyses are triggered by plain-language prompts and return visual and narrative outputs within seconds.

Results:AI-agents successfully reproduced established clinical-genomic associations and uncovered novel, clinically meaningful insights. AI-HOPE-PI3K identified INPP4B mutations enriched in Hispanic/Latino early-onset CRC; AI-HOPE-TGFβ detected MSI-associated survival benefits in SMAD4-mutant tumors; and AI-HOPE-PM revealed worse survival in TP53-mutant CRC cases experiencing financial strain, along with differences in chemotherapy access linked to food insecurity. Additional agents identified prognostic variation across stage, treatment exposure, and demographic groups within MAPK, RTK-RAS, and WNT pathways. Accuracy exceeded 90% across use cases, with all analyses completed in real time without requiring programming expertise.

Conclusions: Multi-agent conversational artificial intelligence ecosystem provides a scalable, interoperable, and population-informed multi-agent architecture for precision oncology. Development of Agent-to-Agent (A2A) and Modular Collaborative Protocols (MCPs) will enable coordinated, cross-domain analysis and hypothesis generation, advancing a collaborative AI ecosystem for cancer research. By unifying clinical, molecular, and SDoH data under a conversational interface, AI-agents ecosystem introduces a new paradigm for data intelligence, accelerates biomarker discovery, and supports population-informed precision oncology across populations.

#0005 Artificial intelligence-driven precision medicine identifies prognostic WNT pathway alterations in African American colorectal cancer patients treated with FOLFOX.

Tsion Z. Minas[1], Brigette Waldrup[2], Francisco G. Carranza[2], Sophia Manjarrez[2], **Enrique Velazquez-Villarreal**[3]

[1]Department of Pathology, Johns Hopkins School of Medicine, Baltimore, MD,[2]Integrative Translational Sciences, Beckman Research Institute, City of Hope, Duarte, CA,[3]Integrative Translational Sciences, City of Hope Comprehensive Cancer Ctr., Duarte, CA

Background: African Americans (AA) experience disproportionate burden of colorectal cancer. Dysregulation of the Wingless-related integration site (WNT) and transforming growth factor-beta (TGF-β) pathways contributes to tumor progression, yet their prognostic roles in FOLFOX-treated CRC among AA patients remain understudied.
Methods: We analyzed 2,562 colorectal cancer cases stratified by ancestry, age at onset, and FOLFOX treatment using Fisher's exact, chi-square, and Kaplan-Meier analyses from AACR Project GENIE andcBioPortal databases. To enhance data integration and interpretation, we applied AI-HOPE and AI-HOPE-WNT/TGFβ, conversational artificial intelligence (AI) platforms designed to integrate clinical, genomic, and treatment data through natural language-driven queries.
Results: Overall survival analyses showed that early-onset AA patients treated with FOLFOX who had WNT pathway alterations experienced significantly better survival ($p = 0.035$). WNT pathway alterations were less frequent in late-onset AA patients treated with FOLFOX compared to those not treated (80% vs. 92%; $p = 0.05$). Similarly, TGF-β pathway alterations were reduced in late-onset non-Hispanic White (NHW) patients receiving FOLFOX compared to untreated cases (23% vs. 31%; $p = 0.0005$).
Conclusions: Chemotherapy exposure may influence pathway-specific mutation frequencies across ancestry and disease stage. AI-enabled integrative analyses highlight the potential of conversational AI platforms to accelerate biomarker discovery and reveal ancestry- and treatment-specific vulnerabilities in colorectal cancer.

#0006 Empowering populations at risk through conversational artificial intelligence: a framework for patient advocacy and precision oncology.

Araceli Estrada[1], Brigette Waldrup[2], Francisco G. Carranza[2], Sophia Manjarrez[3], **Enrique Velazquez-Villarreal**[4]

[1]Office of Science Policy and Government Affairs, AACR, Baltimore, MD,[2]Integrative Translational Sciences, Beckman Research Institute of City of Hope, Duarte, CA,[3]Beckman Research Institute of City of Hope, Duarte, CA,[4]Integrative Translational Sciences, City of Hope Comprehensive Cancer Ctr., Duarte, CA

Background:
Populations at risk for colorectal and other cancers continue to face barriers to equitable healthcare, including limited health literacy, fragmented communication, and underrepresentation in genomic research. Traditional approaches to patient engagement often overlook cultural and linguistic variety, leaving many patients without the knowledge or tools to fully participate in their care. To address this gap, we developed a Conversational AI-Patient Advocacy framework designed to help patients understand, access, and benefit from precision oncology in a personalized informed way.

Methods:
Built upon our validated AI-HOPE ecosystem, which has been successfully implemented and tested across several precision oncology research applications, this innovative platform functions as a digital patient advocate that integrates insights from the AACR Project GENIE database—a global cancer registry linking clinical and genomic data from all populations. Using natural language processing and explainable AI, the system translates complex cancer related questions into accessible, plain-language explanations, supports patient comprehension of diagnostics and treatment options, and connects users to advocacy and educational resources. The framework emphasizes empathy-driven dialogue, cultural adaptability, and accessibility for all populations, including those historically underrepresented in precision medicine.

Results:
Preliminary implementation using GENIE-derived datasets enabled population-level insights into cancer mutation patterns that were then translated into conversational narratives for patients. Early testing demonstrated improved understanding of genomic results, enhanced confidence in patient-provider communication, and increased engagement with advocacy resources and clinical trial information.

Conclusions:
Conversational AI-Patient Advocacy represents a new paradigm for virtual patient advocacy, combining patient education with precision oncology insights derived from large-scale databases like AACR GENIE. By acting as a virtual advocate, this technology empowers patients to navigate their care journey with clarity and trust—bridging the gap between complex cancer data and actionable understanding for all populations.

#0007 Molecularly-informed prediction of treatment efficacy in the GENIE BPC NSCLC cohort using computational reasoning.

Barbara Vodicska[1], Eniko Kispeter[1], Dora Lakatos[1], Gabor Gy Kalmar[1], Robert Doczi[1], Dora Gorog-Tihanyi[1], Anna Dirner[1], Reka Szalkai-Denes[1], William T. Beck[2], Arkadiusz Z. Dudek[3], Christophe Le Tourneau[4], Istvan Petak[1]

[1]Genomate Health, Cambridge, MA,[2]University of Illinois at Chicago, Chicago, IL,[3]Division of Oncology, Mayo Clinic, Rochester, MN,[4]Gustave Roussy, Villejuif, France

Background: Digital Drug Assignment (DDA) is a computational reasoning model that scores cancer therapies based on the complete molecular profile of a tumor, and stratifies them by predicted efficacy (Petak et al., 2021). In a prior study of 111 lung cancer patients, DDA-derived high-score molecularly targeted agents (MTAs) were associated with improved clinical outcomes (Dirner et al., 2025). Here, we extend this analysis to the GENIE BPC NSCLC cohort to assess the broader clinical validity of DDA.
Methods: From the GENIE BPC NSCLC cohort data available on Synapse, we included 1,078 patients with a single-sample genomic profile, available primary treatment data and survival outcomes (total 2,103 treatment lines, therapies included: afatinib, erlotinib, osimertinib, crizotinib, nivolumab, pembrolizumab, atezolizumab, bevacizumab+chemo, ramucirumab+chemo; and chemotherapy alone). DDA scores were generated for all cases, and the individual score of the administered MTAs (incl. immune checkpoint inhibitors) was used to stratify outcomes into low (<0), intermediate, and high DDA-score (≥1000) tiers. Progression-free survival (PFS, by imaging) and overall survival (OS) were analyzed using Kaplan-Meier statistics.
Results: Median PFS and OS differed significantly across DDA score tiers, increasing with higher scores (see table). Intermediate-tier drugs had similar mPFS values as chemotherapies (3.9 vs 4.2 months). Six-month PFS and twelve-month OS rates increased with DDA-tiers and were all significantly different by χ^2 test. DDA-high therapies provided greater benefit across treatment types than lower-score counterparts.
Conclusions: Across a large, real-world NSCLC cohort, DDA effectively distinguished therapies with higher clinical efficacy based on the full molecular profile of each patient. These results reinforce the potential of DDA to enhance personalized treatment selection based on NGS diagnostics in precision oncology.

	DDA-low	DDA-intermediate	DDA-high	Statistical test	Chemo
mPFS (months)	1.7 (n = 72)	3.9 (n = 303)	5.1 (n = 554)	log-rank p<0.0001; HR high vs low = 0.52	4.2 (n = 709)
mOS (months)	9.0 (n = 74)	16.2 (n = 327)	23.3 (n = 601)	log-rank p<0.0001; HR high vs low = 0.49	23.5 (n = 1094)
6-month PFS rate	14%	28%	40%	X^2 p<0.0001	25%
12-month OS rate	36%	53%	63%	X^2 p<0.0001	65%

#0008 Using *in vitro* models to predict imatinib responses in PDGFRA-mutant gastrointestinal stromal tumor.

Homma M. Khosroyani[1], Alina Teuber[2], Ajia Town[1], Lillian Klug[1], Denisse Evans[3], Jerry Call[3], Sara Rothschild[3], Neeta Somaiah[4], Prapassorn Thirasastr[4], Ping Chi[2], Marion Liu[2], Peter Hohenberger[5], Piotr Rutkowski[6], Patrick Schoffski[7], Abbas Agaimy[8], Mehdi Brahmi[9], Carol Beadling[10], Sebastian Bauer[11], Johanna Falkenhorst[11], Michael C. Heinrich[1]

[1]Portland VA Health Care System and OHSU Knight Cancer Institute, Portland, OR,[2]Memorial Sloan Kettering Cancer Center, New York, NY,[3]Life Raft Group, Wayne, NJ,[4]UT MD Anderson Cancer Center, Houston, TX,[5]Mannheim University Medical Center, Mannheim, Germany,[6]Maria Sklodowska-Curie Memorial Cancer Center and Institute of Oncology, Warsaw, Poland,[7]KU Leuven Cancer Center, Leuven, Belgium,[8]University of Erlangen, Erlangen, Germany,[9]Centre Leon Berard, Lyon, France,[10]Knight Diagnostic Laboratories- OHSU Knight Cancer Institute, Portland, OR,[11]West German Cancer Ctr., Essen, Germany

Gastrointestinal stromal tumor (GIST) is the most common sarcoma, and 85% of cases harbor mutations in KIT or PDGFRA receptor tyrosine kinases. Imatinib (IM), a type II TKI, can treat many KIT-mutant GIST, but not GIST with the most common PDGFRA mutation, exon 18 D842V. D842V is resistant to all type II TKIs. Avapritinib (AVA), a type I TKI, was developed and is FDA-approved for all PDGFRA exon 18 mutant GIST but is costly and has severe cognitive side effects in some patients. AVA is also not widely available outside the United States, leaving many exon 18 mutant GIST patients without treatment options. However, limited clinical evidence reports the usage of IM to treat non-D842V exon 18 mutations. As IM is a more tolerable, cost-effective, and accessible drug than AVA, utilizing IM therapy in certain cases would provide treatment for those who cannot access or tolerate AVA. As it is not feasible to model every observed mutation, we utilized *in vitro* models to predict exon 18 mutations that could be treated with IM. Through collaboration and AACR GENIE, we curated a cohort of 1000+ PDGFRA-mutant GIST. 66% had D842V while the remaining had non-D842V point mutations and complex in/dels. Strikingly, 78% of mutations involved the D842 residue, which plays a key role in the autoinhibition of PDGFRA, and mutations like D842V disrupt this. As nearly every single amino acid substitution at the 842-residue was observed in our cohort, we hypothesized that the characteristics of the 842-position amino acid determine IM sensitivity and will predict treatment responses for any exon 18 mutation. To test our hypothesis, we used Ba/F3 and CHO cells to express every possible D842X and D842_D846delinsX mutation. This 4-residue deletion was the most common in/del in the cohort; therefore, we chose to profile this mutation backbone as well. IM sensitivity was determined by calculating an IC_{50} value using immunoblotting for phosphorylated and total PDGFRA. We observed similar trends in IM sensitivity depending on the class of amino acid at the 842-position, with little difference between D842X and D842_D846delinsX mutant kinases. Seven out of eight hydrophobic residues conferred IM resistance while amino acids from other classes (polar, +/- charged, special case) conferred IM sensitivity/intermediate sensitivity. Notably, alanine conferred IM sensitivity, different than the other hydrophobic substitutions and *in silico* modeling revealed how the side chain structure at the 842-position affects IM binding/activity. Lastly, we determined that our results are concordant with first-line IM response data, as patients with predicted IM-sensitive mutations experienced a longer median progression-free survival than those with predicted or known IM-resistant mutations (30 vs 4 months, $p < 0.0001$). Our work highlights an approach to optimize clinical guidelines for the TKI treatment for PDGFRA-mutant GIST based on specific patient mutations.

#0009 ShinyEvents: Harmonizing real-world longitudinal data for clinical insights and survival analytics.

Alyssa Obermayer[1], Joshua Davis[2], Roger Li[3], Rodrigo Rodrigues Pessoa[3], Brandon J. Manley[3], G. Daniel Grass[3], Aik Choon Tan[4], Dung-Tsa Chen[3], Timothy Shaw[3]

[1]Biostatistics and Bioinformatics, H. Lee Moffitt Cancer Center & Research Institute, Tampa, FL,[2]H. Lee Moffitt Cancer Center & Research Institute, Hudson, FL,[3]H. Lee Moffitt Cancer Center & Research Institute, Tampa, FL,[4]University of Utah Huntsman Cancer Institute, Salt Lake City, UT

Background: Harmonizing patient longitudinal data is critical to uncovering variables and events that can influence outcomes or molecular data, yet existing tools have significant limitations in integrating multilayered time-series data, particularly in linking treatment events with survival outcomes. Due to their observational nature, real-world data (RWD) can be comprehensive and heterogeneous, posing a challenge when visualizing and interpreting the data. We developed ShinyEvents, an open-source tool and application to facilitate interaction and exploration of longitudinal data, which we demonstrate in the application of the AACR Project GENIE a global consortium that pools real-world cancer genomic and clinical data to advance precision oncology.

Methods: ShinyEvents is a web-based framework that allows users to upload longitudinal data and generate interactive patient timelines to view clinical events and perform cohort-level analyses through treatment clustering and endpoint assignment. The tool provides informative cohort visualizations, such as a Sankey diagram of the treatment line, swimmer diagrams of the clinical course and treatment duration, as well as heatmaps to view unsupervised clustering on patient treatments. Our tool can infer real-world progression-free survival (rwPFS) based on user-defined endpoints and perform Kaplan-Meier and Cox proportional hazards regression analysis. We incorporated the AACR Project GENIE data on non-small cell lung cancer (NSCLC) and colorectal cancer (CRC) into a dedicated wed instance to visualize and interact with the data. The application is publicly accessible at the following link: https://shawlab-moffitt.shinyapps.io/ShinyEvents_AACR_GENIE/.

Conclusions: ShinyEvents provides a unified framework integrating longitudinal real-world data with survival analytics to facilitate transparent and reproducible collaboration between clinicians and data scientists. Based on the GENIE data, the tool is able to provide dynamic longitudinal visualization on the patient treatment regimen and relate back to the molecular data by identifying complexities surrounding sample collection in relation to treatment regimens. This standardized approach to RWD analysis will facilitate additional collaboration across the global GENIE network.

#0010 A continuous modeling framework for age-dependent selection on melanoma driver mutations.

Yihan Liu[1], Moein Rajaei[1], Jeffrey D. Mandell[1], Jorge Alfaro-Murillo[2], Jeffrey P. Townsend[1]

[1]Yale University, New Haven, CT,[2]Universidad de Costa Rica, San Jose, Costa Rica

Aging is a major risk factor for melanoma, yet whether age alters tumor evolution by altering mutation rates, the strength of selection on drivers—or both—has not been investigated. We developed a continuous age-selection modeling framework that estimates strength of selection as a function of patient age from large-scale sequencing data. Using whole-exome (TCGA) and targeted-panel (AACR Project GENIE) data from 5,472 melanomas, we inferred neutral mutation rates from synonymous substitution counts and mutational covariate data within <40, 40-59, and ≥60 year age groups, calibrating site-specific rates within each tumor using COSMIC mutational signatures. Age-dependent selection on individual variants was then modeled within a shared Poisson-likelihood framework using three parametric forms—linear, logistic, and generalized sigmoid—allowing flexible continuous relationships between age and the strength of selection. Model fits were evaluated by likelihood-ratio tests. To quantify uncertainty, we used adaptive Metropolis-Hastings sampling around the maximum-likelihood estimates to build likelihood-ratio-based confidence intervals and to estimate the posterior probability that the inferred age effect reverses direction. Applied to melanoma, neutral mutation rates rose modestly with age, and UV-associated signatures dominated at all ages, but endogenous processes (SBS1, SBS3) increased in older tumors. In contrast, this framework revealed strongly age-dependent and variant-specific selection: BRAF V600E exhibited a steep, continuous decline in selection with age; NRAS Q61 substitutions showed the opposite pattern, with increasing selection in older patients; and TERT-promoter mutations (C228T, C250T) became more frequent yet conferred weaker selective advantage with age. Gene-level analyses of TP53, PTEN, and CDKN2A revealed monotonic declines in selection, consistent with convergently lower oncogenicity in late-life tumors. At BRAF codon 600, single- and double-base substitutions (DBS) producing V600E provided similar selective benefits, despite the rarity of DBS events, whereas the DBS variant V600K showed increasing selection with age. Together, these results demonstrate that age shapes the somatic evolution of melanoma primarily through age-dependent selection rather than mutation supply or identity, mechanistically tying the differing burdens of BRAF- versus NRAS-driven disease across the lifespan to the differential state of aging tissues and providing a framework for age-aware cancer prevention, molecular testing, and therapeutic strategies.

#0011 Artificial intelligence-based spatial analysis of the local tumor microenvironment in relation to c-MET expression in non-small cell lung cancer.

Ji-Hyang Lee[1], Joshua Littrell[2], Chiyoon Oum[1], Taebum Lee[1], Sanghoon Song[1], Yoojoo Lim[1], Chang Ho Ahn[1], Jim Christian[2], Seokwhi Kim[3], Siraj M. Ali[1]

[1]Lunit, Seoul, Korea, Republic of,[2]Agilent Technologies, Inc., Carpinteria, CA,[3]Department of Pathology, Ajou University School of Medicine, Suwon, Korea, Republic of

Introduction: MET is a well-known oncogenic driver that confers various genomic aberrations. Recent approval of antibody drug conjugates has expanded therapeutic options for c-MET expressing non-small cell lung cancer (NSCLC). However, the relationship between MET expression, tumor microenvironment (TME), and immunotherapy response remains unclear. This study explores the association between c-MET expression and spatial TME features in NSCLC to better understand its immunologic behavior.
Methods: This study analyzed a total of 25,674 NSCLC samples from various cohorts, including AACR GENIE, TCGA, Ajou University Medical Center (AUMC), and Agilent Technologies. AI-powered analyzers (Lunit SCOPE IO and SCOPE uIHC) were previously developed using 19,112 H&E and 4,638 IHC whole slide images of 25 cancer types, stained with over 20 different antibodies. These platforms enabled the quantitative assessment of both the TME, and subcellular expression levels detected by IHC staining.
Results: MET alterations occurred in 27 (2.9%) of TCGA and 909 (3.8%) of GENIE, including exon 14 skipping (n=388, 1.5%), amplification (n=380, 1.5%), and others (n=223, 0.9%). MET-altered tumors had higher MET RNA expression compared with wild-types (median: 0.4 vs. -0.2, $p<0.001$). TME analysis of samples with high (Z-score ≥2) and low RNA expression showed no significant difference in tumor-infiltrating lymphocyte (TIL) density (/mm^2, median: 851 vs. 673, $p=0.46$). In 640 pairs of H&E and IHC slides from AUMC and Agilent, c-MET positive (3+, ≥50%) samples tended to have lower TIL density across the whole slide compared to c-MET negative samples (median, AUMC, 78.5 vs. 79.2, $p=0.16$; Agilent, 80.6 vs. 211.3, $p=0.23$, respectively). This trend became significant with cell and subcellular spatial analysis. The density of TIL was markedly reduced within 30um of tumor cells exhibiting strong (3+) c-MET expression (median:85.5 vs. 121.6, $p<0.001$; 132.2 vs. 162, $p=0.013$, respectively). Notably, a similar reduction in TIL density was also observed around tumor cells with membrane-specific c-MET expression (median: 106.6 vs. 122.3, $p<0.001$; 144.9 vs. 165.8, $p=0.002$, respectively).
Conclusion: Spatial analysis of IHC demonstrated sparse immune cells near tumor cells with strong c-MET expression or membrane-specific localization. These findings suggest a mechanistic link between c-MET overexpression and immune evasion, indicating the potential benefit of combining MET-targeted and immunotherapy.

#0012 Integrative spatial multi-omics profiling enhanced by artificial intelligence reveals ancestry-associated molecular features in early-onset colorectal cancer among Southern California patients.

Francisco G. Carranza, Brigette Waldrup, Yuxin Jin, Yonatan Amzaleg, David Craig, John Carpten, PE-CGS Network, Enrique I. Velazquez Villarreal

Department of Integrative Translational Sciences, City of Hope National Medical Center, Duarte, CA

Introduction: Colorectal cancer (CRC) is the third most common malignancy and the second leading cause of cancer-related mortality worldwide. Although overall CRC incidence has stabilized in many high-income countries, early-onset CRC (EOCRC; <50 years) continues to rise. This increase is especially noticeable in our catchment area, the greater Los Angeles, CA region. Despite this trend, little is known about this population at risk, limiting insight into ancestry-associated biological factors and tumor microenvironment (TME) features.
Methods: A total of 2,730 colorectal cancer (CRC) tumor samples were analyzed from patients in our NIH Cancer Moonshot COPECC PE-CGS Network and from public data repositories, including the AACR Project GENIE database. High-resolution spatial transcriptomics (10x Genomics Visium HD), together with whole-exome sequencing (WES) and RNA sequencing (RNA-seq), was used to assess regional gene expression patterns. Compartment-specific signatures were quantified using SpaCET, focusing on CRC-related genes and pathways. Clinical and molecular datasets were harmonized and analyzed through an AI-driven multi-omics platform, enabling natural-language-based exploration of genomic, transcriptomic, and clinical features.
Results: EOCRC tumors showed a high median genetic similarity to the 1000 Genomes Peruvian-in-Lima (1KG-PEL) reference population. Key CRC-associated mutations were more frequent in EOCRC, particularly among patients with stronger 1KG-PEL-like similarity. Integrated analyses revealed ancestry-associated differences in gene expression between EOCRC and late-onset CRC within the catchment cohort. Spatial transcriptomics demonstrated marked variation in pathway activity across malignant, immune, and stromal regions, with EOCRC displaying distinct compartment-specific patterns.
Conclusions: EOCRC in populations from our catchment area is defined by ancestry-associated genomic alterations and notable spatial heterogeneity in CRC-relevant pathways. These findings underscore the importance of ancestry-informed CRC molecular profiling to advance precision oncology.

#0013 Integrating transcriptomic data to improve multi-omic tumor-of-origin classification.

Pranav Gadde, Naga Mudda, Pratayanch Sav, Krithik Senthilkumar, Aadarsh Sivaraman, Krithik Mudda

Illinois Mathematics and Science Academy, Aurora, IL

Background: Cancers of Unknown Primary (CUP) make up approximately 2-5% of malignancies with a poor prognosis due to empirical therapy. Existing genomic classifiers only have approximately 60-75% accuracy. The AACR Project GENIE consortium and database provide large-scale and real-world genomic data, but there are currently no integrated transcriptomic features with AACR GENIE data. We hypothesized that developing a validated multi-omic framework on TCGA data could create an approach for integrating transcriptomic data into GENIE, with the expected outcome of improving the precision of the tumor-of-origin classification.
Method: We examined a cohort of 1,556 solid tumors from the TCGA PanCancer Atlas, via cBioPortal, across four cancer types: COAD (n=76 test), HNSC (n=103), LUAD (n=102), and READ (n=31). Two XGBoost classifiers were trained (80/20 held-out split) with SMOTE: (1) Genomic-Only baseline classifier (Tumor Mutation Burden, MSI Score, Aneuploidy Score) and (2) Multi-Omic (same genomic features plus 20,506 RNA-Seq genes). Performance was evaluated on a held-out test set (n=312).
Results: The Multi-Omic classifier achieved 93.0% accuracy compared to 52.2% for the Genomic-Only classifier (40.7% improvement). Per-class F1 scores were: COAD=0.86, HNSC=1.00, LUAD=1.00, and READ=0.58. The baseline classifier demonstrated near random performance (COAD F1=0.50 and READ F1=0.33). A feature importance analysis also confirmed known lineage markers as the top predictive features, KRT5 (9.2% importance, HNSC squamous marker), SFTPB (6.1% importance, LUAD lung surfactant), GPA33 (2.9% importance, COAD/READ intestinal marker), CDX1 (2.7% importance, intestinal transcription factor), HOXB13, NAPSA, and EVX2, therefore demonstrating meaningful biological pattern recognition.
Conclusions: Multi-omic integration significantly increases tumor-of-origin classification compared to genomic methods. Its reliance on established, tissue-specific biomarkers provides biological validity critical for diagnostics. READ performance was lower (F1=0.58) due to the limited number of samples and the similarity to COAD. Overall, the framework showed good discrimination across other cancer types. This TCGA proof-of-concept establishes a validated pipeline for expanding to 15-20 cancer types using the AACR Project GENIE, helping advance clinical diagnosis of CUP and precision oncology.

#0014 Mutational profiling of chondrosarcoma across multicenter cohorts.

Luyuan Li[1], Wensi Tao[2], Robert L. Walker[3], Manish KC[1], Darshan Gundala[2], Josiane E. Eid[3], Zhenfeng Duan[3], Jonathan C. Trent[3]

[1]North Alabama Medical Center, Florence, AL,[2]Nova Southeastern University Dr. Kiran C. Patel College of Osteopathic Medicine, Fort Lauderdale, FL,[3]University of Miami Miller School of Medicine, Miami, FL

Background: Molecular therapies for chondrosarcomas remain limited, in part due to the rarity of these cancers, which hampers efforts at broad genomic characterization. The establishment of large, standardized, multicenter databases, such as the AACR Project GENIE, along with subsequent individual studies, has begun to assemble an extensive mutational profile of this disease. This abstract provides a preliminary analysis of the mutational data from these studies.

Methods: The GENIE Cohort v18.0, MSK Nature Communications Sarcoma 2022, and UCLA Cell 2024 sarcoma datasets, accessed via cBioPortal, were collated and analyzed. These datasets included patient information for conventional chondrosarcoma (CS), dedifferentiated chondrosarcoma (DDCS), and mesenchymal chondrosarcoma (MCS). Available data included patient age, sex, race, mutational profiles, and, for CS and DDCS, survival outcomes.

Results: In total, the datasets encompassed 518 patients with chondrosarcoma: 428 CS, 38 DDCS, and 52 MCS. The average age at biopsy was 52 for CS patients, 63 for DDCS patients, and 33 for MCS patients. Women comprised 40.4%, 54.1%, and 55.8% of CS, DDCS, and MCS patients, respectively. Among patients with recorded race, the racial distribution was 74% White, 5% Black, 10% Asian, and 12% Other for CS; 89% White, 5% Black, 3% Asian, and 3% Other for DDCS; and 83% White, 13% Black, and 4% Other for MCS. The average mutation count per patient sample was 10.1 for CS, 5.4 for DDCS, and 2.6 for MCS. The top five most frequently mutated genes for each disease were as follows - CS:*TP53* (124/439), *IDH1* (113/437), *IDH2* (35/423), *KMT2D* (15/186), and *TERT* (14/179); DDCS:*TP53* (24/40), *IDH1* (18/40), *TERT* (13/38), *IDH2* (12/40), *FLT4* (8/40); MCS: *MAP3K13* (5/18), *INSR* (4/17), *SDHA* (5/23), *KMT2D* (4/24), and *KMT5A* (2/13). Median overall survival was 58 months for CS patients versus 25 months for DDCS patients. Notably, many of the most frequently mutated genes beyond *TP53*, *IDH1*, and *IDH2* are involved in chromatin regulation and genomic stability (*KMT2A*, *KMT2D*, *TERT*, etc.), and these mutations are more common in DDCS.

Conclusion: This multicenter mutational analysis confirms that, after *TP53*, the most frequently mutated genes in CS and DDCS are *IDH1* and *IDH2*. Mutations in genes involved in chromatin regulation and genomic stability are more prevalent in DDCS, which may contribute to its increased aggressiveness. These findings support ongoing efforts to target these pathways in chondrosarcoma.

: DNA Damage and Repair 1
Poster Session

#0230 AZD4956, a potent and selective inhibitor of DNA polymerase theta, enhances the activity of DNA-damaging agents in HRR defective cellular backgrounds and improves efficacy of the new generation PARP1-selective inhibitor, saruparib.

Josep V. Forment[1], Lee Mulderrig[1], Christelle de Renty[1], Harriet Southgate[1], Gemma Jones[2], Martina Gesu[3], Rebecca Sargeant[3], Daniel Sutton[3], Lenka Oplustil O'Connor[4], Susan Critchlow[1], Sabina Cosulich[5]

[1]Oncology Targeted Discovery, AstraZeneca R&D, Cambridge, United Kingdom,[2]Cancer Biomarker Development, AstraZeneca R&D, Cambridge, United Kingdom,[3]Clinical Pharmacology and Safety Sciences, AstraZeneca R&D, Cambridge, United Kingdom,[4]Oncology Translational Medicine, AstraZeneca R&D, Cambridge, United Kingdom,[5]Early Oncology Programs Group, AstraZeneca R&D, Cambridge, United Kingdom

Introduction: Loss-of-function mutations in the tumour suppressors *BRCA1*/*BRCA2* inactivate the homologous recombination repair (HRR) pathway, driving genomic instability and cancer progression but conferring sensitivity to DNA double-strand break–inducing agents such as platinum salts and poly(ADP-ribose) polymerase inhibitors (PARPi). *BRCA1*/*BRCA2* mutations are frequent in ovarian, breast, pancreatic, and prostate cancers, underpinning approvals of PARPi in these settings. Despite strong activity in HRR-defective tumours, PARPi responses vary and resistance emerges. Attempts to boost efficacy by combining PARPi with other DNA damage response inhibitors have been limited by enhanced myelosuppression, constraining dose intensity and benefit.**Results:** AZD4956 is a novel, potent, and selective inhibitor of the polymerase activity of DNA polymerase theta (Polθ), a key effector of microhomology-mediated end joining—a repair pathway critical when HRR is compromised. Combining AZD4956 with the PARP1-selective inhibitor saruparib improves efficacy versus either agent alone across HRR-defective cellular backgrounds, with no activity in HRR-proficient settings. Enhanced efficacy correlates with increased genomic instability: in HRR-deficient cells, the combination produces a ~4-fold rise in chromosomal aberrations. AZD4956 also potentiates other DNA-damaging agents (e.g., cisplatin, TOP1 inhibitors) specifically in HRR-deficient lines.AZD4956 shows single-agent *in vitro* activity in the low-nanomolar range in cell lines with *PALB2*, *BRCA2*, and *RAD51C* mutations, like PARPi, but no single-agent activity in *BRCA1*-mutant cells. *In vivo*, AZD4956 monotherapy yields modest tumour growth inhibition (TGI ~50–80%) in some *BRCA2* and *PALB2* mutant models. By contrast, AZD4956 (≥10 mg/kg BID) combined with the maximal efficacious mouse dose of saruparib (1 mg/kg QD) consistently outperforms either monotherapy. Increased efficacy aligns with pharmacodynamic modulation: the combination drives an average ~2-fold increase in micronuclei in red blood cells versus monotherapy. Combination activity is observed in both *BRCA1*- and *BRCA2*-mutant patient-derived xenografts from diverse tissues (breast, prostate) and is restricted to HRR-deficient models where PARPi alone confers some TGI. Notably, maximal combination benefit requires the maximal efficacious saruparib dose.**Conclusions:** Preclinical pharmacology supports AZD4956 selectivity and its potential to amplify antitumour activity when combined with PARPi in HRR-defective cancers. AZD4956 is being evaluated in PARTHENON, a first-in-human, open-label, multicentre, phase 1/2a study of AZD4956 plus saruparib in patients with HRR-deficient solid tumours.

#0231 Polymerase iota drives aberrant mitotic DNA synthesis and replication stress in BRCA2 deficient human mammary epithelial cells.

Kavya Vipparthi[1], Ariana Bellare[2], Resul Ozbilgic[1], **Mihriban Karaayvaz**[1]

[1]Cancer Sciences, Cleveland Clinic, Cleveland, OH,[2]Biochemistry, Case Western Reserve University, Cleveland, OH

Germline mutations in *BRCA2* greatly increase breast cancer risk, yet the early molecular events preceding tumor initiation remain incompletely defined. Prior work shows that mammary epithelial cells with compromised BRCA2 function, including cells from mutation carriers, exhibit replication-associated genome instability. Here, we investigated the role of polymerase iota (Pol ι), an error-prone translesion polymerase upregulated in breast cancer and linked to replication stress.Using primary human mammary epithelial cells (HMECs) from *BRCA2* mutation carriers and *BRCA2*-silenced MCF10A cells, we found that loss of BRCA2 augments Pol ι expression at both mRNA and protein levels. We demonstrate that Pol ι is required for mitotic DNA synthesis (MiDAS), a compensatory pathway engaged when DNA under-replication persists into mitosis. Pol ι silencing significantly reduced MiDAS in BRCA2-silenced cells, but not in wild-type cells, revealing a context-specific dependency on Pol ι for completing mitotic replication.Unexpectedly, silencing Pol ι in BRCA2-silenced cells *reduced* chromosomal breaks, 53BP1 bodies, and micronuclei, lesions typically associated with impaired MiDAS. Moreover, Pol ι loss markedly decreased replication stress markers, including phosphorylated γH2AX and RPA. These findings indicate that Pol ι -mediated MiDAS in the setting of BRCA2 deficiency is not protective but instead amplifies replication stress and genome instability.Our results uncover a previously unrecognized regulatory interaction in which BRCA2 restrains Pol ι, and loss of this restraint permits aberrant Pol ι -driven MiDAS that exacerbates genome instability. This work identifies Pol ι as a potential early intervention target for reducing replication stress in individuals carrying *BRCA2* mutations.

#0232 IDE034, A bispecific antibody-drug conjugate co-targeting PTK7 and B7-H3, exhibits avidity-driven selectivity and enhanced antitumor activity versus mono-specific ADCs.

Diana M Munoz Delgado[1], Ying Zhu[2], Yanan Guo[2], Yuelei Shen[2], Peiran Li[2], Reeja Maskey[1], Pei Xin Lim[1], Megan Conway[1], Marcus M. Fischer[1], Vidhya Nagarajan[1], Arjun A. Rao[1], Christian Frey[1], Yuchen Bai[1], Paul A. Barsanti[1], Claire Neilan[1], Mike A. White[1]

[1]IDEAYA Biosciences, South San Francisco, CA,[2]Biocytogen, Beijing, China

IDE034 is a humanized IgG1 bispecific antibody-drug conjugate (bsADC) that co-targets protein tyrosine kinase 7 (PTK7) and B7-homolog 3 (B7-H3), two tumor-associated antigens broadly expressed across refractory solid tumors but largely absent from normal tissues. Dual-antigen engagement by IDE034 is designed to enhance tumor cell-specific binding, avidity-driven internalization, and intracellular payload release relative to monospecific ADCs, thereby maximizing tumor payload exposure while minimizing normal tissue uptake. IDE034 binds human and cynomolgus PTK7 and B7-H3 with sub-nanomolar affinity and shows no cross-reactivity with other B7-family members. In dual-antigen-positive tumor cells, IDE034 exhibits saturable co-binding and superior internalization kinetics compared with B7-H3- or PTK7-monospecific ADCs. Target-dependent intracellular release of its topoisomerase I inhibitor (TOP1i) payload induces S-phase enrichment, G_2/M arrest, and apoptosis, with bystander cytotoxicity. *In-vivo*, IDE034 produced rapid and durable tumor regressions across PTK7/B7-H3 co-expressing xenograft models and consistently outperformed monospecific comparators. Because poly(ADP-ribose) glycohydrolase (PARG) is essential for resolving TOP1-DNA cleavage complexes, its inhibition has emerged as a strategy to amplify TOP1i-induced DNA damage. The clinical-stage PARG inhibitor IDE161 enhances accumulation of TOP1-DNA crosslinks and replication stress, resulting in deep and durable responses when combined with TOP1 inhibition. The combination of IDE034 with IDE161 reproduced the enhanced antitumor activity observed with TOP1 inhibitors, demonstrating that blockade of PARG-dependent DNA repair can maximize the therapeutic benefit of bispecific TOP1i-ADC-mediated DNA damage. By coupling dual-antigen recognition with a cleavable, membrane-permeable TOP1i payload, IDE034 has the potential to broaden the therapeutic window and address intratumoral heterogeneity. Given the reported frequency of detection of B7H3 and PTK7 protein expression across numerous tumor samples, double positive disease is anticipated to be prevalent in colorectal, non-small cell lung, and breast cancers. Together, these findings support IDE034 as a potential first-in-class bispecific TOP1i-ADC with broad opportunity across disease indications as a monotherapy and in combination with IDE161.

#0233 Preclinical development of EIK1005, a potent and selective inhibitor of Werner helicase.

Fernando Rodriguez Perez[1], Danny Murnock[2], Juanita Ezemba[2], Tamer Ahmed[2], Jose Ortega[1], Huntly M. Morrison[1], Rafael Miranda[1], Taylor Heuer[2], Stephen Jones[2], Brenda Smith[1], Ali Tabatabaei[1], Stephen Basham[1], Melissa Dumble[2], **Marcus P. Kelly**[2]

[1]Eikon Therapeutics, Millbrae, CA,[2]Eikon Therapeutics, New York, NY

The RecQ Werner (WRN) helicase plays a critical role in DNA repair and genomic stability and has been identified as a promising synthetic lethal target in microsatellite instability-high (MSI-H) cancers. Here we present preclinical cellular and in vivo data demonstrating the potent and selective activity of WRN inhibitor EIK1005 across multiple MSI-H cancer models. EIK1005 potently inhibited the biochemical activity of WRN (IC_{50} = 30 nM), with no activity against BLM and other related RecQ helicases. In MSI-H HCT116 cells, EIK1005 induced DNA damage (EC_{50} = 90 nM) that correlated with significant anti-proliferative effect (EC_{50} = 28 nM). Mechanistic studies using our cellular Single Molecule Tracking platform revealed that EIK1005 potently decreased WRN motion, traps WRN on chromatin and promotes WRN degradation, illustrating robust target engagement. No effects of EIK1005 could be measured in microsatellite stable cell lines. EIK1005 has robust pharmaceutical properties including high bioavailability across preclinical species and dose proportional PK. As such, EIK1005 was tested in several mouse models of cancer. In HCT116 xenografted mice, once-daily oral dosing of EIK1005 at 15 and 30 mg/kg induced tumor regression of 48.7% and 47.6%, respectively. In RKO and IGROV-1 MSI-H models that are less sensitive to WRN inhibition, EIK1005 showed dose-dependent tumor growth inhibition across the 30, 90 and 180 mg/kg dose levels assessed. Robust dose-dependent pharmacodynamic activity of EIK1005 was observed in the HCT116 and RKO tumor models, with significant degradation of WRN protein (~ 70%, 8 h post dosing) observed at 15 and 90 mg/kg EIK1005 dose levels respectively. EIK1005 also mediated consistent elevation of DNA damage response markers in these models. A significant increase in GDF-15 was observed in vitro and in mouse plasma following EIK1005, suggesting GDF-15 elevations as a possible peripheral biomarker of WRN inhibition. The pharmacodynamic changes observed at the 15 and 90 mg/kg dose levels correlated with robust and dose responsive plasma concentrations. Further studies elucidated several mechanisms of potential resistance to WRN inhibition. Overall, our preclinical characterization of EIK1005 demonstrates its strong activity and favorable pharmacologic profile that provide impetus to the ongoing clinical development of EIK1005 in patients with MSI-H cancers.

#0234 Proteomic profiling of FEN1 inhibition by BSM-1516 reveals chromatin-associated biomarkers for preclinical pharmacodynamic evaluation.

Jason Munguia[1], Sanjay Agarwalla[1], Dave Martin[1], Junhua Fan[1], Jack Schultz[2], Celeste Giansanti[2], David Cortez[2], David Puerta[1], Zachary Zimmerman[1], **Konstantin Taganov**[1]

[1]Blacksmith Medicines, San Diego, CA,[2]Vanderbilt-Ingram Cancer Center, Vanderbilt University, Nashville, TN

Flap endonuclease 1 (FEN1) is a structure-specific metallonuclease essential for Okazaki fragment maturation and DNA repair. We previously reported the discovery of BSM-1516, a potent and selective small-molecule FEN1 inhibitor that synergizes with PARP-targeted and other DNA damage response therapies and exhibits favorable in vivo pharmacokinetic properties. Pharmacologic inhibition of FEN1 increases its chromatin association, induces poly(ADP-Ribosyl)ation and ssDNA gaps, and is selectively cytotoxic to cells with homologous recombination deficiency. To characterize chromatin protein dynamics following FEN1 inhibition and identify potential pharmacodynamic (PD) biomarkers of target engagement, we employed isolation of Proteins On Nascent DNA (iPOND) coupled to mass spectrometry in proliferating cells treated with BSM-1516, alone or in combination with olaparib. FEN1 inhibition reproducibly enriched replication and DNA repair proteins, including FEN1, PARP1/2, LIG3, XRCC1, and CHD1L, reflecting PARP-dependent engagement of an alternative Okazaki fragment maturation pathway that was abrogated by co-treatment with olaparib. Orthogonal assays for chromatin-bound proteins confirmed selective enrichment of several iPOND-identified hits, establishing tractable PD biomarker candidates. Collectively, these findings delineate a proteomic signature of FEN1 inhibition at the replication forks and lay the groundwork for ongoing in vivo studies assessing these markers as indicators of target engagement in preclinical models.

#0235 Cellular comparison of a covalent and non-covalent WRN inhibitor reveals shared and unique response biomarkers.

Gerarda van de Kamp, Daphne J. F. Kluitmans, Tsang W. Lam, Jeroen A. D. M. de Roos, Janneke J. T. M. Melis, Jeffrey J. Kooijman, **Jorg C. J. Benningshof**

Oncolines B.V., Oss, Netherlands

Werner Syndrome ATP-dependent helicase (WRN) is crucial for preserving genome integrity through its involvement in key cellular processes such as DNA repair and DNA replication. The WRN helicase has emerged as a promising target for cancer therapy since the discovery of the synthetic lethal interaction between WRN deficiency and microsatellite instability. Although no WRN inhibitors have been approved to date, several candidates, including HRO761 and VVD-214 (RO7589831), have entered clinical trials. HRO761 inhibits WRN non-covalently by interacting with its D1 and D2 helicase domains, while VVD-214 covalently binds to cysteine 727 within an allosteric pocket of WRN. This study aimed to find shared and unique predictive response biomarkers for these two WRN inhibitors. HRO761 and VVD-214 were profiled on a panel of 114 cancer cell lines in cell viability assays using ATP as readout. Response data were related to the microsatellite status of the cell lines as well as to publicly available basal gene expression levels, protein expression levels and *WRN* dependency based on CRSIPR knock-out and RNAi knock-down screens. Additionally, a selection of microsatellite stable (MSS) and microsatellite instable (MSI) cell lines was used to assess sensitivity to the WRN inhibitors in colony formation unit assays and to evaluate DNA damage induction using fluorescent imaging. Despite their distinct binding mechanisms, the two WRN inhibitors showed nearly identical response patterns across the 114 cancer cell lines. Notably, VVD-214 was 1.7 times more potent than HRO761. The response to the two inhibitors did not correlate well with basal *WRN* gene expression and WRN protein expression, but showed a significant positive correlation with *WRN* dependency from a CRISPR knock-out screen and RNAi knock-down screen. The gene expression analysis identified *MLH1* expression as a potential resistance marker for both WRN inhibitors. After splitting the 114 cell lines into an MSS and an MSI group, all cell lines in the MSS group were found to be insensitive to the WRN inhibitors, as expected. Surprisingly, the MSI group included both sensitive and non-sensitive cell lines for the two inhibitors. Within the MSI group, VVD-214 was 2.9-fold more potent than HRO761, whereas in the MSS group the difference was only 1.5-fold. Colony formation unit assays and DNA damage imaging further confirmed the differential responses to the WRN inhibitors between MSS and MSI cell lines. The WRN inhibitors HRO761 and VVD-214 showed similar response profiles in the tested cancer cell lines, although some differences were observed. This study highlights potential shared and unique response biomarkers for the WRN inhibitors HRO761 and VVD-214.

#0236 Targeting DNA damage sensors (DDS) to enhance Osimertinib response in EGFR-driven cancers.

Pamela L. Mendoza-Munoz[1], Madison E. Gerbig[1], John J. Turchi[2], Shadia I. Jalal[1]

[1]Department of Medicine, Indiana University School of Medicine, Indianapolis, IN,[2]Department of Biochemistry, Molecular Biology & Pharmacology, Indiana University School of Medicine, Indianapolis, IN

Lung cancer remains the leading cause of cancer-related mortality worldwide. Approximately 85% of cases are classified as non-small cell lung cancer (NSCLC) and activating mutations in the epidermal growth factor receptor (EGFR) are present in about 16% of metastatic NSCLC tumors. The development of EGFR tyrosine kinase inhibitors (EGFR-TKIs) including the third-generation agent Osimertinib, have significantly improved patient outcomes. Nonetheless, its efficacy is limited by both on-target and off-target resistance mechanisms, including the C797S mutation, MET amplification, and histological transformation. Emerging evidence has shown that EGFR signaling influences DNA repair, and that persistent proliferative signaling in EGFR-driven tumors elevates replication stress (RS), making them uniquely vulnerable to inhibition of the DNA damage response (DDR). While prior approaches have primarily targeted DDR kinases such as ATR, CHK1, and WEE1, the role of DNA damage sensors (DDS), including replication protein A (RPA) and the Ku70/80 complex, remains largely unexplored. In this study, we focus on this strategy by targeting RPA and Ku70/80, which recognize DNA structures generated by direct DNA damage or RS and initiate the DDR. Using small molecule inhibitors that target RPA and Ku-DNA binding in combination with clinically relevant EGFR-TKIs, we aimed to dissect the mechanistic interactions between DDR pathways and EGFR signaling to elucidate how DDR modulation impact therapeutic response and resistance in EGFR-driven NSCLCs. Our results show that the DDS inhibitors NERx-329 (RPAi) and Ku-DBi 3392 (Ku70/80) in combination with Osimertinib further enhances antiproliferative and cytotoxic effects in TKI-sensitive, EGFR-mutant NSCLC cells in an additive manner. Our data demonstrate that DDR inhibition is effective in TKI-sensitive EGFR-driven models potentiating Osimertinib activity. Importantly, this is independent of a DNA damaging agent, suggesting that inhibition of DDR itself is enough to increase the therapeutic effect of Osimertinib. This effect appears to be EGFR-specific, as no potentiation of Alectinib activity was observed in an EML4-ALK driven NSCLC model. These preliminary findings support a functional crosstalk between DDS-mediated DDR pathways and EGFR signaling highlighting a potential therapeutic strategy to overcome, delay, or prevent the recurrence of resistance in EGFR-driven NSCLC cancers.

#0237 Selective Cytotoxicity of Base Excision Repair Inhibitor, TRC102, in DNA Damage Response Hyperactivated Glioblastoma.

Shaunak Sathe, Qi Li, Jinkyu Jung, Peng Lu, Zach Sergi, Herui Wang, Jing Wu

National Cancer Institute, National Institutes of Health, Bethesda, MD

Background Glioblastoma is the most aggressive and lethal type of brain tumor. Tumor heterogeneity and DNA repair pathways contribute strongly to poor outcomes, highlighting the need for more personalized approaches. TRC102 (methoxyamine hydrochloride) is a small-molecule inhibitor of base excision repair that acts by covalently binding to abasic sites and preventing downstream repair enzymes from repairing the lesion. Clinical studies utilizing TRC102 in glioblastoma have identified hyperactivated DNA damage response (DDR) gene signature among exceptional responders, suggesting DDR-hyperactivity as a potential clinical biomarker. Here, we evaluated whether glioblastoma cells reliant on DDR signaling are particularly vulnerable to TRC102 treatment. *Methods* We performed gene set enrichment analysis using RNA-seq data across 24 glioblastoma cell lines within the NCI, Neuro Oncology Branch database and identified three patient-derived cell lines (L0, L1, GSC627) with hyperactivated DDR signature. Treatment efficacy was evaluated using cell viability, colony formation, DNA damage, repair and immunofluorescence assays. *Results* TRC102 treatment alone induced significant DNA damage and cell death in DDR-hyperactivated glioblastoma cell lines, whereas DDR-hypoactivated cells showed minimal sensitivity. In L0 and L1 cell lines, TRC102 treatment significantly inhibited colony formation and cell proliferation over 72-hour treatment. Mechanistic studies through western blotting revealed that TRC102 led to significant suppression of CHK2 activity, a key kinase involved in the DDR that controls cell cycle progression. Abrogation of cell cycle checkpoint blockades through CHK2 depletion may allow glioblastoma cells to initiate mitosis without fully resolving DNA damage, leading to mitotic catastrophe and cell death. Interestingly, TRC102 also suppressed HIF protein expression in hypoxic conditions, leading to eventual cell death. *Conclusions* The antitumor effect of TRC102 appears to be mediated through targeting of the newly identified ATM-CHK2-HIF axis, allowing for selective cytotoxicity in DDR-hyperactivated glioblastoma. These results suggest a specific vulnerability to TRC102 in DDR-hyperactivated glioblastoma that are typically resistant to conventional chemotherapy and radiation therapy, supporting biomarker-driven patient selection in future clinical studies.

#0238 Targeted degradation of DNA ligase IV through a double-stranded DNA-based PROTAC for precision radiosensitization.

Monica Pandey, Daniel S Higginson

Radiation Oncology, Memorial Sloan Kettering Cancer Center, New York, NY

DNA ligase IV (LIG4), the terminal ligase of the non-homologous end-joining (NHEJ) pathway, represents one of the most potent yet least druggable radiosensitization targets in double-strand break repair. To overcome this challenge, we designed a first-in-class, double-stranded DNA-based proteolysis-targeting chimera (PROTAC; termed as NHEJ-P) that couples a short 32-bp duplex “DNA bait” to a cereblon-binding E3 ligase ligand, enabling selective proteasomal degradation of LIG4. NHEJ-P achieves near-complete loss of endogenous LIG4 at ~10 nM, verified by western blot and rescued by MG132, confirming proteasome dependence. In vitro, NHEJ-P induces sustained γH2AX and 53BP1 foci with no effects on RAD51 foci, disrupts end-joining kinetics, and enhances radiation-induced cytotoxicity in U2OS and HeLa cells but not in non-transformed RPE1 or HEK293T models, defining a favorable tumor-to-normal therapeutic index. These results suggest that genomically unstable cancer cells are uniquely dependent on LIG4 for survival under replication stress. Building on this foundation, we are conjugating NHEJ-P to trastuzumab using a site-directed enzymatic approach to generate t-NHEJ-P, a HER2-directed antibody-oligonucleotide conjugate (AOC) for tumor-restricted delivery. Planned studies will assess pharmacokinetics, tissue-selective LIG4 degradation, and radiosensitization in $HER2^{+}$ xenografts, along with prospective safety in gastrointestinal, cardiac, pulmonary, and skin radiation-toxicity models. Together, these findings establish targeted LIG4 degradation as a new paradigm for DNA-damage-response modulation and lay the groundwork for next-generation, bystander-limited radiosensitizers that integrate molecular precision with translational safety.

#0239 Potent synergy between CHK1/2 inhibitor ACR-368 and the ADC payload topoisomerase I inhibitor: Rationale for ADC + ACR-368 combination therapy.

Portia Lombardo[1], Ahmed Youssef[1], Mohamed Eldeeb[2], Nina Lipjankic[3], Martina Pasetto[3], Ruban Cornelius[3], Sofija Skoric[3], Ignacio Arribas Diez[3], Zachary Best[1], Anna-Maria Alves[1], Subodh Kumar[1], Kate Rappard[1], Calvin Yang[1], Corey Xu[1], Emma Ahrman[3], Valentina Siino[3], Taronish Dubash[1], Joelle Baddour-Sousounis[1], Reina Improgo[1], Magnus E. Jakobsson[3], Ayesha Murshid[1], Helen Asa Nilsson[3], Lei Shi[1], **Caroline Maria Wigerup**[3], Michail Shipitsin[1], Joon Jung[1], David Proia[1], Erick Gamelin[1], Mansoor Mirza[1], Kristina Masson[1], Peter Blume-Jensen[1]

[1]Acrivon Therapeutics, Watertown, MA,[2]Acrivon AB, Lund, Sweden,[3]Acrivon Therapeutics, Lund, Sweden

Antibody-drug conjugates (ADCs) enable targeted delivery of cytotoxic payloads to tumor cells, improving the therapeutic index compared with conventional chemotherapy. Topoisomerase I (Topo I) inhibitors are potent ADC payloads that trap the Topo 1-DNA cleavage complex, leading to replication-fork collapse and tumor cell death. However, this also activates the DNA damage response through CHK1/2-dependent cell cycle checkpoints, attenuating cytotoxicity and enhancing resistance to Topo1-containing ADCs. CHK1/2 inhibition exploits this therapeutic vulnerability, abrogating these checkpoints, increasing replication stress, and hence enhancing the efficacy of Topo I inhibitors across multiple tumor models. Consistent with this, treatment with the potent, selective CHK1/2 inhibitor ACR-368 combined with irinotecan has demonstrated encouraging clinical activity in heavily pretreated patients with sarcomas who had progressed on prior irinotecan therapy. Combined, these data provide a strong rationale for combining ACR-368 with Topo I inhibitor-based therapies.

Using the Acrivon Predictive Precision Proteomics (AP3) platform for “Indication Finding”, we previously identified endometrial cancer as a tumor type predicted to be particularly sensitive to ACR-368, which has been shown and is being further evaluated in a Phase 2 registrational trial. In a panel of endometrial cancer cell lines, the combination of ACR-368 with exatecan or SN38 demonstrated synergy in a majority of these, with comparable synergy scores between both Topo I inhibitors. Synergy was observed in both Topo I-sensitive and -resistant lines, supporting the potential to overcome resistance to Topo I inhibitor-based ADCs. To elucidate the pathway mechanisms underlying Topo I inhibitor sensitivity and resistance and the potent, synergistic activity with ACR-368, results from our AP3 Generative Phosphoproteomics approach applied to endometrial cancer will be presented.

Combined, these findings demonstrate that CHK1/2 inhibition with ACR-368 synergizes with Topo I inhibitors to enhance cytotoxicity and overcome resistance mechanisms, supporting a mechanistically rational combination strategy with potential to improve the therapeutic benefit of Topo I inhibitor-based ADC therapies.

#0240 Allele-specific sensitization of pancreatic ductal adenocarcinoma to PARP inhibition via adenine base editing.

Jin Zhang[1], Jingrui Yan[2], Tianxing Zhou[2], Xiuchao Wang[2], Chao Yang[2], Jun Yu[2], Jihui Hao[2]

[1]Tianjin Medical University Cancer Institute and Hospital, Tianjin, China,[2]Tianjin Medical Univ. Cancer Inst. & Hospital, Tianjin, China

Synthetic lethality represents a promising therapeutic paradigm in oncology, particularly for pancreatic ductal adenocarcinoma (PDAC) patients with BRCA1/2 mutations, who demonstrate increased sensitivity to PARP inhibitors (PARPi) like olaparib. However, the broader application of this strategy is constrained by the limited incidence of homologous recombination deficiency (HRD) in PDAC that parallels BRCA loss. To address this, we employed SpRY-mediated adenine base editing (ABE) to screen for allele-specific mutations in HR-related genes across normal pancreatic epithelial (HPNE) and PDAC cell lines, including both KRAS-G12D mutant (PANC-1) and wild-type (BxPC-3) models. These edited cells were subjected to olaparib treatment at three escalating doses. A subsequent slope-based analysis of viability reduction identified several mutations that specifically sensitized PDAC cells to PARPi. Strikingly, the NBN-X mutation conferred robust olaparib hypersensitivity in KRAS-wild-type BxPC-3 cells, while PALB2-Y and RAD50-Z mutations markedly enhanced olaparib efficacy in KRAS-G12D mutant PANC-1 cells compared to normal HPNE controls. Mechanistically, the NBN-X variant sensitizes non-KRAS mutant PDAC by disrupting MYC-driven homologous recombination (HR) repair. In contrast, the RAD50-Z variant synergizes with KRAS-driven suppression of HR to potentiate PARPi efficacy. These allele-specific effects were functionally validated, demonstrating up to a 4.1-fold decrease in olaparib IC50 and a 2.5-fold increase in apoptosis. Critically, this potent sensitization was highly tumor-specific, yielding a significantly improved safety profile over conventional BRCA-mutant models both in vitro and in vivo. Leveraging these findings, we are using virtual screening and AI-driven drug design to develop small molecules that mimic the PARPi-hypersensitivity induced by our identified mutations. These lead compounds will be advanced for evaluation in sophisticated PDAC models, including patient-derived xenografts (PDX) and genetically engineered mice. Our results highlight a novel strategy for personalizing PARPi therapy in PDAC and suggest a substantially expanded therapeutic window that could improve outcomes for patients with this aggressive disease.

#0241 Targeted drug screening identifies novel compounds enabling accelerated mismatch repair deficiency (MMRd) for immunotherapy sensitization.

Benoit Rousseau[1], Miteshkumar Patel[1], Karthik Rangavajhula[1], Lin Zhang[1], David Mieles[1], James R. White[2], Oliver Artz[1], Shrey Patel[1], Somer Abdelfattah[1], Neil Segal[3], Luis A. Diaz[1]

[1]Memorial Sloan Kettering Cancer Center, New York, NY,[2]Resphera Biosciences, Baltimore, MD,[3]Memorial Sloan Kettering Cacner Center, New York, NY

Background: MMRd tumors respond exceptionally to immunotherapy, and pharmacologic MMR inactivation has the potential to improve immunosensitivity of MMR-proficient tumors. We previously showed that temozolomide plus cisplatin (TMZ+CDDP) induces MMRd through MSH2 silencing. However, clinical translation revealed limited efficacy, potentially due to delayed MMR inactivation preventing sufficient tumor mutational burden (TMB) and microsatellite instability (MSI) accumulation on treatment. We hypothesized that compounds enabling rapid MMR inactivation could overcome this limitation.
Methods: Preclinical models treated with TMZ+CDDP were analyzed longitudinally for TMB and MSI. Clinical trial data (NCT04457284) combining TMZ+CDDP with nivolumab in metastatic colorectal cancer patients were assessed using serial ctDNA profiling. We performed computational screening of open-source databases to identify compounds inducing rapid *MLH1* or *MSH2* downregulation (≤3 days) across cancer cell lines. Candidates were studied using CT26 cells transfected with an out-of-frame luciferase-microsatellite reporter, where MSI-induced frameshift mutations restore luciferase expression, enabling real-time MSI monitoring. These repurposed compounds underwent MMR expression analyses.
Results: In vivo, TMZ+CDDP induced MSH2 loss only after 4 weeks (W) of treatment, with MMRd genotype recapitulated only after 8W. Clinical trial analysis of 16 evaluable patients revealed that only 5 patients (31%) developed a MMRd-like genotype with gains in TMB and MSI at a median of 8W, which associated with improved survival. Critically, patients failing to increase TMB and/or MSI developed aneuploid gains in MMR genes on treatment suggesting a compensatory resistance mechanism to mutagenesis. These findings indicate that delayed MMR inactivation with TMZ+CDDP limits clinical efficacy. To address this limitation, our drug screen identified 6 compounds inhibiting significantly *Msh2* and/or *Mlh1* after short course treatment. Three compounds were confirmed to generate sustained bioluminescence increases within 1-2W compared to 4-8W with TMZ+CDDP. Two compounds were showed to completely abolish *Msh2* expression by 1 or 2W, while the third reduced expression by 70%. The three other agents showed only transient *Msh2* or *Mlh1* downregulation without change in bioluminescence. These novel compounds demonstrate substantially accelerated MMR inactivation kinetics compared to TMZ+CDDP.
Conclusions: While TMZ+CDDP can induce a MMRd genotype in patients, delayed MMR inactivation and compensatory MMR gene amplification limit therapeutic efficacy. Repurposed compounds enabling rapid MSH2 inhibition may prevent adaptive resistance mechanisms and improve clinical responses when combined with immunotherapy, warranting further preclinical/clinical development.

#0242 Targeting the DNA damage response sensor replication protein A for first in class cancer therapy.

Pamela VanderVere-Carozza[1], Matthew R. Jordan[1], Katherine Pawelczak[2], **John J. Turchi**[1]

[1]Indiana University School of Medicine, Indianapolis, IN,[2]Nerx Biosciences, Inc., Indianapolis, IN

The DNA damage response (DDR) and replication stress response (RSR) are validated pathways for targeted cancer therapy, particularly through the exploitation of synthetic lethal interactions. We have pursued the discovery and development of DDR and RSR sensor protein inhibitors to disrupt these dysregulated pathways in cancer. We have demonstrated the therapeutic efficacy of the novel Replication Protein A inhibitor (RPAi), NERx-329, which disrupts the RPA-DNA interaction, induces chemical exhaustion of RPA function, and exhibits potent anticancer activity in vivo. We identified a series of synthetic lethal interactions that revealed the RPAi mechanism of action and therapeutic efficacy is primarily mediated by molecular events at the replication fork in response to replication stress (RS). These studies showed that RPAi exacerbates both genetically and pharmacologically induced RS via chemical RPA exhaustion resulting in further genomic instability, replication catastrophe, and cell death of cancer cells, with minimal toxicity in vivo. Data presented demonstrate the development of a combined treatment regimen targeting RPA and PARP that abrogates cancer growth in an in vivo BRCA1-deficient breast cancer model and ovarian cancer cell line. To assess markers of genome instability, we performed metaphase spreads on single agent- and combination agent-treated TNBC MDA-MB-436 cells. Single-agent RPAi treatment had no observable effect on the chromosome structure, whereas olaparib treatment increased chromosome pulverization. However, the combination strikingly induced chromosome pulverization. Taken together, NERx-329 chemically exhausts RPA such that olaparib-induced ssDNA gaps are degraded, and chromosomal integrity is compromised. Considering the induction of chromosome pulverization, we assessed the generation of micronuclei (MN) following RPAi treatment in combination with olaparib and the PARP1-specific PARPi saruparib. The data revealed that PARPi treatment resulted in a significant increase in MN, whereas treatment with RPAi alone did not affect MN formation. The combination of RPAi-PARPi treatment did not significantly alter MN occurrence. These results indicate that MN formation is not required for the enhanced cell killing effect of the combination treatment. Overall, these data support a model in which loss of BRCA1 and its prevention of ssDNA gaps during replication is further exacerbated by PARP inhibition. This data suggests that RPAi-PARPi combination enhances therapeutic efficacy and offers a strategy to overcome PARPi resistance by targeting gap protection mechanisms.

#0243 DNA fiber-based replication phenotypes distinguish WEE1-inhibitor response in high-grade endometrial cancer patient-derived organoids (PDOs) treated with azenosertib.

Elena Ivanova[1], Ke Cong[1], Shrabasti Roychoudhury[1], David Han[1], Magdalena Zielinska[1], Minh Ha[1], Abrielle Jens[1], Vaishnavi Anand[1], Bose S. Kochupurakkal[1], Courtney H. Qi[1], Arunika Shee[1], Maureen Mulready[1], Madison Zizzo[1], Alexis Rabbitt[1], Jennifer D. Curtis[1], Nabihah Tayob[1], Marisa R. Nucci[2], Cam A. Tran[1], Panagiotis A. Konstantinopoulos[1], Geoffrey I. Shapiro[1], Dipanjan Chowdhury[1], Cloud P. Paweletz[1], Ursula Matulonis[1], Joyce Liu[1]

[1]Dana-Farber Cancer Institute, Boston, MA,[2]Brigham and Women's Hospital, Boston, MA

Background: High-grade endometrial cancers (EC), including serous, carcinosarcoma, and clear cell subtypes, frequently harbor *TP53* mutations, replication stress (RS), and cell-cycle dysregulation, suggesting vulnerability to WEE1 inhibition. We conducted a translational study to define RS-linked pharmacodynamics and *ex vivo* correlates of response in high-grade EC PDOs.

Methods: PDOs from high-grade EC biopsies and surgical samples were treated *ex vivo* with azenosertib (200 nM, 24 h). DNA-fiber assays measured: (i) fork speed (CldU+IdU as ongoing replication forks), (ii) replication fork stability under RS caused by hydroxyurea (HU), using the IdU:CldU ratio after WEE1i+HU, and (iii) single-stranded (ss)DNA gap formation via the S1 nuclease assay (WEE1i±S1).

Results: Four PDOs were profiled: DF4850 and DF4161 (WEE1i-sensitive; IC50s<100nM) and DF042 and DF4968 (insensitive; IC50s>1500nM). Across all four models, fork speed decreased after azenosertib, consistent with on-target effects on RS. However, fork degradation and gap formation aligned with viability. Specifically, under WEE1i+HU, the sensitive models (DF4850, DF4161) showed a significant reduction in the IdU:CldU ratio, indicating impaired fork restart/stability. The insensitive models (DF042, DF4968) were able to protect forks from degradation despite WEE1 inhibition and showed no change. In the S1 gap assay, DF4850/DF4161 exhibited shorter fiber tracts with WEE1i+S1 vs WEE1i alone, consistent with increased ssDNA gaps, whereas DF042/DF4968 again showed no difference, indicating the ability to tolerate WEE1i-induced stress. Thus, while fork slowing is a uniform pharmacodynamic effect of WEE1 inhibition, HU-sensitive fork instability and S1-sensitive gap formation are enriched in sensitive PDO models.

Conclusions: In high-grade EC PDOs, azenosertib uniformly slows replication forks, but fork stability under HU and S1-detectable gap formation distinguish WEE1i-sensitive (DF4850, DF4161) from insensitive (DF042, DF4968) models. These mechanism-anchored DNA-fiber readouts merit prospective evaluation as predictive and pharmacodynamic biomarkers for WEE1 inhibitors in high-grade EC. Additional biomarker analyses, including immunohistochemical analyses of RS proteins, are ongoing and will be presented.

#0244 DHX9 inhibition is synthetically lethal with homologous recombination deficient and dMMR/MSI-H cancers and synergizes with PARP1 inhibition and chemotherapy.

Samantha S. Hodge, Natalie Hill, Jhansi L. Leslie, **Umida Djakbrova**, Logan Chinn, Saranya Chandrasekar, Susan Paprcka, Ester Fernandez-Salas

Arcus Biosciences Inc., Hayward, CA

BACKGROUND: DHX9 is an RNA/DNA helicase that unwinds various RNA/DNA secondary structures, including R-loops and G-quadruplexes, which increase replication stress and transcription-replication collisions if not properly resolved. Homologous recombination deficient (HRD) and mismatch repair deficient/microsatellite instability-high (dMMR/MSI-H) cancer cells exhibit dependence on DHX9 due to enhanced formation of RNA/DNA secondary structures. PARP inhibitors (PARPi) are a front-line standard of care (SOC) for BRCA-deficient and HRD cancers but exhibit limited efficacy and durability. Topoisomerase 1 (TOP1) inhibitors are commonly used in dMMR/MSI-H cancers post-immunotherapy and in PARP and chemo-refractory HRD cancers. Both PARP1 and TOP1 have roles in R-loop prevention and resolution. We hypothesized that DHX9 inhibition combined with PARP or TOP1 inhibition might elicit deeper responses in a greater fraction of HRD or dMMR/MSI-H tumors than SOC therapy alone.
METHODS: Cell lines were categorized as HRD based on genomic scar scores or as dMMR/MSI-H based on MMR LOF or MSISensor scores. Sensitivity of cell lines to siDHX9, DHX9 inhibition, or WRN inhibition was assessed using viability assays. Cell cycle changes after DHX9 or WRN inhibition were monitored using the PIP-FUCCI sensor using live cell imaging. Combined inhibition of DHX9 and PARP or TOP1 was evaluated using a viability assay, and synergy was quantified using Bliss Synergy scores.
RESULTS: siDHX9 decreased cell viability in HRD and dMMR/MSI-H cells with no effect on homologous recombination proficient (HRP), microsatellite stable (MSS), and non-tumorigenic cells. Similarly, DHX9 inhibition altered the cell cycle and decreased viability in HRD and dMMR/MSI-H cell lines while sparing HRP, MSS, and non-tumorigenic cells. DHX9 inhibition exhibited synergism with both saruparib (PARPi) in HRD cell lines and with SN38 (TOP1i) in HRD and dMMR/MSI-H cell lines. On the other hand, WRN inhibition had no effect on the cell cycle or viability of HRD cell lines. While WRN inhibition reduced viability in a subset of dMMR/MSI-H cell lines, a greater number of dMMR/MSI-H cell lines were sensitive to DHX9 inhibition.
CONCLUSION: These data support that DHX9 inhibition is synthetically lethal in HRD and dMMR/MSI-H cancers and demonstrate that DHX9 inhibition synergizes with SOC therapies. For the first time, these data highlight that DHX9 inhibition synergizes with both PARPi or TOP1i to elicit robust tumor cell killing in HRD and dMMR/MSI-H cancers. Additionally, these data demonstrate that DHX9 inhibition is a superior synthetic lethal target compared to WRN inhibition in both HRD and dMMR/MSI-H cancers.

#0245 Expanding the therapeutic window of PARP inhibitors by co-administering PARG inhibitors.

Giacomo G. Rossetti[1], Michalis Petropoulos[1], Theodoros Rampias[2], Thanos D. Halazonetis[3]

[1]University of Bern, Bern, Switzerland,[2]Biomedical Research Foundation Academy of Athens, Athens, Greece,[3]Cancentus Pharma and University of Bern, Bern, Switzerland

Background:
Homologous recombination (HR) deficiency sensitizes tumors to PARP inhibitors (PARPi), which are standard-of-care for HR-deficient cancers. Despite their efficacy, clinical use of PARPi is limited by on-target toxicity, particularly anemia, leading to dose reductions and drug holidays in about half of treated patients. To address these limitations and expand the therapeutic window of PARPi, we investigated co-administration with selective PARG inhibitors (PARGi).
Methods:
Cell survival assays were used to evaluate the interaction between potent PARP inhibitors (talazoparib, saruparib), less potent PARP inhibitors (niraparib, olaparib, rucaparib), and selective PARG inhibitors in HR-deficient cell lines. Bone marrow toxicity was assessed in mice and rats treated with talazoparib (0.2-0.25 mg/kg) or saruparib (0.1 mg/kg), administered alone or in combination with selective PARG inhibitors undergoing clinical development, using a 4-days-on/2-days-off/4-days-on regimen. Red blood cell counts, hematocrit, and body weight were measured one day after treatment. Antitumor efficacy was evaluated in DLD1-BRCA2-knockout cell line-derived xenografts (CDX) using a 3-days-on/4-days-off dosing schedule, administered alone or in combination with PARG inhibitors.
Results:
In cell survival assays, PARG inhibitors did not antagonize the cytotoxicity of potent PARPi in HR-deficient cells. In vivo, PARPi monotherapy induced anemia, weight loss, and mortality. Co-administration of PARG inhibitors rescued anemia, attenuated weight loss, and prevented treatment-related deaths. CDX studies demonstrated that tumor growth inhibition by PARPi was maintained or enhanced in combination with PARG inhibitors, allowing higher PARPi dosing without compromising safety. In rats, anemia induced by PARPi was similarly rescued by a PARG inhibitor. Overall, the combination improved the therapeutic window, enabling enhanced efficacy at higher PARPi doses.
Conclusions:
PARG inhibition selectively mitigates PARPi-induced toxicity without compromising anticancer efficacy in HR-deficient tumors, thereby expanding the therapeutic window. This approach enables higher PARPi dosing for improved tumor control or equivalent efficacy with fewer adverse events, particularly anemia. By reducing PARPi-associated toxicity, PARG inhibition may also facilitate combination therapies, warranting further investigation.

#0246 Discovery and mechanistic characterisation of the first oral bioavailable FEN1 inhibitor for treatment of HRD and EWS cancers and combination with various DDR inhibitors.

Lars T. Burgdorf[1], Julien Lefranc[1], Lucy Armstrong[2], Roch Boivin[3], Joerg Bomke[1], Xiaoling Chen[3], Paula Costales[2], Owen A. Davis[2], Lizbeth DeSelm[3], Elias Elinati[2], Maria Filipa Pinto[2], Bruce Follows[3], Alessandro Galbiati[2], Catherine Jorand-Lebrun[3], Timothea Konstantinou[2], Julian Kreis[1], Claudio A. Lademann[1], Birgitta Leuthner[1], Jayesh B. Majithiya[2], Balca R. Mardin[1], Bethany Mason[2], Claire L. McWhirter[2], Djordje Musil[1], Ulrich Pehl[1], David Perera[2], Silvia Peripolli[2], Carl Petersson[1], Eeson Rajendra[2], Christin Rakers[1], Ada Sala-Hojman[1], Graeme C. M. Smith[2], Fiona Sorrell[1], Ana Toste Rego[2], Helen M. R. Robinson[2], Frank T. Zenke[1], Robert A. Heald[2], Sam E. Mann[2]

[1]Merck Healthcare KGaA, Darmstadt, Germany,[2]Artios Pharma Ltd., Cambridge, United Kingdom,[3]EMD Serono Research & Development Institute, Billerica, MA

Flap endonuclease 1 (FEN1) has emerged as a critical target in the DNA damage response (DDR) landscape, particularly due to its synthetic lethal interactions with homologous recombination-deficient (HRD) cancers, such as those harboring BRCA mutations. Despite the therapeutic potential of FEN1 inhibition, the development of effective small molecule inhibitors has been limited, with existing compounds exhibiting modest selectivity and lacking oral bioavailability. In this presentation, we highlight the discovery of MSC778, the first potent, selective, and orally bioavailable FEN1 inhibitor and its mechanistic characterization. Utilizing a metal-chelating fragment-based screening approach combined with structure-based optimization, we successfully identified MSC778, which demonstrates strong cellular activity and selectivity and induces cell death in BRCA-deficient cancer cells. Our medicinal chemistry optimization campaign led to the development of oral bioavailable compounds that potentiate the activity of the PARPi niraparib *in vivo* to induce tumor stasis in a *BRCA2* KO DLD-1 mouse xenograft model. Mechanistically we could demonstrate that MSC778 enhances FEN1 retention on chromatin and disrupts active DNA replication, leading to S-phase accumulation and subsequent DNA damage. Our findings also reveal a novel sensitization of Ewing sarcoma (EWS) cells to FEN1 inhibition, driven by the expression of SLFN11. Through CRISPR and drug combination screening, we elucidate a spectrum of synthetic lethal interactions between FEN1 and key DDR factors, including PARP1, USP1, PARG, and ATR, highlighting the synergistic potential of combining FEN1 inhibition with existing and emerging DDR-targeting agents. Together, these data underscore the relevance of FEN1 inhibition as a precision oncology strategy, with significant implications for the treatment of HRD and EWS cancers, as well as potential for combination therapies that leverage the DDR landscape.

#0247 Multiomic and preclinical assessment of ATR and Aurora kinase inhibitors in diverse TNBC models.

Nathan M. Merrill, Hamadi Madhi, Nathalie M. Vandecan, Athena Marie Apfel, Habib Serhan, Peter J. Ulintz, Liwei Bao, Aki Morikawa, Matthew B. Soellner, Soffia D. Merajver

University of Michigan, Ann Arbor, MI

Introductory Sentence: This study investigated the efficacy of combined ATR and Aurora kinase (AK) inhibition in triple-negative breast cancer (TNBC), emphasizing racially diverse patient-derived models and mechanisms of therapeutic resistance.
Pertinent experimental procedures: Through high throughput screening, we identified an ATR inhibitor, berzosertib, that targets the DNA damage response (DDR) pathway, and whose efficacy correlates with AK expression and activity. When combined with danusertib, a pan-AK inhibitor, berzosertib produced synergistic cell death across a broad range of TNBC cell lines. To validate this drug combination, we initiated a 1x1x1x1 patient-derived xenograft (PDX) trial using 30 racially diverse PDX models (15 from Caucasian and 15 from African descent patients), allowing assessment of potential ethnicity-based differences in response, given the higher TNBC incidence in African American women of West African ancestry. Mice were first exposed to the berzosertib-danusertib combination to evaluate toxicity and optimize dosing. Once dosing was established, PDX tumors were serially implanted and treated with berzosertib, danusertib, their combination, or vehicle control for 21 days. After treatment, tumors were collected for single-cell RNA sequencing and spatial transcriptomics analysis. Finally, baseline DNA and RNA sequencing will be conducted across all PDX models to identify predictive biomarkers of therapeutic response.
Summary of new unpublished data: Initial experiments in NSG mice revealed unexpected toxicity with the combination therapy, which was resolved by switching to NRG mice without RAG1 knockout. Screening four PDX models showed synergistic effects in three, indicating strong anti-cancer potential. Single-cell and spatial transcriptomic analysis of treated tumors revealed enrichment of extracellular matrix remodeling genes, especially MMP7, and proliferation genes at the tumor periphery. This upregulation suggests possible activation of pro-invasive pathways and increased metastatic risk with the combination treatment. These preliminary studies established workable experimental protocols, but further testing in additional models with deeper sequencing is needed. While initial transcriptomic studies compared combination therapy to vehicle controls, it will be important to perform similar analyses for danusertib and berzosertib monotherapies to determine if either drug alone is responsible for the increased proliferation and extracellular remodeling observed with the combination.
Statement of the conclusions: Overall, these findings suggest that dual ATR and Aurora kinase inhibition benefits select TNBC models and uncover gene expression changes, highlighting the need for ongoing surveillance for metastatic indicators.

#0248 Nesuparib (JPI-547), a dual tankyrase/PARP inhibitor, exhibits potent antitumor activity in small-cell lung cancer models by modulating Wnt and Hippo signaling pathways.

Jun Kim[1], Joon-Hyung Lee[1], John Kim[1], Hyunju Cha[1], Seounghun Kang[2]

[1]Onconic Therapeutics, Seoul, Korea, Republic of,[2]Soongsil University, Seoul, Korea, Republic of

Objectives: Small-cell lung cancer (SCLC) accounts for 13-15% of lung cancers and remains an aggressive malignancy with rapid progression and poor prognosis, as median survival for extensive-stage disease is below 10 months. Nesuparib (JPI-547) is a potent, orally active dual inhibitor of Tankyrase-1/2 (TNKS1/2) and Poly (ADP-ribose) Polymerase-1/2 (PARP1/2). This study evaluated in vitro cytotoxicity and in vivo antitumor efficacy of nesuparib in BRCA wild-type SCLC models. The research aimed to characterize the antitumor activity and mechanism of nesuparib compared with olaparib and irinotecan and assess the synergistic efficacy of nesuparib combined with irinotecan. These investigations sought to clarify the mechanistic and therapeutic potential of dual TNKS1/2-PARP1/2 inhibition in SCLC.
Methods: Human SCLC NCI-H146 cells were treated with nesuparib, olaparib, or irinotecan to assess in vitro cytotoxicity by CellTiter-Glo assay. For in vivo evaluation, two independent xenograft studies were performed: a mono-treatment study comparing each agent's antitumor efficacy and a combination study assessing synergistic activity of nesuparib with irinotecan. Tumors from nesuparib-treated mice were analyzed by RT-qPCR, Western blot, and IHC to elucidate molecular mechanisms.
Results: In vitro, nesuparib showed the strongest potency among tested agents (IC_{50} = 2.4 nM), being ~133-fold and ~25-fold more potent than olaparib and irinotecan, respectively. In vivo, nesuparib exhibited a clear dose-dependent tumor-growth inhibition in the NCI-H146 xenograft model. At 50 mg/kg, nesuparib achieved a TGI of 65.4%, exceeding the efficacy of olaparib (36.0%) and irinotecan 10 mg/kg (42.9%). Combination with irinotecan produced a significant synergistic effect, resulting in enhanced and sustained tumor regression, which was superior to the combination of olaparib with irinotecan. Mechanistic analyses revealed that nesuparib suppressed Wnt and Hippo signaling pathways, leading to inhibition of tumor growth, as confirmed by qPCR, Western blot, and IHC.
Conclusions: Nesuparib (JPI-547), a dual TNKS1/2-PARP1/2 inhibitor, showed strong dose-dependent antitumor activity in BRCA wild-type SCLC. Combination with irinotecan produced a synergistic tumor-suppressive effect. Mechanistic studies indicated that nesuparib inhibited tumor growth by suppressing Wnt and Hippo signaling, supporting its potential as a novel therapeutic strategy for SCLC alone or with DNA-damaging agents.

#0249 MOMA-313, an inhibitor of the DNA polymerase theta helicase domain, prevents BRCA reversions in preclinical models.

Giulia Bottoni, Anthony Tubbs, Kelly McGlynn, Vinny Motwani, Michael Reutershan, Timothy Guzi, Erica Evans, Peter Hammerman, **Jordan A. Krall**

MoMa Therapeutics, Cambridge, MA

MOMA-313 is a small molecule inhibitor of the DNA polymerase theta (Polθ) helicase domain in development for the treatment of homologous recombination (HR)-deficient tumors. Polθ repairs DNA double-strand breaks (DSBs) by annealing flanking regions of microhomology, a process called theta-mediated end-joining (TMEJ). In preclinical models, MOMA-313 synergizes with PARP inhibitors to drive deeper responses both in vitro and in vivo, demonstrating the potential for combination benefit in the clinic. Clinical resistance to PARP inhibitors is caused by BRCA reversions – secondary mutations that restore BRCA function – that often have the hallmarks of Polθ-mediated DNA repair. It has been hypothesized that, in addition to providing mechanistic synergy, inhibiting Polθ may extend the duration of PARP inhibitor responses by preventing or delaying the emergence of BRCA reversions. However, due to the challenge of creating reversion mutations via a clinically relevant mechanism, this hypothesis has not been experimentally addressed. Here, we use genetic tools to create targeted DNA single-strand breaks (SSBs) – the most common form of endogenous DNA damage – which can be converted to DSBs during DNA replication and are efficiently repaired by HR. As expected, SSBs in HR-proficient cells show no evidence of mutagenic DNA repair. In contrast, we find that in the context of HR deficiency, SSBs are repaired as genomic deletions flanked by regions of microhomology, suggesting a specific role for Polθ in the DNA repair process. Using MOMA-313 to inhibit Polθ activity, we demonstrate a broad role for Polθ in DNA repair initiated by SSBs in HR-deficient models, with MOMA-313 preventing the vast majority of DNA repair products. The extent of Polθ-mediated repair was unexpectedly broad, extending beyond canonical TMEJ products to include a large proportion of repair products with only one base pair of DNA microhomology. Importantly, the induction of SSBs adjacent to the pathogenic BRCA2 mutation in Capan-1 cells produced genomic deletions that restored the BRCA2 reading frame and caused cellular resistance to PARP inhibitor treatment. MOMA-313 dramatically reduced the frequency of these BRCA reversion mutations, preventing the emergence of PARP inhibitor resistance. These data provide experimental evidence that Polθ activity is a key contributor to PARP inhibitor resistance and provide a strong rationale for early and sustained Polθ inhibition in BRCA-mutant tumors to drive deeper and more durable clinical responses.

#0250 Targeting DNA damage repair pathway and CCR2$^+$ myeloid cell to overcome radioimmunotherapy resistance in small cell lung cancer.

Zhuoran Yao[1], Hui Wang[2], Kai Kang[1], Min Yu[2], Feifei Na[2], Ren Luo[2], Linglu Yi[2], Ruizhan Tong[3], Jianxin Xue[4], You Lu[5]

[1]West China Hospital, Sichuan University, Chengdu, China,[2]Department of Thoracic cancer, West China Hospital, Sichuan University, Chengdu, China,[3]Department of Thoracic cancer, West China Hospital, Chengdu, China,[4]Department of Thoracic Oncology, West China Hospital, Sichuan University, Philadelphia, PA,[5]Sichuan University West China School of Medicine, Chengdu, China

Background: Small cell lung cancer (SCLC) is a highly aggressive neuroendocrine carcinoma characterized by rapid progression and a high relapse rate. Although the combination of immune checkpoint inhibitors (ICIs) with radiotherapy (RT) has improved patient outcomes, acquired resistance remains inevitable. This study aims to elucidate the underlying mechanisms of radioimmunotherapy resistance and explore potential novel strategies.
Methods: We established a murine SCLC model of acquired radioimmunotherapy resistance by subjecting tumor-bearing mice to multiple cycles of RT + ICI until resistance developed. Subsequently, longitudinal single-cell RNA sequencing (scRNA-seq) analysis of tumor specimens was performed to validate the findings. The DNA damage repair (DDR) pathway was investigated using Western Blot, ELISA, and Transwell assays. The efficacy of adding PARP inhibitor (PARPi) to RT+ICI was evaluated *in vivo*.
Results: Analysis of the radioimmunotherapy-resistant murine SCLC model revealed that enhanced DDR activity, elevated CCL2 secretion, and increased of infiltration of CCR2$^+$ myeloid-derived suppressor cells (MDSCs), which were further validated by longitudinal scRNA-seq. Targeting the CCL2-CCR2 axis significantly delayed tumor relapse following RT + ICI treatment. Next, i*n vitro*, combining PARPi with RT synergistically suppressed DDR activation and inhibited CCL2-dependent MDSC migration. *In vivo*, concurrent administration of PARPi with RT + ICI was essential for achieving better tumor control and survival benefit compared with RT + ICI treatment, whereas delayed intervention of PARPi proved ineffective. Tumor microenvironment analysis demonstrated that the triple therapy (RT + ICI + concurrent PARPi) effectively suppressed the DDR pathway, significantly reduced CCR2$^+$ MDSC infiltration, and increased effector T cell recruitment.
Conclusion: DDR-driven CCL2 secretion recruits CCR2$^+$ MDSCs to mediate radioimmunotherapy resistance in SCLC. PARPi disrupts this axis through dual blockade of tumor DDR and MDSC recruitment. Our data revealed that the combination of concurrent PARPi with radio-chemo-immunotherapy as first line therapy in ES-SCLC is worth exploring and a prospective clinical trial is ongoing (NCT06217757).

#0251 Targeting cyclin K-CDK12 synergizes with ATR inhibition by limiting RPA chromatin loading in triple-negative breast cancer.

Eun-Bee Choi[1], Sophia Podeszwa[1], Ah-Ram Kim[2], Ashwani Bahl[3], Geoffrey I. Shapiro[1]

[1]Department of Medical Oncology, Dana-Farber Cancer Institute, Boston, MA,[2]Department of Genetics, Blavatnik Institute, Harvard Medical School, Boston, MA,[3]Carrick Therapeutics, Dublin, Ireland

Targeting cyclin K-CDK12 is a promising therapeutic due to its ability to induce homologous recombination (HR) repair deficiency through transcriptional regulation. Reduced CDK12 activity sensitizes HR repair-proficient tumor cells to PARP inhibitors (PARPi) and DNA-damaging agents. However, recent studies show that *CDK12*-mutant cancers lack the genomic signatures associated with HR repair deficiency and derive limited therapeutic benefit from PARPi. It is therefore essential to understand additional mechanisms by which cyclin K-CDK12 depletion promotes genomic instability beyond impaired HR repair. Here, we demonstrate that cyclin K-CDK12 depletion drives a replication stress (RS)-associated vulnerability and synergizes with ATR inhibition, using CT7311 (Carrick Therapeutics), a protein degrader of cyclin K. Triple-negative breast cancer (TNBC) cells, especially those with high *MYC* expression, were the most sensitive to CT7311 compared with estrogen receptor-positive (ER+) BC and non-transformed breast cells. Notably, CT7311 sensitivity did not correlate with HR repair status. In a DNA damage response-focused CRISPR screen with CT7311, DNA replication-related genes were highly enriched among the sensitizers, with effects stronger than those of HR repair-related factors. We validated three sensitizers, *TOPBP1*, *PRIM2*, and *PRPF19*, which are closely linked to ATR activation, a central RS regulator. Consistent with the screen, cyclin K-CDK12 depletion yielded synergistic cytotoxicity with ATR inhibition only in TNBC, not in ER+ BC cells. Mechanistically, CT7311 induces transcription-replication conflicts (TRCs), a known RS source, but fails to robustly activate ATR. Rather, it limits ATR activation by reducing the chromatin loading of Replication Protein A (RPA). This impaired ATR activation is further exacerbated when combined with tuvusertib (ATRi), leading to marked DNA damage specifically in replicating cells. Strikingly, RPA overexpression conferred resistance to the combination, indicating that the synergy arises from impaired availability of RPA. We further show that cyclin K-CDK12 regulates RPA chromatin loading via the PRPF19 E3-ligase complex. AlphaFold-Multimer predictions revealed interactions between cyclin K-CDK12 and the PRPF19 complex. CT7311 disrupted PRPF19 complex assembly, compromising its activity and impairing RPA ubiquitination. Notably, CDK12-mediated phosphorylation of CDC5L, a PRPF19 complex subunit, was required for RPA chromatin loading. Collectively, our work identifies cyclin K-CDK12 as a critical regulator of RPA dynamics and uncovers ATR dependency driven by cyclin K-CDK12 depletion. These insights extend the rationale for cyclin K-CDK12 targeted therapy beyond HR repair-focused applications, supporting its use in RS-high tumors including TNBC, as monotherapy or in combination with ATR inhibition.

#0252 Targeting replication stress promotes immunogenic cell death in chordoma.

Nindo Punturi[1], Arijit Ghosh[2], Caitlin King[1], Wendy Leung[3], Joan B. Levy[4], Lee Zou[2], Gregory M. Cote[3], Dan Freed[1]

[1]Chordoma Foundation, Durham, NC,[2]Duke University School of Medicine, Durham, NC,[3]Massachusetts General Hospital, Boston, MA,[4]Melanoma Research Alliance, Hamden, CT

Chordoma is a rare bone cancer with a high rate of recurrence and no approved systemic therapies. Target discovery efforts have uncovered complex genomic rearrangements, alterations in DNA damage response (DDR) and chromatin-remodeling genes, and a reliance on DDR pathways that stabilize stalled replication forks. Additionally, a subset of chordomas is highly infiltrated by multicellular immune aggregates, but the underlying mechanisms driving an antitumor immune response remain unclear. We hypothesized that replication stress presents an actionable therapeutic vulnerability in chordoma and that targeting this pathway could induce lethal DNA damage and immunogenic cell death. To assess the effects of exacerbating replication stress in chordoma, a panel of 14 cell lines was treated with the DNA synthesis inhibitor gemcitabine or the ATR inhibitor elimusertib (BAY 1895344). Most lines were highly sensitive, with 9 of 14 showing EC_{50} values below 10 nM (gemcitabine) or 100 nM (elimusertib). Biochemical analysis showed that gemcitabine-induced DNA damage leads to activation of Chk1 in an ATR-dependent manner, with DNA fiber assays revealing decreased replication fork speed, symmetry, and stability following ATR inhibition (ATRi). Sensitivity to ATRi or gemcitabine was mirrored in chordoma PDX models, with ATRi promoting 85–90% tumor growth inhibition in sensitive models and gemcitabine driving tumor regressions. Exceptional synergy was observed in vitro when these therapies were combined, with significant reductions in cell viability, enhanced DNA double-strand breaks, and near-complete S-phase collapse. Moreover, treatment with either drug resulted in the accumulation of double-stranded DNA in the cytoplasm, along with upregulation of type I interferon, immunomodulatory chemokines CXCL10 and CCL5, and cell surface PD-L1. These findings are consistent with a model where ATRi or gemcitabine treatment promotes lethal DNA damage and immunogenic cell death in chordoma, which may be further augmented by PD-1 checkpoint blockade.

#0253 Antitumor activity of PARP inhibitors in combination with Temozolomide in fumarate hydratase-deficient RCC.

Sameer Issaq, Kylie Enten, Emily Hnath, **Komal Rawal**, Ramaprasad Srinivasan

Urologic Oncology Branch, National Cancer Institute, National Institutes of Health,, Bethesda, MD

Hereditary Leiomyomatosis and Renal Cell Cancer (HLRCC) is a rare form of RCC associated with an aggressive clinical course. Despite the recent availability of therapeutic approaches active in FH-deficient RCC, most patients with advanced HLRCC die from their disease; identification of additional effective treatment strategies for these patients is, therefore, a therapeutic imperative. HLRCC is characterized by germline pathogenic variants in the *fumarate hydratase (FH)* gene, that encodes a key Tricarboxylic Acid (TCA) Cycle enzyme. Loss of FH activity leads to the accumulation of its substrate, fumarate. Excess fumarate serves as an oncometabolite and has been reported to suppress DNA damage repair. We evaluated the activity of PARP inhibitor-based combinations in preclinical models of HLRCC. The antitumor activity of two PARP inhibitors, Talazoparib and Niraparib, either as single agents or in combination with the alkylating chemotherapy agent temozolomide, was evaluated in several patient-derived HLRCC cell lines. In vitro viability assays demonstrated that both PARP inhibitors induced dose-dependent growth inhibition in HLRCC lines. The addition of temozolomide to either PARP inhibitor led to more pronounced reductions in cell proliferation across the HLRCC lines tested, compared to control single PARP inhibitors or temozolomide alone. At the molecular level, western blot analysis demonstrated that PARP inhibitors inhibited PARylation with concomitant upregulation of phosphorylated (γ) H2AX expression, and increased apoptosis. Furthermore, the effects on PARylation, γH2AX accumulation, and apoptosis were more pronounced in the PARP inhibitor/temozolomide combinations than with PARP inhibitors alone and were accompanied by substantial increases in cleaved PARP. These results demonstrate that PARP inhibitors have antitumor activity against HLRCC cells and that their activity is potentiated by the addition of the alkylating agent temozolomide. Additional in vitro and in vivo studies are ongoing to further define the activity of these combinations and to better understand the underlying molecular mechanisms. This study highlights the potential therapeutic utility of PARP inhibitor-based combinations in targeting DNA repair defects in HLRCC and provides the impetus for further exploration of this strategy.

#0254 The PARP1-selective inhibitor and trapper saruparib achieves extended PARP1 target engagement *in vitro*, *in vivo* and in the clinic.

Mark Robert Albertella[1], Giuditta Illuzzi[1], Anna D. Staniszewska[1], Domenic Pilger[1], Sophie Cooke[1], Spiros Linardopoulos[2], Anna Beckett[1], Christopher Stubbs[3], Ganesh Moorthy[4], Mark J. O'Connor[1]

[1]Bioscience, AstraZeneca Oncology R&D, Cambridge, United Kingdom,[2]Translational Medicine, AstraZeneca Oncology R&D, Cambridge, United Kingdom,[3]Discovery Sciences, AstraZeneca R&D, Cambridge, United Kingdom,[4]AstraZeneca Oncology R&D, Boston, MA

Saruparib (AZD5305) is a potent and selective inhibitor and trapper of PARP1 which is currently in ph3 clinical development. Initial preclinical characterisation highlighted nanomolar PARP1 inhibition potency and differentiated PARP1 binding profile with longer residence time kinetics compared with approved non-selective PARP inhibitors (PARPi). Here we describe the consequences of this in pre-clinical and clinical studies where we analysed PARP1 inhibition duration and phenotypic effects after different exposure times to saruparib. Surface plasmon resonance (SPR) of purified PARP1 showed that saruparib has a very slow dissociation rate, K_{off}, and extended residence time on purified PARP1 protein (>5 days) compared to approved PARP1/2 inhibitors (hours). In cellular assays, saruparib treatment followed by wash-off resulted in sustained suppression of Poly ADP Ribose (PAR) over several days, whereas PAR levels recovered within 24 hours after olaparib exposure. We explored the duration of *in vivo* pharmacodynamic effects by monitoring PAR levels after steady state dosing of saruparib to mice bearing BRCA1-mutant MDA-MB-436 tumours, for up to 7 days after cessation of dosing. Saruparib at 0.01, 0.03 or 0.1mg/kg maintained PAR inhibition of >90% for up to 7 days, although the drug levels were not detectible in plasma after 2 days, confirming this extended duration of action *in vivo*. In contrast, PAR levels were substantially recovered by 24 hours after olaparib dosing. The functional consequences of the extended duration of action of saruparib were evaluated for *in vivo* efficacy. Multiple intermittent schedules of saruparib, compared to olaparib or talazoparib were evaluated in the BRCA1m-MDA-MB-436 model. Strong regressions were observed with saruparib on intermittent schedules where even 1 wk on, 2 wk off schedule at 1mg/kg (equivalent to the clinical RP2D dose of 60mg) gave durable regressions. A reduced dose of saruparib of 0.1mg/kg was still effective on an intermittent schedule, but lost significant activity compared to the higher dose. Intermittent dosing schedules of saruparib were clearly superior to the same schedules of olaparib or talazoparib at clinically equivalent doses. The long duration of activity of saruparib observed in preclinical studies were also observed in the PETRA clinical study (NCT04644068). A single dose of saruparib resulted in >90% PAR inhibition for up to 7 days, despite no drug being detected in plasma after 48 hours. These data suggest that short-term dose interruptions are unlikely to result in reduced efficacy, in contrast to approve non-selective PARPi where dose interruptions have been shown to reduce efficacy. These data also suggest that intermittent scheduling may be effective for saruparib in circumstances where minimising exposure may provide an optimal risk-benefit - for example cancer prevention.

#0258 Preclinical study of nucleic acid therapeutics targeting the Warburg effect.

Keita Matsumoto, Hirokatsu Hayashi, Seito Fujibayashi, Noriki Mitsui, Takeshi Horaguchi, Yuji Hatanaka, Ryoma Yokoi, Ayana Yokoyama, Chika Mizutani, Masashi Kuno, Masahiro Fukada, Ryuichi Asai, Itaru Yasufuku, Yuta Sato, Jesse Yu Tajima, Yoshihiro Tanaka, Nobuhisa Matsuhashi

Gifu Univ. Hospital, Gifu, Japan

[Background] Cancer cells rely on glycolysis for energy, known as the Warburg effect, which supports survival by promoting nucleotide synthesis, reducing oxidative stress, and inhibiting cell death.
Polypyrimidine tract-binding protein 1 (PTBP1) regulates pyruvate kinase muscle (PKM1/PKM2) splicing, maintaining a PKM2-dominant state. Suppressing PTBP1 shifts cellular metabolism to a PKM1-dominant state, reduces glycolysis, alters ATP production, and increases oxidative stress, ultimately resulting in cell death.
We developed optimized chemically modified siR-PTBP1 derivatives to evaluate their therapeutic potential.
[Methods] Anti-proliferative activity in human colorectal DLD-1 cells was tested by chemically modified siR-PTBP1 derivatives. Cell viability was assessed by CVS assay, and PTBP1, PKM1/PKM2, and cleaved PARP protein levels were analyzed by Western blotting and immunostaining after the transfection. ATP production and oxidative stress assay were performed to examine the alternation from glycolysis-dominant to oxidative phosphorylation via TCA cycle. Metabolome analysis was also examined.
[Results] Among 14 derivatives, the derivative siR-2-6 significantly suppressed PTBP1, increased PKM1 expression, and raised the PKM1/PKM2 ratio. Increased cleaved PARP expression indicated apoptosis induction and Warburg effect suppression. Also, siR-2-6 increased ATP production and oxidative stress, resulting in apoptosis. The higher RNase resistance and biological activity under RNase-containing conditions were shown in comparison to those of the SiR-2-1 that is not chemically modified.
[Conclusion] Optimized siR-PTBP1 derivatives increased the PKM1/PKM2 ratio and partially shifted cellular metabolism from glycolysis dependence to oxidative phosphorylation, highlighting their potential as nucleic acid therapeutics.
The enhanced RNase resistance of siR-2-6 further supports its promise for in vivo application and clinical translation.

#0259 Targeted STEAP2 knockdown with self-delivering antisense oligonucleotide reduces cancer malignant behavior.

Nagesh K. Panchal[1], Araceli Bernal[1], Brittany Michelle Barre[1], Francisco Cigarroa[2], LuZhe Sun[1]

[1]Cell System and Antomy, The University of Texas Health Science Center At San Antonio, San Antonio, TX,[2]Transplant Center, The University of Texas Health Science Center At San Antonio, San Antonio, TX

Background: The STEAP (Six-Transmembrane Epithelial Antigen of Prostate) family encodes metalloreductases involved in iron and copper metabolism, with increasing evidence linking dysregulated metal homeostasis to tumor progression. Increased STEAP2 expression has been implicated in the development and progression of several cancers, with enhanced cellular proliferation, migration, but its precise role in cancer remains obscure. The goal of this project is to investigate the significance and prognostic potential of targeting STEAP2 in oncogenesis.

Methods: Our study investigated a self-delivering antisense oligonucleotide (ASO) targeting STEAP2 in cancer. Human liver cancer SNU398 and prostate cancer PC3 cells were treated with increasing ASO concentrations (0.25, 0.5, 1 and 5 μM) for 92 hours, followed by assessment of cell viability (WST-1), migration (transwell), and anchorage-independent growth (soft agar). For the in vivo study, orthotopic xenografts were created by injecting SNU398-luc/GFP cells into the livers of immunodeficient mice. Beginning on day 7, mice received 12 doses of the STEAP2-ASO or scrambled control (5 mg/kg, every two days). Tumor growth was monitored non-invasively via IVIS imaging. Upon treatment completion, tumors and adjacent liver tissues were harvested. Expression of EMT markers (Vimentin and SNAIL1) was evaluated in cell and tissue lysates using western blot analysis.

Results: ASO mediated KD of STEAP2 induced a dose dependent reduction in STEAP2 expression, leading to significantly reduced cell viability, migration, and anchorage-independent growth in both SNU398 and PC3 cell lines. In addition, STEAP2 knockdown resulted in decreased expression of key EMT markers, including Vimentin and SNAIL1. *In vivo* analysis demonstrated that treatment with STEAP2 targeting ASOs resulted in a substantial decrease in tumor size, together with downregulation of STEAP2 levels, highlighting a clear association between STEAP2 suppression and inhibition of cancer progression. Consistent with the in vitro findings, tumors from ASO-treated mice also showed reduced Vimentin and SNAIL1 expression, further supporting EMT attenuation. Thus, our findings emphasize STEAP2 as an essential regulator of cancer development and progression as well as the therapeutic promise of the ASO-based STEAP2 silencing for abrogating the progression of liver and prostate cancer.

Conclusion: Overall, these findings establish STEAP2 as a potential biomarker and therapeutic target for the intervention of various cancers.

#0260 EpCAM-CD3 bispecific antibody-encoding mRNA delivered by lung targeted lipid nanoparticles suppresses orthotopic lung tumor growth.

Dong Wang[1], Gang Liu[1], Yuhe Han[2], Maorong Fu[3], Tingting Li[3], Xiangnan Qiang[1], Shunchuan Zhang[3], Zhixiang Zhang[1], Letian Kuai[1]

[1]WuXi AppTec, Shanghai, China,[2]WuXi AppTec, Nantong, China,[3]WuXi AppTec, Chengdu, China

The therapeutic use of bispecific T-cell engaging (BiTE) antibodies has shown great potential for treating malignancies. However, full exploitation of the potential of BsAbs is hindered by manufacturing challenges and short serum half-lives. In contrast, mRNA therapeutics have emerged as a powerful approach for treating a wide range of diseases. Their applications are increasingly linked to advancements in targeted delivery technologies and the production of mRNA encoded antibody is more flexible and cost-effective than the traditional method. In this work, We developed a lung selective organ targeting lipid nanoparticles (SORT LNPs)-formulated RNA (RNA-LNP) encoding a T cell-engaging bispecific antibody that binds the T cell marker CD3 and bivalently binds epithelial cell adhesion molecule (EpCAM), an epithelial antigen that is expressed on various solid tumors. We first performed *In vitro* flow cytometry analysis, which revealed that mRNA lipid nanoparticles (LNP) effectively mediated the killing of EpCAM positive tumor cells and activated human T cells. Then we established NCI-H441 lung orthotopic tumor model in PBMC humanized mice. We observed robust antitumor efficacy of mRNA LNP in this tumor model. To assess mRNA distribution, we quantified its content in various organs using qPCR. Results confirmed the lung targeting specificity of LNP. Moreover, we analyzed the activation of tumor-infiltrating T cells post mRNA LNP treatment. Finally, we conducted histopathological examination of various organs and we didn't find signs of adverse effects from LNP formulated mRNA administration. In this comprehensive preclinical evaluation, we demonstrated that mRNA-encoded bispecific antibody promoted the activation and cytotoxicity of human T cells, exhibiting significant inhibition of orthotopic lung tumor growth *in vivo*. These findings underscore the potential research value of mRNA-encoded CD3-EpCAM T cell engager in treating solid tumors, marking a potential shift in the clinical application of protein-based T-cell engagers.

#0261 A mRNA-encoded trispecific CD19xBCMAxCD3 T cell engager to treat cancer and autoimmunity.

Beibei Cao[1], Bingxu Zhang[1], Shuting Yao[1], Qiang Zhang[2], Shanshan Zhou[1], Lun Zhang[1], Lei Li[2], Chenxing Ni[2], Jianqi Zhang[2], Ya Zhou[1], Xiaoyun Ma[2], Xiaoju Zhang[1], Hongya Han[1], **Wei Xu**[1]

[1]METiS TechBio, Hangzhou, China,[2]METiS TechBio, Beijing, China

Background: B-cell-directed therapies have transformed treatment for B-cell-driven cancers and autoimmune diseases, yet current T-cell-based modalities, including CAR-T cells and T-cell engagers (TCEs), are limited by safety concerns such as cytokine release syndrome (CRS)—a particular risk for autoimmune patients requiring wide safety margins. In addition, plasma cells drive disease progression and relapse but are not efficiently eliminated by CD19-targeted treatments. To overcome these limitations, we developed a first-in-class mRNA-encoded trispecific TCE targeting CD19, BCMA, and CD3 to achieve broad B-cell and plasma-cell depletion with improved safety.

Methods: The TCE was constructed by fusing a CD3-binding scFv with VHH domains targeting CD19 and BCMA. The encoding mRNA was optimized through codon and structural engineering to balance Codon Adaptation Index (CAI) and Minimal Free Energy (MFE) across untranslated regions and the coding sequence. The optimized mRNA was formulated in a novel lipid nanoparticle (LNP) designed for preferential biodistribution to secondary lymphoid organs, including spleen, bone marrow, and lymph nodes. B-cell cytotoxicity was evaluated using PBMCs from healthy donors, autoimmune patients, or in BCMA+ multiple myeloma co-culture assays. In vivo B-cell depletion, pharmacokinetics, biodistribution, and safety were tested in humanized immune-deficient mice reconstituted with CD34+ HSCs or systemic lupus erythematosus (SLE) PBMCs, in human CD19/CD3 transgenic mice, and in non-human primates (NHPs). Activity against BCMA+ tumors was assessed in PBMC-reconstituted multiple myeloma xenografts.

Results: The mRNA-encoded TCE induced potent B-cell killing in human PBMC assays, achieving an EC50 of ~0.1 pM. Robust B-cell depletion was confirmed across multiple mouse models. In the SLE-PBMC model, treatment significantly reduced autoantibody levels. In OPM2 tumor-bearing mice, the TCE induced profound CD19+ B-cell depletion in blood and lymphoid tissues and complete regression of BCMA+ tumors. In NHPs, ultra-low mRNA-LNP dosing (5 μg/kg) produced complete peripheral B-cell depletion within 6 hours, with broad depletion of naïve, memory, and plasma cell compartments in spleen, lymph nodes, and bone marrow by day 15. B-cell reconstitution began ~3 weeks post-dose and was dominated by naïve phenotypes, suggesting immune resetting. Subcutaneous dosing achieved efficacy comparable to intravenous delivery but with markedly reduced cytokine release, consistent with the favorable pharmacokinetic profile of mRNA translation. No toxicity or clinical pathology abnormalities were observed at doses up to 100 μg/kg.

Conclusion: This mRNA-encoded trispecific CD19×BCMA×CD3 TCE demonstrates potent and broad B-cell and plasma-cell depletion, anti-tumor activity, and an improved safety profile, supporting ongoing First-in-Human clinical evaluation.

#0262 Leveraging cancer-activated gene expression and cGAS-STING activation for efficient tumor killing via a DNA-LNP delivery platform.

Moataz Reda, Evan Bishop, Priyanka Balasubrahmanyam, Blaine McCarthy, Sushil Lathwal, Robby Chandra, Audrey Smith, Xiao Wu, Jesse Simons, Kim Tran, Ajda Rojc, Jayalakshmi Ramani, Suyog Shaha, Dang Dang, David Rosen, Badri Ananthanarayanan, Nadege Morisot, David Suhy

Earli Inc., Redwood City, CA

Background: Despite rapid advances in immunotherapy, the clinical use of potent immune-modulating agents remains constrained by systemic toxicities. Earli is developing a DNA-based immunotherapy platform that uses synthetic cancer-activated promoters (CAPs) to drive selective expression of therapeutic payloads in malignant cells, while remaining silent in normal tissues and benign lesions. DNA is delivered systemically to the tumor cells by lipid nanoparticles (LNPs). The platform also engages innate immunity via the immunostimulatory nature of DNA. This study highlights the dual mechanism of combining 1) CAP-driven expression of a potent immunostimulatory payload such as IL-12 with 2) cGAS-STING-induced innate immune activation.
Methods: Naïve or tumor-bearing mice were treated with LNPs encapsulating either a DNA nanoplasmid encoding IL-12 under a cancer-activated promoter (CAP-IL-12) or a matched construct with three stop codons (Control-DNA). Mice were assessed for tumor growth inhibition, cytokines (IL-6, IL-1β, TNF-α), and IL-12 levels in tumor and serum.
Results: LNP encapsulating Control-DNA increased transcript levels of STING downstream targets and triggered a transient rise in pro-inflammatory cytokines. This innate immune response resulted in a partial (i.e. non-durable) inhibition of tumor growth across multiple syngeneic tumor models and showed enhanced efficacy when combined with PD-1 checkpoint blockade. Importantly, in STING knockout mice, the anti-tumor response to the formulated Control-DNA was completely lost. In contrast, IV treatment with an LNP encapsulating CAP-IL-12 DNA led to complete and durable tumor regression. Surprisingly, although modest IL-12 protein was detectable in tumors, there were no substantial IL-12 levels measured in serum, demonstrating the platform's ability to concentrate a highly potent therapeutic at the tumor site while avoiding systemic exposure. Further, immune profiling showed both IL-12 and STING induced changes including increases in T cell and NK cell proliferation, granzyme B upregulation, and enhanced myeloid activation and antigen presentation. Importantly, the anti-tumor efficacy of CAP-IL-12 was retained in syngeneic tumors in STING knockout mice, demonstrating that cancer-specific payload expression is sufficient to drive efficacy even in the absence of adjuvant STING agonism. Our current work focuses on modulating STING agonism through LNP engineering approaches to fine-tune its activity in the tumor for a balanced therapeutic response.
Conclusions: Overall, our findings highlight the dual-function nature of Earli’s DNA-LNP platform: a programmable, tumor-selective gene therapy system with built-in innate immune activation through STING agonism. The approach supports a new class of immunotherapies that combine precision and potency in a single genetic modality.

#0263 Towards personalized cancer vaccines: LNP-mediated delivery of multi-epitope mRNA extends survival in aggressive melanoma cancer model.

Jay Paquette, Gayatri Namala, Leanna Yee, Sams MA Sadat, Ruchi Sharma, Darius Menezes, Pierrot Harvie, Nikita Jain, Zhengyu Chen, Malathi Anantha, Tony Wu, Vicente Lacap, Richard Jiang, Vinay Mayya, Sijo Chemmannur, Avisek Deyati, Anitha Thomas

Cytiva, Vancouver, BC, Canada

Personalized cancer vaccines (PCVs) open new doors for immunotherapy by harnessing the immune system to target tumor specific neoantigens — mutated proteins — unique to an individual's cancer. Lipid nanoparticle (LNP)-based mRNA vaccines, shown to be effective against COVID-19, serve as a suitable platform for delivering multi-epitope neoantigen mRNA payloads. LNP drug product for PCV applications however, may require optimization of the multi-antigenic mRNA cargo, target tissue uptake, and endosomal release, along with frequent therapeutic dosing. We identified 10 melanoma-specific antigens and synthesized multiple multi-antigen mRNA constructs encoding various antigen combinations, with and without marker epitopes such as ovalbumin (OVA), eGFP, and firefly luciferase (Fluc). We developed proprietary ionizable lipids and encapsulated the various multi-epitope mRNA constructs in LNPs and evaluated their performance in well-established *in vitro* cell based assays and a B16F10 syngeneic mouse melanoma model. The *in vitro* cell-based assays confirmed effective LNP-mediated delivery, mRNA translation, and antigen presentation via major histocompatibility complex (MHC) molecules. *In vivo* imaging demonstrated payload expression 6 hours post-injection. Selected multi-epitope mRNA-LNP formulations were administered intramuscularly in B16F10 tumor-bearing mice. Multi-epitope comprising LNPs significantly reduced mean tumor growth rate and extended survival in vaccinated mice compared to controls. Additionally, repeated dosing regimens showed favorable safety profiles. These results demonstrate that our proprietary LNP platform efficiently delivers multi-epitope mRNA LNPs, eliciting potent anti-tumor immune responses in a relevant melanoma model and demonstrating safety of repeated LNP administrations for shared or individualized cancer vaccine applications. This positions our LNP as a promising candidate for further developing PCVs and accelerating new personalized medicine to clinic.

#0264 A novel gene therapy approach for treating breast cancer through the overexpression of mutant estrogen receptor.

Seung-hwan Jeong[1], Seokbong Hong[2], Hyeong Dong Yuk[2], Cheol Kwak[2]

[1]Seoul National University, Seoul, Korea, Republic of,[2]Seoul National University Hospital, Seoul, Korea, Republic of

Background: Endocrine therapy (ET) is the primary treatment for hormone receptor-positive (HR+) breast cancer, but resistance inevitably develops, leading to endocrine-resistant breast cancer. While agents like tamoxifen and aromatase inhibitors improve outcomes, resistance mechanisms remain significant challenges. This suggests a complex role for estrogen receptor (ER) signaling. We hypothesized that maintaining a non-functional, mutant ER (mER) could overcome this resistance.
Methods: We synthesized a full-length ER (ESR1) gene with a mutation in the DNA-binding domain (DBD). To ensure targeted delivery, the mER-encoding plasmid was encapsulated within poly(lactic-co-glycolic acid) (PLGA) nanoparticles. These nanoparticles were surface-functionalized with 4-carboxyl-17beta-estradiol, an ER ligand, to facilitate active targeting to ER-positive breast cancer cells. The effects of mER overexpression were investigated in vitro using HER2-ER+PR+ MCF7 and T47D cell lines, as well as their tamoxifen-resistant (TamR) counterparts. In vivo antitumoral effects were assessed using xenograft mouse models.
Results: The ER-targeted PLGA nanoparticles effectively delivered the mER plasmid to ER-expressing breast cancer cells in vitro and in vivo. Overexpression of mER did not activate estrogen-responsive genes and exerted a potent antiproliferative effect in both MCF7 and T47D cells. Notably, mER overexpression maintained its strong antitumoral activity in tamoxifen-resistant (TamR) MCF7 and T47D cells. Mechanistically, mER overexpression led to a reduction in wild-type ER (wtER) levels and suppressed DNA replication-related gene pathways. In vivo, mER treatment significantly inhibited the growth of both standard and tamoxifen-resistant tumors. Furthermore, a synergistic antitumoral effect was observed when mER was combined with tamoxifen.
Conclusions: Overexpression of a mutant ER with a non-functional DBD, delivered via an ER-targeted nanoparticle system, represents a novel therapeutic strategy for advanced HR+ breast cancer, including endocrine-resistant and tamoxifen-resistant disease. By suppressing wtER, disrupting DNA replication, and maintaining activity in resistant models, mER effectively inhibits tumor growth and overcomes therapeutic resistance.

#0265 Engineering robust AAV vectors: Addressing ITR instability for effective cancer gene therapy.

Crystal Richardson, Sofija Markovic, Cassandra Koole, Andrea O'Hara, Sumit Kumar

Azenta Life Sciences, Burlington, MA

Introduction: Cancer remains one of the most challenging diseases to treat due to the complexity of tumor biology and barriers to effective drug delivery. Gene therapy using adeno-associated viruses (AAVs) offers a promising approach for oncology, particularly with the development of engineered capsids such as AAV-DJ, which demonstrate enhanced tissue penetration and targeted gene expression in tumor microenvironments. Importantly, AAV-based strategies are also being explored in neuro-oncology, where capsid variants capable of crossing the blood-brain barrier provide new opportunities for treating aggressive brain tumors such as glioblastoma. The AAV genome consists of a therapeutic transgene flanked by 145 bp inverted terminal repeats (ITRs), which are prone to mutations and deletions but also essential for viral packaging. While capsid engineering has improved tumor targeting and systemic delivery, ITR instability remains a critical challenge for consistent therapeutic outcomes.
Methods: In this study, we evaluated the impact of five common ITR mutations on vector integrity and performance. HEK293T cells were co-transfected with transfer, Rep/Cap (AAV-DJ), and helper plasmids for viral packaging. ITR mutations were confirmed via Sanger sequencing, and purified vectors were assessed for viral titers using qPCR and transduction efficiency via GFP fluorescence microscopy. Mutant ITRs were subsequently repaired to wild-type sequences to compare recovery of function. To model therapeutic relevance, AAV vectors were tested in tumor-bearing mice using immunofluorescence markers to assess transgene expression within cancerous tissues.
Results: Even minor ITR alterations, such as single base pair deletions, demonstrated significantly reduced viral titers and transduction efficiency, with more pronounced effects in constructs carrying large therapeutic cassettes. Although mutant vectors retained some tumor-targeting capability, wild-type ITR constructs achieved the highest efficiency.
Conclusion: This work underscores the critical role of ITR integrity in AAV-based oncology applications, including neuro-oncology. Even small sequence disruptions can compromise vector potency, highlighting the need for rigorous quality control during vector design and production. These findings inform the development of robust AAV platforms for cancer gene therapy, ensuring optimal delivery and therapeutic impact.

#0266 Redtail: A dual-programmable virotherapy platform for systemic tumor targeting and localized gene delivery.

Yunyi Kang[1], **Duong H. Nguyen**[1], Stephanie Songco[1], Trevor Smith[1], David Nguyen[1], Yan Pang[1], Lina Schulte[2], Hongli Zhang[2], Sinje Tigges[2], Fabian Kortum[2], Daniela Kleinholz[2], Susan Tamraz[2], Ivelina Minev[1], Evan Cassavaugh[1], Travis Clifton[1], Thomas Herrmann[2], Barbara Hartl[2], Antonio F. Santidrian[1]

[1]Calidi Biotherapeutics, San Diego, CA,[2]StemVAC GmbH, Bernried, Germany

RedTail is a next-generation gene therapy platform combining systemic delivery with tumor selectivity. Unlike conventional oncolytic viruses, RedTail integrates programmable targeting for precise tumor specificity and genetic payload delivery for immune modulation of the tumor microenvironment (TME). It employs a tumor-specific, replicating extracellular enveloped vaccinia virus (EEV) cloaked in a second human cell-derived membrane (the “Envelope”) from engineered host cell lines; chimeric CD55 overexpression in the Envelope confers resistance to complement and neutralizing antibodies, enabling systemic administration. The Envelope can be further designed to express targeting proteins. The viral genome can be modified to deliver immune-cell activating therapeutic payloads such as IL-15 Superagonist along with bispecific T-cell engagers (BiTEs) for localized expression in the tumor microenvironment. Delivering BITEs at high concentrations to the tumor while simultaneously activating T-cells in the TME through in situ expression of an immunostimulatory payload may overcome the challenges seen to date with T-cell engagers in solid tumors.
Methods: RedTail EEVs were produced using engineered host cell lines expressing chimeric antigen receptors (CARs). The RedTail EEVs were further engineered to express BITEs and T-cell activating payloads at high concentrations in situ. Tumor targeting, viral amplification, and transgene expression were assessed by viral titers, ELISA, flow cytometry, and immunohistochemistry.
Results: The first programmable characteristic of RedTail is its extracellular membrane. RedTail EEVs were manufactured using host cell lines engineered to express CARs, producing particles that displayed CARs (e.g., anti-HER2, anti-Trop2) on their surface with corresponding tropism.The second programmable characteristic is the viral genome, engineered to express genetic payloads including BiTEs targeting tumor antigens along with CD3 to recruit and activate T cells. A T-cell activating payload was also included. Viral infection was enhanced for tumor cells that displayed the cognate target, and resulted in tumor cell lysis along with high levels of expression of the BITE and the immune stimulating payload.This dual programmability—membrane engineering for targeting and genome programming for payload delivery—represents a unique approach among systemic virotherapies.
Conclusions: This dual programmability enables systemic tumor targeting, immune priming, and localized expression of both a T-cell engager and an immune priming payload, positioning RedTail as a next-generation systemic platform with a unique approach to T-cell targeting in solid tumors.

#0268 Engineering a novel epithelial-tropic pseudovirus platform for targeted gene therapy to carcinomas.

Kendall Wesley Knechtel, Daniel Pelaez

University of Miami Miller School of Medicine, Miami, FL

Carcinomas represent over 80% of all cancer diagnoses and remain difficult to treat due to genetic heterogeneity, acquired drug resistance, and limited therapeutic specificity. Oncolytic viral therapies (OVTs) have shown promise for many cancers; however, current platforms such as the modified herpes simplex virus rely on intratumoral delivery and remain highly immunogenic, restricting their use against deep-seated and metastatic epithelial malignancies. To address this, we developed a non-replicative pseudotyped lentiviral platform designed with epithelial tropism and stable genomic integration. Our engineered chimeric envelope surface receptor retains key native receptor interactions of the L1 capsid protein of the human papilloma virus, designed in-silico to exploit functional domains, while preserving vital molecular mechanisms. This glycoprotein, combined with lentiviral backbone elements, yields a morphologically intact virion, confirmed by negative-stain TEM, that avoids virus-like-particle formation prior to plasma membrane trafficking. Transduction assays demonstrated selective infection and sustained transgene expression in epithelial cell lines as opposed to non-epithelial controls. To enhance selectivity, cancer-specific promoters would further confine payload expression to malignant epithelial cells. The pseudovirus can deliver a larger payload (8-10 kb) greater than that of Adeno-Associated Virus (≤ 4.7 kb) supporting complex therapeutic cassettes, including suicide genes and barrier-repair payloads. Our ongoing in-vitro and in-vivo studies are evaluating therapeutic delivery and efficacy in specific carcinoma models.

#0269 Functionalization of virus-like particles for improved *in vivo* immune cell engineering.

Frances Rocamora[1], Matthew S. Kim[1], Barbara S. Perez[2], Vivian Le[1], Trinidad Kellemen[1], Enaaya Mahmood[1], Dan Kaufman[1]

[1]UC San Diego School of Medicine, La Jolla, CA,[2]UC San Francisco, San Francisco, CA

To address the limitations of conventional chimeric antigen receptor (CAR) T cell manufacturing, we developed a novel *in vivo* CAR engineering platform based on functionalized virus-like particles (VLPs) that self-assemble with a minimal viral genome to efficiently package and deliver mRNA payloads. Our initial studies compared the level and stability of transgene (GFP) expression in primary human T cells transduced with VSV-G pseudotyped lentivirus (LV) with those transduced with our mRNA-delivering VLPs and circular DNA-forming non-integrating LV (NILV). In these studies, our VLPs transduce over 20% more cells at an equivalent titer than both LV and NILV. As expected, GFP expression from VLP-treated and NILV-treated T cells declined 72 hours after VLP removal, consistent with transient transgene expression. To further improve the platform, we modified the VLP envelope in two ways. First, we added an anti-CD3-targeting single-chain variable fragment (scFv) fused to a low-density lipid (LDL) receptor-blind mutant of the VSV-G fusogen protein (VSVg mut). This construct promotes T cell-specific targeting without non-specific cell binding. In a co-culture model of T cells and Raji B cells, we demonstrated that our scFv-coated VLPs can transduce up to 15% of T cells while less than 1% of B cells are transduced. Because the targeting molecule is derived from blinatumomab, anti-CD3 scFv-coated VLPs also induced upregulation of activation markers CD69 and CD25 in primary human T cells relative to a non-functionalized VLP control. Second, we engineered our VLPs to express an immune-enhancing molecule to both improve mRNA delivery and augment the cytotoxic activity of engineered T cells. While scFv-coated VLPs delivering an anti-CD19 CAR transduced less than 5% of rested primary T cells, enhancer-coated VLPs transduced about 35% of cells and dual-functionalized VLPs (scFv + enhancer) transduced approximately 24% of cells. Next, we used *in vitro* live cell imaging assays (Incucyte) to quantify killing of CD19+ Nalm6 cells with functionalized VLP-treated rested T cells over 72 hours. While the cells treated with only anti-CD3 scFv-coated VLPs did not elicit a significant anti-tumor activity (demonstrated by continued growth of the tumor cells), targeting T cells using just the enhancer-coated VLPs lead to ~75% decrease in tumor cells compared to control targeted T cells. Notably, T cells treated with dual functionalized VLPs (anti-CD3 scFv plus enhancer) led to almost complete tumor cell killing (>95%). In conclusion, our novel VLP system with using dual immune cell targeting via anti-CD3 and functionalized envelope enhances mRNA delivery and anti-CD19 CAR-T cell-mediated cytotoxicity *in vitro*. In vivo studies using humanized mouse models are underway to validate this *in vivo* engineering and anti-tumor efficacy.

#0270 pIR-a new antibiotic free plasmid production platform for non-viral DNA delivery.

Dan Zhao, Yifei Wang, Junhao Wang, Zak D. Carden, Perry Ayn Mayson Maza, Dana Rae Cyril-Ramirez, Yong Li

Baylor College of Medicine, Houston, TX

Plasmid-based non-viral DNA delivery systems are widely utilized in gene therapy and cancer immunotherapy due to their safety and scalability. However, conventional production depends on antibiotic resistance markers, creating regulatory hurdles and complicating manufacturing. To overcome these limitations, we developed pIR, an antibiotic-free plasmid production platform that employs an arabinose-inducible Cre recombinase system to excise the antibiotic resistance gene during amplification. This system uses a pir+ bacterial strain supporting replication of R6K-origin plasmids, enabling high-yield production of antibiotic-free DNA suitable for clinical applications. We first verified that pIR generates high-purity DNA with over 80% of the final product in supercoiled form. Next, we compared pIR-derived plasmids to the traditional gWiz vector using Firefly luciferase (Fluc) and NanoLuc reporters in both in vitro and in vivo models. Our plasmids exhibited superior transgene expression and favorable safety profiles. Further comparison with the commercially available Nanoplasmid™ NTC9385R revealed comparable performance, with slightly higher NanoLuc expression in vitro and in vivo. To demonstrate versatility, we applied pIR to produce a plasmid encoding LINE1 ORF1p, a transposable element protein implicated in aging and cancer that constitutes ~20% of the human genome. In vitro studies confirmed robust ORF1p expression, and in vivo immunization via electroporation elicited a significantly stronger immune response compared to gWiz. By eliminating antibiotic sequences, pIR reduces the risk of horizontal gene transfer and aligns with regulatory requirements for clinical-grade DNA. Its ability to produce high-performance plasmids for both reporter and immunogenic payloads underscores its potential for gene therapy and cancer vaccine development. As non-viral DNA delivery gains momentum in oncology and personalized medicine, platforms that combine safety, efficiency, and compliance will be essential for accelerating translation. In conclusion, we establish pIR as an alternative to existing technologies, offering broad applications in cancer immunotherapy and beyond.

#0271 IL-7-secreting *Salmonella* synergizes with PD-L1 blockade to induce durable antitumor immune memory.

Minju Han

Chungnam National University, Yuseong, Daejeon, Korea, Republic of

Background: Interleukin-7 (IL-7) is a key cytokine that maintains the survival and homeostasis of T cells and induces antitumor immune responses. This study investigated the antitumor effects of attenuated *Salmonella* genetically engineered to secrete IL-7 against cancer by activating immune cell responses.

Methods: Mouse colorectal cancer cell line CT26 and *S. typhimurium* were used. The *S. typhimurium* was engineered to secrete IL-7 based on an arabinose induction system. The anti-tumor effect of the engineered *Salmonella* was examined *in vitro* and *in vivo*, both alone and in combination with anti-PD-L1 treatment. Flow cytometry was performed to analyze immune cell populations in tumors and spleens to elucidate the underlying mechanisms.

Results: The genetically engineered *Salmonella* secreted IL-7 upon arabinose induction without affecting its growth. IL-7 secretion in response to arabinose was confirmed via ELISA. In *in vivo* experiments, the arabinose-induced group exhibited enhanced antitumor effects and improved survival compared to the non-induced group, with body weight recovery observed within five days post-*Salmonella* injection. TUNEL analysis showed increased apoptosis in tumor tissues following arabinose induction, along with a significant reduction in Ki67 expression. On days 3 and 7 post-induction, flow cytometry revealed an increased T cell population. The activation of cytotoxic T cells was confirmed by elevated levels of granzyme B, perforin, and IFN-γ. Co-administration of IL-7-secreting *Salmonella* with anti-PD-L1 antibody resulted in significantly greater tumor suppression compared to *Salmonella* secreting IL-7 alone. Notably, in the arabinose-induced group, complete tumor regression was observed in 4 out of 5 mice. When tumor cells were re-challenged on the opposite flank 60 days later, no tumor recurrence was detected, indicating the establishment of long-term antitumor immunity. Subsequent flow cytometric analysis of splenocytes confirmed an increased population of memory T cells, supporting the development of durable immune memory following IL-7 secretion. Biodistribution analysis showed that *Salmonella* was cleared from other organs over time, with predominant accumulation in tumor tissue. Biochemical analyses of liver and kidney function revealed no abnormalities in the arabinose-treated group. The biological safety of the *Salmonella* strain was confirmed through biodistribution studies and H&E staining.

Conclusion: The *Salmonella* secreting IL-7 enhances antitumor activity by inducing T cell-mediated immune responses, particularly showing potential as an immunotherapy strategy for solid tumors when combined with anti-PD-L1 antibodies. Further research is needed to evaluate its efficacy in various tumor models, long-term safety, and the potential for combination with other immune checkpoint inhibitors.

#0272 Attenuated *Salmonella* secreting IFN-β via the flagellar secretion system enhances antitumor immunity and therapeutic efficacy.

Kim Eunji

Chungnam National University, Yuseong, Daejeon, Korea, Republic of

Purpose: Bacterial cancer therapy offers a unique approach to target tumor tissues and modulate the immune microenvironment. Here, we aimed to establish an attenuated *Salmonella* platform capable of secreting interferon-β(IFN-β) through the flagellar type III secretion system(FT3SS) to potentiate antitumor immunity, and to evaluate its therapeutic efficacy as monotherapy and in combination with PD-L1 blockade.

Methods: The attenuated *Salmonella Typhimurium* strain was constructed by deleting the *rcsB* gene from the parental *BRD509* background and engineered to secrete IFN-β through the FT3SS under L-arabinose induction. IFN-β secretion was verified by Western blot and ELISA. The biodistribution of the strain was evaluated using IVIS bioluminescence imaging. The antitumor efficacy and immune activation induced by the IFN-β secreting *Salmonella* were assessed in CT26 tumor-bearing mice by evaluating tumor growth inhibition, apoptosis, and immune cell activation. Combination therapy with an anti-PD-L1 antibody was performed to potentiate the therapeutic effect. In addition, the *in vivo* safety of the strain was confirmed by monitoring serum liver and kidney function markers, body weight, and H&E histology of major organs.

Results: In this study, we developed an attenuated *Salmonella* strain capable of secreting IFN-β through the FT3SS. IFN-β secretion was regulated by L-arabinose induction without affecting the viability of the *Salmonella* strain. *In vivo* bioluminescence imaging of Lux-expressing IFN-β secreting *Salmonella* demonstrated rapid tumor colonization and selective intratumoral proliferation, confirming its tumor-targeting capability. In CT26 tumor-bearing mice, treatment with the IFN-β secreting strain followed by L-arabinose induction from day 3 post-injection inhibited tumor growth and induced tumor cell apoptosis. The therapy also promoted N1-type neutrophil infiltration and activation of antitumor immune responses, and its safety was confirmed *in vivo*. However, IFN-β monotherapy did not completely eradicate tumors, and PD-L1 expression was upregulated in the tumor tissues after bacterial injection. Therefore, combination therapy with the IFN-β secreting *Salmonella* and an anti PD-L1 antibody resulted in synergistic antitumor effects, including markedly enhanced tumor regression and prolonged survival compared to either monotherapy. These results highlight the clinical potential of this controllable bacterial platform for next-generation cancer immunotherapy.

Conclusion: Overall, these findings demonstrate that the FT3SS-based IFN-β secreting *Salmonella* represents a safe, potent, and versatile therapeutic platform that enhances antitumor immunity and synergizes with immune checkpoint blockade.

#0273 High-avidity reversible engager proteins efficiently redirect the entry of intravenously delivered lentiviral vectors, simplifying the direct *in vivo* delivery of CAR-T cell therapy.

Gopal Naik Nenavath[1], Nandakumar Packiriswamy[1], Diana Gataulin[2], Md Sharif Hasan[1], Tatenda Kadungure[1], Harshitha Anantharama[1], Pragati Jain[1], Kyle Gromer[1], Karina Krotova[1], Miriam Eisenstein[2], Gideon Schreiber[2], Patrycja Lech[3], Luis Blancas Mejia[3], Colin Caine[3], Thipparat Suwanmanee[3], Luke Breigenzer[3], Darren Phung[3], Tim Carey[1], Hamid Salimi[1], Emma Buck[1], Christian Kinney[1], Luke Russell[3], Kah-Whye Peng[3], Stephen J Russell[3], Menachem Rubinstein[2]

[1]Imanis Life Sciences, Rochester, MN,[2]Weizmann Institute of Science, Rehovot, Israel,[3]Vyriad, Rochester, MN

We have developed engager proteins that reversibly block VSV-G, directing VSV-G-pseudotyped lentiviral vectors (LVV) into resting CD3-positive T cells. Following selective binding of the engager-modified LVV particles to CD3, they are internalized into endosomes, where the engager is detached by the low pH and the absence of calcium ions, releasing unmodified LVV. Free LVV particles then fuse with the endosomal membrane and efficiently deliver their genetic cargo to the cytoplasm. These engager proteins are stable and easily produced in high yields, making them suitable for practical use. Reversible bi-specific engagers that bind to the homotrimeric VSV-G protein and redirect it to a targeted receptor were initially developed by genetically fusing a cell-targeting polypeptide to the VSV-G binding domains CR2 and CR3 of the LDL receptor (Israel Patent application No. 296547, 2022. Inventors: M. Rubinstein, G. Schreiber, D. Gataulin, Weizmann Institute). When pre-incubated with VSV and VSV-G-LVV, these engagers mediated selective vector entry into mammalian cells via the targeted receptor while preventing non-specific entry through LDLR. The monomeric engagers blocked binding of VSV-G to LDLR with an ED_{50} of 3 nM. Trimeric engager versions exhibited an ED_{50} of 20 pM. To increase the binding avidity of the engager to VSV-G, we engineered and produced trimeric engagers consisting of CD3-specific scFv fused through a trimerizing peptide to VSV-G binding domains of LDLR. When co-incubated with LVV, the engagers bound stably to LVV, preventing transduction through LDLR or its other family members, while mediating efficient transduction via the targeted CD3 receptor. CD3-directed engager-modified LVVs efficiently transduced and activated primary human T cells in PBMC cultures, exhibiting stable CD3 targeting even after prolonged storage at room temperature and freeze-thaw cycling. CD3-engager-modified LVV particles encoding an anti-BCMA CAR were administered intravenously to (human) PBMC-engrafted NSG-DKO mice bearing established BCMA-positive human myeloma xenografts. Rapid and complete tumor regressions were observed in all animals treated with the engager-modified LVVs. In summary, we have generated trimerizing bifunctional engagers that redirect the attachment and entry of VSV-G-pseudotyped lentiviral vectors into resting human T cells. Engager-modified LVVs encoding a CAR transgene were therapeutically effective when administered intravenously to tumor-bearing animals. Clinical translation is planned.

#0274 Overcoming recombination in semi-replicating retroviral vectors: A novel double suicide gene therapy for glioblastoma.

Soojin Kim[1], Moonkyung Kang[1], **Yeon-Soo Kim**[2]

[1]Articure, Yuseong, Daejeon, Korea, Republic of,[2]Chungnam National University, Yuseong, Daejeon, Korea, Republic of

One of the longstanding challenges in developing semi-replicating retroviral vector (sRRV) systems has been the loss of therapeutic genes due to non-homologous recombination during reverse transcription in dividing tumor cells. To address this, we developed a genetically stabilized sRRV platform capable of efficient combinatorial gene therapy, preserving the integrity of multiple therapeutic genes while replicating and spreading exclusively within tumors. Our system consists of two trans-complementing, replication-defective retroviral vectors: one encoding MuLV-Gag-Pol and cytosine deaminase (CD), and the other encoding GaLV-Env and HSV1-thymidine kinase (TK). These vectors co-infect tumor cells and propagate selectively within the tumor microenvironment. By eliminating homologous sequences between vectors, we achieved a recombination-resistant design, ensuring long-term genetic stability during serial replication. The antitumor efficacy of this platform was validated in two glioblastoma models. First, in a syngeneic rat orthotopic glioma model, C6 glioma cells were implanted intracranially into Wistar rats.The therapeutic vectors were directly injected into the tumor site, followed by systemic administration of prodrugs 5-fluorocytosine (5-FC) and ganciclovir (GCV). Histological analysis on day 98 revealed dose-dependent tumor regression, with complete tumor eradication in the high-dose, dual-prodrug cohort. Survival analysis confirmed significantly extended survival in treated groups. Second, in an intracranial xenograft model using athymic nude mice, human glioma cells were implanted in the brain parenchyma, followed by stereotactic delivery of the sRRV vectors and systemic prodrug treatment. Remarkably, complete tumor remission was again observed in the combination treatment group, despite the absence of adaptive immunity, highlighting the platform's intrinsic efficacy. Analysis of vector genomes recovered from tumor tissues revealed no evidence of recombination or gene loss, confirming the system’s robust genetic stability. The vectors maintained persistent coexpression of both therapeutic genes, which are essential for synergistic prodrug activation and tumor cell killing. In conclusion, this study presents a next-generation sRRV platform that resolves a major technical barrier—recombination-mediated gene loss—while enabling stable and tumor-selective delivery of multiple therapeutic genes. Its potent efficacy in both immunocompetent and immunodeficient brain tumor models, including intracranial xenografts, positions it as a promising candidate for clinical translation in glioblastoma and other refractory solid tumors.

#0275 Bioluminescent tools for quantification of *in vivo* CAR-T delivery systems.

Julia K. Gilden[1], Pete Stecha[2], Rich Moravec[2], Jun Wang[3], Rod Flemming[1], Jim Harnett[1], **Steven Edenson**[1], Kristin Riching[1], Jamison Grailer[1], Mei Cong[2]

[1]Promega, Madison, WI,[2]R&D, Promega, Madison, WI,[3]Promega, Fitchburg, WI

In vivo CAR-T engineering using mRNA-LNP, lentiviral (LV), or AAV vectors requires analytical methods that are rapid, scalable, and mechanistically informative across CMC and bioassay workflows. We assembled an integrated luminescent toolkit to quantify vector input, functional potency, and innate-immune risk. For mRNA-LNP, a Lumit® dsRNA detection assay uses a split luciferase system to quantify double-stranded RNA impurities that can trigger innate sensing and diminish transfection. For broader assessment of immunogenicity, cell-based TLR reporter assays profile vector- or formulation-induced pathway activation. For quantification of LV vectors, the homogeneous, no-wash Lumit® p24 Immunoassay measures the LV p24 capsid protein as a surrogate for viral particle count with a wide linear range in ~60 minutes. Functional potency can be measured using a cell-based reporter bioassay in which Jurkat T cells stably expressing an NFAT-Luc2 reporter are transduced with CAR LV and co-cultured with antigen-positive targets to generate an antigen-dependent luminescent signal that reflects LV identity and potency. Together, these assays streamline development, release, and comparability for in vivo CAR-T delivery systems.

#0276 Anti-tumor activity in humanized xenograft models and B-cell aplasia in non-human primates with a novel CD3-directed in vivo gene-modifying CAR (GCAR) lentivector encoding chimeric antigen receptors and a cellular fitness-enhancing co-stimulatory protein.

Michael Betts[1], Matilda Mostrom[2], Ewa A. Jaruga-Killeen[1], Frederic Vigant[1], Anirban Kunda[1], Michelle Andraza[1], Cody Gowan[1], Iryna Oliinyk[1], Gregory Wade[1], Gregory Schreiber[1], Carter Bir[1], Jason P. Dufour[2], Robert V. [1]EXUMA Biotech Corp, West Palm Beach, FL,[2]Tulane National Biomedical Research Center, Covington, LA,[3]Shanghai- Jiaotong University Medical School, Ruijin Hospital, Shanghai, Shanghai, China

Introduction: An *in vivo* gene-modifying CAR (GCAR) platform has been developed to mitigate known clinical and logistical challenges with traditional ex-vivo manufactured CAR-T products. The GCAR platform incorporates an NHP/human reactive CD3-targeted lentivector (LVV) with complement resistant fusogen that encodes CD3zeta based CARs and a compact synthetic costimulatory protein (FD) optimized for proliferation, persistence, and cytotoxicity. The ability of GCAR LVVs to elicit potent, specific and persistent cytotoxicity towards target cells was evaluated *in vitro* and in humanized and non-human primate models. In *M. nemestrina*, GCAR CD20 CAR was evaluated for B-cell depletion compared to LVVs encoding conventional 41BB CARs without FD.

Methods: Anti-CD19 or anti-CD20 LVV's manufactured from 6L and 25L scales were characterized for CD3 reactivity in M. *nemestrina* and human PBMC *in vitro* and *in vivo*. Serum complement sensitivity and activation assays were used to characterize GCAR LVVs (encoding anti-CD20 CAR and FD) against human and NHP sera and CD3 positive lymphocytes. Escalating doses (IV or IN) of purified LVV's were evaluated in the NHPs. B-cells were quantified by flow cytometry and safety by clinical chemistry, hematology, and physical assessments.

Results: Exposure of human or *nemestrina* PBMC to GCAR LVVs resulted in dose and target-dependent cell lysis with rapid tumor clearance in Raji-Luc disseminated PBMC-humanized DKO NSG models. In CD34-humanized models, GCAR LVV generated CAR-T cells with durable B-cell depletion over >8 weeks of observation. Administration of GCAR CD20 LVV (IV or IN) was well tolerated in NHPs at all doses w/o severe CRS or neurologic toxicity. B-cell depletion kinetics post IV dosing of CD20 CARs with FD were dose dependent: minimally active doses demonstrated delayed onset of B cell depletion (from day 21 post dose) vs. B cell aplasia by day 7 at the most active doses. In contrast, a comparable GCAR LVV encoding 41BB CD20 CAR (w/o FD) by IV and IN injection elicited B cell depletion at 7 days post dose with reduced duration.

Conclusion: GCAR LVVs generated genetically modified lymphocytes resulting in durable CAR-dependent cell removal across mechanistic, murine, humanized, and NHP immune systems. The incorporation of FD may further improve cellular expansion and persistence, yielding *ex vivo*-like CAR-T activity profiles without lymphodepletion or cytokine support. The absence of acute and subacute safety signals, low off-target transduction, serum complement resistance, and deep B-cell depletion support the GCAR platform as a potential next-generation opportunity for clinical investigation as a novel gene modifying CAR approach.

#0277 IMV102, an *in vivo* BCMA-targeting CAR-T therapy, achieves durable tumor control in multiple myeloma models.

Yantao Li, Shuangshuang Zhang, Xiaojiang Fan, Zhenggang Jiang, Ruidong Hao, Minmin Sun

Shanghai Immunofoco Biotech Research Co., Ltd, shanghai, China

Introduction
Autologous CAR-T therapy has achieved marked success in hematologic malignancies, yet its widespread use remains challenging due to complex manufacturing and high costs. To overcome these limitations, we developed the iMagic platform, a lentiviral-based in vivo CAR-T system composed of a mutated MxV glycoprotein (MxV-G-mut) and a T cell targeting module (TCM3). This platform enables selectively activation and transduction of T cells in vivo. Here, we evaluated the specificity, efficacy, and safety of IMV102, a lentivirus carrying the BCMA-targeting CAR as the gene of interest based on the iMagic platform, for the treatment of multiple myeloma in preclinical models.
Methods
The transduction specificity and efficiency of IMV102 was assessed using tumor cell lines (Jurkat, H929, and Raji) and primary human cells (hepatocytes and PBMCs). In vitro cytotoxicity and IFN-γ secretion were measured following co-culture with target cells. In vivo efficacy was assessed in two separate models, H929-Luc or MM1.S-Luc xenografted MHC-I/II-DKO immunodeficient mice reconstituted with human PBMCs. Tumor burden, body weight, CAR-T expansion and plasma IFN-γ levels were monitored per schedule.
Results
After coincubation with IMV102, BCMA-CAR expression was detected on Jurkat T cells, while it showed significantly lower levels in Raji or NCI-H929 cells. Importantly, IMV102 coincubation resulted in negligible CAR expression on primary human hepatocytes. In PBMCs, IMV102 efficiently transduced T cells with similar transduction ratio on CD4 and CD8 cells and showed negligible off-target B cell transduction. IMV102-generated CAR-T cells displayed potent cytotoxicity against BCMA-positive tumor cells and secreted significant levels of IFN-γ. Furthermore, intravenous administration of IMV102 at dose of 5e6 TU/mice showed potent and durable tumor inhibition all through the over 50 days observation periods in both the NCI-H929 xenografted model and the MM1.S xenografted model. And the antitumor efficacy was accompanied by robust CAR-T generation and expansion, as well as IFN-γ release. Treatment was well tolerated, with no significant weight loss observed.
Conclusions
IMV102 enables efficient and selective in vivo generation of functional BCMA CAR-T cells, resulting in potent and durable antitumor activity in multiple myeloma models. These results pave the way for further clinical investigation.

#0278 *In vivo* adenine base editing of *STK11*^{Q37*} reprograms tumor for radiosensitizing effect.

Jiazhuo Yan[1], Yihan Xu[2], Qingxiao Fang[2], Jinpu Yu[2], Zhiyong Yuan[2]

[1]Department of Radiation Oncology, Tianjin Medical Univ. Cancer Inst. & Hospital, Tianjin, China,[2]Tianjin Medical Univ. Cancer Inst. & Hospital, Tianjin, China

In this study, we aim to investigate the therapeutic potential of in vivo genetic therapy using AAV-mediated adenine base editor (ABE) delivery for non-small cell lung cancer (NSCLC) carrying the *STK11* nonsense mutation *STK11*^{Q37*} (c.109C>T), and further explore the molecular mechanisms underlying its impact on radiosensitivity. Radiotherapy is a standard treatment for locally advanced or inoperable NSCLC patients, radiation resistance driven by tumor-promoting somatic mutations severely limits clinical efficacy, underscoring the urgent need for targeted strategies such as precise gene correction to overcome this barrier. Through CRISPR-based in vivo mutation library screening combined with whole-exome sequencing, we identified *STK11*^{Q37*} as a critical driver of radiation resistance. To restore *STK11* function, we engineered a panel of ABEs with distinct PAM/TAM compatibilities and further developed a high-fidelity variant, A8E-N108Q-R26G, which enables precise correction of the pathogenic adenine without bystander editing. Using HEK293T reporter cells stably harboring the *STK11*^{Q37*} locus, we found that spCas9-A8EQR (N108Q-R26G) achieved the highest overall correction efficiency, repairing up to 60% of mutant alleles with superior fidelity. The optimized editor was subsequently packaged into a dual-AAV system and delivered in vivo to humanized mice bearing subcutaneous patient-derived organoid xenografts. AAV-mediated base editing combined with radiotherapy produced synergistic antitumor effects and significantly suppressed tumor progression. Mechanistic studies revealed that precise correction of *STK11*^{Q37*} restores endogenous LKB1 protein expression and kinase activity, reactivating downstream signaling required for maintaining redox homeostasis. Restored LKB1 directly stabilizes the transcriptional regulator BACH1 by limiting its ubiquitination and proteasomal degradation, thereby preserving BACH1-mediated repression of antioxidant gene programs. Concurrently, LKB1 re-expression dampens *NRF2* nuclear accumulation and transcriptional activity, leading to reduced expression of *NRF2*-driven detoxification and antioxidant pathways. This coordinated regulation markedly elevates intracellular ROS levels following irradiation and reinstates radiation-induced cytotoxic stress, collectively enhancing tumor radiosensitivity. In summary, our study identifies *STK11*^{Q37*} as a therapeutically actionable driver of radiation resistance and demonstrates that precise ABE-mediated correction provides a promising gene-editing-based strategy to improve treatment outcomes in NSCLC.

#0279 Completion of IND-enabling studies for NRT-YHD_001, a macrophage checkpoint inhibitor in liver cancer.

Suk Woo Nam[1], In Seop Yoon[2], Sang Yean Kim[3], Minjeong Na[3], Jin Woong Ha[3], Soyoung Jeon[3], Hyunmin Lee[2], Seo Hyeon Mun[2], Chang Won Park[2]

[1]Catholic University of Korea, College of Medicine, Seoul, Korea, Republic of,[2]NEORNAT Inc, Seoul, Korea, Republic of,[3]The Catholic University of Korea, Seoul, Korea, Republic of

NRT-YHD_001 is a modified antisense microRNA targeting let-7i-5p, developed as a novel therapeutic candidate for hepatocellular carcinoma (HCC). This compound functions as a key regulator of macrophage activation within the tumor microenvironment. In in vitro phagocytosis assays, NRT-YHD_001 (GalNAc-conjugated form) demonstrated stronger macrophage activation than NRT-YHD (GalNAc-unconjugated form). Following a single intravenous injection in mice, NRT-YHD_001 selectively inhibited let-7i-5p without affecting other members of the let-7 family, confirming its high target specificity.To evaluate the in vivo efficacy of NRT-YHD_001 against advanced HCC, Ras-transgenic mice that spontaneously develop hepatic tumors at approximately 15-20 weeks of age, were used. After confirming tumor formation (~5 mm2) by ultrasonography, NRT-YHD_001 was administered intravenously once weekly at 5 mg/kg. Compared with the sorafenib-treated group, NRT-YHD_001-treated mice exhibited greater tumor suppression, demonstrating superior therapeutic efficacy.The NRT-YHD_001 formulation satisfied all CMC quality control criteria. After lyophilization, the formulation was reconstituted into a clear, colorless solution, with an assay value of 105.1% of the label claim (specification range: 90.0-110.0%). All other parameters, including impurity levels, pH (7.5), osmolality (324 mOsm/kg), endotoxin (<2.0 EU/mg), and sterility, met specification limits, confirming excellent quality attributes.Pharmacokinetic and ADME studies, metabolic stability assessments in serum and liver homogenates, and metabolite profiling were conducted in mice and cynomolgus monkeys. No treatment-related abnormalities were observed in the 4-week repeated-dose toxicity study. The drug substance (DS) and drug product (DP) were both manufactured and analytically validated by a global CDMO with FDA-approved manufacturing experience.Collectively, these results demonstrate that NRT-YHD_001 is a potent and selective let-7i-5p antisense therapeutic with macrophage-modulating activity and superior in vivo antitumor efficacy in an advanced HCC model. A complete nonclinical IND submission package has been finalized, with FTO clearance and full intellectual property protection secured. IND submissions to the MFDS (Korea) and FDA (U.S.) are planned for 2026.

#0283 Severe acidity in human tumors for pH-activatable cytokine therapy.

Qiang Feng[1], Jun Chen[1], William Hartnett[1], Raymundo Pantoja[1], Gang Huang[1], Isaac Chan[2], Baran Sumer[1], Jinming Gao[1]

[1]Simmons Comprehensive Cancer Center, University of Texas Southwestern Medical Center, Dallas, TX,[2]Internal Medicine, University of Texas Southwestern Medical Center, Dallas, TX

Introduction: Precise tumor targeting is essential for improving the therapeutic index of cancer immunotherapies. Systemic cytokine therapies, such as interleukin-2 (IL-2), suffer from narrow therapeutic windows due to dose-limiting toxicities. While receptor engineering and prodrug approaches have been widely investigated, their application is often limited to tumor subtypes that express the corresponding targets. In contrast, tumor acidity is a universal hallmark of the microenvironment, driven by elevated glycolysis, and offers a broadly applicable opportunity for tumor-specific therapy. However, the spatial heterogeneity of tumor acidity remains poorly understood, and its therapeutic application has not been fully demonstrated.
Methods: To systematically evaluate the heterogeneity of tumor acidity and its potential for targeted therapy, we employed ultra-pH-sensitive (UPS) nanoparticles that exhibit sharp ON/OFF transitions at defined pH thresholds. In 3D tumor cultures, we embedded UPS nanoprobes within extracellular matrix gels and assessed the spatial distribution of acidity at single-cell resolution. In human cancer patients, we evaluated the tumor-imaging properties of this acidity-targeting strategy and further investigated acidity patterns by analyzing UPS nanoparticle distribution in tumor tissues following intravenous injection. Building on these findings, we developed a formulation strategy to encapsulate IL-2-Fc into UPS micelles, enabling selective cytokine release in acidic microenvironments. This platform aims to provide a comprehensive understanding of spatial acidity and to test the therapeutic index of pH-activatable cytokine delivery.
Results: Through this work, we identified a severe acidity phenotype in cancer, where extracellular pH drops below 5.3 due to spatially polarized lactate export. Targeting acidity allows demarcation of tumor from surrounding tissue in intraoperative imaging, even when tumors are as small as 2 mm. Spatial transcriptomic analysis of human head and neck tumors after UPS nanoprobe injection revealed that these severely acidic regions co-localize with immune-infiltrated stromal zones. These regions serve as critical entry points for acid-targeting nanosystems, linking tumor metabolism, immune cell infiltration, and immune suppression in both preclinical models and human tissues. The UPS/IL-2-Fc formulation selectively releases IL-2-Fc within these regions and demonstrates potent antitumor efficacy with markedly reduced systemic toxicity, expanding the therapeutic window by over 10-fold compared to free IL-2-Fc in preclinical models.
Conclusion: This study identifies severe acidity as a spatially heterogeneous and translatable hallmark of the tumor microenvironment, enabling tumor-targeted imaging and immunotherapy.

#0284 From undruggable to actionable: Transcriptomic discovery of small-molecule modulators of oncogenic transcription factors.

Arianna Sabo, QUANTRO's Team

QUANTRO Therapeutics GmbH, Wien, Austria

Transcription factors (TFs) and their associated signaling networks remain among the most challenging and underexplored targets in oncology drug discovery. To address this gap, QUANTRO Therapeutics has developed a Transcriptomic Discovery Platform that measures cellular transcriptional activity by detecting changes in nascent RNA synthesis as early as one hour after cellular perturbation. Unlike conventional RNA-seq approaches, which capture only steady-state mRNA abundance with limited temporal resolution, this platform directly quantifies immediate transcriptional responses, providing a high-fidelity readout of TF activity.The QUANTRO platform currently comprises three complementary assays—QUANTROsens, QUANTROseq, and QUANTROslam—that together enable the identification, confirmation, and mechanistic characterization of transcriptional modulators. In particular, QUANTROseq enables high-throughput generation of dynamic transcriptional “fingerprints” induced by small molecules, which can be directly compared with signatures resulting from acute, controlled degradation of specific target proteins. By correlating these profiles, the platform precisely distinguishes compounds acting directly on TFs or cofactors from those exerting indirect effects through upstream pathways. As a demonstration of its capabilities, we present a systematic re-evaluation of published MYC inhibitors, revealing how traditional transcriptomic or reporter-based assays can misclassify indirect modulators as direct MYC inhibitors.Leveraging this technology, QUANTRO has initiated screening campaigns targeting key oncogenic drivers such as c-MYC and YAP/TEAD, leading to the identification of multiple high-quality hit clusters with clear on-target activity and minimal off-target effects. Collectively, these studies demonstrate the power of dynamic transcriptomic profiling to expand the druggable target space, accelerate discovery of first-in-class therapeutics, and illuminate transcriptional control mechanisms underlying cancer progression.

#0285 NEBNext UltraShear® Long Read: Enzymatic DNA fragmentation for long read sequencing of clinically relevant samples.

Keerthana Krishnan, Brittany S. Sexton, Matt Angel, Karen McKay, Jonathan Sanford, Ruby Moulton, Louise Williams, Bradley W. Langhorst, Pingfang Liu, V.K. Chaithanya Ponnaluri

New England Biolabs, Inc., Ipswich, MA

Advances in long read sequencing technologies have significantly improved accuracy and throughput, making them useful for clinical applications and personalized medicine. Ultra-long DNA molecules resulting from high quality extractions, if left intact, are generally inefficiently converted into libraries and sequenced on long-read platforms. Therefore, fragmentation is strongly recommended for high-throughput long read sequencing. DNA fragmentation upstream of long read sequencing typically also results in comparable fragment sizes across samples and experiments with higher and consistent N50 lengths as well as improved sequencing yields compared to ultra-long DNA. Current methods for DNA fragmentation include mechanical shearing and enzymatic fragmentation. Mechanical shearing (e.g., Covaris® g-TUBE and Megaruptor®) is the gold standard method for DNA fragmentation upstream of long read library preparation. Drawbacks to these methods include the use of expensive consumables and instruments that are not automation-friendly and result in sample loss. In contrast, enzymatic DNA fragmentation does not require expensive instruments and is automation friendly, however existing fragmentation parameters may not be optimal for long read sequencing.

To address these constraints, we developed a novel enzymatic fragmentation solution, NEBNext UltraShear® Long Read (UltraShear LR), that is quick, tunable, and automation friendly. Enzymatic fragmentation is time-dependent and can be used to generate a wide-range of DNA fragment sizes (2 to 30 kb) suitable for different applications and sequencing platforms. UltraShear LR is robust across a wide range of gDNA input amounts (250 to 5,000 ng) as well as different gDNA samples and species (e.g., animal, plant and human). Here we demonstrate that UltraShear LR fragmentation generates high quality libraries with tunable read lengths by sequencing on Oxford Nanopore™ Technologies and PacBio® platforms. UltraShear LR libraries retain base modifications (including CpG methylation) and identify more CpGs than mechanically sheared libraries at the same read count. Additionally, we applied the Twist cancer hotspot long read sequencing capture panel using matched normal and tumor samples to identify copy number variations and perform variant calling, demonstrating the applicability of UltraShear LR for clinically relevant samples.

The UltraShear LR system generates time-dependent DNA fragment sizes that are reproducible in a robust and cost-effective manner. UltraShear LR overcomes many limitations of mechanical shearing methods by simplifying sample processing, increasing throughput, and preserving base modifications. These advantages collectively improve usability and data quality in long read sequencing library preparation, making the approach well-suited for clinical applications and personalized medicine.

#0286 New approach methodologies for risk assessment and functional evaluation of immuno-oncology drug candidates.
Christoph Schifflers, Martijn Vlaming, Sofie Pattyn

IQVIA Laboratories, Gosselies, Belgium

Functional screening as well as safety and toxicity assessment of new drug candidates has routinely involved animal research. These models often involve time-consuming experiments and are associated with ethical concerns and high costs. New Approach Methodologies (NAM) are alternative methods for accelerated and cost-effective lead selection based on functionality and predictive risk assessment. Thereby, NAM further contribute to efforts to Replace, Reduce and Refine animal research. In this context, a variety of customized *in vitro* bioassays were developed to evaluate the risk of unwanted immunogenicity of immuno-oncology drug candidates as well as their potency. Drug candidates include biologics as well as small molecules and cell or gene therapy products. These *in vitro* assays are based on well-characterized high-quality primary immune cells from >1300 healthy donors. In addition, variants using non-lethal blood collections of animals such as cynomolgus monkeys, dogs, pigs etc. were established for functional and risk assessment screenings. These assays characterize the phenotype and function as well as secretions of a multitude of lymphoid and myeloid populations in cell type specific cultures or complex co-culture systems using multiplex Flow Cytometry, ELISA/Luminex Assays as well as Live-Cell Imaging.Thus, customized *in vitro* bioassays contribute to NAM, reducing animal requirement for drug development and promoting cost-effective lead selection.

#0287 Chemically ligated proteins enable quantitative ELISAs for p53 post-translational modifications.

Thomas Bailey

Abcam plc (UK), Cambridge, United Kingdom

Introductory Sentence: We developed chemically ligated protein standards to enable fully quantitative ELISAs for key post-translational modifications of p53, providing robust tools for cancer research.

Analysis of post translationally modified (PTM) proteins often relies on methods such as mass spectrometry or western blotting, which are non-quantitative, time consuming and costly. ELISAs offer a faster and more economical alternative; however, most PTM-targeted ELISAs are only semi-quantitative because they lack reference standards to generate a standard curve. To address this limitation, we developed chemically ligated proteins (CLPs) that serve as reference standards in ELISAs, enabling accurate detection and quantification of PTMs. This strategy was applied to quantify PTMs on the tumor suppressor p53 which is mutated or deleted in 50% of cancer tumors.[1] PTMs of p53 regulate its activity in the cell, making their precise measurement critical for understanding p53 function. Phosphorylation at serine 15 and serine 392 and acetylation at lysine 382 are well-characterized modifications associated with p53 activation. [2] To support oncology studies of this target, we developed ELISA kits to quantify these modifications. Development involved pair screening as well as biological validation. CLPs of modified, unmodified, and non-specifically modified p53 were used to select antibody pairs specific to each PTM site over unmodified or proximal modification sites of p53. Biological validation included detection of native signal, induction in cell extracts, and signal reduction following phosphatase treatment. Additional biological validation confirmed linearity of dilution, recovery, and precision across all sample types. Using this strategy, we generated three ELISA kits capable of accurately quantifying p53 pS15, pS392, and acK382, providing robust tools to advance research on p53 regulation and function.

AB0578_v1.0_111725

#0288 Two-color bioluminescence analyses pairing NanoLuc® and red-shifted NanoPrism™ luciferases.

Juliano Alves, Karilyn Porter, Mike Killoran, Robin Hurst, Mark Klein, Debayan De Bakshi, Rahele Esmatpour, James J. Cali, Thomas Machleidt, Rachel F. Ohana, Hicham Zegzouti

Promega Corporation, Madison, WI

NanoLuc® luciferase (NLuc) and its complementation technologies, including the NanoBiT® LgBiT/HiBiT system, are widely applied in functional biology because of their exceptional brightness, broad dynamic range, and suitability for monitoring real-time cellular processes. Despite their versatility, NLuc-based reporters emit primarily at a single, blue-shifted wavelength (~460 nm), restricting their use in multiplexed assays where independent spectral channels are required. To overcome this limitation, we developed NanoPrism™ luciferases, engineered NLuc variants that employ highly efficient intramolecular energy transfer to red-shift the emission. Building on BRET-based strategies, we inserted circularly permuted NLuc or LgBiT into a surface loop of HaloTag®, enabling optimal positioning to covalently bound fluorophores and achieving exceptional BRET efficiency (~90%). By pairing these red-shifted NanoPrism™ reporters with unmodified NLuc® or NanoBiT®, we created a robust two-color bioluminescent platform with strong signal intensities and >100 nm spectral separation. This dual-channel system allows simultaneous monitoring of two proteins or cellular events, such as targeted protein degradation, signaling dynamics, or internal control measurements - in real time within a single experimental context.

#0289 Tracking APOBEC3A to overcome drug resistance in lung cancer.

Maria Vittoria Di Marco[1], Christopher Eggers[2], Aaron N. Hata[1]

[1]Massachusetts General Hospital, Charlestown, MA,[2]Promega Corp., Madison, WI

Targeted therapies have transformed treatment for advanced non-small cell lung cancer (NSCLC), but acquired resistance remains a challenge. We recently showed that the cytidine deaminase APOBEC3A (A3A) is induced by lung cancer targeted therapies and plays a crucial role in promoting acquired drug resistance by facilitating the evolution of drug-tolerant persister (DTP) cells. While A3A mutational signatures are found in 70-80% of tumors post-TKI treatment versus 20-25% in untreated samples, some resistant tumors lack these mutations. Similarly, while many lung cancer cell lines upregulate A3A expression upon TKI treatment, others do not. Our understanding of intra- and inter-tumoral heterogeneity of therapy-induced A3A expression and activity is limited. Most available methods for studying A3A expression and activity are endpoint assays performed on bulk populations. Because A3A activation is episodic and occurs before detectable genomic changes can be quantified, resolving the activity of A3A in single cells over time has not been possible. To overcome these barriers we adapted the HiBiT nano-luciferase reporter system to develop a method for real-time single-cell monitoring of A3A activity in drug-treated tumor cells.Leveraging the preference of A3A for mRNA hairpin substrates, we incorporated optimized A3A-substrate sequences into the HiBiT tag. In the unedited configuration, HiBiT is unable to complement with LgBiT. However when A3A creates a C>U edit within the mRNA hairpin loop, complementation occurs and the resulting luminescent signal reports that A3A is actively editing. We introduced the A3A-HiBiT reporter into patient-derived EGFR, ALK, and KRAS-mutant NSCLC cell lines. TKI treatment induced reporter editing, as detected by HiBiT luminescence and validated by allele-specific droplet digital PCR. No reporter activity was observed in the presence of catalytically inactive $A3A^{E72A}$ or in cell lines with deletion of A3A, confirming specificity for A3A-mediated editing. To investigate intra-tumoral heterogeneity of therapy-induced A3A activity in lung cancer cells treated with targeted therapies, we generated A3A-HiBiT cells stably expressing LgBiT. Experiments are underway to optimize ultra-sensitive bioluminescent microscopy to characterize and monitor the episodic nature of A3A editing in live single cells, as well as to correlate A3A-HiBiT editing with single cell transcriptional heterogeneity using single cell RNA-seq. In summary, our A3A-HiBiT reporter provides a sensitive, scalable, and quantifiable system for real-time monitoring of A3A activity, enabling new opportunities to study the role of A3A in tumor evolution and drug resistance.

#0290 Scientific justification for setting up an appropriate specification of residual solvent based on ICH guideline.

Zhanxiang Sun[1], Jianqiang Li[2], **Lynn Wang**[2], Xudong Wei[3]

[1]Payload-Linker Department, WuXi XDC, Cranbury, NJ,[2]Payload-linker Department, WuXi XDC, Cranbury, NJ,[3]WuXi XDC, Cranbury, NJ

Residual solvents present in payload-linkers, critical intermediates in antibody-drug conjugate (ADC) manufacturing, can be challenging to fully remove during process development. This may lead to levels exceeding ICH Q3 guidelines at the payload-linker stage. To address this, XDC conducted a comprehensive scientific assessment considering toxicological data from ICH Q3C(R8), process clearance capabilities, clinical safety requirements, and conjugation reaction conditions. Based on this evaluation, scientifically justified extensions of residual solvent limits were proposed to ensure both product safety and process feasibility. Assuming certain solvents cannot be completely eliminated during manufacturing and purification, a justification framework was developed to calculate appropriate specification limits for each residual solvent. This approach incorporates safety factors and regulatory guidance to establish scientifically sound limits. The outcome provides a practical solution for cases where complete removal is technically challenging, ensuring compliance with safety standards while supporting efficient ADC development.

#0291 Dual PHD2-HDAC inhibitor 31c prevents cisplatin-bevacizumab nephrotoxicity and preserves antitumor efficacy in cervical cancer.

Xi Chen[1], Dongyu Han[1], Xiaohua Kong[1], Wenfeng Gou[2], Yang Song[3], Huiqiang Wei[2], Yiliang Li[2], Yong Qin[1]

[1]The University of Texas at El Paso, El Paso, TX,[2]Peking Union Medical College & Chinese Academy of Medical Sciences, Tianjin, China,[3]The First Affiliated Hospital of Jinzhou Medical University, Jinzhou, China

Cisplatin-based chemotherapy combined with bevacizumab (CB) remains the standard first-line treatment for advanced or recurrent cervical cancer, integrating cytotoxic and anti-angiogenic mechanisms to improve clinical outcomes. However, treatment success is frequently undermined by dose-dependent nephrotoxicity caused by cisplatin and bevacizumab-induced vascular alterations. Thus, strategies capable of safeguarding renal function without attenuating antitumor activity are urgently needed to optimize treatment durability and patient survival. We previously developed 31c, a novel dual inhibitor of prolyl hydroxylase domain-containing protein 2 (PHD2) and histone deacetylases (HDACs), as a nephroprotective agent. Therefore, we evaluated the nephroprotective potential of 31c in a HeLa xenograft mouse model. Mice were treated with cisplatin, bevacizumab, or their combination, with or without 31c. Tumor growth kinetics and body weight were monitored to assess therapeutic response and systemic toxicity. Renal function was examined through blood urea nitrogen (BUN), serum creatinine (Scr), and erythropoietin (EPO) levels. Kidney tissues underwent histopathological evaluation using hematoxylin and eosin (H&E) and Masson's trichrome staining to quantify tubular injury and fibrosis. RNA sequencing (RNA-seq) of kidney samples identified transcriptomic alterations, and immunofluorescence staining validated renal injury markers lipocalin-2 (Lcn2/NGAL) and kidney injury molecule-1 (Havcr1/KIM-1). Co-administration with 31c preserved the antitumor efficacy of the CB regimen, yielding tumor inhibition comparable to CB alone. Notably, 31c markedly reduced renal toxicity. Mice receiving CB alone displayed significant increases in BUN and Scr levels, extensive tubular degeneration, and marked collagen accumulation, hallmarks of acute renal injury and fibrosis. In contrast, 31c significantly reduced these pathological changes and maintained normal tubular structure. Transcriptomic profiling revealed distinct clustering among treatment groups, with 31c partially reversing CB-induced transcriptional dysregulation. Among the most upregulated genes in CB group, Lcn2 and Havcr1 were significantly suppressed by31c, consistent with immunofluorescence validation. The dual PHD2-HDAC inhibitor 31c confers robust nephroprotection against cisplatin-bevacizumab-induced renal injury without compromising antitumor activity. This integrated protective strategy highlights a promising approach to enhance the safety, tolerability, and continuity of platinum-anti-angiogenic therapies. By preserving renal integrity, 31c may support sustained treatment intensity and prolonged therapeutic benefit in patients with advanced cervical cancer and potentially other malignancies treated with similar regimens.

#0292 AOH1996, a cancer-associated PCNA inhibitor, restores platinum sensitivity in urothelial carcinoma: *In vitro* and *in vivo* study.

Kuan-Lin Kuo[1], Kuo-How Huang[2], Yi Ju (Ellen) Kao[3], Chen-Hsun Hsu[1]

[1]Urology, National Taiwan University Hospital and National Taiwan University College of Medicine, Taipei, Taiwan,[2]National Taiwan University Hospital and National Taiwan University College of Medicine, Taipei, Taiwan,[3]National Taiwan University Hospital, Taipei, Taiwan

Urothelial carcinoma (UC) frequently develops resistance to platinum-based chemotherapy, resulting in limited treatment efficacy and dismal clinical outcomes. Proliferating cell nuclear antigen (PCNA) is a key regulator of DNA replication and repair, and cancer-associated PCNA (caPCNA), a structurally altered form selectively expressed in malignant cells, has emerged as a promising therapeutic target. AOH1996 is a first-in-class small-molecule inhibitor that selectively binds caPCNA and disrupts PCNA-dependent survival pathways. In this study, we investigated the antitumor activity of AOH1996 in UC and its ability to overcome resistance to cisplatin-based chemotherapy. Cisplatin-sensitive (T24, BFTC905) and cisplatin-resistant (T24/R) UC cell lines were treated with AOH1996 alone or in combination with cisplatin or gemcitabine. AOH1996 significantly reduced cell viability and clonogenic survival in both sensitive and resistant cells, induced apoptosis as evidenced by increased Annexin V-positive fractions and cleavage of caspase-3 and PARP, and caused cell-cycle arrest with accumulation of cells in the S/G2 phase. Mechanistically, AOH1996 downregulated PCNA-dependent DNA repair signaling and enhanced DNA damage, as shown by increased γH2AX expression. Combination index analysis demonstrated synergistic interactions between AOH1996 and cisplatin or gemcitabine, particularly in cisplatin-resistant T24/R cells. In a xenograft mouse model of UC, AOH1996 significantly inhibited tumor growth and further potentiated the antitumor effect of cisplatin without causing overt systemic toxicity or significant body weight loss. Together, these findings provide preclinical evidence that targeting caPCNA with AOH1996 exerts robust antitumor activity and restores chemosensitivity in UC, supporting caPCNA inhibition as a promising therapeutic strategy for patients with platinum-resistant disease.

#0293 Anti-cancer drug usage analysis among Korean patients with colorectal cancer.

Yu Jin Lim[1], Jeongseon Kim[2]

[1]The George Washington University, Washington, DC,[2]Department of Cancer Biomedical Science, Graduate School of Cancer Science and Policy, National Cancer Center, Goyang, Korea, Republic of

Combination chemotherapy has long been central to the management of colorectal cancer, and treatment patterns have evolved in response to emerging clinical evidence, changing guidelines, and the availability or withdrawal of specific agents. This study aims to characterize changes in medication utilization over time by providing a descriptive analysis of temporal changes in anticancer drug use among Korean colorectal cancer patients treated at the National Cancer Center (NCC) of Korea. Two patient cohorts were examined: individuals treated between 2000-2004 and those treated between 2010-2020. Sixteen anticancer agents administered to ≥10 patients in both cohorts were included. A total of 1,188 patients from the 2000-2004 cohort and 1,043 patients from the 2010-2020 cohort were analyzed using Stata/BE 18.0. In the 2000-2004 cohort, monotherapy was the most predominant treatment approach (55.89%), followed by two-drug combination therapy (17.68%). Among monotherapies, 5-fluorouracil (5-FU) was most frequently used (45.96%). The most common two-drug regimen during this period was capecitabine plus 5-FU (4.88%). By 2010-2020, treatment patterns shifted as two-drug combination chemotherapy became more common than monotherapy (38.73% vs. 32.02%). The 5-FU plus oxaliplatin combination emerged as the most frequently used regimen (25.98%). Capecitabine was the most common regimen for monotherapy (21%). Although the use of capecitabine monotherapy increased in 2010-2020 compared to 2000-2004 (21% vs. 5.56%), the difference in overall capecitabine usage was not statistically significant ($p = 0.872$), likely because capecitabine had frequently been used in combination regimens in earlier years. In contrast, use of 5-FU significantly declined ($p < 0.001$), while use of oxaliplatin and bevacizumab markedly increased (both $p < 0.001$). Meanwhile, tegafur/uracil and megestrol usage decreased significantly (both $p < 0.001$). This descriptive analysis highlights shifts in chemotherapy use among colorectal cancer patients treated at the NCC of Korea across two distinct periods. The earlier cohort (2000-2004) was characterized by predominant use of 5-FU-based monotherapy, whereas the later cohort (2010-2020) showed a marked transition toward two-drug combinations. These patterns mirror global changes in anticancer therapy drug usage. Further analyses should link treatment patterns to clinical outcomes, including evaluations of overall survival (OS) and disease-free survival (DFS), clarification of treatment lines, and resolution of overlapping-prescription or regimen-coding issues. This study was approved by the Institutional Review Board of the NCC (NCC2025-0115).

#0294 Comparative biochemical kinase activity analysis identifies lirafugratinib as a highly selective FGFR2 inhibitor.

Alison M. Schram[1], Grace Lee[2], Tracey Wei[2], Seong Jang[2], Kristin Ryan[2]

[1]Memorial Sloan Kettering Cancer Center, New York, NY,[2]Elevar Therapeutics, Fort Lee, NJ

Background: Genomic alterations in fibroblast growth factor receptor (FGFR) occur across tumor types and pan-FGFR inhibitors are standard-of-care in FGFR fusion positive cholangiocarcinoma (CCA). Recent efforts focused on designing more selective and covalent inhibitors to improve efficacy, safety, and tolerability. Lirafugratinib, a highly selective and irreversible FGFR2 inhibitor, was designed to target oncogenic *FGFR2* alterations to enhance efficacy outcomes without worsening toxicities due to inhibitions of other FGFR isoforms (e.g., hyperphosphatemia and diarrhea related to FGFR1 and FGFR4, respectively).
Methods: To understand and compare the relative selectivity of lirafugratinib kinase inhibition, we performed a head-to-head biochemical analysis against four pan-FGFR inhibitors. A KINOMEscan Profiling Service scanMAX and TREEspot™ interaction maps were used for evaluation and visualization of inhibition of kinases: a panel of 468 human target kinases and disease-relevant kinase mutant variants were tested at a concentration of 500 nM for lirafugratinib and four other pan-FGFR inhibitors (futibatinib, pemigatinib, erdafitinib, and AZD4547). The 90% and 75% inhibition thresholds were selected based on established and published research for methodologies related to kinome mapping.
Results: Among the 468 kinases and disease-relevant kinase mutants, lirafugratinib at 500 nM inhibited >90% of only two kinases (FGFR2 [94.1%] and MEK5 [92.4%]). The rest of kinases, including FGFR1, FGFR3 and FGFR4, were inhibited <75% except MKNK2 (89% inhibition). In contrast, futibatinib inhibited FGFR1, FRFR2, FRFR3, and FGFR4 by more than 90%, while showing minimal (<75%) inhibition of other kinases except MKK7 (83% inhibition). Similarly, pemigatinib, erdafitinib, and AZD4547 inhibited multiple kinases (including all FGFRs) - 11, 37, and 37 kinase targets, by more than 90%. Overall, lirafugratinib demonstrated the highest selectivity to inhibit FGFR2 without substantial inhibition of FGFR1, FGFR3 and FGFR4, compared to the FGFR inhibitors tested.
Conclusions: The head-to-head kinome analysis of lirafugratinib and four other FGFR inhibitors revealed that lirafugratinib inhibited FGFR2 with high selectivity, suggesting minimal off-target and off-isoform-related toxicities compared to pan-FGFR inhibitors used in clinical practice.

#0295 Antitumor effect of a new pyruvate kinase M2 (PKM2) inhibitor Acyclovir in experimental esophageal adenocarcinoma.

Md Sazzad Hassan[1], Mallory Turner[2], Elizabeth Heffernan[2], Katherine Millett[2], Oliver O'Reilly[2], Niranjan Awasthi[1], Usama Usama[2], Aktar Ali[2], Urs von Holzen[1]

[1]Indiana University School of Medicine (South Bend, IN), South Bend, IN,[2]University of Notre Dame, South Bend, IN

Background: Esophageal adenocarcinoma (EAC) is one of the most aggressive human cancers with poor prognosis even with modern combination therapies due to high resistance to chemotherapy. Therefore, new therapeutic approaches are urgently needed. Pyruvate kinase M2 (PKM2) is not only a key enzyme regulating cancer glycolysis but also translocate into the nucleus to regulate transcription. Although PKM2 is overexpressed in various tumor tissues including EAC, its functional role in esophageal EAC chemotherapy remains unexplored. The objective of this study was to determine whether acyclovir can act as an inhibitor of PKM2 and EAC tumor growth.
Methods: Virtual in silico screening using molecular docking was conducted to screen an FDA-approved chemical library for identification of potential PKM2 inhibitors. HER-2 overexpressing OE19, LPR-OE19 and OE33 EAC cell lines were used. The lapatinib-resistant OE19 (LPR-OE19) cell line was generated from parent OE19 cells through intermittent exposure to increasing concentrations of lapatinib for over six months. Acyclovir and nanoparticle albumin-bound paclitaxel (nab-paclitaxel), alone or in combination, were tested for effects on cell proliferation, lactate production, apoptosis, signaling pathways and tumor growth. Antiproliferative activities were measured by WST-1 assay. Western blotting was performed to evaluate expression of PKM2, apoptotic markers and cell signaling proteins. In-vivo antitumor efficacy was measured in a patient-derived xenograft (PDX) model of human EAC.
Results: Molecular docking identified acyclovir as a potential PKM2 inhibitor that showed lowest docking and glide scores, indicating a strong binding interaction with PKM2. Acyclovir inhibited both PKM2 expression and lactate production. It inhibited cell proliferation in 2D, 3D and organoid cultures of EAC in a dose dependent manner. Interestingly, addition of nab-paclitaxel enhanced the antiproliferative effect of acyclovir. Acyclovir increased expression of proapoptotic proteins and decreased expression of phospho AKT in EAC cells. In a subcutaneous PDX model, acyclovir induced a tumor regression compared to control as monotherapy, and acyclovir in combination with nab-paclitaxel showed a significant enhancement effect of tumor regression. The net change in tumor size in the control, acyclovir, nab-paclitaxel, and combination groups was 551.19 ± 99.69 mm^3, 347.33 ± 71.41 mm^3, 221.55 ± 43.73 mm^3, and 159.37 ± 39.29 mm^3. Reduction in PDX tumor growth corroborated decreased tumor cell proliferation results.
Conclusions: These data suggest that acyclovir, acting as a PKM2 inhibitor, in combination with nab-paclitaxel should be further investigated as a potential therapeutic strategy for HER2-positive EAC patients and could be a novel treatment strategy for EAC.

#0296 Evaluation of ingenane diterpenoids for BL2 triple-negative breast cancer.

Pamela R. Duarte, April L. Risinger

Pharmacology, UTHSA, San Antonio, TX

Breast cancers with high expression of estrogen receptor (ER), progesterone receptor (PR), or Human Epidermal Growth Factor Receptor 2 (HER2) have benefited dramatically from receptor-directed targeted therapies. In contrast, triple-negative breast cancers (TNBCs), which lack ER, PR, and HER2 expression, remain a significant therapeutic challenge. The basal-like 2 (BL2) molecular subtype of TNBC is of particular concern due to its extremely low rate of pathological response to standard chemotherapy. We found that BL2 TNBC cell lines are highly sensitive to protein kinase C (PKC)-activating diterpenes, including ingenol 3-angelate (I3A), tigilanol tiglate, and yuanhuacine, with potency in the nanomolar to picomolar range. Strikingly, these compounds demonstrate over a thousand-fold selectivity against BL2 cells as compared to other TNBC lines or normal breast cells, suggesting they could have a favorable therapeutic index for this indication. Preliminary evidence indicates that the vulnerability of BL2 TNBC lines is mediated by PKC, although it is unclear which isoform(s) and downstream signaling pathways are required for subtype-specific cytotoxicity. This project uses zebrafish tumor-bearing models as a strategy to establish the therapeutic index of these PKC agonists following systemic administration and to compare compounds that target distinct PKC isoforms. By integrating tumor response with pharmacologic profiling, this work aims to define the relationships between PKC activation, compound potency, and subtype-selective efficacy to identify the most promising candidate for preclinical development. Ultimately, this research aims to leverage PKC activation as a targeted therapeutic strategy for BL2 TNBC, expanding treatment options for this lethal breast cancer subtype.

#0297 Cymirafen: A protein-drug conjugate that delivers very intense short pulses of MMAE on a weekly schedule.

Maria Carmen Mulero Roig, Sukshala A. Jadhav, Willie Pi, Stephen B. Howell

UC San Diego-Moores Cancer Center, La Jolla, CA

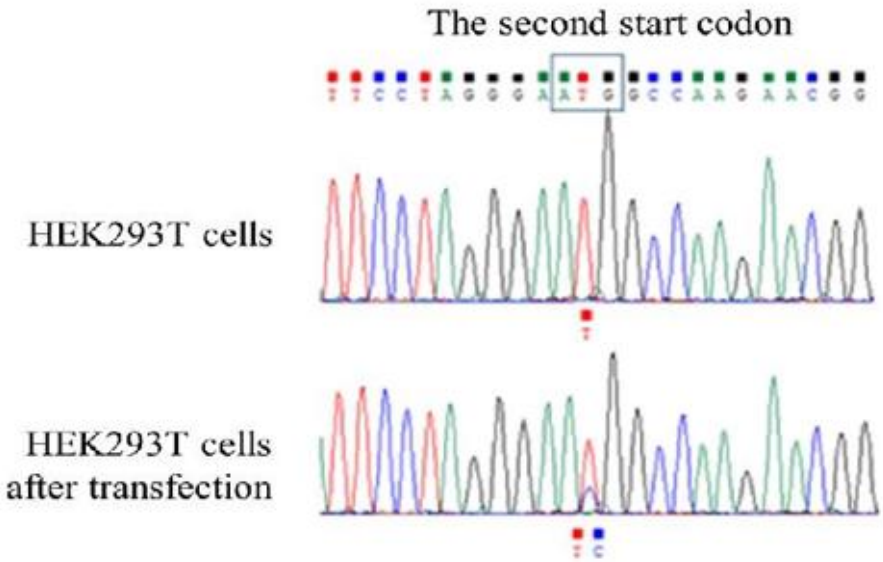
INTRODUCTION: Cymirafen is a novel protein-MMAE conjugate that targets the LGR4/LGR5/LGR6 receptor whose pharmacokinetics suggest that it can address many of the limitations of existing ADCs that use MMAE as their warhead. The human doses of MMAE ADCs are very small (1.2 - 4.5 mg/kg/3 wk) because larger doses are simply not tolerated. At these doses the ADCs do not penetrate deeply into tumors, the plasma concentrations are too low to saturate all receptors on those cells the ADC can reach, and the very long duration exposure to high plasma free MMAE concentrations cause neurotoxicity. However, long exposures are not required for MMAE efficacy; intracellular MMAE kills with even short durations of exposure (days rather than weeks).
METHODS: PK studies used mice and Sprague-Dawley rats, and the SC OVCAR5 CDX model. Plasma and tumor lysate cymirafen was measured by ELISA using antibodies to different epitopes. Free MMAE was determined by LC-MS/MS.
RESULTS: Cymirafen is very potent. Across a panel of cell lines of mixed cancer types, IC_{50} was <10 nM in 70% and <5 nM in 34%. Nevertheless, very high doses are well tolerated in mice and rats. In nu/nu mice the MTD is 125 mg/kg and a dose of 85 mg/kg can be given weekly for 8 weeks without net weight loss. Single dose HNSTD of MMAE ADCs in the rat is 5 - 10 mg/kg whereas the HNSTD for cymirafen is 75 mg/kg, >10 times higher than MMAE ADCs. In both mouse and rat, the initial and terminal half-lives of cymirafen are ~ 4 h and 0.8 - 1.0 d whereas terminal half-lives for MMAE ADCs are 8.6 -14.6 d. In rats given 60 mg/kg, the peak total cymirafen was 3001 ± 813 nM. Free plasma MMAE peaked immediately after injection at 3.8 nM and declined with a half-life of 7 h to become undetectable after 48 h. Cymirafen was found to deliver MMAE to tumors very rapidly. Following an IP injection of cymirafen 85 mg/kg in nu/nu mice, free MMAE in the OVCAR5 tumor lysates rose very rapidly reaching 100 nM by 8 h and persisted for a prolonged period. The dose density of cymirafen (moles of MMAE per tolerated dose) is estimated to be ~2.5 times higher than that of MMAE ADCs because the MW of cymirafen is only half that of an ADC and very much larger doses are tolerated.
CONCLUSIONS: In contrast to MMAE ADCs, because of the much larger doses tolerated and the very much shorter half-life, cymirafen achieves very high plasma concentrations that load MMAE into tumors at a very high rate over just a few days. This favors deep penetration and complete saturation of receptors. The much higher payload dose means that many more moles of MMAE are delivered/dose, and since large doses of cymirafen can be given weekly, the rate and total amount of MMAE delivered over 3 weeks is far higher than what can be delivered by an MMAE ADC. Peak plasma free MMAE is only 0.09% of total cymirafen, and all free MMAE is cleared by 48 h. Low free MMAE plasma levels, and its short half-life, markedly reduce exposure of normal tissues to free MMAE and permits injection of very high doses.

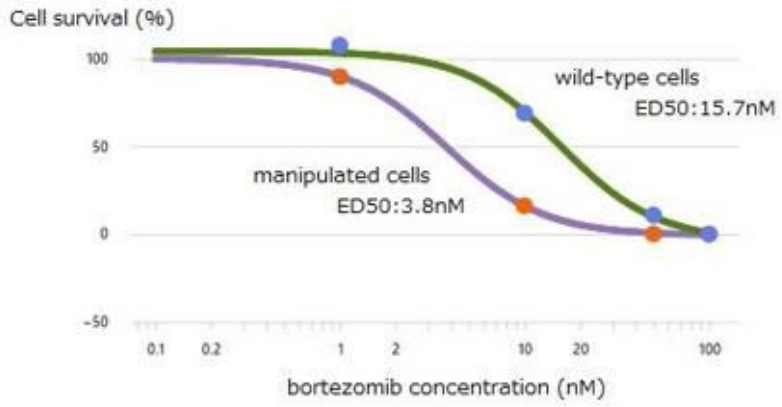
#0298 An engineered human myeloid cell line with a UBA1 mutation frequently detected in VEXAS syndrome is sensitive to the proteasome inhibitor bortezomib.

Hina Yazawa[1], Youhei Sasaki[2], Norihiko Kawamata[3]

[1]Medical Technology, School of Health Sciences, Tokyo University of Technology, Tokyo, Japan,[2]Hematology, Showa Medical University, Tokyo, Japan,[3]Hematology, Sasaki Institute/Tojun Medical Plaza Hospital, Tokyo, Japan

VEXAS syndrome is a systemic inflammatory disorder caused by somatic point mutations ofthe UBA1 gene in hematopoietic progenitor cells. Myelodysplastic syndrome (MDS) is oneof hematologic malignancies, in which hematopoietic stem cells have genetic mutations,without curable drugs. The same types of point mutations of the UBA1 gene as detected inVEXAS syndrome are occasionally detected in MDS. Reagents targeting mutated UBA1proteins may be able to eradicate the abnormal cells with the UBA1 point mutations.To examine this hypothesis, we have established a model cell line with the UBA1 mutationand analyzed drug-sensitivity of the mutated cells. First, we employed AI-based predictionanalyses to find the most reliable target sites and enzymes for introduction of the mutationinto the UBA1 gene. Second, we introduced the point mutation into the second start codonof the UBA1 gene, which is often detected in VEXAS syndrome, using a modifiedCRISPR/Cas9 method, adenosine-base-editing (ABE) enzyme and a targeting sgRNAconstruct. Third, we introduced the mutation into 293T cells using polyethyleneimine andconfirmed the base-change of the target site and absence of non-specific base-changes aroundthe target site. Fourth, we also introduced the UBA1 mutation into a human myeloid cell line,K562, using electroporation and found massive cell death of the introduced cells afterbortezomib treatment (ED_{50} of wild-type cells was 15.7nM and ED_{50} of the introduced cellswas 3.8nM), which inhibits proteasome activity.UBA1 plays an important role in ubiquitin/proteasome pathway to destroy degraded proteins.The mutation of the UBA1 gene leads to accumulation of degraded proteins in the abnormalcells. Further accumulation of degraded proteins by inhibition of the ubiquitin/proteasomepathway with bortezomib may have killed the mutated cells.Of note, since only 30-40% of K562 cells had the base-change by this method, cells with thebase-conversion may have secreted cytotoxic cytokines/chemokines, killing neighboring cellswithout the base-conversion, causing the massive cell death.We successfully isolated single cells with the base-conversion and evaluated effects of a drug, bortezomib, which is frequently used at bedside for treatments of multiple myeloma, for thecells with the mutation of UBA1 gene.The engineered cell line we have established would help clinicians to find new drugs effectivefor MDS patients with the UBA1 mutations.





#0299 From factory to patient: *In vivo*-expressed biologics as a new paradigm for immunotherapy manufacturing.

Henry Leonard[1], Dan Rocca[1], Philipp Meyer[2], Ina Rohleff[2], Eva Oswald[2], Sarah L. Martin[3], Matthew Benson[3], Namrata Jayanth[4], Christian Cobaugh[5], Michael Shaw[5], Julia Schueler[2], Gemma Moiset[4], Roxana Redis[4], **Louise Brackenbury**[1], Justin Bryans[3]

[1]Charles River Laboratories, Bristol, United Kingdom,[2]Charles River Laboratories, Freiburg, Germany,[3]Charles River Laboratories, Cambridge, United Kingdom,[4]Charles River Laboratories, Leiden, Netherlands,[5]Vernal Biosciences, Colchester, VT

Advances in in vivo-expressed biologics are redefining how advanced modality therapeutics can be manufactured, delivered, and rapidly iterated for oncology and immune-modulating applications. Building on our existing mRNA-LNP platform for therapeutic antibody expression, we now extend this capability to mRNA-encoded chimeric antigen receptor (CAR) T cells, establishing an integrated, modular framework for generating functional biologics directly from modified RNA templates. Using clinically validated lipid nanoparticle (LNP) formulations, we have demonstrated efficient translation, secretion, and functional integrity of mRNA-encoded trastuzumab across in vitro, in vivo PK, and xenograft efficacy models. mRNA-derived antibody retained antigen specificity and ADCC potency equivalent to recombinant comparators, while in vivo studies showed sustained exposure and superior tumour growth control at reduced doses relative to protein-infused benchmarks. Additionally, we describe a complementary workflow enabling transient CAR expression in primary human T cells using SM-102-containing LNPs. Non-viral delivery of HER2-CAR mRNA resulted in >65% CAR-positive T cells following expansion, with robust surface expression and preserved viability. Functional cytotoxicity assays demonstrated potent, antigen-dependent killing of HER2-expressing tumour targets across a range of effector-to-target ratios, confirming that mRNA-encoded CAR T cells can be rapidly generated and evaluated using standard immunological assay infrastructure. Together, these datasets establish a unified platform for the rapid prototyping, optimisation, and functional validation of in vivo-expressed biologics. By combining antibody and cellular engineering workflows within a common mRNA-LNP framework, this approach enables scalable screening of candidate designs, supports mechanism-of-action studies, and lays a foundation for future in vivo investigations using targeted LNP technologies. The platform provides a flexible route to accelerate preclinical development of next-generation biologics, lowering dependency on complex manufacturing and enabling rapid iteration cycles aligned with the emerging field of mRNA-nanomedicine.

#0300 Mapping cellular fate: From metabolic dynamics to DNA damage responses.

Lorena Sueiro-Ballesteros, Henry Leonard, Dan Rocca, Lauren Schewitz-Bowers, **Louise Brackenbury**

Charles River Laboratories, Bristol, United Kingdom

Cellular homeostasis is maintained through a tightly regulated interplay of metabolic activity, cell cycle progression, programmed cell death, and genomic integrity. Perturbation of these pathways is a hallmark of oncogenesis. Analysis of these processes not only elucidates mechanisms of disease but also informs on therapeutic strategies. Here we present an integrated experimental framework designed to interrogate metabolism, cell cycle regulation, apoptosis, and DNA damage responses (DDR) in both immortalized cell lines and human primary cells. To assess cellular metabolic dependencies, we employed the SCENITH approach [1], which uses puromycin incorporation as a proxy for translational activity and, by extension, ATP production. This method enables quantification of reliance on glycolysis versus oxidative phosphorylation under defined conditions. Using metabolic inhibitors; 2-deoxyglucose to block glycolysis and oligomycin to inhibit mitochondrial ATP synthase, we observed distinct metabolic profiles. $CD8^+$ T cells exhibited pronounced dependence on oxidative phosphorylation, whereas HeLa cells maintained translational activity despite mitochondrial inhibition, indicating metabolic flexibility. Parallel to metabolic profiling, we implemented flow cytometric cell cycle analysis using FxCycle™ staining to determine DNA content and the proliferative state of cells. Cell lines, MOLT-4, were exposed to therapeutics with established antiproliferative activity. Cisplatin and palbociclib induced G_1-phase arrest, consistent with DNA crosslinking and CDK4/6 inhibition, respectively, while nocodazole, a microtubule disruptor, arrested cells in G_2/M. Apoptotic responses were concurrently evaluated via caspase 3 /DAPI staining, revealing cisplatin as the most potent inducer of early and late apoptosis compared to palbociclib and nocodazole. Finally, DDR was quantified by monitoring γH2AX and RAD51 foci formation following cisplatin treatment or exposure to irradiation. High-content imaging facilitated dose-response characterization and demonstrated that co-treatment with an ataxia-telangiectasia mutated (ATM) kinase inhibitor markedly amplified DNA damage accumulation, underscoring the therapeutic potential of DDR modulation. Collectively, these assays provide a customizable platform for dissecting cellular vulnerabilities and resilience under pharmacological stress. Such multidimensional profiling offers critical insights for precision oncology and immunotherapy, enabling the identification of context-specific targets and combinatorial strategies to overcome resistance. #0301 Population pharmacokinetics of nab-paclitaxel following administration of a nano-immunoconjugate with bevacizumab.

Mohd Beshr Chama[1], Matthew Stephen Block[1], Vera J. Suman[2], **Joel M. Reid**[1]

[1]Mayo Clinic College of Medicine and Science, Rochester, MN,[2]Mayo Clinic, Rochester, MN

Introduction. This study aimed to characterize the population pharmacokinetics (PopPK) of nab-paclitaxel following the administration of the nano-immunoconjugate nab-paclitaxel-bevacizumab to patients with unresectable stage IV melanoma or gynecological cancers (NCT02020707). The core objective was to characterize the population mean drug concentration-time profile, understand the variability in drug concentrations and identify factors that explain differences in paclitaxel plasma clearance. Also, we sought to explore the impact of the nano-immunoconjugate formulation on paclitaxel clearance.

Methods. Using Pumas AI - an advanced pharmacokinetic software program, integrating Machine Learning methods - a PopPK analysis was conducted using concentration-time data collected from 29 subjects, (681 concentration measurements). Patients received 75 - 175 mg/m^2 (total dose, 160 - 360 mg). Data were fitted to a 2-compartment model based biphasic decline observed in plasma concentration following intravenous administration. A critical requirement for the model was the inclusion of saturable elimination to accurately describe the drug's disposition. A comprehensive modeling workflow was implemented, starting with base models (mixed vs. non-linear clearance), followed by the sequential addition of covariates (Age, Sex, BSA, Tumor, Cycle). The Parsimony Principle was applied to select the most appropriate model.

Results. Population estimates for paclitaxel clearance and volume of distribution were 41.7 L/hr and 312 L, respectively. The analysis found paclitaxel clearance higher when compared with published data for nab-paclitaxel alone (21.1 or 25 L/h/m^2; Sparreboom et al, CCR 11:4136, 2005 and Ando et al, CCP 69:457, 2012). A covariate model incorporating BSA and Gender is the best. For every 2 m^2 increase in BSA, linear clearance (CL) increases by 6.9%. Females have 16.6% lower CL than males, which successfully characterized systematic differences in PK between subgroups of subjects.

Conclusion. The administration of nab-paclitaxel via the nano-immunoconjugate formulation led to increased clearance for paclitaxel consistent with known clearance mechanisms for therapeutic antibodies. The differences in drug clearance among patients were primarily attributable to covariates BSA and gender. These findings are crucial for identifying safe and effective dosing regimens and informing future clinical simulations.

#0302 Evaluating the influence of cholesterol content on the cellular uptake and formulation activity of nanoliposomal formulations against uveal melanoma.

Shrey Mehulkumar Patel, Francielle Mourisso, Bilal Habibeh, Anna Kleckerova, Robert B. Campbell

Massachusetts College of Pharmacy and Health Sciences, Worcester, MA

Introduction: Uveal melanoma (UM) is a rare but aggressive intraocular malignancy with limited responsiveness to current therapies. Nanoliposomal delivery systems can enhance intracellular drug transport, but their performance depends on lipid composition and the tumor's metabolic profile. UM exhibits dysregulated cholesterol metabolism driven by altered expression of enzymes such as SREBP2. Because cholesterol is a key structural membrane component that influences liposome properties, this study evaluated how cholesterol inclusion affects nanoliposome uptake and drug effects in UM cells.

Methodology: MP41 uveal melanoma cells (ATCC®) were cultured in RPMI supplemented with 25% FBS. Cells (2×10^4/mL) were seeded in vented centrifuge tubes and exposed to DPPE-rhodamine-labeled nanoliposomes containing 0, 5, 10, or 20 mol% cholesterol substituted for DOPC. Tubes were placed in an oscillating incubator at 37 °C for 60 minutes to promote liposome-cell interactions. Cellular uptake was quantified using a fluorescence microplate reader, and Quad Count™ was used for cell counting, viability, and growth-inhibition assessments.

Result: At 1 hour, the inclusion of cholesterol decreased the uptake of nanoliposomes by MP41 uveal melanoma cells. DOPC consistently demonstrated the highest cellular uptake values (≈2594-4543 RFU), while 95/5 and 90/10 formulations displayed lower values (≈800-3451 RFU) by comparison. These findings reveal a reproducible inverse relationship between cholesterol content and cellular uptake, suggesting that the inclusion of cholesterol in nanoliposome diminishes cellular uptake. Ongoing studies will evaluate additional time points and conditions, and whether the findings correlate with cytotoxicity studies.

Conclusion: Reduced cholesterol content in nanoliposomal formulations markedly enhanced cellular uptake by uveal melanoma cells. The consistently higher internalization observed with DOPC (100%) supports the use of relatively low-cholesterol (or cholesterol-free) preparations to enhance targeting. Cholesterol modulation could potentially enhance the effectiveness of therapeutics against uveal melanoma.

#0303 Turning tumors into therapeutic drug factories: Efficacy across oncology indications.

Moataz Reda, Blaine McCarthy, Sushil Lathwal, Evan Bishop, Priyanka Balasubrahmanyam, Robby Chandra, Nikki Kimura, Xiao Wu, Kim Tran, Jesse Simons, Ajda Rojc, Jayalakshmi Ramani, Dang Dang, David Rosen, Badri Ananthanarayanan, Nadege Morisot, David Suhy

Earli Inc., Redwood City, CA

Although DNA can be used to drive expression of cancer therapeutics, clinical use is often restricted to intratumoral injection due to lack of specificity. Earli's cancer-activated expression platform permits broad systemic DNA delivery to a multitude of cancers by using conditionally active promoters to drive potent anti-tumor activity while minimizing systemic toxicity. This is achieved via orthogonal levers of specificity: (1) lipid nanoparticles (LNP) for extrahepatic delivery of nucleic acids following intravenous (IV) injection to maximize tumor DNA delivery, and (2) highly engineered synthetic cancer-activated promoters (CAP) that restrict expression to malignant cells. As a result, the therapeutic protein production is concentrated within the diseased tissues while avoiding broad systemic exposure and corresponding dose-limiting toxicities.

Typically, IV-dosed LNPs are rapidly opsonized and cleared by the liver. Proprietary Earli LNPs were optimized for systemic delivery of DNA beyond the liver including solid tumors. Biodistribution and expression from different LNPs were assessed using a DNA with a CAG promoter driving luciferase in subcutaneous xenograft models. The lead LNP achieved more than a 6-fold higher tumor expression than the same DNA formulated in an LNP used in a commercial siRNA product. Importantly, tumor tropism confirmed a robust 88-fold difference in tumor-to-liver BLI ratio. Cancer-activated expression was initially tested in syngeneic subcutaneous models. An IV-dosed CAP-driven IL-12 DNA construct resulted in tumor regression in all treated animals, achieving a 100% cure rate at modest DNA levels. This response was accompanied by robust $CD8^+$ T cell activation. IL-12 was detected in the tumor but remained undetectable in the serum, confirming selective expression driven by the CAP element.

To demonstrate utility in clinically relevant models, the platform was tested in orthotopic models of lung cancer. In an aggressive lung metastases model, CAP-IL-12 significantly reduced lung tumor burden by over 7-fold compared to a non-expressing control construct, and significantly reduced metastatic nodules and lung weights. Immune-profiling revealed IL-12-driven immune activation, such as 2-fold increases in $Ki67^+$ cells and a 4-fold increase in cytotoxic $CD8^+$ T cells compared to control. Central and effector memory T cells were also elevated by 2-fold. Myeloid cells showed enhanced activation with a 3-fold increase in MHC II expression on dendritic cells, indicative of improved antigen presentation within the tumor microenvironment. Ongoing experiments are evaluating the efficacy of CAP-driven IL-12 delivered with newly developed LNPs in orthotopic bladder and liver models.

Overall, our findings demonstrate Earli's cancer-activated expression platform across cancer indications, supporting its development for broad application across oncologic indications.

#0304 A phase 1 study of intratumoral ultra-high concentration nitric oxide (UNO) gas injection in cutaneous and subcutaneous solid tumor metastases.

Amichay Meirovitz[1], Steve Lisi[2], Kim Sheva[1], David Greenberg[1], John Jett[2]

[1]Soroka Medical Center, Beer-Sheva, Israel,[2]Beyond Air, Inc., New York, NY

Background: Ultra-high concentration nitric oxide (UNO; >10,000 ppm) administered intratumorally has shown survival benefits in murine colon and breast cancer models. UNO modulates the tumor immune microenvironment, influencing M1 macrophages, Tregs, and $CD8^+$ T cells, and upregulates PD-1 expression, thereby enhancing the activity of immune checkpoint inhibitors (ICIs). In preclinical studies, UNO combined with anti-PD-1, anti-PD-L1, or anti-CTLA-4 improved tumor inhibition, and UNO alone surpassed anti-PD-1 efficacy in 4T1 breast tumor-bearing mice.

Methods: This phase 1 trial (NCT05351502) evaluated the safety, maximum tolerated dose (MTD), and recommended phase 1b dose of a single intratumoral UNO injection in patients with unresectable cutaneous or subcutaneous solid tumors (superficial axis 4.5-30 mm). UNO was administered at 25,000 or 50,000 ppm using a 23-gauge needle inserted horizontally through the tumor to create an exit portal, then retracted to the lesion center for treatment. Gas was delivered intratumorally at 0.2 L/min for 5 minutes.

Results: Ten heavily pretreated patients were enrolled: squamous cell carcinoma (n=2), melanoma (n=2), and breast cancer (n=6). Patients received a mean of 5.5 prior systemic therapies and 10.3 total cancer-directed treatments. Six patients were treated with 25,000 ppm UNO and four with 50,000 ppm. Overall, treatment was well tolerated; most treatment-related adverse events (AEs) were grade 1. One serious (S)AE (hypoxia) that occurred during a 25,000 ppm administration, was considered related but was not dose-limiting and resolved fully. No deaths occurred within 12 weeks post-treatment. As of October 1, 2025, seven of ten patients remain alive 19-37 months post-single UNO injection; one patient died of disease progression 25 months post-treatment. Two patients with triple negative breast are disease free.

Conclusions: Intratumoral administration of ultra-high-concentration UNO was feasible and well tolerated in patients with unresectable solid tumors. Durable long-term survival observed in this heavily pretreated population supports further evaluation of UNO, including in combination with ICIs.

#0305 Non-melanoma skin cancer treated with electrochemotherapy: Clinical outcomes and tolerability.

Felipe Horacio Maglietti[1], Raquel Lertora[2], Nazarena S. Martinez[1], Alexandre Da Rosa Silva[1], Marina Ribeiro Damasceno Silva[1], Sebastian D. Michinski[3]

[1]Instituto Barcelo de Investigacion Traslacional, Buenos Aires, Argentina,[2]Hospital Petrona V de Cordero, San Fernando, Argentina,[3]INFINA-CONICET, Buenos Aires, Argentina

Background: Electrochemotherapy (ECT) combines electroporation and chemotherapy to enhance cytotoxic drug uptake in tumor cells. This study evaluates the efficacy and safety of ECT using intravenous bleomycin in patients with non-melanoma skin cancer (NMSC).
Methods: Sixteen patients with histologically confirmed NMSC were treated under neuroleptoanalgesia in an outpatient setting. Intravenous bleomycin was administered at a dose of 15,000 IU/m² of body surface area. Electric pulses were delivered using the OncoPore device (BIOTEX SRL, Buenos Aires, Argentina). Each session lasted less than one hour, and all but one patient required a single treatment. Tumor response was assessed according to RECIST criteria, and adverse events were graded following CTCAE guidelines.
Results: Among the 16 treated patients, 11 had squamous cell carcinoma and 5 had basal cell carcinoma. Twelve patients (75%) achieved Complete Response, three (19%) had Partial Response, and one (6%) exhibited Stable Disease (SD), yielding an Objective Response rate of 94%. Notably, one patient with recessive dystrophic epidermolysis bullosa achieved a complete response without complications. Adverse events were mild to moderate and transient. The most frequent was pain (grade 2), effectively managed with nonsteroidal anti-inflammatory drugs. Erythema (grade 1) and swelling (grade 1-2) resolved spontaneously within one week. Infection (grade 2) occurred in four patients (25%) and was successfully treated with oral antibiotics. No severe or systemic adverse events were observed. Esthetic outcomes were excellent in all cases, with preservation of surrounding healthy tissue and minimal scarring.
Conclusions: ECT with intravenous bleomycin represents a safe, effective, and well-tolerated therapeutic option for patients with non-melanoma skin cancer. The high objective response rate, minimal toxicity, and favorable cosmetic results support its implementation in outpatient settings. Furthermore, its efficacy in a patient with epidermolysis bullosa suggests potential applicability in selected fragile-skin conditions. These results reinforce ECT as a valuable addition to the therapeutic armamentarium for NMSC management.

#0306 Integrative computational and functional genomic approach reveals UBE2Z-UBR2-Ecadherinaxis as a beta-catenin-specific vulnerability in colorectal cancer.

Chunhua Wan, Hugh Gao, Claire Sun, **Ron Firestein**

Hudson Institute of Medical Research, Clayton, Australia

Synthetic lethality provides a powerful framework for cancer therapy by targeting gene interactions that are selectively essential in tumor cells, but are non-essential in normal tissues.. This approach is particularly attractive in malignancies driven by oncogenes considered “undruggable”. Using a machine-learning multi-omics approach we identify UBE2Z/USE1, a key ubiquitin-conjugating enzyme of non-canonical E1 UBA6-charged ubiquitination cascade, as a synthetic lethal partner of oncogenic β-catenin. UBE2Z knockout markedly impairs nuclear β-catenin accumulation, suppresses Wnt target gene expression, and induces differentiation in cell lines, tumouroids and in vivo models. Strikingly, UBE2Z is exclusively necessary for oncogenic β-catenin activity and completely dispensable for physiological Wnt/β-catenin signaling, highlighting its tumor-specific role. Genome-wide CRISPR rescue screens identified E-Cadherin as a critical intermediate of UBE2Z activity. Integrative transcriptomic and proteomics analyses suggest that UBE2Z supports oncogenic β-catenin transcriptional activity by promoting the degradation of intracellular E-cadherin via UBRfamily N-end rule E3 ligases. Manipulating UBE2Z’s ubiquitin-conjugating activity recapitulates the potent inhibitory effect of E-cadherin overexpression on oncogenic β-catenin activity, underscoring its translational significance. These findings reveal the UBA6-UBE2Z non-canonical ubiquitination cascade as a druggable vulnerability in β-catenin-addicted cancers and underscore synthetic lethality as a rational strategy for targeting β-catenin-driven tumorigenesis.

#0307 Triple-negative breast cancer growth and metastasis suppression by CCN5 is mediated by Merlin/NF2 and Orai-1 molecular signatures.

Inamul Haque[1], Gargi Maity[2], Jamie L. Porter[2], Snigdha Banerjee[2], Sushanta K. Banerjee[2]

[1]Cancer Biology, University of Kansas Medical Center, Kansas City, KS,[2]Pathology and Laboratory Medicine, University of Kansas Medical Center, Kansas City, KS

Breast cancer (BC) is the second leading cause of cancer-related death among women, both in the United States and globally. This disease affects approximately one in eight women (around 12%), impacting nearly every family worldwide. The statistics are similarly relevant for female U.S. veterans. Current therapies for BC are thought to improve patient survival; however, one-third of patients with aggressive triple-negative breast cancer (TNBC) may experience more frequent relapses compared to those with hormone receptor-positive subtypes, and may eventually develop distant metastatic disease. Currently, there are no targeted therapies available for invasive and metastatic breast cancer, highlighting a critical need for improved treatment options. TNBC is a heterogeneous mix of cells, with significant variability both between and within tumors, which often makes therapeutic regimens less effective. A novel approach, diverging from existing treatment strategies, could positively influence both clinical study designs and future practices in BC, potentially increasing the number of TNBC survivors. Our previous studies examined CCN5 expression in a large cohort of primary BC samples and cell lines, finding that CCN5 expression is inversely correlated with disease in most samples. In this study, we demonstrated that CCN5 inhibits tumor growth and metastatic spread in genetically engineered mouse models (GEMMs) and human TNBC xenograft models, without causing any side effects. CCN5 may facilitate these critical processes by regulating the expression and activity of Merlin (a tumor suppressor gene) and Orai1 (a gene involved in metastasis) in TNBC cells. In addition, CCN5 suppresses the JunB/AP-1 transcription factor and VEGF-A, while protecting against ZO-1 loss (a downstream target of VEGF-A and a protein that acts as a barrier to metastasis), mirroring the blockade of permeability in endothelial cell (EC) monolayers. These collective findings suggest that CCN5 prevents or delays the growth, invasion, and metastasis of TNBC cells by regulating multiple gene signatures. Therefore, CCN5 treatment or restoration may represent a promising novel therapeutic intervention for breast cancer. (This work is supported by the VA Merit grants)

#0308 Melatonin activity in uterine leiomyoma and leiomyosarcoma cell lines: A preliminary study of its inhibitory potential in mesenchymal tumors.

Tatielly T. Miranda[1], Edmund C. Baracat[2], Roseli S. Soares[2], **Katia C. Carvalho**[1]

[1]Obstetrics and Gynecology, HCFMUSP, Sao Paulo, Brazil,[2]Sao Paulo University, Sao Paulo, Brazil

Background: Uterine smooth muscle tumors (USMT) encompass benign leiomyomas (LM) and highly aggressive leiomyosarcomas (LMS). Although melatonin has been reported to exert antiproliferative and oncostatic effects in several tumor models, its impact on the growth dynamics of LM and LMS cells remains poorly understood. Here, we evaluated the dose- and time-dependent effects of melatonin on the proliferation and migration of LM and LMS cell lines to investigate the responsiveness of both benign and malignant USMT cells.

Methods: LM and LMS cells were plated at a density of 1×10^4 cells per well in 96-well plates. Cell proliferation was assessed at 0, 24, 48, 72, and 96 hours following treatment with melatonin at 3 mM, 5 mM, or 10 mM. Each condition included six technical replicates and two experimental replicates. Control groups consisted of untreated cells (medium only) and vehicle controls (medium plus ethanol). Fluorescence-based viability/proliferation readings (Presto Blue reagent®) were used as a measure of cell growth over time. Scratch assays were used to assess the effects on the cell migration using the same time and doses of melatonin, followed by Image J® software analyses of the acquired pictures.

Results: Melatonin significantly inhibited proliferation in both LM and LMS cells in a dose-dependent manner. In LM cells, melatonin induced a marked and sustained reduction in proliferation at all-time points, with the strongest suppression observed at 10 mM, which maintained minimal proliferative activity throughout the experiment. LMS cells also exhibited reduced proliferation in response to melatonin, although the inhibitory effect was less pronounced than in LM cells, particularly at earlier time points. At 72 hours, control LMS groups displayed a sharp proliferative peak, whereas melatonin-treated cells - especially at 10 mM - showed substantial attenuation of this growth increase. Across both tumor types, 10 mM consistently showed the most robust antiproliferative effect. Very similar results were obtained for the migration analyses, both to LM and LMS cells.

Conclusion: Melatonin exerts clear inhibitory activity in USMT cells, with a stronger suppressive effect in LM cells compared with LMS cells. These findings suggest intrinsic differences in melatonin responsiveness between LM and LMS, potentially reflective of altered growth-regulatory pathways associated with malignant transformation. Melatonin may represent a biologically relevant modulator of uterine smooth muscle cells tumorigenesis, warranting further mechanistic studies and exploration as an adjunct therapeutic strategy.

#0309 Oncogenic cooperation of MUC13 and NDRG1 signaling in liver cancer.

Shabnam Malik[1], Mohammed Sikander[1], Daniel Zubieta[1], Mirza Sarwar Baig[2], Iris Enriquez[1], Murali M. Yallapu[1], Subhash C. Chauhan[1]

[1]The University of Texas Rio Grande Valley, Edinburg, TX,[2]School of Interdisciplinary Science and Technology, Jamia Hamdard, New Delhi, India

Background: Liver cancer is one of the leading causes of cancer-related mortality worldwide, highlighting the vital importance of understanding its molecular mechanism for the development of targeted therapies. Mucin 13 (MUC13), a transmembrane glycoprotein, has been associated with the oncogenic processes that cause liver cancer. Our previous studies have shown its significance in promoting cancer cell survival, proliferation, and metastasis. Emerging evidence indicates that NDRG1 (N-Myc downstream regulated gene 1), played a critical role in cell growth, development, stress response, invasion and migration, may also be implicated in the pathogenesis of liver cancer. The current study aims to investigate the influence of the co-expression of MUC13 and NDRG1 on liver cancer progression and determine if their co-expression is correlated with clinical outcomes.
Methodology: We employed liver cancer cell lines corresponding to different tumor grades characterized by MUC13 positivity. The expression levels of MUC13 and NDRG1 were evaluated in these cell lines. We performed confocal microscopy for immunofluorescence to examine co-localization of MUC13 and NDRG1. Furthermore, we conducted immunohistochemical analysis of MUC13-positive patient samples to evaluate NDRG1 expression levels. We additionally examined public databases to assess the correlation of NDRG1 and MUC13 expressions with patient survival.
Results: We identified a notable association between increased levels of MUC13 expression and elevated NDRG1 expression in MUC13-positive liver cancer cell lines, suggesting a potential interplay that may facilitate cancer progression. Immunofluorescence assays performed on these cell lines provided yields strong evidence of co-localization between MUC13 and NDRG1. Additionally, our studies demonstrated a direct molecular interaction between MUC13 and NDRG1 in liver cancer cells as evidenced by proximity ligation assay (PLA). We further confirmed NDRG1 expression in MUC13-positive and negative patient samples through immunohistochemical staining. To corroborate our findings, we conducted a correlational analysis using public clinical database, which revealed an association between NDRG1 and MUC13 expression levels, suggesting that higher co-expression of these two molecules is linked to poor overall survival (OS) rates.
Conclusion: The outcomes of this study indicate a notable co-expression of MUC13 and NDRG1 in liver cancer, potentially highlighting their cooperative involvement in tumor progression.

#0310 Translational development of NEU-002: Engineered therapeutic elastases demonstrate systemic anti-tumor activity via intraperitoneal and intravenous administration.

Maria Fumagalli, Chang Cui, Ravindra Gujar, Nicole Martinez, **Peter Haberz**, Court Turner, Lev Becker

Onchilles Pharma Inc, San Diego, CA

NEU-002 is a systemically deliverable engineered elastase targeting the ELANE pathway and is under development for solid tumors. To advance NEU-002 toward clinical translation, two optimized candidates, N17474 and N17482, were generated through rational sequence engineering. This optimization strategy focused on preserving elastase activity in blood by protection from serine protease inhibitors, as evaluated using a range of biochemical assays. Furthermore, we show that NEU-002 program compounds maintained robust anti-tumor efficacy in the CT26 colon cancer model following intravenous administration, demonstrating that essential functional properties were retained during optimization. In addition, we explored a new intraperitoneal route of administration to expand delivery options for NEU-002 and observed reductions in tumor burden in orthotopic colon cancer mouse models, supporting the feasibility of accessing tumors within visceral compartments. Collectively, these findings establish a strong translational foundation for NEU-002 and, together with planned pharmacokinetic studies in non-human primates, will directly inform the selection of the final development candidate for advancement toward clinical evaluation in solid tumor indications.
Generative artificial intelligence was used to assist in drafting text for this abstract.

#0311 Integrated strategies for producing functional recombinant proteins to advance autoimmune disease therapeutics.

Wenlin Ren[1], **Siwen Wang**[2], An Ouyang[2], Spencer Chiang[1], Yu Sun[1]

[1]ACROBiosystems Co., Ltd., Beijing, China,[2]ACROBiosystems Inc., Newark, DE

Autoimmune diseases result from immune dysregulation, characterized by loss of self-tolerance, chronic inflammation, and multiorgan pathology. However, the immune signaling pathway is a host of complex protein architectures, including polymeric cytokines, transmembrane receptors, and intracellular pathway mediators. Each are essential but challenging due to structural intricacies such as oligomerization, domain organization, and transmembrane regions. Herein, we present an integrated strategy to produce functional recombinant proteins to support research and therapeutic development in autoimmune disease. For soluble polymeric targets, structure-guided engineering is employed, encompassing linker optimization for IL-17A/IL-17F heterodimer stabilization. For other targets such as the assembly of IL-2 receptor subunits, the incorporation of protein tags is the optimal methodology for recombinant protein production. Finally, by utilizing targeted mutagenesis, oligomerization can be controlled for TL1A disulfide bonds to control oligomerization. With the incorporation of process optimization in culture and purification, the development of hard-to-express recombinant proteins helps preserve native conformation and bioactivity. These are encapsulated into three complementary platforms are implemented to ensure solubility and functional reconstitution: detergent micelles for structural studies, ELISA, and surface plasmon resonance; nanodiscs for detergent-free, cell-based assays; and virus-like particles providing a native membrane context and high immunogenicity. These proteins further enable antibody discovery, including epitope-focused immunogen design, for example, IL-23/IL-12 chimeras to reduce off-target responses. By adhering to Quality-by-Design principles, this closed-loop workflow from structural analysis through application validation ensures maintenance of native functionality, stability, and homogeneity. Collectively, these approaches accelerate drug discovery in autoimmune disease by generating high-quality reagents for mechanistic studies, screening, and therapeutic development, overcoming longstanding production bottlenecks in structurally complex targets.

#0312 Postbiotic based on sequential fermentation of *L.paracasei* NPB01 and *L.rhamnosus* GG exerts antitumor activities against breast cancer.

Roberto Berni Canani[1], Chiara Luongo[1], Laura Pisapia[1], Franca Oglio[1], Roberta Di Santillo[1], Alessia Gaeta[1], Chiara Scocco[1], Marco Michelini[1], Vittoria Mauriello[1], Alessia Cadavere[1], Camilla Messuri[1], Saranya Chumsri[2], Dawn Mussallem[1]

[1]University of Naples Federico II, Naples, Italy,[2]Mayo Clinic Florida, Jacksonville, FL

Backgroud. Breast cancer (BC) is the most common and deadly cancer in women worldwide. Emerging evidence highlights the role of gut microbiota in modulating breast cancer risk, treatment response, and recurrence through various mechanisms, including the production of biologically active compounds and metabolites. These non-viable microbial products and metabolic byproducts from probiotic fermentation, known as postbiotics, exert beneficial effects on the host without the need for live microorganisms. Postbiotics derived from *Lacticaseibacillus* species represent a novel class of therapeutics with potential anti-cancer properties. In this study, we investigated the therapeutic effects of an innovative postbiotic product (iPB), developed through sequential fermentation of *L.paracasei* NPB01 and *L.rhamnosus* GG, in BC experimental models.

Methods. The following cell lines were used to represent main BC subtypes: MCF7 cells (ER+/HER2), MDA-MB-231 (triple negative breast cancer), SKBR3 (HER2+). MCF-10A (normal breast epithelial cells), Caco-2 (enterocytes), and peripheral mononuclear blood cells (PBMC) were used as control. Cell viability was assessed by colony formation assay. Apoptosis was evaluated using Annexin V/7-AAD staining, HLA class I surface expression by flow cytometry, and cancer cells migration by wound healing assay.

Results. iPB exposure resulted in >50% colony formation reduction in MCF7, >30% in MDA-MB-231 and >40% in SKBR3 cells starting from 0.5 mg/ml for 72 h ($p<0.01$). iPB increased early and late apoptotic cell rate in all BC cell lines starting from 0.5 mg/ml for 72 h. On the contrary, iPB exposure up to 5 mg/ml for 120 h did not affect cell viability in control cells (MCF-10A, Caco-2, PBMC). 1.20 to 1.30 fold increase in HLA class I expression was observed in all BC cell lines after the exposure with iPB starting from the dose of 0.5 mg/ml for 72 h. A less intense HLA class I expression increase was observed in control cells after the iPB exposure. Cell migration process and inflammatory cytokines response were inhibited by the iPB exposure in all BC cell models.

Conclusions. iPB reduces cell viability and cell migration in all main BC phenotypes. These effects parallel with HLA class I surface expression increase in all BC cell phenotypes, potentially enhancing immunogenicity. These findings suggest that iPB may represent a promising novel agent in BC treatment and prevention.

#0316 Subcellular localization of PARP1 by protein kinase D1 modulated cellular response to olaparib.

Sanjeev Shukla[1], Joseph McGrath[1], Robert Willis[2], Arjun Venkatesh[1], Jean-Pierre Kanumuambidi[1], Reynier Rodriguez-Rosales[1], Mario Mietzsch[3], Robert McKenna[3], K.C. Balaji[1]

[1]Urology, University of Florida Health, Jacksonville, FL,[2]Alabama College of Osteopathic Medicine, Dothan, AL,[3]University of Florida, Gainesville, FL

DNA damage and repair play a dual role in cancer: unrepaired lesions drive mutations and tumor growth, while repair pathways enable cancer cells to resist therapies like chemotherapy and radiation. PARP1 detects DNA breaks, adds poly(ADP-ribose) to target proteins, and recruits repair factors, with localization mainly in the nucleus but extending to other compartments under certain conditions. Inhibition of PARP1 prevents DNA repair, leading to cancer cell death, and FDA-approved PARP1 inhibitors show efficacy in metastatic castration-resistant prostate cancer, though dose-limiting toxicities reduce effectiveness. This study examines Protein kinase D1 (PrKD1) as a modulator of PARP1 and its impact on sensitivity to PARP inhibition. Using prostate cancer cell lines with altered PrKD1 expression (LNCaP, LNCaP ShPrKD1, C4-2, and C4-2 PrKD1), we found that PrKD1 overexpression increased sensitivity to Olaparib (PARP1 inhibitor), while downregulation conferred resistance. Pharmacological inhibition of PrKD1 with Compound-10 also enhanced Olaparib sensitivity. Co-immunoprecipitation studies suggest PrKD1-PARP1 interaction in subcellular fractionations, and PrKD1 transfection in C4-2 prostate cancer cells increased PARP1 membrane localization. Compound-10 treatment in prostate cancer cells and PDX models represented elevated PARP1 expression. *In-silico* modeling also identified a potential PrKD1 binding site adjacent to PARP1 WGR (tryptophan-glycine-arginine-rich) domain. Overall, PrKD1 emerges as a novel PARP1 regulator. Co-targeting PARP1 using Olaparib and Compound-10 may improve efficacy at lower doses, enhance tolerability, and expand therapeutic options. Based on the *in-vitro*, *in-vivo* and *in-silico* studies we may suggest the interaction between PrKD1 and PARP1 in subcellular membrane compartments. The discovery of PARP1 at the membrane opens new opportunities for theragnostic applications.

#0317 Glucose conditions influence CAMKK2-targeted therapy sensitivity in triple-negative breast cancer of different ancestry.

Elham Amini, Sree latha Aramgam, Kenisha Webb, Sean Kimbro

Morehouse School of Medicine, Atlanta, GA

Background: Triple-negative breast cancer (TNBC) is associated with a higher incidence and mortality in women with specific metabolic comorbidities, including obesity, diabetes, and dyslipidemia. Calcium/calmodulin-dependent protein kinase kinase 2 (CAMKK2) is a central kinase regulating cellular energy metabolism and stress adaptation in TNBC cells. This study examines how different glucose conditions affect the survival and response of TNBC cell lines to CAMKK2 inhibitors.
Methods: A panel of commonly used TNBC cell lines (MDA MB 231, MDA MB 468, MDA MB 157, HCC1806) were treated with STO 609 and SGC CAMKK2 1 at various glucose levels. Cells were incubated under four glucose conditions, 0.33 mM (severe hypoglycemia), 5 mM (physiological/normal), 17.5 mM (moderate hyperglycemia), and 50 mM (extreme hyperglycemia). IC_{50} values and cell viability were assessed following drug treatment across these conditions.
Results and Conclusion: In all cell lines, results indicated an overall increase in IC_{50} (reduced inhibitor sensitivity) as glucose levels changed from moderate (5, 17.5 mM) to either low (0.33 mM) or high (50 mM). For STO-609, IC_{50} values improved from 71-2533 µM at 0.33 mM to 32-91 µM at 17.5 mM but increased again to 92-894 µM at 50 mM. With SGC-CAMKK2-1, IC_{50} ranged from 112-619 µM at 0.33 mM to 48-148 µM at 17.5 mM and increased again to 154-520 µM at 50 mM. Notably, HCC1806 cells were the most sensitive to both CAMKK2 inhibitors, while MDA MB 157 was overall more resistant. Different glucose conditions have a significant impact on the efficacy of CAMKK2-targeted inhibitors in TNBC, with some cell lines displaying more metabolic sensitivity than others. These findings demonstrate that personalized therapeutic strategies, considering the metabolic background, may improve treatment outcomes in aggressive breast cancers.

#0318 The combination of STX-478 and lorlatinib for the treatment of *PIK3CA* mutant colorectal cancer.

Addison T. Zick[1], Alexa E. Schmitz[1], Cheri A. Pasch[1], Dustin A. Deming[2]

[1]Univ. of Wisconsin Madison Sch. of Med. & Public Health, Madison, WI,[2]University of Wisconsin Carbone Cancer Center, Madison, WI

Background: Over 15% of colorectal cancer (CRC) patients are *PIK3CA* mutant, making it a critical pathway for drug development. Recently, we performed a high throughput drug screen with STX-478, a mutant-selective *PIK3CA* inhibitor, and identified lorlatinib, an ALK inhibitor, as a potential means to enhance therapeutic efficacy. Here we confirm this efficacy and evaluate potential mechanisms of action, including the potential impact of lorlatinib on MYC protein abundance and target gene expression.

Methods: CRC cell lines SW48 and SW48PK (Horizon Discovery; SW48 with a *PIK3CA*^{H1047R} mutation) were used in a cell viability assay. Immunoblotting was performed on SW48, SW48PK and patient derived cancer organoids (PDCOs) with STX-478, lorlatinib, and combo treatment. ImageJ was used to quantify these blots to evaluate PI3K protein expression. *PIK3CA*^{H1047R} mutant PDCOs were treated, imaged, and the longest diameter of any organoid was measured. Glass's delta (GD) was used to determine effect size for each treatment group compared to control. Gene expressions for five MYC target genes were measured by quantitative PCR (qPCR).

Results: In SW48 and SW48PK cells, there were no significant differences in cell viability following lorlatinib single-agent treatment. However, combo treatment with STX-478 and lorlatinib significantly reduced cell viability in both cell lines (lorlatinib 500 nm, STX-478 500 nm; SW48 p=0.001, SW48PK p<0.001) In SW48PK, immunoblot analysis demonstrated a marked decrease in phosphorylation levels of ribosomal protein S6 (RPS6) and 4EBP1 under combo treatment, indicating suppression of downstream PI3K signaling (pRPS6: p=0.02, 4EBP1: p=0.03). There were no significant changes in protein expression of c-MYC and pAKT in any of the treatment groups. RT- qPCR analysis overall did not demonstrate a change in MYC target gene expression. The expression of LDHA, a key glycolytic gene upregulated under hypoxic conditions, was significantly decreased in SW48PK cells following treatment, indicating a potential reduction in glycolytic activity associated with the combined therapy (p=0.005). *PIK3CA*^{H1047R} mutant PDCOs treated with the combo of STX-478 and lorlatinib had a significant reduction in growth compared to control (relative change in diameter control versus combo = 42.9% vs 12.3%; GD=1.37).

Conclusion: The combination of STX-478 and lorlatinib was confirmed to have significant efficacy in PIK3CA mutant CRC models. This activity does not seem to be related to effects on MYC. Further studies look to determine the mechanism of action for the combo treatment, and confirm efficacy in vivo.

#0319 An analysis of orthosteric missense kinase mutations among a clinical sequencing cohort of over 90,000 cancer patients.

Jessica B. White[1], John D. Chodera[2], Wesley Tansey[3]

[1]Tri-Institutional PhD Program in Computational Biology and Medicine (Memorial Sloan Kettering Cancer Center), New York, NY,[2]Sloan Kettering Institute, Computational & Systems Biology Program, Memorial Sloan Kettering Cancer Center, New York, NY,[3]Computational Oncology, Memorial Sloan Kettering Cancer Center, New York, NY

Being among the most well-studied family in the human proteome, the approximately 500 kinases that constitute the human kinome possess ample sequence, structural, and functional annotations within both pan-proteome and kinase-specific resources. Analyzing mutations in homologous residues, particularly in the orthosteric binding pocket, can provide insights into recurrent mechanisms of pathogenicity and drug resistance. However, harmonizing these resources poses a non-trivial task: identifier disambiguation, mapping between disparate sequence representations, and even concordance between resources as to what constitutes a kinase enzyme all pose significant challenges. Here, we describe the creation of a Python package to reliably and reproducibly curate and harmonize kinase sequences. We use this toolkit to interrogate missense mutations within the orthosteric kinase binding site from Memorial Sloan Kettering Cancer Center's (MSKCC) clinical sequencing cohort. We mapped the 85-residue binding site from the Kinase-Ligand Interaction Fingerprints and Structures (KLIFS) database to the canonical UniProt sequence for a superset of kinases from various resources. Among the 126,930 samples from the 93,249 patients in MSKCC's clinical sequencing cohort as of mid-November 2025, we identified 99 kinase genes assessed for somatic mutations. Within the 87 kinases that mapped to the canonical UniProt sequence, we detected 6,198 unique single amino acid substitutions in the ATP-binding pocket in at least one sample in 11,071 (11.9%) of patients. KLIFS regions with significantly higher percentages of kinases containing one or more such alterations included the gatekeeper (median: 65.9%), linker (65.3%), catalytic loop (61.8%), activation loop/xDFG motif (61.2%), and glycine-rich loop (56.5%), while β-sheet regions (47.1%) had significantly lower percentages. Kinase families that possessed a significantly higher percentages of KLIFS residues containing one or more such alterations included tyrosine kinase (61.9%) and STE (59.5%), while tyrosine kinase-like (54.8%), AGC (51.8%), calcium/calmodulin-dependent protein kinase (51.2%), and atypical kinases (44.0%) had significantly lower percentages. Since our toolkit harmonizes sequences across the human kinome, it provides a multiple sequence alignment to evaluate species-level protein family conservation. We identified highly conserved, frequently mutated residues in the glycine residues of the glycine-rich loop, the arginine of the HRD motif, and the aspartic acid of the xDFG motif. Our analysis provides a unique pan-cancer assessment of missense mutations across the human kinome, suggesting shared functional mechanisms of pathogenicity for further characterization. Our tools can be used to interrogate missense kinase mutations in any cBioPortal cohort in a similar manner.

#0320 Targeting overexpressed TTK and NEK2 decreases early metastatic potential of triple-negative breast cancer cell lines.

Alexandra N. Aquino-Acevedo[1], Angel D. Colon-Burgos[1], Esther M. Irizarry-Quintana[2], Elliott Rodriguez-Lopez[1], Joel A. Orengo-Orengo[1], Marileana Rodriguez-Ruiz[3], Gretchen M. Albarran-Acosta[1], Melanie E. Cruz-Robles[1], Harold I. Saavedra[1]

[1]Basic Sciences, Ponce Health Sciences University, Ponce, PR,[2]U54 REC InterAmerican Undergraduate Program, Ponce Health Sciences University, Ponce, PR,[3]Moffitt U54 Summer Research Program, Ponce Health Sciences University, Ponce, PR

Triple-negative breast cancer (TNBC) is an aggressive form of breast cancer lacking estrogen, progesterone, and HER2 receptors, making it unresponsive to hormonal or anti-HER2 therapies. Non-Hispanic Black (NHB) and Hispanic/Latino (H/L) women have lower survival rates, partly due to later-stage tumor detection and higher TNBC prevalence. Higher African ancestry has been associated with increased expression of mitotic kinases, such as TTK and NEK2, which regulate cell division and tumor progression. Our research confirms that TTK overexpression is associated with TNBC growth and epithelial-to-mesenchymal transition (EMT). Preliminary analyses indicate that molecular functions and processes, such as β-catenin binding, are associated with TTK and NEK2 expression.Therefore, this study aims to investigate, via in vitro assays, the expression levels of EMT markers and transcription factors, as well as changes in the invasive capacity and motility of metastatic TNBC upon downregulation of TTK, NEK2, and β-catenin. To assess this, TNBC cell lines, MDA-MB-231 (NHW) or MDA-MB-157 (NHB), were cultured, followed by TTK/NEK2 or β-catenin siRNA-mediated knockdown. Western blotting was used to measure EMT-related proteins and transcription factors. Immunocytochemistry evaluated β-catenin co-localization. Invasion and migration assays used Matrigel-coated chambers and wound-healing models, respectively. In vitro assays showed a significant decrease in Vimentin protein levels in all TTK-, NEK2-, and double-knockdown treatment groups of the MDA-MB-231 cell line. TTK/NEK2 double knockdown, specifically, reduced N-cadherin, β-Catenin, and SNAIL transcription factor. In contrast, results from MDA-MB-157 cell lines showed a significant reduction in β-catenin protein levels upon NEK2 knockdown. Immunocytochemistry results also showed a decrease in cytoplasmic, nuclear, and membrane levels of β-catenin in the MDA-MB-157 cell line. Furthermore, downregulation of TTK, NEK2, and β-catenin reduces the invasive capacity and motility of both TNBC cell lines.These findings support a pivotal role for TTK and NEK2 in β-Catenin regulation, EMT, and the invasive behavior of TNBC cells. Dual targeting of these mitotic kinases may be a promising strategy to reduce the expression of key proteins involved in TNBC progression and metastasis.

#0321 PTPN1 activates neuroendocrine of treatment emergent prostate cancer by targeting the AR and REST complex.

Yu-An Chen, Mickey Glover, Rey-Chen Pong, Payal Kapur, Jer-Tsong Hsieh

UTSW, Dallas, TX

Treatment emergent neuroendocrine prostate cancer (t-NEPC) is a highly aggressive subtype of castration resistant prostate cancer (CRPC) with rapid progression and a very limited therapeutic arsenal. Clinical outcomes remain poor, and new treatment strategies with clear translational potential are urgently needed. Analyses of publicly available prostate cancer datasets showed that high PTPN1 expression is strongly associated with poor recurrence free survival in metastatic disease, suggesting that PTPN1 may serve as a clinically relevant molecular determinant of aggressive prostate cancer. We found that PTPN1 promotes t-NEPC progression and discovered a reciprocal interaction between PTPN1 and the androgen receptor and the RE1 silencing transcription factor (REST) repressor complex. This interaction represents a key regulatory mechanism driving the trans differentiation of androgen receptor positive CRPC into t-NEPC. Through CRISPR mediated PTPN1 knockout, PTPN1 cDNA overexpression, and pharmacologic inhibition in prostate cancer cells, we demonstrated that PTPN1 modulates neuroendocrine lineage plasticity. PTPN1 inhibition reduced neuroendocrine features and restored responses to anti androgen therapy in both in vitro and in vivo models. The therapeutic efficacy observed with PTPN1 inhibition highlights its translational potential as a druggable target for patients with t-NEPC, a population with urgent unmet clinical needs. These findings support further development of PTPN1 directed therapies and provide a strong rationale for future clinical investigation.

#0322 Differential effects of SRPK1 inhibition on HPV$^+$ and HPV$^-$ in cervical cancer: Transcriptome and splicing rewiring.

Afra Tsitsi Basera[1], Mohammed Alaouna[2], Janie Duvanhage[3], David Bates[4], **Zodwa Dlamini**[5], Rahaba Marima[5]

[1]Medical Oncology, University of Pretoria, Pretoria, South Africa,[2]SAMRC Precision Oncology Research Unit (PORU), DSI/NRF SARChI Chair in Precision Oncology and Cancer Prevention, Pan African Cancer Research Institute (PACRI), University of Pretoria, Pretoria, South Africa,[3]Nuclear Medicine Research Infrastructure NPC, Pretoria, South Africa,[4]Center for Cancer Sciences, BioDiscovery Institute, University Park, Nottingham, United Kingdom,[5]SAMRC Precision Oncology Research Unit (PORU), DSI/NRF SARChI Chair in Precision Oncology and Cancer Prevention, Pan African Cancer Research Institute (PACRI), University of Pretoria, Hatfield, Pretoria, South Africa

Background: Cervical cancer (CCa) remains a major cause of cancer-related mortality worldwide, largely driven by persistent infection with high-risk human papillomavirus (hrHPV) types such as HPV16 and HPV18. The viral E6 and E7 oncoproteins disrupt the p53 and Rb tumour suppressor pathways and reprogram host RNA processing, resulting in the production of tumour-promoting splice isoforms. Serine/arginine protein kinase 1 (SRPK1), a key regulator of splicing factor phosphorylation, has emerged as a potential therapeutic target. This study aimed to identify and evaluate splicing patterns in cervical cancer in response to SRPK1 inhibition.
Materials and Methods: HeLa (HPV18$^+$), SiHa (HPV16$^+$), and C33A (HPV$^-$) cervical cancer cell lines were treated with the SRPK1 inhibitor SPHINX31 (0.3-10 µM). Cell viability was assessed using the Alamar Blue assay, while cell cycle progression and apoptosis were evaluated by flow cytometry using fluorescence-activated cell sorting (FACS) and Annexin V/propidium iodide staining. Transcriptomic profiling was performed by RNA sequencing to identify differentially expressed genes and alternative splicing (AS) events, followed by pathway enrichment and protein-protein interaction (PPI)/MCODE network analyses. Molecular docking was used to assess the binding of SPHINX31 within the SRPK1 ATP pocket.
Results and Discussion: Treatment of cervical cancer cells with SPHINX31 resulted in a non-significant cellular response, with no effect on cell viability, cell cycle progression, or induction of apoptosis. In HPV-negative C33A cells, SRPK1 inhibition upregulated genes involved in translation, RNA processing, and glycosylation, which revealed ribosomal network hubs suggesting possible translational and metabolic adaptation. C33A also displayed skipped exon (SE) and retained intron (RI) events along with alternative 5' splice site (A5SS) alterations. In contrast, HPV16$^+$ SiHa cells exhibited downregulation of oncogenic signalling pathways, including Hippo, Wnt, PI3K-AKT, and ERK1/2. SiHa exhibited fewer overall AS events but with greater effect sizes. Molecular docking analyses supported a computationally predicted binding.
Conclusion: This study provides insight into the effects of SRPK1 inhibition on cellular response, splicing patterns, and the transcriptomic landscape. Overall, SRPK1 inhibition in CCa may induce changes that differ according to HPV status, with HPV$^+$ cells exhibiting vulnerability, while HPV$^-$ cells may display a possible metabolic adaptation.

#0323 Dual inhibition of SIK2/3 induces ER Stress and ER-phagy, enhancing the cytotoxicity of autophagy blockade in ovarian cancer.

Rumeysa Ozyurt, Gamze Bildik Elcik, Weiqun Mao, Robert C. Bast, Zhen Lu

Department of Experimental Therapeutics, UT MD Anderson Cancer Center, Houston, TX

Cancer cells rely heavily on protein quality control mechanisms to survive intrinsic stress from rapid proliferation and extrinsic stress from the tumor microenvironment. Among these mechanisms, endoplasmic reticulum (ER)-selective autophagy (ER-phagy) has emerged as a critical process that maintains ER homeostasis by removing damaged ER components and misfolded protein aggregates. When the protein-folding capacity of the ER is exceeded, misfolded proteins accumulate and trigger ER stress, activating the unfolded protein response (UPR) through three major branches: PERK-eIF2α-ATF4, IRE1-XBP1s, and ATF6. ER stress, in turn, can induce ER-phagy as an adaptive mechanism to alleviate proteotoxic stress. Salt-inducible kinases SIK2 and SIK3 (SIK2/3) are serine/threonine kinases that regulate cellular metabolism and stress responses. While SIK2 has been implicated in ER-associated degradation (ERAD) and in promoting ovarian cancer progression and survival, the roles of SIK2/3 in regulating ER stress and ER stress-mediated autophagy remain poorly understood in cancer. We hypothesized that inhibition of SIK2/3 induces ER stress, which subsequently activates ER-phagy to maintain proteostasis. Further, combining dual SIK2/3 inhibition with GRN-300 (a selective SIK2/3 inhibitor) and autophagy blockade using chloroquine (CQ, an autophagy inhibitor) should enhance proteotoxic stress and exert potent anti-tumor activity in ovarian cancer. Here we report that inhibition of SIK2/3 triggers ER stress and activates ER-phagy as an adaptive survival mechanism in ovarian cancer cells. Genetic or pharmacological inhibition of SIK2/3 activated all three UPR pathways (PERK-eIF2α-ATF4, IRE1-XBP1s, and ATF6), leading to accumulation of polyubiquitinated proteins and aggregates, as well as the induction of CHOP and apoptotic cell death. SIK2/3 inhibition also upregulated the ER-phagy receptor CCPG1 in an ATF4-dependent manner, enhancing autophagic flux. Notably, combination treatment with GRN-300 and CQ synergistically reduced cell viability (combination index, CI < 0.9), exacerbated proteotoxic stress, and triggered CHOP-dependent apoptosis in multiple ovarian cancer cell lines. In three ovarian cancer xenograft models (OVCAR8, OC316, and SKOv3), GRN-300 plus CQ markedly suppressed tumor growth, increased apoptotic markers, and significantly prolonged survival compared to either monotherapy. These findings reveal a previously unrecognized role of SIK2/3 inhibition in driving ER stress and CCPG1-mediated ER-phagy and provide strong rationale for combining GRN-300 with autophagy inhibition as a promising therapeutic strategy for ovarian cancer.

#0324 ASCL1-mediated transcriptional regulation of RET in neuroendocrine prostate cancer.

Sachi B. Tengse[1], Song Yi Bae[1], Hannah E. Bergom[1], Ella Boytim[1], Halena R. VanDeusen[1], Quynh Chau Dinh[1], Abderrahman Day[1], Rayhan Biswas[1], Farzana Kabir[1], Laura E. Hirsch[1], Yingtian Xie[2], Daniel A. Harki[1], Sylvan C. Baca[2], Henry Long[2], John K. Lee[3], Leigh Ellis[4], Justin Hwang[1], Justin M. Drake[1]

[1]University of Minnesota, Minneapolis, MN,[2]Dana-Farber Cancer Institute, Boston, MA,[3]University of California, Los Angeles, Los Angeles, CA,[4]Center for Prostate Disease Research, Bethesda, MD

Resistance to second-generation anti-androgen therapies can cause neuroendocrine prostate cancer (NEPC), an aggressive disease variant, in castration-resistant prostate cancer (CRPC) patients. With low survival outcomes and limited therapies, it is imperative to study the molecular basis of NEPC. We show that the receptor tyrosine kinase RET has elevated activity in aggressive variant prostate cancer cell lines. We also show that RET kinase is crucial for the growth and survival of NEPC cells. We aim to unravel the mechanism of RET activation in NEPC to develop novel approaches to target RET and identify additional drug targets. NEPC can be categorized into two subtypes based on the expression of ASCL1 or NEUROD1, two pro-neuronal transcription factors. We show that RET gene expression strongly correlates to ASCL1 gene expression, but not NEUROD1 gene expression in NEPC patient samples. This data is corroborated by single cell-RNA-sequencing data in NEPC patient samples. Informatics modeling of whole transcriptome sequencing data from patient samples shows that RET and ASCL1 have substantially similar gene network signatures in NEPC, implying that these genes share a gene ecosystem in NEPC. To investigate the relationship between RET and ASCL1, we analyzed publicly available ChIP-sequencing data from LuCaP NEPC PDX models and small cell lung cancer (SCLC) cell lines. NEPC and SCLC are known to have similarities, including disease aggressiveness, expression of neuroendocrine markers, and the presence of ASCL1-positive and NEUROD1-positive subtypes. Our analysis showed that ASCL1 directly regulates RET by binding to RET promoter regions. Hence, we note a similar relationship between RET and ASCL1 in SCLC where ASCL1 regulates RET expression. Using knockdown models, we show that the RET-ASCL1 axis is unidirectional with RET having no impact on ASCL1 expression. To drug this pathway, we aim to focus on cell surface targets such as RET. RET inhibitors are approved for non-small cell lung cancers or thyroid cancers with RET fusions, however, they may induce resistance via mutations. Additionally, they may be less effective in tumors with wild-type RET expression, which is typically seen in NEPC. PROTACs can bypass these drawbacks by degrading the entire protein instead of enzymatically inhibiting it, thus overcoming drug resistance. Additionally, PROTACs have a catalytic mechanism that can cause degradation of several target molecules with one PROTAC molecule, leading to longer elimination of target protein with lower doses. We are using RD-23, a published RET PROTAC based on the RET inhibitor selpercatinib, to investigate its effects on NEPC and SCLC cells. While further studies are needed to stratify patients and develop novel pharmacological interventions, these results highlight the crucial role of ASCL1 in mediating RET signaling in NEPC and SCLC.

#0325 Development of the pyridopyrimidine derivative KC12 as a selective dual Pim/Mnk inhibitor to inhibit leukemia cell growth.

Linxiang Zhao[1], Kun Xing[1], Jingyi Zhang[1], Shuwei Zuo[1], Fuyao Zhang[1], Samuel Waxman[2], Yongkui Jing[1]

[1]Shenyang Pharmaceutical University, Shenyang, China,[2]Samuel Waxman Institute for Aging and Cancer, New York, NY

Myeloid leukemia is an abnormal proliferative disease relying on fast cap-dependent protein translation. Both provirus integration in Maloney murine leukemia virus (Pim) kinases and mitogen-activated protein kinase-interacting kinases (Mnk) play key roles in activating cap-dependent translation, making them attractive targets for anticancer drug development. Although several selective Pim or Mnk inhibitors entered clinical trials, their efficacy was limited. We propose that concurrent inhibition of both Pim/Mnk kinases is necessary for effective treatment. Previously, we reported the first dual Pim and Mnk inhibitor 21o with a pyrido[3,2-*d*]pyrimidine core (IC_{50} Mnk1: 9 nM, Mnk2: 5 nM, Pim1: 120 nM), but suffered from poor solubility. We optimized 21o based on molecular docking and obtained a compound KC12 with enhanced kinase inhibitory activity (IC_{50} Mnk1:32 nM, Mnk2 3 nM; Pim 1 32 nM) and improved selectivity (only 4 out of 42 tested kinases showed >40% inhibition at 100 nM). KC12 exhibits increased aqueous solubility and superior anti-proliferative activity compared to 21o, as well as to the Pim inhibitor TP-3654 and the Mnk inhibitor eFT508. KC12 induced G0/G1 phase cell cycle arrest in K562 cells and apoptosis in MOLM-13 cells, correlated to the suppression of both eIF4E and 4EBP1 phosphorylation, and the cap-dependent translation products c-Myc and Mcl-1. Moreover, KC12 demonstrated a more favorable pharmacokinetic profile than 21o and exhibited enhanced antitumor efficacy in MOLM-13 xenograft models. These findings suggest that KC12 acts as a novel, potent, and selective dual Pim/Mnk inhibitor and is worthy of further development as a therapeutic agent.

#0326 Association of off targets of ALK inhibitors with their adverse reactions revealed by a novel comprehensive phosphorylation profiling platform.

Katsuhisa Horimoto[1], Satoshi Mikami[2], Lili Feng[3], Yu Zhang[3], Dongyin Chen[3], Feng Han[3], Satoshi Yamasaki[1], Shota Takei[1], Hiroshi Kagamu[1]

[1]Saitama Medical University International Medical Center, Hidaka, Japan,[2]SOCIUM Inc., Fujisawa, Japan,[3]Nanjing Medical University, Nanjing, China

Introduction: Five ALK inhibitors are currently approved for clinical use. Although all target ALK fusion proteins, their side-effect profiles differ markedly. These variations are suspected to result from off-target kinase interactions, but the molecular links remain unclear. We aimed to reveal this connection using a novel phosphorylation-based profiling system that comprehensively maps kinase-substrate relationships and pathway activations.

Materials and Methods: Using a recently developed cell-free phosphorylation array, we measured the overall phosphorylation activity within cells. This system does not focus on specific phosphorylation sites; instead, it identifies substrates that become phosphorylated under each experimental condition from a pool of 1,492 proteins (816 substrates for 190 kinases and 845 proteins constituting 273 pathways).Cell lysates treated with ALK inhibitors were applied to the array, enabling phosphorylation reactions that mimic intracellular kinase activity. Computational analyses extracted three layers of information, condition-specifically phosphorylated substrates, activated pathways and kinases, allowing simultaneous assessment of both on-target and off-target effects.

Results: Phosphorylation profiles induced by five ALK inhibitors were measured in EML4-ALK mutant cell line (NCI-H2228 [H2228]), and analyzed across substrates, kinases, and pathways. Each drug exhibited a distinct inhibition signature, indicating specific kinases and pathways selectively affected beyond ALK. Several off-target kinases and pathways associated with known clinical adverse reactions, providing mechanistic insight into drug-specific toxicities.

Conclusion: This comprehensive phosphorylation profiling platform enabled simultaneous evaluation of on-target and off-target effects of kinase inhibitors. By linking molecular signaling changes to clinical side effects, the system provides a powerful approach for understanding complex kinase networks and guiding the development of safer next-generation inhibitors.

#0327 MARK2/MARK3/MARK4 kinases are therapeutic targets for human head and neck squamous cell carcinoma with co-dependencies of YAP-TEAD pathway.

Se Eung Oh[1], Hwan Jung Lim[2], Seong Jun Park[2], Sang Uk Han[1], Jee Hung Kim[3], Seo Young Lee[3], Hei-Cheul Jeung[3]

[1]Medical Oncology, Yonsei University College of Medicine, Seoul, Korea, Republic of,[2]Drug Discovery, Korea Research Institute of Chemical Technology (KRICT), Daejeon, Korea, Republic of,[3]Medical Oncology, Gangnam Severance Hospital, Yonsei University College of Medicine, Seoul, Korea, Republic of

Background: Head and neck squamous cell carcinoma (HNSCC) requires the identification of new therapeutic targets to improve treatment outcomes. This study investigated the biological significance of Microtubule Affinity-Regulating Kinases (MARKs), a family of serine-threonine kinases that regulate microtubule-associated proteins (MAPs). Because MARK activity influences cell structure, intracellular transport, and proliferation, these kinases may represent promising therapeutic targets.
Materials and Methods: Protein expression levels of MARK family genes were evaluated in 20 human HNSCC cell lines. Cisplatin and docetaxel-resistant models were established by gradually escalating cisplatin and docetaxel concentrations up to 4 μM and 15 nM, respectively in CA9-22 and YD-8 cells. Cell viability was determined using WST assays. CRISPR/Cas9 genome editing was employed to generate MARK2/3/4 knockout cell lines. In addition, the anticancer efficacy of several newly developed MARK2/3/4 hits was assessed.
Results: MARK2/3/4-knock-out cells demonstrated significantly reduced proliferation and impaired matrigel invasion compared with wild-type controls. MARK kinase loss was associated with suppression of the MAPK- and PI3K-AKT signaling pathways. Because MARK proteins are known to interfere with MST/SAV and LATS complex formation through phosphorylation-dependent mechanisms, we further showed that MARK4 depletion reduced nuclear YAP/TAZ localization and decreased expression of YAP/TEAD transcriptional targets. Collaborative screening identified multiple candidate molecules for MARK-specific inhibition at the hit-compound stage; notably, one lead compound exhibited strong antiproliferative activity in HNSCC cells, including cisplatin-resistant models.
Conclusions: MARK proteins function as negative regulators of the HIPPO kinase cascade, thereby enhancing YAP/TAZ oncogenic activity in HNSCC. Loss of MARK function reduces tumorigenic phenotypes, supporting MARKs as promising therapeutic targets for future drug development.

#0328 Establishment of assay systems for drug development against the oncogenic phosphatase WIP1.

Daniel Feger[1], Daniel Muller[1], Lena Pilgermayer[1], Carolin Heidemann-Dinger[1], Sarah Ulrich[1], Michael Kubbutat[1], Holger Weber[1], Joe Lewis[2], Birgit Zech[2], **Jan E. Ehlert**[1]

[1]Reaction Biology Europe GmbH, Freiburg im Breisgau, Germany,[2]Anavo Therapeutics GmbH, Heidelberg, Germany

The serine/threonine phosphatase WIP1 (PPM1D) is a key negative regulator of the DNA damage response (DDR) and a recognized oncogene, frequently amplified or truncated in various cancers including breast, ovarian, neuroblastoma, and glioblastoma. Its inhibition restores DDR signaling, offering a promising therapeutic strategy. Despite initial efforts, including the development of the allosteric inhibitor GSK2830371, clinical translation has been limited. We report the establishment of a comprehensive assay platform to support drug development targeting WIP1. Biochemical assays were optimized using fluorescein diphosphate (FDP), malachite green with phosphopeptides (p53, H2AX, p38 MAPK), and TR-FRET formats, enabling robust activity profiling. Cellular mechanism-of-action assays were developed to monitor phosphorylation changes in WIP1 substrates, with pS15-p53 ELISA in U2OS cells selected for medium-throughput iterative compound profiling. Phenotypic assays demonstrated compound efficacy in 2D and 3D proliferation models, with leukemic cell lines showing pronounced sensitivity. Combination studies revealed strong synergy between WIP1 inhibitors and MDM2 antagonists (e.g., Nutlin3a), supporting a dual-targeting approach for p53 pathway reactivation. In vivo efficacy was confirmed in MV4-11 xenograft models, with dose-dependent tumor growth inhibition and favorable tolerability profiles. Our integrated assay suite enables iterative screening and lead optimization, culminating in the identification of a potent allosteric WIP1 inhibitor with nanomolar activity and promising preclinical efficacy. These findings support WIP1 as a viable target in oncology and provide a foundation for future clinical development.

#0329 PLK1 inhibitor onvansertib potentiates the antitumor efficacy of trastuzumab deruxtecan (T-DXd) and reverses its resistance in therapy-resistant HER2-low breast cancer models.

Sreeja Sreekumar[1], Elodie Montaudon[2], Zeena Eblimit[1], Migdalia Gonzalez[1], Davis Klein[1], Heloise Derrien[2], Ahmed Dahmani[2], Tod Smeal[1], Elisabetta Marangoni[2], Maya Ridinger[1]

[1]Cardiff Oncology, Inc., San Diego, CA,[2]Preclinical Investigation Laboratory, Translational Research Department, Institut Curie, Paris, France

HER2-low tumors represent 55-60% of all breast cancers, of which about 60-70% are hormone receptor-positive (HR+) and the rest triple-negative (TNBC). Most metastatic HER2-low breast cancers become resistant to standard therapies, underscoring the need for improved treatments. Trastuzumab deruxtecan (T-DXd) is a HER2-directed antibody-drug conjugate with a topoisomerase I inhibitor (TOP1i) payload approved for therapy-resistant metastatic HER2-low breast cancer. Combining T-DXd with agents that potentiate TOP1i activity may enhance its efficacy. Onvansertib, a selective polo-like kinase 1 inhibitor, has shown clinical benefit in combination with the TOP1i irinotecan in metastatic colorectal cancer. Here, we investigated the combination of onvansertib and T-DXd in HER2-low breast cancer models resistant to first-line therapies. The combination was evaluated in eight HER2-low breast cancer cell lines and six patient-derived xenograft (PDX) models, including one TNBC and five HR+ breast cancer models. The TNBC model was derived from a patient who had progressed on chemotherapy and immunotherapy. The HR+ PDXs originated from primary or metastatic tumors and were resistant to fulvestrant and/or CDK4/6 inhibitors. Tumor-bearing nude mice were treated with vehicle, onvansertib (45 mg/kg, orally, five times weekly), T-DXd (4 or 10 mg/kg, intravenously, every three weeks), or the combination and monitored for body-weight changes and tumor growth. The effects of the combination on cell viability, DNA damage and apoptosis were examined *in vitro*. The combination of onvansertib and T-DXd synergistically inhibited the viability of HER2-low breast cancer cell lines, including fulvestrant and CDK4/6i-resistant cells. *In vivo*, the combination was well tolerated and showed robust antitumor activity across all PDX models including five models resistant to T-DXd. In the resistant TNBC model and two HR+ models, the combination treatment induced tumor regression in nearly all mice, achieving complete response rates up to 62%. In the one T-DXd-sensitive model, the combination further increased tumor regression and complete responses compared with monotherapies. In the remaining resistant models, the combination enhanced tumor growth inhibition and extended event-free survival relative to single agents. Mechanistically, the combination induced increased and prolonged DNA damage, resulting in higher levels of apoptosis than either single agent alone in HER2-low breast cancer cell lines. Taken together, our data indicate that onvansertib enhances T-DXd's antitumor activity and overcomes resistance through synergistic induction of DNA damage and apoptosis. The findings support the clinical potential of this combination for advanced HER2-low breast cancer resistant to standard-of-care therapies.

#0330 EGFR suppression and drug-induced potentiation are widespread features of oncogenic RTK fusions.

Carol Gao[1], David Gonzalez Martinez[1], Sofia Wissert[1], Hana Bader[1], Nidhi Sahni[2], Anh T. Le[3], Robert C. Doebele[4], Lukasz Bugaj[1]

[1]University of Pennsylvania, Philadelphia, PA,[2]UT MD Anderson Cancer Center, Houston, TX,[3]University of Colorado, Denver, CO,[4]Rain Therapeutics, Aurora, CO

Regulation of cancer cells by their environment contributes to tumorigenesis and drug response, though the extent to which the oncogenic state can alter a cell's perception of its environment is not clear. Prior studies found that EML4-ALK, a receptor tyrosine kinase (RTK) fusion oncoprotein, suppresses transmembrane receptor signaling through EGFR. Moreover, suppression was reversed with targeted ALK inhibition, thereby promoting survival and drug tolerance. Here we tested whether such modulation of EGFR was common among other RTK fusions, which collectively are found in ~5% of all cancers. Using live- and fixed-cell microscopy in isogenic and patient-derived cell lines, we found that a wide variety of RTK fusions suppress transmembrane EGFR and sequester essential adaptor proteins in the cytoplasm, as evidenced by the localization of endogenous Grb2. Targeted therapies rapidly released Grb2 from sequestration and potentiated EGFR. Synthetic optogenetic analogs of RTK fusions confirmed that cytoplasmic sequestration of Grb2 was sufficient to suppress perception of extracellular EGF and could do so without driving signaling from the synthetic fusion itself, demonstrating that fusion signaling and suppression of EGFR could be functionally decoupled. Our study uncovers that a large number of RTK fusions simultaneously act as both activators and suppressors of signaling, the mechanisms of which could be exploited for new biomimetic therapies that enhance cell killing and suppress drug tolerance.

#0332 AKT1 mediated post translational modification of the glucocorticoid receptor drives resistance to prostate cancer therapy.

Surendra Gulla[1], Tej Sharma[1], Ephraim Gardner[1], Abbas Jawadala[1], Sasikumar Ponnusamy[1], Tobi Ogunbowale[1], Maddie Aust[1], Jonathan E. Bard[2], Remi Adelaiye-Ogala[1]

[1]Medicine, University at Buffalo, State University of New York, Buffalo, NY,[2]Genetics, Genomics and Bioinformatics Program, University at Buffalo, State University of New York, Buffalo, NY

Increasing evidence shows that resistance to androgen-deprivation therapy (ADT) and next-generation androgen receptor (AR) antagonists in advanced prostate cancers develops partly through compensatory activation of alternative nuclear hormone receptors. Notably, induction of the glucocorticoid receptor (GR) has been demonstrated in both preclinical and clinical studies to confer resistance to AR-targeted therapies. Although total GR is crucial for tissue homeostasis and normal inflammatory responses, our preliminary GR-phospho proteomics data reveal that, under enzalutamide resistance, GR undergoes increased phosphorylation, especially at serine-134 (p-GR(s134)), suggesting a post-translational mechanism driving a pro-oncogenic GR activation in therapy-resistant tumors. We have previously shown that inhibiting AKT signaling, GR expression, and its pro-oncogenic activity restores sensitivity to AR-directed therapy. Predictions from PhosphoNET.ca and functional studies identify AKT1 as the AKT isoform responsible for phosphorylating GR at S134. Importantly, both functional and pharmacologic inhibition of AKT1 reduced GR phosphorylation at s134 without affecting total GR protein levels. While GR can be activated by ligands such as dexamethasone, our data suggest that, in PCa cells that adopt GR compensatory signaling for survival, GR activation is mediated by AKT1 phosphorylation. Overall, our data show that suppression of pGR-s134 activity renders these cancer cells re-vulnerable to AR-targeted drugs such as enzalutamide and enhances their response to GR modulators.

#0333 Downregulation of AURKA and AURKB promotes a decrease in cell invasion in TNBC by modulating the expression of SNAIL1.

Joel Alexis Orengo Orengo[1], Elliott Rodriguez-Lopez[2], Selimar Alvarez Velazquez[3], William Frank Rodriguez[3], Alexandra N. Aquino-Acevedo[3], Melanie E. Cruz Robles[3], Harold Ivan Saavedra[4]

[1]Basic Sciences, Ponce Health Sciences University, Ponce, PR,[2]Ponce Health Sciences University, Ponce, PR,[3]Ponce Health Sciences University, Ponce, Puerto Rico,[4]Assistant Professor, Dept. of Rad. Oncology, Ponce Health Sciences University, Ponce, PR

Although chemotherapy is still the gold standard treatment in TNBC, patients often experience high levels of recurrence. Additionally, several studies have demonstrated that non-Hispanic Black (NHB) and Hispanic/Latino (H/L) women are more likely to be diagnosed and die from TNBC compared to non-Hispanic White women (NHW), indicating a significant health disparity in TNBC. While different molecular players can drive this aggressiveness and resistance in TNBC, mitotic kinases such as AURKA and AURKB are overexpressed in NHB diagnosed with TNBC. AURKA and AURKB play a pivotal role in regulating the cell cycle by promoting centrosome maturation, mitotic spindle formation, and proper chromosome alignment and segregation. However, when dysregulated, they can contribute to the epithelial-to-mesenchymal transition (EMT) by promoting the expression of EMT drivers. We hypothesize that the combined knockdown of AURKA and AURKB will significantly decrease the expression of EMT drivers and reduce the cells' ability to invade. TCGA data suggests a significant overexpression of AURKA and AURKB in breast cancer. Kaplan-Meier analysis indicates that overexpression of AURKA and AURKB is associated with a worse relapse-free survival rate compared to women who have normal expression. After performing the siRNA-mediated knockdown, MTT assay, immunoblotting, immunofluorescence, and invasion assays were performed. MTT data demonstrate that co-targeting AURKA and AURKB decrease cell viability; but most cells still proliferate. Immunoblotting data suggests that co-targeting AURKA and AURKB significantly decreases SNAIL expression in MDA-MB-157 (NHB), while immunofluorescence data indicate a decrease in Beta-catenin expression in both cell lines. Moreover, co-targeting AURKA and AURKB in both cell lines results in a significant reduction in the cells' ability to invade. Preliminary results in MDA-MB-231 (NHW) also suggest a decrease in the invasion capacity after a single knockdown of SNAIL1. Thus, this indicates that AURKA and AURKB can form a specific axis between beta-catenin and SNAIL1 in TNBC. As a future direction, we will use chemical inhibitors in combination to evaluate the expression of these EMT biomarkers. In addition, we will study tumour growth and metastasis rates in vivo models. In conclusion, since treatment options are limited in TNBC, our results suggest that combined targeting of AURKA and AURKB may be a potential approach to decrease the metastatic phenotype of TNBC while lowering the dose of each drug and thus the toxicity in patients.

#0334 A novel inhibitor of the atypical protein kinase C-ι decreases the proliferation of malignant gastric cancer cells and disrupts the Skp-2 pathway.

Abiral Hasib Shourav, Nuzhat Nowshin Oishee, Abigail Oluwafisayo Olatunji, Mahfuza Marzan, Khandker M. Khalid, Radwan Ebna Noor, Shreejana Rimal, Mildred Acevedo-Duncan

Chemistry, University of South Florida, Tampa, FL

Global data on Gastric Cancer (GC) exhibit that it is the fifth most common type of cancer and as far as mortality is concerned, it is the third most common type. Late-stage diagnosis of GC is an important cause for high mortality. Even though *Helicobacter pylori* are known to be the most common cause of gastric cancer, other notable risk factors also include high salt intake, age and diets lacking in fruits and vegetables. Endoscopic resection is considered as the major treatment procedure for early detected gastric cancer while those diagnosed in later stages are treated with surgeries such as D2 lymphadenectomy. Previously, the Atypical Protein Kinase C Iota (PKC-ι) has been documented to play significant roles in elevated cell proliferation in various cancer types. Here, we employed a novel inhibitor, ICA-1S (5-amino-1-((1R,2S,3S,4R)-2,3-dihydroxy-4-methylcyclopentyl)-1H-imidazole-4-carboxamide that specifically inhibits PKC-ι on a gastric cancer cell line (i.e., AGS) to observe its effects on cell proliferation. In separate trials, AGS cells were treated with ICA-1S for 96 hours (about 4 days). An assortment of drug concentrations for the inhibitor was tried and the analysis of the cell count demonstrated that the cell proliferation decreases were statistically significant. The highest decrease in cell proliferation was observed at 20 μM ($p < 0.0001$). Our previous research have revealed that this PKC inhibitor blocks PKC-ι and interferes with established cancer pathways to cause cell deaths. Based on that and the results from the preliminary data on this project, it can be hypothesized that this PKC inhibitor has the potential to lead to Gastric Cancer cell deaths by inducing apoptosis, which could potentially open a new door for Gastric Cancer therapeutics. Henceforth, the Western Blot analysis of AGS cells treated with ICA-1S has shown enhanced inhibition of PKC-ι, and increased apoptosis by the elevated cleavage of Caspase 3 and poly(ADP-ribose) polymerase (PARP). Moreover, we have seen an increased degradation in the S-phase kinase-associated protein 2 (Skp-2), an oncoprotein, suggesting that ICA-1S has the potential to be a drug candidate for the treatment of GC. Current investigations include examining how ICA-1S affects other proteins in the Skp-2 pathway to support our hypothesis that blocking PKC-ι disrupts the Skp-2 pathway, thereby killing GC cells.

#0335 Inhibition study of protein kinase C-iota mediated signaling pathways in diffuse midline glioma by ICA-1S inhibitor and temozolomide.

Radwan Ebna Noor[1], Nuzhat Nowshin Oishee[1], Abir Hasib Shourav[1], Mahfuza Marzan[1], Javad Nazarian[2], Michelle Monje[3], Mildred Acevedo-Duncan[1]

[1]Chemistry, University of South Florida, Tampa, FL,[2]DMG Research, George Washington University, Washington, DC,[3]Stanford Hospital, Stanford, CA

The Diffuse Midline Glioma (DMG) is a subtype of glial carcinoma that develops in the brain, primarily affecting the pons, midbrain, and thalamus. This malignant and fast-growing cancer affects both children and young adults. At present, pediatric DMG is an incurable childhood brain cancer. Interpreting the regulation of cell signaling pathways in pediatric DMG is crucial for targeting tumor cell migration and metastasis. These pathways must be understood comprehensively for effective treatment of this incurable primary brain tumor. Our goal is to investigate the role of atypical Protein Kinase C-iota (PKC-ι) expression levels in DMG cells, given that the kinase is over-expressed in most cancer cells. We aim to understand the PKC-ι-mediated cellular pathways involved in migration, invasion, and apoptosis in DMG (D1008) cells. Moreover, our study focuses on the inhibition of PKC-ι by the inhibitor ICA-1S (5-Amino-1-[(1R,2S,3R,4R)-2,3-dihydroxy-4[(phosphonooxy)methyl]cyclopentyl]-1H-imidazole-4-carboxamide) in combination with the FDA-approved glioblastoma treatment drug named temozolomide (TMZ) in the DMG D1008 cells. In this study, the effect of in vitro combination treatment with ICA-1S and TMZ on D-1008 cells is being investigated using cell viability assays, western blot analysis, scratch and wound healing assays, immunoprecipitation, flow cytometry, immunofluorescence, and small interfering RNA (siRNA) technology. The dose-response curve suggests that the ICA-1S and TMZ combination treatment is viable, as indicated by the half-maximal inhibitory concentrations (IC50). The Western blot analysis suggests that, in ICA-1S-treated DMG D-1008 cells, the expression of phosphorylated PKC-ι and total PKC-ι is reduced compared to untreated control cells. Moreover, our findings indicate that the inhibition of PKC-ι in D-1008 cells with ICA-1S leads to a significant increase in apoptotic markers, such as cleaved PARP and P53, compared to dual inhibition. The immunoprecipitation experiments in a previous study demonstrated that dual inhibition with ICA-1S and TMZ decreased the invasion of glioma cell lines by lowering the phosphorylation of Focal Adhesion Kinase (FAK) and paxillin in the PKC-ι/FAK/Paxillin pathway. In D-1008 cells, the complex between PKC-ι and FAK was not observed in immunoprecipitation, indicating a distinction in the cellular invasion pathway. The results from scratch & wound healing assays, immunoprecipitation, flow cytometry, immunofluorescence, and siRNA techniques will also be reported in this study. The objective is to establish the correlation between PKC-ι expression levels in D-1008 cells and the effects on PKC-ι-related cell signaling pathways when inhibited by the PKC-ι inhibitor ICA-1S and the drug TMZ as part of a new personalized treatment approach for this pediatric glioma.

#0336 Modular control of Pancreatic ductal adenocarcinoma (PDAC) progression by the substrate interaction domains of ERK2.

Monika Verma[1], Billy Truong[1], Sven Miller[2], Rachael Price[1], Dietmar Kappes[1], Paul Shapiro[3], Igor Astsaturov[2], David L. Wiest[1]

[1]Nuclear Dynamics and Cancer Program, Fox Chase Cancer Center, Philadelphia, PA,[2]Cancer Signaling and Microenvironment Program, Fox Chase Cancer Center, Philadelphia, PA,[3]Department of Pharmaceutical Sciences, University of Maryland School of Pharmacy, Baltimore, MD

Background: PDAC is a lethal disease with 5-year survival rate of just 13%, in desperate need of new therapeutic interventions. The primary driver of PDAC pathogenesis is the KRAS; however, current therapeutics targeting the activities of components of the KRAS/MAPK pathway fail to provide lasting benefit. We hypothesize that this results from active-site directed drugs attenuating the function of both substrate binding domains of ERK, which perform opposing roles in cancer pathogenesis. In myeloproliferative neoplasms, the ERK2-D domain promotes, and the ERK2-DBP domain impedes progression. Consequently, attenuating RAS/MAPK activity is akin to pressing both the gas and brake pedals on an automobile. Here we investigated the possibility that ERK signaling may also have cancer promoting and opposing roles in PDAC.
Methods: Here, we seek to determine which ERK family member (ERK1 or ERK2) is the primary driver of PDAC pathogenesis and if the ERK D and DBP substrate domains play opposing roles. To do so, we utilize the KPC-PDAC mouse model and cross it to mice deficient in ERK1, ERK2, or an ERK2-DBP mutant to assess the impact on PDAC pathogenesis. We also utilized an ERK2 allelic series of isogenic KPC mouse cell lines (FC1245) to study the impact of ERK2-D and DBP mutants on pathogenesis in vitro and upon transplantation into mice.
Results: We found that while ERK1 loss had no impact on PDAC pathogenesis, ablation of ERK2 markedly attenuated PDAC progression in KPC mice, indicating that ERK2 is primarily responsible for progression. Moreover, we found that inactivation of the ERK2-DBP domain was sufficient to delay PDAC progression to the same degree as ablation of ERK2. Attenuation of PDAC progression by ERK2-DBP mutation was associated with reduced expression and nuclear localization of c-Myc, a critical driver of PDAC progression. In addition to the cell autonomous effects of the ERK2-DBP mutation on PDAC, we also found differences in tumor-infiltrating immune cells, including fewer phenotypic myeloid derived suppressor cells and reduced expression of Tim3 on infiltrating T cells. The DBP mutation also attenuated colony formation in vitro, however, this was not observed for the ERK2-D domain, suggesting distinct functions in pathogenesis by the two ERK2 substrate domains. To investigate the therapeutic implications, we tested the efficacy of ERK2-DBP domain inhibitors to attenuate PDAC growth in vitro and in initial studies, determined that PDAC growth was substantially inhibited by DBP domain selective inhibitors.
Conclusion: ERK2 DBP is the domain responsible for PDAC progression and its inactivation delays tumor development. We are now using generative modeling to identify DBP inhibitors that have superior efficacy and ability to co-modulate the cell-autonomous effects on PDAC growth and the cell extrinsic effects on the immune system, alone and in combination with immune interventions.

#0337 Off-target activation of GCN2 by BRAF^{V600}inhibitors attenuates melanoma outgrowth.

C. Ryland III[1], Nasreen C. Marikar[1], Vu T. Nguyen[2], Brianna Fernandez[1], Varuna Nangia[1], Alicia M. Darnell[3], Matthew G. Vander Heiden[4], Philip Reigan[2], Sabrina L. Spencer[1]

[1]Biochemistry, University of Colorado, Boulder, CO,[2]Pharmacology, University of Colorado, Anschutz, CO,[3]Pharmacology & Cancer Biology, Duke University, Durham, NC,[4]Koch Institute for Integrative Cancer Research at MIT, Cambridge, MA

Clinical efficacy of small-molecule inhibitors can sometimes be attributed to multiple drug effects acting in concert. Herein, we define an off-target effect in which several clinical BRAF^{V600} inhibitors, including the widely used dabrafenib and encorafenib, interact directly with GCN2 to activate the Integrated Stress Response and ATF4. Blocking this off-target effect by co-drugging with a GCN2 inhibitor in A375 melanoma cells causes enhancement rather than suppression of cancer cell outgrowth, suggesting that the off-target activation of GCN2 is detrimental to these cells. This result is mirrored in PC9 lung cancer cells treated with erlotinib, an EGFR inhibitor, that shares the same off-target activation of GCN2. Using an *in silico* kinase inhibitor screen, we identified dozens of FDA-approved drugs that appear to share this off-target activation of GCN2 and ATF4. We further describe the activation of GCN2 signaling in melanoma patient-derived xenograft models treated with dabrafenib and trametinib, and observe a significant decrease in disease-free survival in a cohort of human melanoma patients with altered GCN2 pathway components. Finally, we describe the benefits of combining the next-generation “paradox breaker” RAF inhibitor naporafenib with a GCN2 activator, HC-7366, in A375 melanoma cells. Thus, GCN2 is emerging as a promising cotreatment candidate in melanoma and potentially beyond.

#0338 Discovery of novel pan-PI3K and mTOR dual inhibitors as first-in-class antibody-drug conjugate payloads.

Qi Liu[1], Lan Pham[1], Chin Pan[1], Jin Wang[2], Kamaldeep S. Dhami[1], Yingchun Li[2], Jeffrey Serrill[1], Ravi Kasiappan[1], Felix DeAnda[1], Screenivas Punna[1], Karl Haelsig[1], Apeksha Villath[1], Ketaki Gadkari[1], Geunbae Rha[2], Deanna Haasch[2], Albert Lai[1], James W. Purcell[1], Xueqing Wang[1]

[1]AbbVie Bay Area, South San Francisco, CA,[2]AbbVie Inc., North Chicago, IL

Despite the clinical success of microtubule inhibitor- and topoisomerase inhibitor-based ADCs, new classes of payloads with alternative mechanisms of action are needed to address clinical resistance and increase tumor responses. Constructing next-generation ADC payloads that target cancer-dependent pathways with a strong biological rationale for combination with other targeted agents, provides an opportunity to develop better-tolerated and more differentiated ADCs. The PI3K/AKT/mTOR signaling pathway is one of the most dysregulated in human cancers. Numerous small molecule efforts have targeted PI3K and mTOR, but these have achieved limited success. These agents are often associated with frequent dose interruptions and discontinuations due to undesirable on-target toxicities, as well as the emergence of drug resistance resulting from AKT reactivation.

Here, we present novel pan-PI3K and mTOR dual inhibitors developed as first-in-class ADC payloads. We hypothesize that this novel payload strategy will achieve more robust and durable inhibition of the PI3K/AKT/mTOR pathway. Delivery via an ADC approach is expected to provide meaningful improvements in efficacy and tolerability compared to systemic small molecule treatments.

Existing pan-PI3K and mTOR dual inhibitors often lack sufficient potency and present challenges for linker installation to enable an ADC approach. Guided by structure-based design, we have identified novel cores that significantly boost potency against various class I PI3K isoforms and mTOR enzymes, while maintaining excellent selectivity across a broad kinase panel. Additionally, we have explored multiple exit vectors to facilitate ADC linker installation, which is a critical component of ADC development.

The resulting PI3Ki/mTORi ADCs exhibited favorable drug-like properties and picomolar potency in cell-killing assays across a range of *in vitro* tumor models. Importantly, these ADCs also demonstrated a strong bystander effect, attributable to the highly efficient release of the cleavable linker within lysosomes and the permeable nature of the payloads being developed. These ADCs demonstrated significant *in vivo* efficacy by inducing tumor regressions across a variety of hematological and solid tumor models harboring PI3K genetic alterations, following administration of a single dose ranging from 3 to 10 mg/kg. Moreover, owing to their dual inhibitory activity against both PI3K and mTOR, our ADCs exhibited robust antitumor effects even in models with wild-type PI3K backgrounds, highlighting their broad therapeutic potential.

Taken together, the PI3K/mTOR dual-inhibitor modality, combined with an ADC platform, offers an opportunity to target various cancer indications with dependencies on the PI3K/mTOR pathway, and provides opportunities for combination treatment regimens with other anticancer agents.

#0342 LYW-105: A novel bispecific antibody-drug conjugate with enhanced antitumor efficacy and broader therapeutic index.

Qianqian Zhao, Zhangsheng Lu, Xun Cao, Xiaobing Tang, Liguo Wang, Peixiang Liu, Lu Wang, Jiajie Feng, Cexiong (Winston) Fu

LyncBio Therapeutics Co., Ltd., Shanghai, China

Introduction: Antibody-drug conjugates (ADCs) have made remarkable progress in cancer therapy; however, the development of ADCs with a wide therapeutic window that can effectively combat drug resistance and tumor recurrence remains a significant challenge. The fourth-generation ADC developed by LyncBio features homogeneous conjugation, a target-fit linker-payload design, and superior drug-like properties, aiming to break through the limitations of existing ADC therapeutic indices. LYW-105 is an innovative bispecific ADC designed to achieve more extensive and profound tumor regression through a dual-target approach. Its bispecific antibody components utilize a 1+1 format, with each arm demonstrating high affinity and efficient internalization, thereby enhancing therapeutic efficacy by addressing tumor heterogeneity and minimizing resistance. The linker design of LYW-105 allows for rapid lysosomal release and excellent buffer stability, resulting in reduced systemic toxicity and favorable pharmacokinetics. The payload is a topoisomerase I inhibitor with optimal potency and membrane permeability, effectively balancing tumor cytotoxicity with bystander effects.
Methods: We assessed the binding affinity of the bispecific antibody to its targets using ELISA, FACS, and BLI techniques. Internalization activity was measured using the pHrodo method, while developability was evaluated through methods such as SEC and HIC. The efficacy of LYW-105 was tested both in vitro and in vivo using established solid tumor models.
Results: In vitro studies showed that LYW-105 exhibited strong binding affinity to its targets and demonstrated approximately 2- to 30-fold greater internalization activity in tumor cell lines compared to reference monoclonal antibodies. Additionally, LYW-105 displayed 2- to 25-fold enhanced inhibition of tumor cell proliferation compared to in-house benchmark ADCs. Biophysical properties and stability assessments at 40°C indicated good developability, comparable to that of monoclonal antibodies. In vivo, LYW-105 demonstrated robust antitumor activity in mouse models, showing superior efficacy and prolonged tumor suppression compared to benchmark ADCs. Body weight changes remained stable across treatment groups, indicating that LYW-105 is well-tolerated.
Conclusions: In summary, LYW-105 has been thoroughly compared to benchmark single-target ADCs in preclinical settings. It demonstrated potent cytotoxicity in vitro and significant antitumor activity in vivo across various tumor cell lines, showcasing a broader therapeutic index than benchmark ADCs.

#0343 Role of BEN domain protein 4 (BEND4) in prostate cancer (PCa) and the effect of silencing BEND4 in PCa cell lines.

Janani Harikrishnan, Gnanasekar Munirathinam

Biomedical Sciences, University of Illinois College of Medicine (Rockford), Rockford, IL

Prostate cancer (PCa) is diagnosed in approximately 13% of men in their lifetime and is the second most diagnosed cancer in men. The existing treatments for PCa cause many severe side effects, including erectile dysfunction, hair loss, and anemia, while their effects may be reduced due to the development of treatment resistance. Due to these drawbacks associated with traditional treatments, research on targeted cancer therapy is conducted in the field of molecular oncology to develop efficient and safer treatment approaches for PCa. Many of the targets explored are involved in DNA Damage Response (DDR). One such potential cancer target is the BEN domain (BEND) protein, which is a chromatin boundary marker that recruits chromatin-modifying factors and regulates transcription. It has many functions in cancer cells related to DDR and cell proliferation. Recent studies have suggested that silencing BEND4 expression in pancreatic ductal adenocarcinoma (PDAC) promotes the accumulation of DNA damage and sensitizes cells to ATM/ATR inhibitors, thereby increasing cancer cell apoptosis. Moreover, it has been shown to be hypermethylation target in diffuse large B-cell carcinoma (DLBCL) and colorectal cancer. Therefore, these results demonstrate the potential of targeting BEND4 in the treatment and diagnosis of PCa. However, limited research has been conducted on BEND4 in PCa. The expression profile of BEND4 in PCa cell lines (androgen-dependent and androgen-independent) suggests, according to online prediction tools such as Betastasis and PCA tools, that androgen receptor-dependent (AR+) PCa cells express high levels of BEND4, indicating AR-dependent regulation of BEND4. They also imply that as the Gleason score increases, BEND4 expression decreases. To validate these findings in vitro, western blot and RT-qPCR were conducted, revealing that BEND4 expression is high in AR+ PCa cells, such as MDA-PCa-2b, LNCaP, and VCaP , and is lower in NCI-H660 and LASCPC (AR-negative and aggressive PCa cell lines). DepMap analysis assigned negative gene effect scores to AR+ cell lines such as VCaP and LNCaP, suggesting that BEND4 silencing has differential effects on PCa cells based on their androgen dependency. Follow-up studies of siRNA silencing of BEND4 reduced proliferation with an increase in siRNA concentration in AR+ cells, such as VCaP and MDA-PCa-2b. Taken together, our results suggest that BEND4 may have a role in promoting AR-driven PCa and may serve as a potential therapeutic target for AR-dependent PCa.

#0344 TIP60 mediates chemoresistance by reducing cisplatin-DNA adduct formation and enhancing their repair.

Madhavi P. Kadakia[1], Akshay Hira[1], Caroline McLaughlin[1], Michael Craig[1], Ramzi Nahhas[2], Jin Zhang[1], Mike Kemp[3]

[1]Biochemistry and Molecular Biology, Wright State University, Dayton, OH,[2]Population and Public Health Sciences, Wright State University, Dayton, OH,[3]Pharmacology and Toxicology, Wright State University, Dayton, OH

Cisplatin is a frontline chemotherapeutic agent for squamous cell carcinoma (SCC), yet resistance remains a major obstacle to effective treatment. Our previous work demonstrated that genetic knockdown or pharmacological inhibition of TIP60 sensitizes cisplatin-resistant SCC cells, induces cell cycle arrest and promotes cell death, suggesting a central role for TIP60 in mediating platinum resistance. Here, we demonstrate that TIP60 promotes cisplatin resistance by upregulating drug efflux transporter, suppressing intracellular drug accumulation, and enhancing DNA damage repair. Using both intrinsic and acquired cisplatin-resistant SCC cell line models, we show that elevated TIP60 levels correlate with reduced cisplatin-DNA adduct formation, accelerated repair kinetics, and increased cell survival. Mechanistically, we demonstrate that TIP60 plays a significant role in facilitating resistance to cisplatin through two key pathways. First, it increases the expression of ABCC1, which enhances the efflux of cisplatin and decreases its intracellular accumulation. Second, TIP60 promotes the expression of XPC, an essential element of the nucleotide excision repair (NER) pathway, facilitating the repair of DNA adducts. We show that TIP60 depletion decreases ABCC1 expression and increases cisplatin-DNA adduct accumulation, an effect also observed with the ABCC1 inhibitor, MK-571. Similarly, TIP60 knockdown impairs DNA repair and downregulates DNA damage response (DDR) genes, including XPC. Combining TIP60 inhibition with either ABCC1 inhibitor, MK-571 or spironolactone, which blocks NER further decreases cell survival and increases cell death. Together, these findings reveal a dual role for TIP60 in promoting cisplatin resistance through the coordinated regulation of drug efflux and DNA repair highlighting its potential as a therapeutic target to overcome platinum resistance in SCC.

#0345 Therapeutic restoration of p53 via engineered synthetic mRNA analogs in p53 mutant cancer.

Yong Ho Heo, Seung-Hyun Shin, Youngjin Han, Sol-Bi Shin, Innah Kim, Soye Jeon, Aran Park, Jooyun Byun, Daejin Kim, In Young Choi

Hanmi Pharm. Co., Ltd., Seoul, Korea, Republic of

TP53, which encodes the tumor suppressor protein p53, is a critical regulator of the cell cycle and apoptosis. Mutations in TP53 are among the most common oncogenic events across a wide range of cancers, contributing significantly to tumor development and poor clinical outcomes. Numerous therapeutic strategies have been investigated to restore wild-type p53 activity, including small molecules designed to reactivate specific mutant forms of p53, inhibition of p53 negative regulators to prevent its degradation, and gene delivery approaches using adenoviral vectors. However, these methods often face challenges due to the diverse spectrum of p53 mutations and limited therapeutic efficacy. In this study, we present an advanced synthetic mRNA-based therapeutic platform aimed at restoring p53 functionality in cancers characterized by high p53 mutation rates. Rather than relying on the wild-type p53 sequence, we engineered a more potent p53 analog with enhanced transcriptional activity to overcome the limitations posed by diverse mutation profiles. The Hanmi p53 mRNA construct was meticulously optimized—featuring customized 5′ and 3′ untranslated regions (UTRs), a refined open reading frame (ORF), and Hanmi's proprietary 5′ capping technology—to maximize expression and stability. The therapeutic efficacy of this analog mRNA was evaluated in both *in vitro* and *in vivo* models derived from p53 mutant cancers, including lung, ovarian, and other tumor types. Our study demonstrates that Hanmi's synthetic p53 mRNA analog therapy effectively suppresses the proliferation of p53 mutant cancer cells by inducing apoptosis and cell cycle arrest. Notably, the engineered p53 analog exhibited superior tetramerization capacity compared to the wild-type protein, resulting in enhanced transcriptional activity. *In vivo* ovarian xenograft model, p53 mRNA analog showed marked tumor growth inhibition without observable adverse effects on body weight. Moreover, in taxane-resistant cancer cell lines, the p53 mRNA analog demonstrated superior efficacy compared to wild-type p53 mRNA. These results highlight Hanmi's p53 mRNA analog as a promising therapeutic modality for p53 mutant cancers. Importantly, it also demonstrated the potential to overcome taxane resistance, offering a novel avenue for precision oncology.

#0346 TIP60 regulates PTEN expression, acetylation, and localization in cisplatin-resistant SCC.

Caroline McLaughlin, Akshay Hira, Madhavi Kadakia

Biochemistry and Molecular Biology, Wright State University, Dayton, OH

Non-melanoma skin cancers (NMSCs), including squamous cell carcinoma (SCC), remain highly prevalent, with global incidence rising each year. Cisplatin, a platinum-based chemotherapy drug, is commonly used to treat advanced SCC and several other cancers. Although many patients initially respond, intrinsic or acquired resistance frequently emerges, limiting its clinical efficacy. TIP60, a histone acetyltransferase that modifies both histone and non-histone substrates, plays key roles in DNA damage repair, cell-cycle progression, and apoptosis. Our research demonstrates that elevated TIP60 expression correlates with increased resistance to cisplatin in SCC cell lines. In contrast, the tumor-suppressor PTEN is essential for maintaining controlled cell growth and survival. Loss, decreased expression, or mislocalization of PTEN promotes drug resistance, proliferation, and enhanced cell survival across various cancer types. PTEN activity is regulated in part by acetylation and our lab has previously shown that ΔNp63α negatively regulates PTEN expression and activity. We hypothesize that TIP60 promotes resistance to cisplatin by suppressing PTEN expression, or modifying PTEN through acetylation, and altering its subcellular distribution. Consistent with this model, we found that PTEN levels were significantly reduced in cisplatin-resistant SCC cell lines compared with their cisplatin-sensitive counterparts. TIP60 knockdown in resistant cells increased PTEN transcript and protein levels, and enhanced PTEN promoter activity, supporting a transcriptional mechanism. TIP60 knockdown also reduced phosphorylated Akt levels, whereas TIP60 overexpression decreased PTEN and increased phosphorylated Akt. Subcellular fractionation demonstrated that TIP60 knockdown increased cytoplasmic PTEN in cisplatin-resistant cells. In addition, both TIP60 knockdown and pharmacological inhibition reduced PTEN acetylation, suggesting a post-translational mode of regulation. Together, these findings support a model in which TIP60 acetylates PTEN and negatively regulates its overall and cytoplasmic abundance, thereby enhancing pro-survival PI3K/Akt signaling and promoting cisplatin resistance. Defining the mechanisms underlying the TIP60-PTEN axis may uncover a novel therapeutic vulnerability to improve cisplatin effectiveness and support its continued use in SCC patients.

#0347 Dual dependency of large cell neuroendocrine carcinoma on Ras and ASCL1 oncogenic pathways.

Alyssa Cordes, Michael J. Peyton, Urooba Nadeem, Shreoshi Pal Choudhuri, Seth Hamilton, Shruti Raghavan, Kimberley Avila, Luc Girard, John D. Minna, Benjamin J. Drapkin

UT Southwestern Medical Center, Dallas, TX

Background: Large cell neuroendocrine carcinomas (LCNECs) harbor frequent activating alterations in Ras and Raf family members, which represent targetable oncogenes in non-small cell lung cancers (NSCLCs) lacking neuroendocrine (NE) gene expression. LCNECs also overexpress neurodevelopmental transcription factors such as Achaete-scute homolog 1 (ASCL1), which act as oncogenes in small cell lung cancers (SCLCs) and drive NE gene expression. We investigate whether these pathways represent dependencies in LCNEC that could be therapeutically targeted.
Methods: Most well-characterized lung cancer cell lines predate the introduction of LCNEC into the World Health Organization (WHO) Classification of Tumors in 2015. To address the scarcity of bona fide LCNEC models, candidate lung cancer cell lines were identified by genomic and transcriptomic features and credentialed rigorously through blinded review of cell line-derived xenografts by a multi-institutional panel of thoracic pathologists. In validated LCNEC lines, Ras pathway dependence was tested by comparing sensitivity to pharmacologic inhibitors with non-NE NSCLC lines harboring the same mutations, using rescue alleles to rule out off-target cytotoxicity. In parallel, ASCL1 dependence was assessed by survival after CRISPR-Cas9 gene deletion, and the therapeutic potential of targeting ASCL1-driven NE gene expression was explored with agents against Delta-like Ligand 3 (DLL3), a transcriptional target of ASCL1.
Results: LCNEC cell lines with Ras or Raf activation were sensitive to oncogene-targeted inhibitors. Among 20 lung cancer lines with oncogenic Ras alterations, efficacy of the pan-Ras inhibitor RMC-6236 did not differ between LCNEC (8) and non-NE NSCLC (12) models. In contrast, lines with alterations that bypass Ras, such as activating BRAF mutations, were comparably resistant to RMC-6236 regardless of NE expression. The first LCNEC lines to be re-credentialed (HCC1833, NCI-H1755, and NCI-H1385) expressed high ASCL1 and harbored activating Ras or Raf alterations. Each showed sensitivity to oncogene-targeted inhibitors comparable to non-NE models with the same alterations, and this sensitivity was rescued by on-target or bypass mutations. Proliferation of HCC1833 was greatly reduced by CRISPR-mediated ASCL1 loss, and its sensitivity to tarlatamab, a bispecific T-cell engager (BiTE) against DLL3, was comparable to the most responsive SCLC models.
Conclusions: Human LCNEC models demonstrate frequent dependence on both the Ras-activated kinase cascade and neurodevelopmental transcription factors such as ASCL1. This is unexpected, as forced Ras expression inhibits SCLC proliferation, and forced ASCL1 expression does the same in lung adenocarcinoma. Dual dependence on the Ras-activated kinase cascade and ASCL1 may be a defining feature of LCNEC, and we are now exploring therapeutic strategies to exploit this vulnerability.

#0348 GFH603: A molecular glue-like allosteric activator of the KEAP1-CUL3 E3 ligase complex for targeting NRF2-activated tumors.

Xiang Yu, Tao Jiang, Tao Liang, Feng Yan, Li Wang, Jingyang Zhang, Siyuan Le, Fusheng Zhou, Jiong Lan, Qiang Lu

GenFleet Therapeutics, Shanghai, China

Background:
Constitutive activation of NRF2, driven by *NFE2L2* gain-of-function or *KEAP1* or *CUL3* loss-of-function mutations, disrupts KEAP1-CUL3-mediated NRF2 degradation and contributes to resistance to chemotherapy, immunotherapy, and targeted therapies, including RAS inhibitors. This oncogenic pathway is frequently altered in squamous cell carcinomas — such as esophageal (ESCC) and lung squamous cell carcinoma (LUSC) — via *NFE2L2* hotspot mutations in the DLG/ETGE motifs. In lung adenocarcinoma (LUAD), *KEAP1* mutations are common and often co-occur with *KRAS* mutations. Although *KEAP1/NFE2L2* mutations are relatively uncommon in pancreatic ductal adenocarcinoma, more than half of tumors exhibit pronounced nuclear NRF2 accumulation, likely driven by activation of the RAS pathway. Despite the clinical relevance of this pathway, no approved therapies directly target *KEAP1/NRF2*-mutant tumors.
Methods:
GFH603 was developed as a molecular glue-like allosteric activator of KEAP1 to restore KEAP1-CUL3 E3 ligase function. Its ability to promote KEAP1-CUL3 complex formation, induce NRF2 degradation, and suppress proliferation of NRF2-driven cancer cells was evaluated *in vitro*. *In vivo* anti-tumor efficacy was assessed using xenograft models. Combination studies with pan-RAS inhibitors were conducted in KRAS/KEAP1 co-mutant cell lines. ADMET profiling was performed to assess drug-like properties.
Results:
GFH603 enhanced KEAP1-CUL3 complex assembly and promoted NRF2 degradation. *In vitro*, it induced NRF2 degradation in *NFE2L2 W24C*-mutant KYSE70 cells (IC_{50} = 1.7 nM) and inhibited proliferation of *NFE2L2*-amplified HCC95 cells (IC_{50} = 3.6 nM). In the HCC95 xenograft model, GFH603 (5 mg/kg once daily) achieved significant tumor growth inhibition (TGI = 114%) and robust NRF2 degradation in tumor tissues. In the LU6407 *NFE2L2*-mutant patient-derived xenograft model, GFH603 (10 mg/kg once daily) demonstrated strong tumor regression as a single agent, indicating its potential as an effective monotherapy. Furthermore, GFH603 demonstrated synergistic anti-proliferative activity when combined with pan-RAS inhibitors in *KRAS/KEAP1* co-mutant cell lines. ADMET profiling revealed favorable characteristics, including high oral bioavailability, low hERG liability, and negative Ames test results.
Conclusions:
GFH603 restores KEAP1-CUL3 E3 ligase activity through a molecular glue mechanism, enabling targeted degradation of NRF2 in *KEAP1/NFE2L2*-mutant tumors. It demonstrates potent efficacy as monotherapy in NRF2-activated squamous cancer models (e.g., ESCC, LUSC) and synergizes with pan-RAS inhibitors in *KRAS/KEAP1* co-mutant cells. These findings support GFH603 as a promising therapeutic candidate for overcoming NRF2-driven resistance and addressing a critical unmet need in oncology. Further preclinical and clinical development are warranted.

#0349 Next-generation sequencing and phospho-kinase analysis expose partner-specific profiles in CD74-ROS1 fusions.

Jasmine Vargas[1], Julia Olivieri[2], Georgios Pantouris[1]

[1]Chemistry, University of the Pacific, Stockton, CA,[2]Computer Science, University of the Pacific, Stockton, CA

The oncogenic fusion CD74-ROS1 is a genetic alteration found in a small subset of patients diagnosed with non-small cell lung cancer (NSCLC). This fusion can promote cancer progression in these individuals at both early and late stages, making it an attractive therapeutic target when the standard treatment plans fail. Currently, CD74-ROS1 is targeted with tyrosine kinase inhibitors (TKIs), which inhibit the activity of ROS1. Nevertheless, drug resistance often occurs leaving patients with no alternative therapeutic options. Because CD74-ROS1 is particularly aggressive, supporting the formation of metastatic lesions, dissecting the roles of each fusion partner is of great importance for understanding the biological mechanisms that drive its cancer-promoting properties. Our work focuses on the establishment and characterization of methodically designed CD74-ROS1 variants expressed in the A549 lung adenocarcinoma cell line. The goal is to advance our understanding of the individual and cooperative functions of CD74 and ROS1 in the context of the CD74-ROS1 fusion. Next-generation sequencing (NGS) analysis revealed distinct gene expression profiles across the different transfectants, while phospho-kinase analysis further supports the idea that each protein partner possesses unique functional features. This study aids the efforts in understanding the functionality of CD74-ROS1 positive NSCLC, providing at the same time new biological targets for future signaling studies and therapeutic targeting.

#0350 VHL loss-driven accumulation of GCN5L1 drives clear cell Renal Cell Carcinoma by regulating acetylation of mitochondrial proteins and metabolic reprogramming.

Bradley R. Webster[1], **Kumarkrishna Raychaudhuri**[2], Christopher Ricketts[1], W. Marston Linehan[1], Ramaprasad Srinivasan[1]

[1]Urologic Oncology Branch, National Cancer Institute, Bethesda, MD,[2]Urologic Oncology Branch, National Cancer Institute, NIH, Bethesda, MD

VHL loss-associated clear cell Renal Cell Carcinoma (ccRCC) is the most common renal malignancy. VHL is a component of an E3 ubiquitin ligase that targets hypoxia inducible factor (HIF) transcription factors to proteasomal degradation under normoxic conditions. VHL loss-driven stabilization of HIF1 and HIF2 results in numerous metabolic changes favoring tumorigenesis and cancer cell survival. Although the VHL-HIF pathway is well characterized, the role of HIF independent VHL targets in ccRCC is less clear and carries immense therapeutic interest. Using patient-derived tumor cell lines, we show that loss of VHL in ccRCC leads to an accumulation of GCN5L1, which mediates lysine hyperacetylation of mitochondrial proteins, thereby attenuating the activity of several enzymes in the β-oxidation pathway. Specifically, we show that HADHA, LCAD, and SCAD enzymes show hypoacetylation and increased activity upon downregulation of GCN5L1 protein. Downregulation of GCN5L1 protein levels results in an increase in lipid metabolism and limits cytoplasmic lipid accumulation. Mechanistically, VHL interacts with and regulates GCN5L1 in a HIF-independent manner and targets GCN5L1 to ubiquitination mediated proteasomal degradation. We also show that GCN5L1 attenuates CPT1A protein levels, a rate limiting enzyme in the β oxidation pathway. In vitro assays show that loss of GCN5L1 expression selectively inhibited cell proliferation, cell invasion and anchorage independent cell growth in ccRCC cell lines but not in RCC subtypes with intact VHL. Interestingly, using etomoxir, an irreversible CPT1a/ β-oxidation inhibitor, we show that the growth repression following GCN5L1 loss is dependent on increased CPT1A expression and activity, directly linking GCN5L1 activity to lipid metabolism and ccRCC growth. Mouse xenograft studies demonstrated diminished tumor-forming ability of ccRCC cells upon loss of GCN5L1 expression compared to wild-type cells. Analysis of TCGA data revealed worse overall survival in ccRCC patients with high GCN5L1 expression, further supporting our observations from in vitro and in vivo studies. The importance of lipid metabolism in ccRCC is only beginning to be appreciated and may offer unique therapeutic targets. Lipid accumulation confers a growth and survival advantage in ccRCC and may help protect tumor cells against oxidative and endoplasmic reticulum stress. Our results identify a novel oncogenic pathway in which unregulated GCN5L1 expression drives mitochondrial lysine hyperacetylation and limits activity of β oxidation pathway enzymes, leading to increased lipid accumulation in ccRCC. Therefore, GCN5L1 could be investigated further as a possible therapeutic target in ccRCC.

#0352 Long non coding RNA plasmacytoma variant translocation 1 alternative splicing in prostate carcinogenesis.

Seidu Adams[1], Dominique Weatherall[2], Rachel E. Bonacci[3], Chinedum Chukwuemeka Udekwu[4], Olorunseun O. Ogunwobi[4]

[1]Biochemistry and Molecular Biology, Michigan State University, East Lansing, MI,[2]Department of Biology,, Northeastern Illinois University, Illinois, IL,[3]Michigan State University, Howell, MI,[4]Michigan State University, East Lansing, MI

Prostate cancer remains a major global health concern and disproportionately affects Black men/men of African ancestry (MoAA). Compared to men of European ancestry (MoEA), MoAA experience both a higher incidence of prostate cancer and significantly elevated mortality rates. According to recent American Cancer Society reports, MoAA have a 67% higher incidence of prostate cancer and are more than twice as likely to die from the disease. While socioeconomic and healthcare access factors contribute to these disparities, growing evidence suggests that underlying molecular mechanisms also play a critical role. One emerging molecular factor is the long non-coding RNA Plasmacytoma Variant Translocation 1 (PVT1), which is consistently overexpressed in prostate tumors from MoAA. Prior studies have implicated PVT1 exon 9 in promoting tumor development and progression. Experimental overexpression of exon 9 in prostate cancer models increases tumor aggressiveness and enhances malignant cellular behavior, supporting a functional role in disease severity. In addition, PVT1 exon 9 induces malignant transformation of prostate epithelial cells. However, recent findings indicate that PVT1 is not expressed as a single transcript, but rather as a diverse set of alternatively spliced isoforms, raising the possibility that specific variants may contribute to the observed racial disparities. We hypothesize that a subset of these alternatively spliced PVT1 transcripts is differentially expressed in MoAA and contributes to the increased prostate cancer incidence and mortality observed in this population. To investigate this, we analyzed PVT1 splicing profiles using prostate cancer datasets from two independent studies, including TCGA. We identified ENST00000666076, an alternatively spliced PVT1 transcript located on Chromosome 8: 27,975,972-27,995,613, as being significantly overexpressed in MoAA compared to MoEA. This transcript includes five exons: ENSE00004271579, ENSE00004271636, ENSE00002081483, ENSE00002020395, and ENSE00004271500. In conclusion, our analysis supports the conclusion that distinct PVT1 splice variants may be involved in prostate carcinogenesis.

#0353 Pancreatic cancer modeling in germline *BRCA2* mutation carriers.

Yi Xu[1], Nur Yucer[2], Alyssa Okimoto[2], Bobbie J. Rimel[3], Kate Lawrenson[4], Pei Wang[1], **Simon A. Gayther**[4]

[1]UT San Antonio, San Antonio, TX,[2]Medicine, Center for Inherited Oncogenesis, San Antonio, TX,[3]UW Medicine, Seattle, WA,[4]Medicine, Center for Inherited Oncogenesis, UTHSA, San Antonio, TX

Background: Germline, pathogenic mutations in *BRCA2* (*BRCA2*^{mut}) are the strongest genetic risk factor for pancreatic cancer in men and women; pathogenic variants in this gene are implicated in about 5% of men and women with heritable risks of this cancer type. Moreover, *BRCA2*^{mut} are associated with increased risk of pancreatic cancer inHispanic/Latino populations specifically. Patient-specific induced pluripotent stem cell (iPSC) methods create opportunities to modelhuman diseases *in vitro*. iPSCs derived from patients with known genetic mutations carry thepatient's unique genetic background, to provide platforms for studying the functional effects ofspecific genes. Several inherited disease models created from iPSCs have successfully replicated high-risk cancers. This study aimed to utilize iPSC-based modeling to investigate thefunctional impact of pathogenic *BRCA2*^{mut} on early-stage pancreatic tissues (PT) and genomicalterations that contribute to pancreatic cancer (PC) progression.

Methods: We generated iPSC from *BRCA2*^{mut} positive and *BRCA widtype (BRCA*^{WT}) women and men. From these *BRCA2*^{mut} and *BRCA*^{WT} iPSCs we generated organoid models of pancreatic ductal and acinar precursors. In addition, we used lentiviral targeting to mimic thefunctional effects of specific genes involved in early stage pancreatic cancer pathogenesis, specifically *TP53* knockdown (using a *TP53* siRNA), and *TP53* and/or *KRAS* overexpression (*TP53* R175H and R273H; *KRAS* G12V) respectively.

Results: Following differentiation into PT organoids heterozygous for *BRCA2*^{mut} pancreatic ductal cells show specific cellular abnormalities - neoplastic transformation, ductal formation, expression of cancer-specific biomarkers - compared to *BRCA*^{WT} controls suggesting that *BRCA2* haploinsufficiency contributes to the observed phenotype. PC models from *BRCA2*^{mut} subjects exhibit abnormalities reminiscent of early-stage neoplastic development. Importantly, PC organoids with combinations of *BRCA2*^{mut}, *TP53* and *KRAS* alterations exhibited a moreaggressive PC phenotypes compared to *BRCA2*^{mut} and *BRCA*^{WT} organoids alone, and sharedgenomic signatures with primary PCs.

Conclusion and Impact: iPSC-derived organoids can accurately replicate *BRCA2*^{mut} and*BRCA*^{WT} pancreatic precursor tissues. This allows cancer to evolve in a dish, making it an ideal model for mechanistic studies and screening approaches to identify novel drug targets.

#0354 Distinct response profiles of TROP2-targeting ADCs Dato-DXd and sac-TMT across a large panel of cancer cell lines.

Janneke J. T. M. Melis, Eef F. P. Smits, Karsten P. F. van Doorn, Tsang W. Lam, Jeroen A. D. M. de Roos, Daphne J. F. Kluitmans, **Jeffrey J. Kooijman**, Guido J. R. Zaman, Jorg C. J. Benningshof

Oncolines B.V., Oss, Netherlands

Antibody-drug conjugates (ADCs) are targeted cancer therapies that deliver cytotoxic drugs directly to tumors by binding to receptors overexpressed on cancer cells. Following receptor binding, the receptor-bound ADC is internalized and the drug is released, triggering cell death.

Trophoblast cell surface antigen 2 (TROP2) is a cell surface receptor highly expressed in epithelial tumors, making it an attractive ADC target. Sacituzumab govitecan gained FDA approval in 2020 for triple-negative breast cancer (TNBC). However, its short plasma half-life motivated the development of more stable alternatives. Two newer ADCs, sacituzumab tirumotecan (sac-TMT) and datopotamab deruxtecan (Dato-DXd), have since been approved for clinical use. Both carry a topoisomerase-1 inhibitor payload but differ in antibody and linker design. Sac-TMT is approved for TNBC in China and has received FDA breakthrough designation for *EGFR*-mutated non-small cell lung cancer (NSCLC). Dato-DXd received FDA approval in 2025 for $HR^+/HER2^-$ breast cancer and *EGFR*-mutated NSCLC. Despite observed correlations between TROP2 expression and drug sensitivity, these ADCs are approved regardless of tumor TROP2 levels. This suggests that TROP2 expression alone may not predict therapeutic benefit, and alternative biomarkers may better explain clinical efficacy.

To explore this further, Dato-DXd and sac-TMT were profiled on a panel of approximately 270 cancer cell lines, representing diverse tumor types, including eight TNBC, three $HR^+/HER2^-$, and six EGFR-mutated NSCLC models. The TROP2 (*TACSTD2*) gene was widely expressed with over 2500-fold difference in basal expression levels across the panel. Surface TROP2 expression levels were quantified by flow cytometry in a subset of cell lines. Cells were exposed to a 9-point dose range of each ADC, and viability was assessed by intracellular ATP measurement. Half-maximum inhibitory concentrations (IC_{50}) were derived and integrated with genomic, transcriptomic and proteomic datasets to identify molecular predictors of drug response.

Dato-DXd exhibited a more selective inhibition profile than sac-TMT. When the IC_{50} “fingerprints” of the two ADCs were compared to a reference dataset of 248 anticancer agents, Dato-DXd clustered with EGFR inhibitors, whereas sac-TMT showed highest similarity to topoisomerase I inhibitors, indicating mechanistically distinct selectivity patterns. Moreover, correlation between drug sensitivity and TROP2 gene expression was stronger for Dato-DXd than for sac-TMT.

This large-scale cell panel profiling study underscores the power of integrative bioinformatic analyses to uncover biomarkers of ADC response, and identifies cell models suitable for investigating mechanisms of action, such as receptor internalization, payload processing, and bystander effects.

#0355 Co-expression of FIH1 and IL-12 in oncolytic HSV-1 blocks Notch signaling and enhances anti-tumor immunity.

Karina Vazquez-Arreguin, Balveen Kaur

Augusta University, Augusta, GA

Glioblastoma (GBM) is the most aggressive brain tumor in adults and remains a lethal disease with limited treatment options despite continuing worldwide efforts to develop new therapies. GBM cells often exhibit increased Notch signaling, whose activity contributes to tumor progression and therapy resistance. Previous clinical trials aimed to target Notch signaling using ɣ-secretase inhibitors (GSIs) but have not been fully successful due off-target effects, dose-limiting toxicity and eventual resistance. Here, we have generated an oncolytic herpes simplex virus (oHSV) that expresses the asparaginyl hydroxylase factor inhibiting HIF (FIH1) which efficiently targets Notch signaling locally and specifically in GBM and other solid tumors. Using this virus, OncoD-F, we have shown successful downregulation of Notch signaling *in vitro* and significant survival improvement in *in vivo* mouse models of GBM. Furthermore, scRNA sequencing analysis of mouse brain tumors treated with OncoD-F have shown a reduction in tumor associated macrophages and an enrichment in the T cell population. Based on these observations, and in order to enhance the cytotoxic activity of the recruited T cells, we combined OncoD-F treatment with intratumoral injections of the immunoregulatory cytokine IL-12 in a subcutaneous tumor model. Mice receiving the combination treatment had a delayed tumor growth and had a longer time to reach endpoint. Given the favorable response of the combination treatment, we have expressed IL-12 in OncoD-F to generate OncoD-F12. The findings from this study suggest the potential of multi-modality therapeutic strategies for GBM and other solid tumors that have oncogenic Notch activation.

#0356 Rezatapopt and KRAS inhibitors for the treatment of TP53 Y220C and *KRAS* mutant cancers.

Argun Akcakanat[1], Ecaterina E. Dumbrava[1], Kurt W. Evans[1], Ran Zhang[1], Ming Zhao[1], Amber Kennon[1], Xiaofeng Zheng[2], Stephen M. Scott[1], Erkan Yuca[1], Gabriela Raso[3], Elisabeth K. Kong[3], Yasmeen Rizvi[1], David Hong[1], Masha V. Poyurovsky[4], Guillermina Lozano[5], Anil Korkut[2], Funda Meric-Bernstam[1]

[1]Investigational Cancer Therapeutics, UT MD Anderson Cancer Center, Houston, TX,[2]Bioinformatics and Comp Biology, UT MD Anderson Cancer Center, Houston, TX,[3]Translational Molecular Pathology, UT MD Anderson Cancer Center, Houston, TX,[4]PMV Pharmaceuticals Inc., Princeton, NJ,[5]Genetics, UT MD Anderson Cancer Center, Houston, TX

Background: *TP53* and *KRAS* are two important genes involved in cancer development. *KRAS* is involved in cell growth and division, and *KRAS* mutant cancers often do not respond to treatments. P53 is a transcription factor that regulates cell cycle and prevents tumor formation. Cancer cells with *TP53* mutations can evade p53-mediated tumor suppression. Combined *TP53*/*KRAS* mutations are associated with drug resistance and worse prognosis. Rezatapopt is a small molecule reactivator of p53 Y220C protein. It binds the mutant protein and stabilizes p53 structure in the wild-type conformation restoring its functions. TP53 Y220C is present in approximately 1% of all solid tumors. We hypothesized that rezatapopt in combination with standard or targeted therapies enhances treatment response in TP53 Y220C/*KRAS* altered tumors.

Methods: We used three TP53 Y220C cell lines that also had KRAS G12D or Q61H mutations to analyze the effects of drug combinations. Following a high-throughput screening with 23 drugs using an ATP quantification-based cell viability assay, we selected 6 agents and confirmed the results using sulforhodamine B (SRB) assay. We used Chou-Talalay and Bliss methods to calculate IC50 and combination index. We analyzed the effect of rezatapopt in combination with pan-RAS inhibitors on long-term viability of treated cells by colony formation assay. *In vivo* antitumor activity was assessed by objective response and event-free survival (as defined by time to tumor doubling) per PDXNET metrics.

Results: Rezatapopt was synergistic with multiple chemotherapeutic and targeted therapy agents. SRB assay showed that both MRTX1133 (KRAS G12D inhibitor) or daraxonrasib (RMC-6236, pan-RAS inhibitor) were synergistic with rezatapopt in two TP53 Y220C and KRAS G12D cell lines. We generated a patient-derived xenograft model from a patient with colorectal cancer bearing TP53 Y220C and KRAS G12A mutations, and treated the model with rezatapopt (100 mg/kg, QD, PO), daraxonrasib (25 mg/kg, QD, PO), or the combination. Four out of 5 rezatapopt + daraxonrasib combination-treated tumors regressed greater than 30% from baseline by day 22 while only 1 out of 5 tumors treated with either single agent regressed by day 22. Event-free survival was significantly longer for combination-treated mice compared to mice treated with daraxonrasib alone ($p=0.013$) or rezatapopt alone ($p=0.016$).

Conclusion: Rezatapopt combined with KRAS inhibition increased antitumor activity. Further studies are needed to understand the mechanism of synergy.

#0357 DIRAS3 mimetic peptide achieves dual MAPK and PI3K pathway suppression across KRAS hotspot mutations.

Gamze Bildik[1], Junchen Liu[2], Weiqun Mao[1], Hailing Yang[1], John F. Hancock[2], Steven W. Millward[1], Robert C. Bast[1], Zhen Lu[1]

[1]The University of Texas MD Anderson Cancer Center, Houston, TX,[2]McGovern Medical School, The University of Texas Health Science Center, Houston, TX

Activating mutations in RAS occur in approximately 30% of human cancers, with hotspot alterations at codons G12, G13, and Q61 driving persistent downstream signaling through the MAPK and PI3K pathways. Although recent tricomplex RAS inhibitors have shown promise, their efficacy varies among different RAS mutants. Accumulating evidence indicates that the biochemical and signaling properties of G12X and Q61X mutants differ substantially, influencing their response to upstream and downstream modulation. G12X mutants depend on receptor tyrosine kinase activity for both MAPK and PI3K pathway activation, whereas Q61X mutants can independently activate MAPK signaling and maintain PI3K output even when RAS is inhibited. Consequently, Q61X tumors display intrinsic resistance to current RAS-targeted therapies, underscoring the need for agents capable of simultaneously suppressing both effector arms. DIRAS3 has emerged as a unique endogenous RAS inhibitor that disrupts RAS nanoclustering and effector engagement, while also modulating the PI3K/AKT axis in ovarian and pancreatic cancers, suggesting broader regulatory potential. To systematically define DIRAS3's inhibitory spectrum, we utilized RASless mouse embryonic fibroblasts (MEFs) reconstituted with individual KRAS hotspot alleles. DIRAS3 expression markedly reduced RAS-dependent clonogenic growth, inhibited MAPK and PI3K/AKT signaling in cells expressing oncogenic KRAS variants, with minimal effect on wild-type KRAS unless stimulated with EGF. Functional analysis demonstrated that both N- and C-terminal domains of DIRAS3 are essential for membrane localization and full inhibitory activity. Importantly, DIRAS3 disrupted KRAS nanoclustering in both G12X and Q61X mutant backgrounds, supporting its capacity to interfere directly with the KRAS-KRAS interface. To recapitulate DIRAS3's inhibitory effects, we designed a conformationally constrained cyclic DIRAS3 mimetic peptide based on the sequence spanning parts of α5 and the hypervariable regions critical for DIRAS3-KRAS binding. For translational comparison, we evaluated the tricomplex RAS inhibitor RMC-7977 alongside this DIRAS3-derived peptide. In G12X cells, both agents suppressed MAPK and PI3K outputs. However, in Q61X cells, RMC-7977 inhibited MAPK signaling but failed to suppress PI3K/AKT activity, whereas the DIRAS3 peptide effectively suppressed both pathways. Reduced PI3K activity correlated with enhanced sensitivity to the DIRAS3 peptide, and cells harboring Q61X mutations, which are less responsive to RMC-7977, remained equally responsive to the DIRAS3 peptide. Collectively, these results indicate that DIRAS3 provides a dual-pathway blockade of MAPK and PI3K signaling across diverse KRAS mutations, including Q61X variants that are refractory to existing agents, supporting its development as a broad-spectrum therapeutic for RAS-driven cancers.

#0358 EV-based delivery of chemically modified siRNA achieves MRTX1133-comparable efficacy in KRAS G12D-mutant pancreatic cancer.

Hyo Kyeong kim[1], Yujeong Choi[1], Kyoung Hwa Kim[1], Jae Hwan Kim[1], Shung Hyun An[1], Dae Ho Bae[1], Minyoung Lee[1], Jihwa Chung[1], Seok-Hyun Kim[1], **Kihwan Kwon**[2]

[1]Exollence Biotechnology Co. Ltd., Seoul, Korea, Republic of,[2]Ewha Womans University College of Medicine, Seoul, Korea, Republic of

Background: KRAS G12D-mutant pancreatic ductal adenocarcinoma (PDAC) remains largely incurable, with no clinically validated targeted therapies. RNA interference can selectively suppress mutant KRAS, yet current delivery technologies fail to achieve sustained, safe in vivo activity. We developed a shock wave-engineered extracellular vesicle (EV) platform (SWEET™) that enables efficient, stable encapsulation of KRAS G12D-targeting siRNA and overcomes key limitations of lipid nanoparticles (LNPs) and small-molecule inhibitors.

Methods: We designed and screened a 105-member panel of chemically modified siRNAs engineered for high stability and reduced innate immune activation to identify potent and allele-specific KRAS G12D silencers. Optimized shock-wave engineering achieved >90% encapsulation and >85% nuclease resistance. Lead candidates were evaluated across PDAC cell lines, patient-derived organoids (PDOs), xenografts, biodistribution studies, toxicity models, and GMP-aligned scale-up workflows.

Results: Five siRNAs exhibited single-digit nanomolar potency (IC50 < 10 nM). The lead, EV-siRNA #41, produced robust KRAS G12D knockdown and suppression of ERK/AKT signaling. In vivo, EV-siRNA #41 achieved markedly superior tumor accumulation relative to LNPs and induced significant tumor regression. Notably, a microdose of 25 μg EV-siRNA #41 produced antitumor efficacy comparable to or exceeding MRTX1133 at 30-60 mg/kg. PDO assays confirmed selective killing of KRAS G12D-mutant tumors with no effect on wild-type controls. Repeated-dose GLP toxicity studies established a high NOAEL without liver enzyme elevation or weight loss. GMP-aligned optimization increased EV yield from 1% to 7.5% with >80% loading efficiency.

Conclusions: Shock wave-engineered EV delivery overcomes the major barriers of RNA therapeutics in PDAC. EV-siRNA #41 demonstrates potent, selective, and durable antitumor activity at microdose levels and outperforms both LNPs and a leading KRAS G12D inhibitor. These data position EV-siRNA #41 as a first-in-class, mutation-specific RNA therapeutic ready for IND-enabling development.

#0359 Development of a collection of cell lines from a genetically engineered mouse model of DICER1 syndrome-associated sarcoma for therapeutic assessment.

Lanlan Fang, Joyce Yu-Han Zhang, Shary Chen, Yannes Wai Yan Choi, Yemin Wang, David Huntsman

Department of Pathology and Laboratory Medicine, University of British Columbia, Vancouver, BC, Canada

Background: DICER1 syndrome, driven by loss-of-function germline variants in the *DICER1* gene, predisposes children and young adults to rare cancers in multiple organs such as the brain, thyroid, lung, kidney, and gynecologic tract. Most of these tumors are sarcomas, which share common histologic and molecular features regardless of their anatomic origins. A second hit impairing DICER1 RNase IIIb occurs in nearly all these cancers. We have recently developed two genetically engineered mouse models (GEMMs) of DICER1 syndrome-associated sarcomas, which fully recapitulates the human counterpart genetically and histologically. Here, we aim to develop a panel of cell lines from the GEMMs of DICER1 syndrome-associated sarcomas and utilize them for developing novel therapeutic strategies.

Methods: Mouse DICER1 syndrome-associated sarcoma cell lines are derived from tumors growing in $Hic1^{CreERT2};Dicer1^{fl/fl\text{-}D1693N};(Rosa26)^{LSL\text{-}tdTomato}$ (HDT) mice. Whole-exome sequencing was performed on HDT cell lines. IVADo regimen (ifosfamide/cyclophosphamide, vincristine, actinomycin-D, doxorubicin) and CDK4/6 inhibitor were selected to treat the cells. MTT assays were performed to assess cell viability. Metaphase chromosome analysis was used to detect chromosomal abnormalities.

Results: We validated that HDT tumors predominantly express the $Dicer1^{IIIb}$-mutant transcript and most tumors were quadriphasic (epithelial, undifferentiated blastema, stromal cells, and rhabdomyoblastic cells) with no to variable amounts of anaplastic sarcoma components. From these murine HDT tumors, we have successfully derived five HDT cell lines (HDT298, HDT340, HDT366, HDT546, and HDT1003 cell lines). Some of these cell lines have aberrant p53 expression (or p53 mutation) and *Kras* mutation, confirming their resemblance to human DICER1-sarcoma. Furthermore, we tested the response of HDT cell lines to the chemotherapeutic agents of the IVADo regimen and found that they are sensitive to vincristine, actinomycin-D, and doxorubicin. Next, we test potential therapeutic agents on these cell lines. Considering that the KRAS-mutant lung cancer cells have been reported to be hypersensitive to CDK4/6 inhibitor, we tested palbociclib sensitivity and found that only one out of two Kras-mutant cell lines was sensitive to palbociclib. Additionally, we identified that these HDT cell lines have an average chromosome number of 73, indicating the presence of chromosomal instability (CIN). Supporting this, our GEMM DICER1 sarcoma cohort has nearly ubiquitous CIN. We are currently investigating the underlying mechanism and testing whether it can be exploited for therapeutic targeting.

Relevance: Our DICER1-sarcoma GEMM and the derived tumor cell lines empower us to study the biology of DICER1 syndrome-associated sarcoma and inform future development of therapeutic strategies.

#0360 TM4SF1 as a promising ADC target for KRAS-mutated cancers.

Sewon Park[1], Youwon Lee[1], Jae-Sang Hwang[2], Ju-hyeon Lee[2], Mi Ran Yun[1], Byoung Chul Cho[3]

[1]Yonsei New Il Han Institute for Integrative Cancer Research, Seoul, Korea, Republic of,[2]Yonsei University College of Medicine SBSI, Seoul, Korea, Republic of,[3]Yonsei University College of Medicine, Seoul, Korea, Republic of

Transmembrane 4 L six family 1 (TM4SF1) is a protein with four transmembrane domains belonging to the transmembrane 4 L six family members. TM4SF1 interacts with tetraspanins, integrins, and various receptor tyrosine kinases. TM4SF1 promotes cancer cell migration and invasion and is overexpressed in many epithelial-derived malignancies, including prostate, breast, pancreatic, lung, colon, and gastric cancers, while found at low concentrations in normal human tissues like endothelium, skin, lung, and germ cells. In this study, we evaluated TM4SF1 as an ADC (antibody-drug conjugate) target and investigated its connection with KRAS-mutated cancer.To evaluate the potential of TM4SF1 as an ADC target, we employed both in silico analysis and in vitro assays. In silico analysis included data from TCGA/GTEx, single-cell RNA sequencing, and DEPMAP. In vitro assays comprised flow cytometry, internalization assays using IncuCyte, colony formation assays after gene knockdown, and cell viability assays using an ADC which was conjugated by ADC kit (CellMosaic, Inc., MA, USA).The key findings suggest that TM4SF1 is highly expressed in various solid tumors, particularly in KRAS-mutated tumors, indicating it is a promising ADC target. In silico analysis results revealed that TM4SF1 expression was significantly higher in lung cancer, pancreatic cancer, colorectal cancer, and bile duct cancer tumors compared to normal tissues; specifically, following our in-house scRNA sequencing data, expression was increased in EGFR wild-type and post-TKI treated lung tumors, and viability decreased upon gene knockout in many types of solid tumor. In vitro analysis confirmed TM4SF1 expression levels suitable for ADC targeting in 86% to 100% of various cancer cell lines (lung, pancreatic, colorectal, liver, gastric, etc.). Functional analysis demonstrated that TM4SF1 was internalized efficiently (comparable to or greater than the positive control CD71), and lung cancer cell line with high expression and KRAS mutation responded more sensitively to TM4SF1-targeting ADCs compare to low expression and without KRAS mutation or normal cell line. Our findings demonstrate that TM4SF1 is highly expressed in various solid tumors, particularly in specific genetic subsets such as those with KRAS mutated tumors. The observed high expression levels, efficient internalization kinetics (comparable to the positive control CD71), and robust in vitro efficacy of TM4SF1-targeting ADCs strongly suggest that TM4SF1 is a promising therapeutic target. These results provide a strong rationale for the clinical development of TM4SF1-targeting ADCs as a novel precision oncology treatment strategy across multiple cancer types.

#0362 Targeting RUNX transcriptional activity reduces tumor heterogeneity and aggressiveness in triple-negative breast cancer.

Natalia Brenda Fernandez[1], Facundo Luis Couto[2], Maria Sofia Sosa[1], Natalia Rubinstein[2]

[1]Instituto de Biociencias, Biotecnologia y Biologia traslacional (iB3); Facultad de Ciencias Exactas y Naturales (FCEN); Universidad de Buenos Aires (UBA), Buenos Aires, Argentina,[2]Instituto de Biociencias, Biotecnologia y Biologia traslacional (iB3); Facultad de Ciencias Exactas y Naturales (FCEN); Universidad de Buenos Aires (UBA). Consejo Nacional de Investigaciones Cientificas y Tecnicas (CONICET), Buenos Aires, Argentina

Triple-negative breast cancer (TNBC) is a highly aggressive disease, characterized by early relapse and enriched with cancer stem cells (CSCs), contributing to chemoresistance and metastasis. Our research focuses on RUNXs role in TNBC aggressiveness, cell migration promotion and regulation of gene expression. We reported that RUNX1 influences chemoresistance in androgen-responsive TNBC cell lines and Ferrari (2016) showed its correlation with poor prognosis in TNBC patients. Lv (2024) showed that RUNX2 is also implicated in chemoresistance, and Halperin (2022) established that RUNX1 is upregulated in cancer-associated fibroblasts of breast cancer patients and predicts poor disease outcomes. Our study explores how inhibiting RUNX transcriptional activity impacts TNBC cell lines aggressiveness and drug response. Using RUNX-CBFβ commercial inhibitors (AI-10-104 and AI-10-49) we observed significant reduction in viability and migration, and increased apoptosis in MDA-MB-231 and -468 cell lines. In a forced-suspended cell model, inhibiting RUNX transcriptional activity decreased mRNA levels of crucial genes for CSC maintenance. In MDA-MB-231 cells, RUNX inhibition completely hindered mammosphere formation. RUNX1 mRNA and protein expression increased in doxorubicin (Doxo) and paclitaxel (Px) treated cells. RUNX inhibition enhances drug toxicity, reducing viability and boosting apoptosis. Combined AI-10-104 and Doxo significantly reduced the number of mammospheres even more than Doxo alone, while AI-10-104 restored Px sensitivity in Px-resistant cells. By flow cytometry we observed that RUNX inhibition significantly downregulates PD-L1 expression, suggesting an important role in tumor immune escape. Furthermore, RUNX1 inhibition alters mitophagy-related gene expression and induces mitochondrial fragmentation in SUM-159PT cells. Finally, by transcriptomic analysis (cDNA-seq) using long-read oxford nanopore technology, we compare the expression profiles of adherent with forced-suspension growing MDA-MB-468 cells, treated with AI-10-104, and gain insights into the underlying mechanisms. Analyses have identified 10 genes including metabolic, stress, drug resistance' genes, among others, whose expression is differentially affected by RUNX transcriptional inhibition depending on the culture model. These findings point to potentially distinct RUNX-dependent regulatory mechanisms across tumor subpopulations, which are currently under our investigation. In summary, our results suggest that RUNXs play a critical role in generating chemoresistant TNBC cells by influencing intracellular heterogeneity and immune surveillance cancer hallmarks.

#0363 Targeting scaffold/matrix associated regions in pancreatic ductal adenocarcinoma: A novel carbazole-derived therapeutic.

Jack Prochnau[1], Daisy Medina[1], Jian Huang[2], Phat Do[1], Deepika Singh[3], Panneerdoss Subbarayallu[4], Stanton McHardy[5], Manjeet K. Rao[6]

[1]Cancer Biology, University of Texas San Antonio, San Antonio, TX,[2]University of Texas San Antonio, San Antonio, TX,[3]UT Health San Antonio Greehey Children's Cancer Res. Inst., San Antonio, TX,[4]UT Health San Antonio, San Antonio, TX,[5]UT San Antonio, San Antonio, TX,[6]Assistant Professor, Greehey Children's Cancer Research Institute, San Antonio, TX

Pancreatic cancer is the tenth most common cancer in the United States and is projected to become the second leading cause of cancer-related death by 2030. Most cases arise in exocrine cells and are driven by genetic mutations, such as *KRAS* and *CDKN2A*, as well as modifiable risk factors, including alcohol use, chronic pancreatitis, and obesity. The aggressive nature of pancreatic ductal adenocarcinoma (PDAC), coupled with its complex tumor microenvironment, leads to late-stage diagnoses and a five-year survival rate of 13%. Despite advances in treatment, which include surgical resection, radiotherapy, and chemotherapeutic regimens like gemcitabine and FOLFIRINOX, therapy-related toxicity and chemotherapy resistance remain significant barriers to improved outcomes. One promising therapeutic approach involves exploiting vulnerabilities in the DNA damage response (DDR) pathways unique to cancer cells. While cancer cells rely on an aberrant DDR to sustain unchecked replication, their increased mutational burden renders them particularly susceptible to DNA-targeting therapies. However, existing DNA-targeting treatments are limited by off-target effects, resulting in toxicity and the emergence of resistance. This underscores the need for novel, selective drugs capable of targeting DNA processes specific to cancer cells. We report on a novel carbazole-derived compound that represents a significant advancement in PDAC therapy. Carbazole, a nitrogen-containing heterocyclic molecule, serves as a pharmacophore in therapeutics with diverse applications, including antitumor, antiviral, and anti-inflammatory agents. Our compound demonstrates potent inhibition of PDAC growth and metastasis in both *in vitro* and *in vivo* models while sparing normal cells. Its mechanism of action involves selective targeting of Scaffold/Matrix Associated Regions (S/MARs), which play critical roles in chromatin organization and gene expression regulation. By disrupting S/MARs and their associated binding proteins, our compound downregulates essential genes involved in replication and DNA repair, including *CDK4*, *MCMs*, *GINS*, and *CDC6*. These findings suggest that our compound offers a unique therapeutic mechanism with high specificity and minimal toxicity. Furthermore, its potential to complement existing treatments and advance toward Investigational New Drug (IND) approval positions it as a promising candidate for PDAC therapy.

#0364 EMT-driven alterations promote dependency on nuclear kinase VRK1 activity to synergize with immune therapy in triple negative breast cancer.

Priyanka Sahu[1], Raymond Liu[1], Sergey Shmelkov[1], Uger Ozerdem[1], William C. Hahn[2], Jonathan So[1]

[1]NYU Langone Health Perlmutter Cancer Ctr., New York, NY,[2]Dana-Farber Cancer Institute, Boston, MA

Introduction: Triple-negative breast cancer (TNBC) is aggressive and often immune-cold, with ~12% 5-year survival and few targeted options. Cancer Dependency Map analyses identify the nuclear serine/threonine kinase VRK1 as broadly essential, with strongest dependency in EMT-high states. We propose that EMT-driven remodeling of the nuclear envelope (NE) creates a liability that heightens reliance on VRK1 to preserve NE integrity and genome stability. Pharmacologic or genetic VRK1 inhibition destabilizes the NE, generates micronuclei, and activates cGAS-STING/type I interferon signaling, offering a strategy to inflame refractory tumors and improve responses to immune checkpoint blockade.

Methods: Patient-derived TNBC lines (HCC1937, HCC1806, HCC1143) were treated with TGF-β for 72 h to induce EMT. EMT markers (E-cadherin, N-cadherin, Vimentin, SNAIL), NE proteins (LAMIN-B1, BANF1), and DNA damage (γH2AX) were quantified by immunoblotting and immunofluorescence. Functional dependency was assessed by CRISPR/Cas9 knockout of VRK1 or VRK2 with analyses of growth, cytoskeletal organization, and EMT dynamics. For in vivo studies, E0771 murine TNBC cells engineered to express a dTAG-degradable VRK1 were implanted into immunocompetent C57BL/6 mice and treated with the dTAG-V1 degrader, anti-PD-1, or both; tumor growth and immune modulation were evaluated.

Results: TGF-β induced EMT across TNBC lines, increasing Vimentin and N-cadherin and decreasing E-cadherin. EMT coincided with cytoskeletal remodeling, NE disruption, and elevated γH2AX. VRK1 and VRK2 expression increased during EMT. VRK1 knockout in epithelial-like TNBC cells heightened EMT marker expression and restricted growth under TGF-β, indicating a requirement for VRK1 to preserve NE integrity under EMT stress. In murine models, VRK1 depletion reduced tumor growth versus vehicle ($p<0.0001$); anti-PD-1 alone also reduced growth ($p<0.0001$). The combination of dTAG-V1 and anti-PD-1 produced the greatest reduction versus vehicle ($p<0.0001$) and outperformed either monotherapy, supporting synergy between VRK1 targeting and checkpoint blockade.

Conclusion: EMT-driven remodeling sensitizes TNBC to VRK1 inhibition, establishing VRK1 as a tractable vulnerability in mesenchymal-like disease. VRK1 sustains NE integrity; its inhibition destabilizes the NE, activates cGAS-STING, and converts immune-refractory TNBC toward an inflamed, therapy-responsive state. These findings support clinical exploration of VRK1 inhibition combined with anti-PD-1 to enhance antitumor immunity in aggressive TNBC.

: Mechanisms of Drug Resistance 1
Poster Session

#0368 CDC20 drives acquired resistance to CDK4/6 inhibitors in estrogen receptor positive breast cancer.

Kamal Pandey, SM Nashir Udden, Jamsey Mathew, Prasanna G. Alluri

Radiation Oncology, University of Texas Southwestern Medical Center, Dallas, TX

Purpose: Cyclin-dependent kinase (CDK) 4/6 inhibitors, such as palbociclib, in combination with endocrine therapy are the standard of care for patients with metastatic Estrogen Receptor-positive (ER+) breast cancer. Despite significant clinical benefit, acquired resistance to CDK4/6 inhibitors is nearly universal, and therapeutic strategies to overcome such resistance remain limited. To identify novel molecular mediators of resistance, we employed an unbiased integrative approach combining transcriptomic profiles with palbociclib sensitivity data to uncover molecular drivers of CDK4/6 inhibitor resistance.
Methods: We integrated RNA sequencing data from over 45 breast cancer cell lines with half-maximal inhibitory concentration (IC_{50}) values for palbociclib. We performed correlation analyses and identified candidate genes whose expression was associated with palbociclib response. Top correlated gene was validated using western blotting in parental MCF-7 cells and multiple genetically engineered palbociclib-resistant derivatives. Functional relevance was assessed through siRNA-mediated knockdown and overexpression experiments. *In vitro* cell survival assays and *in vivo* xenograft studies using athymic nude mice were performed to determine the impact of CDC20 modulation on palbociclib response.
Results: CDC20 expression showed a strong positive correlation with palbociclib IC_{50} values across multiple breast cancer cell lines, suggesting a potential role in mediating palbociclib response. Consistently, we observed a marked upregulation of CDC20 in palbociclib-resistant MCF-7 and T-47D derivative cells compared to their parental counterparts. Functional studies further supported this association; silencing CDC20 expression in resistant cells significantly restored their sensitivity to palbociclib. Conversely, overexpression of CDC20 in both MCF-7 and T-47D cells was sufficient to confer resistance to palbociclib. *In vitro* cell survival assays showed significantly reduced sensitivity to palbociclib in CDC20-overexpressing cells compared to parental controls ($p<0.001$, two-tailed t-test). *In vivo*, palbociclib treatment (100 mg/kg by oral gavage, daily) was completely ineffective in inhibiting the growth of MCF-7-CDC20 xenografts ($p>0.5$ for palbociclib vs. vehicle, unpaired two-tailed t-test).
Conclusion: Together, these findings identify CDC20 as a key functional mediator of palbociclib resistance and highlight its potential as a therapeutic target to overcome resistance to CDK4/6 inhibitors in ER-positive breast cancer.

#0369 Elucidation of intratumoral heterogeneity using patient-derived lung cancer cell line.

Tomoko Funazo[1], Hiroaki Ozasa[1], Takahiro Tsuji[2], Kazutaka Hosoya[1], Yusuke Shima[1], Masahiro Ooi[1], Keiichiro Suminaga[1], Kentaro Hashimoto[1], Hiroshi Yoshida[1], Hitomi Ajimizu[1], Takashi Nomizo[1], Hironori Yoshida[1], Toyohiro Hirai[1]

[1]Respiratory Medicine, Graduate School of Medicine Kyoto University, Kyoto, Japan,[2]Fred Hutch Cancer Center, Seattle, WA

Intratumoral heterogeneity has been reported to be associated with treatment resistance in various cancers, including lung cancer. Elucidating intratumoral heterogeneity is a critical issue that must be addressed to improve patient prognosis. Previous studies on intratumoral heterogeneity have primarily focused on collecting and analyzing patient-derived cancer cells, classifying them into subclones with distinct characteristics, and conducting comparative analyses. In contrast, few studies have focused on the early phase of intratumoral heterogeneity. We established a patient-derived cancer cell line (KTOR83) using pleural effusion collected from a lung cancer patient harboring a BRAF gene mutation. From KTOR83, we generated single-cell-derived clones and established five subclones (clones A, B, C, D, and E). In drug sensitivity assays using the BRAF inhibitor dabrafenib, clones A and B exhibited resistance, whereas clones C, D, and E were sensitive. In cell migration assays, clones D and E demonstrated high migratory capacity. In xenograft models, clones A, B, and C showed strong tumorigenic potential, while clones D and E exhibited low tumor-forming ability. Furthermore, flow cytometric analysis revealed that in clone C, the expression pattern of the cell surface marker EpCAM shifted from a unimodal to a bimodal distribution before and after dabrafenib exposure. To investigate whether this bimodal expression of EpCAM corresponds to two phenotypically distinct subclones, we plan to isolate EpCAM-high and EpCAM-low populations using flow cytometry and compare their phenotypic characteristics. Through cloning of patient-derived cancer cells, we confirmed the presence of subclones with distinct phenotypes. Moreover, in one of these clones, exposure to an anticancer drug induced a shift to bimodal expression of a cell surface marker, capturing an early event of intratumoral heterogeneity in which a single cell differentiates into phenotypically distinct populations. This study presents a novel approach to capturing the early phase of intratumoral heterogeneity and provides new insights into the mechanisms underlying tumor progression.

#0370 Low physiological pH drives P300 mediated acetylation of PARP1 and promotes PARP inhibitor resistance.

Hao Nie[1], Wei Zhou[2], Kaixin Cheng[1], Dajiang Guo[3], Liping Liao[1], Xu Zhang[1], Chen Wang[1], Rafal Zielinski[1], Janardan N. Gavade[1], Shruthi Sriramkumar[1], Yiming Fang[1], Shuai Wu[4], Hsin-Yao Tang[3], Andrew V. Kossenkov[3], Yuan Qi[1], Jinsong Liu[1], Kang Le[1], Dorothea C. Gruber[5], Michael Soth[6], Miriam D. Post[7], Anil K. Sood[1], Stefanie Fluckiger-Mangual[5], Timothy A. Yap[1], **Benjamin G. Bitler**[7], Rugang Zhang[1]

[1]MD Anderson Cancer Center, Houston, TX,[2]The University of Pennsylvania, Philadelphia, PA,[3]The Wistar Institute, Philadelphia, PA,[4]The Wistar Institute, Philadelpahia, PA,[5]Tolremo Therapeutics AG, Basel, Switzerland,[6]Institute for Applied Cancer Science, MD Anderson Cancer Center, Houston, TX,[7]University of Colorado Anschutz Medical Campus, Aurora, CO

Resistance to PARP inhibitors (PARPi) is a major clinical obstacle in epithelial ovarian carcinoma (EOC). Intrinsic and acquired PARPi resistance ultimately limit therapeutic efficacy and contribute to patient mortality. Despite multiple reported mechanisms of PARPi resistance, few studies have defined the contribution of the tumor microenvironment (TME) in modulating PARPi response. Here, we demonstrate that the acidic TME, commonly observed in EOC, drives a novel mechanism of PARPi resistance. In multiple in vitro and in vivo models, a physiologically low pH of 6.5 is sufficient to enhance DNA damage repair, reduce PARPi-mediated PARP trapping, and attenuate PARPi-mediated anti-tumor efficacy. Through three independent, epigenetically focused CRISPR/Cas9 screens conducted under low pH conditions, we identified p300 as a druggable target for overcoming pH-induced PARPi resistance. Mechanistically, in an unbiased functional proteomic evaluation, we identified an ERK1/2-p300-PARP1 signaling axis activated under low pH, which alleviates PARPi-induced PARP1 trapping and associated DNA damage by directly acetylating PARP1. In primary human tumors, elevated PARP1 acetylation significantly correlates with poorer overall survival and PARPi resistance. In multiple in vivo patient-derived and syngeneic EOC models, novel p300 bromodomain inhibitors, TT125-802 and IACS-16559, synergize with PARP inhibitors (olaparib or saruparib) to inhibit the growth of therapy-resistant tumors. Together, our findings establish p300 as a promising therapeutic target for overcoming acidosis-driven PARPi resistance.

#0371 Integrative analysis of capivasertib mediated AKT blockade with AR inhibition in mouse PTEN-deficient prostate cancer.

Marco A. De Velasco[1], Kazuko Sakai[1], Daiki Nakatsu[1], Takafumi Minami[1], Mamoru Hashimoto[1], Shingo Toyoda[1], Saizo Fujimoto[1], Kazuhiro Yoshimura[1], Simon T. Barry[2], Cath Eberlein[2], Claire Rooney[2], Kazuto Nishio[1], Hirotsugu Uemura[1], Kazutoshi Fujita[1]

[1]Kindai University Faculty of Medicine, Sakai City, Japan,[2]AstraZeneca, Cambridge, United Kingdom

Background: PTEN-deficient prostate tumors have poor prognosis and limited response to AR-targeted therapies. PI3K/AKT activation compensates for AR inhibition, reducing the efficacy of androgen deprivation therapy (ADT) and agents such as abiraterone (Abi). Capivasertib (Capiva, AZD5363), a potent pan-AKT inhibitor, is the first to demonstrate clinical benefit when combined with Abi and ADT in PTEN-deficient metastatic hormone-sensitive prostate cancer (HSPC), as shown in the Phase 3 CAPItello-281 trial.
Objective: To investigate biological responses and therapeutic outcomes of AKT inhibition with capivasertib plus AR-targeted therapy in HSPC using an integrative approach with a clinically relevant PTEN-deficient mouse model, enabling simultaneous assessment of cancer cell signaling and the tumor microenvironment.
Methods: Gene expression profiling, quantitative immunohistochemistry, and flow cytometry were combined with computational analysis to characterize molecular responses to ADT (A, n=13), ADT plus abiraterone (AA, n=14), and ADT plus Abi with Capiva (AAC, n=15) in an aged PTEN-deficient mouse model of locally invasive prostate adenocarcinoma. Treatment response was classified by tumor burden (TB) relative to the population median: ≥20%, high TB; <20% and >-20%, moderate TB; ≤-20%, low TB—serving as surrogates for progressive disease, stable disease, and partial response. Progressive disease was considered unfavorable; stable disease and partial response were favorable.
Results: Favorable outcomes occurred in 8/13 (61.5%), 7/14 (50%), and 12/15 (80%) of A, AA, and AAC groups. Approximately 70 markers related to signal transduction, AR signaling, DNA damage, epigenetic regulation, proliferation/apoptosis, angiogenesis, and immune composition were analyzed. Unfavorable AA outcomes correlated with high AKT signaling, PMN accumulation, and vascularization. AAC favorable responders showed sustained AKT inhibition, increased DNA damage, and reduced PMN infiltration; poor responders exhibited persistent AR signaling.
Conclusion: Capiva improved response to ADT and Abi in PTEN-deficient prostate cancer. Favorable outcomes were associated with sustained AKT inhibition, reduced pro-tumor immune infiltration, and decreased vascularization. These findings underscore the importance of targeting PI3K/AKT to overcome AR therapy resistance and highlight the value of integrative approaches for biomarker discovery and optimizing therapeutic outcomes.

#0372 ARNT2 and AhR promote resistance to HIF2a inhibitor belzutifan.

Dongkook Min, Sunil Poudel, Robert Morris, Irene Mitsiades, Monica Perez, Eric Zaniewski, Toshi Shioda, Esther Rheinbay, Mo Motamedi, Wilhelm Haas, Othon Iliopoulos

Krantz Family Center for Cancer Research, Massachusetts General Hospital, Boston, MA

Introduction: The von Hippel-Lindau (*VHL*) tumor suppressor gene is inactivated in all VHL disease-associated tumors and in more than 90% of sporadic renal cell carcinomas and central nervous system hemangioblastomas. VHL-depleted cells constitutively express high levels of the oncogenic transcription factors Hypoxia-Inducible Factors (HIF1a and HIF2a). HIF2a belongs to the family of bHLH-PAS proteins, it is a sensor of hypoxia and forms nuclear obligatory heterodimers with several adaptor bHLH-PAS protein. HIF-ARNT heterodimers bind HRE sequences in the promoters of hypoxia inducible genes. Belzutifan, a first in class oral medication, disrupt the interaction of HIF2a with ARNT (HIF1b) and suppresses HIF2a target genes expression that drive VHL tumor growth. De novo and acquired resistance to this medication has been detected.

Experimental procedures: Here we show that the nuclear levels of the bHLH-PAS protein ARNT2 contribute to the sensitivity or resistance of RCC to belzutifan. Knock down or knock out of ARNT2 in human cancer cell lines renders the cells resistant to belzutifan, while overexpression of exogenous ARNT2 increases the sensitivity of the cells to the anti-proliferative effect of belzutifan in vitro. Belzutifan disrupts preferentially the ARNT-HIF2a but not the ARNT2-HIF2a heterodimers and its effect depends on levels of ARNT-HIF2a. The global gene expression from bulk RNA sequencing in ARNT2 knock out cells clustered with HIF2a overexpression cells in PCA plot analysis and significantly induced detoxification signaling that functionally involved in AhR (Aryl hydrocarbon Receptor) sensor protein. Treatment of cells with belzutifan or an AhR ligand re-arranges these programs based on the nuclear levels of sensor and adaptor molecules. We show that belzutifan and/or AhR agonist, FICZ treatment increased AhR-Luc activity and CYP1A1 expression, which is a target gene of AhR, and affected to the sensitivity to belzutifan.

Summary: Our data suggest that strategies to increase ARNT2 cellular levels may help in combating de novo or acquired resistance to belzutifan.

#0373 Mitochondrial bioenergetics sustain ABCB1-driven temozolomide resistance in glioblastoma multiforme.

Ashutosh Shrivastava[1], Manendra Singh Tomar[1], Chirag Kulkarni[2], Sreyanko Sadhukhan[2], Priyanka Prajapati[3], Amit Lahiri[3], Naibedya Chattopadhyay[2]

[1]Center for Advance Research, King George's Medical University, Lucknow, India,[2]Division of Endocrinology, CSIR-Central Drug Research Institute, Lucknow, India,[3]Division of Toxicology and Experimental Medicine, CSIR-Central Drug Research Institute, Lucknow, India

Glioblastoma multiforme (GBM) is the most aggressive primary brain tumor and remains difficult to treat. Temozolomide (TMZ) is a cornerstone chemotherapeutic agent for GBM; however, the early development of TMZ resistance significantly limits its therapeutic benefit. ATP-binding cassette transporters such as ABCB1 reduce intracellular drug levels through active efflux. We hypothesized that ABCB1 mediates resistance to TMZ through metabolic rewiring. We investigated whether enhanced mitochondrial bioenergetics fuels ABCB1 function and promotes TMZ resistance. To test this, we generated LN-229 cells stably overexpressing ABCB1 and examined metabolic and bioenergetic changes using gas chromatography–mass spectrometry based metabolomics. We also conducted ATP and lactate assays, mitochondrial mass measurements, ROS profiling, and apoptosis analyses. ABCB1 overexpression caused marked metabolic shifts, including increased tricarboxylic acid (TCA) cycle intermediates, glycolytic activity, higher ATP levels, and increased mitochondrial mass. These findings indicate that metabolic alterations potentially fueled ABCB1drug efflux, as evidenced by reduced doxorubicin retention. We next inhibited mitochondrial complex I with metformin, which decreased ATP production, impaired efflux activity, and restored TMZ sensitivity. Combined metformin and TMZ treatment induced increased apoptotis, demonstrated by caspase-3 activation, PARP cleavage, and increased Annexin V-positive cells. Our findings identify mitochondrial metabolism as a key driver of ABCB1-mediated chemoresistance in GBM and suggest that targeting bioenergetic pathways may be an effective strategy to overcome TMZ resistance.

#0374 On-target WRN mutations drive resistance to WRN inhibitors in TA-repeat-expanded MSI cancers.

Gabriele Picco[1], Yanhua Rao[2], Angham Al Saedi[1], Samantha Walker[1], Shriram Bhosle[1], Yang Lee[3], Maria Garcia-Casado[1], Gilberto Valdes Garcia[2], Kieron May[4], Francesco Sassi[5], James P. Phelan[2], Philip Landis[2], Brian Jones[6], Diana Munoz[6], Jay Prakash Jain[6], Paul A. Barsanti[6], Joshua P. Taygerly[6], Michael P. DeMartino[2], Emanuel Goncalves[7], Andrea Bertotti[5], Livio Trusolino[5], Michael A. White[6], Geeta Sharma[3], Matthew A. Coelho[1], Jonathan Houseley[4], Benjamin Schwartz[3], Mathew J. Garnett[1]

[1]Wellcome Sanger Institute, Cambridge, United Kingdom,[2]GSK, Upper Providence, PA,[3]GSK, Cambridge, MA,[4]Babraham Institute, Cambridge, UK, United Kingdom,[5]Candiolo Cancer Institute, Candiolo, Torino, Italy, Italy,[6]IDEAYA Biosciences, South San Francisco, CA,[7]Instituto Superior Tecnico (IST), Lisboa, United Kingdom

Werner helicase inhibitors (WRNi) are in clinical development for microsatellite-unstable (MSI) tumours with defective DNA mismatch repair. A key genetic feature underlying this vulnerability is the expansion of TA dinucleotide repeats, which renders cells selectively reliant on WRN function. Despite this clear synthetic lethality, routes of tumour cell evolution under the selective pressure of WRN genetic loss or inhibition remain entirely unknown. Here, we investigate how cancer cell evolution shapes response to WRN inhibition and informs resistance mechanisms. Genome-wide CRISPR screens combined with complete WRN knockout revealed no bypass pathways, underscoring WRN's essential and non-redundant function in MSI cells. Pharmacogenomic profiling identified modulators of WRNi sensitivity, including the MRN complex, ATM, and SMARCAL1, but none rescued viability, confirming the robustness of the WRN-MSI synthetic-lethal interaction. WRN-MSI synthetic lethality remains robust across diverse models, including patient-derived organoids and immunotherapy-refractory tumours. Using semi-saturation mutagenesis, prolonged drug exposure across cell lines from diverse tissue lineages, and in vivo validation, we identified a spectrum of recurrent on-target WRN mutations driving acquired resistance to multiple WRNi. This was supported by in vivo evidence of acquired WRN mutations in both cell line-derived and patient-derived xenografts treated with HRO761, providing direct preclinical validation of this resistance mechanism. TA repeats, inferred by short-read sequencing and measured by long-read sequencing, remained stable under WRNi treatment and were unlinked to resistance. Resistant clones showed no evidence of MMR restoration or other bypass mechanisms. Some WRN mutations conferred broad cross-resistance, whereas others preserved sensitivity to alternative WRNi; for example, I852F retained sensitivity to VVD-133214 but not to HRO761, whereas F730L conferred pan-resistance to both yet remained vulnerable to GSK4418959. All three compounds are clinically advanced WRN inhibitors currently progressing through Phase I trials. Some differential sensitivity and resistance patterns were also validated in patient-derived organoids that acquired secondary resistance to HRO761 in vitro. Finally, resistant clones remained vulnerable to rational strategies: combining WRNi with irinotecan suppressed resistant outgrowth, while ATR inhibitors and orthogonal WRNi offer additional routes to extend response. These findings establish on-target WRN mutation as the dominant mechanism of resistance to WRN inhibitors and define a framework for resistance-informed clinical trial design. They also outline actionable strategies to detect and overcome resistance, including ctDNA-based molecular monitoring and rational combination therapies to extend clinical benefit.

#0377 Effects of aneuploidy associated RAD21 gain on therapeutic response to PARP inhibition in Ewing sarcoma and prostate cancer.

Chloe Springer[1], Elise DeArment[1], Ruoxi W. Wang[2], Thomas Janas[1], Xiaofeng A. Su[1]

[1]Center for Prostate Disease Research (CDPR), Bethesda, MD,[2]David H. Koch Institue for Integrative Cancer Research, Cambridge, MA

Chromosome 8 (chr8) gain, particularly the gain of its long arm 8q, represents one of the most frequent chromosomal abnormalities across multiple human cancers. In Ewing sarcoma, approximately 50% of cases exhibit chr8 gain while in prostate cancer, high level amplification of 8q occurs in about 24% of primary cases with much higher frequencies in metastatic cases. Across both diseases, the cohesin subunit gene *RAD21*, located on 8q24.11 region, has emerged as a key driver that facilitates chr8 gain by alleviating replication stress associated with oncogene activation. RAD21 is a highly conserved protein essential for establishing sister chromatid cohesin, chromatin looping, DNA replication, transcriptional regulation, and DNA damage repair. Our recent study demonstrated that elevated RAD21 expression correlates with increased cancer-specific mortality in prostate cancer, underscoring its potential role in tumor progression. However, how RAD21 mitigates replication-stress-associated DNA damage and modulates therapeutic response remains poorly understood. To address this gap, we investigated RAD21's role in the DNA damage response (DDR) and treatment resistance using Ewing sarcoma and prostate cancer cell models. Using TurboID-based protein proximity labeling and mass spectrometry, we have demonstrated that RAD21 interacts with several key DNA damage initiating factors upon oncogenic induction including PARP1 and MRE11, suggesting that RAD21 engages with DNA repair initiating and homologous recombination (HR)-associated machinery. Given the clinical use of DNA damage-inducing PARP inhibitors (PARPi) for targeting HR-deficient cancers, we evaluated FDA-approved PARPi in isogenic Ewing sarcoma and prostate cancer cell models engineered to express distinct levels of RAD21. Our data showed that RAD21 overexpression markedly altered the cellular response to PARP inhibition in both models and this effect appears to be independent from cell-cycle regulation, consistent with a potential role for RAD21 enhancing HR-mediated DNA repair. In summary, our findings reveal an often overlooked function of RAD21 in altering DNA repair and influencing the response to therapeutic drugs targeting DNA repair pathways. Dysregulation of cohesin could contribute to therapeutic resistance and a potential biomarker for stratifying patients for DDR-targeted treatments.

#0378 PGRMC1 induced lipid metabolic reprogramming leads to sorafenib resistance in hepatocellular carcinoma.

Poornima Devi Narayanan[1], Abigail Ramirez[2], Jazmin Lopez[2], Mahalakshmi Vijayaraghavan[2], Alfredo Roman[3], Kyle Nguyen[2], Mitchel Amador Rojo[2], Kariina Garcia[2], Kritika Soni[2], Grace Hua[2], Rajkumar Lakshmanaswamy[2], Ramadevi Subramani[2]

[1]Texas Tech University HSC El Paso, El Paso, TX,[2]Texas Tech Univ. Health Sciences Ctr. El Paso, El Paso, TX,[3]TTUHSC, EL PASO, TX

Background: Hepatocellular Carcinoma (HCC) is the most predominant type of liver cancer and are often diagnosed at advanced stage resulting in high rates of mortality. Sorafenib is a first-line medication which increases survival by an average of 10.7 months in patients with advanced patients. However, numerous studies have shown that after six months, patients develop resistance to sorafenib treatment. Therefore, understanding the molecular mechanisms of sorafenib resistance (SR) and determining the most promising therapeutic target for the treatment of HCC is of vital importance. Among the various pathways that lead to the development of SR are disruptions in the lipid homeostasis of HCC. PGRMC1, a protein that regulates lipid metabolism and heme stacking, has been recently identified as an onco-target in a number of malignancies. Thus, we have investigated PGRMC1's role in SR in HCC.
Methods: We established SR-HCC cell lines (Hep3B, HepG2, and Huh7) through a gradual rise in sorafenib dosage. PGRMC1 expression levels in THLE3 (normal liver cell line), parental HCC, and SR-HCC cell lines was assessed. Genetically modified HCC cell lines with PGRMC1 overexpression or silencing were evaluated for SR using cell viability, apoptosis, colony formation, migration, and invasion assays. To investigate the mechanism of PGRMC1-related SR, we conducted RTPCR using lipoprotein signaling and cholesterol synthesis pathway focused microarray. RT^2PCR, immunoblot, and immunofluorescence were utilized to validate the role of PGRMC1 in lipid metabolism associated with SR.
Results: PGRMC1 expression was higher in SR-HCC cell lines in comparison to HCC cells and normal liver cells. Furthermore, overexpression of PGRMC1 increased SR, but the silencing of PGRMC1 in HCC and SR-HCC led to the opposite effect. It is interesting to note that our studies revealed that SR-HCC and ovPGRMC1-GFP-Hep3B cells exhibited higher levels of membrane cholesterol and lipid peroxidation in comparison to parental HCC cells. Moreover, our findings indicate that PGRMC1alters lipid metabolism in HCC by upregulating APOC3, HMGCS2, NR0B2, STARD3, and SREBF2, and downregulating APOD. In addition, our data also demonstrates that inhibition of PGRMC1 effectively enhanced the anticancer effect of sorafenib by altering lipid metabolism in HCC.
Conclusions: We conclude that PGRMC1 is a feasible target for increasing sorafenib sensitivity through reprogramming lipid metabolism.

#0379 Cysteine-driven drug inactivation undermines covalent drug efficacy and drives resistance.

Maximilian Kobiesa, Jennifer A. Brain, Kelli J. Che, Leah G. Rector, Abby C. Jurasin, Sita Kugel, Lucas B. Sullivan

Fred Hutchinson Cancer Center, Seattle, WA

Background: Constitutive activation of ATF4 drives metabolic rewiring in cancer, enhancing tumorigenesis and therapy resistance. A key consequence is upregulation of the cystine/glutamate antiporter SLC7A11, leading to increased cystine import and excessive intracellular cysteine. Cyclin-dependent kinase 7 (CDK7) inhibitors, such as YKL-5-124, are emerging anticancer agents that target proteins essential for cell proliferation. These inhibitors can be subdivided into covalent and noncovalent classes. Covalent drugs, such as YKL-5-124, act via electrophilic warheads that irreversibly react with nucleophilic amino acids, whereas noncovalent drugs, such as SY-5609, inhibit through intramolecular interactions at the protein's active site. We hypothesized that excess intracellular nucleophiles, particularly cysteine, can sequester electrophilic drugs, reducing target engagement, and promoting resistance.
Methods: We quantified the efficacy of CDK7 inhibitors in pancreatic ductal adenocarcinoma (PDAC) cell lines upon treatment conditions that alter cysteine availability. Cell growth was quantified using Sulforhodamine B (SRB) assay following drug exposure. For studies of drug-thiol reactivity, both CDK7 inhibitors were preincubated with freshly prepared cysteine (10:1 ratio, thiol:drug) in degassed PBS on ice for 1 hour, then applied to cells. For LC-MS analysis, polar metabolites were extracted from cells with 80% methanol normalized to total cell volume. Drug metabolites were measured by untargeted LC-MS using a Q-Exactive HF-X Orbitrap.
Results: Pancreatic ductal adenocarcinoma (PDAC) cell lines with high SLC7A11 expression were resistant to the covalent CDK7 inhibitor YKL-5-124 compared to their low-SLC7A11 counterparts. Pharmacological inhibition of SLC7A11 with erastin sensitized high-SLC7A11 cells to YKL-5-124, whereas cotreatment of low-SLC7A11 cells with N-acetylcysteine, a cysteine prodrug, induced resistance. Sensitivity to SY-5609, a noncovalent CDK7 inhibitor, was unaffected by cysteine availability. These results suggested that cysteine may be directly acting upon covalent CDK7 inhibitors to prevent their efficacy. Indeed, pre-incubation with cysteine drastically decreased the efficacy of YKL-5-124, while SY-5609 was unaffected. LC-MS analysis detected YKL-cysteine conjugates in vitro and in cells grown under high-cystine conditions, supporting direct nucleophile-drug adduct formation.
Conclusion: Elevated intracellular cysteine can chemically sequester electrophilic drugs and drive resistance. Ongoing studies aim to determine if cysteine accumulation alone suffices to confer resistance to covalent CDK7 inhibition. These results highlight cysteine metabolism as a therapeutically actionable vulnerability, potentially guiding drug selection and combination regimens for patients receiving covalent inhibitors.

#0380 Chromatin rewiring and transcriptional plasticity drive a distinct dual-resistant state in ovarian cancer.

Won-Young Choi[1], Rachel Perkins[1], Jisun Kang[1], Haoxiang Lyu[1], Matthew S. Jung[1], Xiaoya Hou[1], Wei Li[2], Junming Yue[1], **Wenjing Zhang**[1]

[1]Pathology, University of Tennessee Health Science Center, Memphis, TN,[2]University of Tennessee Health Science Center, Memphis, TN

Background: Resistance to platinum-taxane combination therapy is a major clinical barrier in ovarian cancer (OC), yet the molecular determinants of dual resistance remain poorly defined. Single-agent cisplatin- or paclitaxel-resistant models are well characterized, but whether dual resistance represents an additive or fundamentally distinct state is unknown.
Methods: We performed paired RNA-seq and ATAC-seq on A2780 parental cells and isogenic cisplatin-resistant (CpR), paclitaxel-resistant (TxR), and dual-resistant (TxCpR) derivatives. Differential expression, chromatin accessibility, motif enrichment, and enhancer-promoter integration analyses were used to identify transcriptional and epigenomic features unique to each resistance state.
Results: CpR and TxR cells exhibited expected drug-specific adaptations, including upregulation of DNA repair genes (e.g., MLH1, LIG4) or cytoskeletal regulators and drug-efflux transporters (e.g., ABCB1, ALDH1A1). In contrast, TxCpR cells formed a distinct transcriptional and chromatin state, characterized by a hybrid epithelial-mesenchymal program, activation of developmental pathways, and selective retention of advantageous single-agent resistance traits. ATAC-seq revealed extensive remodeling of distal regulatory elements in TxCpR cells, with enrichment of MAFF, NFATC4, YY1, and ZNF549 motifs, implicating stress-response and chromatin-architectural regulators. Integrative analysis identified TxCpR-specific enhancers, including a CTCF-associated regulatory element near AIM2, suggesting emergent 3D chromatin restructuring that stabilizes dual-resistance transcriptional programs.
Conclusions: Dual resistance to cisplatin and paclitaxel is not a composite of single-agent responses but a reprogrammed regulatory state driven by enhancer remodeling and coordinated transcription factor networks. This dataset provides a unique paired RNA-seq/ATAC-seq resource and identifies candidate enhancer and architectural dependencies that may be therapeutically targetable in multidrug-resistant OC.

#0381 β-Hydroxybutyrate-mediated lysine butyrylation determines therapy response in liver cancer.

Minghe Zhang, Yunong Xie, Linglin Liu, Yimiao He, Carol Man Carol Tong

The Chinese University of Hong Kong, HONG KONG, Hong Kong

Hepatocellular carcinoma (HCC) has been a major public health concern worldwide for decades because of its high mortality rates and poor prognosis, which are attributable to frequent tumor relapse and limited treatment strategies. Lenvatinib is one of the tyrosine kinase inhibitors approved for first-line treatment of advanced HCC, but its efficacy remains modest. Growing evidence suggests that the unsatisfactory survival benefits of lenvatinib could be attributed to the acquired drug resistance developed in HCC patients. In this study, we aim to explore the intrinsic metabolic vulnerability which could be exploited to enhance the treatment efficacy of lenvatinib in HCC. Metabolomic profiling of lenvatinib-resistant HCC mouse models revealed significant alterations in the butanoate metabolism pathway, with β-hydroxybutyrate (BHB) identified as the most deregulated metabolite. Functional assays demonstrated that BHB treatment inhibited HCC cell proliferation and synergistically enhanced lenvatinib-induced apoptosis. Consistent with in vitro findings, BHB administration in HCC patient-derived xenograft models produced synergistic tumor-suppressive effects with lenvatinib. Combination treatment of lenvatinib and ketogenic diet which induces BHB level could drastically attenuate tumor development in mice bearing tumors. This study presents a potentially translatable combination treatment strategy to potentiate the therapeutic efficacy of lenvatinib in advanced HCC.

#0382 Exploring the role of LONP1 in lon-traditional mechanisms of glioblastoma resistance.

Shashi Jain[1], Dahlia A. Ordaz[2], Javier Lepe[2], Naomi Lomeli[2], James Pham[2], Bhaskar Das[3], Daniela A. Bota[4]

[1]Department of Neurology, School of Medicine, University of California Irvine, Irvine, CA,[2]UCI School of Medicine, Irvine, CA,[3]School of Pharmacy and Pharmaceutical Sciences,, SUNY, NY., NY,[4]Department of Neurology, University of California Irvine, Irvine, CA

Temozolomide (TMZ) continues to serve as the frontline chemotherapy for glioblastoma (GBM), yet its long-term efficacy remains critically compromised due to the emergence of treatment resistance. While the DNA repair enzyme O6-methylguanine-DNA methyltransferase (MGMT) is the well-known contributor to TMZ resistance, clinical observations have shown that even tumors with minimal or silenced MGMT expression eventually acquire resistance, indicating additional, MGMT-independent pathways are involved. To investigate these alternative resistance mechanisms, we established two distinct glioblastoma models: TMZ-resistant (TR) cells characterized by high MGMT expression, and O6-Benzylguanine and TMZ-resistant (OTR) cells exhibiting low MGMT levels relative to parental controls. Our extensive analyses reveal a key function of the mitochondrial protease LonP1 in promoting TMZ resistance through metabolic adaptation. Both TR and OTR cell lines demonstrated significantly upregulated LonP1 expressions compared to parent glioblastoma cells, implicating elevated LonP1 as a central mediator in resistance development.Functional studies underscore that increased LonP1 expression contributes to a metabolic shift within resistant glioblastoma cells, transitioning from glycolytic metabolism towards enhanced oxidative phosphorylation (OXPHOS). This metabolic reprogramming equips resistant cells with improved capacity to sustain energetic and biosynthetic demands under TMZ-induced therapeutic stress. To validate LonP1's causal role in resistance, we genetically overexpressed LonP1 in established glioma and patient-derived glioblastoma cell lines, resulting in robust acquisition of TMZ resistance. Conversely, downregulating LonP1 via targeted knockdown or pharmacologic inhibition restored sensitivity to TMZ, reducing cell viability and disrupting mitochondrial integrity. It is noteworthy that while our data firmly establish the necessity of LonP1 in maintaining TMZ resistance, the sufficiency of LonP1 overexpression to initiate resistance de novo in naïve tumor cells remains untested, as LonP1 knockout models were not leveraged for resistance induction.Collectively, our findings identify mitochondrial LonP1 protease as a promising target to overcome TMZ resistance in glioblastoma therapy. Inhibition of LonP1 activity could potentially reverse metabolic adaptations, thereby resensitizing resistant tumor cells to TMZ and improving treatment efficacy. This study provides a strong rationale for developing LonP1-targeted therapeutics as adjunctive agents in standard TMZ chemotherapy regimens, with the hope of delaying or reversing chemoresistance to improve clinical outcomes for glioblastoma patients.

#0383 Single-cell transcriptomic analysis of treatment-persistent residual disease in BRAF-mutant lung adenocarcinoma.

Constance Nicq[1], Etienne Vignaud[1], Alice Da Silva[2], Raphael Schneider[1], Genevieve De Souza[1], Ludovic Bigot[2], Aurelie Swalduz[1], Olivier Calvayrac[3], Pierre Saintigny[1], Luc Friboulet[4], **Sandra Ortiz-Cuaran**[1]

[1]Univ Lyon, Claude Bernard Lyon 1 University, INSERM 1052, CNRS 5286, Centre Leon Berard, Cancer Research Center of Lyon, Lyon, France,[2]Paris-Saclay University, Gustave Roussy, INSERM U981, Villejuif, France,[3]Centre de Recherches en Cancerologie de Toulouse,[4]Paris-Saclay University, Gustave Roussy, INSERM U981, Villejuif, France., Villejuif, France

Despite the encouraging results of BRAF-targeted therapies (BRAF-TT) in *BRAF*-mutant lung adenocarcinoma (LUAD), most tumor responses are only partial and limited in time, and ultimately all patients develop resistance to treatment. The limited number of pertinent preclinical models of *BRAF*-mutant LUAD has hindered the identification of molecular determinants of BRAF-TT response. In this context, treatment resistance may emerge from a subpopulation of drug-tolerant persister cells (DTP) that survive to treatment through early, non-genetic tumor cell adaptation, and might constitute the source of incomplete tumor responses and disease recurrence.

Here, we assessed the prevalence and dynamics of cell states associated with DTP in patient-derived LUAD models and established LUAD cell lines representing each of the three *BRAF* mutation classes.

Upon treatment with BRAF-TT (either with combined BRAF/MEK inhibitors or EGFR/MEK inhibitors), DTP exhibit different transcriptomic cell states, compared to treatment-naïve (TN) populations, in V600E, G469A and G466V-mutant cell lines and in a patient-derived organoid (PDO), generated from a G469A-mutant LUAD resected specimen. A small fraction of cycling DTP was observed in V600E and G469A cell lines. In both established cell lines and PDO, DTP systematically display features of phenotypic plasticity depicted by the enrichment of gene signatures related to epithelial-to-mesenchymal transition (EMT) and cell adhesion. Moreover, gene signatures associated with a dedifferentiation phenotype (i.e., alveolar and embryonic diapause) were increased in G469A treatment-residual organoids and cell lines but unchanged V600E-mutant cells.

In V600E-mutant cells and G469A-mutant PDO we identified a transition-like cluster, including subpopulations of DTP and TN cells, characterised by enriched EMT and cell migration signatures, down-regulation of G2/M checkpoint and intermediate “drug-tolerant_up” scores, suggesting that these constitute early events of BRAF-TT adaptation. Of note, in a BRAF-TT resistant patient-derived xenograft (PDX), scRNAseq revealed the presence of six different transcriptomic cell states, including a DTP-like cluster: increased “drug-tolerant_up” and embryonic diapause scores, and deregulation of G2/M checkpoint, denoting the dynamic nature of the DTP-like phenotype under treatment.

Trajectory and gene regulatory network bionformatic analyses are ongoing, together with functional experiments, to determine the role of phenotypic plasticity in treatment-persistent residual disease in BRAF-mutant LUAD.

Our results show evidence on how BRAF-mutant LUAD DTP remodel their molecular portraits at the single-cell level, and provide insights into the pertinence of these models to study treatment-residual disease in *BRAF*-mutant LUAD.

#0385 A genome derived non coding reporter of dynamic cancer cell state.

Noha Shendy[1], Yang Zhang[2], Stephanie Nance[2], Ha Won Lee[1], Shivendra Singh[1], Yousef Khashana[2], Vernon Ebegboni[2], Estevez Prado Daniel[2], Mohammad Ali Mohammad Nezhady[1], K. Pharmacology, St. Jude Children's Research Hospital, Memphis, TN,[6]Associate Member, Chemical Bio. & Therapeutics, St. Jude Children's Research Hospital, Memphis, TN

Sequential changes in transcriptional cell state are essential for normal development and are coopted in cancer. Controlling these changes for therapeutic benefit has been limited due to a lack of tools that reflect different states in live cells. Here, we describe a new reporter method termed “TRECS” that integrates epigenomic and transcriptomic measurements to define endogenous genomic elements that label individual cells in different cell states. We use TRECS in the neural crest-derived, high-risk pediatric solid tumor neuroblastoma, where we demonstrate broad presence of cells with distinct transcriptomes, associated with functional chemoresistance and sensitivity. Experiments using neural crest stem cells and TRECS mouse knock-in model identified that TRECS-labelled cells reflect early developmental stages in the neural crest. These cells display real-time plasticity of transcriptional state and phenotype, in a manner unlinked to cell cycle control. Investigation of nominated loci demonstrates state-specific enrichment of elements marked by H3K27ac, H3K4me1 and open chromatin by ATAC-seq, which flexibly change as cells transition between these phenotypically divergent states. To investigate whether the primary nominated locus is a driver or reporter of cell state, we integrate micro-C, transcriptomics, truncation experiments and functional CRISPRi to identify that this region functions as a pure endogenous reporter of cell state. This, therefore, provides a mechanism to identify new, state-controlling transcription factors. Motif analysis demonstrated enrichment of AP1 transcription factor motifs in the chemoresistant state, and knockout of these AP1 transcription factors results in rewiring of cell state and enhanced chemosensitivity without effects on cell growth. To capitalize on the endogenous flexibility in this system and identify mechanisms to enforce cell state changes independent of cell growth and death, we performed high-content image-based small molecule screening to identify targets suitable to enhance chemosensitivity. These experiments identified EP300/CBP, master histone acetyltransferases, as crucial controllers of a primitive, chemoresistant cell state. Transient acetyltransferase and bromodomain-based inhibition of EP300/CBP results in transcriptional and epigenetic reprogramming *in vitro* and *in vivo*, leading to enhanced chemosensitivity and prolonged survival in murine models. These results demonstrate an unbiased method to identify non-coding genomic loci enriched in specific cell states, which can be harnessed to identify master transcription factors driving these cell states and similarly, mechanisms to enforce changes in cell state.

#0386 Targeting the YBX1-SREBP2 axis to overcome drug resistance in hepatocellular carcinoma.

Veerababu Nagati, Yamile Abuchard Anaya, Miguel Salazar, Kaylee Renteria, Ricardo Pequeno Bracho, Manish K Tripathi

Medicine and Oncology ISU, South Texas Center of Excellence in Cancer Research, The Univeristy of Texas Rio Grande Valley, McAllen, TX

Hepatocellular carcinoma (HCC) is a leading cause of cancer-related death worldwide, with limited treatment options and poor outcomes. Multikinase inhibitors remain the first-line therapy for advanced HCC. However, therapeutic resistance remains a significant challenge in HCC, and the molecular mechanisms underlying metabolic adaptation to drug resistance remain poorly understood. Here, we identify Y-box binding protein 1 (YBX1) as a key regulator of cholesterol metabolism that promotes tumor growth and drug resistance in HCC. Multi-omics and mechanistic analyses reveal that YBX1 transcriptionally activates Sterol Regulatory Element-Binding Protein 2 (SREBP2), a critical master regulator of cholesterol metabolism, and suppresses the cholesterol efflux transporter ABCA1, resulting in increased expression of cholesterol biosynthetic enzymes and intracellular cholesterol accumulation. Additionally, Cholesterol modulates TGFβ signaling and is implicated in drug resistance. This metabolic rewiring stabilizes membrane receptor tyrosine kinases (RTKs) and sustains downstream PI3K/Akt/mTORC1 and EMT signaling pathways, thereby fostering the development of drug resistance. Genetic silence or pharmacological inhibition of YBX1 or SREBP2 with SU056/Betulin restores sorafenib sensitivity and reduces tumor growth. Clinically, higher levels of YBX1 and SREBP2 expression are associated with poor therapeutic response and decreased overall survival in patients with HCC. These findings uncover a YBX1/SREBP2/Cholesterol metabolic axis that mediates adaptive resistance, offering a new therapeutic target to overcome drug resistance in HCC.

Keywords: Hepatocellular carcinoma, Drug resistance, YBX1, SREBP2, Cholesterol metabolism, Akt/mTOR signaling.

#0387 Precision combination therapy opportunities in colorectal cancer revealed by PDX drug screening.

Alexey Sorokin[1], Preeti Kanikarla Marie[1], Jay Saynonh[1], Christian Beke Onana[1], Fengqin Gao[1], Zhensheng Liu[1], Maya Ridinger[2], Scott Kopetz[1]

[1]UT MD Anderson Cancer Center, Houston, TX,[2]Cardiff Oncology, Inc., San Diego, CA

Colorectal cancer (CRC) exhibits extensive molecular heterogeneity driven by oncogenic alterations such as KRAS, NRAS, and BRAF mutations. Despite the promise of targeted therapies, clinical responses are variable and often limited by resistance, underscoring the need for improved molecular stratification and rational combination strategies. We conducted large-scale in vivo drug screening using 140 patient-derived xenograft (PDX) models representing key CRC molecular subtypes: KRAS G12C (n=40), RAS/RAF wild-type (n=40), and BRAF V600E (n=60). Models were treated with standard-of-care agents, including anti-EGFR, BRAF/EGFR, and KRAS G12C/EGFR inhibitors. Tumor responses were assessed alongside molecular profiling via whole-exome sequencing, RNA sequencing, and Reverse Phase Protein Array. Integrated multi-omics analyses identified biomarkers of response and resistance mechanisms. Resistant tumors frequently exhibited MAPK reactivation and RTK/PI3K-AKT pathway activation. BRAF V600E models showed heterogeneous responses to BRAF/EGFR inhibition (40% disease control), which improved with co-targeting of PI3K or downstream MAPK components. RAS/RAF wild-type models responded to anti-EGFR therapy (100% in treatment-naïve; 40% in pretreated), with resistance driven by RTK signaling mitigated via MAPK inhibition. KRAS G12C models demonstrated modest responses to KRAS/EGFR inhibitors (70% disease control), enhanced by SOS1, SHP2, or AKT inhibition. Additional genotype-specific vulnerabilities, including WEE1 and EZH2 sensitivity in KRAS G12C tumors, support rational combination strategies. This comprehensive PDX-based screen delineates actionable, genotype-specific vulnerabilities in CRC and provides a preclinical framework for precision combination therapies to guide future clinical trials.

#0388 DYRK1A-mediated quiescence establishes a therapeutically-resistant reservoir for glioblastoma recurrence.

Ameesha Paliwal[1], Kevin Faust[2], Okty Abbasi Borhani[2], Rifat S. Sajid[1], Evelyn R. Kamski-Hennekam[2], Ingrid Jin[1], Johnny L. McRae[2], Anzar Alvi[2], Parsa Babaei Zadeh[2], Dimitrios G. Oreopoulos[2], Lauren Omoto[1], Phedias Diamandis[2]

[1]Laboratory Medicine and Pathobiology, University of Toronto, Toronto, ON, Canada,[2]Princess Margaret Cancer Centre, Toronto, ON, Canada

Glioblastoma (GBM) is the most common and aggressive primary brain cancer in adults, owed to its extensive intratumoral heterogeneity and rapid disease progression. It is hypothesized that standard-of-care radio- and chemotherapy (temozolomide) treatments act as evolutionary pressures to select a minority subpopulation of temporally stable cells, which seed aggressive, therapeutically resistant recurrent tumors. This study aims to identify and target the therapeutic vulnerabilities of treatment-resistant GBM cells at diagnosis to proactively address disease progression.

We developed and applied a deep learning model to analyze whole patient-matched primary and recurrent GBM specimens to nominate temporally stable cell populations by conserved morphology, successfully identifying these cells in 31 of 40 analyzed cases. Morphologic feature analysis of nominated populations revealed irregular nuclear shape metrics consistent with mesenchymal histology, including reduced nucleus circularity (-8.6%; $p<0.0001$; $n=18$), increased nuclear axis length (+8.2%; $p<0.01$; $n=18$) , and increased cell area (+13.0%; $p<0.05$; $n=18$). Features of stable cells further correlated with a 38.6% reduction in overall survival in an external glioma cohort ($p<0.05$; $n=51$). To define molecular mechanisms underpinning stability, we performed mass spectrometry-based proteomic profiling of matched clinical specimens, which revealed the enrichment of DYRK1A-mediated cell quiescence programs via the DREAM complex as a potential mechanism for chemotherapy evasion ($p<0.01$; $n=36$). Consistent with a quiescence-driven resistance mechanism, Ki67 immunohistochemistry staining demonstrated a 47.5% reduction in the proliferative index of stable subpopulations in the primary tumor compared to the tumor bulk ($p<0.05$; $n=9$). To model these observations in vitro, we cultured CRISPR-Cas9 DYRK1A overexpressing GBM cells in an ex vivo mouse brain slice model and evaluated the effects of temozolomide administration. DYRK1A overexpression was found to ablate chemotherapy-induced GBM cell death in patient-derived cultures, compared to wildtype controls ($p<0.05$), confirming a functional role for DYRK1A in establishing therapeutic resistance in vitro.

Pre-clinical studies of DYRK1A/DREAM complex inhibition have been shown to reverse tumour cell quiescence and sensitize resistant cells to chemotherapy in extra-CNS cancers. These findings extend this concept to GBM and support strategies to target drivers of therapeutic resistance at diagnosis. Current therapeutic approaches in GBM are limited to reducing disease burden; this study informs interventions to proactively anticipate and interrupt disease progression.

#0389 GSDMB drives cGAS-STING-mediated immune evasion in HER2-amplified colorectal cancer.

Junyong Weng[1], Tianchen Xiong[2], Xinxiang Li[3], Ajay Goel[4]

[1]Beckman Research Institute of The City of Hope, Duarte, CA,[2]City of hope, DUARTE, CA,[3]Fudan shanghai cancer center, Shanghai, China,[4]City of Hope, Duarte, CA

Background: HER2-amplified metastatic colorectal cancer (CRC) represents an aggressive disease subtype with poor prognosis and limited response to standard therapies. The molecular mechanisms underlying its malignant behavior and immune evasion, particularly the contribution of specific genes and signaling pathways involved in tumor progression and immune regulation, remain insufficiently defined. This study investigated the biological mechanisms driving tumor progression and immune escape in HER2-amplified CRC.
Methods: We analyzed GSDMB and HER2 expression, copy number variations (CNVs), and patient survival in The Cancer Genome Atlas (TCGA) cohort, and compared expression across clinical stages, BRAF mutation status, and microsatellite status. Mechanistic studies, including RT-qPCR, western blotting, flow cytometry, and immunofluorescence, were conducted to evaluate the effects of GSDMB overexpression on mitochondrial integrity, activation of the cGAS-STING pathway, and immune-related molecule expression. Transcriptome analyses were conducted to identify pathways enriched in GSDMB-high tumors.
Results: GSDMB was the most significantly co-enriched gene in HER2-high CRC (FDR<0.001). Although overall GSDMB expression was not associated with survival (p=0.55), high expression predicted poorer survival in stage IV patients (p=0.005). GSDMB and HER2 are adjacent on the chromosome, and HER2 amplification was consistently accompanied by GSDMB co-amplification; all patients with GSDMB CNV gains (6.4%) or losses (0.3%) showed corresponding HER2 CNV changes. GSDMB expression was significantly elevated in BRAF-mutant (p<0.001) and MSI-H (p<0.001) tumors. Transcriptomic analyses revealed that GSDMB overexpression was associated with enrichment of HER2 signaling and IFNα Response pathways (FDR<0.001). Experimental validation demonstrated that GSDMB overexpression induced mitochondrial membrane pores, resulting in chronic, low-level leakage of mitochondrial double-stranded DNA into the cytoplasm, which activated the cGAS-STING pathway and induced chronic type I interferon responses. This, in turn, upregulated immune checkpoint molecules, impaired antigen presentation, and promoted T cell exhaustion/tolerance.
Conclusion: GSDMB is a recurrently co-amplified gene in HER2-amplified CRC and remodels the tumor immune microenvironment via mitochondrial dysfunction and chronic cGAS-STING/type I interferon signaling, driving immune evasion. Although GSDMB alone is not prognostically significant across all stages, it elevated expression predicts poor outcomes in advanced metastatic disease. These findings highlight GSDMB and its downstream immune pathways as promising therapeutic targets and prognostic biomarkers in HER2-amplified CRC.

#0390 Single cell multiomics reveals evolutionary and epigenomic trajectories of PARP inhibitor resistance in BRCA mutant TNBC.

Wei Hong[1], Pavan Kumar[1], Faiza Baameur Hancock[2], Helen M. Piwnica-Worms[3], **Mahinur Mattohti**[1]

[1]Houston Methodist Research Institute, Houston, TX,[2]UT MD Anderson Cancer Center, Houston, TX,[3]Vice Provost, Science, UT MD Anderson Cancer Center, Houston, TX

Poly (ADP-ribose) polymerase (PARP) inhibitors show marked efficacy in BRCA-mutant triple-negative breast cancer (TNBC), yet nearly half of patients treated with neoadjuvant PARP inhibition fail to achieve pathological complete response, revealing a major obstacle of intrinsic and therapy-induced resistance. To dissect the mechanisms enabling tumor persistence, we performed integrated single-cell transcriptomic and chromatin-accessibility profiling on paired pre- and post-treatment patient-derived xenograft (PDX) samples from a Phase II trial of single-agent talazoparib in germline BRCA1/2-mutant TNBC. This multi-omic framework resolved therapy driven remodeling of tumor ecosystems and gene regulatory circuitry at cellular resolution. We uncover that rare, pre-existing homologous-recombination proficient subclones selectively expand under PARP inhibition and act as reservoirs for residual disease. Network-level integration of expression and chromatin accessibility further revealed extensive epigenomic rewiring in therapy-induced resistant populations, characterized by elevated DNA-repair activity, metabolic reprogramming, and activation of survival pathways. We also identify candidate master transcription factors that likely orchestrate these resistance-associated regulatory states. Collectively, our findings delineate the evolutionary routes by which BRCA-mutant TNBC evades PARP inhibition and highlight how both baseline HRR-proficient subpopulations and transcription factor driven chromatin reprogramming shape therapeutic outcome. These insights nominate actionable vulnerabilities that may be exploited to prevent or overcome resistance and enhance the durability of PARP-inhibitor therapy.

#0391 TROP2 and PTEN are biomarkers of primary resistance to *TUSC2* gene therapy in non-small cell lung cancer (NSCLC).

Ismail M. Meraz[1], Renduo Song[1], Shuhong Wu[1], Yi Xu[1], Meng Feng[1], Lihui Gao[1], Chenghui Ren[1], Qi Wang[2], Jun Li[3], Mourad Majidi[1], Jing Wang[2], Mark Berger[4], Jack A. Roth[1]

[1]Thoracic and Cardiovascular Surgery, UT MD Anderson Cancer Center, Houston, TX,[2]Bioinformatics & Computational Biology, UT MD Anderson Cancer Center, Houston, TX,[3]School of Data Science and Society, University of North Carolina, Chapel Hill, NC,[4]Genprex Inc., Austin, TX

Primary resistance to targeted therapies, immunotherapies, and gene therapies in NSCLC continues to be a significant challenge. *TUSC2* tumor suppressor gene therapy has shown promising anti-tumor efficacy by overcoming resistance to targeted therapy and enhancing checkpoint blockade immunotherapy, including in a mutant *KRAS/LKB1*-driven immunotherapy-resistant NSCLC model. *TUSC2* protein expression is downregulated or absent in over 80% of NSCLC and 100% of SCLC cases., TUSC2 mediates cancer cell death through several mechanisms: inhibiting MAPK and mTOR signaling pathways, arresting cell growth, inducing programmed cell death, and activating immune responses. We established models primarily resistant to *TUSC2* gene therapy to find biomarkers indicative of *TUSC2* gene therapy resistance in NSCLC patient-derived xenografts (PDXs), PDX-derived organoids (PDXOs), and cell lines. A panel of 10 NSCLC cell lines screened for *TUSC2* sensitivity showed resistance in 50% of the cell lines, as assessed by annexin V staining and colony formation assays. We evaluated *TUSC2* sensitivity in 12 NSCLC PDXOs using ATP-based viability assays in 3D culture following TUSC2 or empty vector transfection. While some PDXOs were highly responsive to *TUSC2* within 72 hours post-transfection, 50% of PDXOs exhibited primary resistance. We developed TC314AR (Acquired Resistance) PDX tumors and xenograft models (A549, H1299, H23AR) in NSG mice and treated them with *TUSC2* gene therapy. 20-30% of tumors in every model showed resistance, with no significant reduction in size compared to the control tumors after treatment. Protein expression profiling using reverse-phase protein array (RPPA) analysis of 500 proteins showed distinct expression signatures, with several candidate biomarkers significantly altered in resistant cell lines and PDXOs. RPPA analysis of residual tumors from both the xenograft and PDX models revealed significant but model-specific alterations in protein expression between responders and non-responders. Comparative analyses across the three models showed low expression of TROP2 and high expression of PTEN as potential biomarkers of primary resistance. Overexpression of TROP2 in H1299 and H460 cells increased *TUSC2-induced* apoptosis. These findings suggest that TROP2 and PTEN may serve as biomarkers to predict *TUSC2* response and guide therapeutic strategies in NSCLC.

#0392 EMT-like reprogramming drives drug-tolerant persister cell plasticity in mantle cell lymphoma via ribosome biogenesis.

Wei Wang[1], Yang Liu[1], Heng-Huan Lee[1], Fangfang Yan[1], Yue Fei[1], Yijing Li[1], Chengtai Yu[1], Lin Tan[1], Lorenzi Phil[2], Qingsong Cai[1], Lei Nie[1], Michael Wang[1]

[1]UT MD Anderson Cancer Center, Houston, TX,[2]City of Hope, Los Angeles, CA

Epithelial-mesenchymal transition (EMT) is an evolutionarily conserved developmental program frequently co-opted in solid tumors to drive metastasis and therapy resistance. Whether analogous transcriptional and metabolic machinery operates in blood cancers has remained unexplored. Here, we demonstrate—for the first time—that drug-tolerant persister (DTP) cells in mantle cell lymphoma (MCL), a lethal non-Hodgkin's lymphoma, exploit an EMT-like program distinct from cancer stem cell pathways to establish stable resistance to BTK inhibitors (BTKi) and anti-CD19 CAR T-cell therapy. Using pirtobrutinib (a clinically approved non-covalent BTKi), we established a reproducible, non-stochastic DTP cell model in MCL. Integrated RNA sequencing and ultra-high-resolution metabolomics revealed that therapeutic pressure triggers a striking morphogenetic switch: proliferative lymphoma cells transform into enlarged, quiescent "Giant cells" characterized by profound dedifferentiation and loss of B-cell identity (including CD19). Upon drug withdrawal, Giant cells rapidly revert to proliferative, normal-sized progeny, exposing a previously unrecognized reversible plasticity in hematologic malignancies. Mechanistically, DTP cells rewire the TCA cycle by engaging the malate-aspartate shuttle, sustaining anabolic metabolism during drug exposure. Drug removal abruptly shifts the TCA cycle to catabolic mode, fueling re-entry into cell cycles. This metabolic switch orchestrates global transcriptomic reprogramming and elevates acetyl-CoA levels, which stabilize the core EMT transcription factor SNAI1 via non-histone protein acetylation. Remarkably, acetylated SNAI1 translocates to nucleoli, driving explosive ribosome biogenesis (marked by fibrillarin upregulation)—a hallmark less studied in conventional EMT of epithelial cancers. Perturbing ATP-citrate lyase (ACLi), SNAI1, or fibrillarin disrupts this axis: ACLi/SNAI1 blockade accelerates exit from the Giant cell state, whereas fibrillarin loss traps cells in quiescence, collectively ablating DTP plasticity and restoring therapy sensitivity. In therapy-refractory MCL patients, DTP/Giant cells can be dynamically abundant—far exceeding classic minimal residual disease—and detectable by immunohistochemistry, metabolic imaging, and single-cell RNA sequencing. Thus, unlike solid tumors where EMT primarily enables invasion, blood cancers repurpose this ancient developmental program for metabolic resilience and immune evasion. Our work establishes that an EMT-like network, orchestrated by metabolic reprogramming and nucleolar SNAI1-driven ribosome biogenesis, governs DTP cell fate in MCL. Targeting this axis—particularly ribosome biogenesis—offers a transformative strategy to eradicate persister cells and overcome resistance to BTKi and CAR T-cell therapy.

#0393 Uncovering mechanisms of PARP inhibitor resistance in IDH1-mutant cancers via serial tumor transplantation and genome wide CRISPR-Cas9 knockout screen.

Daniel Andres Colon-Rios[1], Jonathan Dow[1], Adam Krysztofiak[1], Yanfeng Liu[2], Faye A. Rogers[1], Peter M. Glazer[1]

[1]Department of Therapeutic Radiology, Yale School of Medicine, New Haven, CT,[2]Yale School of Medicine, New Haven, CT

Over the last two decades, novel cancer therapies have targeted genetic profiles identified through whole exome sequencing data, including mutations in the homology-directed repair (HDR) proteins breast cancer-associated genes 1 and 2 (BRCA1 and BRCA2), as well as cancer-linked mutations in isocitrate dehydrogenase (IDH), an essential tricarboxylic acid cycle enzyme. Our group and others recently reported that cancers harboring IDH1/2 mutations have defective recruitment of HDR factors to sites of DNA damage due to changes in chromatin dynamics and consequent sensitivity to poly(ADP-ribose) polymerase inhibitors (PARPi). These findings have led to multiple clinical trials exploiting this vulnerability to PARPi monotherapy and combinatorial therapy. To investigate potential mechanisms by which PARPi resistance might arise, we first modeled PARPi-resistance in IDH1-mutant tumors via serial transplantation of patient-derived xenografts in mice treated with the PARPi talazoparib. An analysis of candidate DNA repair factors in these resistant tumor populations revealed downregulation of end protection factors 53BP1, RIF1 and REV7—which are established negative regulators of HDR. Knockout of these factors by CRISPR/Cas9 in IDH1-mutant cancer cells conferred robust resistance to PARPi and restored HDR capacity, supporting the initial observation that mutations in IDH confer a fundamental HDR defect. To overcome this resistance, we found that treatment with the receptor tyrosine kinase inhibitor, cediranib, previously reported to suppress expression of downstream HDR factors, resensitizes these PARPi-resistant cells to PARPi treatment. As a next step, a genome wide CRISPR-Cas9 knockout screen is underway to uncover undescribed mechanisms PARPi resistance in IDH-mutant tumors. Our findings identify key pathways driving PARPi resistance in IDH1-mutant cancers and highlight potential therapeutic strategies to overcome this resistance.

#0394 Adaptive resistance mechanisms to mTOR inhibitor in lung squamous cell carcinoma.

Milica Momcilovic

UCLA David Geffen School of Medicine, Los Angeles, CA

Resistance to small molecule inhibitors targeting key metabolic pathways in lung tumors remains a significant challenge in personalized cancer therapy. In this study, we investigated the mechanisms of resistance to the small molecule mTOR inhibitor TAK228 across lung squamous cell carcinoma (LUSC) models, including cell lines, xenografts, and patient-derived xenografts (PDXs). Our findings reveal that LUSC cells adapt to mTOR inhibition by engaging macropinocytosis, a form of endocytosis that facilitates enhanced uptake of extracellular nutrients, thereby increasing amino acid availability. Co-inhibition of both mTOR and macropinocytosis using small molecule inhibitors effectively reduced tumor growth. Additionally, we identified angiogenesis as a key mechanism limiting the efficacy of mTOR inhibition in vivo. Notably, inhibiting angiogenesis in combination with inhibitors of mTOR and macropinocytosis reduced tumor growth in xenografts and PDXs. Moreover, prolonged treatment of LUSC PDXs with TAK228 and the glutaminase inhibitor CB-839 led to upregulation of vascularization, which coincided with a rebound in tumor growth despite continued therapeutic administration. These findings highlight adaptive resistance mechanisms to small molecule inhibitors that target key metabolic pathways, lending insight into potential future clinical strategies for the treatment of LUSC.

#0395 Identification of drug resistance factors in ALK-rearranged lung cancer using genome-wide CRISPR activation screening.

Mai Nagasaka, Marie Kawahara, Ken Uchibori, Makoto Nishio, Ryohei Katayama

Japanese Foundation for Cancer Research, Tokyo, Japan

Anaplastic lymphoma kinase (ALK)-rearrangements occur in approximately 2-5% of non-small cell lung cancers (NSCLC). Several ALK tyrosine kinase inhibitors (ALK-TKIs) have been developed, and six are currently approved for clinical use. Although these therapies have markedly improved clinical outcomes, most patients eventually relapse due to acquired drug resistance, which remains a significant clinical challenge and limits long-term survival. To date, numerous mechanisms of ALK-TKI resistance have been identified, including secondary mutations in the ALK kinase domain and activation of bypass signaling pathways, such as EGFR or MET. However, in a significant number of cases, the underlying mechanisms remain unknown, highlighting the need for unbiased approaches to identify novel drivers of ALK-TKI resistance. In this study, we first performed a genome-wide CRISPR activation (CRISPRa) gain-of-function screen in patient-derived ALK-positive NSCLC cell lines to identify genetic pathways conferring resistance to ALK-TKIs. The CRISPRa system enables sgRNA-directed activation of endogenous genes via dCas9-VP64, a nuclease-dead Cas9 fused to the transcriptional activator VP64. In JFCR-028-3 cells expressing dCas9-VP64, introduction of sgEGFR or sgMET led to upregulation of the targeted proteins and conferred resistance to ALK-TKIs. For the genome-wide CRISPRa screen, cells expressing dCas9-VP64 were transduced with a pooled sgRNA library targeting over 18,000 genes. The in vitro CRISPRa screen was performed by culturing the cells with alectinib, lorlatinib, or brigatinib for nine days, and sgRNAs enriched in the surviving drug-tolerant cells were analyzed by next-generation sequencing. The top-ranked hits in JFCR-028-3 included receptor tyrosine kinases (RTKs) such as EGFR, MET, and FGFR1, as well as the anti-apoptotic factor BCL2. Gene ontology analysis further revealed significant enrichment of pathways related to cell proliferation, RTK signaling, and regulation of apoptotic signaling among the hit genes. The screens with the three ALK-TKIs identified both shared and drug-specific hit genes, which may reflect differences in their off-target inhibitory profiles. Furthermore, the in vivo CRISPRa screen revealed top hits that differed from those in vitro, with enrichment of ligand-dependent factors, including EGFR and KIT, reflecting the influence of the physiological microenvironment. Together, these results reveal multiple novel factors responsible for ALK-TKI resistance, providing insight into previously unidentified mechanisms.

#0396 Nrf2 role in regulating kaempferol's inhibitory action on CDKs, PD-L-1, CCL2, and TGM2 in triple-negative breast cancer cells.

Sukhmandeep Kaur[1], Patricia Mendonca[1], Shubham D. Mishra[1], Karam F. a. Soliman[2]

[1]Pharmaceutical Sciences, Florida A&M University College of Pharmacy & Pharmaceutical Sciences, Tallahassee, FL,[2]Florida A&M University College of Pharmacy & Pharmaceutical Sciences, Tallahassee, FL

Triple-negative breast cancer (TNBC) is one of the most aggressive forms of breast cancer, marked by rapid progression, high recurrence, and limited treatment options. Emerging evidence suggests that both oxidative stress signaling and the tumor immune microenvironment (TIME) contribute to therapy resistance in TNBC. Kaempferol, a naturally occurring flavonoid found in fruits and vegetables, has shown promise as a multi-target anticancer compound, but its mechanisms of action remain incompletely understood. In this study, we explored how kaempferol regulates tumor growth, immune checkpoint activity, and inflammatory mediators in two genetically distinct TNBC cell lines, MDA-MB-231 (Caucasian) and MDA-MB-468 (African American). The results showed that kaempferol significantly reduced cell viability and proliferation, induced apoptosis, and caused S-phase cell cycle arrest by inhibiting the expression of CDK1, CDK4, CDK6, and CDK7. Under cytokine stimulation, kaempferol downregulated IFN-γ-induced PD-L1 via inhibition of the JAK1/STAT3 pathway and reduced TNF-α-induced CCL2 expression, indicating broad immunomodulatory activity. To understand the contribution of redox regulation, we silenced the transcription factor Nrf2 (NFE2L2) using Nrf2 siRNA. Interestingly, Nrf2 knockdown did not alter kaempferol's inhibition of PD-L1, suggesting that PD-L1 modulation occurs independently of Nrf2. In contrast, silencing Nrf2 markedly increased CCL2 and transglutaminase-2 (TGM2) expression, confirming Nrf2's repressive role in inflammatory signaling. Kaempferol treatment reversed these increases, bringing CCL2 and TGM2 levels back towards baseline. Together, these findings highlight kaempferol's dual ability to regulate both immune checkpoints and inflammatory mediators through distinct, Nrf2-dependent and independent pathways. In conclusion, this study describes the anticancer effects of kaempferol through various molecular mechanisms and targets, which may lead to the development of more effective adjuvant therapies against TNBC.

: Novel Antitumor Agents 1
Poster Session

#0398 NOVO-111: A macrocycle drug conjugate engineered for improved tumor targeting and tolerability.

Jonathan Felipe Aramubla[1], Guangan He[2], Gregory Thiabaud[3], Kathryn Shelton[4], Luke J. Segura[5], Jonathan L. Sessler[6], Rick A. Finch[7], Zahid H. Siddik[2]

[1]INNOVOTEX INC., Austin, TX,[2]UT MD Anderson Cancer Center, Houston, TX,[3]University of Texas at Austin, Austin, TX,[4]Texas Biomedical Research Institute, San Antonio, TX,[5]Comparative Medicine, UT MD Anderson Cancer Center, Bastrop, TX,[6]Chemistry, University of Texas at Austin, Austin, TX,[7]Associate Professor, Veterinary Sciences, UT MD Anderson Cancer Center, Bastrop, TX

Background: NOVO-111 is a novel gadolinium(III) texaphyrin-platinum(IV) complex designed as a tumor-affinic prodrug of oxaliplatin (1,2-diaminocyclohexane-platinum(II) oxalate). The texaphyrin moiety confers redox activity and tumor localization properties intended to improve platinum delivery and reduce systemic toxicity. Preclinical data suggest NOVO-111 is not only more effective as an antitumor agent but also better tolerated than oxaliplatin.
Methods: Pharmacokinetic (PK), biodistribution, and pharmacodynamic (PD) studies were performed in nude mice bearing HCT-116 colorectal xenografts (KRAS^G13D^). Animals received intravenous oxaliplatin (4 mg/kg, MTD) or equimolar (17 mg/kg) and three-fold higher (50 mg/kg; ≤MTD) doses of NOVO-111. Plasma and tissue samples were analyzed for platinum (Pt) levels and for activation of the p53/p21 pathway by immunoblotting.
Results: Following administration, ~97% of NOVO-111 became plasma bound over 2 hours. A small free Pt fraction (as NOVO-111) decayed slowly ($t_1/_2$ = 11.4 h), suggesting prolonged systemic exposure. Compared to oxaliplatin, NOVO-111 produced higher Pt accumulation (1.5-7-fold) in plasma, liver, kidney, heart, ovary, and testes, while tumor and ileum exposure were comparable at equimolar doses. At 50 mg/kg, Pt levels increased ~3-fold in normal tissues but >5-fold in tumor, consistent with selective texaphyrin-mediated accumulation. In vivo, NOVO-111 achieved greater HCT-116 tumor growth inhibition than an equi-tolerated dose of oxaliplatin, without increased systemic toxicity. Both agents, however, induced comparable tumor p53/p21 upregulation. indicating that PK features resulting in enhanced exposure and sustained Pt(II) release also likely drive NOVO-111's superior efficacy.
Conclusions: NOVO-111 displays unique PK and tumor-targeting characteristics that yield improved therapeutic performance relative to oxaliplatin. Prolonged Pt(II) persistence, enhanced tumor accumulation, and favorable tolerability together support its advancement as a next-generation platinum-based therapeutic for colorectal and other solid tumors. These findings underscore the translational potential of texaphyrin-guided delivery platforms to overcome long-standing limitations of traditional platinum chemotherapy.

#0399 Cyclopamine tartrate enhances antitumor immunity and suppresses triple-negative breast cancer growth.

Tianyuan Wang, Lorena Arango, **Li Liu**

UT Southwestern Medical Center, Dallas, TX

Introduction: Triple-negative breast cancer (TNBC) remains a clinical challenge due to limited therapeutic options and poor response to immune checkpoint inhibitors (ICIs). Tumor hypoxia and abnormal vasculature contribute to an immunosuppressive microenvironment that restricts T-cell infiltration. Cyclopamine tartrate (CycT), a heme-targeting small molecule, has been shown to inhibit tumor oxidative metabolism and improve oxygenation [1-2]. This study examined whether CycT suppresses tumor growth and modulates the immune microenvironment in TNBC.

Methods: Female BALB/c mice bearing orthotopic 4T1-Luc syngeneic tumors were treated with CycT (7.5 mg/kg Retro-Orbital Injection, twice weekly) or vehicle control. Digital calipers monitored tumor growth. Tumors were harvested for histology (H&E) and analyzed by multiparameter flow cytometry to quantify $CD8^+$ T-cell density and PD-1 expression on tumor-infiltrating lymphocytes. Statistical significance was determined using unpaired two-tailed t-tests.

Results: CycT significantly inhibited 4T1 tumor growth compared with control ($p < 0.001$), as shown by markedly smaller resected tumors and reduced volumes over 24 days of treatment. Flow cytometric analysis demonstrated that CycT increased intratumoral $CD8^+$ T-cell density ($p < 0.05$) and elevated PD-1 median fluorescence intensity on $CD8^+$ cells ($p = 0.016$), indicating a more active or antigen-experienced T-cell phenotype.

*Conclusion*s: These data indicate that CycT shows significant antitumor effects in a TNBC model while promoting $CD8^+$ T-cell infiltration and activation. The results suggest that CycT reprograms the tumor microenvironment to become immune-accessible, providing a mechanistic basis for future combination strategies with immune checkpoint blockade in TNBC.

#0400 Combinatorial treatment of glioblastoma with temozolomide (TMZ) plus 5-ethynyl-2'-deoxyuridine (EdU).

Humeyra Kaanoglu, Yasemin Akyel, Adebimpe Adefolaju, Alain Valdivia, Dominique Higgins, Shawn D. Hingtgen, Andrew B. Satterlee, Aziz Sancar

University of North Carolina at Chapel Hill, Chapel Hill, NC

Background: Glioblastoma (GBM) remains highly lethal despite surgery, radiotherapy, and temozolomide (TMZ). We identified a therapeutic role for 5-ethynyl-2′-deoxyuridine (EdU), a thymidine analog whose incorporation is recognized and excised by nucleotide excision repair (NER). We hypothesized that combining TMZ (lesions processed by mismatch repair and base excision repair) with EdU (NER-triggered) would overload complementary DNA repair pathways and improve efficacy.
Methods: We tested TMZ+EdU across GBM cell lines (U87, GBM8), orthotopic mouse models (U87, GBM8), and living, passage-zero GBM patient tumor tissues on organotypic brain slice culture (OBSC). Viability was quantified by bioluminescence imaging; synergy via CompuSyn (cells) and ZIP scores (patient tissues). Short-course EdU dosing followed by histology assessed targeted localization of EdU to tumor cells.
Results: In vitro, TMZ+EdU produced strong synergy in U87 and GBM8 across TMZ doses. In mice bearing U87 orthotopic xenografts, median survivals, reported in days (d), were 29 d (PBS), 37 d with 200 mg/kg EdU (+~30% vs PBS, $p<0.001$), 43 d with 5 mg/kg TMZ (+~50% vs PBS, $p<0.001$), and 67 d with 5 mg/kg TMZ + 200 mg/kg EdU (+~131% vs PBS, $p<0.001$). Notably, the combination yielded a +~60-80% improvement over monotherapies ($p<0.001$). Approximately 13% of combination-treated mice survived to the study endpoint with no detectable tumor. In mice bearing orthotopic GBM8 xenografts, median survivals were 46 d (PBS), 51 d with 1 mg/kg TMZ (+~11% vs PBS, $p=0.004$), 135 d with 5 mg/kg TMZ (+~193% vs PBS, $p<0.001$), and 167.5 d with 200 mg/kg EdU (+~264% vs PBS, $p=0.001$). Median survival was not reached for either TMZ+EdU regimen (1 mg/kg TMZ + 200 mg/kg EdU or 5 mg/kg TMZ + 200 mg/kg EdU); all animals were alive with no detectable tumor at Day 170, significantly outperforming each monotherapy. Short-course dosing followed by histology in U87-bearing mice showed marked tumor-cell selectivity of EdU (~70-83-fold in tumor cells vs adjacent non-tumor cells). In living, passage-zero GBM patient tumor tissues on OBSC, TMZ+EdU was synergistic in 1/4 tumors (ZIP 14) and additive in the remainder (ZIP 2-3).
Conclusions: TMZ and EdU act through distinct DNA repair pathways to deliver synergistic antitumor activity across GBM cell lines, mouse models of GBM, and living, passage-zero GBM patient tumor tissues. Given EdU's brain penetration, the survival benefit observed preclinically, and the demonstration of synergy in a subset of GBM patient tumor tissues, TMZ+EdU represents a compelling strategy for translational development in GBM.

#0401 Targeting Hsp90β potentiates nab-paclitaxel-based chemotherapy response in pancreatic cancer models.

Mayra Garcia[1], Nicola Grimaldi[2], Nathan Tuchscherer[1], Md Sazzad Hassan[1], Urs von Holzen[3], Brain Blagg[4], **Niranjan Awasthi**[1]

[1]Indiana University School of Medicine, South Bend, IN,[2]Preprofessional Studies, University of Notre Dame, South Bend, IN,[3]Surgery, Indiana University School of Medicine, South Bend, IN,[4]Chemistry & Biochemistry, University of Notre Dame, South Bend, IN

Objective:
Pancreatic ductal adenocarcinoma (PDAC) is a highly aggressive malignancy with an extremely poor prognosis. Standard treatment with nab-paclitaxel and gemcitabine (NPT+GEM) yields a median survival of only 8.5 months. Heat shock protein 90 (Hsp90) client proteins—including EGFR, IGF-1R, Raf, PI3K, AKT, CXCR4, and MMP2/9—are implicated in proliferation, survival, angiogenesis, metastasis, and chemoresistance in multiple tumor types, including PDAC. Traditional Hsp90 inhibitors that bind to the N-terminal ATP-binding site exhibit pan-inhibitory activity against all four Hsp90 isoforms, leading to induction of the heat shock response, which causes chemoresistance and dose-limiting toxicities. Here, we evaluated the antitumor efficacy of novel Hsp90β-selective inhibitors in preclinical PDAC models.
Methods:
In vitro cell proliferation assays were performed using the colorimetric WST-1 method. Protein expression levels were analyzed by immunoblotting. Tumor growth studies were conducted using NOD/SCID mice bearing subcutaneous xenografts, and survival studies were carried out in PDAC peritoneal dissemination xenograft models.
Results:
Overexpression of Hsp90β and its client proteins—including EGFR, IGF-1Rβ, CXCR4, and AKT—was observed across PDAC-associated epithelial, endothelial, and stromal cells, whereas normal human pancreatic tissue showed negligible expression. The Hsp90β-selective inhibitors NDNB-25 and NDNB-21, synthesized through a structure-based approach, demonstrated dose-dependent antiproliferative activity and synergistic effects when combined with standard chemotherapy in Hsp90β-expressing PDAC epithelial and stromal cell lines. NDNB-25 reduced expression of key Hsp90 client proteins (EGFR, IGF-1R, HER2, p-MEK, p-ERK, p-S6, and c-Myc) without inducing HSP90 expression. Treatment also induced expression of apoptosis markers (cleaved caspase-3 and cleaved PARP-1) and the epithelial differentiation marker E-cadherin. In subcutaneous xenograft models using Hsp90β-overexpressing PDAC cell lines (AsPC-1 and Panc-1), NDNB-25 and NDNB-21 significantly inhibited tumor growth, with synergistic effects in combination with chemotherapy. In AsPC-1 xenografts, tumor growth inhibition ranged from 47-61% with NPT+GEM, 58-72% with NDNB-25 or NDNB-21 monotherapy, and 79-85% with combination treatment. In AsPC-1 peritoneal dissemination models, Hsp90β inhibitors provided limited survival benefit. In Capan-2 PDAC xenografts with low Hsp90β expression, the antitumor effects of NDNB-25 and NDNB-21 were less pronounced.
Conclusion:
Our preclinical data support the continued development of Hsp90β-selective inhibitors as next-generation agents capable of improving treatment outcomes in PDAC, particularly in tumors with high Hsp90β expression.

#0402 Discovery of JMKX005425, a potent WRN inhibitor highly efficacious in multiple MSI-H gastric cancer models.

Liyan Yue, Xiaoqin Lin, Xinfeng Liu, Yangyang Qiu, Shurong Yang, Dongdong Li, Wei Chen, Taylor B. Guo, Jianbiao Peng

Shanghai Jeyou Pharmaceutical Co., Ltd., Shanghai, China

The Werner Syndrome Helicase (WRN) plays an important role in DNA repair and the maintenance of genome integrity. Recent studies have validated WRN as a promising synthetic lethal target for microsatellite instability-high (MSI-H) tumors, which have the highest prevalence in colorectal (CRC), gastric (GC) and endometrial cancers (EC). While WRN inhibitors as monotherapy in MSI-H CRC have showed promising efficacy, their therapeutic potential in MSI-H GC needs to be further evaluated. JMKX005425 is a clinical-stage, oral WRN inhibitor developed by JeYou to treat MSI-H cancers. JMKX005425 potently inhibited WRN activity and showed selective anti-proliferative effects against various MSI-H CRC, GC and EC cells but not microsatellite stable cancer cells. JMKX005425 also caused DNA damage response as measured by γH2AX induction and WRN degradation in MSI-H cells. In vivo, JMKX005425 monotherapy was highly efficacious in multiple MSI-H Cell Line-Derived Xenografts (CDX) and Patient-Derived Xenografts (PDX) models, including those from heavily-treated, immunotherapy-refractory patients. Notably, in a panel of MSI-H GC PDX (n=14), daily oral administration of JMKX005425 led to significant tumor regression, defined as tumor growth inhibition (TGI) over 100%, in over 50% of the models after 4 weeks of treatment, and all but two of the models showed a TGI over 65% (range: 68.2% to 118.8%). Furthermore, low dose of JMKX005425 in combination with irinotecan completed suppressed tumor growth in an MSI-H CDX model. Last, whole-genome CRISPR screens in MSI-H cells identified several modifiers of sensitivity to JMKX005425 treatment, which may provide information for further studies of drug resistance or patient selection. In conclusion, JMKX005425 is a potent, selective WRN inhibitor and shows high efficacy in multiple MSI-H models, especially in GC PDX models, highlighting its potential as a promising treatment for MSI-H gastric cancer. JMKX005425 is current in a phase I dose escalation study in patients with advanced MSI-H/dMMR solid tumors in China (CTR20253477).

#0403 Synthesis and anti-cancer screening of benzopyran derivatives.

Razia Shaika[1], Brijesh Sharma[1], Mariappan Gurusamy[2]

[1]Pharmacy, Institute of Biomedical Education and Research, Manglayatan University, Aligarh, India,[2]Dept of Pharm Chemistry, St Mary's College of Pharmacy, Secunderabad, India

Introduction: Global cancer incidence continues to rise, with an estimated 20 million new cases and 10 million deaths reported in 2025. Despite significant advances in early detection and therapeutic strategies, cancer remains one of the leading causes of mortality worldwide. Current research efforts are directed toward the discovery and development of novel compounds that offer enhanced anticancer efficacy with minimal side effects.

Objectives of the Study: This study aims to synthesize and characterize a series of novel 2-(toluene sulfonamido)-3-cyano-7,7-dimethyl-4-substituted phenyl-5,6,7,8-tetrahydrobenzopyran-5-one derivatives and evaluate their anticancer potential against MCF-7 breast cancer cells. Cytotoxic activity is assessed using the MTT assay to determine IC_{50} values, with the objective of identifying a potent lead compound for the development of an effective breast cancer therapy.

Experimental Procedure: Substituted benzaldehyde and malononitrile were condensed in ethanol using sodium hydroxide to afford the arylidene-malononitrile intermediate which was subsequently refluxed with dimedone to yield the cyclized benzopyran compound, which was then treated with aryl sulfonyl chloride in the presence of triethylamine to furnish the final benzopyran derivatives. The reaction sequence proceeds through a Knoevenagel condensation followed by a Michael addition mechanism.

Spectroscopic Characterization: The synthesized compounds (THBP2 to THBP8) were characterized by melting point, UV, IR, ^1H NMR, and mass spectrometry. The spectral data obtained were in good agreement with the proposed molecular structures, confirming the successful synthesis and purity of the target compounds. MTT assay in MCF-7 cell line The cytotoxic activity of THBP2 to THBP8 was evaluated against MCF-7 breast cancer cells using the MTT assay at concentrations ranging from 6.25-100 µg/ml. Cell viability was determined from the reduction of MTT to formazan, and IC_{50} values were calculated from the dose response curves.

Research Outcome: A series of benzopyran derivatives were successfully synthesized and characterized using spectroscopic techniques. The MTT assay results demonstrated that THBP-6 exhibited the highest cytotoxic activity, with an IC_{50} value of 20.99 µg/mL, highlighting its potential as a promising anticancer lead compound. THBP6 exhibits low IC_{50} despite containing electron-donating groups, likely due to enhanced lipophilicity and optimal electronic or steric factors that promote stronger binding to the target in MCF-7 cells.

Conclusion: Five novel benzopyran derivatives were synthesized and screened for anticancer activity against MCF-7 cells. In future perspectives, the potent activity of THBP-6 suggests that sulphonamide and cyano substituted benzopyran scaffolds could be further optimized and explored as promising candidates for anticancer drug development.

#0404 The non-pungent N-AVAM capsaicin analog DOHEVANIL displays robust growth-suppressive activity in human endrometriod ovarian cancers *in vitro* and *in vivo*.

Kaitlyn Conley[1], Sarah L. Miles[2], Rama S. Gadepalli[3], John M. Rimoldi[4], Timothy E. Long[5], Yi Charlie Chen[6], Piyali Dasgupta[1]

[1]Marshall University, Joan C. Edwards School of Medicine, Huntington, WV,[2]Department of Biomedical Sciences, Joan C. Edwards School of Medicine, Marshall University, Huntington, WV,[3]Department of Biomolecular Sciences, School of Pharmacy, University of Mississippi, Oxford, MS,[4]University of Mississippi, Oxford, MS,[5]Department of Pharmaceutical Sciences, School of Pharmacy, Marshall University, Huntington, WV,[6]Department of Biology and Environmental Science, Bluefield State University, Bluefield, WV

Purpose of the Study: Endometrioid ovarian carcinomas (EOC) account for ~10% (range 8-15%) of all ovarian cancers. They are considered the second most common malignant ovarian neoplasm, after high-grade serous ovarian cancer (HGSOC). EOCs tumors are characterized by complex tubular and solid-cystic masses. The development of EOC may occur as a secondary event to an endometriosis lesion. The first line-treatment for EOC is surgery and combination chemotherapy involving platinum drugs and taxanes. However, most EOC patients become resistant to chemotherapy and the disease relapses within 12-36 months. Several lines of evidence show that nutritional compounds display robust anti-cancer activity in human cancers. Our laboratory observed that capsaicin (the spicy component of chili peppers) potently inhibited the growth of human EOCs. However, the clinical application of capsaicin as a viable anti-cancer drug is limited by its adverse side effect profile. Using SAR studies, we have identified a non-pungent analog of capsaicin, namely Dohevanil. The primary objective of this research project was to explore the growth-hindering activity of gemcitabine and Dohevanil in EOCs.
Experimental Procedures: MTT assays used to measure perform SAR studies in human EOC cell lines. The growth-suppressive activity of Dohevanil was tested in both human EOC cell lines and in normal human epithelial cells. The results obtained from the MTT assays were confirmed using the chicken chorioallantoic membrane (CAM) assay. Finally, the anti-cancer activity of Dohevanil was evaluated in SCID mouse tumor xenograft models of EOCs.
Results: Dohevanil displayed robust growth inhibitory activity in human EOC cell lines and in chicken CAM and mouse models
Conclusions: Non-pungent capsaicin analogs like Dohevanil may be useful adjunct therapies in human EOCs.
Support or Funding Information Funding for our study was supported by the NIH R15-AREA Grant (2R15CA161491-02 and 2R15CA161491-03), the Women's Health T3: 3P20GM103434-23W1 (PI: Dr. G Rankin) to PD and MAV and the NIAID-AI151970 grant to TEL. Furthermore, this study was supported in part by the West Virginia IDeA Network of Biomedical Research Excellence (WV-INBRE) grant (NIH grant P20GM103434; PI: Dr. G. Rankin), the National Institute of General Medical Sciences of the National Institutes of Health under the award number P30GM122733.

#0405 (Z)-endoxifen modulates estrogen receptor and cell-cycle signaling to induce synergistic antiproliferative effects with CDK4/6 inhibition in endometrial cancer models.

Grace Choong[1], Xiaonan Hou[1], Sandra Suarez Hammer[2], Scott M. Blackburn[2], John Weroha[1], Steven C. Quay[2]

[1]Department of Oncology, Mayo Clinic College of Medicine, Rochester, MN,[2]Atossa Therapeutics Inc, Seattle, WA

Background: Endometrial cancer (EC) remains a major gynecologic malignancy driven in part by aberrant estrogen receptor (ER) signaling. The active tamoxifen metabolite (Z)-endoxifen exhibits dual SERM/SERD-like activity, modulating ER function while exerting additional noncanonical antiproliferative effects. Understanding (Z)-endoxifen's mechanisms of action and its interaction with cell-cycle regulators is critical to optimizing targeted therapy in EC. This study investigated the molecular and functional effects of (Z)-endoxifen, alone and in combination with the CDK4/6 inhibitor abemaciclib, across diverse EC models to define mechanistic activity and translational potential.

Methods: ER+ (Ishikawa, HCI-EC23, patient derived organoid U1561.005) and ER-variable (ARK1, ARK2) EC models were treated with estrogen (0-10 nM), (Z)-endoxifen (125 nM-10 μM) or fulvestrant (0-2.5 μM), and abemaciclib (0-10 μM), as single agents or in combination. Cell viability was assessed using luminescence-based assays. Dose-response analyses and combinatorial synergy were evaluated to determine endocrine sensitivity, ER dependency, and downstream cell-cycle effects.

Results: Estrogen induced biphasic proliferative responses in ER+ models, confirming ligand-driven mitogenic signaling. (Z)-Endoxifen monotherapy suppressed viability across all cell lines, demonstrating superior potency to fulvestrant and activity independent of ER expression status. Mechanistically, (Z)-endoxifen abrogated estrogen-induced proliferative peaks, consistent with ER antagonism and potential receptor degradation, while also exerting ER-independent effects suggestive of cell-cycle modulation. Abemaciclib monotherapy inhibited viability in both ER+ and ER– models, and its combination with (Z)-endoxifen yielded strong synergistic activity (Chou-Talalay combination index < 1), including in ER-negative ARK2 and the ER+ U1561.005 organoid. This synergy likely arises from concurrent disruption of ER signaling and CDK4/6-cyclin D regulatory pathways.

Conclusions: (Z)-Endoxifen demonstrates dual ER-dependent and ER-independent activity in EC preclinical models. Synergy was observed in combination a CDK 4/6 inhibitor. These findings broaden the current understanding of (Z)-endoxifen's efficacy and support further exploration of its potential therapeutic role in ER-driven and mixed-phenotype EC, including evaluation of responses across ER expression levels.

#0406 Discovery of potent and selective TRIB2 inhibitors with therapeutic efficacy in therapy-resistant neuroendocrine prostate cancer<!--EndFragment-->.

Jitender Monga[1], Sang-Yoon Lee[2], Sharad K. Suthar[2], Sudha Sadasivan[3], Shirish Gadgeel[3], Craig Rogers[1]

[1]Department of Urology, Henry Ford Health + Michigan State University Health Sciences, Detroit, MI,[2]Department of Neuroscience, Neuroscience Research Institute, Gachon University, Incheon, Korea, Republic of,[3]Division of Hematology & Oncology, Henry Ford Health + Michigan State University Health Sciences, Detroit, MI

Background: Lineage plasticity and therapy resistance remain major challenges in advanced prostate cancer, where a subset of tumors evade androgen receptor (AR)-targeted therapy and acquire neuroendocrine (NE) features. Neuroendocrine prostate cancer (NEPC), whether arising de novo or following antiandrogen treatment, is highly aggressive and lacks effective targeted therapies. We previously identified the pseudokinase TRIB2 as a critical regulator of enzalutamide resistance, lineage plasticity, and tumor survival, establishing it as a potential therapeutic target. However, no TRIB2 inhibitors are currently available for clinical use, underscoring the need for therapeutic development.

Methods: Using structure-guided in-silico modeling, cell-based screening, and biochemical validation, we identified and optimized TRIB2-targeting small molecules. The lead compound, TBI-001, was evaluated for target engagement, specificity, and functional efficacy. Downstream signaling, phenotypic changes, viability, and apoptosis were evaluated in antiandrogen-resistant and NEPC cell models, as well as engineered cells with TRIB2 overexpression (e.g., LNCaP-TRIB2, RWPE1-TRIB2) using western blotting, IHC, and functional assays. Drug metabolism and pharmacokinetics were examined in preclinical models.

Results: TBI-001 is a potent and bioavailable TRIB2 inhibitor that directly binds TRIB2, induces its protein degradation, and suppresses downstream survival signaling, including pAKT and BCL2. TBI-001 broadly inhibited TRIB2-regulated NE and lineage-plasticity programs, including epigenetic and transcriptional regulators (EZH2, BRD4, SOX2, NMYC), canonical NE transcription factors (ASCL1, BRN2), the NE antigen DLL3, and the effector PEG10. Importantly, TBI-001 reduced CD56 (NCAM1), a NEPC surface marker linked to lineage plasticity, metastasis, and immune evasion, as well as the immune-modulatory molecule B7-H3 (CD276), indicating effects on both NE differentiation and immune-evasive signaling. Functionally, TBI-001 markedly reduced viability and induced apoptosis in antiandrogen-resistant prostate cancer cell lines and NEPC models (NCI-H660, LASCPC-01), while demonstrating limited effects in control epithelial cells. In vivo, TBI-001 treatment led to significant tumor regression in therapy-resistant NEPC xenograft models, decreased NE marker expression, and showed no observable toxicity. Metabolic profiling in human hepatocytes confirmed efficient hepatic metabolism and favorable stability.

Conclusions: These findings establish that pharmacologic targeting of TRIB2 with TBI-001 disrupts oncogenic signaling and neuroendocrine programs that drive aggressive prostate cancer behavior. TBI-001 demonstrates strong anti-tumor activity, favorable tolerability, and promising pharmacologic profile, supporting its advancement toward clinical development as TRIB2-targeted therapy for advanced, therapy-resistant prostate cancer.

#0407 Targeting AhR suppresses the generation of amivantamab-lazertinib-induced drug-tolerant persisters in EGFR-mutant lung cancer.

Joo Sung Shim[1], Mi Hyun Kim[2], Heekyung Han[2], Seongsu Jeong[2], Jae-Hwan Kim[1], Mi Ran Yun[3], Sun Min Lim[4], Byoung Chul Cho[5]

[1]Yonsei University Hospital Cancer Center, Seoul, Korea, Republic of,[2]Yonsei New Il Han Institute for Integrative Lung Cancer Research, Seoul, Korea, Republic of,[3]Yonsei University College of Medicine, Seoul, Korea, Republic of,[4]Yonsei Cancer Center, Yonsei University College of Medicine, Seoul, Korea, Republic of,[5]Yonsei University College of Medicine, Seoul

Introduction: In 2024, the U.S. FDA approved first-line amivantamab-lazertinib based on the MARIPOSA trial, which showed superior overall survival compared with osimertinib. However, mechanisms of resistance to this dual-target therapy remain poorly understood. Using multi-omics analyses of patient-derived and preclinical models, we identified the aryl hydrocarbon receptor (AhR) as a potential target to overcome amivantamab-lazertinib resistance.
Methods: Fresh tumor samples from a treatment-naïve EGFR exon 19 deletion patient were transplanted into athymic nude mice to establish patient-derived xenograft (PDX) models. Mice were treated with amivantamab-lazertinib for 10 days, followed by single-cell and bulk RNA sequencing, whole-exome sequencing, and immunohistochemistry to assess early-phase responses. In vitro, flow cytometry measured lazertinib-induced AhR expression, and HepG2 AhR-luciferase reporter assays evaluated lazertinib-AhR binding. In silico docking (SAMSON) assessed binding affinity. CellTiter-Glo and colony-formation assays tested combinatorial effects of amivantamab, lazertinib, and DA-4505, an investigational AhR antagonist.
Results: Single-cell RNA-seq identified AhR among the most upregulated genes in drug-tolerant persister (DTP) cells after amivantamab-lazertinib exposure. Docking analysis suggested lazertinib acts as an AhR agonist. FACS confirmed that the combination markedly increased AhR expression across NSCLC cell lines. Adding DA-4505 enhanced growth inhibition in H1975 and YU-1185 patient-derived cells, with colony assays confirming additive effects. Transcriptomic and phospho-flow analyses indicated that cell lines with activated Src signaling were most sensitive to triple-drug treatment. Early clinical data from a phase I trial showed DA-4505 monotherapy was well tolerated up to 400 mg.
Conclusion: Targeting AhR with DA-4505 augments the efficacy of amivantamab-lazertinib and may mitigate resistance in EGFR-mutant NSCLC. Ongoing clinical evaluation will determine its translational potential.

#0408 Discovery of a first-in-class dual microtubule- and RAF—targeting inhibitor.

Joshua W. Large, Yeni K. Romero, Kylie Luther, Molly M. Hood, Ranjan Preet, Cale L. Heiniger, Chase K. Crawley, Salim Javed, Yu Mi Ahn, Cynthia B. Leary, Forrrest A. Stanley, Justin T. Proto, Lakshminarayana Vogeti, Bertrand Le Bourdonnec, Bryan D. Smith, Daniel L. Flynn, Jeffery D. Zwicker, **Stacie L. Bulfer**

Deciphera Pharmaceuticals, LLC, Waltham, MA

Background: Microtubule-targeting agents (MTAs) are effective first-line cancer therapies, but novel agents are needed to overcome resistance mechanisms, minimize toxicities, improve delivery, and enhance outcomes with new combination strategies. Several kinase inhibitors have been shown to be MTAs, with some dual inhibitors demonstrating lower toxicities. However, no reported compounds have demonstrated dual RAF kinase-and microtubule-targeting activities. Given that mutations in the RAS/MAPK pathway drive 30% of all cancers, we sought to develop dual microtubule- and RAF—targeting inhibitors.

Methods: Tubulin polymerization inhibition and competition with a BODIPY-colchicine probe were measured using recombinant tubulin. RAF kinase inhibition and off-rate analysis were measured using recombinant enzymes. Structure-based drug design was enabled by X-ray crystallography. Cellular microtubule modulation was determined by a microtubule sedimentation assay, and cellular inhibition of pERK and pRSK was measured by AlphaLISA or ELISA. Cellular proliferation was monitored via resazurin. Spindle formation, cell cycle, and apoptosis were measured by immunofluorescence, flow cytometry, and Western blot. Pharmacokinetics (PK) in plasma, brain, and cerebrospinal fluid compartments were measured following oral dosing in rats. In vivo efficacy was assessed in *RAF*- and *RAS*-mutant mouse xenograft models.

Results: Compound D is an MTA that binds at the colchicine binding site and is also potent and selective for inhibition of RAF kinases. The dual-targeting mechanism was further validated via co-crystallization with the tubulin-stathmin-TTL complex and separately with BRAF. Inhibition of MAPK pathway signaling and cellular proliferation was observed in a wide range of *BRAF*- and *KRAS*-altered cell lines. In addition, compound D overcomes the tubulin-inhibitor resistant mechanism of MDR1 overexpression. Mechanistically, compound D disrupts normal spindle formation and induces G2/M arrest and apoptosis. Compound D has favorable ADME and PK properties, is orally available, and CNS-penetrant. Oral treatment as a single agent resulted in tumor regression or tumor growth inhibition in *BRAF*- and *KRAS*-mutant mouse xenograft models.

Conclusions: Compound D is the first reported microtubule destabilizing agent with dual RAF activity, leading to tumor regression or growth inhibition as a single agent in preclinical models. Our data provide proof of concept for designing orally available CNS-penetrant inhibitors targeting both microtubules and RAF kinases.

#0409 Subcellular targeted therapy using HMCD-artemisinin conjugates for metastatic castration-resistant prostate cancer.

Yan Ou[1], Adrian Lim[2], Mouad Edderkaoui[1], Ruoxiang Wang[1], Qiang Wang[1], Stephen J. Pandol[1], Yi Zhang[3]

[1]Department of Medicine, Cedars-Sinai Medical Center, Los Angeles, CA,[2]Department of Medicine and David Geffen School of Medicine, Cedars-Sinai Medical Center and University of California, Los Angeles, Los Angeles, CA,[3]Department of Biomedical Sciences, Cedars-Sinai Medical Center, Los Angeles, CA

Background: Resistance to androgen-deprivation therapy leads to metastatic castration-resistant prostate cancer (mCRPC), a lethal stage with limited treatment options. Artemisinin (ART) derivatives exert anti-tumor activity through reactive oxygen species (ROS) generation and mitochondrial disruption but lack tumor selectivity. Our laboratory identified a near-infrared (NIR) heptamethine carbocyanine dye (HMCD) that preferentially accumulates in tumors via organic anion-transporting polypeptides (OATPs) upregulated under hypoxia, enabling tumor-specific delivery.
Methods: To achieve subcellularly targeted chemotherapy, four HMCD-ART conjugates with distinct linkers were synthesized: HMCD-ART1 (artesunate linker), HMCD-ART2 (carbamate linker), HMCD-ART3 (ether linker), and HMCD-ART4 (ester linker). These were evaluated in androgen-independent prostate cancer models (22Rv1, PC-3, C4-2B, and resistant derivatives). Cytotoxicity, selectivity, and chemosensitization were analyzed in vitro, while subcellular localization, ROS generation, and cell-death mechanisms were examined by fluorescence microscopy, flow cytometry, and Western blotting. Tumor targeting and therapeutic efficacy were determined by NIR imaging and 22Rv1 xenograft models.
Results: Among the conjugates, HMCD-ART1 showed the greatest potency and selectivity, effectively killing taxane-, abiraterone-, and enzalutamide-resistant prostate cancer cells while sparing normal prostate epithelial cells. HMCD-ART1 enhanced sensitivity to chemotherapeutics, inhibited colony formation and migration, and demonstrated prolonged tumor retention for up to eight weeks. Mechanistic analyses revealed mitochondrial and lysosomal co-localization, ROS induction, cytochrome c release, DNA damage (pATM, γH2AX), and mitochondrial-fission-dependent necrotic death. In vivo, HMCD-ART1 significantly suppressed xenograft tumor growth without observable systemic toxicity.
Conclusion: HMCD-ART1 integrates NIR-guided tumor targeting with mitochondrial-specific cytotoxicity, providing a novel therapeutic platform to overcome drug resistance in mCRPC. This strategy represents a next-generation precision chemotherapeutic approach combining targeted delivery, subcellular selectivity, and enhanced safety.

#0410 Characterization of CGT1263, a KRAS (ON/OFF) inhibitor clinical candidate with selectivity for mutant KRAS over HRAS and NRAS.

John Fischer, Kim Alley, Karyn Bouhana, Richard Brizendine, Paul Carlson, Mark Chicarelli, Michelle Crow, Brad Fell, Jennifer Fulton, Anna Guarnieri, Jackie Harrison, Ravi Jalluri, Amber Johnson, Keith Koch, Cori Malinky, Macedonio J. Mejia, Brad Newhouse, Scott Niman, Rob Rieger, John Robinson, Mareli Rodriguez, Leah Salituro, Vinny Scarato, Aaron Smith, Francis Sullivan, Yang Wang, Shannon Winski, Silas Wood, Yeyun Zhou

Cogent Biosciences, Inc, Boulder, CO

Oncogenic KRAS mutations occur across multiple cancer types, including pancreatic, lung, and colorectal malignancies. While allele-specific KRAS inhibitors have demonstrated clinical benefit in patients, the majority of KRAS mutant cancers remain without effective therapies. Recent efforts to address this disparity have resulted in the identification of pan KRAS inhibitors that target clinically relevant mutations and alterations. Herein, we highlight the clinical candidate CGT1263, a novel pan KRAS inhibitor that engages both the active (ON) and inactive (OFF) states of KRAS while sparing HRAS and NRAS inhibition. CGT1263 demonstrates robust anti-proliferative activity across a tumor spheroid panel of KRAS altered cell lines. In vivo characterization of CGT1815, the prodrug of CGT1263, includes steady state pharmacokinetics across species, pharmacodynamics, and efficacy in KRAS altered mouse tumor models.

#0412 Tanshinone analog induces ER stress mediated growth suppression via inhibition of MYC and E2F pathways in prostate cancer cells.

Ching-Feng Cheng, Hui-Chen Ku, Guo-Zhou Cheng

Taipei Tzu Chi Hospital, Buddhist Tzu Chi Medical Foundation, New Taipei City, Taiwan

Prostate cancer (PCa) is the most common malignancy among men in developed countries, and its increasing incidence is closely associated with the rising prevalence of obesity and metabolic syndrome. Our previous studies demonstrated that the Tanshinone analog (TA) enhances *ATF3* expression, inhibits adipogenesis and lipogenesis, and promotes adipocyte browning. Although both native Tanshinones and their analogs have been reported to influence PCa cell growth, the underlying mechanisms remain incompletely understood. This study aimed to investigate whether TA regulates the growth of PCa cells through modulation of the endoplasmic reticulum (ER) stress/unfolded protein response (UPR) and E2F family-related pathways. Using androgen-dependent LNCaP cells and androgen-independent DU145 and PC3 cells as PCa models, we examined the effects of TA on cell growth and associated signaling pathways. TA treatment significantly reduced cell numbers in all three PCa cell lines in a dose-dependent manner, as determined by hemocytometer counting. Colony formation assays confirmed a marked decrease in both colony number and diameter, indicating strong anti-tumor activity. Gene Set Enrichment Analysis (GSEA) of RNA sequencing data revealed that TA markedly suppressed MYC- and E2F target-associated pathways in LNCaP and DU145 cells. In contrast, differential gene expression (DEG) enrichment analysis showed upregulation of ER stress-related pathways, which was further validated by qPCR and western blot analyses of ER stress markers including PERK, ATF6, IRE1α, ATF4, and CHOP. Additionally, TA reduced androgen receptor protein levels and its nuclear translocation in LNCaP cells. In vivo, TA treatment (10 mg/kg, i.p., twice weekly for six weeks) significantly reduced tumor growth in DU145 xenograft-bearing immunodeficient mice compared with controls (2.30 ± 0.23 g vs. 3.53 ± 0.43 g; $P < 0.05$). TA treatment also decreased lung weight relative to the control group (0.21 ± 0.03 g vs. 0.36 ± 0.06 g; $P < 0.05$), indicating effective inhibition of lung metastasis. Histological analysis further confirmed that both primary prostate tumors and metastatic lung tumors were smaller in the TA-treated group than in controls. Moreover, there was no biochemical evidence of hepatotoxicity or nephrotoxicity, as hepatic (ALT, AST) and renal (BUN, creatinine) biomarkers remained unchanged after six weeks of TA treatment. In conclusion, TA exerts multiple anti-tumor effects in PCa by activating ER stress and suppressing MYC- and E2F-related signaling. These findings highlight TA as a promising therapeutic candidate for prostate cancer treatment.

#0413 ADT-007: A mechanistically distinct Pan-RAS inhibitor with capacity to escape acquired resistance common to other RAS inhibitors.

Junwei Wang[1], Xi Chen[1], Sindhu Ramesh[1], Jeremy B. Foote[2], Chung-Hui Huang[1], Kristy L. Berry[1], Khalda Fadlalla[1], Dhana Sekhar Reddy Bandi[2], Purnachandra Ganji[2], Elmar Nurmemmedov[3], Ivan Babic[3], Donald Buchsbaum[2], Asfar S. Azmi[4], Yulia Y. Maxuitenko[1], Adam B Keeton[1], Bassel El-Rayes[2], Gary A. Piazza[1]

[1]Drug Discovery and Development, Auburn University, Auburn, AL,[2]University of Alabama at Birmingham, Birmingham, AL,[3]CellarisBio LLC, San Diego, CA,[4]Wayne State University School of Medicine, Detroit, MI

Gain-of-function mutations in RAS genes are the most prevalent oncogenic mutations responsible for about one-third of all human malignancies. Despite decades of research, direct targeting of RAS remains a major clinical challenge as RAS inhibitors recently FDA-approved or in clinical trials appear to have limited efficacy due to the emergence of acquired resistance. We recently described a mechanistically distinct pan-RAS inhibitor, ADT-007, that selectively kills cancer cells harboring activated RAS, whether driven by oncogenic mutations or activation by upstream receptor tyrosine kinase signaling. ADT-007 potently inhibited the growth of an array of cancer cell lines harboring various RAS mutations or activated RAS with low nM IC_{50} values. In contrast, cancer cells with downstream RAF mutations or cells of normal tissues were essentially insensitive. Cellular, biochemical, and biophysical studies demonstrated that ADT-007 binds nucleotide-free RAS to block GTP loading and activation of the MAPK/AKT signaling pathway, resulting in mitotic arrest and apoptosis. ADT-007's unique selectivity was attributed to metabolic detoxification by glucuronidation from UDP-glucuronosyltransferases (UGTs), which we found to be enriched in normal cells compared with RAS-mutant cancer cells. Notably, ADT-007 induced apoptosis and caused nearly complete inhibition of colony formation of Mia-PaCa-2 human pancreatic cell line, while the pan-KRAS inhibitor, BI-2865, and the pan-RAS inhibitor, RMC-6236, did not induce apoptosis, but only suppressed proliferation and marginally inhibited colony formation under the same conditions. Furthermore, RAS mutant colon and pancreatic cancer cells did not develop resistance to ADT-007 under chronic exposure, in contrast to sotorasib, BI-2865, and RMC-6236, which readily produced cultures that were essentially unresponsive to the inhibitor they were exposed to. Moreover, the resistant cell lines exhibited cross-resistance to mechanistically distinct classes of RAS inhibitors, including pan-KRAS, pan-RAS, and allele-specific KRAS inhibitors, but not to ADT-007 or a second-generation inhibitor, ADT-030. These observations suggest a shared mechanism of acquired resistance that may limit the efficacy of currently known RAS inhibitors (approved or in development). An orally bioavailable prodrug of ADT-007, ADT-1004, demonstrated favorable tolerability and suppressed tumor growth in orthotopic and patient-derived xenograft models of pancreatic cancer, accompanied by reductions in activated RAS and p-ERK levels. Consistent with resistance experiments, ADT-1004 displayed superior efficacy than sotorasib or adagrasib in a xenograft model using a resistant MIA-PaCa-2. These findings support further development of ADT-1004 that holds promise for broad and durable efficacy against RAS-driven cancers.

#0414 QED-203, a dual TRPV6 and AR small molecule preclinical candidate for advanced prostate cancer resistant to standard of care.

Kimberley Beaumont[1], Rebecca Pouwer[1], Mei Yeh[1], Melanie Robitaille[2], Rebecca Farrow[1], Matthew McLachlan[1], Therese Johnson[1], Akanksha Upadhyaya[1], Aaron Gregson[1], Raphael Rahmani[1], Claire Levrier[1], Hasanthi Wijesekera[1], Malika Kumasiri[1], Grant Stuchbury[1], Terrie-Anne Cock[1], Andrew Harvey[1], Gregory Monteith[2], Brian Dymock[1]

[1]QEDDI, UniQuest, University of Queensland, Brisbane, Australia,[2]School of Pharmacy, University of Queensland, Brisbane, Australia

TRPV6, a calcium channel, is an oncochannel that is overexpressed in epithelial cancers, especially prostate cancer. We have observed that concomitant TRPV6 and AR inhibition is synergistic in prostate cancer cells resulting in a strong anti-proliferative effect. Our preclinical candidate QED-203 inhibits TRPV6-mediated calcium influx (FLIPR and electrophysiology) and NFAT activity (NFAT luciferase reporter) with low nM potency and potently inhibits AR (AR ligand displacement, AR luciferase reporter and translocation assay). QED-203 maintains effectiveness in prostate cancer cell lines that are resistant to next generation AR inhibitors including enzalutamide with multiple resistance mechanisms. QED-203 has high oral bioavailability with a pharmacokinetic profile amenable to once-a-day dosing. QED-203 is well tolerated in rodents with excellent *in vivo* efficacy in castrated mouse models of prostate cancers, including a PDX model with resistance to first and second-generation AR inhibitors (HID-28). TRPV6 target engagement has been demonstrated for QED-203 in rodents through changes in urine calcium levels, and via gene expression changes consistent with TRPV6 and AR inhibition in xenograft tumours. QED-203 thus targets a novel dual axis pathway (AR/TRPV6) to supress prostate cancer growth. QED-203 may offer a new opportunity to treat prostate cancer patients who have developed resistance to next generation AR therapies, where there is a clear clinical need for new therapeutic approaches

#0415 Combination of VLS-1488 and taxanes induces anti-tumor synergistic effect in cancer cells.

Song Chen, Adriana Roopnariane, Arshi Arora, Samuel Bakhoum, Timothy Bowler, Sarah Bettigole, Scott Drutman, Celia Andreu-Agullo

Volastra Therapeutics, New York, NY

VLS-1488 is an oral small molecule inhibitor of kinesin family member 18 A (KIF18A) that has demonstrated a tolerable safety profile and preliminary efficacy in patients with advanced cancers such as high grade serous ovarian cancer (HGSOC). We and others have previously identified KIF18A, a mitotic kinesin, as a vulnerability specifically in chromosomally unstable cancer cells. VLS-1488 treatment in cancer cells results in defects in chromosome alignment and prolonged mitotic arrest. Taxanes are microtubule-stabilizing chemotherapy agents commonly used in many cancers including ovarian cancer, breast cancer, and non-small cell lung cancer (NSCLC). However, response rates vary widely and most resistance develops rapidly, resulting in limited treatment options thereafter. The similar mechanism of action of VLS-1488 and taxanes, which includes disruption of spindle dynamics and activation of the spindle assembly checkpoint, suggests a potential for synergistic anti-tumor activity when administered in combination. In this current study, we selected a panel of ovarian and NSCLC cell lines with different sensitivities to KIF18A inhibition and treated cells with a range of concentrations of VLS-1488 and taxanes, alone and in combination. Drug combination effects on cell growth inhibition were evaluated using Bliss synergy score. *In vitro*, combination of low doses of taxanes and VLS-1488 consistently resulted in synergistic growth inhibition in cell lines with low sensitivity or resistant to KIF18A inhibition, compared to that of VLS-1488 or taxanes alone. *In vivo*, xenograft studies using ovarian cancer cells resistant to VLS-1488 and paclitaxel single agent treatment, demonstrated that combination treatment of VLS-1488 and paclitaxel results in a synergistic anti-tumor activity, total prevention of tumor growth, and no significant loss in body weight. Further mechanistic studies revealed pronounced mitotic arrest with the combination treatment *in vivo*. We hypothesize that combination treatment of VLS-1488 and taxanes in cancer cells prolongs mitotic arrest and prevents mitotic slippage to an extent that induces cell death. Overall, our findings presented suggest that combination treatment of VLS-1488 and taxanes may offer benefit to patients with limited or no response to VLS-1488 monotherapy and/or taxanes.

#0416 HEC201625, a novel oral small molecule inhibitor of PD-L1, demonstrated potent anti-tumor activities both *in vitro* and *in vivo*.

Bing Liu, Mingyu Guan, Shaoyan Li, Ning Kang, Ming Li, Ying Zeng, Jing Li, Cliff Cheng, Yingjun Zhang, **Kai Lin**

Sunshine Lake Pharma Company, Ltd., Dongguan, China

Background: Despite the clinical success of PD-1 and PD-L1 antibodies, there remains a need for improvement, including the requirement for intravenous administration, suboptimal response rates, and immune-related toxicities. In contrast, orally bioavailable small molecule inhibitors of PD-L1 may address these issues by offering treatment convenience, better tissue distribution, and easier adverse events management in combination therapies. Herein, we report the discovery of HEC201625, a novel small molecule inhibitor of PD-L1, to enhance antitumor immune response by blocking the PD-1/PD-L1 pathway, providing an alternative for cancer immunotherapy.

Experimental Methods: *In vitro* efficacy was tested in HTRF binding and NFAT-driven reporter assays. Functional immune activation was evaluated in co-cultures of human primary T cells with tumor cells. *In vivo* efficacy was assessed in syngeneic MC38-hPDL1 models and PBMC humanized xenograft models with A375, NCI-H358, or MDA-MB-231 cells. Combination studies were performed with 5-FU, anti-VEGF, and KRAS G12C inhibitors. PK and toxicity profiles were evaluated both *in vitro* and in animal studies.

Results: HEC201625 binding induced PD-L1 dimerization and blocked PD-1/PD-L1 interaction potently and selectively with an IC_{50} of 2 nM. In the PD-1/PD-L1 NFAT blockade bioassay, HEC201625 effectively reversed PD-1/PD-L1 interaction and restored Jurkat T cell activity. In the co-culture assay with human primary T cells and tumor cells, HEC201625 enhanced human primary T cell activation in a dose-dependent manner. *In vivo*, HEC201625 showed antitumor activities comparable to those of the anti-PD-L1 antibody atezolizumab in the MC38-hPDL1 murine colon carcinoma model. HEC201625 also demonstrated equivalent or superior efficacy to atezolizumab across multiple humanized immune system tumor models, including A375, NCI-H358, and MDA-MB-231. Synergistic antitumor effects were observed when HEC201625 was combined with 5-FU, anti-VEGF, or KRAS G12C inhibitors. In contrast, no activity was detected in the immunodeficient NCG mice treated with HEC201625, confirming its immune-dependent mechanism. Moreover, HEC201625 demonstrated good bioavailability across multiple animal species, no significant inhibition against 87 off-target receptors, and a favorable safety profile in animal toxicology studies.

Conclusion: HEC201625 is a novel oral small molecule inhibitor of PD-L1 demonstrating potent and selective immune activation and favorable pharmacokinetics and preclinical safety profiles. These results support its further development as a clinical candidate, with IND-enabling studies ongoing and Phase I trials planned.

#0417 Structure-guided design of JZY3032, a dual-engaging DALTAC that miswires AR-p300 in prostate cancer.

Jianzhang Yang[1], Jie Luo[1], Mi Wang[1], Shicheng Jin[1], Arul M. Chinnaiyan[1], Shaomeng Wang[2]

[1]University of Michigan, Ann Arbor, MI,[2]Professor, University of Michigan, Rogel Cancer Center, Ann Arbor, MI

Chemical-induced proximity (CIP) strategies have expanded the therapeutic landscape by modulating protein-protein interactions, yet most current modalities, such as PROTACs and molecular glues—juxtapose non-physiological partners, often yielding variable or unpredictable outcomes. To address this limitation, we developed Domain-ALTeration Chimeras (DALTACs), a mechanistically distinct platform that selectively miswires endogenous protein complexes by enforcing *non-productive* domain-domain interactions between physiologic partners. Rather than degrading targets or stabilizing native interfaces, DALTACs reconfigure the topology of multi-domain complexes through rational ligand selection and linker engineering. As a proof of concept, we designed JZY3032, the first-in-class AR-p300 DALTAC, to disable the androgen receptor (AR)-p300 transcriptional complex, a critical regulatory node in prostate cancer. Guided by iterative medicinal-chemistry optimization, we conjugated an AR LBD inhibitor to a selective p300 bromodomain inhibitor using a tunable linker optimized for cooperative, simultaneous dual engagement. The resulting construct redirects the physiological AR-p300 interaction surface into a sterically misaligned, non-productive configuration, thereby preventing AR N-terminal domain communication with p300 and suppressing enhancer activation. Mechanistic specificity was confirmed using two negative-control analogs that selectively disrupt AR or p300 binding; both lacked biological activity, demonstrating that dual engagement and domain-reconfiguration are required for DALTAC function. SAR studies revealed that linker length, rigidity, and exit-vector orientation are key determinants of complex miswiring efficiency. Functionally, JZY3032 potently inhibits growth of AR- and p300-co-dependent prostate cancer models while sparing AR-negative lineages, establishing the lineage-selective therapeutic potential arising from engineered domain miswiring. Collectively, these data establish DALTACs as a new class of proximity-based therapeutics capable of disabling oncogenic transcriptional complexes through topology engineering. JZY3032 exemplifies a broadly extensible, modular chemistry platform for rationally designing future DALTAC molecules targeting diverse disease-relevant protein assemblies.

#0418 ETX-929, a potential best-In-class, oral, highly potent and selective dual ON / OFF state Pan-KRAS small molecule inhibitor for the treatment of KRAS mutant and wild-type amplified cancers.

Meghana M. Kulkarni, Lei Cui, Hongbo Deng, Tao Liu, Jingyan Gao, Fei Peng, Ying Lin, Yong Tang, Karan Kapoor, Minghong Hao, Robert F. Koncar, Robbie Chen, Eric Simone, Raj Nagaraja, Shengfang Jin, Jeffery Kutok

Ensem Therapeutics Inc., Waltham, MA

Oncogenic *KRAS* alterations occur in approximately 23% of all human cancers. The most common oncogenic *KRAS* alterations are G12D (~31%), G12V (~24%), and G12C (~15%) mutations. In addition, ~10% of KRAS-altered cancers have wild-type (WT) *KRAS* amplification or harbor multiple oncogenic *KRAS* alterations, including co-occurring *KRAS* mutations and amplifications. While there have been drug approvals for $KRAS^{G12C}$ targeting covalent inhibitors, there are currently no approved targeted therapies against other oncogenic *KRAS* alterations. Pan-KRAS inhibitors that target multiple oncogenic *KRAS* alterations while sparing other RAS isoforms have the potential to treat broad patient populations and address resistance to mutant selective KRAS inhibition while avoiding the on-target toxicities associated with pan-RAS inhibition. ETX-929 is an orally bioavailable, potent, dual GTP (ON)- and GDP (OFF)-state pan-KRAS inhibitor with excellent selectivity over other RAS isoforms. ETX-929 binds WT and mutant KRAS in active (ON) and inactive (OFF) conformations with high affinity [K_D(ON-state) = single digit nanomolar; K_D(OFF-state) = picomolar] and >100-fold selectivity over NRAS and HRAS. In the KRAS-RAF1 RAS-binding domain biochemical assay, ETX-929 potently inhibited complex formation when KRAS (WT / mutant) was either in the active GMPPNP-bound state (single digit nM IC_{50}) or inactive GDP-bound state (pM IC_{50}). In cells, ETX-929's dual ON / OFF-state inhibitory activity potently inhibits KRAS mutants that rapidly cycle between GTP- and GDP-bound states ($KRAS^{WTamp}$, $KRAS^{G12C}$) as well as slow cycling mutants ($KRAS^{G12V}$ and $KRAS^{Q61H}$) that predominantly reside in the ON state. In a broad panel of *KRAS* mutant (G12X, G13D, Q61H) and WT amplified cancer cell lines, ETX-929 potently inhibited the KRAS pathway (pERK median IC_{50} = 0.9 nM) and cell proliferation (median IC_{50} = 6.23 nM), while showing no viability effects on low copy number WT KRAS or mutant NRAS / HRAS cells. Oral ETX-929 showed dose-dependent exposures with concordant sustained tumor pERK reductions, inducing tumor stasis or regression in colorectal, stomach, and lung cancer cell line-derived xenograft models harboring *KRAS* alterations (G12D, G12V, G12C, and WT amplified). ETX-929 also shows good cross-species pharmacokinetics including higher species, excellent pre-clinical tolerability, and no meaningful off-target activity or *in vitro* safety signals, supporting its advancement toward clinical development. Overall, ETX-929 is a potential best-in-class, pan-KRAS inhibitor with superior potency, selectivity over NRAS / HRAS, excellent efficacy and favorable drug-like properties that could improve outcomes for KRAS-driven cancers that currently lack targeted therapeutic options.

#0419 Targeting NAMPT using Novel Inhibitor RPT-E-037 in Pancreatic Neuroendocrine Tumor.

Md Hafiz Uddin[1], Husain Yar Khan[2], Amro Aboukameel[3], Sahar F. Bannoura[3], Irfana Muqbil[4], Hugo Jimenez[1], Filza Khan[1], Rafic Beydoun[3], Gregory Dyson[3], Yang Shi[3], Mohammed N. Al Hallack[3], Nitin Vaishampayan[3], Ibrahim Azar[3], Steve Kim[3], Eliza W. Bael[3], Miguel Tobon[3], Khalil Choucair[3], Walid Sukkari[1], Hafsa Imtiaz[1], Herbert Chen[3], Muhammad W. Saif[3], Anthony Frank Shields[5], Ramzi M. Mohammad[3], Philip Philip[6], Bassel F. El Rayes[7], Min Wu[8], Michael Schelle[8], Boris Pasche[3], Asfar S. Azmi[3]

[1]Oncology, Barbara Ann Karmanos Cancer Institute, Wayne State University, Detroit, MI,[2]Barbara Ann Karmanos Cancer Institute, Detroit, MI,[3]Barbara Ann Karmanos Cancer Institute, Wayne State University, Detroit, MI,[4]Lawrence Technological University, Southfield, MI,[5]Associate Director for Clinical Research, Barbara Ann Karmanos Cancer Institute, Detroit, MI,[6]Henry Ford Cancer Institute, Henry Ford Health, Detroit, MI,[7]University of Alabama at Birmingham, Birmingham, AL,[8]Remedy Plan Therapeutics, Gaithersburg, MD

Background and Objective: Advanced pancreatic neuroendocrine tumors (pNETs) respond poorly to current FDA-approved therapies, emphasizing the urgent need to find new and effective treatment targets. Nicotinamide phosphoribosyltransferase (NAMPT), a key enzyme in the NAD biosynthesis pathway, has emerged as a crucial therapeutic target in pNETs. Despite its importance, specific inhibitors directly targeting NAMPT for pNET treatment are currently lacking. This study aimed to evaluate the efficacy of RPT-E-037, a novel NAMPT inhibitor, in preclinical models of pNETs. **Methods:** Growth inhibition was determined by MTT, colony formation and apoptosis assays. We also measured growth arrest using cell cycle analysis. Expression of gene or protein was determined using quantitative PCR, and western blotting techniques. The impact of NAMPT inhibitor RPT-E-037 was evaluated in pNET *in vitro* cultures and in *in vivo*. **Results:** RPT-E-037 demonstrated its growth inhibitory effect in BON-1 and QGP-1 pNET cell lines at pharmacologically relevant concentrations. The inhibitory concentration-50 (IC_{50}) were determined as 0.3 and 1.2 micromolar (μM) in BON-1 and QGP-1 cells respectively. Importantly, RPT-E-037 demonstrated selectivity, showing no adverse effects on normal islet cells (ABC-TC4286, AcceGen) at concentrations effective against tumor cells (reflected by its 40-folds higher IC_{50}). In addition, growth inhibitory effect of RPT-E-037 significantly rescued by nicotinic acid (niacin) treatment in BON-1 cells. Niacin also diminishes its colony reduction and apoptotic ability of RPT-E-037 in this cell line. The novel NAMPT inhibitor RPT-E-037 was shown to induce “DNA synthesis (S) phase” cell cycle arrest. However, niacin treatment switches “S phase” cell cycle arrest to “G0/G1 phase” cell cycle arrest. RPT-E-037 synergized with pNETs standard of care mTOR targeted agent everolimus in both BON-1 and QGP-1 cell lines leading to superior cell deaths (CI<1). The *in vivo* efficacy of RPT-E-037 in BON-1 and QGP-1 cell line derived xenografts (CDxs) are under way. **Conclusion:** For the first time, this study reveals the therapeutic potential of RPT-E-037, a new NAMPT inhibitor, for pNETs in preclinical models. RPT-E-037 shows promise as a novel NAMPT inhibitor and deserves further clinical investigation for pNETs.Generative AI was used for improving the language of the abstract.

#0420 Targeting proliferating cell nuclear antigen via a miRNA-CSC axis as a new therapeutic approach in multiple myeloma.

Jeffrey A. Zonder[1], **Bin Bao**[1], Amro Aboukameel[1], Sahar F. Bannoura[1], MD Hafiz Uddin[1], Husain Y. Khan[1], Rayyan Siddiqui[1], Yin Wan[1], Yang Shi[1], Ramzi Mohammad[1], Long Gu[2], Pouya Haratipour[2], Robert J. Hickey[2], Linda Malkas[2], Asfar Azmi[1]

[1]Oncology, Barbara Ann Karmanos Cancer Institute, Detroit, MI,[2]City of Hope National Medical Center, City of Hope, CA

Multiple myeloma (MM) is a plasma cell cancer, which is ranked as the second most common hematologic malignancy. Despite advances in treatment MM remains incurable. Proliferating cell nuclear antigen (PCNA) is an essential protein which plays a key role in regulation of cell growth and proliferation. A post-translationally modified isoform of PCNA plays a critical role in the pathogenesis of a wide variety of malignant diseases including MM. Increased expression of PCNA has been shown to be associated with an aggressive MM phenotype, making it an attractive therapeutic target. We tested the anti-tumor activity of the novel small molecule PCNA inhibitor AOH-1996 (alone and in combination with either bortezomib or venetoclax) against 5 different sub-types of MM cell lines. We assessed the cytotoxic anti-MM effects of varying doses AOH-1996 using standard viability assays and also 3D spheroid degradation assays. Changes in gene expression relevant to cell growth, cell-cycle progression, apoptosis, methylation status, and cytokine production following AOH-1996 exposure were analyzed using RT-qPCR and Western blotting, as appropriate. We also evaluated the impact of AOH-1996 exposure on miRNA levels. The anti-MM effect of AOH-1996 monotherapy and combinations versus the same cell lines was then further evaluated in xenograft animal model. AOH-1996 demonstrated dose-dependent reduction of cell growth (2D) and CSC-like sphere formation (3D) of different subtypes of MM cell lines. Cell cycle assay revealed that AOH1996 treatment resulted in the delayed mitosis in MM cells. AOH-1996 treatment also significantly down-regulated the gene expression of selected anti-apoptotic markers (PCNA, CDK4/6, BCL2), cancer stem cell markers (EZH2, Sox2), and inflammatory and pro-survival cytokines (IL-6, FGF2). AOH-1996 treatment down-regulated oncogenic miRNA (miR-21, miR-30a, miR-99a, miR-100, miR-142, miR-191 and miR-222) levels and up-regulated anti-oncogenic miR-145 along with the reduced cytokine production of VEGF. There was a synergic effect on cell growth and CSC-like sphere formation when either bortezomib or venetoclax was added to AOH-1996. AOH-1996 and its combination with venetoclax or velcade showed decreased the protein expressions of EZH2, c-Myc, and PARP in MM cells, and significantly inhibited MM.1S cell line-derived xenograft tumor growth. Re-expression of miR-145 by its mimic transfection decreased cell growth and increased the drug sensitivity of AOH-1996 along with the down-regulation of EZH2, CDK4, and CDK6 genes in MM cells, suggesting an important role of AOH1996-mediated miR-145 in MM cells. These findings clearly suggest that PCNA is a potential therapeutic target in MM. We have demonstrated for the first time that the PCNA inhibitor AOH-1996 shows potent anti-myeloma activity through its effects on several key tumor-associated genes/proteins and miRNAs.

#0421 Kirsten rat sarcoma virus (KRAS) oncoprotein as a new therapeutic target in multiple myeloma.

Jeffreay Zonder[1], **Bin Bao**[1], Amro AbouKameel[1], Sahar Bannoura[1], Husain Y. Khan[1], MD Hafiz Uddin[1], Walid M. Sukkari[1], Ramzi Mohammad[1], Long Gu[2], Pouya Haratipour[2], Robert J. Hickey[2], Linda Malkas[2], Asfar S. Azmi[1]

[1]Oncology, Barbara Ann Karmanos Cancer Institute, Detroit, MI,[2]Beckman Research Institute of The City of Hope, Duarte, CA

Kirsten rat sarcoma virus (KRAS) gene, a member of the well-known RAS oncogene family, has been identified in a wide variety of malignant diseases and plays a crucial role in oncogenesis and progression. KRAS mutations have been strongly associated with shorter overall and progression-free survival in many different malignant diseases, including multiple myeloma (MM). Multiple myeloma (MM) is a malignant plasma cell disorder ranked as the second most common blood cell malignancy. Clinically, it manifests as anemia, renal damage, skeletal lesions, and a high frequency of infections, often resulting in death. Despite significant progress in treatment such as immunotherapeutic drugs, proteasome inhibitors, and apoptosis inhibitors, MM remains incurable due to the development of drug resistance in patients. The overall survival rate is approximately 60% at 5 years, highlighting the urgent need for new and affective agents. At least 20% of MM patients have been reported to carry KRAS point mutations. Therefore, targeting the KRAS oncoprotein provides a potential therapeutic strategy in MM. Early evidence revealed that down-regulation of KRAS using siRNA inhibited MM tumor growth both in vitro and in vivo. Daraxonrasib (RMC6236), an FDA-approved small molecule pan-Ras (ON) state inhibitor, has shown anti-tumor activity in U.S. clinical trials. In this study, we evaluated the anti-myeloma activity of RMC6236 in MM cells. Our results showed that RMC6236 inhibited cell growth in a dose response manner across different MM cell subtypes, including both KRAS mutant and wild-type (WT) cells. Depending on the KRAS genotype mutational status, the IC50 of RMC6236 was estimated to range from 20 to 800 nM, Also, cell cycle assays revealed that RMC6236 treatment significantly decreased the number of cells in S phase (DNA synthesis), suggesting an inhibition of cell cycle progression in MM cells. Moreover, combining RMC6236 with anti-myeloma agent venetoclax or a novel anti-PCNA agent AOH1996 significantly reduced cell growth in KRAS mutant and WT MM cells. RT-qPCR assays revealed that RMC6236 treatment led to decreased gene expression of KRAS, CSC signature markers, anti-apoptotic markers, IL-6, STAT3, and mTOR in MM cells, along with the down-regulation of EZH2 and MEK/ERK signal pathways. These findings suggest that the inhibition of MM cell growth by RMC6236 may be linked to the down-regulation of these tumor-associated genes. Ongoing studies aim to further evaluate the anti-myeloma potential of RMC6236.

#0422 A novel potent tetrahydroisoquinoline analog: A cytostatic taxol-like agent.

Kinfe K. Redda[1], Madhavi Gangapuram[1], Suresh Eyunni[2], Elizabeth Mazzio[1], Karam F. A. Soliman[1]

[1]College of Pharmacy and Pharmaceutical Sciences, Florida A&M University, Tallahassee, FL,[2]College of Science and Technology, Florida A&M University, Tallahassee, FL

In 2024, according to the American Chemical Society, approximately 310,720 new cases of invasive breast cancer will be diagnosed among US women, and 42,250 women will die from breast cancer. Triple-negative breast cancer (TNBC) represents 10 to 15% of all breast cancers. TNBC has fewer treatment options than other types of invasive breast cancer, which limits the effectiveness of targeted hormonal or HER2-directed therapies and is heavily reliant on cytostatic agents such as taxanes and vinca alkaloids. The limited efficacy and increasing side effects of these agents highlight the urgent need for alternative small molecules that block proliferation through novel but less toxic mechanisms. We previously synthesized and characterized tetrahydroisoquinoline (THIQ) derivatives, identifying MG-KKR-4-53 as a highly soluble, non-toxic, and cytostatic agent that halts TNBC cell proliferation without functioning as a spindle poison. Instead, it arrests the cell cycle at G2/M phase. Continuing our research, we further developed a more potent analogue, MG-KRR-5-268, and performed comprehensive *in-silico* ADMET and cheminformatics analyses, comparing it with Taxol, vinblastine, and MG-KKR-4-53, which map directly to well-known predictive toxicology and metabolism databases/models powered by ADMETlab, SwissADME, and CYP/clearance data. The compounds of interest were synthesized in our lab using O-mesitylene sulfonylhydroxylamine as an aminating agent. Reaction of the Isoquinoliniumamino salt with substituted acid chlorides in anhydrous tetrahydrofuran gave stable ylides. Reduction of the ylides using sodium borohydride gave the target THIQ compounds, which were characterized by NMR and elemental analysis. Compound *3-fluoro-N-(7-hydroxy-3,4-dihydroisoquinolin-2(1H)-yl)-4-methylbenzamide* (MG-KKR-5-268) showed significant cytostatic activity with IC_{50} of 169 nM representing a 7.1-fold increase over MG-KKR-4-53 (IC_{50} = 1.2 µM). Paclitaxel (250 nM) solidified tumor spheroids at submicromolar concentrations, whereas vinblastine (123nM) caused their disassembly. MG-KRR-5-268 (257nM) exhibited strong prevention of spheroid compaction across submicromolar doses, phenocopying the disassembly of the vinblastine phenotype through a non-tubulin mechanism, compared to the other THIQ analogs. These findings highlighted MG-KRR-5-268 acted as the most potent compound with a novel capacity to prevent 3D tumor solidification through transcriptome reprogramming rather than microtubule binding.

#0423 ETX-880, a potential best-in-class, oral, highly potent and selective covalent inhibitor of Werner helicase for the treatment of microsatellite instability-high (MSI-H) cancers.

Robert F. Koncar, Daliya Banerjee, Mingzong Li, Tao Liu, Upul Bandarage, Alexandra Weinheimer, Jingyan Gao, Fei Peng, Ying Lin, Yong Tang, Karan Kapoor, Minghong Hao, Robbie Chen, Eric Simone, Raj Nagaraja, Shengfang Jin, Meghana M. Kulkarni, Jeffery Kutok

Ensem Therapeutics, Inc., Waltham, MA

DNA mismatch repair (dMMR) defects occur in a broad range of cancers and are characterized by genomic instability due to TA repeat expansion, a condition known as microsatellite instability-high (MSI-H). The use of immune checkpoint inhibitors (ICI) in MSI-H cancers has improved patient outcomes, but ~30-40% of patients do not respond and ~20-25% become refractory to ICI. Genetic ablation or pharmacological inhibition of Werner RecQ like, ATP-dependent helicase (WRN) activity has been shown to induce growth arrest and apoptosis in MSI-H cancer cells, but not in microsatellite stable (MSS) cells. Early clinical data with RO7589831 (covalent) and HRO761 (non-covalent) WRN inhibitors demonstrated clinical responses, validating WRN as an actionable target, but uncertainty remains on their ability to fully engage WRN. ETX-880 is a novel, potent and selective small molecule inhibitor of WRN for the treatment of MSI-H cancers. ETX-880 acts through an allosteric, ATP-cooperative binding mechanism and covalent ligation of WRN at cysteine 727 (C727). The preclinical activity of ETX-880 was characterized and compared to clinical stage WRN inhibitors, including RO7589831, HRO761, and GSK4418959 (non-covalent). ETX-880 demonstrated >2-fold tighter binding to WRN than RO7589831 (ETX-880 K_I = 0.44 µM versus RO7589831 K_I = 1.05 µM) with comparable reactivity for WRN C727. ETX-880 selectively inhibits the ATPase and DNA unwinding activities of WRN with 2-fold greater potency than RO7589831, excellent selectivity against other RecQ helicases, and no activity for the WRN^{C727A} mutant protein. ETX-880 shows strong anti-proliferative effects in a broad panel of MSI-H cancer cell lines with no measurable effects in MSS cells. In MSI-H cancer cells, ETX-880 shows 4-fold more potent anti-proliferative activity than RO7589831 and HRO761 and is ~30-fold more potent than GSK4418959. *In vivo*, ETX-880 depletes WRN protein and induces DNA damage markers in tumors and leads to deeper and more sustained tumor regressions than RO7589831 in an MSI-H colorectal cancer xenograft model. At the efficacious dose, ETX-880 achieves 100% target occupancy (TO) at 2 hours post dose and maintains ~85% TO at 24 hours, in contrast to RO7589831 which shows substantial loss (~40%) of TO by 24 hours. ETX-880 displays favorable drug-like properties, including good *in vitro* ADMET, excellent metabolic stability with low *in vivo* clearance and high oral bioavailability and exposures across animal species. Importantly, human PK predictions reveal low clearance, high oral bioavailability and long half-life, supporting a low once daily oral efficacious dose. Overall, ETX-880 is a potent, selective, covalent WRN inhibitor with excellent ADMET properties leading to deep and sustained target coverage, highlighting its best-in-class potential in MSI-H cancers.

#0424 Targeting tGLI1 in breast cancer brain metastases with a novel ketoconazole derivative.

Mariana Najjar[1], Daniel Doheny[2], Sara Manore[2], Joshua Cha[1], Phi-Long Tran[3], Elissa Bloom[1], Hui-Wen Lo[3]

[1]UT MD Anderson Cancer Center, Houston, TX,[2]Wake Forest University School of Medicine, Winston-Salem, NC,[3]Texas A&M University Health Science Center, Houston, TX

Metastasis is the major cause of mortality for breast cancer. Common metastatic sites include bones, lungs, brain, and liver; with breast cancer brain metastasis (BCBM) accounting for 20-40% of the metastatic cases. HER2-enriched and triple-negative breast cancer (TNBC) subtypes are more likely to develop BCBM compared to others. BCBM is associated with poor prognoses, with a median survival time of 7.9 months. The dismal outcomes are due to limited understanding of the molecular mechanisms driving BCBM and the lack of effective drugs capable of penetrating the blood-brain barrier (BBB). This underscores the critical need to identify new druggable targets and therapeutics for HER2 and TNBC BCBM. To address this urgent need, in earlier work our group identified a tumor-specific, alternatively spliced variant of the transcription factor GLI1 (glioma-associated oncogene homolog 1), termed truncated GLI1 (tGLI1). tGLI1 represents a novel therapeutic target for BCBM because of its selective overexpression in BCBM and the promotion of breast cancer stem cells (CSC), BCBM progression, and tumor microenvironment remodeling. In prior studies, screening of commercial drug libraries for tGLI1-selective agents revealed that the FDA-approved antifungal ketoconazole (KCZ) selectively inhibited tGLI1-positive breast cancer cells *in vitro* and suppressed tGLI1-driven brain metastases *in vivo*. However, KCZ's potent inhibition of the CYP3A4 enzyme raises safety concerns, including liver damage, adrenal insufficiency, and drug-drug interactions. To overcome these issues with toxicities, we modified the chemical structure of KCZ and identified the novel derivative KCZ-229A as a tGLI1 inhibitor candidate. We found that KCZ-229A retains selective inhibition of tGLI1-positive breast CSCs but loses the ability to inhibit CYP3A4 enzymatic activity *in vitro*. Additionally, KCZ-229A demonstrates no toxicity to normal brain, liver, or mammary epithelial cells *in vitro*, while *in vivo* studies confirmed no liver toxicity (normal serum ALT), no adrenal insufficiency (normal serum ACTH), no hematologic abnormalities, and no adverse effects on major organs. Moreover, mass spectrometry analysis of serum showed that KCZ-229A has enhanced bioavailability and BBB permeability. Mechanistic studies revealed that KCZ-229A binds directly and specifically to tGLI1 protein, induces apoptosis, suppresses the CD44+/CD24- stem cell population, and hampers migration and invasion of tGLI1-positive BCBM cells *in vitro*. An experimental mouse metastasis study using intracardiac inoculation demonstrated that systemic administration of KCZ-229A suppressed the progression of tGLI1-positive BCBM. These findings establish KCZ-229A as a brain-penetrant, and safe tGLI1-targeting compound, supporting its further preclinical development to optimize its pharmacological profile and assess its potential to both treat and prevent BCBM.

#0425 ISM6166, a novel oral pan-KRAS (ON/OFF) inhibitor discovered with generative AI shows robust anti-tumor activity in solid tumors with KRAS alterations.

Sujing Shi[1], Defeng Shen[1], Jianping Wu[1], Tingting Liu[1], Jinxin Liu[1], Qingshuo Meng[1], Zuoxiao Shi[1], **Suguna Rachakonda**[2], David Gennert[2], Luoheng Qin[1], Xin Cai[1], Man Zhang[1], Feng Ren[1], Alex Zhavoronkov[2]

[1]Insilico Medicine, Shanghai, China,[2]Insilico Medicine, Cambridge, MA

The small membrane-bound GTPase KRAS functions as an on/off switch for multiple important cellular signaling pathways, including RAF/MEK/ERK and PI3K/AKT. As one of the most prevalent cancer drivers, KRAS alterations occur in approximately 17% of all solid tumors, including pancreatic, colorectal, lung adenocarcinoma, and esophagogastric cancers. Despite recent advances, KRAS G12C-selective inhibitors face clinical challenges in achieving durable therapeutic efficacy due to acquired drug resistance, while the mutational diversity of KRAS-driven cancers restricts their utility across patient populations, representing a significant unmet medical need. On the other hand, targeting all RAS proteins, including HRAS and NRAS, might raise potential toxicity risk, as the RAS family is essential in normal cells. Here, we report an oral pan-KRAS (ON/OFF) inhibitor ISM6166 that selectively targets all major oncogenic KRAS variants in both inactive and active conformations across multiple solid tumors while sparing HRAS and NRAS.

Surface plasmon resonance revealed that ISM6166 binds to GDP-bound KRAS (inactive, or “off”) with picomolar affinity and to GTP-bound KRAS (active, or “on”) with sub-nanomolar affinity. Nucleotide exchange assays and RAS-cRAF binding assays further supported dual inhibitory function, together identifying sub-nanomolar IC50 values against KRAS variants (G12D, G12V, G12C, and WT). In cellular assays, ISM6166 suppressed cell growth with single-digit nanomolar IC50 values across cancer cell lines harboring major KRAS mutations or KRAS amplification, including GP2D (KRAS G12D), SW620 (KRAS G12V), NCI-H358 (KRAS G12C), and MKN1 (KRAS WT amplification).

Treatment *in vivo* at 10-30 mg/kg (BID) induced tumor regression in multiple CDX models driven by different KRAS alterations (KRAS G12D/V/C mutations or KRAS amplification), along with dose-dependent pharmacodynamic responses, including changes in ERK phosphorylation and DUSP6 transcription.

ISM6166 demonstrated reasonable solubility and permeability. *In vivo*, it exhibited good plasma clearance and bioavailability across mouse, rat, dog, and monkey. Additionally, mini-Ames and off-target safety panel profiling indicated no potential risk. Collectively, these findings highlight the potential of this novel molecule as a potent pan-KRAS (ON/OFF) inhibitor for the treatment of solid tumors with KRAS alterations.

#0426 Development of heptamethine carbocyanine based small molecule targeting platform for tumor specific drug delivery.

Paul Algate[1], Jeffrey A. Kern[2], Lyle Small[1], Ruizheng Wang[1], Ryan Westberry[1], Margaret Karow[1], Steve LaMond[1]

[1]Lahjavida, Colorado Springs, CO,[2]Medicine, National Jewish Health, Denver, CO

Improved tumor-targeting strategies are needed to enhance a cytotoxic drug's therapeutic efficacy while minimizing systemic toxicity. Antibody-drug conjugates (ADCs) have shown this potential but are limited by a restricted tumor-epitope diversity; Each ADC is designed for a single tumor type, with development, manufacturing, and cold-chain requirements adding complexity and cost. A targeting platform that is inexpensive, modular, and applicable across tumor types could address these gaps. Dye-drug conjugates (DDC) have the potential to overcome these limitations. DDCs are composed of heptamethine carbocyanine (HCC) compounds that selectively interact with Organic Anion-Transporting Polypeptides (OATPs), chemically conjugated to diverse cytotoxic payloads. DDCs target OATPs which are overexpressed across human tumor types and represent a novel class of tumor-selective transporter targets. Additionally, they possess near-infrared (NIR) fluorescence enabling both imaging and therapy delivery making them attractive as a single small molecule delivery framework. Novel HCC analogs were synthesized and characterized as tumor-targeting scaffolds. These compounds exhibited minimal intrinsic cytotoxicity in normal and tumor cell lines. In vitro imaging of tumor cell lines confirmed HCC uptake. In vivo and ex vivo imaging of tumor xenografts following HCC systemic administration confirmed HCC tumor accumulation with minimal accumulation in other organs. Two of the novel HCCs were synthesized with cytotoxic payloads including doxorubicin, SN38 and MMAE as pro-drugs, linked via a cathepsin B cleavable linker. Upon linker cleavage, the released drugs become active. These DDCs were assessed for solubility, thermodynamic stability and plasma stability (mouse, human) identifying promising candidates. Studying candidates further, in tumor cell lines HCC-MMAE was internalized, and cleaved to release MMAE, resulting in cell death. At 72H, IC50 of HCC-MMAE in A549 cells was 92.7±9.6nM, in MCF7 cells 59.3±4.6nM, and SW620 79.6±37.6nM. The IC50 for MMAE alone was 0.49±0.2nM, while HCC alone >1,000nM across all cell lines. In vivo and ex vivo imaging of tumor xenografts following systemic administration confirmed DCC tumor accumulation with minimal accumulation in other organs. In conclusion, novel HCC-based DDCs have been developed as tumor-selective targeting agents. Conjugation of cytotoxic payloads to the HCC scaffold allowed effective delivery of payload, with the potential ability to use compounds previously limited by their systemic toxicity. The HCC platform allows conjugation of diverse payloads, with broad tumor applicability through the OATP target, and is synthetically simple and cost-effective to produce.

#0427 PMR-116, a second-generation RNA polymerase I inhibitor displaying therapeutic efficacy in a broad spectrum of malignancies.

Nadine Hein[1], Rita Ferreira[2], Amee George[2], Katherine Hannan[1], Karagh Loring-White[3], Konstantin Panov[4], Eric Kusnadi[5], Richard Rebello[5], Alisee Huglo[5], Shelley Hedwards[5], Mitchell Lawrence[5], Mustapha Haddach[6], Denis Drygin[6], Ross D. Hannan[3], **Luc Furic**[5]

[1]Cancer Biology and Therapeutics, JCSMR, Acton, ACT, Australia,[2]ANU, Canberra, Australia,[3]ANU, Canberra City, Australia,[4]Queen's University, Belfast, United Kingdom,[5]Peter MacCallum Cancer Centre, Melbourne, Australia,[6]Pimera Inc, San Diego, CA

Ribosome biogenesis (RiBi) is a key driver of cell growth and is strongly elevated in cancers with high MYC activity. First-generation Pol I inhibitor CX-5461 showed clinical benefits but also triggered non-specific DNA damage. PMR-116 was developed to provide selective Pol I inhibition with improved tolerability, minimal off-target induced DNA damage and stronger on-target inhibition of rRNA synthesis.

PMR-116 anti-cancer activity was assessed across >100 cancer cell lines representing 20 major tumour types. It showed broad anti-proliferative activity, with GI50 values from 32-4500 nM and a median of approximately 300 nM. Normal tissue-derived cells were significantly less sensitive, with GI50 values between 6-33 µM. In vivo, PMR-116 significantly reduced tumour burden and improved survival in preclinical cancer models, including Vk*MYC multiple myeloma, CT26 colorectal cancer, MMTV-PyMT breast cancer and MLL-ENL+Nras AML (with and without TP53 mutation).

Given the strong dependence of MYC-driven cancers on elevated RiBi, PMR-116 produced marked responses in MYC-addicted cancer models, consistent with exploiting a core vulnerability in MYC-amplified disease. In the large MURAL cohort of advanced prostate cancer PDX, weekly PMR-116 monotherapy at 300 mg/kg produced complete responses in two models, including a neuroendocrine prostate cancer PDX, a subtype with limited therapeutic options. A targeted 3D culture screen identified synergy between PMR-116 and PARP inhibitors, and between PMR-116 and AR-targeting agents, both of which have clear clinical translation pathways.

In a phase I clinical trial, PMR-116 was well tolerated, demonstrated robust on-target activity producing approximately 50 percent reduction of rRNA synthesis in patient PBMCs within 24 hours. No global DNA damage signalling was detected at active dose levels.

Overall, PMR-116 shows potent anti-cancer activity across a wide range of malignancies, with particular strength in MYC-driven tumours. Its selectivity for Pol I and favourable safety profile support its progression into an MRFF-funded phase II basket trial commencing in 2026.

Poster Session

#0431 A new approach methodology (NAM) for specificity testing: ISTAND qualification of the membrane proteome array to evaluate off-target binding of MAb-based therapies.

Diana Norden, Jonathan T. Sullivan, Carmen Navia, **Jonathan Richards**, Alexander Hobby, Rachel Fong, Benjamin Doranz

Integral Molecular, Philadelphia, PA

Background: Scientifically validated New Approach Methodologies (NAMs) provide an opportunity to better predict drug safety in humans while also accelerating drug development and regulatory review. The FDA has established pathways to qualify NAMs as Drug Development Tools (DDTs) through various mechanisms that now include the Innovative Science and Technology Approaches for New Drugs (ISTAND) program.
Methods: We developed the Membrane Proteome Array (MPA) platform for specificity testing of antibody-based therapeutics. The MPA assesses binding interactions across ~6,000 membrane proteins, each individually expressed in their native structural configuration within live or unfixed cells. The screen uses high-throughput flow cytometry, allowing for quantitative and high-sensitivity detection, and any identified targets are validated by titration analysis. The MPA is being qualified as a novel DDT through FDA's ISTAND program.
Results: As part of our DDT qualification, we performed a comparison study of 35 antibody therapeutics evaluated for specificity using both our MPA and conventional tissue cross-reactivity (TCR) studies. We found that 17% of these drugs had an off-target that was not expected based on TCR results. Overall, the MPA and TCR results were consistent for only about half of the molecules tested. In numerous instances, TCR results were inconclusive based on technical variability, nonspecific or cytoplasmic staining, or false-positive staining. Such results highlight the difficulty of using TCR data for deciding actionable next steps. In contrast, off-targets from the MPA are de-risked by statistically quantifying relative affinity and binding levels, localizing binding to extracellular vs. intracellular epitopes, and determining tissue expression patterns in humans to assess the in vivo safety risk. Through the MPA qualification process, we have also quantified the sensitivity and reproducibility of the platform and implemented additional quality control procedures and data analyses.
Conclusions: MPA data is already routinely used in regulatory applications for antibody-based biotherapeutics and may be used to replace or complement other cross-reactivity studies. The MPA is currently in the last stages of review for DDT qualification through FDA's ISTAND program.

#0432 Targeting Brachyury with small molecules: A new therapeutic paradigm for chordoma and neuroendocrine carcinomas.

Gaelle Mercenne, Brian McEllin, Julia Robbins, Lindsay Pino, Gavin Hirst, Alexander Joel Federation

Talus Bio, Seattle, WA

Chordoma is a rare cancer arising from embryonic notochord remnants, most often in the sacrum and cervical spine. Although surgery and radiation are standard treatments, complete removal is frequently not possible and recurrence is common, leaving patients without effective targeted therapies. A defining molecular hallmark of chordoma is the aberrant reactivation of the transcription factor (TF) Brachyury (TBXT), a developmental regulator normally silenced in adult tissues. TBXT functions as a lineage-survival factor, driving tumor initiation and progression and establishing itself as both a diagnostic marker and compelling therapeutic target.However, TFs like TBXT are inherently difficult to drug due to their structural disorder and dependence on chromatin context. To overcome these barriers, we developed TF-Scan, a proteome-wide mass spectrometry platform that directly quantifies TF chromatin occupancy in live cells, enabling functional assessment and therapeutic targeting of TFs that were previously considered undruggable.Using TF-Scan, we discovered TAL61, a first-in-class covalent small-molecule hit that selectively binds TBXT and displaces it from chromatin. We initiated an iterative medicinal chemistry campaign, generating multiple analog series with improved covalent engagement, potency, and drug-like properties. Lead compounds strongly suppressed TBXT-dependent transcriptional programs and showed potent cytotoxicity in TBXT-expressing chordoma cell lines while sparing TBXT-negative controls. In vivo, optimized analogs produced robust tumor growth inhibition in UCH1 xenografts and the CF-365 patient-derived xenograft model, with excellent tolerability and durable pharmacodynamic activity.Transcriptomic analyses of TCGA, cBioPortal, and CRO datasets revealed aberrant TBXT expression in subsets of NECs, including Merkel Cell Carcinoma and Small Cell Lung Cancer. Ongoing work using cancer cell lines and patient-derived organoids is defining TBXT dependency in these diseases, suggesting that TBXT may serve as a broader lineage survival factor.Together, these results establish TF-Scan as a powerful TF drug discovery- platform and demonstrate the feasibility of pharmacologically targeting TBXT. Our covalent inhibitors show potent, selective antitumor activity in chordoma and point to new therapeutic opportunities in neuroendocrine cancers lacking targeted treatments.

#0433 A robust automated workflow for precise oncoprotein quantification to accelerate targeted degradation and oncology research.

Alex M. Strom[1], Quynh Nguyen[1], Qiuyan Ma[2]

[1]Protein, OriGene Technologies, Inc., Rockville, MD,[2]OriGene Technologies, Inc., Rockville, MD

Quantitative and reproducible measurement of oncoproteins is essential for evaluating signaling biology, validating biomarkers, and advancing targeted degradation strategies such as Proteolysis-Targeting Chimeras PROTACs. Traditional Western blotting is widely used but is limited by variable assay performance and poor reproducibility, hindering its ability to support rigorous protein quantification across diverse sample types.[1] Similarly, ELISA detection methods are often not sufficiently sensitive and do not confirm the molecular weight of the detected protein. We developed a fully automated, calibration-based workflow using the Jess™ automated Western system to enable sensitive and absolute quantification of endogenous and overexpressed proteins. KRAS was used as a representative oncogenic target. While historically KRAS has been regarded as an undruggable target, recent advances in the field have demonstrated that PROTAC strategies can effectively degrade this oncogenic protein, increasing the important of precise KRAS quantification tools.[2] A recombinant KRAS standard curve (0.012-1.5 ng/µL) demonstrated excellent linearity ($R^2 > 0.99$), broad dynamic range, and high sensitivity. Precision testing showed robust peak area agreement across capillaries and days, confirming stable performance suitable for quantitative protein profiling. Application of this workflow to HeLa lysates, transiently transfected HEK293 cells, and extracellular vesicle samples enabled reliable detection of both high- and low-abundance KRAS populations. Quantitative assessment of the constitutively active KRAS mutant G12D antibody further highlighted the platform's ability to resolve clinically relevant variants with high specificity and sensitivity.[3] Although demonstrated using KRAS, this automated workflow is broadly applicable to additional oncoproteins, signaling molecules, and degradation substrates. Its integration of automated capillary electrophoresis, defined calibration standards, and digital quantification supports key applications including PROTAC efficacy assessment, variant-specific analysis, and biomarker development. By coupling reproducible assay performance with absolute quantification, this method provides a powerful platform to accelerate oncology research and therapeutic discovery across multiple protein targets.

#0434 Target agnostic phage display for nanobodies that alter immune cell function.

Peter Qian Leung[1], Todd A. Aguilera[2], Eslam A. Elghonaimy[2], Thillai Sekar[3], Mike Whitney[4], Isaac Gonzalez[2]

[1]UTSW, Dallas, TX,[2]University of Texas Southwestern Medical Center, Dallas, TX,[3]Pondicherry University, Puducherry, India,[4]UCSD, San Diego, CA

Introduction: The discovery of novel cancer immunotherapies is currently limited by a reliance on known antigens and screens that prioritize binding affinity over function. To overcome this, we developed INSPIRE-seq, a platform integrating NGS and phage display to unbiasedly select for nanobodies against cell subtypes within the tumor microenvironment (TME). Here, we advance this technology to address a critical unmet need: the direct isolation of nanobodies that functionally modulate immune cell behavior. Our objective is to move beyond simple binding and deploy a strictly target-agnostic strategy to identify therapeutic candidates based solely on their ability to enhance T cell efficacy, without prior knowledge of their molecular targets.

Experimental Procedures: To validate this functional selection strategy, we established an *ex vivo* model using bead-purified naïve CD8 T cells. Cells were activated with αCD3 and αCD28 antibodies in the presence of recombinant PD-L1 to mimic TME inhibitory signaling. Simultaneously, the cells were co-incubated with a library of nanobody-displaying bacteriophage. The top 10% of live T cells expressing the highest levels of the activation marker CD69 were sorted via flow cytometry to capture nanobodies capable of enhancing T cell activation, independent of their binding target. Enrichment dynamics were tracked via Oxford Nanopore sequencing. Individual phage clones were subsequently amplified and re-tested for both binding and functional modulation within the same assay.

New Data: We initiated the screen using a library with confirmed *in vivo* efficacy, verifying that this activity translated to detectable baseline modulation in our *ex vivo* model to ensure the presence of enrichable candidates. From this validated starting point, we performed four rounds of biopanning and sorting for increased CD69 expression. We isolated individual clones that, based on amplicon sequencing, collectively represented 25% of the starting library population. These dominant clones were individually tested for activity. Notably, clone 9-1-12 exhibited significant binding to CD8 T cells compared to controls. Critically, this binding was functionally linked to activation: the specific population of T cells bound by the nanobody displayed a significantly increased frequency of CD69 positivity despite the presence of PD-L1 inhibition. This demonstrates the feasibility of recovering a functional modulator solely through phenotypic selection.

Conclusions: Our findings provide evidence that INSPIRE-seq can select and enrich for nanobodies that alter cell function in a target-agnostic manner. This supports our central hypothesis that phenotypic screening can identify immunomodulators without prior antigen knowledge, offering a novel pipeline to uncover therapeutic candidates that overcome TME immunosuppression.

#0435 Novel anti-CD3 heavy chain-only antibodies for use in T-cell engaging therapeutics.

Noel Pauli, Hannah Watkins, Paul Khalife, Elizabeth Parker, Cameron Henkel, Todd Boland, Hailey Heston, Christin Strong, Jinfu Zhao, Irina Burnina, Michael Brown, Jessica Dawson, Garrett Rappazzo, Beth Sharkey, Morgan Morrill, Michael Battles, Robert Pejchal, Eric Krauland

Adimab, Lebanon, NH

Background: Multispecific T cell-engager (TCEs) antibodies have shown great promise as immunotherapeutic molecules. These therapies redirect T cells to recognize and kill cancer cells through co-engagement of tumor associated antigens and a T cell antigen, often CD3. Despite their clinical efficacy, the molecular complexity of current TCEs poses challenges for drug manufacturability, developability, and achieving desirable pharmacokinetic/pharmacodynamics. Currently, all approved TCE multispecifics rely on αCD3 binders derived from conventional IgG antibodies.Heavy chain-only antibodies (HCAbs) featuring a single-domain (VHH) binding moiety are attractive alternatives to conventional IgGs in immunotherapies. The absence of a light chain in HCAbs notably simplifies multispecific development. To-date, no αCD3 HCAbs with properties comparable to best-in-class clinically approved IgGs have been reported.

Methods: Functional αCD3 HCAbs were discovered by combining llama immunization and a novel yeast-based HCAb discovery technology. Following rounds of yeast-based HCAb selection, T cell stimulating αCD3 HCAbs were identified, humanized, and optimized to exhibit desirable drug profiles. We demonstrated the potency of these lead molecules in two bispecific formats: 1+1 αCD3 X αCD20 and as a VHH-TCR fusion using a TCR specific for the gp100 peptide HLA complex. CD3ε binding was confirmed by x-ray crystallography using one of the lead HCAbs.

Results: This study resulted in a panel of six functional αCD3 TCEs. These molecules predominantly competed with a known CD3 epitope, recognizing the CD3ε subunit of the human T cell receptor complex with weak to strong affinities and robust drug developability profiles. Crystallographic data and subsequent structural modelling show a unique angle of approach for our lead stimulating HCAb suggesting the interaction with the TCR complex is likely limited to only the CD3δε heterodimer, as CD3γε docking is modeled to produce significant steric clashes. The panel displayed a promising functional potency range as multispecifics; with two molecules displaying comparable *in vitro* tumor cell killing efficacy to clinically validated molecules such as the first-in-class TCR-αCD3 fusion TCE, tebentafusp.

Conclusions: We showcase the discovery and engineering of novel αCD3 HCAbs with functional potency comparable to other clinically validated molecules. This panel of highly-developable HCAbs provide new building blocks to expand the design space for TCE multispecifics and enable the next generation of multispecific immunotherapeutics.

#0436 Redox-DNA repair co-targeting with IP-DNQ and rucaparib induces oxidative DNA damage and GSDME-mediated pyroptosis in NQO1-positive tumors.

Soumya Tumbath[1], Hao Zhou[1], Jiangwei Wang[1], Lingxiang Jiang[1], Elin H. Chen[2], Celine Thormann[1], Xiumei Huang[1]

[1]Department of Radiation Oncology, Indiana University School of Medicine, Indianapolis, IN,[2]Benjamin Franklin High School, New Orleans, LA

Cancer remains a leading cause of mortality worldwide, with current therapies often failing to eradicate resistant tumor populations. This highlights the need for strategies that exploit tumor-specific metabolic and DNA repair vulnerabilities. NAD(P)H:quinone oxidoreductase 1 (NQO1), commonly overexpressed in solid tumors, enzymatically activates redox-cycling prodrugs, offering a selective tumor targeting strategy. Isopentyl-deoxynyboquinone (IP-DNQ), a potent NQO1-bioactivatable quinone, undergoes futile redox cycling to generate reactive oxygen species (ROS), induce oxidative DNA damage, and deplete NAD^+/ATP. Given that PARP activation is an early response to DNA damage, we investigated the mechanistic synergy between NQO1-dependent redox cycling and PARP inhibition using IP-DNQ combined with rucaparib, an FDA-approved PARP inhibitor. Rucaparib significantly enhanced IP-DNQ-induced ROS accumulation, DNA strand breaks, and metabolic collapse in an NQO1-dependent manner. This combination triggered caspase-3 activation and gasdermin E (GSDME) cleavage, leading to pyroptotic cell death characterized by LDH release and IL-1β secretion. Both pharmacologic inhibition and genetic knockout of NQO1 abolished these effects, confirming the essential role of IP-DNQ bioactivation. Importantly, the IP-DNQ/rucaparib combination suppressed tumor growth and prolonged survival in orthotopic pancreatic and lung cancer models without causing systemic toxicity. These findings uncover a novel redox-DNA repair co-targeting strategy that amplifies oxidative DNA damage and redirects apoptosis toward immunogenic GSDME-mediated pyroptosis. This approach broadens the therapeutic scope of PARP inhibitors and offers a promising platform for treating NQO1-overexpressing cancers.

#0437 Targeting RNA demethylase ALKBH5 with mefloquine enhances antitumor immunity and reduces osteosarcoma progression and metastasis.

Victoria Chen Mai[1], Daisy Medina[2], Manjeet K. Rao[3]

[1]UT Health Science Center San Antonio, San Antonio, TX,[2]UT Health Science Center at San Antonio, San Antonio, TX,[3]Assistant Professor, Greehey Children's Cancer Research Institute, San Antonio, TX

Background: Osteosarcoma (OS) is the most common form of bone cancer in youth, with a second incidence peak observed in adults over the age of 50. Current OS treatments rely on aggressive chemotherapy and surgery, which remain largely ineffective for patients with metastatic or relapsed disease. Approximately 20% of patients present with metastases at the time of diagnosis, with a five-year survival rate below 30%. This highlights an urgent need for a novel drug to treat OS. Recently, our group identified the RNA demethylase ALKBH5 as a key promoter of OS growth and metastasis. Using high throughput FDA approved drug library, we identified mefloquine as a small-molecule inhibitor of ALKBH5. Importantly, we discovered that mefloquine improves the efficacy of immunotherapy in OS. These findings indicate that mefloquine may serve as an effective therapeutic for treating osteosarcoma patients.

Methods: shRNA and CRISPR-Cas9 based knockout were used to assess the effects of ALKBH5 depletion on osteosarcoma growth and metastasis. Fluorescence-based high-throughput screening (HTS) of FDA-approved and LOPAC compound libraries identified mefloquine as a potential ALKBH5 inhibitor. RNA sequencing was performed to identify genes altered in mefloquine-treated OS cells. In vitro human and murine OS models were used to identify the inhibitory potency of mefloquine. Surface plasmon resonance (SPR) and m6A dot blot assays were used to validate mefloquine’s interaction with ALKBH5. In vivo orthotopic intratibial and tail vein mouse models were used to test the efficacy of mefloquine for reducing OS growth, metastasis, and improving immunotherapy response. Ongoing experiments aim to further elucidate the mechanisms of mefloquine-mediated OS suppression.

Results: Here, we demonstrate that mefloquine is a promising inhibitor of ALKBH5, suppressing OS growth and metastasis, and improving immunotherapy response. Loss of ALKBH5 in vitro and in vivo significantly reduced osteosarcoma cell growth and tumor burden. RNA sequencing revealed that mefloquine treatment led to upregulation of immune-related genes. In vivo mouse models showed reduction of tumor volume and metastatic burden in mice treated with mefloquine.

Conclusion: Our results establish mefloquine as a promising inhibitor of ALKBH5 in osteosarcoma, effectively suppressing tumor growth and metastasis while enhancing antitumor immune responses. As an FDA approved drug for malaria, mefloquine could be repurposed as a safe and effective therapy for OS.

#0438 The multibody drug conjugate (MDC) BD200 mediates anti-tumor activity through a novel dual-targeting mode.

Michael D. Oberst, Dror Luger, Micheal Kebede, Devi Gunasekera, Meital Gadrich, Yonit Ben David, Leah Asulin, Noam Grossman, Reut Fuchs, Hezi Sasson, Yael Diesendruck, Guy Nimrod, Tim Wyant, Ronald Herbst, Yanay Ofran, Inbar Amit

Biolojic Design, Rehovot, Israel

Purpose: The therapeutic efficacy of antibody drug conjugates (ADCs) relies on effective tumor targeting. However, intra-tumor and inter-lesional heterogeneity of target expression limit ADC efficacy. Moreover, treatment with an ADC exerts selective pressure favoring antigen-negative clones, thus enhancing drug resistance. To address this challenge, we introduce the Multibody technology, which allows for specific recognition of multiple tumor associated antigens through a simple symmetrical antibody.
Methods: Multibodies maintain the format of natural, symmetrical IgGs but can adjust their binding to different tumor surface-enriched antigens. This multi-specificity is designed to improve drug efficacy, reduce resistance and widen the responding patient population. BD200 is a multibody drug conjugate (MDC) whose fragment variable (Fv) domain is designed to bind alternatively to either TROP2 or Nectin-4 with high specificity. In its symmetrical human IgG1 format, two such identical Fv domains create an “OR" gate enabling the MDCs to bind bivalently to cells that express target A, cells that express target B or cells that express both A and B. BD200 incorporates a topoisomerase 1 inhibitor-based linker-payload. We tested BD200’s internalization and cell-killing on a wide array of tumor types, each expressing one or both antigens. In a series of in-vivo mouse studies using human cell line-derived xenograft (CDX) and patient-derived xenograft (PDX) models, we compared BD200’s efficacy to that of several approved anti-TROP-2 and anti-Nectin-4 ADCs. In these studies, we also tested BD200 in tumors that are refractory to approved ADCs. Finally, we assessed PK in NHPs to cross-compare with data from approved ADCs.
Results: BD200 demonstrated rapid internalization and strong cytotoxic potency across a wide range of tumor cells. While each approved monospecific ADC performed well on some tumor cell lines, BD200 was comparable or superior to approved ADC comparators with all cell lines tested in vitro. Assessing in vivo anti-tumor efficacy, BD200 showed deep and durable anti-tumor responses including in models refractory to approved ADCs. BD200 showed similar or superior serum stability and PK properties compared to approved ADCs.
Conclusion: The preclinical data suggest that a bivalent MDC addresses the challenge of tumor heterogeneity, while retaining the developability and the functional traits of a natural, simple, symmetrical human IgG. This may allow BD200 to drive deeper responses in more tumor types and more patients than existing ADCs.

#0439 Inhibition of extracellular matrix remodeling and metastatic activity by dichloroacetate and chloroquine in the presence of arsenite in 4nqo-induced oral squamous cell carcinoma.

Mounia Benbelkacem[1], Nabila Moulai[2], Eimen Kais Kadri[1], Lina Stamboul[1], Henni Chader[3], Wahiba Ouhaioune[2], Mehdi Bourouba[1]

[1]Laboratory of Cellular and Molecular Biology (LBCM), Team Biotechnology and System Biology, Faculty of Biological Sciences, University of Sciences and Technology Houari Boumediene (USTHB), Bab-Ezzouar, Algiers, Algeria,[2]Laboratory of Anatomopathology, Frantz Fanon Hospital, Blida: University of Blida, Faculty of Medicine, Blida, Algeria,[3]Laboratory of Pharmaco-toxicology, National Agency of Pharmaceutical Products, Faculty of Pharmacy, University of Algiers 1, Algiers, Algeria

Introduction: Oral squamous cell carcinoma (OSCC) is characterized by extracellular matrix (ECM) remodeling associated to a pro-inflammatory and protumoral metabolic activity that promote invasion and metastatic progression. This study assessed the effect of a triple therapy combining sodium arsenite (NaAsO2), chloroquine (CQ), and dichloroacetate (DCA) on inflammatory signaling and ECM remodeling in a 4-nitroquinoline-1-oxide (4NQO)-induced tongue OSCC mouse model.
Methods: Eight-week-old female BALB/c mice were exposed to chemical induction with the carcinogen (100 µg/ml) or treated with placebo (water control) for 16 weeks, then observed for up to 16 additional weeks. At 32 weeks post-treatment, mice were sacrificed, and their tongues were removed. The oral tumor tissues were then cultured for 24 hours in the presence of NaAsO2, CQ, and DCA. Tumor tissues and explants were analyzed for TNF-α, nitric oxide (NO), matrix metalloproteinase-9 (MMP-9), and collagen integrity.
Results: 4NQO carcinogenic activity on animal tongues led to a significant development of dysplasia and invasive SCC cases. OSCC explants culture showed in comparison to healthy tissues elevated levels of nitric oxide production, associated with increased expression of the pro-tumoral TNF-α, MMP-9 expression and collagen fiber disorganization were increased in such conditions. Surprisingly whereas NaAsO2 alone amplified inflammatory mediators, its combination with CQ and DCA significantly decreased NO and TNF-α levels. Strikingly this effect led to a significant downregulation of MMP-9, and preserved Type IV collagen architecture. Masson's trichrome staining revealed a restoration of dense, parallel collagen fibers resembling those found in an ECM architecture observed in low-grade dysplasic tongues in comparison with OSCC. These findings demonstrate that TNF-α/NO-driven MMP-9 activation is a central mechanism of ECM degradation in OSCC, and that a simultaneous modulation of aerobic glycolysis and autophagy may disrupt the metastatic signaling axis involved in extracellular matrix remodeling and metastatic activity in 4nqo-induced oral squamous cell carcinoma.
Conclusion: Altogether, our findings show that our combined treatment was able to reprogram the inflammatory process of tumor progression by inhibiting the molecular processes involved in extracellular matrix remodeling and invasion. This combined treatment represents a novel avenue for metabolic-inflammation-targeting strategy for OSCC in particular in view of the limited treatment options and the risk of chemoresistance.

#0440 Targeting oncogenic TBRI signaling inhibits androgen-independent prostate cancer growth and metastasis.

Per Flodbring Larsson[1], Alexej Schmidt[1], Yabing Mu[1], Guangxiang Zang[1], Jie Song[1], Vishnupriya Gajavilli[2], Junting Tao[2], Olena Rahkimova[1], Madelene Ericsson[1], Karthik Aripaka[1], Sofia Halin Bergstroem[1], Wei Yuan[3], Denisa Bogdan[4], Aaron Zhang[5], Jon Welti[5], Anders Bergh[1], Johann de Bono[6], Carl-Henrik Heldin[7], **Marene Landstroem**[1]

[1]Umea University, Umea, Sweden,[2]Department of Medical Biosciences, Umea University, Umea, Sweden,[3]The Institute of Cancer Research, London, London, United Kingdom,[4]The Institute of Cancer Research, Sutton, Sutton,[5]Institute of Cancer Research, London, United Kingdom,[6]Institute for Cancer Research, London, United Kingdom,[7]Uppsala University, Uppsala, Sweden

Metastatic castration-resistant prostate cancer (mCRPC) remains the primary cause of prostate cancer-related mortality. Despite available treatments, the molecular mechanisms underlying tumor invasion and metastasis are not fully understood, highlighting the need for novel therapeutic strategies. In this study, we developed fully human monoclonal antibodies (mAbs) that prevent the proteolytic cleavage of the transforming growth factor-beta (TGFβ) type I receptor (TβRI) by steric hindrance. This cleavage, mediated by the metalloprotease ADAM17 (a disintegrin and metalloprotease domain 17), also known as TACE, results in the generation of a soluble intracellular domain (TβRI-ICD) that translocates to the nucleus of castration-resistant prostate cancer (CRPC) cells and promotes epithelial-to-mesenchymal transition (EMT), invasion, and metastasis. High levels of *TGFBR1* were found to correlate with poor survival in two independent clinical cohorts of patients with mCRPC, and a strong positive association between *TGFBR1* and *ADAM17* expression was observed. In a preclinical human mCRPC mouse model, treatment with our therapeutic mAbs effectively prevented nuclear accumulation of TβRI-ICD, inhibited EMT, and suppressed tumor growth, invasion, and metastasis. Notably, the therapeutic effect was comparable to that of docetaxel, a current standard-of-care chemotherapy, and without noticeable side effects. These findings suggest that targeting TβRI cleavage using specific mAbs offers a novel precision medicine approach for mCRPC. By selectively blocking the pro-metastatic activity of TβRI-ICD without disrupting physiological TGFβ signaling, this strategy may provide a safer and more effective alternative to existing therapies for advanced prostate cancer.

#0441 Breaking the KRAS inhibitor induced resistance-wall: Targeting KRAS-SOS1 to disarm hypoxic survival.

Jooyun Byun[1], Heesun Moon[2], Jongmin Hong[3], Soye Jeon[3], Jaeyul Choi[3], Seung Hyun Jung[4], Yongjae Park[1], YoungGil Ahn[5], In Young Choi[6]

[1]Hanmi Pharmaceutical Co., Ltd., Seoul, Korea, Republic of,[2]Hanmi Pharmaceutical Co., Ltd., Hwaseong-si,[3]Hanmi Pharmaceutical, Hwaseung, Korea, Republic of,[4]Hanmi Pharmaceutical Co., Ltd., Seoul,[5]Hanmi Pharmaceutical Co., Ltd., Hwaseong-si, Korea, Republic of,[6]Hanmi Pharmaceuticals, Seoul, Korea, Republic of

Significant progress has been made in targeting KRAS, however, KRAS G12C inhibitors like sotorasib and adagrasib have shown only modest efficacy with ORR of 28-43% and PFS of around 6 months, highlighting unmet needs for overcoming the resistance compared to EGFR inhibitors like osimertinib with ORR of 77% and PFS of 18.9 months. Acquired resistance involves $KRAS^{G12C}$ amplifications, activating KRAS/NRAS mutations, and bypass activation of RTK, PI3K-AKT, YAP/TAZ-TEAD or JAK-STAT3 pathway. KRAS inhibitors also disrupt ERK-driven negative feedback, causing ERK reactivation and adaptive resistance. To address these limitations, vertical inhibition across the RTK-RAS-MAPK axis has gained attention[1)]. Here, to investigate mechanisms underlying acquired resistance and identify effective combination strategies, we established KRAS G12C inhibitor-resistant clones from NCI-H358 cells by performing ENU mutagenesis followed by single-cell selection, and then gradually exposing the selected clones to increasing concentrations of sotorasib and adagrasib for 6-9 months. In both sotorasib- and adagrasib-resistant clones, p-ERK was suppressed while elevation of p-AKT and YAP expression with enhanced nuclear localization was observed compared with parental cells. Surprisingly, SOS1 expression was significantly elevated over 3-fold in both sotorasib- and adagrasib-resistant clones without change in SOS2 levels, which is known to play a compensatory role, indicating that SOS1 co-inhibition is critical for overcoming KRAS inhibitor resistance. Our SOS1-panKRAS modulator, HM101207 exhibited strong synergy with KRAS G12C, RAS(ON) or MAPK pathway inhibitors in KRAS G12C-mutant NCI-H2122 and SNU-1411 cells. In NCI-H1373 and NCI-H2122 xenograft models, oral administration of HM101207 at 100 mg/kg produced a marked enhancement of antitumor activity when combined with adagrasib at low dose 20 mg/kg and high dose 100 mg/kg, or with RMC-6236 25 mg/kg. Notably, HM101207 restored tumor regression even after tumors relapsed under adagrasib or RMC-6236 monotherapy. To explore how SOS1 inhibitor modulates KRAS inhibitor-induced resistance, we performed RNA-seq on mouse xenograft tumors derived from KYSE-410 cell harboring the KRAS G12C mutation after HM101207 treatment. Differential expression analysis revealed that HM101207 significantly inhibited the expression of hallmark hypoxia genes including ALDOC, ENO2, HK2, MKNK2, PFKFB3, PGK1, SERPINE1, SLC2A1, VEGFA. Hypoxia is associated with the drug-tolerant persister state and eventually leads to drug-resistance. Therefore, HM101207 can overcome KRAS inhibitor resistance by strongly suppressing both MAPK and hypoxic pathways. As a combination therapy, it enables more durable pathway inhibition and enhanced antitumor efficacy. GLP toxicology studies are ongoing to support IND submission.

#0442 Crippling cancer's energy and escape: NAMPT and BCL2 as dual targets in T-ALL.

John Robert Sanchez[1], Daisy Diaz-Rohena[1], Valerio Ciaurro[1], Min Wu[2], Francis Roushar[2], Dennise A. De Jesus-Diaz[2], Gregory Crimmins[2], Pratibha Sharma[3], Vinay Puduvalli[3], Francisco Vega[4], Palaniraja Thandapani[1], Deepa Sampath[1]

[1]Hematopoietic Biology and Malignancy, UT MD Anderson Cancer Center, Houston, TX,[2]Remedy Plan Therapeutics, Gaithersburg, MD,[3]Neuro-Oncology, UT MD Anderson Cancer Center, Houston, TX,[4]Hematopathology, UT MD Anderson Cancer Center, Houston, TX

T-cell acute lymphoblastic leukemia (T-ALL) is a highly aggressive hematologic malignancy with limited targeted therapies. While chemotherapy induces remission, relapse remains a major challenge, with long-term event-free survival of only ~30%. Transcriptomic profiling of patient samples (GSE33469, GSE33470) revealed that T-ALL exhibits elevated oxidative phosphorylation (OXPHOS) activity and upregulation of NAMPT, the rate-limiting enzyme of NAD^+ salvage pathway. The salvage pathway is the main pathway utilized by eukaryotic cells to produce NAD+, a critical energy currency used for biological processes such as glycolysis, oxidative phosphorylation, and the DNA damage response. Previous targeting of NAMPT was unsuccessful because complete inhibition of NAMPT was associated with unacceptable toxicities. Here, we evaluate RPT1G, a novel hyperbolic NAMPT inhibitor designed to avoid toxicities associated with complete inhibition, as a therapeutic candidate for relapsed/refractory (R/R) T-ALL. RPT1G eliminates NAD+ in cancer cells while allowing NAD+ production in healthy tissues. This was linked to cytotoxicity in T-ALL whereas toxicity in normal PBMCs was mitigated sparing these cells. We hypothesized that hyperbolic inhibition of NAMPT with RPT1G would selectively impair T-ALL cell metabolism while sparing normal cells, and that combining RPT1G with agents targeting compensatory survival pathways could enhance therapeutic efficacy. RPT1G was evaluated in a Phase 1 healthy volunteer clinical study and showed a favorable safety and tolerability profile (NCT06667765). In T-ALL, RPT1G rapidly depleted intracellular NAD^+/NADH and ATP, with Seahorse assays confirming suppression of mitochondrial energy pathways such as glycolysis and OXPHOS compared to vehicle controls. Further, a CRISPR loss-of-function screen identified the antiapoptotic protein BCL2 as a synthetic lethal partner with RPT1G. Consistently, combining RPT1G with venetoclax, a clinically available BCL2 inhibitor, produced enhanced cytotoxicity across T-ALL cell lines and significantly enhanced ATP depletion compared to single agents. BH3 profiling, a functional assay used to determine BCL2 family dependencies, was used on several patient-derived xenograft (PDX) models. Using different concentrations of BH3 mimetics (BIM, BAD, MS1, and XXA1 0.01uM - 100uM) we demonstrated modest BCL2 dependency in these models, further supporting this strategy. In vivo, the RPT1G-venetoclax combination significantly extended survival in PDX-bearing mice compared to vehicle or monotherapy groups. These findings establish NAMPT inhibition with RPT1G plus BCL2 blockade with venetoclax as a promising therapeutic approach for R/R T-ALL, warranting further translational investigation.

#0443 LMTK2: A novel driver of endocrine resistance in ERα+ breast cancer.

Anna Detry[1], Sofia Marigliano[1], Jenna Heinen[1], Adam Bass[1], Calley Jones[1], Rajeev Muthyala[1], Matthew Goetz[2], John Hawse[1]

[1]Biochemistry and Molecular Biology, Mayo Clinic, Rochester, MN,[2]Oncology, Mayo Clinic, Rochester, MN

Breast cancer is the most common female malignancy in the U.S. and the leading cause of cancer-related deaths in women worldwide. Nearly 80% of breast tumors express estrogen receptor alpha (ERα) which drives tumor progression. While endocrine therapies and CDK4/6 inhibitors have increased overall survival, many patients experience recurrence of metastatic disease that is largely refractory to additional lines of endocrine therapy. Metastatic disease remains incurable, highlighting the need for alternative treatment approaches. Through a genome-wide CRISPR knockout screen, we identified Lemur Tail Kinase 2 (LMTK2) as the top hit exhibiting synthetic lethality in the presence of the endocrine therapy, endoxifen, in both endocrine-sensitive and -resistant cell line models. Using publicly available patient tumor databases we identified *LMTK2* copy number gain/amplification in 67% of ERα+ human metastatic breast tumors, while only 1% of primary tumors harbored these genomic alterations. Elevated LMTK2 expression in early-stage primary breast tumors was associated with worse recurrence-free survival and overall survival. We discovered that LMTK2 mRNA and protein levels were substantially elevated in nearly all cell-line and patient-derived models of endocrine and CDK4/6i resistance. Utilizing siRNAs and dox-inducible shRNA expressing cell lines, we found that knockdown of LMTK2 enhanced the efficacy of multiple endocrine therapies in treatment naïve models and resensitized resistant models to their respective treatment. LMTK2 overexpression was found to be sufficient for conferring resistance to all standard of care therapies tested including endocrine agents, CDK4/6i, and PI3K inhibitors. RNAseq and global proteomics of LMTK2 overexpressing and knockout models revealed the PI3K/AKT pathway and estrogen signaling as highly regulated pathways by LMTK2. Confirmatory western blot studies demonstrated that LMTK2 overexpression results in dramatic increases in AKT and ERα phosphorylation and activity, while knockout of LMTK2 diminishes these effects. Attempts to completely ablate LMTK2 in endocrine/CDK4/6i-resistant models via CRISPR were not successful, and continuous siRNA or shRNA-mediated knockdown was lethal in resistant cell lines, confirming its essentiality in this setting. In summary we have uncovered LMTK2 as a novel mediator of endocrine/CDK4/6i resistance that is mechanistically linked to the PI3K/AKT pathway among others. Genetic manipulation of LMTK2 has validated it as an ideal therapeutic target for both advanced and newly diagnosed forms of ERα+ breast cancer.

#0445 Evaluation of HERV-K as an unusual cancer therapeutic target.

Monica Gordon[1], James H. Torpey[2], Andy D. Martin[2], Benjamin R. Miller[2], Marica Speranza[3], Kenneth W. Hance[4]

[1]Oncology ETCT BU, GlaxoSmithKline plc, Stevenage, United Kingdom,[2]GlaxoSmithKline plc, Stevenage, United Kingdom,[3]Oncology ETCT BU, Glaxosmithkline, Boston, MA,[4]GlaxoSmithKline, Malvern, PA

Human endogenous retroviruses (HERVs) are abundant genomic elements, transcriptionally repressed under normal physiological conditions. However, epigenetic alterations during disease reactivate HERV expression. HERV-K, specifically, has been identified as prevalent in numerous tumor types, including prostate, lung, breast, colon, and ovarian cancers and its presence correlates with tumor progression and protumoral signalling. In addition, HERV-K's immunosuppressive role in the placenta, where it is usually expressed, points to a potential similar function within the tumor microenvironment, making it an attractive therapeutic target. We have comprehensively evaluated HERV-K as a potential target for T-cell Engagers (TCEs) and Antibody-Drug Conjugates (ADCs). This evaluation has been limited by the availability of tool antibodies. Employing flow cytometry and immunohistochemistry (IHC), HERV-K expression on the tumor cell surface was consistently low and unstable, often lost upon enzymatic cell detachment, indicating susceptibility to proteolytic cleavage. Receptor quantification on HERV-K+ tumor cell lines varied from 0-25,000 receptors per cell. IHC results confirmed low membranous staining across various tumor types, with a significant proportion of the protein detected in the cytoplasm, and thus, not available for antibody engagement. In vitro functional evaluation was performed by generating HERV-K tool TCEs and ADCs. While HERV-K TCEs demonstrated moderate and specific tumor cytotoxicity, HERV-K tool ADCs did not elicit HERV-K-dependent cytotoxic effects. In conclusion, while HERV-K presents an intriguing opportunity due to its tumor-selective expression, its inconsistent and labile surface presentation poses considerable challenges. Our findings suggest that HERV-K may be a viable target for TCE-based therapies, but less so for ADCs, primarily due to insufficient receptor density. Future efforts necessitate the development of high-quality specific antibodies to fully harness HERV-K's therapeutic potential in cancer. Note: Human biological samples were sourced ethically, and their research use was in accord with the terms of the informed consents. IHC experiments were done by DLS.

#0446 Pre-targeting with click chemistry facilitates selective MMAE activation in CEACAM5+ tumors: A first-in-class approach to enhance clinical benefit in targeted therapy.

Sangeetha Srinivasan, Masa Alečković, George Coricor, Stefanie Wagner, Jesse M. McFarland, Nathan A. Yee, Tri-Hung Nguyen, Michael Zacharian, Travis L. Biechele, Jose M. Mejia Oneto

Shasqi, Inc., San Francisco, CA

Targeted therapies such as antibody-drug conjugates (ADCs) have transformed the delivery of cytotoxic payloads to tumors, yet their clinical efficacy is often hampered by off-target toxicities. These toxicities arise when the antigen-binding component undergoes systemic catabolic elimination that leads to premature release of the cytotoxic payload in healthy tissues. A pre-targeting approach which separates the targeting binder from the cytotoxic payload and enables them to unite only at the tumor site, offers a promising solution. In this paradigm, the binder is allowed to concentrate at the tumor but clear systemically before the protodrug is administered, It ensures that the payload is activated predominantly where the binder has accumulated—at the tumor—thereby reducing off-target toxicity and increasing the therapeutic index. We present preclinical data on Shasqi's Click Activated Protodrugs Against Cancer (CAPAC®), a click chemistry-based pre-targeting technology that powers tumor-directed in vivo payload activation. The therapeutic candidate consists of a CEACAM5-targeted, clickable small format antibody binder and a chemically attenuated, clickable protodrug of monomethyl auristatin E (MMAE). Upon administration, the binder accumulates at the tumor, and a subsequent protodrug dose 'clicks' specifically with the binder, restoring cytotoxic activity. The CEACAM5 binder showed high affinity (KD 0.046 nM) and binding potency (EC50 3.06 nM) with minimal internalization while retaining its ability to activate protodrugs. The MMAE protodrug was attenuated ~700-fold in vitro and cleared rapidly in vivo (thalf, fast = 6 min, thalf, slow =19 min), minimizing systemic exposure. In multiple CEACAM5+ xenograft models, CAPAC enabled superior tumor control compared to a cognate ADC, including complete responses in highly sensitive tumors (pancreatic and lung) and durable stasis in minimally sensitive tumors (gastric). The treatment also induced marked tumor regression in large mouse tumors. It was well tolerated in naïve rodents. This first-in-class CEACAM5-directed pre-targeting strategy addresses key limitations of conventional targeted therapies by leveraging in vivo click chemistry to selectively concentrate cytotoxic payloads at the tumor. It illustrates robust anti-tumor efficacy in multiple tumor models, including large tumors, more representative of the disease in humans, and a favorable tolerability profile. By decoupling the targeting from the payload delivery, pre-targeting with CAPAC minimizes off-target toxicity, enables higher dosing and has the potential to enhance clinical benefit.

#0447 A M2-like tumor-associated macrophage-targeted nanoparticulate TLR7/8 agonist, UI-102, reprograms its phenotypes to induce potent anti-tumor immunity.

Yasuhiro Nagai, Ayaka Matsumoto, Nami Mizoguchi, Mina Tsukamoto, Junki Tashiro, Tadashi Inoue, Takatoshi Soga, Naozumi Harada

United Immunity Co., Ltd., Kobe, Japan

Background: Tumor-associated macrophages (TAMs) are a major component of the tumor microenvironment (TME) and exhibit functionally distinct phenotypes: anti-tumoral M1 and pro-tumoral M2 TAMs. The predominance of M2-like TAMs promotes tumor growth, angiogenesis, and immunosuppression, making them a promising target for cancer immunotherapy. M2-like TAMs frequently express the C-type lectin DC-SIGN/CD209, and we discovered that nanoparticles composed of pullulan polysaccharide are preferentially engulfed by DC-SIGN-expressing M2 macrophages. Leveraging this property, we developed UI-102, a novel nanoparticulate TLR7/8 agonist using pullulan nanoparticles as an M2 TAM-targeted drug delivery system. This study aimed to evaluate the anti-tumor efficacy and mechanism of action of UI-102, focusing on its ability to reprogram TAM phenotypes and activate anti-tumor immunity.
Methods: The anti-tumor activity of UI-102 was assessed in multiple murine syngeneic subcutaneous tumor models. Mechanistic studies included analysis of TAM phenotypic shifts and activation of the anti-tumor immune cascade. Biodistribution and TAM accumulation were examined in an orthotopic mouse model, comparing UI-102 with resiquimod sulfate and the naked TLR7/8 agonist used in the UI-102 formulation.
Results: UI-102 exhibited broad and potent anti-tumor activity across diverse cancer models, correlating with the degree of myeloid/macrophage infiltration in the TME. Despite a short plasma half-life (T1/2), UI-102 rapidly and selectively accumulated in TAMs in the orthotopic model. This targeted delivery induced a robust phenotypic switch from immunosuppressive TAMs to an M1-like state, triggering downstream anti-tumor immune cascades. These changes were associated with increased infiltration of T cells and NK cells and the induction of tumor antigen-specific CD8+ T cells. The anti-tumor effects of UI-102 were significantly superior to those of control agents, including resiquimod sulfate and the naked TLR7/8 agonist.
Conclusion: UI-102 effectively targets and reprograms immunosuppressive TAMs to an M1-like phenotype, thereby unleashing a strong anti-tumor immune response. This unique mechanism positions UI-102 as a promising novel immunotherapeutic agent for a wide range of solid tumors. A first-in-human clinical trial of UI-102 in solid tumors is planned for initiation in Q1 2026.

#0448 Intranodal chemokine therapy targeting the sentinel lymph node in head and neck squamous cell carcinoma.

Anais Aurelia Zourelidis[1], Jonathan Gunn[2], Tomoya Kurokawa[1], Sayuri Miyauchi[1], Kelsey Decker[1], Peter Vo[1], Pardis Mohammadzadeh[1], Jason Wu[2], Ester J. Kwon[2], Joseph A. Califano[1]

[1]Moores Cancer Center, University of California San Diego, La Jolla, CA,[2]Shu Chien-Gene Lay Department of Bioengineering, University of California San Diego, La Jolla, CA

Emerging evidence highlights the potential of lymphatic-sparing strategies in head and neck squamous cell carcinoma (HNSCC), as well as the sentinel lymph node (SLN) as a critical immunological niche [1-3]. Within this context, CCR7$^+$ dendritic cells (DCs) have been identified as an essential subpopulation for the response to immunoradiotherapy [4]. Here, we investigated the therapeutic effect of intranodal CCR7 agonists CCL19/21 into the SLN using a sustained-release fibrin gel-conjugate system in the syngeneic, orthotopic, partially programmed death-1 inhibitor (PD-1i) sensitive 4MOSC1 model of HNSCC [5], aiming to enhance DC function along the tumor-SLN axis. C57Bl/6 mice were injected with 4MOSC1 cells in the buccal space and underwent SLN mapping and injection of CCL19/21 conjugated (con.) to fibrinogen intranodal (i.n.), CCL19/21 unconjugated (uncon.) to fibrinogen i.n., PD-1i intraperitoneal (i.p.), CCL19/21 con. to fibrinogen i.n. + PD-1i i.p., or sham surgery following 6 days after tumor implantation. Animals were monitored for tumor volume and survival. Primary tumors were assayed by flow cytometry. Intranodal con. CCL19/21 led to a significantly reduced tumor growth (p= <0,0001 vs. sham) and complete response (CR) rate of 60%, whereas uncon. CCL19/21 i.n. (p=0,3354 vs. sham) and sham groups showed no CR. Combination of con. CCL19/21 + PD-1i significantly improved overall survival with 80% survival by day 34, compared to 60% for con. CCL19/21 i.n., and 0% for uncon. CCL19/21 i.n. and controls. Flow cytometric analysis 48 h following treatment shows enhanced DCs and enhanced activated DCs in tumors in con. CCL19/21 treated mice. Intranodal delivery of CCR7 agonists CCL19/21 significantly enhances DCs and activated DCs in tumors, reduces tumor growth and prolongs survival in the HNSCC 4MOSC1 mouse model.

#0449 Albumin-based DLL3-targeted nano-immunoconjugates of SN38 preserve potency and demonstrate high-affinity DLL3 binding in small cell lung cancer.

Mohamed Shanshal[1], Lin Yang[2], Liyi Geng[3], Wendy Nevala[3], Aaron S. Mansfield[4], Bharath Wootla[5], Konstantinos Leventakos[1], Kyle Korshavn[1], Svetomir N. Markovic[3]

[1]Mayo Clinic Cancer Center Minnesota, Rochester, MN,[2]Research Associate, Dept. of Lab. Med. and Pathology, Mayo Clinic College of Medicine, Rochester, MN,[3]Mayo Clinic, Rochester, MN,[4]Mayo Clinic College of Medicine and Science, Rochester, MN,[5]Mayo Clinic Business Development, Mayo Clinic Cancer Center Minnesota, Rochester, MN

Background: Small cell lung cancer (SCLC) remains an aggressive malignancy with limited treatment options and a 5-year survival rate under 10%. Delta-like ligand 3 (DLL3), expressed in >85% of SCLC but absent from normal tissue, represents an attractive therapeutic target. Existing DLL3-directed antibody-drug conjugates suffer from poor payload stability and limited tumor penetration. To overcome these limitations, we engineered a DLL3-targeted nano-immunoconjugate (NIC) of SN38, the active metabolite of irinotecan, using an albumin-based nanoscaffold.

Methods: SN38 was encapsulated in a human serum albumin (HSA) matrix and non-covalently coated with a recombinant anti-DLL3 monoclonal antibody to yield DLL3-SN38-NIC. Stable conjugation was confirmed by HSA-IgG interactions and zeta-potential shift. Binding kinetics were evaluated using Biacore surface plasmon resonance (SPR) and Octet bio-layer interferometry (BLI) employing AHC biosensors to determine DLL3-antibody affinity and specificity. Cytotoxicity was assessed using IncuCyte live-cell imaging across five SCLC cell lines (DMS454, SHP77, NCI-H82, NCI-H889, and NCI-H211) with varying DLL3 expression.

Results: DLL3-SN38-NIC retained high-affinity DLL3 binding (KD ≈ 3×10^{-10} M) and demonstrated potent cytotoxicity in SCLC cell lines. NIC formation did not reduce cytotoxic activity compared with free SN38, confirming preserved potency. Cytotoxicity trends were consistent across lines with variable DLL3 expression, and DLL3 antibody alone exhibited negligible cytotoxicity. These findings confirm that nano-immunoconjugate formation maintains drug activity and DLL3 binding; additional in-vivo studies are underway to evaluate pharmacokinetics and tumor selectivity.

Conclusions: Albumin-based DLL3-SN38-NICs represent a novel nano-oncologic platform that preserves SN38 potency and achieves high-affinity DLL3 engagement. Ongoing studies will assess in-vivo selectivity, biodistribution, and therapeutic potential in DLL3-positive SCLC and other neuroendocrine malignancies.

Keywords: DLL3, nano-immunoconjugate, SN38, albumin nanocarrier, small cell lung cancer

#0450 JZY-2233: An antigen-targeted CBP/p300 degrader-antibody conjugate for advanced prostate cancer therapy.

Mi Wang[1], Jianzhang Yang[1], Brandon Bordeau[2], Shicheng Jin[1], Yu Wang[1], Shaomeng Wang[1]

[1]Department of Internal Medicine, University of Michigan, Ann Arbor, MI,[2]Department of Pharmaceutical Sciences, University of Michigan, Ann Arbor, MI

Background: CBP/p300 are essential transcriptional coactivators of the androgen receptor and play a critical role in prostate cancer pathogenesis. Small-molecule CBP/p300 degraders have demonstrated potent efficacy against prostate cancer but are limited by toxicity, impeding clinical translation.
Methods:To enhance tumor specificity and minimize systemic toxicity, we developed a Degrader-Antibody Conjugate (DAC) by linking a highly potent CBP/p300 degrader to a prostate-specific membrane antigen (PSMA) antibody, generating JZY-2233. In vitro antiproliferative activities were assessed using VCaP and LNCaP prostate cancer cell lines. In vivo efficacy, pharmacodynamics, and toxicity were evaluated in a LNCaP xenograft mouse model.
Results: JZY-2233 induced robust growth inhibition in VCaP and LNCaP cells, with picomolar IC50 values. In vivo, treatment with JZY-2233 led to sustained CBP/p300 degradation and suppression of c-Myc and PSA in tumor tissues, with effects persisting up to 168 hours post-dose. A single administration at 10 mg/kg resulted in complete tumor suppression for over 90 days in the LNCaP model, significantly exceeding the effect of the unconjugated parent degrader. Importantly, JZY-2233 markedly reduced systemic toxicity.
Conclusions: JZY-2233 is a highly potent, antigen-targeted CBP/p300-PSMA DAC, offering prolonged tumor suppression and reduced toxicity in models of advanced prostate cancer. This approach provides a strong rationale for further evaluation in clinical studies and may be adapted for targeting additional tumor antigens across diverse cancers.

#0451 Investigating SIX1 as a driver and target for a first in-class EMT degrader in head-and-neck squamous cell carcinoma.

Vic Scharfenberger, Asad Faili, Lucia Zoe Miehe, Ellen Weber, Samaneh Heydarzadeh, Reinhard Buettner, Tristan Lerbs

Pathology, University Hospital of Cologne, Cologne, Germany

Prognosis for head-and-neck squamous cell carcinoma (HNSCC) remains poor in advanced stages, and patients suffer from severe treatment-associated adverse effects. Here, we have preliminarily investigated whether the embryonic transcription factor SIX1 drives HNSCC and could serve as a target for a first-in-class EMT degrader. While SIX1 is required during embryonic development, it is no longer or only weakly expressed in adult tissue. However, many cancers show a reactivation of SIX1, leading to various pro-tumorigenic effects such as an increase in proliferation and an induction of epithelial-mesenchymal transition (EMT). This makes SIX1, particularly combined with its absent or low expression in normal tissue, a potentially therapeutic target. For this purpose, we developed a SIX1-specific PROTAC (ELX19) through a CRO. In this project, we have applied sequential immunofluorescence for the analysis of patient tissue, and in vitro assays to test the efficiency of the SIX1 degradation through ELX19 and detect associated phenotypic effects. The 36-marker immunofluorescence panel confirmed an increased SIX1 expression in cancer tissue and showed a correlation between SIX1 and an immunosuppressive immune infiltrate, highlighting potential mechanistic links between SIX1 and HNSC progression. Regarding the PROTAC, ELX19 led to an efficient SIX1 degradation in the nanomolar and low micromolar range (depending on the cell line) and induced therapeutically desirable effects, such as an increase in apoptosis under cisplatin. In conclusion, these preliminary results indicate the potential of SIX1 as a therapeutic option in HNSCC - an option that patients urgently need.

#0452 Therapeutic potential of AURKA inhibition in ER+ inflammatory breast cancer.

Tanu Sharma[1], Azadeh Nasrazadani[2], Ma Wencai[3], Jennifer Chen[4], Megumi Kai[2], Bora Lim[2], Michael Lewis[5], Lacey Dobrolecki[5], The MDACC IBC Team, Nikita Kotlov[6], Oleg Baranov[6], Disha Malani[6], Daria Goncharova[6], Anastasiya Evdokimova[6], Francesca Paradiso[6], Michael Hensley[6], Rachel Layman[2], Wendy Woodward[1]

[1]Breast Rad Onc - Research, UT MD Anderson Cancer Center, Houston, TX,[2]Breast Medical Oncology, UT MD Anderson Cancer Center, Houston, TX,[3]UT MD Anderson Cancer Center, Houston, TX,[4]Breast Surgical Oncology, UT MD Anderson Cancer Center, Houston, TX,[5]Baylor College of Medicine, Houston, TX,[6]BostonGene Corporation, Waltham, MA

Background: ER+ inflammatory breast cancer (IBC) is under-appreciated and under-investigated as an aggressive subset of ER+ breast cancer, despite having rates of metastasis comparable to triple negative (TN) IBC. Recent genome-wide profiling of tumors from patients with metastatic breast cancer has shown that IBC samples have a higher frequency of AURKA amplification than non-IBC samples. Our pilot studies in IBC validate these findings and suggest AURKA is amplified in TNIBC. We hypothesize that Aurora Kinase A (AURKA) is a viable therapeutic target in metastatic IBC and in particular ER+ IBC and may exhibit synthetic lethality with ARID1A and SMARCA4 in IBC.

Methods: We reviewed RNA and DNA data from clinically ordered BostonGene tumor assays for IBC versus non-IBC at MDACC. Using ER- IBC cell lines we examined the protein expression of AURKA and Alisertib efficacy was tested using WST assay in IBC cell lines. Senescence was examined using β-gal staining and ELISA assay. In vivo efficacy was studied in a novel ER+ IBC patient derived xenograft (PDX) MDA-BCM-IBC-102.

Results: We previously demonstrated using a large multi-institutional IBC data set including 137 IBC patient tissues analyzed using Affymetrix gene expression arrays, no clear clustering among ER response genes by ER+ subtypes and high AURKA expression in both ER+ and ER- cases. Comparing 23 ER+ IBC to 164 ER+ NON-IBC patient samples from Boston Gene, we find AURKA is amplified in 70% cases and a statistically significant inverse relationship between AURKA and SMARCA4 in IBC. Expression of AURKA by immunoblotting in IBC cell lines demonstrates AURKA expression in four IBC cell lines, including two HER2+ (IBC3 and KPL4) and two triple negative (A3250 and SUM149). Higher doses of Alisertib promote reversible senescence assayed by SA-βgal assay and high IL6 by ELISA validated senescence associated secretory phenotype. In collaboration with the PDX program at Baylor College of Medicine led by Dr. Lewis, our team has developed first novel ER+ PDX model from an ER+ IBC patient. *In vivo* study demonstrated combination treatment with Alisertib and fulvestrant significantly inhibited tumor growth in ER+ PDX models at 28 days compared to either monotherapy, indicating potential synergistic efficacy.

Conclusions: AURKA is commonly amplified in IBC and often associated with gene alterations that may predict synthetic lethality to AURKA targeting. In ER+ IBC AURKA amplification is inversely correlated with putative synthetic lethal partner SMARCA4. We have characterized IBC models with high AURKA expression and demonstrated sensitivity to AURKA inhibition with fulvestrant. Senescence at higher doses of Alisertib in TNIBC models may provide a direction for targeting resistance or escape. Further studies in ER+ organoids are ongoing.

#0453 Small molecule targeting of SERPINB3 as an anticancer strategy in cervical cancer.

Sarah Yu[1], Liyun Chen[1], Eric Liu[1], Ethan Memming[1], Clifford Luke[2], Gary Silverman[2], Stephanie Markovina[1]

[1]Department of Radiation Oncology, Washington University School of Medicine in St. Louis, St. Louis, MO,[2]Department of Pediatrics, Washington University School of Medicine in St. Louis, St. Louis, MO

SERPINB3, also known as squamous cell carcinoma antigen (SCCA) is a cysteine protease inhibitor and prognostic marker associated with poor outcomes in cervical cancer. SERPINB3 blocks lysosomal-mediated cell death by inhibiting lysosomal cysteine proteases such as Cathepsin L and S (CatL, CatS) promoting radioresistance, metastasis, and recurrence. Thus, SERPINB3 is a promising target for translational treatment. We hypothesize that SERPINB3-binding small molecules will sensitize tumor cells to radiation therapy (RT) by disrupting its protease inhibitor activity. Small molecule candidates were identified on a DNA-encoded library screen of 4.4 billion compounds. To test top candidates for cytotoxicity, cervical cancer cell lines CaSki vector control (CTRL) and SERPINB3-overexpressing (B3OE) cells were treated with SERPINB3-targeting small molecules for four hours, followed by increasing doses of RT. Cell death and viability were measured using LDH and CCK8 assays at 48 and 72 hours post-RT, respectively, and significance assessed with ANOVA analyses. Protease activity assays were performed using fluorogenic CatS substrate conversion following preincubation of recombinant SERPINB3 with candidate small molecules. One small molecule enhanced RT-induced cell death in CaSki cells in a concentration-dependent manner. SERPINB3-OE cells displayed even more radiosensitization by this compound compared to CTRL cells. Additionally, no cytotoxic effects were observed in non-malignant END1 cervical epithelial cells. Interestingly, none of the candidate small molecules blocked SERPINB3 function in in vitro protease assays, suggesting an alternative mechanism may be at play. Collectively, these results suggest that small molecule approaches may represent promising therapeutic avenues for targeting SERPINB3 to overcome radioresistance in cervical cancer, and further preclinical development is underway.

#0454 Overcoming PD-1 resistance with a first-in-class dual-mode agent that transforms ‘cold’ tumors to ‘hot’.

Tong Zhu[1], **Lixin Li**[2]

[1]Syntabio, San Diego, CA,[2]Birdiebio, Beijing, China

Background: Immune checkpoint blockade fails in most colorectal cancers (CRCs) because they are immunologically ‘cold’ and mismatch repair-proficient (pMMR). This stands in stark contrast to mismatch repair-deficient (dMMR) ‘hot’ tumors, which are highly responsive; neoadjuvant anti-PD-1 achieves a 100% clinical complete response in early-stage dMMR CRC. This profound disparity underscores the urgent need for a strategy to therapeutically convert pMMR tumors into a dMMR-like state. Current approaches lack the coordinated mechanism necessary to induce and sustain this conversion at the cellular level.

Methods: We have designed a panel of dual-mode agents to deliver two synergistic insults to individual tumor cells, directly and indirectly disrupting DNA mismatch repair (MMR) *MSH2/6* genes. Using a real-time microsatellite instability (MSI) reporter screen, we identified lead compounds that mechanistically induce a high MSI (MSI-H) phenotype. The most promising candidate was subsequently evaluated in murine models of pMMR CRC resistant to PD-1 blockade.

Results: We identified BDB025, a potent, first-in-class dual-mode agent that induces a robust MSI-H phenotype while simultaneously epigenetically silencing critical MMR genes. Crucially, this dMMR-like conversion is achieved at very low, sub-cytotoxic dosages, demonstrating a unique non-cell-death-mediated mechanism of action. This coordinated, two-pronged attack within the same cell overwhelms the DNA mismatch repair machinery, specifically *MSH2/MSH6*, increases tumor mutational burden and T cell influx. Consequently, BDB025 converts ‘cold’ pMMR tumors to ‘hot’, ablates established tumors, and overcomes resistance to anti-PD-1 therapy, significantly outperforming standard agents.

Conclusion: We demonstrate a paradigm-shifting therapeutic strategy: a single molecule that pharmacologically induces a synthetic dMMR state by co-opting two synergistic mechanisms of action. Our lead candidate, BDB025, effectively breaks PD-1 resistance, paving the way to extend the curative potential of immunotherapy to the vast population of patients with pMMR cancers.

Keywords: PD-1 resistance, colorectal cancer, MSI-H, DNA mismatch repair, MSH2, MSH6

#0455 MC001: A novel chemoimmunotherapy antibody drug conjugate for treating folate receptor alpha expressing pancreatic cancer.

Seah H. Lim[1], Hailiang Zheng[2], Peipei Zhong[2], Tawei Huang[2]

[1]Medicovestor, Inc., New York, NY,[2]Sanyou Biopharmaceuticals, Shanghai, China

Background: The prognosis for patients with advanced pancreatic ductal adenocarcinoma (PDAC) remains dismal, even with intensive multi-agent chemotherapy. Many patients are also unable to tolerate these regimens due to systemic toxicity. Folate receptor alpha (FRα), overexpressed in up to 80% of PDAC cases, is associated with poor clinical outcomes and represents a promising therapeutic target. MC001 is a novel chemoimmunotherapy antibody-drug conjugate (ADC) designed to target FRα and to harness both payload-mediated and antibody-mediated cytotoxic mechanisms. Here, we evaluated the preclinical efficacy and safety of MC001 in FRα-expressing PDAC models.

Methods: A high-affinity FRα-specific antibody was isolated from a human v-gene phage display library and engineered into a dimeric, tetravalent IgG1 antibody (ADoBind) through a disulfide bond generated by an S444C mutation. MC001 was synthesized by lysine-based conjugation of the ADoBind antibody to monomethyl auristatin E (MMAE) via an enzyme-cleavable linker, achieving an average drug-to-antibody ratio of 6.

Results: The tetravalent ADoBind antibody demonstrated higher avidity to FRα than its monomeric counterpart and mediated robust antibody-dependent cellular cytotoxicity (ADCC) against FRα-positive SU.86.86 human pancreatic cancer cells using human peripheral blood mononuclear cells (PBMCs), while complement-dependent cytotoxicity was not detected. In a SCID mouse xenograft model co-administered with human PBMCs, ADoBind antibodies induced potent ADCC in vivo and achieved significant tumor growth inhibition. In a single-dose PDAC xenograft study, ADoBind-MMAE ADC (MC001) produced approximately fivefold greater tumor inhibition than its monomeric ADC counterpart at equivalent molar dosing. Tumor suppression was durable, persisting beyond 30 days after a single injection, and resulted in improved overall survival. Single-dose toxicology studies in SD rats and cynomolgus monkeys showed that MC001 was well tolerated, with no significant systemic toxicities. Only transient, mild neutropenia was observed at the highest dose level (12 mg/kg). The serum half-life of MC001 was 5.4 days following a single 3 mg/kg dose, supporting favorable pharmacokinetics for intermittent dosing.

Conclusions: Up to 40% of ADC payloads may be released extracellularly before cellular internalization, revealing an opportunity to exploit the intrinsic antitumor activity of the antibody moiety. By combining antibody-mediated immune cytotoxicity with targeted delivery of a payload, MC001 represents a next-generation chemoimmunotherapy ADC capable of killing both proliferating and quiescent (G_0-phase) tumor cells. These results in preclinical models support advancement of MC001 and the ADoBind platform, which are currently progressing through IND-enabling development.

#0456 Discovery of KAT6A degrader enabled by structural proteomics and AI.

Yonatan Kedem[1], Nitzan Simchi[1], Anjana Shenoy[1], Andrew Morley[2], Alon Shtrikman[1], Michal Ran Shchory[1], Yaron Ben Shoshan-Galeczki[1], Dimitri Kovalerchik[1], Iris Alchanati[1], Galina Otonin[1], Noam Cohen[1], Gali Arad[1], **Eran Seger**[1], Kirill Pevzner[1]

[1]Protai, Ramat Gan, Israel,[2]O2H Discovery, Cambridge, United Kingdom

Lysine acetyltransferase 6 (KAT6A/B) is a MYST family member of histone acetyl transferases (HATs), with elevated activity across different cancer types. Due to its driving role in activation of hormonal signaling, KAT6 is a promising drug target specifically in estrogen receptor positive (ER+) breast cancer. Indeed, efficacy has been demonstrated in clinical trials investigating KAT6 inhibition in ER+ breast cancer. Proteolysis-targeted chimeras (PROTACs) are heterobifunctional molecules inducing the proximity between a target protein and an E3 ligase (e.g. CRBN), leading to target ubiquitination and subsequent degradation. KAT6 PROTAC can target both its enzymatic and scaffold functionalities, potentially leading to improved efficacy. In addition, selectivity towards KAT6A could increase drug tolerability and reduce adverse events.In the current work, we present a novel KAT6A-selective PROTAC, developed using the AIMS™ proteomics and AI platform. Using structural mass spectrometry (MS) data and AI modeling, we generated confident structures of the KAT6-E3-PROTAC ternary complex and identified PROTAC-dependent conformations, enabling accurate modeling of the complex for further optimization. The resulting PAI-PROTAC demonstrates efficient KAT6A degradation and growth inhibition in ER+ breast cancer cell lines, with high selectivity over KAT6B and over other KAT enzymes, as well as no degradation activity in CRBN neosubstrates. Altogether, these results illustrate how proteomics-aware-AI enables rational PROTAC design, leading to discovery of a potent and selective KAT6A degrader.

#0457 Nebivolol triggers apoptosis, ferroptosis and necroptosis in triple-negative breast cancer.

Wangjia Cao[1], Anh Vuong[1], Somik Chattertjee[1], Tagari Samanta[2], Radbod Darabi[1], Ashok Kumar[1], Benny A. Kaipparettu[2], Meghana Trivedi[1]

[1]University of Houston, College of Pharmacy, Houston, TX,[2]Baylor College of Medicine, Houston, TX

Background: Triple-negative breast cancer (TNBC) lacks effective targeted therapies and remains associated with poor outcomes. We are investigating nebivolol, an FDA-approved third-generation β-blocker, as a candidate for drug repurposing in TNBC. We have previously reported that nebivolol inhibits TNBC cell growth, proliferation, clonogenic potential and disrupts autophagic flux, leading to accumulation of autophagosomes and lysosomes. RNA-seq analysis further revealed enrichment of ferroptosis (FDR = 0.076), apoptosis (FDR = 0.111), and necroptosis (FDR = 0.133) pathways following nebivolol treatment. Here, we aimed to conduct deeper mechanistic investigation of nebivolol-induced cell death pathways.
Methods: Two TNBC cell lines (MDA-MB-231 and SUM159) were used for all the experiments. The effects of nebivolol (10 μM, 24h) on ferroptosis were assessed using the BODIPY C11 lipid peroxidation assay kit. Apoptosis and necroptosis were evaluated after treatment with 10 μM nebivolol for 24, 48, and 72h using FITC Annexin V Apoptosis Detection kit. Annexin V-positive cells were classified as apoptotic, whereas Annexin V-positive/PI-positive cells represented necroptotic and late-stage apoptotic populations. Nebivolol-induced apoptosis was confirmed using western blot analysis of cleaved/total PARP and caspase-3 and -7 at 24, 48, and 72h. Necroptosis-mediated membrane damage was measured by LDH release following 3-100 μM nebivolol treatment for 24h. All experiments included a minimum of three biological replicates, each with at least three technical replicates. Data were analyzed using GraphPad Prism 10.1, and statistical significance was determined by one-way ANOVA with multiple comparisons ($p < 0.05$).
Results: Consistent with RNA-seq results, nebivolol 10 μM significantly increased lipid peroxidation by 1.5- to 2-fold, confirming ferroptosis induction. Nebivolol 10 μM significantly increased Annexin V-positive/PI-positive but not Annexin V-positive/PI-negative populations in a time-dependent manner, suggesting its role in late-stage apoptosis and necroptosis. Nebivolol 10 μM treatment elevated cleaved PARP and caspase-7,but not caspase-3 levels, in a time-dependent manner, confirming apoptosis induction. Nebivolol 30 and 100 μM significantly increased LDH release indicating pronounced necroptosis-mediated membrane rupture.
Conclusion: Overall, nebivolol elicits multimodal programmed cell death in TNBC by activating both apoptotic and non-apoptotic pathways. These findings support nebivolol as a promising repurposed drug candidate for TNBC and identify ferroptosis and necroptosis as previously unrecognized components of its antitumor mechanism.

#1320 Interim results of clinical trial phase 1 of pan-mKARS or PTEN loss tumor targeting peptide drug conjugates (Maleimide-KGDEVD-Doxorubicin/Exatecan).

Byoungmo Kim[1], Ha Kyeoung Lee[1], Yun-Gun Ko[2], Kyu-pyo Kim[3], **Youngro Byun**[1], Sang Yoon Kim[4]

[1]Seoul National University College of Pharmacy, Seoul, Korea, Republic of,[2]Pharosgen Co, Seoul, Korea, Republic of,[3]Department of Oncology, University of Ulsan College of Medicine, Seoul, Korea, Republic of,[4]Professor, Otolaryngology, University of Ulsan College of Medicine, Seoul, Korea, Republic of

mKRAS and *PTEN* alterations are highly prevalent across multiple cancer types - occurring in approximately 45% of colorectal cancers (CRC) and up to 30-50% of non-small cell lung cancers (NSCLC) - yet they remain largely undruggable. These malignancies exhibit enhanced albumin metabolism and macropinocytosis to sustain their elevated metabolic demands, presenting a unique opportunity for selective, metabolism-guided drug delivery. We developed a next-generation platform of albumin-binding peptide drug conjugates (PDCs) to target *mKRAS* and/or *PTEN loss* tumors. The lead candidate, MPD-1 (Maleimide-KGDEVD-Doxorubicin), represents the first clinical-stage prototype in this series. MPD-1 couples a maleimide anchor for covalent albumin conjugation with a dual-cleavable KGDEVD linker that responds to both cathepsin B and caspase-3/7, enabling highly selective, apoptosis-responsive payload release within the tumor microenvironment. This dual-trigger mechanism ensures intracellular liberation of doxorubicin through lysosomal cathepsin B activity and secondary amplification via caspase-3/7 cleavage in neighboring apoptotic cells - sustaining cytotoxic activity through *in-situ* feedback amplification and a potent bystander effect. Preclinical studies demonstrated that MPD-1 exhibits strong antitumor efficacy in *mKRAS*-mutant colorectal and *PTEN*-loss NSCLC models, with approximately ten-fold lower systemic toxicity than free doxorubicin. Combination regimens with radiation, PARP inhibition, DNA-PK blockade, or immunotherapy yielded further synergistic effects. The ongoing Phase I clinical trial [NCT06944457] is open-label, single-center, dose-escalation and dose-finding trial to evaluate the MTD, RP2D and pharmacokinetics of MPD-1 in patients with advanced *mKRAS* and/or *PTEN loss* solid tumors. We are going to report the interim results of clinical study of MPD-1 as a first-in-class, caspase/cathepsin-responsive, albumin-binding peptide drug conjugate. We next engineered MPD-5 (Maleimide-KGDEVD-Exatecan) as a second-generation conjugate optimized for higher potency. MPD-5 extends the platform to topoisomerase I inhibition, and it showed superior efficacy in various mKRAS cancers and PTEN loss cancers.

Acknowledgments: This research was supported by the Korea Drug Development Fund (HN21C0264).

#5646 Fully human monoclonal antibodies for antibody drug conjugate development to a cell surface target expressed in cancers with unmet needs.

Ginette Serrero[1], Jorge Marquez[1], Jianping Dong[2], Jun Hayashi[3]

[1]A&G Pharmaceutical, Inc., Columbia, MD,[2]Target Discovery, A&G Pharmaceutical, Inc., Columbia, MD,[3]Precision Antibody, A&G Pharmaceutical, Inc., Columbia, MD

The development of Antibody drug conjugates (ADCs) has shown to provide a powerful approach for the development of targeted therapies in Oncology. The majority of approved ADCs are focused on a few targets using a limited number of antibodies conjugated to a large array of liners and payloads combinations. However, in spite of the availability of these approved ADCs, there are several cancer types with poor prognosis for which the availability of targeted therapies remains limited. Addressing this limitation would require the identification of cell surface targets overexpressed in these cancers, the determination whether these targets are internalized, thus enabling the development of internalizing monoclonal antibodies able to deliver cytotoxic payload within the cancer cells. We have recently identified by proteomics approach such a target named PTGFRN as an internalizing, cell surface protein overexpressed in several cancers in need of targeted therapies such as head and neck, lung, pancreatic cancers, medulloblastoma and mesothelioma. We have demonstrated that PTGFRN expression was associated with migration, proliferation and spheroid formation, key steps in the metastasis process making PTGFRN a target of interest for the development of novel anti-cancer therapy. PTGFRN expression was overexpressed in mesothelioma, head and neck and medulloblastoma while it remained negative in corresponding normal tissues. Using humanized transgenic mice, we have developed and characterized fully human monoclonal antibodies to PTGFRN. Several screening assays were used to select high affinity, internalizing fully human monoclonal antibodies. ADCs derived from these antibodies were efficacious in a dose dependent fashion at the nM range to inhibit proliferation in vitro and tumor formation in vivo. for several PTGFRN expressing human cancer cell lines while it had no effect on PTGFRN negative human cell line. These in vitro and in vivo data will be presented here. These results establish PTGFRN as a target for antibody-drug conjugate development for cancers with unmet needs.

#7455 The therapeutic potential of CCL5 and endoglin in ER-positive breast cancer.

Dominick Lomonaco, **Kideok Jin**

Albany College of Pharmacy and Health Sciences, Albany, NY

Estrogen receptor (ER) signaling drives approximately 75% of all breast cancers and remains the central target of endocrine therapies. However, therapeutic resistance—particularly in metastatic ER-positive tumors harboring activating ESR1 ligand-binding domain mutations such as Y537S and D538G—continues to pose a major clinical challenge. These mutations frequently arise under endocrine treatment pressure and are readily detected in metastatic lesions and circulating tumor DNA (ctDNA). Although CDK4/6 inhibitor-based combination therapies have improved patient outcomes, the mechanisms sustaining resistance in ESR1-mutant tumors and their associated therapeutic vulnerabilities are still not fully defined. To address this gap, we examined the crosstalk between endocrine-resistant breast cancer (ERBC) cells and the tumor microenvironment. Using co-culture systems comprising seven ERBC cell lines—including genome-edited ESR1 mutants—and four stromal cell types, we profiled 28 tumor-stroma secretome pairs using cytokine antibody arrays. This analysis identified CCL5 and endoglin as consistently upregulated in resistant tumor-stroma interactions. We hypothesized that CCL5 and endoglin promote endocrine resistance and metastatic progression through paracrine signaling within the microenvironment. To test this, we generated CCL5-knockout EO771 cells via CRISPR-Cas9 and validated CCL5 loss by qRT-PCR and ELISA. CCL5-deficient cells exhibited significantly reduced proliferation and migration in vitro. In orthotopic mouse models, CCL5 knockout tumors showed markedly diminished growth and metastatic spread. Furthermore, treatment with the CCR5 antagonist maraviroc and the anti-CD105 monoclonal antibody carotuximab selectively impaired the viability of wild-type but not CCL5-deficient cells. Together, these findings identify CCL5 and endoglin as key drivers of endocrine resistance and metastatic potential in ER-positive breast cancer, establishing them as actionable therapeutic targets. This work provides a foundation for future clinical strategies aimed at overcoming resistance in ESR1-mutant disease by disrupting CCL5-endoglin signaling.

#0459 CAR T cells engineered via mRNA exhibit enhanced targeting of colorectal cancer.

Walison Nunes da Silva[1], Pedro Henrique Dias Moura Prazeres[1], Marco Tullio Rodrigues Alves[1], Vivian Vasconcelos Costa[2], Mauro Martins Teixeira[3], **Pedro Pires Goulart Guimaraes**[1]

[1]Physiology and Biophysics, Universidade Federal de Minas Gerais (UFMG), Belo Horizonte, Brazil,[2]Morphology, Universidade Federal de Minas Gerais (UFMG), Belo Horizonte, Brazil,[3]Biochemistry and Immunology, Universidade Federal de Minas Gerais (UFMG), Belo Horizonte, Brazil

Chimeric antigen receptor (CAR) T-cell therapy has revolutionized the treatment of hematologic malignancies, achieving unprecedented remission rates in patients with refractory leukemias, lymphomas, and multiple myeloma. However, translating CAR T therapy to solid tumors remains challenging due to intratumoral heterogeneity, an immunosuppressive tumor microenvironment, and limited tumor-specific antigens. In this work, we employed a lipid nanoparticle (LNP)-based mRNA delivery platform to transiently generate CAR T cells targeting Claudin-6 (CLDN6), an oncofetal tight junction protein aberrantly expressed in multiple tumors, including colorectal cancers. To enhance antitumor efficacy, we combined CAR T cell therapy with localized LNP-mediated delivery of TRAIL mRNA (LNP-TRAIL). We evaluated this dual approach in a subcutaneous xenograft model using Colo 205-GFP+Luc+ human colorectal cancer cells in NSG mice. Tumor growth was monitored by quantitative bioluminescence imaging and caliper-based tumor volume measurements. Tumor-infiltrating lymphocytes (TILs) were profiled for activation markers, proliferation, cytotoxic mediators (IFN-y, Granzyme B), and immune checkpoint expression (PD-1, CTLA-4) to assess T cell exhaustion. To examine translational potential, we performed ex vivo assays using freshly resected human colorectal tumor fragments treated with CAR-T cells. The resulting CAR-T cells generated via LNP-mRNA exhibited robust activation, proliferation, and cytotoxicity against CLDN6+ colorectal cancer cells both in vitro and in vivo. Combined CAR-T and intratumoral LNP-TRAIL therapy significantly reduced tumor burden, enhanced T cell infiltration and effector function, and reversed markers of T cell exhaustion. Ex vivo co-culture with primary human tumor samples further confirmed the improved cytotoxic and immunostimulatory effects of the dual strategy. These results establish a modular mRNA nanoplatform that integrates transient CAR expression with LNP-TRAIL delivery to overcome major barriers to CAR-T efficacy in solid tumors, highlighting its translational potential for CLDN6+ malignancies.

#0460 A generic, high throughput unwinding assay for discovery of RNA helicase inhibitors.

Ha Pham[1], **Robert Lowery**[2]

[1]R&D, BellBrook Labs, LLC, Madison, WI,[2]BellBrook Labs, Madison, WI

DEAD-box (DDX) helicases catalyze ATP-dependent remodeling of RNA and nucleic acid-protein complexes. Because of their overlapping roles in RNA metabolism and innate immune signaling, they are emerging as important therapeutic targets in oncology, autoimmunity, and antiviral drug discovery. To enable discovery and mechanistic characterization of selective helicase inhibitors, we have developed a panel of high-throughput biochemical assays for measuring helicase enzymatic functions in homogenous (mix-and-read) format with far red fluorescent readouts. We previously demonstrated detection of RNA-dependent ATPase activity for a panel of DDX enzymes using the Transcreener® ADP[2] assay. Here, we describe the development and validation of the Heliscreener™ unwinding assay, which uses a fluorescence dequenching strategy to monitor separation of a labeled RNA duplex. We evaluated multiple reporter and capture RNA pairs and identified a single combination that supports robust, generic detection of unwinding by several helicases, including DDX3, DDX5, DHX9, and DDX17. Systematic optimization of ATP and RNA concentrations yielded conditions that provide strong signal-to-background with enzyme concentrations from 1.7 to 66 nM. Under these conditions, Heliscreener enables detection of unwinding activity in continuous or endpoint formats with Z′ factors >0.8, supporting its suitability for high-throughput screening. A pilot screen of 1,280 bioactive compounds identified 20 inhibitor hits and 6 apparent activators, ~50% of which were eliminated as fluorescent interference. Inhibitor selectivity profiles were generally concordant between ATPase and unwinding assays, but potencies often differed, with most compounds showing higher apparent potency in the unwinding assay, consistent with partial uncoupling of ATP hydrolysis from duplex separation. These results highlight the value of combining ATPase and unwinding readouts to obtain mechanistic insights that may impact the efficacy and selectivity of RNA helicase inhibitors.

#0461 Next-generation ERβ agonists with superior brain uptake suppress glioblastoma and enhance temozolomide response.

Uday Pratap[1], Karinel Nieves-Merced[2], Sridharan Jayamohan[3], Michael Tidwell[4], Annabel Maciolek[5], Khaled Mohamed Nassar[3], Henriette U. Balinda[6], Nicholas Clanton[7], Suryavathi Viswanadhapalli[1], Gangadhara R. Sareddy[3], Stanton McHardy[2], Andrew J. Brenner[3], Ratna K. Vadlamudi[1]

[1]UTHSA, San Antonio, TX,[2]Chemistry, UTSA, San Antonio, TX,[3]UT Health Science Center at San Antonio, San Antonio, TX,[4]Chemistry, UTSA, San ANtonio, TX,[5]Chemistry, UTSA, ntonio, TX,[6]Mays Cancer Center, UTHSA, San Antonio, TX,[7]Pharmacology, UTSA, San Antonio, TX

Background: Glioblastoma (GBM) is the most common and aggressive primary brain malignancy in adults, with a dismal 5-year overall survival rate. Epidemiologic studies suggest that estrogen receptor beta (ERβ) exerts tumor-suppressive effects in the brain, supporting its potential as a therapeutic target. However, the lack of potent, selective, and brain-penetrant ERβ ligands has hindered translational progress. We recently identified indanone- and tetralone-keto/hydroxyloxime derivatives (CIDD-0149897) as promising ERβ agonist. Here, we report the structure-guided design, synthesis, and preclinical validation of next-generation ERβ agonists with markedly improved potency, selectivity, safety, and blood-brain barrier permeability for GBM therapy.
Methods: To optimize the CIDD-0149897 scaffold and define key pharmacophores, we designed and synthesized 177 analogues using structure-based drug design incorporating ERβ-LBD X-ray data across multiple chemotypes. ERβ versus ERα selectivity was quantified using dual-luciferase reporter assays. Cytotoxicity and apoptosis were assessed in patient-derived and mouse glioblastoma stem cells (GSCs) via CellTiter-Glo and Annexin-V assays. Mechanistic studies employed Western blotting, RT-qPCR, comet assays, RNA-seq, and mass spectrometry. In vitro ADME and PK were performed through the UTSA Center for Innovative Drug Discovery. Therapeutic efficacy of lead ERβ agonists was evaluated in orthotopic syngeneic and patient-derived xenograft GBM models.
Results: Five optimized ERβ agonists displayed substantially improved potency and selectivity. ADME analyses demonstrated 20-50-fold higher aqueous solubility and excellent plasma stability relative to CIDD-0149897. Two analogues CIDD-0169124 and CIDD-0166596 showed ≥10-fold higher brain exposure than CIDD-0149897, with a peak brain/plasma ratio of 3.12 ± 0.84 at 15 minutes, indicating rapid brain uptake. Both lead molecules reduced human and mouse GSC viability with low-micromolar IC_{50} values and significantly enhanced temozolomide (TMZ) response, increasing DNA damage and suppressing neurosphere formation. Comet assays revealed marked increases in olive tail moment with combination treatment compared to monotherapy. In vivo, CIDD-0169124 and CIDD-0166596 significantly reduced tumor burden and prolonged survival in orthotopic xenograft GBM models. Combination with TMZ further extended survival. Immunohistochemistry of tumor sections showed decreased Ki-67 and increased cleaved caspase-3 in combination-treated tumors.
Conclusion: Two improved ERβ agonists outperformed CIDD-0149897 in potency, selectivity, safety, and brain penetration. These compounds show strong anti-GBM action and enhance TMZ efficacy, supporting their development as next-generation ERβ-targeted therapeutics for GBM. Supported by NIH RO1 CA269866.

#0462 Therapy and malignant progression reshape the splicing landscape to generate shared, tumor-wide neoantigens in IDH-mutant gliomas.

Tim Wu[1], Darwin Kwok[2], Joseph Costello[3], Hideho Okada[4]

[1]UCSF Helen Diller Family Comprehensive Cancer Ctr., San Francisco, CA,[2]UCSF - University of California San Francisco, San Francisco, CA,[3]University of California, San Francisco, San Francisco, CA,[4]UCSF - University of California San Francisco, Mill Valley, CA

Background: The low mutational burden and high heterogeneity of gliomas limit the efficacy of immunotherapy. Aberrant RNA splicing can generate targetable neojunctions (NJs) (Kwok et al., 2025), yet the impact of therapy and malignant transformation on this landscape remains unclear. We investigate these effects in IDH-mutant gliomas to identify conserved, upregulated, and potentially targetable splice-derived neoantigens.

Methods: Paired bulk RNA-seq data from primary and recurrent IDH-mutant gliomas were obtained from the UCSF Brain Tumor Center patient data and AG-120-treated glioma cell line data (Wu et al., Science 2025). NJs and their subsequent peptide sequences were characterized using the SSNIP pipeline (Kwok et al., Nature 2025). High confidence n-mer sequences were prioritized using HLAthena, MHCflurry, NetMHCpan, MUNIS, and HLApollo across five HLA-I alleles (A0101, A0201, A0301, A1101, A2402). Peptides scoring within the top first percentile on ≥ 3 platforms were filtered by FPKM × splice read frequency. DESeq2 and GSEA were used for differential gene expression analyses. Publicly available eCLIP sequencing near NJ sites identified potential cis-binding RNA-binding regulators.

Results: In patients treated with standard chemoradiation (n = 90), 1,806 of 57,400 NJs (3.1%) were significantly upregulated ($\log_2$[JPM] > 1; $p < 0.05$). In AG120-treated IDH-mutant glioma cell lines, 90 of 5,520 NJs (1.6%) were significantly upregulated versus non-treated controls. Across paired samples, NJ expression increased at recurrence ($p = 0.033$), a trend absent with AG120-treated cell lines ($p = 0.7$). NJ elevation was primarily associated with grade progression and differential gene expression analysis showed enrichment of intron-recognition/exclusion pathways. Further analysis of the chemoradiation cohort identified *BCAN, PTPRZ1* and *EEF1A1* NJ-derived targets as top HLA-A*11:01, HLA-A*24:02, HLA-A*11:01 candidates, respectively. Notably, the PTPRZ1 and EEF1A1 NJs were intratumorally conserved, and were more abundant than the immunogenic *GNAS* NJ reported by Kwok et al. Two upregulated AG120 NJs overlapped with those from the chemoradiation cohort and generated proteins. These two NJs generated distinct cancer 9-mers from *S100A13* and *RANBP2*, which were recurrently expressed and strongly predicted to bind HLA-A*02:01. Leading-edge analysis showed *IGF2BP3* upregulation, and eCLIP confirmed binding sites near the *S100A13* and *RANBP2* NJ sites. *IGF2BP3* knockdown in HepG2 cells caused distinct splicing alterations without global loss, while *S100A13* NJ expression decreased significantly post-KD.

Conclusion: We show that therapy and malignant progression remodel the splicing landscape of IDH-mutant gliomas via altered splicing regulator expression. Moreover, this remodeling produces conserved, tumor-wide, and putatively immunogenic NJs.

#0463 Inflammatory breast cancer patients derived explants: Autologous post-mastectomy wound fluid enhances the expression of adhesome and matrisome genes associated with recurrence and metastasis.

Mona Mostafa Mohamed[1], Hossam Taha Mohamed[2], Alshimaa Tarek[1], Shrouk Khalaf El-Sayed[3], Wendy A. Woodward[4], Jon Mark Hirshon[5]

[1]Cairo University Faculty of Science, Cairo, Egypt,[2]October University for Modern Sciences and Arts, Giza, Egypt,[3]Maadi Military Hospital, Cairo, Egypt,[4]Associate Professor, Radiation Oncology, UT MD Anderson Cancer Center, Houston, TX,[5]School of Medicine, University of Maryland, Baltimore, Maryland, MD

Inflammatory breast cancer (IBC) is an aggressive phenotype, cases diagnosed by IBC is increasing worldwide. Our previous study showed that cytokinome composing wound healing fluid contribute to the aggressive phenotype of inflammatory breast cancer (IBC) by inducing expression of genes associated with extracellular matrix remodelling, recurrence and metastasis. Indeed, studying whether wound drainage fluid, collected after modified radial mastectomy may contribute to IBC recurrence and activation of cancer stem cells is limited by the lack of models. Herein, we hypothesized that post-mastectomy wound fluid (WF) after neoadjuvant chemotherapy (NACT) contains biological mediators that induce recurrence.

Methods: Fifty patients (31 non-IBC; 19 IBC) who underwent mastectomy for breast cancer after neoadjuvant chemotherapy were enrolled in the present study. Patient-derived explants (PDEs) were generated from cancer and normal breast tissue of non-IBC and IBC to examine changes in the expression of matricellular- and stemness-related genes after exposing the PDEs to collected autologous postmastectomy-WF for each patient.

Results: Gene expression in non-IBC normal primary tissue was significantly different compared to IBC. The IBC cancer tissues showed a significant increase in E-cadherin gene (*CDH1*) a hall mark of IBC tumor emboli and Matrix metalloproteinases (*MMP*s). While the proteomic composition of IBC WF was significantly enriched for leptin, PDGF-BB, OSM, angiogenin, IL6, IL8, EGF, and others compared to non-IBC. Autologous IBC WF increased *SPARC*, *MMP2,*and *MMP3* in normal PDEs, and *CDH1*, *COL6A1*, *LAMA2*, *MMP1*, *MMP3*, *SELL*, and *THBS3* in cancer PDEs. We utilized different bioinformatics tools and applications such as Gene Ontology (GO) and Kyoto Encyclopedia of Genes and Genomes (KEGG) that bridges the gap between biological results and holistic approach to understand the difference between non-IBC and IBC disease biology. Findings provide a robust molecular framework for IBC, identifying candidate biomarkers for recurrence and potential therapeutic targets. The multi-layer validation of expression, interaction, survival, and mutation data strengthens the translational relevance of the detected candidate genes in IBC biology.

#0464 Assessment of tumor heterogeneity for Integrin beta-6 expression in non-squamous non-small cell lung cancer specimens using an investigational Integrin beta-6 IHC assay.

Stefanie Nicole Kapucija[1], Jim Christian[1], Dana Sprague[1], Nicole Medina[2], Laina Quinones[2], Maggie Hime[1], Kiera Borgert[1], Kevin Brown[1], Jason Berndt[3], Pauline Cronin[3], Emin Oroudjev[1], Juan Gutierrez[1], Juan Gutierrez[1]

[1]Agilent Technologies Inc., Carpinteria, CA,[2]Agilent Technologies, Inc., Carpinteria, CA,[3]Pfizer, Bothell, WA

Rapidly evolving investigational targeted therapies, such as antibody drug conjugates (ADCs), are introducing novel targets in oncology. An investigational ADC, sigvotatug vedotin (SV), is currently being studied in non-small cell lung cancer (NSCLC) and is directed to the novel target integrin beta-6 (IB6). IB6 is overexpressed in multiple solid tumor types and is a proposed negative prognostic indicator in many cancers, including NSCLC.

Integrin Beta-6 IHC 6.2A1 pharmDx is an immunohistochemistry assay developed for the detection of IB6 protein expression and is being used to assess IB6 expression in the ongoing Be6A-Lung-01 trial. Recent data showed this assay is sensitive, specific and precise at detecting IB6 protein expression in a large set of non-squamous NSCLC (nsqNSCLC) specimens. Tumor heterogeneity, originating from genomic instability, is a hallmark of cancer. Tumor heterogeneity in relation to changes in Integrin Beta-6 clinical diagnostic status needs to be understood. Here we present data on IB6 biomarker heterogeneity and further elaborate on the assay's reproducibility as it relates to clinically relevant assay parameters.

This assay uses Monoclonal Mouse Anti-Human Integrin Beta-6, Clone 6.2A1 on the Dako Omnis staining platform. IB6 expression in nsqNSCLC was evaluated by calculating the percentage of viable invasive tumor cells showing partial or complete IB6 membrane and/or cytoplasmic staining at ≥2+ staining intensity. The clinical diagnostic status of IB6 High or IB6 Low was determined using the cutoff ≥50%. Tumor heterogeneity was assessed by comparing staining across 200 µm of an FFPE block (intra-block, n=52), between blocks from the same tumor (intra-case, n=44), and between blocks from primary and metastatic tumor sites in the same patient (n=30 patients). Other clinically relevant assay parameters were also tested, including tissue section thickness, glass slide vs. digital whole slide image (WSI) scoring, and preanalytical variables.

Intra-block resulted in 96.3% overall agreement (OA) (n=52). Intra-case resulted in 95.5% OA (n=44). Primary vs. metastatic comparisons resulted in 83.3% OA (n=30). Tissue section thickness resulted in 99.1% OA. Evaluation of IB6 on glass slides compared to WSIs resulted in 98.9% OA. There was no significant difference in the detection of IB6 positivity across ischemia times of 0.5-72 hours and 10% NBF fixation times of 6-72 hours.

Integrin Beta-6 IHC 6.2A1 pharmDx demonstrates high reproducibility with respect to tissue heterogeneity around the ≥50% diagnostic cutoff, indicating there is uniformity in biomarker expression across and within tumor sites for nsqNSCLC. These preliminary findings may provide confidence that assessment of IB6 expression can be reliably performed across tumor sites and within tumor sites.

#0465 Targeted repression of UBTF inhibits growth and metastatic phenotypes of pancreatic cancer *via* inhibition of ribosome biogenesis.

Mudassier Ahmad[1], Sahir Sultan Alvi[2], Haider Ahsan[1], Rajasekhar Baru[1], Ayati Marzieh[3], Jose L. Gonzalez Hernandez[2], Genaro R. Corea[4], Dae Joon Kim[1], Mohammad Moshahid Khan[5], Subhash C. Chauhan[1], Bilal Bin Hafeez[2]

[1]Department of Medicine and Oncology-ISU, University of Texas Rio Grande Valley, Edinburg, TX,[2]Department of Pharmaceutical Sciences, College of Pharmacy and Allied Health Professions, South Dakota State University, Brookings, SD,[3]Department of Computer Science, College of Engineering and Computer Science, University of Texas Rio Grande Valley, Edinburg, TX,[4]Department of Human Genetics, University of Texas Rio Grande Valley, Edinburg, TX,[5]Department of Neurology, University of Tennessee Health Science Center, Memphis, TN

Pancreatic cancer (PanCa) is the third leading cause of cancer-related deaths in the United States due to lack of molecular understanding, diagnostic methods and effective therapeutic options. Emerging evidence suggests that cancer cells alter ribosome biogenesis machinery at genetic and epigenetic levels to meet high demand of protein synthesis. This study reveals a UBTF mediated novel ribosome biogenesis-associated molecular mechanism that might be crucial for pancreatic cancer progression. Our study suggests upregulation of UBTF, an upstream binding transcription factor (member of the HMG-box DNA-binding protein family) in pancreatic tumors. Its stable shRNA mediated knockdown in human PanCa cells (HPAF-II and MIA PaCa-2) showed remarkable decrease in tumorigenic and metastatic phenotypes of these cells in different functional assays (cell proliferations, colony formation, migration, invasion assays) along with altered expression of E-Cadherin (increase) and N-Cadherin (decrease). Additionally, ChIP assay showed that UBTF-knockdown decreased the occupancy of key components of RNA Polymerase I complex such as RPA194, RPA135, TAF1C and Rrn3 on rDNA which leads to the reduced transcription of rDNA products such as 5' ETS (a marker of pre-rRNA synthesis) and 18S rRNA in these cells. The UBTF repression also effectively inhibited tumor growth in ectopic xenograft mouse model and the growth inhibition was correlated with decreased expression of proliferative (PCNA and Ki67), and ribosome biogenesis (UBTF, RPA194) markers as compared to respective controls tumors. These findings suggest a critical role of UBTF in ribosome biogenesis in pancreatic cancer and that its strategic inhibition could be helpful for developing new therapeutic strategies for pancreatic cancer. In conclusion, this study elucidates a new molecular mechanism that can serve as a potential target for pancreatic cancer treatment.

#0466 Combinatorial screening reveals novel gene-drug synergies in breast cancer cells.

Jifeng Wang[1], Joshua A. Bauer[2], Jie Wu[1], Lili Xu[1], Regina Courtney[1], Guochong Damon Jia[1], Jirong Long[1], Wei Zheng[1], Qiuyin Cai[1]

[1]Vanderbilt University Medical Center, Nashville, TN,[2]Postdoctoral Fellow, Dept. of Biochemistry, Vanderbilt University, Nashville, TN

Background: Breast cancer is the most common malignancy among women in the United States. It is a molecularly heterogeneous disease with diverse therapeutic responses. Our previous transcriptome-wide association (TWAS) and fine-mapping studies identified candidate genes potentially involved in breast cancer susceptibility. To advance personalized chemo-preventive and therapeutic strategies, we conducted a gene-drug synergy study on selected candidate susceptibility genes.

Methods: Based on our previous multi-omics analyses, TWAS, and fine-mapping, we conducted a high-throughput siRNA screen to assess cell proliferation and prioritized 25 candidate genes for combinatorial screening. Using reverse transfection with ON-TARGETplus SMARTpool siRNAs (Dharmacon), these genes were silenced in three breast cancer cell lines (MCF-7, T47D, and MDA-MB-231). Following knockdown, cells were treated for 72 h with 18 clinically relevant agents for cancer therapy, including PARP inhibitors, CDK4/6 inhibitors, endocrine therapies, and chemotherapeutics, at clinically relevant concentrations. Cell viability and cytotoxicity were assessed by Hoechst 33342 and propidium iodide staining with automated image analysis. Gene-drug combinations showing >2-fold increase in cell death versus siRNA-silenced DMSO controls were considered synergistic. Statistical significance was determined using Student's t-test.

Results: This combinatorial screening approach revealed multiple gene-drug synergies. In MCF-7 cells, silencing *R3HDM2* markedly increased sensitivity to CDK4/6 inhibitors, with fold-changes >8 for abemaciclib and >4 for palbociclib, implicating a critical role in cell cycle regulation. *SUGP1* knockdown enhanced responsiveness to docetaxel (3.81-fold) and everolimus (3.37-fold). In T47D cells, knockdown of *SLC25A12*, *DNAJC27*, and *DYNC1I2* genes sensitized cells to everolimus, docetaxel, and lapatinib (fold-change >14, >6, and >5). In MDA-MB-231 cells, knockdown of *CEP192* and *SLC25A12* genes significantly enhanced sensitivity to anastrozole and docetaxel (fold-change >7 and >4).

Conclusions: Knockdown of several newly identified putative breast cancer susceptibility genes profoundly altered drug sensitivity in breast cancer cells, revealing mechanistic insights and potential drug targets for breast cancer. Genes such as *R3HDM2, SUGP1, CEP192*, and *SLC25A12* exhibited strong synergy with CDK4/6 inhibitors, taxanes, and mTOR-targeted agents, implicating roles in cell cycle regulation, microtubule dynamics, and metabolic signaling. These findings support using genetic information to guide treatment and personalized approaches in breast cancer care.

#0467 Profiling the effects of Peroxiredoxin 3 (PRX3) pharmacological inhibition and genetic deletion with the AVITI24™ multi-omic spatial biology platform.

Victoria Gibson[1], Seana Lymer[2], Trevor Wolf[2], Brian Cunniff[1]

[1]University of Vermont Cancer Center, Burlington, VT,[2]Element Biosciences, San Diego, CA

Targeting metabolic vulnerabilities of tumor cells, including tumor cell escape from oxidative stress, is an attractive therapeutic approach in oncology. Thiostrepton (TS), the active pharmaceutical ingredient of RSO-021, is a clinical stage peroxiredoxin 3 (PRX3) covalent inhibitor currently in phase 2 testing for the treatment of pleural mesothelioma (NCT05278975). PRX3 expression supports tumor cell escape from oxidative stress and genetic deletion via CRISPR/Cas9 or pharmacological targeting of PRX3 with TS inhibits mesothelioma tumor growth. To further profile cellular responses to PRX3 deletion and inhibition with TS we utilized the AVITI24™ multi-omic spatial biology platform to profile hundreds of thousands of cells in a single run. Using the Teton™ CytoProfiling assay, we analyzed high-dimensional morphology, targeted transcriptomic data, and multiplexed proteomic data, enabling direct linkage of molecular markers to pathway-level readouts. Differential expression was evaluated using two complementary approaches. Single-cell analyses used a Wilcoxon rank-sum test between conditions, while pseudobulk analyses aggregated replicate wells into pseudo-bulk groups and used DESeq for differential expression testing. Marker genes for each condition were identified using a $\log_2$FC threshold of 0.1, and results from both methods were compared to assess concordance. Deletion of PRX3 in the H-MESO-1 human mesothelioma cell line reduced expression of cell cycle and proliferation genes at the RNA level (ie. CDK1 and Kif11) and protein level (ie. phospho-p38, phospho-AKT1, phospho-CDK1). TS treatment of H-MESO-1 cells increased transcript and protein levels of genes related to Mitogen-activated protein kinase (MAPK) signaling (MAPK10, MAPK11), stress response (HSP70), and apoptosis (FASLG). TS treatment reduced expression of genes related to mitochondrial function, cell migration, and growth. TS treatment did not elicit the same effects on gene expression in PRX3 deleted cells as wild type treated cells with MAPK signaling being one common increased feature across PRX3 deletion and TS treatment (ie. MAPK13 and MAP3K5). Together the AVITI24™ multi-omic spatial biology platform provides a robust workflow that supported profiling genetic and pharmacological targeting of PRX3 in mesothelioma tumor cells, further supporting PRX3 as a novel and actionable therapeutic target in cancer.

#0468 Leveraging single-cell multiomics for a generalizable approach to differentiation therapy.

Scott C. Friedland[1], Tianli Ding[2], Gary Schweickart[2], Alice Mims[3], Katherine Miller[2], Adithe Rivaldi[2], Elizabeth Garfinkle[2], Sunkel Benjamin[2], Jaye Navarro[2], Michelle Wedemeyer[4], Ann-Kathrin Eisfeld[3], Elaine R. Mardis[5]

[1]Internal Medicine, Division of Medical Oncology, The Ohio State University James Cancer Hospital and Solove Research Institute, Columbus, OH,[2]Steve and Cindy Rasmussen Institute for Genomic Medicine, Nationwide Children's Hospital, Columbus, OH,[3]Division of Internal Medicine, Department of Hematology, Ohio State University College of Medicine, Columbus, OH,[4]Neurosurgery, Nationwide Children's Hospital, Columbus, OH,[5]Nationwide Children's Hospital, Columbus, OH

Among the different types of systemic therapies used in cancer treatment, differentiation therapy, perhaps the least frequently utilized but typically most tolerable form of treatment, aims to set cancer cells back on the developmental path from which they strayed, leading to cell death through multiple mechanisms. Acute promyelocytic leukemia (APL) is the exemplar for differentiation therapy wherein leukemic blasts arrested in a progenitor-like state are induced to continue their myeloid differentiation after treatment with all-trans retinoic acid (ATRA) and arsenic trioxide, resulting in >95% cure rates. In contrast to APL, other types of acute myeloid leukemia (AML) have only a 5-year survival of ~33%. However, recent advances in targeted therapies with novel, differentiation-inducing agents for AML with alterations in *IDH1/2 (isocitrate dehydrogenase 1* and *2)*, *NPM1 (nucleophosmin 1)*, and *KMT2A* (*lysine methyltransferase 2A*) have demonstrated efficacy in patients who are older, frail, or who have relapsed or refractory disease. However, the underlying mechanism of differentiation induction remains incompletely understood, limiting adoption for other AML subtypes or non-hematologic diseases. Establishing a rational means of discovering regulators of differentiation therapy could accelerate development of this class of drugs. Here, we present a platform for discovering the central regulators of differentiation as a means of identifying targets for downstream therapeutic development. Using single-cell multiomic (RNA- and ATAC-seq - scMultiome) data from clinical samples of *IDH1/2*-mutated (IDHm) AML as a test case, we utilized a software package called CellOracle to dissect the gene-regulatory networks (GRNs) underpinning the differentiation response throughout the course of IDH inhibition. With these analyses, we recapitulated a known pattern of “BRCAness” in IDHm AML with *in silico* knockout of *BRCA1 (breast cancer gene 1)* appearing to support the differentiation effect of IDH inhibition. We also discovered putative as-yet unidentified regulators of the differentiation phenotype including several Ikaros transcription factors. With this new platform, we also sought to identify targets for differentiation therapy in a solid tumor type, wherein examples of differentiation therapy are almost entirely lacking, with the noteworthy exception of ATRA for neuroblastoma. We utilized scMultiome data from H3K27M diffuse midline gliomas of the pons, which are known to have an epigenetically-based inhibition of terminal differentiation. These aggressive and devastating brain cancers affect exclusively school-aged children and have an approximately 95% 2-year mortality. Using the same pipeline we have identified several putative regulators of a malignant-to-normal transition, including several genes known to be important to normal glial development and maintenance of the cancer state.

#0469 Quaratusugene ozeplasmid mediated TUSC2 upregulation in EML4-ALK bearing non-small cell lung carcinoma induces apoptosis and is highly effective in preclinical studies.

Ananya Banerjee[1], Neeke Busette[1], Xu Cheng[1], Kerslee Kohagen[1], Liwei Bao[1], Lluis Lopez-Barcons[1], Mark S. Berger[2], Matthew B. Soellner[3], Angel Qin[1], Sofia Merajver[1], Nathan Merrill[1]

[1]Department of Internal Medicine, University of Michigan, Ann Arbor, MI,[2]Genprex, Inc., Austin, TX,[3]Medicinal Chemistry and Chemistry, University of Michigan, Ann Arbor, MI

Background: Non-Small Cell Lung Carcinoma (NSCLC) harboring the EML4-ALK fusion gene (Echinoderm Microtubule-Associated Protein-Like 4-Anaplastic Lymphoma Kinase) comprises about 5% of NSCLC cases. Tumors with this genetic alteration are initially responsive to ALK Tyrosine Kinase Inhibitors (TKIs), which constitute first- and second-line therapy. However, nearly all ALK-positive (ALK+) lung cancers ultimately develop resistance to ALK TKIs, highlighting the urgent need for alternative treatment options.
Methods and Results: Tumor Suppressor Candidate 2 (TUSC2) is a tumor suppressor gene with low endogenous expression in NSCLC. Quaratusugene ozeplasmid (QO), developed by Genprex, is a novel gene therapy that encapsulates the TUSC2 plasmid in non-viral lipid nanoparticles, effectively upregulating TUSC2 in cancer cells. We evaluated TUSC2 expression in a range of ALK+ cell lines and patient-derived organoids (PDOs), both prior to and following exposure to QO. Our findings show that QO-driven TUSC2 overexpression initiates a robust pro-apoptotic response in ALK+ models, not only in cells that are sensitive but also with acquired resistance (generated in the lab) to the ALK inhibitor, alectinib. This is evidenced by increased pro-apoptotic markers and lower cell viability when QO is used in combination with alectinib. To further assess the QO and alectinib combination, we tested it in two *in vivo* models: (1) an alectinib-sensitive model using subcutaneous injection of NCI-H2228 ALK+ cells into nude mice, and (2) an alectinib-resistant model using ALK167 PDX implants in NSG mice. Once tumors reached ~ 100 mm^3, mice were randomized into four groups: vehicle control; QO alone (25 µg/mouse, IV, every three days); alectinib alone (0.5 mg/kg for sensitive or 15 mg/kg for resistant, oral, daily); and QO plus alectinib at the same doses. In the sensitive model, tumors in the alectinib-treated group shrank by 60%. Notably, treatment with QO alone, and particularly QO combined with alectinib, resulted in 79% tumor shrinkage (p value 0.0135 versus control), demonstrating a 23% improved outcome than alectinib alone. This suggests that QO might serve as a valuable adjunct therapy, especially for patients who have advanced disease and/or experience resistance to TKIs.
Major new unpublished results: In the resistant model, the QO and alectinib combination produced a synergistic effect, achieving the greatest tumor reduction and improved overall survival (p value 0.0001 versus control), further supporting the clinical potential of this therapeutic strategy in ALK+ NSCLC. Altogether, our *in vitro* and *in vivo* studies indicate that QO-mediated TUSC2 overexpression in ALK+ NSCLC effectively curtails tumor growth and proliferation via activation of apoptotic pathways, providing a compelling rationale for progressing towards clinical trial.

#0470 JZP898, a conditionally activated interferon alpha, generates efficacy and robust TME engagement in syngeneic mouse models.

Ankur Karmokar[1], Emanuele Loro[2], Zhiling Zhang[3], Rao Mukavilli[3], Aparna Gupta[1], Kevin Trouba[4], Vian Amber[5], **Robin C. Humphreys**[1]

[1]Oncology Research, Jazz Pharmaceuticals, Palo Alto, CA,[2]Bioinformatics, Jazz Pharmaceuticals, Cambridge, United Kingdom,[3]DMPK Bioanalytical Science, Jazz Pharmaceuticals, Palo Alto, CA,[4]Toxicology, Jazz Pharmaceuticals, Palo Alto, CA,[5]Clinical Development, Jazz Pharmaceuticals, Oxford, United Kingdom

Interferon alpha (IFNα) is a cytokine belonging to type I IFNs that exert pleiotropic effects on cell functions. IFNα induces antitumor activity and has been extensively applied in clinical oncology. However, use of IFNα has historically been restricted in clinical practice largely due to systemic toxicity and limited clinical activity compared to currently approved immunotherapies. JZP898, a conditionally activated IFNα, has the potential to minimize the toxicity associated with systemic IFNα therapy, preferentially releasing IFNα to tumors and thereby expanding its clinical utility in treating cancer. Cleavage of a proprietary linker by tumor associated proteases controls the release of active IFNα into the tumor microenvironment. Here we describe the preclinical tumor activity, pharmacokinetic (PK) and pharmacodynamic (PD) profiles of JZP898 using a mouse specific analog of JZP898 (JZP898S). Targeted release of IFNα by JZP898S in syngeneic mouse tumor models increased tumor exposure relative to peripheral circulation, translating into greater achievable efficacy, both as a single agent and in combination with CPIs. JZP898S-induced antitumor activity correlated with immune cell activation in the TME and increased cytokine levels in the periphery; elevated peripheral cytokine levels correlated with increased JZP898S exposure. We observed increased number of activated cytotoxic T-cells and decreased number of regulatory cells within the TME. This effect on immune cells in the TME was extended a week beyond the last dose suggesting increased and sustained IFNα effects due to the conditional release of IFNα over time. Predictably, an IFNα gene expression profile was detected in treated tumors in a time and dose dependent manner and demonstrated a PK/PD relationship. From this data, we derived a JZP898-specific gene expression signature in tumors treated with JZP898S. These data support the utility and effectiveness of JZP898 as a novel mechanism to drive IFNα exposure in the TME and impact tumor growth while potentially attenuating IFNα associated tolerability and supports exploring the combinatorial effects with checkpoint inhibitors (CPIs).

#0471 DELs in cells: Small-molecule hits for transcription factor identified by intracellular DNA-encoded library screening.

Leif K. Larsen[1], Allan B. Christensen[1], Andrzej Taranta[1], Charlotte Andersen[1], Frank A. Slok[2], Lars K. Petersen[2], Ole Kristensen[1], Rico G. Petersen[2], Peter Blakskjar[2], Tobias N. Hansen[2], Nils J. V. Hansen[3]

[1]Biology, Vipergen Aps, Copenhagen, Denmark,[2]Chemistry, Vipergen Aps, Copenhagen, Denmark,[3]Vipergen Aps, Copenhagen, Denmark

Transcription factors (TFs) are high value yet challenging therapeutic targets in oncology. Most are considered “undruggable” due to the lack of well-defined small-molecule binding pockets, and the presence of extensive intrinsically disordered regions and shallow protein-protein interaction surfaces. Their active conformations further depend on post-translational modifications, cofactors, and the intracellular milieu - conditions difficult to recapitulate in vitro - therefore, strategies that interrogate TFs in their native cellular environment are preferable. DNA-Encoded Libraries (DELs) provide ultra-high-throughput access to small-molecule binders, but a complicating factor for screening DNA-binding proteins is false positives arising from barcode sequences that resemble native binding motifs. Mutant TF versions engineering to disrupt DNA-binding domains can reduce this issue but risks compromising TF structure and function. Therefore, screening full-length proteins appear highly desirable. Here, clusters of small-molecule hits were identified in an intracellular DEL screen against a full-length, cancer-relevant TF and positively validated in orthogonal assays. Importantly, in the screen, a duplex DNA containing the cognate binding motif was included and successfully suppressed barcode-mediated artifacts. A parallel screen including unrelated duplex DNA confirmed retention of sequence-specific TF-DNA interactions showing that the DNA-binding activity of the TF was intact during the screening. These findings demonstrate that intracellular DEL screening can overcome key mechanistic limitations in targeting transcription factors and enable robust discovery of small-molecule binders to functional, full-length TFs - expanding the druggable space for oncogenic transcriptional regulators previously inaccessible to small-molecule approaches.

#0472 Adapting a TR-FRET platform to decipher G protein-coupled receptor internalization and recycling kinetics.

Jie Gao[1], An Ouyang[2], Spencer Chiang[1], **Yu Sun**[1]

[1]ACROBiosystems Co., Ltd., Beijing, China,[2]ACROBiosystems Inc., Newark, DE

G protein-coupled receptors (GPCRs) represent one of the largest family of membrane receptors, mediating an extensive array of physiological responses through the activation of diverse intracellular signaling pathways. Due to their prominence as therapeutic targets, regulation of GPCR trafficking including internalization and recycling is a critical determinant of drug efficacy and signaling bias. Traditional biochemical and imaging approaches, while informative, often lack the throughput and temporal resolution required to systematically characterize receptor kinetics across large compound libraries. Herein, we describe the adaptation of a time-resolved Förster resonance energy transfer (TR-FRET)-based platform to quantitatively monitor GPCR internalization and recycling dynamics in living cells. By integrating donor-acceptor fluorophore pairs with receptor constructs labeled at extracellular epitopes, the assay enables real-time tracking of ligand-induced receptor trafficking with high sensitivity and minimal perturbation of cellular physiology. The TR-FRET readout allows precise kinetic profiling of receptor endocytosis and recycling across different ligand classes, facilitating the discrimination of biased agonists and the elucidation of pathway-specific trafficking signatures. As an example, an energy-donor tag-modified GLP-1R cell line was stimulated by energy-acceptor-modified agonists for comparison against activation by modified GLP-1. Before internalization, a high TR-FRET signal can be observed. As the receptor gets internalized, the increased distance between the membrane-bound donor with the acceptor agonists quenches the TR-FRET signal before resurfacing as the receptor gets recycled. Altogether, this mechanism helps researchers elucidate the signal duration, intensity, de/re-sensitization of the agonist on its receptor, impacting efficacy, potency and tolerance. Altogether, this optimized TR-FRET approach provides a scalable, high-throughput framework for assessing GPCR trafficking kinetics, bridging the gap between molecular pharmacology and system-level drug screening. By enabling rapid, quantitative evaluation of receptor dynamics, this platform holds significant potential to accelerate the discovery and optimization of therapeutics that leverage GPCR signaling for improved efficacy and safety profiles.

#0473 Accelerating integrated tumor profiling with QIAseq xHYB Pro: A fast, modular approach to CGP and HRD assessment.

Peter Hahn[1], Markus Storbeck[1], **Krishna Amin**[2], Jonathan Shaffer[2], Leif Schauser[3]

[1]QIAGEN GmbH, Hilden, Germany,[2]QIAGEN Sciences Inc., Frederick, MD,[3]QIAGEN, Aarhus A/S, Denmark

Comprehensive Genomic Profiling (CGP) and Homologous Recombination Deficiency (HRD) testing are critical components of precision oncology, guiding therapeutic decisions across a range of solid tumors. While CGP provides broad mutational insights, HRD status offers predictive value for PARP inhibitor response. However, integrating both assays into a streamlined workflow remains challenging due to reagent compatibility, workflow complexity, and sample limitations. QIAseq xHYB Pro is a next-generation hybrid-capture reagent chemistry designed to accelerate high-sensitivity, low-input genomic analysis for cancer research. Its optimized protocol enables a single-day hybrid capture workflow, with hybridization completed in minutes rather than hours, dramatically reducing turnaround time without compromising data quality. Among its key applications are HRD and CGP, two essential assays for therapeutic stratification and biomarker discovery. The HRD panel, developed in collaboration with Myriad Genetics, enables detection of genomic instability signatures including loss of heterozygosity (LOH), telomeric allelic imbalance (TAI), and large-scale state transitions (LST). Using QIAseq xHYB Pro, HRD can be deployed as a standalone assay (QIAseq xHYB HRD Panel) or integrated as a spike-in module within the QIAseq xHYB CGP Panel. This modularity allows researchers to flexibly configure assays based on study needs, enabling broad and deep tumor characterization from limited FFPE samples in a single, efficient workflow.

#0474 A comprehensive LinkLight platform for GPCR mechanistic profiling to support cancer drug discovery.

Yong Wan, Alisha D. Ianni, Haiching Ma, Jianghong Wu

Reaction Biology, Malvern, PA

Background: G protein-coupled receptors (GPCRs) are increasingly recognized as important targets in cancer therapy due to their roles in tumor growth, angiogenesis, and metastasis. LinkLight technology is a protein-protein interaction (PPI) detection platform that monitors β-arrestin recruitment to activated G protein-coupled receptors (GPCRs), complementing second messenger-based assays for ligand activity characterization. Here, we use LinkLight stable cell lines co-expressing TEV-protease-tagged GPCRs and permuted luciferase (pLuc)-tagged β-arrestin to study β-arrestin recruitment, cAMP signal, and calcium-influx within the same cellular context.
Methods: Cell-based functional assays were conducted in both agonist and antagonist modes across three GPCR LinkLight stable cell lines representing distinct G-protein couplings (Gs, Gi, and Gq). β-Arrestin-1/2 recruitment was quantified using the LinkLight PPI luminescence readout, while G-protein-mediated signaling was measured via cAMP or calcium-influx fluorescence, depending on receptor class.
Results: Ligands produced consistent, mechanism-appropriate responses across β-arrestin and second-messenger pathways. For Gq-coupled ADRA1A, the agonist Cirazoline induced robust β-arrestin-1/2 recruitment (EC_{50} = 2.51×10^{-8} M) and calcium influx (EC_{50} = 8.2×10^{-9} M), while the antagonist Prazosin inhibited both (β-arrestin EC_{50} = 2.51×10^{-8} M; calcium EC_{50} = 2.06×10^{-7} M). For Gi-coupled ADRA2A, the agonist Brimonidine stimulated β-arrestin-1/2 recruitment (EC_{50} = 2.64×10^{-8} M) and suppressed cAMP (EC_{50} = 8.88×10^{-10} M), whereas the antagonist Yohimbine blocked β-arrestin recruitment (EC_{50} = 1.78×10^{-8} M) and reversed cAMP inhibition (EC_{50} = 2.69×10^{-7} M). For Gs-coupled ADRB2, the agonist Fenoterol induced β-arrestin-2 recruitment (EC_{50} = 8.83×10^{-10} M) and cAMP signaling (EC_{50} = 1.52×10^{-9} M), while the antagonist Yohimbine (S)-Propranolol inhibited both (β-arrestin EC_{50} = 3.98×10^{-8} M; cAMP EC_{50} = 3.6×10^{-8} M). Across all receptors, β-arrestin recruitment aligned with G-protein-specific signaling in response to the same ligand, demonstrating the robustness of the comprehensive GPCR portfolio.
Summary: By enabling simultaneous assessment of β-arrestin recruitment and G-protein signaling in a unified cellular context, LinkLight technology offers a comprehensive, mechanistically informative platform for GPCR pharmacology. Integrated with G-protein activation data, LinkLight technology also supports high throughput profiling of ligand efficacy, bias, and receptor regulation for GPCR drug discovery against cancer.

#0475 A bioluminescent assay for detection of fatty acid oxidation.

Maggie Bach, Michael P. Valley, Hui Wang, Xavier Aguilar-Enriquez, Wenhui Zhou, Jolanta Vidugiriene

Promega Corp, Madison, WI

Research scientists measure fatty acid oxidation (FAO) to assess how efficiently cells and tissues convert fats into energy and how this process shifts under different physiological or pathological conditions. Because FAO is central to mitochondrial energy metabolism, its measurement reveals insights into metabolic flexibility, mitochondrial health, and substrate preference. Altered FAO is implicated in many diseases including diabetes, obesity, heart failure, and cancer, making it an important marker for both mechanistic studies and drug screening. Additionally, FAO measurements help evaluate the effects of exercise, diet, or pharmacological interventions on energy balance and cellular metabolism. Radiolabeled fatty acids and oxygen consumption assays are the most common methods for measuring fatty acid oxidation (FAO), but these approaches can be labor-intensive and technically demanding. To simplify FAO measurement, we developed a bioluminescent assay based on a fatty acid-linked pro-luciferin substrate. The substrate readily enters cells, where FAO enzymes remove the fatty acid moiety, releasing a modified luciferin precursor. Addition of a detection reagent converts this intermediate to luciferin, generating luminescence proportional to FAO activity. The signal scales with cell number and incubation time and is compatible with both cancer cell lines and primary cells. With just 20,000 cells and a 1-hour incubation, the assay generates strong signal-to-background ratios - about 200 in HEK293 cells and 100 in primary human hepatocytes. The assay is sensitive to inhibition by etomoxir, confirming dependence on carnitine palmitoyltransferase (CPT1) activity, a key regulatory step in mitochondrial FAO. After media removal, all steps are performed in an add-and-read format suitable for 96- or 384-well plates, enabling convenient, high-throughput quantification of FAO. AI was used to help construct this abstract.

#0476 A practical workflow for adaptive immune receptor profiling and screening of antigen-specific clonotypes with applications in cancer.

Alex Chenchik, Tianbing Liu, Dongfang Hu, Kitt Paraiso, Lester Kobzik, **Khadija Ghias**, Paul Diehl

Cellecta, Inc., Mountain View, CA

We developed a streamlined workflow linking adaptive immune receptor (AIR) profiling to antigen-specific functional screening for cancer-relevant T-cell receptor (TCR) and B-cell receptor (BCR) discovery. Bulk AIR sequencing of DNA and RNA from matched samples quantified clonal expansion while distinguishing transcriptionally activated tumor-infiltrating lymphocytes. Paired TCR chains were obtained using a 96-well plate-based, multiplex single-cell assay for TCR α β chain-pairs together with 36 T-cell marker genes, enabling simultaneous identification of full-length receptor sequences and functional phenotype.Reconstructed paired TCRs were cloned into GFP-reporter Jurkat cells, which were then screened using antigen-binding dextramers and co-cultured with K562 APCs expressing tumor-associated peptides. Reporter activation provided a sensitive readout of antigen recognition and allowed ranking of tumor-specific clonotypes. In proof-of-principle studies, the single-cell assay identified the most abundant TCR-α β clonotype in leukemic T cells (35 wells) and revealed co-expression of NKG7 and CCL5, markers associated with cytotoxic activation in cancer. Functional assays confirmed antigen-responsive signaling in the engineered Jurkat cells.This integrated workflow—from repertoire profiling to TCR-α β chain-pair reconstruction and antigen validation—will enable rapid discovery of tumor-associated clonotypes, characterization of cancer-specific immune responses, and the development of receptor-based cellular immunotherapies.

#0477 Lumit® hKi-67 immunoassay for cell proliferation with optimized performance for screening applications.

Kevin Kupcho[1], Jean Osterman[2], Hui Wang[2], Chao Gao[2], Wenhui Zhou[2], **Dan F. Lazar**[1]

[1]Promega Corporation, Madison, WI,[2]Promega Biosciences, LLC, San Luis Obispo, CA

Ki-67 is a well-established marker of cell proliferation and a valuable readout for evaluating anticancer agents across diverse biological models. Here, we describe an improved homogeneous luminescent immunoassay for detection of human Ki-67 using Lumit® technology. The assay incorporates optimized chemistry and a streamlined workflow and can be multiplexed with a same-well cytotoxicity readout. These features make the platform well suited for screening of proliferative and antiproliferative agents in primary immune cells, immortalized cell lines, and 3D cancer spheroids.

To enable use in automated and screening environments, we developed a robust detection reagent for room-temperature “on-deck” stability. This NanoBiT® substrate and buffer formulation yielded a detection reagent that retained ~90% brightness after a 4-h room temperature hold, with no loss in signal-to-background. The reagent also delivered stable glow kinetics, with a signal half-life of ~6 h. Assay robustness was demonstrated by treating Jurkat cells for 48 h with palbociclib (CDK4/6 inhibitor) or BAY-1895344 (ATR kinase inhibitor). Palbociclib reduced Ki-67 levels with an IC_{50} of 164 nM, while BAY-1895344 showed slightly more potent antiproliferative activity (IC_{50} = 94 nM). Normalized dose-response curves were unchanged whether the detection reagent was freshly prepared or held 4 h at room temperature, and results remained consistent when luminescence was measured between 5 min and 6 h after reagent addition. Same-well multiplexing with a cell-impermeant fluorogenic DNA dye revealed that palbociclib induced no cell death, whereas the ATR inhibitor was cytotoxic, enabling clear resolution of proliferative versus cytotoxic drug effects.

To increase ease of use and workflow flexibility, the assay protocol was optimized. Following the addition of an optimized lysis buffer, a brief shake and 10-min incubation produced maximal Ki-67 recovery in both adherent and suspension cell lines. Under these conditions, anti-CD3/CD28 stimulation of primary human $CD8^+$ T cells increased Ki-67 levels by 57-fold after 72 h, whereas total ATP levels increased by ~2-fold, highlighting the superior sensitivity of Ki-67 to changes in proliferative activity. The assay also performed robustly in 3D models: HCT116 spheroids generated over 3 days displayed >90% reductions in Ki-67 following 48-h treatment with BAY-1895344 or nutlin-3a (MDM2/p53 inhibitor), with the ATR kinase inhibitor demonstrating ~20-fold greater potency.

Together, these results demonstrate that the Lumit® hKi-67 immunoassay is a stable, scalable, and automation-friendly platform suitable for high-throughput screening and for profiling proliferative and antiproliferative mechanisms across 2D, 3D, and primary immune cell systems.

#0478 Implementation of single B-cell screening to select antibodies in one day based on affinity and multiple binding properties.

Marie-Claire Phelipot, Eric Chabrol, Julie Lichiere, Alice Aymard, alexandre Baagnolini, Nadjiba Mares, Cecile Lemoigne, Matthieu Tassa, Sophie Mesnard, Caroline Huber, Ester Morgado, Marion Seillier, **Jacques Fieschi**

Mimabs, Marseille, France

Purpose: The aim of this study was to establish a rapid and de-risked workflow enabling the selection and functional characterization of antibody-secreting plasma cells based on function, within a single day to streamline therapeutic antibody discovery.
Methods: BALB/c and transgenic mice carrying human VH/Vκ repertoires were immunized with the recombinant extracellular domain of a tumor-associated immunomodulatory protein. High-titer animals were screened on the Bruker Beacon microfluidic platform, which isolates single plasma cells in nanowells and enables multiplexed assessment of their secreted antibodies. First, beads coated with the ligand and a soluble target conjugated to a fluorochrome allowed simultaneous evaluation of binding affinity and neutralizing capacity. In a second step, beads coated with a structural analog of the target were used to assess the cross-reactivity. Plasma cells producing antibodies of interest were exported for VH/VL amplification, sequencing, and cloning into a mammalian expression vector. Recombinant antibodies were produced and purified for in-depth characterization. Binding affinity and functional blocking were confirmed by biolayer interferometry, while internalization kinetics were quantified using a lanthanide-based pH-sensitive probe. In-silico sequence analysis and structural modeling were applied to identify potential liabilities and exclude clones at risk of poor developability.
Results: The single-day screening workflow enabled high resolution discrimination of plasma cells based on fine differences in affinity and functional binding properties. 215 clones displayed high specificity for the target with no detectable cross-reactivity to analogs and effectively blocked target-ligand interactions. BLI confirmed the accuracy of the phenotypes identified on the microfluidic platform. Internalization assays identified a subset of antibodies with rapid uptake properties compatible with ADC development and computational filtering further refined the panel of antibodies of therapeutic interest by discarding clones with predicted structural liabilities or developability risks.
Conclusions: This integrated and accelerated workflow provides high-resolution functional screening of antibody-secreting plasma cells in a single experiment. By combining affinity ranking, specificity and cross-reactivity assessment, neutralization, internalization profiling, and developability evaluation, our antibody discovery process efficiently yields diverse and high-value therapeutic antibody leads with strong potential for development as immunomodulators or ADC candidates.

#0479 SONNET 5010, a novel proprietary peptide drug conjugate lock and load platform.

John K. Cini[1], Susan Dexter[1], Stephen McAndrew[1], Arron Hearn[2], Evert Bokma[2], Gavin Birch[2], Grant Harradence[2], Christopher Sayer[2], Rosa Gonzalez-Serrano[2], Joao Nunes[2]

[1]Sonnet Biotherapeutics, Inc., Princeton, NJ,[2]Abzena, Cambridge, United Kingdom

Background: Conventional IgG-based antibody-drug conjugates (ADCs) face major limitations, including heterogeneous drug-to-antibody ratios (DAR), variable pharmacokinetics, limited tumor penetration, and linker instability that can lead to off-target toxicity. To overcome these challenges, Sonnet has developed a non-IgG peptide drug conjugate (PDC) platform that enables precise drug loading and improved distribution. SON-5010 is the first proof-of-concept PDC generated using this approach and incorporates Sonnet's F_HAB® (Fully Human Albumin Binding) domain to enhance half-life, tumor accumulation, and overall pharmacokinetics.

Methods: SON-5010 consists of a dual anti-HER2 single-chain variable fragment (scFv) targeting domain flanking the F_HAB motif, combined with an 18-amino-acid Docking Peptide-Payload Domain (DPPD). The DPPD contains three lysine residues that enable deterministic DAR3 conjugation with MMAE. The scFv-F_HAB-scFv targeting domain was expressed in CHO cells, while the MMAE-loaded DPPD was chemically synthesized. The components were linked through standard conjugation chemistry to generate an ~88 kDa PDC. In vitro assessments included serum stability at 37°C and cytotoxicity testing in HER2-high (SKBR3) and HER2-negative (A549) cells. In vivo antitumor activity was evaluated in the HER2-positive BT-474 breast carcinoma xenograft model. SON-5010 was designed for direct comparison with trastuzumab, which contains the same anti-HER2 domain and Lys linker chemistry as MMAE (DAR3), except that it is attached to the DPPD rather than an IgG.

Results: SON-5010 demonstrated strong serum stability and potent cytotoxicity in HER2-expressing SKBR3 cells, with no activity in HER2-negative A549 cells. In vivo, SON-5010 produced tumor growth inhibition comparable to HER2-directed MMAE ADC control of trastuzumab. At 10 mg/kg, SON-5010 showed no detectable toxicity, with stable body weight and no adverse clinical signs. The smaller size of the PDC and the F_HAB-mediated albumin binding likely contributed to improved tumor penetration and favorable tolerability.

Conclusions: SON-5010 demonstrates the potential of Sonnet's modular PDC platform to address key limitations of IgG-based ADCs. The architecture enables full DAR control, enhanced penetration, and flexible engineering of targeting domains and payload chemistries. The platform also supports dual-payload and multispecific designs, offering opportunities to overcome resistance and improve therapeutic index. Early results indicate that SON-5010 is a promising next-generation targeted therapeutic candidate.

#0480 An HTS assay for detection of XRN1 exoribonuclease activity with unmodified RNA.

Mahbbat Ali, **Robert Lowery**

BellBrook Labs, Madison, WI

XRN1 is a 5' to 3' exoribonuclease that degrades both single- and double-stranded RNA to nucleotide 5' monophosphate products. It plays an important role in mRNA turnover and in innate immunity, by damping activation of cytosolic RNA sensors, e.g., PKR and MDA5. Loss of XRN1 has been linked to high interferon signaling in cancer cell culture models, making it an attractive target for cancer immunotherapy. Here we describe development of HTS-compatible assays for screening and profiling inhibitors using the Transcreener AMP^2/GMP^2 Assay. Existing assays for RNAses rely on fluorescently labeled RNAs, which impose limitations on the substrates that can be used and may affect enzyme binding or catalysis. WIth the Transcreener AMP^2/GMP^2 Assay, purine monophosphates produced by XRN1 are directly detected by a competitive immunoassay with a far-red, fluorescence polarization (FP) or time-resolved Förster-resonance-energy-transfer (TR-FRET) readout. This format is homogenous (mix-and-read), compatible with diverse RNA substrates, and resistant to interference from screening compounds. Using full length human XRN1 produced in BaV-infected insect cells, we tested a number of RNA substrates, including synthetic double and single strand oligos with different ends (blunt, overhang, etc.) as well as total yeast RNA. Rates of AMP/GMP formation ranging from 0.054 sec^{-1} to 0.52 sec^{-1} were observed, with single strand RNAs yielding higher activity than double strand substrates; polyA was used for more detailed studies. Though the K_m for poly-A was not length-dependent, the rate and extent of degradation was higher for a 100-mer than a 300-mer. A probe inhibitor, pAp, was tested in dose response experiments yielding an IC_{50} of 114.8 nM, which aligns well with the value measured using a fluorescently labeled DNA/RNA hybrid. The assays were validated for HTS by screening a collection of 1280 bio-actives, yielding a Z'> 0.9 and identification of hits that were confirmed in dose response experiments.

#0481 Drug sensitivity profiling of oncology drugs reveals candidate therapeutic targets in uterine leiomyoma subtypes.

Helmiina Jarvi[1], Simona Bramante[1], Juuli Raivola[1], Emilia Piki[2], Alice Dini[2], Maija Jantti[1], Emma Siili[3], Ralf Butzow[3], Oskari Heikinheimo[4], Annukka Pasanen[3], Niko Valimaki[1], Daniela Ungureanu[2], Kristiina Rajamaki[1], Lauri A. Aaltonen[1]

[1]Department of Medical and Clinical Genetics, University of Helsinki, Helsinki, Finland,[2]Disease Networks Unit, Faculty of Biochemistry and Molecular Medicine, University of Oulu, Oulu, Finland,[3]Department of Pathology, University of Helsinki and Helsinki University Hospital, Helsinki, Finland,[4]Department of Obstetrics and Gynecology, University of Helsinki and Helsinki University Hospital, Helsinki, Finland

Uterine leiomyomas (ULs) are benign smooth muscle tumors and the most common neoplasms in reproductive aged women affecting up to 80% globally. Although ULs rarely evolve into malignant leiomyosarcomas, they inflict a huge financial and social burden. ULs are known to emerge through a few distinct mutually exclusive genetic driver events, the most common being a hotspot mutation in *MED12* and genomic rearrangements of *HMGA2*.

Currently, ULs are often treated uniformly with surgery as the only curative option. Hormonal therapies can reduce tumor size and symptoms but are limited in efficacy and duration and do not consider the genetic subclass. Therefore, our aim was to characterize drug responses in UL-derived primary cell cultures representing the different tumor subtypes.

We established patient-derived primary cell cultures from 5 MED12 and 5 HMGA2 aberrated ULs and their matched normal myometrium. High-throughput drug sensitivity and resistance testing (DSRT) was performed using a comprehensive compound library with 526 clinically approved and investigational cancer drugs.

Preliminary results revealed clear differences in drug responses between ULs and matched myometrial cells, including distinct subclass-specific patterns. Principal component analysis and hierarchical clustering of drug response profiles separated ULs from normal tissue, as well as from epithelial ovarian cancer samples previously analyzed using the same compound library and DSRT workflow.

Among the 526 tested compounds for UL and myometrium, 280 were considered to have a substantial effect in at least one cell culture sample based on the drug sensitivity score (DSS) threshold set at 80th percentile of responses. Out of these compounds, 18% (N=50) induced stronger effects in tumor cell viability, while 82% (N=230) affected myometrial cells more. At the subclass level, 84% of drugs induced a stronger response in MED12 tumors compared to HMGA2. Notably, compounds inhibiting the insulin-like growth factor 1 receptor (IGF1R) and the phosphoinositide 3-kinase (PI3K), pathways recurrently activated across cancers, produced particularly strong effects in the UL cells with also responses varying between the two subtypes.

To date, broad drug discovery efforts for ULs have not been established. Despite their benign nature, ULs share dysregulated signaling pathways with cancers, making these pathways interesting drug targets. While we recognize that cancer drugs often have significant side effects and would not directly be suitable for UL treatment, integrating these cancer drug approaches could enable the development of effective personalized therapies for ULs. Moreover, comparison of drug responses in benign tumors and cancers could help to elucidate how alterations in the same pathways lead to different phenotypic characteristics.

#0482 Development of high-affinity human antibodies targeting POR006: A novel target in squamous cell carcinoma identified by spatial transcriptomics.

MinKyu Kim, Jinyeong Choi, Jae Eun Lee, Hongyoon Choi, Hyung-Jun Im

Portrai, Seoul, Korea, Republic of

Background: Squamous cell carcinoma (SQCC) is a malignant epithelial cancer that arises in various organs, including the lung and head and neck region. Spatial transcriptomics (ST) offers high-resolution mapping of gene expression while preserving spatial context within the tumor microenvironment, thereby facilitating the identification of tumor-specific targets for antibody drug conjugates (ADC) or radiopharmaceuticals. Through a data-driven discovery platform leveraging large-scale transcriptomic and ST datasets, POR006 was identified as a prioritized target associated with SQCC. Here, we generated and characterized human recombinant antibodies exhibiting high specificity and affinity toward POR006.
Methods: Phage display screening was performed to isolate hit antibodies with strong binding potential to POR006. ELISA was used to evaluate binding selectivity, confirming that the antibodies are preferentially bound to POR006 over control proteins. Surface Plasmon Resonance (SPR) was conducted to determine binding kinetics and affinity. Furthermore, flow cytometry and immunocytochemistry (ICC) were carried out to validate target-specific binding in POR006-positive and -negative cell lines.
Results: PortraiTARGET, a target prioritization platform based on human spatial transcriptomics data, identified POR006 as a novel therapeutic target exhibiting high tumor specificity and spatial homogeneity, suggesting potentially superior payload or radioisotope delivery to cancer cells compared to peer targets. Immunohistochemistry analyses confirmed that POR006 is highly expressed in lung and head and neck SqCC tissues, while its expression was minimal across a wide range of normal tissues. Two lead antibodies were isolated from a human phage display library and exhibited strong, selective binding to POR006. SPR analysis demonstrated sub-nanomolar affinities of 0.58 nM and 0.09 nM, respectively. Both antibodies showed selective binding to POR006-positive cells as determined by flow cytometry, with binding levels significantly higher than those of the IgG isotype control. Also, ICC confirmed target-specific staining patterns in agreement with the flow cytometry data.
Conclusion: Our study identified POR006 as a novel SQCC-specific therapeutic target and generated two fully human antibodies exhibiting high specificity and sub-nanomolar binding affinities. These antibodies selectively recognize POR006-expressing cells, supporting their potential for targeted therapeutic development. Based on these findings, ADC and radiopharmaceuticals formats are under development, and their therapeutic efficacy will be evaluated through comprehensive in vitro and in vivo studies. This work highlights the utility of spatial transcriptomics in uncovering novel, clinically relevant targets for precision oncology.

#0483 Organoids-based high-throughput drug screening identifies selective vulnerability of AR$^{-/lo}$ CRPC to inhibitors of neurotransmission signaling.

Shan Wu[1], Ruize Zhao[1], Xiaozhuo Liu[1], Wen (Jess) Li[1], Moyi Wang[1], Amanda Tracz[1], Henry Withers[2], Brian Buckley[3], Katerina Gurova[3], Prashant Singh[4], Eduardo Cortes[2], Jianmin Wang[2], Jason S. Kirk[1], Dean G. Tang[1]

[1]Department of Pharmacology & Therapeutics, Roswell Park Comprehensive Cancer Center, Buffalo, NY,[2]Department of Biostatistics & Bioinformatics, Roswell Park Comprehensive Cancer Center, Buffalo, NY,[3]Department of Cell Stress Biology, Roswell Park Comprehensive Cancer Center, Buffalo, NY,[4]Department of Cancer Genetics & Genomics, Roswell Park Comprehensive Cancer Center, Buffalo, NY

Introduction of the next generation of potent antiandrogens (abiraterone, enzalutamide, apalutamide, darolutamide) about a decade ago into the clinical management of advanced prostate cancer (PCa) patients has led to a substantial increase in a subtype of castration-resistant PCa (CRPC) that becomes independent of androgen receptor (AR) signaling and frequently lacks AR expression (i.e., AR$^{-/lo}$). The AR$^{-/lo}$ CRPC is *de novo* resistant to castration and enzalutamide (Enza), and there are currently no targeted therapies available for this subtype. To identify novel regulators and therapeutic targets in AR$^{-/lo}$ CRPC, we developed an organoids platform from the AR$^{-/lo}$ LAPC9-AI (androgen-independent, i.e., CRPC) xenograft model (Li and Deng et al., *Nat. Commun*. 2018) that recapitulates the AR$^{-/lo}$ CRPC phenotype and drug responsiveness. Using this platform, we conducted high-throughput screening (HTS) in a total of ~6,000 compounds and drugs (including 4,480 bioactive agents and 1,508 FDA-approved drugs). Secondary screening and validation experiments, surprisingly, uncovered 21 compounds effective in inhibiting the AR$^{-/lo}$ CRPC organoids, including JTC-801, Penfluridol and Terfenadine, which normally target the G protein-coupled receptors activated by neurotransmitters including dopamine receptor and opioid receptor. Notably, JTC-801 and Penfluridol specifically inhibited the growth of AR$^{-/lo}$ LAPC9-AI *in vivo*. Collectively, our study identifies novel therapeutic vulnerabilities in castration/Enza-resistant AR$^{-/lo}$ CRPC.

#0484 Hit finding and assay enablement for VRK1, a paralog synthetic lethal kinase target in VRK2-deficient cancers.

Katarzyna B. Handing, Kevin M. Cottrell, Mu-Sen Liu, Patrick McCarren, Brett Williams, Kiera M. Vassallo, Alvin Lu, Alice Tsai, Maria Dam Ferdinez, Sirimas Sudsakorn, Brian McMillan, Jannik N. Anderson, William D. Mallender, Wenhai Zhang, John Maxwell, Kimberly J. Briggs

Tango Therapeutics, Boston, MA

Vaccinia-related kinases (VRKs) are a family of serine/threonine kinases that regulate diverse cellular processes, including transcription factor activity, chromatin remodeling, nuclear envelope formation, and cell-cycle progression. Among them, VRK1 has emerged as a paralog-selective synthetic lethal target in cancers with low VRK2 expression, encompassing nearly all neuroblastomas and over 60% of glioblastomas, with potential for therapeutic expansion into additional tumor types.
Here, we describe the biochemical, biophysical, and cellular assays that enabled the discovery and optimization of novel inhibitors of VRK1 activity found through variety of binding screens, activity-based screens, and rational design. High-resolution crystal structures of both VRK1 and VRK2 in complex with inhibitors revealed their binding poses, identified key interactions, and confirmed orthosteric binding. Medicinal chemistry optimization yielded chemical series capable of achieving >4000X selectivity over the VRK1 paralog VRK2 in a biochemical assay conducted with a physiologically relevant ATP concentration, and >70X selectivity for VRK2-deficient cells in cellular viability assays. Notably, strong correlations between biochemical potency, cellular target engagement, pharmacodynamic response, and functional viability supported both the specificity of the chemical matter and the robustness of the assay platform.
Together, these findings establish VRK1 as a tractable and structurally enabled target and demonstrate that high paralog selectivity in cells can be achieved through orthosteric inhibition. This work provides the strong foundation necessary for structure-guided optimization of VRK1 inhibitors with potential therapeutic applications in cancers with low VRK2 expression, such as glioblastoma and neuroblastoma.

: Genomic Dissection to Define Novel Therapeutic Strategies

#0489 Multi-omic single-cell combinatorial indexing of gRNA, epitopes, and transcriptome uncovers modulators of drug sensitivity in K562 cells.

Sangwon Kang[1], Su-Hyeon Lee[2], Byungjin Hwang[2]

[1]Department of Biomedical Sciences, Graduate School of Medical Science, Brain Korea 21 Project, Yonsei University College of Medicine, Seoul, Korea, Republic of,[2]Department of Biomedical Sciences, Yonsei University College of Medicine, Seoul, Korea, Republic of

Identifying genes that modulate drug response is critical for understanding therapeutic resistance and discovering new targets to improve cancer therapy. Conventional pooled CRISPR screens, based on bulk measurements of guide RNA (gRNA) abundance, provide limited resolution and cannot capture transcriptomic or proteomic changes associated with gene perturbations. To overcome these limitations, we developed Single-cell combinatorial Guide RNA, Epitope, and Transcriptome Mapping Of Signals Across Integrated Cellular omics (scGET-MOSAIC) sequencing, a Cas13-based single-cell CRISPR screening platform that simultaneously captures gRNA identity, transcriptome, and surface protein expression from individual cells. This approach integrates the scalability of pooled screening with the molecular depth of single-cell multi-omics, enabling comprehensive functional interrogation of large druggable gene libraries. Compared to traditional bulk CRISPR screens, scGET-MOSAIC provides not only broader gRNA coverage but also multi-modal phenotypic profiles that reveal how each perturbation alters cellular states. Furthermore, the platform overcomes gene library size constraints found in other single-cell CRISPR methods, such as CROP-seq, allowing a substantially higher number of perturbations to be analyzed in a single experiment. We applied scGET-MOSAIC sequencing to the chronic myeloid leukemia cell line K562 treated with the tyrosine kinase inhibitor imatinib. Single-cell analysis across thousands of perturbed cells revealed distinct transcriptional and surface protein signatures associated with drug response. Through integrative analysis, we identified gene X as a critical modulator that enhances imatinib sensitivity, suggesting a potential combinatorial target for overcoming drug resistance. In summary, scGET-MOSAIC sequencing, powered by Cas13-mediated RNA targeting, establishes a versatile framework for large-scale, high-content CRISPR screening that connects genetic perturbations to transcriptomic and proteomic phenotypes. By directly perturbing RNA, this platform enables the exploration of both coding and non-coding gene functions, expanding the capacity of functional genomics to uncover novel therapeutic vulnerabilities in cancer.

#0490 High-throughput pooled CRISPR screening with high-capacity single cell analysis of the protein kinome using a dual inducible Cas9 system.

Clarence Mills[1], Anna Sheydina[2], Jesse Stombaugh[1], Emily Feldman[1], Josien Levenga[1], Kevin Taylor[2]

[1]Revvity, Lafayette, CO,[2]Revvity, San Diego, CA

Kinases are critical regulators of cellular processes such as proliferation, survival, and apoptosis. Dysregulation of kinase activity is implicated in a wide range of diseases, including autoimmune disorders, inflammatory conditions, and cancer, making kinases highly valuable therapeutic targets. Identifying clinically relevant drug targets is a foundational yet complex step in drug discovery. Genomic screening using CRISPR technology addresses this challenge by offering deep genetic insights. Traditional pooled CRISPR screens with phenotypic readouts are often limited to detecting changes that confer a fitness advantage or disadvantage or to sorting cells using proteins or intracellular components labeled with fluorescent dyes, reporters, or antibodies. Here we developed a unique, dual transcriptionally and post-translationally regulated inducible Cas9 system for rapid small-molecule induction of Cas9 with minimal background expression in the “OFF” state, allowing for precise temporal control of gene editing. We then transduced two cancer cell lines expressing the system with a guide RNA library targeting the protein kinome and employed a microfluidics-free, single cell workflow for unbiased analysis of transcriptional changes resulting from kinase-regulated signaling pathways and protein-protein interactions. This massively scalable approach facilitated the screening of 760 known protein kinases, with 99% of the guide RNA library recovered in the sequencing analysis and a median of >5000 transcribed genes detected per cell. Critically, it enabled the characterization of many kinases whose knockout do not elicit pronounced growth phenotypes. This proof of concept demonstrates the efficacy of high-throughput combinatorial CRISPR screening with high-capacity single cell analysis for kinase activity in cancer cell lines.

#0491 A 100 million cell single cell atlas enabling mechanistic and genotype-specific drug response discovery.

Aisling Sinclair, **Joey Pangallo**, Vuong Tran, Efthymia Papalexi, Simone Marrujo, Bryan Hariadi, Crina Curca, Olivia Kaplan, Sarah Schroeder, Ajay Sapre, Guillermo Gallareta Olivares, Maria Nigos, Oliver Sanderson, Hoai Hguyen, Alec Salvino, John Thompson, Ryan Koehler, Sam You, Gokhan Demirkan, Charles Roco, Alexander Rosenberg

Parse Biosciences, Inc., Seattle, WA

Machine learning promises major advances in drug discovery, but training effective models requires large, well-controlled datasets capturing how diverse compounds affect human cells. Traditional perturbation studies are limited by batch effects and experimental variability. Recent advances in combinatorial barcoding now allow tens of millions of transcriptomes to be profiled in unified workflows, greatly reducing technical noise.We created Tahoe-100M, a single cell atlas of more than 100 million cells spanning 50 human cell lines and 379 compounds. Mixed cell lines (Tahoe Therapeutics) were grown as 3D spheroids, treated for 24 hours across three doses, fixed, and processed in pooled batches of ~10 million cells using the Parse Biosciences GigaLab platform. Sequencing on the UG100 followed by Demuxlet assignment produced high quality transcriptomes at unprecedented scale.Tahoe-100M covers ~56,000 line-drug-dose combinations and reveals thousands of dose-dependent expression changes. Stratification by genotype uncovers lineage- and mutation-specific responses, including unexpected Dabrafenib sensitivity in additional cell lines not typically classified as BRAF-dependent. Cell cycle analysis exposes compound-specific effects, such as G1 or G2/M arrest by CDK inhibitors and G2/M accumulation after microtubule inhibition.The atlas also enables mechanistic discovery. For example, transcriptional similarity mapping shows that Saquinavir induces an adrenoceptor-agonist-like program, resembling Vilanterol and Norepinephrine, providing a molecular explanation for its known cardiovascular effects. Exploratory analyses further identify compounds that up-regulate MHC-I pathways, highlighting candidates that may enhance tumor immunogenicity.By processing fixed cells in massive pooled batches, we minimized batch effects and enabled direct comparison across the entire perturbation space. Tahoe-100M establishes a new benchmark for large scale drug response mapping and provides a foundation for AI-driven discovery across human cell models.

#0492 Uncovering therapeutically targetable mutations from The Cancer Genome Atlas (TCGA) whole-genome datasets.

Ryul Kim[1], Chunyang Bao[1], Hansol Park[1], Gang-Hee Lee[1], Won-Chul Lee[1], Jonghoon Lee[1], Yoonsuh Lee[1], Beomki Lee[2], David Lehotzky[3], Ron Solan[3], Antonia Kowalewski[3], Xavi Loinaz[3], Vasuki Narasimha Swamy[3], David I. Heiman[3], Samantha Van Seters[3], Saveliy Belkin[3], Sam Wiseman[3], Andrew D. Cherniack[3], Luis Antonio Corchete Sanchez[3], Brian P Danysh[3], Zachary Everton[3], Chip Stewart[3], Haruna Tomono[3], Gengchao Wang[3], Esther Rheinbay[3], Gad Getz[3], Young Seok Ju[1]

[1]Inocras, San Diego, CA,[2]Korea Advanced Institute of Science and Technology, Daejeon, Korea, Republic of,[3]Broad Institute of MIT and Harvard, Cambridge, MA

The systematic identification of therapeutically actionable genomic alterations across tumor types is essential to advance precision oncology. Using the CancerVision^{TM} whole-genome analysis platform, we analyzed >8,000 whole-genome sequencing (WGS) samples spanning more than 30 cancer types to characterize clinically actionable mutations. Actionability was defined according to the Cancer Knowledgebase evidence levels, where Level A denotes biomarkers linked to FDA-approved on-label therapies. Overall, 2903 patients (~32%) harbored at least one Level A actionable alteration encompassing ~20,100 events (median 2 per sample). Level A on-label targets were detected in more than half of THCA (thyroid cancer), KIRC (kidney clear-cell), SKCM (skin cutaneous melanoma), BRCA (breast cancer), and COAD (colon adenocarcinoma), underscoring their clinical relevance. The ten most frequent Level A targets were *PIK3CA, KRAS, BRAF, VHL, PTEN, ERBB2, BRCA1/2, NRAS,* and *EGFR*, showing variable frequencies among cancer types. Among *KRAS* alterations, p.G12C was the predominant actionable hotspot, mainly in lung adenocarcinoma with a few cases in colorectal and rectal cancers. A total of 950 fusion targets were identified across the cohort. BRCA exhibited the highest frequency (45 cases; 2.5%), including 40 *ESR1-CCDC170* fusions, followed by THCA (55 cases; 9.7%), dominated by *CCDC6-RET* (25 cases). *NRG1* fusions were found in 145 samples (1.7%), markedly higher than the historical pan-cancer frequency (~0.2%). Other recurrent targetable fusions included *NTRK* (0.7%; 60 samples), *RET* (0.7%), *ALK* (0.7%), *BRAF* (0.6%), and *FGFR* (2.5%; 210 samples), the latter largely involving *FGFR2* (~180 cases). Across all fusion classes, >80% retained the kinase domain, supporting oncogenic potential. Clinical-trial-matched targets were most commonly *TP53, PIK3CA*, and *CDKN2A*, reflecting their broad inclusion in precision-medicine studies. This comprehensive pan-cancer analysis defines the most extensive WGS-based landscape to date of actionable mutations and druggable fusions. The whole-genome approach enabled high-resolution detection of rare structural variants that are often missed by targeted sequencing panels, highlighting the potential of whole-genome profiling to uncover therapeutically relevant but under-recognized targets, supporting the integration of WGS into future tumor-agnostic clinical trial design.

#0493 Genomic landscape of targetable drivers in lung cancer.

Olivia Lee[1], Soo-Ryum Yang[2], Wei Zhao[1], Huu Phuc Hoang[1], Tongwu Zhang[1], Maria Teresa Landi[1]

[1]National Cancer Institute, Bethesda, MD,[2]Memorial Sloan Kettering Cancer Center, New York, NY

Lung cancer is the most commonly diagnosed cancer and the leading cause of cancer death worldwide. As global smoking rates decline, the incidence of lung cancer in never-smokers (LCINS) is rising, motivating more detailed investigation into its etiology. Non-small cell lung cancer (NSCLC) accounts for approximately 85% of lung cancers and is often driven by alterations in the MAPK pathway, including receptor tyrosine kinases (RTKs) and downstream RAS-RAF-MEK signaling, which are key targets of many current molecular therapies. However, 12-30% of NSCLC lack actionable driver alterations, and rare drivers (≤5%) remain poorly characterized, leaving many patients without targeted options. Currently, no large-scale study has systematically compared the distribution of genomic drivers by smoking history and ancestry, or comprehensively profiled rare oncogenic drivers in NSCLC. We analyzed whole-genome and RNA sequencing data from 799 treatment-naïve NSCLC from never-smokers (NS-NSCLC) and 336 NSCLC from smokers (S-NSCLC) in the Sherlock-Lung study. We integrated single-nucleotide variants (SNVs), structural variants, copy number alterations, and RNA-seq data with public cancer databases to identify canonical and potential drivers.

Overall, 98% of NSCLC harbored at least one genomic driver. More than half of both smokers and never-smokers carried at least one RTK/RAS/RAF (RPA)-positive driver. NS-NSCLC more frequently carried RPA-positive drivers than S-NSCLC ($p = 3.16 \times 10^{-19}$) and showed higher frequencies of fusions and tumor-suppressor deletions ($p < 7.10 \times 10^{-3}$). In contrast, S-NSCLC showed higher frequencies of *KRAS* mutations, oncogene amplifications, and rare drivers ($p < 2.10 \times 10^{-4}$). RPA-negative tumors were enriched in PI3K, NOTCH, and WNT signaling pathways, suggesting alternative oncogenic pathways may drive some NSCLC. We describe 60 novel rare driver genes in RPA-negative NSCLC.

Among NS-NSCLC, tumors from East Asians (EAS) showed significantly higher *EGFR* mutations ($p = 1.27 \times 10^{-13}$), while tumors from Europeans (EUR) exhibited heterogeneous SNV and fusion drivers. *EGFR* mutations from EAS tumors were enriched for classical activating variants, while EUR tumors had greater *EGFR* mutation heterogeneity. Furthermore, within RPA-positive NSCLC, EUR tumors showed a broader spectrum of RPA alterations, including *ERBB3, FGFR3/4,* and *ARAF*, whereas EAS tumors predominantly harbored canonical RTK/MAPK pathway oncogene mutations.

Together, these multi-omics analyses describe the genomic driver landscape of NSCLC in smokers and never-smokers, including rare molecular subtypes previously undetected in genomic landscapes. This study may help guide future molecular testing strategies and therapeutic management, particularly for patients with rare or currently non-targetable molecular alterations.

#0494 Multi-omics patient-derived organoid embeddings predict targeted therapy response and KRAS inhibitor sensitivity.

Lelia Polit, Nico Trummer, Rafal Pietrzak, Mateo Longarini, Alexis Finkbeiner, Anna-Rose Gryspeert, Jean Bouteiller, Jerome Caron, Fanny Jaulin, Gustave Ronteix

Orakl Oncology, Villejuif, France

Clinical trials remain a major bottleneck in contemporary drug development. Functional assays based on patient-derived organoids (PDOs) are a promising tool to derisk clinical trials, but their impact has been limited by small cohort sizes and a lack of systematic validation. Using the largest cohort of matched PDOs, longitudinal clinical data, transcriptomic data and WGS data, we generate multi-modal patient representations. We then evaluate how large collections of these representations can be used to characterize drug response phenotypes and to map how tumor-intrinsic features relate to sensitivity to targeted therapies, with a particular emphasis on KRAS inhibition.

Methods: We assembled 135 PDOs from colorectal (CRC) and pancreatic (PDAC) cancers, derived from primary tumors and metastatic biopsies. Patients were 31-89 years old and had received a mean of 2.6 prior lines of treatment at the time of tissue sampling. Each PDO underwent WES and bulk RNA-seq and was profiled in functional drug screens with a panel of targeted agents, including KRAS inhibitors. We generated embeddings from omics features for each PDO. These embeddings were used as inputs to machine-learning models trained to predict drug AUC values, enabling in silico estimation of PDO drug sensitivity from baseline molecular profiles. Within the same framework, we analysed KRAS inhibitor response by identifying molecular neighborhoods in the embedding space enriched for sensitive or resistant PDOs and stratifying samples accordingly.

Results: Embeddings captured major axes of biological variation across the PDO collection, including tumor type, key oncogenic alterations and clinically relevant subgroups, and enabled accurate prediction of AUC values for multiple targeted agents, including KRAS inhibitors. Predicted sensitivities were concordant with experimentally measured responses and reflected known dependencies associated with specific mutational backgrounds. We identified biomarkers and pathway-level signatures associated with response to different KRAS-targeted treatments. These signatures were reproducible across cross-validation procedures and aligned with reported mechanisms of KRAS inhibitor activity and escape.

Conclusions: Large, clinically annotated PDO collections coupled with multi-omics profiling support the construction of embeddings that both predict ex vivo drug response and highlight molecular contexts associated with sensitivity to targeted agents. Integrating these predictive models with systematic pathway interpretation provides a rigorous framework to uncover transcriptomic and genomic markers of response and resistance. For drug developers, this approach shows how PDO-based functional genomics combined with AI driven analysis can be used to derisk development of targeted therapies and inform patient stratification and trial design.

#0495 Single-cell multiomic drug response profiling of PRISM-multiplexed cancer cell lines sequenced with SBX.

Houlin Yu[1], Guoping Wang[1], Stephanie Yaung[2], Heejo Choi[1], Megan Rogers-Peckham[3], Michael Kartje[2], Matthew Rees[1], Paul Lund[4], Brian Haas[1], Charlotte Yang[3], Laura Doherty[1], Lacey McGee[3], Kendall Berg[3], Cynthia Cech[3], Salka Barrett[3], Anasha Arryman[3], Joanne Leadbetter[3], Taylor Lehmann[3], John Mannion[2], Chen Zhao[2], Marc Prindle[3], Melud Nabavi[3], Carolyn Morrison[4], Peter Smibert[4], Kit Nazor[5], Todd Golub[1], Catarina D. Campbell[1], Jennifer Roth[1], Niall Lennon[1], Victoria Popic[1], Dean Procter[1], Kokoris Mark[3], Aziz M. Al'Khafaji[1]

[1]Broad Institute of MIT and Harvard, Cambridge, MA,[2]Roche Sequencing Solutions, Inc, Santa Clara, CA,[3]Roche Sequencing Solutions, Inc, Seattle, WA,[4]10x Genomics, Pleasanton, CA,[5]Proteintech Genomics, San Diego, CA

Inter-individual variability in drug response is a key challenge in precision oncology. Despite recent breakthroughs in targeting RAS-mutant cancers, clinical responses remain heterogeneous. To systematically dissect the molecular determinants of drug sensitivity and resistance, we implemented a high-throughput single-cell multi-omic profiling framework using a PRISM pool: a barcoded co-culture platform of ~400 human cancer cell lines spanning diverse lineages and genetic backgrounds. We treated the PRISM pool with two RAS inhibitors (BI-2865 and RMC-6236), as well as a negative control (DMSO) and a positive control (Panobinostat), and collected cells at early time points (3h and 12h) to capture initial drug response dynamics. We employed a modified 10x Genomics Flex protocol enabling simultaneous capture of the whole transcriptome, a targeted proteome (~320-plex Proteintech panel), and PRISM identity via expressed DNA barcodes. The prototype Sequencing by Expansion (SBX) platform was leveraged to generate ~230 billion reads, enabling the analysis of 315,547 high-quality single cells.

Drug treatments induce diverse and cell line-specific shifts in transcriptional and proteomic states. Applying Non-negative Matrix Factorization (NMF) on each cell line's single-cell transcriptome data and then performing hierarchical clustering, we identified 20 drug-responsive, recurrently co-expressed gene meta-programs (MPs), condensing 1831 underlying programs related to cell cycle, growth, structure, and stress response. Multiple MP dynamics are associated with drug sensitivity and often stratified by genetic background. Notably, cell lines that exhibited a delayed stress-response MP (non-responsive at 3 hours but catching up at 12 hours) exhibited high drug sensitivity. To identify key protein players in drug response, we conducted differential expression (DE) analysis for each cell line comparing drug treatments and controls, identifying recurrently significant DE proteins whose altered expression was also significantly associated with cell viability. Importantly, these protein changes frequently lacked a corresponding significant change in the expression of their encoding RNA transcripts, underscoring the power of multi-modal profiling to more comprehensively illuminate functional mechanisms driving drug response.

Our study establishes a scalable paradigm for linking genotype, transcriptome, and proteome to pharmacologic phenotype at single-cell resolution across genetically diverse human models. These data, enabled with massively high-throughput sequencing using SBX, provide a rich resource for mechanistic discovery and rational design of combination therapies targeting the RAS pathway.

#0496 Oncolinkage: Discovery of tumor-selective surface targets for cancer therapy.

McKensie A. Collins, Benjamin T. Hallisey, Andrew Astley, Rick Nicoletti, **Murray O. Robinson**

Rubik Therapeutics, Cambridge, MA

Cancer therapeutics such as CAR T, Radioligand , ADC, and Bispecifics are all reliant on targeting cancer-selective surface proteins. A major limitation to these tethered killing strategies is the lack of targets that are exclusively expressed on tumor cells and not healthy tissues. Most cancer surface targets exhibit “lineage” expression properties, in which expression is shared by both the tumor and the normal tissue lineage from which the tumor developed. In many cases, expression in normal tissue leads to on-target off-tumor toxicity that can severely limit therapeutic benefit. To address this challenge, we developed Oncolinkage, a computational platform to identify novel tumor targets through their association with genomic changes that drive cancer development. Oncolinkage computationally identifies proteins whose expression is driven by an oncogenic event. While genomic lesions (e.g.amplification, epigenetic dysregulation) activate oncogenes in the developing tumor, many bystander genes are also dysregulated by the non-specific nature of these alterations. Oncolinkage screens for computational signals of cancer genomic lesions mathematically connecting the lesion to target upregulation. Because target expression is “linked” to the pro-tumorigenic lesion, Oncolinked targets are under positive selection, resulting in advantageous properties such as low tumor heterogeneity and resistance to loss. We show that the Cancer/Testis antigens of the MAGE family act as oncolinked targets. Normally restricted to male germ cells, MAGE genes are dysregulated in subsets of multiple solid tumors. Oncolinkage algorithms reveal a distinct set of tumor altered loci that correlate with this tumor-specific expression. We postulate that one or more transcription factors or epigenetic regulators in these loci drives tumor-selective dysregulation of these intracellular targets. Oncolinkage was further used to identify expression-disruptive lesions linked to germ cell restricted surface targets. Among more than a dozen identified oncolinked surface proteins, we found RT1, a protein with testis-restricted expression in normal tissue, but expression in 50% of TNBC and 70% of Ovarian Cancers. Tumor expression was linked to copy number gain on Chr10, the genomic locus of RT1. The known oncogene RET is also present on Chr10 providing a hypothesis that an amplification event targeting the RET oncogene also results in the dysregulation of CAR T target RT1 in subsets of breast and ovarian cancer. The oncolinkage platform is a promising computational approach to identify best-in-class targets for CAR T, RLT, and other tethered killing cancer therapies.

#0497 Transcriptomic predictors of therapy response across age groups in an omani breast cancer cohort.

Muna Al Dlali[1], Habiba El Keraby[1], Hamza Zaidom[1], Radiya Al ajmi[1], Cheryl Crozier[2], Jane Bayani[2], Sirin A. Adham[1]

[1]Sultan Qaboos University, Muscat, Oman,[2]Ontario Institute for Cancer Research, Toronto, ON, Canada

Breast cancer (BC) exhibits profound heterogeneity influenced by age, intrinsic subtypes, and treatment-induced molecular remodeling. We performed molecular analysis to identify transcriptomic biomarkers predictive of tumor biology, treatment response, and survival outcomes in Omani BC patients.

Methods: Archived FFPE tissues from 39 BC patients at Sultan Qaboos University Hospital were analyzed. Transcriptomic profiling using the NanoString Breast Cancer 360 assay was integrated with clinical and pathologic data. Spearman correlations were used to assess the relationships between age and biosignatures. Decision tree models were constructed to identify molecular determinants of (i) treatment allocation across age groups, (ii) pathologic complete response (pCR) versus partial response (pPR), and (iii) survival.

Results: Age showed a strong molecular pattern: older patients had higher ESR1, AR, PTEN, stromal, and Claudin-Low expression signatures, while younger patients exhibited higher $CD8^+$ T-cell, proliferation, HRD, p53, and BRCAness scores, consistent with a genomically unstable, immune-active phenotype. In early-onset disease, *ERBB2* was the dominant treatment classifier, with *CDK6* and macrophage signatures further stratifying endocrine versus TNBC chemotherapy; in late-onset tumors, IFN-γ and *SOX2* defined treatment branches, suggesting age-specific immune and stemness programs. Across response strata, pCR was driven by high*ERBB2* and $CD8^+$-rich immune signatures. In contrast, pPR was characterized by BRCAness and Cell Adhesion, indicating an overlap between HRD-like and adhesion-driven aggressiveness, as well as the impact of targeted therapies, such as trastuzumab, on response. Survival models mirrored this, linking long-term survival to HER2 modulation and immune activation and non-survival to AR and Claudin-Low-like states.

Conclusions: In this Omani cohort, age is associated with distinct, contextualized molecular programs. Younger patients exhibit HER2-driven, HRD-enriched, highly proliferative and immune-active biology, while older patients show hormone receptor-dominated, stromal and PTEN-preserved phenotypes. The data obtained indicate that integrating ERBB2 variations, immune metrics, and HRD-like signatures into future risk-adapted strategies in Middle East and North Africa (MENA) populations may be considered for diagnostic and treatment purposes.

#0498 The perturbation data gap: Accelerating discovery with CRISPR screening.

Elena Vialetto[1], Ronay Cetin[1], Sebastian Susser[2], Simran Rastogi[1], Angela Hinchie[1], **Jessica Martyn**[1], Martin Wegner[1], Manuel Kaulich[1]

[1]Vivlion GmbH, Frankfurt am Main, Germany,[2]IBCII, Goethe-Universitat Frankfurt am Main, Frankfurt am Main, Germany

At Vivlion, we continually strive to enhance CRISPR library and screening solutions. We introduce Alexandria, our flagship genome-wide PRCISR™ CRISPR knockout library, available in single-targeting and fixed-pair formats. The fixed-pair design delivers two sgRNAs per cell for the same gene (or predefined gene pairs), boosting editing efficiency and enabling combinatorial strategies. Alexandria broadens discovery by including ~1,800 newly annotated genes overlooked by previous reagents and covers 20,381 genes (~99.8% of ENSEMBL) with 4 sgRNAs per gene (2 pairs) to support confident hit calling across cell types and states.

All PRCISR™ libraries are produced with Vivlion's 3Cs technology, which utilizes the oligo pool directly and avoids PCR bias and cloning artefacts—yielding highly uniform gRNA distributions that preserve representation even in down-scaled screens (e.g., limited primary or iPSC material). Building on this, our library formats decouple sequence diversity from distribution, so users can deploy single-targeting, fixed-pair, or multiplex designs as their biology demands.

In practice, Alexandria enables researchers to identify context-dependent dependencies, explore pathway mechanisms, paralog buffering, and prioritise actionable targets that standard screens may miss. To streamline execution, Vivlion offers pooled and optical pooled screening, bioinformatics support, leveraging ReCo, our automated NGS read-counting pipeline for single and combinatorial CRISPR data that simplifies downstream analysis.

By combining advanced CRISPR screening with uniform, low-coverage reagents like Alexandria, researchers can accelerate discovery across disease and non-disease contexts alike.

#0499 Integrated genomic and spatial analyses elucidate the origins and vulnerabilities of urachal carcinoma.

Toru Imai[1], Tatsunori Shimoi[2], Akiko Maeshima[3], Jumpei Kashima[3], Ibuki Tsuru[1], Hisashi Hashimoto[1], Jun Takahashi[1], Eijiro Nakamura[4], Yoshiyuki Matsui[4], Hiroyuki Mano[1], Kan Yonemori[2], Yosuke Tanaka[1]

[1]Division of Cellular Signaling, National Cancer Center Research Institute, Tokyo, Japan,[2]Department of Medical Oncology, National Cancer Center Hospital, Tokyo, Japan,[3]Department of Diagnostic Pathology, National Cancer Center Hospital, Tokyo, Japan,[4]Department of Urology and Retroperitoneal Surgery, National Cancer Center Hospital, Tokyo, Japan

Introduction: Urachal carcinoma (UrC) is a rare and aggressive malignancy arising from the urachal remnant, an embryonic remnant located at the bladder dome. Despite its anatomic location, its pathological features—predominantly adenocarcinoma—resemble those of gastrointestinal adenocarcinomas. Due to its rarity, the molecular basis of UrC and the precise mechanisms underlying its carcinogenesis from the urachal remnant remain insufficiently understood, hindering the development of effective therapies. These gaps have limited therapeutic progress. To address this, we performed an integrated multi-omics and spatial analysis to delineate the molecular landscape, cellular origins, and evolutionary trajectory of UrC.

Methods: We conducted a comprehensive analysis of 53 UrC and 39 non-malignant urachal remnant samples. The multi-modal investigation included whole-exome sequencing (WES), RNA sequencing, spatial transcriptomics, and immunohistochemical analysis. To specifically investigate the pre-cancerous state, epithelial cells from urachal remnants were isolated using laser microdissection (LMD) for subsequent genomic analysis.

Results: Genomic analysis identified mutations in the RTK/RAS/MAPK pathway in approximately 60% of the tumor cases. The most frequent driver mutations were identified in *TP53*, *KRAS*, and *SMAD4*. The mutational profile was distinct from both colorectal and bladder cancers, establishing UrC as a unique molecular entity. While transcriptomic analyses clearly distinguished the pathological subtypes, investigation of cell clonality demonstrated shared ancestry among these different subtypes, implicating significant tumor plasticity. Importantly, our investigation into the tumor's origin revealed that urachal remnants undergo intestinal metaplasia, losing native urothelial characteristics while activating gastrointestinal-specific genes. We confirmed that UrC directly originates from these remnants through spatial trajectory analysis, and that genomic analysis of LMD-isolated epithelium identified shared clonal mutations between the precursor lesion and the adjacent tumor. Furthermore, spatial transcriptomics successfully characterized the unique tumor microenvironment (TME) of UrC.

Conclusion: We have elucidated key aspects of the molecular basis and origins of UrC, demonstrating that its diverse subtypes arise from a common ancestry within precursor lesions that undergo metaplasia and clonal expansion. Moreover, the characterization of the TME provides new insights into tumor biology. These findings may ultimately inform strategies for novel therapeutic intervention and the prevention of this lethal cancer.

#0500 Co-occurrence of gene fusions and microsatellite instability (MSI) defines a clinically distinct subtype of colorectal cancer.

Scott Kulm, Sebastia Franch-Exposito, Paul Fields, Catherine Igartua

Tempus, Chicago, IL

Background: Microsatellite instability (MSI) is a well-established biomarker in colorectal cancer. Gene fusions may also influence prognosis, but the clinical significance of their co-occurrence with MSI remains poorly understood.
Methods: We analyzed a cohort of colorectal (N = 29,099) cancer patients, all profiled with Tempus AIs xT platform. Fishers tests assessed the enrichment of pathogenic and likely pathogenic gene fusions within microsatellite stability groups. Cox models evaluated the independent and interaction effects of MSI status and gene fusions on real-world overall survival from at biopsy collection, adjusting for age, stage, line of therapy, tumor purity, tumor mutation burden, and PD-L1 combined positive score. We tested for enrichment of all fusions, kinase fusions (*NTRK1*, *NTRK3*, *RET*, *ALK*, *FGFR2*, *BRAF*), and NTRK fusions (*NTRK1*, *NTRK3*).
Results: The proportion of clinically relevant gene fusions was higher in MSI versus MSS colorectal cancer tumors (5.9% vs 1.8%): *NTRK1* (2.2% vs. 0.048%), *NTRK3* (1.2% vs. 0.14%), *RET* (0.87% vs. 0.096%), and *TPM3* (1.0% vs. 0.0074%). Survival analyses revealed that all fusions and kinase fusions were both associated with significantly worse overall survival (Table 1). These trends persisted in sub-cohorts. MSI was associated with increased overall survival in models including all fusions, kinase fusions, and *NTRK* fusions. We did not detect a significant interaction between MSI and gene fusions across any of the models, likely due to smaller sample sizes. However, we confirmed fusions remained associated with poor overall survival when restricting to MSS tumors for all gene fusions and kinase fusions. Additional models fit to patients treated with specific therapies, such as immunotherapy, did not converge.
Conclusion: Gene fusion rates differ between MSI and MSS colorectal tumors. While most fusions are generally associated with worse survival, this effect may be reversed in MSI cases.

#0501 Integrated multiomic profiling reveals SWI-SNF subunit-specific pathway alterations and targetable vulnerabilities.

Clemence Astier[1], Jorge Bretones Santamarina[2], Marlene Garrido[1], Leo Colmet-Daage[1], Thibault Delobel[2], Marcos Bolanos[2], Marianne Chasseriaud[1], Elodie Anthony[3], Daphne Morel[4], Roman M. Chabanon[1], Theo Roumeliotis[5], Mercedes Pardo[5], Elaine Del Nery[3], Jyoti Choudhary[5], Annabelle Ballesta[2], Sophie Postel-Vinay[6]

[1]Inserm U981, ATIP-Avenir, ERC StG, (Epi)genetic Vulnerabilities in Solid Tumors and Sarcoma Laboratory Institut Gustave Roussy, Villejuif, France,[2]Inserm U1331, Cancer Systems Pharmacology ATIP-Avenir team, Institut Curie, MINES ParisTech, CBIO, PSL Research University, Paris, France,[3]Biophenics, Institut Curie, PSL Research University, Department of Translational Research, Cell and Tissue Imaging Facility (PICT-IBiSA), Paris, France,[4]Universite Paris-Saclay, Kremlin-Bicetre, Institut Gustave Roussy, Villejuif, France,[5]Functional Proteomics group; The Institute of Cancer Research, London, United Kingdom,[6]Inserm U981, ATIP-Avenir, ERC StG, (Epi)genetic Vulnerabilities in Solid Tumors and Sarcoma Laboratory Institut Gustave Roussy, Drug Development Department (DITEP), Institut Gustave Roussy, University College of London, UK, Villejuif, France

Background: Mutations in subunits of SWI/SNF chromatin remodeling complex frequently occur in cancer and no targeted therapy is currently available for this patient population. To systematically characterize novel targetable vulnerabilities in SWI/SNF-deficient cancers, we integrated multiomics profiling and drug screening of tumor cell lines with publicly available molecular profiling and CRISPR screen, using newly developed bioinformatic methodologies.

Methods: We generated in-house transcriptome and proteome profiling with high-throughput drug screening on a panel of isogenic HAP1 cell lines knocked-out (KO) for genes encoding SWI/SNF subunits or other chromatin remodelers. We further acquired publicly available molecular profiling and CRISPR-screen datasets from the TCGA and DepMap projects, respectively, and integrated all results. Gene set enrichment analyses were performed using an optimized pipeline based on (i) a pruned version of the Reactome pathway database, (ii) combining ROntoTools and GSEA algorithms, which scored as top performant strategy. Synthetic lethal interactions (SLi) from the DepMap CRISPR screening were identified using a new benchmarked SLi algorithm, based on expression levels of genes on interest, to consider functional deficiencies.

Results: *Metabolism of proteins*, which had not previously been linked to SWI/SNF, was the most frequently dysregulated pathway category both in HAP1 SWI/SNF-KO mutant cell lines and in the DepMap analysis comparing models with low and high SWI/SNF subunit expression; it was the third most dysregulated in SWI/SNF-defective TCGA patient tumors (after *Signal transduction* and *Immune system*, potentially due to the presence of an immune microenvironment). High-throughput drug screen identified multiple pharmacological vulnerabilities, including inhibitors of the histone acetyltransferase CBP/EP300 or mitochondrial respiration, which were selectively cytotoxic in SWI/SNF-defective models. Our new SLi algorithm, also independently identified genetic synthetic lethality between SWI/SNF defects and *EP300* or mitochondrial respiration genes. These orthogonal genetic and chemical vulnerabilities were revalidated experimentally in histotype-relevant SMARCA4-isogenic models, using two highly selective EP300 inhibitors and the mitochondrial respiratory chain complex III inhibitor Antimycin A.

Conclusion: Integrating multi-omics profiling with high-throughput drug- and genetic- screening, respectively analyzed using an optimized enrichment pipeline and a newly developed SLi algorithm, enabled the identification of actionable genetic dependencies in SWI/SNF-defective cancers. These predicted synthetic lethal interactions were experimentally validated in relevant models, supporting their clinical relevance.

JBS and CA contributed equally. SPV and AB contributed equally.

#0502 Comparison of *MTAP* loss by immunohistochemistry (IHC) and *MTAP* homozygous deletion by next-generation sequencing (NGS) and DNA fluorescence in-situ hybridization (FISH).

Lisa Huang[1], Lauren Giampapa[1], Paige Montanaro[1], Ishwarya Krishna[1], Shannon Chilewski[1], Haeun Hwangbo[1], Wen-Chi Chou[1], Sarah Jamerson[1], Lynn Dong[1], Olufemi Adelakun[1], Juliana Coculo[1], John Rassa[1], Jonathan Baden[1], Travis Hollmann[1], **Igor Katsyv**[2]

[1]Bristol Myers Squibb, Princeton, NJ,[2]Bristol Myers Squibb, Cambridge, MA

Background: Methylthioadenosine phosphorylase (MTAP) deletion, resulting from genomic alteration, is observed in approximately 10%-15% of solid tumors, including NSCLC, PDAC, and others. Second-generation MTA-cooperative PRMT5 inhibitors have shown encouraging efficacy and safety in patients with advanced solid tumors, emphasizing the need for precise patient selection strategies. DNA NGS, DNA FISH, and IHC are the primary methods of MTAP loss detection in patient tumor samples. FISH is often considered the gold standard for confirming gene deletions due to its high spatial resolution and direct DNA-level detection; however, its limited scalability, longer turnaround, and operational complexity make it less practical for routine screening. NGS enables multiplexed, high-throughput detection of genomic alterations including MTAP deletions with strong analytical performance and broad molecular context. It supports treatment selection, prognostic assessment, and trial eligibility from a single tumor specimen. IHC offers rapid turnaround, preserves tumor morphology, and allows visualization of intratumoral heterogeneity. With the promising results that have been shown so far for MTA-cooperative PRMT5 inhibitors, flexibility in testing methods is important to meet the diverse needs of patients and physicians as the development of these agents moves forward. Here, we present the results of a study assessing the concordance of IHC, NGS, and FISH testing to assess the presence of MTAP loss.

Methods: We developed an MTAP IHC assay by screening, optimizing, and biophysically characterizing 13 commercially available antibody clones. We subsequently benchmarked our IHC assay using validated DNA NGS and/or FISH on > 160 solid tumor samples.

Results: IHC was highly concordant with NGS (> 90% agreement, Cohen's Kappa > 0.85) and with FISH (> 85% agreement, Cohen's Kappa > 0.70). Similarly, NGS and FISH showed strong concordance (> 90% agreement, Cohen's Kappa > 0.80). Through in-depth assessment of tumor morphology and review of FISH images, we attributed most discordance in the context of apparent MTAP loss on IHC without concomitant MTAP deletion detection on NGS and/or FISH to low/borderline tumor purity. When investigating preliminary patterns of exon-level MTAP homozygous deletion by NGS and FISH in our cohort, we observed some heterogeneity between methods in tumors with partial MTAP deletion.

Conclusions: These data demonstrate high overall agreement among IHC, NGS, and FISH for the detection of MTAP loss. IHC offers rapid screening with retained morphologic context, whereas NGS and FISH provide orthogonal molecular resolution. Our findings support IHC as a practical method for MTAP loss detection, along with NGS or FISH.

#0503 Assessing paralog dependency in ovarian cancer to drive target discovery.

Amy R. Lowe, Siobhan O'Brien, Marissa Fujimoto, Alice H. Berger

Fred Hutchinson Cancer Center, Seattle, WA

Ovarian cancer is the deadliest gynecologic cancer, and the fifth leading cause of cancer-related mortality in individuals assigned female at birth. Though some targeted therapies are available for the treatment of ovarian cancer, there is an unmet need especially for non-RAS or *BRCA1/2* mutant cases. Recent developments in CRISPR technology have allowed for high-throughput identification of genetic dependencies, accelerating the identification of new drug targets for cancer treatment. However, we and others have shown that many cellular dependencies are missed due to genetic redundancy within the human genome. Indeed, paralog genes can compensate for each other's functions and obscure gene-dependent phenotypes when using only single gene knockout tools. To assess paralog dependency, multiple genes must be knocked out at the same time. In this study, we developed the focused dual gene-targeting library pgMI, which is comprised of 3,800 paired-guide RNAs (pgRNAs) targeting 116 paralog pairs that have been identified as synthetic lethal in at least two published double knockout CRISPR screens. To aid in genetic interaction mapping, pgMI contains both single and double-targeting pgRNAs. In an initial analysis of six non-small cell lung cancer cell lines, we uncovered several cell line specific and pan-essential paralog dependencies. To assess paralog dependencies specific to ovarian cancer, we then performed pgMI CRISPR screens in three common ovarian cancer cell lines - SKOV3, JHOS4, and OVCAR8. These cell lines represent a diverse set of cancer driver genes, which include activating mutations in both the Wnt and RAS signaling pathways. pgMI screening uncovered paralog dependencies both unique and shared across ovarian cancer cell lines, providing a narrowed list of potential therapeutic targets for further study.

#0504 Interferon enriched gene expression signatures are associated with ADAR1 dependency in oral squamous cell carcinoma.

Pei San Yee[1], Jie Ying Teo[1], Shi Mun Yee[1], Shiyin Ooi[1], Yee Hua Tan[1], Mathew J Garnett[2], Siew Kit Ng[3], Annie Wai Yeeng Chai[1], Sok Ching Cheong[1]

[1]Cancer Research Malaysia, Subang Jaya, Malaysia,[2]Wellcome Sanger Institute, Cambridge, United Kingdom,[3]Universiti Sains Malaysia, Bertam, Malaysia

Oral squamous cell carcinoma (OSCC) is prevalent in Southeast Asia, and the 5-year survival rate remains poor due to limited effective treatments, underscoring the need for new therapeutic strategies. Our recent work shows that *adenosine deaminase acting on RNA 1* (*ADAR1*), particularly the p150 isoform, is essential for OSCC cell survival, making it a promising therapeutic target. However, determining which patients may respond from ADAR1 inhibition remains challenging because the basis of this dependency is not fully understood. This study aimed (1) to predict ADAR1 dependency in OSCC tumors and (2) to define the gene expression changes associated with ADAR1 loss. For Aim 1, differential gene expression (DEG) analysis was performed on OSCC cell lines with validated ADAR1 dependency status using RNA-sequencing data. ADAR1-dependency signature scores were generated from the average z-scores of these DEGs and applied to 313 OSCC tumors in The Cancer Genome Atlas (TCGA). For Aim 2, we selectively knocked down the p150 isoform using siRNA in multiple OSCC cell lines followed by RNA-sequencing. Gene Set Enrichment Analysis (GSEA) was used to identify pathways altered by ADAR1-p150 knockdown in both dependent and less-dependent lines. We found that ~93% of OSCC tumors were predicted to be ADAR1-dependent, consistent with our previous CRISPR screen findings. GSEA revealed enrichment of interferon (IFN)-alpha/beta signaling and keratinization pathways in ADAR1-dependent tumors. ADAR1-p150-dependent cell lines exhibited higher basal expression of numerous interferon-stimulated genes (ISGs). Upon ADAR1-p150 knockdown, these lines showed significant cell lethality accompanied by enrichment of IFN-related pathways, whereas less-dependent lines showed neither growth inhibition nor substantial upregulation in IFN signaling. Quantitative PCR and protein analyses confirmed upregulation of IFN-β and several ISGs including CXCL10 and ISG15 in dependent OSCC line upon ADAR1-p150 knockdown. Together, these findings show that ADAR1 dependency signatures can stratify OSCC tumors and identify patients likely to benefit from ADAR1-targeted therapies. OSCCs with enriched ISG expression are more susceptible to ADAR1-p150 loss, and the resulting upregulation of IFN-related gene signatures may serve as a biomarker of therapeutic response.

#0505 Molecular Standard of Care.

Sam Phillips, Eric Collisson

Fred Hutchinson Cancer Center, Seattle, WA

Background Molecular testing has transformed cancer care by enabling risk stratification, targeted therapy selection and improved patient outcomes. To evaluate the state of the field and ensure that molecular testing is consistently implemented in the appropriate clinical contexts, we developed a systematic framework—termed the *Molecular Standard of Care (MSoC)*—rooted in established guideline-based recommendations for molecular profiling.

Methods Assessment of the MSoC consisted of four components: (1) Establishment of Evaluation Criteria (EC), defining the molecular information required for guideline-concordant treatment; (2) Cohort Identification, including patients with (a) newly diagnosed metastatic disease and (b) receipt of treatment at Fred Hutch; (3) Data Abstraction, involving manual chart review of relevant disease-specific data elements and (4) Evaluation Synthesis, summarizing molecular testing data to determine adherence to the MSoC.

Results Four metastatic cancers (lung, colorectal, breast, and prostate) were evaluated using multiple cohort identification approaches. MSoCs were assembled. We reviewed 605 patients across 10 clinics over three months. 212 met inclusion criteria for MSoC assessment. The disease-specific MSoC criteria were met 89% across all four disease groups.

Conclusions MSoC can be quantitatively described with disease-specific criteria that will evolve with progress in the field. Fred Hutch Cancer Center demonstrated high adherence to guideline-based molecular testing standards across major metastatic cancers. Future work will focus on automating MSoC evaluation to reduce manual review burden and enable real-time assessment of molecular testing adherence across patient populations. This model may serve as a scalable approach to benchmarking molecular testing adherence in academic and community cancer centers.

#0506 High content CRISPR activation screens identified synthetically lethal RNA-based mechanisms to sensitize cancer cells to targeted T cell cytotoxicity.

Jeehyun Yoe, Reece V. Akana, Olivia Laveroni, Chang Sun, Young-Min Kim, Livnat Jerby

Department of Genetics, Stanford University, Stanford, CA

T cells recognize cancer (neo)antigens via T cell receptor (TCR) and selectively eliminate the target cancer cells, yet cancer cells often evolve evasion mechanisms or lack sensitizing cues that limit the efficacy of immunotherapy. While cancer CRISPR knockout screens have revealed genes whose loss drives immune evasion, far less is known about gain-of-function mechanisms capable of restoring tumor susceptibility to targeted T cell cytotoxicity. To address this gap, we developed an integrated framework combining CRISPR activation (CRISPRa), single-cell transcriptomics, and a new optical pooled high-content screening approach to uncover RNA-based mechanisms that sensitize cancer cells to TCR-specific cytotoxicity. In melanoma cells, CRISPRa screens uncovered functionally diverse regulators of T-cell killing, including the chromatin remodeler *SAFB* and additional sensitizing genes that restore susceptibility in cancer and virally infected cells. To decode how these regulators act within the native tumor context, we developed in situ Perturb-seq, a pooled optical genetic screening platform that enables single-molecule spatial transcriptomic readouts directly in intact tissues. In situ Perturb-seq, together with Perturb-seq, revealed that sensitizing perturbations converge on shared cell-autonomous and intercellular programs involving stemness-differentiation axes, cytokine networks, and ligand-receptor circuits. Notably, Wnt ligands that were found as sensitizing hits in cancer cells significantly enhanced T-cell effector functions, demonstrating how tumor-intrinsic gain-of-function perturbations can identify new modalities to reprogram and engineer T cells. Together, this work introduces a scalable platform to identify RNA-based immunomodulators and resolve their multicellular mechanisms across scales. By coupling CRISPRa screens with in situ Perturb-seq, we establish a broadly applicable framework for discovering and mechanistically defining gene activations that re-sensitize tumors to cytotoxic immune attack - including applicability beyond T cells to innate cytotoxic lymphocytes such as natural killer (NK) cells - and across distinct solid tumor types, thus opening avenues for RNA-based immunotherapies for disease treatment and prevention.

: Agentic AI in Cancer
Poster Session

#0016 DrBioRight: an AI research assistant for cancer data analysis.

Han Liang[1], Wei Liu[2]

[1]UT MD Anderson Cancer Center, Houston, TX,[2]UT MD Anderson Cancer Center

We present DrBioRight, a next-generation conversational AI platform that streamlines cancer omics analysis through a multi-agent large language model (LLM) architecture. Modern sequencing and imaging technologies generate vast and complex datasets, yet conventional analysis tools often require substantial computational expertise. DrBioRight overcomes this barrier by enabling researchers to engage in natural language dialogue with the system, transforming intricate analytical tasks into intuitive, conversational interactions. DrBioRight's chatbot-driven interface allows users to search and query datasets, execute multi-omics analyses, access interpretable insights, and generate publication-quality visualizations—all through simple questions or commands. This interaction model removes the need for programming, lowering the barrier to advanced bioinformatics and making omics research accessible to a broader scientific community. Key features include: (i) LLM-powered conversational analysis for RNA-seq, proteomics, single-cell, spatial, and clinical-genomic data ; (ii) A curated, high-performance cancer omics datastore drawing from TCGA, CPTAC, DepMap, and other public repositories; (iii) An extensible App Store integrating bioinformatics software packages, pipelines, and custom tools; (iv) Real-time task prediction, workflow guidance, and troubleshooting; (v) Collaborative workspace functionality for sharing analyses and results across research teams; (iv) Community-driven extensibility, enabling seamless integration of new datasets, modules, and analytical frameworks. By shifting from traditional technical interfaces to an interactive conversational paradigm, DrBioRight functions as an intelligent research assistant. It democratizes the use of complex omics analytics, enhances collaborative discovery, and accelerates translational research across the cancer research community.

#0017 A multicenter, prospective validation of an AI-based software (PanClaudinAI) for predicting claudin 18.2 expression via contrast-enhanced CT in pancreatic cancer.

Yaqi Zhang[1], Tianxing Zhou[2]

[1]Tianjin medical University Cancer Institute & Hospital, Tianjin, China,[2]Tianjin Medical Univ. Cancer Inst. & Hospital, Tianjin, China

Background: Claudin 18.2 (CLDN18.2) is a promising therapeutic target in pancreatic cancer. Current immunohistochemistry (IHC)-based assessment is invasive and limited by tumor heterogeneity. We developed a deep learning model using contrast-enhanced CT (CECT) to predict CLDN18.2 expression and validated it in a multicenter prospective cohort via a dedicated software application (PanClaudinAI).

Methods: We retrospectively collected CECT images and matched CLDN18.2 IHC data from 800 patients across three centers (Center A: n=400; Center B: n=230; Center C: n=170). CLDN18.2 positivity was defined as ≥75% moderate-to-strong staining. A Vision Transformer (ViT) model was trained using arterial-phase CT images. The model was integrated into a user-friendly software application (PanClaudinAI) for real-time inference. We subsequently conducted a prospective multicenter validation (Center D: n=100; Center E: n=120; Center F: n=140) to evaluate its clinical utility.

Results: The prevalence of CLDN18.2 positivity was 45.7% in the retrospective cohort and 50.2% in the prospective cohort. The AI model achieved an AUROC of 0.81 (95% CI: 0.76-0.86) with a sensitivity of 78.2% and specificity of 75.4% in center A; an AUROC of 0.84 (95% CI: 0.81-0.89) with a sensitivity of 81.5% and specificity of 79.3% in center B; and an AUROC of 0.86 (95% CI: 0.83-0.89) with a sensitivity of 82.7% and specificity of 80.1% in center C within the retrospective training set. In the prospective multicenter validation, the model maintained an AUROC of 0.79 (95% CI: 0.73-0.84) with a sensitivity of 76.5% and specificity of 74.2% in center D; an AUROC of 0.78 (95% CI: 0.74-0.82) with a sensitivity of 75.8% and specificity of 73.6% in center E; and an AUROC of 0.85 (95% CI: 0.82-0.91) with a sensitivity of 81.2% and specificity of 79.0% in center F. Moreover, the PanClaudinAI software demonstrated high usability and integration into clinical workflow, with an average processing time of <2 minutes per case.

Conclusions: We developed and prospectively validated a robust AI-based software (PanClaudinAI) that non-invasively predicts CLDN18.2 expression from routine CECT images across multiple centers. This tool facilitates rapid, reproducible, and accessible biomarker identification, potentially guiding patient selection for CLDN18.2-targeted therapies and reducing the need for invasive biopsies.

#0018 GP CoPilot: An AI-enhanced agent for cancer research.

Michael M. Reich, Thorin Tabor, Ted Liefeld, Anthony Castanza, Alexander T. Wenzel, Jill P. Mesirov

UCSD Medical Ctr., San Diego, CA

We have released GP CoPilot, a large language model (LLM)-based, chatbot-style interface allowing scientists to design and execute bioinformatic analyses and workflows conversationally. Agentic features range from basic operations such as managing files and finding and executing available analyses, to more complex behaviors such as designing workflows, monitoring running jobs, and executing bulk actions. The addition of a knowledgebase containing detailed information about the available analyses, use of the software tools, and a help forum with over 20 years of questions and answers, ensures that the recommendations that GP CoPilot provides are in general more accurate and specific than those provided by plain LLMs alone such as ChatGPT, Claude, Gemini, etc.GP CoPilot uses as its base the GenePattern platform for reproducible genomics research. First released in 2004, GenePattern provides non-computational scientists with a web-based, code-free user interface to hundreds of genomic analysis tools. These include preprocessing, expression analysis for bulk and single-cell RNA-Seq data, network and pathway analysis, proteomics, flow cytometry, as well as many general machine learning methods. Cancer-specific analyses include copy number alteration using GISTIC 2.0, significance of variants with MutSigCV, driver gene identification with MutPanning, ecDNA identification and structure elucidation with AmpliconArchitect, variant annotation with OpenCRAVAT, etc. A pipeline building tool allows for the creation of detailed workflows. When analyses are run, their inputs, parameters, and code version are recorded, ensuring reproducibility.The integration of large language models with the GenePattern platform enables a user interface that surpasses previous efforts at providing scientists with the power to design complex workflows without the learning curve required to become proficient with a tool. Even technical users can shorten the time it takes to perform analyses due to the ease with which an agent can perform low-level tasks such as retrieving data from web sites and reformatting datasets.

#0019 GenerAItive: An AI system for interpretation of gene expression analyses in cancer.

Muiz Khan, Alan Carbajo, Sorin Draghici

Computer Science, Wayne State University, Detroit, MI

High-throughput cancer studies are increasingly generating transcriptomic datasets of substantial size and complexity, prompting the adoption of systems biology approaches in medical research. Because transcriptomics analyses can yield thousands of differentially expressed genes (DEGs), enriched gene-sets, pathways, and associated regulators, pinpointing drivers of important biological processes is often time-consuming and challenging. To address this, we developed GenerAItive, an agent-based artificial intelligence (AI) that interprets gene expression analyses from iPathwayGuide, a widely used bioinformatics platform that reveals statistically significant downstream gene-sets, pathways, diseases, and upstream regulators. Our system retrieves iPathwayGuide output data and iteratively analyzes each result layer—including top DEGs, enriched gene sets (MSigDB, Gene Ontology), impacted pathways (KEGG), predicted upstream regulators (genes, miRNAs, chemicals), and associated diseases—using task-specific reasoning agents. These AI agents can investigate and interpret results that are most relevant in biological context, retrieving supporting evidence from literature and pathway analyses, and synthesizing them through large-language model reasoning to produce clear mechanistic explanations of how gene expression changes affect cancer-related processes. In testing, our system produced accurate, literature-supported interpretations of pathway activation, predicted regulators, and downstream effects. It also reproduced established findings in cancer datasets without prior exposure to those studies. These results suggest that generative AI can aid in interpretation of transcriptomic data, reduce overlooked relationships, and help researchers understand complex biological signals more quickly.

#0020 An agentic AI workflow for automated, high-fidelity curation of cancer diagnosis and staging from unstructured patient records.

Tian Kang, Elizabeth Dougherty, Shivam Mishra, Ryan Godart, Arpita Saha, Jonathan Wills, Victoria L. Chiou, Maria A. Berezina, Kunal Nagpal

Tempus AI, Inc., Chicago, IL

Purpose
Artificial intelligence (AI)-driven clinical document abstraction (CDA) using large language models (LLMs) is transforming oncology data management by extracting crucial data, such as staging and molecular profiles, from unstructured notes. We validated an agent that autonomously abstracts cancer diagnoses into structured, high-quality real-world evidence (RWE), accelerating research and supporting timely evidence-based treatment decisions with clinical-grade accuracy at scale and operational sustainability.
Methods
Our AI-CDA workflow uses a three-stage hybrid multi-agent AI design for high-accuracy, cost-efficient data abstraction:
1. Pre-screening: two specialized natural language processing (NLP) models fine-tuned on clinical notes scan the entire patient chart, classifying documents and identifying key cancer diagnosis events to select up to 100 relevant documents, reducing the LLM inference cost.
2. Extractor: a non-reasoning LLM (GPT-4.1) extracts all relevant diagnostic information from selected documents.
3. Structuring and normalization: a GPT-4.1 call synthesizes diagnosis summaries to produce structured clinical fields (e.g., diagnosis date, stage, histology) according to a predefined data model. Finally, structured fields are normalized to a fixed taxonomy by o3-mini.
System performance was benchmarked against manual abstraction on a cohort of 1497 patients (499 breast, 499 lung, 499 pan-cancer) sampled from the Tempus RW database.
Results
The automated workflow performed strongly against manual abstraction. Tissue of origin abstraction achieved a micro F1-score of 0.94, with excellent performance on common cancers (e.g., lung: 0.98, breast: 0.98, colon: 0.97). Metastasis status detection achieved 0.92 F1-score, histology 0.91, and overall stage 0.83. Initial diagnosis date accuracy was 0.90. A subsequent, adjudicated re-evaluation of discordance revealed an even higher real-world performance by correcting initial manual labeling errors. Histology F1-score rose to 0.96 (+0.05) and overall staging rose to > 0.91 (a lift of over 10%).
With regard to cost efficiency: pre-screening with two specialized NLP models reduced the average number of documents requiring LLM review >90% (from 266 to 24 per patient). This lowers LLM cost, mitigates performance degradation associated with longer context, and prioritizes only the most pertinent information.
Conclusions
This study demonstrates the feasibility and operational sustainability of an agentic AI-CDA workflow for highly accurate cancer data abstraction. This hybrid solution addresses three critical needs: scaling clinical research through automated, high-fidelity data abstraction; supporting timely evidence-based treatment decisions; and achieving operational sustainability by reducing inference cost and resourcing through a hybrid NLP/LLM workflow.

#0021 AI analysis agent to accelerate end-to-end spatial biology analysis for MERSCOPE.

Harihara Muralidharan[1], Cheng-Yi Chen[2], Friedrich Preusser[2], Ruben Cardenes[2], Kenny Workman[1], Hannah Le[1], Alfredo Andere[1], **Lorenz Rognoni**[2]

[1]LatchBio, San Francisco, CA,[2]Vizgen, Cambridge, MA

Background: Spatial biology assays on the MERSCOPE platform enable subcellular mapping of RNA transcripts and proteins within the tumor architecture. However, these assays generate terabyte-scale datasets that require complex computational workflows. Post-acquisition analysis including cell segmentation, cell typing, and spatial domain detection remains computationally intensive and requires specialized bioinformatics expertise. This can limit accessibility for many cancer biology laboratories. To overcome these barriers, Vizgen and LatchBio have developed an AI-driven workflow powered by large language model (LLM) agents, designed to streamline and simplify end-to-end spatial biology analysis for MERSCOPE in oncology research.
Methods: We implemented an LLM-driven agent tailored to the Vizgen data ecosystem. The agent (1) parses MERSCOPE outputs (multi-channel z-stack images, transcript coordinate files, metadata) and launches optimized GPU-accelerated workflows for image segmentation and transcript assignment; (2) presents an interactive notebook interface (Markdown, plots, widgets) so users can specify downstream questions in natural language (e.g., “Identify Cytotoxic T-Cells within tumor border regions”); (3) triggers bioinformatics pipelines for clustering, cell-type annotation, spatial domain detection, and differential expression/regulation; and (4) integrates with LatchBio’s scalable compute/storage infrastructure for large-scale runs (>1 TB per dataset). We validated performance on breast cancer and colorectal cancer samples processed on MERSCOPE.
Results: The agent successfully handled large-scale, multi-sample MERFISH spatial transcriptomics datasets. It performed end-to-end analysis (cell re-segmentation, unsupervised clustering, spatial domain detection, and differential expression in selected cell populations) within a single run. Outputs were delivered as interactive, reproducible notebooks for a rapid review of cell-type-annotated clusters, spatial domain maps, and differential expression summaries. Compared with a conventional manually scripted workflow, the agent completed full analyses in ~6 hours (vs ~72 h traditionally). In end-user testing, it reduced manual scripting and dependency management efforts by ~60 % and decreased downstream errors, improving pipeline reliability.
Conclusions: The Vizgen-LatchBio AI-agentic workflow provides a scalable, user-friendly solution for advanced MERSCOPE data analysis, enabling spatial biology labs to self-serve complex computational tasks. By abstracting computational complexity and embedding domain-specific logic, this system empowers biologists to focus on biological insights rather than technical tool-chaining. Consequently, it shortens time-to-insight and facilitates high-throughput workflows across drug discovery, disease research, and academic studies.

#0022 Multi-agent AI system for autonomous CAR-T development: Integrated target discovery, toxicity prediction, and rational molecular design for cancer immunotherapy.

Yi Ni, Liwei Zhu

Bio LIMS INC, Boston, MA

Background: Chimeric antigen receptor T-cell (CAR-T) therapy has achieved remarkable success in hematologic malignancies, yet only 6 products have gained FDA approval since 2017, with target selection and toxicity remaining critical bottlenecks. Conventional pipelines require 8-12 years with 40-60% failure rates due to inadequate validation or safety liabilities. Notable clinical setbacks underscore urgent need for autonomous systems predicting safety risks before costly trials.
Methods: We developed Bio AI Agent, a multi-agent AI system powered by large language models enabling autonomous CAR-T development. The architecture comprises six agents: (1) Target Selection for antigen prioritization, (2) Toxicity Prediction integrating tissue atlases and pharmacovigilance databases, (3) Molecular Design for modular CAR engineering, (4) Patent Intelligence for freedom-to-operate analysis, (5) Clinical Translation for regulatory guidance, and (6) Decision Orchestration for multi-agent coordination. Agents communicate through shared knowledge base with vector database and natural language interfaces.
Results: Retrospective validation demonstrated autonomous capabilities across key stages. Target assessment streamlined 3-4 month workflows to rapid processing. Toxicity prediction accurately identified problematic targets through expression profiling and adverse event analysis. Patent intelligence flagged infringement risks enabling compliant design strategies. Molecular design demonstrated systematic optimization with real-time prediction. Decision orchestration generated comprehensive roadmaps spanning validation, pathway development, and clinical translation.
Conclusions: Bio AI Agent addresses critical CAR-T development gaps through intelligent collaboration across target discovery, safety prediction, and molecular optimization. Autonomous identification of liability targets with mitigation strategies demonstrates potential for reducing attrition and improving safety. Multi-agent architecture enables parallel processing and specialized reasoning superior to monolithic systems. As CAR-T expands into solid tumors, autonomous platforms will be essential for accelerated precision oncology.

#0023 ImmunoVerse-Chat: A conversational agentic-AI engine for next-generation immunotherapeutic target discovery.

Aman Sharma[1], Guangyuan (Frank) Li[2], Xinya Liu[2], Mark Yarmarkovich[2]

[1]Perlmutter Cancer Center, Perlmutter Cancer Center, New York University Grossman School of Medicine, New York, NY,[2]Perlmutter Cancer Center, New York University Grossman School of Medicine, New York, NY

T-cell based immunotherapies such as CAR-T Cells, BiTEs and an expanding class of next-generation T-cell-engaging modalities, have revolutionized cancer treatment and dramatically improved outcomes for many patients. Yet, the success of these therapies fundamentally relies on identifying safe, tumor-specific targets. However, current practice relies on labor-intensive convoluted bioinformatics efforts that require deep domain expertise and extensive coordination between computational scientists and clinicians. These fragmented workflows slow the pace of discovery and significantly delay the transition of emerging targets into therapeutic development. To overcome these challenges and motivated by recent advances in large language models and agentic AI, we developed ImmunoVerse-Chat, an interactive agentic framework that integrates LLM-driven reasoning with high-performance immunogenomic pipelines to streamline and accelerate tumor-specific antigen discovery. Built upon our previously established ImmunoVerse, the most comprehensive pan-cancer therapeutic T cell targets to date, spanning over 21 tumors, 11 classes of molecular events. Together, these system-level innovations allow ImmunoVerse-Chat to uncover clinically meaningful antigen patterns that are often overlooked or inaccessible to conventional pipelines. ImmunoVerse-Chat streamlines the entire immunopeptidomic workflow from raw multi-omic data to pHLA identification and provides an interactive, reasoning-driven interface that enables rapid comparison of antigen landscapes, real-time target prioritization, and assessment of T-cell therapeutic potential. By leveraging the underlying pan-cancer antigen atlas, the system, through automated visualization modules, further contextualizes these findings across tissue types and molecular aberrations to distinguish shared and tumor-restricted pMHC candidates and uncover recurrent, population-relevant antigens, tumor-resident microbial epitopes, and molecular signatures linked to splicing, immune regulation, and endogenous retrovirus expression, including ERV-derived peptides. These integrated, multi-layered insights directly guide the selection of safe, immunogenic, and clinically meaningful T-cell targets. Overall, ImmunoVerse-Chat combines AI reasoning with multi-omic depth into a unified, interactive, and population-aware engine for T-cell target discovery, and we envision the broad adoption of this platform will democratize antigen discovery across oncology research and accelerate the development of next-generation immunotherapies.

#0024 CertisAI Assistant: An agentic AI platform for dynamic preclinical oncology model selection.

Luke Jervis, Warren Andrews, Yuan-Hung Chien, Raffaella Pippa, **Long Hoang Do**

Certis Oncology Solutions, San Diego, CA

Conventional tumor model selection often operates as a target-driven process, relying primarily on established biomarker strategies and prior treatment profiles to identify models aligned with a specific therapeutic goal. This methodology, rooted in static, retrospective datasets, frequently limits the scope of investigation and can result in selecting models that have reduced predictive power for complex clinical outcomes. To enhance the selection criteria for preclinical tumor models, we developed the CertisAI Assistant, an agentic AI platform that integrates real-time, on-demand therapeutic response prediction with deeply characterized tumor model datasets within a unified research environment.

The CertisAI Assistant functions as an interactive research tool, integrating models from the Cancer Cell Line Encyclopedia (CCLE) and Certis' proprietary patient-derived xenograft (PDX) data. Its core is CertisAI, an ensemble of machine learning models trained on extensive monotherapy and combination drug response data, leveraging gene expression and molecular fingerprints. We engineered a secure, self-service client that enables users to upload novel therapeutic compounds (via SMILES string) or sequencing data (via FASTQ files) for immediate, on-demand therapeutic predictions.

Prediction results are dynamically integrated into the generative AI assistant, allowing for natural language querying and comparative analysis. Key visualizations, including mono and combination therapy prediction results, are instantly available. The CertisAI Assistant moves beyond static data delivery, providing a dynamic, real-time analysis environment for therapeutic response prediction and model selection. This platform significantly accelerates preclinical oncology research by empowering users to rapidly test hypotheses, evaluate novel agents, and guide the development of effective combination strategies.

#0025 Agentic AI for RNA-Seq: From workflow automation to actionable insights.

Arthur Liberzon, Pablo Cingolani, Steven Wood Criscione, Etai Jacob

Oncology R&D, AstraZeneca, Waltham, MA

Automating bioinformatic analyses of RNA-seq data is challenging because each project requires unique combinations of analytical steps and frequent, case-specific adjustments. These project-specific processes limit the reusability of workflows to other analyses and require extensive manual coding. Large language model (LLM) agents are well-suited to address these challenges because they can interpret natural language instructions, dynamically plan workflows, and adapt to study-specific requirements without manual coding.We developed an agentic AI platform that uses LLMs to plan, execute, and interpret bulk RNA-Seq analyses via natural language instructions. The platform includes two implementations: an interactive Streamlit app where users can upload data and describe the project, and a non-interactive API for integration into larger agentic ecosystems to enable extension to single-cell RNA-Seq and mutation analyses. Our system leverages vetted, state-of-the-art methods to ensure reproducibility while performing analyses such as PCA, differential expression, and pathway enrichment in Python. The platform generates actionable reports that contextualize tables and figures in the project context. Key capabilities include automatic contrast generation, covariate handling, and accurate identification of differentially expressed genes and enriched pathways. Validation studies demonstrate that PCA clustering, differential expression and pathway scores align with expected biology and match manual pipeline accuracy.This agentic approach reduces coding effort, improves reproducibility, and democratizes the accessibility of RNA-Seq analysis, with the possibility of expanding multi-omics analyses.

#0026 Multi-agent AI orchestration for temporal-aware extraction of social determinants of health from unstructured clinical records in cancer populations.

Asim Waqas[1], Aakash Gireesh Tripathi[2], Kris Bowles[1], Brianna Miner[1], Jessica Yasmine Islam[3], Anna E. Coghill[1], Anastasia Jones[4], Matthew B. Schabath[3], Ghulam Rasool[5]

[1]Cancer Epidemiology, Moffitt Cancer Center, Tampa, FL,[2]H. Lee Moffitt Cancer Center,[3]Moffitt Cancer Center, Tampa, FL,[4]Anesthesiology, Moffitt Cancer Center, Tampa, FL,[5]Machine Learning, Moffitt Cancer Center, Tampa, FL

Purpose: Social determinants of health (SDOH) influence cancer outcomes, yet extraction of these variables from unstructured clinical documents in electronic health records remains challenging due to their temporal complexity and narrative dispersion across multiple document types. Single large language models (LLMs) frequently hallucinate, misidentify temporal context, and cannot reliably distinguish between current barriers and historical mentions. We developed a multi-agent artificial intelligence (AI) orchestration framework that employs specialized agents with defined roles to extract temporally-aware SDOH variables for cancer research and clinical decision support.

Experimental Design: We implemented coordinated agents with different roles, focused on specific social determinant domains, directing task allocation, verifying extracted information, and assembling temporally-ordered patient timelines. We assembled two retrospective cohorts including cancer patients with HIV (n=100) and peri-operative pain management (n=524), encompassing 81k words/patient (≈8.1M words in 3,460 documents) and 49k words/patient (≈25.8M words in 15,484 documents), respectively. The framework processed clinical data, nursing communications, social work assessments, pathology reports, and imaging reports.

Results: We successfully extracted temporal SDOH variables with >95% confidence across both cohorts, constructing comprehensive patient timelines that distinguished between current and historical barriers. The multi-agent architecture addressed single-model limitations by cross-validating extractions, grounding findings in specific document evidence, and maintaining temporal accuracy. For HIV cohort, the system processed 10.8M model tokens, automatically identifying financial difficulties, transportation barriers, and housing instability with dates and supporting documentation. The peri-operative pain cohort required 34.3M tokens, revealing temporal patterns in social support availability and medication access challenges. Beyond SDOH variables, system automatically extracted complementary clinical information, including diagnoses and care transitions, enabling researchers to contextualize SDOH within broader clinical narratives.

Conclusions: We demonstrated that orchestrated multi-agent AI can reliably extract temporally-aware SDOH from real-world clinical documentation, addressing critical limitations of single LLM approaches. By providing structured, time-stamped extraction with evidence provenance, the framework enables practical clinical applications including patient triage for social work intervention, standardized disparities reporting, and research cohort characterization, making it suitable for deployment across diverse cancer populations.

#0027 An MCP-enabled AI agent for automated multimodal genomics analysis in the Isabl Platform.

Juan E. Arango Ossa[1], Dylan Domenico[2], Asher Preska Steinberg[1], Eliyahu Havasov[2], Gunes Gundem[2], Konstantinos Liosis[2], Alessandro Grande[1], Jesus Gutierrez-Abril[3], Elli Papaemmanuil[2], Sohrab Shah[2], Andrew William McPherson[2]

[1]Computational Oncology, Memorial Sloan Kettering Cancer Center, New York, NY,[2]Memorial Sloan Kettering Cancer Center, New York, NY,[3]Memorial Sloan Kettering Cancer Center, New York

Background:
Modern precision oncology pipelines generate petabyte-scale multimodal genomics data requiring coordinated access to databases, APIs, and reproducible workflows. The Isabl Platform (Medina et al., BMC Bioinformatics 2020) is broadly adopted across multiple groups at Memorial Sloan Kettering Cancer Center (MSKCC) and external research institutions. In the Halvorsen Center for Computational Oncology at MSKCC, the platform manages 470 projects, 105k sequencing experiments from 70k individuals, and 580k analyses totaling more than 4.5 PB of data. Although powerful, its depth and schema complexity create a learning curve for analysts, clinicians, and computational researchers. Large Language Models (LLMs) reduce this barrier by translating natural-language questions into actionable queries, retrieving documentation, and safely interacting with evolving scientific tools.
Methods:
We developed the Isabl AI agent and an Isabl MCP, enabling any MCP client to access Isabl tools through a standardized interface. The agent integrates Retrieval-Augmented Generation (RAG), which retrieves relevant documentation to ground outputs, with the Model Context Protocol (MCP), a common standard for tool discovery and safe execution in LLM-based applications. GitBook documentation, the OpenAPI schema, CLI references, laboratory pipeline definitions, and core Isabl modules are indexed into a multi-vector semantic store. A ReAct-style agentic controller selects MCP tools such as call_isabl_api or run_isabl_app, supported by recursive chunking and modern embeddings.
Results:
The agent handles analytical tasks such as:
• Cohort discovery, e.g.: “Identify pediatric B-ALL tumors with IKZF1 deletions and available RNA-seq.” It retrieves samples, summarizes counts, and reports assay availability.
• Multi-step reasoning, e.g.: “How many high-risk neuroblastomas have 17q gain?” It finds eligible cases, locates CNV analyses, extracts 17q21-17q25 copy-number values, applies thresholds, and reports frequencies.
• Workflow execution, e.g.: “Launch the whole-genome variant-calling pipelines for newly added pediatric sarcoma patients with matched germline controls.” It identifies tumor-normal pairs, checks existing analyses, and submits pipelines. These tasks show reduced onboarding time, intuitive schema navigation, and improved execution through natural language.
Conclusions:
Isabl AI Agent + MCP demonstrates how RAG, MCP’s standardized interface, and agentic reasoning simplify access to complex genomic systems. As MCP adoption grows in AI for scientific discovery, an Isabl MCP enables domain-specific capabilities to integrate into general-purpose AI models, providing a sustainable path for AI copilots that accelerate translational genomics research.

#0028 PortrAIgent: Co-scientist agent for end-to-end spatial transcriptomics discovery.

Yuchang Seong, Dongjoo Lee, Chanho Park, Hongyoon Choi

Portrai, Inc., Seoul, Korea, Republic of

Background
Spatial transcriptomics (ST) technology maps gene expression within tissue structures, offering unprecedented insights into tissue organization and cellular interactions. Analyzing these complex datasets, however, remains a significant bottleneck. Current workflows demand specialized, multi-domain expertise and rely on heavy manual intervention, an expertise barrier that hinders the rapid translation of data into biological insights.
Method
To address this challenge, we developed 'PortrAIgent,' a co-scientist AI agent that autonomously manages complex analysis workflows. The system operates by having (1) a multimodal LLM for reasoning, planning, and code generation; (2) a LangGraph-based workflow manager control the execution order of analysis steps; and (3) specialized computational tools, including a code execution environment and a real-time literature retrieval tool. A core feature of the agent is its Retrieval-Augmented Generation (RAG) system, which leverages codebases from scanpy, squidpy, and scvi-tools to integrate diverse informatics tools for specialized objectives like cell typing, spatial profiling, or data integration.
Results
Two workflows were successfully validated: 1) Hypothesis-Driven Exploration: When a user presents a biological hypothesis, the agent proposes alternative hypotheses, refines them via literature search, and then passes the plan to a ‘Reviewer Agent’. Following this validated plan, the agent proceeds to execution. 2) Analysis-Driven Workflow: For simple requests (e.g., "group comparison"), the agent's Planner checks the AnnData object's state to determine the optimal analysis functions before generating and executing the code. We demonstrated PortrAIgent by applying it to analyzing TME by ST data. Autonomous reasoning capability of this framework was validated by testing the system on multiple ST datasets with varying preprocessing states. The agent consistently detected missing steps (e.g., normalization, HVG selection, batch correction), revised its own plan, and regenerated the appropriate code without manual intervention. It interpreted the biological meaning of the discovered patterns using real-time literature search and generated a comprehensive research report summarizing the entire discovery process.
Conclusion
PortrAIgent offers a novel approach to automated scientific discovery in spatial biology for oncology. Beyond the primary case study, the system was tested across multiple tissue contexts, where it reliably adjusted analysis plans, corrected missing preprocessing steps, and generated coherent biological interpretations comparable to expert feedback. By integrating dynamic RAG-based code generation, autonomous execution, and comprehensive report generation, PortrAIgent streamlines complex spatial data analysis and lowers the expertise barrier for understanding complex biological systems.

#0029 Reasoning-guided retrieval improves oncology trial eligibility matching from clinical notes.

Vivek Shetye, **Patrycja Nikol Krawczuk**, Ryan Godart, Arpita Saha, Gabriel Altay, Chelsea Osterman, Gena Rangel, Samantha Garrett, Victoria L. Chiou, Kunal Nagpal

Tempus AI, Inc., Chicago, IL

Purpose: Under-enrollment in oncology trials is exacerbated by the manual effort required to screen unstructured clinical records against complex eligibility criteria. Large language models (LLMs) augmented with retrieval mechanisms show promise for automating the process but often fail to capture dispersed evidence required for complex, multi-criterion eligibility decisions. We hypothesized that an agentic retrieval strategy, which empowers an LLM to autonomously and iteratively search, synthesize, and validate relevant information, would enhance evidence completeness and accuracy in eligibility classification.

Methods: Evaluation encompassed two task types: (i) complex eligibility reasoning and (ii) biomarker extraction. The complex tasks drew on two non-small cell lung cancer (NSCLC) studies with intricate eligibility criteria: stage III unresectable NSCLC and metastatic NSCLC. Each query represented a patient-level eligibility assessment (total n=618 queries) that required integrating multiple evidence types, including molecular findings, prior therapies, and clinical status. The biomarker task included 148 evaluations targeting key genomic alterations (EGFR, ESR1, RAS).We compared a retrieval-augmented generation (RAG) system that retrieved fixed, similarity-based text chunks with an agentic retrieval approach performing up to 8 adaptive searches. The agent autonomously assessed retrieved evidence, reformulated its queries, and iteratively expanded the search scope to assemble a comprehensive context. Both systems, using LLM (Gemini 2.5 Pro), reviewed up to 64 text chunks per query. Model outputs were benchmarked against expert-curated ground truth using F1-score, recall, and accuracy.

Results: Agentic retrieval improved performance across complex eligibility reasoning tasks. In the stage III NSCLC, accuracy rose from 68% to 80% (+12.7 pp; 95% CI: 7.9-17.7), driven by a 15% gain in recall (69% to 84%) and a 9% increase in F1-score from 79% to 88%. In metastatic NSCLC, accuracy improved from 77% to 84% (+6.3 pp; 95% CI: 1.3-11.6) and the F1-score from 86% to 90%. In contrast, the biomarker extraction task showed comparable performance (accuracy 95-96%, F1 96%) for both methods, indicating minimal benefit from agentic reasoning where retrieval complexity was low.

Conclusions: This study demonstrates the translational value of agentic retrieval for precise, scalable oncology trial screening. By enabling adaptive evidence synthesis rather than static retrieval, the system improves the completeness of eligibility assessment and minimizes manual review effort.

#0030 Automated cohort extraction from real-world oncology data using adaptive LLM-based agentic systems for clinical trial feasibility and patient selection.

Brandon Theodorou[1], Thomas Schmitt[2], Zifeng Wang[1], Venugopal Thati[1], Angela Watkins[2], Kimberly Banks[2], Jimeng Sun[1], Amar Das[2]

[1]Keiji AI, Seattle, WA,[2]Guardant Health, Palo Alto, CA

Clinical feasibility analysis and cohort identification have essential applications in precision oncology, including feasibility assessment for clinical trial and other study designs, cohort extraction for digital twin modeling and virtual trial simulation, and real-world evidence generation for regulatory submission and comparative effectiveness research. However, real-world oncology datasets pose significant challenges due to heterogeneous, nonstandard data formats and complex, interconnected inclusion criteria. These technical barriers are compounded by functional hurdles like technical understanding, data access, and code execution. Traditional approaches rely on slow, unscalable manual query construction, and even recent state-of-the-art large language models (LLMs) struggle with multi-step reasoning and adaptation to diverse data structures.

To address these issues, we developed an adaptive LLM-based agentic platform that autonomously learns data structures, generates and executes code, and iteratively refines analyses to extract patient cohorts meeting complex criteria. Unlike conventional LLMs that generate static code without execution capabilities or dataset adaptation, our platform's agentic architecture dynamically explores data schemas, validates intermediate outputs, and self-corrects errors. It also accepts expert guidance and allows fully auditable, editable, and exportable outputs at each step of the process. The system accepts natural language queries specifying complex criteria such as specific diagnoses, genomic profiles, treatment histories, and temporal relationships, then autonomously navigates real-world data (RWD) of any shape, size, and format to identify qualifying patients.

We evaluated performance by replicating 15 historical feasibility analyses from the GuardantINFORM™ database, which integrates genomic and epigenomic RWD from >550K patients with de-identified administrative claims data across multiple oncology indications and data tables. Our validation study found that the platform successfully extracted exact cohorts for 12 requests and delivered clinically acceptable approximations for 2 more. The final analysis failed due to a clinical misunderstanding but was correctable post hoc with improved guidance. In contrast, state-of-the-art LLMs without tuned agentic capabilities failed to adapt to dataset-specific structures and had low task completion rates, highlighting the critical importance of the task-based design, iterative execution, and self-correction. This performance democratizes access to sophisticated data analysis, addressing a critical bottleneck in translating RWD into actionable clinical insights and establishing a foundation for autonomous, adaptive AI systems that can accelerate oncology research.

#0031 Charles: A self-critical agentic AI drug discovery analyst for cancer.

Seyedmehdi Orouji, Ying Zhu, David Maxwell, Kaitlyn Russell, Bissan Al-Lazikani

UT MD Anderson Cancer Center, Houston, TX

Background: Agentic AI will be members of scientific teams of the future. AI hallucinations and unreliable and untraceable public data cast shadows on such a role. We developed what is to our knowledge the first self-critical, self-correcting agentic-AI drug discovery analyst: Charles. It supports information synthesis and hypothesis generation for cancer drug discovery while maintaining scientific robustness.

Methods: Charles is an agentic GPT-based LLM. Building Charles consisted of fact-constrained, imitation-based teaching exercise led by the human PI. A human supervisor carefully optimized the environment to constrain Charles to reliable sources and prevent retrieving external knowledge. An adversarial AI agent acts as the self-critical 'conscience' to test the veracity of Charles's answers against the true data. We further evaluated this by injecting decoy raw data, allowing quantitative evaluation of the models' veracity. The trained model was used to synthesize factual target summaries. We then developed a multi-agent LLM that leverages these data-grounded summaries to answer real-word drug discovery questions. A planner agent digests the user's questions and orchestrates a coordinated plan of action to direct the specialist agents (bio-/chemo-/systems etc). Finally, a critical AI agent fact-checks the responses from specialist agents, reporting them to the planner agent for further refinement of actions. Together, these modules form Charles.

Results: We demonstrate that Charles' responses are strictly grounded in the curated data. Initial evaluations show Charles reproduces all adversarial decoys indicating no outside leakage. To further evaluate the reasoning and factual accuracy of Charles, we utilized a question-answer dataset that Charles answers through interpretation of the >1000 protein summaries. Using the self-critical agent, we evaluated both the summaries and the answers to questions. The initial evaluation of the multi-agent framework shows 99% accuracy in Charles's responses. The planner successfully recruited the appropriate specialized agents while the critical agent showed promising behavior in detecting semantic and factual inconsistencies to the planner. The output summaries are publicly available via canSAR.ai.

Conclusions: Charles represents a self-critical, drug discovery-trained, AI analyst capable of synthesizing multimodal information, evaluating its own outputs, and refining the next steps based on that. By combining the reasoning power of LLM-based interactions with the assurance of verified curated data, Charles provides reliable access to complex oncological knowledge while minimizing hallucinations and enabling researchers to make data-driven decisions with more confidence in cancer research.

#0032 Agentic AI-enabled exploration of real-world immune-related adverse events.

Gabriela Fort[1], David Stone[1], Ching-Nung Lin[1], Arabella Young[2], Aik Choon Tan[1]

[1]Department of Oncological Sciences, University of Utah, Salt Lake City, UT,[2]Department of Pathology, University of Utah, Salt Lake City, UT

Immune checkpoint inhibitors (ICIs) have transformed cancer therapy, but their clinical benefit is often limited by the onset of immune-related adverse events (irAEs), which can be severe and lead to treatment interruption or discontinuation. A deeper understanding of irAEs is urgently needed to identify patients at highest risk of developing adverse events and to guide strategies for irAE prevention and risk management. The FDA's Adverse Event Reporting System (FAERS) database contains over 32 million adverse event reports submitted to the FDA to support drug safety surveillance. However, although a public dashboard exists to perform basic exploration of FAERS data, extracting immuno-oncology-related safety events or executing complex, multiparameter queries of this data still requires substantial technical expertise, programming skills, and a familiarity with the underlying database structure. To address this gap and to enhance the accessibility of this public resource, we downloaded all FAERS reports from 2012-2025 and systematically filtered for cancer cases treated with ICIs. We curated a high-quality, oncology-specific irAE dataset and generated a standardized flat-file resource for downstream data exploration and analysis. To further facilitate access and enable non-programmers to easily explore these data, we developed an agentic AI-driven interface and workflow that allows natural language querying of the dataset. Our system uses open-source large language models with specialized prompting to classify user intent and generate executable python code for complex analytical tasks including filtering, visualization, and statistical analyses, returning results in real time. This framework enables interactive and flexible exploration of irAE patterns across tumor types, drug classes, and other clinical features. Preliminary analyses recapitulate known irAE associations in cancer (e.g. elevated endocrine and cutaneous toxicities compared to other irAEs in anti-PD-1-treated patients) and reveal potential tumor and treatment-specific irAE profiles that warrant further investigation. In summary, this platform provides a transparent, scalable, and user-friendly approach for mining real-world immunotherapy safety data that may be leveraged to inform biomarker discovery, fuel hypothesis generation, and/or guide irAE risk mitigation strategies in immuno-oncology.

#0033 A healthcare system scale multimodal whole patient temporal foundation model.

Andrew Zhang[1], Tong Ding[1], Sophia J. Wagner[1], Caiwei Tian[1], Ming Yang Lu[1], Alexandre Misrahi[1], Joshua E. Lewis[1], Rowland Pettit[1], Long P. Le[2], Faisal Mahmood[1]

[1]Harvard Medical School/Brigham and Women's Hospital, Boston, MA,[2]Pathology, Harvard Medical School/Massachusetts General Hospital, Boston, MA

Healthcare data are fragmented across time and modalities, including clinical reports, imaging, and lab tests. While Electronic Health Records (EHRs) capture rich longitudinal health trajectories, current predictive modeling approaches typically model individual modalities in isolation, missing the context needed to understand complex diseases such as cancers. To bridge this gap, we aim to synthesize the entirety of a patient's medical history into a unified computable representation.

We curated a retrospective cohort from a major U.S. healthcare system, comprising 25 billion medical events from 7.2 million patients spanning 33 years. This dataset integrates 28 distinct clinical modalities, including structured data (diagnoses, medications, vital signs, flowsheet, and laboratory results), clinical notes, and imaging data. We developed a transformer-based multimodal temporal foundation model that tokenizes each modality with modality-specific encoders and fuses events over time into a unified patient embedding.

We evaluated frozen patient embeddings on 246 downstream prediction tasks, including new onset of 87 diseases, progression of 56 diseases, treatment response for 100 therapy-outcome pairs, and three short-term operational tasks. Across all tasks, the model achieved a mean AUROC of 0.77, outperforming age-sex, clinical text, and task-specific supervised baselines. On oncology-focused tasks spanning solid and hematologic malignancies and systemic therapies, the model outperformed the age-sex baseline by 9% for new neoplasm onset, 18% for neoplasm progression, and 16% for treatment response. Unsupervised clustering of patient embeddings recovered clinically coherent groupings of cancer types, comorbidities, and treatment patterns, forming a multiscale, data-driven atlas of medical phenotypes. The same embeddings enabled similarity search to identify patients with comparable trajectories, supporting automated cohort discovery and fine-grained clinical trial matching. Gradient-based interpretability analyses identified multimodal risk factors for disease onset and treatment response that aligned with clinical expectations, providing transparent attribution at both patient and population level.

A single multimodal, temporally aware EHR foundation model can learn general-purpose whole-patient representations that support accurate early prediction and phenotyping of cancer outcomes while remaining applicable across diverse diseases. By consolidating fragmented data into a continuously updated patient representation, this approach lays the groundwork for shifting oncology from reactive, episodic care to proactive, continuous risk management, and provides a scalable basis for risk stratification, trial optimization, and discovery of clinically interpretable multimodal biomarkers.

#0034 Attitudes and perception of artificial intelligence in healthcare: A cross-sectional survey among Arkansas-Louisiana-Texas (ArkLATX) veterans with cancer.

Philip A. Haddad[1], Sireesha Vutukuri[2], Philip Bouchette[2], Crystal Barmer[2], Ankita Gupta[2]

[1]LSUHSC-S/Overton Brooks VAMC, Shreveport, LA,[2]Overton Brooks VAMC, Shreveport, LA

Background: The attitudes about the use of Artificial Intelligence (AI) in healthcare are controversial. Unlike the perception of healthcare professionals, the attitudes of cancer patients, especially veterans, have hardly been explored. In this quality improvement study, we aimed at investigating veterans' perception of AI within the VA among this highly relevant group, along with digital affinity and sociodemographic factors.

Methods: We conducted a cross-sectional survey using a questionnaire-based interview with patients at Overton Brooks VA Medical Center Hematology-Oncology Clinics from December 2024 to February 2025. The questionnaire consisted of sections exploring demographics, participants' technical affinity, and their perception of the utility of AI in healthcare, the providers' AI competence, their concerns, and the need for oversight.

Results: A total of 250 participants were accrued with a median age of 72. Ninety-one percent were men, with 52% finishing high school and 44% feeling comfortable using technology. More than 78% read or heard about artificial intelligence, but only 8% reported knowing a lot. Asked about their general perception of AI utility in healthcare, 55% of the respondents rated the use of artificial intelligence as positive or very positive, 48% agreed to its incorporation in their own medical care, but only 11% held a negative or very negative perception. Forty percent of veterans expressed concerns about potential AI safety and security issues. Forty-five percent thought the providers knew enough about AI to use it properly. Ninety-five percent wanted artificial intelligence to be rigorously tested and deployed with a physician in the loop. Unlike age, sex, and educational level, only certain aspects of technical affinity statistically impacted the perception of AI healthcare utility, concerns, and AI oversight.

Conclusions: ArkLATX veterans with cancer are mostly open to the use of AI in healthcare. Although showing little to no knowledge about AI, a majority had a positive perception of its utility in healthcare. Nevertheless, veterans insist that a physician supervises AI and assumes ultimate responsibility for diagnosis and therapeutics.

#0035 Humans cannot live by artificial intelligence (AI) alone.

Kim Blenman, Ondrej Blaha, Sherry Qiu, Kelly Chen, Kiera Spall, Yiran Liu, Madsion Williams, Marissa Villa, Valeri Vankov, Kwabena Oteng Agyapong, Di Li, Holly Rushmeier

Yale University, New Haven, CT

INTRODUCTION: Differential expression (DE) analysis is the cornerstone of omics evaluation. It is used to identify biomarkers for cancer, therapeutic response, and drug-induced adverse events. DE methods use AI/ML (machine learning). If multiple DE methods could identify the same biomarkers, this would strongly support the biomarker's use as a robust candidate(s) for wet lab validation studies. It is unclear if the top DE methods identify the same biomarkers (i.e., shared). Therefore, we evaluated 4 DE methods for their ability to identify shared serum autoantibodies in cancer patients with and without immune-checkpoint inhibitor induced hypothyroidism (TEAE ThyDis).
METHODS: Patients with breast cancer (N=8) or melanoma (N=25) who were treated with durvalumab, ipilimumab, pembrolizumab, nivolumab, or combination who had TEAE ThyDis (N = 18) or No TEAE (N = 15) were included. Four DE methods (limma, DESeq2, edgeR, randomForest) were used in R. 15,500 pre-treatment autoantibodies with and without ComBat batch correction were evaluated for each patient.
RESULTS: In patients with breast cancer, limma, DESeq2, edgeR, and randomForest identified 201, 109, 158, and 472 biomarkers, respectively (Table 1). However, only up to 53 biomarkers were shared between the 4 DE methods. ComBat batch correction with limma or randomForest led to identification of 125 and 484 biomarkers respectively and up to 114 shared biomarkers between the 4 methods. In patients with melanoma, limma, DESeq2, edgeR, and randomForest identified 198, 244, 568, and 1042 biomarkers respectively with up to 183 biomarkers shared (Table 1). ComBat batch correction with limma or randomForest led to identification of 196 and 1088 biomarkers respectively and up to 257 shared. There was no biomarker that was shared in all methods.
CONCLUSIONS: Our data suggests that top AI/ML DE analysis methods identify different biomarkers. As a field, it is time to re-evaluate and re-vamp these tools as well as create new tools to ensure robust reproducible biomarker identifications.

#0510 Early metabolic and differentiation remodeling in *BRCA1/2* high-risk fallopian tube epithelium revealed by single-cell multi-omics.

Quentin Chartreux[1], Marcela Haro[1], Josh Brand[2], Andrew Li[3], Bobbie J. Rimel[4], Patrick Sung[5], Simon Gayther[1], Huy Dinh[2], Fabiola Medeiros[3], Kate Lawrenson[1]

[1]Center for Inherited Oncogenesis, University of Texas at San Antonio, San Antonio, TX,[2]School of Medicine and Public Health, University of Wisconsin-Madison, Madison, WI,[3]Cedars-Sinai Medical Center, Los Angeles, CA,[4]University of Washington, Seattle, WA,[5]Department of Biochemistry and Structural Biology, University of Texas at San Antonio, San Antonio, TX

Germline mutations in *BRCA1* and *BRCA2* greatly increase the risk of developing high-grade serous carcinoma (HGSC), yet the earliest molecular events driving malignant transformation in the fallopian tube epithelium, the likely site of origin, remain poorly understood. Defining these early alterations is essential for improving risk prediction and informing preventive strategies for *BRCA*-associated ovarian cancer.To investigate the initial cellular and molecular perturbations in high-risk individuals, we performed single-cell transcriptomic and multi-omic profiling on fallopian tube fimbrial samples obtained through exfoliative cytology brushings and conventional tissue specimens. Single-cell RNA sequencing was conducted on 14 brushings from BRCA1/2 mutation carriers, 3 brushings from average-risk individuals, and 12 tissue samples from average-risk controls. In parallel, single-cell multi-omic analysis was applied to short-term epithelial cultures derived from 4 high-risk and 2 average-risk individuals, enabling an integrated assessment of transcriptional states, chromatin accessibility, and gene regulatory programs.Brushings were enriched for epithelial and immune populations, facilitating high-resolution characterization of epithelial differentiation. Cells from *BRCA1/2* mutation carriers exhibited disrupted secretory-ciliated differentiation trajectories, accompanied by upregulation of mitochondrial respiration and oxidative phosphorylation genes, suggesting early mitochondrial and metabolic remodeling in high-risk epithelia. Multi-omic integration further identified a distinct epithelial cluster enriched in *BRCA1/2* carriers characterized by increased *RUNX3* transcription factor activity. Although these cells remain transcriptionally aligned with secretory epithelium, *RUNX3*-associated programs indicate a partial or intermediate differentiation state—potentially reflecting early lineage instability preceding malignant transformation. Subtle alterations in immune-related pathways were also observed, pointing to microenvironmental changes that may support a permissive niche for tumor initiation.Together, these data reveal early transcriptomic, metabolic, and gene-regulatory remodeling in the fallopian tube epithelium of *BRCA* mutation carriers. By defining epithelial states and pathways perturbed prior to neoplasia, this work provides new mechanistic insight into hereditary ovarian cancer predisposition and highlights potential biomarkers for early detection and prevention.

#0512 Wild-type IDH1 inhibition induces homologous recombination deficiency and enhances PARP inhibitor sensitivity in pancreatic cancer.

Mehrdad Zarei[1], Priyashree Sunita[2], Alexander Loftus[3], Faith Nakazzi[4], Semmer Ali[4], Om Prajapati[5], Soubhi Tahhan[6], Hallie J Graor[2], Shakti Prasad Pattanayak[2], Sami Abul-Khoudoud[7], Luke D. Rothermel[8], Rui Wang[4], Jonathan R. Brody[9], Jordan M. Winter[3]

[1]Surgery, Case Comprehensive Cancer Center, Cleveland, OH,[2]Case Western Reserve University School of Medicine, Cleveland, OH,[3]UH Cleveland Medical Center, Cleveland, OH,[4]Case Western Reserve University, Cleveland, OH,[5]Case Comprehensive Cancer Center, Cleveland, OH,[6]Tulane University, New Orleans, LA,[7]Surgery, University Hospitals, Cleveland, OH,[8]University Hospitals, Cleveland, OH,[9]Knight Cancer Institute, Oregon Health & Science University, Portland, OR

Objective: Pancreatic ductal adenocarcinoma (PDAC) remains one of the deadliest malignancies with limited therapeutic options. While PARP inhibitors benefit tumors with homologous recombination deficiency (HRD), fewer than 10-20% of PDAC cases harbor such mutations. The majority are homologous recombination proficient (HRP), representing a significant unmet need. Here, we identify wild-type isocitrate dehydrogenase 1 (wtIDH1) as a critical regulator of HR repair in HRP PDAC and propose a novel combinatorial strategy using IDH1 and PARP inhibition to induce synthetic lethality.

Methods: We assessed the role of wtIDH1 in DNA repair using HR and non-homologous end joining (NHEJ) reporter assays, Western blotting, and chromatin modification analyses. Effects of IDH1 inhibition (ivosidenib) and PARP inhibition (olaparib), alone and combined, were evaluated in vitro through cell viability, apoptosis, and DNA damage assays. In vivo efficacy was tested in xenograft and orthotopic PDAC mouse models, including survival studies. Additionally, tumor biopsies from patients in the ongoing phase Ib clinical trial (**NCT05209074**) receiving ivosidenib were analyzed for HR pathway activity and chromatin alterations.

Results: Pharmacologic wtIDH1 inhibition depleted α-ketoglutarate and induced histone hypermethylation, impairing HR repair and mimicking a BRCA-like phenotype in HRP PDAC cell lines (MiaPaCa-2, Panc-1). The combination of IDH1 and PARP inhibitors synergistically increased γ-H2AX accumulation and apoptosis, reducing cell viability. In vivo, dual therapy significantly suppressed tumor growth and extended survival compared to monotherapies. Importantly, tumor samples from **NCT05209074** patients treated with ivosidenib exhibited decreased expression of HR repair proteins and epigenetic changes consistent with a BRCAness phenotype, supporting translational relevance.

Conclusion: Our findings reveal a novel role for wtIDH1 in maintaining homologous recombination in PDAC. Inhibition of wtIDH1 functionally induces HR deficiency in HRP tumors, sensitizing them to PARP inhibition. This combination represents a promising therapeutic approach for the majority of PDAC patients lacking canonical HR mutations and warrants further translational development.

#0513 AZD5305, a PARP1 selective inhibitor, exhibits antitumor effects and stimulates immune response in homologous recombination (HR)-deficient gastric cancer cells.

Sujin Ham[1], Hae Min Hwang[1], Youlim Noh[1], Jiwon Koh[2], Chaeyoung Lee[1], Seohyeon Lim[1], Minyoung Jeong[1], Yu-Jin Kim[3], Minyoung Lee[4], Changhee Park[5], Dae-Won Lee[5], Kyung-Hun Lee[5], Seock-Ah Im[5]

[1]Cancer Biology, Graduate School of Interdisciplinary Graduate Program & Cancer Research Institute, Seoul National University, Seoul, Korea, Republic of,[2]Department of Pathology & Cancer Research Institute, Seoul National University Hospital & Seoul National University, Seoul, Korea, Republic of,[3]Cancer Research Institute, Seoul National University, Seoul, Korea, Republic of,[4]Cancer Biology, Graduate School of Interdisciplinary Graduate Program, Seoul National University, Seoul, Korea, Republic of,[5]Department of Internal Medicine & Cancer Research Institute, Seoul National University Hospital & Seoul National University, Seoul, Korea, Republic of

Background : Poly (ADP-ribose) polymerase (PARP) 1, a multifunctional protein, is widely recognized for its critical role in the HR-mediated DNA repair, and its inhibition has therefore been introduced into the treatment of various solid tumors. Besides DNA damage response (DDR), PARP1 has also emerged as a key regulator of immune modulation. This is attributed to the accumulation of cytosolic nucleic acids (NAs), such as dsDNA or dsRNA, which are sensed by innate immune pathways like cGAS-STING. However, the precise mechanisms by which PARP1 inhibition induces these cytosolic NAs and activates innate immune response remain to be elucidated. Thus, we investigated the anti-tumor and immune modulatory effects of AZD5305 in gastric cancer cells to explore the underlying mechanism.

Methods : To evaluate the *in vitro* antitumor effect, colony formation assay (CFA) was performed for 14 days with increasing concentrations of AZD5305 (dose range: 0-5nM). The *in vivo* antitumor activity was assessed using an SNU-601 xenograft model by monitoring tumor growth. Cell cycle distribution was analyzed by flow cytometry and apoptosis was assessed by annexin-V/PI staining. DNA damage was detected by comet assay and the cell immunofluorescence assay (IFA). To investigate immune modulation, the expression of immune-related molecules was quantified by qRT-PCR and western blot, while the formation of dsRNA was detected by cell IFA. RNAseq was performed using the cell lines for differentially expressed gene and gene set enrichment analyses.

Results : The RAD51C-deficient SNU-601 cells were highly sensitive to AZD5305 (IC_{50}: 0.25 nM), unlike the moderately sensitive SNU-668 (IC_{50}: 2.05 nM) or resistant KATOIII cells (IC_{50}>5 nM). Moreover, AZD5305 demonstrated potent antitumor activity in an SNU-601 xenograft model (52.4% TGI, p=0.003). After treatment, SNU-601 cells exhibited G2/M arrest and apoptosis, confirmed by an increased sub-G1 population, positive annexin-V staining, and cleavage of PARP and caspase-7, but not in KATOIII. This cytotoxicity was driven by the accumulation of DNA damage, as indicated by elevated p-RPA, γH2AX, and comet tail formation. Furthermore, AZD5305 increased cytosolic dsRNA and cGAS-STING signaling in SNU-601, triggering the innate immune response. Consistent with this, RNAseq confirmed enrichments of activated IFN-γ response pathways and corresponding increases in the expression of interferon-stimulated genes (ISGs) in SNU-601, but not in KATOIII.

Conclusion : AZD5305 exhibits potent cytotoxic effects in HR-deficient gastric cancer cell lines *in vitro* and *in vivo*, by inducing DNA damage and apoptotic cell death. Immune modulation by AZD5305 was characterized by innate immune activation with increased interferon signaling, and our findings suggest the formation of cytosolic dsRNA as a key mediator of this effect.

#0514 Potentiation ofPARP inhibitor activity in*BRCA*-wildtype breast cancer cell lines by 2-hydroxyflavanone.

Harshit Khosla[1], Sharda P. Singh[2], Chhanda Bose[2], Sharad S. Singhal[3], Sanjay Awasthi[4]

[1]UT Health Houston, Houston, TX,[2]Texas Tech University Health Sciences Center, Lubbock, TX,[3]Beckman Research Institute of The City of Hope, Duarte, CA,[4]Professor, Oncology & Diabetes, Texas Tech University Health Sciences Center, Lubbock, TX

Background: 2-hydroxyflavanone (2HF) is citrus derived compound which has demonstrated in vitro anticancer activity against multiple malignancies. Its presence inhibits RLIP, a protein encoded by RALBP1 gene which functions as an ATP dependent efflux pump for glutathione-electrophile conjugates, oxidative and alkylating intermediates and, mediates epidermal growth factor receptor endocytosis. Thus RLIP promotes oncogenesis with growth modulation and ability to resist chemotherapy with glutathione mediated xenobiotic efflux. Reduced RLIP expression by 2HF reduces spontaneous carcinogenesis in p53 null mouse models, indicating its utility in tumors with DNA repair-deficiency. BRCA1, BRCA2, and PALB2 are the pivotal genes involved in homologous recombination (HR) mutation which can be targeted by poly(ADP-ribose) polymerase pathway (PARP) inhibitors. Through this study we assessed the effects of PARP inhibitor AZD2461 alone and in combination with 2HF on cell viability of MDA-MB-231 and MCF-7 breast cancer cell lines.

Methods: Expression of mRNA of BRCA1, BRCA2 and PALB2 genes was assessed in MDA-MB-231 (triple negative) and MCF-7 (ER+) breast cancer cell lines after exposure to 2HF and LNA by using quantification cycle in Polymerase chain reaction. LDH release at 72 hours was measured and compared with controls in cells treated with 2HF or AZD2461 alone or in combination. Cytotoxicity was measured using absorbance of reduced WST-8 produced by the viable cells.

Results: RLIP depletion by 2HF reduced the expression of mRNA of HR genes BRCA1, BRCA2, and PALB2 to 2% - 20% of the level of untreated controls. PARP inhibitor induced LDH release with incremental dose of 2HF at 10, 20 and 40 µM, with greatest cytotoxic effects at 40 µM 2HF ($p < 0.001$). Addition of 2HF to PARP inhibitor AZD2461 increased cell lysis in MCF-7 and MDA-MB-231 cells, however only diminished cell viability in MCF-7 but not in MDA-MB-231.

Discussion: PARP inhibitors are very effective in tumors with HRD mutation, however their utility is limited in subjects with mutations involving non HRD pathways. RALBP1 inhibition with 2HF decreases the expression of gene involved in HR pathway thus stimulating a transcriptomic environment that is similar to HRD mutated cells. 2HF could thus sensitize BRCA-wildtype ER+ and possibly triple negative breast cancers to PARP inhibitors. This potentially has clinical application among patients who may benefit from PARP inhibitors outside of current indications such as BRCA or HRD deficient mutations. Through this work, we look forward to inspire more work on clinical exploration of 2HF with PARP inhibitors.

#0515 Substrate selectivity and RPA-mediated regulation of Topoisomerase3-Rmi1 decatenation.

Minyong Kim, Quan Wang, Hengyao Niu

Biochemistry, Indiana University, Bloomington, IN

Mutations in the RecQ helicase BLM, which cause the cancer-prone disorder Bloom syndrome, lead to a high frequency of sister chromatid exchanges (SCEs). This phenotype is attributed to defects in processing double Holliday Junctions (dHJs) formed during homologous recombination. The BLM-Topo IIIα-RMI1/2 complex (Sgs1-Top3-Rmi1 [STR] in *S. cerevisiae*) is critical for resolving dHJs into non-crossover products, thereby suppressing SCEs. This dissolution requires the Sgs1 helicase to drive convergent junction migration, creating a hemicatenane that is decatenated by the Topoisomerase III (Top3)-Rmi1 subcomplex in the model organism, *S. cerevisiae*.However, the precise molecular mechanism of this final strand passage is poorly understood. One of the key ambiguities is the role of Replication Protein A (RPA), the universal ssDNA-binding protein. Previous studies have shown contradictory findings, with some reporting that RPA *inhibits* TopoIIIα decatenation, while others—using different methodologies—suggest it *promotes* the reaction. Furthermore, the specific substrate requirements of Top3-Rmi1, such as sequence or polarity preference, remain uncharacterized.To elucidate the role of RPA and define the substrate requirements for Top3-Rmi1, we devised *in vitro* decatenation assay using a single-strand catenane substrate. This system allowed us to make two key discoveries: First, we reveal that Top3-Rmi1 activity has selectivity for both the sequence and polarity of the DNA substrate. Second, we propose that RPA plays a sophisticated regulatory role, acting to guide the strand passage activity of Top3. This model suggests RPA ensures that Top3 cleaves DNA only when the substrate is properly configured for productive strand passage and resealing.Furthermore, we used a key tool, Top3-W77A, a mutant we identified that exhibits an ~10-fold lower DNA binding affinity. We found that this mutant's decatenation activity is significantly diminished in the presence of RPA, suggesting its weakened DNA affinity makes its substrate more difficult to access when the DNA is coated by RPA. We used this mutant as an *in vivo* probe to determine the physiological involvement of RPA in two key STR-dependent pathways: double Holliday junction dissolution and replication fork template switching. Specifically, we are probing its function in defined genetic backgrounds: a rad18 deletion to assess its role in replication template switching, and an sgs1 deletion to determine the relative contributions of Sgs1.

#0516 Integrated genomic and transcriptional profiling of patient-derived ovarian cancers reveals HRD-associated features and *in vivo* response to PARP inhibition.

Kyle C. Strickland[1], Sheri Barnes[2], Zachary D. Wallen[1], Michelle F. Green[1], Laine V. Morris[1], Paul DePietro[1], Kobina A. Amoah[1], Jennifer B. Jackson[1], Pratheesh Sathyan[3], Taylor J. [1]Labcorp, Durham, NC,[2]Labcorp, Ann Arbor, MI,[3]Illumina Inc., San Diego, CA,[4]Labcorp, Burlington, NC

Introduction

Homologous recombination deficiency (HRD) and BRCA1/2 alterations are key biomarkers for PARP inhibitor sensitivity in ovarian cancer. Transcriptional features such as RB1 expression may further refine biologic subgroups and therapeutic hypotheses. We performed integrated DNA/RNA profiling of FFPE ovarian tumors to characterize histologic distribution, genomic alterations, genomic instability score (GIS), RB1 expression, and in vivo olaparib response in selected HRD-positive models.

Methods

Thirty-two patient-derived FFPE ovarian tumor blocks were prepared, and H&E sections were reviewed by an anatomic pathologist (SR) to confirm sufficient tumor content prior to next-generation sequencing. Comprehensive genomic, immune profiling, and HRD assessment were performed. RNA-seq quantified RB1 expression, with “RB1-low” defined as TPM ≤ 6.26 (study 25th percentile). Two HRD-positive models were subjected to in vivo testing of olaparib response in female NSG mice following subcutaneous implantation.

Results

The cohort consisted predominantly of serous adenocarcinomas (71.9%), followed by ovarian adenocarcinoma NOS (21.9%), mucinous adenocarcinoma (3.1%), and carcinosarcoma (3.1%). TP53 mutations were present in 93.8% of cases. BRCA1 alterations were identified in 37.5% of tumors and BRCA2 alterations in 25.0%. HRD status was positive in 34.4% of cases, negative in 43.8%, and indeterminate in 21.9%. GIS scores varied across HRD categories, with HRD-positive tumors showing a range of 12-61 (median 29, mean 32.9), HRD-negative tumors ranging from 3-41 (median 11.5, mean 17.2), and indeterminate tumors ranging from 7-32 (median 19, mean 18.1). RB1-low expression was observed in 21.9% of tumors overall, with enrichment in HRD-positive cases (45.5%) compared to HRD-negative (7.1%) and indeterminate (14.3%) groups. To assess translatability of HRD findings, two HRD-positive serous adenocarcinomas were tested for olaparib response in vivo. One BRCA2-mutated tumor (LCOV-2089, GIS=32) demonstrated a robust therapeutic effect, with a median tumor volume reduction of 68.1% and durable complete responses in 33.3% of treated mice. In contrast, a second BRCA2-mutated tumor (LCOV-2118, GIS=17) did not exhibit tumor regression but showed an increased time to progression of >85% compared to untreated controls.

Conclusions

Overall, these findings suggest a meaningful correlation between genomic HRD status and in vivo therapeutic response, supporting the translational relevance of integrated profiling and the use of patient-derived models for preclinical investigations.

#0517 Comprehensive & precise structural variant detection with a single assay.

J. Zachary Sanborn, James Durbin, Mital Bhakta, Lisa Munding

Cantata Bio, LLC, Scotts Valley, CA

Structural variants (SVs) are increasingly recognized as key drivers of tumorigenesis, yet current technologies struggle to detect and accurately characterize them due to resolution limitations and sequencing constraints. As a result, attempts to produce complete somatic SV truth sets often suffer due to the gaps in detection performance of the sequencing technology utilized, impacting the truth sets' usefulness for benchmarking alternative technologies and/or SV callers. To this end, the National Institute of Standards & Technology (NIST) performed a deep benchmarking experiment for somatic SV detection, fully characterizing the structural changes of a pancreatic ductal carcinoma (PDAC, labeled HG008T) across 16 whole genome sequencing technologies and analyzing with multiple datatype-specific SV callers. NIST has published its Benchmark SV callset that is the result of integrating and manually curating calls from all analytes. With this benchmarking data, we tested the capability of Dovetail's LinkPrep chemistry alone to reproduce the NIST Benchmark callset using both open source and proprietary SV callers.

Dovetail LinkPrep libraries were generated for the HG008T cell line sample and sequenced to approximately 55x genomic coverage. Sequencing data was aligned to hg38 with bwa and SV calls generated by running a standard, HiC-based SV caller, HiC-Breakfinder, and Dovetail Precise (DP), a new SV caller developed by Dovetail Genomics. These callsets were separately compared to the NIST Benchmark callset to assess their performance in categories based on SV type and size.

Of the 109 total SVs in the NIST Benchmark callset, HiC-Breakfinder and DP detected 19 (18%) and 97 (92%) SVs, respectively. HiC-Breakfinder's ability to detect SVs was limited to translocations (8 of 12, 67%) and large intra-chromosomal SVs greater than 2 Mb in size (10 of 11, 91%), while unable to find any intra-chromosomal SV smaller than 2 Mb. In contrast, DP detected all translocations (12 of 12, 100%), the same number of large intra-chromosomal SVs (10 of 11, 91%), and the majority of smaller intra-chromosomal SVs (75 of 85, 88%) down to 47 bp in size. Furthermore, the difference in breakend locations between HiC-Breakfinder and the NIST Benchmark SVs ranged from 1,636 bp to 189 kb, while over 96% of DP calls (94 of 97) achieved base-level precision.

Dovetail's LinkPrep chemistry with the Dovetail Precise (DP) caller detected 92% of somatic structural variants (SVs) in the NIST Benchmark callset, including small variants down to 47 bp, strongly outperforming HiC-Breakfinder across all SV types and sizes. This high-resolution SV detection enables more comprehensive cancer genome characterization from a single assay and supports more accurate diagnostics and targeted therapy development.

#0518 Caspase-4 deficiency impairs nuclear actin-mediated DNA double-strand break repair and increases radiosensitivity in cancer cells.

Shohei Nagasaka[1], Tomomitsu Doi[2], Kunie Obayashi[3], Masaoki Kohzaki[4], Kazuhiro Sumida[3], Yosuke Chiba[3], Junkoh Yamamoto[5], Motoyoshi Endo[3]

[1]Neurosurgery and Molecular Biology, University of Occupational and Environmental Health, Kitakyushu, Japan,[2]Molecular Biology and Cellular Biology, University of Occupational and Environmental Health, Kitakyushu, Japan,[3]Molecular Biology, University of Occupational and Environmental Health, Kitakyushu, Japan,[4]Radiobiology and Hygiene Management, Institute of Industrial Ecological Sciences, University of Occupational and Environmental Health, Kitakyushu, Japan,[5]Neurosurgery, University of Occupational and Environmental Health, Kitakyushu, Japan

Background: Radiotherapy induces cytotoxicity primarily through DNA double-strand breaks (DSBs), and the efficiency of DSB repair is a key determinant of tumor radiosensitivity. Caspase-4 (CASP4), frequently overexpressed in human malignancies, has been implicated in actin cytoskeletal remodeling; however, its involvement in nuclear actin dynamics and DNA repair remains unclear.
Methods: We investigated the functional role of CASP4 in radioresponse using CASP4 knockout (KO) HepG2 and NCI-H292 cells. Colony formation assays, 53BP1 foci analysis, and a newly developed measurement system that enables the quantification of nuclear actin levels were used to assess DNA repair efficiency and actin distribution. Forced nuclear actin expression was used to evaluate its ability to rescue CASP4-dependent defects.
Results: CASP4 KO significantly sensitized tumor cells to ionizing radiation, associated with decreased colony formation and persistent 53BP1 foci, indicative of impaired DSB resolution. Although CASP4-deficient cells exhibited elevated cytoplasmic F-actin, nuclear actin translocation was reduced despite comparable total actin levels, suggesting defective actin shuttling. Quantitative imaging confirmed substantially diminished nuclear actin signals in CASP4 KO cells. Notably, enforced nuclear actin expression restored 53BP1 foci resolution in CASP4-deficient cells.
Conclusions: These findings identify a previously unrecognized role of CASP4 in promoting DNA DSB repair through regulation of nuclear actin dynamics. CASP4 facilitates the balance between cytoplasmic and nuclear actin to maintain efficient DNA repair and enhance radioresistance. Targeting CASP4 may therefore represent a promising strategy to overcome tumor resistance to ionizing radiation.

#0519 Decoding oncogene amplification structures from retinoblastoma aqueous humor cfDNA as a model for chromothripsis and ecDNA biology.

Yilin Chen, Liya Xu

Vision Center, Children's Hospital Los Angeles, Los Angeles, CA

Purpose: Complex oncogene amplifications—including MDM4 1q gains and MYCN high-level amplification—frequently arise through mechanisms such as chromothripsis, tandem-duplication cycles, and extrachromosomal DNA (ecDNA). These structural drivers shape tumor aggression and therapy resistance across cancers, yet they remain largely inaccessible in plasma ctDNA due to low tumor fraction and fragment constraints. Retinoblastoma aqueous humor (AH) contains predominantly tumor-derived cfDNA with a genomically simple background, providing a uniquely powerful human model system to benchmark the technical feasibility, data characteristics, and analytical requirements for cfDNA-based amplification profiling.

Methods: Deep whole-genome sequencing (>20×) was performed on AH cfDNA from four RB eyes having *MDM4* focal gain or *MYCN* high-level amplification. Matched long-read nanopore WGS was generated for canonical subtype cell lines: WERI-Rb1 (MDM4) and Y79 (MYCN) to serve as high-confidence reference amplification profiles. We evaluated copy-number resolution, breakpoint features, and junction-spanning fragment representation in cfDNA relative to long-read tumor DNA.

Results: All AH cfDNA samples achieved >20× genome-wide coverage with >90% inferred tumor fraction from Illumina PE150 NGS setting, enabling high-resolution focal amplification assessment. MDM4-positive AH samples demonstrated multi-segment focal 1q gain with moderate copy elevation (~3-8× over baseline) and sharp regional boundaries, while MYCN-amplified samples exhibited ultra-high amplification (>50× copies) with dense, localized breakpoint clustering. Long-read tumor DNA (>1.5× whole-genome coverage) provided a structural reference sufficient to confirm amplification topology and breakpoint positions. Junction-spanning cfDNA fragments aligned to predicted boundaries, supporting direct focal amplification recovery from liquid biopsy.

Conclusions: Aqueous humor cfDNA provides a high-performance testbed for characterizing focal amplification signatures and defining technical performance thresholds relevant to liquid biopsy assay development. These results establish analytical parameters—minimum sequencing depth, copy-number resolution limits, and junction-fragment detectability—that may inform future platform optimization for lower-tumor-fraction biofluids such as plasma and CSF.

#0520 Topoisomerase IIb binding delineates localized mutational processes and driver mutations in cancer genomes.

Liis Uuskula-Reimand[1], Christian A. Lee[2], Robin H. Oh[3], Zoe P. Klein[2], Nina Adler[4], Sana Akhtar Alvi[1], Ellen Langille[3], Elisa Pasini[5], Kevin C. Cheng[2], Evgenija Serafimova[3], Diala Abd Rabbo[2], Huayun Hou[1], Ricky Tsai[3], Mamatha Bhat[5], Daniel Schramek[3], Michael Wilson[1], Juri Reimand[2]

[1]The Hospital for Sick Children, Toronto, ON, Canada,[2]Ontario Institute for Cancer Research, Toronto, ON, Canada,[3]Lunenfeld-Tanenbaum Research Institute, Toronto, ON, Canada,[4]University of Toronto, Toronto, ON, Canada,[5]University Health Network, Toronto, ON, Canada

Type-II topoisomerases resolve topological stress in DNA by inducing and repairing double-strand breaks in a coordinated fashion. While topoisomerases are chemotherapy targets linked to therapy-related genotoxicity, TOP2B is uniquely positioned to influence mutagenesis through its activity in non-dividing cells and sensitivity to topoisomerase poisons. Here, to understand the role of TOP2B in mutagenesis and cancer driver mechanisms, we generated unique DNA-binding maps of TOP2B, CTCF, and RAD21 in human liver cancer samples using chromatin immunoprecipitation sequencing (ChIP-seq). Next, we conducted a systematic analysis of these genome-wide maps for cancer driver mutations and somatic mutational processes across a dataset of 6500 whole cancer genomes representing 18 major cancer types. We show that TOP2B-CTCF-RAD21 and TOP2B-RAD21 sites are enriched in somatic small mutations (SNVs, indels) as well as structural variants (SVs), particularly at sites with evolutionary conservation, high transcription and long-range chromatin interactions. When focusing on evolutionarily selected genes using a systematic driver analysis, TOP2B binding appears to underlie SVs and hotspot mutations in cancer-driving genes such as TP53, MYC, FOXA1, and VHL, and many frequently mutated non-coding regions. We show that the TOP2B-bound mutational hotspot at RMRP is a novel non-coding driver mutation that causes tumor initiation and growth in vivo and leads to transcriptional deregulation of migration and cell adhesion pathways. Together, these data highlights TOP2B as a safeguard of the genome integrity and a marker of mutational processes and hotspots in cancer, underscoring implications for cancer genomics research.

#0521 Impression of AKT inhibitor in chromatin accessibility in mCRPC.

Sasikumar Ponnusamy[1], Surendra Gulla[1], Tej Sharma[1], Ephraim Jeremiah Gardner[1], Abbas Jawadala[1], Adaora Amobi[1], Maddie Aust[1], Tobi Ogunbowale[1], Roberto Pili[2], Remi M. Adelaiye-Ogala[1]

[1]Department of Medicine, Jacobs School of Medicine and Biomedical Sciences, University at Buffalo, Buffalo, NY,[2]University at Buffalo, Buffalo, NY

The Androgen Receptor (AR) pathway is a primary target for metastatic castration-resistant prostate cancer (mCRPC) treatment, and AR blockade with enzalutamide is a well-established therapeutic option for targeting the AR pathway in mCRPC. However, prostate cancer cells can bypass AR blockades through induction of other pathways for survival, and recently numerous preclinical studies have made the PI3K-AKT pathway a target of interest for the treatment of drug-resistant mCRPC. The PI3K-AKT pathway has pleiotropic effects, and its inhibition has long been of interest in the management of prostate cancer. We previously reported that AKT inhibition (Ipatasertib) significantly decreases cell proliferation, increases canonical AR activity, and remodels the chromatin landscape *in vitro* and *in vivo*. However, the effects of AKT inhibition on chromatin accessibility remain poorly understood. This study aims to assess chromatin landscape modifications under PI3K-AKT pathway inhibition. In this study, LuCaP 167 patient-derived organoid (PDO) models were treated with AKT inhibitors (Ipatasertib and MK2206), and the chromatin landscape was studied using ATAC-seq. Preliminary results reveal that both Ipatasertib and MK2206 significantly altered chromatin accessibility in LuCaP 167 PDO compared with the non-treated control group. Interestingly, footprinting and motif analysis revealed several transcription factor motifs enriched by AKT inhibition, including KLF15, a tumor suppressor. While the results are preliminary, our data provide additional insights into AKT's influence on chromatin accessibility.

#0522 Oncometabolite D-2-hydroxyglutarate impairs homologous recombination by disrupting chromatin topology.

Fengchao Lang[1], Karambir Kaur[2], **Chunzhang Yang**[3]

[1]National Institutes of Health, Bethesda, MD,[2]NIH-NCI, Bethesda, MD,[3]NIH-NOB (Neuro-Oncology Branch), Bethesda, Maryland, MD

D-2-hydroxyglutarate (D-2-HG) is an abnormal metabolite produced in high concentrations in cancers with isocitrate dehydrogenase (IDH) mutations, such as glioma, acute myeloid leukemia, and chondrosarcoma. The IDH mutant enzyme exhibit neomorphic activity, driving the production of D-2-HG, which induces a unique oncogenic phenotype, characterized by genome-wide hypermethylation, reprogrammed metabolic landscape, and impaired DNA repair. Although these alterations contribute to tumor progression and increase therapeutic vulnerabilities, the exact molecular mechanisms linking D-2-HG to impaired DNA repair remain elusive. In the present study, we explore how D-2-HG affects chromatin structure to impair the DNA repair pathway, focusing specifically on homologous recombination (HR). We demonstrate that D-2-HG inhibits TET (ten-eleven translocation) methylcytosine dioxygenase activity, leading to widespread CpG island hypermethylation. This epigenetic modification dissociates the chromatin architectural protein CTCF (CCCTC-binding factor) from CpG-rich DNA regions. The loss of CTCF binding disrupts higher-order chromatin contacts critical for maintaining the structural integrity at the DNA damage sites. Consequently, key HR repair proteins, such as BRCA2 and RAD51, fail to be recruited to sites of DNA damage sites, significantly impairing HR efficiency. Our findings provide mechanistic insights into how the cancer metabolic signature leads to DNA repair deficiency, mediated by D-2-HG-induced chromatin alterations. The disruption of chromatin topology and loss of CTCF-mediated loops extrusion at DNA damage sites abolish effective DNA repair signaling, indicating a therapeutic vulnerability in IDH-mutant cells. Our study suggests that IDH-mutant tumors may be particularly susceptible to DNA repair inhibitors, such as PARP inhibitors, or other agents that further compromise HR repair.

#0523 Pan-cancer assessment of an RNA-based signature of HRD.

Stephanie N. Thiede, Hannah J. Glover, Matthew E. Berginski, Joshuah Kapilivsky, Andrew Sedgewick, Kyle A. Beauchamp, Chithra Sangli, Michelle M. Stein, Justin Guinney, Timothy Taxter

Tempus AI, Chicago, IL

Background. Pan-cancer biomarkers of homologous recombination deficiency (HRD) are an area of unmet clinical need due to efforts to develop second generation PARP inhibitors across solid tumor cancers. An RNA-based method has the potential to overcome limitations of DNA scar-based signatures, which are less robust across indications and represent historical, static measures of HRD.
Methods. We developed a 1660 gene expression-based logistic regression signature using Tempus xR to predict HRD status in solid tumors, including *BRCA*-cancers (pancreatic, prostate, ovarian, and breast) and 35 other cancers. Training labels were defined with DNA data (Tempus xT) with *BRCA1/2* biallelic loss as positive and wildtype (WT) in 14 homologous recombination repair (HRR) genes as negative. Data were split into training (N ~ 100k), evaluation for threshold selection (N~25k), and validation (N~25k).
Results. Sensitivity was 84% (ovarian), 82% (breast, pancreatic, prostate), and 54% for other cancers. Predicted HRD (HRD-RNA) prevalence was 27% in ovarian, 22% in breast, 14% in prostate, 8.9% in pancreatic and 5.4% in all other cancers. HRD-RNA prevalence was higher in HRR-biallelic altered tumors compared to HRR WT (31% vs. 11% in *BRCA*-cancers; 11% vs. 4.7% in other cancers). Among *CCNE1*-amplified ovarian tumors, thought to be mutually exclusive with HRD, HRD-RNA prevalence (12%) was lower than gwLOH-based calling (20%), highlighting improved specificity of this RNA-based approach. The model showed equivalent performance to cancer-specific models trained individually on pancreatic, ovarian, and prostate cancer, demonstrating generalizability.
Model gene features were positively enriched for hallmark pathways associated with DNA damage and repair including *E2F* family of transcription factors, G2/M checkpoint, *MYC* targets, mitotic spindle, HRR, and DNA damage response pathways. Negative enrichment was seen in the epithelial to mesenchymal transition pathway. The association of ssGSEA scores of these hallmark pathways with HRD-RNA status was consistent across most individual cancers. Similar associations of these pathways with other models of HRD have been shown in publicly available data (PMID: 39073402).
We also observed cancer-specific expression associated with HRD-RNA status. For example, *BRCA2* expression is positively associated with HRD-RNA in ovarian cancer and negatively associated in most other cancers, namely in prostate cancer. Notably, there is a strong positive relationship with the oxidative phosphorylation pathway ssGSEA scores in ovarian cancer, consistent with reports that HRD results in a shift from glycolytic to oxidative metabolism (PMID: 32400970).
Conclusion. The RNA signature detects HRD within and beyond *BRCA1/2* biallelic loss pan-cancer. Similar pathways were associated with HRD-RNA status as reported in DNA-based methods of HRD, highlighting the biological validity of an RNA-based HRD signal.

#0524 Characterizing PTEN:Ki67 interactions and contribution to radioresistance in glioblastoma.

Brandon Marshall Jones[1], Sejal Patel[2], Brett Taylor[3], Nidhi Nathwani[2], Takayuki Morimoto[2], Yashpreet Kaur[2], Frank Furnari[4]

[1]Biomedical Sciences, University of California San Diego, La Jolla, CA,[2]University of California San Diego, La Jolla, CA,[3]UC San Diego School of Medicine, La Jolla, CA,[4]Division of Regenerative Medicine, Department of Medicine, University of California San Diego, La Jolla, CA

Glioblastoma (GBM) is the most common and lethal primary brain tumor in adults, comprising approximately 50% of newly diagnosed solid brain tumors. Newly diagnosed GBM patients have a poor prognosis and median survival of only 12-15 months with current standard of care therapy. Precision oncology approaches that have worked in other cancers have largely failed to translate to GBM due to several unique GBM properties, including resistance to cell death caused by DNA damaging agents such as radiation therapy. One novel mechanism of radioresistance is through enhanced DNA damage response (DDR) mediated by nuclear-localized tyrosine-phosphorylated PTEN (pY240-PTEN) recruited to chromatin through interaction with the PP1 Binding Domain (PP1BD) of Ki67. While PTEN is known to play an important tumor-suppressive role and is found to be altered in approximately 40% of GBM, an analysis of an EGFR-positive, PTEN-positive patient cohort revealed that the presence of pY240-PTEN correlated with worse overall survival. As a more complete understanding of this interaction may provide valuable insight as to the role that Ki67 plays in GBM radioresistance, N-terminal biotinylated peptides were utilized to examine the contribution of each amino acid of the Ki67-PP1BD to PTEN binding. Through streptavidin pulldown assays, we uncovered a basic 5-amino acid patch critical for PTEN:Ki67 binding and through phosphorylation of these synthetic peptides, determined that Ki67 pT525 may play a role in determining occupancy of the Ki67-PP1BD. To further investigate the impact of PTEN:Ki67 interaction-dependent DDR, a Ki67 KO TS528 glioma stem-like cell line was established. Characterization of this line indicated that Ki67 loss had little impact on unperturbed cells but following radiation, resulted in decreased proliferation, decreased DDR, and a more significant G2 cell cycle arrest compared to WT TS528. Additionally, *in vivo* radiation treatment of mice harboring TS528 Ki67 KO tumors imparted a significant increase in overall survival, while TS528 parental cells had no benefit. To determine the contribution of PTEN to the observed Ki67 KO phenotype, Ki67 was knocked out in PTEN-null U87 glioma cells. In concordance with previous findings of PTEN:Ki67 interactions following radiation, I found that Rad51 foci formation was increased only in U87 cells expressing both Ki67 and PTEN. The impact of PTEN binding was also examined in TS528 Ki67 KO cells through lentiviral restoration of Ki67 with minigene constructs expressing WT Ki67-PP1BD, or harboring mutations disrupting PTEN binding, fused to the chromatin binding LR domain. Alanine substitution of critical PTEN binding residues disrupted interaction by CoIP and is currently being tested for radiosensitizing effects *in vivo*. This work characterizes a novel DNA damage repair pathway implicated in GBM radioresistance and proposes a new potential target for therapeutic intervention.

#0526 The role of ssDNA in alternative DNA DSB repair and the opportunity for therapeutic intervention.

Jessica Lynn Kersey[1], John J. Turchi[2]

[1]Biochemistry, Molecular Biology and Pharmacology, Indiana University School of Medicine, Indianapolis, IN,[2]Indiana University School of Medicine, Indianapolis, IN

DNA double-stranded breaks (DSBs) create genomic instability, a driving factor in cancer development. Targeting DNA repair is a pivotal strategy in cancer therapy by exploiting synthetic lethal interactions with PARP inhibitors in patients deficient in homologous recombination (HR) DSB repair. Despite these advances, the clinical outcomes and recurrence rate for these patients have remained relatively stagnant. Recurrence is a direct result of treatment resistance mechanisms which can include reactivation of HR or the use of alternative end-joining (alt-EJ) DSB repair pathways. Theta-Mediated End Joining (TMEJ) and Single-Strand Annealing (SSA) can be employed to maintain genome stability and elevated expression of proteins involved in these pathways, including PolQ and XPF, have been reported in ovarian and lung cancer. SSA and TMEJ repair pathways involve common steps of resection, homology searching/annealing, and DNA synthesis. However, protection and processing of the ssDNA intermediates has not been addressed. Replication Protein A (RPA) is the major single-stranded DNA (ssDNA) binding protein involved in replication and repair and has been implicated in both TMEJ and SSA repair pathways though definitive involvement and the putative mechanisms have not been elucidated. We propose that RPA impacts TMEJ and SSA dependent DNA DSB repair via binding to ssDNA intermediates. The impact of RPA activity on TMEJ and SSA was assessed via genetic knockdown (KD) of RPA using siRNA in HEK293T and H1299 cell lines. Following siRNA KD, TMEJ and SSA repair activity were measured using a repair pathway specific dual luciferase extrachromosomal reporter assay. Results demonstrate that RPA stimulates both TMEJ and SSA activity as loss of RPA activity resulted in a ≥50% reduction repair activity for both pathways. Furthermore, a qPCR based extrachromosomal reporter assay requiring an additional 25bp of synthesis for complete repair was also reliant on RPA. Interestingly, treatment of RPA KD cells with ART558, a PolQ inhibitor, had less of an impact compared the control cells suggesting that cells can use a PolQ-independent mechanism of TMEJ for repair under certain conditions. Additionally, the impact of XPF-ERCC1 activity on SSA repair was considered as XPF-ERCC1's major function is to cleave 3' ssDNA overhangs, a key intermediate that must be processed in SSA. The impact was assessed via SSA repair activity in H1299 XPF-ERCC1 genetic knockout cells compared to the H1299 Cas9 control cells. Loss of XPF-ERCC1 activity resulted in approximately a 6-fold decrease in SSA activity indicating that SSA repair heavily relies of XPF-ERCC1 for ssDNA processing. Collectively, these data establish that RPA and XPF have a stimulatory role in TMEJ and SSA repair. The insights gained from this research can be used to better understand how certain types of cancer modify their DNA repair mechanisms to enhance their chances of survival.

#0527 Development of novel Ku-targeted DNA-PK inhibitors for cancer therapy.

Katherine Pawelczak[1], Pamela S. VanderVere-Carozza[2], Maria Casiano[3], Lacey Dobrolecki[1], John J. Turchi[2]

[1]NERx Biosciences, Indianapolis, IN,[2]Indiana University School of Medicine, Indianapolis, IN,[3]Biochemistry, Indiana University School of Medicine, Indianapolis, IN

The DNA-dependent protein kinase (DNA-PK) is a clinically validated target for cancer therapy. It plays essential roles in the repair of DNA double-strand breaks (DSBs) via non-homologous end joining (NHEJ), and in the broader DNA damage response (DDR) signaling pathway. Given its pivotal roles in maintaining genomic stability, and its upregulation and hyperactivation in many cancers, DNA-PK is an attractive therapeutic target for single agent therapy and in combination with radiation or other DNA damaging chemotherapeutics. Existing DNA-PK inhibitors target the catalytic subunit (DNA-PKcs) but have suffered from poor selectivity, suboptimal pharmacokinetics, and dose-limiting toxicity. To overcome these limitations, we have developed a first-in-class series of small-molecule inhibitors that block Ku70/80 binding to DNA, the initial and essential step of DNA-PK activation. Our structure-based drug discovery program has led to the development of novel, drug-like Ku inhibitors that bind to unique pockets within the Ku interface, blocking DNA access and effectively shutting down DNA-PK activity. This novel, ATP-independent mechanism prevents assembly of NHEJ complexes, offering enhanced selectivity, reduced off-target toxicity, and a powerful new strategy for cancer therapy. Lead compounds potently inhibit DNA-PK catalytic activity at nanomolar concentrations, block Ku-dependent DNA binding, and sensitize cancer cells to ionizing radiation, etoposide, and bleomycin while sparing normal cells. Proof-of-concept studies confirm on-target mechanism, pharmacodynamic engagement, and enhancement of IR-induced antitumor activity in non-small cell lung cancer (NSCLC) xenograft models. Additionally, newly emerging and growing class of ADCs that induce DNA damage as their primary efficacious mechanism have been increasingly popular in the clinic. Ku inhibitors have strong mechanistic rationale as combination partners for ADCs, with the potential to overcome resistance and improve the therapeutic index of DNA damage inducing ADCs. Our results show significant increased efficacy in combination with the ADC topoisomerasel inhibitor, DXd, suggesting that Ku inhibition enhances DXd-induced cytotoxicity by impairing non-homologous end joining and sensitizing tumor cells to payload-mediated DNA damage. These results support the further development of Ku inhibitors as anticancer therapeutics.

#0528 Sun exposure shapes distinct mutational profiles in human skin cells.

Neda Bahrani, Aravind K. Bandari, Bishal Tandukar, Delahny Deivendran, Harsh Sharma, Alan Hunter Shain

UCSF Helen Diller Family Comprehensive Cancer Ctr., San Francisco, CA

Surprisingly little is known about how ultraviolet (UV) radiation exposure affects individual skin cell types. Prior studies relied on bulk sequencing of whole biopsies, masking cell type-specific mutational patterns, and often used narrow UV spectra, non-physiological doses, or focused only on immediate DNA damage rather than lasting mutations. To delineate the enduring genetic effects of UV-radiation, we measured somatic mutations and cellular viability in melanocytes, keratinocytes, and fibroblasts exposed to physiologically relevant simulated solar radiation.

We exposed primary neonatal melanocytes, keratinocytes, and fibroblasts to simulated solar radiation under three conditions: no irradiation (control), 5 minutes (~70.2 J/m^2), and 10 minutes (~129.9 J/m^2), corresponding to ~0, 0.42, and 0.83 Minimal Erythema Dose (MED). Cell counts were measured on days 1 (pre-irradiation), 3, and 5 (post-irradiation) to assess viability and proliferation. For mutational profiling, single cells from each condition were sorted, clonally expanded, and subjected to exome and transcriptome sequencing using G&T-seq. In total, we analyzed 9 fibroblast clones (n=4, 2, 3), 13 keratinocyte clones (n=5, 3, 5), and 12 melanocyte clones (n=4 per condition) to quantify UV-induced mutational burden.

All three cell types exhibited a dose-dependent reduction in cell counts following irradiation, though with differing magnitude. Keratinocytes showed the most pronounced decline, whereas melanocytes displayed a dose-dependent decrease but to a lesser extent. Fibroblasts were the most resilient, with the smallest reduction in cell count and the fastest post-irradiation recovery. Mutational profiling revealed a corresponding dose-dependent increase in mutation burden (mutations per megabase) and in the fraction of canonical UV-signature substitutions (C>T and CC>TT) across all cell types. After 10 minutes of simulated solar radiation, median mutation burdens reached 1.30 mut/Mb in keratinocytes, 0.52 mut/Mb in melanocytes, and 0.36 mut/Mb in fibroblasts. The cells also showed distinct mutation signature and gene expression profiles.

Together, these findings highlight both the physiological and genomic consequences of solar radiation in distinct skin cell types. The differences in mutational landscapes point to cell type-specific mutational processes and DNA repair mechanisms, providing a framework for understanding how UV exposure shapes the genomic architecture of human skin.

#0529 Interplay of circadian cryptochrome 1 (CRY1) and DNA repair in prostate cancer (PCa).

Arwa Fallatah[1], Stefan DiFazio[1], Lakshmi Ravindranath[1], Orly Richter[1], Christopher McNair[2], Ayesha Shafi[1]

[1]Center for Prostate Disease Research, Bethesda, MD,[2]Sidney Kimmel Cancer Center, Thomas Jefferson University, Philadelphia, PA

Background: Disruptions in circadian rhythm are linked to prostate cancer (PCa). Previous studies indicate that the core circadian clock factor cryptochrome 1 (CRY1) is pro-tumorigenic and associated with poor clinical outcomes in PCa. Beyond its transcriptional co-regulatory function, CRY1 was recently identified as a modulator of DNA damage repair (DDR) in advanced PCa. Molecular and pharmacological suppression of CRY1 impairs PCa cell growth, induces G2/M arrest, and disrupts homologous recombination (HR)-mediated DNA repair. However, the mechanistic role of CRY1 in disease progression from hormone therapy sensitive (HTS) to castration resistant prostate cancer (CRPC) remains incompletely defined.
Methods: We employed doxycycline-inducible CRY1 knockdown models of both HTS, using LNCaP cell line, and CRPC, using C4-2 cell line, along with pharmacological strategies to recapitulate physiologically relevant CRY1 modulation. Transcriptomic profiling, DDR-focused CRISPR knockout (KO) screening, and downstream functional assays were used to define CRY1-dependent transcriptional and repair programs across disease stages. This allows for the identification of potential novel targeted therapies as well as predicts patient response to DDR targeted therapy.
Results: Transcriptomic analyses revealed distinct CRY1-regulated gene networks in HTS versus CRPC models. In HTS, CRY1 activity was associated with pathways including base excision repair, mismatch repair, and G2/M checkpoint regulation, while in CRPC, CRY1 was specifically linked to HR-mediated DNA repair. DDR-targeted CRISPR screening further demonstrated that CRY1 promotes tumorigenesis via nucleotide excision repair in HTS and shifts to HR reliance in CRPC, suggesting stage-specific rewiring of repair pathway choice driven by CRY1. These findings identify a novel mechanism of DDR regulation across PCa progression.
Conclusions: In sum, our study reveals that CRY1 supports PCa progression via distinct DDR mechanisms in HTS and CRPC. Thus, targeting CRY1, alonge or in combination with DDR inhibitors, offers a promising therapeutic strategy tailored to disease stage in PCa.

#0531 Germline HRR alterations and ancestry-related outcomes in Brazilian triple-negative breast cancer patients: A comprehensive genomic and clinical study.

Rafael C. Brianese[1], Karina M. Santiago[1], Gabriel Bandeira do Carmo[1], Leticia S. Pimentel[1], Diego Ortunes[2], Rafaella Ormond[2], Marcos L. Santoro[2], Giovana T. Torrezan[1], Marcelo Moreno[3], Andrea R. dos Santos[4], Marina de Brot[5], Fabiana B. A. Makdissi[6], Solange M. Sanches[7], Jose C. C. Rocha[8], **Dirce Maria Carraro**[1]

[1]Clinical and Functional Genomics Group, A.C.Camargo Cancer Center, Sao Paulo, Brazil,[2]Department of Biochemistry, Federal University of Sao Paulo (UNIFESP), Sao Paulo, Brazil,[3]Medicine Course and Biomedical Sciences, Federal University of Fronteira Sul (UFFS), Chapeco, Brazil,[4]Laboratory of Human and Medical Genetics, Postgraduate Program of Genetics and Molecular Biology, In, Federal University of Para (UFPA), Belem, Brazil,[5]Department of Anatomic Pathology, A.C.Camargo Cancer Center, Sao Paulo, Brazil,[6]Department of Breast Surgery, A.C.Camargo Cancer Center, Sao Paulo, Brazil,[7]Department of Medical Oncology, A.C.Camargo Cancer Center, Sao Paulo, Brazil,[8]Department of Oncogenetics, A.C.Camargo Cancer Center, Sao Paulo, Brazil

Triple-negative breast cancer (TNBC) is an aggressive and heterogeneous breast cancer subtype frequently associated with early-onset, African ancestry, and germline pathogenic variants (GPVs), particularly in *BRCA1*. Loss of function germline mutation in homologous recombination repair (HRR) genes culminate in homologous recombination deficiency (HRD), a molecular phenotype that confers increased susceptibility to DNA-damaging agents such as platinum-based chemotherapy and PARP (poly ADP-ribose polymerase) inhibitors. While this mechanism is well-characterized in European and North American cohorts, studies in admixed populations remain limited. We conducted a comprehensive retrospective study of 320 unselected Brazilian TNBC patients, integrating multigene next-generation sequencing (NGS) panels, ancestry analysis, and clinical-pathological data. Germline variants were analyzed across cancer predisposition multi gene panels, and ancestry was determined in 248 patients using the Axiom Precision Medicine Diversity Array and ADMIXTURE (K=4). GPVs were detected in 29.1% of patients, with *BRCA1* being the most frequently altered gene (14.7%), followed by *BRCA2* (4.4%) and non-*BRCA* HRR genes (4.7%). Overall, 23.8% of patients harbored GPVs in HRR-related genes. *BRCA1* carriers were significantly younger at diagnosis, more likely to present bilateral tumors, and showed improved 3-year progression-free survival (3y-PFS) compared to non-carriers ($p = 0.0162$). Carriers of other HRR genes also had superior 3y-PFS ($p = 0.0398$). Combined, HRR-carriers exhibited better 3y-PFS ($p = 0.0025$) and 5-year overall survival (5y-OS, $p = 0.0260$) than non-carriers. Ancestry analysis revealed a predominance of European ancestry (87.1%) but also substantial African and Native American components (≥1% in 68.5% and 81.4%, respectively), confirming Brazil's complex admixture. Patients with predominant African ancestry had significantly worse 3y-PFS ($p = 0.0011$) and 5y-OS ($p = 0.0117$) compared to those with European ancestry. Self-reported race only partially correlated with molecular ancestry. Local ancestry analysis focused on the *BRCA1* locus showed that 25% of individuals carried African-derived haplotypes, but no significant associations were found between *BRCA1* local ancestry and cancer type ($p > 0.05$). This is the largest TNBC germline study conducted in a Latin American population to date, uniquely integrating genetic, clinical, and ancestry data. Our findings reinforce the central role of HRR genes, particularly *BRCA1*, in TNBC predisposition and prognosis, and reveal ancestry-related survival disparities that merit further investigation. Ongoing analyses of local ancestry components will provide additional insights into the genomic and clinical heterogeneity of TNBC in highly admixed populations.

#5134 *In vitro* and *in vivo* biology characterization of two novel inhibitors targeting the different domains of DNA polymerase theta (Polθ).

Omar Loss[1], Michael Bestwick[1], Tammy Ladduwahetty[1], Mark Andrews[1], Ju Wang[2], Jiangchuan He[2], Linli Ding[2], Tan Pang[2], Rui Yang[2], Hing Sham[3], Kui Lin[3]

[1]Pharmaron, Hoddesdon, United Kingdom,[2]Pharmaron, Beijing, China,[3]NewBay Pharma, Ningbo, China

DNA polymerase theta (Polθ) is a 290 kD specialized and error-prone Polymerase A family enzyme that executes microhomology-mediated end joining (MMEJ), possessing an N-terminal helicase-like domain and a C-terminal DNA polymerase domain, which are linked by a large, unstructured central region. Polθ is normally expressed at low levels but is frequently overexpressed in tumours and is critical for the survival of homologous recombination (HR)-deficient cancer cells. Accordingly, Polθ has been proposed as an attractive therapeutic target for the treatment of BRCA deficient and DNA repair pathway defective cancers. Several inhibitors targeting either the polymerase or the helicase domain of Polθ have been described and progressed to the clinic. However, it is not clear which axis of intervention is the most beneficial even though inhibition of either domain elicits synthetic lethality with BRCA genes preclinically. Here we compare the *in vitro* biological profile of two novel Polθ inhibitors, one targeting the C-terminal DNA polymerase (Pol) domain and the other targeting the N-terminal helicase-like domain (Hel). Both inhibitors exhibit similar potency in their respective biochemical assays (Hel inhibitor IC_{50} = 2.1 nM, Pol inhibitor IC_{50} = 4.2 nM). However, in a colony formation cellular assay the Hel inhibitor elicited significantly stronger synthetic lethality in BRCA2-mutant tumour cells (Hel inhibitor IC_{50} = 2.1 nM; Pol inhibitor IC_{50} 125.6 nM). Furthermore, this differentiation was evident mechanistically, where the Hel inhibitor inhibited MMEJ-mediated repair with a 3-fold higher potency and increased micronuclei formation in cells with a 200-fold higher potency when compared to the Pol inhibitor. When tested *in vitro*, in combination studies with the PARP inhibitor Niraparib, Hel showed a synergistic effect even at the lowest combination of concentrations tested (4 nM Hel, 15 nM Niraparib), whereas a 10-fold higher concentration of Pol inhibitor was needed to achieve the same synergistic effect. Based on its superior *in vitro* profile, the helicase inhibitor was progressed to BRCA1- and BRCA2-deficient xenograft models, where it evoked DNA damage and showed a dose-dependent sustained regression of tumour volume, in combination with a PARP inhibitor, even at the lowest dose tested of 3 mg/kg PO QD. The dose selection was based on the unbound exposure of the Hel inhibitor being in excess of the unbound cellular IC50 during the treatment period. Given the tumour regressive effects *in vivo* and favourable ADME profile in preclinical species and early human dose predictions, the helicase compound is currently undergoing evaluation in non-GLP toxicology studies.

#0535 Acute sleep deprivation reprograms metabolic and mitochondrial pathways linked to cancer risk.
Behzad Varamini[1], Harrison Kim[1], Priscilla Kim[1], Madeline Lange[1], Stephanie Zeng[1], Jennifer Tudor[2]

[1]Biola University, La Mirada, CA,[2]Saint Joseph's University, Philadelphia, PA

Sleep deprivation is common and has been linked to elevated cancer risk, yet the immediate mammalian responses that connect acute sleep loss to cancer remain unclear. We asked whether a single 5-hour bout of acute sleep deprivation (ASD) reprograms metabolic and mitochondrial pathways across organs that govern whole-body energetics in a mouse model. Twelve-week C57BL/6 female mice underwent ASD or ad lib sleep; liver, hippocampus, prefrontal cortex, and gastrocnemius were collected immediately and profiled by RT-qPCR for energy sensing (AMPK), glucose transport (GLUT3), mitochondrial dynamics (DRP1/MFN1/OPA1), and hepatic lipid/cholesterol handling (ABCA1/SCARB1/apolipoproteins). ASD triggered rapid, tissue-selective remodeling: AMPK/GLUT3 and mitochondrial-dynamics transcripts rose in brain regions, while hepatic cholesterol transport and apolipoproteins were altered; however skeletal muscle showed minimal change. These coordinated shifts map to cancer-relevant processes—deregulated cellular energetics, mitochondrial quality control/redox, and sterol flux that shapes membrane signaling and tissue inflammation, positioning sleep state as a modifiable, system-wide determinant of cancer susceptibility and progression. Ongoing work will examine whether repeated ASD or sleep restoration tunes these pathways and related tumor-relevant endpoints.

#0536 A multiplexed LC-MS/MS metabolite assay to enable patient stratification and pharmacodynamic monitoring for MTA-cooperative PRMT5 inhibitors.

Ethan Stancliffe[1], Ashima Mehta[1], Douglas Guzior[1], Adam Richardson[1], Tom Cohen[1], Kevin Cho[2], Gary Patti[2]

[1]Panome Bio, St. Louis, MO,[2]Washington University in St. Louis, St. Louis, MO

The development of Protein Arginine Methyltransferase 5 (PRMT5) inhibitors, particularly MTA-cooperative agents that selectively target *MTAP*-deleted cancers, has created an urgent need for robust biomarkers to identify target patient populations and confirm pharmacodynamic (PD) target engagement. The purpose of this study was to develop and apply a highly sensitive, multiplexed liquid chromatography-mass spectrometry (LC-MS/MS) assay to quantify key PRMT5-related metabolites such as methylthioadenosine (MTA), symmetric dimethylarginine (SDMA), S-adenosylmethionine (SAM), and asymmetric dimethylarginine (ADMA), as well as interacting metabolites in the folate cycle, methionine cycle, and polyamine metabolism. The developed multiplexed LC-MS/MS method enables simultaneous quantification of MTA, SDMA, SAM, and SAH, and 12 other related metabolites from cell lysates, tumor tissue, and biofluids. The assay leverages isotopically labeled internal standards and fragment ion monitoring for robust quantitation and resolution of key PRMT biomarkers ADMA (Type I PRMTs, e.g., PRMT1) and SDMA (PRMT5). We then applied this assay to matched adenocarcinoma tumor and normal adjacent tissue (NAT) specimens from n=6 human patients. The results showed statistically significant ($p<0.05$) increases in SAM and MTA as well as S-adenosylhomocysteine (SAH) levels in the tumor. The elevated MTA levels was driven by a subset of patients, suggesting these individuals have *MTAP*-deleted tumors. SAM and SAH are reactants and products, respectively, of PRMT5 and Type I PRMTs like PRMT1. The elevation of SAM and SAH in the tumor suggests elevated PRMT activity. In examining SDMA and ADMA levels, we found that ADMA (PRMT1 biomarker) was elevated by 40% in the tumor, while SDMA (PRMT5 biomarker) showed less than 20% elevation. In total, these data demonstrate the utility of the developed metabolite assay for the development of PRMT5 therapies. The differences between tumor and NAT metabolite profiles are consistent with upregulated PRMT1 (or another Type I PRMT) in the tumor, leading to elevated ADMA, SAM, and SAH. PRMT5, on the other hand, is likely inhibited by elevated MTA levels in the *MTAP*-deleted tumors, making them more susceptible to MTA-cooperative PRMT5 inhibitors, despite not significantly increasing SDMA levels in the tumor.

#0537 Constitutive NRF2 activation drives excess cysteine stress.

Jennifer A. Brain[1], Anna-Lena B. G. Vigil[1], Kristian Davidsen[1], Ayaha Itokawa[1], Abby C. Jurasin[1], Hannah J. Kerbyson[1], Maximilian Kobiesa[1], Madeleine L. Hart[1], Sang Jun Yoon[2], Gina M. DeNicola[2], Lucas B. Sullivan[1]

[1]Fred Hutchinson Cancer Center, Seattle, WA,[2]H. Lee Moffitt Cancer Center, Tampa, FL

Constitutive NRF2 activation is prevalent in human cancers and drives increased cystine uptake via SLC7A11-mediated xCT antiporter activity, exceeding cysteine demands for conventional pathways including glutathione and protein synthesis. The metabolic fates and functional consequences of this excess cysteine remain incompletely understood. To identify potentially unknown cysteine fates, we developed RMA tracing, an untargeted isotope tracing/mass spectrometry approach using equimolar mixtures of labeled [$^{13}C_6$,$^{15}N_2$] and unlabeled cystine to identify cysteine metabolic fates based on characteristic isotopologue peak pairs. Our LC-MS tracing identified 29 cysteine fates, including 20 previously unknown metabolites enriched in NRF2-activated cells and tumors. Many derived from reactions between cysteine thiols and glucose-derived sugar metabolites, forming irreversible thioether conjugates with sugar phosphates and reversible hemithioacetal/thiazolidine products with carbonyl compounds. We were able to identify these novel fates in greater abundance in NRF2-activated cultured cells, mouse tumors, and human tumor samples. We then asked if there was a functional phenotype associated with excess intracellular cysteine. We grew cells in media with increased cystine and observed a dose-dependent proliferation impairment rescued by SLC7A11 inhibition with erastin. We note this proliferation defect was independent of glutamate depletion or NADPH consumption. Additionally, inhibiting glutathione synthesis with buthionine sulfoximine intensified cysteine accumulation and proliferation defects by preventing enzymatic cysteine consumption. Alternate cysteine delivery methods (beta-mercaptoethanol or N-acetylcysteine supplementation) similarly increased intracellular cysteine and conjugate accumulation, and impaired cell growth in an SLC7A11-independent manner. We define “excess cysteine stress” as both accumulation of novel cysteine-derived metabolites and a proliferation defect in high cystine conditions. Mechanistically, we attribute NRF2 activation with this cancer-associated metabolic vulnerability to excess cysteine through constitutive SLC7A11 expression. These findings delineate novel cysteine conjugates, validate their physiological relevance across models, and identify excess cysteine stress as a distinct metabolic vulnerability in NRF2-activated cancers that may inform future therapeutic strategies.

#0539 Cholesterol triggers chromatin stress to drive senescence and inflammation.

Yiqun Han[1], Yaobin Ouyang[2], Shouhai Zhu[2], Hangcheng Xu[2], Bin Chen[1], Ping Yin[2], Qin Zhou[1], Jinzhou Huang[2], Kuntian Luo[2], Zheming Wu[1], Huaping Xiao[1], Xinyi Tu[1], Jake A. Kloeber[2], Jiajun Jing[2], Xiaofeng Huang[2], Meng Xu Welliver[1], Zhenkun Lou[2], Robert Mutter[1]

[1]Radiation Oncology, Mayo Clinic, Rochester, MN,[2]Oncology, Mayo Clinic, Rochester, MN

Cholesterol has long been viewed as a structural component of cellular membranes, yet its role in DNA damage response remains poorly defined. Here, we show that ionizing radiation (IR) induces broad transcriptional upregulation of cholesterol biosynthesis, transport, and storage pathways, leading to sustained intracellular accumulation of cholesterol. BODIPY-cholesterol imaging, Filipin III staining, and quantitative subcellular fractionation confirmed selective nuclear enrichment of cholesterol following IR, coinciding with extensive chromatin remodeling. Proteomic profiling of cholesterol-interacting proteins revealed a strong enrichment of chromatin-associated factors, suggesting a previously unrecognized lipid-chromatin interface in irradiated cells. Functionally, cholesterol accumulation promoted chromatin compaction and repressive histone modification patterns, impairing DNA damage sensing and checkpoint activation despite increased underlying DNA lesions. These alterations facilitated aberrant mitotic entry, formation of cytoplasmic chromatin fragments (CCFs), and activation of cGAS-STING-NF-κB signaling. Cholesterol exposure ultimately diverted damaged cells toward a senescent fate, marked by Lamin B1 loss, p21 induction, and a robust senescence-associated secretory phenotype (SASP) enriched for IL-1 and TNF family cytokines. In vivo, dietary cholesterol exacerbated radiation-induced inflammation and weakened systemic anti-tumor immunity. Transcriptomic analyses of immunotherapy-treated patients revealed that tumors enriched for cholesterol import and senescence signatures were associated with poor response to PD-L1 blockade and worse survival. Together, these findings identify a cholesterol-chromatin-senescence axis that links metabolic remodeling to defective DNA damage signaling and immune suppression after radiation, highlighting cholesterol metabolism as a potential therapeutic vulnerability in cancer therapy.

#0540 Cancer cells are sensitive to methionine cycle perturbation in low-lipid environments.

Diya Lakshmi Ramesh[1], Keene L. Abbott[1], Ryan Elbashir[1], Edrees H. Rashan[2], Raphael Ferreira[3], Matthew G. Vander Heiden[4]

[1]Massachusetts Institute of Technology (MIT) Biology and Koch Institute for Integrative Cancer Research at MIT, Cambridge, MA,[2]Koch Institute for Integrative Cancer Research at MIT, Cambridge, MA,[3]Wyss Institute for Biologically Inspired Engineering and Harvard Medical School, Harvard University, Boston, MA,[4]Massachusetts Institute of Technology (MIT) Biology, Koch Institute for Integrative Cancer Research at MIT, and Dana-Farber Cancer Institute, Cambridge, MA

Nutrient availability varies across tissues and shapes how cancer cells use metabolism to proliferate and survive, creating context-specific vulnerabilities that might be targeted for improved therapy. Because access to lipids is constrained in some tissue environments, we sought to identify metabolic pathways required for proliferation under lipid-depleted conditions. Specifically, we performed a CRISPR/Cas9 loss-of-function screen targeting metabolic synthesis genes in human cancer cells cultured in lipid-replete versus lipid-depleted media. The screen identified methionine synthase (MTR), an enzyme linking the folate and methionine cycles, as a top hit required for proliferation in lipid-depleted conditions. Genetic validation confirmed that MTR knockout (KO) cell proliferation is impaired in lipid-depleted compared to lipid-replete conditions. Follow-up pharmacologic studies revealed that inhibition of methionine adenosyltransferase 2A (MAT2A), an enzyme in the methionine cycle that generates S-adenosylmethionine (SAM), also reduced proliferation in lipid-depleted conditions, suggesting that cells become broadly dependent on the methionine/folate cycle when lipids are scarce.To determine how methionine/folate cycle perturbations alter intracellular metabolism in lipid-depleted conditions, we performed LC-MS-based metabolomics. MTR KO in lipid-depleted media caused depletion of multiple nucleotide species, and supplementation with purine nucleotides or folinic acid fully rescued proliferation, consistent with impaired folate-dependent nucleotide synthesis. MTR KO cells also exhibited elevated markers of DNA damage, supporting a model in which MTR loss limits nucleotide availability under lipid-depleted conditions, leading to DNA damage. In contrast, MAT2A-inhibited cells were not rescued by nucleotides or folinic acid. Instead, supplementation with phosphatidylcholine, a major membrane phospholipid synthesized in a SAM-dependent manner, restored proliferation in lipid-depleted media. These results suggest that perturbing different nodes of the methionine cycle triggers distinct metabolic liabilities: MTR loss primarily limits nucleotide availability, whereas MAT2A inhibition restricts SAM-dependent phospholipid synthesis. Together, these findings reveal that cancer cells rely more heavily on methionine and folate metabolism when lipids are scarce and uncover two mechanistically distinct vulnerabilities that emerge in low-lipid environments with potential relevance for treating cancer.

#0541 102 Cancer studies including differentially expressed potassium channel (KCN) genes reveal pH sensitivity with stochastic preservation of a proposed K^+/H^+ initiated H^+ release strategy for pH reversal.

Marie E. Beckner

Brain Health Research Institute, Kent State University, Kent, OH

The potassium channel (KCN) family of proteins (≥90 members) is interactive and influenced by numerous factors including oncogenes. K^+ is the likely monovalent cation (versus Na^+) to shed its water with relative ease and replace protons on anions of cell membranes. H^+ is released for diffusion as H_3O^+, putatively into a Grotthuss water matrix for rapid transfer of protons to cell exits, including transporters of lactate with H^+, resulting in higher extracellular H^+ and lower intracellular H^+ to aid pH reversal (Beckner ME, Cell Settling, Migration, and Stochastic Cancer Gene Expression⋯, Biomolecules: 2025, 15,1177, https://doi.org/10.3390/biom15081177). 102 studies (new total), with no intent to include KCN genes, yielded results in 30 cancer types with ≥ 1 KCN differentially expressed gene (DEG) encoding a pH sensitive protein in 74.3% of studies, shown in heat maps, volcano plots etc. The most common cancers were breast, lung, and glioblastoma in 16, 14, and 12 studies, respectively, with 68.8%, 71.4%, and 83.3% containing ≥ 1 pH sensitive KCN DEG. 63 coding KCN genes found include 34 KCN(A-I,Q,S) encoding Kv proteins, 11 KCN (M,N,T) encoding KCa proteins, 8 KCNJ encoding Kir proteins, and 10 KCNK encoding K2P proteins. 3 non-coding KCNs were found. Among coding KCNs, 40 (63.5%) are pH sensitive. The most frequent KCN DEG (all pH sensitive), *KCNN4*, *KCNMA1, KCNN3,* and *KCNJ16*, were in 11, 9, 6, and 6 studies, respectively. With KCN DEG present, relatively intact non-KCN DEG were found that are needed in steps of H^+ release from cancer cells initiated by K^+/H^+ exchange on inner membranes. Na/K-ATPase and its regulators (*ATP1A2*,*B1*,*B2* and/or *FXYD1*,*D2* DEG in 9.8% of studies) that aid K+ intake, and for H+ exit with lactate (*LDHA* DEG in 2.9% of studies) and the monocarboxylate transporter complex (*CA2*, *CA9*, *SLC16A3* DEG in 1.0, 1.0, and 2.0% of studies, respectively). Also, lack of enhanced cytosolic H^+ transport by taurine is suspected (*SLC16A6* and *SLC36A1*(*PAT1*) taurine transporter DEG, 1% each) consistent with alternative cytosolic Grotthuss rapid proton transfer. Gap junction proteins are probably not at enhanced levels (*GJA1*, *GJB2*, *GJC3* DEG were 2.0, 1.0, and 1.0%, respectively). The most frequent oncogenic non KCN DEG were *BCL2* and *TGFB1*, 8 (100% pH sensitive) and 6 (83.3% pH sensitive) studies, respectively. Many pertinent non-KCN DEG were 0%. Stochastic findings are consistent with K^+/H^+ exchange on inner membranes initiating cytosolic proton diffusion via Grotthuss rapid water transfer to sites with release of H^+ along with lactate or alone to achieve pH reversal (pHe greater than pHi) in cancer cells. Without bias for KCN DEG, gene expression malignant landscapes stochastically suggest altered pH sensitive K^+ flux may promote K^+/H^+ exchange to initiate enhanced H^+ efflux underlying pH reversal in a subset of cancers.

#0542 A novel one carbon pathway generates nuclear SAM for chromatin methylation in cancer.

Tiziano Bernasocchi

Mass General Brigham, Boston, MA

Pancreatic Ductal Adenocarcinoma (PDAC) stands as the most common and one of the deadliest forms of pancreatic cancer, largely due to liver metastasis and the lack of effective targeted treatments 1,4. Emerging evidence comparing primary and metastatic cancer lesions suggests that key steps of metastasis are controlled by reversible epigenetic mechanisms, specifically DNA methylation and Histone Post Translational Modifications (PTMs) 10,11. These epigenetic changes are intricately linked to metabolic networks, which supply the essential substrates and cofactors for these modifications, thereby potentially playing a crucial role in metastasis adaptation 12. To explore this interplay between metabolism and epigenetics in PDAC, we leveraged the DepMap database to identify metabolic dependencies in pancreatic cancer cells. Our unbiased analysis revealed Methionine Adenosyltransferase 2A (MAT2A) as a specific vulnerability. MAT2A is a key enzyme in the One Carbon Metabolism (OCM), the pathway for transferring single-carbon units to various substrates. Crucially, the OCM is integral to DNA and histone methylation processes by generating S-adenosylmethionine (SAM), the universal methyl donor whose availability is tightly regulated by MAT2A itself 13. Strikingly, preliminary data reveal a specific nuclear localization of MAT2A in metastatic liver lesions, contrasting with its distribution in primary tumors. Additionally, untargeted metabolomic analysis of human liver metastases revealed that most one-carbon metabolism (OCM) intermediates, including SAM, are downregulated, indicating a high demand for these metabolites in metastatic cells. To mimic these conditions, we developed a Metastasis-like Media (MLM), and our in vitro experiments confirmed that under these conditions, MAT2A translocates to the nucleus, binds to chromatin and is required to sustain histone methyltransferases (HMTs) activity, forming a previously unrecognized OCM nuclear network. Targeting the nuclear activity of MAT2A—including its chromatin binding and interactions with chromatin-associated proteins—could represent a novel therapeutic strategy for metastatic PDAC. Furthermore, this proposal seeks to elucidate the specific mechanisms by which one-carbon metabolism influences DNA and histone methylation patterns, an area that remains unexplored in cancer treatment. Understanding these underlying mechanisms will enable the identification of potential metabolism-targeted therapies to improve the prognosis for PDAC patients. <!--EndFragment-->

#0543 Prevalence and significance of PSAT1 expression in human cancer.

Fiete Gehrisch[1], Hendrina Contreras[1], Maximilian Lennartz[1], Katharina Moller[1], Nathalia Gorbokon[1], Martina Kluth[1], Claudia Hube-Magg[1], Maria Christina Tsourlakis[1], Nina Schraps[1], Florian Viehweger[1], David Dum[1], Andrea Hinsch[1], Christoph Fraune[1], Christian Bernreuther[1], Patrick Lebok[1], Guido Sauter[1], Till S. Clauditz[1], Till Krech[1], Andreas H. Marx[2], Ronald Simon[1], Eike Burandt[1], Sarah Minner[1], Stefan Steurer[1], Ria Schlichter[1], Seyma Buyucek[1]

[1]Institute of Pathology, University Medical Center Hamburg-Eppendorf, Hamburg, Germany,[2]Department of Pathology, Academic Hospital Fuerth, Fuerth, Germany

Phosphoserine aminotransferase 1 (PSAT1) is an enzyme involved in de novo biosynthesis of L-serine by catalyzing the conversion of 3-phosphohydroxy-pyruvate to 3-phosphoserine. This reaction simultaneously produces α-ketoglutarate, thereby directly linking serine biosynthesis to glutamine metabolism, the tricarboxylic acid cycle and one carbon metabolism. L-serine is a vital substrate for numerous cellular processes such as the synthesis of proteins and neurotransmitters as well as nucleotide production and cell proliferation. Previous studies have linked PSAT1 upregulation to enhanced tumor cell proliferation, invasion and migration in various tumor entities, thereby suggesting a crucial role for PSAT1 in cancer development and progression. To learn more on the prevalence of PSAT1 expression and potential associations with phenotype across human malignancies, this study analyzed PSAT1 protein expression in a cohort of 14,966 tumor tissue samples from 134 different tumor entities in a tissue microarray format. PSAT1 staining was cytoplasmic and/or nuclear and occurred in various normal cell types and was seen in at least a fraction of cases in most tumor entities (124 of 134; 91.8%). Out of the 12,305 interpretable tumor samples, PSAT1 staining was found in 4,633 samples, including 3,168 (25.7%) with weak, 765 (6.2%) with moderate, and 700 (5.7%) with strong positivity. PSAT1 staining positivity was particularly frequent and high level in granular cell tumor (92.7%), urothelial carcinoma of the bladder (47.7-91.0%), embryonal carcinoma of the testis (88.4%), several subtypes of uterine cancer (65.1-87.5%), adrenal cortical adenoma and carcinoma (65.2-86.0%), ovarian cancer (15.4-84.6%), colorectal neuroendocrine carcinoma (63.3%), paraganglioma (63.3%), and in squamous cell carcinomas from different sites (50.6-62.2%). High PSAT1 expression was associated with unfavorable tumor phenotype in invasive breast carcinoma of no special type, clear cell renal cell carcinoma, papillary renal cell carcinoma, gastric adenocarcinoma, adenocarcinoma of the colon, and endometrioid endometrial carcinoma ($p \leq 0.05$ each). Low PSAT1 expression was associated with invasive tumor growth in urothelial carcinoma ($p \leq 0.05$ each). In conclusion, our data establish PSAT1 as a highly upregulated metabolic enzyme across a broad spectrum of human tumors. Its potential as both a prognostic biomarker and a therapeutic target is supported by an association with aggressive clinicopathological features in numerous tumor types.

#0544 Dissecting the biological functions of various isoforms of ferredoxin reductase for cell survival and DNA damage response.

Kenichi Nakajima, Shakur Mohibi, Kyle Kenji Hong, Xinbin Chen, Jin Zhang

UC Davis, Davis, CA

The ferredoxin reductase (FDXR) gene is expressed as seven isoforms: 1-6 by alternative splicing and 7 by alternative promoter. FDXR, primarily the reference mitochondrial isoform 1, is required for biosynthesis of sterols, heme and iron-sulfur clusters, but isoforms 2-7 are undefined. Here, we found that isoform 1 is the most abundant one, accounting for ~70% of total FDXR whereas isoforms 4 and 7 account for ~10% and ~7%, respectively. We found that isoforms 1 and 4 are mainly localized in the mitochondria whereas isoform 7, which lacks a mitochondria localization signal, is expressed in the cytosol. We also found that like the promoter for isoforms 1-6, the P2 promoter for isoform 7 can be induced by DNA damage in a p53-dependent manner. To determine isoform-specific activity, we generated multiple MCF7 cell lines in that one or more isoforms are knocked out. While total FDXR-KO MCF7 cells are non-viable, cells deficient in isoforms 1-6, isoforms 4 or 7 remain viable but are weak in cell proliferation, DNA damage response and repair. These data suggest that each FDXR isoform contributes to cell survival and that isoform 7 has an extra-mitochondrial activity sufficient for cell survival.

#0545 PFAS-mediated DRP1 deamidation couples mitochondrial dynamics to purine biosynthesis.

Xinchi Xie[1], Yongzhen Liu[1], Chao Qin[1], Jessica Carriere[2], Pinghui Feng[1]

[1]Herman Ostrow School of Dentistry, USC - University of Southern California, Los Angeles, CA,[2]Cedars-Sinai Health System, Los Angeles, CA

Cancer cells dynamically remodel mitochondrial networks to balance energy production and biosynthetic precursor generation, but how mitochondrial dynamics are coordinated with specific biosynthetic pathways during cell cycle progression remains unclear. Phosphoribosylformylglycinamidine synthase (PFAS) is a key enzyme in *de novo* purine synthesis. It forms purinosome with other purine synthetic enzymes to support rapid nucleotide synthesis. As the scaffold of this mitochondria-adjacent multienzyme complex, how PFAS links mitochondrial dynamics to purine synthesis remains unknown. We found that PFAS deletion markedly impaired cancer cell proliferation and depleted the nucleotide pool. Moreover, PFAS deletion led to reduced cellular energy production and disrupted redox balance. Interestingly, hypoxanthine supplementation in PFAS-deleted cells successfully restored nucleotide levels to control levels, but it did not rescue redox balance or cell proliferation, indicating a purine-independent function of PFAS. Moreover, [U-^{13}C]glucose isotope tracing experiments demonstrated that PFAS deletion reduced glucose-derived carbon entry into the TCA cycle, consistent with suppressed oxidative metabolism. In parallel, [U-^{13}C]glutamine tracing revealed that glutamine contribution to TCA intermediates and aspartate was increased upon PFAS depletion, indicating a shift toward glutamine-supported anaplerosis. Furthermore, mitochondrial proteomics showed that PFAS deletion caused a compensatory upregulation of enzymes in tricarboxylic acid (TCA) cycle and electron transport chain. PFAS-deletion-mediated metabolic defects suggested an impaired mitochondrial function. We therefore examined mitochondrial morphology in control and PFAS-deleted cells. Indeed, transmission electron microscopy revealed strikingly increased fragmentated mitochondria in PFAS-deficient cells. We then focus on the molecular mechanisms by which PFAS regulates mitochondrial morphology. LC-MS/MS and biochemical assays demonstrated that PFAS is a bona fide deamidase of DRP1. Deamidated DRP1 (N267D/N268D) completely lost GTPase activity and showed impaired GTP binding activity, further failing to drive mitochondrial fission. Interestingly, DRP1 deamidation increased during G1 phase and peaked in S phase, coinciding with mitochondrial elongation and the heightened nucleotide synthesis. Thus, PFAS-mediated DRP1 deamidation couples mitochondrial networks to the metabolic demand of proliferative cells. Collectively, the *de novo* purine synthetic enzyme PFAS deamidates DRP1 to regulate mitochondrial morphology, further promoting mitochondrial oxidative phosphorylation and nucleotide synthesis. These findings uncover a previously unrecognized link between nucleotide biosynthesis and mitochondrial dynamics, providing a framework for targeting the PFAS-DRP1 axis in cancer.

#0549 BTM-3566 activation of the mitochondrial protease OMA1 increases sensitivity to venetoclax and azacitidine in acute myelogenous leukemia..

Matthew Kostura, Michael Luther, Todd Hembrough, Glen J. Weiss, Michael T. Stocum

Bantam Pharmaceutical, Durham, NC

Background: BTM-3566 is a member of the chemical class, 1-thiazol-2-yl-N-3-methyl-1H-pyrozole-5-carboxylic acids, which are potent, single agent anti-tumor agents in both B-cell lymphomas and select solid tumor malignancies. Therapeutic response is associated with activation of the mitochondrial metalloprotease OMA1. Drug induced activation of OMA1 leads to changes in mitochondria including alterations in cristae structure, morphology, and reduced expression of BH3 proteins such as MCL1. The therapeutic outcome is Bax-dependent apoptosis in B-cell lymphomas and regression or growth inhibition in solid tumors. We hypothesized that reductions in BH3 protein content and changes in mitochondrial cristae structure and function prime tumor cells for apoptosis. This may allow the use of BTM-3566 more broadly in conjunction with standard chemotherapy or targeted agents such as BH3 mimetics. Because venetoclax (a BH3 mimetic) and azacitidine are established standard-of-care (SOC) therapies for AML patients ineligible for intensive chemotherapy, we tested whether BTM-3566 enhances their activity. To test this hypothesis, BTM-3566 was evaluated in acute myelogenous leukemia (AML) cell lines to determine if synergy occurred in combination with venetoclax, azacytidine, or the ternary combination.
Methods: The activity of BTM-3566, venetoclax, and/or azacitidine was determined in AML cell lines (HL-60, Kasumi-1 and KG-1) using Cell-Titre Glo (CTG) which serves as a surrogate for cell numbers. Apoptosis was measured using Caspase 3/7 Glo. Drug activity interactions were quantified using Synergyfinder + software.
Results: BTM-3566 was active in all three AML cell lines (IC_{50} range 300-600 nM). BTM-3566 acted synergistically with venetoclax to inhibit cell growth in all cell lines, while synergy with azacitidine was observed only in HL-60 cells. The ternary combination of BTM-3566, venetoclax, and azacitidine resulted in increased cell killing with an apparent increase in the potency of venetoclax. Caspase 3/7 assays confirmed that BTM-3566 and venetoclax each induced a time-dependent increase in apoptosis in HL-60 and Kasumi-1, but not KG-1 cells. Binary drug treatment of venetoclax and BTM-3566 led to increased Caspase 3/7 activation and a BTM-3566 dose dependent increase in the activity of venetoclax in HL-60 and Kasumi-1 cells.
Conclusions: BTM-3566 targets a pathway important for mitochondrial integrity and control of apoptosis leading to reduced tumor cell growth and survival. Rational combinations of BTM-3566 with AML SOC agents demonstrate synergistic activity. Together, the findings support further evaluation of BTM-3566 to potentially broaden the utility of BH3-directed therapies in AML and potentially other difficult to treat malignancies. BTM-3566 is currently being evaluated in Phase I trials for DLBCL and select solid tumors.

#0550 Targeting heat shock factor 1 in pancreatic ductal adenocarcinoma autophagy and iron-sulfur cluster protein stability.

Rejina Shrestha, Shruti Ghai, Hannah Nam, Kuo-Hui Su

University of Toledo, Toledo, OH

Background: Pancreatic ductal adenocarcinoma (PDAC) cells exhibit elevated copper levels, an essential cofactor for cellular function, to support pancreatic tumor growth. Recent studies show that high levels of copper disrupt mitochondrial function by downregulating iron-sulfur (Fe-S) cluster proteins, leading to proteotoxic stress response and cell death; however, the detailed mechanism remains unclear. Heat shock factor 1 (HSF1), a key regulator of the proteotoxic stress response, is highly expressed in PDAC and supports protein stability, mitochondrial function, and tumor progression. This suggests HSF1 may help PDAC cells resist copper-induced cytotoxicity. The copper treatment also induces autophagy, yet whether copper-induced autophagy is regulated by HSF1 is not fully understood.
Objective: The objective of this study is to study the role of HSF1 in copper-mediated loss of mitochondrial Fe-S cluster proteins and autophagy in PDAC cells.
Methods and Results: In PDAC cell lines MIA PaCa-2 and PANC-1, treatment with copper ionophore elesclomol-copper (ES-Cu) led to reduced protein levels of mitochondrial Fe-S cluster proteins, including aconitase 2 (ACO2), ferredoxin 1 (FDX1), and lipoic acid synthase (LIAS), but not mRNA expression. Notably, HSF1 overexpression rescued the ES-Cu-decreased protein levels of ACO2, FDX1, and LIAS. Pharmacological inhibition of HSF1 led to increased lipidation of the autophagy marker microtubule-associated protein 1A/1B-light chain 3 (LC3). To investigate the mechanism of ES-Cu-mediated decrease of Fe-S cluster proteins, we pre-treated MIA PaCa-2 cells with hydroxychloroquine (CQ) along with ES-Cu. CQ did not rescue the ES-Cu-mediated decrease in Fe-S cluster proteins, suggesting that the degradation of Fe-S cluster proteins is not mediated by autophagy in copper-mediated cytotoxicity. Interestingly, inhibition of the mitochondrial-specific protease reversed the decrease in Fe-S cluster proteins under ES-Cu stress. Further, HSF1 inhibition with a small-molecule inhibitor significantly enhanced ES-Cu-reduced cell viability in PDAC cells.
Conclusion: Our findings suggest that HSF1 protects PDAC cells from mitochondrial toxicity by maintaining the stability of Fe-S proteins under copper stress. Targeting HSF1 in combination with copper-based therapies may enhance treatment efficacy by disrupting mitochondrial stress adaptation in PDAC.

#0551 Advancing cancer treatment through targeting dipeptidyl peptidase 8 an innovative strategy for overcoming resistance.

Paras Jawaid[1], Mati Ur Rehman[2], Azhar Hussain Rajabali[2], Ather Enam[3]

[1]Biological and Biomedical sciences, Centre of Oncological Research in Surgery, Aga Khan University Hospital, Karachi, Pakistan,[2]Biological and Biomedical Sciences, Aga Khan University Hospital, Karachi, Pakistan,[3]Neurosurgery, Centre for regenerative medicine and stem cell research, Aga Khan University, Karachi, Pakistan

Cancer remains one of the most complex and challenging diseases because of its heterogeneity and the ability of tumor cells to become resistant to the treatment. Among various cancers, glioblastoma and colon cancers are the most prevalent and deadliest cancer worldwide. It is responsible for significant burden on the healthcare system and affects millions of lives every year. Despite advancement in cancer treatment, including chemotherapy, radiotherapy, targeted therapies, and immunotherapy, achieving complete remission remains challenging that contributes to the poor prognosis of glioblastoma patients. One promising area of research involves a group of enzymes called dipeptidyl peptidases DPPs, a family of serine proteases which are known to regulate various biological processes, including immune function, metabolism, and cancer progression. Dipeptidyl peptidases DPPs, particularly DPP8, have emerged as promising molecular targets in cancer therapy. This study investigates the mechanistic role of DPP8 inhibition in glioblastoma and colorectal cancer cells. Cell viability was assessed using trypan blue and CCK8 assays, while apoptosis was evaluated via Giemsa staining, DNA fragmentation, Annexin V FITC PI, and cell cycle analysis. Flow cytometry revealed increased ROS production, loss of mitochondrial membrane potential and intracellular calcium level following treatment. Western blotting showed enhanced expression of apoptosis-related proteins 24 hr after treatment with DPP8 inhibitor. These findings suggest that DPP8 inhibition induce mitochondria mediated apoptotic pathways and may serve as a novel therapeutic strategy, offering potential for targeted and personalized cancer treatment approaches.

#0552 Functional effects of miPEP133 on mitochondrial integrity and treatment response in ovarian cancer.

Samantha Goncalves Novo, Miranda Mansolf, Tobias M. Hartwich, Jasmine Jathan, Viktoriia Kolesnyk, Yang Yang-Hartwich

Yale School of Medicine, New Haven, CT

Background: MiPEP133 is a microprotein encoded by the miR-34a precursor. In normal cells, it functions as a tumor suppressor and is expressed in colon, stomach, ovary, uterus, and pharynx, but its levels are markedly reduced in cancer. Localized in the mitochondria, miPEP133 regulates mitochondrial homeostasis through interactions with mitochondrial chaperones and has been reported to induce apoptosis and inhibit tumor cell migration in other cancer types. However, its functional role in ovarian cancer remains poorly defined. We investigated the biological impact of miPEP133 overexpression in patient-derived high grade serous ovarian cancer cell lines to further characterize its cellular effects and therapeutic relevance.

MethodsMiPEP133 was overexpressed in two patient-derived ovarian cancer cell lines using lentiviral vectors. Protein expression was confirmed by western blot. Cell growth kinetics were assessed using flow-cytometry-based proliferation assays. Mitochondrial morphology was evaluated by immunofluorescence staining. Sensitivity to chemotherapeutic agents (carboplatin and paclitaxel), MEK inhibitors, and mitochondrial modulators were measured using CellTiter-Glo assays. Apoptosis was quantified by Annexin V/PI staining and flow cytometry. Gene expression changes in treated and untreated miPEP133-overexpressing and control cells were evaluated by quantitative PCR (qPCR).

ResultsOverexpression of miPEP133 in the ovarian cancer cell lines led to a moderate reduction in cell proliferation, consistent with growth suppression. Immunofluorescence analysis revealed disruption of mitochondrial network structure and a decrease in mitochondrial mass. MiPEP133-overexpressing cells exhibited significantly increased sensitivity to MEK inhibitors and selected chemotherapeutic agents compared with control cells. Annexin V staining demonstrated increased apoptotic populations following chemotherapeutic treatment. qPCR analysis validated upregulation of genes involved in apoptosis, mitochondrial stress response, and oxidative stress pathways in miPEP133-overexpressing cells treated with MEK inhibitors and mitochondrial modulators.

ConclusionThese findings further characterize miPEP133 as a suppressor of ovarian cancer cell growth and a regulator of mitochondrial integrity in cancer cells. The restoration of miPEP133 function in ovarian cancer cells can enhance their sensitivity to chemotherapeutic and MEK-inhibitors. MiPEP133 represents a promising tumor suppressor with potential utility as both a therapeutic sensitizer and a biomarker in ovarian cancer.

#0553 Selective induction of cuproptosis in vivo by a soluble Elesclomol analog.

Piyush Mishra[1], Mainak Banerjee[2], Jian-Ren Lin[3], Shannon Coy[3], Jeffrey Hsiao[1], Jonah Lee[1], John Clohessey[1], Alexandre Detappe[4], Todd R. Golub[5], Loic Charbonniere[2], Sandro Santagata[3], Peter Tsvetkov[1]

[1]Beth Israel Deaconess Medical Center, Boston, MA,[2]Institut Pluridisciplinaire Hubert Curien, Universite de Strasbourg, Strasbourg, France,[3]Harvard Medical School, Boston, MA,[4]Strasbourg Drug Discovery and Development Institute (IMS), University of Strasbourg, Strasbourg, France,[5]Broad Institute, Cambridge, MA

Copper overload induced by specific ionophores can trigger cuproptosis, a newly defined form of regulated cell death that offers a novel strategy to target cancer. While this mechanism has been well characterized in cultured cells, its relevance in vivo and potential for therapeutic use remain unclear. The best-characterized ionophore, elesclomol (ES), had been previously tested in clinical trials with limited success; however, these studies were conducted without knowledge or consideration of its copper-binding mechanism or its ability to induce cuproptosis. Here, we define the biological and pharmacologic determinants of ES-induced cuproptosis in vivo, guiding the design of a more effective and tolerable ES analog. We first established that pre-bound ES (ES-Cu) is more potent and pharmacologically active than ES alone, maintaining on-target cuproptosis activity in culture and showing superior efficacy in a xenograft model. Although ES-Cu treatment produced marked tumor responses, complete regression was not achieved. To uncover mechanisms limiting response, we performed a genome-scale ORF overexpression screen and identified CYP11A1 and CYP27A1, mitochondrial partners of FDX1, as resistance factors. These findings indicate that FDX1 expression alone is not sufficient for sensitivity and that effective cuproptosis requires FDX1 activity uncoupled from CYP metabolism, a relationship that may also protect FDX1-high organs such as the adrenal gland and kidney from toxicity. To further overcome ES's poor solubility and pharmacokinetic limitations, we synthesized a new copper ES analog, which exhibits improved solubility, enhanced antitumor efficacy, and reduced systemic toxicity. Multiplexed imaging confirmed intratumoral aggregation of lipoylated proteins consistent with on-target cuproptosis induction. Together, these findings uncover a previously unrecognized role of FDX1-CYP coupling in regulating cuproptosis sensitivity and define a path toward biomarker-guided development of copper ionophore-based cancer therapies.

#0554 Asbestos exposure induces carcinogenesis via minority MOMP and displays characteristics of drug-tolerant persister cells.

Jaylon C. Aggison, Cristian G. Medina, Siqi Wu, Naren Li, Francisco A. Molina-Pelayo, Jessica B. Ji, Ritika Raj, Yuan Xu, Robert Taylor Ripley

Michael E. DeBakey Department of Surgery, Baylor College of Medicine, Houston, TX

Background Pleural mesothelioma (PM) occurs many years after asbestos fiber exposure; yet the mechanism that converts chronic damage into malignancy remains unclear. Asbestos fibers induce persistent oxidative and genomic stress that should activate apoptosis via mitochondrial outer membrane permeabilization (MOMP); however, these cells do not undergo apoptosis and instead develop into malignancy. MOMP normally triggers cytochrome c (cyt c) release as well as mitochondrially derived damage-associated molecular patterns (DAMPs), resulting in caspase activation and cell death. Sublethal activation of MOMP can lead to a phenomenon known as Incomplete or Minority mMOMP, in which cells survive and develop somatic mutations which contribute to carcinogenesis. In this study, we evaluated whether minority MOMP induced carcinogenesis in PM cells.

Methods We investigated whether prolonged exposure to asbestos fibers drives mMOMP in non-transformed, pleural mesothelial cells (MeT-5A). Cells were cultured for six months with chrysotile (Chry-Asb) or crocidolite (Croc-Asb) asbestos fibers. Cellular phenotypes were assessed by clonogenicity, migration, and invasion assays to evaluate malignant transformation. Reactive oxygen species (ROS) production, cytochrome (cyt) c release, γH2AX phosphorylation, and caspase 3 activation were measured to evaluate mitochondrial and apoptotic responses.

Results Chronic asbestos exposure increased clonogenicity, migration, and invasion of MeT-5A cells, suggesting transformation toward a malignant phenotype. Additionally, we observed the phenotypic characteristics of minority MOMP, including elevated ROS, cyt c release, an increase in the MOMP effector proteins (Bax/Bak), caspase activation, and γH2AX phosphorylation while lacking induction of apoptosis. Furthermore, the anti-apoptotic mitochondrial protein Myeloid Cell Leukemia-1 (MCL-1) was upregulated by asbestos, facilitating minority MOMP by preventing a shift to complete MOMP. Metabolomic analysis revealed a Warburg effect. Consistent with the Warburg effect, both Seahorse analysis and Gene Set Enrichment Analysis showed increased glycolysis in both cell lines. Additionally, asbestos-induced minority MOMP was associated with characteristics of drug-tolerant persister cells (DTPs) including slower proliferation, change in cell phenotype, and resistance to cisplatin.

Conclusion Minority MOMP promotes malignant transformation of mesothelial cells while enabling resistance to apoptosis. Our findings suggest that minority MOMP contributes to carcinogenesis by altering mitochondrial dynamics and metabolic reprogramming, reprogramming cells to a DTP phenotype. Targeting mitochondrial pathways to convert Minority MOMP into complete MOMP may represent a novel therapeutic strategy to overcome treatment resistance in pleural mesothelioma.

#0555 Prostaglandin E2 increases lipid droplet accumulation and peri-droplet mitochondria population in acute lymphoblastic leukemia.

Byourak Shabane, Cristiane Beninca, Michael Cohen, Nikole Scillitani, Ugochukwu Ihenacho, Orian Shirihai, Steven D. Mittelman

University of California, Los Angeles, Los Angeles, CA

Acute lymphoblastic leukemia (ALL) is the most prevalent childhood cancer, representing approximately 70% of all pediatric malignancies. While some patients attain remission following intensive chemotherapy regimens, multiple demographical and biological factors have been identified that worsen treatment outcomes. Obesity, clinically defined by body mass index (BMI), has been strongly associated with reduced survival rates, increased toxicity from chemotherapy, and increased risk of relapse. Our laboratory has previously demonstrated that adipose tissue supplies free unsaturated fatty acids and amino acids to ALL cells and protects the cells from chemotherapy. To identify the mechanisms by which adipose tissue alters the metabolism of ALL, we previously performed a single-cell RNA sequencing experiment on mice to compare the gene expression profiles of ALL cells between adipose tissue and bone marrow. This experiment uncovered a potential link between adipose tissue prostaglandin E2 (PGE2) synthesis and ALL cell lipid droplet maturation. To explore this, we cocultured human BV173 and RS4-11 ALL cells in transwell inserts above human visceral adipose tissue explants obtained from UCLA's Translational Pathology Core. Coculture with adipose tissue increased ALL cell lipid droplet-associated proteins perilipin (PLIN) 2 and 5 gene and protein expression (n=4-8). We next treated ALL cells with PGE2 (200ng/mL) and observed increased gene and protein expression in PLIN2 and PLIN5 (n=3-4). Confocal imaging confirmed that PGE2 induced lipid droplets in human ALL cell lines, along with peri-droplet mitochondria, a specialized subset of mitochondria known to promote lipid droplet synthesis. We hypothesize that adipose tissue PGE2 induces ALL cell lipid droplet accumulation and peri-droplet mitochondria formation and that these may contribute to protecting ALL cells from cytotoxicity.

PLIN5 and PLIN2 gene and protein expression in human ALL cells cocultured w human adipose explants

#0556 Inhibition of mitochondrial protein MAGMAS increases sensitivity to standard of care treatment.

Javier J. Lepe[1], Shashi Jain[2], Naomi Lomeli[1], Claire Chen[3], Bhaskar C. Das[4], Daniela A. Bota[1]

[1]UCI School of Medicine, Irvine, CA,[2]UCI School of Medicine,, Irvine, CA,[3]UCI, Irvine, CA,[4]Weill Cornell Medical College, New York, NY

Glioblastoma is a highly aggressive CNS cancer that affects 3 in 100,000 people every year in the U.S. The majority of patients experience tumor recurrence within the first year after initial diagnosis and after receiving standard of care treatment. GBM is characterized by its high mitotic index, capacity to invade other regions of the brain and modulate the tumor microenvironment (TME). Options are extremely limited for patients suffering from recurrent GBM as tumors become increasingly resistant to chemotherapy. Resistance to chemotherapy can be attributed to several factors that include DNA damage response (DDR), glioma stem cells (GSCs), TME, senescence mechanisms, and metabolic reprogramming. Mitochondria-associated granulocyte macrophage colony-stimulating factor molecule (MAGMAS), a mitochondria protein and subunit of the translocase of the inner membrane 23 (TIM23) complex, regulates protein trafficking into the mitochondria by recruiting DNAJC19 to the TIM23 complex. The present work was to investigate the role of MAGMAS in GBM tumor biology and mechanisms of resistance to TMZ. Computational analysis of MAGMAS/PAM16 expression levels from publicly available databases revealed that MAGMAS levels are significantly elevated in recurrent tumors and is positively correlated with the DNA repair enzyme O(6)-methylguanine-DNA methyltransferase (MGMT) expression in primary patient tissues. We generated genetically modified glioma cells expressing shpam16 constructs and found that MAGMAS deficient glioma cells were sensitized to standard of care treatment that include TMZ, radiation and tumor treating fields (TTFs). Additionally, we discovered that silencing PAM16/MAGMAS reduced MGMT expression and reduced extracellular excretion of lactic acid. Interestingly, we also discovered that the cytokine IL7 and IL15 were significantly upregulated in MAGMAS KD cells. Taken together, our results demonstrate that MAGMAS plays an important role in chemotherapy resistance, metabolic reprogramming and potentially modulating the TME. By targeting MAGMAS, we can promote favorable conditions to enhance anti-tumor response using immunotherapy strategies in the future.

#0557 TRAP1 represents a mitochondrial target and biomarker of dedifferentiated liposarcoma.

Roma Karna[1], Esin Ulker[2], Sydney Rentsch[1], Marina Capece[1], Sayumi Tahara[1], Qi Zhang[1], Patricia Sarchet[1], Giovanni Nigita[1], Paolo Fadda[1], Fernanda Costas Casal de Faria[1], Valerie Grignol[1], Nicholas C. Denko[2], Carlo M. Croce[3], Raphael E. Pollock[1], Federica Calore[1]

[1]The Ohio State University, Columbus, OH,[2]Dept. of Rad. Onc., OSU Comprehensive Cancer Center, Columbus, OH,[3]OSUCCC - James, Columbus, OH

Dedifferentiated liposarcoma (DDLPS) is a rare and aggressive adipocytic malignancy with a nearly 85% local recurrence rate, exceptionally high compared to other tumors, and a 10-year survival rate of only 10%. No reliable biomarkers currently predict recurrence or therapeutic response. Current management relies primarily on radical surgery, often combined with non-specific chemotherapy, which yields poor outcomes and severely compromises patients' quality of life. The aggressiveness of DDLPS and the lack of effective systemic therapies highlight an urgent need for novel molecular targets and treatment approaches.

We identified the mitochondrial chaperone TRAP1 (TNF Receptor-Associated Protein 1) as a potential oncogenic driver and therapeutic target in DDLPS. TRAP1 is a master regulator of mitochondrial metabolism, oxidative stress, and apoptosis, yet its role in DDLPS remains unknown. Our preliminary data show that TRAP1 protein and mRNA levels are significantly overexpressed in DDLPS compared to low grade well-differentiated liposarcoma (WDLPS) and Normal Adjacent Tissue (NAT), suggesting a contribution to tumor progression.

To explore its therapeutic potential, we silenced TRAP1 using siRNA and inhibited its activity with MitoQuinone (MitoQ), a TRAP1 inhibitor currently evaluated in non-cancer clinical trials. TRAP1 silencing significantly reduced DDLPS cell proliferation and increased cell death, as shown by MTS assays and Annexin V/PI assays. MitoQ treatment led to significant, dose- and time-dependent cytotoxicity in DDLPS cells compared to their WDLPS counterpart, and impaired spheroid growth in 3D models. Moreover, TRAP1 knockdown significantly decreased mitochondrial membrane potential compared to control conditions, and triggered G1/S cell-cycle arrest, indicating disruption of mitochondrial function.

Ongoing studies are investigating how TRAP1 modulation affects ROS production, mitochondrial dynamics and energy metabolism using Seahorse metabolic flux analysis, to define its contribution to metabolic reprogramming and redox balance in DDLPS. Finally, to establish TRAP1's clinical relevance, we will assess TRAP1 mRNA expression in a larger cohort of liposarcoma patient samples to correlate its levels with recurrence rates and survival outcomes. This work positions TRAP1 as a mitochondrial therapeutic target and potential biomarker, offering novel mechanistic insight and paving the way for innovative DDLPS treatment strategies.

#0558 Benzyl isothiocyanate induced mitochondrial dysfunction via ROS generation sensitizes head and neck squamous cell carcinoma to cisplatin and radiation.

Imani Aliah Kirven[1], Francesca Spirito[2], Patrice Penfornis[3], Kristin S. Edwards[1], Gary R. Bishoop[1], Linda L. Eastham[1], Chunli Yang[4], Rojymond Jacob[4], Pier Paolo Claudio[1]

[1]Pharmacology & Toxicology, University of Mississippi Medical Center, Jackson, MS,[2]Clinical and Experimental Medicine, University of Foggia, Foggia, Italy,[3]Cancer Institute, University of Mississippi Medical Center, Jackson, MS,[4]Radiation and Oncology, University of Mississippi Medical Center, Jackson, MS

Accounting for nearly 4% of all cancer diagnoses and 2% of all cancer-related mortality in the United States, head and neck squamous cell carcinoma (HNSCC) originates from the squamous epithelial cells lining the mucosal surfaces of the oral cavity, pharynx, larynx, lips, and sinonasal tract. HNSCC is notable for its resistance to conventional therapy, with mitochondria serving as central mediators through multifaceted contributions, including the regulation of cellular signaling pathways, modulation of energy metabolism, and control of apoptotic responses. Although modulation of mitochondrial pathways has emerged as a potential therapeutic target, its role in HNSCC progression and treatment response remains incompletely understood. Benzyl isothiocyanate (BITC), a naturally derived bioactive compound found in cruciferous vegetables, selectively induces excessive reactive oxygen species (ROS) and depletes glutathione in cancer cells, leading to mitochondrial dysfunction and impaired bioenergetic flexibility. Building on the role of mitochondria in therapeutic resistance, we explored the effects of BITC in sensitizing paired primary and metastatic HNSCC cell lines isolated from two patients to cisplatin (CDDP) and radiotherapy (RT). Cell viability and caspase-3/7 activity were assessed at 72 hours on HNSCC cells pretreated for 1 hour with BITC, followed by 24 hours of cisplatin with or without the addition of 4 or 8 Gy radiation. Electron Paramagnetic Resonance (EPR) and glutathione (GSH) rescue assays were used to measure oxidative stress, identify different types of ROS produced, and investigate resistance mechanisms to therapy after up to 24 hours of BITC exposure. Real-time fluororespirometry was employed to evaluate the overall mitochondrial bioenergetic status, also following up to 24 hours of BITC exposure. In all four HNSCC lines, BITC treatment significantly increased sensitivity to both CDDP and RT by inducing apoptosis through Caspase-3/7 activation. BITC treatment effectively induced ROS, which was rescued by the addition of GSH. Within one hour, BITC exposure induced a pronounced decline in mitochondrial respiration and Bioenergetic Health Index (BHI), followed by a transient increase in respiration at 3-5 hours, suggesting metabolic reprogramming. However, by 24 hours, metabolic exhaustion culminated in cell death. Our findings demonstrate that BITC disrupts mitochondrial bioenergetics, limits metabolic adaptability, and increases the efficacy of standard-of-care therapies through excessive ROS production, supporting its potential as a novel adjuvant therapeutic strategy for HNSCC.

#0559 Combination of PRMT5 and Mcl-1 inhibitors overcomes immune checkpoint inhibitor resistance in pleural mesothelioma.

Siqi Wu, Jaylon Aggison, Cristian Medina, Naren Li, Francisco Molina-Pelayo, Ritika Raj, Yuan Xu, Robert T. Ripley

Baylor College of Medicine, Houston, TX

Introduction: Pleural mesothelioma (PM) is an aggressive cancer with a poor prognosis. Primary resistance to chemotherapy and immune checkpoint inhibitors (ICI) is common, demanding new therapeutic strategies. Our previous work showed the anti-apoptotic protein, Myeloid Cell Leukemia 1(MCL-1) drives chemoresistance. What is unknown is whether targeting MCL-1 will sensitize PM to ICIs. Our multi-omic data linked Mcl-1 to ICI resistance through the methionine metabolic pathway, in which PRMT5 is a critical enzyme. This study evaluates whether targeting the PRMT5/MCL-1 axis will overcome ICI resistance in PM to increase response rates.
Methods: Inhibition of PRMT5 and Mcl-1 was assessed in PM cell lines (H28 and H2452) and Patient-Derived Xenograft (PDX) models. Transcriptomics, metabolomics and reverse-phase protein array were performed on PDX model comparing treatment arms of PRMT5 inhibition, MCL-1 inhibition, and the combination (Cmb) versus vehicle control (Cnt). Additionally, ICI treatment response was evaluated by in *vitro* T-cell co-culture assays. The synergistic effects of PRMT5 and Mcl-1 inhibition were investigated in PM lines by Western Blot with both shRNA-mediated gene knockdown or inhibitor treatment. Annexin V/propidium Iodide staining and flow cytometry analysis were performed.
Results: In vitro, the combination of PRMT5 and Mcl-1 inhibition significantly increased apoptosis compared to either single agent alone and control (Cnt vs Cmb, H28: 8.1% vs 34.1%; H2452: 7.2% vs 25.1%). These cells also displayed synergistic lack of proliferation (Cnt vs Cmb: H28: ~1.6-fold; H2452: ~2-fold). In the PDX model, PRMT5 and Mcl-1 inhibition showed a significant decrease of tumor growth (Cnt vs Cmb: ~1.8-fold). Multi-omic analyses implicated the PI3K/Akt signaling pathway in tumor growth suppression with the combined treatment. Western blot analysis confirmed this mechanism based on phosphorylation of proteins in PI3K/Akt and mTOR signaling pathway, including GSK-3a/b, PRAS40, mTOR, TSC2, P70S6K and AKT1. The combination of PRMT5 and Mcl-1 inhibitors also showed a significant improvement of ICI (anti-PD-L1) response in *vitro* (Cnt vs Cmb: ~1.4-fold).
Conclusion: Co-targeting PRMT5 and Mcl-1 synergistically enhance apoptosis and proliferation via PI3K/Akt/mTOR pathway in PM. Inhibition of PRMT5/Mcl-1 axis may improve treatment response and overcome primary resistance. Our findings provide a novel strategy to translate into clinical trials.

#0563 WEE1 reinforces C-MYC driven oncogenic programs through GSK3ß inhibition.

Krishnapriya Thangaretnam[1], Islam MD Obaidul[2], Jialun Lyu[2], Zhenzhen Zhang[1], Lei Chen[2], Farah Ballout[1], Heng Lu[1], Dunfa Peng[3], Alexander I. Zaika[4], Wael El-Rifai[5], Zheng Chen[6]

[1]University of Miami Miller School of Medicine, Miami, FL,[2]Surgery, University of Miami Miller School of Medicine, Miami, FL,[3]University of Miami, Miami, FL,[4]Professor of Surgery & Cancer Biology, University of Miami, Miami, FL,[5]Director, Surgical Oncology Research, University of Miami, Miami, FL,[6]Surgery, University of Miami, Miami, FL

Background: Esophageal adenocarcinoma (EAC) remains a lethal malignancy with a 5-year survival rate below 20%. The nuclear kinase WEE1 is a key regulator of the G2/M checkpoint, whereas the oncogenic transcription factor c-MYC, dysregulated in ~70% of human cancers, is challenging to target directly. Identifying upstream regulators that control MYC stability offers an alternative therapeutic strategy. Here, we discovered that WEE1 reinforces MYC-driven oncogenic programs by inhibiting GSK3β, and that inhibition of WEE1 promotes proteasome-mediated MYC degradation.
Methods and Results: Gene set enrichment analysis across TCGA and GEO datasets showed consistent enrichment of MYC target gene signatures in WEE1-high EAC tumors. Immunofluorescence in normal esophagus and EAC tissues demonstrated strong overexpression and positive correlation between WEE1 and C-MYC, which was also validated in EAC cell lines compared to non-cancerous and Barrett's esophagus cells. Genetic knockdown or pharmacologic inhibition of WEE1 reduced MYC protein levels, transcriptional activity, and downstream gene expression, as confirmed by reporter assays, qRT-PCR, and RNA sequencing. Cycloheximide chase assays revealed a shortened MYC half-life upon WEE1 inhibition, whereas the proteasome inhibitor MG132 rescued MYC degradation.
Mechanistically, WEE1 inhibition activated GSK3β, a kinase required for MYC ubiquitination and proteasomal turnover. Conversely, WEE1 overexpression stabilized MYC by elevating inhibitory GSK3β-S9 phosphorylation. A kinase-dead WEE1 mutant failed to stabilize MYC, indicating a catalytic-activity-dependent mechanism. Proximity ligation assays further demonstrated increased GSK3β-MYC interaction following WEE1 inhibition. A high-throughput screen of 892 FDA-approved drugs identified Panobinostat as a synergistic partner of the WEE1 inhibitor MK1775. The combination significantly
suppressed the growth of human EAC PDX-derived organoids and inhibited tumor progression in EAC PDX models in vivo.
Conclusion: These findings define a WEE1-GSK3β-MYC signaling axis in which WEE1 stabilizes MYC and sustains MYC-driven oncogenic programs. WEE1 inhibition activates GSK3β, promoting proteasome-mediated MYC degradation. The combination of WEE1 inhibition and Panobinostat represents a promising therapeutic approach for MYC-driven EAC.

#0564 Clonal diversity drives cooperative growth in lung cancer.

Yan Jennifer Gu[1], Salil Garg[2]

[1]Laboratory Medicine, Yale School of Medicine, New Haven, CT,[2]Laboratory Medicine, Genetics, Pathology, Yale University, New Haven, CT

Cell-cell communication within the tumor microenvironment is critical for cancer growth and therapy resistance. While many studies have focused on interactions between tumor cells and the surrounding microenvironment, this study investigates how interactions between distinct tumor cell states contribute to tumor growth. We constructed an in vitro system using the H1975-Clonebow lung cancer cell line, which allows for stochastic recombination of distinct fluorescent proteins to yield unique color signatures for lineage tracing. From the parental H1975-Clonebow line, we derived and expanded 218 single-cell clones and compared each clone's growth rate to the heterogeneous parental population. The parental line grew faster than 86% of clones, suggesting a cooperative advantage of clonal diversity. Systematic "mixing" at fixed total cell numbers showed that mixed-clone populations consistently outperformed single clones, which we interpret as evidence for adaptive heterogeneity. Across 4-clone mixes, quantification during unmixing revealed that both fast- and slow-growing clones proliferated better in mixtures than in isolation, indicating non-random cooperation that promotes collective growth. To capture cooperation-associated programs, we performed bulk RNA-seq on clones fluorescently sorted after 4-clone mixing, with identically sorted single-clone cultures grown alone as controls. Transcriptomes clustered primarily by clone identity but converged on shared signaling modules in mixes, consistent with the observed growth boost. Mix-induced gene programs were more strongly enriched in malignant cells from patient-derived NSCLC tumors than programs from individually grown clones. Ligand-receptor (LR) analysis highlighted an integrin-centered adhesion program: multiple integrin LR pairs consistently ranked among the top tumor cell-cell interactions in vitro and in patient tumors, with β1-integrin (ITGB1) recurring as a hub. Consistent with this, β1-integrin blockade preferentially reduced the mix-specific growth advantage. Future experiments will involve longitudinal live-cell imaging to directly test whether the cooperative growth phenotype requires sustained inter-clone contact. Together, these data suggest that emergent cooperation between tumor cells promotes growth and may be targetable for therapeutics. Targeting β1-integrin-mediated adhesion at the tumor cell-cell interface represents a feasible strategy to disrupt cooperative growth in EGFR-mutant lung cancer.

#0565 Establishing the mechanistic link between chemotherapy response and Hippo-YAP signaling in ovarian cancer.

Jonathan C. Vose, Elizabeth I. Harper, Sheetal Kooduvalli, Joanne Kotelawala, Ashani Weeraratna, Jennifer M. Kavran

Biochemistry and Molecular Biology, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD

Ovarian cancer is one of the leading causes of cancer related deaths for women. First-line treatment includes surgical resection followed by a regimen of cisplatin. More than 70% of tumors, however, acquire chemoresistance. Our understanding of the molecular mechanisms mediating this resistance remains limited. Increased expression of YAP, a transcriptional co-factor inhibited by the Hippo pathway, correlates with poor prognosis, and is a biomarker of poor response to metal-based chemotherapies; yet the mechanistic link between chemotherapy treatment, regulation and changes of YAP driven transcription, and tumor cell response remains unclear. Using a combination of biochemistry, biophysics, and cell-based assays we sought to determine the molecular mechanism and consequences of cisplatin induced YAP activation in ovarian cancer. To determine whether and how cisplatin alters YAP activity in ovarian cancer, we monitored YAP localization, using immunofluorescence, and YAP target-gene transcription, using qPCR, in two ovarian cancer cell lines in the presence or absence of treatment. We find that cisplatin increased YAP nuclear localization and target gene transcription. To identify the step in Hippo signal transduction inhibited by cisplatin, we monitored known phosphorylation events in the Hippo core kinase cassette, via Western blot, in both ovarian cancer cells and in a recombinant system using purified proteins in the presence or absence of cisplatin. In both scenarios, we find that cisplatin prevented activation of the Hippo kinase LATS1/2 but did not alter the activity of the upstream Hippo kinase MST1/2. To determine the mechanism by which cisplatin inhibits LATS1/2, we monitored the solution behavior of LATS1 and its allosteric activator MOB1A; using mass photometry we find that the addition of cisplatin disrupts complex formation between LATS1 and MOB1A. Together, our data provides the first insights into the molecular mechanism by which cisplatin inhibits signal transduction in the Hippo pathway driving YAP activation in ovarian cancer. Future work aims to identify the YAP driven transcriptional changes that mediate chemoresistance to identify potential therapeutic strategies.

#0566 UVRAG-ITCH-ESCRT axis mediates a lysosomal off-switch dampening NOTCH1 signaling in cancer.

Behzad Mansoori[1], Zihan Zheng[1], Chintan Parekh[2], Chengyu Liang[1]

[1]The Wistar Institute, Philadelphia, PA,[2]Children's Hospital Los Angeles, Los Angeles, CA

NOTCH1 signaling is a conserved pathway essential for cell fate decisions, and its dysregulation drives multiple cancers such as T-cell acute lymphoblastic leukemia (T-ALL). Precise control of NOTCH1 signal strength and duration is critical, yet mechanisms fine-tune NOTCH1 signaling remains poorly understood. Here we identify a previously unrecognized endo-lysosomal “off-switch” for NOTCH1 mediated by the UVRAG-ITCH axis. We demonstrate that UVRAG (UV radiation resistance-associated gene), traditionally known for its role in autophagy, acts independently of autophagy to negatively regulate NOTCH1 signaling. UVRAG physically engages the membrane-tethered NOTCH1 extracellular truncation (NOTCH1ΔE), the activated intermediate generated after ligand-induced or mutational S2 cleavage, and recruits the E3 ubiquitin ligase ITCH. The UVRAG-ITCH complex catalyzes non-canonical Lys27-linked ubiquitination of NOTCH1ΔE at a conserved lysine (K1795) in its RAM domain, thereby tagging this intermediate for recognition by endosomal sorting complexes (ESCRT) and routing to lysosomes for degradation. Consequently, UVRAG-ITCH-mediated degradation of NOTCH1ΔE limits its availability for γ-secretase (S3) cleavage, reducing the generation of the NOTCH1 intracellular domain (NICD) and attenuating downstream transcriptional activity. Disruption of this UVRAG-ITCH-ESCRT checkpoint leads to accumulation of NOTCH1ΔE and excessive NICD production. In T-ALL cells harboring hyperactive NOTCH1 mutations, we found that UVRAG expression is often suppressed. Restoration of UVRAG in T-ALL models reinstated the lysosomal off-switch: it promoted NOTCH1ΔE ubiquitination and degradation, lowered NICD levels, and dampened oncogenic NOTCH1 signaling. UVRAG re-expression in these cells significantly impaired leukemia cell proliferation and self-renewal, reduced the population of leukemia-initiating cells, and even enabled partial differentiation of malignant T-cell blasts. Notably, reinstating UVRAG also sensitized T-ALL cells to γ-secretase inhibitors (GSIs). The combination of UVRAG reactivation with GSI treatment synergistically induced apoptosis and tumor regression. In xenograft and patient-derived T-ALL models, enforced UVRAG expression combined with GSI therapy dramatically reduced leukemic burden and prolonged survival, underscoring the therapeutic potential of co-targeting this pathway. In conclusion, our study reveals that the UVRAG-ITCH axis functions as a lysosomal off-switch to terminate aberrant NOTCH1 signaling at the membrane intermediate stage. This degradation-based checkpoint offers a novel therapeutic target to restrain NOTCH1-driven malignancies and potentially enhance the efficacy of NOTCH1 pathway inhibitors.

#0567 SGK1 may represent a therapeutic target in BRAF-mutant melanoma.

Boyd Griffiths[1], Camden VanTassell[1], Joshua Knight[1], Madison Hawkins[1], Landen Barnett[1], Katie Culver[2], Ashley Thompson-Chadwick[2], Sheri L. Holmen[3], Gennie Lynne Parkman[1]

[1]Dept of Zoology, Weber State University, Ogden, UT,[2]University of Utah, Salt Lake City, UT,[3]University of Utah Huntsman Cancer Institute, Salt Lake City, UT

Despite advancements in treatment, the five-year survival rate for Stage IV melanoma remains low, around 30%, highlighting the urgent need for new therapies. Two key signaling pathways, RAS>RAF>MEK>ERK (MAPK) and PI3K>AKT, are often co-activated in melanoma and play a central role in its initiation and progression. About 50% of melanomas have a BRAF mutation, but many patients develop resistance to therapies targeting this pathway. Additionally, disruptions in the PI3K>AKT pathway, such as loss of the tumor suppressor PTEN or activation of PI3K or AKT, are common in BRAF-mutant melanomas. Despite promising preclinical studies, no PI3K or AKT inhibitors have been approved for advanced melanoma treatment. The serine/threonine kinase SGK1 (serum and glucocorticoid-regulated kinase 1) plays a pivotal role in cellular processes such as survival, proliferation, and migration, and has been implicated in various cancers, including melanoma. Our previous work has shown that AKT was inhibited, SGK1 was upregulated, potentially rescuing cell survival and acting as an inherent resistance mechanism for AKT inhibition. SGK1 was also found to be higher in primary melanoma tumors compared to normal skin lesions. *In vivo* experiments in a mouse melanoma model demonstrate that overexpressing SGK1 promotes tumor growth and reduces survival, and these experiments are currently ongoing to examine the impact on metastasis in this mice. These findings position SGK1 as a promising therapeutic target for melanoma, particularly in combination with existing treatment strategies. This body of work underscores the importance of further investigating SGK1's molecular mechanisms and its potential to improve melanoma treatment outcomes.

#0568 The YAP1-IGFBP2 axis as a predictive biomarker and therapeutic target in gastric cancer metastasis.

Emily Hancin[1], Hyun-Kyung Ko[2], Madeline B. Torres[1], Xiaodan Yao[3], Yibo Fan[4], Melissa Pool Pizzi[4], Shilpa S. Dhar[5], Francis Spitz[1], Generosa Grana[2], Jaffer A. Ajani[5], Shumei Song[3]

[1]Department of Surgery, Cooper University Hospital, Camden, NJ,[2]MD Anderson Cancer Center at Cooper, Camden, NJ,[3]Coriell Institute for Medical Research, Camden, NJ,[4]Department of GI Medical Oncology, The University of Texas MD Anderson Cancer Center, Houston, TX,[5]The University of Texas MD Anderson Cancer Center, Houston, TX

Background: Gastric cancer (GC) with peritoneal metastasis (PM) carries a poor prognosis, with a five-year survival rate of only 5%. Insulin-like growth factor binding protein 2 (IGFBP2) has been implicated in tumor proliferation, invasion, and metastasis through both IGF-dependent and independent mechanisms in various cancers. However, its role in GC progression and PM remains undefined. This study investigates the functional significance of the IGFBP2-YAP1 axis in GC tumorigenesis and metastasis, particularly to the peritoneum.

Methods: Single-cell RNA sequencing (scRNA-seq) of GC primary tumors, matched normal tissues, and PM was performed to characterize IGFBP2 expression across cellular compartments. Bulk RNA sequencing of Yes-associated protein 1 (YAP1) knockout (KO) vs control GC cell lines, followed by quantitative PCR (qPCR) and enzyme-linked immunosorbent assay (ELISA), evaluated YAP1-dependent regulation of IGFBP2 transcription and secretion. Protein expression of IGFBP2 and YAP1 was assessed by Western blotting (WB) in multiple GC cell lines. IGFBP2 knockdown (KD) was achieved by short-hairpin RNA (shRNA) vectors in HGC27 and MKN7 cells. ELISA, migration, and invasion assays were conducted to determine the functional impact upon depletion of IGFBP2.

Results: scRNA-seq revealed that both YAP1 and IGFBP2 are highly enriched in PM of GC compared to primary and normal gastric tissues, and their elevated expression correlates with poor prognosis. Among nine GC cell lines, AGS, GA0518, SNU16, HGC27, and MKN7 cells exhibited high expression of both YAP1 and IGFBP2 proteins. RNAseq of YAP1 KO vs control cells revealed significant downregulation of IGFBP2 upon YAP1 depletion, implicating YAP1 as an upstream regulator. Consistently, qPCR and ELISA confirmed reduced IGFBP2 transcription and secreted protein levels in YAP1 KO cells. Functionally, recombinant IGFBP2 (rIGFBP2) rescued the impaired invasiveness of YAP1 KO patient-derived GC PM cells (GA0518). IGFBP2 KD in HGC27 and MKN7 cells was validated by qPCR and WB, and these cell lines demonstrated reduced extracellular IGFBP2 levels along with diminished migration and invasion compared with controls.

Conclusions: Our findings define the YAP1-IGFBP2 axis as a key driver of GC and PM. Elevated co-expression of IGFBP2 and YAP1 in PM, combined with loss of function studies demonstrating reduced migration and invasion upon IGFBP2 deletion, underscores their cooperative role in metastatic adaptation. These findings identify IGFBP2 as a YAP1-regulated effector that promotes tumor aggressiveness, highlighting the clinical potential of targeting the YAP1-IGFBP2 axis. Collectively, the YAP1-IGFBP2 axis may serve as both a predictive and prognostic biomarker and a promising therapeutic target for advanced GC patients with PM.

#0569 Acetylcholine-induced YAP stabilization enhances HIF-1 signaling under hypoxia via the nAchR-α7/PI3K/PDPK1 pathway in pancreatic cancer cells.

Yunmi Cho, Ha Hyeong Kim, Eun-Taex Oh

Department of Biomedical Sciences, Inha University College of Medicine, Incheon, Korea, Republic of

The pancreas is highly innervated by the autonomic nervous system. Recent studies have extensively addressed the potential role of the autonomic nervous system in the development of pancreatic ductal adenocarcinoma (PDAC).Hypoxia-inducible factor-1α (HIF-1α) regulates tumor adaptation to hypoxia by controlling genes linked to angiogenesis, metastasis, and therapy resistance. We previously showed that neurotransmitter acetylcholine (Ach) enhances HIF-1α expression in pancreatic cancer cells via the nAchR-α7/PDPK1/YAP pathway under hypoxia, but the underlying molecular mechanisms remained unclear. Following our previous findings, this study aims to elucidate the molecular signaling mechanism by which Ach regulates HIF-1α expression under hypoxic conditions in pancreatic cancer cells. Here, we treated human pancreatic cancer cells with Ach under 0.5% oxygen. Protein levels, phosphorylation, and interactions were assessed using Western blot, qRT-PCR, and co-immunoprecipitation. PI3K, PDPK1, and YAP expression were silenced by siRNA. In vivo, the effect of Ach was tested using tail-vein Ach injections in a subcutaneous xenograft mouse model. We found that Ach activated PI3K downstream of nAchR-α7, increasing PDPK1 phosphorylation. This reduced YAP phosphorylation at serine 397, stabilizing YAP and promoting its nuclear translocation. In the nucleus, YAP bound to HIF-1α, enhancing its stability and transcriptional activity. Knockdown of PI3K, PDPK1, or YAP suppressed Ach-induced HIF-1α upregulation. *In vivo*, Ach significantly promoted tumor growth in mice implanted with control pancreatic cancer cells, but had no effect in mice bearing tumors derived from nAchR-α7-silenced cells. Analysis of clinical datasets revealed that high nAchR-α7 expression correlates with poor prognosis in PDAC patients. Collectively, these findings reveal that Ach promotes pancreatic tumor progression under hypoxia via the nAchR-α7/PI3K/PDPK1/YAP pathway, which stabilizes HIF-1α. This signaling axis represents a promising therapeutic target in acetylcholine-associated pancreatic cancer.

#0570 Soft extracellular matrix orchestrates gastric cancer progression by triggering RNF146-mediated AMOT degradation and YAP/TAZ-driven senescence in macrophages.

Guofei Deng[1], Yusheng Luo[1], Yuxi Pan[1], Xiaorong Lin[1], Yuzhi Zhang[1], Yuqing Lin[1], Fuhui Wang[2], Jiancheng Wang[1], Shuo Fang[1]

[1]The Seventh Affiliated Hospital of Sun Yat-sen University, Shenzhen, China,[2]University of South Florida, Tampa, FL

The mechanical properties of the tumor microenvironment (TME) are critical regulators of cancer progression. While the role of a stiff extracellular matrix (ECM) is well-established, how soft ECM—common in early or remodeled tumors—modulates immune function in gastric cancer remains elusive. This study unveils a complete mechano-immunological pathway wherein soft ECM drives tumorigenesis by inducing pro-tumorigenic senescence in tumor-associated macrophages (TAMs). We demonstrate that soft ECM initiates this cascade through cytoskeletal remodeling and F-actin depolymerization, which displaces Angiomotin (AMOT) from the actin network, increasing its cytoplasmic pool. The liberated AMOT is then specifically targeted by the E3 ubiquitin ligase RNF146, which is upregulated in TAMs in response to soft mechanical cues, leading to AMOT ubiquitination and proteasomal degradation. This degradation relieves the cytoplasmic sequestration of YAP/TAZ, enabling their nuclear translocation and transcriptional activation within TAMs. This mechanochemical reprogramming initiates a distinct senescence-associated secretory phenotype (SASP), characterized by elevated secretion of CCL2, IL-8, MMP-12, and TGF-β, which collectively promote tumor cell invasion, angiogenesis, and immunosuppression. Functional validation using co-culture assays and orthotopic gastric cancer models confirmed that RNF146-mediated AMOT loss is sufficient to induce senescence and accelerate tumor growth and metastasis. Conversely, myeloid-specific RNF146 knockout stabilized AMOT, suppressed the SASP, and potently inhibited tumor progression. Our findings thereby delineate a complete pathological axis in gastric cancer: from soft ECM sensing and cytoskeletal remodeling to RNF146-mediated degradation of displaced AMOT, YAP/TAZ-driven macrophage senescence, and ultimately tumor progression. This work resolves the long-standing paradox of soft ECM in cancer by mechanistically linking it to pro-tumorigenic immune senescence, and nominates the RNF146-AMOT axis as a novel and promising stromal target for therapeutic intervention.

#0571 WNT and Notch crosstalk in pregnancy-associated breast cancer.

Charles Moore, Wen-Cheng Chung, Shifa Khan, Keli Xu

UMMC Cancer Center and Research Institute, Jackson, MS

Introduction Pregnancy-Associated Breast Cancer (PABC) is defined as breast cancer diagnosed during pregnancy, lactation, or throughout the post-partum period. Approximately 1 in 3000 pregnant women will be diagnosed with this condition. The purpose of this study was to identify cell-of-origin and relevant signaling pathways implicated in the development and progression of PABC.
Methods Immunohistochemistry was used for lineage tracing and protein expression patterns. Tumor-free survival calculations were made to asses tumor onset phenotypes in transgenic mice. Western blot was used to determine protein expression differences in comparative genotypes.
Unpublished Data We have generated a PABC mouse model by crossing oncogenic $Kras^{G12D}$ with WAP-Cre mice. These mice develop tumors in a pregnancy-dependent manner that are histologically heterogeneous as well as estrogen and progesterone receptor negative. Our model recapitulates many features of PABC, including aggressive biological nature and frequent lung metastasis. Indeed, nearly all mice developed distant lung tumors during the lactational period. Preliminary studies using this model suggest that alveolar progenitor cell populations may represent the primary cell-of-origin in PABC. Lineage tracing in virgin mammary glands revealed very few cells labeled by WAP-Cre. Interestingly, mice that express $Kras^{G12D}$ exhibited drastic expansion of WAP-labeled cells, along with the development of precancerous lesions, even before pregnancy. WNT and Notch, two evolutionarily conserved pathways, regulate the fate of alveolar progenitors in normal mice, where dysregulation of these pathways facilitates oncogenic transformation and rapid tumor formation. Deletion of Notch3 significantly delayed Kras-driven tumor onset. Surprisingly, deletion of Jagged1, a Notch ligand, accelerated tumor onset. Further lineage tracing shows that deletion of Notch3 reduced the number of WAP-labeled progenitor population. Contrastingly, Jagged1 deletion leads to an expansion of WAP-labeled cells. Interestingly, despite accelerated tumor onset, deletion of Jagged1 significantly reduced the incidence of lung metastasis. In all mice, some percentage of tumor histology demonstrated a squamous phenotype. Deletion of Jagged1 resulted in 100% of these tumors developing a squamous phenotype. Overexpression of beta-catenin, the signaling effector of WNT, has been shown to promote squamous transdifferentiation. We show an increase in beta-catenin associated with the deletion of Jagged1. Additionally, strong positive immunostaining for non-phosphorylated, active, beta-catenin in Kras;WAP-Cre tumors was seen.
Conclusions These findings suggest a crosstalk between Notch and WNT signaling. We propose that WAP-labeled alveolar progenitor cells serve as the cell-of-origin in PABC and that Notch and WNT signaling are key factors in tumor initiation, progression, and metastasis.

#0572 Defining a DLG5-NUAK2-LATS1 complex that regulates Hippo signaling output.

Youchen Song[1], Abiodun Ogunjimi[2], Siyuan Song[3], Jeffrey L. Wrana[2], Liliana Attisano[3]

[1]Medical Biophysics, Univ. of Toronto Faculty of Medicine, Toronto, ON, Canada,[2]Lunenfeld-Tanenbaum Research Institute, Toronto, ON, Canada,[3]Biochemistry, Univ. of Toronto Faculty of Medicine, Toronto, ON, Canada

Introduction: The Hippo signaling pathway is a critical regulator of cell growth and organ size, and its dysregulation, leading to activation of the transcriptional effectors YAP/TAZ, is common in solid cancers. The AMPK-related kinase NUAK2 is an established positive regulator of Hippo signaling through its interaction with LATS1, yet the precise mechanisms governing this interaction remain undefined. Our research aimed to identify novel proximal interactors of NUAK2 to uncover new regulatory complexes that control Hippo pathway output.

Methods: We utilized a BioID-mass spectrometry screen to identify NUAK2 proximal interactors. Validation of protein-protein interactions was performed using co-immunoprecipitation and GST pull-down assays. The potential structure interface was predicted using AlphaFold, and the physical assembly of the complex was validated via Ni-NTA affinity purification. The effect of DLG5 loss on Hippo signaling was assessed in both 2D cancer cell lines and 3D colorectal cancer organoids by RT-qPCR of Hippo target genes, immunofluorescence microscope for YAP/TAZ localization, and cell growth assays.

Results: Our proteomic screen identified the scaffolding protein DLG5 as a prominent and novel NUAK2 interactor. We subsequently validated that DLG5 scaffolds a trimeric complex, co-eluting with both NUAK2 and the core Hippo kinase LATS1 in affinity purification assays. Functionally, knockdown of DLG5 disrupted Hippo signaling, leading to YAP/TAZ cytoplasmic localization and a corresponding decrease in the transcription of canonical YAP/TAZ target genes (e.g., *ANKRD1, CTGF*) in cell lines and CRC patient-derived organoids. The loss of DLG5 also suppressed cell growth in cancer cells, consistent with NUAK2 inhibition.

Conclusion: Our findings reveal a previously unknown regulatory axis where DLG5 acts as a scaffold to assemble the DLG5-NUAK2-LATS1 complex. This scaffolding allows NUAK2 to interact with LATS1, thereby regulating Hippo signaling. Our work identifies a novel role of DLG5 in the Hippo pathway, and future structural studies will further define the molecular architecture of this complex to guide therapeutic targeting.

#0573 Cooperative mechanisms driving prostate cancer progression.

Runhua Liu, Chao Zhang, Haiyan Yui, Lizhong Wang

UAB Heersink School of Medicine, Birmingham, AL

Signal transducer 24 (CD24) is a GPI-anchored cell surface molecule expressed in hematopoietic and immature neuronal cells, but at very low levels in normal differentiated cells. Although commonly used as a stem cell marker, CD24 is also linked to poor prognosis in many cancers, including prostate cancer (PCa). PCa poses major clinical challenges due to its diverse progression mechanisms and pronounced heterogeneity. Recent studies have identified overexpression of Regulator of Chromosome Condensation 2 (RCC2), a multifunctional protein involved in mitosis and cell motility, which contributes to cancer development across tumor types. This study reveals a novel interaction between CD24 and RCC2 in PCa, highlighting their cooperative roles in tumor growth and metastasis. Functionally, RCC2 knockout inhibited proliferation but enhanced migration, while CD24 knockout suppressed both processes; dual knockout synergistically reduced proliferation. In mouse models, RCC2 loss increased lung metastasis, whereas CD24 loss reduced both tumor growth and metastatic spread. Mechanistically, RCC2 regulates motility through vimentin ubiquitination, whereas CD24 promotes RCC2 degradation to modulate β-catenin signaling. Overall, CD24 regulates RCC2 stability and function, influencing key pathways that control proliferation, migration, and epithelial-mesenchymal transition (EMT). This CD24-RCC2-vimentin-β-catenin axis provides new insight into prostate cancer progression and represents a potential therapeutic target to limit metastasis.

#0574 Exploring the therapeutic vulnerability of castration-resistant prostate cancer via Hippo-YAP/TAZ-TEAD signaling.

Vandana Mohan, Sweaty Koul, Mousa Vatanmakanian, Santosh Lamichhane, Praveen K. Jaiswal, **Hari K. Koul**

LSU-LCMC Cancer Center, LSUHSC, School of Medicine, New Orleans, LA

Background: The Hippo-YAP/TAZ-TEAD signaling axis is frequently upregulated in many cancers, including subsets of prostate cancer (PCa). However, its role in therapy resistance remains incompletely understood. In this study, we investigated the therapeutic potential of targeting YAP/TAZ-TEAD signaling in PCa, with an emphasis on androgen-independent and enzalutamide-resistant disease.
Methods: LNCaP, PC3, and DU145 cells were obtained from ATCC. Enzalutamide-resistant lines (LNCaP-ENZR/PCaNO1 and C4-2-ENZR/PCaNO2) were generated by culturing LNCaP and C4-2 cells with 5 μM enzalutamide for >6 months. mRNA expression was quantified by qRT-PCR, and protein levels were examined by western blotting. Anti-tumor effects of YAP/TAZ-TEAD inhibitors (GNE-7883, K-975) were assessed using IncuCyte live-cell imaging for proliferation; long-term survival was measured by colony formation assays. Cell migration and invasion were evaluated using scratch-wound healing and Matrigel transwell assays, respectively.
Results: Androgen-independent PCa cells (PC3 and DU145) exhibited marked upregulation of YAP/TAZ-TEAD transcriptional targets compared to LNCaP cells. Enzalutamide-resistant PCaNO1 and PCaNO2 cells displayed strong induction of YAP/TAZ-TEAD target genes and increased YAP1, TAZ, and TEAD protein levels relative to parental controls. Enzalutamide resistance was also associated with elevated PD-L1 expression. Pharmacologic inhibition of YAP/TAZ-TEAD signaling significantly suppressed cell growth and proliferation, and reduced colony formation, migration, and invasion across PCa models. Ongoing experiments are assessing the impact of YAP/TAZ-TEAD inhibition on PD-L1 regulation.
Conclusion: YAP/TAZ-TEAD inhibitors effectively block proliferation and invasiveness of prostate cancer cells, including enzalutamide-resistant models. These findings support YAP/TAZ-TEAD signaling as a promising therapeutic vulnerability and potential strategy to overcome therapy resistance in subsets of advanced prostate cancer.

#0575 Cooperative regulation of YAP activity by STK40 and CDK7 in cancer progression.

Pei Yi Li, Yi Chin Chen, Feng Chiao Tsai

National Taiwan University, Taipei, Taiwan

Yes-associated protein (YAP) is a mechanosensitive transcriptional co-activatorthat drives cell proliferation and tumorigenesis. We previously identified thepseudokinase STK40 as a scaffold that directly binds and post-translationallyregulates YAP, with STK40 knockdown reducing YAP abundance and nuclearlocalization. In hormone receptor positive breast cancer, resistance to CDK4/6inhibitors remains a major challenge, and emerging evidence from ourcollaborative studies suggests that CDK7 transcriptionally regulates YAPthrough a CDK7-RNAPII-YAP-CDK6 axis contributing to therapeutic resistance.Whether STK40 and CDK7 function independently or converge on a sharedmechanism remains unknown. Using SAS cells, we found that CDK7knockdown reduced YAP protein levels in both cytosol and nucleus anddecreased the nuclear-to-cytosolic ratio, whereas dual CDK7 and STK40knockdown phenocopied CDK7 loss alone. CDK7 overexpression partiallyrescued YAP depletion caused by STK40 knockdown, indicating that CDK7acts downstream of STK40 in the same regulatory pathway. Proximity ligationassays confirmed a direct STK40 and YAP interaction. Reducing actomyosintension caused YAP to relocalize to the plasma membrane, but thisredistribution was abolished by STK40 knockdown. ROCK inhibition enhancedYAP Y357 phosphorylation at the plasma membrane, a modification requiredfor nuclear entry, yet this phosphorylation was completely lost in STK40-depleted cells, indicating that STK40 is required for positioning YAP at themembrane to initiate mechanotransduction driven nuclear import. In contrast,CDK7 knockdown did not prevent YAP membrane recruitment but caused YAPto accumulate at the nuclear envelope without entering the nucleus, suggestingthat CDK7 regulates a downstream step essential for nuclear translocation.Together, these data reveal a previously unrecognized STK40 and CDK7regulatory mechanism that cooperatively controls YAP abundance andsubcellular distribution. STK40 directs YAP to the plasma membrane for Y357phosphorylation, whereas CDK7 acts as a critical checkpoint enabling tension-dependent nuclear import. This mechanism represents a potential therapeuticvulnerability in YAP-driven cancers, including CDK4/6 inhibitor-resistant HR+breast cancer.

#0576 Investigating BMP signaling as a therapeutic vulnerability in endometrial cancer.

Purva Vinayak Gade, Craig Ceol

University of Massachusetts Medical School, Worcester, MA

Introduction: Endometrial cancer (EC) is the sixth most common malignancy in women worldwide, with nearly 400,000 new cases annually. Aggressive EC subtypes are associated with poor prognosis, highlighting the urgent need for mechanism-based therapies. Emerging evidence implicates Bone Morphogenetic Protein (BMP) signaling as a driver of EC progression. Approximately 5% of EC tumors harbor ACVR1(R206H) gain-of-function mutations, which overactivate BMP signaling. Our goal is to define the prevalence, sources, and functional consequences of BMP activation in EC and assess whether pharmacologic inhibition suppresses tumor growth.
Methods: Phospho-SMAD1/5/8 (pSMAD) levels were quantified in EC tumors and normal endometrium to assess BMP pathway activation. Genomic and transcriptomic datasets were analyzed to identify ACVR1 mutations and BMP ligand expression associated with patient survival. Functional studies were conducted in multiple EC cell lines using the pan-BMP inhibitor DMH1. pSMAD was measured by western blot, downstream BMP target gene transcription (ID1/ID3) was assessed by qPCR, and cell viability was evaluated to determine the effect of BMP inhibition on tumor cell survival and proliferation.
Results: pSMAD levels were elevated in over half of EC tumors compared with low-to-moderate levels in normal endometrium. High expression of BMP ligands GDF6 and BMP7 correlated with poor overall survival. DMH1 selectively reduced pSMAD without affecting total SMAD, downregulated ID1 and ID3, and decreased viability in Ishikawa, HEC1A, and AN3CA cells within 24 hours, demonstrating that BMP signaling is required to sustain tumor growth and proliferation.
Conclusions: BMP signaling is recurrently activated in EC through receptor mutation and ligand overexpression, promoting aggressive tumor behavior. Pharmacologic inhibition reverses downstream transcriptional activity and suppresses tumor cell viability, establishing BMP signaling as an actionable therapeutic vulnerability. These findings support the development of BMP-directed strategies to improve clinical outcomes in patients with endometrial cancer.

#0577 Defects in junctional localization of desmosomal proteins in cancer cells triggered by loss of Septin-9.

Cate G. Lyerly, Zach N. Pierce, Adi Dara Dubash

Furman Univ., Greenville, SC

Desmosomes are specialized adhesive junctions that link adjacent cells and provide structural integrity in tissues exposed to significant mechanical stress, such as the skin and heart. Disruption of the desmosome adhesion complex is observed in a range of different cutaneous syndromes and during tumor progression. Dysregulation of desmosomal proteins has been associated with enhanced cancer motility, invasion and metastatic potential. Diverse mechanisms for the disruption of desmosome dynamics have been reported, but the specific signaling pathways regulating the expression and localization of desmosome proteins remain elusive. Prior studies have shown that Septin family proteins play an important role in the maintenance and function of adherens junctions and tight junctions. Referred to as the fourth component of the cytoskeleton, Septins are GTP-binding proteins that form oligomeric filamentous structures that associate with cellular membranes and act as scaffolding proteins for a variety of different cellular functions. In particular, Septin-2 has been found adjacent to VE-cadherin containing cell-cell junctions, and loss of Septin-2 disrupts adherens junction structure and barrier integrity in endothelial cells. Septin-9 has also been shown to control adherens junction structure, apico-basal polarity and lumen formation in polarized MDCK cells. In our study, we sought to investigate the importance of Septins in the formation of desmosomal cell-cell adhesions by performing knockdown experiments for Septin-9 in squamous cell carcinoma 9 (SCC9) cells and T47D breast cancer cells. Our experiments show a significant disruption of desmosomal cell-cell junctions in both cancer cell types expressing siRNA specific for Septin-9 (siSept9), in comparison to control siRNA-expressing cells. In particular, border localization of the desmosomal cadherin Desmoglein-2 (Dsg2) and the desmosomal plaque protein Plakophilin-2 were dramatically perturbed in siSept9 cells (determined via immunofluorescence), while the localization of other desmosomal proteins (such as Plakoglobin) remained unaffected. Loss of Dsg2 and PKP2 border staining was not accompanied by changes in total protein expression, suggesting that these changes are predominantly an effect of protein localization. This study has therefore uncovered an important role for Sept9 in maintenance of desmosomal structure in cancer cells, providing insight into mechanisms which may perturb junction structure during cancer progression.

#0578 Emerging roles of Cyclin F in Non-small lung cell carcinoma during metabolic stress.

Rohini Tamang[1], Sanjeev Das[2], Sangeeta Choudhury[1]

[1]Department of Biotechnology and Research, Sir Ganga Ram Hospital, New Delhi, India,[2]Molecular Oncology Laboratory, National Institute of Immunolgy, New Delhi, India

Introduction: Cyclin F, the orphan Cyclin, is unique from other Cyclins- 1) it does not bind to any cyclin dependent kinase (cdk) and 2) It has a domain which categorizes Cyclin F as a member of a distinct class of proteins the F-box proteins. Proteins such as Cyclin F, thereby facilitates the recognition of substrate proteins and mediates the ubiquitylation and degradation of the protein by the Skp1-Cul1- F box (SCF) complex. Role of Cyclin F in tumorigenesis is obscure but owing to its role as a genome guardian and nutrient sensing molecule, we explored its role in tumor in a lung cancer model

Aim: To delineate the unique function of Cyclin F driven ubiquitylation and regulation of cellular proteins which alters the tumorigenic capacity of cancers.

Methodology: Identification of Cyclin F interactome- ectopic expression of Cyclin F using adenoviral system; immunoprecipitation of Cyclin F and its putative interacting proteins, detection of proteins with LC-MS/MS. Investigate the dynamics of the interaction under physiological conditions. Understanding the effect of Cyclin F mediated regulation of proteins in cellular pathways in cancer cells (Non-small lung cell carcinoma**;** NSCLC).

Results: We developed an adenoviral vector expressing Cyclin F along with HA and FLAG tags (Ad-CCNFHF-GFP). Adenovirus expressing Cyclin F and the tags were produced from HEK293A cells. The viral titer was used to ectopically express Cyclin F in H1299 cells, followed by immunoprecipitation of Cyclin F and identification of the proteome associated with Cyclin F. We identified an RNA binding protein in our screen, called PTBP1. PTBP1, is associated with aberrant splicing activity in tumor cells and its expression is associated with poor prognosis. We verified that Cyclin F upregulation during a period of starvation led to concomitant decrease in PTBP1 protein levels. PTBP1 downregulation led to exclusion of exon 10 of PKM mRNA and altered the PKM2/PKM1 ratio. We observed that Cyclin F mediated depletion of PTBP1 and PKM2, lowering the glycolytic capacity in tumor cells. It further led to decrease in proliferation and invasion and migration rates of cancer cells upon starvation. Mice data also corroborate similar results.

Conclusion: Our study provides clues on how protein interaction during metabolic stress can shift the fate of cancer cells. It establishes that Cyclin F negatively regulates PTBP1/PKM2 levels and reduces the tumorigenic potential of NSCLC cells in in-vitro/in-vivo models. Elucidating molecular interactions will provide insight into NSCLC progression and therapeutic resistance, which is the first step towards designing targets.

Key words: Non-small lung cell carcinoma, Cyclin F, tumorigenic capacity, adenoviral expression, RNA binding proteins

#0579 Effects of arylsulfatase B and pembrolizumab on the progression of syngeneic B16F10 metastatic pulmonary melanomas.

Joanne Kramer Tobacman[1], Insug O-Sullivan[2], Sumit Bhattacharyya[3]

[1]Medicine, University of Illinois at Chicago and Jesse Brown VA Medical Center, Chicago, IL,[2]Research, Jesse Brown VA Medical Center and University of Illinois Chicago, Chicago, IL,[3]Research, Jesse Brown VA Medical Center, Chicago, IL

The chondroitin 4-sulfate (C4S) sulfatase Arylsulfatase B (ARSB; N-acetylgalactosamine-4-sulfatase) inhibits the growth and improves survival of C57BL/6J mice with B16F10 subcutaneous melanomas, inhibits the growth of A375 human melanomas in humanized mice with PBMC implants, and reduces the progression of metastatic pulmonary melanomas in the B16F10 syngeneic mouse model. Cleaved caspase-3 is enhanced by treatment with rhARSB and is mediated by increased expression of the E3 ubiquitin ligase constitutive photomorphogenic (COP)1, which reduces nuclear ETS-1 and thereby BCL2 expression. Combined treatment of B16F10 pulmonary melanomas by rhARSB and Pembrolizumab leads to greater increase in cleaved caspase-3 and greater decline in Bcl2, but no further increase in COP1 than by rhARSB alone. Similarly, in cultured A375 cells, cleaved caspase-3 is increased and BCL2 is reduced further by combined treatment of rhARSB and Pembrolizumab in the presence of PBMC, without further increase in COP1. The greater decline in Bcl2 is attributable to effects of rhARSB and Pembrolizumab in the presence of PBMC on Granzyme B. In contrast to no effect of Pembrolizumab, rhARSB reduces expression of the matrix metalloproteinases MMP2 and MMP9 in A375 melanoma cells and in B16F10 pulmonary melanomas, leading to decline in invasiveness. The mechanism by which ARSB regulates MMP expression is attributable to rhARSB-mediated decline in chondroitin 4-sulfate binding with SHP2, leading to declines in ERK1/2 phosphorylation, nuclear c-Myc-DNA-binding, and MMP2 and MMP9 promoter activation. In the B16F10 pulmonary melanomas, the combination of Pembrolizumab and rhARSB increased the mRNA expression of MCP1 and IL-10 and reduced the expression of KC and IL-6, more than either treatment alone. ARSB alone increased IL-17α and TNFα, which was reduced by Pembrolizumab and overall by their combination. The combined effects of rhARSB and Pembrolizumab demonstrate synergism which may be of significant clinical benefit. Enhanced apoptosis mediated by different Bcl2 regulatory mechanisms, decline in matrix metalloproteinases and associated invasiveness of tumor cells due to signaling effects of rhARSB, as well as combined effects on cytokine expression are anticipated to inhibit melanoma progression.

#0580 TPM4 overexpression modifies differentiated colon epithelial cell barrier integrity.

Brenna Backus[1], **Michael Papetti**[2]

[1]Touro University, New York City, NY,[2]High Point University, High Point, NC

Colon epithelial cell migration out of the stem cell compartment in colon crypts is essential for normal differentiation and growth arrest. Altered expression of contractility- and migration-specific genes may disrupt these processes and contribute to early stages of colon tumorigenesis. One such gene, tropomyosin-4 (*TPM4*), is overexpressed in early and late stages of colorectal cancer. Determining how *TPM4* overexpression contributes to colon cell tumorigenesis may identify novel therapeutic targets. We hypothesized that *TPM4* overexpression may promote colon tumorigenesis by disrupting cell-cell junctions and reducing epithelial barrier integrity in differentiating colon epithelial cells. To test this, we utilized Caco2 cells, an *in vitro* model of colon epithelial cell differentiation derived from a human colon adenocarcinoma. Our approach was to determine whether artificially increasing *TPM4* expression by stable transfection in differentiating Caco2 cells, when *TPM4* is normally suppressed, will decrease integrity of the Caco-2 cell monolayer. To assess this, we measured transepithelial electrical resistance (TEER), an indicator of cell-cell junction integrity, in differentiating *TPM4*-overexpressing Caco-2 monolayers relative to control transfectants. 100,000 Caco2 cells were seeded in 6 well filter inserts in wells of a 6-well plate at day 0. TEER measurements were recorded in triplicate every other day from day 6 to 24 using the Millicell ERS 3.0 Digital Voltohmmeter. We observed significant differences between TEER measurements in two clones of *TPM4*-overexpressing Caco2 cells and control transfectants. TEER values in control empty vector stable transfectants plateaued between 1237-1445 ohm-sq. cm, while those in two *TPM4*-overexpressing stable clones plateaued between 464-898 ohm-sq. cm (clone 1) and 1743-1868 ohm-sq. cm (clone 7). Clone 1 TEER values plateaued at a similar time point (day 12) as empty vector control, whereas clone 7 TEER values plateaued later (day 16). In addition, we observed alterations in expression of genes encoding junctional complex proteins in TPM4-overexpressing cells relative to controls. These results indicate that *TPM4* overexpression modulates the integrity of cell-cell junctions in an *in vitro* model of differentiating colon epithelial cells. Future experiments will determine whether differences observed between the two distinct clones may be due to the extent of *TPM4* overexpression in each clone. Our study suggests that sustained *TPM4* overexpression may disrupt colon epithelial cell differentiation and promote tumorigenesis by altering normal epithelial barrier formation and junctional integrity. Therefore, we identify a potential mechanism that may link *TPM4* overexpression to early colorectal tumorigenesis and elucidate possible novel approaches to prevent and treat colon cancer, particularly at early stages.

#0581 FUT8-mediated fucosylation promotes colorectal cancer growth and metastatic potential via tumor-fibroblast interactions.

Zimo Huang[1], Sree K. Kondapuram[1], Xiang Y. Zheng[1], Praveen Agrawal[1], Chaoyuan Kuang[2]

[1]Albert Einstein College of Medicine, Bronx, NY,[2]MonteFiore Einstein Comprehensive Cancer Center, Albert Einstein College of Medicine, Bronx, NY

Colorectal cancer (CRC) remains a major clinical burden despite advances in targeted therapies. Aberrant glycosylation, including fucosylation, is increasingly recognized as a key regulator of tumor progression. Analysis of TCGA COAD/READ datasets identified FUT8, the sole enzyme mediating core fucosylation, as significantly elevated in CRC tumors. Its expression pattern and functional activity position FUT8 as a key driver of CRC growth and metastatic traits, including cancer-associated fibroblast (CAF)-mediated tumor-stroma interactions.

Transcriptomic and survival analyses were performed using TCGA COAD/READ and the Montefiore-Einstein Comprehensive Cancer Center (MECCC) CRC biobank datasets. FUT8 protein expression was evaluated in paired tumor and normal tissues from MECCC TMAs. Functional characterization was carried out using FUT8 overexpression (OE) and knockdown (KD) CRC cell models, followed by proliferation assays, colony-forming assays, and transwell invasion assays under baseline and CAF-conditioned medium conditions.

FUT8 was consistently upregulated in CRC tumors compared with matched normal tissues across TCGA COAD/READ and MECCC transcriptomic cohorts. Stage I/II CRC patients with high FUT8 expression (Q4) exhibited significantly reduced 5-year overall survival compared with the lowest quartile (Q1) (log-rank $p = 0.03$). In sixteen paired samples from MECCC TMAs, FUT8 protein levels were markedly elevated (about 2-fold) in tumors compared with normal tissues ($p < 0.001$). Functionally, FUT8 modulation did not alter CRC cell proliferation but robustly regulated aggressive properties: FUT8 OE increased colony size and markedly enhanced transwell invasion, whereas FUT8 KD suppressed both colony formation and invasion. These effects were further amplified in CAF-conditioned medium, suggesting that FUT8 enhances CRC-CAF crosstalk and drives an invasive phenotype.

Across transcriptomic analyses and functional assays, FUT8 emerges as a clinically relevant regulator of CRC progression. FUT8 enhances colony formation and invasion independent of proliferation, with its pro-invasive effects strengthened by CAF signaling, establishing FUT8-mediated fucosylation as a driver of CRC aggressiveness.

#0582 Disruption of *Cenpj,* a centriole biogenesis regulator, diminishes oral cancer susceptibility through p53-dependent DNA-damage repair and apoptosis pathways.

Mousumi Bhattacharjee, Heena Dave, Rekha Jalandra, Radhika R. Gudi, Chenthamarakshan Vasu

The Medical University of South Carolina, Charleston, SC

Mutations in centrosomal P4.1-associated protein (CPAP; Gene: CENPJ), a microtubule-bindingcentriolar protein, can lead to microcephaly (MCP) in humans. While CPAP dysfunction is knownto cause centrosome aberrations and genomic instability, its impact on tumor initiation andprogression is largely unknown. Our recent reports showed that CPAP regulates endocyticvesicular transport function and epidermal growth factor receptor (EGFR) homeostasis andsignaling dynamics. CPAP depletion endows human oral squamous cell carcinoma (OSCC) celllines with epithelial-mesenchymal transition (EMT) phenotype, and enhanced EGFR-dependentinvasive and tumorigenic properties in vitro and in a xenotransplant model, respectively. Here, weemployed a mouse model with hypomorphic allele of *Cenpj*, which shows dwarfism andmicrocephaly phenotype (MCP mice), to determine the impact of CPAP function on EGFR levelsand chemical carcinogen-induced oral tumorigenesis. Similar to human OSCC cell lines,fibroblasts, and tongue epithelium organoids from MCP mice exhibited defective vesiculartransport function and markedly increased EGFR protein levels. However, to our surprise, MCPmice exhibited diminished susceptibility to 4-Nitroquinoline 1-oxide (4NQO) -induced oraltumorigenesis as compared to their wild-type counterparts. Epithelial cell proliferation at all stagesof tumor progression and the eventual tumor burden were profoundly lower in MCP mice. Tonguefibroblasts and epithelial organoids treated with DNA damage-inducing agents were used todetermine the molecular mechanism(s) of reduced tumor susceptibility of *Cenpj* hypomorphicmice. These cells from MCP mice were highly susceptible to DNA damage and showed higheractivation of p53 and DNA-damage repair (DDR)- and apoptotic- pathways. For instance, gamma-H2AX and cleaved caspase-3 levels, and apoptotic death were significantly higher in cells withhypomorphic allele of *Cenpj* as compared to cells with WT allele. Our ongoing studies are focusedon determining how CPAP-mediated EGFR homeostasis and centriolar function impactgenotoxicity and epithelial cell transformation at different stages of oral tumorigenesis. Overall,our findings, for the first time, show a role for critical centriole biogenesis and microcephaly-associated protein in tumor initiation and progression under genotoxic stress and are expected tohelp design novel targeted therapies for OSCC.

#0583 Septin-9 binds to Desmoglein-2 and controls cell-cell junction strength in cancer cells.

Michael W. Jaber, Emily G. Bernier, Adi Dara Dubash

Furman Univ., Greenville, SC

Septins are a conserved family of GTP-binding cytoskeletal proteins which form oligomeric filamentous structures that play important roles in a wide variety of dynamic cellular processes, including cytokinesis, membrane remodeling and cell migration. Expression of Septins is dysregulated in different tumors, with some isoforms being either upregulated or downregulated, and prior evidence has highlighted a role for several Septins in controlling malignant phenotypes. In particular, Septin-9 is frequently dysregulated in cancer, with genomic amplification at the SEPT9 locus being commonly detected in high-grade carcinomas. Several different mechanisms have been put forth to explain a role for Septin-9 in cancer progression, including control of cell-matrix adhesion, migration and invasion. For example, overexpression of Septin-9 has been shown to enhance extracellular matrix degradation and invasion in breast cancer via recruitment of matrix metalloproteinases. In contrast, less is known about how Septin-9 affects cell-cell junctions, which are also frequently perturbed during cancer progression and metastasis. In our study, we provide evidence that Septin-9 localizes to desmosomal cell-cell junctions in the T47D cancer cell line. Desmosomes have a tripartite organizational structure wherein transmembrane cadherins (Desmoglein and Desmocollin) link adjacent cells, plaque proteins (Plakoglobin and Plakophilin) stabilize arrays of desmosomes on the intracellular face, and a cytoskeletal linker proteins (Desmoplakin) anchors desmosomes to the intermediate filament cytoskeleton. Importantly, we show an interaction between the cadherin Desmoglein-2 and Septin-9 via immunoprecipitation experiments. Loss of Septin-9 does not dramatically perturb mRNA or protein levels of different desmosomal components in T47D cells. Nevertheless, Septin-9 knockdown does result in a statistically significant loss of cell-cell junction strength in squamous cell carcinoma (SCC9) cells (measured via dispase assays), likely as an effect of disrupted localization of desmosomal proteins to cell-cell junctions. Taken together, these studies highlight an important role for Septin-9 in maintenance of desmosome-mediated adhesion in cancer cells.

#0584 Context-dependent roles of sFRP1 in melanoma.

Cierra Perron[1], Douglas Quilty[1], Farzaneh Afzali[1], Bianca Dauber[1], Tyler Cooper[2], Krista M. Vincent[3], Ivan Topisirovic[4], Lynne-Marie Postovit[1]

[1]Biomedical and Molecular Science, Queen's Univ. Cancer Research Inst., Kingston, ON, Canada,[2]Department of Obstetrics and Gynecology, Centre de recherche du Centre hospitalier de l'Universite de Montreal, Montreal, QC, Canada,[3]Anatomy and Cell Biology, Western University, London, ON, Canada,[4]Department of Oncology, McGill University, Montreal, QC, Canada

Elevated levels of secreted Frizzled-Related Protein 1 (sFRP1) in melanoma patient datasets correlate with reduced overall and distant metastasis-free survival, suggesting a clinically significant role in disease progression. To explore the mechanisms underlying this association, we compared melanoma cell lines with differing basal sFRP1 levels and assessed proliferation, migration, and invasion following sFRP1 overexpression or knockdown. Proliferation was measured with standard assays, while migration and invasion were quantified using scratch and Boyden chamber assays.

Across cell lines, sFRP1 produced divergent phenotypic outcomes, indicating that its activity is highly context-specific. Preliminary mechanistic analyses suggest that sFRP1 does not act through a single canonical pathway; instead, it appears to influence components of the tumor microenvironment, including markers linked to immune-regulatory pathways. These context-dependent changes highlight a broader role for sFRP1 in shaping interactions between melanoma cells and their surrounding microenvironment. Overall, these findings support a model in which sFRP1 modulates melanoma progression through multifactorial, microenvironment-dependent mechanisms rather than exerting uniformly oncogenic or suppressive effects. The impact of sFRP1 on melanoma appears shaped by intrinsic features of individual tumors. Ongoing studies aim to define the mechanisms, extracellular pathways, and tumor contexts that determine sFRP1-driven phenotypes and their potential clinical relevance.

#0585 Effects of bisphenols on gene expression and cellular outcomes in MDA-MB-231 breast cancer cells mediated via G protein-coupled estrogen receptor.

Norman R. Estes, Cameron Sheeler

University of Alabama at Birmingham, Birmingham, AL

Bisphenol A (BPA) is used in the manufacturing of consumer products such as plastic bottles, food-can epoxy resins, thermal printing paper, and dental sealants. BPA functions as an endocrine disruptor and can mimic estrogen through activation of estrogen receptor signaling pathways and can regulate estrogen-responsive genes through classical estrogen receptor-mediated mechanisms. BPA exposure is linked to several health risks, including hormone-dependent cancers, metabolic diseases, and developmental defects. However, the effects of BPA and its alternatives on gene expression and cellular behavior through the membrane-bound G-protein-coupled estrogen receptor (GPER) remain unclear. MDA-MB-231 triple-negative breast cancer (TNBC) cells express GPER but lack the classical estrogen receptor (ER), progesterone receptor (PR), and human epidermal growth factor receptor 2 (HER2). These studies aim to determine whether BPA and BPA alternatives, acting through GPER, differentially affect gene expression, cell proliferation, and cell migration. Preliminary RNA sequencing data show distinct gene expression changes in cells treated with BPA or 17β-estradiol, including alterations in cancer-related pathways, CREB signaling, and G-protein-coupled receptor mediated pathways. Cell migration assays performed on MDA-MB-231 cells treated with BPA, BPB, BPC, or 17β-estradiol further suggest differential effects on migration, with BPC inducing the highest degree of cell migration. These findings indicate that BPA and its alternatives influence both gene expression and cell migration in TNBC cells and may impact therapeutic outcomes in TNBC patients. Current studies focus on validating key pathways identified through RNA sequencing and clarifying the role of GPER-mediated signaling in TNBC cells exposed to BPA and BPA alternatives.

#0586 Pdcd4/mTORC2 axis regulates glycolysis via PFKFB3 in NSCLC.

Elham Zokaei[1], Hsin-Sheng Yang[2], Qing Wang[2], Yanquan Zhang[2]

[1]Toxicology and cancer biology, University of Kentucky, Lexington, KY,[2]University of Kentucky, Lexington, KY

Programmed cell death 4 (PDCD4) is a tumor suppressor frequently downregulated in non-small cell lung cancer (NSCLC), yet its role in metabolic regulation remains poorly understood. Using reverse-phase protein array analysis, we found that loss of PDCD4 significantly upregulates the glycolytic enzyme PFKFB3, which produces fructose-2,6-bisphosphate to activate the rate-limiting enzyme PFK1. PFKFB3 is highly expressed in NSCLC and correlates with advanced tumor stage. Because PDCD4 suppresses mTORC2 activity, we investigated whether mTORC2 regulates PFKFB3. Co-immunoprecipitation and in vitro kinase assays showed that mTORC2 directly interacts with and phosphorylates PFKFB3, and mapping analysis identified Ser461 as the targeted phosphorylation site. To determine its functional significance, we generated phosphorylation-deficient (S461A) and phospho-mimetic (S461D) PFKFB3 mutants. Protein stability assays revealed that S461A undergoes rapid proteasomal degradation, whereas S461D exhibits enhanced stability compared with wild-type (WT) PFKFB3. Seahorse XF glycolysis stress tests demonstrated that WT and S461D significantly increased basal and maximal glycolytic activity, while S461A markedly impaired glycolysis and metabolic capacity. Consistent with these effects, WT and S461D promoted proliferation and colony formation, whereas S461A suppressed cell growth. These findings identify mTORC2-mediated phosphorylation of PFKFB3 at Ser461 as a critical regulator of PFKFB3 stability and glycolytic function and show that PDCD4 loss enhances mTORC2 activity to drive glycolytic reprogramming in NSCLC. Targeting the PDCD4-mTORC2-PFKFB3 axis may offer a promising therapeutic approach to disrupt tumor metabolism in lung cancer.

#0587 Choline Acetyltransferase: A novel drug target in lung adenocarcinoma patients who are exposed to tobacco smoke.

Piyali Dasgupta[1], Eric W. Bow[2], Krista Denning[3], Rama S. Gadepalli[2], John M. Rimoldi[2], Yi Charlie Chen[4], Sarah L. Miles[5]

[1]Marshall University, Joan C. Edwards School of Medicine, Huntington, WV,[2]Department of Biomolecular Sciences, University of Mississippi, University, MS,[3]Department of Pathology, Marshall University, Joan C. Edwards School of Medicine, Huntington, WV,[4]Department of Biology and Environmental Sciences, Bluefield State University, Bluefield, WV,[5]Department of Biomedical Sciences, Marshall University, Joan C. Edwards School of Medicine, Huntington, WV

Purpose of the study: Lung cancer is not a single disease entity; it represents a spectrum of malignancies. Out of these lung adenocarcinoma (LUAD) accounts for about 65% of all lung cancers and shows a strong etiological correlation with smoking. Clinical studies show that about 30% of LUAD patients continue to smoke after being diagnosed with lung cancer. In addition, many others are exposed to nicotine via secondhand smoke and smoking cessation devices. Nicotine, the addictive component of tobacco smoke, accelerates the growth of human LUADs via the by nicotinic acetylcholine receptors (nAChRs) on target cells. The first-line therapy for LUAD patients involves the administration of tyrosine kinase inhibitors (TKIs) targeting EGFR, ALK, MET kinases. Such targeted therapies show potent anti-cancer activity in non-smokers and never smokers but show poor efficacy in patients who continue to smoke after their diagnosis. The primary objective of our research is to evaluate the potential of choline acetyltransferase (ChAT, the enzyme which synthesizes acetylcholine) as a drug target for LUAD in smokers. We evaluated the anti-neoplastic activity of BW813U (small molecule inhibitor of ChAT) in LUADs associated with moderate-heavy smoking history. We also investigated the anti-angiogeneic activity of BW813U (as a molecular mechanism underlying its growth-inhibitory effects) LUAD.
Experimental procedures. Primary human microvascular endothelial cells from the lung (HMEC-L) were used for all the experiments. These cells were used between passage 3-7. The anti-angiogenic activity of BW813U was measured in cell culture models by using the “MATRIGEL ASSAY”. The results obtained from the “MATRIGEL ASSAY” were confirmed using chicken chorioallantoic membrane (CAM) angiogenesis experiments. Finally, the anti-tumor activity of BW813U was measured *in vivo* by using xenograft model systems in SCID mice. Our studies also investigated the signaling pathways underlying the anti-angiogenic activity of BW813U, using chemical inhibitors and siRNA methodology.
Results: BW813U robustly suppressed angiogenesis in Matrigel assays and CAM model systems. The administration of BW813U potently decreased the growth rate of H838 tumors xenotransplanted in SCID mice. Immunohistochemical staining experiments revealed that the anti-tumor activity of BW813U was correlated with decrease of CD31 angiogenic biomarker in H838 tumor sections. The anti-angiogenic activity of BW813U was mediated by the alpha7-nAChR pathway and involved the nitric oxide pathway. Taken together, our studies show that ChAT may be a valuable drug target for the therapy of LUAD.
Conclusions: ChAT antagonists like BW813U decrease the growth of LUAD by suppressing tumor angiogenesis.

#0588 Enhancing the efficacy of 5-fluorouracil in targeting thymidylate synthase (TYMS) for breast cancer treatment using honokiol.

Santosh K. Singh, Rajesh Singh

Morehouse School of Medicine, Atlanta, GA

Breast cancer (BrCa), in particular, triple-negative breast cancer (TNBC), is a complex disease to treat and respond to conventional chemotherapy. Recently, thymidylate synthase (TYMS), has gained attention as important enzyme whose inhibition has been reported to be effective in the inhibition of the de novo production of 2 2-deoxythymidine-5-monophosphate (dTMP), involved in DNA synthesis in cancer cells. TYMS is a known target of 5-fluorouracil (5-FU), a widely used antimetabolite chemotherapeutic agent, effective against various tumors. Nevertheless, clinical application is commonly compromised by serious side effects, resistance to drugs, and upregulation of TYMS. Additionally, drug-induced activation of NF-κB contributes to the overexpression of TYMS, thereby promoting tumor cell proliferation and chemotherapeutic resistance. Therefore, identifying new anti-cancer agents that can be used alongside 5-FU to target cancer cells while sparing healthy cells is crucial. Recently, honokiol (HNK), a natural biphenolic compound from *Magnolia officinalis*, has shown promise as an anti-inflammatory, antioxidant, and anti-tumor agent. HNK is known to inhibit NF-κB activation in response to various stimuli. In this study, we investigated the synergistic effects of HNK and 5-FU in TNBC cells (MDA-MB-468 and MDA-MB-231), with a focus on the suppression of NF-κB-mediated TYMS expression. To determine the optimal IC50 values and synergy, TNBC cells were treated with HNK, 5-FU, or a combination of both at various time points and dosages, followed by a cell viability assay (MTT assay). Our results, which include cell cytotoxicity assays, apoptosis assays, cell cycle assays, RT-qPCR analysis, and Western blots, demonstrate that the combined treatment is most effective in inhibiting TYMS, reducing cell proliferation, and inducing apoptosis. The combination inhibits NF-κB p65 activation, thereby disrupting the transcriptional regulation of target genes associated with cell survival and communication with TYMS. This dual inhibition causes a cell cycle arrest at the G_0/G_1 phase, and upregulates the cell cycle inhibitors, including p21, which, in turn, downregulates the expression of the cyclin D1/CDK2 and CDK4 complexes. These findings suggest that NF-κB may stimulate TYMS transcription under inflammatory conditions. Additionally, the combinatorial treatment increased the number of apoptotic cells compared to the individual or control groups. These results suggest that the combination of HNK and 5-FU may alter DNA synthesis and repair, predisposing TNBC cells to apoptosis. This dual-targeting strategy, which involves direct inhibition of TYMS by 5-FU and suppression of its NF-κB-mediated upregulation by HNK, presents a promising approach to overcoming chemoresistance and improving therapeutic outcomes in patients with BrCa.

#0589 Ubiquitin specific peptidase 37 (USP37) facilitate Replication stress tolerance to promote prostate cancer oncogenesis.

Suraja Kumar Das[1], Lakshay Malhotra[2], Gunjan Dagar[1], Teena Haritwal[3], Atul Batra[4], Ajaz A. Bhat[5], **Mayank Singh**[3]

[1]Medical Oncology Lab, All India Institute of Medical Sciences (AIIMS) New Delhi, New Delhi, India,[2]Sri Venkateswara College University of Delhi, New Delhi, India,[3]All India Institute of Medical Sciences (AIIMS) New Delhi, New Delhi, India,[4]Medical Oncology, All India Institute of Medical Sciences (AIIMS) New Delhi, New Delhi, India,[5]Translational Medicine, Sidra Medicine, Doha, Qatar

Several reports have suggested that the DUBs (Deubiquitinating enzymes) are highly-elevated in various cancers, Reverses the process of ubiquitination and are responsible for stabilization of oncoproteins. Among DUBs, Ubiquitin-specific peptidase 37 (USP37) is one of the least studied member of the Ubiquitin specific protease family. USP37 controls numerous aspects of oncogenesis, including stabilizing many oncoproteins as reported in our recent studies. Prostate cancer (PC) is the most common cancer diagnosis made in men remains the leading cause of cancer death in men. However, the biological functions of USP37 in prostate cancer remain unclear. Analysis of TCGA data indicated that overexpression of USP37 correlated with reduced progression free survival (PFS) in prostate cancer patients. Mass spectrometry (MS) analysis of Prostate cancer cells (DU145) indicated that distinct set of genes were altered on knockdown of USP37. Survival Data indicate that USP37 overexpression confers survival advantage while its depletion enhances sensitivity for cell killing in PC cells. USP37 overexpressing cells were able to resolve DNA damage foci much more rapidly than the control cells or cells in which USP37 was depleted in response to genotoxic stress. USP37 depletion results in reduced resolution of γ H2AX and 53BP1 DNA damage foci which indicates the reduced ability of cells to carry out constitutive DNA replication. USP37 was found to interact with different replication factors as also seen in our MS analysis including many previously reported partners. We further correlated our data with archived tissue blocks of PC patients by analyzing if USP37 overexpression correlated with disease progression. Present data suggests that USP37 is required for tolerance of replication stress in PC and is required to dock additional replication factors and stabilize DNA replication fork. The current data provides novel pathways regulated by USP37 in PC cells which reinforce development of targeting strategies against USP37 in context of Prostate Cancer.

#0590 Role of cellular prion protein in breast cancer through Wnt signaling.

Parul Dubey, Manoj Kumar Mishra

Department of Biological Sciences, Alabama State University, Montgomery, AL

Cellular prion protein (PrP^C) is a GPI-anchored surface glycoprotein encoded by the *PRNP* gene. While PrP^C is widely studied in neurodegenerative diseases, recent evidence has revealed its involvement in various aspects of cancer biology. Although PrP^C contributes to tumor progression, its mechanistic role in breast cancer aggressiveness remains elusive. In this study, we investigate the role of PrP^C on key properties of tumors and on WNT/β-catenin signaling in triple-negative breast cancer (TNBC) cells. Using *PRNP*-targeted siRNA, the *PRNP* was transiently silenced, resulting in a significant reduction in migration and invasion, as demonstrated by the scratch and transwell invasion assays. This data was consistent with a shift in epithelial-mesenchymal transition (EMT) markers, characterized by increased E-cadherin and decreased N-cadherin expression. The metabolic activity, assessed by Alamar-blue assay, was significantly alleviated in the siPRNP group, accompanied by reduced proliferative activity, consistent with decreased PCNA levels. Additionally, flow-cytometric cell-cycle profiling demonstrated a significant accumulation of cells in the G0 phase, indicating growth arrest, consistent with reduced proliferation and metabolic quiescence. Furthermore, to determine whether WNT signaling mediated these effects, we examined the key pathway components. Silencing *PRNP* decreased GSK3β phosphorylation and increased its active form, promoting β-catenin phosphorylation at Ser (33/37) and its subsequent degradation. These changes indicate effective attenuation of canonical WNT signaling. Collectively, our findings suggest that PrP^C promotes TNBC cell migration, invasion, and proliferation through activation of WNT/β-catenin signaling and maintenance of EMT characteristics. Therefore, targeting PrP^C may offer a promising therapeutic strategy to limit TNBC aggressiveness.

#0591 The ubiquitin ligase HUWE1 controls the balance between β-catenin functions in WNT signaling and cell adhesion.

Caleb Kwame Sinclear, Joseph McKenna, Yalan Wu, Praveen Sonkusre, Andres M. Lebensohn

Laboratory of Cellular and Molecular Biology, Center for Cancer Research, NIH-NCI, Bethesda, MD

β-catenin plays two major roles in the cell, one as the key mediator of transcriptional responses to WNT signaling in the cytoplasm and nucleus, and the other as a structural component of adherens junctions, cell-cell adhesion complexes at the plasma membrane. How the balance between these spatially separate and functionally distinct pools of β-catenin is controlled is not well understood. WNT/β-catenin signaling is a fundamental signaling pathway, dysregulation of which can drive many types of cancer. Disassembly of adherens junctions, often caused by reduced β-catenin, is a hallmark of epithelial-mesenchymal transition (EMT), a process that promotes cancer metastasis. The goal of this study was to investigate the mechanisms that regulate the balance between the two spatially and functionally distinct pools of β-catenin. During WNT/β-catenin signaling, the main regulated step is β-catenin phosphorylation and degradation mediated by the destruction complex, composed of the scaffold proteins APC and AXIN1/2, and the kinases casein kinase 1α and GSK3α/β. Using CRISPR, we created two disease model cell lines from haploid human (HAP1) cells: 1. casein kinase 1α knock-out cells, and 2. β-catenin ST-A cells, containing mutations in β-catenin that render it insensitive to phosphorylation and degradation by the destruction complex. In both cell lines, we observed by confocal microscopy that β-catenin accumulates in the cytoplasm and the nucleus, and promotes hyperactive WNT signaling. Importantly, we found that loss of the E3 ubiquitin ligase HUWE1 in casein kinase 1α knock-out cells induced a marked change in the localization of β-catenin from the nucleus to the plasma membrane, which was accompanied by a substantial reduction in WNT/β-catenin signaling. Through proximity ligation assays and a new adherens junction-dependent cell adhesion assay that we developed, we found that localization of β-catenin to the plasma membrane caused by HUWE1 loss promotes β-catenin incorporation into adherens junctions and increases its functional contribution to cell-cell adhesion. In β-catenin ST-A cells that contain non-degradable β-catenin, regulation of β-catenin subcellular localization by HUWE1 was also observed. Taken together, these results demonstrate that HUWE1 regulates the balance between β-catenin transcriptional activity in WNT signaling and its cell adhesion functions. Therefore, regulation of β-catenin functions through HUWE1 may open new therapeutic avenues for cancers caused by hyperactive WNT signaling, and/or in metastasis driven by EMTs.

#0592 NSD2 regulates cell growth and oncogenic signaling pathways in laryngeal carcinoma.

Ahmed Ismail[1], Iuliia Topchu[2], Amr Ismail[1], Tingting Zhang[1], Xu Jia[1], Peter Makhov[3], Yanis Boumber[1]

[1]Section of Hematology and Oncology, Department of Medicine, University of Alabama at Birmingham & O'Neal Comprehensive Cancer Center, Birmingham, AL,[2]Kazan Federal University, Kazan, Russian Federation,[3]Fox Chase Cancer Center, Philadelphia, PA

Head and neck squamous cell carcinoma (HNSCC) is the sixth most common cancer worldwide. Despite the current advances in management, the 5-year survival rate for HNSCC remains around 66%. HPV-negative HNSCC accounts for approximately 70% of all diagnosed HNSCC cases. Therefore, a better understanding of the HPV-negative HNSCC drivers and targetable points may lead to significant clinical advances. NSD2 is a histone methyltransferase that catalyzes histone H3 lysine 36 di-methylation ($H3K36me^2$). Mutations leading to NSD2 loss-of-function are associated with improved outcomes in about 5% of HNSCC, including about 15% of laryngeal carcinoma (LC) patients. In our study, we demonstrate that NSD2 shRNA depletion in JHU-011 and JHU-022 LC cell lines results in a reduction of H3K36me2 levels and reduced cell growth in these cells in vitro. To evaluate downstream cancer signaling regulated by NSD, we performed a reverse-phase protein array (RPPA) upon NSD2 depletion in LC cell lines. Validation of RPPA using Western blot analysis suggests that NSD2 may regulate the expression of critical proteins responsible for the DNA damage response (DDR), including ATM kinase, PTEN, Akt/mTORC1 signaling pathway, and the cell cycle-related protein CDC2/p-CDC2 Y15 (CDK1/p-CDK1 Y15). Taken together, these data identify NSD2 as a likely regulator of the DNA damage response, Akt/mTORC1 signaling, cell cycle transition, and cell growth in HNSCC, suggesting that NSD2 may be a valuable therapeutic target in LC.

#0596 DDX3 modulates mitochondrial function to inhibit HCC progression.

Jun-Huan Huang[1], Heng-Yu Lin[2], Yi-Yuan Su[3], **RU-TSUN MAI**[3]

[1]Institute of Molecular Medicine and Bioengineering, National Yang Ming Chiao Tung University, Hsinchu, Taiwan,[2]Center for Intelligent Drug Systems and Smart Bio-devices (IDS2B), National Yang Ming Chiao Tung University, Hsinchu, Taiwan,[3]Department of Biological Science and Technology, National Yang Ming Chiao Tung University, Hsinchu, Taiwan

Background: Mitochondria are essential organelles responsible for ATP generation and play pivotal roles in diverse cellular processes. Mitochondrial dysfunction contributes to various pathological conditions, including cancer development. As the central organ for nutrient metabolism, the liver contains a particularly high density of mitochondria. Impaired mitochondrial function leads to excessive generation of reactive oxygen species (ROS) and oxidative stress, resulting in cellular damage closely associated with hepatocellular carcinoma (HCC). Cancer cells frequently undergo metabolic reprogramming to sustain their high energy demands during rapid proliferation. Given our previous findings identifying DDX3 as a tumor suppressor in HCC, this study aims to elucidate the effects of DDX3 on mitochondrial function and redox regulation, as well as its implications for HCC tumorigenesis.
Methods: Mitochondrial morphology in DDX3-deregulated HCC cells was analyzed using super-resolution confocal microscopy. The expression of mitochondrial dynamics-related proteins was assessed by immunoblotting and quantitative real-time PCR. Metabolic activity was examined by MitoTracker Red/Green staining and Seahorse extracellular flux analysis. Redox homeostasis was evaluated by MitoSOX and DCFH-DA staining, along with measurements of the GSH/GSSG ratio and NADPH/$NADP^+$ levels. DDX3-regulated cellular functions were investigated through proliferation, colony formation, and transwell migration/invasion assays, with or without metabolic inhibitors. Cancer stemness was assessed using sphere-formation, chemoresistance, and flow cytometry-based assays.
Results: Reduced DDX3 expression in HCC cells led to marked alterations in mitochondrial morphology and increased mitochondrial oxidative phosphorylation (OXPHOS), resulting in elevated mitochondrial superoxide accumulation. Unexpectedly, the total cellular ROS levels were decreased in DDX3-knockdown cells. Further analyses revealed that low DDX3 expression enhances the cellular capacity to maintain redox balance, conferring a more robust antioxidant defense. Additionally, HCC cells with reduced DDX3 expression exhibited greater proliferation and self-renewal potential under varying nutrient conditions, effects that were attenuated upon treatment with metabolic inhibitors.
Conclusion: Our results suggested that DDX3 may suppress HCC progression by inhibiting mitochondrial activity, thereby reinforcing its role as a tumor suppressor in HCC.

#0597 CREBBP mutation promotes tumor growth by impairing HDAC3 acetylation-dependent expression of PTEN.

Xiang Wang, Wenquan Hu, **Qing Robert Miao**

NYU Langone Hospital - Long Island, Mineola, NY

Somatic mutations in CREB binding protein (CREBBP or CBP), which encodes a histone acetyltransferase, are frequently observed in cancers such as lymphoma and non-small cell lung cancer. Here, we report that CREBBP loss-of-function (LOF) mutations lead to the deacetylation of histone deacetylase 3 (HDAC3) and promote cancer cell growth by transcriptional silencing of the tumor suppressor gene phosphatase and tensin homolog (PTEN). Mechanistically, we found that CBP specifically binds to HDAC3 and acetylates it at a previously unknown residue, which is necessary for reducing HDAC3 activity and increasing histone acetylation. Additionally, our data show that HDAC3 acetylation is crucial for maintaining PTEN expression via acetylated histone-regulated transcription. The loss of HDAC3 acetylation in cancers with CBP LOF mutations results in PTEN deficiency, thereby promoting tumor development and resistance to chemotherapy. Our findings reveal a novel epigenetic mechanism regulating PTEN expression and suggest that HDAC3 could be a potential alternative target for cancers with CBP LOF mutations.To our knowledge, this is the first report of the previously unrecognized acetylation of HDAC3, a critical deacetylase involved in cancer. This discovery is significant because our data show that HDAC3 acetylation is essential for regulating its activity by disrupting the CK2a-mediated phosphorylation of HDAC3. We clarify that HDAC3 acetylation is controlled by the acetyltransferase CBP and the deacetylase Sirt1. The key finding is the connection between HDAC3 acetylation and PTEN loss in CBP mutant cancers. Our data also link HDAC3 acetylation to cancer patient survival and suggest that targeting HDAC3 could help restore the tumor suppressor PTEN in cancers with CBP LOF mutations. Our results provide a new understanding of the epigenetic regulation of PTEN in tumor development.

#0598 CRISPR Cas9 Screens in Mice to Identify Tumor Suppressors of Aggressive Human Lymphoma.

Vivian Morris[1], Julius Enssle[1], Ashok Kumar[1], Arnold Bolomsky[1], Moyi Li[1], Yandan Yang[1], Da Wei Huang[1], George Wright[2], Weihong Xu[1], Hong Zhao[1], James Phelan[1], Jagan Muppidi[1], Louis Staudt[1]

[1]Lymphoid Malignancies Branch, NIH NCI, Bethesda, MD,[2]Biometric Research Branch, Division of Cancer Treatment and Diagnosis, NIH NCI, Bethesda, MD

Diffuse Large B Cell Lymphoma (DLBCL), the most common form of aggressive Non-Hodgkin's Lymphoma, has been subdivided into genetic subtypes that respond differentially to therapy. The MCD subtype, characterized by MYD88L265P and CD79B mutations, is a subtype of DLBCL with some of the worst clinical outcomes. Patients have the lowest response rates to the standard of care - R-CHOP immunochemotherapy. To study MCD biology, we have developed a mouse model harboring four MCD-associated genetic alterations. With age, these mice develop DLBCL that arises in the spleen following an accumulation of spontaneous germinal center B Cells (GC Bs) suggesting they play a role in the transformation to malignancy. These MCD mice develop DLBCL with age which suggests additional genetic events are necessary to accelerate tumor development. The MCD genetic subclass of DLBCL is enriched for mutations in many genes that could potentially function as tumor suppressors. Thus, we conditionally expressed Cas9 in the MCD murine model enabling loss-of-function assays to study putative tumor suppressors in a premalignant setting. We screened candidate tumor suppressor genes using CIRSPR/Cas9 mediated knockout, which revealed that loss of Setd1b, a histone methyltransferase, and Tbl1xr1, a subunit of a transcriptional repressor complex, caused the largest increase in premalignant splenic GC Bs, suggesting they play a key role in driving MCD pathogenesis. Furthermore, the combined loss of these genes causes an even larger increase in this premalignant subpopulation, indicating a functional relationship between these two genes. Single cell RNA sequencing data showed that loss of Setd1b and Tbl1xr1 alters the phenotype of splenic GC B, resulting in a neomorphic cell state with features of both GC Bs and memory B cells. The combinatorial loss of these genes also induced gene expression signatures characteristic of the oncogenic signaling pathways that human MCD tumors depend upon. These data point towards a cooperative functional relationship between these genes, a discovery that is further supported by analysis of human MCD tumors, in which SETD1B and TBL1XR1 are genetically inactivated in the same tumors significantly more often than expected by chance. Thus, we aged MCD-Cas9 mice transduced with either guide-RNAs against both Setd1b and Tbl1xr1 or a non-targeting control and found the double knockout mice had accelerated tumorigenesis. As we continue to investigate the role of these now validated tumor suppressors in the development of MCD-DLBCL, we hope to shed valuable light on their contribution to lymphomagenesis, which may reveal new therapeutic vulnerabilities in this aggressive cancer.

#0599 AKT2 loss inhibits mixed lineage liver malignancy induced by PTEN loss involving TGFb-Notch-SOX9 signal.

Qi Tang, Yiwei Gu, Jingyu chen, Lina He, Ni Zeng, Shunan Hu, Slarve Ielyzaveta, Diala Alhousari, Guo Zhang, Zifei Xu, Phillip Nguyen, Gray Kanel, Shefali Chopra, Liyun Yuan, Bangyan L. Stiles

University of Southern California, Los Angeles, CA

Primary liver malignancies—including hepatocellular carcinoma (HCC) and cholangiocarcinoma (CCA)—originate from the oncogenic conversion of hepatocytes and cholangiocytes, respectively. Loss or attenuation of phosphatase and tensin homolog (PTEN), a critical negative regulator of the PI3K-AKT signaling axis, is frequently observed in roughly 70% of CCA and 50% of HCC cases. Intriguingly, the incidence of PTEN mutations is approximately doubled in tumors manifesting a combined HCC-CCA phenotype relative to tumors classified as either HCC or CCA alone. Using lineage-specific liver-specific PTEN-deficient mouse models, we show that PTEN loss drives cellular dedifferentiation and oncogenic progression, a process that exhibits strict dependence on AKT2. Mechanistically, we show that PTEN deficiency induces upregulation of NOTCH and SOX9 signal, with SOX9 playing important roles in tumor cell transformation. Furthermore, PTEN loss deficiency enhances the susceptibility of tumor cells to TGFβ, with TGFβ treatment repressing the expression of SOX9 in the absence of PTEN. Together, our study identifies PTEN-AKT2 signaling as a key regulator of hepatocyte lineage fidelity and reveals how its disruption enables the reprogramming of mature hepatocytes or cholangiocytes into liver cancer stem cells (LCSCs). We further delineate the cooperative interplay between NOTCH and TGFβ pathways in PTEN loss-driven liver tumorigenesis.

#0600 ZNF865 as a novel molecular target for cancer treatment.

Cansu Umran Tunc[1], Hamid Ghandehari[1], Robert Bowles[2]

[1]Molecular Pharmaceutics, University of Utah College of Pharmacy, Salt Lake City, UT,[2]Biomedical Engineering, University of Utah College of Engineering, Salt Lake City, UT

Despite the advancements and increased availability of conventional cancer therapies, there is a need for strategies to enhance treatment, prolong survival, and prevent recurrence and resistance. Gene therapies can address the limitations of traditional anti-cancer therapies to improve outcomes. Modulation of cancer-related genes has shown promising results. Identifying specific proteins and pathways that drive cancer cell proliferation and survival as molecular targets is fundamental for cancer gene therapy. ZNF865 is a 1056 amino acid-long protein with 20 unique ZNF and two transactivation domains identified by our team [1]. Even though ZNF865 is widely expressed in all cell types, the function of this protein is not fully known. We have demonstrated that the expression of ZNF865 affects the viability and proliferation of multiple cell types, and that upregulation of ZNF865 leads to the repair of DNA damage, while downregulation leads to rapid DNA damage accumulation, which pushes cells into and out of senescence. DNA damage/cellular senescence is recognized as a key tumor-suppressor mechanism in cancer. A dramatic decrease in cell proliferation capacity in ZNF865 downregulated cells suggests that this protein may be a molecular target for cancer. Survival analysis of lung and esophageal cancers showed a correlation between ZNF865 expression and survival probability. The purpose of this study is to investigate the role of ZNF865 in cancer cell proliferation and invasion. For this, ZNF865 was knocked down in lung adenocarcinoma cells (A549) with CRISPRi using the lentivirus system. The ZNF865 downregulated cells were sorted with flow cytometry. The proliferation of the cells was assessed using colony formation assay. The cells were allowed to proliferate for 14 days. The changes in the invasive potential of the cells were assessed using scratch assay for 48 h. Apoptosis rates of the cells were determined using Annexin-V/PI analysis, and the cell cycle phase distributions of the cells were analyzed by flow cytometry. The toxicity of cisplatin was tested using CCK8 viability assay. The ZNF865 knockdown resulted in approximately 90% decrease in clonogenic survival of the lung cancer cells ($p<0.001$). The gap closure in scratch assay was inhibited by 35% in the ZNF865 downregulated cells compared to the non-target control at 24 h ($p<0.001$). Apoptosis rates, cell cycle phase distributions, and cisplatin toxicity were not significantly affected by inhibition of ZNF865 expression, indicating alternate molecular mechanisms of action. Our findings suggest that silencing ZNF865 gene inhibited proliferation and decreased the invasion rate of the A549 cells, indicating ZNF865 may be a therapeutic target for lung cancer treatment. Future studies include validating the effect of ZNF865 downregulation on cancer proliferation and invasion in additional cancer cell types. 1. Lewis, C., et al., ZNF865 (BLST) Regulates Human Cell Senescence and DNA Damage. 2025.

#0601 Translational reprogramming disrupts mitosis to drive SMAD4-deficient esophageal adenocarcinoma.

Julia V. Milne, Ka Meng Wu, Sasha Witts, Eric Kusnadi, Kenji Fujihara, Katherine Papastratos, Maree Pechlivanis, Anna Trigos, Metta Jana, Luc Furic, Kaylene Simpson, David Liu, Cuong Duong, Wayne Phillips, Nicholas Clemons

Peter MacCallum Cancer Centre, Melbourne, Australia

Esophageal adenocarcinoma (EAC) develops from a precursor lesion named Barrett's esophagus; a progression that can be mapped by increasing genomic instability. We have previously shown that SMAD4 loss induces tumorigenesis and increased copy number alterations (CNA) in Barrett's esophagus cells with an existing *TP53* mutation. The observed CNA increase was especially pronounced in the resultant SMAD4-deficient tumor cells, suggesting that accumulation of mitotic errors occurs in these cells throughout their oncogenic progression. However, such an effect cannot be explained by our current understanding of canonical SMAD4 signalling. Thus, in this study, we aimed to delineate the role of SMAD4 in maintaining chromosomal stability in EAC. Our multi-omics (RNA-sequencing, proteomics and reverse-phase protein array) approach detected both deregulated translation and mitosis signatures in SMAD4-deficient cells. Using live cell imaging, we demonstrated that *TP53*-mutant SMAD4-deficient cells exhibit significantly more mitotic errors than *TP53*-mutant only cells, particularly chromosome segregation defects, which frequently result in chromosomal instability (CIN). Consistent with this, analysis of TCGA data demonstrated that CIN was more prevalent in tumours with both *SMAD4* and *TP53* mutation than either mutation alone. Further biochemical analyses revealed an increase in cap-dependent translation in these cells, and a decrease in internal ribosome entry site (IRES)-mediated translation. IRES-mediated translation is essential for synthesis of many important mitotic proteins, including a mitosis-specific isoform of a cell cycle kinase. Polysome sequencing showed decreased translation (but not transcription) of this kinase in SMAD4-deficient cells. Ectopic expression of mitosis-specific isoform of this kinase rescued the mitotic errors that arose as a consequence of SMAD4 loss. In sum, we present a model where translational reprogramming disrupts mitosis, inducing CIN and potentially driving EAC tumorigenesis in response to loss of SMAD4. This represents a novel mechanism of tumorigenesis in EAC and a previously unknown role of SMAD4 in maintaining chromosomal integrity.

#0602 Primary site specific distribution and prognostic significance of p53 immunohistochemistry patterns in 1,515 patients with head and neck squamous cell carcinoma.

Takane Watanabe[1], Yoshitaka Honma[2], Toshihide Ueno[3], Yukiko Nakamura[2], Eijitsu Ryo[4], Hideaki Takahashi[2], Akiko Mori[5], Yuko Kubo[6], Mitsuhiko Katoh[7], Kohtaro Eguchi[7], Azusa Sakai[7], Toshihiko Sakai[7], Chihiro Fushimi[7], Go Omura[7], Kenji Okami[1], Yasushi Yatabe[8], Hiroyuki Mano[3], Seiichi Yoshimoto[7], Taisuke Mori[8]

[1]Otorhinolaryngology/Head and Neck Surgery, Tokai University Hospital, Isehara, Japan,[2]Head and Neck, Esophageal Medical Oncology, National Cancer Center Hospital, Tokyo, Japan,[3]Cellular Signaling, National Cancer Center Research Institute, Tokyo, Japan,[4]Molecular Pathology, National Cancer Center Research Institute, Tokyo, Japan,[5]Dental Surgery, National Cancer Center Hospital, Tokyo, Japan,[6]Diagnostic Radiology, National Cancer Center Hospital, Tokyo, Japan,[7]Head and Neck Surgery, National Cancer Center Hospital, Tokyo, Japan,[8]Diagnostic Pathology, National Cancer Center Hospital, Tokyo, Japan

Background: Head and neck squamous cell carcinoma (HNSCC) is characterized by a high prevalence of TP53 mutations, reported in approximately 70% of cases in The Cancer Genome Atlas (TCGA). Although primary site-specific variation in TP53 mutation prevalence and related clinical behavior has been suggested, the TCGA cohort is biased toward certain primary sites—particularly the oral cavity and larynx—with limited representation of oropharyngeal and hypopharyngeal tumors. To address this sampling bias, we aimed to clarify the prevalence and anatomical distribution of HNSCC, as well as its prognostic implications, using comprehensive p53 immunohistochemistry (IHC) in a large institutional cohort.

Methods: We retrospectively analyzed 1,515 patients with HNSCC who underwent biopsy or surgery at the National Cancer Center Hospital between 2013 and 2023. TP53 status was inferred from p53-IHC patterns (wild-type, lost-type, or accumulation-type), and p16-IHC was performed to assess HPV association. Primary site-specific and subsite-specific prevalence patterns were evaluated using Fisher's exact test and odds ratios (ORs). Overall survival (OS) and disease-specific survival (DSS) were assessed in 1,364 patients after excluding carcinoma in situ, best supportive care, and outside-treated cases.

Results: Among 1,515 HNSCC cases, 409 (27.0%) were classified as p53 wild-type, 736 (48.6%) as accumulation-type, and 370 (24.4%) as lost-type. The prevalence of p53 mutated-type tumors varied markedly across anatomical sites. Mutation-enriched primary sites included the hypopharynx/cervical esophagus (OR = 5.10, 95% CI: 3.49-7.46, $p < 0.01$), larynx (OR = 1.88, 95% CI: 1.22-2.88, $p < 0.01$), and oral cavity (OR = 1.54, 95% CI: 1.19-2.00, $p < 0.01$). In contrast, p53 wild-type tumors were significantly frequent in the oropharynx (OR = 0.25, 95% CI: 0.19-0.33, $p < 0.01$) and nasopharynx (OR = 0.24, 95% CI: 0.13-0.47, $p < 0.01$). Survival analysis revealed significantly improved outcomes in the p53 IHC wild-type group compared with the mutated-type group (median OS: not reached vs. 110 months; HR = 0.59, 95% CI: 0.46-0.76, $p < 0.01$; median DSS: both not reached; HR = 0.65, 95% CI: 0.47-0.89, $p = 0.01$).

Conclusion: This large cohort study demonstrates substantial primary site-specific variation in p53 alteration patterns across HNSCC, with notable enrichment of IHC p53-mutated tumors in the hypopharynx and larynx, and enrichment of p53 IHC wild-type tumors in oropharyngeal, nasopharyngeal, and gingival cancers. The p53 IHC wild-type pattern was consistently associated with significantly better survival. These findings highlight the importance of anatomical subsite context when interpreting TP53 status and suggest that p53 IHC serves as a robust, clinically relevant biomarker in HNSCC.

#0603 Variation at the R181 residue of p53 confers loss of p53 DNA binding cooperativity with the retention of mitochondrial-associated apoptosis.

Renyta Moses[1], Alexandra Indeglia[2], Alison Schwartz-Levine[3], Ryan Hausler[1], Gregory Kelly[1], Sven Miller[4], Isabel Anez[3], Melissa Heller[1], Rosella Delgado[1], Caitlin Orr[1], Wendy Kohlmann[5], Anne Naumer[5], Jennie Vagher[5], Sophie H. Cahill[3], Luke D. Maese[5], John Karanicolas[4], Judy E. Garber[6], Maureen E. Murphy[7], Kara N. Maxwell[8]

[1]University of Pennsylvania, Philadelphia, PA,[2]Brigham and Women's Hospital, Boston, MA,[3]Dana-Farber Cancer Institute, Boston, MA,[4]Fox Chase Cancer Center, Philadelphia, PA,[5]University of Utah Huntsman Cancer Institute, Salt Lake City, UT,[6]Director, Center for Cancer Genetics and Prevention, Dana-Farber Cancer Institute, Boston, MA,[7]Professor, The Wistar Institute, Philadelphia, PA,[8]Perelman School of Med. Univ. of Pennsylvania, Philadelphia, PA

TP53 is the most frequently mutated gene in cancer, and its encoded protein p53 has many tumor-suppressive functions. p53 primarily acts as a transcription factor and binds to target sites on DNA cooperatively as a tetramer. This cooperative binding is mediated by salt-bridge interactions between p53 residues E180 and R181 from two different p53 monomers. Variants at the R181 residue are one of the most identified *TP53* pathogenic variants by germline genetic testing, however the mechanism by which these variants disrupt p53 tumor suppression is not understood. We show that families with *TP53* p.R181H and p.R181C variants have an attenuated cancer risk phenotype compared to patients with hotspot loss of function *TP53* variants. Despite this clinical phenotype, we find that p53 R181H and R181C variants have significantly diminished ability to transactivate a set of ~300 known p53 target genes in CRISPR knock-in colorectal and breast cancer cell lines. This loss of transactivation ability does not occur through defects in p53 structure or oligomerization, but through reduced cooperative binding to p53 target sites on DNA as determined using fluorescence polarization assays on purified p53 proteins and using chromatin immunoprecipitation sequencing in R181-mutant cancer cells.
Despite the complete loss of p53's transcriptional function, R181 mutants retain some tumor suppressive function. Colony formation assays show efficient colony suppression by R181H and R181C, and injecting R181 knock-in cancer cells into the subcutaneous tissue of mice results in comparable tumor progression levels between R181H, R181C, and wild-type p53. Interestingly, we observe residual apoptotic activity in R181H and R181C mutant cells when treated with DNA-damaging agent 5-fluorouracil, despite the poor transactivation of p53's proapoptotic targets. This suggests that the R181 mutants retain the p53 transcription-independent mechanism of apoptosis, where p53 goes to the mitochondria to induce apoptosis. Indeed, proximity ligation assays between p53 and mitochondrial BAK show that R181 mutants traffic to the mitochondria upon genotoxic stress. Our study elucidates p53 tumor suppressive activities that are lost versus retained by R181 variants, which is estimated to account for 0.5% of all p53 missense mutations.

#0604 Second site rescue mutants as tools to uncover reactivation mechanisms of p53 cancer mutants.

Fiona Law, Zane Norman, Mark Villamil, Peter Kaiser

Uc-Irvine, Irvine, CA

TP53 is an important tumor suppressor and is the most frequently mutated gene in human cancer. A large fraction of cancers with mutated p53 carry missense mutations, so they express full-length but nonfunctional p53. Therefore, reactivating mutated p53 to a wildtype-like conformation has long been a major therapeutic goal. However, the mechanisms underlying p53 reactivation are still poorly understood. To dissect this mechanism, this study employs a genetic strategy in which a second amino acid is mutated in addition to the G245S mutation found in cancer. This second mutation induces structural changes to compensate for the defect caused by p53 cancer mutations. Two second site rescue mutations were used in this study: N239Y, known to stabilize p53, and T123P, located within the transient L1/S3 pocket implicated in small molecule binding. When expressed alongside the cancer mutation G245S, both second site rescue mutations restored tumor suppressive properties, including suppressed growth, activated canonical p53 downstream targets, and restored DNA binding both in vitro and in cells. Differential scanning fluorimetry confirmed that N239Y increased folding stability of the G245S mutant. However, despite rescuing p53 activity, T123P further destabilized the structural stability of the G245S mutant. These findings demonstrate that p53 reactivation can occur through distinct and mechanistically divergent pathways, including those independent of global thermostabilization.Our results provide a genetic framework to classify reactivation mechanisms of p53 cancer mutants and define gene-expression signatures associated with each mechanism. Rather than being a direct treatment, this framework can help guide the identification and development of future small molecule p53 reactivators.

#0605 Mapping loss of heterozygosity in Li-Fraumeni Syndrome to uncover early molecular drivers of tumorigenesis.

Hailey Stack[1], Ashby Kissoondoyal[1], David Malkin[2]

[1]Genetics and Genome Biology, The Hospital for Sick Children, Toronto, ON, Canada,[2]The Hospital for Sick Children, Toronto, ON, Canada

Li-Fraumeni syndrome (LFS) is a cancer predisposition syndrome caused by germline mutations in TP53. Mutant p53 impairs DNA damage repair, causing dysregulation in cell growth and division. LFS patients have a 40% chance of developing cancer during childhood/early adolescence, and an almost 100% lifetime risk of developing a variety of cancers. A recent study found that 86% of tumors in LFS patients exhibit loss of the wild-type (WT) allele (loss of heterozygosity (LOH)), which was absent in healthy tissue, indicating specificity to pre-malignant and malignant cells. LOH appeared to occur many years before tumor diagnosis, likely in utero or early life, suggesting it plays an early role in LFS precancer development and later tumorigenesis. In cancers with somatic TP53 mutations, LOH is an early event in tumor evolution, leading to detrimental genomic events and accelerated tumor development. While the aftermath of TP53 LOH has been explored in sporadic cancers, the extent and contribution of LOH to cancer evolution and development in LFS remains poorly understood. We leveraged LFS patient-derived skin fibroblasts, collected either pre- or post-cancer diagnosis, to map LOH in cell culture over time. Droplet digital PCR was used to determine the allelic ratio between the WT and mutated copy of TP53. Interestingly, a significant increase in the mutated TP53 allele was seen in fibroblasts collected from patients years after diagnosis, suggesting loss of the WT allele, which was not observed in fibroblasts collected prior to cancer diagnosis. Single-cell RNA sequencing (scRNA-seq) will be used to identify gene expression at an individual cell level to distinguish between cells which have undergone allelic change and those which have not. This method will help identify transcriptomic changes, with subsequent GO analysis revealing biological pathway changes before, during, and after loss of WT TP53, generating specific LOH signatures in vitro. This signature identified will be mapped back to an in vivo LFS mouse model ($Trp53^{R172H/WT}$), probing for these in vitro transcriptomic signatures in scRNA-seq data across embryonic, post-natal and post-cancer development. LOH of WT TP53 precedes tumorigenesis, many years before tumor diagnosis in LFS. Knowing this, it is important to better understand mechanisms influencing, contributing, and responding to LOH in LFS. This is critical for cell evolution and precancer development in LFS, offering insight into opportunities for tumor prevention or interception. This project is generating the first map of LOH in LFS patient-derived fibroblasts, integrating allelic analyses and transcriptomic data, providing critical insights into the earliest stages of precancer evolution. By uncovering pathways that are differently regulated across distinct LOH states, the mechanisms of precancer development and potential therapeutic targets will be revealed.

#0606 DACH1 conveys isoform specific tumor suppressor functions.

Kenneth A. Iczkowski[1], Zhiping Li[2], HIdetoshi Mori[3], Danni Li[2], Samiha Nasser[4], Csaba Kerepesi[5], Andras Benczur[5], Hallgeir Rui[6], Ritika Harish[2], Xuanmao Jiao[2], Fred Saad[7], **Richard G. Pestell**[2]

[1]Pathology and Laboratory Medicine, University of California- Davis, Sacramento, CA,[2]Pennsylvania Cancer and Regenerative Medicine Research Center, Baruch S. Blumberg Institute, Wynnewood, PA,[3]University of California-Davis, Davis, CA,[4]The Ohio State University Wexner Medical Center, Columbus, OH,[5]Institute for Computer Science and Control (SZTAKI), Hungarian Research Network (HUN-REN), Budapest, Hungary,[6]Thomas Jefferson University, Philadelphia, PA,[7]University of Montreal, Montreal, ON, Canada

Introduction. DACH1 is expressed in renal glomerular podocytes and distal tubules. DACH1 has been described as either a tumor suppressor or oncogene, with increased or decreased abundance depending upon the tissue type. Recent studies showed that poor outcome of prostate cancer was correlated with the deletion of the DACH1 gene, within the 13q21 region, and prostate-specific deletion promoted prostatic intraepithelial neoplasia in prostate onco-mice. DACH1 generates several splice variant isoforms with a common carboxyl (C) terminus that cross-reacts with commercially available antibodies.

Methods. We characterized the function of three DACH1 isoforms. We developed a DACH1a isoform-specific antibody. We assessed DACH1a variant vs. DACH1 common C terminal immune reactivity in prostate cancer. Analysis included patient gene expression, tumor histology, tissue culture, and tissue-specific gene knockout transgenic mice.

Findings. Expression of DACH1a inhibited AR activity. DACH1a inhibited DNA synthesis and indicators of EMT, contrasting with the effects of DACH1b and DACH1c.

Compared to normal tissue, DACH1 expression was reduced in urogenital cancer (kidney cancer (chromophobe, clear cell, papillary) and testicular germ cell), sarcomas, and lung cancer, but increased in acute leukemia, lymphoma, colon and ovarian tumors. The relative levels of expression of the three isoforms of DACH1 (DACH1a, 1b, 1c), however, varied substantially between cancer types. The C terminal antibody cross-reacted with each isoform-generated DACH1 protein.

Monoclonal DACH1a specific antibody, which detected DACH1a in the kidney glomerular podocyte and distal tubule, showed a substantially different subcellular distribution to C terminal antibody immune reactivity in benign prostate vs. cancer. We conducted quantitative immunofluorescence at a single cell level using the opal multi-fluorophore technology, using the DACH1a specific antibody and additional DACH1a candidate interactors. Immunofluorescent staining of DACH1a showed reduced staining in prostate cancer compared to adjacent benign tissue.

Conclusions. Functional analysis shows DACH1 conveys isoform-specific tumor suppressor functions. Since the DACH1a isoform conveys specific and distinct functions, compared to other DACH1 isoforms, DACH1a isoform specific analysis may be required to predict patient outcome.

#0607 Quantitative analysis of microtubule lattice damage in NF1-deficient HER2-positive breast cancer under mitotic and pharmacological stress.

Eleonora Messuti[1], **Alessia Castiglioni**[1], Simona Rodighiero[1], Ambra Dondi[1], Bruno Achutti Duso[2], Luca Mazzarella[1]

[1]Department of Experimental Oncology, IEO - European Institute of Oncology, Milan, Italy,[2]Department of Cancer Medicine, Gustave Roussy Cancer Campus Grand Paris, Paris, France

Our understanding of microtubule (MT) dynamics has recently expanded to include remodeling events within the lattice, where mechanical stress generates discontinuities repaired through intra-lattice tubulin incorporation and EB1 redistribution. Only two factors, CLASP1 and SSNA1, are known to recognize and modulate this form of MT damage. Methods to reliably estimate MT damage and repair are not established, leaving their contribution to tumorigenesis and anticancer drug activity unclear. In our previous work, we demonstrated that loss of the tumor suppressor NF1, a new MT-associated protein (MAP), leads to increased MT damage in HER2-positive breast cancer cells. This in turn causes mitotic defects (potentially contributing to tumorigenesis) but also sensitization to maytansinoids like DM1, a drug class frequently used in Antibody-Drug Conjugates (ADC, T-DM1 and Mirvetuximab Soravtansine). To investigate MT damage and repair upon pharmacological and mechanical stress, we analyzed the distribution of EB1, normally confined to growing MT tips but known to redistribute along the MT body upon structural disruption or when repair factors like CLASP are ablated. We developed a novel method to systematically quantify EB1 and tubulin signal along single MTs. To achieve the spatial precision required to resolve EB1 we combined DeepSIM and expansion microscopy (ExM) with two complementary analytical strategies: manual 3D MT tracing using SNT ImageJ plugin (designed for neurite tracing) and an automated pipeline for MT segmentation and EB1 signal extraction. Upon DM1 treatment, EB1 showed progressive re-localization from the tip to the MT body, consistent with partial intra-lattice disruption in addition to its established de-polymerizing activity at the tip. In NF1 deficient cells, an initial increase in intra-lattice EB1 was followed by a sharp reduction in overall EB1 signal and pronounced MT fragmentation, indicating faster DM1-induced MT fracturing and depolymerization; this was abolished by NF1 re-expression. These results directly show how failed MT repair, more prominent in NF1 deficient cells, creates further intra-lattice DM1 binding sites explaining increased sensitivity. In mitosis, NF1 deficient cells showed strongly increased EB1 signal on the MT shaft, consistent with failure of repair under strong mechanical stress. EB1 shaft localization and mitotic defects (chromosome missegregation, aneuploidy) were rescued by NF1 re-expression.By establishing a quantitative framework to measure EB1 redistribution at single MT resolution, our study provides a previously unavailable strategy to monitor intra-lattice damage in cancer cells. These findings establish for the first time a direct causative link between unrepaired MT damage and chromosomal instability, providing a new model to understand maytansinoid mechanism of action.

#0608 Ccn6 loss cooperates with EZH2 overexpression to induce sarcomatoid differentiation in metaplastic breast carcinoma.

Maria E. Gonzalez[1], Ahmad Eido[1], Kendall Miller[1], Celina G. Kleer[2]

[1]University of Michigan, Ann Arbor, MI,[2]Harold A. Oberman Collegiate Professor, Dept. of Pathology, University of Michigan Medical School, Ann Arbor, MI

Background: Triple negative breast cancers (TNBC) have proven resistant to conventional and immune therapies with 5-year survival rates of 50%. Among the most aggressive of these is metaplastic breast carcinoma (mBrCA), a unique histopathology with spindle or sarcomatoid (chondroid/osseous) components and low immune cell infiltration with poor responses to immunotherapy. We have reported that mammary epithelial cell-specific *Ccn6* knockout mice (MMTV-Cre;*Ccn6*$^{fl/fl}$) develop mBrCAs like human spindle mBrCAs, defining *CCN6 as a tumor suppressor for spindle mBrCA*. Lately we showed CCN6 antagonizes the pro-invasive effects of Wnt/ β-catenin/EZH2 signaling. Here, we tested the hypothesis that CCN6 genetically interacts with EZH2 to induce a phenotypic switch from spindle to sarcomatoid cancer cell phenotype and limits CD8$^+$T cell infiltration.

Methods: MDA-MB-231 (TNBC) and Ccn6-KO cells derived from MMTV-Cre;Ccn6$^{fl/fl}$ (Ccn6-KO) TNBC mouse model were transduced with vector or EZH2 shRNA knockdown (KD). Ccn6-KO EZH2 KD cells were rescued with lentivirus containing EZH2-wild-type (WT). To overexpress EZH2 we infected cancer cells with adenovirus with vector or EZH2-MYC construct. We investigated how Ccn6 loss and EZH2 affect mBrCA sarcomatoid by differentiation assays of the breast cancer cells in chondrogenic and osteogenic specialized media compared to controls. In vivo, to recapitulate the bone microenvironment, we injected Ccn6-KO cells into the tibia of FVB mice and treat them with the EZH2 inhibitor EPZ-6438. Flow cytometry analyses of tumors derived from Ccn6-KOshC, shEZH2 and EZH2-wild type rescue cells and IHC of Ccn6-KO tumors treated with EZH2i were used to measure the percentage of CD8$^+$gzmb$^+$IFNg$^+$ T cells. ChIP-sequencing studies in dominant negative (dn)TCF4 mutant vs. controls were used to study regulation of bivalent genes in Ccn6-KO cells.

Results: EZH2 overexpression in Ccn6-KO spindle mBrCA cells induces chondrogenic and osteogenic differentiation in cells grown in specialized media and EZH2 inhibition rescues the sarcomatoid phenotype in vivo. We found that EZH2 shRNA KD or pharmacological inhibition increases CD8+T cell infiltration in Ccn6-KO tumors, which is rescued by EZH2 overexpression. WNT/β-catenin signaling blockade in Ccn6-KO cells using dnTCF4 downregulates EZH2 and H3K27me3 mark at the promoter regions of 19 bivalent gene targets with roles in development.

Conclusion: These data provide a clear link between CCN6 defects and EZH2 overexpression as inducers of sarcomatoid immune cell-low mBrCAs. We demonstrate the effectiveness of pharmacological inhibition of EZH2 methyltransferase activity in reversing these aggressive phenotypes. These data reveal a novel oncogenic cooperation and provide evidence to support the potential therapeutic value of CCN6 restoration, Wnt pathway and EZH2 inhibition as promising strategies for mBrCA patients

#0609 Investigating tumor suppressor function and regulatory control of NISCH in breast cancer.

Abigail E. Rink[1], Suresh K. Alahari[2]

[1]Louisiana State University Health Sciences Center, New Orleans, LA,[2]Brazda Professor, Biochem. & Molec. Bio., Louisiana State University Health Sciences Center - New Orleans, LA, New Orleans, LA

Purpose: This study aimed to characterize the role of Nischarin (NISCH) in breast cancer by examining its expression patterns in relation to clinical outcomes and exploring potential regulatory mechanisms—specifically promoter methylation and copy number alterations—that may underlie its dysregulation.

Methods: Data were acquired for NISCH from the Molecular Taxonomy of Breast Cancer International Consortium (METABRIC) and The Cancer Genome Atlas (TCGA) via UCSC Xena and cBioPortal, including expression levels of NISCH and several DNA methyltransferases (DNMTs), promoter methylation beta values, copy-number values, demographic variables, and clinical data. All retrospective analyses were performed using GraphPad Prism.

Results: High expression of NISCH was significantly associated with improved overall survival in breast cancer, as well as longer distant metastasis-free survival and relapse-free survival. When comparing demographics, a lower expression of NISCH was observed in patients diagnosed at younger ages, within the Basal PAM-50 subtype, and among the Asian race. Several CpG islands proximal to the promoter region showed both a negative correlation with NISCH expression and elevated methylation in tumor samples. Co-expression studies revealed inverse correlations between three DNMTs and NISCH, indicating possible involvement in the silencing of the gene. Furthermore, shallow deletions at the NISCH locus correlated with reduced mRNA expression and were linked to poorer survival outcomes.

Conclusions: Together these findings support NISCH's profile as a tumor suppressor in breast cancer, with high mRNA expression consistently linked to better survival outcomes across multiple clinical metrics. Moreover, identifying lower NISCH expression in biologically aggressive subsets of breast cancer—the Basal PAM-50 subtype and younger age at diagnosis—enhances NISCH as a putative marker for poor prognosis. Both promoter methylation and shallow deletions reduced expression of NISCH, indicating that the locus may be regulated through several genomic and epigenetic mechanisms. Inverse expression patterns between NISCH and three DNMTs across similar demographic subsets provides additional evidence that promoter-methylation may drive the silencing process. Collectively, these findings strengthen the rationale for future functional studies to investigate the mechanisms controlling NISCH expression, and to evaluate its potential as a biomarker or therapeutic target in breast cancer.

#0610 Lack of circadian regulator PER2 enhances breast cancer susceptibility and progression via immunosuppression.

Yixin Duan[1], **Helen Zhang**[1], Hongyong Zhang[2], Jie Huang[3], Xiong Zhang[1], Aris Alexandro[4], Dake Hao[5], Jonathan I. Berg[1], Ming Fan[1], Yili Wang[6], Loning Fu[7], Hong-Wu Chen[8], Jian Jian Li[1]

[1]UC Davis Medical Center, Sacramento, CA,[2]UC Davis, Davis, CA,[3]Hangzhou Cancer Hospital, Hangzhou, China,[4]Holy Cross College, Notre Dame, IN,[5]UC Davis, Sacramento, CA,[6]Jiaotong University, Xian, China,[7]Asst. Professor, Dept. of Pediatrics, Baylor College of Medicine, Houston, TX,[8]Associate Professor, UC Davis Comp. Cancer Center, Sacramento, CA

Circadian rhythm (CR) orchestrates the physiological functions of nearly all organs in the human body. Disruption of circadian rhythm (CRD), caused by environmental factors such as shift work or by loss of core clock genes, is associated with heightened susceptibility to malignancies of the female reproductive system, particularly breast cancer (BC). However, whether deficiency of a specific clock gene directly confers breast cancer susceptibility and systemic immune suppression remains largely unresolved. Here, we investigated the role of the circadian regulator Period 2 (PER2) in breast tumorigenesis and immune evasion.

Combined the data from TCGA datasets and a DMBA-induced mammary tumor model established in $Per2^{def}$ and $Per2^{wt}$ mice we analyzed the tumor immune profiles assessed by IHC and flow cytometry. The effects of PER2 loss on breast cancer malignancy were tested using proliferation, invasion, and clonogenic assays. Mechanistic studies (Western blot, qRT-PCR, and luciferase assays) defined the PER2-dependent pathway regulating tumor immune escape. PER2 expression was markedly reduced in BC and correlated with poor prognosis in female patients. Per2^def mice exhibited significantly increased susceptibility to DMBA-induced mammary tumor formation, indicating an intrinsic tumor-protective role for PER2. Immune profiling revealed a profoundly immunosuppressed microenvironment in Per2^def tumors, characterized by reduced cytotoxic $CD8^+$ T cells and $CD80^+$ M1 macrophages, accompanied by elevated pro-tumor $FOXP3^+$ regulatory T cells and $CD206^+$ M2 macrophages.

In human breast cancer cells, PER2 knockdown induced aggressive and clonogenic phenotypes, whereas PER2 reconstitution reversed these effects. Loss of PER2 led to increased expression of HER2 and CD47, two oncogenic drivers of proliferation and immune evasion, respectively. Consistent with this, PER2 overexpression suppressed, whereas PER2 silencing enhanced, the transcriptional activities of HER2 and CD47 promoters. JASPAR predictions identified CLOCK-binding motifs within both promoters, and mutation of these motifs markedly diminished transcriptional activation in MCF7 and SKBR3 cells. Luciferase reporter assays further demonstrated that PER2 represses HER2 and CD47 expression by inhibiting CLOCK-mediated transactivation.

Collectively, these findings reveal that PER2 deficiency triggers CLOCK-dependent upregulation of HER2 and CD47, promoting both tumor aggressiveness and immune escape. This study uncovers a dual mechanism by which clock gene loss enhances breast cancer susceptibility with systemic immunosuppression, highlighting $PER2^{def}$-CLOCK-HER2/CD47 signaling as a potential integrated therapeutic axis to mitigate CRD-associated breast cancer risk and tumor aggressiveness.

#0611 NSD1-AURKA-SETD2 axis creates novel mitotic vulnerabilities in clear cell renal cell carcinoma.

Manga Motrapu, Ashley Boice, Richard Han, Xiaoli Wang, Pratim Chowdhury, Sung Jung, **Ruhee Dere**

Baylor College of Medicine, Houston, TX

Background: Chromothripsis-driven 3p deletion and 5q amplification are early, clonal events in clear cell renal cell carcinoma (ccRCC). These lesions respectively target the epigenetic regulators SETD2 and NSD1. Paradoxically, although NSD1 is amplified on 5q, it is frequently hypermethylated and transcriptionally silenced, suggesting functional inactivation is selected for. The mechanistic implications of *NSD1* and *SETD2* loss in mitotic control remain poorly understood.

Methods: We integrated multi-pronged approaches using in vitro kinase and methyltransferase assays, mass spectrometry, molecular modeling, and CRISPR-engineered models to dissect the regulatory relationship between NSD1, AURKA, and SETD2. Protein-protein interactions and post-translational modifications were characterized via co-immunoprecipitation, immunoblotting, fluorescence microscopy, and quantitative proteomics.

Results: We identified NSD1 as a methyltransferase that directly methylates AURKA, serving as a negative regulator of its kinase activity and subcellular dynamics during mitosis. Loss of *NSD1*, through genetic deletion or pharmacologic inhibition, led to AURKA hyperactivation, defective spindle architecture, chromosome mis-segregation, and increased micronuclei formation. Unexpectedly, we found that AURKA phosphorylates SETD2, functionally linking these two epigenetic regulators. This phosphorylation selectively regulated SETD2's cytoskeletal activity without affecting its chromatin-associated roles. Disruption of this modification—via AURKA inhibition or mutation of the phosphorylation site—compromised mitotic fidelity and enhanced genomic instability.

Conclusions: Our findings reveal a novel regulatory pathway in which NSD1-mediated methylation suppresses AURKA, while AURKA phosphorylation regulates SETD2 activity on the cytoskeleton, linking these two tumor suppressors altered in renal cell carcinoma (RCC). Disruption of this NSD1-AURKA-SETD2 axis creates a state of mitotic vulnerability, opening the door for therapeutic intervention using AURKA inhibitors in genetically defined subsets of ccRCC. Our data present a rationale for loss of *NSD1* and *SETD2* in the setting of RCC aimed at dismantling this regulatory axis to drive tumor evolution. This dual loss creates a state of dependency on AURKA activity, providing a rationale for AURKA-based inhibition in a subset of RCC patients with dual loss of *NSD1* and *SETD2*.

#0612 A novel regulatory pathway as a driver of malignant transformation in mesothelioma..

Flavia Novelli[1], Lydia Giannakou[1], Jin Hee Kim[1], Joelle S. Suarez[1], Cristina Favaron[1], Qian Wang[2], Angela Bononi[1], Michele Carbone[1], Haining Yang[1]

[1]University of Hawaii Cancer Center, Honolulu, HI,[2]University of Science and Technology of China, Hefei, China

Mesothelioma is a highly aggressive malignancy of the serosal membranes. Alterations in regulatory mechanisms controlling tumor suppressor gene expression play a critical role in Mesothelioma and other malignancies. Although tumor suppressor genes are central to cancer biology, the upstream regulation networks governing their activity remain poorly defined. Here, we identify a novel molecular pathway that directly regulates BAP1 tumor suppressor gene transcription and drives oncogenic phenotypes in Mesothelioma. Using patient-derived fibroblasts harboring germline mutations, mesothelioma cell lines, and a genetic knockout mouse model, we demonstrate that disruption of this pathway markedly decreases tumor suppressor expression, whereas its activation restores gene transcription and promotes cell proliferation, migration, and invasion. These findings reveal a novel regulatory loop mechanism in which tumor suppressor gene inactivation facilitates malignant transformation, while its activation sustains tumor progression. Similar regulatory dynamics were observed across additional cancer types, including lung, colon, and cholangiocarcinoma, indicating a conserved process. This work defines a novel transcriptional axis integrating tumor suppressive and oncogenic signaling in Mesothelioma and other cancers, offering new therapeutic opportunities.

#0613 Bap1 driven soft tissue sarcomas: Mouse modeling and therapeutic strategies.

Xingliang Liu, William Haugh, Bryan R. Bell, **Jianguo Huang**

Earle A. Chiles Research Institute, Portland, OR

Objective: Soft tissue sarcomas (STS) are rare in both pediatric and adult cancer patients, yet they remain highly lethal and understudied. Many STS subtypes, including undifferentiated pleomorphic sarcoma (UPS) and embryonal rhabdomyosarcoma (eRMS), exhibit significant genetic heterogeneity and lack recurrent oncogenic driver mutations, complicating the development of broadly effective therapies. A promising strategy is to design targeted treatments for subsets of STS driven by specific tumor suppressor alterations. However, the molecular pathogenesis of UPS and eRMS remains poorly understood, limiting therapeutic progress. Germline and somatic mutations in BRCA1-associated protein 1 (BAP1), an epigenetic regulator, have been linked to multiple STS subtypes, yet its role in suppressing sarcoma development is unclear. Using a murine model, we recently identified BAP1 deletion as a driver event in STS development. This model provides a platform to dissect BAP1's functional role and to explore novel therapeutic strategies.

Methods: We established well-characterized Bap1-deficient sarcoma cell lines derived from mouse models of STS driven by somatic deletion of Bap1 and Trp53. A high-throughput epigenetic inhibitor screen using the CellCyte proliferation assay was performed to identify the most effective inhibitors. Additional approaches included syngeneic and primary sarcoma mouse models, CRISPR/Cas genetic tools, flow cytometry, multiplex immunohistochemistry (IHC), single-cell RNA sequencing, and bulk RNA sequencing to evaluate the impact of epigenetic inhibitors on Bap1-driven STS and its immune-suppressive microenvironment.

Results: Bap1-deficient sarcoma cells exhibited marked sensitivity to several potent epigenetic inhibitors, including histone deacetylase inhibitors (HDACi), bromodomain and extra-terminal domain inhibitors (BETi), and histone demethylase inhibitors. Studies assessing their effects on the immune-suppressive microenvironment are ongoing.

Conclusion: Our findings establish Bap1 deficiency as a driver of STS development and reveal that Bap1-deficient sarcomas are highly susceptible to epigenetic inhibition. These results lay the foundation for translating epigenetic therapies into effective treatment strategies for patients with Bap1-driven STS, a population currently lacking targeted options.

#0615 AMBRA1-mediated nucleocytoplasmic control promotes early onset of liver cancer.

Yimiao He[1], Linglin Liu[2], Yunong Xie[1], Minghe Zhang[1], Yan Liu[1], **Man Tong**[3]

[1]The Chinese University of Hong Kong, Shatin, Hong Kong,[2]The Chinese University of Hong Kong, Hong Kong SAR, China,[3]The Chinese University of Hong Kong, Hong Kong, Hong Kong

Hepatocellular carcinoma (HCC) is one of the leading causes of cancer-related mortality worldwide, largely driven by uncontrolled cell proliferation and the loss of tumor suppressor activity in the liver. By analyzing publicly available genome-wide CRISPR screening datasets, we identified AMBRA1 as a strong anti-proliferative candidate. Analysis of a clinical HCC patient cohort revealed that AMBRA1 expression was significantly reduced in tumor tissues, and its downregulation was tightly associated with poor patient outcomes. The downregulation of AMBRA1 was consistently validated in multiple HCC mouse models established through somatic mutations and high-fat diet challenge at early stages. Functionally, CRISPR-mediated knockout of AMBRA1 accelerated early spontaneous liver tumor initiation in vivo. AMBRA1 co-immunoprecipitated with key proteins involved in nucleocytoplasmic transport, suggesting a novel function for AMBRA1 in modulating nucleocytoplasmic trafficking in HCC. Collectively, our findings establish AMBRA1 as a bona fide tumor suppressor with clinical and functional importance in HCC.

#0616 Making sense of mis-sense and non-sense: Tumor cells hijack mutation-induced mis-localization of tumor suppressors.

Murali Dharan Bashyam[1], Sanjana Sarkar[2], Jimlee Saikia[1]

[1]Laboratory of Molecular Oncology, BRIC-Centre for DNA Fingerprinting and Diagnostics (BRIC-CDFD), Hyderabad, India,[2]BRIC-Centre for DNA fingerprinting and Diagnostics (BRIC-CDFD), Hyderabad, India

The SWI/SNF chromatin remodeler utilizes energy of ATP hydrolysis to slide or evict nucleosomes or histones, thus enabling nuclear processes by driving an 'open' chromatin architecture. The mammalian SWI/SNF, also termed the BrG1/Brm associated factor (BAF) complex, is the major chromatin remodeler in ontogeny and adult life. Three biochemically distinct BAF complexes namely canonical (cBAF), polybromo (PBAF), and non-canonical (ncBAF) have been characterized. BAF components, classified as canonical nuclear tumor suppressors, exhibit frequent inactivating mutations in cancers. Though, several studies have evaluated the functioning of BAF subunits, very few have attempted to characterize the role of BAF component mutation identified across cancer types. In our previous studies, we identified early-onset rectal cancer specific truncation mutations in the gene encoding the PBAF component 'A-T rich interaction domain containing 2' (*ARID2*), precluding its nucleal localization signal (NLS). These truncations were also identified across cancer types based on analysis of cancer mutation databases. NLS-inactivated ARID2 exhibited cytoplasmic localization (cARID2) and promoted tumorigenesis in colorectal, breast and lung cancer cell lines. Here, we present detailed mechanistic characterization of ARID2 truncations, presumed to be inactivating in nature, but exhibiting a gain of oncogenic function. We show that the glutamine rich GLN domain (amino acids 793-1128) is essential for the oncogenic function of cARID2. Tandem affinity purification mass spectrometry identified PBAF components in the interactome of wild-type but not of cARID2, as expected. More importantly, a novel interaction between cARID2 (but not wild type ARID2) and AKAP8L, validated using biochemical approaches. cARID2 devoid of the GLN domain, did not interact with AKAP8L. AKAP8L belongs to the AKAP95 domain containing family of proteins that interact with and activate protein kinase A (PKA) leading to oncogenic activation of CREB signalling. Further, cARID2 effected an increase in the phosphorylated (active) form of CREB and in transcript levels of canonical CREB targets including ATF3, ATF4, and CREM, indicators of activation of the CREB signalling axis. AKAP8L itself was shown to activate oncogenesis in CRC cells. Analysis of RNA Sequencing is currently underway to confirm the activation of the PKA/CREB oncogenic signalling by cARID2. Nude mice xenograft assays are also underway to confirm the oncogenic potential of cARID2. Overall, the findings reveal a Yin-Yang tumor suppressor/oncogenic role for ARID2 in cancer, similar to our previous discovery for ARID1B, an ARID2 paralogue. More importantly, our study has revealed novel therapeutic options for tumors exhibiting cytoplasmic ARID2.

#0617 OSTM1 is a ubiquitin E3 ligase that suppresses B-cell malignancy by activating the cAMP/PKA pathway.

Muhammad Usama Tariq[1], Namratha Sheshadri[1], Julia Shen[1], Jaeyong Jung[1], Rongrong Li[1], Kevin Lu[2], Junrong Yan[1], Mark Koch[3], Hassan Sajjad[1], Barbara Rosati[3], Giuseppe Caso[3], Richard LIN[3], Brinda Vallat[1], Stephen Burley[1], Tong Liu[4], Hong Li[4], Christian Hinrichs[1], Jun Wang[1], Lynn Wang[5], Jean Vacher[6], Ping Xie[7], Wei-Xing Zong[1]

[1]Rutgers University - New Brunswick, New Brunswick, NJ,[2]Rutgers Graduate School of Biomedical Sciences, Paramus, NJ,[3]Stony Brook, Stony Brook, NY,[4]New Jersey Medical School, Newark, NJ,[5]Fox Chase Cancer Center, Philadelphia, PA,[6]Montreal clinical research institute, Montreal, QC, Canada,[7]Rutgers University - New Brunswick, Piscataway, NJ

Osteoclastogenesis-associated transmembrane protein 1 (OSTM1) is a membrane-integral glycosylated protein that regulates lysosomal homeostasis and osteoclast maturation. Its loss-of-function mutations cause autosomal recessive osteopetrosis (ARO). In addition, OSTM1 was described as a putative ubiquitin E3 ligase yet with ill-defined substrates and biological functions. Using a whole-genome CRISPR/Cas9 screening in the interleukin-3 (IL3)-dependent Ba/F3 murine pro-B cell line, we identified OSTM1 whose silencing confers IL3-independent growth and in vivo transformation of Ba/F3 cells. In humans, OSTM1 is frequently deleted or downregulated across a wide range of B cell malignancies. In mice, B cell-specific monoallelic and biallelic ablations of Ostm1 cooperates with Cdkn2a ablation to drive lymphomagenesis with a near 100% penetrance. Mechanistically, a fraction of OSTM1, non-glycosylated and cytosol located, acts as an E3 ligase and interacts with phosphodiesterase 3B (PDE3B) to promote its proteasomal degradation. As PDE3B catalyzes the conversion of cAMP to AMP hence negatively regulates the cAMP-dependent PKA/CREB/CREBBP tumor suppressive pathway, loss of OSTM1 leads to PDE3B stabilization and increased cell growth. Together, our findings uncover OSTM1 as a tumor-suppressive E3 ligase by promoting the proteasomal degradation of PDE3B and activating the cAMP-dependent PKA pathway.

#0618 Evaluating the role of choline acetyltransferase (ChAT) in T cell malignancies.

Arwa Hilal[1], Maureen A. Cox[2], Michael St. Paul[3], Tak W. Mak[4]

[1]Immunology, University of Toronto, Toronto, ON, Canada,[2]University of Oklahoma Health Sciences Center, Oklahoma City, OK, Canada,[3]University of Toronto, Toronto, ON, Canada,[4]UHN Princess Margaret Cancer Centre, Toronto, ON, Canada

Acetylcholine (ACh) is a classical neurotransmitter increasingly recognized for its immunoregulatory roles. Beyond neural tissues, activated T cells express choline acetyltransferase (ChAT), enabling the local synthesis and release of ACh, which acts through nicotinic and muscarinic receptors to modulate activation, cytokine production, and vascular tone. While this pathway can dampen inflammation and sustain immune homeostasis, its function within malignant T cells remains poorly understood. PTEN loss, a hallmark of aggressive T cell malignancies, constitutively activates the PI3K-Akt pathway to promote unchecked growth and survival. We hypothesized that tumour-intrinsic ChAT restrains these Akt-dependent stress responses, serving as an intrinsic brake on malignant progression. Using a conditional T cell PTEN-deficient mouse model, we found that ChAT is upregulated at specific thymocyte developmental stages that coincide with PI3K Akt hyperactivation, and that ChAT-positive thymocytes in the pre-malignant PTEN-deficient setting display higher activation marker expression and a more activated developmental phenotype compared to ChAT-negative cells. Loss of ChAT in the PTEN-null background further increases pAkt levels and alters early activation markers, which is consistent with a shift toward heightened oncogenic stress. Functionally, deleting T cell-specific ChAT in this model shortens lymphoma survival in an allele dosage-dependent manner, indicating that endogenous cholinergic activity provides a measurable constraint on tumour aggressiveness. Together, these findings support a model in which cholinergic signalling intersects with oncogenic PI3K Akt activity in T cell malignancy. This proposal will define the cellular, molecular, and therapeutic relevance of this interaction, with the overall goal of identifying cholinergic pathways as new entry points for modifying tumour evolution in PTEN-deficient T cell cancers.

Poster Session

#0622 Infant *KMT2A::AFF1* acute lymphoblastic leukemia stem cell model reveals early impact on the proteome.

Alexandra Prosser-Dombrowski[1], Irina Pushel[1], Priyanka Prem Kumar[1], Thomas Gremminger[2], Michaella Rekowski[2], Midhat S. Farooqi[3], Michael Washburn[2], Jay L. Vivian[1], John M. Perry[1]

[1]Children's Mercy Kansas City, Kansas City, MO,[2]The University of Kansas Medical Center, Kansas City, MO,[3]Children's Mercy Research Institute, Kansas City, MO

Infants with acute lymphoblastic leukemia (iALL) are at high risk of early relapse, rapid progression, and poor survival despite intensive therapies. Rearrangement of *KMT2A* (*KMT2A*-r) is an established feature of these cases, creating a fusion oncogene that leads to epigenomic dysregulation. Genomic studies have failed to find collaborating oncogenic drivers that would explain why infants have such a high risk of relapse compared to older patients with the same rearrangement. To expand our understanding of *KMT2A*- driven leukemogenesis, we applied global proteomic profiling to identify potential nongenomic drivers that could provide novel therapeutic targets.For this study, we performed proteomics with our human inducible pluripotent stem cell model (iPSC) of *KMT2A*-r iALL. We have engineered this model with a human *KMT2A*-r transgene construct (rearranged with the most common partner *AFF1*) incorporated with an established doxycycline (dox) regulated platform. These cells tightly express the *KMT2A::AFF1* transgene only in response to dox treatment. We have developed functional hematopoietic stem cells (HSPC) that we have induced with dox to express *KMT2A*-r and represent the preleukemic state. With replicates of dox-induced *KMT2A::AFF1* HSPC and of non-dox control, we generated proteomic profiles via data independent acquisition (DIA) using the timsTOF HT (Bruker). Data were searched in DIA-NN using the Bruker spectral library and human protein database downloaded from Uniprot on 05-05-2024. Data analysis was performed in R 4.3.3 including differential expression analysis using limma 3.58.1, pathway enrichment using gProfiler 0.2.3, and network analysis using STRING 12.0.Differential expression analysis identified 149 proteins with higher and 381 proteins with lower expression in *KMT2A*-r HSPC as compared to the control ($p < 0.05$, $|log2FC| > 1$). Histone binding is a top upregulated pathway of proteins with the most significance (adjusted $p < 0.05$), which is what we would expect with induction of a epigenomic regulator. Pathways downregulated in *KMT2A*-r HSPC largely involve the extracellular environment (for example, cell adhesion mediator activity, collagen binding, extracellular matrix organization). STRING analysis of the downregulated proteins also demonstrates a prominence of extracellular factors (i.e. MFAP4, L1CAM, COL5A1). Comparison to bulk RNA sequencing on the model at the same timepoint reveals protein expression correlates with gene expression about half of the time. Phosphoproteomics has been performed and is currently being analyzed for further comparison. Preleukemic *KMT2A*-r HSPC demonstrate early changes in the proteome that suggest the extracellular environment may play a key role in leukemogenesis. With further validation and testing of these factors, we will aim to identify essential drivers that may provide new therapeutic targets for this devastating disease.

#0623 Targeting PAX3::FOXO1 condensates in fusion-positive alveolar rhabdomyosarcoma via disordered-region mimetic peptides.

Michael Di Martino, Yanghao Zhong, Shasha Chong

Division of Chemistry and Chemical Engineering, California Institute of Technology, Pasadena, CA

Background: PAX3::FOXO1 (P3F1) is a fusion oncoprotein that drives fusion-positive alveolar rhabdomyosarcoma (aRMS), a highly lethal pediatric cancer with <30% 5-year survival in high-risk patients. Targeted therapy development has been limited by P3F1's largely disordered structure and poorly understood interaction mechanisms. Recent work has shown that short peptides targeting intrinsically disordered regions (IDRs) can disrupt transcriptional hubs and impair tumor growth, but this strategy requires identifying key interaction partners that often regulate other signaling pathways. We previously discovered that P3F1 demonstrates a neomorphic hub formation propensity that corresponds with its transcriptional activity, suggesting that disrupting these hubs can hinder said activity.
Purpose: To design short peptides modelled from the P3F1 IDR itself that disrupt P3F1 hubs and suppress P3F1-mediated transcription and aRMS cell proliferation.
Experimental Procedures and Results: Using the LacO array assay, an established in-cellulo method that quantifies IDR interaction strength, we discovered that truncating the P3F1 392-510 region significantly decreased IDR interaction strength. Further, the same truncation significantly altered its interaction strength with p300, a key transcriptional coactivator known to promote P3F1's function. Finally, dual luciferase assay results showed that a 392-510 deletion significantly decreased P3F1's transactivation ability. Taken together, this suggested that P3F1 392-510 is a key interaction hotspot that influences its transcriptional capability. Sequence analysis revealed that P3F1 392-510 is enriched in cationic and aromatic residues, consistent with cation-π and π-π interactions common in IDRs. FINCHES interaction mapping showed that mutating either all cationic or all aromatic residues in this region reduces P3F1 homotypic interactions, with aromatic-to-alanine mutations producing the stronger effect. Ongoing experiments utilizing the LacO array assay are probing these interaction modes to guide the design of optimized P3F1 392-510 peptide mimics.
Conclusions: P3F1 392-510 is critical for P3F1's IDR-mediated interactions and transcriptional activity. Its cationic and aromatic composition suggests cation-π and/or π-π interactions as key interaction modes. Future work will experimentally dissect these interaction modes and develop peptide inhibitors informed by this mechanistic insight.

#0625 Early tumor priming in Li-Fraumeni Syndrome muscle using a rhabdomyosarcoma model.

Ashby Kissoondoyal, Paula Rosanna Quaglietta, Brianne Laverty, David Malkin

The Hospital for Sick Children, Toronto, ON, Canada

Li-Fraumeni Syndrome (LFS), caused by germline *TP53* mutations, markedly increases the risk of developing rhabdomyosarcoma (RMS) and other childhood cancers, often emerging during early neonatal life. This early onset, in conjunction with findings that genomic alterations occur well before cancer onset in LFS, strongly suggests malignant transformation in LFS begins during embryogenesis, within developmental windows where differentiation is normally tightly regulated. Despite the developmental connection to LFS tumorigenesis, mechanisms through which inherited *TP53* dysfunction perturbs embryonic muscle development to create tumor-permissive states are not well understood. Using LFS-associated RMS (LFS-RMS) as a model, we examined how germline *Trp53* mutations alter myogenesis and predispose LFS muscle to tumorigenesis. We performed single-nuclei RNA sequencing (snRNA-seq) across LFS-RMS tumors, matched distal muscle, and healthy embryonic, postnatal muscle tissue from *Trp53*$^{R172H/+}$ (R172H) and wild-type (WT) littermates. To map accompanying genomic changes, we also generated deep (800x) whole-exome sequencing (WES) from these samples. The two datasets were integrated to identify genomic alterations that aligned with developmental transcriptional shifts observed in LFS. We identified a reproducible myogenic LFS-RMS signature enriched for WNT signaling, RNA metabolic pathways, and glycolytic reprogramming. This signature was present in LFS-RMS tumors and elevated in R172H embryos during the peak of myogenesis (E12-E14). Further analyses revealed delayed myogenic maturation in LFS embryos and the presence of progenitor-like cell states that become enriched in LFS-RMS, indicating that tumor-relevant states arise during LFS embryogenesis. By integrating WES with snRNA-seq, we found that transcriptionally unstable developmental periods in LFS embryos overlap with early genomic alterations, suggesting that transcriptional and genomic disruptions emerge in parallel. By defining these molecular patterns, our work identifies early transcriptomic and genomic predictors of LFS-RMS and how germline *Trp53* mutations reshape developmental programs. Ongoing efforts include incorporating extra-embryonic tissues such as placenta and amniotic fluid to evaluate their potential as accessible prenatal cancer risk indicators. Ultimately, characterizing developmental progression in a germline *Trp53* mutant model will reveal the sequence of events that drive LFS-RMS. From these findings we can better and define windows of vulnerability and work towards a prenatal screening tool for LFS.

#0626 *TLX3* represses IKZF2 to activate PI3K/AKT signaling: A novel transcriptional axis driving leukemia initiation.

Gisele Rodrigues, Julie Hixon, Hila Winer, Timothy Gower, Francisco Lobo, Nathan Wong, Erica Matich, Steven Hsu, Emma Wachter, Elijah Edmondson, Maggie Cam, Caroline Andrews, Sarah Cramer, Wenqing Li, Scott Durum

NIH-NCI, Frederick, MD

Background/Methods: Despite major therapeutic advances, current treatment protocols for acute lymphoblastic leukemia (ALL) remain limited by toxicity and relapse, driving efforts to develop safer and more selective therapeutic strategies. We have shown that oncogenic IL7Rα mutations (mutIL7R) occur in approximately 10 percent of ALL cases but require cooperating lesions to induce transformation. In a related context, IL-7R signaling pathway components are also recurrent in mixed phenotype acute leukemia (MPAL), where they frequently coincide with TLX3 dysregulation. However, the mechanism by which TLX3 cooperates with mutIL7R remains unknown.

Results: In this study, we first show that co-expression of TLX3 and mutIL7R in murine double-negative thymocytes induces aggressive mixed-lineage leukemia within three weeks following transplantation into Rag1 knockout mice. We then integrated single-cell RNA-seq, CITE-seq, and TCR beta repertoire analysis and observed that Helios (IKZF2) is specifically downregulated by TLX3. Mechanistically, TLX3-mediated repression of IKZF2 amplifies PI3K/AKT signaling. Enforced IKZF2 expression suppressed AKT phosphorylation, whereas IKZF2 knockdown enhanced it, establishing IKZF2 as a key regulator that limits PI3K/AKT signaling downstream of TLX3 and mutant IL7R. Leukemia serial transplantation further demonstrated increasing disease aggressiveness and a lineage shift from mixed T or myeloid to B-like phenotypes, recapitulating the plasticity observed in patient MPAL.

Conclusions: Our data identify TLX3 and mutant IL7R as cooperative drivers that reprogram transcriptional and signaling landscapes, linking lineage plasticity with oncogenic PI3K/AKT activation. Taken together, our results define the IL7R-TLX3 leukemogenic program, revealing a targetable vulnerability in TLX3-positive and mutIL7R-positive leukemias and providing a strong rationale for PI3K pathway-directed therapeutic intervention.

#0627 Investigating ATRT cell of origin and tumor heterogeneity via hiPSC-derived models.

Clark G. Wang[1], Qi Wang[2], Nidhi Nathwani[3], Bryan K. Li[4], Takayuki Morimoto[3], Alison D. Parisian[1], G. Praveen Raju[5], Frank B. Furnari[3]

[1]Biomedical Sciences Program, Division of Regenerative Medicine, Department of Medicine, University of California San Diego, La Jolla, CA,[2]Department of Bioengineering, University of California San Diego, La Jolla, CA,[3]Division of Regenerative Medicine, Department of Medicine, University of California San Diego, La Jolla, CA,[4]Department of Pediatrics, University of California San Diego, La Jolla, CA, Division of Pediatric Hematology/Oncology, Rady Children's Hospital, San Diego, CA,[5]Department of Neurosciences, University of California San Diego, La Jolla, CA, Rady Children's Health, San Diego, CA

Atypical teratoid rhabdoid tumors (ATRTs) are rare, highly malignant pediatric brain cancers that almost always result from biallelic inactivation of *SMARCB1*, a core subunit of the SWI/SNF chromatin remodeling complex. Despite presenting a remarkably simple genome defined by SMARCB1 loss, ATRTs are molecularly diverse, consisting of three subgroups with distinct DNA methylation profiles, transcriptomes, and clinical outcomes, suggesting differences in cells of origin and unique mechanisms of oncogenesis. Neural progenitor cells (NPCs) and neural crest cells (NCCs) have been proposed as potential cells of origin, with NPCs aligning more with the ATRT-SHH subgroup. On the other hand, NCCs may account for the molecularly identical extracranial malignant rhabdoid tumors as well as the remaining intracranial subgroups, ATRT-TYR and ATRT-MYC, which have suspected extra-CNS origins. To study SMARCB1 loss in a genetically defined neural progenitor cellular context, our lab previously engineered human induced pluripotent stem cells (hiPSCs) with doxycycline (DOX)-inducible *SMARCB1* knockdown. NPCs derived from these hiPSCs, that were differentiated without *SMARCB1* expression, exhibited an ATRT-SHH subgroup transcriptome and formed orthotopic tumors. Building upon these findings, these engineered hiPSCs were differentiated into neural crest cells. In comparison with isogenic controls, neural crest cells differentiated without *SMARCB1* expression acquired a proliferative phenotype, enhanced clonogenic potential, and became arrested in a “progenitor” state by maintaining expression of neural crest differentiation pathway genes. Furthermore, *SMARCB1* knockdown during neural crest differentiation upregulated target genes of REST, a transcription factor that is enriched in ATRT-MYC. In contrast, REST target genes were found to be downregulated in SMARCB1-depleted NPCs, highlighting the impact of cell identity upon phenotypes and the utility of hiPSC-derived models for investigating mutations within different clinically relevant cellular contexts. Future work aims to orthotopically engraft SMARCB1-depleted NCCs and characterize chromatin accessibility of SMARCB1 loss within NPCs versus NCCs via ATACseq. Furthermore, since recent findings suggest that the p53 pathway is often suppressed in rhabdoid tumors via MDM2 overexpression, MDM2 and a dominant-negative p53 mutant will be introduced individually into this model to determine whether p53 pathway inactivation cooperates with SMARCB1 loss within these cellular contexts.

#0628 Investigating the role of *BRCA2* in the development of pediatric rhabdomyosarcoma.

Phillip Adam Weinstein[1], Elif Asik[1], Pagna Sok[1], Cem Ozdemir[2], Wei-Che Tseng[2], Ryan Zabriskie[1], Aniko Sabo[1], Philip J. Lupo[2], Alison A. Bertuch[1], Kyle Miller[2], Sharon E. Plon[1]

[1]Baylor College of Medicine, Houston, TX,[2]Emory University School of Medicine, Atlanta, GA

Introduction: In a large-scale exome sequencing study of pediatric rhabdomyosarcoma (RMS) patients (n=615), we identified a statistical enrichment of patients with germline pathogenic variants in *BRCA2 (Li et al., JNCI, 2020)*. However, paired tumor-normal investigations of pediatric cancers have demonstrated that pediatric tumors do not typically exhibit somatic loss of *BRCA2*, a departure from what is typical of adult cancers which result in profound homologous recombination (HR) deficiency. These findings prompted our multi-pronged study to assess the role of heterozygous *BRCA2* variants in the development of pediatric RMS.

Methods: All patient samples were obtained from ongoing Children's Oncology Group protocols. As part of the Gabriella Miller Kids First Program, paired tumor-normal whole genome sequencing and somatic RNA sequencing of RMS patients was conducted at HudsonAlpha. This included a subset of the initially detected six patients with germline *BRCA2* variants. As a potential precursor model for RMS, we engineered *BRCA2* loss-of-function (LOF) variants in immortalized mesenchymal stem cell (MSC) lines. We used CRISPR to induce frameshift alleles in exons 10 and 11 (c.1345dup and c.5680del) and prime editing to create two RMS patient-specific LOF variants in exons 5 and 17 (c.7857G>A and c.462_463del), followed by DNA repair and genomic stability assays of the recombinant cell lines.

Results: Evaluation of three RMS tumors from patients with germline *BRCA2* variants was negative for loss-of-heterozygosity at *BRCA2*, additional somatic *BRCA2* mutations, or decrease in *BRCA2* expression. However, these tumors showed evidence of modest decrease in homologous recombination (HR) relative to other age-matched RMS tumors (n=21), measured via the DirectHRD pipeline. The *BRCA2* heterozygous MSC cell lines demonstrate equivalent overall DNA double-strand break repair capacity but significantly diminished HR activity when assayed by integrating larger (700bp) repair cassettes, and increased micronucleus formation after treatment with ionizing radiation. Despite these functional impairments, we found no change in response to targeted therapies, including the PARP inhibitor olaparib and newer generation polymerase theta inhibitors.

Conclusions: Through RMS tumor analysis and *in vitro* assays, we observed modest HR impairment resulting from heterozygous *BRCA2* mutations, but to a lesser extent than seen in adult cancers with complete loss of *BRCA2* and PARP sensitivity. These findings support a model where heterozygous germline variants in *BRCA2* modestly increase genomic instability, leading to an increased risk of pediatric RMS and may explain other pediatric tumors where enrichment of *BRCA2* germline variants has been described.

#0629 SMARCD3-regulated Purkinje cell migration underlies cerebellar development and group 3 medulloblastoma metastasis.

Yash Patel[1], Han Zou[1], Allen Zheng[2], Anjali Talluru[2], Nirja Divekar[2], Chaim Sneiderman[1], Meghana Dodda[2], Katie Dietrich[2], Siheng Chao[2], Sameer Agnihotri[3], Gary Kohanbash[3], Antony Michealraj[3], Ian Pollack[3], Baoli Hu[3]

[1]University of Pittsburgh School of Medicine, Pittsburgh, PA,[2]University of Pittsburgh, Pittsburgh, PA,[3]Department of Neurological Surgery, University of Pittsburgh, Pittsburgh, PA

Medulloblastoma (MB) is a heterogeneous brain tumor arising in the cerebellum and is the most common malignant pediatric brain tumor. Group 3, one of four molecular MB subgroups (WNT, SHH, Group 3, and Group 4), is the most aggressive and malignant type in children, usually characterized by metastasis at diagnosis. In this study, we identify that SMARCD3/BAF60c (SMARCD3 hereafter), a core component of the SWI/SNF chromatin-remodeling complexes, is highly expressed in Group 3 MB and Purkinje cells (PCs) of the developing cerebellum. Elevated SMARCD3 expression is associated with poorer patient outcomes, MB metastasis, and activation of the Disabled1 (DAB1)-Reelin signaling pathway that is required for PC migration and positioning during cerebellar development. Conditional SMARCD3 deletion in early PCs results in embryonic and early postnatal lethality in mice, and the surviving animals exhibit significant deficits in motor coordination and balance. Immunostaining of SMARCD3 deleted murine cerebellar tissue shows disorganized PC alignment and reduced dendritic branching, confirming the critical role of the SMARCD3-Reelin pathway function in PC migration, positioning, and maturation. These data demonstrate that the SMARCD3-associated SWI/SNF chromatin-remodeling complex regulates Reelin signaling pathway in PC migration and positioning during cerebellar development; however, this neurodevelopmental program is hijacked to promote MB metastatic dissemination. To further understand this mechanism, we analyzed spatiotemporal gene expression and chromatin accessibility data of the human and mouse cerebellum, noting the SMARCD3/Reelin signaling decreased in the mature cerebellum, but is highly upregulated in metastatic medulloblastoma. The study provides compelling functional evidence of SMARCD3 and the associated SWI/SNF complexes' involvement in cerebellar development, tumor metastasis, and the molecular connections between early brain development and tumorigenesis, offering new rationales for the development of innovative therapies for patients with MB.

#0630 Elucidation of PAX3::FOXO1 tumor initiation mechanisms in human induced pluripotent stem cell models.

Bradley T. Stevens, Yang Zhang, Brian J. Abraham, Mark E. Hatley

St. Jude Children's Research Hospital, Memphis, TN

Rhabdomyosarcoma (RMS) is the most common pediatric soft tissue sarcoma. Alveolar RMS (ARMS) is driven by either t(2;13)(q35;q14) or t(1;13)(p36;q14) resulting in the PAX3-FOXO1 (P3F) and PAX7-FOXO1 (P7F) fusion oncoproteins, respectively and has a poor prognosis. A deeper understanding of P3F mediated tumorigenesis is needed to discover novel targets. Current model systems fail to recapitulate the human disease in terms of timing, location, and the formation of other tumor types. Previously, our lab generated an ARMS model system derived from human induced pluripotent stem cells (iPSCs), in which forced P3F expression during endothelial directed differentiation blocked endothelial maturation instead reprogramming cells to skeletal muscle-like that form ARMS tumors in mice. Building off this model, we generated a doxycycline inducible iARMS model driven by degradable P3F-FKBP12^{F36V} (ddP3F cells) allowing for fine control over P3F expression. Degradation of P3F did not significantly reduce viability or proliferation but reduced the ability of ddP3F cells to undergo myogenic differentiation. P3F-negative ddP3F cells continued to proliferate for multiple passages and retained the ability to form foci. Transcriptional analyses revealed ARMS cell states remained stable upon P3F loss. Taken together, this data shows that P3F is important for ARMS fate initiation but not maintenance, indicating further examination of the initiation event was needed for insight into ARMS biology. To elucidate the P3F-mediated initiation mechanism, I turned to our previously established iARMS model. I utilized CUT&RUN for P3F and H3K27ac to assess P3F occupancy and enhancer landscape and RNA-seq to assess gene expression changes at timepoints throughout the transformation event. Analysis of this data revealed that ARMS fate commitment occurred within two days of P3F expression that was reinforced throughout the time course. Mechanistically, P3F established a novel enhancer landscape resulting in the early expression of one myogenic and a few neural transcription factors (core TFs). Single cell multiome profiling confirmed early fate commitment and revealed heterogeneous expression of the core TFs. Taken together, these data show that P3F initially establishes cell fate through enhancer landscape alterations with both myogenic and neural transcription factors but not necessarily in the same cells. Overall, our novel cellular models revealed insights into P3F independent maintenance of ARMS cell fate, uncovered a mechanism of P3F-mediated establishment of ARMS cell state, and provides a platform to dissect the specific dependencies required for ARMS cell state. Understanding the fundamental mechanism of ARMS tumorigenesis provides greater resolution into the key disease determinants to generate better model systems, focus pre-clinical efforts, and identify novel targets.

#0631 Trans-species analysis of central nervous system developmental-specific replication repair deficiency reveals differential patterns of gliomagenesis and response to immunotherapy.

Zoya Aamir, Melissa A. Galati, Emma Gattoni, Owen Crump, Nemanja Ilic, Anirban Das, Nicholas R. Fernandez, Angel K. Q. Wong, Lucie Stengs, Jose R. Dimayacyac, Yuan Chang, Vanessa Bianchi, Melissa Edwards, David Malkin, Cynthia Hawkins, Nuno M. Nunes, Uri Tabori

Sick Children's Hospital, Toronto, ON, Canada

Introduction: Replication repair deficiency (RRD) is a pan-cancer mechanism caused by germline and/or somatically acquired mutations in the replication repair machinery - DNA polymerase proofreading and the mismatch repair (MMR) system. Germline monoallelic (Lynch Syndrome, LS) or biallelic (Constitutional Mismatch Repair Deficiency, CMMRD) mutations in MMR genes are present in 5-10% of glioblastomas in children, adolescents, and young adults. RRD gliomas are lethal, chemoradiation-resistant cancers, characterized by universal hypermutation and variable susceptibility to immune-checkpoint inhibition (ICI). These tumors exhibit variability in patient age of onset, type, location, and response to ICI.

Methods: To understand the clinical and biological differences associated with RRD central nervous system (CNS) tumors, we used germline mutations and brain development-specific *Cre*-drivers to generate murine models that recapitulate the phenotypic and genomic characteristics of each human RRD subgroup: **1) MMRD+PPD** (*Nestin*- and *Olig2-Cre*$^{+}$*/ Msh2*$^{LoxP/LoxP}$*/Pole*$^{S459F/+}$ and *LSL-Pole*$^{P286R/+}$): MMR-deficiency (MMRD) in combination with polymerase proofreading deficiency (PPD). **2) MMRD-only** (*Nestin-Cre*$^{+}$*/Trp53*$^{LoxP/LoxP}$ and *Msh2*$^{LoxP/LoxP}$ or *Mlh1*$^{-/-}$): MMRD lacking PPD associated with *TP53* mutations.

Results: Using trans-species comparative approach, we elucidated a mechanistic model of RRD-driven brain tumorigenesis. We revealed that the cell-of-origin significantly contributes to determining brain tumor type, location, and age of tumor onset, suggesting a strong impact of early- or late-RRD mutational onset in shaping tumor biology ($p<0.0001$). Importantly, using murine neural stem cells, we discovered that germline mutagenesis onset directly influences timeline of brain tumor formation and survival between CMMRD and LS patients ($p<0.05$). We further demonstrate the interplay between *POLE* mutations and MMRD status in modulating the likelihood of brain tumorigenesis in both species. To understand the interaction between hypermutation and the immune system, we characterized the tumor immune microenvironment in spontaneously forming tumors. We uncovered subgroup-specific immune landscapes, with $CD8^{+}$ T cell activity emerging as a key modulator in controlling brain tumor growth ($p<0.0001$), suggesting an underlying mechanism that may inform therapeutic strategies in RRD patients.

Significance: Altogether, our models accurately mimic the human condition, providing a mechanistic framework of RRD-driven brain tumorigenesis, optimization of subgroup-tailored immunotherapy approaches, and putative surveillance protocols.

#0632 Dynamic characterization of tumor-microenvironment factors that drive pediatric low-grade gliomas.

Jenna Robinson[1], Joohee Lee[1], Sarah Reel[2], Shriya Rangaswamy[1], Michelle Boisvert[1], John Doench[3], David TW Jones[4], Timothy Phoenix[2], Pratiti Bandopadhayay[1]

[1]Dana-Farber Cancer Institute, Boston, MA,[2]University of Cincinnati, Cincinnati, OH,[3]Broad Institute, Cambridge, MA,[4]DKFZ, Heidelberg, Germany

Pediatric low-grade gliomas (pLGGs) are the most common brain cancers diagnosed in children, often leading to life-long neurological impairments. Whilst targeted inhibitors exist, their effects are often short-lived, highlighting the urgent need for innovative treatments. Notably, some pLGG tumors spontaneously regress with age, suggesting that changes in the tumor microenvironment can arrest tumor growth. In this work, we aim to characterize which signaling interactions promote the growth of pLGG cells and how these interactions change dynamically with time. To achieve this, we have optimized a protocol for introducing pLGG mutations into developing mouse brains via in utero electroporation. This study revealed that brains harboring the common *KIAA1549::BRAF* fusion mutation have a striking phenotype characterized by increased astrocyte reactivity and myeloid cell infiltration. To better understand how signals derived from immune cells may impact pLGG cell fitness, we are additionally performing a high-throughput cytokine screen. We are developing barcoded cytokine constructs tethered to the cell membrane to comprehensively screen the impact of cytokine signaling on the growth of neural stem cells engineered to overexpress common pLGG mutations. Together this work aims to unravel which signaling factors govern the age-dependent growth of pLGG tumors, which may reveal targetable aspects of the tumor microenvironment amenable to therapeutic intervention.

#0633 AVIL's dependency on YAP as a key mediator of oncogenic activity offers a therapeutic opportunity in rhabdomyosarcoma.

Martyna Glowczyk-Gluc, Robert Cornelison, Zhongqiu Xie, Julie Fanburg-Smith, Robin D. LeGallo, Eyas Alzayadneh, Hui Li

University of Virginia, Charlottesville, VA

Rhabdomyosarcoma (RMS) is a prevalent pediatric soft-tissue cancer with a survival rate below 27% for high-risk patients. Despite significant genetic differences among RMS subtypes, frontline therapy remains largely uniform and ineffective for metastatic and recurrent cases. After decades of research, targeted therapies are currently unavailable, underscoring the urgent need for novel targets and effective treatment strategies. Our previous published studies identified *AVIL* as a novel, *bona fide* RMS oncogene. *AVIL* encodes a calcium-regulated, actin-binding protein critical for actin cytoskeleton organization. While its expression in healthy adult tissue is limited, *AVIL* is aberrantly upregulated in RMS and correlates with poor patient prognosis. *AVIL* silencing significantly reduces cell proliferation and migration, induces cell death *in vitro*, and prevents tumor formation *in vivo*. Our recent studies reveal that AVIL functions upstream of the transcriptional coactivator YAP, a key regulator of proliferation, survival, and stemness that is frequently hyperactivated in RMS. Through integrated transcriptomic, biochemical, and imaging analyses, we discovered that AVIL promotes YAP nuclear translocation, enhances its transcriptional activity, and increases cellular sensitivity to YAP pathway blockade. Conversely, genetic silencing of *AVIL* disrupts YAP signaling and restores the expression of myogenic differentiation markers, implicating AVIL's role in maintaining the undifferentiated, proliferative state of RMS cells. Functionally, AVIL-high RMS cells exhibit enhanced response to pharmacologic YAP inhibition, while AVIL depletion diminishes this effect, underscoring a mechanistic dependency of AVIL-driven oncogenic programs on YAP signaling. *In vivo*, administration of a YAP inhibitor to patient-derived RMS xenografts with high AVIL expression significantly reduces tumor incidence compared with vehicle-treated controls. Together, these findings uncover a previously unrecognized mechanism by which AVIL modulates YAP activity in RMS, revealing a therapeutically actionable axis that sustains tumor growth and impedes myogenic differentiation.

#0634 Subpopulations of CAF contribute to chemotherapy resistance in tumors through different MYCN-dependent and independent mechanisms.

Kevin Louault[1], Laurence Sarte[1], Liron D. Grossmann[2], Bruce Pawel[1], John M. Maris[3], Shahab Asgharzadeh[1], Yves Albert DeClerck[1]

[1]Children's Hospital Los Angeles, Los Angeles, CA,[2]Edmond and Lily Safra Children's Hospital, Tel-Hashomer, Israel,[3]Children's Hospital of Philadelphia, Philadelphia, PA

Cancer-associated fibroblasts (CAF) are among the most prevalent non-malignant cell subtypes in the tumor microenvironment (TME) of neuroblastoma (NB). CAF cooperate with tumor-associated macrophages to promote therapeutic escape in many cancers including NB. CAF are heterogeneous and several subpopulations have been described based on specific transcriptomic signatures. In recent work, we show by single cell (sc)RNA sequencing the presence of different subpopulations of CAF in human NB tumors, including myofibroblasts (myCAF), inflammatory (i)CAF, dividing (d)CAF and vascular (v)CAF. However, the specific functions of these sub-populations are not entirely known because of difficulties in isolating CAF subpopulations. Here, we have isolated by flow cytometry and characterized two subpopulations of CAF from human NB tumors based on their expression of the receptor for platelet-derived growth factor-beta (PDGF-Rβ) and CD29 (Integrin β1). We show that these sub-populations maintain a stable phenotype *in vitro* (for at least 31 days) allowing to study their specific function. According to their gene and protein expression, PDGF-Rβ+/CD29- cells were identified as myCAF and CD29+/PDGF-Rβ- cells as iCAF. myCAF secreted TGF-β1 and activated a TAK1/NF-κB signalling pathway in NB cells, whereas iCAF secreted interleukin (IL)-6 and IL-8 and activated STAT3 in NB. We discovered that both subpopulations enhanced resistance to doxorubicin and etoposide but through different paracrine mechanisms. myCAF increased the expression of multi-drug resistance proteins MRP1 and MDR1 via a TGF-β/TAK1/NF-κB signalling pathway, and iCAF increased the expression of anti-apoptotic proteins BCL-xL and BCL2 via an IL-6/STAT3 signalling pathway. Furthermore, myCAF also activated an autocrine IL-6/STAT3 pathway in NB cells in a MYCN-dependent mechanism. A multiplex immunochemistry analysis of human NB revealed the presence of myCAF expressing PDGF-Rβ and iCAF expressing CD29 in TME-rich tumors but an absence of myCAF in TME-poor tumors. Our data highlights differences in the contribution of CAF subtypes to drug resistance and points to a potentially critical role of CAF in the emergence of therapeutic resistance.

#0635 Defining the intertumoral and intratumoral transcriptional heterogeneity of EWS::FLI1 in Ewing sarcoma.

Rachael Hinshaw[1], Zachary P. Tolstyka[1], Susan M. Kitchen-Goosen[2], Seneca Kinn-Gurzo[3], Rebecca Kaufman[3], Maggie Chasse[3], Elizabeth Wilson[3], Gretchen Lam[1], Stephanie The[1], Elissa Boguslawski[1], Patrick J. Grohar[1]

[1]Pediatrics, University of Michigan, Ann Arbor, MI,[2]Van Andel Institute (VAI), Grand Rapids, MI,[3]Children's Hospital of Philadelphia, Philadelphia, PA

Introduction: Ewing sarcoma (ES) is an aggressive pediatric bone and soft tissue cancer that is absolutely dependent on the EWS::FLI1 fusion transcription factor. Despite this dependency, ES tumors demonstrate substantial variability in EWS::FLI1 transcriptional activity both across tumors and within individual tumors. Here, we investigate the inter- and intra-tumoral heterogeneity of EWS::FLI1 and its functional importance.
Methods: We established a highly optimized siRNA knockdown protocol for EWS::FLI1 in 6 preclinical ES cell line models to achieve equal levels of suppression and evaluate differences in induced and repressed transcriptional targets and DNA binding events of EWS::FLI1. In order to investigate underlying mechanisms driving resistance, we employed state-of-the-art techniques including Cleavage Under Target (CUT&Tag), single nuclei RNA sequencing, and spatial transcriptomics of preclinical cell line models and ES patient samples to characterize the inter- and intra-tumoral heterogeneity of EWS::FLI1.
Results: Differential expression analysis of 6 cell lines with knockdown of EWS::FLI1, revealed that each cell line exhibited as many unique induced targets as shared ones, and repressed targets were even more cell line specific. The heterogeneity was functionally important as cell migration and migration signatures varied among the 6 models. Knockdown of EWS::FLI1 resulted in increased migration in one cell line and impaired migration in other cell lines. Intratumoral heterogeneity was also evident in single cell data with multiple transcriptional clusters evident in different proportions across the models. These different clusters also appear to be functionally important as at least two clusters resisted suppression by the EWS::FLI1 targeted agent, trabectedin, in patient samples collected on a recent trial. The heterogeneity was rooted in a combination of cell line specific EWS::FLI1 DNA binding events determined by CUT&Tag, cell specific copy number variants (CNV), and cofactor expression.
Conclusion: Our data suggests that EWS::FLI1 exhibits highly unique transcriptional activity between models which leads to a heterogeneous representation of target genes. In patients, EWS::FLI1 heterogeneity leads to the expression of a high-risk population of cells resistant to EWS::FLI1 targeting. We are working to understand mechanisms driving the high-risk population of ES cells and identify new druggable targets for these transcriptionally distinct tumor cell populations.

#0636 Dissecting the complex ecosystem of intracranial germ cell tumors by spatial RNA and protein analysis.

Torsten Pietsch[1], Verena Dreschmann[1], Pia Zapka[1], Evelyn Dorner[1], Christian Vokuhl[2]

[1]Institute of Neuropathology, University of Bonn Medical Center, Bonn, Germany,[2]Department of Pathology, University of Bonn Medical Center, Bonn, Germany

Background and Objectives: Central nervous system germinomas are characterized by a massive immune cell infiltrate. This inflammatory component can be so extensive that tumor diagnostics is challenging because of masking of the malignant germ cell tumor (GCT) component. Similarely, it is often difficult to detect other malignant components in mixed germ cell tumors that dictate the biology and treatment stratification. In this study we employed recent comprehensive technologies to study the composition and spatial distribution of malignant as well as inflammatory components of the tumor microenvironment (TME).
Methods: We systematically characterized immune cells in a cohort of germinomas by immunophenotyping and image analysis of formalin-fixed, paraffin-embedded (FFPE) tumor samples. Bulk mRNA expression data was generated by Nanostring technology and high-resolution spatial RNA expression data by Visium-HD technology. With the latter method we studied 10 germinomas and 3 mixed germ cell tumors. Individual candidate transcripts and proteins were validated by in-situ RNA hybridization and immunohistochemistry.
Results: Spatial transcriptomics by Visium-HD allowed the sensitive detection of different malignant germ cell tumor components including germinoma, yolk sac tumor, embryonal carcinoma and choriocarcinoma components, as well as the spatial distribution of immune cells. Tumor infiltrating lymphocytes in germinomas were abundant and predominated by CD3-positive T cells, including CD4-positive T-helper cells, CD8-positive cytotoxic T cells and interspersed FoxP3-positive regulatory T cells. B lymphocytes outnumbered plasma cells. Some germinomas and mixed GCT showed tertiary lymphoid structures. Tumor-associated macrophages (TAM) consisted of clusters of activated PD-L1-positive macrophages and interspersed anti-inflammatory macrophages expressing CD163. While germinoma cells did not express PD-L1 on both the RNA and protein level, a high expression of *BIRC5* (survivin) as anti-apoptotic gene was identified. Spatial mRNA expression analysis indicated specific ligand-receptor interactions between malignant GCT cells and TME components. In particular, germinoma cells produced high levels of macrophage migration inhibitory factor (MIF), and its receptor CD74 was found expressed in adjacent inflammatory cells.
Conclusions: In conclusion, spatial high resolution transcriptomics was able to sensitively identify different malignant germ cell tumor components by their signature. The strong immune reaction observed in germinomas involved various inflammatory as well as suppressive mechanisms. Interaction analysis between GCT and TME cells indicated paracrine mechanisms in the control of growth and survival of intracranial GCT cells.

#0637 CyTOF analysis of heterogeneity between Ewing sarcoma cell lines in vitro and in vivo.

Piper Harrell, Lily Golzar, Kenzie Wells, Poornima Gourabathini, Kimberly Q. McKinney, Erin M. Trovillion, Javier Oesterheld, **Kaitlyn H. Smith**

Atrium Health Wake Forest Baptist Comprehensive Cancer Center, Charlotte, NC

Introduction: Ewing sarcoma (ES) is the second most common bone cancer in children and is known to be driven by an oncogenic fusion, most commonly EWS:FLI1. Recent work has identified that ES tumors are heterogenous and there are populations of cells within tumors with varying levels of the EWS:FLI1 fusion. These populations have differences in morphology, proliferation, drug sensitivities, and invasiveness. Further, it is known that cancer stem cell populations are also found within ES tumors and these cells also have differences in morphology and drug sensitivity. The purpose of this study was to use CyTOF to assess differences in EWS:FLI1 fusion and cancer stem cell heterogeneity and immune infiltration between various ES cell lines in vitro and in vivo.
Methods: In vitro, A673, TC71, RDES, and SL00015 cells were seeded separately at equal numbers and stained for CyTOF the following day. In vivo, A673, RDES, or SL00015 cells were injected subcutaneously into Nude mice. Once tumors reached 1500-2000mm^3, they were harvested and dissociated for CyTOF analysis. The CyTOF panel used was designed to assess EWS:FLI1 fusion heterogeneity, the cancer stem cell population, and immune cell infiltration. OMIQ was used for data analysis which included phenograph clustering with UMAP visualization, heatmap of expression patterns, and changes in tumor and immune cell populations.
Results: In vitro, each of the 4 cell lines have varying morphologies and their growth ranges from adherent to clusters of cells in suspension. Phenograph clustering revealed different expression patterns among the cell lines. Interestingly, the expression patterns of different cell lines grown in vivo clustered together more than the in vivo grown cells did with their in vitro counterpart. Overall, the cells grown in vivo had a higher percentage of the EWS:FLI1^{low} population compared to the respective cell line grown in vitro. The amount of cancer stem cells varied among cell lines and sample types, though the percentage was generally higher in the in vitro samples compared to in vivo. Further, immune infiltration also varied across tumors formed from different cell lines with the RDES tumors having the most overall infiltration.
Conclusions: The CyTOF panel used in this study can identify distinct expression patterns among cell lines and sample types. The differences in expression patterns identified between a cell line grown in vitro or in vivo could be an important consideration in drug efficacy or mechanism studies in the context of Ewing sarcoma.

#0638 Spatial organization of epithelial- and neural-like tumor phenotypes and their cellular neighborhoods in desmoplastic small round cell tumors.

Jiaqian Fan, Kevin Murgas, Diana Shamsutdinova, Davis Ingram, Alexander Lazar, Danh Truong, Joseph A. Ludwig

UT MD Anderson Cancer Center, Houston, TX

Desmoplastic small round cell tumor (DSRCT) is a rare and aggressive sarcoma driven by the EWSR1::WT1. Histologically, DSRCT is characterized by distinct spatial heterogeneity of tumor nests surrounded by a desmoplastic stroma. Our previous study showed that DSRCT exhibits heterogeneous expression of androgen receptor (AR)-associated and neuron-specific enolase (NSE)-associated markers, highlighting these as important lineage features of the disease. However, how these AR (Epithelial-like)- and NSE (Neural-like)- associated phenotypes are organized at the single-cell level and contribute to tumor biology remains poorly understood. This study aims to define these phenotypes and delineate their spatial and neighborhood patterns within the DSRCT microenvironment. We used the Lunaphore COMET system to evaluate 12 DSRCT patient specimens, comprising a 20-marker panel on nine slides and a separate 24-marker panel on three slides, which collectively covered epithelial, neural, fibroblast, endothelial, and immune cell types. Using Visiopharm, we applied deep-learning algorithms to identify individual cells and quantify protein expression data. Four custom RNAscope probes targeting EWSR1::WT1-associated neogenes were used to detect tumor cells and identify EWSR1::WT1 activity. Tumor cells were distributed along an AR-NSE expression spectrum, including AR-high, AR-low, double-negative (AR-NSE-), NSE-positive, top 1% NSE-strong, and hybrid phenotype (AR+NSE+). Among AR-associated phenotypes,gradient analysis revealed that AR-high tumor cells were enriched at the tumor nest center and gradually decreased in abundance toward the tumor-stroma interface, where AR-low tumor cells were more prevalent and in closer proximity to fibroblast-rich stromal regions. Among NSE-associated phenotypes, NSE-positive tumor cells were positioned closer to fibroblast-rich stromal regions. In contrast, both the top 1% NSE-strong and AR+NSE+ hybrid phenotypes localized deeper within the tumor region and were farther from fibroblasts. Our work identified novel conserved neighborhoods across samples: tumor-centered, transitional, and fibroblast-enriched neighborhoods. AR-high phenotypes predominantly mapped to tumor-centered neighborhoods, whereas AR-low phenotypes were enriched in transitional and stromal-interacting neighborhoods. These spatial distributions suggest distinct microenvironmental contexts at the center and periphery of the tumor nests, where stromal interactions are more pronounced. Future work will elucidate how stromal cues mediate phenotypic changes in DSRCT.

#0639 Distinct microenvironments define subtypes of neuroblastoma.

Joseph Seamus Toker[1], Katherine Elizabeth Masih[2], Noemi Kedei[2], Zahin Islam[2], Ben J. Somerville[2], Amir Jassim[1], Michail Mamalakis[1], Aysen Yuksel[3], Daniel R. Catchpoole[3], Li Zhou[3], Paul Aiyetan[4], Yong Yean Kim[5], David Milewski[2], Shaoli Das[2], Xinyu Wen[2], Yong Song[2], Jun Wei[2], Richard J. Gilbertson[1], Javed Khan[2]

[1]University of Cambridge, Cambridge, United Kingdom,[2]National Cancer Institute, Bethesda, MD,[3]Tumour Bank, Children's Cancer Research Unit, The Children's Hospital at Westmead, Westmead, NSW, Australia,[4]Neopathology Corp, Frederick, MD,[5]Pediatrics, Stanford University, Stanford, CA

Originating from the neural crest, neuroblastoma is the most common extracranial solid tumor in children. Infiltrating immune cells contribute to the tumor's growth and treatment response, as patients with high-risk disease, associated with *MYCN* amplification, benefit from anti-GD2 antibody immunotherapy. However, *MYCN*-amplified disease remains lethal in more than half of cases and has been associated with immunosuppression in bulk RNA studies. We thus hypothesize that *MYCN* activation, in conjunction with other molecular and clinical traits, influences the tumor microenvironment (TME), which can either support or suppress the disease. To comprehensively characterize the neuroblastoma TME, we performed CO-Detection by indEXing (CODEX), a multiplex immunohistochemistry technique, on 5 clinically annotated tissue microarrays containing 371 neuroblastic tumors from 179 patients representing all major disease subgroups and treatment protocols. In a subset of specimens, we also applied Visium HD spatial transcriptomics to identify regional malignant programs and their associated immune infiltrates. In parallel, we developed a novel natural language processing approach to detect generalizable spatial cell networks across these tissues. Interrogating more than 40 tumor-, immune-, and stroma-associated proteins revealed that neuroblastomas, despite downregulating MHC class I (MHC-I), harbor rich TMEs composed of about 20 phenotypically distinct cell populations, including multiple lymphoid- and myeloid-derived subsets. *MYCN*-amplified tumors are profoundly deficient in infiltrating helper, memory, and cytotoxic T cell lineages, whereas they form prominent tertiary structures in non-amplified disease. By contrast, antigen-presenting suppressor-like myeloid cells dominate the *MYCN*-amplified microenvironment, where they persist in chemotherapy-resistant tumors. These subtype-specific differences prompted functional studies of intrinsic immune and cytokine programs. RNA-seq of multiple human *MYCN*-amplified cell lines revealed that the differentiation therapy retinoic acid, while suppressing *MYCN*, drastically upregulated class I antigen presentation and pro-inflammatory cytokines. To further understand *MYCN*- and treatment-related changes in the inflammatory secretome, we are currently performing extracellular proteomics on these cell lines. Integrative spatial profiling by CODEX and Visium HD reveals that MYCN amplification fosters a T cell-poor, myeloid-rich microenvironment, in contrast to the organized lymphoid structures characteristic of non-amplified neuroblastoma. Together with the finding that retinoic acid restores MHC-I and pro-inflammatory programs in MYCN-amplified tumors, these results suggest that combining retinoic acid with cellular immunotherapies and myeloid-targeting approaches may significantly improve survival in patients with high-risk neuroblastoma.

#0640 Multiomic profiling reveals endothelial cell plasticity in metastatic osteosarcoma.

Ying Wu, Julian Burks, Demond Williams, Carly Sayers, Vidhur Daulatabad, Neeraja Syed, John F. Shern, **Troy A. McEachron**

Pediatric Oncology Branch, National Cancer Institute, Bethesda, MD

Metastatic osteosarcoma is an aggressive malignant bone tumor that primarily affects pediatric, adolescent, and young adult populations and represents an understudied disease with significant unmet medical need. Recent research has increasingly focused on understanding the complex biology of the osteosarcoma microenvironment. While prior studies have primarily examined the roles of macrophages, lymphocytes, and, to a lesser extent, fibroblasts, the tumor vasculature has received comparatively little attention.
To address this critical gap, we performed single-nuclei multiome (RNA+ATAC) sequencing on a cohort of 24 human metastatic osteosarcoma specimens. Our data reveal that endothelial cells within the metastatic microenvironment adopt a hybrid transcriptional state indicative of endothelial-to-mesenchymal transition (EndMT). Leveraging our multimodal dataset, joint copy number analysis identified a subset of tumor cells that cluster with endothelial cells, demonstrating that osteosarcoma cells engage in vascular mimicry. Further investigation of gene regulatory networks revealed a subset of endothelial cells undergoing endothelial-to-osteoblastic conversion and confirmed endothelial-specific regulatory programs in the osteosarcoma vascular mimics. Analysis of immunosuppressive gene expression suggests that endothelial cells in metastatic osteosarcoma also function in an immunoregulatory capacity.
Both *in vitro* and *in vivo* functional assays were employed to validate these findings. Modified transwell co-culture assays demonstrated that osteosarcoma-derived factors induce osteoblastic gene expression programs in lung microvascular endothelial cells. Additionally, using endothelial lineage-tracing mice in combination with GFP^+ syngeneic murine osteosarcoma cells, we provide *in vivo* evidence that endothelial cells can be reprogrammed into osteoblast-like cells that integrate into malignant osteoid, while osteosarcoma cells themselves are capable of vascular mimicry.
Collectively, these findings highlight the remarkable plasticity and lineage infidelity of both endothelial and tumor cells, provide novel insights into the functional role of endothelial cells in the metastatic osteosarcoma microenvironment, and challenge current understanding of osteosarcoma biology.

#0641 Identifying vulnerabilities through an elucidation of the tumor-host interplay that drives osteosarcoma lung colonization.

Fatemeh Yazarlou, Matthew Cannon, Yogesh Budhathoki, Amy C. Gross, Leyre Jimenez Garcia, James Reinecke, **Ryan D. Roberts**

Nationwide Children's Hospital, Columbus, OH

Metastasis is the single most critical determinant of outcome in many solid tumors. In pediatric osteosarcoma, the development of lung metastases is associated with more aggressive and treatment-resistant tumor behavior. While many have assumed that metastasis is a consequence of this more aggressive behavior, emerging evidence suggests that interactions driving colonization reshape the behavior of both tumor and stromal compartments, reinforcing the resilience of metastatic lesions.

Our recent work has shown that colonization induces changes in lung epithelial cells, infiltrating macrophages, and tumor cells, forming a microenvironment dominated by a dense, scar-like matrix that promotes tumor survival and proliferation. While we have shown that this aberrant niche can be disrupted by several multireceptor tyrosine kinase inhibitors (TKIs), each agent appears to affect lesions through distinct mechanisms. Identifying the specific pathways responsible for these anti-tumor effects has proved challenging.

To address this, we developed an algorithm that identifies aberrantly activated, kinase-dependent signaling pathways within each individual cell type. This approach revealed that several distinct, self-reinforcing microenvironments can emerge during lung colonization, and that each of these emergent networks activates a characteristic subset of kinase-dependent pathways. Importantly, these pathway signatures can be matched against the known activity profiles of available TKIs to predict which agents may be most effective for a given tumor.

To improve the effectiveness of this algorithm, we refined this predictive process by using CROP-seq to generate a purpose-built database for the accurate identification of kinase-driven transcriptional programs within each relevant cell type. The incorporation of spatial transcriptomics further refines predictions by resolving cellular neighborhoods to identify the most meaningful interactions occurring within a metastatic lesion.

Through this process, we aim to make every patient an exceptional responder by elucidating the targetable pathways driving the formation and maintenance of individual metastatic lesions and matching these vulnerabilities to the most effective available drug.

#0642 Extracellular viscosity modulates spheroid formation in SMARCB1-deficient brain tumor cells.

Yihsuan Chen[1], Long-Sheng Lu[2], Yu-Chun Lin[1]

[1]Graduate School of Advanced Technology, National Taiwan University, Taipei, Taiwan,[2]Graduate Institute of Biomedical Materials and Tissue Engineering, Taipei Medical University, Taipei City, Taiwan

Background In the developing pediatric brain, the viscosity of the tissue microenvironment changes dynamically with tissue maturation, providing a unique mechanical microenvironment that may influence cellular behavior through mechanotransduction. SMARCB1 deficiency causes the most aggressive pediatric central nervous system malignancies, which have high tissue specificity, extremely early onset, epigenetic dysregulation, and altered metabolic states. Despite this unique biological context, whether extracellular viscosity interacts with SMARCB1 loss to alter tumor cell behavior has never been explored.

Methods To investigate how extracellular viscosity affects SMARCB1-deficient brain tumor cells, gellan gum (GG), a biocompatible viscosity modifier, was incorporated into culture medium to generate viscosities of 2.2 (0%), 10 (0.01%), and 34 (0.03%) mPa·s at 37 °C. SMARCB1-deficient Re1P6 cells (c.157>T mutation and established from a patient-derived xenograft) were compared with SMARCB1-proficient glioma cell lines (T98G). Single-cell suspensions were seeded on ultra-low attachment plates and cultured in media of increasing viscosities to monitor cell growth and spheroid formation. Pre-formed spheroids were also transferred into media with varying viscosities to evaluate spheroid stability and dispersion. Changes in stemness markers and other cellular phenotypes were further examined under each condition.

Results We found that elevated extracellular viscosity selectively modulates spheroid formation in SMARCB1-deficient Re1P6 cells but not in SMARCB1-proficient glioma cells. Re1P6 exhibited a nonlinear response to viscosity, forming the most uniform spheroids (~200 μm in diameter) with increased cell growth (~30-fold) at 10 mPa·s, whereas spheroid formation was almost suppressed and proliferation remained unchanged at 34 mPa·s. SMARCB1-proficient glioma cells showed minimal changes in spheroid formation or cell growth across the same viscosity conditions. Pre-formed Re1P6 spheroids developed irregular boundaries at higher viscosity, suggesting viscosity-dependent disruption of spheroid cohesion. High-viscosity conditions also appeared tp decrease SOX2 and increase vimentin expression. Overall, Re1P6 cells exhibited greater phenotypic modulation in response to viscosity-dependent microenvironments than SMARCB1-proficient controls.

Conclusion Our early findings suggest a potential link between extracellular viscosity and the malignant behavior of pediatric SMARCB1-deficient tumors. Future work will investigate whether the viscosity-dependent response is linked to mechanosensing signaling pathway and metabolic-epigenetic changes, providing new insights into their tissue-specificity.

#0643 The Sean Karl Cohort: An international single-cell RNAseq study of paired patient Ewing sarcoma specimens.

Abbe Pannucci[1], Elina Mukherjee[1], Jessica D. Daley[2], Shireen Sita Ganapathi[3], Elissa Boguslawski[4], Lea Surrey[5], Lauren Gutstein[5], Patrick Azar[6], Emily Stockfisch[7], Azfar Neyaz[2], Ivy John[8], Jennifer Picarsic[8], Yutaro Tanaka[9], Byron Butaney[9], Riaz Gillani[9], Brian D. Crompton[9], Katherine A. Janeway[9], Jaclyln Taroni[10], Jessica Davis[6], Damon Reed[7], Adam Shlien[11], Theodore W. Laetsch[5], Rajen Mody[4], Clemence Henon[12], Thomas G. Grunewald[12], Elizabeth R. Lawlor[3], Filemon Dela Cruz[7], Patrick J. Grohar[13], Jovana Pavisic[14], Ally Hawkins[10], Anthony R. Cillo[1], **Kelly M. Bailey**[15]

[1]University of Pittsburgh, Pittsburgh, PA,[2]UPMC, Pittsburgh, PA,[3]Seattle Children's Research Institute, Seattle, WA,[4]University of Michigan, Ann Arbor, MI,[5]Children's Hospital of Philadelphia, Philadelphia, PA,[6]Indiana University, Indianapolis, IN,[7]Memorial Sloan Kettering Cancer Center, New York, NY,[8]The University of Pittsburgh School of Medicine, Pittsburgh, PA,[9]Dana-Farber Cancer Institute, Boston, MA,[10]The Childhood Cancer Data Lab, Wynnewood, PA,[11]Graduate Student, Dept. of Genetics & Genome Bio., The Hospital for Sick Children, Toronto, ON, Canada,[12]Hopp Children's Cancer Center Heidelberg (KiTZ), Heidelberg, Germany,[13]University of Michigan Medicine, Ann Arbor, MI,[14]Memorial Sloan Kettering, New York, NY,[15]Mayo Clinic, Rochester, MN

Introduction: Ewing sarcoma (EwS) is a FET::ETS family member-driven primary bone cancer demonstrating vast heterogeneity. Between a patient's primary diagnosis and disease progression, tumor cell state adaptation, microenvironment changes, and the landscape of evolving therapeutic vulnerabilities remain poorly understood. To address these gaps, the Sean Karl Cohort was established in 2025 to conduct the largest single-cell transcriptomic analysis of retrospective paired tumor samples from patients with EwS. Here, we present data from the five analytic teams, and through shared SOPs now expand this cohort to Europe.
Methods: Common sample processing SOPs were established to isolate cells from FFPE material from paired patient EwS samples. Single-cell (sc) RNAseq was generated using the GEM-X Flex Gene Expression protocol (10x Genomics). Alex's Lemonade Stand Foundation (ALSF) Data Lab established a common data processing and integration pipeline with an EwS-specific cell annotation workflow to create a harmonized dataset for downstream analyses. Analytic teams were created to define tumor cell subpopulations and their therapeutic vulnerabilities and to characterize the tumor microenvironment.
Data: We demonstrate the feasibility of generating high-quality scRNAseq profiles from retrospective FFPE-preserved EwS tumors. To date, 116 samples have yielded ~800,000 cells. Integrated analysis reveals reproducible EwS tumor cell states shared across patients with regulatory network analyses nominating candidate therapeutic vulnerabilities. The scale of this international cohort enables saturation analysis for rare cell populations. Paired and longitudinal samples further allow correlation of emergent cell states with therapy resistance and metastatic progression. For example, immune-focused analyses show increases in T cell and macrophage populations in post-therapy samples. A novel, standardized EwS-specific cell annotation workflow has been developed to harmonize analyses and findings. These data will be openly shared with the community through the ALSF Single-cell Pediatric Cancer Atlas Portal.
Conclusion: Large-scale international collaborative sample sharing, standardized processing pipelines, and harmonized EwS-specific annotations now enable deep single-cell analyses to characterize tumor heterogeneity in this rare pediatric and adolescent cancer. An in vivo expansion of the Sean Karl Cohort is underway to assess conservation of EwS tumor cell states and regulatory vulnerabilities identified in human tumors pre- and post-therapy in preclinical models, further supporting translation of these findings toward therapeutic strategies.

#0644 Evaluating GD2-targeting antibody-drug conjugates for DIPG using human organoid-based preclinical platforms.

Zhikun Wang, Emily Miller, Wei Huang, Satoru Kawakita, Lauren Vanderpool, Francisco Bustamante, Uijin Kim, Zhaohui Wang

Terasaki Institute for Biomedical Innovation, Los Angeles, CA

Diffuse intrinsic pontine glioma (DIPG) is a universally fatal pediatric brain tumor with a median survival of less than 12 months. Although the recent FDA accelerated approval of ONC201 offers a long-awaited sense of progress for the DIPG/DMG community, the central therapeutic problem remains far from solved. The frequent presence of H3K27M mutations in DIPG is associated with elevated expression of GD2, a clinically actionable surface antigen. GD2-directed CAR-T therapies have shown encouraging early activity in DIPG. However, challenges such as antigen heterogeneity, inherent manufacturing lead time, and risks of neurotoxicity remain. Antibody-drug conjugates (ADCs) offer a more controllable, off-the-shelf therapeutic approach that could overcome these limitations, yet their potential in DIPG remains unexplored. To evaluate the efficacy, resistance, and safety of GD2-targeting ADCs, we employed two complementary human-derived organoid platforms. First, DIPG models were generated using NanoGlio, a high-throughput nanoliter-volume droplet 3D organoid system. Second, we established a co-culture model with DIPG NanoGlio and iPSC-derived brain organoids to assess neurotoxicity. We successfully generated NanoGlio derived from 9 DIPG models reflecting the key genetic alterations typically identified in DIPG, including mutations in *H3.3 (H3F3A)* or *H3.1 (HIST1H3B).* We assessed the expression of GD2 by flow cytometry and 3D-Fluorescence Antibody Cell Tracking (3D-FACT) and observed widely variable GD2 expression across DIPG models. We tested M3554, a first-in-class clinical-stage anti-GD2 ADC conjugated to exatecan, a topoisomerase I inhibitor, in these models. M3554 exhibited potent cytotoxicity across DIPG NanoGlios. Resistance profiling using its unconjugated payload, Exatecan, revealed that reduced ADC response was primarily driven by intrinsic payload resistance rather than low GD2 expression. DIPG models with very low GD2 expression, including SF7761 and SU-DIPG-IV, also responded strongly to M3554, consistent with a bystander killing effect. iPSC-derived brain organoids (GD2-negative) showed minimal toxicity with M3554, whereas equivalent doses of Exatecan induced extensive cell death. Future work will systematically evaluate GD2 ADC bystander effect via co-encapsulation of GD2+ and GD2- DIPG cells, and assess the efficacy and neurotoxicity of M3554 using our DIPG-brain co-culture model. Successful completion of this study will provide critical preclinical evidence supporting the assessment and use of GD2-targeting ADCs in DIPG treatment.

#0645 Enhancement of antigen presentation restores immune recognition in rhabdomyosarcoma.

Maya Groff[1], David Milewski[1], Hsien-Chao Chou[1], Vineela Gangalapudi[1], Alexandra Urbanek[2], Young Song[1], Meijie Tian[1], Yong Yean Kim[1], Jun Wei[1], Javed Khan[1]

[1]Center for Cancer Research, NIH-National Cancer Institute, Bethesda, MD,[2]NIH-National Eye Institute, Bethesda, MD

Background: Immunotherapy offers a promising therapeutic option against pediatric tumors, but it is limited by suppression of the antigen processing machinery (APM), including major histocompatibility complex class I (MHC-I). In this study, we quantify antigen presentation in pediatric tumors and explore the role of transcriptional regulators and epigenetic-targeted therapies to restore antigen presentation and immune recognition in rhabdomyosarcoma (RMS).
Methods: Expression of HLA-A/B/C was quantified by RNA sequencing (RNA-seq) in adult tumors (n=657) and pediatric cell lines (n=131). Surface MHC-I expression was quantified by flow cytometry in pediatric cell lines (n=76). RMS cell lines (n=9) were treated with IFN-γ and clinically relevant drugs, decitabine (DAC), mocetinostat, and tazemetostat. Changes in MHC-I and APM gene expression were measured by RNA-seq and flow cytometry. NLR family CARD domain-containing 5 (NLRC5) was induced in RMS cell line and patient derived xenograft (PDX) models using lentiviral overexpression or CRISPR activation. MHC-I and APM expression were measured by RNA-seq, flow cytometry, and western blot. T cell cytotoxicity assays were performed with T cells expressing a PRAME-specific HLA-A*02:01 T cell receptor (TCR).
Results: Pediatric tumors exhibited variable MHC-I expression, as determined by flow cytometry, and this expression was significantly lower than adult tumors, with RMS displaying low or absent expression. IFN-γ and pharmacologic treatment increased MHC-I surface expression and immune gene signatures in RMS. NLRC5, a key immune regulator, was found to be most significantly correlated with MHC-I expression and induced by treatment with DAC. Epigenetic priming with DAC and upregulation of NLRC5 was sufficient to restore MHC-I expression and sensitized an RMS PDX to killing by engineered TCR-T cells targeting PRAME.
Conclusions: Pediatric tumors show distinct patterns of antigen presentation, such as high MHC-I in alveolar soft part sarcoma and low expression in RMS, though individual tumor subtypes exhibit internal variability. IFN-γ and epigenetic agents restore antigen presentation, including increased NLRC5 expression. Pharmacological treatment and NLRC5 restoration enhanced antigen presentation and sensitized RMS PDX to TCR mediated T-cell cytotoxicity. Compounds that reverse APM silencing will be systematically evaluated for their ability to enhance adoptive TCR therapies. This work will establish a foundation for overcoming immune resistance and expanding the impact of MHC-I dependent cancer immunotherapies.

#0646 Exploring actionable therapeutic targets associated with SMARCB1 deficiency in Epithelioid sarcoma.

Jiyeon Park[1], Ryo Miyamoto[2], David G. Kirsch[1]

[1]Department of Medical Biophysics, University of Toronto, Toronto, ON, Canada,[2]Princess Margaret Cancer Centre, University Health Network, Toronto, ON, Canada

Epithelioid sarcoma (EPS) is a rare, slow-growing yet highly metastatic mesenchymal neoplasm characterized by inactivation of SMARCB1. Although the EZH2 inhibitor Tazemetostat has been approved for EPS patients, clinical outcomes remain poor. In this study, we performed functional genomic studies to identify therapeutic vulnerabilities of EPS and to elucidate their underlying mechanisms.CRISPR screening using an sgRNA library targeting ~2,700 druggable genes identified dependencies of EPS cells on; BAF complex subunits (SMARCA4, SMARCC2 and SMARCD1), integrin pathway genes (ITGAV, PTK2, PTPN11) and the cyclin-dependent kinases (CDK4 and CDK6). A clinically available CDK4/6 dual inhibitor Palbociclib effectively inhibited EPS cell proliferation *in vitro* and significantly delayed tumor growth in human EPS cell line-derived xenograft models. Moreover, the CDK4-selective inhibitor Atirmociclib showed profound cytotoxicity in cell lines with low CDK6 expression, suggesting the feasibility of tailoring CDK4/6-targeted therapy based on CDK6 expression levels.Re-expression of SMARCB1 using a Tet-ON conditional expression system induced growth arrest, accompanied by reduced RB phosphorylation and decreased cyclin A2 (CCNA2) expression. SMARCB1 re-expression also upregulated the CDK inhibitors, p21 and p27, indicating compromised cell cycle control. The strong dependency of EPS on p21/p27-CDK4/6 axis supports CDK4/6 inhibition as a therapeutic strategy. Our CRISPR screen and *in vitro* viability assays demonstrated that EPS cell lines are intrinsically resistant to Tazemetostat, with genetic and epigenetic silencing of p16 emerging as a potential mechanism underlying this resistance.Together, functional genomic screens define key therapeutic vulnerabilities in EPS, suggesting CDK4/6 inhibitors as a promising treatment option for EPS patients. We propose that expression levels of CDK6 and p16 may serve as predictive biomarkers for response to EZH2 and CDK4/6 inhibitors, thereby informing patient stratification and improving clinical outcomes.

#0647 EWSR1::FLI1 suppresses ribosome biogenesis and creates a targetable vulnerability in Ewing sarcoma.

Anisimova[3], Anja Wagner-Schrittwieser[4], Tamina Stelzer[1], Aikaterini M. Formouzi[1], Bernadette Liegl-Atzwanger[5], Marita Koelz[6], Anke Scharrer[6], Markus Schosserer[4], Peter Schlogelhofer[3], Thomas G. P. Grunewald[7], G. Elif Karagoz[3], Alice Soragni[2], Eleni M. Tomazou[1]

[1]St. Anna Children?s Cancer Research Institute, Vienna, Austria,[2]Department of Orthopaedic Surgery, David Geffen School of Medicine, University of California Los Angeles, Los Angeles, CA,[3]Max Perutz Labs, Vienna BioCenter Campus (VBC), Vienna, Austria,[4]Center for Pathobiochemistry and Genetics, Medical University of Vienna, Vienna, Austria,[5]Diagnostic and Research Institute for Pathology, Medical University of Graz, Graz, Austria,[6]Department of Pathology, Medical University of Vienna, Vienna, Austria,[7]Division of Translational Pediatric Sarcoma Research, German Cancer Research Center (DKFZ), Heidelberg, Germany

Enhanced ribosome biogenesis has long been regarded as a defining feature of malignant growth, sustaining the elevated biosynthetic and translational demands of cancer cells. However, emerging evidence suggests that the relationship between ribosome production and cancer biology is more complex, with alterations in ribosome biogenesis exerting diverse cellular effects. This complexity is particularly evident in Ewing sarcoma (EwS), a malignancy affecting children and young adults, and is driven by the EWSR1::FLI1 fusion oncoprotein. Intriguingly, its histological hallmark of inconspicuous nucleoli suggests profoundly altered ribosome biogenesis. Given its low mutational burden and reliance on non-genetic mechanisms, we reasoned that dissecting the rewiring of post-transcriptional regulation and ribosome biogenesis could reveal previously unexplored therapeutic vulnerabilities. Using super-resolution imaging (STED), we found that EwS cells display pronounced nucleolar disorganization, characterized by aberrant clustering of the rDNA transcription factor UBF1 and loss of canonical nucleolar compartmentalization. Mechanistically, the EWSR1::FLI1 fusion protein sequesters endogenous EWSR1, leading to R-loop accumulation at rDNA loci and suppression of rDNA transcription. As a result, EwS cells exhibit reduced ribosome biogenesis and global protein synthesis - an unexpected deviation from the hyperactive state typical of most tumors. Despite this reduction, polysome sequencing revealed a compensatory translational program with selective enhancement of 5′TOP mRNAs translation, sustaining a minimal yet efficient ribosome output. This compensatory mechanism, while sufficient to sustain baseline survival, operates at the edge of translational capacity, creating a therapeutically exploitable vulnerability to agents that further compromise ribosome biogenesis. Indeed, pharmacologic inhibition of RNA polymerase I with CX-5461 disrupts this fragile balance, inducing rapid translational shutdown and apoptosis specifically in EwS cells, an effect that is reversed by EWSR1::FLI1 depletion. Moreover, etoposide treatment selectively triggers SLFN11-dependent translational shutdown in EwS cells, in addition to inducing DNA damage, highlighting its dual impact on both the genome and the already fragile translational machinery. Finally, CX-5461 demonstrated potent therapeutic activity with evidence of synergistic effects when combined with the PARP inhibitor Olaparib selectively in EwS, warranting further investigation of rational combination strategies. Together, our findings reveal that reduced ribosome biogenesis - rather than its hyperactivation - is an important feature of EwS and creates a distinct therapeutic vulnerability. Targeting this constraint offers a promising new strategy for a disease that currently lacks effective targeted therapies.

#0648 PP2A reactivation upregulates *FGA* gene in neuroblastoma.

Nazia Nazam[1], Shamza Manzoor[1], Maryam Ghufran[1], Morgan L. Brown[1], Ali M. Eakes[1], Pranava Nande[1], Joel C. Opara[1], Abdulraheem Kaimari[1], Michael Ohlmeyer[2], Elizabeth A. Beierle[1]

[1]University of Alabama at Birmingham, Birmingham, AL,[2]Atux Iskay, LLC, Plainsboro, NJ

Background: High-risk neuroblastoma (NBL), driven by *MYCN* amplification, remains fatal for many children. Our previous work demonstrated that pharmacologic PP2A reactivation decreases NBL in vivo tumor growth through suppression of MYCN expression and stability by reducing MYCN phosphorylation and promoter acetylation, concurrent with BRD4 and RNA Pol II dephosphorylation. The current study is an extension of this previous work, in that we performed loss-of function tests validating the previous findings, and identified a downstream target regulated by *MYCN* within this PP2A-controlled network.

Methods: The *MYCN* amplified human NBL cell line SK-N-BE(2) was treated with the PP2A activator, ATUX-1215, or the PP2A inhibitor, okadaic acid (OA). Immunoblotting quantified phospho-BRD4, BRD4, MYCN, PP2Aαβ-C subunit, acetylated histones (H3K27ac, H3ac), total H3, and GAPDH. PP2A activity was measured enzymatically. Bulk RNA sequencing identified transcriptional alterations, and qRT-PCR confirmed the findings. Public NBL datasets (TARGET and Capasso) were analyzed.

Results: OA treatment increased phospho-BRD4, MYCN, H3K27ac, and H3ac while decreasing PP2A expression and activation. Densitometric analysis of immunoblots validated these transcriptional and epigenetic marker changes. Bulk RNA-seq revealed fibrinogen alpha chain (*FGA*) as a significantly upregulated gene following PP2A activation with ATUX-1215. Gene Set Enrichment Analysis (GSEA) identified enrichment of MYCN associated pathways, specifically the WEI_MYCN_TARGETS_WITH_E_BOX gene set, with *FGA* among upregulated targets. Increased *FGA* mRNA abundance was confirmed with qRT-PCR in ATUX-1215 treated NBL cells (24 h - 72 h). Public dataset analysis demonstrated that elevated *FGA* expression correlated with improved overall survival in *MYCN* amplified and stage 4 NBL patients.

Conclusion: We have found that PP2A reactivation involves BRD4-mediated epigenetic regulation and histone acetylation, upregulates *FGA* gene, and that increased *FGA* is associated with improved NBL survival. These findings suggest that PP2A reactivation may restore beneficial MYCN-linked transcriptional programs, offering potential therapeutic strategy for high-risk NBL.

#0649 Site-specific phospho-regulatory collapse of PML governs RTK hyperactivation in high-risk pediatric malignancy..

Sreenidhi Mohanvelu, Poorvi Subramanian, Natarajan Aravindan

Oklahoma State University, Stillwater, OK

High-risk neuroblastoma (HR-NBL), a deadly pediatric malignancy of neural crest origin is characterized by persistent hyperactivation of receptor tyrosine kinases (RTKs) such as ALK, EGFR that orchestrates oncogenic trajectory and perpetuates aggressive, treatment refractory phenotype. Despite extensive characterization of the RTK signaling, the upstream regulatory mechanism that constrain RTK activity and restore lineage commitment remain elusive, limiting the efficacies of differentiation-based therapies. Stability and functional integrity of promyelocytic leukemia protein (PML) and its nuclear body architecture are essential for sustaining differentiation and therapeutic sensitivity. Our recent studies identified a mechanism that derange PML stability, defining a site-specific (serine 518, S^{518}) post-translational modification that dictates PML functional integrity. Herein, we delineate a S^{518} phosphorylation-centric signaling architecture driving oncogenic RTK signaling. To this end, we employed a dual modality framework integrating RD3 expression modulation (knockout, $RD3^{-/-}$ or overexpression, $RD3^{+/+}$) that dictates S518 phosphorylation, and stable site-specific mutagenesis of PML S^{518} to phospho-dead (A^{518}) or phosphomimic (E^{518}), in patient-derived NBL cells representing distinct clinical stages, diagnostic (Dx) and progressive disease (PD). Functionally, RD3-loss dependent PML destabilization ($RD3^{-/-}$ and $RD3^{+/+}$PML E^{518}) led to a hyperphosphorylated cellular state, disrupting post-translational signaling control and reinforcing an aggressive, therapy defiant phenotype. Quantitative profiling of RTKs phosphorylation (curated panel of 71 human RTKs, phospho-RTK array) was performed to assess pro-oncogenic transformation signaling. $RD3^{-/-}$ and $RD3^{+/+}$PML E^{518} clones exhibited a pronounced increase in phospho-RTK signals, consistent with hyperactivated receptor landscape. Notably, RD3 loss driven PML S^{518} site specific phosphorylation included robust activation of tightly integrated oncogenic RTKs (e.g., Lyn, SYK, Tie-1), that are decisively documented in HR-NBL pathogenesis. In contrast, RD3 overexpression and PML S^{518} phospho-dead mutants attenuated RTK phosphorylation profiles, with minimal activation of canonical oncogenic RTKs. These findings critically demonstrate that RD3 loss driven S^{518} site-specific phosphorylation of PML reprograms the cellular signaling landscape towards a programmed RTK hyperactivation, mechanistically bridging nuclear architectural disruption with membrane-proximal oncogenic signaling. Targeting the RD3-PML-RTK axis offers a mechanistically anchored strategy restoring differentiation competence and attenuate the malignant trajectory of HR-NBL. Funding: Department of Defense CA-210339; OCAST-HR19-04; NIH-P20GM103639; and supported by P30CA225520 and P30GM154635.

: Ex Vivo Systems: Patient-Derived, Patient-Specific Tumor Cultures
Poster Session

#0653 Rapid drug sensitivity testing of passage-zero patient brain tumor tissues to inform preclinical and clinical decisions: results from a clinical feasibility study.

Breanna Mann[1], Nichole Artz[1], Adebimpe Adefolaju[1], Alain Valdivia[1], Xiaopei Zhang[1], Rajaneekar Dasari[1], Caroline Stockwell[1], Morrent Thang[1], Allison Murray[1], Noah Bell[1], Andrew Buckley[1], Rami Darawsheh[1], Kerry Fitzgerald[2], Jonathan Williams[2], Hardik Parikh[3], Shuang Gao[3], Jie An[3], Yvette Rodriguez[3], Daniel Metzger[3], Collin Parrow[3], Dylan Riley[3], Robert Seager[3], Stephanie B. Hastings[4], Taylor Jensen[4], Shakti Ramkissoon[4], Dominique Higgins[1], Yasmeen Rauf[1], Scott Elton[1], Kimberly Hamilton[1], Jeremy Wang[1], Albert Baldwin[1], Shawn Hingtgen[1], David Kram[1], Andrew Satterlee[1]

[1]University of North Carolina at Chapel Hill, Chapel Hill, NC,[2]Labcorp, San Diego, CA,[3]Labcorp, Buffalo, NY,[4]Labcorp, Durham, NC

Functional precision medicine (FPM) offers a promising path forward in neuro-oncology, where genomic profiling alone often fails to predict therapeutic response. To bridge this gap, we developed the Screening Live Cancer Explants (SLiCE) platform, a rapid *ex vivo* drug screening assay that functionally tests passage-zero patient brain tumor tissues engrafted atop living organotypic brain slice cultures (OBSCs). With an assay time of just four days, SLiCE preserves key tumor characteristics not maintained *in vitro*, including genomic fidelity, growth, invasion, and treatment response, with higher engraftment rates and faster assay speeds than *in vivo* models. Our standard cryopreservation workflow enables reproducible, iterative, and on-demand testing of a single zero-passage specimen banked in multiple replicate aliquots, setting SLiCE apart from organoid and precision-cut tumor explant models. Here, we describe results from our actively accruing clinical feasibility study (NCT05978557), where we successfully engrafted and tested 35 of 36 diverse brain tumor specimens on SLiCE, achieving our study's primary endpoint ahead of schedule. SLiCE produced multi-parametric drug sensitivity scores (DSSs), each normalized to off-target toxicity, for all samples within a clinically actionable 28-day window. Across 530 experiments, we generated 142 DSSs from unique drug-tumor combinations, forming a reference library for future benchmarking. We then further analyzed a subset of IDH-WT glioblastoma tumor specimens in which SLiCE DSSs correlated with patient response to temozolomide (AUC = 0.875, p = 0.0175) and overall survival (R^2 = 0.73). Additionally, this study validated surgically aspirated tumor tissue as a genomically, transcriptomically, and functionally similar tumor source compared to the standard, manually excised remnant tumor sample approved by clinical pathology. Collecting this often-discarded tumor source increased the mass of tumors accrued by nearly 5-fold and enabled collection from 11 additional patients, significantly increasing tumor tissue for downstream testing on SLiCE. These findings establish SLiCE as a scalable, clinically relevant platform for FPM in brain cancer, with potential to guide individualized treatment decisions and accelerate preclinical drug development.

#0654 A modular positioning platform for standardized ex vivo specimen analysis in preclinical optical imaging.

Max Harlacher, Jeffrey D. Peterson, James Tseng, **Jessica Pesner**, Bincy John

Revvity, Waltham, MA

Efficient and organized handling of ex vivo specimens is critical for advancing preclinical imaging workflows, particularly in studies requiring high-throughput analysis of tumors, organs, and bone tissues. We developed a novel modular ex vivo sample holder, specifically designed to integrate seamlessly with Revvity's IVIS optical imaging systems for bioluminescence, fluorescence, or x-ray imaging applications. This innovative accessory addresses key challenges in specimen organization, imaging throughput, and experimental reproducibility. In this study, we designed two ex-vivo sample holders with 16-25 separate non-reflective chambers that enable researchers to image multiple samples simultaneously and efficiently. Each chamber has light-blocking walls to prevent crosstalk of signal emission and sample. A wide range of ex vivo specimens including brain, heart, lung, kidneys, liver, spleen, bladder, and gastrointestinal tract were placed on the sample holder with a unique optically dark sheet and imaged using Revvity's IVIS optical systems. We tested multiple types of black sheets and the ideal optically dark sheet was selected based on minimum background effects, reproducibility, and ease-of-operation. The sample holder is designed to incorporate the disposable optically dark paper and minimizes cross-contamination of ex-vivo samples. This paper provides a clean, non-reflective surface that is easily replaceable between experiments, ensuring optimal imaging conditions. Furthermore, the holder's design enhances workflow efficiency by reducing setup time and facilitating rapid specimen arrangement, making it ideal for high-throughput imaging studies. Additionally, IVIS software tools support region of interest (ROI) template creation, allowing for precise and consistent quantitative analysis. The holder's modular compartments allow for different configurations that can be customized to accommodate varying specimen sizes, offering flexibility across diverse experimental needs. This accessory represents a significant advancement for ex vivo optical imaging, providing researchers with a practical solution for improving imaging efficiency, reproducibility, and data quality. By combining ergonomic design, modularity, and software integration, the novel ex vivo sample holder empowers laboratories to achieve greater throughput and precision in preclinical imaging applications.

#0655 Clinical validation of pembro response predictions from TNBC patient biopsies using E slices.

Kyuson Yun[1], Viridiana L. Leyva-Aranda[2], Claire Yun[2], Nourhan ABDELFATTAH[1], Clinton Yam[3], Fransisca Leonard[1], Reece Kang[1], Jangsoon Lee[4], Naoto Ueno[4]

[1]Houston Methodist Research Institute & Weill Cornell Medical College, Houston, TX,[2]EMPIRI, Houston, TX,[3]UT MD Anderson Cancer Center, Houston, TX,[4]U Hawaii Cancer Center, Honolulu, HI

The efficacy of immunotherapies depends on complex and dynamic interactions among immune cells, stromal cells, and cancer cells. Currently, no functional precision medicine assays can accurately predict individual patient responses to immunotherapies in a clinically actionable timeframe. The E-slice platform is a proprietary 3D human tumor tissue culture system that enables rapid, personalized drug sensitivity testing in 8-12 days from the time of tumor biopsies or surgical resections.E-slices are distinct from other 3D human model systems in multiple, critical ways. E-slices are:
1) never dissociated or reconstituted or expanded ex vivo; therefore, the platform maintains individual patient tumors' histoarchitecture, cellular composition including tumor-infiltrating immune cells, and the spatial relationships among different cell types, enabling evaluation of immunotherapies (antibody drugs, ADCs, cell therapies, oncolytic virus, etc.) in intact human tumor tissues;
2) cultured in serum-free, chemically defined medium, preventing artificial activation or altering of immune and cancer cell states;
3) validated at single-cell RNA-sequencing level to maintain tumor associated immune cells ex vivo for at least 8 days, not only in numbers but also in their activation states;
4) scalable and can be generated from needle biopsy cores to inform clinical trials or patient care as well as surgical samples for multi-dimensional analyses; 5) compatible with all major solid tumor types in human, and 6) compatible with all anti-cancer treatment modalities, including biologics, small molecules, cell based therapies, and virotherapies.Here, we report two retrospective and one prospective clinical studies that demonstrate that E-slices are highly accurate in predicting patient responses to anti-cancer agents. Two small retrospective studies, using colorectal cancer patient PDX tumors, demonstrated that E-slices can accurately predict patients' responses to chemo + targeted therapy combinations with 100 percent Specificity and sensitivity. An interim analysis of an ongoing prospective clinical study using TNBC patient biopsy cores (n=10) shows that E-slice can accurately predict patient responses to the KEYNOTE-522 regimen, which includes pembrolizumab plus chemotherapies with Specificity at 100 percent and Sensitivity at 87.5 percent. Furthermore, this platform enables treatment response to Pembo alone ex vivo, which showed 14 percent response rate from the first 14 patients, which is remarkably similar to the benefit reported in the KEYNOTE-522 study (13.6%). In summary, we report a novel 3D human tumor culture system that can accurately predict patient responses to immunotherapy in a clinically actionable time frame and can provide deep molecular and cellular insights to accelerate immunotherapy testing and development.

#0656 A patient-derived *ex vivo* platform for personalized evaluation of both direct and immune-mediated drug responses.

Jie Wen, Hao Cheng, Nan Yang

PharmaLegacy Laboratories, Shanghai, China

Patient-derived xenograft (PDX) models represent a milestone of preclinical oncology research, serving as a valuable *in vivo* system for evaluating drug efficacy in mice and informing potential personalized therapeutic strategies. However, widespread application of PDX models has been limited by prolonged and variable engraftment timelines, relatively low success rates, and substantial operational costs. Moreover, the gradual replacement of human tumor microenvironment (TME) with murine stromal components compromises the fidelity of PDX models, particularly for evaluating immunomodulatory agents, which requires an intact human immune context. While patient-derived organoids (PDOs) offer a faster and more efficient modeling alternative, their utility is limited by absence of a representative TME, difficulties in assay standardization, and inherent selection bias towards specific cancer cell clones. These limitations raise concerns regarding their ability to provide reliable prediction on efficacy to complex treatment regimens, thereby motivating the development of more holistic *ex vivo* approaches.

In the current study, we established an *ex vivo* tissue culture platform utilizing freshly resected patient tumors to evaluate anti-tumor efficacy of test articles across a panel of patient tumors. Tumor samples obtained from surgery were processed immediately into uniform sections by tissue slicing and cultured in a trans-well system exposed to various stimulants and/or test articles. Post incubation, the cultured tumor tissues were subjected to multiple downstream analyses, including tumor killing assessment, immune cell profiling, biomarker analysis, immunohistochemistry (IHC) and immunofluorescence (IF). The culture medium was analyzed to profile secreted cytokines and chemokines. An illustrative application: tumor tissues collected from lung cancer patients were evaluated on this platform to compare anti-PD1 responses. Tumor collected from anti-PD1 responsive patient revealed pronounced tumor suppression characterized by a 25% increase in $CD8^+CD103^+$ T cells and a 22% reduction in $CD163^+$ macrophages by flow cytometry, enhanced caspase-3 staining, decreased Ki-67 and TGF-β signals via IF, and elevated expression levels of cytokines associated with immune suppression and TAM recruitment as measured by Luminex, collectively distinguishing this profile from that of non-responders.

This *ex vivo* tissue culture system dramatically expands the utility of clinical specimens while maintaining native architecture and cellular heterogeneity. It enables rapid and direct assessment of therapeutic responses and shows strong correlation with *in vivo* outcomes, bridging a critical gap between traditional *in vitro* assays and subsequent *in vivo* studies. This approach may accelerate the pipeline for anti-cancer drug discovery and development.

#0657 The era of NAMS, incorporating tumor heterogeneity and immune context into human-relevant patient avatar cancer models.

W. Gregory Sawyer, Ryan Smolchek, Duy Nguyen, Alfonso Pepe, Diego Pedro, Erin George, Roger Li

Moffitt Cancer Center, Tampa, FL

Patient-derived microtumor avatars are at the forefront of NAMs (New Approach Methodologies) that recapitulate intratumoral heterogeneity and incorporate the full immune cell tumor microenvironment. To address ongoing challenges in translational cancer modeling, we developed a platform enabling secondary addition of tumor-infiltrating lymphocytes (TILs), CAR T-cells, PBMCs, checkpoint blockade agents (aPD1), antibody-drug conjugates, and conventional chemotherapies to these microtumor systems. Using validated models from ovarian, pancreatic, bladder, colorectal, and endometrial cancers, we have demonstrated high-fidelity assessment of therapeutic response and immune dynamics. High-resolution time-lapse imaging reveals spatiotemporal kinetics of tumor clearance by immune effectors at single-cell resolution, and additional movies demonstrate mechanisms of immune-mediated tumor eradication. These findings benchmark the robustness and translational potential of microtumor avatars for preclinical immuno-oncology research and mechanistic testing.

Purpose: To evaluate the use of microtumor avatars in cancer research, focusing on the integration of tumor heterogeneity and immune context for faithful translational models in NAMs.

Methods: NAMs viability was regularly assessed via immunofluorescence imaging using LIVE/DEAD cell imaging and a Nikon AXR and Multiphoton confocal microscope outfitted with the NSPARC super-resolution detector. Characterization of the patient microtumors was performed using a variety of stains for nuclei, Ki67 activity, Collagen Type I, EpCAM, E-Cadherin, N-Cadherin, VE-Cadherin, Vimentin, CD45, CD3, Trop-2, Nectin-4, and others. Following long duration time-lapse experiments, super-resolution microscopy was performed using our typical fixation and permeabilization protocols.

Results: Patient-derived microtissues were maintained in culture for extended periods and exhibited sustained viability and diverse cellular composition, as confirmed by the above imaging techniques. Proliferative activity, dynamic tissue architecture, and variable marker expression were revealed using immunofluorescence across all microtumors. Drug response studies using targeted agents, immune checkpoint inhibitors, and broad-spectrum cytotoxics demonstrated in vitro outcomes concordant with patient therapies, including both sensitivity and resistance patterns in solid tumor models. Furthermore, functional assays with engineered immune cells such as CAR T-cells and TILs confirmed robust immune-mediated tumor killing within these microtumor platforms.

Conclusions: These results support that advanced patient-derived microtissue NAMs now enable robust opportunities for increased precision in translational cancer research and therapeutic discovery.

#0658 Establishment of a novel ex vivo bone metastasis culture platform for triple-negative breast cancer.

Tiina E. Kahkonen[1], Saif Wahid[2], Sangita Kushary[2], Debabani Roy Chowdhury[2], Arnab Roy Chowdhury[2], Jussi M. Halleen[1]

[1]OncoBone Ltd, Kiviniemi, Finland,[2]Mestastop Solutions Pvt Ltd, Bangalore, India

Drug development for bone metastasis has been hindered by the lack of appropriate in vitro models in early testing. Typical in vitro models lack the crucial bone microenvironment, leading to wrong conclusions about efficacy on bone metastases in vivo. We have established a novel bone metastasis ex vivo culture platform including bone discs from tibiae of mice with 4T1 triple-negative breast cancer (TNBC) tumors.

Female Balb/c mice were injected intratibially with 10,000 (10k) or 20,000 (20k) 4T1 mouse TNBC cells or PBS (control). Tumor-induced bone changes were monitored by X-ray imaging. 4T1 tumor and control bones were collected and cut into 2-3 mm thick discs, rinsed with antibiotic-containing medium, and cultured in basal medium (RPMI-1640 medium supplemented with 10% FBS) in a humidified incubator. Osteoblastic medium included ascorbic acid and beta-glycerophosphate, and osteoclastic medium included M-CSF and RANKL supplements. The culture medium was partially replenished every 72 hours. Culture lengths from 7-21 days were tested and analyzed for cell viability (trypan blue), proliferation (CCK-8 assay), bone resorption (TRACP5b ELISA) and bone formation (PINP EIA and Alizarin S Red staining).

Intratibial inoculation of 10k and 20k 4T1 cells induced progressive osteolytic lesions that were monitored for 13 days by X-ray imaging. Based on the extent of osteolytic lesions, days 3-5 were selected to model early bone metastasis growth with visible tumor-induced effects on bone, and 20k 4T1 cells were selected for future studies due to more uniform tumor growth. In ex vivo cultures of tibia bone discs in basic medium, cell viability remained high at days 7 and 10 (88 and 91%, respectively) but dropped to 47% at day 14. Therefore, 10 days was considered maximum culture length. In discs with 4T1 tumors, cell doubling time was higher than in control discs. Addition of osteoblastic supplements increased PINP levels in control discs and in discs including 4T1 tumors at day 10, after which the values decreased. Increased Alizarin Red staining was observed at day 10. Addition of osteoclastic supplements increased TRACP5b levels at days 10 and 14, after which the values decreased. Similar increase was not observed when adding both osteoblastic and osteoclastic supplements. Discs with 4T1 tumors had higher baseline TRACP5b levels than control discs, and the values were further increased with osteoclastic and both osteoclastic and osteoblastic supplements.

We have established a novel ex vivo bone metastasis culture platform where cancer cell, osteoclast and osteoblast activities were maintained after in vivo extraction of bone discs, indicating that the ex vivo cultures were able to maintain in vivo properties of the tumor and its bone microenvironment. We conclude that this platform provides a miniaturized, labor and cost-effective way for preliminary testing of effects of experimental therapies on bone metastases.

#0659 Ex vivo evaluation of a MUC1-targeted bispecific T-cell engager in ovarian tumoroids using Nilogen's 3D-EXpress platform.

Vanessa Garrido, Janine DeBlasi, Andrea Mockabee, Seth Currlin, Justin Silberman, Jessica Linkous, Alliyah Humphrey, Jared Ehrhart

Nilogen Oncosystems, Tampa, FL

BACKGROUND: Mucin 1 (MUC1) is a relevant target for bispecific T-cell engagers due to its expression in epithelial malignancies. Nilogen Oncosystems' 3D-EXpress ex vivo tumoroid platform enables direct assessment of patient-specific responses to immunotherapies in a physiologically preserved tumor-immune microenvironment. This study evaluated the activity of a commercially available recombinant Anti-CD3 x Anti-MUC1 bispecific T cell engager antibody (MUC1-TCE) in cryopreserved ovarian tumor-derived tumoroids to characterize immune activation using Nilogen's integrated platform combining flow cytometry, cytokine profiling, and RNA transcriptomic analysis.

METHODS: Pathology reports were reviewed for all tissues and confirmed characteristic histological features consistent with high-grade ovarian carcinoma. Tissues were evaluated for MUC1 expression, showing high to low levels. Tumoroids were generated by mechanical dissociation without enzymatic digestion or in vitro propagation. After thawing, tumoroids were treated with MUC1-TCE, isotype control, or positive control. Multiparametric flow cytometry measured T-cell activation. Parallel supernatants were collected for multiplex cytokine profiling, and RNA was isolated for downstream transcriptional analysis.

RESULTS: MUC1-TCE treatment induced clear immune activation across multiple tissues. CD4+ T cells upregulated 4-1BB, CD25, CD69, OX40, and PD-1, while CD8+ T cells upregulated 4-1BB, CD25, ICOS, and OX40. Cytokine profiling showed strong induction of inflammatory mediators, with IFN-γ and TNF displaying the greatest response. Preliminary RNA analysis revealed enrichment of immune-activated, inflammatory, and cytokine-driven pathways consistent with effector engagement.

CONCLUSIONS: These findings demonstrate the feasibility of using cryopreserved patient-derived tumoroids for ex vivo testing of bispecific T-cell engagers while preserving the native tumor-immune microenvironment. Integration of cytokine measurements, transcriptomic readouts, and immune phenotyping provides a scalable approach for characterizing mechanisms of action of MUC1-targeted agents and supports continued development of bispecific immunotherapies for solid tumors.

#0660 Integrating passage-zero patient tumor tissues from distant institutions into a rapid, ex vivo drug screening platform.

Adebimpe Adefolaju[1], Breanna Mann[1], Rajaneekar Dasari[1], Emma Livne[1], Caroline Stockwell[1], Alain Valdivia[1], Sonia Lipp[2], Angel Augst[2], Kerry Fitzgerald[3], Jonathan Williams[3], Hardik Parikh[4], Shuang Gao[4], Jie An[4], Taylor Jensen[5], Shakti Ramkissoon[5], Dominique Higgins[1], Yasmeen Rauf[1], Scott Elton[1], Kimberly Hamilton[1], Yair Gozal[2], Vincent DiNapoli[2], Albert Baldwin[1], Shawn Hingtgen[1], David Kram[1], **Andrew Satterlee**[1]

[1]University of North Carolina at Chapel Hill, Chapel Hill, NC,[2]Mayfield Clinic, Cincinnati, OH,[3]Labcorp, San Diego, CA,[4]Labcorp, Buffalo, NY,[5]Labcorp, Durham, NC

Access to living patient tumor tissue remains a major barrier to accelerating preclinical drug development and informing clinical care. Over the last decade, we have developed a “New Approach Methodology” platform called Screening Live Cancer Explants (SLiCE), which reproducibly engrafts living, passage-zero patient tumors atop substrates of living tissue. Our streamlined four-day drug screening workflow enables tumor engraftment within one day of resection, drug addition one day post-engraftment, and quantification of tumor survival three days later. This procedure is fast enough to accelerate preclinical workflows and inform clinical decisions while minimizing genetic drift. As we expand use of SLiCE in the preclinical setting, our established protocols for collecting and cryopreserving passage-zero tumor tissue have thus far enabled us to cryopreserve over 150 grams of viable brain tumor tissue in over 700 cryovials from 41 patients for personalized drug sensitivity profiling and preclinical testing. Through an active collaboration between UNC and Labcorp, we have shown that replicate cryopreserved aliquots of tumor samples post-thaw are equivalent by whole-exome sequencing (WES), RNA sequencing, and functional drug response. Still, availability of living, passage-zero patient tumor tissue remains our limiting component to further scaling this assay for broad adoption and impact. To overcome this hurdle, our SLiCE Team at UNC is expanding collection of viable tumor tissue to other groups and institutions. A new collaboration with the Mayfield Clinic has successfully yielded shipment of tumor tissues freshly resected from patients at partnering hospitals to UNC. These tumor specimens were viably maintained throughout overnight shipping at 4C, quantified by live tumor cell metabolism via Presto Blue assay, and have been successfully engrafted on SLiCE, quantified by live tumor cell bioluminescence on Day 4 after seeding, the length of our standard drug screening assay. These data provide our first proof-of-concept evidence that tumors resected from patients at distant institutions can be shipped fresh to UNC for testing on SLiCE. Our goal is to continue receiving 3-4 tumors per month from Mayfield to optimize and refine this process. These efforts position SLiCE as a leading New Approach Methodology to test promising experimental agents and one day guide clinical care using passage-zero patient tumor tissues, including fresh, living tumors shipped from other sites.

#0661 Rapid CAR T testing in an ex vivo platform that maintains passage-zero patient tumor tissues and their native immunosuppressive microenvironment.

Xiaopei Zhang[1], Breanna Mann[1], Adebimpe Adefolaju[1], Alain Valdivia[1], Rajaneekar Dasari[1], Caroline Stockwell[1], Noah Bell[1], Ashley Geiger[1], Tracy A. Withers[1], Xin Zhou[1], Alexa Rodriguez[1], Kerry Fitzgerald[2], Jon Williams[2], Hardik Parikh[3], Shuang Gao[3], Jie An[3], Taylor Jensen[4], Shakti Ramkissoon[4], Dominique Higgins[1], Yasmeen Rauf[1], Scott Elton[1], Kimberly Hamilton[1], Albert Baldwin[1], Barbara Savoldo[1], Shawn Hingtgen[1], David Kram[1], **Andrew Satterlee**[1]

[1]University of North Carolina at Chapel Hill, Chapel Hill, NC,[2]Labcorp, San Diego, CA,[3]Labcorp, Buffalo, NY,[4]Labcorp, Durham, NC

Adoptive T cell therapies, including chimeric antigen receptor (CAR) T cells, have shown limited success in solid tumors, largely due to widespread preclinical models that fail to capture patient tumor heterogeneity and the immunosuppressive tumor microenvironment (TME). Conventional systems, including cell lines, xenografts, and organoids, often lack critical TME features, leading to overestimation of therapeutic potency. Progress in next-generation CAR T therapies requires more biologically representative models. We have therefore developed Screening Live Cancer Explants (SLiCE), a New Approach Methodology platform that engrafts living, passage-zero patient tumors onto substrates of living tissue. This design preserves tumor heterogeneity better than in vitro culture and enables investigation of how patient tumor-associated cells influence T cell activity. As proof of concept, we tested B7-H3-targeted CAR T cells from three healthy donors against cell lines and passage-zero adult and pediatric brain tumors (n = 3 GBM, 2 medulloblastoma, 1 ATRT). B7-H3 expression was quantified by IHC (H-score) and flow cytometry. CAR T or control T cells were added to SLiCE-engrafted tumors at effector-to-target ratios from 1:3 to 3:1. Tumor kill was measured by live tumor cell bioluminescence within four days of seeding. Killing of B7H3+ tumors occurred only in the presence of CAR+ T cells and not non-transduced T cells; killing among multiple tumor specimens collected from the same patient positively correlated with B7H3 expression (assessed by flow cytometry). Notably, the ATRT tumor showed minimal killing despite high B7-H3 expression (H-score = 152). Flow/CyTOF analyses revealed inhibitory myeloid cells, regulatory T cells (~30% CD4+CD25+FoxP3+), and >60% PD-L1+ tumor cells, features likely suppressing CAR T activity. These findings indicate SLiCE maintains key immunosuppressive TME elements and can dissect mechanisms of immune evasion. Ongoing studies aim to overcome these barriers. Together, these data highlight SLiCE as a model that can uniquely leverage passage-zero patient tumor and tumor-associated cells to rapidly predict outcomes and potential challenges for CAR T cells and other cell-based therapies.

#0662 Non-animal platforms using ex-vivo human tissue and live-cell biosensors enable functional drug testing in renal cell carcinoma.

Shuchi Gulati[1], Madhura Patankar[2], Elijah Kofke[3], Michael Pargett[3], Daniel Oberbauer[3], Ching-Hsien Chen[4], John G. Albeck[3]

[1]UC Davis Comprehensive Cancer Center, Sacramento, CA,[2]UC Davis Comprehensive Cancer Center, Davis, CA,[3]University of California Davis, Davis, CA,[4]UC Davis, Sacramento, CA

Background: Animal models frequently fail to recapitulate the immune and metabolic complexity of renal cell carcinoma (RCC). To address this, we developed two complementary non-animal platforms, a patient-derived ex vivo tissue system and a biosensor platform to enable rapid, mechanistic, and clinically relevant drug testing.
Experiments: i) Fresh RCC specimens were sectioned into precision-cut tissue slices (PCTS) and co-cultured with autologous peripheral blood mononuclear cells (PBMCs) (5x10^5 co-cultured with one PCTS) for six days. Treatment groups included: a) cabozantinib (cabo) alone, b) cabo with cemiplimab (cemi, a PD-1 inhibitor), c) cemi with fianlimab (fin, a LAG-3 inhibitor). The co-cultured PCTS were analyzed using H&E staining and a Live-Dead stain to assess cell viability. ii) Using RCC cell line 786O, which recapitulates the canonical metabolic phenotype of clear cell RCC (high glycolytic flux and HIF1A stabilization), we performed time-course experiments to assess dynamic changes in biosensor signal. Cells were plated on biosensor-compatible microplates and treated with metabolic inhibitors (2-DG, oligomycin) and pharmacological targeted drugs relevant to RCC [(PI103- PI3K/mTOR inhibitor), sunitinib and cabozantinib (tyrosine kinase inhibitors), and linsitinib (IGF1R inhibitor)]. Biosensor output was recorded at 30-minute intervals over 12 hours to generate high-resolution kinetic profiles.
Results: i) Viability assessment of co-cultured PCTS indicated a significantly higher proportion of dead cells in the cabo+cemi compared with either a single agent or cemi+fin doublet strategy. Additionally, the number of viable PBMCs, assessed six days post-co-culture, was also highest in the cabo+cemi-treated tumors. MxIF analysis is ongoing.
ii) In the biosensor experiment, 786O RCC cells showed minimal AMPK response to oligomycin, suggesting reliance on glycolysis. Further, these cells, upon treatment with Linsitinib and PI103, induced a rapid and sustained reduction in HYLIGHT (glycolysis) signal intensity. A more gradual decrease was observed with cabozantinib, whereas sunitinib showed almost no effect, suggesting partial metabolic inhibition or pathway compensation. Ongoing work is using a modified protocol, SCENITH (Single-Cell ENergetic metabolism by profiling Translation Inhibition), which allows evaluation of cellular energy metabolism at single-cell resolution using puromycin-based labeling to quantify protein synthesis in the presence of metabolic inhibitors.
Conclusion: This integrated, fully non-animal strategy overcomes key limitations of animal models by combining preserved human tumor microenvironments with high-resolution metabolic biosensing. Together, these platforms enable rapid and mechanism-based profiling of therapeutic vulnerabilities in RCC.

#0663 TOP1i-ADC demonstrates immune-stimulating activity in colorectal cancer explants.

Irene I. Lee, Durga B. Dandamudi, Yoshiko Hashikawa, Marion L. Refici, Michelle Belmont, Iraz Aydin, Rhyannon Spangler, Steven Chirieleison, David Sharon, PK Epling-Burnette, Athan Vasilopoulos, Tamar Uziel, Jack Chen, Lloyd Lam

AbbVie Inc., North Chicago, IL

Topoisomerase 1 (TOP1) is a ubiquitous enzyme that primarily regulates the topology of DNA by governing the relaxation of DNA supercoiling. When TOP1 is inhibited by camptothecin and its analogs, re-ligation of TOP1 cleavage complexes (TOP1cc) is prevented, leading to the accumulation of TOP1cc-associated DNA damage, inhibition of cellular proliferation, and eventual cell death. Antibody drug conjugates (ADCs) are a class of cancer therapeutics in which a potent cytotoxic payload is linked to a tumor-targeting antibody. ADCs allow direct delivery of a drug to tumor cells, thus enhancing tumor cell-specific killing. Several TOP1 inhibitor-ADCs (TOP1i-ADCs) have been approved, and others are under clinical investigation, showing efficacy in solid tumors. Beyond direct cytotoxicity, recent evidence suggests that TOP1i and TOP1i-ADCs trigger immunogenic changes in cancer cells, fostering immune activation. In studies using colorectal (CRC) cell lines treated with adizutecan, a proprietary AbbVie TOP1 inhibitor, we observed upregulation of gene pathways involved in the Type I Interferon response. Notably, adizutecan increased surface expression of immunogenic markers including MHC-I, MHC-II, CALR, and PD-L1 in CRC lines. To evaluate TOP1i-ADC-induced immune activation within a native tumor microenvironment, organotypic tumor slices from fresh human metastatic colorectal carcinoma were utilized for this study. We treated these fresh human metastatic colorectal carcinoma tissue slices with TOP1i-ADC and evaluated changes in both the tumor and immune cells by flow cytometry and spatial transcriptomics. TOP1i-ADC treatment led to reduced tumor cell proliferation and viability, and consistent activation of dendritic cells as well as CD4 T cells. CD8 T cell activation was observed in 3 out of 5 explant samples. The flow cytometry data was further supported by the secretome profile, which shows elevated levels of pro-inflammatory chemokines and cytokines such as CCL3, CXCL10, G-CSF and granzyme B (GZMB). Spatial transcriptomics analysis revealed TOP1i-ADC treatment reduced DNA replication and cell cycle gene signatures consistent with TOP1i payload release within the tumor explant. Consistent with the flow cytometry data, immune cell responses displayed dendritic cell maturation in both proximal and distal regions to the tumor cells. CD8 T cell activation, evidenced by higher granzyme B (*GZMB*) expression, was especially prominent in distal areas consistent with spatially distinct regional activation. Collectively, these findings support that TOP1i-ADC therapy drives potent immune activation and immunogenicity, complementing its direct antitumor effects and highlighting its promise for enhancing cancer treatment efficacy.

#0664 Bulk cancer spheroid preservation and post-thaw viability for high-throughput screening applications.

Hilary Sherman[1], Rock Pulak[2]

[1]Corning Incorporated, Tewksbury, MA,[2]Union Biometrica, Holliston, MA

Three-dimensional cancer spheroids provide physiologically relevant models that closely mimic in vivo tumor architecture, making them valuable tools for drug screening and tumor biology research. Despite their advantages, integration into high-throughput workflows is often hindered by labor-intensive and time-sensitive culture processes. In this study, we investigated the feasibility of bulk cryopreservation of cancer spheroid lines using Corning's 12K Flask format, followed by assessment of post-thaw viability and performance in downstream assays. Our findings demonstrate that bulk freezing effectively preserves spheroid morphology and cellular viability across multiple cancer cell types. Post-thaw spheroids retained structural integrity and metabolic activity, supporting their use in screening applications. This scalable approach enhances experimental reproducibility and workflow flexibility, enabling broader adoption of 3D models in preclinical research. These results support the incorporation of cryopreserved spheroids into high-throughput platforms, advancing the utility of 3D culture systems in cancer drug discovery.

#0665 Bridging tumor heterogeneity and drug response: A patient-derived immune-competent 3D spheroid model for translational oncology.

Charlotte Veser, Zuzanna Kotkowska, Irina Agarkova, Sue Grepper, Madhu Nag-LAL, Laure-Anne Ligeon

Insphero, Schlieren, Switzerland

The tumor microenvironment (TME) and immune context are critical determinants of therapeutic outcome. Further, inter-patient variability in cellular composition and immune activity drive differential responses to therapy. However, the majority of preclinical models depend on epithelial monocultures and lack stromal and immune components. This failure to capture multicellular interactions limits their translational relevance for drug development and patient stratification.To address these limitations, we established a patient-derived immune-competent 3D tumor spheroid platform. This platform preserves patient-specific cellular diversity and microenvironmental interactions while maintaining compatibility with high-throughput applications. We demonstrate the pipeline's capabilities using patient samples from cases of breast, colorectal, and non-small cell lung cancer.Patient tumor resections were dissociated into single-cell suspensions and subsequently re-aggregated under defined conditions to form uniform3D tumor spheroids. The single-cell suspensions are analyzed to identify different cell types, such as epithelial, stromal, endothelial, and immune cells, and to assess patient-specific tumor and stromal marker expression. Flow cytometry and high-content imaging confirmed retention and self-organization of diverse cell populations within aggregated spheroids. Functional assays revealed patient-specific responses to standard-of-care and targeted therapies, reflecting patient heterogeneity observed in the clinic. Parallel isolation of autologous peripheral blood mononuclear cells (PBMCs) enabled immune co-culture assays reflecting autologous tumor-immune interactions and cytokine secretion.This platform offers a robust and scalable approach to modelling the complex tumor- immune microenvironment across multiple solid cancers in a patient-specific manner. This approach enables more predictive preclinical testing and supports precision oncology.

#0666 Developing an ascitic fluid-derived organoid model for transcriptomic and therapeutic investigations in ovarian cancer.

Md Mynul Hassan[1], Zulfikar Azam[2], Taslim A. Al-Hilal[2], Sourav Roy[3]

[1]The University of Texas at El Paso, El Paso, TX,[2]Department of Molecular Pharmaceutics, University of Utah, Salt Lake City, UT,[3]Biological Sciences, The University of Texas at El Paso, El Paso, TX

Introduction: Epithelial ovarian cancer (EOC) spreads freely within the intraperitoneal cavity, enabling tumor dissemination, abdominal organ adhesion, and ascites formation through lymphatic obstruction. Because solid-tumor samples are scarce after debulking surgery, ascites provide a crucial window into disease evolution. Its rich cellular and acellular components fuel tumor survival, immune evasion, and chemoresistance but remain underused in preclinical models. We therefore aim to establish and characterize an ascites-derived organoid (AsO) platform that captures this heterogeneous tumor microenvironment (TME) and improves drug-response profiling.
Methods: Malignant ascites and tumor tissues were collected from consenting Hispanic patients under an approved IRB protocol. Ascitic fluid was centrifuged and repeatedly lysed to remove red blood cells. The whole ascitic cells (WhAs) were divided for organoid culture and biobanking. Part of WhAs was embedded in extracellular matrix and overlaid with optimized organoid culture media. Organoids were passaged every 8-13 days and cryopreserved in freezing media. We documented morphology with brightfield imaging, stained FFPE sections with H&E, and immuno-stained whole-mount organoids. Bulk RNA-seq was performed on matched primary tumors (WhTu), WhAs and AsO, and we quantified expression using standard bioinformatics pipelines followed by correlation and pathway analyses. Drug sensitivity in organoids was measured by live/dead assay (CC50) and luminescence assay (IC50).
Results: Organoid culture media optimization markedly improved organoid formation, passaging efficiency, and long-term expansion. A major achievement was the successful cryopreservation of both WhAs and AsO, which resumed growth after resuscitation in nearly all cases. H&E staining revealed nuclear atypia, a hallmark of EOC, and immunofluorescence confirmed expression of key biomarkers including PAX8, p53, CK8, and Ki67. Pearson correlation coefficients demonstrated strong global transcriptional similarity ($R^2 = 0.87$) between AsO and WhAs. To identify ascites-specific genes within the ovarian cancer (OC) TME, we also examined transcriptional differences (DEGs) between AsO and WhTu. We identified 22 overlapping genes when comparing between the top 50 highly expressed genes from AsO and OC tumor-derived organoid datasets from Gene Expression Omnibus (GEO). Patient-specific drug responses to Carboplatin, Paclitaxel, Lenvatinib, and Saruparib have been observed.
Conclusion: The comprehensive characterization of ascites-derived organoids at histological, protein marker, and transcriptomic levels, along with systematic drug sensitivity comparisons across multiple experimental platforms, will significantly enhance their clinical and translational relevance.

#0667 Mapping and targeting spatial heterogeneity in CRC through patient-derived organoids.

Maxim Norkin[1], Jonathan Bac[1], Louis McConnel[1], Sylvie Andre[1], Marina Alexandra Gaveta[1], Joerg Huelsken[2], Marianna Rapsomaniki[1], Raphael Gottardo[1], Krisztian Homicsko[1]

[1]Oncology, CHUV, Centre hospitalier universitaire vaudois, Lausanne, Switzerland,[2]EPFL, Lausanne, Switzerland

Inter- and intra-patient heterogeneity, as well as spatial heterogeneity of cancer cells and the tumor microenvironment (TME), is a formidable barrier for cancer therapies. Ex vivo, patient-derived organoids (PDOs) hold promise as better platforms for drug development and can be applied in personalized medicine. Previous work has shown that genomic and clonal heterogeneity of tumors, as well as expression heterogeneity, can be maintained in PDOs. However, it remains unclear whether PDOs preserve the same degree of spatial expression heterogeneity observed in the original tumors. We propose an analytical pipeline combining spatial transcriptomic and phenotypic analysis of PDOs that can capture and track spatial heterogeneity across multiple assays, including during drug treatment.We have developed an organoid multi-embedding platform that allows parallel analysis of multiplex organoid cultures using imaging-based spatial transcriptomics. We validate the platform by comparison to non-spatial single-cell transcriptomic and donor tumor spatial transcriptomic analyses. With that, we have analyzed 40 CRC (colorectal cancer) PDOs and 16 CRC PDO-tumor pairs by spatial transcriptomics (Xenium 10x), including drug treatments, organoid developmental trajectories, and co-culture experiments. We have discovered intra- and inter-patient heterogeneity in tumors and PDOs and linked gene expression to organoid shapes. We further distinguished different expression programs in CRC and linked them to the spatial positioning of malignant cells in tumors. Finally, we have identified and analyzed dormant organoids in heterogeneous PDO cultures and compared them to the original tumors.The combination of ex vivo PDOs and spatial transcriptomics could open novel avenues for drug development selectively targeting spatial subsets of cancer cells and the TME.

#0668 Establishment of a patient-derived organoid-immune cell co-culture platform for evaluating the efficacy of immuno-oncology therapies.

Yuhui Wang, Pengyu Li, Chuyue Yu, Mingshuo Zhang, Pengwei Pan, Fang He

Pharmaron Beijing Co., Ltd., Beijing, China

Introduction: Tumor immunotherapy, known for its high specificity and favorable safety profile, inhibits tumor progression and prolongs patient survival by activating the immune system. However, the full potential of many immuno-oncology agents and the underlying mechanisms of therapeutic resistance remain incompletely understood. The emergence of organoid technology has not only improved the accuracy of tumor modeling but also enabled co-culture with immune cells, thereby advancing the study of tumor-immune interactions and immunotherapy evaluation. Here, we established a human tumor organoid-immune co-culture platform for assessing responses to multiple immunotherapies.

Methods: We established human tumor-immune co-culture models by introducing immune components-including allogeneic PBMCs with PDX-derived organoids (PDXOs) across several cancer types. For drug efficacy assessment, above co-culture models were treated with monoclonal antibodies (mAb) to evaluate antibody-dependent cellular cytotoxicity (ADCC). Additionally, ovarian cancer (OVC) PDXOs were co-cultured with PBMCs to assess T-cell engager (TCE)-mediated, TROP2-targeted T-cell-dependent cytotoxicity (TDCC). To mitigate graft-versus-host effects associated with allogeneic PBMCs, we further developed a PDO-autologous tumor-infiltrating lymphocytes (TILs) co-culture system and used it to modeling the patient responses to immune checkpoint inhibitors (ICIs).

Results: In the PDXO-PBMC co-culture system, live-cell and high-content imaging revealed that in the presence of Trastuzumab, HER2-high CRC PDXOs were effectively targeted and infiltrated by immune cells, whereas these results were not observed in HER2-low PDXO models. Similarly, Sacituzumab only induced significant ADCC in TROP2-high PDXO models. The co-culture platform also proved effective for evaluating TCEs: a TROP2xCD3 bispecific TCE significantly mediated TDCC in TROP2-high OVC PDXOs. Furthermore, screening of ICIs across multiple PDO-TILs co-culture models demonstrated that this co-culture system accurately predicted clinical treatment efficacy.

Summary: We have established a versatile tumor organoid-immune co-culture platform that recapitulates key features of the tumor immune microenvironment. This platform enables efficient evaluation and validation of diverse immunotherapies, including mAbs-mediated ADCC, TCE-mediated TDCC, and the efficacy of ICIs. This biomimetic in vitro model provides a powerful tool for immuno-oncology drug screening, accelerates drug development, and offers a human-relevant alternative that circumvents species-specific limitations and animal welfare concerns associated with preclinical animal models.

#0669 Development and characterization of a patient-derived liver organoid biobank for toxicology and functional studies.

Rudra Bhowmick[1], Benjamen O'Donnell[1], Fong Cheng Pan[1], Mahi Rahman[1], Sameena Wani[1], Willem Kools[2], Vi Chu[1]

[1]MilliporeSigma, Temecula, CA,[2]MilliporeSigma, Burlington, MA

Liver is the largest solid internal organ and performs numerous critical functions. Annually, liver diseases claim about 2 million lives globally (1). Traditional models for investigating liver biology, including 2D cultured cell lines, primary cells, and 3D spheroids, fail to accurately represent the in vivo metabolic and structural complexities. Additionally, animal models are expensive, time-consuming, ineffective, and may pose ethical dilemmas. Therefore, there is an urgent need for advanced liver models that can accurately mimic tissue characteristics.Organoids are self-organizing 3D structures that replicate the architecture and functionality of the original tissue (2). Patient-derived organoids (PDOs) closely resemble the source tissue and may reflect individual responses to therapy. In this study, we present the development and characterization of a biobank consisting of 11 individual liver PDO lines, which capture donor variability and enhance the applicability of these models for toxicology studies.Liver tissues were collected with donor consent. PDOs were created by adapting a previously published protocol (3). Briefly, tissue samples were minced, digested, filtered, combined with Matrigel (Corning), and cultured in liver PDO-specific growth media. When suitable, undifferentiated PDOs were matured using tailored media.PDO lines were effectively expanded and cryopreserved, demonstrating their robustness. All lines expressed liver-specific biomarkers, verified by qPCR and confocal microscopy. Each line was confirmed to be free of infectious agents and validated as unique via short tandem repeat analysis. Upon maturation, these lines exhibited increased albumin and urea production, along with inducible cytochrome P450 (CYP) activity, confirming their functional maturity. Donor-dependent variability in these phenotypes indicated that the biobank may represent the patient population. Four liver PDO lines were also evaluated for their response to 3 DILI drugs. Based on these results, the liver biobank was concluded to be a robust in vitro model for testing drug responses.Our liver PDO biobank reflects the patient population and will be a valuable tool for pharmaceutical clients. We have successfully established and characterized 11 liver PDO lines, with further characterization efforts ongoing. These PDOs will significantly advance our understanding of liver biology and disease mechanisms, offering applications in drug testing, including DMPK and ADME/ Tox studies. Future initiatives will focus on scaling up, developing specific assays, and creating PDOs from patients with liver conditions, such as hepatocellular carcinoma.

#0670 Understanding the role of the tumor suppressor gene *ARID1A* in gastric cancer initiation.

Alexa Morales Arana, Nicole Britney Halmai, Jasmine Diaz, Hongyong Zhang, Paul Lott, UCaMP consortium, UCaTS consortium, Luis Carvajal-Carmona

UC Davis, Davis, CA

Introduction: Gastric cancer remains a major cause of global cancer mortality and disproportionately affects underserved racial and ethnic minority populations in the United States. Latino patients experience a higher incidence and worse outcomes, yet genomic data and patient-derived models remain underrepresented. Whole-exome sequencing (WES) of our Latino GC cohort showed that 30% of tumors harbor pathogenic ARID1A mutations, paralleling TCGA frequencies. ARID1A, a core subunit of the SWI/SNF chromatin-remodeling complex, regulates enhancer activity and transcriptional accessibility. Its loss is linked to poor prognosis and metastasis. We hypothesized that ARID1A loss establishes an early premalignant state through chromatin dysregulation and transcriptional reprogramming. To test this, we developed long-term gastric organoid models derived from Latino patients to define the earliest cellular and molecular consequences of ARID1A loss.

Methods: We generated multiple isogenic gastric organoid lines using CRISPR/Cas9 editing in Latino patient-derived normal gastric organoids, including ARID1A/TP53 double-knockout (dKO) organoids and TP53 knockout controls. Organoids were cultured long-term for up to 350 days, with early (~150-day) and late (~350-day) time points analyzed. Multi-omic characterization included H&E histology, RNA sequencing, whole exome sequencing, and CUT&RUN profiling. Comparisons across dKO, TP53 KO, and wild-type controls were used to define the effects of ARID1A loss on early tumorigenesis.

Results: Genome editing generated ARID1A and TP53 loss, and dKO organoids developed progressive morphological abnormalities, including increased proliferation and distinct architectural changes compared to controls. RNA-seq analyses showed genotype-specific and time-dependent transcriptional reprogramming. Differential expression analysis revealed downregulation of digestion and iron transport pathways and upregulation of cilium movement and ciliogenesis. Whole exome sequencing analysis showed fourteen variants were shared across long-term dKO clones, while each clone independently acquired 1-6 additional unique mutations. Affected genes were involved in transcriptional regulation, extracellular matrix remodeling, vesicle trafficking, and receptor tyrosine kinase signaling. The presence of shared and clone-specific variants suggests progressive genomic instability and supports early neoplastic evolution driven by dual ARID1A/TP53 loss.

Conclusion: Latino-derived gastric organoid models demonstrate that ARID1A and TP53 loss cooperatively drive transcriptional reprogramming, genomic instability, and early dysplastic progression. Ongoing CUT&RUN profiling will define chromatin accessibility changes. This work provides a mechanistic foundation for drivers of gastric cancer and a platform for precision prevention strategies.

#0672 Mapping tumor heterogeneity: Ex-Vivo drug responses in synchronous matched primary and metastatic tumors using a 3D functional precision platform.

Rajeshwar Nitiyanandan, Ivan Trus, Chiara Maestri, Ricardo J. Parker, Chris Apfel

SageMedic Corp., Redwood City, CA

Background: Tumor heterogeneity remains a major driver of therapeutic resistance and determining how metastatic dissemination affects functional drug response is critical for clinical decision making. We have developed a 3D microtumor functional profiling assay that preserves native tumor architecture and produces reliable drug response profiles within 7 to 10 days in a CLIA lab environment. This update expands our earlier dataset with additional synchronous pairs of cancer specimen.
Methods: Matched synchronous tumors were obtained from primary ovary, colon, and breast cancers with metastases into the omentum, liver, peritoneum, lung, and axilla. All samples were cooled and shipped overnight, processed within 24 hours, and exposed to NCCN recommended and mechanistically relevant chemo or targeted therapies. Viability was assessed after 72 h to generate cytotoxicity dose responses and concordance was measured using coefficient of determination (R2).
Results: We are reporting on 162 drug comparisons from seven patients with matched primary and metastatic tumors. Drug-response concordance varied substantially by metastatic route. Local metastases showed the highest correlation. A lymphogenic metastasis (breast to axilla) showed moderate correlation. Hematogenic metastases exhibited the weakest correlation, with colon-lung and ovarian soft-tissue/colon pairs showing only modest similarity. However, one ovarian local spread to the omentum demonstrated only moderately strong correlation.
Conclusions: The data suggest that sensitivity and resistance spectra from local metastases tend to correlate well with those from the primary tumors. Furthermore, for metastases from lymphogenic or hematogenic spread, while the correlation tends to be only modest, functional profiling may still be useful to significantly reduce the risk for receiving ineffective treatment.

Correlation of synchronously matched tumor samples

Tumor Type	**Metastasis**	**Relationship**	**R^2**
Ovarian	Omentum	Local	0.98
Ovarian	Liver Capsule	Local	0.93
Colon	Peritoneum	Local	0.93
Ovarian	Omentum	Local	0.47
Breast	Axilla	Lymphogenic	0.77
Colon	Lung	Hematogenic	0.51
Ovarian	Soft Tissue and Colon	Hematogenic	0.42

#0673 Longitudinal mapping of immune activation to tumor response in anti-PD1-treated patient-derived organotypic tumor spheroids (PDOTS).

Jun Yang[1], Julia Vail[2], Eunju Shin[1], Kyungjin Boo[1], Kirti Khardenavis[2], Sinal Patel[2], Kyoung Wan Yoon[1], **Michael A. Perricone**[2]

[1]NEX-I, Inc, Seoul, Korea, Republic of,[2]Xsphera Biosciences, Inc., Cambridge, MA

Nivolumab is an anti-PD-1 immune checkpoint inhibitor approved for colorectal cancer (CRC) with an Microsatellite Instability-High (MSI-Hi) profile, yet patient-to-patient variability and the short-term dynamics of immune and tumor signaling is not well characterized. Patient-derived organotypic tumor spheroids (PDOTS) preserve the multicellular architecture and immune microenvironment of individual tumors, providing an ex vivo platform to monitor these dynamics under controlled conditions. In this study, we used CRC PDOTS from eight patients to characterize day-scale effects of nivolumab on tumor burden and transcriptional programs over a 72 hour peroid. Freshly resected tumors were processed into PDOTS, loaded into microfluidic devices, and treated with nivolumab (100 µg/mL) or a media control. The tumor response to nivolumab was quantified on days 1, 2, and 3 using Hoechst/propidium iodide imaging and automated analysis of live tumor area and the percent tumor killing relative to matched controls. In parallel, RNA was isolated from treated and control PDOTS at each timepoint and profiled using the NanoString IO360 panel to capture coordinated changes in tumor-associated transcripts and immune- and signaling-related gene sets. Across the cohort, nivolumab induced distinct temporal patterns of transcriptional change rather than a uniform on/off signature. A subset of PDOTS showed rapid day-1 increases in immune- and inflammation-related transcriptional programs that remained elevated through 72 hours. A second subset appeared transcriptionally cold at day 1 but developed coordinated shifts in immune and signaling pathways on days 2-3, with preferential upregulation of genes associated with interferon signaling, T-cell engagement, and leukocyte trafficking. A third group displayed minimal changes in these programs over the full 72-hour window. Notably, many PDOTS with strong day-3 pathway modulation showed little or no change from day 1, underscoring the risk of underestimating drug-associated biology from single early timepoints. These temporal patterns of immune activation loosely preceded tumor response. These findings demonstrate that longitudinal profiling in CRC PDOTS reveals discrete patterns of nivolumab-induced immune and tumor signaling dynamics that are not apparent from single terminal measurements, and support the use of time-resolved ex vivo platforms to refine mechanistic studies and biomarker development for immune checkpoint blockade.

#0674 Expansion of multilineage prostate organoids derived from human tissue in ProstaCult™ organoid medium.

Angela Tsai, Allen C. Eaves, Sharon A. Louis, John Stingl

STEMCELL Technologies Inc., Vancouver, BC, Canada

Organoids have emerged as a powerful model for studying normal and tumour cell biology; however, the application of organoid technology for culturing human prostate epithelial cells has been challenging due to the difficulty in maintaining multilineage organoids with androgen receptor (AR)-expressing cells in culture for extended periods of time. To address this, we developed serum-free ProstaCult™ Organoid Medium (Human) to robustly expand human prostate epithelial cells long-term as organoids. Benign human prostate tissue was dissociated and seeded either directly into Matrigel® dome cultures or pre-cultured up to 4 passages in adherent culture in EpiCult™ Plus medium prior to seeding. The resulting organoids were passaged as small fragments every 10 - 12 days. Cultures were analyzed by flow cytometry and immunocytochemistry for the expression of pan epithelial marker EpCAM, luminal markers CD26, keratin 8 (K8), and androgen receptor (AR) protein, and basal markers CD271 and K14. Our results demonstrate that prostate epithelial cells can generate multilineage organoids consisting of a polarized epithelium with both basal ($EpCAM^+$, $K14^+$, $CD271^{high}/CD26^{low}$) and luminal cells ($EpCAM^+$, AR^+, $K8^+$, $CD271^{low}/CD26^{high}$) in 10 - 12 days. These human prostate organoids can be expanded for at least 7 passages while maintaining appropriate marker expression (n = 5) and can be cryopreserved without losing long-term expansion potential. The organoids were responsive to dihydrotestosterone (DHT) removal from the culture medium, with a 43 ± 7% decrease in the total number of luminal cells generated over 3 passages (mean ± SEM; n = 4; $p \leq 0.01$, paired t-test) and a downregulation of AR expression (n = 4). Similarly, enzalutamide treatment resulted in a 24 ± 9% decrease in the total number of luminal cells generated over 3 passages (mean ± SEM; n = 4). These results demonstrate that ProstaCult™ Organoid Medium (Human) enables robust long-term maintenance of multilineage organoids containing AR+ luminal cells *in vitro*, providing an optimized and standardized model system for prostate cancer research.

#0675 B7-H3 targeting ADC GSK5764227 demonstrates broad and varied anti-tumor activity across solid tumor translational models.

Michael Adam[1], Miriam Doepner[1], Ning Sun[1], Chris Hopson[1], Derek Poore[1], Prajna Behera[2], Jenny Laraio[1], Anthony Mazurek[1], Andrew Gehman[1], Shannon McKearnan[1], Jacob Parsons[1], Bjoern-Philipp Kloke[1], Shoba Shetty[1], Ken Hance[1], Jeremy Waight[1], Klaas Bakker[1]

[1]GSK, Collegeville, PA,[2]GSK, Waltham, MA

B7-H3 (B7 homolog 3 protein), also known as CD276 (cluster of differentiation 276), is a cell surface protein that is over-expressed across multiple solid tumors. B7-H3 suppresses T-cell function (e.g. proliferation, activation, and cytokine release) to promote tumorigenesis. Due to its tumor-promoting functions and broad expression profile on a range of malignancies, B7-H3 is an attractive therapeutic target for antibody-drug conjugates (ADCs). GSK5764227 is a B7-H3 targeting ADC conjugated to a topoisomerase I (TOPO1) inhibitor payload, with a DAR of 4. Here we demonstrate in vitro and in vivo efficacy data of GSK5764227 in different preclinical models - including cell lines, *in vitro* patient-derived organoids (PDOs), and *in vivo* patient-derived xenografts (PDX) - across multiple tumor indications including lung, bladder, pancreatic, colorectal (CRC), uterine, prostate, and gastric cancers, supporting the broad therapeutic potential of GSK'227 across different malignancies. Activity was highly varied across tumor histologies in cell lines and PDO models. Similarly, responses were observed across a wide range of PDX indications, but depth of response varied among models within indications. These findings underscore the promise of B7-H3 targeting ADCs with topoisomerase payloads for treating a broad range of cancers, while highlighting the need for further exploration of patient population and/or predictive biomarkers to elucidate determinants of response. Together, this work supports GSK5764227 ongoing clinical development as an innovative therapeutic strategy to address unmet patient needs.

#0676 Modeling patient-specific therapeutic outcomes in cervical cancer using organoid technology.

Shalmoli Bhattacharyya[1], Surbhi Singla[1], Reena Sharma[2], Bhavana Rai[2], Rashmi Bagga[3], Radhika Srinivasan[4], Prateek Bhatia[5]

[1]Biophysics, PGIMER, Chandigarh, India,[2]Radiotherapy and Oncology, PGIMER, Chandigarh, India,[3]Obstetrics and Gynecology, PGIMER, Chandigarh, India,[4]Cytology and Gynecological Pathology, PGIMER, Chandigarh, India,[5]Pediatrics, PGIMER, Chandigarh, India

Organoids have emerged as good preclinical models of human tumors, facilitating translation from basic research to clinical practice. Patient derived organoids recapitulate the heterogeneity and pathophysiology of the cancer and represent the complex tissue environment of clinical tumors more closely than *in vitro* cell lines and animal models. In the present study, we established patient-derived cervical cancer organoids (CC-PDOs) using a modified culture protocol. Tumor specimens were obtained from treatment-naive patients diagnosed with different histological subtypes of cervical cancer (squamous cell carcinoma and adenocarcinoma). The tissues were enzymatically dissociated to generate single-cell suspensions. The cells were embedded in Matrigel and cultured in DMEM media containing defined growth factors to initiate organoid formation. Comprehensive characterization of the established PDOs (n=12) demonstrated that they retained the HPV status and histopathological features of the corresponding primary tumors. The key somatic mutations in cervical cancer-associated genes like *PIK3CA, LRP1B, KMT2A, NF1, TTN,* and *FGFR2* were consistent in both the PDOs and the corresponding patient tumor tissue. Base variant analysis further confirmed that the organoids preserved the mutational landscape of the parent tissue, with C>T transitions representing the predominant base substitution type. The organoids directly derived from patients represent the heterogeneity of cervical cancer patients. To investigate organoids' potential for clinical translation, the correlation between the sensitivity of *ex vivo* tumor organoids and clinical outcomes were recorded. The *ex vivo* chemo-radiation responses of the PDOs showed strong concordance with the clinical outcomes of the respective patients during a six-month follow-up period, thus demonstrating their ability to capture patient radiation heterogeneity. Collectively, these findings demonstrate the feasibility of generating cervical cancer PDOs that faithfully mirror patient-specific tumor characteristics and therapeutic responses, thereby establishing a robust *in vitro* platform for drug screening and the advancement of personalized therapeutic strategies.

#0677 Development of an in vitro exhaustion assay for functional screening of CAR T cell enhancements.

Carla N. Castro[1], Veronica Bergo[1], Marina Zintchenko[2], Susana Minguet[2], Philipp Metzger[1], Cynthia Obodozie[1], **Holger Weber**[1]

[1]Reaction Biology Europe GmbH, Freiburg, Germany,[2]Signaling Research Centres BIOSS and CIBSS; Department of Synthetic Immunology, Faculty of Biology, University of Freiburg, Freiburg, Germany

Chimeric antigen receptor (CAR) T cells have emerged as a powerful tool in cancer immunotherapy, particularly in hematologic malignancies such as B-cell leukemia and lymphoma. CAR T cell therapy involves genetically engineering patient-derived T cells to express synthetic receptors that target tumor-associated antigens, enabling precise and potent immune responses against cancer cells. Despite remarkable clinical successes, especially with CD19-targeted CAR T cells, the therapy has limitations that hinder broader application and long-term efficacy. A significant challenge is T cell exhaustion, a dysfunctional state involving reduced proliferation, diminished cytokine production, and impaired cytotoxicity. Exhaustion often arises in the tumor microenvironment, where persistent antigen stimulation, immunosuppressive signals, and metabolic stress collectively impair CAR T cell function. This limits durability and contributes to relapse in many patients. Overcoming CAR T cell exhaustion is essential to improving efficacy and durability of cellular therapies. Strategies under investigation include optimizing CAR architecture by using alternative co-stimulatory domains, transiently modulating inhibitory pathways, and refining manufacturing protocols to preserve T cell fitness.

An in vitro assay that reliably mimics exhaustion is essential for identifying and validating improvements. In this study, we present several approaches to inducing exhaustion-like phenotypes in CAR T cells. Chronic, antigen-agnostic stimulation and repeated co-culture with antigen-expressing target cells are used to model persistent activation, and to compare various functional readouts. We discuss the advantages and limitations of different assay setups to help identify the most suitable approach depending on the specific experimental needs. A robust and reproducible assay system is key to reliably screening novel CAR T cell designs and therapeutic interventions aimed at mitigating T cell exhaustion. We compare T cell functionality using multiple readout technologies, including impedance-based measurements using xCelligence for adherent and selected suspension cells and luminescence assays with luciferase-expressing target cells as well as flow cytometry. This allows us to highlight the strengths and constraints of each method in capturing functional decline and exhaustion phenotypes.

Our findings support the use of standardized in vitro exhaustion models as valuable tools for the preclinical evaluation of next-generation CAR T cell therapies and combination strategies. Furthermore, our antigen-agnostic model enables evaluation of the impact of any T cell modulation approach on exhaustion dynamics. These models enable more predictive and efficient development of strategies to enhance therapeutic performance.

#0679 BRAF-defined canine urothelial carcinoma organoids as a comparative oncology platform for drug response evaluation.

Kieun Bae[1], Kyong-Ah Yoon[1], Doyoung Jeon[1], Jimin Park[1], Aryung Nam[2], Jung-Hyun Kim[2], Hyun-Jung Han[3], Hun-Young Yoon[4]

[1]Department of Veterinary Biochemistry, College of Veterinary Medicine, Konkuk University, Seoul, Korea, Republic of,[2]Department of Veterinary Internal Medicine, College of Veterinary Medicine, Konkuk University, Seoul, Korea, Republic of,[3]Department of Veterinary Emergency and Critical Care, College of Veterinary Medicine, Konkuk University, Seoul, Korea, Republic of,[4]Department of Veterinary Surgery, College of Veterinary Medicine, Konkuk University, Seoul, Korea, Republic of

Canine urothelial carcinoma, also referred to as transitional cell carcinoma (TCC), is the most common malignancy of the canine urinary tract, with the BRAF V595E mutation reported in approximately 70-85% of cases. This mutation is the canine homolog of the human oncogenic BRAF mutation, which is frequently detected in melanoma and papillary thyroid carcinoma. However, whereas BRAF mutation is a potent therapeutic target in human cancers, clinical efficacy in canine TCCs remains unclear, highlighting the need for additional research. In this study, cancer organoids were established from surgically resected tissues of canine patients six BRAF V595E-mutated TCCs, two BRAF wildtype TCCs, and two cystitis samples. The organoids expressed urothelial markers (cytokeratin-7, uroplakin-3A) and retained BRAF status identical to the parental tumors. Organoids harboring BRAF mutation showed enhanced proliferation and motility, consistent with Ki-67 and vimentin expression. To validate these in vitro results, canine TCC organoids were injected into mice via the tail vein. After seven weeks, all injected mice developed multiple pulmonary nodules, confirming strong metastatic capacity. Tumors were re-cultured as organoids, which retained aggressive phenotypes ex vivo alongside sustained ERK phosphorylation and the BRAF V595E mutation. Organoid-based in vitro assays demonstrated that six targeted inhibitors commonly used in human cancers effectively reduced phosphorylated-ERK expression. Among these agents, sorafenib showed the strongest cytotoxic activity. In xenografted mice, six weeks of oral administration of sorafenib or vemurafenib, markedly reduced tumor formation. Mice treated with BRAF inhibitors also showed decreased p-ERK expression in metastatic lesions and lower BRAF mutant allele fractions in circulating tumor DNA, indicating suppression of metastatic progression through inhibition of the BRAF/MAPK pathway. Collectively, our findings demonstrate that canine TCC organoids function as a comparative model bridging human and canine cancers, enabling us to dissect BRAF-dependent oncogenic mechanisms, evaluate anti-metastatic drug efficacy, and monitor treatment response via ctDNA.

#0680 Clinically predictive patient-derived cells and organoids platforms for precision therapeutic evaluation in NSCLC.

Jiwoo Hwang[1], **Min Hak Lee**[2], Gang-Taik Lee[1], So Young Park[1], Byoung Chul Cho[3]

[1]Department of Research Support, Yonsei Biomedical Research Institute, Yonsei University College of Medicine, Seoul, Korea., Seoul, Korea, Republic of,[2]JEUK Institute for Cancer Research, Gumi-City, Korea, Republic of,[3]Division of Medical Oncology, Department of Internal Medicine and Yonsei Cancer Center, Severance Hospital, Yonsei University College of Medicine, Seoul, Korea., Seoul, Korea, Republic of

Purpose: Patient-derived cells (PDCs) and organoids (PDOs) are established from pleural effusion or ascites to recapitulate the biological features of individual patients. In cancer research, PDC/PDOs serve as valuable preclinical tools because they preserve tumor-specific mutations. Conventional cell lines often fail to capture resistance mechanisms to modern targeted therapies. Consequently, PDC/PDOs offer robust systems for predicting the efficacy of next-generation anticancer treatments. This study aims to demonstrate that PDC/PDO lines serve as suitable platforms for evaluating the efficacy of investigational therapeutics and screening novel therapies for non-small cell lung cancer (NSCLC).

Experimental design: PDC/PDO models were generated from malignant pleural effusions or ascites, using only cytologically confirmed specimens that formed tumor colonies. Genomic alterations were profiled by Sanger sequencing, Whole-exome sequencing (WES), or RNA sequencing. Drug responses were evaluated according to each patient's treatment history to directly compare clinical outcomes with ex vivo sensitivity.

Results: A total of 60 PDCs and 181 PDOs were established from NSCLC patients, including models harboring sensitizing EGFR mutations, KRAS mutations, uncommon mutations, ALK fusions, ROS1 fusions, EGFR exon 20 insertion, and BRAF V600E. Whole-exome sequencing (WES) was performed on 41 newly established NSCLC PDO lines to characterize their genomic alterations. The analysis revealed that EGFR alterations in the PDO cohort comprised 29 amplifications, 20 missense mutations (including L858R, T790M, G719X, C797S, and other mutations), 9 in-frame deletions (E19del), and 1 in-frame insertion (E20ins). Furthermore, MET alterations included 16 amplifications and 1 loss, while ERBB2 exhibited 6 amplifications and 1 in-frame insertion. In three newly established BRAF V600E-mutant PDC models (YU-1171, YU-1172, and YU-1195), exposure to the targeted agents dabrafenib and trametinib revealed distinct patterns of drug sensitivity. The IC_{50} values for dabrafenib and trametinib in YU-1171 were 31.2 nM and 2.96 nM, respectively. In YU-1172, the IC_{50} for dabrafenib exceeded 1 μM, whereas that for trametinib was 14.2 nM. In YU-1195, the corresponding IC_{50} values were 438.4 nM and 10.9 nM. These in vitro trends were concordant with clinical outcomes, as the duration of dabrafenib and trametinib treatment in the corresponding patients was significantly associated with the respective IC_{50} profiles.

Conclusions: Clinically matched patient-derived cells and organoids reliably recapitulate tumor characteristics, providing a robust ex vivo platform for precision therapeutic evaluation in NSCLC.

#0681 C3PO: complex 3D patient organoids for preclinical drug testing in brain tumors.

Antonino Cucinotta, Maria Rosaria Battista, Francesco Scalabri, Anastasiya Kraynyeva, Chiara Soldati, Cristina Alli, Carlo Toniatti, **Alessandro Carugo**, Francesca Puca

IRBM Spa, Pomezia, Italy

Background. Glioblastoma (GBM) remains one of the most aggressive and therapeutically challenging brain tumors, with current treatments offering limited survival benefits. One of the major obstacles in developing effective therapies is the lack of physiologically relevant preclinical models that can accurately recapitulate the structural, molecular, and cellular complexity of the human tumor microenvironment. Conventional 2D cultures and animal models often fail to predict clinical efficacy and are associated with high variability and limited translational value.

Methods. To overcome these limitations, we have developed advanced *ex vivo* 3D glioblastoma models, termed Complex 3D Patient Organoids (C3POs), designed to reproduce the architecture, multicellular composition, and microenvironmental gradients of GBM. Each C3PO integrates patient-derived glioma stem-like cells (PD-GSCs) with astrocytes and microglia in defined ratios, generating self-assembled spheroids that mimic the tumor-stroma interactions observed *in vivo*. To ensure biological relevance, all patient-derived GSCs were also profiled for key genomic alterations commonly associated with GBM. Distinct models representing different molecular GBM subtypes were established and characterized using high-content imaging and fluorescent tracking of individual cell populations. These models have been used to evaluate both proprietary compounds and clinically used agents such as temozolomide, under conditions that more faithfully reproduce the pathophysiological features of GBM.

Results. Preliminary findings revealed subtype-specific responses to treatment, with C3POs of mesenchymal background displaying higher drug resistance and C3POs of proneural background showing higher sensitivity, consistent with a subtype-specific clinical outcome. Furthermore, 3D co-culture systems exhibited reduced drug sensitivity compared to monocultures, underscoring their higher biological fidelity. Current studies are focused on correlating *in vitro* efficacy and pharmacokinetic (PK) data from C3PO models with results previously obtained in orthotopic GBM mouse models, to quantitatively assess their predictive potential.

Conclusions. The C3PO platform provides a robust and scalable tool for *ex vivo* pharmacological testing of anti-GBM agents. By improving translational predictivity and reducing reliance on animal models, these complex 3D systems represent a promising advancement toward more ethical, cost-effective, and clinically relevant preclinical strategies for the development of new therapies targeting brain tumors.

#0685 eTRACER illuminates the spatiotemporal landscape of immune escape in EGFR-mutant lung adenocarcinoma.

Hongbin Ji[1], Zheng Hu[2], Jinhua Yang[3], Liangzhen Hou[4], Xue Wang[3]

[1]Westlake University, Hangzhou, China,[2]Shenzhen Institute of Advanced Technology, Chinese Academy of Sciences, Shenzhen, China,[3]Center for Excellence in Molecular Cell Science, Shanghai, China,[4]Shenzhen Institutes of Advanced Technology, Shenzhen, China

EGFR-mutant lung adenocarcinoma (LUAD), prevalent among East Asian non-smoking women, typically exhibits a strong initial response to tyrosine kinase inhibitors. However, resistance inevitably develops and these tumors often show poor responsiveness to immune checkpoint blockade. Deciphering the mechanisms of cellular evolution underlying immune evasion in EGFR-mutant LUAD could provide critical insights for developing effective immunotherapies. Here we developed eTRACER, an endogenous gene 3'UTR-based CRISPR-Cas9 lineage tracer that avoids lineage information-disruptive large deletions of traditional techniques and enables the reconstruction of high-fidelity spatiotemporal phylogeny through integration of single-cell RNA-seq, chromatin accessibility and/or spatial transcriptome. We applied eTRACER to systematically decode clonal and phenotypic fate maps of EGFR-mutant LUAD under $CD8^+$ T cell-mediated cytotoxicity in mice. Quantitative analyses of temporally-resolved single-cell lineages across baseline, early- and late-immune escape stages revealed the dynamics of cell-state transitions from the Hypoxic and Proliferative states to the epithelial-mesenchymal transition (EMT) state leading to immune evasion. Spatially-resolved lineage tracing unveiled evident stratification of distinct tumor cell states and location-primed transitions to the EMT state. Multiomic study uncovers the cooperation between the intrinsic role of the activator protein 1 (AP-1) in cancer cells and the spatially stratified interactions between macrophages and tumor cells in promoting the transition to the EMT state. Collectively, we have developed a powerful lineage tracing system eTRACER and uncovered the spatiotemporal cell-fate dynamics underlying immune evasion in EGFR-mutant LUAD. These findings hold important implication for future design of effective immunotherapy.

#0686 Dissecting colorectal cancer heterogeneity and microbiota interactions using murine and patient-derived organoids.

Markus Tschurtschenthaler[1], Valentina Brunner[1], Nicholas Bodenstein[1], Expedito M. Diogenes[1], Lisa Niedermeier[2], Nicole A. Schmid[1], Miguel G. Silva[1], Moritz Jesinghaus[3], Roland Rad[1], Barbel Stecher[2], Julius Fischer[1], Dieter Saur[1]

[1]TUM Universitatsklinikum, TranslaTUM, Technical University of Munich, Munich, Germany,[2]Chair of Intestinal Microbiome, ZIEL - Institute for Food and Health, Technical University of Munich, Freising, Germany,[3]Institute of Pathology, University Hospital Marburg, Marburg, Germany

Alterations in gut microbiota composition and metabolism are tightly linked to colorectal cancer (CRC) initiation, progression, and therapy response, yet underlying mechanisms remain unclear. We established an integrated platform combining organoid biobanks, germ-free orthotopic models, and microbial communities to dissect the interplay between oncogenic signaling, microbiota composition, microbial metabolism, and therapy response in CRC. We generated a comprehensive murine CRC organoid biobank encompassing distinct genotypes, histological subtypes, and tumor stages, together with a complementary collection of patient-derived organoids (PDOs). To probe microbial influence *in vivo*, we developed the first germ-free orthotopic CRC model enabling colonoscopy-guided engraftment of tumor organoids under germ-free (GF) conditions. Parallel transplantation into specific pathogen-free (SPF) and GF mice allows direct assessment of microbiota-dependent effects on tumor progression. We also established stool-derived *in vitro* communities (SDICs) from oncogenic and wild-type backgrounds. Cultured anaerobically in physiologically relevant media, SDICs preserve their native metabolic output, enabling functional assessment of microbiota-derived metabolites on organoid viability and therapy response without artifacts from direct bacteria-organoid co-cultures. Comparative analyses of SPF and GF mice revealed comparable survival after carcinoma organoid transplantation, whereas GF mice showed significantly prolonged survival after adenoma transplantation, indicating tumor growth and progression are slowed without microbiota. To dissect this host-microbiota interplay, we analyzed SDIC-derived metabolites and found that supernatants from wild-type SDICs were more effective than those from oncogenic SDICs in reducing tumor organoid viability. Notably, wild-type SDIC metabolites also sensitized tumor organoids to radiation therapy, highlighting microbiota-mediated modulation of therapeutic response. These findings demonstrate that epithelial oncogenic mutations not only drive tumorigenesis but also remodel the gut microbiota, depleting protective taxa and enriching tumor-promoting species. Consistent with this, 16S rRNA and metagenomic analyses confirmed host genotype dictates gut microbiota composition. To provide a translational bridge to murine models, we transplanted PDOs orthotopically and showed that both PDOs and their xenografts faithfully recapitulated patient-specific histology, molecular features, and therapy responses, establishing robust preclinical models to target colorectal cancer heterogeneity. Together, these findings identify microbiota-derived metabolites as critical regulators of CRC evolution and therapy response, and establish a modular framework for microbiota-informed precision oncology.

#0687 *In situ KRAS*-mapping and spatial -omics characterization in lung premalignancy.

Amanda Lindberg[1], Bartosz Sobocki[2], Patrick Micke[1], Carina Strell[1]

[1]Immunology, genetics and pathology, Uppsala University, Uppsala, Sweden,[2]Department of Oncology and Radiotherapy, Medical University of Gdańsk, Gdańsk, Poland

Introduction: Lung cancer symptoms typically do not appear until advanced stages, leading to late diagnoses. This delay is a major contributor to its poor prognosis, resulting in lung cancer being the leading cause of all cancer-related deaths worldwide. Essential biological understanding of how lung cancers arise and progress is still lacking. Studying premalignant lesions that eventually develop into invasive carcinomas helps to bridge this knowledge gap. We are focusing on adenocarcinomas (ACs), the most common subtype of lung cancer, and especially, activating mutations in the *Kirsten rat sarcoma virus oncogene (KRAS),* which is among the most common oncogenic mutations and has previously been reported in premalignant lung lesions. Given that *KRAS* signaling is growth-promoting, it is reasonable to assume that *KRAS*^{mut} promotes tumor formation and progression. However, the extent of its influence, the timing of when it arises, and particularly its connection to histologic and phenotypic changes driving tumor evolution, remain unclear.

Methods: We have collected a cohort from biopsy material, initially collected for diagnostic purposes from AC patients at varying stages of tumor evolution, with some matched 'normal-histology' samples when available. In total, tissue from 38 patients with AC premalignancies is available for investigation. To map *KRAS* mutations *in situ,* we employed a BaseScope assay with commercial detection probes against the different *KRAS*^{mut} transcripts. To map *KRAS* statuses to cellular phenotypes in the microenvironment, we are running a 6K panel on the CosMx platform (Bruker) on a subset of patients, which is a highly sensitive spatial transcriptomics technique at single-cell resolution. Spatial Mass Spectrometry (MS) tracking metabolic features on the timsTOF flex MALDI-2 (Bruker) is also being performed on a subset of patients.

Results: Initial tests of the BaseScope assay have revealed specific, yet not sensitive, signals of *KRAS*^{mut} transcripts in premalignant lesions. While advanced cancers display distinct signals, premalignant lesions have fewer, if any, signals. This might be due to the lower expression levels of *KRAS* at the earlier stages. To address this, we are now applying a BaseScope assay with signal amplification to be able to track *KRAS* expressed at lower levels. Preliminary analyses of the Spatial MS matrix have revealed highly individual metabolomics features, with great inter-patient heterogeneity. This pattern is also reflected in bulk RNA-seq data, revealing expression profiles more similar across, e.g., Adenocarcinoma *in Situ* (AiS) and invasive AC from the same patient, than between the AiSs from different patients.

Conclusions: By applying this state-of-the-art multi-omics approach to premalignant adenocarcinomas, we hope to identify key regulators of early lung cancer progression and to translate these findings to clinically relevant basic molecular diagnostics.

#0688 Pan-cancer mapping of genetic immune escape evolutionary trajectories.

Shengqing Gu, Wenjie Chen, Toby Baker, Zhihui Zhang, Huw A. Ogilvie, Peter Van Loo

UT MD Anderson Cancer Center, Houston, TX

Immune escape is a fundamental hallmark of cancer, facilitating disease progression and resistance to therapy. The temporal dynamics and genetic evolution underlying immune escape across diverse cancers remain incompletely characterized. Here we developed an integrative framework that systematically identifies immunomodulatory genes from functional genomic screens and reconstructs tumor evolutionary history using whole-genome sequencing data to infer mutation timing. Applying this approach to 2,658 tumors across 38 cancer types, we generated the first pan-cancer atlas of immune escape evolution, revealing distinct trajectories such as late amino acid metabolism mutations in pancreatic adenocarcinoma, early neuroactive ligand-receptor and IFNγ pathway mutations in esophageal adenocarcinoma, and late protein methylation mutations in breast adenocarcinoma. These findings provide a comprehensive map of genetic immune evasion evolution, offering insights that may inform early detection strategies, immunoprevention, and therapeutic interventions across cancers. To facilitate easy access to the results, we further built a user-friendly website to interactively interrogate the evolution of immune escape.

#0689 Significance of prostaglandin E_2 signaling in the carcinogenesis of ulcerative colitis.

Tatsunari Fukuoka[1], Masakazu Yashiro[2], Hiroaki Kasashima[3], Nobuhiro Naito[4], Iguru Omori[4], Yasuhiro Fukui[4], Yuki Seki[4], Kenji Kuroda[4], Yuichiro Miki[4], Mami Yoshii[4], Tatsuro Tamura[4], Masatsune Shibutani[4], Takahiro Toyokawa[4], Kiyoshi Maeda[4]

[1]Gastroenterological surgery, Osaka City General Hospital, Osaka, Japan,[2]Molecular Oncology and Therapeutics, Osaka Metropolitan University Graduate School of Medicine, Osaka, Japan,[3]Department of Gastroenterological Surgery, Graduate School of Medicine, Osaka Metropolitan University, Osaka, Japan,[4]Department of Gastroenterological Surgery, Osaka Metropolitan University Graduate School of Medicine, Osaka, Japan

Background The incidence of colorectal cancer arising in the setting of long-standing inflammatory bowel disease (IBD) has been increasing with the rising prevalence of ulcerative colitis (UC). Patients with long-standing UC have an approximately five-fold higher risk of colorectal cancer (CRC) compared with the general population. However, the molecular mechanisms underlying UC-associated carcinogenesis remain poorly defined. Prostaglandin E_2 (PGE_2) signaling is one of a key mediators of inflammation, and elevated PGE_2 levels have been observed in inflamed colonic tissue of UC patients. PGE_2 signaling also promotes tumor proliferation and metastasis in several cancer types.

Objective To clarify the involvement of PGE_2 signaling in UC-associated carcinogenesis by examining the expression of PGE_2 receptors EP2 and EP4 in UC-related neoplastic lesions.

Methods Forty-one patients who underwent the surgical operation for UC-associated neoplasia (16 dysplasia, 25 carcinoma) at our institution were included. Paraffin-embedded sections of dysplastic and cancerous lesions were subjected to immunohistochemical staining for EP2 and EP4. Expression intensity and proportion of EP2/EP4 were scored, and correlations between EP2/EP4receptor expression and clinicopathological parameters were analyzed.

Results Cancer tissues showed higher expression of EP2 and EP4 than dysplastic tissues in UC-associated neoplasia. Expression of either receptor (EP2 or EP4) was more frequent ($p = 0.0678$) in cancer lesions (81.5%, 22/27) compared with dysplastic lesions (50.0%, 7/14). EP2 positivity was observed in 66.7% of cancer lesions (18/27) and 42.9% of dysplastic lesions (6/14) ($p = 0.189$). EP4 expression tended to be higher ($p = 0.0516$) in cancer lesions (63.0%, 17/27) than in dysplastic lesions (28.6%, 4/14) ($p = 0.0516$) while EP2 positivity was not ($p = 0.189$;observed in 66.7% of cancer lesions (18/27) and 42.9% of dysplastic lesions) (6/14) ($p = 0.189$). Expression of either receptor (EP2 or EP4) was more frequent in cancer lesions (81.5%, 22/27) compared with dysplastic lesions (50.0%, 7/14) ($p = 0.0678$). In contrast, EP2 or EP4 Receptor expression was not significantly associated with cancer tumor stage, depth of invasion, or prognosis.

Conclusion These findings suggest that PGE_2 signaling, particularly through the EP4 receptor, may might contribute to the carcinogenesis in UC ulcerative colitis. EP4-mediated pathways may represent potential therapeutic or preventive targets in UC-associated CRC colorectal cancer.

#0690 Hierarchical mixed effects cubic spline modeling of methylation-based tumor fraction dynamics for pan-cancer assessment of treatment response and outcomes in immunotherapy patients.

Christopher Pretz[1], Amar Das[1], Carin Espenschied[2], Sara Wienke[3], Samantha I. Liang[4], Christopher Cabanski[4]

[1]Real World Evidence, Guardant Health Laboratory, Redwood City, CA,[2]Guardant Health, Spokane, WA,[3]Guardant Health, Charleston, SC,[4]Parker Institute for Cancer Immunotherapy, San Francisco, CA

Background: Methylation-based tumor fraction (TF) dynamics are a promising surrogate marker for monitoring disease, but their evolution varies widely across patients and cancer types. To characterize these patterns, we developed a hierarchical mixed-effects cubic spline model that captures non-linear longitudinal TF trends while accounting for patient-level heterogeneity and clinical covariates. Compared with traditional approaches, this framework supports multiple cancer types, baseline factors, and generates outcome-stratified trajectories (e.g., disease progression and survival). By enabling trajectory bifurcation by outcome, the model simultaneously reflects treatment response and prognosis, improving our understanding of how TF dynamics relate to therapeutic efficacy across diverse cancer types.

Methods: We analyzed 519 patients from the RADIOHEAD study consisting of 1,070 immunotherapy-naive patients receiving standard-of-care immune checkpoint inhibitor (ICI) regimens. Included patients had ≥2 plasma samples beyond baseline. TF was measured using Guardant Reveal, a clinically validated methylation-based assay. Model selection using Akaike information criterion compared linear, non-linear, and spline models; a natural cubic spline with five knots best fit the data. Covariates included age, smoking status, stage (III vs IV), and gender. Cancer types analyzed were lung, bladder, melanoma, renal cell carcinoma, and head and neck carcinoma. Binary outcomes were 15-month survival (alive/deceased) and disease progression (yes/no).

Results: Because spline coefficients are not interpretable, findings were presented graphically. After adjusting for covariates, TF trajectories diverged beyond 95% confidence bands and exhibited distinct patterns by cancer type and outcome. An interactive R Shiny application was developed to display these trajectories, along with velocity plots providing the instantaneous rate of TF change to aid interpretation.

Conclusions: This analysis provides a framework for characterizing TF evolution during immunotherapy and how these dynamics differentiate clinical outcomes across cancer types. Outcome-stratified trajectories and TF velocity may help identify early indicators of treatment response, supporting more informed therapeutic decisions. Additionally, since TF dynamics vary by disease indication, future studies could integrate TF dynamics with genomic and other clinical indicators to better understand response mechanisms, resistance factors, and other biological drivers that may underly a heterogeneous response to ICIs.

#0691 Visualizing differential prostate cancer lesion growth in longitudinal MRIs of patients on active surveillance: Quantitative mapping by Habitat Risk Score and digital pathology.

Sandra M. Gaston[1], Yuwei Zhang[2], Veronica M. Wallaengen[1], Amanda Galvez[1], Leonard Salcedo[1], Adrian L. Breto[1], Ahmad Algohary[1], Noah C. Lowry[1], Jakub Karczmarzyk[2], Gupta R. Rajarsi[2], Erich Bremer[2], Tahsin Kurc[2], Benjamin O. Spieler[1], Oleksandr N. Kryvenko[1], Alan Pollack[1], Sanoj Punnen[1], Joel Saltz[2], Radka Stoyanova[1]

[1]University of Miami Miller School of Medicine, Miami, FL,[2]Stony Brook University, Stony Brook, NY

Introduction: Active surveillance (AS) is now incorporated into many prostate cancer (PCa) management guidelines to reduce overtreatment, but it requires frequent monitoring because of the risk of disease progression. Improved risk-stratification tools are needed to distinguish indolent from aggressive disease early in surveillance so that the window for curative treatment is not missed. At many institutions, multiparametric MRI (mpMRI) and MRI-ultrasound (MRI-US) fusion biopsies are standard of care for interval monitoring of patients on AS. Here, we show that a quantitative mpMRI system, the Habitat Risk Score (HRS), identifies differential lesion growth on longitudinal mpMRI and correlates strongly with quantitative analysis of digital pathology from radical prostatectomy (RP) specimens.

Study Methods: Patients from “MRI-Guided Biopsy Selection of PCa Patients for Active Surveillance versus Treatment: The Miami MAST Trial” (ClinicalTrials.gov: NCT02242773; total accrual = 208) with confirmed PCa underwent 12-36 months of AS prior to RP. The mpMRI exams consisted of T2-weighted (T2W), Dynamic Contrast Enhanced (DCE)-MRI, and Diffusion Weighted Imaging (DWI) acquired according to PI-RADSv2 recommendations. The HRS approach automatically identifies suspicious prostate lesions on mpMRI by assigning a 10-point pixel-by-pixel risk score presented as a heat map, overlaid on the T2W. Longitudinal mpMRI images, biopsy pathology at 12, 24 or 36-months of surveillance and RP specimen pathology were analyzed. The temporal changes in HRS mpMRI volumes were tracked and HRS maps from the last time point (prior to RP) were examined for correlation with H&E and digital pathology.

Results: Detailed HRS mpMRI review of 34 MAST participants with biopsy progression followed shortly (within six months) by RP showed that 55% exhibited mpMRI evidence of histopathological progression that was not detected on their last surveillance biopsy. Standard-of-care prostate mpMRI, including that used in MAST, is limited by subjective interpretation, and even expert radiologists may miss significant lesions. In contrast, HRS provides an objective, quantitative assessment of prostate mpMRI images. Findings on HRS correlated closely with both expert pathology review and quantitative digital pathology, with the strongest spatial concordance observed between HRS maps and digital pathology.

Conclusion: Our results indicate the utility of HRS mpMRI to detect tumor growth in AS patients. The differential growth in the lesions can be used to guide tissue selection for genomic testing. The study found excellent correlation between HRS and H&E and digital pathology from RP specimens. HRS volumes may serve as quantitative biomarkers for early detection of progression.

#0692 Novel single cell and bulk NGS assays for improved assessment of MRD (measurable residual disease) and clonal dynamics in acute myeloid leukemia (AML).

Crystal Zhou[1], Ruwan Gunaratne[1], Emily Yang[1], Rachel Agoglia[2], Diwash Jangam[3], Charu Tiwari[1], Kailee Tanaka[4], Tsoyu Chiang[3], Chandler Ho[3], Sydney Lu[1], James L. Zehnder[3], Bing Melody Zhang[3], Henning Stehr[3], Tian Yi Zhang[1]

[1]Hematology, Stanford University School of Medicine, Stanford, CA,[2]Mission Bio, South San Francisco, CA,[3]Pathology, Stanford University School of Medicine, Stanford, CA,[4]Stanford Cancer Institute, Stanford, CA

Background: The genomic heterogeneity of AML and high rates of relapsed/refractory (R/R) disease necessitate improved tools for detecting MRD and studying clonal evolution. Standard-of-care (SOC) MRD methods, namely multiparametric flow cytometry (MFC) or single-variant molecular assays, are limited in sensitivity, applicability across diverse AML genomes, and ability to resolve clonal dynamics. We evaluated the Tapestri single-cell multiomics AML assay (Mission Bio) and HemeSTAMP-MRD, a novel high-sensitivity bulk NGS assay, as alternative platforms for MRD detection and clonal profiling.

Methods: We analyzed 72 bone marrow or peripheral blood mononuclear cell samples from 24 AML patients at diagnosis (n=18), remission (n=35), or R/R disease (n=19). Tapestri single-cell genotypic and immunophenotypic analysis was performed after CD34+/CD117+ enrichment using a 41-gene panel and 17-cell surface marker panel. HemeSTAMP-MRD, a bioinformatically optimized version of an in-house 203-gene error-corrected clinical NGS panel (Kim et al. 2022), was performed on paired whole blood samples in the CLIA-certified Stanford Molecular Pathology Laboratory. Each patient had ≥ 1 trackable diagnostic variant(s). MRD results were compared with SOC MFC.

Results: 87% (21/24) of patients achieved initial clinical remission (CR1), of whom 62.5% (15/21) relapsed. MFC detected MRD in only 33% (5/15) of patients with pre-relapse CR1 samples, while Tapestri and HemeSTAMP each identified MRD in 67% (10/15), including 8 patients with positive concordance. Among MFC-negative cases (n=10/15), 4 had detectable MRD by Tapestri and/or HemeSTAMP at variant allele frequencies < 1%, including one with actionable *IDH2*-mutant disease who relapsed and died before receiving targeted therapy. The 3 patients who relapsed despite negative MRD by all assays either had exclusively extramedullary relapse, loss of trackable variants, or inadequate sampling prior to relapse. Among patients yet to relapse, Tapestri and HemeSTAMP-MRD detected residual variants during CR1 in 5 of 6 patients, although 4 of whom later received allogenic transplant as a confounding factor.
During active disease (diagnosis or R/R timepoints), Tapestri identified a median of 4 clones per sample (range 1-9). In paired samples, 8/9 (88%) patients showed clonal evolution between diagnosis and R/R disease: 3/8 (37.5%) gained at least one emergent clone and 5/8 (62.5%) lost at least one. The most dynamic genes were *NRAS*, *NF1*, *PTPN11* and *TET2*, while *TP53* and *DNMT3A* were most stable.

Conclusion: Tapestri and HemeSTAMP-MRD both demonstrated improved MRD level detection, relapse prediction, and greater capacity to identify actionable mutations compared to MFC, with Tapestri uniquely enabling single-cell resolution of clonal dynamics to interrogate drivers of R/R disease. Larger cohort validation is ongoing.

#0693 ET-resistant cell populations in ER positive breast cancer: From profiling to therapeutic targeting.

Svetlana Semina[1], Rosemary Huggins J. Huggins[2], Huiping Zhao[3], Virgilia Macias[4], Leo Feferman[5], Andre A. Kajdacsy-Balla[6], Debra A. Tonetti[7], Kent F. Hoskins[8], Geoffrey L. Greene[9], Jonna M. Frasor[3], Jonathan Coloff[3]

[1]Physiology and Biophysics, University of Illinois Chicago, Chicago, IL,[2]Office of Education and Career Development, Comprehensive Cancer Center, University of Chicago Medicine, Chicago, IL, USA, Chicago, IL,[3]University of Illinois Chicago, Chicago, IL,[4]Department of Pathology, University of Illinois Chicago, Chicago, IL,[5]Research Informatics Core, Research Resourced Center, University of Illinois Chicago, Chicago, IL,[6]Director of Transdisciplinary Path., University of Illinois Medical Center, Chicago, IL,[7]Associate Professor of Pharmacology, Biopharmceutical Sci., University of Illinois at Chicago, Chicago, IL,[8]University of Illinois College of Med. at Chicago, Chicago, IL,[9]University of Chicago, Chicago, IL

Even though most women with estrogen receptor positive (ER+) breast tumors can benefit from endocrine therapy (ET), up to 40% of these patients will eventually experience relapse. Moreover, when these tumors recur, they tend to be more metastatic and therapy-resistant, resulting in disease progression and fatalities. One contributing factor to ET failure and recurrence is intratumoral heterogeneity, where tumors have distinct populations of cells with different sensitivity to ET. Here, we developed an integrated framework that combines clinical and experimental data with cutting edge bioinformatics tools to systematically identify and target ET-resistant cell populations. Leveraging single cell RNA sequencing data from the FELINE clinical trial, we profiled tumors from nine ER+ breast cancer patients treated with letrozole at baseline and after 14 days of therapy. We found that ET-sensitive populations are conserved across patients, whereas ET-resistant populations are more heterogeneous and not defined by ER expression, signaling activity, or molecular subtype. Moreover, gene signatures from ET-resistant clusters are predictive of poor patient survival and adverse pathological features in METABRIC dataset. To functionally validate these findings and target ET-resistant cell populations, we build a panel of patient-derived xenograft organoid (PDxO) models that retain key features of the original tumors and mirror findings from the clinical trial. Using a novel predictive therapeutic pipeline that integrates transcriptional profiling with drug response modeling on PDxOs, we identified and validated candidate drugs targeting both shared and patient-specific ET-resistant populations, including known drugs already used in clinic, such as dasatinib, as well as novel compounds such as pluripotin and AZD8055. These findings demonstrate that ET-resistant cell states emerge early under therapeutic pressure and persist despite treatment, representing a major barrier to ET response. Our integrated framework allowed us to uncover both patient-specific and shared ET-resistant cell populations, and to test personalized therapeutic strategies for targeting ET resistance. Together, our findings reveal a complex and heterogeneous landscape of endocrine therapy response, highlighting the critical importance of single-cell resolution to inform therapeutic strategies aimed at overcoming resistance and improving patient outcomes.

#0694 Spatially resolved genomics reveals evolutionary modes and imaging correlates in glioblastoma.

You Jin Song[1], Yelyzaveta Miller-Michlits[2], Karl-Heinz Nenning[3], Christoph Bock[4], Ji Yoon Lee[1], Jiwon Kim[1], Jisoo Hong[1], Dayoung Lee[1], Namsung Moon[1], Harim Koo[5], Jason K. Sa[1], Adelheid Woehrer[2]

[1]Korea University College of Medicine, Seoul, Korea, Republic of,[2]Medical University of Innsbruck, Innsbruck, Austria,[3]The Nathan S. Kline Institute for Psychiatric Research, New York, NY,[4]Austrian Academy of Sciences, Vienna, Austria,[5]Graduate School of Medical Science, University of Ulsan, Ulsan, Korea, Republic of

The spatial evolutionary dynamics of glioblastoma remain poorly understood. Here, we performed spatially resolved molecular profiling of 78 multi-regional tumor specimens from 24 GBM patients by integrating neuro-navigation-guided intraoperative sampling with deep whole-exome sequencing. This dataset represents one of the most spatially detailed genomic resources for GBM to date. By coupling spatial coordinates with genomic complexity, we delineated two distinct evolutionary trajectories: an “Expansive” model, in which three-dimensional growth and molecular diversification proceed in parallel, and a “Stochastic” model, where genomic diversification occurs independently of spatial expansion. These models were supported by phylogenetic reconstruction and radiogenomic analyses, revealing how spatial architecture constrains clonal dynamics. Quantitative integration of molecular and physical distances uncovered that tumors with greater spatially correlated genomic diversity exhibited worse clinical outcomes. Patients harboring “Stochastic” tumors demonstrated inferior survival probabilities compared to those with “Expansive” tumors, suggesting that spatially derived molecular metrics may serve as prognostic indicators of tumor aggressiveness. Furthermore, MRI-derived radiomic features, particularly texture-based metrics from T1-contrast enhanced images, mirrored underlying genomic complexity and aligned with evolutionary modes, establishing a link between intratumoral heterogeneity and noninvasive imaging phenotypes. While prior genomic studies have characterized GBM evolution at the molecular level, most lacked spatial resolution and failed to capture the three-dimensional architecture of tumor growth within the human brain. Our study overcomes this limitation through an international collaboration between the Medical University of Innsbruck and Korea University College of Medicine. Together, these results define anatomically distinct evolutionary trajectories of GBM and underscore how spatial context shapes molecular diversity, clinical behavior, and imaging manifestations. This spatially integrated framework provides a foundation for precision oncology approaches that incorporate spatial evolutionary constraints into therapeutic stratification.

#0696 In vivo clonal lineage tracing using methylation barcodes in the protocadherin gene cluster.

Christopher T. Boniface[1], Samuel Hackett[2], Adriana V. A. Fonseca[2], Akemi Ramos-Yamasaki[2], Caroline Watson[2], Joanna Baxter[2], Jyoti Nangalia[3], Sadik Esener[1], Hisham Mohammed[1], Jamie Blundell[2]

[1]Division of Oncological Sciences, OHSU Knight Cancer Institute, Portland, OR,[2]University of Cambridge, Cambridge, United Kingdom,[3]Wellcome Sanger Institute, Hinxton, United Kingdom

Resolving the lineage history of cells is crucial for understanding tissue development, stem cell dynamics, and cancer, but is hampered by methods that are invasive, low-resolution, or prohibitively expensive for human studies. Clonal expansion of a single stem cell lineage is a hallmark of pre-cancer in both solid tissue tumors and hematological malignancies. Here, we describe a native, in vivo lineage tracing system that utilizes the stochastic (de)methylation of CpGs in the protocadherin (PCDH) gene cluster. By phasing these CpGs in bulk methylation sequencing we construct in situ evolvable methylation “barcodes” that uniquely mark stem cell clones. We longitudinally tracked these barcodes in annual blood samples from 50 individuals and age-matched controls up to a decade prior to acute myeloid leukemia (AML) diagnosis. We show that polyclonal tissues have high barcode diversity—reflecting a broad stem-cell pool—which then collapses during a clonal sweep. The fractional abundance of dominant barcodes provides a quantitative measure of clone size that precisely tracks genetic estimates from somatic mutations. However, 10% of pre-AML donors harbored expanded barcodes but lacked detectable somatic driver mutations, suggesting the presence of clonal expansions with cryptic drivers years before diagnosis. Barcode trajectories also reveal subclonal competition and interference. Because these barcodes evolve by stochastic (de)methylation at approximately 1% per CpG per year, heritable diversity is generated in clonal populations enabling the tracking and quantification of subclonal growth dynamics. We then demonstrate that barcodes containing dozens to hundreds of PCDH CpGs produced from long-read sequencing allow for deep phylogenetic reconstruction from a single time point. Finally, we observed expanded barcodes in solid tumor tissues, including prostate and kidney. PCDH methylation barcodes therefore represent a scalable, cost-effective, and pan-tissue tool for high-resolution lineage tracing in humans, opening new avenues for studying somatic evolution in health and disease.

#0697 Label-free spatial profiling of the melanoma tumor microenvironment using metasurface-enhanced Raman spectroscopy.

Kai Chang[1], Mamatha Serasanambati[1], Feven Naba[1], Priyanuj Bordoloi[1], Antony Georgiadis[1], Emma Wagner[1], Hamish Carr Delgado[1], Chih-Yi Chen[1], Varun Dolia[1], Baba Ogunlade[1], Remi Dado[1], Ariel Stiber[1], Jack Hu[2], Amanda R. Kirane[3], Jennifer Dionne[1]

[1]Stanford University, Stanford, CA,[2]Pumpkinsed Technologies, Inc., Palo Alto, CA,[3]Stanford University School of Medicine, Stanford, CA

The spatial organization of the tumor immune microenvironment (TIME) is a critical determinant of cancer progression and response to precision therapies. Understanding this complex ecosystem holds immense potential for developing diagnostics and immunotherapies. Current spatial omics methods, including transcriptomics and proteomics, however, have limited translational and clinical adoption. These methods require invasive or destructive, time-intensive protocols, are expensive, and may not always capture structural or post-translational modifications driving tumor behavior. Here, we propose a high-throughput, label-free spatial profiling method combining metasurface-driven surface-enhanced Raman spectroscopy (mSERS) and machine learning (ML) that enables holistic cell phenotyping in melanoma TIME.

Our metasurfaces are composed of dielectric (high-index silicon nitride) nanoresonators on microscope slides optimized for 785 nm laser excitation. These slides localize Raman scattering in uniform and discretized sub-wavelength “hot-spots” that can span full tissue surface areas, all while minimizing cell heating damage. On these slides, we collect subcellular SERS maps across monoculture of TIME-relevant melanoma and immune cell lines and simplified TIME cocultures of two cell types (YUMM1.7, RAW264.7). We compare Raman spectral features against brightfield and fluorescence imaging and develop cell segmentation algorithms to isolate single-cell spectral maps. For a small cohort of FFPE patient tumors with complete, partial, and non-responses to immune checkpoint inhibitor PD-1 (nivolumab), we image and construct a melanoma tumor atlas with co-registered Raman, spatial transcriptomics, and multiplex immunofluorescence (mIF) data.

We show enhancements of $>10^5$ over non-SERS at 10 nm above the surface and across the cell membrane. We achieve >96% differentiation accuracy across cell types and confirm spectral features associated with subcellular features (e.g. nucleus, membrane). Our segmentation algorithm correctly labels coculture cells in agreement with co-registered mIF. In our patient tumor data, we show unique nivolumab-relevant biomarkers identifiable by mSERS and not by other modalities in isolation. By extending our findings to tumor FFPE and historical clinical specimens, the implications of our all-optical approach have the potential to advance cancer knowledge, clinical biomarker efforts, and impact precision treatment decisions for cancer patients.

#0699 Dynamic adaptation and heterogeneity in tumor patient-derived organoids: Insights into cancer evolution and drug resistance.

Javier Frias Aldeguer, Jasmin Pourfarzad, Alessandro Gregory, Farzin Pourfarzad, Rene Overmeer, Robert G. J. Vries, Sylvia F. Boj

HUB Organoids B.V., Utrecht, Netherlands

Tumor plasticity and cellular heterogeneity have long been recognized as major contributors to the limited success of cancer therapies, underscoring the need for more physiologically relevant preclinical models. Patient-derived organoids (PDOs) offer a three-dimensional, heterogeneous platform that better reflects tumor complexity compared to traditional cell lines or animal models. Their adoption in drug development pipelines and avatar clinical trials has grown significantly in recent years. In this study, tumor PDOs were characterized using single-cell RNA sequencing, whole-exome sequencing, and sub-lethal therapeutic exposure to assess intra- and inter-patient heterogeneity and adaptive dynamics. PDOs from different donors exhibited patient-specific transcriptional signatures while retaining stem-like features. Mutational landscapes evolved over time, with variants being retained, lost, or acquired relative to the original tissue. Notably, subpopulations persisted through treatment and gave rise to distinct clonal cultures with unique transcriptional profiles upon drug withdrawal. These findings confirm that tumor PDOs preserve cellular heterogeneity and exhibit dynamic adaptability, making them powerful tools for investigating cancer evolution, drug resistance, and mutation dynamics. Inter-patient variability highlights the need for personalized therapeutic strategies, while intra-patient heterogeneity positions PDOs as ideal models for studying complex cellular interactions and mechanisms of pharmacological persistence.

#0700 Feasibility to detect genomic loss of HLA alleles by One Lambda LABType products combined with novel data analysis algorithm.

Svetlana Argounova, Bernabe Valdez, Kevin Lam, Hanna Bennett, **Anna Chikova**

One Lambda Inc., Thermo Fisher Scientific, West Hills, CA

Loss of heterozygosity in human leukocyte antigens (HLA) is a phenomenon frequently observed in relapses of myeloid leukemia treated by allogeneic hematopoietic stem cell transplantation. Loss of HLA was also described in multiple studies of solid tumors (Montesion et al. 2021, Zhang et al. 2022) where loss of HLA may be particularly important for patients treated by HLA restrictive immunotherapy. Identifying loss of heterozygosity (LOH) during relapses may provide information critical for treatment selection in affected patients. One Lambda LABType products utilize reverse-sequence-specific oligonucleotide (rSSO) typing method with the LABScan 100 or LABScan3D instruments, to provide HLA typing in up to 11 HLA loci. Though this product is used for HLA genotyping in transplant diagnostic practices, we explored potential feasibility to use LABType kits to detect complete or partial loss of HLA alleles in human genome. We used homozygous DNA samples well characterized for all 11 HLA loci and tested different ratios of DNAs in each mixture to mimic LOH characteristics and analyzed all samples with One Lambda LABType products for several loci. Our new loss of HLA analysis algorithm was able to clearly distinguish between homozygous DNA and DNA mix containing only 10% of minor allele. Assay allowed clearly distinguish 1:1 DNA mix from 30, 20 and 10% of minor allele and comparing different SSO products showed that LABType CWD kits were quantifying residual allele with higher level of confidence. To challenge our algorithm further, we tested mixture of 3 DNAs imitating haplo-matched stem cell transplant, when donor is sharing one set of HLA alleles with the patient while other donor's allele is different. We mimicked different levels of chimerism and different levels of HLA loss by mixing these 3 DNAs representing heterozygous donor and two patients alleles in different ratios. Experiment demonstrated ability of LABType CWD test to detect as little as 1% of minor allele present in 20 ng of total DNA per reaction. Further evaluation of new data analysis approach using LABType technology for complete or partial loss of HLA may be beneficial for both transplant medicine related research and oncology fields. New algorithm is intended for research use only and is not commercially available at this time.

#0701 Patient-derived organoid biobanks preserve tumor heterogeneity and molecular signatures.

Rene Overmeer, Farzin Pourfarzad, Alejandra Hernandez Segura, Merel Derksen, Carla Verissimo, Robert G. J. Vries, Sylvia F. Boj

HUB Organoids B.V., Utrecht, Netherlands

Tumor heterogeneity—both within individual tumors and among different patients—poses a significant challenge for effective cancer treatment. To advance precision oncology, preclinical models that capture this complexity are essential. Patient-derived organoids (PDOs) provide a physiologically relevant platform that maintains the architecture and diversity of the original tumor, making them ideal for studying heterogeneity and patient-specific biology. In this study, we established and characterized PDO biobanks from colorectal and bladder cancers to evaluate their ability to represent intra-tumor heterogeneity and patient-specific molecular signatures. We profiled organoids using whole-exome sequencing and bulk RNA sequencing to assess their genomic and transcriptomic fidelity. Our analyses revealed that PDOs retain key mutational profiles and transcriptional programs of the original tumors, including subtype-specific signatures. Importantly, we observed distinct cellular subpopulations within individual PDO cultures that reflect intra-tumor diversity, including stem-like and differentiated phenotypes. These features persisted over time, confirming the stability of heterogeneity in vitro. Across the biobank, PDOs captured the spectrum of molecular subtypes present in colorectal and bladder cancers, enabling subtype-specific drug testing and biomarker discovery. This diversity highlights the potential of PDO platforms to model patient variability and inform personalized therapeutic strategies. Our findings demonstrate that PDOs are not only accurate representations of patient tumors but also dynamic systems that preserve heterogeneity at multiple levels. By integrating genomic and transcriptomic profiling with functional assays, PDO biobanks provide a powerful resource for studying tumor complexity and accelerating precision medicine.

#0702 Harnessing clonal dynamics to overcome resistance: An adaptive therapy framework in colorectal cancer.

Harley I. Richker[1], Bailey Sierra Kane[1], Gissel Marquez Alcaraz[1], Ellie Pahl[1], Ryan Carr[2], Nagarajan Kannan[2], Carlo C. Maley[3]

[1]Arizona State University Biodesign Institute, Tempe, AZ,[2]Mayo Clinic, Rochester, MN,[3]Arizona State Univ. Biodesign Institute, Tempe, AZ

Therapeutic resistance to chemotherapy is frequently the proximate cause of increased tumor burden, cancer treatment failure, and ultimately, patient mortality. The most successful therapy strategy derived from evolutionary practices to date, Adaptive Therapy (AT), leverages the fitness cost of developing therapeutic resistance. AT avoids treating cancer cells with the Maximum Tolerated Dose (MTD) of therapeutic drugs and instead incorporates a series of adaptive dosing schedules. Treatment-sensitive cells are bolstered by modulating or pausing treatment to out-compete and suppress treatment-resistant cell growth. We are evaluating AT for the first time in colorectal cancer, using a syngeneic orthotopic xenograft model. This work represents several key advances: it is the first to longitudinally and non-invasively track sensitive and resistant clones in vivo, to evaluate adaptive therapy in an immunocompetent mouse model, to incorporate multi-drug treatment regimens, and to integrate a targeted therapeutic agent. The dual-bioluminescent sensitive and resistant CT26 cell lines developed for this study allow real-time visualization and quantification of each population throughout tumor progression and treatment. Together, these advances establish a robust and clinically relevant platform for characterizing resistance dynamics and refining adaptive therapy strategies aimed at improving treatment outcomes in colorectal cancer.

#0703 Tracking tumor evolution and heterogeneity in fusion-driven sarcomas through cell-free DNA analysis.

Tom T. Fischer[1], Panna Lajer[2], Konstantin Okonechnikov[1], Anke King[1], Karla Catacora[1], Katharina Bauer[2], Iris Oezen[1], Tanja Jutzi[2], Katherine Kelly[1], Calvin Hans Setiadi[2], Waqar Hussain[3], Kendra K. Maass[1], Roland Imle[1], Anja Speicher[4], Kamelia Soleiman-Masihi[4], Nadine Volk[4], Birgit Besenbeck[4], Robert Kuechler[4], Anu Mathews[4], Editha Gnutzmann[4], Julia Ketzer[5], Daniela Richter[3], Daniel Huebschmann[4], Ana Banito[1], Claudia Ball[3], Kathrin Schramm[1], David T. W. Jones[1], Jan-Philipp Mallm[2], Uta Dirksen[5], Sabine Stegmaier[6], Monika Sparber-Sauer[6], Richard F. Schlenk[4], Hanno Glimm[3], Stefan Froehling[2], Stefan M. Pfister[1], Supat Thongjuea[1], Kristian W. Pajtler[1], Daniel B. Lipka[2]

[1]Hopp Children's Cancer Center (KiTZ), Heidelberg, Germany,[2]German Cancer Research Center (DKFZ), Heidelberg, Germany,[3]National Center for Tumor Diseases Dresden (NCT/UCC), Dresden, Germany,[4]National Center for Tumor Diseases Heidelberg (NCT), Heidelberg, Germany,[5]University Hospital Essen, Essen, Germany,[6]Zentrum fur Kinder-, Jugend- und Frauenmedizin (Olgahospital), Klinikum der Landeshauptstadt Stuttgart, Stuttgart, Germany

Background: Tumor evolution and intra-tumoral heterogeneity drive therapy resistance and relapse, yet remain poorly understood and difficult to track in real time. HEROES-AYA, a German multi-center consortium funded by the National Decade Against Cancer, leverages fusion-driven bone and soft tissue sarcomas in children, adolescents, and young adults as a model system to dissect these processes. Defined by diverse oncogenic fusions, these aggressive tumors frequently evade therapy, leading to poor outcomes. In parallel with bulk and single-cell multi-omics profiling of tumor tissue, we employ plasma liquid biopsies as a minimally invasive, serially collectable source of circulating tumor DNA (ctDNA) to map spatiotemporal tumor dynamics.

Methods: 112 plasma samples from 60 patients (12 alveolar rhabdomyosarcoma, 11 synovial sarcoma, 8 myxoid liposarcoma, and 29 other fusion-driven sarcomas) were collected retro- and prospectively in several German sarcoma trials (1-15 samples per patient). Plasma from healthy donors served as control. Cell-free DNA (cfDNA) was profiled using an ultra-sensitive enzymatic methylation sequencing assay optimized for pico- to nanogram inputs and sequenced at 10-20x. A multi-layered bioinformatics framework integrated copy number variations (CNVs), single-nucleotide variants (SNVs), and methylation profiles of cfDNA, benchmarked against matched tumor profiles. For 30 patients (58 tumor samples), single-cell multi-omics profiling (RNA, ATAC, and DNA sequencing) of paired tumor tissue was used to decode cfDNA clonal composition.

Results: Despite low cfDNA input amounts (median: 3ng; range: below detection limit - 17ng), genome-wide cfDNA profiles were successfully generated for all samples. ctDNA signals showed strong concordance with matched tumor tissue across CNV, SNV, and methylation layers. Longitudinal plasma sampling added molecular time points unavailable from tissue biopsies, revealing newly acquired broad copy number alterations and focal amplifications (affecting, e.g., *CDK6*) at progression. Integration with single-cell data enabled deconstruction of bulk cfDNA profiles, revealing distinct compositions in the plasma with dominant, multiple, or divergent clones relative to tumor tissue. For example, in a case of pediatric alveolar rhabdomyosarcoma, ctDNA at relapse more closely resembled the profiles of the primary tumor rather than those in a concurrent lymph node metastasis, demonstrating how liquid biopsies capture tumor dynamics across anatomical sites.

Conclusions: The integration of a multi-layered cfDNA assay with single-cell tumor sequencing provides an improved understanding of clonal dynamics and tumor evolution. By identifying cfDNA markers of heterogeneity and emerging resistance, this approach may establish a translational path for their longitudinal assessment via liquid biopsies in precision oncology.

#0704 Full-range genomic analysis at single-cell resolution reveals genetic, epigenetic, and parallel evolution of melanoma subclones.

Chi-Ping Day[1], Yuelin Liu[1], Anton Goretsky[1], Ayse Keskus[1], Salem Malikic[1], Eva Perez-Guijarro[2], Glenn Merlino[3], Eytan Ruppin[1], Suleyman Cenk Sahinalp[1], Mikhail Kolmogorov[1]

[1]National Cancer Institute, Cancer Data Science Laboratory, NIH, Bethesda, MD,[2]Institute for Biomedical Research Sols-Morreale, Universidad Autonoma de Madrid, Madrid, Spain,[3]National Cancer Institute, Laboratory of Cancer Biology and Genetics, NIH, Bethesda, MD

Tumor evolution is driven by various mutational processes, ranging from single nucleotide variants (SNVs) to large structural variants (SVs) to dynamic shifts in DNA methylation. Current short-read sequencing methods struggle to accurately capture the full spectrum of these genomic and epigenomic alterations, as well as their relations, due to inherent technical limitations. Here we used Nanopore long-read sequencing to profile 23 subclones, each derived from a single cell of a mouse melanoma cell line, for precise detection and evolutionary ordering of SNVs, SVs, copy number alterations (CNAs), and DNA methylation changes at subclonal level. Through phylogenetic analysis of these subclones, we reconstruct the timing of mutational processes and their contributions to diverse clonal phenotypes. The analysis reveals recurrent amplifications of putative driver genes, generated by independent SVs across different lineages, suggesting parallel evolution. Additionally, we described lineage-specific methylation changes associated with aggressive tumor subclones, highlighting epigenetic trajectories linked to tumor progression. Overall, we demonstrate that our long-read approach enables a uniquely comprehensive view of melanoma progression, highlighting that SVs and methylation played an important role in initiation, clonal diversification, and development of therapeutic resistance in this tumor, in consistence with recent clinical findings. We will release the sequencing data and curated variant calls to encourage developments of new computational methods.

#0706 Beyond a single core biopsy: Spatial genomic profiling improves therapeutic target detection in glioblastoma.

Enmar Harfoush[1], Taylor Weiskittel[1], Mylan Blomquist[2], Dustin Grief[3], Aadel A. Chaudhuri[1], Leland S. Hu[3], Nhan L. Tran[3], Shannon Fortin-Ensign[3]

[1]Mayo Clinic, Rochester, MN,[2]University of California San Francisco, San Francisco, CA,[3]Mayo Clinic Arizona, Scottsdale, AZ

Purpose: Despite advances in molecular diagnostics, glioblastoma (GBM) remains incurable, with recurrence driven by residual invasive tumor cells that escape surgical resection and therapy. Current genomic profiling to guide therapy for recurrent disease typically relies on a single-site clinical biopsy (SSCB) obtained from the contrasting-enhancing (CE) tumor core - the region targeted for maximal resection and most visible on Magnetic Resonance Imaging (MRI). However, this region poorly represents the non-enhancing (NE) invasive tumor margins, which harbor treatment-resistant and genetically distinct cell populations responsible for disease recurrence. GBM exhibits extensive spatial heterogeneity, raising concerns that a single tissue may underrepresent the true actionable landscape of the tumor.

Experimental Procedures: We analyzed 302 biopsies from 66 GBM patients who underwent multiregional whole exome and RNA sequencing across CE and NE tumor regions. Of these, 17 patients also had standard-of-care SSCB molecular profiling utilizing clinically available genomic sequencing panels outside of the multiregional protocol. Variants that have been targeted in ongoing or successful human clinical trials were annotated as actionable. We compared actionability profiles between SSCB and multiregional sampling, to determine the gain of actionable variant detection across the two sampling strategies. We performed an in-silico biopsy simulation to model the coverage of these alterations across the tumor landscape with increasing sampling frequency in the multiregional protocol, versus the coverage from clinical sequencing panels on SSCBs.

Results: Clinical sampling identified a median of one actionable mutation per patient (range 0-3). In contrast, multiregional profiling revealed additional potentially actionable variants in over 70% of patients, particularly within NE infiltrative regions that are not captured by conventional resection. Notably, nine potentially actionable copy-number variants, including *PDGFRA* amplification, were consistently absent from SSCB results and underrepresented in most clinical panels. In silico biopsy simulations demonstrated that actionable variant detection continues to rise even after sampling five additional regions, reflecting spatial segregation of therapeutic targets.

Conclusions: These findings demonstrate that a single sample from the CE tumor core fails to capture the biologically diverse invasive tumor populations responsible for GBM recurrence. Multiregional sequencing uncovers clinically meaningful alterations that would otherwise remain undetected with conventional sampling, highlighting the risk of incomplete molecular characterization in current clinical biopsy workflows.

#0707 Phylogenetic and machine learning analyses of simulated ancestral sequences reveals heterogeneous ccRCC evolution.

Nic Fisk[1], Christopher Cross[2], Brian M. Shuch[3], Jeffrey Peter Townsend[2]

[1]University of Rhode Island, Kingston, RI,[2]Yale University, New Haven, CT,[3]UCLA Medical Center, Santa Monica, CA

Clear-cell renal-cell carcinoma (ccRCC) accounts for 70-80% of kidney cancers, with increasing incidence driven by improved imaging, aging populations, and rising obesity rates. No routine diagnostic tests currently predict which small renal masses will progress to large, aggressive tumors, leaving a fundamental clinical question unresolved: do lethal tumors arise with inherently aggressive molecular characteristics, or do they gradually evolve from indolent precursors?

To investigate size-specific evolutionary trajectories, we integrated cancer effect size quantification, mutational signature analysis, phylogenetic reconstruction, and machine learning classification. We calculated cancer effect sizes stratified by tumor size (≤3 cm vs >3 cm) using single-nucleotide variant data from TCGA-KIRC (n=339) combined with five additional studies (total n=656). We additionally leveraged multi-region tumor sequencing data from 20 patients to investigate the evolutionary history of these tumors by performing Bayesian phylogenetic reconstruction to generate chronograms. To characterize ancestral tumor states, we developed a novel binomial sampling simulation parameterized by variant allele frequencies to generate mid-branch sequence states representing likely ancestral tumor configurations, which were then classified as "small" or "large" using a neural network trained on mutational matrices incorporating recurrent cancer effect sizes and de novo mutational signature weights.

Our neural network classified ccRCC size with 86.48% accuracy and an F1 score of 0.86. Among the patient subset with large tumors, half showed small-like ancestral midpoints while half showed large-like midpoints; in contrast, small tumors overwhelmingly classified as having small ancestral states, supporting model reliability. We also found that VHL mutations clustering around the binding pocket exhibited the highest cancer effects, supporting observations from the literature. Interestingly, while feature importance analysis identified approximately 1000 variants contributing discriminatory power, only one VHL mutation (a truncation mutation) was in the 100 most informative variants, despite VHL's overall importance in ccRCC and may be especially influential on evolutionary trajectory.

These results suggest that ccRCC tumors follow heterogeneous evolutionary paths—some large tumors pass through small-like feature states while others do not. This framework demonstrates the utility of evolutionary embeddings for machine learning classifiers and offers a generalizable approach for investigating ancestral tumor characteristics.

#0711 Single-cell and spatial profiling identifies tumor features and actionable surface targets in primary breast angiosarcoma.

Asumi Iesato, Masashi Akiya, Kazutaka Otsuji, Sumito Saeki, Natsue Uehiro, Tetsuo Noda, Tomo Osako, Takayuki Ueno, Reo Maruyama

Japanese Foundation for Cancer Research, Tokyo, Japan

Background: Primary breast angiosarcoma (PBA) is an extremely rare and aggressive vascular malignancy with limited therapeutic options. Genomic studies have identified recurrent alterations such as KDR, PIK3CA, TP53, and FLT4, but gene-expression patterns have been scarcely reported, and their spatial context remains poorly defined. Only two spatial transcriptomic studies have been published, both from a single institution and focused mainly on immune-cell distribution while analyzing breast and non-breast angiosarcomas together. These two studies identified tumor regions based on endothelial markers (ERG/CD31); yet these markers can be diminished in dedifferentiated angiosarcoma, and reliable tumor-specific markers remain unavailable. Whether PBA shares molecular features with angiosarcomas from other anatomical sites also remains unclear. **Objective**: To delineate transcriptional programs of primary and metastatic PBA and validate them using integrated spatial analysis, and to identify candidate tumor cell markers with therapeutic applicability.
Methods: We integrated single-cell RNA sequencing (scRNA-seq) and spatial transcriptomics from matched PBA specimens. Fresh tumors (361T, 256T) were profiled using BD Rhapsody scRNA-seq and integrated with normal breast tissue (388D). CNVs were inferred by InferCNV. Visium spatial transcriptomics were performed on FFPE samples from two cases, with ovarian and liver metastases available from one (256T). CD276 expression was evaluated by immunohistochemistry in 3 PBA cases.
Results: Integrated scRNA-seq from the three samples identified three endothelial clusters: c5 (normal ECs), c7 (tumor ECs), and c11 (lymphatic ECs). Cluster 7 expressed PECAM1/CDH5 and angiogenic/lymphangiogenic regulators, and InferCNV confirmed its tumor identity. Differential expression between c7 and c5 yielded a tumor-specific gene set (AS_signature) enriched for extracellular-matrix organization, receptor tyrosine-kinase signaling, and basement-membrane remodeling. Spatial InferCNV reproduced tumor-associated CNVs in Visium tumor regions. Joint analysis of ovarian and liver metastases of 256T showed complete UMAP separation and divergent CNV architectures; primary-tumor subclusters localized preferentially to ovarian or hepatic lesions, suggesting organ-selective subclonal dissemination. Twelve membrane-localized candidates were identified, and CD276 (B7-H3) showed strong membranous staining.
Conclusions: Integrated single-cell and spatial profiling delineated tumor-derived endothelial features in PBA and validated their spatial and CNV context. The AS_signature robustly distinguished tumor from normal endothelium. Divergent metastatic CNV profiles suggest subclonal evolution with organ-specific tropism. CD276 emerged as a clinically actionable membrane antigen for ADC development.

#0713 Quantitative 3D histology: Million-cell-scale spatial multi-omics in intact FFPE specimens.

Lichun Zhang[1], William C. S. Cho[2], Li Joshua[3], Molly Li[4], Tony S. Mok[4], **Hei Ming Lai**[1]

[1]Chemical Pathology, The Chinese University of Hong Kong, Hong Kong, Hong Kong,[2]Clinical Oncology, Queen Elizabeth Hospital, Hong Kong, Hong Kong,[3]Pathology, University of Hong Kong, Hong Kong, Hong Kong,[4]Chinese University of Hong Kong, Hong Kong, Hong Kong

Cancer exhibits profound heterogeneity both within and between patients, spanning from individual cell phenotypes to complex microenvironmental niches. Current technologies fail to capture this multiscale complexity while preserving native tissue architecture holistically. Here we present a quantitative 3D histology platform that enables spatially resolved, million-cell-scale multi-omic profiling of intact formalin-fixed paraffin-embedded (FFPE) specimens. It eliminates sampling error and subjectivity in histopathology, and facilitates quantitative phenotyping to guide patient selection in treatments.

We applied this platform to profile diverse cancer specimens, uncovering cancer-nerve interactions, cancer-immune cell interactions, and generating quantitative continuous scores for actionable targets, including TROP2 and HER2, through normalised membrane ratios (NMRs) in >0.5 million cells per sample. We also identified missed cancers, pre-cancerous lesions, and lymphovascular invasion in designated normal tissue blocks, as well as decision dilemmas and errors in 2D quantitative digital pathology efforts, due to the fundamental limitations offered by a random specimen cut.

In developing this platform, we devised novel chemistry for low-temperature FFPE retrieval to prevent biomolecular damage, followed by custom supramolecular reaction systems that enable deep antibody penetration for up to 28-plex multiplexed immunostaining in > 1,000 µm-thick specimens. Non-destructive tissue clearing, coupled with light-sheet microscopy, then captures the entire specimen in 3D with optical sectioning. We then trained a family of neural networks to segment individual cells in their native 3D positions with precise cellular geometry, allowing computation of distances to tissue boundaries and features (vessels, nerves), as well as spatial relationships between cell types. These 3D masks quantify marker expression across major subcellular compartments, generating continuous molecular scores for each cell.

Crucially, tissues remain structurally and molecularly intact throughout processing. Comparative analyses pre- and post-3D profiling show indistinguishable results for H&E, immunohistochemistry, whole-genome sequencing, bulk RNA-seq, laser-capture mass spectrometry proteomics, and 2D spatial transcriptomics. We demonstrate the feasibility of integrating 2D spatial transcriptomic data into the 3D volume for comprehensive single-cell molecular profiling. Moreover, the 3D histology pipeline requires no specialized equipment, is fully automatable, and generalizes across tissue types, enabling rapid clinical deployment for precision oncology applications where spatial context drives therapeutic decisions.

Our technology addresses the fundamental limitations of current 2D pathology methods, with broad applicability across multiple cancers.

#0714 Enhanced in vivo and ex vivo analysis enables deeper characterization of humanized mouse models for immuno-oncology research.

Maria Stecklum[1], Joshua Alcaniz[1], Lea Bornemann[2], Jens Hoffmann[1]

[1]EPO GmbH, Berlin, Germany,[2]Miltenyi Biotec B.V. & Co. KG, Bergisch Gladbach, Germany

Background
We previously demonstrated that humanized mouse models can be generated using peripheral blood mononuclear cells (PBMCs), PBMC subpopulations such as T and NK cells, or $CD34^+$ hematopoietic stem cells (HSCs), depending on the research objective. As next-generation immunotherapies advance—including checkpoint inhibitors (CPIs), engineered immune cells, and immune-cell engagers—establishing suitable in vivo and ex vivo analytical platforms becomes essential. Fully humanized mouse models containing both a human immune system and human tumors provide a more physiologically relevant setting for evaluating these therapies.
Methods
Humanized mice were established through intravenous transplantation of $CD34^+$ cells, PBMCs, or purified NK or T cells into immunodeficient mice. Cell-derived xenograft (CDX) and patient-derived xenograft (PDX) tumors were engrafted either subcutaneously (s.c.) or orthotopically (intravenously or into the mammary fat pad). Tumor progression was assessed using caliper measurements (s.c.) or bioluminescence imaging (BLI) for orthotopic models.
Quantitative immune cell composition in blood, bone marrow, spleen, and tumor tissue was analyzed by flow cytometry. 3D-Light-sheet fluorescence microscopy with the Ultramicroscope Blaze was established to enable spatial analysis and localization of immune-cell infiltration in tumors and spleen.
Results
Both CDX and PDX tumors from multiple cancer types successfully engrafted in humanized mice, with >70% engraftment success and no significant differences in tumor growth kinetics compared to non-humanized controls. Immunotherapy treatment revealed distinct responder and non-responder profiles, characterized by differential immune-cell infiltration patterns.
Flow cytometry reliably monitored human immune reconstitution and quantified immune and tumor cell populations over time. Flow cytometry has also been used to follow therapeutic treatment effects. BLI provided a non-invasive method for longitudinal tumor assessment in orthotopic models.
3D-Light-sheet imaging with the Ultramicroscope Blaze enables the confirmation of FACS-based findings and visualized tumor-infiltrating lymphocytes (TILs), unlocking spatial mapping of immune-cell localization within tumors and lymphoid organs.
Conclusions
Continuous refinement of our humanized mouse models enables robust preclinical evaluation of emerging immunotherapies. Integration of spatial biology enhances mechanistic insight by providing high-resolution visualization of immune-cell behavior within the tumor microenvironment, strengthening the translational value of these platforms.

#0715 Robust segmentation-free stain quality concordance metrics in the SpaceIQ™ multi-omic analysis platform.

Brian Falkenstein[1], Raymond Yan[1], A. Burak Tosun[1], S. Chakra Chennubhotla[2], Filippo Pullara[1]

[1]Computational and Systems Biology, PredxBio, Inc., Pittsburgh, PA,[2]Computational and Systems Biology, PredxBio, Inc. / University of Pittsburgh, Pittsburgh, PA

Background: Spatial imaging outputs continue to grow in scale and complexity. While brightfield IHC and H&E remain the qualitative gold standard for antibody-based assessment, mIF offers quantitative protein measurement on a single slide. However, challenges such as non-specific binding, imaging artifacts, and variability across sites and operators limit confidence in mIF reproducibility. A quantitative, robust method is needed to assess concordance between IHC and mIF stains.
Methods: Using a pan-cancer dataset with a 4-plex mIF panel and matched IHC sections from consecutive slides, we first co-registered images into a shared coordinate space with Valis, applying global rigid and non-rigid transformations from feature matches. IHC stain channels were isolated via stain-matrix-based deconvolution. A tissue mask was generated on the mIF image using Otsu thresholding and morphology operations and then projected onto the IHC slide.Tissue was divided into tiles whose size accounted for section-to-section distance, registration error, and biological variability. Within each tile, random windows were sampled to perform two tests: (1) identify whether the tile contains high stain intensity and (2) determine whether the corresponding IHC and mIF tiles exhibit statistically concordant staining. This approach yields both a DICE score for high-stain region overlap and a stain concordance metric capturing agreement across high- and low-stain regions. Tile-level results and heatmaps are visualized in SpaceIQ™.
Results: Concordance between mIF and IHC varied substantially across markers, with CD8 showing the highest and FoxP3 the lowest agreement, a trend consistent across samples. Concordance heatmaps also revealed strong spatial effects, with some tissue regions highly concordant and others clearly discordant. Expert visual review matched these quantitative findings.
Conclusions: This segmentation-free framework identifies substantial marker- and region-specific variation in concordance between mIF and IHC staining. Because the method is marker-agnostic and compensates for registration error and inter-section biological differences, it provides a generalized, quantitative approach for evaluating agreement between paired mIF and IHC slides across platforms.

#0716 AI-driven live 3D/4D spatial multimodal evaluation of a HER2-targeting ADC: delivery, lysosomal cleavage, payload action, and bystander effects resolved by holotomography and fluorescence.

Seock-Jin Chung[1], Eric Sha[2], Minji Kim[3], Youngwon Cho[3], Seunghyi Kook[3], Soonyoung Lee[4], Jongseong Jang[4], Eunyoung Choi[3], Tae Hyun Hwang[3]

[1]Surgery Department, Vanderbilt University Medical Center, Nashville, TN,[2]Vanderbilt University, Nashville, TN,[3]Vanderbilt University Medical Center, Nashville, TN,[4]LG AI Research, Seoul, Korea, Republic of

Background: Enhertu (trastuzumab-deruxtecan) is a HER2-targeting antibody-drug conjugate (ADC) that has demonstrated remarkable efficacy in HER2-positive cancers. Its design features a GGFG tetrapeptide linker that is selectively cleaved by lysosomal enzymes such as cathepsins to release the potent cytotoxic payload, deruxtecan (DXd). However, the precise intracellular trafficking, timing of linker cleavage, and kinetics of payload release remain poorly understood. This study aimed to elucidate these mechanisms using advanced 3D imaging platforms.

Methods: HER2-positive NCI-N87 and HER2-negative AGS gastric cancer cell lines were used for comparative analysis. Enhertu was labeled with Alexa 647 dye using a commercial labeling kit. Cells were stained with LysoTracker and treated with fluorescence labeled Enhertu, followed by 3D correlative imaging with holotomography (HT) and multichannel fluorescence imaging machine (HT-X1 Plus; Tomocube). The target specificity of Enhertu was confirmed by pretreating cells with an excess of trastuzumab before Enhertu treatment. HER2-positive gastric cancer organoids (SC128) were cultured in both 2D and 3D conditions. After Enhertu treatment, 3D HT and fluorescence imaging were taken, followed by HER2 immunofluorescence staining after fixation.

Results: Enhertu selectively bound to the plasma membrane of NCI-N87 cells, followed by internalization and subsequent merging with lysosomes, as visualized by LysoTracker staining. Blocking experiments validated the HER2 specific binding of Enhertu. Enhertu demonstrated higher cytotoxicity in HER2-positivie NCI-N87 cells compared to HER2-negative AGS cells and induced a bystander effect in co-culture, highlighting its potential to overcome tumor heterogeneity. In SC128 organoids, Enhertu bound to apical regions with strong HER2 expression and gradually internalized into the organoid interior. Prolonged exposure disrupted the organoid membrane and led to cell death, consistent with DXd-mediated cytotoxic effects.

Conclusions: This study provides a comprehensive analysis of Enhertu's intracellular trafficking and functional mechanisms. Using 3D holotomography and multichannel fluorescence imaging, we visualized the processes of HER2-specific binding, cleavage by lysosome, and DXd release. These findings will enhance our understanding of ADC mechanisms and offer valuable insights for optimizing future ADC designs to improve therapeutic efficacy.

#0717 Advancing spatial oncology research with open-panel multiplex IHC/IF using a novel heat-free antibody stripping reagent.

Shuhui Chen, **Erika Leonard**, Shamali Roy

Vector Laboratories, Inc., Newark, CA

Purpose: Spatially resolved multiplex immunohistochemistry (IHC) and immunofluorescence (IF) assays are essential for profiling the tumor microenvironment and identifying biomarkers that predict response to cancer immunotherapies, yet many platforms rely on proprietary closed antibody panels and harsh, heat-based stripping that damage FFPE tissue and reduce antigenicity, limiting target choice and rapid adoption of new markers. We developed a heat-free stripping reagent that removes primary and secondary antibodies and other non-covalently bound detection reagents between staining cycles while preserving tissue architecture and antigen integrity. This abstract summarizes its performance in multiplex IHC, IF, and tyramide-based workflows and its compatibility with common autostainers.

Experimental Procedures: FFPE tumor and normal tissues were stained using sequential multiplex IHC, IF and TSA workflows in both manual and automated staining, with panels targeting immune, stromal, and tumor markers. After each staining round, slides were treated with the heat-free reagent before the next cycle. Residual signal was assessed by imaging previously used channels after stripping and by chase experiments to detect previously applied antibodies. Antigen preservation was evaluated by comparing staining intensity and distribution for the same targets across early and late cycles, and morphology by H&E.

Summary of New Data: The stripping reagent consistently removed bound antibodies and associated detection reagents, with no detectable residual signal in previously used channels. Across multiple sequential rounds, key tumor and immune markers maintained expected expression patterns and subcellular localization, with no appreciable loss of antigen detectability. Tissue morphology remained intact after repeated stain-strip cycles. The reagent performed robustly in chromogenic IHC, IF, and TSA multiplex workflows, enabling multi-marker panels on a single section without cross-reactivity or signal carryover. Protocols were easily adapted to autostainers, integrating into translational and biomarker pipelines.

Conclusions: This heat-free stripping reagent enables robust multiplex IHC, IF, and TSA staining on FFPE tissue while preserving morphology and antigenicity across multiple sequential cycles and is readily adaptable to autostainers. It simplifies adoption of multiplex panels in oncology research, conserves clinical specimens, and enables deeper characterization of the tumor immune microenvironment and biomarkers for precision oncology. Unlike closed multiplex platforms, it is compatible with investigator-selected antibodies and detection reagents, supporting flexible panels that keep pace with evolving oncology targets.

#0718 Novel characterization of tumor transport dynamics using Cross-Voxel eXchange Model and DCE-MRI.

Janny Kim[1], Noha Sinno[2], Michael Milosevic[2], Catherine Coolens[2]

[1]University of Toronto, Toronto, ON, Canada,[2]Princess Margaret Cancer Centre, Toronto, ON, Canada

Despite significant advances in oncology, tumor heterogeneity continues to drive inconsistent responses to emerging therapeutics. Biophysical features of the tumor microenvironment (TME) - particularly elevated interstitial fluid pressure (IFP) and reduced hydraulic conductivity (K) generate outward convective flow that limits drug and tracer transport, contributing to resistance. Improved characterization of these parameters is essential for understanding TME-mediated barriers across tumor sites. In this work, the diverse ME180 tumor microenvironments were evaluated to test the ability of the Cross-Voxel eXchange Model (CVXM) to quantify transport properties and elucidate dynamic interactions between the TME and pharmacokinetics.ME180 cervical carcinoma xenografts were established in orthotopic, intramuscular, and subcutaneous sites in immunodeficient NRG mice. CVXM applied to 7T DCE-MRI (Biospec, Bruker) yielded voxel-wise estimates of extravasation, convection (velocity), diffusion, and hydraulic conductivity. Direct IFP measured with a solid-state transducer and ex vivo hydraulic conductivity measurements were used to validate CVXM-derived K. A subset of orthotopic tumors received fractionated radiotherapy (RT): 5×5 Gy (SmART+, Precision), and DCE-MRI acquired five days post-RT was used to assess CVXM sensitivity to RT-induced TME changes.CVXM produced spatial maps of key transport parameters (extravasation, tracer velocity, diffusion, and hydraulic conductivity) across tumor models. Extravasation ranged from 0.002-0.084min^{-1}, peripheral velocity from 0.91-6.8μm/s and mean diffusion from 168-250$μm^2/s$, all within reported physiological ranges. CVXM-derived K strongly correlated with convection-derived velocity (R^2 = 0.49-0.65, $p < 0.001$), with mean values ranging from $9.96×10^{-8}$ to $3.88×10^{-7}cm^2/(mmHg·s)$, consistent with previously published ME180 measurements. Following RT, orthotopic tumors exhibited a 12% reduction in IFP, accompanied by a 49% decrease in tracer velocity and a 29% decrease in CVXM-derived K at five days post-RT. These data indicate that CVXM provides a non-invasive means to characterize transport behavior within tumors and to detect biophysical changes resulting from treatment.These findings demonstrate that CVXM provides a non-invasive, imaging-based platform for quantifying tumor transport properties and detecting treatment-induced shifts in TME biophysics. By linking radiologic transport metrics with underlying physiology, CVXM offers a translational tool for monitoring therapy response and identifying biophysical biomarkers relevant to drug delivery and radiation efficacy.

#0719 A multi-scale imaging pipeline identifies regions of NMII activation in colorectal cancer which promote tumor survival.

Derek H. Abbott[1], Bassel Dawod[2], Arely Perez Rodriguez[2], Tai Ngo[1], Gaudenz Danuser[3], Kevin M. Dean[1], Todd A. Aguilera[2]

[1]Lyda Hill Department of Bioinformatics, UT Southwestern Medical Center, Dallas, TX,[2]UTSW, Dallas, TX,[3]UT Southwestern Medical Center, Dallas, TX

The aim of this study is to define the spatial activation of non-muscle myosin II (NMII) in colorectal cancer (CRC) and determine how it promotes tumor survival. Our lab has identified curvature-sensing, pro-survival signaling hubs that form at the base of ROCK1/NMII-driven blebs in low-adhesion environments. Adoption of this weakly adherent, highly contractile amoeboid phenotype is associated with metabolic shifts and immunosuppression that worsen prognosis. However, these observations come largely from mouse models and have yet to be validated in human disease. We hypothesize that, in human CRC, elevated actomyosin contractility sustains tumor survival in poorly adherent regions by activating ROCK1/NMII signaling and reducing tumor-immune cell engagement. To test this hypothesis, we developed a cyclic multiplexed immunofluorescence panel (CODEX) and applied it to a CRC tissue microarray and whole-slide CRC specimens. The panel included markers of cell identity, metabolism, proliferation, and immune activation. Spatial analysis was performed using SPACEMAP, a consensus machine-learning platform that integrates multiple phenotyping algorithms to improve cell-type classification accuracy. To characterize nanoscale architecture, a 30-µm section adjacent to each CODEX-imaged slide was embedded in a hydrogel, expanded, and imaged using Axially Swept Light-Sheet Microscopy (ASLM). Expanded volumes were registered to the multiplexed immunofluorescence dataset, enabling subcellular analysis with ~80-nm isotropic resolution. 3D segmentation and morphological quantification were performed using u-Segment3D. Active NMII (pMLC2) signal in the tumor epithelium was observed in 25% of CRC cases, localizing to discrete regions with reduced cell-cell adhesion, including necrotic zones, mucin pools, luminal surfaces, and isolated tumor cells. pMLC2-high tumor cells exhibited decreased proliferation and increased mitochondrial abundance. Strikingly, both granulocytes and cytotoxic T cells also demonstrated elevated pMLC2 expression, and these pMLC2-high immune cells showed increased markers of immunosuppression. Registration of CODEX and ExASLM datasets enabled high-resolution assessment of membrane architecture, revealing distinct alterations in tumor cell morphology and cell-cell interfaces within pMLC2-high niches. Together, these findings demonstrate that CRC tumors upregulate pMLC2 within low-adhesion microenvironments, supporting tumor survival through coordinated changes in proliferation, metabolism, membrane architecture, and immune engagement. This work identifies spatially regulated actomyosin contractility as a critical survival program in CRC and highlights it as a potential therapeutic vulnerability.

#0720 Nerve innervation in solid tumors.

Hui Yu[1], Aglaia Schiza[1], Victor Ponten[1], Viktoria Thurfjell[1], Amanda Lindberg[1], Julia Sidenius Johansen[2], Ulrike Segersten[3], Anca Dragomir[1], Bengt Glimelius[1], Artur Mezheyeuski[4], Astrid Borretzen[5], Yun-Fan Sun[6], Lars A. Akslen[5], Patrick Micke[1], Carina Strell[5]

[1]Department of Immunology, Genetics and Pathology, Uppsala University, Uppsala, Sweden,[2]Herlev Hospital, Herlev, Denmark,[3]Department of Surgical Sciences, Uppsala University, Uppsala, Sweden,[4]Molecular Oncology Group, Vall d'Hebron Institute of Oncology, Barcelona, Spain,[5]CCBIO, Department of Clinical Medicine, University of Bergen, Bergen, Norway,[6]Liver Surgery & Transplantation, Zhongshan Hospital, Shanghai, China

The role of nerve innervation in cancer progression remains highly debated. While various in vitro and in vivo models suggest that tumor cells can actively induce neoneurogenesis, tissue-based evidence remains sparse. In this project, we critically examine the hypothesis of tumor-associated nerve innervation by seeking direct, tissue-based evidence of nerve innervation and sprouting in relation to histopathological tumor features.Our study cohort comprises diagnostic FFPE whole-tissue samples from six solid tumor types: breast cancer (Luminal A/B, HER2+, TNBC), non-small cell lung cancer (adenocarcinoma, squamous cell carcinoma), colorectal cancer, pancreatic cancer (PDAC and periampullary adenocarcinoma), prostate cancer, and urinary bladder cancer.Nerve structures are identified via multiplexed immunofluorescence and multispectral imaging, targeting neurofilament light chain (NFL, 70 kDa) and growth-associated protein 43 (GAP43). To delineate the tumor microenvironment, additional markers include CD34 (perineural sheath), CD31 (endothelial cells), CD3 (T-cells), and pan-cytokeratin (tumor cells). We developed both a deep-learning-based algorithm and a thresholding approach to segment nerve fibers and characterize their spatial organization. A custom Python script quantifies nerve density (nerves/tumor area), nerve size (μm²), and the integrity of the perineural sheath via CD34 staining. In parallel, we are constructing 3D nerve reconstructions by aligning and analyzing 30 consecutive 4 μm sections using tailored Python tools.Perineural invasion, as defined as direct contact between tumor cells and nerves, is most frequently observed in tumors from highly innervated organs such as PDAC and prostate cancer, while appearing only sporadically in the other tumor types.In subsequent analyses, nerve features will be systematically correlated with histopathological tumor characteristics, microenvironmental profiles, and clinical data. Ultimately, this study aims to generate a comprehensive atlas of nerve-tumor interactions in human cancer and to delineate both shared and tumor-type-specific patterns of innervation and perineural invasion.

#0721 High-plex 3D imaging of the tumor-immune microenvironment.

Peter Karl Sorger[1], Clarence Yapp[2], Alex Wong[2], Yi Daniel Lu[2]

[1]Dept. of Systems Biology, Harvard Medical School, Boston, MA,[2]Laboratory of Systems Pharmacology, Harvard Medical School, Boston, MA

Solid tumors evolve in competition with the immune system and must attract resources such as nutrients and oxygen to proliferate and invade normal tissue. This results in complex spatial distribution of tumor, immune, and stromal cell types within the tumor microenvironment (TME). Regulatory interactions among these cells involved in tumor progression and response to therapy are found on a wide range of length scales from subcellular membrane domains (involved in autocrine signaling between PD1 and PDL1 for example) to extended structures spanning thousands of cell diameters such as lymphoid aggregates and tumor invasive boundaries. Highly multiplexed tissue imaging (spatial proteomics), in combination with other single cell methods, promises to reveal the composition and regulation of these TME features in molecular detail but the great majority of data collected to date, including all classical histopathology based on hematoxylin and eosin (H&E) and immunohistochemistry (IHC), involves thin 2D tissue slices. We have recently demonstrated that no cells in such 5 micron tissue section are intact and that this substantially impacts cell type identification and interaction analysis (Yapp...Sorger et al (2025) *NatMeth,* PMID: 41023436). We will now describe the development of a suite of computational and experimental methods for performing 3D image-based profiling of human tumor sections at different resolutions and spatial scales ranging from ~50 micron thick (with confocal imaging) to 1 mm thick (with cyclic light sheet microscopy). Thick section 3D cyclic immunofluorescence (CyCIF) makes it possible to map cell-cell interactions based on the proximity of cell membranes rather than simply the location of nuclei, as commonly done in spatial tissue analysis. Moreover, by performing 50-plus marker, high resolution (below 200 nm), thick section CyCIF we are able to infer dynamic biological processes using fixed time data and trajectory analysis. Chief among these processes is T-cell mediated cytotoxicity as assayed by formation of immune synapses and polarized secretion of granzyme and/or granulysin containing vesicles toward tumor cells. To date, light sheet fluorescence microscopy (LSFM) has been applied primarily to the analysis of tissues in model organisms (particularly mice and fish) with structures of interest labelled either by fusion to fluorescence proteins or by injecting dyes. We have now developed methods to perform cyclic LSFM on human FFPE tissue, enabling large multi-cellular assemblies to be studied in detail. We will describe an analysis of secondary and tertiary lymphoid structures and their roles in programming B and T cells for anti-tumor immunity. Finally, we will describe how different types of 3D profiling can be combined to span the diversity of spatial scales and regulatory interactions within the human TME.

#0722 Discovery of an evolutionarily conserved GPCR-like protein shaping glioblastoma cell networks.

Jennifer Arcuri[1], Bruno Colon[2], Shraddha ChandThakuri[3], Daniel Isom[1]

[1]University of Miami Sylvester Comprehensive Cancer Center, Miami, FL,[2]3Molecular and Cellular Pharmacology Graduate Program, University of Miami, Miami, FL,[3]University of Miami Miller School of Medicine, Miami, FL

Glioblastoma multiforme (GBM) is among the most aggressive and lethal brain cancers, and despite advances in surgery, radiation, and chemotherapy, median survival remains approximately 20 months. A defining morphological feature of GBM is the formation of tumor microtubules (TMs), thin cytoplasmic extensions that create open-ended channels between tumor cells. These structures transform isolated GBM cells into a coordinated multicellular network capable of rapidly transferring cytoplasmic components across distance, reshaping tumor behavior and promoting therapy resistance. Using AI-driven structural approaches, our lab identified TM184C, an ancient GPCR-like protein that regulates autophagy and the formation of intercellular connections and transcellular material and organelle transfer. Notably, HEK293A cells overexpressing TM184C generate intercellular connections that phenocopy the TM184C-positive structures and vesicle distributions observed in patient-derived GBM cells. Given these findings, and the observation that TM184C expression correlates with poor prognosis in GBM, we will report on our efforts to define how TM184C contributes to GBM projections, intercellular connectivity, and tumor progression.

#0723 Geometry and orientation influences beam hardening in a new high-throughput bone imaging cassette system for microCT.

James Tseng, Max Harlacher, Alex Allphin, Jeffrey D. Peterson, Jeroen Hostens, Tomasz J. Czernuszewicz, Wendy Harrop, **Zachary H. Houston**

Revvity, Waltham, MA

Primary and metastatically derived bone cancers can significantly change bone structure and composition. Visualization and quantification of changes in bone morphology and bone mineral density using high-resolution microCT is a key diagnostic measurement of disease progression and treatment efficacy. The scan quality needed to measure small changes within internal bone structures of mice requires a smaller field of view and longer imaging times across high quantities of samples. Bones are also individually scanned to ensure data quality is not corrupted by beam hardening, a well-known microCT artifact that can reduce the accuracy of calibrated density measurements. In this study, we found that the geometry and corresponding orientation of multiple bones within the field of view are crucial to ensure accurate quantification of cortical bone. By combining the fast-scan rates of the Quantum GX3 microCT (Revvity, Inc.) and a high-capacity (18) bone holder, we report a high-resolution/high-throughput (6 µm, 40 s/bone) microCT imaging methodology, without sacrificing statistical significance in quantification of cortical bone due to beam hardening. To confirm the optimal configuration, healthy bones harvested from age-matched mice with similar mean HU values for cortical bone were arranged in different patterns (2/3/6 bones) in a customized, 3D printed bone holder using low a density plastic scaffold. As a reference, the same bones were scanned individually to compare the effect of beam hardening attenuation in cortical bone (defined as >3000 HU). The mean HU values for each bone's cortical tissue were used to assess the effect of the geometry of one (control), two, three and six bones. Each configuration was scanned in the same field of view (18 mm), time (4 mins) and resolution (6 µm) at soft (70kV, 160 µA,1.0 mm Al filter) and hard (85 kV, 140 µA, 0.5/0.06 mm Al/Cu) x-ray conditions. Calculated HU values (Analyze 15) and the dimensions of the stage and bore were used to design and 3D-print three interlocking cassettes, each with a capacity of six bones for a total of 18 per image. In both hard and soft x-ray images measurable differences in mean HU values were observed, confirming the influence of beam hardening is directly influenced by the geometry of the bones in the holder; however, when compared to the control, a maximum of 4% or 5% difference was observed for any bone in hard and soft x-ray conditions, respectively. Our results show potential for high-throughput and accurate quantification of high-resolution bone scans in the Quantum GX3 microCT. Future work will focus on refining the cassette's design to improve sample loading, evaluating time savings, increasing flexibility in sample type, and providing seamless software integration with AI-enabled segmentation tools.

#0724 Engineered synthetic nano-composite hydrogels as tunable SERS substrates for biomolecule detection.

Harlie G. Rios[1], Cason M. Hancock[2], Swarna Ganesh[2]

[1]Biomedical Engineering, University of Arizona, Tucson, AZ,[2]University of Arizona Cancer Center, Tucson, AZ

The development of reproducible and sensitive plasmonic materials is essential foradvancing single-molecule detection using surface-enhanced Raman spectroscopy (SERS),specially for label-free biomedical sensing and cancer diagnostics. We fabricated silvernanoparticle–embedded hydrogels that are stable, active SERS substrates enabling highlysensitive, label-free molecular analysis. SERS enhances Raman scattering by placing targetmolecules in close proximity to a roughened metallic surface, generating localized surfaceplasmon resonances that amplify the Raman signal. Silver, which induces strong and consistentplasmonic enhancement compared to other metals, and methylene blue, a model analyte forwell-defined Raman peaks, provide a reliable standard for measuring enhancement performance.Silver nanoparticles were synthesized by chemical reduction of silver nitrate ($AgNO_3$),combination of PVP K90 and L-ascorbic acid and the addition of heat to promote nucleation andgrowth before purification into concentrated pellets. Nanoparticle size will be measured usingdynamic light scattering (DLS),and SERS performance was evaluated using methylene blue,which produced characteristic peaks at 770, 1389, and 1620 cm^{-1}. Comparative analysis showedthat the nanoparticle-embedded hydrogels produced stronger signal than conventional Ramanmeasurements, confirming effective SERS amplification for low-concentration biomoleculardetection.Hydrogel matrices made from poly(ethyleneglycol)diacrylate (PEGDA)provided ahydrated, tunable backbone that uniformly dispersed and stabilized the nanoparticles.Optimization efforts targeted UV curing time, PEGDA concentration, and nanoparticle loadingto maintain structural integrity and maximize signal enhancement. By varying nanoparticle sizeand comparing reducing agents such as L-ascorbic acid and sodium borohydride, we found thathigher particle concentrations did not always improve SERS intensity, underscoring the need tooptimize particle size and distribution for effective plasmonic coupling.In conclusion, the PEGDA–silver composite hydrogels functioned as robust,reproducible, and tunable SERS substrates for label-free molecular sensing with clear potentialfor cancer diagnostics. Optimizing nanoparticle synthesis, reduction chemistry, and hydrogelformulation improved both sensitivity and structural stability. Demonstrating a promisingpotential for future SERS-based chemical and diagnostic applications.

#0725 *In-vivo* fluorescence lifetime tomography for detection and quantification of programmed death ligand-1.

Rahul Pal[1], Murali Krishnamoorthy[2], Xin Liu[3], Satoru Morita[3], Atsuyo Morita[4], Hak Soo Choi[3], Dan Duda[5], Anand T. N. Kumar[1]

[1]Otolaryngology - Head and Neck Surgery, Mass Eye and Ear, Boston, MA,[2]Biomedical Engineering, Indian Institute of technology, Madras, India,[3]Massachusetts General Hospital, Boston, MA,[4]MGH, Boston, MA,[5]Houston Methodist Academic Institute, Houston, TX

Programmed death ligand-1 (PD-L1) is the only clinically approved predictive biomarker for cancer immunotherapy; however, its expression is highly heterogeneous and routinely assessed by *ex vivo* immunohistochemistry. To enable spatially resolved, noninvasive PD-L1 quantification, we employed fluorescence lifetime (FLT) tomography with a normalization strategy designed to account for nonspecific probe uptake. C57BL/6 mice bearing orthotopic RIL-175 liver tumors (n=10) were injected with αPDL1-800 (anti-PD-L1 antibody conjugated to IRDye 800CW). 48 hours post-injection, we performed *in vivo* time-domain FLT imaging with co-registered CT, followed by *in situ* FLT imaging and western blotting to validate PD-L1 expression. Bi-exponential fitting of the time-resolved fluorescence data yielded spatial maps of FLT (τ) and amplitude (*a*). The top 10% of FLTs within the tumor were averaged to define the bound lifetime component (τ_b), while the mean FLT in the normal liver was considered as the FLT of the unbound component (τ_u). Amplitudes of bound (a_b) and unbound (a_u) probes were extracted and segmented into tumor (a_b,T; a_u,T) and normal (a_b,N; a_u,N) ROIs. Among four normalization strategies tested, one correcting for background cross-talk (a_b,T - a_u,T) and normalizing by total uptake (a_b,N - a_u,N) showed the strongest correlation with PD-L1 expression (R^2 = 0.77). 3D reconstructions using asymptotic time-domain analysis confirmed accurate tumor localization and size. FLT tomography distinguished bound from unbound αPDL1-800 and enabled quantitative assessment of PD-L1 expression in deep-seated tumors. The normalization method enabled accurate quantification of PD-L1 expression across tumors, supporting the utility of FLT imaging for preclinical immunotherapy evaluation and biomarker-guided therapy monitoring.

#0726 Engineered multiplexed optical sensors to detect inflammatory cytokines in the tumor microenvironment.

Ryan M. Williams[1], Amelia Ryan[2], Syeda Rahman[2], Atara Israel[2]

[1]Medicine, Stony Brook University, Stony Brook, NY,[2]Biomedical Engineering, City College of New York, New York, NY

Inflammation is a hallmark of cancer development as well as a consequence of cancer progression. Chronic inflammatory pathways promote solid tumor growth, metastasis, and immune evasion. Indeed, chronic signaling of several inflammatory cytokines that lead to tumor formation include TNF-alpha, while persistent IL-6 signaling drives cell survival and proliferation as well as angiogenesis. IL-12, however, is a powerful anti-tumor cytokine, which promotes macrophage and T-cell cytotoxicity in addition to inhibiting angiogenesis. Despite their importance, it is difficult to model and monitor real-time inflammatory cytokine signaling in the tumor microenvironment during cancer initiation and progression. The ability to do so non-invasively in animal tumor models would allow for a better understanding of the key drivers of this important cancer hallmark, while the ability to do so in a patient could be a diagnostic and prognostic tool.

To this end, we have engineered a multiplexed optical sensor platform for inflammatory cytokines TNF-alpha, IL-6, and IL-12. Individual sensors are synthesized from species-sorted single-walled carbon nanotubes (SWCNT), which exhibit tissue-transparent near-infrared fluorescence. For each cytokine, we non-covalently attached an antibody or ssDNA aptamer to SWCNT, allowing for molecularly-specific detection and a change in emission spectra upon biomarker binding. We found that sensor performance was quantitative with a limit of detection in the clinical range following inhibition of non-specific surface adsorption with passivation agent polymers and proteins. Further, we demonstrated the ability to detect IL-6 and IL-12, key pro-tumor and anti-tumor cytokines respectively, simultaneously in solution, as well as IL-6 excreted by macrophages in response to pro-inflammatory stimuli. Together, we anticipate further deployment of these inflammatory cytokine monitoring sensors in vivo and translation to patient diagnostic and prognostic profiling.

#0727 Tumor specific induction of surface calreticulin by doxorubicin in pancreatic ductal adenocarcinoma.

Jasmine A. Watts[1], Ronald Watts[1], Chloe La Prairie[2], John B. Rose[3], Rachael Guenter[1]

[1]Surgery, University of Alabama at Birmingham, Birmingham, AL,[2]Pediatric Dentistry, University of Alabama at Birmingham, Birmingham, AL,[3]Surgery, Birmingham VA Medical Center, Birmingham, AL

BackgroundPancreatic ductal adenocarcinoma (PDAC) accounts for most pancreatic cancer cases. Despite advances in surgery and chemotherapy, the 5-year survival rate is only 13%. The aggressive nature of PDAC combined with delayed diagnosis highlights the need for new targeted diagnostic and treatment strategies. Calreticulin (CALR) is an endoplasmic reticular chaperone protein that can translocate to the cell surface under stress conditions such as chemotherapy. We hypothesized that systemic doxorubicin induces tumor specific surface translocation of CALR in PDAC.

MethodsMouse 2838c3 PDAC cells were injected subcutaneously into mice. Once the tumors were palpable, the mice were treated with two intraperitoneal injections of doxorubicin (10 mg/kg) or saline, spaced 48 hours apart and then sacrificed. Tumors and major organs (heart, lung, kidney, pancreas, colon, small intestine, liver, and spleen) were harvested and prepared for either flow cytometry or immunofluorescence analyses. For flow cytometry, tumors and organs were dissociated into non-permeabilized, fixed single cell suspensions and stained with a fixable live/dead dye and an anti-CALR antibody. Immunofluorescence staining was performed under non-permeabilized conditions using an anti-CALR antibody and wheat germ agglutinin (WGA) membrane mask. Signal intensity was quantified in Fiji as integrated density/area. Unpaired t-test with Welch's correction was utilized for comparison.

ResultsDoxorubicin treatment significantly increased surface CALR expression in PDAC tumors compared to saline-treated controls as measured by flow cytometry (3.0-fold increase; $p < 0.05$) and immunofluorescence (1.3-fold increase; 9623 AU ± 522.6 vs. 7341 AU ± 485.9, mean ± SEM, $p = 0.0021$). Increases in surface CALR were consistent across biological replicates. Importantly, there were no significant differences in CALR expression after doxorubicin induction in non-tumor tissues such as liver, spleen, heart, lung, kidney, pancreas, colon, or small intestine via flow cytometry or immunofluorescence analyses.

#0731 From hours to seconds: a new tool for accelerating in vivo rodent imaging data analysis using AI algorithms.
Hannah Sweezo[1], Juan Rojas[1], Thomas Kierski[1], Adam Aji[1], Jessica Pesner[1], Joseph Betthauser[1], Zachary Houston[1], Kyle Kloepping[1], James Tseng[1], Craig McMannus[1], Bincy John[1], Jeffrey Peterson[1], Julia B. Schueler[2], **Ryan Gessner**[1], Tomasz Czernuszewicz[1]

[1]Revvity, Waltham, MA,[2]Charles River Labs, Freiburg, Germany

Background: Advances in noninvasive imaging for cancer research have increased the demand for larger animal cohorts to achieve statistical power. However, in vivo image analysis remains challenging, often requiring skilled users to manually process organs or tumors in 2D and 3D images—a time-intensive task that can take hours to weeks depending on study size. The need to master multiple software platforms for different imaging modalities further extends analysis time, often surpassing image acquisition time.
Methods: To address these challenges, we developed a Python-based multimodal software application designed to accelerate data processing through AI-assisted segmentation and batch analysis across multiple timepoints. Here, we report the performance of the software and multiple integrated AI segmentation models for ultrasound and optical imaging.
Results: Analysis throughput improved by 9x for 3D ultrasound and up to 60x for 2D optical imaging compared to manual workflows. The software demonstrated strong agreement compared to human ground truth segmentations and ex vivo validation standards.
BLI Imaging: Deep learning-based masking showed near-perfect agreement with standard quantification methods ($R^2 = 0.995$ vs circular ROI; $R^2 = 0.996$ vs bounding boxes) while reducing analysis time from 15-20 seconds to ~2 seconds per study.
Ultrasound Imaging: AI-measured spleen size correlated strongly with postmortem spleen weights ($R^2 = 0.93$) and MRI volumes ($R^2 = 0.90$). AI segmentations achieved an average Dice score of 0.89 against ground truth human segmentations with predicted volumes correlating at $R^2 = 0.95$. For subcutaneous tumors, agreement was lower, but still strong when comparing AI versus human segmentations (Dice = 0.82; $R^2 = 0.78$) despite a more challenging heterogeneous echotexture profile.
Conclusions: AI-driven automation significantly accelerates multimodal image analysis without compromising accuracy. These advances highlight the potential of integrated automation to streamline preclinical imaging workflows and enhance research efficiency.

#0732 Enhanced antitumor efficacy of combination therapy via intravesical perfusion in an orthotopic muscle-invasive bladder cancer model.

Balaji Ramachandran, Satheeshkumar Rajendiran, Girish Joshi, Krishnappa Haladasappa

In vivo Pharmacology, Adgyl Lifesciences Private Limited, Bangalore, India

Bladder cancer is a prevalent and aggressive disease with serious health risks if not properly treated. Muscle-invasive orthotopic animal models closely replicate the pathophysiology of human bladder cancer. Orthotopic muscle-invasive bladder cancer model is more technically demanding but essential for translational research. In these models, IVIS-based optical imaging provides a non-invasive and dynamic method to monitor tumor progression in real time. Given the disease's heterogeneity and resistance to therapy, combination treatments are essential to enhance efficacy by targeting multiple oncogenic pathways. In this study, a muscle-invasive orthotopic bladder cancer model was developed in athymic nude rats by injecting T24-Luc cells directly into the bladder wall. A minor abdominal incision exposed the bladder for catheter placement, which was secured with a purse-string suture and tunnelled to the neck, connected to a harness. After recovery, T24-Luc cells were accurately delivered into the bladder wall without leakage. Tumor progression was monitored twice weekly using IVIS optical imaging. Rats were grouped by total flux intensity, then treated via bladder cannulation with Erdafitinib (5µg/mL), Doxorubicin (400µg/mL), Gemcitabine (90µg/mL) as standalone and combination with Erlotinib, delivered through continuous perfusion over a 7-day period. Total flux (photons/second), changes in body weight, clinicals signs, mortality were monitored twice weekly up to 2 weeks. At end of the study, bladder was excised for assessment of treatment efficacy through multiple parameters, including ex-vivo bioluminescence imaging, bladder weight measurement, photographed, and histopathological and IHC analysis. In the current orthotopic muscle-invasive bladder cancer (MIBC) model, treatment with standalone Erdafitinib, Doxorubicin, or Gemcitabine led to moderate tumor regression. Whereas combination of Doxorubicin and Gemcitabine with Erdafitinib demonstrated the highest anti-tumor efficacy, as evidenced by marked reductions in bioluminescence signal intensity, bladder weight. Histopathological analysis revealed no signs of tumor formation or invasion into deeper bladder layers, and the combination therapy significantly prolonged survival compared to individual treatments. Overall, the findings from this study indicate that combination therapy integrating conventional chemotherapeutic agents with targeted FGFR inhibitors significantly enhances anti-tumor efficacy than monotherapies. Continuous intravesical perfusion via bladder cannulation enables localized drug delivery, effectively minimizing systemic toxicity while maximizing tumor exposure and therapeutic impact

#0733 Targeting HCC tumor microenvironment interactions using an advanced HCC patient-derived on-chip model.

Orsola Mocellin[1], Stephane Treillard[1], Abbie Robinson[1], Aleksandra Olczyk[1], Thomas Olivier[1], Chee P. Ng[1], Arthur Stok[1], Giles van Tienderen[2], Monique Verstegen[2], Jeroen Heijmans[1], Dorota Kurek[1], Sebastian J. Trietsch[1], Henriette Lanz[1], Paul Vulto[1], Jos Joore[1], **Karla Queiroz**[1]

[1]MIMETAS B.V, Oegstgeest, Netherlands,[2]Department of Surgery, Erasmus MC-University Medical Center Rotterdam, Rotterdam, Netherlands

Hepatocellular carcinoma (HCC) is the most common type of liver cancer, with rising incidence closely linked to advanced liver disease. Interactions within the HCC tumor microenvironment (TME)—between tumor cells and associated stroma—actively regulate tumor initiation, progression, metastasis, and therapy response. Current in vitro systems often fail to replicate this complex microenvironment, including vascular structures, limiting accurate efficacy evaluation and the translational value of preclinical studies. To address these gaps, we developed a scalable, vascularized 3D HCC patient-derived Organ-on-a-Chip (PDChip) model using the OrganoPlate Graft platform. This advanced system incorporates relevant cellular players of the HCC microenvironment and enables medium- to high-throughput phenotypic drug screening. Approximately 1,200 patient-derived cultures from 8 primary HCC tumors and 2 cell lines were grown under perfusion flow, exposed to 28 treatment conditions—including standard of care (SoC), single agents, and combinations—and assessed for viability, vascular bed responses, and chemokine/cytokine changes. The screen revealed that SoC drugs sorafenib and lenvatinib reduced culture viability and induced profound changes in vascular bed organization, while atorvastatin decreased viability without affecting vascular structures. All three compounds also altered chemokine and cytokine profiles. Tocilizumab, galunisertib, and vactosertib lowered IL6 levels, whereas halofuginone increased IL6. These findings highlight the utility of the PDChip model in visualizing drug-induced responses at both molecular and morphological levels, providing detailed insights into drug effects on specific cellular compartments within the HCC TME. This platform enabled a detailed evaluation of drug-induced responses in the tumor and associated microenvironment, highlighting their importance in preclinical research for understanding diseases and developing new drugs.

#0734 High-content image analysis of colorectal cancer patient-derived tumroids identifies high intra- and inter-patient heterogeneity associated with drug activity and mode-of-action.

Peter W. Eide[1], Nicolas Pasquir[1], Christer A. Andreassen[1], Anne Hansen Ree[2], Knut M Augestad[2], Sebastian Meltzer[2], **Jarle Bruun**[1]

[1]Oncosyne AS, Oslo, Norway,[2]Akershus University Hospital, Lorenskog, Norway

Background: Ex vivo culture of colorectal cancer (CRC) patient-derived tumoroids reveals a rich heterogenous pool of growth morphologies, within and among models. Quantitative analysis of tumoroid morphologies can uncover new biology and predictive relationships. Studies have shown that compact vs. cystic morphology reflects drug sensitivity, with cystic tumoroids being sensitive to Wnt inhibitors and resistant to MEK inhibitors as compared to compact tumoroids.
Methods: Individual tumoroids (n=4049) were annotated based on visual assessment of brightfield, nuclear and nuclear dead stain multi-channel images. ConvNeXt v2 classifiers were trained on the resulting dataset, using brightfield or all three channels as inputs.
Results: We developed a phenotyper algorithm (iCANdy) stratifying CRC tumoroids into 10 classes: compact, budding, acinar, cystic (thick-walled), cystic (thin-walled), invasive, fibroblastic, monolayer, single/apoptotic and mixed/other. Performance was similar for brightfield and multi-channel inputs. Classifying all tumoroids according to the nearest morphology yielded an F1-score of 0.80 and balanced accuracy of 0.75, the most ambiguous class being mixed/other as expected. iCANdy was applied on brightfield images of 10.2 million tumoroids from a total of 22k drug treatment/control wells from 57 tumoroid models, using 37 drugs or drug combinations. For untreated controls, the dominant morphology in terms of total area varied across models with compact (39%), invasive (32%), single/apoptotic (12%), budding (9%), and cystic (thick-walled) (7%) being most common. We observed high intra-patient heterogeneity, the proportion of the dominant morphology ranging from 20% to 54% with a median of 36% (excluding single/apoptotic structures). Inter-patient heterogeneity was also associated with the activity of several drugs. While atorvastatin showed a similar single-oriented shift for both compact (82%) and invasive (100%) structures, other drugs such as 5-FU exhibited strong differences (68% and 18% respectively). Other compounds with limited impact on cell viability induced morphological phenotypes indicating mode-of-actions such as cytostasis or senescence. Interestingly, methotrexate caused an invasive-oriented shift for 80% of the cystic (thick-walled) structures but only 14% of the compact clusters.
Conclusions: Quantitative phenotyping of tumoroids can identify novel predictive morphological relationships, drug mode-of-action and more accurately predict drug activity.

#0735 Establishing diffuse gastric cancer patient-derived organoids for drug response analysis.

Carolina Bizama[1], Patricia Garcia[1], Franz Villarroel[2], Marcelo Garrido[3], Arnoldo Riquelme[4], Nicole Babbitt[5], Gareth-I Owen[5], Enrique Norero[6], Ignacio Carrasco[1], Adolfo Rojas[7], Vinicius Maracaja-Coutinho[7], Yareni Avalos-Guajardo[1], Angel Castillo[1], Juan Carlos Roa[1]

[1]Department of Pathology, Faculty of Medicine, Pontificia Universidad Catolica de Chile, Santiago, Chile,[2]Fundacion Arturo Lopez Perez (FALP), Santiago, Chile,[3]Centro de Oncologia de Precision, Universidad Mayor, Santiago, Chile,[4]Department of Gastroenterology, Faculty of Medicine, Pontificia Universidad Catolica de Chile, Santiago, Chile,[5]Department of Physiology, Faculty of Biological Sciences, Pontificia Universidad Catolica de Chile, Santiago, Chile,[6]Complejo Asistencial Hospital Dr. Sotero del Rio, Santiago, Chile,[7]Facultad de Ciencias Quimicas y Farmaceuticas & Facultad de Medicina, Universidad de Chile, Santiago, Chile

Introduction: Gastric cancer (GC) is a major health problem in Chile, with high incidence and mortality rates, particularly among younger populations. Diffuse GC is the most aggressive subtype, characterized by a poorly cohesive and signet-ring cell features, matching the genomically stable molecular subtype. These tumors are frequently linked to advanced nodal metastasis and peritoneal dissemination. Response to chemotherapy is generally limited, although a subset of GC patients can achieve significant clinical efficacy from first-line immunotherapy (PD-1/PDL-1 inhibitors plus chemotherapy). Patient-derived organoids (PDOs), three-dimensional cultured generated from stem cells, can recapitulate tumor heterogeneity and have emerged as a powerful preclinical model for studying tumor biology and predicting response to anticancer treatments. The aim of this study was to characterize GC PDOs and evaluate their responses to drug treatment.

Material and Methods: Fresh tumor tissues and ascites samples obtained from GC patients were enzymatically dissociated using collagenase/dispase solution and cultured following a modified protocol previously described. PDOs and their corresponding original tissues were characterized using H&E staining, immunohistochemistry, immunofluorescence, and flow cytometry. GC PDOs were then subjected to chemotherapy dose-response assays using oxaliplatin, 5-fluorouracil and irinotecan, and additionally screened against 103 FDA-approved anticancer drugs. After 72 hours of treatment, cell viability was assessed using the CellTiter-Glo 3D assay.

Results: Eight GC PDOs were successfully established from endoscopic biopsies or ascites fluid samples. The PDOs preserved the histopathological features and epithelial polarity of their tumors of origin and retained key mutations, including *TP53* and *CDH1*. The EPCAM-positive organoid population displayed membranous PD-L1 expression ranging from 0.28-75% by flow cytometry. Based on normalized AUC analysis, the PDOs showed heterogeneous responses to standard chemotherapies, and several specific drugs reduced the organoid viability.

Conclusions: The GC-PDOs effectively recapitulated the histological and molecular characteristics of their epithelium tumor of origin and demonstrated differential sensitivity to chemotherapeutic and targeted agents. These findings support the use of GC PDOs as a valuable tool for investigating tumor biology and provide a promising platform for precision medicine approaches in the treatment of diffuse gastric cancer.

Funding: ANID-FONDECYT 1221253, 1221345. ANID-FONDAP-CECAN 152220002, ANID-FONDAP-ACCDIS 15130011.

#0737 Single cell stiffness analysis using a ferrohydrodynamic-microfluidic platform.

Yuhao Zhang, Yang Liu

CMBE, University of Georgia, Athens, GA

Accurate measurement of cell stiffness is essential for understanding how cells adapt to changes in their physical and biological environment, including those associated with cancer progression, immune activity, and tissue remodeling. Conventional techniques such as atomic force microscopy (AFM), optical tweezers, and micropipette aspiration are widely used, but they are limited by low throughput and cannot be readily integrated with molecular analysis. To overcome these constraints, we developed a ferrohydrodynamic microfluidic platform capable of quantifying single-cell stiffness in a high-throughput and label-free manner, while also enabling direct assessment of cytoskeletal protein expression.

In this platform, the magnetic force acting on each cell varies with cell size, ferrofluid concentration, and magnetic field strength. Stiffness is quantified by estimating the forces acting on the cell at its measured position within the channel, including magnetic buoyancy and hydrodynamic drag. To ensure consistent and comparable measurements, cell size was incorporated into numerical simulations used to optimize the channel-width gradient and the resulting force distribution. Simulated magnetic fields and deformation patterns matched experimental results, confirming the mechanical reliability of the system. The device was further calibrated with polyacrylamide gel beads of known elastic moduli to examine how bead stiffness, ferrofluid concentration, and magnetic force distribution affect measurement accuracy.

We evaluated the platform using human cancer cell lines and generated stiffness maps that revealed substantial mechanical heterogeneity within phenotypically similar populations. To explore the relationship between mechanics and behavior, we incorporated a single-cell migration module and compared the stiffness of cells before and after migration. Cells that successfully migrated consistently exhibited lower stiffness, suggesting that increased deformability may facilitate motility. To identify potential molecular contributors, we used immunofluorescence staining and single-cell western blotting (scWB) to quantify vimentin and lamin A/C. Their expression levels varied in patterns that aligned with stiffness differences across individual cells.

#0738 Organoids from primary human prostate cancer exhibit heterogeneity in the states of tumor-associated epithelial cells.

Nilton J. Santos, Larissa C. R. Caldeira da Costa, Fabiana O. Buono, Fabiano P. Saggioro, Antonio A. Rodrigues Junior, Rafael Neuppmann Feres, Rodolfo Borges dos Reis, Jeremy A. Squire, Leticia Frohlich Archangelo

Ribeirao Preto Medical School, University of Sao Paulo (USP), Ribeirao Preto, Brazil

Prostate cancer (PCa) is the most commonly diagnosed malignant tumour in men and the second leading cause of cancer-related mortality worldwide. Despite the high long-term survival rates in localised PCa, metastatic disease remains largely incurable even after intensive multimodal therapy. Our limited understanding of the drivers of aggressive behaviour in advanced PCa and the molecular pathways that underlie their failure to respond to various drug therapies underscores the need to study tumours in vitro so that more effective therapies can be evaluated. Tumour-derived organoids represent an advanced in vitro model for studying cancer and are increasingly being used in the development of new therapeutic strategies, serving as valuable tools for advancing precision medicine in oncology. Our goal was to characterise patient-derived organoids from our prostate samples cohort of the FMRP-USP, which accurately model the original patient tumours. Our approach involved establishing longer-term organoid cultures from biopsy samples in Matrigel. For this, we used 9 fresh prostatectomy tissue samples that were processed by mechanical dissection and enzymatic digestion, then filtered and cultured in advanced DMEM/F12 medium with supplements (GlutaMAX, B27, N-acetylcysteine, recombinant EGF, FGF-10 and FGF-2, A-83-01, SB202190, nicotinamide, DHT, PGE2, Y-27632, Noggin, and R-spondin). Nine patients were aged between 50 and 75 years and diagnosed with high-risk PCa with ISUP grade of 4 or 5 (Ethics Committee Number 88216025.3.0000.5440). The organoids were characterized using morphological 3D imaging and histological (H&E staining, IHC and IF) approaches and compared to the primary sample of the same tumor to confirm their cancer-modelling capacity and suitability for the downstream assays. We successfully established long-term organoid culture for up to 2 months. We verified through characterisation that the organoids presented a morphology and tumour immune profile similar to the tissues of origin. In summary, we have successfully established and characterised long-term patient-derived PCa organoids, which closely recapitulate the original tumours, providing a robust platform for future pre-clinical studies and precision oncology applications.

#0739 Tissue-engineered organ-specific cancer metastasis model for cancer research.

Yi Yin[1], Andrew Z. Wang[2]

[1]Radiation Oncology, University of Texas Southwestern Medical Center, Dallas, TX,[2]University of Texas Southwestern Medical Center, Dallas, TX

Understanding the biology of cancer metastasis is crucial for developing more effective treatments in oncology. A significant challenge in this area has been the lack of cancer models that accurately reflect the biology of metastasis, especially regarding organ-specificity, which is a key feature of cancer spread. This creates a strong unmet need for new models that can mimic the organ-specific dynamics of tumor spread. Our research group has been utilizing tissue engineering techniques to develop in vitro models of cancer metastasis. We hypothesize that decellularized tissues can effectively replicate the organ microenvironment associated with metastatic processes, serving as platforms for tumor cell growth. We had previously reported the use of decellularized liver and lung tissue as strata for tumor metastasis modeling. In this study, we have expanded the model using a panel of decellularized tissues to study the “good soils” and “bad soils” of metastasis. In experiments using several cancer cell lines, we found that tumor cells can spontaneously cluster and form colonies on biomatrices derived from common metastatic sites, such as the liver and lungs, often referred to as “good soil.” Decellularized biomatrices from the upper and lower gastrointestinal tract, and pancreas can also recapitulate the “bad soil” of cancer metastasis. These findings underscore that our proposed model of cancer metastasis is a powerful tool for cancer biology research and has great potential for precision oncology.

#0741 Illuminate your targets: Endogenous HiBiT knock-in monoclones—inventory + rapid custom.

Xiaomeng Gou, Yue Huang, Yu Wang, jinying Ning, **Feng Hao**

Kyinno Biotechnology Co., LTD, Beijing, China

Background & significance — applications HiBiT is an 11-aa tag that complements LgBiT to reconstitute NanoLuc, delivering a bright, linear bioluminescent readout that scales with target protein abundance. Compared with Western blot-centric workflows, endogenous HiBiT knock-ins enable real-time, quantitative kinetics under native regulation, accelerating mechanism confirmation, potency ranking, SAR, and combination design across modalities—PROTACs, molecular glues, LYTACs, and AbTACs.

Kyinno case series — what's in the panel (representative scope) Kyinno has established a broad, ready-to-run portfolio of HiBiT-KI monoclonal cell lines covering more than 30 endogenously tagged genes across diverse biological categories—oncogenic signaling, kinases, transcription factors, and E3-amenable targets. These include representative nodes such as KRAS, CDK family members, PRMT5, EGFR, AR, BRD family proteins, EZH2, STATs, and so on. The panel thus provides comprehensive coverage of major target classes relevant to targeted protein degradation, signal transduction, and transcriptional regulation. Rapid custom knock-in (N- or C-terminal) further extends the platform to program-specific targets and variants, allowing teams to start immediately with inventory models or quickly obtain bespoke constructs.

Methods & deployment — how it works now We implement a dual-stable system: (i) genome-integrated LgBiT to minimize signal drift, and (ii) CRISPR-Cas9 HDR to precisely insert HiBiT at endogenous loci while preserving gene dosage and protein function. Single-cell clones are sequence-verified, STR-authenticated, and mycoplasma-free. Standardized NanoLuc assays (10-point curves, 72-96 h or live kinetic) output quantitative degradation/turnover trajectories with plate-to-plate comparability. This platform compresses assay setup from weeks to days, unifies readouts across targets and hosts, and provides a scalable path from hit triage to translational method transfer—bringing HiBiT quantitation everywhere you need it.

#0742 Unlocking 3D: TumorMACS media as a dual-purpose solution for primary 2D and 3D tumor organoid cultures.

Lea Eich, Marla Schneider, Olaf Hardt, David Agorku, **Benjamin Theek**

Miltenyi Biotec B.V. & Co. KG, Bergisch Gladbach, Germany

Background: 3D cell culture models are gaining more and more interest in cancer research by more accurately mimicking the in vivo tumor environment compared to traditional 2D cultures. These models provide critical insights into tumor biology, including cell-cell interactions, drug resistance, and gene expression profiles. By offering a more physiologically relevant context, 3D cultures enhance the predictive power of preclinical studies, facilitating the development of more effective cancer therapies. As such, the demand for versatile, reproducible, and efficient media that support both 2D and 3D growth is increasingly important in advancing cancer research and drug discovery. Traditional media often lack the versatility required for seamless transitions between 2D and 3D cultures, posing challenges in workflow efficiency.
Methods: We initially cultivated primary colon, lung and breast cancer cells in 2D using the respective TumorMACS media. These cells were transferred into 3D cultures by generating 4x10^5 cells/ml growth factor reduced Matrigel domes (embedded culture) or using 2x10^4 cells/ml TumorMACS medium with 2%(v/v) Matrigel (suspension culture). For each cell line the entity specific TumorMACS media was supplemented with StemMACS Y-27632 and used for bi-weekly media changes, for up to 14 days of culture. Mature tumoroids were dissociated into single cells for doubling time calculations and surface marker analysis using the MACSQuant Analyzer.
Results: The transition from 2D to 3D cultures was successful across all cell cultures evaluated. Embedded cultures showed doubling times of approximately 3 days for colon and breast cells, and 4 days for lung cells. Although static suspension cultures exhibited similar doubling times, they presented greater variability. The higher uniformity in size of tumoroids grown in embedded cultures suggest improved consistency, which is critical for reliable assay results. However, next to the expansion of cells in 2D, suspension cultures can be an attractive alternative to scale cell numbers more efficiently before the assay start.
Conclusion: TumorMACS media's dual-purpose capability enables seamless transitions between 2D and 3D cultures, enhancing research efficiency and accelerating the development of cancer therapies. Its use simplifies experimental workflows and offers a cost-effective alternative to specialized tumoroid media.

#0743 Characterizing organoid maturation and disease progression through recombinant monoclonal antibodies.

Mark Machak[1], Nicole Schultz[1], Rudra Bhowmick[2], Joseph Boyd[1], Fong-Cheng Pan[1], John Larsen[3], Vi Chu[4], Mary Mills[3], Chandra Mohan[1], I-Fang Ling[1], Arazo Saadat[5], **Mark A. Santos**[1]

[1]R&D, MilliporeSigma, Temecula, CA,[2]MilliporeSigma, Burlington, MA,[3]R&D, MilliporeSigma, St. Louis, MO,[4]MilliporeSigma, Milwaukee, WI,[5]MilliporeSigma, Temecula, CA

Organoids are three-dimensional structures derived from either pluripotent stem cells or adult stem cells, consisting of multiple cell types that interact with one another. They are highly sought after for research in organ development, disease modeling, and drug testing. Organoids can be engineered to replicate specific disease conditions, enabling researchers to study disease progression and design therapeutic modalities. We have used recombinant monoclonal antibodies, produced using a proprietary B-cell immortalization technique and a high-yield expression system, for characterizing organoids. These antibodies provide consistent performance across various experimental conditions and exhibit high specificity and sensitivity, allowing for precise detection of target proteins in biological samples. They can be utilized to identify specific cell types during organoid development, study the time-dependent expression of proteins, and analyze the interactions among multiple cell types during development. We have examined organoid development and maturation through immunohistochemistry using selected recombinant antibodies. Immunohistochemistry analysis conducted on normal liver tissue sections, as well as progenitor and mature organoid sections, revealed remarkable staining patterns for targets such as FOXA2, HNF4alpha, and Keratin 7. These applications may significantly enhance our understanding of the mechanisms involved in tissue development and disease progression.

#0744 In vitro and in vivo evaluation of the bystander-killing effect of ADCs.

Chong Wang, Mengya Tong, **Tan Pang**, Jingqi Huang

Pharmacology, Pharmaron, Ningbo, China

Antibody-drug conjugates (ADCs) represent a promising class of therapeutics with a broader therapeutic window than conventional chemotherapeutic agents, owing to their efficient and specific drug delivery. In addition, some ADCs produce a bystander-killing effect through mechanisms such as soluble toxic mediators, gap junction intercellular communication, immune-mediated killing, or Fc-mediated effector functions. This effect benefits not only antigen-expressing tumor cells, but also adjacent antigen-negative cells. Trophoblast cell-surface antigen 2 (Trop-2) is a transmembrane glycoprotein highly expressed in many epithelial cancers and serves as an attractive target for ADC development. In this study, we assessed the bystander-killing effect of two Trop-2-targeted ADCs—sacituzumab govitecan (SG) and datopotamab deruxtecan (Dato-DXd). To evaluate this effect, we used both in vitro co-culture assays and in vivo mixed-cell xenograft tumor models. Three cell line pairs (BxPC-3/UM-UC-3, HCC1806/UM-UC-3, NCI-N87/UM-UC-3) were selected for the in vitro assay based on Trop-2 expression. Dato-DXd exhibited higher payload release in both the BxPC-3 group and the BxPC-3/UM-UC-3 co-culture group compared to UM-UC-3 alone, which showed minimal payload release. In contrast, SG demonstrated similar payload release across all groups. Cell proliferation assays revealed that Dato-DXd had potent cytotoxicity against Trop-2-positive cells (BxPC-3, HCC1806, NCI-N87) but was ineffective in UM-UC-3 cells. Conversely, SG exhibited comparable cytotoxicity across all four cell lines. Notably, Dato-DXd reduced the viability of UM-UC-3 cells in all co-culture groups, with the BxPC-3/UM-UC-3 group showing the strongest bystander effect (80% inhibition of UM-UC-3 cells). Unlike Dato-DXd, SG exhibited strong cytotoxicity in both co-culture and UM-UC-3 groups. A similar observation was made in vivo using a mixture of BxPC-3 and UM-UC-3-Luc cell line-derived xenograft model, with tumor volume monitored via imaging. These results demonstrate that co-culture systems and in vivo imaging are valuable tools for ADC drug discovery. Both in vitro and in vivo assays are essential for understanding bystander-killing mechanisms and predicting clinical success.

#0745 Immunopeptidomic profiling of OncoPro tumoroid models enables MHC-I enrichment and neoantigen target discovery.

Pradip Shahi Thakuri[1], Logan Wilson[1], Colin D. Paul[1], Chris Yankaskas[1], Shyanne Salen[1], Anastasia Klenke[2], Fernanda Salvato[2], Tonya Pekar Hart[2], Joanna S. Geddes[2], Dominique Figueroa[3], Kevin Yen-Yu Yang[3], Bhavin B. Patel[2], Matthew R. Dallas[1], David Kuninger[1]

[1]Cell Biology, Thermo Fisher Scientific, Frederick, MD,[2]Thermo Fisher Scientific, Rockford, IL,[3]Thermo Fisher Scientific, San Jose, CA

Cancer immunotherapy leverages the immune system's capacity to recognize and eliminate tumor cells through peptides presented by major histocompatibility complexes (MHCs). Immunopeptidomics, the large-scale identification of MHC-bound peptides, provides critical insights into tumor antigen presentation and supports the discovery of targets for personalized immunotherapies. Here, we describe a reproducible workflow for enrichment and profiling of MHC-I peptides from patient-derived tumoroid (also known as cancer organoid) models that recapitulate the complexity and heterogeneity of primary tumors. A panel of OncoPro™ Tumoroid Cell Lines was analyzed using LC-MS–based global proteomics. MHC-I profiling demonstrated high enrichment of HLA-A, HLA-B, and HLA-C proteins in the endometrial donor line HuEn033122, which was selected for immunopeptidome characterization. Tumoroids were cultured in OncoPro™ Tumoroid Culture Medium, pre-treated with 10 ng/mL interferon-γ for 18 hours prior to sample collection to enhance expression of MHC-I expression and antigen presentation capacity, and collected as frozen cell pellets. Pellets of ten million cells were processed per the manufacturer's instructions for the different lysis buffers: Thermo Scientific™ Mem-PER™ Plus Membrane Solubilization Buffer, Thermo Scientific™ Pierce™ IP Lysis Buffer, Thermo Scientific™ T-PER Tissue Protein Extraction Reagent, and Thermo Scientific™ Pierce™ GPCR Extraction and Solubilization Buffer. MHC peptide complexes were immunoprecipitated with W6/32 antibody–coupled supports, eluted with 1% TFA, and analyzed by nanoLC-MS/MS on Thermo Scientific ™ Orbitrap™ instruments. Data was analyzed using PEAKS® Studio 12.5 using the DeepNovo Peptidome workflow (6–30 mers, 1% FDR, DeepNovo score ≥ 70%). Immunopeptidomic profiling revealed a dominant 9-mer peptide population (~53%), consistent with canonical MHC-I binding and confirming high-quality enrichment. This 9-mer dominance serves as a robust quality control indicator of workflow specificity and reproducibility. Integration of immunopeptidomic data with whole-exome and RNA sequencing, and bulk proteomics will enable identification of expressed, mutation-derived neoantigens unique to each tumoroid model. Collectively, this platform establishes a physiologically relevant and reproducible approach for neoantigen discovery, advancing precision cancer immunotherapies.

#0746 Modeling micro- and nanoplastics-induced colon aging in organoids to unravel pathways leading to early-onset colorectal cancer.

Zahra Heydari, Gobinda Sarkar, Lisa A. Boardman

Mayo Clinic, Rochester, MN

Background: Early-onset colorectal cancer (EOCRC) is rapidly increasing, with projections that by 2030, one in ten colon cancers will occur in individuals under 50. Unlike hereditary syndromes, most EOCRC cases are sporadic, implicating environmental and aging-related mechanisms. Accelerated biological aging, characterized by telomere attrition, oxidative stress, and senescence-associated inflammation, is a defining feature of EOCRC. Micro- and nanoplastics (MNPs) can accumulate in the gut, induce oxidative stress, and damage DNA. These processes mirror hallmarks of aging, suggesting that chronic MNP exposure may accelerate colonic epithelial aging and promote EOCRC initiation. Methods: To test this hypothesis, we used patient-derived human colon organoids from normal and polyp tissues. Apical-out organoids, which expose the luminal surface to the environment, were treated with defined polyethylene-derived microplastics (1.7-2.2 µm) and nanoplastics (0.04-0.06 µm) at 0, 1 and10 µg/mL for up to 72 hours. We assessed viability, oxidative stress, senescence markers, and inflammatory cytokines. Telomere length will be quantified by qPCR, and cytokine profiling was performed using Olink proteomics. Results: Live/Dead assays revealed minimal cytotoxicity at 1 µg/mL, while nanoplastics induced greater cell death and oxidative stress at 10 µg/mL. Preliminary data suggest that nanoplastic exposure leads to telomere shortening. Moreover, gene expression analyses showed that nanoplastics triggered stronger mitochondrial and redox stress responses than microplastics, consistent with higher reactivity of smaller particles. Additional experimental groups will be included to validate and expand upon these preliminary findings. Conclusions: Although preliminary, these data point to potential links between MNP exposure and early aging-associated stress pathways in the colon epithelium. Continued refinement of this organoid model, together with expanded sample sizes and multiomic analyses, will be essential for determining whether these early signals represent meaningful contributors to EOCRC risk.
Funding: Individualizing colorectal cancer patient care using the host and tumor telomere phenotype (RO1 CA204013), Curtiss Fund (92541775), C-SiG Core(s): Epigenomics & Spatial Biology Core, and Clinical Core of the Mayo Clinic Center for Cell Signaling in Gastroenterology (P30DK084567)

#0749 Modulating cancer stemness in commercial OCSCC spheroid cultures through microenvironmental stress.

Anuleka Elapavaluru[1], Stephen Keysar[2], Herman Li[1], Antonio Jimeno[2], Minsoo Kim[1], **Farshad N. Chowdhury**[1]

[1]Univ. of Rochester School of Medicine & Dentistry, Rochester, NY,[2]University of Colorado School of Medicine, Aurora, CO

Oral cavity squamous cell cancer (OCSCC) recurrence is linked to cancer stem cells (CSCs), which persist despite treatment. To enable reproducible CSC studies, we established a scalable system using the commercially available ATCC SCC-9 cell line subjected to physical and metabolic stress gradients—standard monolayer, AggreWell spheroids (moderate stress), and ultra-low attachment (ULA) spheroids (maximal stress)—in both nutrient-rich (RMk media) and nutrient-deficient (CSC media) conditions.
SCC-9 cells were expanded in standard tissue culture flasks and seeded at defined concentrations into five experimental conditions: (1) standard attachment monolayer, (2) 24-well AggreWell 400 plates in RMk media, (3) 24-well AggreWell 400 plates in CSC media, (4) ULA plates in RMk media, and (5) ULA plates in CSC media. After four days, spheroids were imaged, dissociated with Accutase, and analyzed for CSC enrichment by flow cytometry. CD44 expression was quantified by median fluorescence intensity (MFI), and increased aldehyde dehydrogenase activity was detected using the Aldefluor assay. MFI for CD44 rose progressively with microenvironmental stress, from 18,340 (monolayer) to 42,924 (ULA plate in CSC media), representing a 2.3-fold increase. The double-positive CSC-like population (CD44high/Aldefluor+) was nearly absent in low-stress monolayer and moderate-stress AggreWell cultures, but increased to 0.12% in ULA RMk and tripled to 0.42% in ULA CSC media. These results demonstrate that both CSC prevalence and marker intensity can be systematically tuned by adjusting physical and metabolic stress.
This protocol allows researchers to enhance CSC-like enrichment in a stepwise manner using a widely available OCSCC cell line. The methodology supports applications in drug testing, differentiation studies, and immune interaction assays, leveraging commercial plates and reagents for reproducibility across laboratories. The dynamic range of CSC induction provides a practical tool for studying OCSCC recurrence and therapeutic resistance.

#0750 Optimization of cancer-associated fibroblast expansion and co-culture with patient-derived tumoroids.

Shyanne Salen, Colin D. Paul, Pradip Shahi Thakuri, Matt Dallas, David Kuninger

Thermo Fisher Scientific, Frederick, MD

Patient-derived 3D cancer models (tumoroids or cancer organoids) maintain key patient-specific mutations and gene expression profiles during in vitro culture. Gibco™ OncoPro™ Tumoroid Culture Medium Kit was developed as an easy-to-use tumoroid culture system for the expansion of tumoroid lines. Consequently, single cell RNA sequencing of established tumoroid models shows decreases in immune, stromal, and endothelial cells compared to the initial tumor samples from which they were derived. The tumor microenvironment (TME), specifically cancer-associated fibroblasts (CAFs), has been shown to contribute to poor prognosis and therapy resistance. Therefore, there is interest in reliably expanding and culturing CAFs from donor cells for integration with tumoroid cultures and in vitro reconstruction of the TME. Here, we optimized culture conditions for CAF generation from donor cancer samples and explored methods for CAF and tumoroid co-culture. We aimed to create a robust workflow to obtain CAFs from dissociated tumor cells procured from Discovery Life Sciences and, when available, fresh tissue resections. Dissociated cells were plated in Gibco™ Human Fibroblast Expansion (HFE) Medium supplemented with 2% Gibco™ Low Serum Growth Supplement in Thermo Scientific™ Nunc™ Multidishes with Nunclon™ Supra Surface. CAFs were passaged when they reached 80-90% confluency and continuously expanded in Thermo Scientific™ Nunc™ EasYFlask™ Flasks with Nunclon™ Supra Surface for up to 8 passages until a bank was established. Flow cytometry was performed on the CAF cultures, and CAFs were identified as being negative for EpCAM, CD45, and CD31. CAFs were considered a line based on morphology, having less than 15% epithelial, endothelial, and immune populations, and obtaining more than 3 cumulative population doublings. We successfully created CAF lines from 5 out of a total of 6 samples, which included lung, breast, and colorectal DTCs or resected tissue. A colorectal tumoroid line was previously engineered with an eGFP lentivirus and used in co-culture studies. CAFs from this same donor tissue were labeled with Invitrogen™ CellTracker™ Red CMTPX and mixed with the engineered tumoroid line. When cultured in suspension in a 50:50 mixture of HFE medium and OncoPro with 2% Gibco™ Geltrex Flex, the stromal cells and tumoroids self-organized with the stromal cells invading around and into the tumoroids, creating large lobular structures after 7 days in culture. In summary, this method can be leveraged for preclinical studies to develop critical new therapies and further explore the role of CAFs in the TME, enabling the investigation of tumor-stroma crosstalk. We anticipate that CAF-integrated models will be valuable for studies exploring mechanisms of drug resistance, metabolic reprogramming, ECM remodeling, and immunomodulation, as well as for evaluating the efficacy of anti-fibrotic or stroma-targeting agents.

#0751 A workflow integrating multi-omics with patient-specific 3D cell models for interrogating precision medicine approaches in clinically-relevant timeframes.

Elahe Minaei[1], Stella Davy[1], **Ali McCorkindale**[1], Peilin Tian[2], Joanna Wasielewska[1], Sean Porazinski[1]

[1]Inventia Life Science, Alexandria, Australia,[2]School of Chemistry and Australian Centre of NanoMedicine, Sydney, Australia

The complexity and heterogeneity of cancers within and between patients has led to the precision medicine paradigm of cancer therapy where treatment should be personalized to individual patients to achieve maximal outcomes. Large scale endeavours such as the NCI-MATCH study [1] have investigated the benefits of tumor DNA sequencing, in order to best match the patient to a targeted therapy for their cancer. These studies demonstrate improved outcomes with matching approaches, but raise questions about genetic influences on drug resistance, suggesting sequencing alone may not be sufficient to guide molecular targeted therapies.

New Approach Methodologies (NAMs) such as tumoroids are patient-derived cancer cells that grow as 3D self-organized, multicellular structures that maintain key characteristics of the patient tumor of origin including genotype and transcriptomic profiles, as well as biological behaviors. These NAMs serve as valuable tools for studying tumor biology and patient-specific responses to various anti-cancer therapies.

Here, we utilize the RASTRUM^{TM} Allegro platform from Inventia Life Science and Gibco^{TM} OncoPro^{TM} colorectal cancer (CRC) Tumoroid Cell Lines (ThermoFisher Scientific [2]) to easily create plug and play patient-derived 3D cell models within synthetic PEG-based hydrogel matrices, which were tuned to mimic the stiffness and ECM composition of CRC tumors. Coupling these biologically-relevant tumoroid models with molecular insights from comprehensive proteomics and transcriptomics characterization, we demonstrate the utility of this workflow for throughput drug screening and determining personalized therapy responses in clinically-relevant timeframes.

Our approach provides a scalable framework for evaluating precision medicine approaches using biologically-relevant patient-derived tumoroids. Future work will focus on the development of processes to support direct dissociation and generation of patient-derived models from specimens from a variety of cancer types. Utilization of the RASTRUM platform in these precision medicine workflows to generate real-time drug sensitivity data, could be leveraged to inform clinical treatment decision making.

#0752 Bioluminescent intestinal reporter organoids as in vitro tools to monitor inflammatory effects of compounds.

Subhashree Kumaravel[1], Carolina J. Sierra[1], Trish T. Hoang[2], Kevin Su[1], Vi Chu[1], Jeong-Hee Lee[2], Helena Borges[2], Thomas Machleidt[2]

[1]MilliporeSigma, Temecula, CA,[2]Promega Corporation, Madison, WI

Intestinal cancer ranks as the second leading cause of cancer-related deaths in the United States, with an anticipated toll of 52,900 fatalities in 2025. Chronic inflammation is a recognized contributor to carcinogenesis. Patients with inflammatory bowel disease, face a 1.7-fold increased risk of developing cancer. Identifying compounds that either induce or mitigate inflammation is crucial for cancer prevention and treatment. Organoids, as in vitro 3D cell culture mimetics of specific organs, provide a more physiologically relevant and reliable human-based model for testing drug efficacy and toxicity compared to traditional 2D cell cultures or animal models. This study focuses on the development and application of bioluminescent intestinal inflammatory reporter organoids to screen and monitor the effects of various inflammatory and anti-inflammatory agents. Healthy intestinal organoids from induced pluripotent stem cells (iPSCs) or patient-derived tissues were transduced with the NF-kB nanoLuc® reporter plasmid, enabling luminescence-based monitoring of NF-kB activity. We employed lentiviral (LV) and adeno-associated viral (AAV) delivery systems to create stable and assay-ready NF-kB reporter organoids respectively. The successfully transduced organoids were assessed in both 3D and 2.5D formats to evaluate the impact of different inflammatory and anti-inflammatory compounds. To measure the activation of NF-kB, we utilized the Lumit® immunoassay to detect phosphorylated p65 levels. Protein and mRNA levels of various secreted and intracellular cytokines and chemokines were quantified through immunoassays and RT-qPCR. Stable NF-kB NanoLuc reporter organoids were established via LV transduction at a multiplicity of infection of 1000, followed by puromycin selection. Additionally, we generated transient, assay-ready reporter organoids using AAV serotype 3. Among the cytokines analyzed, the highest reporter activity was observed following treatment with a cocktail of TNFα, IL-1β, and flagellin at 3- and 6- hours post-treatment. The increase in intracellular phospho-p65 levels correlated with the observed reporter activity. Furthermore, NF-kB activation resulted in significant upregulation of other intracellular and secreted cytokines, including CXCL8, IL-1β, and TNFα. Importantly, treatment with established anti-inflammatory agents, such as Tofacitinib, led to a reduction in elevated reporter activity and downstream cytokine levels. In conclusion, the bioluminescent intestinal NF-kB reporter organoids developed through our optimized protocol represent a high-throughput platform for effectively monitoring the inflammatory effects of potential drug candidates.

#0039 Single-cell dissection of ESCC identifies targetable cells-of-origin and therapeutic vulnerabilities in early tumorigenesis.

Kyung Pil Ko[1], Jie Zhang[1], Sohee Jun[1], Jae-Il Park[2]

[1]UT MD Anderson Cancer Ctr., Houston, TX,[2]Asst. Professor, Exp. Radiation Oncology, UT MD Anderson Cancer Ctr., Houston, TX

Identifying the cells of origin is critical for overcoming therapy resistance and improving early intervention strategies in esophageal squamous cell carcinoma (ESCC). Despite advances in genomic profiling and lineage-trajectory studies, the cellular hierarchies and molecular programs that initiate ESCC remain poorly defined. To address this gap, we applied machine-learning-guided single-cell trajectory analysis to carcinogen (4NQO)-induced ESCC, genetically engineered organoid models, and their normal esophageal counterparts, enabling reconstruction of lineage relationships during early tumorigenesis. Integrating these data with gene regulatory network analysis allowed us to pinpoint transcriptional drivers of tumor initiation, and a transcriptome-based drug repurposing strategy identified candidate compounds capable of targeting these early malignant populations. Our multimodal analyses revealed several distinct epithelial clusters that likely act as cells of origin for ESCC, each exhibiting unique stem- or progenitor-like transcriptional states. Regulatory network analysis highlighted activation of key programs, including PRRX2 and CEBPβ, across these initiating populations. In parallel, the drug repurposing screen identified five candidate compounds, four of which were potent cyclin-dependent kinase (CDK) inhibitors. Correspondingly, CDK inhibitors robustly suppressed ESCC cell proliferation, underscoring their therapeutic potential. Together, these findings define the putative cells of origin in ESCC and their core regulatory networks, establishing a single-cell-driven framework that exposes actionable vulnerabilities in tumor-initiating populations.

#0040 Integrated transcriptomic and immune-clonal evolution defines stepwise molecular progression in lung adenocarcinoma.

Kang Qin[1], An Qin[2], John V. Heymach[3]

[1]University of TEXAS, MD Anderson Cancer Center, Houston, TX,[2]Loyola University of Chicago, Chicago, IL,[3]UT MD Anderson Cancer Center, Houston, TX

Background: Progressive immune remodeling is a hallmark of early lung adenocarcinoma (LUAD) evolution, yet the integrated transcriptional and clonal trajectories underlying this process remain poorly defined.

Methods: Single-cell RNA sequencing (scRNA-seq) data from *GSE189357* and *HDAC000630* were analyzed across 33 lung samples, spanning normal to invasive adenocarcinoma. After quality control (200 < genes < 5,000; mitochondrial < 10%), 187,880 high-quality cells were processed in *Seurat* with Harmony integration, PCA, and clustering (resolution = 0.3). Cell types were annotated using canonical markers and *CellMarker 2.0*. Matched single-cell and bulk T-cell receptor (TCR) repertoires (87 samples from *GSE164789*) were analyzed in *scRepertoire* to quantify clonal expansion, diversity (Shannon, Simpson, D50), overlap, CDR3 length, rare-clone contribution, and TRBV/TRBJ gene usage.

Results: Single-cell transcriptomics resolved 15 major cell types and revealed progressive microenvironmental remodeling. Epithelial, fibroblast, and endothelial lineages expanded from atypical adenomatous hyperplasia (AAH) to invasive adenocarcinoma (IAC), whereas cytotoxic, NK, and dendritic cells declined, indicating immune attenuation and fibrovascular dominance. Stage-specific transcriptional programs showed sequential activation of extracellular-matrix organization, angiogenesis, immune suppression, and oxidative metabolism, capturing the molecular evolution of invasion. Integrated single-cell TCR analysis revealed stage-specific immune compartmentalization and progressive loss of repertoire diversity. UMAP visualization highlighted enrichment of $CD8^+$ cytotoxic and $FOXP3^+$ regulatory T-cell clones with hyperexpanded clonotypes in advanced lesions. Clonal distributions shifted from polyclonal equilibrium in normal tissue to oligoclonal dominance in IAC. Bulk TCR profiling confirmed reduced Shannon and inverse Simpson diversity indices and expansion of high-frequency clonotypes. Clonal overlap analysis demonstrated minimal sharing across lesions, suggesting localized antigen-driven responses. Progressive CDR3 shortening and biased V-J recombination indicated convergent clonal selection along the LUAD continuum.

Conclusions: Integrated single-cell transcriptomic and TCR analyses define a unified trajectory of LUAD evolution driven by transcriptional reprogramming, stromal expansion, and progressive immune restriction. The convergence of epithelial remodeling with oligoclonal T-cell expansion delineates early immunologic bottlenecks and highlights potential therapeutic windows for immune interception.

#0041 Integrative analysis of genomic and transcriptomic data informs precancer progression in the pancreas.

Kathleen Noller[1], Jiaying Lai[2], Daniel Lesperance[3], Ricky S. Adkins[3], Ahmed M. Elhossiny[4], Paola A. Guerrera[5], Kimal Rajapakshe[5], Anirban Maitra[6], Anup Mahurkar[1], Owen White[3], Marina Pasca Di Magliano[7], Michael Ochs[3], Luciane Tsukamoto Kagohara[2], Laura Wood[2], Rachel Karchin[8], Elana Judith Fertig[1]

[1]University of Maryland School of Medicine, Baltimore, MD,[2]Johns Hopkins University, Baltimore, MD,[3]University of Maryland, Baltimore, MD,[4]University of Michigan, Ann Arbor, MI,[5]University of Texas MD Anderson Cancer Center, Houston, TX,[6]NYU Langone, New York, NY,[7]University of Michigan Medical School, Ann Arbor, MI,[8]Johns Hopkins Univ., Baltimore, MD

Pancreatic ductal adenocarcinoma (PDAC) arises from heterogeneous precursor lesions, including intraductal papillary mucinous neoplasms (IPMNs), but the features distinguishing indolent from progressive lesions remain unclear. We performed an integrative analysis of transcriptomic, genomic, and microenvironmental profiles of IPMNs to define multi-omic phenotypes. Using transfer learning, we projected IPMN-derived transcriptional programs onto spatial transcriptomic datasets from IPMNs and pancreatic intraepithelial neoplasias (PanINs). We identified two major phenotypes: one associated with cancer-associated fibroblasts and epithelial-to-mesenchymal transition, shared across IPMN, PanIN, and PDAC; and a second, glycolysis-enriched phenotype with a unique somatic variant profile specific to IPMN. Spatial mapping further revealed grade-specific enrichment of transcriptional programs and distinct interactions with stromal and immune subtypes, underscoring the role of the precancer microenvironment in progression. These findings establish multi-omic phenotypes that unify genetic, transcriptional, and microenvironmental heterogeneity, providing a framework for distinguishing progressive from indolent precancers and a web-based public atlas for future exploration of these data and transcriptional phenotypes.

#0042 Engineering antigen-dependent stability in nanobodies: A bioinformatics tool for tuning intracellular nanobody stability.

Alvin Fu[1], Rohith Leeladharan[2], Junhee Park[3], Shriya Kapila[4], Liuhan Ke[1], Amina Mohamed[5], Cynthia Zhao[6], Radha Manohar Kapgate[1], Anh Leith[1], Jonathan Tang[1]

[1]Center for Integrative Brain Research, Seattle Children's Research Institute, Seattle, WA,[2]Paul G. Allen School of Computer Science & Engineering, University of Washington, Seattle, WA,[3]Information School, University of Washington, Seattle, WA,[4]Nikola Tesla STEM High School, Seattle, WA,[5]University of Washington School of Medicine, University of Washington, Seattle, WA,[6]Department of Statistics, University of Washington, Seattle, WA

Nanobodies, derived from camelid antibodies, are highly prized reagents due to their ability to bind their antigen with high affinity, specificity and due to their ease of genetic expression inside cells. Conditionally stable nanobodies, nanobody variants containing mutations in their sequence, are stable only upon antigen binding, making them ideal biosensors. However, the generalizability of conditionally stable nanobodies depends on contextual interactions between nanobody sequences as well as with their fusion protein sequences. To account for contextual effects and thereby creating an individualized way of engineering nanobody for desired stability modulations, we developed a novel bioinformatics tool based on large language model (LLM) that takes an input nanobody sequence and makes predictions about its intracellular stability. The predictions integrate information about nanobody binding to avoid disruptive mutations, guided by a dataset of 389 nanobody-target interfaces. The LLM was first pre-trained on 1.4 million camelid antibody sequences, then fine-tuned to perform binary classification of intracellular stability, producing an F1 score of 0.8. Generative models were developed using a form of Masked Language Modeling (MLM). Models' predictions were validated using reporter assays and western blot in human cell culture. The tool integrates concepts from LLM, nanobody bidirectional stability modulation, nanobody interface classifications, and web integration of modalities to create a tool that can facilitate biomedical and cancer endeavors in the creation of biosensors against any target intracellular proteins for which nanobodies can be selected. This tool has the potential to greatly speed up biosensor engineering, promoting diverse applications in biomedicine and cancer research.

#0043 Epigenetic-neurotransmitter crosstalk between EZH2 and dopamine D1 receptor signaling in triple-negative breast cancer.

Maciej Pietrzak[1], Xilal Y. Rima[2], Gautam Sarathy[3], Shivani Dhekne[3], Lara Rizotto[4], Dario Palmieri[4], Sanjay Gupta[5], Daniel G. Stover[6], Giovanni Nigita[7], Eduardo Reategui[2], Pierre Giglio[8], Christian Rolfo[7], Eswar Shankar[3]

[1]Department of Biomedical Informatics, College of Medicine, The Ohio State University, Columbus, OH,[2]Department of Chemical and Biomolecular Engineering, The Ohio State University,, Columbus, OH,[3]Division of Medical Oncology, Department of Internal Medicine, Wexner Medical Center, The Ohio State University, Columbus, OH,[4]Department of Cancer Biology and Genetics, The Ohio State University College of Medicine, The Ohio State University, Columbus, OH,[5]Department of Urology, School of Medicine, Case Western Reserve University, Cleveland, OH,[6]OSUCCC - James, Columbus, OH,[7]Division of Medical Oncology, Department of Internal Medicine, Wexner Medical Center, The Ohio State University, Columbus, OH,[8]Department of Neurology, School of Medicine, Wexner Medical Center, The Ohio State University, Columbus, OH

Triple-negative breast cancer (TNBC) remains a clinically intractable subtype defined by the absence of ER, PR, and HER2 and characterized by aggressive progression and limited therapeutic vulnerabilities. EZH2, the catalytic subunit of PRC2, is a known oncogenic driver in TNBC through deposition of H3K27me3 and repression of tumor-suppressive programs. In contrast, dopamine D1 receptor (DRD1) signaling has recently emerged as an unexpected tumor-suppressive axis. However, the mechanistic interplay between EZH2-mediated epigenetic repression and DRD1-mediated neurotransmitter signaling is unknown, representing a critical gap in understanding neuro-epigenetic integration in cancer. We hypothesized that coordinated dysregulation of EZH2 and DRD1 reprograms are transcriptional states that govern TNBC aggressiveness. CRISPR-engineered EZH2 and DRD1 knockouts (KO) were generated in MDA-MB-231 cells and validated by immunoblotting. DRD1 KO significantly increased proliferation and migration, whereas EZH2 KO diminished growth and disrupted cytoskeletal architecture. Notably, DRD1 ablation enhanced EZH2 activity, indicating a previously unrecognized feedback loop linking dopaminergic signaling to epigenetic repression. RNA-seq profiling (n=4/group) revealed extensive remodeling of transcriptional networks with discrete EZH2- and DRD1-dependent signatures (FDR < 0.05, |log2FC| > 2). EZH2 KO selectively induced cytokine activity, calcium ion binding, MHC class II interactions, and biological processes regulating adhesion, cell-cell communication, leukocyte activation, and axon/projection guidance, collectively reflecting cytoskeletal restructuring and immune-modulatory reprogramming. In contrast, DRD1 KO enriched signaling receptor binding, regulator/activator activity, receptor-ligand interactions, and pathways governing adhesion, migration, and IL-10-mediated inflammatory signaling, consistent with a pro-invasive, pro-inflammatory phenotype. Together, these data delineate a coordinated epigenetic-dopaminergic axis in TNBC. DRD1 loss potentiates EZH2-driven inflammatory and migratory programs, while EZH2 depletion activates adhesion and immune-regulatory pathways that constrain tumor aggressiveness. Targeting this dual regulatory node may represent a novel strategy to disrupt pro-tumor transcriptional circuitry and improve therapeutic outcomes in TNBC (Supported by DOD: W81XWH2010065, Eswar Shankar).

#0044 scSubtype2.0: Predictor of breast cancer molecular subtypes at single cell resolution.

Alexander V. Lobanov[1], Hani Jieun Kim[2], Sehrish Kanwal[3], Kate Harvey[2], John Reeves[2], Marcel Batten[2], Beata Kiedik[2], Daniel L. Roden[2], Mun N. Hui[4], Kym Pham Stewart[3], Oliver Hofmann[3], Sandra O'Toole[2], Elgene Lim[2], Sean M. Grimmond[3], Alexander Swarbrick[2], Charles M. Perou[1]

[1]UNC Lineberger Comprehensive Cancer Center, Chapel Hill, NC,[2]Garvan Institute of Medical Research, Darlinghurst, Australia,[3]Collaborative Centre for Genomic Cancer Medicine, Parkville, Australia,[4]Chris O'Brien Lifehouse, Camperdown, Australia

Breast cancer is a heterogeneous disease with distinct clinical and molecular biomarkers used to determine treatment options. The three main clinical subtypes of the disease are Estrogen Receptor (ER+)/HER2-negative, Human Epidermal Growth Receptor 2 positive (HER2+), and Triple Negative Breast Cancer (TNBC). Breast cancer can also be stratified based upon gene expression into four distinct molecular subtypes: Basal-like, HER2-enriched, Luminal A, and Luminal B. These phenotypes are typically assigned using the PAM50 molecular subtyping predictor using bulk-tumor gene expression data. Advances in single cell sequencing now allow researchers to distinguish cell types within tumors and focus on cancerous cells. While PAM50 remains an important biomarker, the algorithm is optimized for bulk-tumor gene expression and performance drops precipitously when applied to individual scRNA-seq cells. An accurate predictor of molecular subtypes of cancer cells at single cell resolution could allow for further exploration into the heterogeneity of breast cancers and their microenvironments.

Previously, we developed a single-cell version of PAM50 called scSubtype, however, it was trained using only 2-3 samples per molecular subtype. Here, we build upon this foundation by greatly expanding our training sample set to 151 breast cancer tumors with matched bulk and single cell RNA-seq. We leveraged this new large-scale dataset to develop scSubtype2.0, an updated cancer cell intrinsic molecular subtype predictor at single cell resolution. We filtered for robust samples of each molecular subtype that have matching bulk and single cell derived pseudo-bulk PAM50 calls, high silhouette width, and high cancer cell content. The final training data is made up of 53 tumors encompassing 118,188 tumor cells and at least 10 tumors per molecular subtype. We performed differential expression analyses to identify single-cell subtype-defining genes (LumA: 60 genes, LumB: 129 genes, HER2-enriched: 231 genes, Basal-like: 271 genes) and used them as a signature to assign each tumor cell to the highest scoring subtype. All training set tumors had 80%+ of their cell calls match their corresponding bulk PAM50 subtype, suggesting our lists encapsulate the full breadth of each molecular subtype. To objectively evaluate the new model's performance and our gene lists, we crafted synthetic, homogenous tumors of each subtype from previously annotated test data set. We show that scSubtype2.0 outputs the correct subtype of the crafted tumors with a 91% accuracy and outperforms its predecessor's classifications. The algorithm continues to be improved and will soon include predictors of additional tumor cell states including the claudin-low/mesenchymal subtype, and a hypoxic state. Overall, we believe scSubtype2.0 is a robust and accurate predictor of molecular subtypes to individual cancer cells and a novel measure of intra-tumor heterogeneity.

#0045 Identification of germline *AEN* polymorphisms as risk factors in cervical cancer.

Golya Shahrokhi[1], Mari Kylleso Halle[2], Vinodh Srinivasasaina-gendra[3], Jianqing Zhang[4], Aishwarya Sundaresan[5], Roshan Kumar[1], Shafiq Shaikh[1], Nichol He[1], Camilla Krakstad[2], Sadeep Shrestha[6], Paul Auer[7], Janet Rader[1], Hemant Tiwari[3], Akinyemi I. Ojesina[1]

[1]Department of Obstetrics and Gynecology, Medical College of Wisconsin, Wauwatosa, WI,[2]Department of Obstetrics and Gynecology, University of Bergen, Bergen, Norway,[3]Department of Biostatistics, University of Alabama at Birmingham, Birmingham, AL,[4]Department of Epidemiology, University of Alabama at Birmingham, Birmingham, AL,[5]Department of Biostatistics, University of Alabama, Birmingham, AL,[6]University of Alabama at Birmingham, Birmingham, AL,[7]Division of Biostatistics, Medical College of Wisconsin, Wauwatosa, WI

Background: Inherited genetic variation contributes 27-36% of cervical cancer risk. While genome-wide association studies (GWAS) and candidate gene approaches have identified both risk and protective alleles, mostly associated with immune and DNA repair pathways, much remains unknown about the role of rare or low-frequency germline variants across the exome.

Methods: We performed gene-based association testing on whole-exome sequencing from blood-derived DNA of 105 Norwegian cervical cancer patients and 263 cancer-free European female controls (1000 Genomes). High-quality and high-confidence variants were identified following GATK best practices for variant calling, and a gene-based sequence kernel association test (SKAT) was performed to identify significant gene-level associations. The presence and linkage of significant variants were further examined in a cohort of 9,286 Norwegian newborn genotypes. To assess the potential functional impact and the effects on cancer risk of the identified variants, vector constructs containing wild-type and variants introduced into C4I cervical cancer cells and cell proliferation rates were measured.

Results: The Apoptosis Enhancing Nuclease (*AEN*), a *TP53*-related gene, showed significant germline association with cervical cancer (SKAT-RC $p = 3.69\times10^{-9}$). The signal was driven by two low-frequency variants, rs61752779 and rs118097475, which were about 9-fold more common in cases than controls. Linkage analysis showed that these two variants were strongly correlated ($r^2 = 0.996$) in cervical cancer patients and similarly linked in the Norwegian newborns ($r^2 = 0.948$). Functional validation revealed that overexpression of the wildtype *AEN* construct in the C4I cervical cancer cell resulted in reduced cellular proliferation. However, overexpression of an *AEN* construct with both variants resulted in increased cell proliferation compared with the wildtype AEN construct.

Conclusions: This study provides both statistical and experimental evidence supporting the role of *AEN* as a tumor suppressor gene and suggests that two highly linked germline variants may contribute to cervical cancer risk.

#0046 High-definition signatures of single-base substitutions in human cancer.

Jessica N. Au[1], Marcos Diaz-Gay[2], Raviteja Vangara[3], Pilar Gallego-Garcia[2], Mousumy Kundu[3], S.M Ashiqul Islam[4], Maria Zhivagui[5], Zichen Jiang[3], Christopher Steele[3], Sarah Moody[6], Michael R. Stratton[7], Paul J. Brennan[8], Ludmil B. Alexandrov[3]

[1]Departments of Bioengineering, Cellular and Molecular Medicine, Moores Cancer Center and BISB, University of California, San Diego (UCSD), La Jolla, CA,[2]Digital Genomics Group, Cancer Genomics Program, Spanish National Cancer Research Center, Madrid, Spain,[3]Departments of Cellular and Molecular Medicine, Bioengineering, and Moores Cancer Center, University of California, San Diego (UCSD), La Jolla, CA,[4]Department of Epidemiology and Biostatistics, College of Integrated Health Sciences, University at Albany- State University of New York, Albany, NY,[5]University of Nevada, Las Vegas (UNLV), Las Vegas, NV,[6]Wellcome Sanger Institute, Cambridge,[7]Wellcome Sanger Institute, Cambridge, United Kingdom,[8]International Agency for Research on Cancer, Lyon, France

Cancer genomes accumulate mutations through diverse biological processes, including defective DNA repair, exposure to carcinogens, and normal aging. These processes leave characteristic patterns known as mutational signatures. Identifying these signatures in patient tumors enables researchers to understand disease mechanisms and infer past exposures.The current standard resource, COSMIC v3.5, catalogs over 90 single base substitution (SBS) signatures using the SBS-96 mutational context, which characterizes each mutation by the substituted base and one flanking nucleotide on each side. This reference is widely used across cancer genomics studies to decode the mutational processes active in tumors. However, challenges have emerged where signatures overlap and can be misassigned, leading to incorrect interpretations of the mutational processes driving individual cancers. While we showed that higher-resolution methods using extended sequence contexts can differentiate these overlapping signatures and reveal novel processes, these findings were limited to specific cancer types such as colorectal, esophageal, renal, and head and neck. Additionally, no comprehensive high-resolution reference currently exists.To address this, we developed a high-definition (HD) mutational signature SBS reference set using over 40,000 whole-genome sequences from 14 cohorts spanning diverse cancer types and non-cancer tissues, including both primary and metastatic tumors. We analyzed mutations at SBS-4608 resolution, combining extended pentanucleotide sequence contexts with strand orientation information. This represents the practical limit of current sequencing technology. Our analysis clarifies several ambiguous signatures from the existing reference, improving accuracy when identifying mutational processes in individual tumors. We also discovered novel signatures that were previously undetectable at standard resolution, revealing new insights into the mutational landscape of human cancers.This HD reference set addresses critical limitations in current mutational signature analysis, enabling more accurate interpretation of mutational processes in cancer genomes and improving the reliability of downstream biological and clinical insights. By providing a comprehensive resource that resolves signature overlaps and reveals previously hidden mutational processes, this work will enhance precision in understanding cancer biology and tumor mutagenesis. The reference will be made publicly available to the research community upon publication.

#0047 Identifying noncanonical sources of cancer neoepitopes using PEPMatch and CEDAR.

Daniel Marrama[1], Ibel Carri[1], Nina Blazeska[1], Randi Vita[1], Hannah K. Carter[2], Morten Nielsen[3], Alessandro Sette[1], Zeynep Kosaloglu-Yalcin[4], Bjoern Peters[1]

[1]La Jolla Institute for Immunology, La Jolla, CA,[2]UC San Diego, La Jolla, CA,[3]Technical University of Denmark, Lyngby, Denmark,[4]La Jolla Institute for Immunology, San Diego, CA

Emerging evidence suggests that immunogenic cancer antigens may originate from the "dark genome", which comprises non-coding regions, alternative open reading frames (ORF), and untranslated regions (UTR), traditionally excluded from most neoepitope prediction pipelines. Consequently, systematic identification and validation of these noncanonical antigens has been technically challenging. To address this gap, we leveraged PEPMatch, a high-throughput peptide search tool, integrated with the Cancer Epitope Database and Analysis Resource (CEDAR) to systematically identify noncanonical sources of experimentally validated neoepitopes. We compiled seven comprehensive human databases encompassing both canonical and noncanonical protein sources: UniProtKB (human reference proteome with isoforms), UniParc (UniProt protein archive), Ensembl canonical proteins (ENSP), validated non-canonical ORFs (ncORF), and three-frame translations of complementary DNAs (cDNA) and non-coding RNAs (ncRNA), and six-frame translations of full gene sequences, including UTRs and introns (ENSG). Using PEPMatch's exact matching algorithm, we performed searches of 28,601 CEDAR neopeptides tested in 40,800 T cell assays against all seven databases.

To validate our pipeline, we first analyzed 840 MHC class I cryptic neopeptides found by mass spectrometry, achieving a total mapping success of 98.33% using a sequential attribution search that revealed an enrichment in noncanonical sources (ncORF: 14.76%, cDNA: 41.55%, ncRNA: 4.76%, ENSG: 1.67%). Out of these cryptic neoepitopes, 5.60% were found in the human reference proteome and 28.93% in the UniParc database prior to the noncanonical sources. Applying this methodology to all 28,601 CEDAR's neopeptides revealed that 1.91% originated from noncanonical sources. We then focused on the relevant subset of 6,394 positive neoepitopes with confirmed immunogenicity from T cell assays. Notably, a significant percentage of these immunogenic positive neoepitopes mapped to noncanonical databases compared with the negative peptides (ncORF: 0.1% vs 0.0%, cDNA: 8.8% vs 2.6%, ncRNA: 1.4% vs 0.6%, ENSG: 3.4% vs 1.5%), suggesting that the 'dark genome' is a source of targetable neoepitopes. The specificity of this mapping approach was validated using randomly shuffled peptide controls, which yielded <1% spurious matches.

These findings demonstrate that PEPMatch successfully identifies noncanonical genomic origins of cancer neoepitopes at scale given the appropriately curated database sources. CEDAR is implementing this annotation pipeline to provide researchers with mappings for dark genome antigens, enabling validation and discovery of unconventional targets for immunotherapy development. This work expands the targetable landscape of cancer immunotherapy by systematically cataloging epitopes from previously overlooked genomic regions.

#0048 Somatic *NFKBIZ v*ariant modulates inflammation at single-cell resolution.

Catherine H. Feng[1], Andrew R. D'Avino[2], Anders W. Rasmussen[2], Dan Landau[3]

[1]Harvard University, Cambridge, MA,[2]New York Genome Center, New York City, NY,[3]Weill Cornell Medical College, New York, NY

The human body is a somatic mosaic, with normal tissue colonized by cell populations carrying distinct mutations. Intriguingly, in tissues affected by chronic disease, such as inflammatory bowel disease (IBD), disease-specific drivers of clonal expansion emerge. IBD is characterized by chronic intestinal inflammation and increased cancer risk. This inflammatory environment exerts selective pressure promoting the growth of clones carrying somatic mutations in IL-17 inflammatory pathway genes. While many such mutations have been implicated in downregulating inflammation and protecting against colitis-associated colorectal cancer, their presence has yet to be characterized at single-cell resolution in solid human tissue. We used SComatic to identify somatic single nucleotide variants in single-cell RNA-sequenced colorectal samples from IBD patients (*n*=204). Among them, we found a novel missense mutation predicted to be highly pathogenic in the ankyrin repeat domain of *NFKBIZ*, which is critical for promoter binding in the IL-17 pathway. *NFKBIZ* is a key regulator of intestinal inflammation and a known driver of clonal expansion in IBD. Notably, while *NFKBIZ* variants are highly prevalent in IBD, they are rarely found in colitis-associated cancer, suggesting this adaptation in chronically inflamed tissue is protective against cancer. Strikingly, we found that the variant appears exclusively in epithelial cells. In this compartment, it exhibited a high variant allele frequency of 0.727, suggesting substantial remodeling of colonic epithelium during chronic inflammation. Functionally, the variant appeared to disrupt IL-17-mediated signaling, as its presence was associated with reduced expression of *DUOX2*, a known IL-17 target gene that causes DNA damage and is frequently upregulated in colonic inflammation in IBD. This shows, for the first time at single-cell resolution in native human tissue, previously hypothesized protective mechanisms driven by somatic *NFKBIZ* mutations. Our work reveals how protective clones emerge in specific cell types in response to chronic inflammation, highlighting how epithelial remodeling can influence IBD disease progression and treatment response.

#0049 The PER3-RORB axis defines a tumor-suppressive circadian state associated with improved survival in head and neck squamous cell carcinoma.

Harold Nathan Tan, Oriol Mirallas, Paul Selvadurai, Michael Wotman, Luana Sousa, Neal Akhave, Khaled Sanber, Renata Ferrarotto, George R. Blumenschein, Maura L. Gillison, Faye M. Johnson, Timothy A. Yap

The University of Texas MD Anderson Cancer Center, Houston, TX

Background: The circadian clock governs DNA repair, cell-cycle progression, metabolism, and stress responses. Circadian disruption has been linked to tumor progression and therapy resistance, yet the clock components influencing prognosis in head and neck squamous cell carcinoma (HNSCC) remain undefined. We sought to characterize circadian dysregulation in HNSCC and identify circadian signatures that predict overall survival (OS).
Methods: RNA-seq, clinical, and survival data from TCGA-HNSCC (n=565) were analyzed using a circadian gene panel comprising core positive regulators (BMAL1, CLOCK, NPAS2, RORA, RORB, RORC) and negative regulators (PER1/2/3, CRY1/2, NR1D1/2). Log_2-normalized expression was z-standardized per gene, and composite positive- and negative-arm scores were generated as mean standardized expression within each panel. Prognostic performance was evaluated using time-dependent ROC curves and multivariable Cox models. Circadian network integrity was assessed using the clock coherence disruption (ΔCCD) metric, comparing clock-gene correlation structure in tumors against a GTEx esophageal mucosa reference across 1,000 permutations. Differential expression between circadian-defined subgroups was evaluated with limma's empirical Bayes-moderated models.
Results: Circadian gene expression was heterogeneous across primary sites and AJCC stages, indicating circadian disruption independent of clinical factors. High RORB (HR= 0.75, p=0.015), and PER3 (HR=0.88, p=0.05) were associated with reduced mortality. In ROC analysis, PER3 and RORB showed modest prognostic discrimination individually (AUC 0.39/0.43 and 0.41/0.47 at 3/5 years, respectively). In contrast, the PER3-RORB composite score (0.52/0.56) outperformed all other circadian metrics. Clock coherence analysis demonstrated preserved circadian correlation structure in PER3-RORB-High tumors (CCD = 0.44) and marked disruption in PER3-RORB-Low tumors (CCD = 0.74), yielding a ΔCCD of 0.31. No permutation replicate exceeded this value (empirical $p < 0.001$), indicating highly non-random network breakdown associated with PER3-RORB loss. PER3-RORB-high tumors showed coordinated upregulation of NPAS2, metabolic and stress-response genes (DHCR24, ABCA1, LRP1, ATP6V1A) and modulation of mitochondrial components (NDUFB6), linking this axis to metabolic and stress adaptation programs.
Conclusion: PER3-RORB defines a biologically coherent circadian state linked to improved survival in HNSCC. While these findings support a tumor-suppressive role for PER3-RORB, independent external validation is required to confirm robustness and clinical generalizability. This work highlights circadian regulation as a mechanistic modifier of tumor behavior and a promising avenue for biomarker development.

#0050 Spatial transcriptomics uncovers patterns of transcriptional reprogramming and immune evasion in small cell lung cancer.

Emmanuel S. Spanos[1], Meng Wang[2], Amin Sabet[2], Esther Redin[2], Charles M. Rudin[2], Joseph Chan[2]

[1]Physiology, Biophysics, and Systems Biology, Weill Cornell Grad. School of Medical Sci., New York, NY,[2]Memorial Sloan Kettering Cancer Center, New York, NY

Histologic transformation from non-small cell lung cancer (NSCLC) to small cell lung cancer (SCLC) is a major mechanism of therapeutic resistance, yet the spatial and molecular programs governing this phenotypic switch remain poorly defined. 10X Xenium In Situ spatial transcriptomics was used to generate subcellular-resolution transcriptomic maps of 22 primary and metastatic lung tumors across 16 patients with SCLC transformation, totaling >10 million cells. Matched single-cell RNA sequencing enabled integrated analysis of transcriptional states and served as a complementary modality to support spatial findings. Spatial profiling with a 389-gene panel encompassing neuroendocrine (NE), epithelial, stemness, immune, and stromal programs revealed 30 distinct cell types and marked inter- and intra-tumoral heterogeneity across lung adenocarcinoma (LUAD), squamous cell carcinoma (LUSC), and small cell lung cancer subtypes (ASCL1+: SCLC-A and NEUROD1+: SCLC-N). Tumors organized into several canonical structural patterns: (1) discrete subtype compartmentalization, (2) speckled NE transformation, and (3) self-contained, multilayered subtype organization.A representative resection of a lymph-node metastasis with SCLC transformation displayed two separate tumor regions, each with a striking radial arrangement. In the first region, admixed LUAD and NOTCH1- SCLC-A formed the tumor core, followed by concentric layers of NOTCH1+ SCLC-A and SCLC-N, with immune cells at the periphery. Given the established role of Notch signaling in SCLC subtype switching, and our observation of inhibitory DLL3-NOTCH1 interactions across neighboring tumor subtypes, these regulatory relationships may contribute to the spatial compartmentalization of tumor subtypes. The second tumor region lacks the LUAD and NOTCH1+ SCLC-A populations, instead composed of a NOTCH1- SCLC-A core encased by SCLC-N, again surrounded by immune zones. Pseudotime analysis of the Xenium data across both regions also recapitulated a trajectory from LUAD to SCLC-A to SCLC-N. These two findings, combined with previous studies characterizing SCLC-N as an “immune-cold” tumor devoid of immune infiltrate, suggest that this spatial patterning and interplay between subtypes may be an important mechanism for immune evasion and progression in a hostile environment.Due to imbalance in cell number and sample area within the cohort, spatial comparisons were constrained to smaller regions of interest (ROIs). Clustering ROI cell-cell adjacency matrices uncovered recurring spatial interaction patterns associated with specific tumor subtypes and microenvironmental states, such as necrosis or immune infiltration. These analyses highlight distinct architectural modes of neuroendocrine transformation and underscore the role of spatial context in shaping phenotypic evolution during resistance.

#0051 RAS(ON) multi-selective inhibition remodels cancer-associated fibroblast subtypes and extracellular matrix in pancreatic cancer.

Lorenzo Tomassoni[1], Allison C. Hess[1], Kevin Munoz Forti[2], Hun Jin Jeong[3], Deanna J. Besart[1], Tanner C. Dalton[1], Urszula N. Wasko[1], Carmine F. Palermo[1], Stephen A. Sastra[1], Chang H. Lee[4], Andrea Califano[1], Simon Schworer[2], Marie C. Hasselluhn[1], Kenneth P. Olive[1]

[1]Columbia University Irving Medical Center, New York, NY,[2]University of Chicago, Chicago, IL,[3]University of Maryland Eastern Shore, Princess Anne, MD,[4]Columbia University, New York, NY

Oncogenic KRAS mutations occur in >90% of pancreatic ductal adenocarcinomas (PDACs) and are the principal drivers of malignant transformation and tumor progression. Sustained KRAS signaling in malignant epithelial cells orchestrates a network of paracrine interactions that define the cellular and extracellular composition of the tumor microenvironment (TME). In the TME, cancer-associated fibroblasts (CAFs) are particularly responsive to KRAS-dependent paracrine signals, including Sonic Hedgehog (SHH), a ligand that is overexpressed and secreted from malignant epithelial cells, thereby driving the proliferation of cancer-associated myofibroblasts. RMC-7977 is a RAS(ON) multi-selective inhibitor that inhibits GTP-bound RAS proteins, including wild type and mutant variants of KRAS, NRAS, and HRAS. It showed broad anti-tumor activity in PDAC preclinical models, extending overall survival of the KrasLSL.G12D/+;Trp53LSL.R172H/+;Pdx1-cretg/+ (KPC) mouse model by more than 3-fold. The KPC mouse model recapitulates the desmoplasia observed in patients, allowing the assessment of KRAS inhibition on stromal composition and function. To study the impact of RAS inhibition in PDAC, we did single cell RNA sequencing (scRNA-seq) on KPC tumors treated with RMC-7977 at multiple timepoints. After a week of RMC-7977 treatment, the dominant CAF subtype in KPC tumors shifted from myofibroblastic CAFs (myCAFs) to inflammatory CAFs (iCAFs). This observation was validated by co-immunofluorescence on tumor sections, which indicated that (PDPN+, αSMA+) myCAFs showed decreased abundance and proliferation whereas (PDPN+, IL6+) iCAF abundance increased. Similar effects were observed ex vivo in human and murine PDAC explants. Mechanistic studies showed that this phenotype was mediated by a downregulation of SHH ligand expression in response to RAS inhibition. We also used the scRNA-seq data to assess the contribution of CAF subtypes to the generation, regulation, and degradation of the extracellular matrix (ECM) in PDAC. We found that myCAFs and iCAFs have both overlapping and distinct roles in the regulation of the ECM and that these were differentially impacted by RMC-7977 treatment. Thus, pan-RAS-GTP inhibition indirectly remodeled ECM composition both by impact CAF subtype distribution and by altering matrix composition and regulation by CAFs. Accordingly, nanoindentation measurements on KPC tumors and human explants confirmed a significant decrease in modulus (a measurement for tumor stiffness) after RMC-7977 treatment. In summary, we report that RMC-7977 switches the myCAF-dominant CAF landscape towards an iCAF-enriched TME through the KRAS-SHH axis and this alters TME composition and reduces tumor stiffness through ECM remodeling. Future studies will examine the impact of these finding on drug delivery, tumor invasiveness, tumor differentiation state.

#0052 Quantifying the selective advantage of copy number amplifications to reveal therapeutic targets in ovarian cancer.

Meng Liu[1], Jeff Mandell[2], Jeffrey Peter Townsend[2]

[1]Yale School of Public Health, Biostatistics, Yale University, New Haven, CT,[2]Yale University, New Haven, CT

Ovarian cancer (OV) remains one of the most lethal malignancies, and target discovery is hindered by limited oncogenic somatic single-nucleotide mutations and extensive chromosomal instability. Conventional strategies prioritize targeting of amplified genes based on frequency and amplitude of copy number amplification. However, these metrics are confounded by regional genomic architecture and abundant passenger events, rendering it difficult to identify the amplifications that truly increase cell proliferation and survival during tumor evolution. To address this problem, we developed an evolutionary model that quantifies the cancer effect size (CES) of amplifications, directly estimating the selective advantage conferred by each event, mirroring methodologies developed for single-nucleotide variants. By integrating observed amplification patterns with regional background copy number alteration (CNA) rates to quantify fitness contributions, we distinguished amplifications that genuinely drive tumor evolution from passengers elevated by genomic instability. Using segmented copy number profiles from a cohort of 554 ovarian cancer tumor sequences, we quantified cancer effects of amplifications across the genome. Known oncogenes like MYC and CCNE1 exhibit high CES. Some oft-reported recurrent amplifications exhibited low CES, consistent with a passenger status, whereas several moderately high-frequency focal amplifications exhibited strong selective advantage, representing key CNA drivers that are obscured by conventional copy-number metrics. This stratification is critical for therapeutic development because high-CES amplifications mark loci where tumors are both dosage-increased and selectively dependent. Dosage-increased, selectively dependent loci have direct translational relevance for triplex-forming oligonucleotide (TFO) therapies, which trigger DNA damage at triplex-forming motifs, with amplified loci providing increased target dosage. High-CES loci simultaneously provide abundant TFO-binding sites and represent core cancer dependencies, embodying a mechanism for durable therapeutic impact. Quantification of selection for amplifications provides a rigorous, evolutionarily grounded basis for cancer effect, identifying true amplification drivers of oncogenesis and precisely positioning therapeutically actionable targets in cancers dominated by chromosomal instability.

#0053 RNA fusions: An untapped source of neoantigens for immune based breast cancer prevention and treatment across all subtypes of breast cancers.

Anjana Bhardwaj[1], Chathurani Ranathunge[2], Shiyanth Thevasagayampillai[2], Aaranyah Kandasamy[2], Brandon H. Than[2], Constance T. Albarracin[3], Isabelle Bedrosian[1]

[1]Department of Breast Surgical Oncology, UT MD Anderson Cancer Center, Houston, TX,[2]University of Houston, Houston, TX,[3]Department of Pathology, UT MD Anderson Cancer Center, Houston, TX

Background: Breast tumors are considered immunologically cold with an overall low to moderate mutation burden resulting in limited neoantigen repertoire that can be used for discovering a breast cancer vaccine. RNA fusions lead to the generation of neoantigens that are more immunogenic than insertion or deletion mutations. Identification of such targets in high risk mammary tissue and tumors represent novel opportunities for breast cancer prevention and treatment. The objective of this study was to characterize the prevalence of chimeric RNAs in precancerous breast tissue and breast tumors from sporadic breast cancer patients.
Methodology: Fusions were identified by RNA sequencing 225 breast tissues from breast tumors and paired adjacent- and distant-tissues of 25 Her2 positive, 25 hormone receptor positive (HR) and 25 triple negative (TN) patients. The RNA sequencing reads were processed through modified ARRIBA fusion discovery pipeline for fusion calling. Breast samples obtained from cancer-free women undergoing breast reduction surgery were obtained from Komen Tissue Bank and used as controls to exclude normal mammary tissue associated chimeric RNAs from analysis.
Results: All major subtypes of breast tumors (TNBC, Her2+ and HR+) express RNA fusions. TNBC and Her2+ tumors expressed substantially larger number of unique RNA fusions than HR+ breast tumors. Every tumor sample possessed at least 2 novel RNA fusions. In line with high genomic instability of TNBC subtype of breast cancer, about 1/3 of the TN breast tumors expressed greater than 15 RNA fusions. We found non-coding RNAs to be also implicated in the biogenesis of RNA fusions in addition to coding genes. Approximately 1/5th of RNA fusions identified in sporadic breast tumors were driven from at least one oncogene partner. Interestingly, we found a substantial number of RNA fusions to possess multiple break points suggesting multiple areas within a gene that are prone to break and fuse with another gene partner. In line with patient tumor heterogeneity, RNA fusions in breast tumors were overwhelming private. In order to identify RNA fusions that are relevant for breast cancer prevention, we investigated the presence of RNA fusions in the paired adjacent samples as compared to the index tumor. Although, we found preneoplastic breast tissue to possess a rich repertoire of RNA fusions, majority of these were different from those identified in paired breast tumors.
Conclusions: RNA fusions are frequently present in breast tumors as well as at risk breast tissue and may provide novel opportunities for developing vaccines for breast cancer prevention and treatment.

#0054 Integrating connectivity mapping resources to prioritize and personalize drug candidates for individual triple negative breast cancer patients.

Lily D. Taub[1], Anna Byrd[1], Daniel J. Clarke[1], Ido Diamant[1], Criseyda Martinez[2], Elisa Port[2], Hanna Y. Irie[2], Avi Maayan[1]

[1]Pharmacological Sciences, Icahn School of Medicine at Mount Sinai, New York, NY,[2]Medicine, Icahn School of Medicine at Mount Sinai, New York, NY

Triple negative breast cancer (TNBC) is the most aggressive type of breast cancer with the least therapeutic options. While some patients respond to aggressive standard treatments, many others do not, and recurrence risk for many patients diagnosed with TNBC remains high. With the aim of furthering our understanding of mechanisms of TNBC tumorigenesis and treatment resistance, and to accelerate the development of novel personalized therapeutics on an individual patient level, we analyzed RNA-seq samples collected from eight primary TNBC tumors and their matched PDX models created from patients treated at the Dubin Breast Center. First, we identified differentially expressed up-regulated genes that are uniquely highly expressed in the primary tumors and their matching PDX models while lowly expressed across hundreds of normal human tissues and cell types profiled and harmonized from GTEx, ARCHS4, and Tabula Sapiens. We then examined the effect of knocking out these up-regulated genes in TNBC by querying the DepMap resource. From each patient's up-regulated genes, we selected those that were most essential to the viability of TNBC cell lines in CCLE and DepMap. To identify small molecule compounds that may down-regulate the expression of individual patient-specific targets, and in turn specifically reduce the viability of the cells within the TNBC tumors, we integrated five Connectivity Mapping resources that measured transcriptomics responses of human cell lines to thousands of approved drugs and other compounds. The Connectivity Mapping resources integrated are the LINCS L1000 dataset (33,571 compounds), Novartis Institutes for BioMedical Research (NIBR) DRUG-seq U2OS MoA Box (4,343 compounds), Gingko Bioworks GDPx1 and GDPx2 (1,353 compounds), and Tahoe-100M (379 compounds). We queried these resources to find consensus FDA approved and pre-clinical compounds that would maximally reduce the expression of the patient-specific identified target genes. This approach is encoded into an online tool called Dr. Gene Budger 2.0 (DGB2), which integrates the Connectivity Mapping resources for the purpose of identifying drugs that maximally increase or decrease the mRNA expression of a single target or a set of genes. With DGB2, we identified candidate therapeutic compounds, individualized for each patient TNBC tumor/PDX model, that are predicted to inhibit tumor growth. Once validated, this approach can be translated to individualize treatment for patients with TNBC, particularly those with disease that is resistant to current standard-of-care treatments. DGB2 is freely available at https://appyters.maayanlab.cloud/#/Drug_Gene_Budger2.

#0055 Differentiation state and immune interaction contribute to drug response in AML.

Natasha R. A. Black[1], Dharani Thirumalaisamy[2], Mira Rajagopalan[3], Trevor Enright[1], Melissa Stewart[1], Evan Lind[1], Elie A. Traer[4], Jeffrey W. Tyner[5], Olga H. Nikolova[1]

[1]Oregon Health & Science University, Portland, OR,[2]Department of Biomedical Engineering, Oregon Health & Science University, Portland, OR,[3]The University of Texas at Austin, Austin, TX,[4]Instructor, Ctr. for Hematologic Malignancies, Oregon Health & Science University, Portland, OR,[5]OHSU Knight Cancer Institute, Portland, OR

Introduction: We and others have linked efficacy of targeted therapies to cellular differentiation state in acute myeloid leukemia (AML). In this study, we refine this link by integrating ex vivo drug response, joint single-cell transcriptomic and proteomic, and cell-surface proteomics data that measures both myeloid differentiation and immune markers.
Methods: A total of 90 AML patient samples were profiled by CyTOF (cytometry by time-of flight) with ~100 immune and myeloid differentiation makers to characterize the landscape of cell-surface protein expression. Matched drug response data was used from the largest assembled AML patient cohort BeatAML. Concurrently, five AML patient samples were profiled following ex vivo drug treatment using CITE-seq (cellular indexing of transcriptomes and epitopes by sequencing) with a total of 6 treatments (3 single agent, 2 pairwise and 1 triple combination treatment) and compared to DMSO treated cells. Custom computational pipelines were developed to enable data analysis. Topic modeling using the latent Dirichlet allocation (LDA) model was used to identify topics emerging in the space of both myeloid differentiation and immune markers. Topics were then stratified by matched drug response. Single-cell drug response prediction methods were trained on sc-RNA-seq to identify cell type-specific drug response signatures.
Results: Our results recapitulate known biomarkers of response to single agents BCL2 inhibitor venetoclax (ven) and menin inhibitor revumenib. Further, we observe known and novel gene expression and cell population shifts when combined with hypomethylating azacytidine. For example, venetoclax eliminates primitive and B-cell populations. When ven is used in combination with revumenib, intermediate populations such as pro-monocytes mature into monocytes, yielding predominantly differentiated cells. Adding azacytidine to ven+revumenib further depletes intermediate populations, including pro-monocytes. Our topic modeling identified 5 (out of 10) topics that have a stark opposing pattern in drugs targeting primitive vs differentiated cells. We further identified the most prominent immune markers associated with each of these topics.
Conclusion: Our results recapitulate previously established links between myeloid differentiation state and selective efficacy to targeted compounds in AML. Notably, our recent findings informed by topics compromised of immune signatures further deconvolute these trends, pointing to new immune programs associated with cell state driven drug response.

#0056 COSMIC: Advancing the cancer genomics knowledgebase of somatic mutations.

Madhumita Madhumita, Madiha Ahmed, Joanna Argasinska, David Armstrong, Nidhi Bindal Dhir, Denise Carvalho-Silva, Lucie Chadelle, Patrick Dao, Stephen Duke, Giovanna Fasanella, Muhammad Fouzan, Abishekraj Gnanasambandam, Avirup Guha Neogi, Susan Haller, Bhavana Harsha, Balazs Hetenyi, Leonie Hodges, Steven Jupe, Rachel Lyne, Thomas Maurel, Karen McLaren, Thomas Mutimer, Sumodh Nair, Hanna Najgebauer, Helder Pedro, Sophie Poole, Amaia Sangrador-Vegas, Zoe Sheard, Manpreet Singh Chawla, Michael Starkey, Rebecca Steele, Sari Ward, Ellen Wiedemann, Jennifer Wilding, Siew Yit Yong, Jon Teague

COSMIC, Wellcome Sanger Institute, Cambridge, United Kingdom

COSMIC (Catalogue Of Somatic Mutations in Cancer) has evolved from an initial catalogue to the world's most comprehensive knowledgebase of somatic variants in cancer, built upon a foundation of continuous, expert curation. COSMIC currently aggregates over 29 million unique somatic variants carefully curated from 1.5 million samples, establishing an essential resource for studying the cancer genome. This rich dataset is the result of extensive, dedicated work, drawing on insights from more than 30,000 scientific publications and major studies.

COSMIC is structured into a suite of specialized modules that collectively transform raw genomic variants into biologically and clinically meaningful insight. These include the Cancer Gene Census (CGC), which systematically classifies causal cancer genes; the Cancer Mutation Census (CMC), which distinguishes driver from passenger mutations through computational and evidence-based annotation; Mutational Signatures, which captures genome-wide mutagenic processes; COSMIC 3D, which contextualizes variants within protein structures; and the Actionability and Resistance resources, which map genomic alterations to therapeutic response and resistance mechanisms. Together, these modules provide a framework essential for interpreting somatic variant landscapes in precision oncology.

We highlight ongoing research on the next iteration of the Cancer Mutation Census (CMC v2), designed to enhance COSMIC’s ability to extract biologically meaningful signals from large-scale somatic datasets. CMC v2 applies refined background models to identify mutation hotspots at the amino acid level across cancer genes in a pan-cancer context, focusing on positions exhibiting statistically significant enrichment of somatic variants. This approach isolates non-random, spatially coherent clusters of mutations that represent strong candidates for driver activity. Although currently under development, these analyses demonstrate the potential of CMC v2 to provide higher-resolution insights into cancer gene dysregulation and support more nuanced interpretation of tumor evolution.

The development of CMC v2 marks a key step in COSMIC’s evolution toward more data-driven, biologically grounded interpretation of cancer variants. By integrating statistical modeling with expert insight, CMC v2 refines our capacity to distinguish meaningful mutational patterns from background noise across diverse tumor contexts. These advances exemplify COSMIC’s ongoing commitment to translating large-scale genomics into actionable biological knowledge. As the knowledgebase continues to expand and engage with the global cancer research community, COSMIC remains an indispensable foundation for understanding cancer gene function, refining biomarker discovery, and supporting precision oncology.

#0057 Functional pathway analysis reveals discordance between clinical HER2 status and downstream effector activation in breast cancer.

Salim Arslan[1], Julian Schmidt[1], Cher Bass[1], Foivos Ntelemis[1], J Carl Barrett[2], Oscar Maiques[3], Jakob Nikolas Kather[4], **Pahini Pandya**[1]

[1]Panakeia Technologies, Cambridge, United Kingdom,[2]University of North Carolina at Chapel Hill, Chapel Hill, NC,[3]Barts Cancer Institute, Queen Mary University of London, London, United Kingdom,[4]Technische Universitat Dresden, Dresden, Germany

Background: HER2-targeted therapies are guided by HER2 protein overexpression or ERBB2 amplification. However, these biomarkers may imperfectly reflect functional dependence on HER2 signaling. We performed an integrative multi-omic analysis to quantify the discordance between clinical HER2 status and its corresponding functional biology, assessing both downstream pathway activation in HER2-positive (HER2+) tumors and inactivity in HER2-negative (HER2−) cases.
Methods: Analysis was performed on the TCGA breast cancer dataset. HER2+ (n=106) and HER2− (n=595) cohorts were defined using clinical HER2 status. Transcriptomic and proteomic over-/under-expression states were derived for clinically relevant driver genes by thresholding RNA/protein expression values. For each tumor, we assessed activation of HER2-associated pathways (e.g., direct HER2 targets, PI3K-AKT-mTOR, MAPK, RTK crosstalk) by comparing expression states against the expected direction of activation. A pathway was considered 'validated' when at least half of the tested states aligned with expected activation patterns. Samples with no available data were excluded from the analysis, reducing the evaluable cases to 85 and 457 for HER2+ and HER2−, respectively.
Results: Among HER2+ tumors, proximal HER2 signaling showed strong concordance with clinical status, with direct targets being active in 80.0% of cases. In contrast, canonical downstream pathways were often inactive, with PI3K-AKT-mTOR and MAPK activity validated in only 29.4% and 15.3% of tumors, respectively. This heterogeneity suggests that many HER2+ tumors may rely less on canonical HER2-driven signaling than expected. In HER2− tumors, proximal HER2 signaling and MAPK pathway activity were appropriately low as validated in >96% cases. However, the PI3K-AKT-mTOR pathway was active in 132/457 (28.9%) HER2− tumors, revealing a sizable subset with HER2-independent PI3K activation.
Conclusions: Our findings highlight biological mechanisms that may underlie therapeutic resistance and reveal alternative targets for expanding precision treatment strategies across breast cancer subtypes. The limited canonical signaling in most HER2+ tumors suggests pathway-independent drivers, feedback inhibition, or gaps in transcriptomic/proteomic measurements that miss critical phosphorylation events. In contrast, activation signatures in a subset of HER2− tumors indicate therapeutically relevant HER2-low biology. The results support complementing standard testing with biology-aware signatures to (i) flag HER2+ tumors unlikely to respond to combination therapies and (ii) stratify HER2− patients into actionable groups, including those who may benefit from PI3K/mTOR inhibitors. Future work will incorporate phospho-proteomic data and link pathway signatures to treatment response to refine patient selection.

#0058 Characterizing tumor-stroma interfaces in chemotherapy-treated ovarian cancer via spatial transcriptomics.

Po-Yuan Chen[1], Tyler M. Yasaka[1], Tzu-Hung Hsiao[2], Tai-Ming Ko[3], Yu-Chiao Chiu[1]

[1]University of Pittsburgh School of Medicine, Pittsburgh, PA,[2]Department of Medical Research, Taichung Veterans General Hospital, Taichung, Taiwan,[3]Department of Biological Science and Technology, College of Engineering Bioscience, National Yang Ming Chiao Tung University, Hsinchu, Taiwan

The tumor-stroma interface (TSI) is a key microenvironmental region where malignant and non-malignant cells interact and influence therapeutic resistance and disease progression. Despite its importance, this area remains insufficiently characterized at the transcriptomic level, and the cellular features that connect its organization to treatment outcomes are not well defined. This gap limits the translational interpretation of spatial microenvironmental structure in the context of patient response. To address this need, we developed an integrative framework that identifies and characterizes the TSI using spatial transcriptomics. The approach combines spot-level tumor detection with a neighborhood analysis that delineates interface regions surrounding cancer spots. We applied this framework to a post-chemotherapy high-grade serous ovarian cancer dataset generated by Elena Denisenko et al. (n = 8; three good responders, two partial responders, and three poor responders) and defined tumor, TSI, and normal regions across all samples. Linear mixed-effects modeling identified significantly different proportions of EIF4A3+ cancer associated fibroblasts, endothelial cells, and myofibroblasts between outcome groups within the TSI. Among them, myofibroblasts were elevated specifically within the TSI of poor responders, but not in tumor or normal regions, indicating a localized rather than tissue-wide shift. Although T-cell proportions were not significantly different between outcome groups, bivariate Moran's I analysis showed strong spatial co-localization between T cells and tumor cells in good responders, whereas this spatial coupling was largely absent in poor responders. These findings suggest that both immune cell organization and abundance may contribute to more effective post-treatment activity in favorable outcomes. Pathway analysis further revealed distinct functional programs within the TSI. Good responders showed enrichment of immune activation and antigen-presentation pathways, whereas poor responders displayed increased extracellular matrix remodeling and stromal signaling. Regression analysis confirmed that myofibroblast proportion was tightly linked to these pro-resistance pathways and negatively correlated with humoral immune response activity, connecting stromal remodeling with reduced immune pathway engagement in poor responders. Collectively, these findings highlight the functional heterogeneity of the TSI and its potential role in modulating treatment response. By integrating tumor detection, interface mapping, and pathway-level analysis, our framework offers a scalable strategy to dissect interface biology and bridge spatial transcriptomics with treatment-related mechanisms. This framework may enable the discovery of spatially informed biomarkers for predicting therapeutic outcomes in ovarian cancer and beyond.

#0059 Mutational signatures in cancer genomes alter short linear protein motifs involved in cellular signaling networks.

Jigyansa Mishra[1], Masroor Bayati[1], Nina Adler[2], Zoe P. Klein[1], Kevin C. L. Cheng[1], Juri Reimand[1]

[1]Ontario Institute for Cancer Research, Toronto, ON, Canada,[2]University of Toronto, Toronto, ON, Canada

Cancer genomes accumulate somatic mutations from diverse mutational processes, driven by extrinsic carcinogen exposures and intrinsic DNA repair deficiencies, leaving distinct genomic imprints referred to as mutational signatures. Mutational signatures are inferred computationally from large cancer genomics datasets and validated in experiments, however their functional impacts on protein-coding sequences and protein function remain largely unexplored. Leveraging machine learning and statistics, we aimed to discern the impact of single base substitution (SBS) mutational signatures in rewiring conserved short linear protein motifs (SLiMs). These are peptide sequences that mediate key protein-protein interactions and post-translational modifications. We performed a proteogenomic analysis of 1.1 million missense single-nucleotide variants (msSNVs) in 12,000 genomes across 19 cancer types. We assessed the impact of msSNVs on 150 classes of SLiMs recognized by kinases and other enzymes involved in cellular signaling networks. Distinct signatures were significantly associated with msSNVs that disrupted, created or switched between specific SLiMs. For example, UV light-associated signature SBS7b disrupted proline-directed kinase motifs, while signatures arising from aberrant APOBEC cytidine deaminase activity, SBS2 and SBS13, disrupted caspase-cleavage motifs, vital for apoptosis, as well as motifs involved in the DNA damage response. These differential signature impacts stem from their trinucleotide-context biases, which steer specific codon changes, inducing amino acid substitutions in distinct SLiMs. At the gene level, recurrent SLiM-rewiring variants clustered in 22 canonical cancer drivers such as *BRAF*, *CTNNB1* and *U2AF1*, and 35 candidate genes revealing mechanistic connections between mutational processes and oncogenic signaling pathways. UV light-induced V600E substitutions in BRAF create a novel polo-like kinase (PLK1)-binding motif, putatively contributing to vemurafenib resistance in melanoma patients. Recurrent S34F substitutions in the splicing factor U2AF1 are driven by APOBEC activity and disrupt a regulatory phosphorylation site critical in splice-site fidelity, suggesting a link between APOBEC-driven mutagenesis and RNA splicing dysregulation in lung cancer. Lastly, motif-rewiring alterations in cellular signaling networks strongly correlated with patient attributes such as smoking status and functional characteristics such as APOBEC gene expression, revealing how lifestyle variables and intrinsic mutagenic programs can potentially reconfigure cellular signaling and protein-protein interactions. Together, our results uncover process-specific proteomic consequences of mutational processes, offering mechanistic insights into cancer etiology and exposing potential therapeutic vulnerabilities.

#0060 CpGene: a DNA methylation-based biomarker discovery platform.

Konstantinos Lazaros[1], Vasiliki Tzelepi[2], Christopher J. Logothetis[3], Aristidis G. Vrahatis[1], **Susan (Souzana) Logotheti**[4]

[1]Informatics, University of Ionion, Corfu, Greece,[2]Pathology, School of Medicine, University of Patras, Patras, Greece,[3]Chairman/Professor, Gu Med. Onc., UT MD Anderson Cancer Center, Houston, TX,[4]Pathology, School of Medicine, Univeristy of Patras, Patras, Greece

Background: DNA methylation (DNAme) has been established as the key player in the epigenetic regulation of the gene expression. While high throughput techniques are essential in rigorous research, data analysis requires in dept bioinformatic knowledge to provide a comprehensive approach to biomarker identification. Recognising this challenge, we developed CpGene, a web application that prioritises accessibility and usability, allowing users to perform robust DNA methylation microarray data analysis (e.g., Illumina 450K, EPIC v1.0, EPIC v2.0) and derive biologically relevant conclusions for biomarker discovery.
Methods: The backbone of CpGene is built upon the integration of well-established and widely known packages, ensuring reliability, transparency and repeatability. Data preprocessing including beta value generation and quality control is conducted using minfi R package, while limma package and machine learning-based feature selection approaches are performed for differential methylation analysis. Functional enrichment analysis is obtained using Enrichr API and result visualization is performed using multiple R and python packages (e.g. ggplot2, lattice, matplotlib).
Conclusions: CpGene offers an accessible, interactive and user-friendly workspace to perform DNA methylation analysis from microarray data. The platform caters not only to experienced bioinformaticians, but also to basic scientists and clinicians who possess foundational bioinformatics knowledge. The intuitive interface and streamlined workspace enable users from various backgrounds to effectively utilise the platform, regardless of their level of computational expertise. As a result, CpGene empowers both scientific and clinical communities seeking to characterize disease-linked epigenetic alterations and pinpoint actionable DNA methylation biomarkers, even in the absence of advanced bioinformatics training.

#0061 Defining spatial biomarkers of survival across solid tumors using a pan-cancer proteomics atlas.

Khoa Huynh[1], Joaquin Reyna[1], Bruno Matuck[2], KEVIN BYRD[3], Jinze Liu[4]

[1]VCU Massey Comprehensive Cancer Center, Richmond, VA,[2]VCU School of Dentistry, Richmond, VA,[3]Philips Institute for Oral Health Research, Richmond, VA,[4]Massey Comprehensive Cancer Center, Richmond, VA

The spatial architecture of the tumor microenvironment (TME) governs cancer progression and therapeutic response, yet pan-cancer analyses linking multicellular organization to patient survival remain unclear. As part of the PROSPECTS (Pancancer Reconstruction Of Spatial Profiles and Therapeutic TargETs) Initiative, we assembled a large-scale spatial proteomic atlas comprising 415 patients across six major malignancies: Head and Neck Squamous Cell Carcinoma (HPV-positive and HPV-negative), Lung Cancer (NSCLC and LUAD), Triple-Negative Breast Cancer, High-Grade Serous Ovarian Cancer, Colorectal Adenocarcinoma, and Hepatocellular Carcinoma (HCC). Our dataset includes over 1,000 tissue cores and over 4.4 million single cells with balanced representation across indications: HNSCC (1,218,385 cells, 145 patients), Lung (906,537 cells; 63 patients), Breast (765,232 cells; 60 patients), Ovarian (590,945 cells; 53 patients), Colorectal (511,610 cells; 37 patients), and Liver (474,237 cells; 57 patients). Using a 30-plex antibody Phenocycler, we spatially mapped 15 major cell types at single-cell resolution. We developed a next-generation multi-scale computational pipeline within AstroSuite (Stratica Biosciences), integrating TACIT and Constellation algorithms to quantify TME architecture at the levels of cell state, intercellular distance, and higher-order motifs including pairwise, triplet, and quartet cellular neighborhoods. These deep spatial metrics were linked to overall survival with adjustment for clinical covariates. We identified marked heterogeneity in TME structure, with each cancer type exhibiting distinct prognostic architectures. In TNBC, Tumor Cell-Neutrophil interactions emerged as one of the strongest adverse prognostic features (P=0.00001). In Lung cancers, vascular-immune and stromal-tumor interfaces were key, particularly vascular endothelial cell-Macrophage adjacency (P=0.0003) and Fibroblast-Tumor Cell interactions (P=0.002). Despite these cancer-specific patterns, PROSPECTS uncovered conserved spatial signatures. A recurrent fibroblast-tumor cell interface motif appeared across malignancies, though stromal drivers varied: Myofibroblast-Treg interactions were prognostic in Colorectal cancer (P=0.002), while Fibroblast-Treg interactions predicted outcome in Ovarian cancer (P=0.002). In HCC, immune-to-immune interactions such as Treg-B Cell crosstalk (P=0.002) were significantly associated with survival. Complex spatial syntax proved superior to simple pairwise interactions for prognosis, highlighting the value of higher-order TME modeling. This work establishes the first pan-cancer spatial proteomic comparison linking TME organization to clinical outcome, revealing that spatially resolved cellular interaction networks constitute a new class of clinically actionable biomarkers.

#0062 Comprehensive characterization of m^{6}A RNA methylation across human cancers.

Yining Zhao[1], Ke Chen[1], Hu Chen[2], Yizhe Song[3], Kamalika Mojumdar[1], Wei Liu[1], Stephanie H Ting[4], Ayush Semwal[5], Hui Shen[6], Li Ding[7], Genomic Data Analysis Network, Katherine Hoadley[4], Han Liang[1]

[1]UT MD Anderson Cancer Center, Houston, TX,[2]Baylor College of Medicine, Houston, TX,[3]Washington University School of Medicine in St. Louis, Saint Louis, MO,[4]University of North Carolina, Chapel Hill, NC,[5]Department of Epigenetics, Van Andel Research Institute, Grand Rapids, MI,[6]Graduate Student, Van Andel Research Institute, Grand Rapids, MI,[7]Washington University School of Medicine in St. Louis, St. Louis, MO

N6-methyladenosine (m^{6}A) is the most abundant internal mRNA modification and plays essential roles in gene regulation, tumor progression, and therapeutic response. However, the biomedical and clinical significance of m^{6}A RNA methylation in human cancer remains incompletely understood. Here, using m^{6}A-seq profiling, we generated a comprehensive transcriptome-wide atlas of m^{6}A modifications across 15,812 sites from 226 tumor samples spanning 23 cancer types in The Cancer Genome Atlas (TCGA). To elucidate the regulatory determinants and downstream consequences of m^{6}A variation, we integrated these data with a broad spectrum of multi-omics features. We found that global m^{6}A patterns segregate into five major clusters largely driven by cancer lineages. Somatic mutations exert widespread yet diverse effects on local m^{6}A levels through alteration of DRACH motifs. Approximately 10% of protein-coding genes showed consistent positive or negative associations between m^{6}A abundance and mRNA or protein expression. These genes are enriched for transcription factors, and their m^{6}A levels strongly influence key tumor cell states such as epithelial-mesenchymal transition (EMT) and hypoxia. We further characterized the protein expression landscape of 15 m^{6}A regulators in 7482 TCGA samples and uncovered frequent dysregulation across cancers arising from multiple distinct genetic and epigenetic mechanisms. Finally, we developed a deep-learning model that integrates local DNA sequence context, gene-level features, m^{6}A regulator states, and tumor-specific context to predict m^{6}A intensity. The model achieved high accuracy for a substantial fraction of m^{6}A sites, enabling large-scale inference of m^{6}A variation and facilitating biomarker discovery in extensive patient cohorts. Together, this study provides a key resource for understanding the genomic landscape and regulatory architecture of m^{6}A methylation in cancer and establishes a foundation for leveraging m^{6}A as a new class of biomarkers and therapeutic targets.

#0063 Intratumoral *Candida albicans* associates with hypoxia and poor outcomes in non small cell lung cancer (NSCLC).

Resistance to radiation, chemotherapy, and immunotherapy remains a major challenge in non-small cell lung cancer (NSCLC), and emerging evidence suggests tumor-resident microbes may influence therapeutic response. To address this, we combined patient-level modeling with mechanistic studies in preclinical models. We first analyzed RNA-sequencing data from 2,156 NSCLC tumors collected under the Total Cancer Care Protocol (NCT03977402) within the ORIEN network using a contamination-aware pipeline to quantify intratumoral *Candida albicans* (CA) and assess its impact on treatment outcomes. We developed MEC-TX (Mechanistic Clustering Treatment), a digital-twin framework that compares patients receiving similar treatment regimens differing only by CA burden. CA was detected in ~55% of tumors; high CA burden was associated with significantly shorter overall survival (hazard ratio 1.6, $p < 0.01$), and similar trends were observed in radiation- and chemotherapy-treated cohorts defined by MEC-TX. After adjusting for clinical covariates (age, sex, stage, BMI), CA remained an independent predictor of poor survival, underscoring MEC-TX's ability to isolate biologically meaningful signals. Transcriptomic profiling revealed CA-high tumors had elevated hypoxia-related gene expression ($p = 0.0045$), suggesting a link between fungal infiltration and tumor microenvironment. To test this, we implanted Lewis lung carcinoma cells into syngeneic C57BL/6 mice and gavaged them with CA, *Blautia obeum* (commensal control), or saline (vehicle control). CA-gavaged tumors were significantly larger ($p = 0.0108$) and exhibited lower pH ($p = 0.024$) and reduced intratumoral pO_2 ($p = 0.051$) compared to controls, as measured by EPR oximetry, after adjusting for tumor size, supporting CA's role in creating a hypoxic, therapy-resistant niche. *In vitro*, CA-conditioned media conferred radioresistance across multiple cell lines ($p = 0.001$), implicating secreted molecules as drivers of this phenotype. Collectively, these findings reveal a novel mechanism by which intratumoral fungi promote hypoxia and treatment resistance, providing a strong rationale for microbiome-informed strategies to overcome hypoxia-driven resistance and improve precision oncology.

#0064 Mechanisms of resistance to CDK4/6 inhibitors: Insights from single-cell nucleus sequencing and spatial transcriptomics.

Seung-eun Bang[1], EunChae Kim[1], Won-Ji Ryu[2], Hyein Jung[2], Yoonjin Cha[3], Joohyuk Sohn[4], Gun Min Kim[4], Kyoo Hyun Kim[4], Byungjin Hwang[1], Min Hwan Kim[5]

Breast cancer incidence is increasing worldwide and represents the second most common malignancy in women after lung cancer. Among its subtypes, luminal B accounts for 10-20% of cases and shows a faster proliferation rate. Also, a poorer prognosis than luminal A, with a 5-year survival rate of only 32% at stage 4. Luminal B tumors are characterized by active estrogen receptor signaling and high expression of proliferation-associated genes such as *Ki-67* and *E2F*, leading to enhanced estrogen-driven cell cycle progression. Consequently, CDK4/6 inhibitors, which block the G1 to S phase transition, have shown favorable therapeutic outcomes. However, in a subset of patients, treatment with CDK4/6 inhibitors induces a luminal-to-basal-like phenotypic conversion, which is associated with poor clinical prognosis. To elucidate the mechanism underlying this phenotype, we performed single-nucleus RNA sequencing and spatial transcriptomic analyses on paired pre- and post-treatment tumor biopsies from three patients who exhibited poor responses to CDK4/6 inhibition. After UMAP projection and batch correction, cell type annotation revealed no major changes in the overall cellular composition, with epithelial/tumor cells remaining dominant. Differential expression analysis showed minimal transcriptional changes in endothelial and fibroblast cells but substantial alterations in tumor/epithelial and immune cell populations. Focusing on immune cells, which displayed the largest number of DEGs, subclustering analysis revealed a marked post-treatment increase in innate lymphoid cells (ILCs), while overall immune cell numbers decreased following treatment. Cell-type-specific DEG analysis further identified substantial transcriptional reprogramming within plasma cells, $CD4^+$, and $CD8^+$ T cells. In parallel, tumor/epithelial cells exhibited distinct subtype redistribution after CDK4/6 inhibition, which is currently under detailed characterization. Spatial transcriptomic mapping based on nucleus-seq-derived cell type signatures is underway to visualize cell-type distribution and microenvironmental remodeling before and after treatment. Collectively, our integrative analyses aim to uncover the mechanisms of CDK4/6 inhibitor resistance, highlighting the potential roles of ILC expansion, immune remodeling, and epithelial plasticity in luminal-to-basal transition, and to identify biomarkers predictive of therapeutic response.

#0065 Integrating spatial transcriptomics and digital pathology with whole-genome data from Genomics England to characterise the tumour and it's microenvironment in colorectal cancer.

Luke McNickle[1], Assya Legrini[1], Yoana Doncheva[1], Mari-Claire McGuigan[1], Ghazal Latifi[1], Claire Kennedy Dietrich[1], Molly McKenzie[1], Phimmada Hatthakarnkul[1], Tom Wright[1], Leonor Patricia Schubert Santana[1], Emma McCargow[2], Cong Chen[2], Henry M. Wood[3], Jon Laye[3], Gemma Hemmings[3], Caroline Cartlidge[3], Derek Magee[4], Phil Quirke[3], Joanne Edwards[1], Nigel Jamieson[1]

[1]School of Cancer Sciences, University of Glasgow, Glasgow, United Kingdom,[2]Genomics England Limited, London, United Kingdom,[3]Division of Pathology and Data Analytics, University of Leeds, Leeds, United Kingdom,[4]School of Computer Science, University of Leeds, Leeds, United Kingdom

Introductory Sentence:
By combining spatial transcriptomics and digital pathology with whole-genome-sequenced samples from Genomics England's 100,000 Genomes Project, we can directly link spatial gene expression patterns to genetic alterations and morphological features.
Brief Description of Pertinent Experimental Procedures:
We applied Bruker Spatial Biology's CosMx™ High Plex (6K) spatial transcriptomics platform to tissue microarray (TMA) cores derived from Genomics England colorectal cancer samples. H&E-stained sections were reviewed by pathologists for morphological assessment and AI-based detection of lymphocytes and stroma. Across 65 TMA cores on three slides, we performed cell segmentation, gene expression quantification, and multi-step quality control. A total of 966,500 cells were detected pre-QC, with 935,262 high-quality cells retained post-QC for downstream analyses, including cell typing, pathway enrichment, spatial neighbourhood, and regulatory network inference. Integrative comparisons were made across MMR status, Klintrup inflammation, SARIFA (Stroma AReactive Invasion Front Areas) scoring, and the underlying mutational landscape from matched whole-genome sequencing data.
Summary of New Unpublished Data:
Our results demonstrate successful implementation of high-plex spatial transcriptomics on Genomics England tissue samples with high-quality pathology input. We observed distinct spatial and transcriptional signatures—at both gene and module levels—between MMR-proficient and MMR-deficient tumours, and across gradients of histopathological inflammation and SARIFA metrics. Integration of genomic variants revealed transcriptional programmes associated with cellular activity and phenotypic divergence. These data highlight the ability of spatially resolved transcriptomics to contextualise genomic alterations within the complex cellular landscape of the tumour microenvironment.
Statement of the Conclusions:
This study establishes the feasibility and analytical power of applying spatial transcriptomics to Genomics England's whole-genome-characterised samples. Integrating spatial, histological, and genomic data provides new insight into immune-stromal dynamics and tumour heterogeneity. This approach demonstrates the potential for large-scale spatial multi-omic profiling across Genomics England cohorts, enabling deeper functional interpretation of genomic data and advancing the next generation of precision oncology research.

#0066 Gene co-amplification and structural patterns reveal principles of extrachromosomal DNA in cancer.

Jens Luebeck[1], Ted Liefeld[1], Edwin Huang[1], Forrest Kim[1], Bhargavi Dameracharla[1], Michael A. Chan[1], Dhruv Khatri[1], Kyra Fetter[1], Kaiyuan Zhu[1], Thorin Tabor[1], Soyeon Kim[2], Hoon Kim[2], Roel Verhaak[3], Michael M. Reich[4], Paul S. Mischel[5], Jill P. Mesirov[1], Vineet Bafna[1]

[1]UC San Diego, La Jolla, CA,[2]Sungkyunkwan University, Suwon, Korea, Republic of,[3]Yale School of Medicine, New Haven, CT,[4]UCSD Medical Ctr., San Diego, CA,[5]Stanford University School of Medicine, Stanford, CA

The amplification of oncogenes on extrachromosomal DNA (ecDNA) enables aggressive, rapidly evolving tumors. Its defiance of Mendelian segregation enables extreme copy number amplifications that escape chromosomal regulatory constraints. Our AmpliconSuite toolset is the most widely used tool for ecDNA analysis in whole genome sequencing data, now deployed on over 43,000 tumor samples. Here, we present novel insights into ecDNA biology enabled through large-scale integrative analysis with these methods.

We analyzed 6,366 whole-genome sequenced tumors from combined ICGC and Hartwig Medical Foundation datasets, identifying 2,366 distinct ecDNA capturing >11,000 different genes. Our systematic gene co-amplification analysis revealed striking patterns of gene selection on ecDNA. CDK4-MDM2 co-amplification occurred predominantly via ecDNA (75% of co-amplifications). These loci, normally separated by >11Mbp on chromosome 12, preferentially assembled onto the same ecDNA molecule 93% of the time as revealed by structural analysis of the ecDNA. This suggests selective pressure for maintaining cell cycle and p53 pathway regulators on the same inheritable unit. Our analysis of frequent co-amplifications also revealed that ecDNA preferentially packages chromatin remodelers (NSD3, RSF1) alongside driver oncogenes, as well as including genes that support transcription and translation (INTS4, BRF2), creating self-contained oncogene “support” hubs. Structural analysis revealed cancer type-specific patterns to ecDNA structures, with EGFR ecDNA showing simple architectures in glioblastoma versus complex rearrangements in lung and breast cancers, suggesting distinct formation histories in different cancers.

Through AmpliconRepository.org, we provide public access to these ecDNA predictions and co-amplification analysis across major cancer cohorts, currently hosting 16,000+ analyzed samples and 5,000+ characterized ecDNA amplifications. Uniquely open to community contributions, this resource enables researchers to explore patterns across datasets and validate findings. These findings reveal fundamental principles governing ecDNA formation and selection, with implications for understanding tumor heterogeneity, therapeutic resistance, and dependencies which underlie ecDNA-targeted therapies.

#0067 Validation of a gene pair-based machine learning model for treatment prioritization in breast cancer.

Rishi Nair[1], Nicholas R. Mistry[1], Roy Khalife[2], Anthony M. Magliocco[2]

[1]University of Central Florida, Orlando, FL,[2]Protean BioDiagnostics Inc, Orlando, FL

Introduction: Drug resistance in breast cancer (BC) can arise from synergistic genetic alterations. We previously developed a machine learning (ML) model that ranks treatment categories by 5-year predicted overall survival (POS) based on altered gene pairs. Here, we perform the first retrospective validation of this model using an independent BC patient cohort that received next-generation sequencing (NGS)-directed therapy.

Methods: Thirty metastatic BC patients who received NGS-directed therapy with FoundationOne Companion Diagnostic (CDx) profiling were analyzed (PMID: 34572791). For each patient, logits scores (representing the probability of death at 5 years) were generated across 8 treatment categories combined with altered gene pair combinations from the CDx gene-set. Inverse logits, representing POS, were computed using a virtual clinical trial where a decoder model received patient data and output probability distributions for each gene pair. Synthetic patient populations were then randomly generated from these probabilities and used to calculate POS rates for each treatment category per patient. Mean inverse logits were analyzed per patient using repeated-measures ANOVA, Friedman tests and pairwise Holm t-tests. The Shapiro-Wilk test and η^2 values assessed model normality and strength of association.

Results: Across all patients, the POS rate was 70.0%, compared to the actual rate of 62.9%. A one-sample z-test indicated a significant difference ($Z=6.82$, $p<0.001$), although the model's predictions were directionally aligned with actual outcomes. Shapiro-Wilk testing indicated that 79.2% of treatment categories across all patients had $W>0.9$, suggesting an approximately normal distribution of logits. Repeated-measures ANOVA confirmed significant treatment-dependent differences in logits for all 30 patients ($p<0.001$, $\eta^2_{avg}=0.72$). This indicates that 72% of the variance in POS is explained by the treatment category, after accounting for differences in gene pair alterations across patients. Radiation and tyrosine kinase inhibitors were the treatment categories that consistently ranked highest across patients, while PI3K inhibitors and DNA damage agents consistently ranked lowest. Pairwise Holm t-tests indicated that metabolic agents and receptor tyrosine kinase inhibitors consistently showed no significant difference in POS among patients who received either treatment in real life ($p>0.05$).

Conclusion: Our findings demonstrate strong internal consistency with a ML-based approach to predict survival using gene pair and treatment data. Promising external validity is shown by POS within 8% of observed outcomes. Further calibration and validation of this model with subtype-stratified cohorts is warranted to improve validity, enhance clinical utility and maintain predictive stability.

#0068 YAP-TEAD-dependent VASP expression increases cell stiffness and migration in TNBC cells under high extracellular glucose conditions.

Wonkyung Lee[1], Seeun Oh[2], Tae-Hyung Kim[3]

[1]Yeungnam University College of Medicine, Daegu, Korea, Republic of,[2]Department of Molecular Genetics & Microbiology, University of New Mexico, School of Medicine, Albuquerque, NM,[3]University of New Mexico, Albuquerque, NM

Triple negative breast cancer (TNBC) is an aggressive subtype lacking targeted therapies, highlighting the urgent need for novel treatment strategies. Clinical observations indicate that TNBC patients with obesity or diabetes have a worse prognosis, underscoring the impact of metabolic dysregulation on disease progression. We previously demonstrated that extracellular glucose regulates F-actin assembly and non-muscle myosin activity via the cAMP-RhoA-ROCK pathway in TNBC cells, linking glucose metabolism to cytoskeletal remodeling and cell invasion. In this study, we aimed to further elucidate the molecular mechanisms by which extracellular glucose regulates cell mechanics and motility. We hypothesized that the Hippo pathway, particularly YAP, regulates expression of a cytoskeletal remodeling gene, VASP in response to glucose metabolic signaling. To test the hypothesis, we utilized public ChIP-seq datasets, to identify four YAP-TEAD binding domains (CBDs) within the human VASP gene enhancer region. TEAD motif analysis using FIMO revealed predicted TEAD-binding sites in each region. We then experimentally validated those identified CBDs. These enhancer fragments were subcloned into luciferase reporters. For exogenous validation, we measured luciferase activity after TEAD inhibitor treatment and performed site-directed mutagenesis to determine whether TEAD binding is required for VASP gene regulation. To determine which TEAD isoforms contribute most to VASP regulation, we performed siRNA-mediated knockdown of TEAD1-4 and found that TEAD1 and TEAD4 were the most significant regulators of VASP expression. For endogenous validation, we conducted Western Blotting after 24hours of TEAD inhibitor treatment. To test whether this regulatory axis is responsive to glucose levels, we performed glucose-dependent luciferase assays for exogenous validation, and RNA sequencing and Western Blotting to evaluate endogenous VASP expression under different glucose conditions. These analyses demonstrated that the YAP-TEAD-VASP axis is upregulated in high-glucose settings. Finally, to explore the translational implications of these findings, we assessed whether TEAD inhibitors could suppress migration in a hyperglycemic context. Since VASP promotes F-actin polymerization, we hypothesized that TEAD inhibition would reduce F-actin rearrangement and thereby decrease cell contracility, which in turn suppress cell migration. In scratch wound healing assays, TEAD inhibitors significantly reduced cell migration across glucose concentrations tested. In summary, we identify VASP as a novel YAP-TEAD target gene regulated under hyperglycemic conditions and demonstrate that TEAD inhibition alters contracility and suppresses migration in TNBC cells.

#0756 Matrix stiffness induces Ca^{2+}-DCLK1-PIP5K1A mechanotransduction as a biomechanical checkpoint in pancreatic cancer progression and chemotherapy resistance.

Haoxiang Zhang[1], Chuanbin Zhao[2], Jiaoshun Chen[2], Xiaoqing Hu[3], Jianwei Bai[4], Long He[2], Zanglong Deng[2], Tao Yin[2]

[1]Department of Hepatopancreatobiliary Surgery, Fuzhou University Affiliated Provincial Hospital, Fuzhou, China,[2]Department of Pancreatic Surgery, Union Hospital, Tongji Medical College, Huazhong University of Science and Technology, Wuhan, China,[3]Department of Ultrasound Medicine, Union Hospital, Tongji Medical College, Huazhong University of Science and Technology, Wuhan, China,[4]Department of Biliary-Pancreatic Surgery, Xiangyang Central Hospital, Xiangyang, China

Background: Alterations in extracellular matrix (ECM) architecture and stiffness are hallmarks of rapid pancreatic cancer progression. However, the mechanisms by which ECM biomechanical properties influence malignant biological behavior remain largely unknown. Calmodulin-dependent protein kinase DCLK1 has been implicated in cancer progression, but its role in integrating biomechanical signals in pancreatic cancer has not been elucidated.
Methods: We investigated the relationship between ECM stiffness and DCLK1 activation in pancreatic cancer using in vitro biomechanical stress models and in vivo solid tumor experiments. DCLK1 expression and activity were manipulated via overexpression or knockdown, and calcium signaling was modulated using specific inhibitors. Single-cell RNA sequencing was performed to identify potential pathways by which calcium inhibition sensitizes tumors to chemotherapy. Multicolor immunofluorescence staining of clinical tumor samples was used to examine the correlation between the PIEZO1-DCLK1-PIP5K1A-AKT signaling axis and ECM stiffness in situ. Mechanistic studies included protein interaction assays and phosphorylation analyses to define the DCLK1-PIP5K1A-PI3K-AKT signaling cascade.
Results: DCLK1 expression and activation were selectively induced under high biomechanical stress mediated by the PIEZO1/calcium/HPCAL1 axis. Overexpression of DCLK1 under low stiffness conditions accelerated tumor progression and chemoresistance, which could be partially reversed by calcium inhibitors. Conversely, under high stiffness conditions, DCLK1 knockdown inhibited tumor growth and increased chemosensitivity, but attenuated the sensitizing effect of combined calcium inhibitor treatment. Single-cell RNA sequencing identified calcium-related pathways contributing to chemotherapy sensitization. Mechanistically, DCLK1 interacted with PIP5K1A by inhibiting its threonine phosphorylation, promoting membrane localization of PIP5K1A and activating the downstream PI3K-AKT pathway. Multicolor immunofluorescence confirmed the correlation of PIEZO1-DCLK1-PIP5K1A-AKT activation with ECM stiffness in clinical samples.
Conclusions: DCLK1 functions as a biomechanical checkpoint in pancreatic cancer, integrating ECM-derived mechanical cues to exacerbate tumor progression and chemotherapy resistance. Targeting the calcium/DCLK1 signaling axis may enhance the efficacy of adjuvant therapy in pancreatic cancer patients

#0757 Matrix stiffness encoded mechanical memory maintains proliferative dominance in tumor metastasis.

Yusheng Luo[1], Yuxi Pan[2], Xiaorong Lin[2], Shuo Fang[2]

[1]Digestive Medicine Center, The Seventh Affiliated Hospital, Sun Yat-Sen University, Shenzhen, China,[2]Department of Oncology, The Seventh Affiliated Hospital, Sun Yat-sen University, Shenzhen, China

Clinical observations revealed that the progression of newly developed pulmonary metastasis during systemic therapy reflected resistance in primary lesions and suggested that metastatic foci may retain biological characteristics similar to those of the primary tumor. However, how tumor cells in pulmonary metastatic lesions retained the biological characteristics of the primary tumor in different microenvironments remained unclear. We reported that mechanical memory enabled tumor cells to resist biomechanical stress and sustain malignant traits. Stiff matrix activated the RhoA-ROCK1 signaling pathway, leading to actin cytoskeletal remodeling and the suppression of mitochondrial fission. This dysregulation of mitochondrial dynamics enhanced fatty acid β-oxidation, accumulating acetyl-CoA and subsequent histone hyperacetylation. This epigenetic reprogramming was mitotically heritable, allowing progeny cells to retain a proliferative advantage after detachment from stiff environments. Inhibiting RhoA-ROCK1 disrupted mechanical memory, reducing HCC pulmonary metastasis. Our findings proposed targeting mechanical memory as a novel metastasis prevention strategy.

#0758 ECM mimicking tunable 3D hydrogels to model Ewing sarcoma.

Aakanksha Jha[1], Cole DeForest[2], Elizabeth Lawlor[1]

[1]Ben Towne Center for Childhood Cancer and Blood Disorders Research, Seattle Children's Research Institute, Seattle, WA,[2]Chemical Engineering, University of Washington, Seattle, WA

The extracellular matrix (ECM) is increasingly recognized as a critical regulator of tumor progression and metastasis. Despite its strong influence on tumor fate, the ECM remains poorly characterized within the solid tumor microenvironment. Ewing sarcoma (EwS), an aggressive bone and soft tissue malignancy affecting adolescents and young adults, may be particularly dependent on ECM-mediated cues for progression. Here, we present a synthetic three-dimensional (3D) hydrogel model designed to recapitulate key biochemical features of the EwS tumor microenvironment. Using a polyethylene glycol (PEG) backbone functionalized with ECM-derived integrin-binding peptides, we engineered hydrogels incorporating motifs from collagen I, fibronectin, and the tumor-associated glycoprotein tenascin-C (TNC). Incorporation of TNC-derived peptides, which are heterogeneously distributed in EwS tumors, enabled controlled ECM heterogeneity within the platform. CHLA10 human EwS cells encapsulated in these hydrogels exhibited peptide-dependent proliferation and altered expression of ECM-related and matrix-remodeling genes, highlighting the role of ECM proteins including TNC in influencing cell state. Importantly, the hydrogels were designed with sortase-degradable crosslinkers, enabling gentle and bioorthogonal retrieval of viable cells for transcriptomic and functional analyses—an advance over traditional biomaterial-based systems. This modular 3D system provides a physiologically relevant, animal-free model to study sarcoma–ECM interactions and identify ECM-regulated mechanisms of tumor adaptation and metastasis. Our findings demonstrate that ECM heterogeneity, particularly TNC enrichment, may be a key driver of EwS progression and highlight the potential of biomaterial platforms in uncovering therapeutic targets within the tumor microenvironment.

#0759 Mechanical remodeling of the tumor microenvironment promotes breast cancer and neutrophil-ssociated immunosuppression through ERG3-ALOX5 signaling.

Lingpeng Tang[1], Liangyu Wei[2], Jinpeng Lu[3], Haoxiang Zhang[4], Songsong Wu[1]

[1]Fujian Medical University, Fuzhou, China,[2]Fuzhou University School of Medicine, Fuzhou, China,[3]Shengli Clinical Medical College of Fujian Medical University, Fuzhou, China,[4]University of Kentucky, Lexington, KY

Background: Tumor extracellular matrix (ECM) stiffness is linked to breast cancer progression and immune evasion. The mechanisms by which mechanical signals influence tumor immune evasion through the immune microenvironment remain unclear. This study explores how ECM stiffness impacts the immune landscape and tumor progression via the “mechanical signal-matrix-neutrophil reprogramming-tumor immune escape” axis.

Methods: ECM stiffness in breast cancer patients was assessed using ultrasound elastography, with correlation to prognosis. In preclinical models, a mouse xenograft and 3D cell cultures were used to investigate the effects of ECM stiffness on tumor growth and immune cell infiltration. Single-cell RNA sequencing (scRNA-seq) and multicolor immunofluorescence analyzed immune cell composition in varying stiffness microenvironments. The role of stromal mechanical signals in neutrophil chemotaxis was studied using Piezo1-Ca^{2+}-EGR3 pathway modulation through gene interference, Ca^{2+} signaling blockade, and ChIP-seq. The efficacy of combined EGR3 inhibition and PD-L1 therapy was evaluated in a mouse model.

Results: Single-cell RNA sequencing revealed significant enrichment of tumor-associated neutrophils (TANs) and regulatory T cells (Tregs) in high-stiffness microenvironments, with a reduction in $CD8^+$ T cells. This remodeling was linked to upregulation of PD-L1, Arg1, and TGF-β, suggesting immune escape. TANs in high-stiffness environments exhibited enhanced immunosuppressive traits, correlating with tumor immune evasion. Increased ECM stiffness elevated tumor cell histone acetylation via Piezo1-mediated Ca^{2+} influx, promoting EGR3 transcription. ChIP-seq analysis showed that EGR3 activates ALOX5, driving LTB4 synthesis and enhancing tumor cell chemotaxis toward TANs. The study reveals that ECM stiffness regulates neutrophil chemotaxis via the Piezo1-Ca^{2+}-EGR3-ALOX5-LTB4 pathway, promoting immune evasion. Functional assays demonstrated that inhibiting EGR3 or ALOX5/LTB4 impaired neutrophil chemotaxis and immune evasion. In a mouse model, combining PD-L1 therapy with inhibition of the EGR3 or ALOX5/LTB4 pathways significantly suppressed tumor growth.

Conclusion: ECM stiffness promotes immune evasion in breast cancer via the Piezo1-Ca^{2+}-EGR3-ALOX5-LTB4 axis, creating an immunosuppressive microenvironment that drives tumor progression. These findings suggest new therapeutic targets for breast cancer immunotherapy.

#0761 Collagen turnover is dominated by fibrogenesis in lung adenocarcinoma and fibrolysis in lung squamous cell carcinomas.

Victoria Batto[1], Marselina Arshakyan[1], Rasmus Sund Pedersen[2], Neel Ingemann Nissen[2], Enrico Almici[3], Noemi Reguart[4], Morten Karsdal[5], Nicholas Willumsen[6], Jordi Alcaraz[1]

[1]Universitat de Barcelona, Barcelona, Spain,[2]Nordic Bioscience, Herlev, Denmark,[3]Institut de Bioenginyeria de Catalunya, Barcelona, Spain,[4]Medical Oncology Department, Hospital Clinic i Provincial de Barcelona, Barcelona, Spain,[5]Nordic Biosciences, Herlev, Denmark,[6]Nordic Bioscience

The tumor stroma in non-small cell lung cancer (NSCLC) is highly desmoplastic/fibrotic and is emerging as a key regulator of tumor progression, immune evasion and therapy resistance. Tumor fibrosis is characterized by the aberrant accumulation of collagen. However, our understanding of collagen turnover and its potential dependence on the histologic subtype is very limited. Here, we combined transcriptional profiling and ELISA-based assays for neoepitope collagen fragments to analyze collagen production (fibrogenesis) and degradation (fibrolysis) in tumor-associated fibroblasts (TAFs) and in tumor samples from the major NSCLC histologic subtypes: lung adenocarcinoma (LUAD) and lung squamous cell carcinoma (LUSC). In culture, LUSC-TAFs exhibited enhanced collagen turnover with increased markers of both production (exPRO-C1, PRO-C3 and PRO-C6) and degradation (C1M, C3M, C6M). Consistently, LUSC-TAFs exhibited higher RNA levels of both fibrillar collagens and collagenolytic MMPs, whereas TIMP-1 (a natural inhibitor of major collagenolytic MMPs) showed opposite patterns at the RNA and secreted protein levels. Consistent hystotype-dependent collagen-turnover signatures were observed in bulk RNA-seq data (TCGA) and in histologic analyses of TMAs from surgical specimens. Our results indicate that fibrogenesis is favored in LUAD through increased production of TIMP-1 and lower levels of collagenolytic MMPs, whereas fibrolysis is dominant in LUSC through increased production of collagenolytic MMPs (notably MMP1) and reduced production of TIMP-1. Mechanistically, TGF-β1 is a major driver of tumor fibrosis, and knocking-down SMAD2 or SMAD3 in normal fibroblasts —to mimic previously reported histotype-specific SMAD2/3 expression patterns in lung TAFs (Ikemori et al, Cancer Res 2020) — was sufficient to recapitulate key differential features of collagen turnover between LUAD and LUSC. Together, these data reveal opposite collagen-turnover programs in NSCLC, in which LUAD are predominantly fibrogenic, whereas LUSC are largely fibrolytic through histotype-dependent regulatory processes. Targeting these divergent programs may help revert pathologic fibrosis and improve responses to chemotherapy and/or immunotherapy in NSCLC.

#0762 A tunable 3D organoid model reveals stiffness-dependent stromal activation and cytokine signaling in pancreatic cancer.

Carolyn M. Ruiz-Rivera[1], Ba Xuan Hoang[1], Jamel Ali[2], Thomas D. Schmittgen[3], Bo Han[1]

[1]Keck School of Medicine of USC - University of Southern California, Los Angeles, CA,[2]FAMU-FSU College of Engineering, Tallahassee, FL,[3]Department of Pharmaceutics, University of Florida, Gainesville, FL

Pancreatic ductal adenocarcinoma (PDAC) is characterized by a dense fibrotic stroma and stiff extracellular matrix (ECM) that together shape the tumor microenvironment (TME) driving disease progression. Mechanical stiffness regulates fibroblast activation and inflammatory signaling through mechanotransduction, yet its contribution to tumor-stroma crosstalk remains incompletely understood. To investigate this, we developed a tunable 3D co-culture organoid model by embedding PDAC cells alone or in combination with stromal cells within soft or stiff collagen-based matrices. Conditioned media were collected one week post-seeding and analyzed via ELISA for TNF-α, IL-1β, and IL-6. Cell viability was assessed using CellTiter-Glo, and fibroblast activation markers (α-SMA, IL-6) were quantified by RT-PCR. Finally, immunostaining was performed to evaluate organoid morphology. Our results show that PDAC cells secreted elevated TNF-α in soft matrices, suggesting early cytokine-driven remodeling. Fibroblasts in stiff matrices exhibited a CAF-like phenotype with strong IL-1β secretion, while both fibroblasts and MSCs produced significantly higher IL-6 under stiff conditions, further amplified in PDAC co-cultures. Stiff ECM enhanced stromal viability and induced α-SMA and IL-6 upregulation, confirming mechanotransductive activation. Morphological analysis revealed that PDAC organoids formed larger, well-organized 3D structures under stiff conditions, indicating matrix-dependent growth and adaptation. We conclude that ECM stiffness acts as a potent regulator of stromal activation and inflammatory cytokine signaling in PDAC, establishing a tumor-promoting feedback loop that sustains fibrosis and inflammation. Future studies will incorporate mechanotransduction inhibitors (e.g., TGF-β or integrin blockers) and extended time courses to further define the dynamics of stiffness-driven inflammation and remodeling in the PDAC microenvironment.

#0763 Bridging the translational gap: Critical TME differences between human PDAC and mouse models.

Rachael Guenter[1], Libby A. Boykin[1], Khidr Kishan K. Budhwani[1], Brahma Mubarak K. Budhwani[1], Chelsea L. Crawford[1], J. Bart Rose[2], **Karim I. Budhwani**[1]

[1]CerFlux, Birmingham, AL,[2]Department of Surgery, University of Alabama at Birmingham, Birmingham, AL

Background: Pancreatic ductal adenocarcinoma (PDAC) develops within a dense, heterogeneous tumor microenvironment (TME) in which collagen and hyaluronic acid (HA) shape tissue architecture, biomechanics, and therapeutic response. Although mouse PDAC models are widely used, their ability to recapitulate human extracellular matrix (ECM) organization remains uncertain. This study aimed to quantitatively compare ECM composition and spatial topology in human PDAC versus a commonly used mouse model.
Methods: Tissue sections from primary human PDAC (n=6) and a syngeneic PDAC mouse model (n=3) were stained with H&E and a dual Picrosirius Red (collagen) and Alcian Blue (HA) protocol. The mouse model was generated by subcutaneous implantation of 2838c3 cells into C57BL/6 mice under approved protocols, with tumors resected at ~100 mm^3. High-resolution brightfield images were acquired under identical conditions using Agilent Lionheart. Quantitative analyses across 63 histomorphometric and spatial parameters, including area fractions, edge-to-core localization, and texture, were performed using the CerFlux PEER AI/ML imaging and analytics platform and cross-validated in Fiji. Texture and spatial order were quantified using gray-level co-occurrence matrix features and Moran's I.
Results: Human PDAC exhibited balanced ECM composition (collagen=0.16±0.04; HA=0.18±0.04), whereas mouse tumors showed HA enrichment and collagen depletion (collagen=0.04±0.002; HA=0.26±0.09). Edge mapping revealed proportionate collagen and HA in human samples (edge ratio=0.9±0.46) but 4-fold peripheral collagen enrichment in mouse tumors (edge ratio=4.3±1.3). Human tumors demonstrated higher entropy (collagen=8.1±0.2; HA=7.9±0.2) and substantial HA autocorrelation (Moran's I=0.58±0.22; 0.60±0.42), reflecting heterogeneous, regionally clustered desmoplasia. Mouse tumors displayed reduced entropy (~7.8) and lower Moran's I (0.32±0.05; 0.17±0.01), indicative of ordered, capsule-like ECM organization. Principal component analysis distinctly segregated species: PC1 (42%) collagen-HA balance, with human samples scoring positive and mouse samples negative; PC2 (21%) textural heterogeneity versus edge-localized order.
Conclusions: These findings show that the murine PDAC model fails to reproduce the balanced collagen-HA composition and spatially disordered desmoplasia of human PDAC, instead forming an HA-rich, collagen-depleted core encased in an ordered collagen capsule with markedly lower stromal entropy and autocorrelation. These findings highlight the limitations of mouse models, particularly subcutaneous tumor models, and underscores the need for human-relevant new approach methods (NAMs) for translational therapeutic studies.

#0764 *Mig-6* deficiency accelerates fibrotic tumor microenvironment formation in *Pten*-deficient endometrial tumors.

Shamsun Nahar[1], Kyeong A So[1], Keun Chen Kim[1], Jung Yoon Yoo[2], Jiyoung Yu[3], Kyunggon Kim[3], Eunhee M Jeong[1], Da-Hye Kang[1], Tae Hoon Kim[1], Jae-Wook Jeong[1]

[1]Department of Obstetrics, Gynecology and Women's Health, University of Missouri, Columbia, MO,[2]Yonsei University Mirae Campus, Wonju, Korea, Republic of,[3]Convergence Medicine Research Center, Asan Institute for Life Sciences, Asan Medical Center, Seoul, Korea, Republic of

Endometrial cancer (EC) is the most common gynecological malignancy, and metastatic or recurrent EC remains largely incurable with current therapies. Emerging evidence shows that alterations in the tumor microenvironment play a critical role in driving therapeutic resistance and poor outcomes in EC. Here, we investigated the molecular pathways that drive aggressive tumor behavior in EC using genetically engineered mouse models. Uterine specific conditional *Pten* and *Pten*/*Mig-6* knockout mice were generated using the Pgr^{cre} system. Quantitative proteomic profiling of uterine tissues using the ASTRAL platform identified 862 differentially expressed proteins (DEPs) (fold change > ±2, FDR < 0.05) between double mutant ($Mig\text{-}6^{d/d}Pten^{d/d}$) and single mutant ($Pten^{d/d}$) uteri at 4-months of age. Ingenuity pathway analysis revealed significant enrichment of fibrosis-related signaling, collagen organization, cellular invasion, and proliferative pathways. Consistent with these results, immunohistochemistry demonstrated increased expression of collagen alpha-1(I) chain, MMP3, and phospho-ERK1/2 in double mutant uteri compared to single mutants, correlating with enhanced fibrotic remodeling. Masson’s trichrome staining further confirmed extensive collagen deposition and fibrosis accompanying tumor progression in the double mutant mice. Collectively, these findings suggest that loss of *Mig-6* in a *Pten*-deficient uterus activates ERK signaling and MMP-mediated extracellular matrix remodeling, promoting a fibrotic and invasive tumor microenvironment that contributes to metastasis and therapeutic resistance in endometrial cancer. This work was supported by NCI R01CA264944.

#0765 Tumor extracellular matrix drivesEMT and cellular reprogrammingin Wilms tumor.

Wilson Yeung[1], Matthew E. Thornton[2], Hripsime Chomoyan[1], David Koos[1], Justin Sunwoo[1], Brendan H. Grubbs[2], Roger E. De Filippo[3], Stefano Da Sacco[3], Laura Perin[3], Astgik Petrosyan[3]

[1]Children's Hospital Los Angeles, Los Angeles, CA,[2]Keck School of Medicine of USC, Los Angeles, CA,[3]Children's Hospital Los Angeles/Keck School of Medicine of USC, Los Angeles, CA

Introduction: The extracellular matrix (ECM) is a dynamic component of the tumor microenvironment (TME) that orchestrates cancer progression, invasion, metastasis, and therapy resistance. Wilms tumor (WT), a pediatric renal malignancy, presents an altered ECM architecture. We investigated how WT ECM influences cellular behavior and transcriptional programs compared to normal kidney ECM.
Methods: Spatial transcriptomics and immunohistochemistry mapped ECM localization in WT and normal kidneys. Decellularization protocols were established to completely remove cellular materials while preserving the fibrillar ECM architecture and embedded soluble matrix proteins, as validated by second-harmonic generation imaging and ECM-associated proteins profiling using a cancer biomarker antibody array. Moreover, cancer and normal cells were cultured on decellularized ECM (dECM) scaffolds of WT and normal kidney for 21 days. Cellular dynamics were monitored via two-photon microscopy, and transcriptional changes were assessed by bulk RNA sequencing.
Results: WT ECM exhibited disorganized collagen networks and elevated levels of inflammatory markers, cytoskeletal proteins, and epithelial-mesenchymal transition (EMT) regulators. Cancer cells cultured on WT dECM upregulated EMT-related genes (e.g., FOXC2, TGFB2) and ECM remodeling enzymes (e.g., ADAMTS5), while downregulating cell cycle and integrin-associated genes. Normal cells seeded on WT dECM also adopted cancer-like transcriptional profiles, including increased expression of survival and proliferation genes (e.g., AKT3, BCL2) and decreased integrin-related gene expression.
Conclusion: WT ECM is structurally and molecularly distinct from normal kidney ECM and actively promotes EMT, stemness, and tumor-supportive reprogramming. These findings underscore the ECM as a crucial driver of cancer progression and highlight ECM-targeted strategies as a promising therapeutic approach for combating aggressive cancers.

#0766 Physically driven chromosome instabilities spur macrophages to attack cooperatively.

Dennis Discher, Markus Sprenger, Joanna Georgiou, Tristan Marchena, Jude Khatib

University of Pennsylvania, Philadelphia, PA

Extracellular matrix often accumulates in and around solid tumors, and such tumors also evolve diverse mutations that drive cancers, confound therapies, and modulate immune interactions. Across cancer types, we observe chromosome number changes associate with collagen-I levels, and our experiments show rare heritable chromosome losses are induced by a stiff 3D matrix around spheroids. Chromosome reporters (ChReporters) reveal losses in as few as ~0.1% of cells, with a mechanism in spheroids based on distortion of mitotic spindles - which increases with knockdown of the candidate tumor suppressor myosin-II. Chromosomes mis-segregate into micronuclei that increase with matrix stiffness despite suppressed cell division. Drugs that increase micronuclei in 2D and that rely on an unperturbed spindle show no effect in 3D where the spindle is perturbed. Tumors *in vivo* that are surrounded by stiff collagen likewise show more but varied chromosome loss and slower growth than 2D cultures. High variance of ChReporter-negative colonies further illustrate increased heterogeneity with 3D matrix stiffness and heritable mutations per Luria-Delbruck theory. Physical learning models of evolving chromosome numbers in proliferating cells are developed and fit key statistical trends.Temperature is another physical stressor - as solid tumors tend to be warm - and we show it has similar outcomes as matrix physical properties. Heating is also now part of various therapies as are immune-engineering approaches. We take advantage of Macrophages that often pervade solid tumors where clusters of macrophages are sometimes seen and associate with longer survival of patients. However, clustering mechanisms, responses to stressor above, and impacts on key functions such as phagocytosis remain obscure. Under conditions that maximize cancer cell phagocytosis within cohesive tumors, we uncover pathways that favor dynamic clusters and find a colocalization of tumor-intrusive pseudopodia which we term “intrudopodia.” Cluster formation is favored by M1 macrophages after exposure to interferons and T cell-derived cytokines. M1 macrophages upregulate specific cell-cell adhesion receptors but suppress actomyosin contractility, with both pathways contributing to cluster formation and unleashing pseudopodia. Macrophage neighbors in tumor spheroids indeed coextend intrudopodia between cancer cell junctions—at least when phagocytosis conditions are maximized by checkpoint disruption and other strategies. Intrudopodia from neighbors help detach and individualize cancer cells for rapid engulfment. Cooperative phagocytosis thus overcomes solid tumor cohesion—and might explain why the macrophage clustering factor *ITGAL* associates with patient survival.

#0767 Tumor stiffness as a functional biomarker of KRAS-mutant NSCLC: Insights from the ARTIDIS prospective clinical cohort.

Jordi Alcaraz[1], Elba Marin[1], Hector Sanz-Fraile[1], Marina Querol[2], Paula Gausa[2], Keat Neal[1], Marselina Arshakyan[1], Marc Rico-Pasto[1], Marc Boada[3], David Sanchez[3], Carolina Ortiz Velez[4], Reinier Oropesa Nunez[4], Gitika Srivastava[4], Ahmed Jizawi[4], Sara Nizzero[4], Tobias Appenzeller[4], Philipp Oertle[4], Marko Loparic[4], Marija Plodinec[4], Noemi Reguart[5]

[1]Biomedicine, Universitat de Barcelona, Barcelona, Spain,[2]Thoracic Oncology Unit, Hospital Clinic i Provincial de Barcelona, Barcelona, Spain,[3]Thoracic Surgery, Hospital Clinic i Provincial de Barcelona, Barcelona, Spain,[4]ARTIDIS AG, Basel, Switzerland,[5]Medical Oncology Department, Hospital Clinic i Provincial de Barcelona, Barcelona, Spain

Background: Nanomechanical properties of tumors are emerging biomarkers reflecting extracellular matrix (ECM) remodeling, immune exclusion, and aggressiveness. The AFM-based ARTIDIS platform measures nanomechanical signatures (NS) from fresh biopsies within hours, providing rapid diagnostic and prognostic information while preserving tissue for conventional analyses. Prior work showed that ARTIDIS NS distinguishes malignant from uninvolved lung tissue and predicts early postoperative recurrence. However, the relationship between NS and oncogenic drivers such as *KRAS* remains unclear. As *KRAS* influences ECM composition, matrix remodeling, and stromal activation, we evaluated the preliminary nanomechanical and microenvironmental features of *KRAS*-mutant NSCLC in our prospective cohort.

Methods: Fresh tumor and paired uninvolved lung tissue were collected from 70 early-stage NSCLC patients undergoing curative resection. NS were measured on the ARTIDIS platform. Samples were formalin-fixed for quantitative immunohistochemistry (IHC) of α-SMA, picrosirius red, Ki-67, CD31, CD4, CD8, FOXP3, CD68, and PD-1. Clinical characteristics, driver mutations, and outcomes were recorded with a 36-month follow-up. A focused analysis was performed in KRAS-mutant cases.

Results: Preliminary analyses showed that ARTIDIS NS distinguished malignant from uninvolved tissue with 88% sensitivity, 86% specificity, and 87% accuracy (n=52 paired samples). Eleven patients carried *KRAS* mutations (G12A/D/F/S, G13D, Q16H). Median age was 68.5 years; 63.4% were former smokers. Most tumors were early-stage (IA-IIB), and 45.5% were poorly differentiated. Across the full cohort, 17 patients recurred, including 3 patients (27.3%) with *KRAS* mutations. ARTIDIS NS predicted progression within 10 months after surgery with 100% sensitivity and 93% specificity, including predictions derived from uninvolved tissue. *KRAS*-mutant tumors showed higher stiffness than *KRAS*-wild-type or driver-negative tumors. Quantitative IHC demonstrated a higher percentage of proliferating cancer cells together with increased Treg infiltration and PD-1 expression in *KRAS*-mutant samples compared with uninvolved lung tissue, suggesting immune exhaustion.

Conclusions: This study provides the first evidence that *KRAS*-mutant NSCLC displays a distinct, stiffer nanomechanical phenotype. These findings support tumor stiffness as a functional characteristic of *KRAS*-driven biology and highlight ARTIDIS NS as a rapid biomarker complementing histopathology and molecular profiling. A 200-patient prospective validation study is underway to confirm the clinical utility of NS for risk stratification and personalized treatment planning.

#0768 Modeling the triple-negative breast cancer extracellular matrix in a 3d tumor scaffold.

Katherine Hebert[1], Thomas Cheng[1], Sophie Dietrich[1], Mackenzie Hawes[1], W. Todd Monroe[2], Jorge Belgodere[1], Elizabeth Martin[3]

[1]Tulane University School of Medicine, New Orleans, LA,[2]Louisiana State University, Baton Rouge, LA,[3]Tulane University, New Orleans, LA

Breast Cancer is the second leading cause of cancer death in women and incidence rates are increasing 0.5% per year. Triple negative breast cancer (TNBC), which is classified by negative hormone receptors (HR-), progesterone and estrogen, and human epidermal growth factor receptor 2 (HER2) negative, is the most aggressive subtype and occurs more often in younger Black and Hispanic women. TNBC, compared to other subtypes, is difficult to treat due to the treatment response rate of 30%. Neoadjuvant chemotherapy is the standard treatment for TNBC. This is attributed to the lack of preclinical models that allow multi-cellular interactions in the highly heterogenous nature of TNBC. Due to this, there is a critical need for 3D TNBC tumor models that recapitulate the complex extracellular matrix (ECM). Most ECM-cancer studies focus on collagen I (COL1); however, COL1 is not a prognostic marker for TNBC and is often not observed to be elevated in TNBC. Evaluation of ECMs overexpressed in a primary TNBC tumor compared to adjacent adipose demonstrated elevated ECM protein expression. To determine the impact of distinct ECMs in TNBC breast cancer progression, we explored changes in ECM protein expression (MFAP5, FN1, and POSTN) in TNBC cell lines and fabricated matrix for *in vitro* systems. qRT-PCR and RNA sequencing, genes associated with epithelial-to-mesenchymal transition and inflammation were significantly upregulated in ECM-OE expressing cells in 2D culture. Next, we created 3D models of TNBC ECM through the fabrication of ECM matrix coated cell culture plates (COL1, FN1, and POSTN) and 3D scaffolds using bioinert fish gelatin methacrylol (fgelMA). Taken together, this work identifies ECM proteins - MFAP5, FN1, and POSTN - attribute to TNBC proliferation and survival through epithelial to mesenchymal transition. Overall, our results establish an extracellular signature for the triple-negative tumor type while also demonstrating fabricated 3D ECM models can be used to advancing the development of potential treatments for TNBC.

#0769 Matrix mechanics modulate cancer cell plasticity and drug responses.

Chantal Kopecky[1], Elvis Pandzic[2], **Morgan Hamon**[3], Sean Porazinski[3], Justin Gooding[1], Kristopher A. Kilian[1]

[1]School of Chemistry, Australian Centre for NanoMedicine, Faculty of Science, UNSW, Sydney, Australia,[2]Katharina Gaus Light Microscopy Facility, Mark Wainwright Analytical Centre, UNSW, Sydney, Australia,[3]Inventia Life Science, Alexandria, Australia

The ability of cancer to adapt and evolve within its microenvironment drives metastasis and therapy resistance, with cancer cell plasticity playing a central role in these processes. To uncover how the tumour microenvironment (TME) shapes cancer cell behaviour to influence drug responses, we built next-generation in vitro models that recapitulate the key biophysical and biochemical cues of in vivo tumours.

Using precision-engineered 2D hydrogel micropatterning techniques and 3D bioprinted matrices, generated with the RASTRUM™ platform, we created spatially controlled “tumour environments" where cancer cells experienced defined stiffness, confinement, and extracellular matrix (ECM) architecture and composition. These mechanically tunable systems enabled interrogation of how substrate-cancer cell interactions and matrix mechanics orchestrate cellular transitions, organisation, and standard-of-care drug responses across cancer models.

Our results reveal that subtle changes in stiffness and confinement dramatically reorganise cancer cell populations, mimicking spatial hierarchies observed in vivo. In 3D, softer matrices enriched stem-like cancer subpopulations with increased invasiveness potential and chemoresistance, underscoring the powerful influence of matrix mechanics on tumour evolution.

Together, these bioengineered platforms offer an accessible, high-throughput approach for investigating the mechanical underpinnings of cancer cell plasticity. By merging bioprinting precision with biological complexity, this work lays the foundation for more predictive models of tumour progression and opens new avenues for developing approaches targeting resistant cancer cell states.

#0771 ECM stiffness and glutamine availability rewire metabolic and immune phenotypes in 3D Co-culture models of pancreatic cancer and cancer-associated fibroblasts.

Jonathan Barajas[1], Carolyn Ruiz[1], Zhi Yang[1], Bo Han[1], Edward Agyare[2], Xueyou Zhu[2], Saun-Joo Yoon[3]

[1]USC - University of Southern California, Los Angeles, CA,[2]Florida A&M University, Tallahassee, FL,[3]University of Florida, Gainsville, FL

Pancreatic ductal adenocarcinoma (PDAC) develops within a dense, tumor microenvironment (TME) enriched with extracellular matrix (ECM) and cancer-associated fibroblasts (CAFs). PDAC tumors also rely heavily on glutamine metabolism. While ECM stiffness and nutrient availability each influence tumor behavior, their combined effects on CAF and PDAC phenotypes in 3D contexts are not well defined. We investigated how matrix stiffness and glutamine supplementation modulate oxidative stress, lipid metabolism, mitochondria, cellular architecture, and PD-L1 expression in CAFs and patient-derived PDAC cells. Soft (3A) and stiff (6A) collagen-based ECM gels were generated in-house. Primary human CAFs or PDAC lines (G43, G46) were embedded in 3D and assessed at 48 hr and 7 days. CAFs were analyzed using CellROX, JC-1, BODIPY, phalloidin, and PD-L1 staining. PDAC cells were cultured in basal DMEM, glutamine-supplemented DMEM, or organoid-like media. Mitochondria were detected using an anti-mitochondrial antibody with AF488 secondary. All samples were imaged in 3D at 20× magnification. ECM stiffness significantly altered CAF oxidative stress responses. At 48 hr, CAFs in soft and stiff ECM showed comparable but detectable CellROX signal, whereas by 7 days, stiff ECM produced a marked increase in oxidative stress with a higher number of strongly CellROX-positive nuclei. Quantification of fluorescence intensity confirmed a time-dependent rise in oxidative stress that was amplified under stiff ECM conditions. This increase aligned with elevated JC-1 J-aggregate formation at 7 days, indicating enhanced mitochondrial polarization. CAFs in stiff ECM also exhibited greater F-actin alignment, cell spreading, and lipid accumulation, suggesting coordinated metabolic and cytoskeletal adaptation to mechanical stress. PD-L1 expression likewise increased over time and remained higher in stiff ECM, supporting a role for mechanosensing in promoting immune-evasive CAF phenotypes. In PDAC cells, ECM stiffness and nutrient environment jointly controlled metabolic outputs. BODIPY staining revealed stiffness-dependent lipid droplet patterns, which were further amplified by organoid-like media. Glutamine supplementation increased mitochondrial signal intensity and reorganized mitochondrial networks in both G43 and G46, consistent with glutamine-driven metabolic activation. ECM stiffness also shaped F-actin architecture and mitochondrial localization, indicating a biomechanical-metabolic interaction. Together, these results show that ECM stiffness and glutamine availability reprogram CAF and PDAC metabolic and immune features. This work underscores the need to incorporate both mechanical and metabolic cues when modeling PDAC and identifies metabolic-immune pathways as potential therapeutic vulnerabilities within the TME.

#0773 Single-cell and spatial transcriptomic profiling reveal fibrosis-related tumor states in lung squamous cell carcinoma associated with idiopathic pulmonary fibrosis.

KENTA MANABE[1], Atsushi Matsuoka[1], Kazuhiko Shien[1], Shuta Tomida[2], Hidejiro Torigoe[1], Kazuya Hisamatsu[1], Ryota Fujiwara[1], Kosei Ishimura[1], Shunsuke Mori[1], Ryunosuke Fujii[1], Asuka Mimata[1], Kazuhiro Okada[1], Ryo Yoshichika[1], Mao Yoshikawa[1], Yuma Fukumoto[1], Haruchika Yamamoto[1], Kumi Nakajima[1], Shin Tanaka[1], Ken Suzawa[1], Kentaroh Miyoshi[1], Mikio Okazaki[1], Seiichiro Sugimoto[1], Shinichi Toyooka[1]

[1]Thoracic, Breast and Endocrinological Surgery, Okayama Univ. Graduate School of Med., Dentistry & Pharm. Sci., Okayama, Japan,[2]Center for Comprehensive Genomic Medicine, Okayama University Hospital, Okayama, Japan

Background: Patients with idiopathic pulmonary fibrosis (IPF) have an elevated risk of lung cancer, particularly lung squamous cell carcinoma (LUSC), which is associated with limited treatment options and poor outcomes. Although LUSC occurring in IPF patients is collectively referred to as LUSC associated with IPF regardless of location, tumors arising within usual interstitial pneumonia (UIP) lesions may harbor distinct molecular traits shaped by the local fibrotic microenvironment compared with those arising outside UIP.
Methods: We performed integrated single-cell RNA sequencing (scRNA-seq) and Digital Spatial Profiling (GeoMx DSP) to characterize tumors and adjacent lung tissue from LUSC patients with UIP patterns. scRNA-seq was performed on paired tumor and adjacent lung tissue from an In-UIP case and an Out-UIP case, while GeoMx profiling was conducted in an independent cohort (In-UIP n=3, Out-UIP n=3). scRNA-seq data were processed using Scanpy (v1.10.4) and spatial transcriptomics data were processed using GeomxTools (v3.8.0). Cellular trajectories were analyzed using scTour (v1.0.0). Spatial deconvolution was performed using Cell2location (v0.9.6), with validation in an external fibrosing ILD spatial dataset.
Results: To infer lineage relationships from the scRNA-seq data, we applied partition-based graph abstraction (PAGA), which demonstrated a connection between basal cells and malignant cells, suggesting basal cells as a cellular origin of LUSC. Tumor cells were further resolved into four transcriptionally distinct malignant states, one of which was characterized by upregulation of oxidative stress-response and detoxification programs, including induction of multiple WNT ligand genes. scTour vector-field and pseudotime modeling showed expansion of this state at late phase exclusively in the In-UIP tumor. Spatial profiling by GeoMx DSP followed by Cell2location deconvolution confirmed significant enrichment of this stress-tolerant malignant state in In-UIP tumors compared with Out-UIP tumors. In adjacent non-malignant regions, UIP lungs exhibited marked expansion of basal and club populations, reflecting UIP-specific epithelial remodeling. Analysis of an independent spatial ILD cohort validated this epithelial shift specifically in IPF.
Conclusions: Single-cell and spatial analyses demonstrate that UIP lesions create a selective niche that reshapes local epithelial composition and promotes regional enrichment of a stress-tolerant malignant cell state. These data indicate that the fibrotic lung microenvironment of IPF conditions malignant cell states and their spatial organization, nominating microenvironment-driven programs as potential therapeutic targets in LUSC associated with IPF.

#0774 Aligned ECM influences neuroblastoma cell plasticity via YAP-WT1 association.

Vic Zamloot[1], Chandra Kaladhar Vemula[1], Antonios Chronopoulos[2], JinSeok Park[1]

[1]Children's Hospital Los Angeles, Los Angeles, CA,[2]Stanford University, Stanford, CA

Introduction

Neuroblastoma (NB) is the most common extracranial pediatric solid tumor and is comprised of two interconvertible cell states: the less-aggressive adrenergic (ADRN) and the aggressive, therapy-resistant mesenchymal (MES) subtypes. Through an ADRN-to-MES transition (AMT), NB cells become more refractory to existing therapeutics, as is often observed in high-risk (HR) and relapsed NB. We previously identified that aligned extracellular matrix (ECM) proteins, featured in HR and relapsed NB, drive AMT in NB by facilitating epigenetic silencing of ADRN signatures. Our study aims to further characterize the underlying mechanisms driving AMT in NB, specifically how aligned ECM increases MES signatures through activation of yes-associated protein (YAP), which interacts with Wilm's Tumor 1 (WT1) to regulate activity of the MES driver, paired related homeobox 1 (PRRX1).

Experimental Procedures

To interrogate how aligned ECM influences MES signatures, we employ a nanogrooved collagen-coated array (NGCA) that models the aligned collagen observed in HR and relapsed NB. Cells plated on this *in vitro* platform are assessed for differences in MES signatures and expression of YAP, WT1, and PRRX1 via biochemical analyses including Western blot, immunofluorescent (IF) staining, and chromatin immunoprecipitation sequencing (ChIP-seq). We also use cells with knockdown and overexpression of YAP as well as knockdown of WT1 to determine their roles in our proposed AMT mechanism. The association of YAP and WT1 is physically evaluated using proximity ligation assay (PLA) and co-immunoprecipitation (co-IP).

Results

Our data demonstrate that aligned ECM modeled *in vitro* with NGCA increases MES signatures and YAP expression in NB. NGCA additionally promotes expression of the MES driver PRRX1 in a YAP-dependent manner, suggesting its recruitment by YAP to increase MES signatures. Furthermore, ChIP-seq highlights an association between YAP and WT1 that promotes PRRX1 expression. Computational analysis identifies WT1 as a transcription factor interacting with PRRX1, an association we confirm through reduction of PRRX1 expression following WT1 knockdown. We show that WT1 expression and nuclear localization are associated with YAP activity; indeed, PLA and co-IP analyses reveal that YAP and WT1 form a complex in response to NGCA, which then translocates to the nucleus.

Conclusions

Together our data support a mechanism by which YAP and WT1 interact in response to aligned ECM to promote PRRX1 expression, thereby increasing MES signatures. Identification of this process uncovers pharmacological and therapeutic targets for re-sensitization of HR and relapsed NB to existing treatments to improve clinical outcomes.

#0775 Matrix stiffness remodels the immunosuppressive tumor microenvironment via the PIEZO1-DCLK1-STAT5B pathway.

Liangyu Wei[1], Lingpeng Tang[2], Jinpeng Lu[2], Ting Hu[2], Shi Chen[2], Zuwei Wang[2], **Haoxiang Zhang**[1]

[1]School of Medecine, Fuzhou University, Fuzhou, China,[2]Shengli Clinical Medical College, Fujian Medical University, Fuzhou, China

Background Pancreatic ductal adenocarcinoma (PDAC) has an abysmal 5-year survival rate (8%), largely attributed to its dense fibrotic stroma that forms a high-stiffness microenvironment. This biomechanical feature exacerbates immunosuppression and promotes immune escape, but the molecular mechanism by which matrix stiffness-derived mechanical signals convert into immunosuppressive cues remains undefined. This study aims to uncover the key mechanotransduction-immunity crosstalk pathway in PDAC and provide novel therapeutic targets.

Methods We utilized our established adjustable extracellular matrix (ECM) stiffness models (in vitro 3D culture and in vivo orthotopic transplantation) as core research platforms. Integrated approaches including CRISPR-Cas9 gene editing, multi-omics (protein modification omics, CUT&Tag-seq), single-cell RNA sequencing, and spectral flow cytometry were employed to dissect the mechanotransduction pathway and its regulatory effect on the tumor microenvironment.

Results We identified a novel PIEZO1-Ca^{2+}-DCLK1-STAT5B axis mediating stiffness-induced immunosuppression. High matrix stiffness specifically activated the mechanosensitive ion channel PIEZO1, triggering Ca^{2+} influx. Intracellular Ca^{2+} upregulated and activated DCLK1 via dual mechanisms: inhibiting ANAPC5/PSMA7-mediated ubiquitination and promoting HPCAL1-dependent serine phosphorylation. Activated DCLK1 bound to STAT5B through its serine/proline-rich linker domain (DCLK1) and SH2 domain (STAT5B), inducing STAT5B phosphorylation and nuclear translocation. Nuclear STAT5B, under the regulation of super-enhancers (marked by H3K27ac/H3K4me1), transcriptionally activated immunosuppressive genes (TGF-β, PD-L1, KRAS), ultimately shaping an immunosuppressive microenvironment characterized by increased infiltration of Tregs, MDSCs, and M2 macrophages, and impaired effector T cell function. Preliminary data confirmed that high stiffness upregulated all components of this axis, and STAT5B inhibition significantly reduced TGF-β/PD-L1/KRAS expression and immunosuppressive cell infiltration.

Conclusion This study is the first to uncover a biomechanics-driven immunosuppression pathway in PDAC, establishing a direct link between matrix stiffness and immune escape. The PIEZO1-Ca^{2+}-DCLK1-STAT5B axis provides a novel therapeutic target for reversing immunosuppression and improving PDAC therapeutic efficacy.

#0776 A cancer cell intrinsic program for matrix remodeling and CAF recruitment in slow growing, poor prognosis colorectal cancers.

Claudio Isella[1], Anna Cassisa[1], Consalvo Petti[2], Alexandra Ambra Ulla[1], Jie Zhou[3], Carlo Leonardi[1], Roberta Porporato[1], Daniela Cantarella[1], Letizia Franco[2], Cinzia Benetti[1], Jill Carol Rubinstein[4], Jessica Erriquez[2], Mariangela Russo[5], Francesco Sassi[2], Elena Grassi[2], Ymera Pignochino[6], Alberto Puliafito[2], Ivan Molineris[1], Rebecca Senetta[7], Andrea Bertotti[8], Livio Trusolino[9], Jeffrey H. Chuang[10], Alberto Bardelli[11], Enzo Medico[12]

To investigate how the molecular programs of cancer cells shape their crosstalk with the tumor microenvironment, we generated mouse xenografts from 19 human colorectal cancer (CRC) cell lines and performed RNA sequencing, separately profiling human (cancer) and murine (stromal) transcriptomes. Xenograft growth rates varied markedly across lines and correlated with stromal abundance: slower-growing tumors accumulated more stroma. Cancer cells from these stroma-rich, slow tumors displayed a coordinated transcriptional program involving epithelial-mesenchymal transition (EMT) and extracellular matrix (ECM) remodeling, which we termed the *EMT-Matrix Remodeling* (EMR) signature. The corresponding stromal fibroblasts exhibited matrix-remodeling activity defined by a *matrix-remodeling cancer-associated fibroblast* (mrCAF) signature. Integration of human CRC bulk, single-cell, and spatial transcriptomics confirmed the co-occurrence and spatial proximity of EMR cancer cells and mrCAFs, both associated with adverse clinical outcome. A pan-cancer analysis revealed that EMR and mrCAF signatures recur across multiple tumor types, where they similarly mark aggressive disease. Collectively, these findings uncover a conserved mechanism of ECM remodeling driven by reciprocal cancer-stromal interactions: cancer cells with an EMT-like, matrix-remodeling phenotype recruit and instruct CAFs to reshape the tumor microenvironment, thereby promoting tumor progression.

#0777 An ATP-grasp superfamily enzyme induced under serum starvation and hypoxia as a potential biomarker for pancreatic cancer diagnosis.

Katsuya Takenaka[1], Yukako Komori[2], Yoshiyasu Nakamura[2], Shiro Koizume[2], Yohei Miyagi[2]

[1]Fundamental Research Unit, TR Business Division, Shin Nippon Biomedical Laboratories, Ltd., Kagoshima, Japan,[2]Molecular Pathology and Genetics Division, Kanagawa Cancer Center Research Institute, Yokohama, Japan

Pancreatic cancer is one of the most prognostically unfavorable cancers worldwide. On the other hand, favorable outcomes have been reported when treatment is initiated at an early stage, and there is great expectation for the development of early diagnostic technologies. Most solid tumors, including pancreatic cancer, contain areas of hypoxia where the dominant cells show increased resistance to both chemo- and radiotherapy. We hypothesized that tumor cells proliferate under the ischemic environment, which is generally unfavorable for cell survival, through specific gene expression. Genes exhibiting such expression changes may serve as candidates for early detection or therapeutic targeting. To identify such candidates, we cultured human pancreatic cancer cell lines under serum starvation and hypoxic conditions to mimic the ischemic tumor microenvironment. Genes synergistically induced by these combined conditions were identified by DNA microarray analysis. One of the candidates was an ATP-grasp superfamily enzyme, RIMKLA, which is involved in glutamine family amino acid metabolic process, and its inducible expression was presented by qRT-PCR for at least four pancreatic cancer cell lines. We raised antibodies against peptides corresponding to specific regions of the polypeptide and showed that the protein synthesis is also induced. In mouse xenograft models, RIMKLA expression was seen in hypoxic regions where HIF-1α was induced, and the product of this enzyme was quantitatively detected by mass spectrometry. Tumorigenicity of the gene knockout cells was significantly reduced compared to that of wild-type cells, and necrotic regions were observed within hypoxic areas even in small xenografts. Immunohistochemical staining and mRNA *in situ* hybridization performed on surgical specimens from pancreatic cancer patients demonstrated that this enzyme is specifically expressed in pancreatic cancer tissues. These observations support the potential application of this protein as a clinical biomarker for pancreatic cancer diagnosis. In addition to detecting and targeting the enzyme molecule in tissue samples, minimally invasive diagnostic methods could be developed based on detecting this relatively small product in peripheral blood. Since the genetic disruption of the enzyme impairs tumor formation, its enzymatic activity appears to play an important role in tumor cell survival. These findings support the potential development of molecular targeted therapies based on gene disruption or enzymatic activity inhibition.

#0778 Hypoxia shapes tumor immune microenvironment through cell-type dependent responses in diffuse astrocytomas.

Aliisa Tiihonen[1], **Iida Salonen**[2], Iina Koivisto[2], Anni Ritamaki[2], Serafiina Jaatinen[2], Tanja Hyvarinen[2], Johanna Tilvis[2], Joose Kreutzer[2], Masi Valkonen[2], Goktug Karabiyik[1], Sonja Mantyla[2], Maryam Mohammadlou[2], Miina Hoikka[2], Jurgen Beck[3], Roland Rolz[3], Mikael Marttinen[1], Matti Nykter[1], Joonas Haapasalo[4], Pekka Ruusuvuori[2], Seppo Parkkila[1], Pasi Kallio[1], Sanna Hagman[2], Juha Kesseli[1], Vidhya Madapusi Ravi[3], Hannu Haapasalo[1], Arja Jukkola[1], Kevin Joseph[3], Kirsi Rautajoki[1]

[1]Tampere University, Tampere, Finland,[2]Tampere University, Faculty of Medicine and Health Technology, Tampere, Finland,[3]Department of Neurosurgery, Medical Center - University of Freiburg, Faculty of Medicine, Freiburg, Germany,[4]Tampere University, Faculty of Medicine and Health Technology and Tampere University Hospital, Department of Neurosurgery, TAYS Cancer Centre, Tampere, Finland

Background
Hypoxia is a critical driver of tumor aggressiveness in high-grade gliomas, yet its cell-type-specific effects on immune cell populations within the tumor microenvironment (TME) remain poorly understood.
Materials and methods
We have investigated how hypoxia shapes the spatial distribution and functional states of monocyte-derived macrophages (MDMs) and brain-resident microglia (MG) in diffuse astrocytomas and glioblastomas (GB) by using cyclic immunohistochemistry (cIHC), single-cell RNA sequencing, spatial transcriptomics, and in vitro cell culture models in controlled oxygen and pH conditions.
Results
Hypoxia induces divergent responses in these myeloid subsets, driving spatial immune patterning. In GB, $CD163^-$ MDMs dominate hypoxic niches, while MG populations are excluded from these regions, correlating with hypoxia-induced TNF upregulation, stress response signatures, and dampened interferon responses. Conversely, MDMs exhibit a shift towards hypoxia-associated immunosuppressive traits, altered metabolism and upregulated cell survival. GBs display elevated hypoxic intensity compared to diffuse astrocytomas, as supported by hypoxia-response gene expression in the TCGA dataset. In vitro, MG are characterized by heightened sensitivity to hypoxia-associated acidity compared to MDMs, suggesting that their exclusion from hypoxic zones results from intrinsic vulnerability.
Conclusion
Our findings reveal that hypoxia and hypoxia-associated acidity remodel the TME by promoting immunosuppressive MDM accumulation and depletion of MG, creating spatially distinct immune landscapes that may underlie GB progression. These results highlight hypoxia-driven immune dysregulation as a therapeutic target and underscore the importance of cell-type-specific strategies to counteract TME-driven immunosuppression in malignant gliomas.

#0779 Hypoxia-driven epithelial reprogramming elevates CD46 and promotes vasculogenic mimicry in immune-desert NSCLC.

Minyeop Kim[1], Youwon Lee[1], Seung Yeon Oh[1], Eun Ji Lee[1], Ji Hyung Moon[1], Ji Ae Ko[1], Ji Woo Lim[1], Sujin Choi[1], Jae-Hwan Kim[2], Jii Bum Lee[1], Min Hee Hong[3], Sun Min Lim[1], Byoung Chul Cho[1], Mi Ran Yun[1]

[1]Yonsei University College of Medicine, Seoul, Korea, Republic of,[2]Yonsei University Hospital Cancer Center, Seoul, Korea, Republic of,[3]Yonsei University College of Medicine SBSI, Seoul, Korea, Republic of

Introduction: Immune-desert non-small cell lung cancer (NSCLC) presents a major challenge for immunotherapy due to poor T-cell infiltration despite the presence of tumor antigens. While immune suppression in these tumors is well recognized, the contributions of epithelial and stromal compartments to shaping the tumor microenvironment (TME) remain poorly defined.
Methods: We analyzed bulk RNA-seq profiles from 60 lung adenocarcinoma (LUAD) tumors and classified them as immune-desert or inflamed using a T-cell inflammed signature. Matched tumors were further characterized using single-cell RNA sequencing (scRNA-seq) to dissect epithelial, stromal, and immune compartments within the TME. Key findings were validated using public datasets, immunohistochemistry (IHC) of patient specimens, and functional assays in CRISPR/Cas9-edited cell lines.
Results: Compared with immune-infiltrated epithelial cells, desert epithelial cells were enriched in complement cascade, hypoxia, cholesterol homeostasis, and EMT pathways, while OXPHOS and antigen-processing programs were downregulated. Regulon analysis identified XBP1 as a key transcription factor in desert epithelial cells, which targeted other genes driving desert-enriched pathways, including CD46, complement-regulatory modules, and cytokines/chemokines involved in myeloid recruitment and immune evasion. These results suggest that desert epithelial cells are in an stress-adapted, plastic state. In the endothelial lineage, Desert tumors exhibited reduced PCV scores, a metric associated with T-cell infiltration, alongside an increased proportion of Epi-like endothelial cells expressing cancer stemness-related genes. Among regulators of this program, ELF3, a hypoxia-inducible transcription factor, was strongly upregulated in vascular mimicry (VM)-associated cells. IHC confirmed robust CD46 expression on epithelial surfaces of Desert tumors. Notably, CD46-high NSCLC lines formed significantly more VM networks than CD46-low lines. Analyses of public datasets further corroborated inverse relationships among CD46 expression, hypoxia signaling, VM enrichment, immune infiltration, and immunotherapy response, consistent with a role for these programs in mediating immune exclusion.
Conclusions These findings indicate that hypoxia-linked epithelial stress programs, driven in part by XBP1, elevate CD46 and support VM-related plasticity, forming both immunologic and structural barriers characteristic of the immune-desert state. Together, these results outline how hypoxia-adapted epithelial and endothelial transitions reorganize the architecture of Desert tumors and help explain their persistent resistance to T-cell infiltration, highlighting the value of considering structural remodeling alongside immune suppression when interpreting the desert phenotype.

#0780 Tumor cell adaptation to nutrient stress via metabolic change due to fibronectin/integrin internalization.

Arin Nam, Tasha Nguyen, Tami von Schalscha, Sara M. Weis, David A. Cheresh

UC San Diego Health, San Diego, CA

Tumor cells that adapt to stressors in the microenvironment gain a stem-like, aggressive phenotype, promoting cancer progression and drug resistance. We previously showed that integrin αvβ3 induced by stress could promote tumor cell adaptation to nutrient stress. Here, we show that tumor cell-derived fibronectin (FN), a ligand for αvβ3, was also upregulated in response to stress and that FN specifically bound to αvβ3 could be internalized providing a survival benefit under nutrient-limited conditions. Nutrient-starved cells either lacking FN or αvβ3 expression displayed decreased intracellular glutamine and TCA cycle metabolites leading to cell death. Surprisingly, while integrin α5β1 is the predominant FN receptor on these cells and is critical for cell surface FN localization, it did not promote FN internalization that protected cells from nutrient stress. These findings highlight a novel mechanism by which αvβ3-mediated uptake of FN mitigate nutrient stress thereby representing a critical property of cancer stem cells.

#0782 Tolerance to extracellular acidic pH facilitates tumor plasticity.

Manami Hasegawa[1], Bo Xu[1], FeiFei Cai[1], Runmei Cui[2], Ritsuko Ando[1], Ken Matsumoto[1], Chisato Iwabuchi-Yoshida[1], Kazuyuki Yamagata[1], Rika Tsuchida[1], Tsuyoshi Osawa[1]

[1]Division of Nutriomics and Oncology, RCAST, The University of Tokyo, Tokyo, Japan,[2]Department of Biological Sciences, Graduate School of Science, The University of Tokyo, Tokyo, Japan

Cancer cells maintain glycolytic metabolism despite oxygen availability, resulting in an acidic microenvironment mediated by enhanced proton and lactate secretion. We have previously reported that this acidic tumor microenvironment induces the activation of the cholesterol biosynthesis pathway and polyamine pathway. Although these metabolic adaptations have been well documented, the mechanisms governing cell survival under acidic conditions are poorly understood. We first demonstrated that severe acidification (pH 5.6) triggered necroptotic cell death, whereas moderate acidification (pH 6.8) prevented necroptosis and allowed anchorage-independent survival and tumor initiation. At pH 5.6, PANC1 and MIA-PaCa2 pancreatic cancer cells exhibited phosphorylation of RIP1 and MLKL, and Calcein-AM live imaging confirmed membrane-rupturing cell death; these features were not observed at pH 6.8. In addition, when PANC1 floating cells (pH 7.4 or pH 6.8) were subcutaneously injected into SCID/SCID mice, tumor initiation was observed only in the mice implanted with pH 6.8 floating cells by day 7. RNA sequencing comparing adherent and floating cells at pH 6.8 and pH 7.4 revealed activation of the complement pathway specifically in pH 6.8 floating cells, suggesting that complement inhibition may selectively eliminate acid-tolerant cancer cells. A genome-wide CRISPR-Cas9 knockout screen in chronically acid-exposed PANC1 cells identified FAM129C as a critical regulator of acid tolerance and cell survival. In xenograft models, FAM129C overexpression led to downregulation of PIGR. Conversely, in murine pancreatic Pan02 cells overexpressing PIGR, immune profiling showed enhanced immune cell infiltration, particularly increased macrophage infiltration. Finally, we evaluated the therapeutic efficacy of combining an anti-PD-L1 antibody (αPD-L1) with PMX53, a complement inhibitor. This synergistic treatment markedly suppressed tumor growth in PIGR-overexpressing Pan02 tumors. Immunohistochemistry revealed that the combination therapy increased IFN-γ^+ $CD8^+$ T cells and reduced macrophage infiltration within the tumor microenvironment. Our findings reveal a previously uncharacterized pathway that evades necroptotic cell death and enhances cellular plasticity under acidic stress, offering new therapeutic approaches for cancer treatment through pH-dependent cell death modulation.

#0783 Exploring landscapes of T cell activation in acidic environment for tumor immunotherapy.

Minkyeong Ro, Youngjun Park

College of pharmacy, Jeju national University, Jeju, Korea, Republic of

Effector T cells are central to anti-cancer immunity but, within the nutrient-poor, hypoxic, and acidic tumor microenvironment (TME) sculpted by dysregulated tumor metabolism, they become dysfunctional. Tumor cell-derived lactic acid accumulates in the tumor microenvironment as lactate and protons; while lactate's immunosuppressive effects are well established, the contribution of the accompanying protons remains largely unknown. We hypothesized that extracellular acidity per se programs T cell activation. Here we show that lactate-independent extracellular acidity—achieved by titrating media with hydrochloric acid or sodium carbonate to tumor-relevant pH—impairs acquisition of inflammatory effector signatures and curtails clonal expansion in T cells. Collectively, the results indicate that protons may underlie the TME-driven limitation on T-cell antitumor activity. Thus, defining the molecular sensors and signaling nodes that transduce proton stress should reveal druggable targets and rational combination strategies for microenvironmental reconditioning to enhance tumor immunotherapy.

#0785 Elucidating the molecular regulation of superdark transmembrane protein 184C (TM184C).

Shraddha ChandThakuri[1], Jennifer Arcuri[2], Daniel Isom[2]

[1]Cancer Biology, University of Miami Miller School of Medicine, Miami, FL,[2]Molecular And Cellular Pharmacology, University of Miami Miller School of Medicine, Miami, FL

Using structure-to-sequence predictions, our lab recently identified TM184C as a previously uncharacterized ‘superdark’ GPCR-like protein. We have shown that this protein is highly enriched in cellular projections and facilitates cargo transfer through microtubule-based intercellular connections. Alongside, we have also shown that TM184C controls the formation and activity of autophagosomes leading to constrained autophagy. Furthermore, our results provide preliminary insights into why TM184C is a poor prognosticator in cancers such as glioblastoma, pancreatic cancer, and ovarian cancer. As such, we are now trying to understand the different modes of TM184C regulation and how they relate to cancer biology.We have shown that TM184C functions primarily in vesicles with acidified lumen, including autophagosomes, late endosomes, and lysosomes. This led us to hypothesize its spatiotemporal function may be partly regulated by pH. To address this question, we performed a structural analysis to identify residues that may confer pH regulation of TM184C. We stably expressed these mutant residues in HEK293A cells as the non-cancerous model, and Panc-1 cells, as the pancreatic cancer model. With the use of live cell confocal fluorescence microscopy, we observed that these mutants produce striking cellular phenotypes, including abnormal nucleus and vesicles, consistent with hyperactivation or loss of function, supporting a model in which TM184C responds directly to vesicular acidity. Our mutational studies thus strongly indicate that TM184C is indeed regulated by vesicular pH, suggesting that any diseases or drugs that alter vesicular pH may modulate TM184C function. Our research has important implications in cancer biology since disrupted pH and autophagy are two of the key components that tumor cells exploit to resist therapy and adapt to the tumor microenvironment.

#0789 PaintScape™ enables in situ, single cell spatial multiomic visualization of 3D genome organization in fresh frozen colorectal carcinoma tissue in spatially resolved tissue microenvironments.

Shyamtanu Chattoraj, Pamela Flatley, Stacy Elliott, David Castillo, Kenny Chung, Doug Werner, Jude Dunne, Huy Nguyen

Research and Development, Bruker Spatial Genomics, San Jose, CA

Intratumoral heterogeneity (ITH) continues to be one of the major challenges in successful cancer treatments causing poor prognosis, therapeutic resistance, metastasis and relapses across many human cancer types. This heterogeneity largely originates from the complex tumor immune microenvironment, where cancer and immune cells engage in intricate signaling crosstalk, shaped by clonal and sub-clonal variations in genomic, transcriptomic, and proteomic networks across cancer and immune cells. In recent years, disruptions in 3D genome architecture, including CNVs, SVs, and topological changes, have been shown to drive oncogene activation, tumor suppressor silencing, and gene expression dysregulation in many different cancers. While methods like WGS and Hi-C offer bulk-level insights into genomic dysregulation, they disrupt native tissue architecture and lack the single cell nuclear examination, limiting the ability to analyze spatial relationships and organizational features essential for understanding cellular context and heterogeneity. Given its emerging role in therapeutic resistance and poor prognosis, understanding the molecular mechanism behind high ITH demands advanced single-cell and spatial technologies for early detection and disease monitoring. Here, we present a novel multiomic jebFISH™ protocol on the PaintScape™ platform that can be used to characterize ITH of 3D chromatin architecture of fresh frozen normal human colon tissue and colorectal cancer (CRC) samples in different tissue microenvironments at single cell, sub-population and population level. Using the ChromoPaint™ PanChromo MPX Panel, which visualizes over 400 genomic loci across all chromosomes per nucleus, we show chromosomal instability including CNVs such as gain in Chr20q, loss in Chr17p, copy loss of Chr 14, SVs such as Chr13-Chr20q translocation and complex rearrangement of Chr13 in different colon cancer cell sub-populations *in situ* within the tissue. These genomic aberrations were specific to histologically cancerous sections and were not detected in the normal region of the tissue. By combining the jebFISH protocol with multiplexed immunofluorescence, we characterize 3D genome organization of cancer cell sub-populations with unique cell states along with associated proteomic signatures e.g. Pan-CK+ CDH1- and Pan-CK+ CDH1+ subpopulations in different tissue microenvironments. We also visualized genome structure in different tumor-immune microenvironments, e.g. M2 macrophage rich vs CD3+ T-cells rich regions within the same CRC tissue section. In-situ multiomic capability of the PaintScape platform enhances understanding of colon cancer progression and reveals 3D genomic heterogeneity of single cells and sub-populations in their spatial context in native tissue microenvironments.

#0790 Cellular decomposition and metabolic profiling of the tumor microenvironment tumor-stroma interface using high-dimensional spatial proteomics and image analytics.

Arutha Kulasinghe[1], Felicia Roland[2], Michelle Poulin[2], Ritu Mihani[2], Katherine Hales[3], Daniel Winkowski[3]

[1]Frazer Institute, University of Queensland, Woolloongabba, Australia,[2]Quanterix, Marlborough, MA,[3]Visiopharm Corp, Broomfield, CO

Introduction There is an urgent need for the development of better prognostic and predictive biomarkers for cancer immunotherapy across a number of solid cancers. Here we sought to characterise the tumour microevironment (TME) using high-dimensional spatial proteomics paired with advance image analytics to define tumour, stomal and interface regions. We developed custom functional and metabolic content to profile these interface regions to determine activity across transitional zones.

Methods Using high dimensional spatial proteomic profiling (Phenocycler Fusion, Quanterix) with a custom immuno-metabolic panel targeting over 68 proteins, including markers for tumor, stroma, structural components, immune cell types, functional states, and metabolic activity, we characterized cell types, sub-types and metabolic activity across the tumor-stromal interface regions. Custom image analytics, utilizing Visiopharm's analytic pipeline and workflow, enabled precise identification and mapping of spatially distinct tumor and stromal interface regions associated with TME composition. Characterization of cellularity and metabolic activity was further performed through the Phenoplex™ guided workflow.

Results We found intra-tumor and intra-stromal regions were distinct from tumor-interface and stromal-interface regions in terms of TME composition and metabolic activity. Moreover, whilst cell proportions alone were not predictive of clinical benefit, the nuances were in the tumor and immune cell sub-types which were functionally and metabolically characterized. We found a tumor metabolic signature predictive of poorer clinical outcomes and reciprocally high metabolic activity in immune cells at the TME interface associated with benefit from immunotherapy.

Conclusion Taken together, this study highlights the value of high-dimensional spatial proteomics covering functional and metabolic profiling of the TME and the advanced image analytics providing insights into the TME.

#0791 Novel tools for spatial profiling of protein glycosylation in cancer biology.

Shuhui Chen, Erika Leonard, Shamali Roy

Vector Laboratories, Inc., Newark, CA

Glycan modifications play critical roles in cell function in both healthy and diseased states, from controlling proliferation to modulating the immune response. Lectins are glycan-binding proteins that recognize specific glycan structures. Their glycan-specific nature makes them important tools to profile, characterize, and capture the complexity of glycans in biological systems. To explore the complexity of glycan modifications, Vector Laboratories provides Glysite™ Scout Glycan Screening Kits, which are fully integrated kits for the detection of glycan expression in tissue sections. Our curated lectin selection enables the detection of the major glycan motifs including sialylation, fucosylation and galactosylation, for the evaluation of glycan distribution in a target specimen. Here, we established a standard workflow of lectin-integrated tissue immunoassays. Formalin-fixed, paraffin-embedded (FFPE) tissue sections were prepared from a selected panel of normal and cancerous tissues including colon, pancreas, breast, kidney, brain, and lung. Our lectin histochemical analysis revealed tissue-dependent glycopatterns, and our result was aligned with morphological changes observed in disease progression. We then utilized Glysite Explorer in situ PLA Glycan Detection Kit, a novel proximity-based detection technology, to investigate protein-specific glycosylation changes from healthy to diseased tissues. Our findings highlight distinct glycosylation patterns associated with pathological conditions, including cancer, underscoring the relevance of glycosylation in disease mechanisms. In summary, Glysite™ Scout Glycan Screening Kits are easily plugged into day-to-day tissue immunoassays that allow comprehensive screening of N- and O-glycan profiles in various tissue sections. Then Glysite Explorer Kit can be used to explore the glycosylation changes of specific biomarkers in cancer tissues. Altogether, this new data will add to the growing understanding of the impact of protein glycosylation on cancer biology, enriching biomarker discovery and therapeutic targeting.

#0792 A standardized pan-cancer framework for spatial profiling of the tumor microenvironment using multiplex immunofluorescence.

Sidney van der Zande[1], Outi H. J. Hasu[1], Zhiying He[1], Katja E. Valimaki[1], Tuomas Mirtti[2], Antti S. Rannikko[3], Heini J. Lassus[4], Ari P. Ristimaki[2], Pia Osterlund[5], Tero A. Aittokallio[1], Lassi Paavolainen[1], Mikko J. Loukovaara[4], Olli P. Kallioniemi[1], Ralf C. Butzow[4], Teijo S. Pellinen[1]

[1]Institute for Molecular Medicine Finland (FIMM), University of Helsinki, Helsinki, Finland,[2]Department of Pathology, Helsinki University Hospital, Helsinki, Finland,[3]Department of Urology, University of Helsinki, Helsinki, Finland,[4]Department of Obstetrics and Gynecology, University of Helsinki, Helsinki, Finland,[5]Faculty of Medicine and Health Technology, Tampere University Hospital, Tampere, Finland

A growing number of studies have shown the key role of the spatial layout and interactions between cells in the TME in determining patient prognosis and therapy response. While substantial effort has been invested in profiling individual cancers, differences in staining methods and analysis pipelines make it increasingly difficult to study spatial TME patterns in a pan-cancer setting. To address this issue, we developed standardized multiplex immunofluorescence (mIF) staining protocols and computational pipelines to profile TME architecture across tissue microarrays from endometrial, ovarian, breast, prostate, and colorectal carcinomas. Our mIF panels include up to 50 protein targets capturing major immune and stromal populations, epithelial states, and markers of stemness, allowing us to profile the TME in great detail. To achieve high-confidence cell classification, we integrated classical thresholding with pixel-based models and unsupervised clustering to produce a consensus cell-type annotation. Our analyses show that pixel-based and unsupervised clustering methods outperform thresholding by enhanced separation of ambiguous signal and improving reproducibility. Incorporating cellular shape parameters further enhanced the identification of morphologically distinct populations such as fibroblasts and macrophages. We first applied this framework to a gynecological discovery set comprising endometrial and ovarian carcinomas (n > 1600 patients, multifocal sampling). Preliminary analyses indicate that endometrial and endometrioid ovarian carcinomas, both derived from Müllerian epithelium, share similar immune and stromal profiles, whereas ovarian clear cell carcinoma shows a distinct TME composition. In addition, reduced fractions of B cells and increased fractions of dedifferentiated epithelial cells were both strongly associated with recurrence in endometrial carcinoma (two-sided t-test with FDR; both $p < 0.001$). Endometrioid ovarian carcinoma showed similar trends for these features, but no statistically significant associations with recurrence were found ($p = 0.453$ and $p = 0.055$, same order). Neither B-cell fraction nor dedifferentiated epithelial cells showed any association with recurrence in ovarian clear cell carcinoma ($p = 0.339$ and $p = 0.339$, respectively). These findings suggest that the cancer cell of origin may exert a stronger influence on TME composition than the anatomical site of disease. Together, our work will establish a harmonized pan-cancer mIF framework and reveal conserved TME features with clinical relevance. These standardized tools enable cross-cancer comparisons, improve the interpretability of spatial biomarkers, and may guide the development of broadly applicable therapeutic strategies.

#0793 Multiplexed spatial profiling of the tumor microenvironment in syngeneic mouse models using Cell DIVE imaging.

Jeremy Fisher[1], Emily Quann Alonzo[1], Vasundhara Agrawal[2], Sophie Struble[2], Richard A. Heil-Chapdelaine[2], Natasha F. Diaz Granados[2], **Arindam Bose**[2]

[1]Cell Signaling Technology, Danvers, MA,[2]Leica Microsystems, Waltham, MA

Comprehensive spatial and phenotypic characterization of the tumor immune microenvironment (TIME) in preclinical models is essential for understanding mechanisms of immune modulation and resistance. In this study, we employed the Cell DIVE™ multiplex immunofluorescence platform to spatially profile formalin-fixed paraffin-embedded (FFPE) sections from syngeneic mouse tumor models—MC38 (colorectal) and LL/2 (lung)—using a panel of antibodies from Cell Signaling Technology (CST), targeting epithelial, stromal, immune, and checkpoint markers. Multiplexed imaging data were analyzed using Aivia software to enable cell-level segmentation, phenotype classification, and spatial context analysis. We conducted a comprehensive comparison of the TME between the two tumor types, revealing distinct immune and stromal cell compositions, including differential infiltration of cytotoxic cells, regulatory T cells, and macrophage subsets. AI-powered spatial analyses uncovered unique patterns of immune cell localization and checkpoint molecule expression, highlighting potential mechanisms of immune exclusion and exhaustion. Co-localization and proximity analyses further elucidated interactions between immune and tumor cells, offering insights into the immunogenicity of each model. This study demonstrates the utility of multiplexed, spatially resolved immunofluorescence to dissect the complex tumor immune microenvironment in syngeneic mouse models. This approach enables a deeper understanding of tumor immunobiology in preclinical models and provides a foundation for identifying spatial biomarker patterns associated with therapeutic response. The combination of highly validated monoclonal antibody conjugates, Cell DIVE™ multiplexing, and advanced AI-powered image analysis, creates a more powerful and comprehensive tool for preclinical evaluation of immune-oncology (IO) therapeutics.

#0794 Spatial analysis of the DLBCL tumor microenvironment via the novel SignalStar® multiplex immunohistochemistry assay.

Jennifer Ziello[1], Jason Weirather[2], Derek Papalegis[1], Lily Vu[1], Gabriella Spang[1], Sizun Jiang[3], Giorgio Ga. Inghirami[4]

[1]Cell Signaling Technology, Danvers, MA,[2]Elucidate Bio, Inc., Boston, MA,[3]Harvard Medical School, Boston, MA,[4]Weill Cornell Medical College, New York-Presbyterian, New York, NY

The complexity of the immune landscape in Diffuse Large B Cell Lymphoma (DLBCL) tumors underscores the necessity of understanding the interplay between T cell activation and immunosuppression within the tumor microenvironment (TME). Given the heterogeneity of these tumors and the importance of cellular interactions within the TME, there is a pressing need for advanced technologies capable of visualizing multiple biomarkers and cell phenotypes simultaneously. Multiplex immunohistochemistry (mIHC) offers an effective solution for this detailed spatial analysis.

Here, we developed a 20-plex SignalStar multiplex immunohistochemistry (mIHC) panel aimed at profiling T cell activation and suppression states, as well as spatially characterizing tumor, myeloid, and vascular cells within the TME. The resulting images underwent processing using the Elucidate Bio Spatial Analysis pipeline. The images were co-registered and segmented based on DAPI staining and marker-specific classifiers were employed to label cells as either positive or negative for each respective stain. Expression intensities were subsequently normalized and clustered using the Leiden algorithm to assign predominant lineage phenotypes. Through graph-based community detection, higher-order cellular neighborhoods were identified. We also correlate the Signalstar spatial proteomics data to an orthogonal single cell RNA sequencing data. Our analysis revealed six distinct cell neighborhoods with unique spatial organization and cellular composition, consisting of those that were rich in either CD4+ T cells, CD8+ T cells, M2-like macrophages, dendritic cells, tumor cells with immune cell infiltration or tumor cells without immune cell infiltration. Substantial heterogeneity was observed with respect to the cell phenotypes and cell neighborhoods that were present, both inter- and intra-tumorally. While there were no statistically significant differences in the numbers of the various cell neighborhoods that were present, the overall number of M1-like macrophages was found to be significantly higher in complete responders vs. progressors. DLBCL tumors are composed of microenvironments filled with diverse cells of various types, all arranged into distinct neighborhoods. Our findings indicate that the SignalStar mIHC assay, when paired with the Elucidate Bio Spatial Analysis pipeline, serves as an effective means to explore the intricate composition and spatial layout of this complex tumor microenvironment.

#0795 Integrating spatial transcriptomics and Imaging Mass Cytometry™ for multi-omic mapping of hepatocellular carcinoma.

Atefeh Khakpoor[1], **Qanber Raza**[2], Merrin Mary Eapen[1], Dina Kazemi[1], Erin Coll[3], Liang Lim[2], Christina Loh[2], Nick Zabinyakov[2], Ling Qiao[4], Anna Di Bartolomeo[4], Helen McGuire[5], Jacob George[3], Ankur Sharma[1]

[1]Garvan Institute, Sydney, Australia,[2]Standard BioTools, Markham, ON, Canada,[3]University of Sydney, Sydney, Australia,[4]Storr Liver Centre, Sydney, Australia,[5]The University of Sydney, Sydney, Australia

Hepatocellular carcinoma (HCC) is a heterogeneous malignancy, requiring spatially resolved multi-omic approaches to advance therapeutic strategies. Spatial transcriptomics using the Xenium™ platform enables high-throughput mapping of hundreds to thousands of RNA targets within intact tissue architecture. While transcript-level insights provide critical context for understanding gene expression patterns, integrating proteomic data adds a complementary layer that enables direct validation of biomarker expression. Spatial proteomics technologies, such as Imaging Mass Cytometry™ (IMC™), complement transcriptomics by providing high-dimensional protein expression data at subcellular resolution. IMC leverages metal-tagged antibodies and laser ablation to simultaneously quantify over 40 protein markers with 5 orders of magnitude linear dynamic range, surpassing traditional immunohistochemistry and immunofluorescence. We demonstrate the feasibility and biological insights gained from applying IMC to same tissue sections previously processed with Xenium, integrating transcriptomic and proteomic data through computational co-registration. Formalin-fixed, paraffin-embedded HCC tissue sections were profiled using a custom Xenium v1 transcriptomic panel, followed by IMC with a 43-marker immuno-oncology themed antibody panel on the same section. IMC was also performed on serial sections without prior Xenium processing for performance comparison. Data integration was achieved using Xenium Explorer software, which employs a computational co-registration algorithm to align nuclei across modalities, enabling overlay of transcriptomic and proteomic biomarkers for spatial correlation analysis. IMC performed post-Xenium processing generated high-quality data comparable to IMC alone, preserving tumor and immune cell phenotyping capabilities. Both techniques localized macrophages, neutrophils, B cells, cytotoxic T cells, and T helper cells and their activation states within distinct tissue regions. Computational integration of transcriptomic and proteomic datasets revealed subpopulations of immune cells and activation states, as well as discrepancies between RNA and protein localization for several markers, underscoring the importance of multi-modal validation. This integrated approach provided a more nuanced view of HCC microenvironmental complexity. Overall, we demonstrate concurrent application of spatial transcriptomics and proteomics at the cellular level on the same tissue section. This integrated workflow, enabled by computational co-registration, delivers a multidimensional perspective of tumor biology and uncovers spatial relationships between unique cell populations with varying activation states offering novel insights into HCC heterogeneity and informing the development of precision therapeutic strategies.

#0796 Digital spatial profiling reveals immune heterogeneity across tumor and stromal compartments in hepatocellular carcinoma.

Min Qing[1], Qibiao Wu[1], Xuesong Lyu[1], Tao Chen[1], Mingxuan Xia[1], Joshua J. Rusbuldt[2], Denis Smirnov[2], Flora Berisha[2], Longen Zhou[1], Chia-Jui Yen[3]

[1]Johnson & Johnson, Shanghai, China,[2]Johnson & Johnson, Spring House, PA,[3]National Cheng Kung University Hospital, Taiwan, China

Introduction: Hepatocellular Carcinoma (HCC) is one of the most devastating malignancies around the world, especially in East Asia. Despite significant advances in immune checkpoint inhibitors in the past decade, many patients show poor response, highlighting the need to better understand tumor heterogeneity, especially at the spatial level. GeoMx™ Digital Spatial Profiler (DSP) is a spatial biology platform that enables high-plex, in situ profiling of FFPE samples, allowing molecular characterization within distinct tissue compartments while preserving spatial context. In this study, DSP was exploited for immune profiling utilizing FFPE samples from HCC patients.

Methods: A total of 4 immune-related panels were used for DSP protein profiling. Thirty HCC FFPE slides were used, and 341 regions of interest were identified from tumor and tumor stroma tissue for DSP analysis. Four morphology markers (CD45/Vimentin/CK8/18/SYTO83) were selected for Immunofluorescence (IF) staining to guide the regions of interest (ROI) selection for tissue structure and distinct cell types.

Results: DSP analysis revealed distinct immune patterns within HCC tissues. Principal component analysis of immune-related markers stratified regions of samples distinctly by tumor and stroma, highlighting the spatial heterogeneity of immune engagement. Notably, stromal compartments exhibited stronger differential expression of immune activation markers (e.g, CD45), particularly T cell-associated proteins such as CD3, CD4, and CD8 compared to tumor regions. Quantitative analysis demonstrated a strong correlation of CD45 expression measured by IF and DSP regardless of tissue compartments. IF staining confirmed low CD45 expression (<2%) within tumor regions in majority of HCC samples, indicating limited immune cell infiltration. However, a subset of samples still showed relatively higher CD45 expression in either the stroma, tumor, or both compartments, suggesting variable immune engagement across patients. Collectively, these results illustrate diverse patterns of immune infiltration in HCC.

Conclusions: This study highlights the spatial heterogeneity of immune cell infiltration within the tumor microenvironment of HCC. Stratification of samples by tissue origin and the distinct expression of immune activation markers in stromal regions underscore the importance of compartment-specific analysis. The strong concordance between DSP and IF quantification for CD45 expressions supports the robustness of spatial profiling approaches. These findings may inform the development of spatially guided immunotherapeutic strategies.

#0797 Integrating hematoxylin & eosin histology with multiplexed imaging mass cytometry for spatial proteomic profiling of antibody-drug conjugate targeted biomarkers.

Nick Zabinyakov, Qanber Raza, Liang Lim, James Mansfield, Christina Loh

Standard BioTools, Markham, ON, Canada

Hematoxylin and Eosin (H&E) staining remains the cornerstone of histopathology, providing essential morphological context for tissue architecture and disease characterization. However, traditional H&E lacks the ability to deliver comprehensive molecular insights required for precision medicine application. Imaging Mass Cytometry (IMC) addresses this gap by enabling simultaneous detection of 40+ biomarkers at subcellular resolution using metal-tagged antibodies. Unlike fluorescence-based multiplexing, IMC is a quantitative, high-throughput spatial proteomics methodology with a huge (5 orders of magnitude) linear dynamic range, making it a perfect match for ADC work. Applying IMC directly to H&E-processed slides and aligning the resulting images combines the familiarity of histology with the power of spatial proteomics, allowing researchers and pathologists to overlay molecular data on conventional morphology without compromising tissue integrity. We implemented a workflow integrating H&E-stained sections with IMC antibody panels targeting biomarkers relevant to antibody-drug conjugate (ADCs) development. Regions of interest were selected based on histological features, followed by IMC acquisition and computational analysis for cell phenotyping and spatial mapping. Alignment of images and integration of H&E morphology with IMC data enabled spatially resolved correlation of histopathological features with multiplexed protein expression on the same tissue section. Using a computational pipeline, H&E-derived regions of interest were aligned with IMC segmentation maps, achieving high registration accuracy across diverse tissue architectures. IMC uses metal-labeled primary antibodies without amplification and maintains the sensitivity to quantitate the intensity of biomarkers. Quantitative analysis demonstrated the ability to identify and enumerate cells expressing ADC targets (HER2, TROP2, EGFR, etc.) within specific histological contexts, providing insights into spatial patterns of biomarker distribution. Overall, this integrated workflow improved cell-type annotation and spatial interpretation, uncovering clinically relevant microenvironmental heterogeneity not apparent from morphology alone. Integrating IMC with H&E histology provides a powerful platform for ADC development, offering unparalleled capability to link tissue architecture, biomarker expression, and immune contexture and enables the use of archival material for spatial proteomic studies. Clinically, this approach could inform patient stratification, guide ADC selection, and predict therapeutic response by correlating immune infiltration with target expression, ultimately supporting personalized oncology strategies. *For Research Use Only. Not for use in diagnostic procedures.*

#0798 Tumor-associated neutrophil density and cancer cell interaction in microsatellite stable and unstable gastric cancer using multiplex immunofluorescence.

Soo Kyung Nam[1], Seo Hwan Yu[2], Sun Young Ahn[3], Yujun Park[4], Yoonjin Kwak[3], Sujin Oh[5], Kyoung Un Park[5], Hye Seung Lee[1]

[1]Interdisciplinary Program in Cancer Biology, Seoul National University College of Medicine, Seoul, Korea, Republic of,[2]Seoul National University College of Medicine, Seoul, Korea, Republic of,[3]Pathology, Seoul National University Hospital, Seoul, Korea, Republic of,[4]Pathology, CHA Bundang Medical Center, Seongnam, Korea, Republic of,[5]Laboratory Medicine, Seoul National University College of Medicine, Seoul, Korea, Republic of

Purpose: Tumor-associated neutrophils (TANs) play diverse roles in the tumor microenvironment, yet their clinicopathologic and prognostic significance in gastric cancer (GC), particularly the relevance of activated TAN subsets and their spatial interactions with tumor cells, remains unclear. This study aimed to characterize TAN density, activation status, and spatial proximity to tumor cells, with focus on microsatellite instability-high (MSI-H) GC.
Methods: Single immunohistochemistry (sIHC) for CD66b, CD8, HER2, p53 and E-cadherin was performed in 1,060 GCs, together with MSI testing and Epstein-Barr virus (EBV) in situ hybridization. To explore potential sex-related differences in TAN-associated survival, ER sIHC was additionally performed. To define functional TAN subsets, Opal multiplex immunofluorescence (mIF) for cytokeratin (CK), CD66b, and CD177 was conducted in 59 microsatellite-stable (MSS) and 60 MSI-H cases. Immune cell densities were quantified using QuPath (sIHC) and InForm (mIF). Spatial proximity between TANs and CK+ tumor cells was calculated. Survival was assessed by Kaplan-Meier analysis.
Results: A high density of CD66b+ TANs on sIHC was more frequently observed in intestinal-type GC and at lower pT stages (P<0.001). A higher TAN density was correlated with HER2 positivity, membranous E-cadherin expression, EBV positivity, and the MSI-H phenotype (P<0.001). A moderate correlation was found in TAN densities between the tumor center and invasive margin. Patients with a high density of CD66b+ TANs tended to have better overall survival (OS), and combined analysis of central and invasive margin TAN densities indicated an independent prognostic factor (P=0.036). In subgroup analysis, higher TAN density was associated with improved OS in female patients (p<0.001). By mIF, the densities of CD66b+ TANs and CD66b+/CD177+ activated TANs were significantly higher in MSI-H than MSS GC (p<0.01). The distance from GC cell to the nearest CD66b+ TAN or CD66b+/CD177+ activated TAN was significantly shorter in MSI-H GC (p<0.001). TAN density was higher in
areas adjacent to tumor cells and lower in distant regions, with a more pronounced gradient in MSI-H GC. A shorter TAN-tumor distance was associated with better survival. In particular, closer proximity of activated CD66b+/CD177+ TANs to tumor cells was independently associated with improved OS (p=0.041).
Conclusions: The distance between TANs and GC cells was significantly shorter in MSI-H tumors, and a shorter TAN-tumor distance-especially for activated CD66b+/CD177+ TANs-was associated with better overall survival. These findings highlight TAN-tumor spatial proximity as a key prognostic factor and a potential target for future therapeutic strategies in GC.

#0799 Integrated spatial multiomics pipeline for visualizing protein interactions in the tumor microenvironment.

Anushka Dikshit[1], Josh Brownlee[1], Ge-Ah Kim[1], Sonali Deshpande[1], Diane Robirds[2], Anne Hellebust[3]

[1]ACD, a Bio-Techne brand, Newark, CA,[2]Leica Biosystems, Deer Park, IL,[3]ACD, a Bio-Techne brand, Albuquerque, NM

Protein-protein interaction is one of the many mechanisms where individual cells communicate with nearby cells or extracellular matrix to modulate the tissue environment. Visualizing these interactions using a spatial platform can validate known interactions implicated in disease pathology within relevant spatial domains, especially in cancer. We developed the ProximityScope™ assay that can be used with the RNAscope™ Multiomic LS assay to detect protein interactions and their impact on molecular pathways by simultaneously visualizing proteins and RNA on a single tissue section. This workflow is fully automated on Leica Biosystems' BOND RX staining platform. The assay detects one protein-protein interaction and can be combined with five RNA/protein targets simultaneously on the same section. Here, we demonstrate a complete end-to-end workflow by staining FFPE human tonsil tissue samples to detect PD1-PDL1 interactions along with immune cell markers such as PDCD1 RNA, CD68 RNA, CD4 protein, CD8 protein, and PanCK protein. Images were acquired using the Aperio FL 120 by Leica Biosystems.[AD1] Using the HALO® image analysis software from Indica Labs, we performed RNA and protein quantification as well as cell phenotyping. PD-1/PD-L1 interactions were successfully visualized between immune cells and tumor cells. T cells were identified by either CD8 or CD4 protein detection, macrophages were identified with *CD68* RNA, while tumor cells were identified by PanCK protein staining. Interactions appear as punctate dots or dot clusters between two cells or on the cell surface. HALO software identified the PD-1/PD-L1 interaction between adjacent cells. This study demonstrates the importance of having an end-to-end spatial solution for staining, imaging, and quantification of target protein interactions to evaluate protein function. The ProximityScope assay has the potential to study a broad range of protein interactions to evaluate signaling pathways and gain biological insights, assess therapeutic success, or detect PD-1/PD-L1 and related interactions that can serve as biomarkers for patient stratification.For Research Use Only. Not for use in diagnostic procedures.

#0801 Genomic and spatial single-cell profiling reveals BRCA-linked tumor microenvironment signatures in high-grade serous ovarian carcinoma.

Jue young Kim, Hayeon Shin, Yoon Joo Kim, Yookyung Lee, Jae-Hoon Kim

Department of Obstetrics and Gynecology, Gangnam Severance Hospital, Yonsei University College of Medicine, Seoul, Korea, Republic of

Background: High-grade serous ovarian carcinoma (HGSOC) is the most aggressive and lethal subtype of ovarian cancer, accounting for more than 70% of ovarian cancer-related deaths. Because most cases are diagnosed at advanced stages with distant metastasis, early detection and effective treatment strategies remain a major challenge. Although PARP inhibitors benefit patients with BRCA mutations or homologous recombination deficiency (HRD), many still develop therapeutic resistance. This study investigates how BRCA-associated immune activation and tumor microenvironment (TME) features influence treatment outcomes using spatial single-cell transcriptomic profiling.
Methods: A total of 89 HGSOC samples were obtained from the Korea Gynecologic Cancer Bank (KGCB) with comprehensive clinicopathological annotation. Whole genome sequencing (WGS) was performed using tumor samples matched with peripheral blood mononuclear cells (PBMCs) to identify somatic and germline genomic alterations. Tissue microarrays (TMAs) were constructed and analyzed using NanoString's spatial single-cell RNA sequencing platform (Human Discovery Panel, 6,000 genes) to characterize spatial heterogeneity within the TME.
Results: WGS profiling revealed distinct genomic alteration patterns associated with BRCA mutation status, highlighting differences in key cancer-related pathways. Spatial single-cell analysis demonstrated heterogeneous tumor-immune-stromal interactions and identified BRCA-linked TME remodeling patterns. BRCA-mutated patients showed higher chemosensitivity ($p=0.045$) and significantly longer progression-free interval (PFI, $p=0.018$), recurrence-free survival (RFS, $p=0.022$), and overall survival (OS, $p=0.032$) compared with BRCA wild-type patients. Kaplan-Meier analysis confirmed significant OS differences according to BRCA mutation status ($p=0.009$), and chemotherapy resistance strongly affected both RFS and OS ($p=0.000$).
Conclusion: BRCA mutations in HGSOC are strongly associated with enhanced chemosensitivity and improved survival outcomes. Integrated WGS and spatial single-cell analysis revealed BRCA-related genomic features and TME remodeling patterns that shape therapeutic response. These findings highlight the potential of combining BRCA status, genomic profiling, and spatial TME analysis as predictive biomarkers for prognosis and personalized treatment strategies in HGSOC.

#0802 Multi-omic profiling maps the immune multicellular environment of renal cell carcinoma.

Thao Tran[1], Maikel L. Colli[1], Nathan H. Patterson[1], Qanber Raza[2], Liang Lim[2], Lauren Tracey[2], Alice Ly[1], Sanja Bajovic[1], James Mansfield[2], Christina Loh[2], Marc Claesen[1]

[1]Aspect Analytics NV, Genk, Belgium,[2]Standard BioTools, Markham, ON, Canada

Clear cell renal cell carcinoma (ccRCC) is a biologically heterogeneous malignancy shaped by complex tumor–immune–stromal interactions that drive progression and influence therapeutic response. Despite advances in immunotherapy and combination regimens, many patients exhibit intrinsic or acquired resistance, underscoring the need for spatially resolved, multimodal profiling of the tumor microenvironment to elucidate mechanisms of treatment failure and discovery of therapeutic targets.

To this end, we integrate Imaging Mass Cytometry (IMC) with Spatial Transcriptomics (ST) to enable simultaneous *in situ* phenotyping of protein and transcript expression within intact tissue architecture. IMC using the Hyperion XTi delivers high-resolution protein mapping across lymphoid, myeloid, and stromal compartments, including extracellular matrix components such as collagen, fibronectin, and αSMA that define desmoplastic barriers and immune-excluded niches. Complementary ST with the Xenium immune-enriched 5000-gene panel reveals transcriptional programs related to T-cell exhaustion, cytotoxicity, antigen presentation, interferon signaling, and stress responses, capturing functional states not readily discernible at the protein level.

The combination of per-cell spatial proteomic and transcriptomic data improves the understanding of the tumor-immune microenvironment. A central advance of this study is the direct correspondence established between protein-defined multicellular embeddings and transcriptomics-derived cellular states. IMC protein markers delineate the structural organization of cell neighborhoods consistently across tissue sections, while spatial transcriptomics assigns the functional programs operating within each niche and show how variable those states are. This integration reveals how specific transcriptional states concentrate within distinct structured microenvironments, including CD8+ T-cell rich inflammatory zones and tumor-stromal cells interface, co-localized with macrophage subpopulations. By anchoring gene expression states to well-resolved protein architectures, the analysis exposes the spatially organized mechanisms through which ccRCC shapes immune responses and promotes therapeutic resistance. This multimodal framework yields a more mechanistic understanding of tumor–immune interactions and enables the identification of spatially grounded biomarkers and intervention points that are not apparent from single-modality profiling.

Combining ST and IMC unlocks a powerful framework for deciphering tumor complexity. By linking molecular expression to spatial context through integrative computational analysis, this strategy has the potential to identify novel biomarkers, refine therapeutic targets, and transform precision oncology.

For Research Use Only. Not for use in diagnostic procedures.

#0803 A spatial profiling approach to evaluating the prognostic impact of heterogeneity in the triple-negative breast cancer immune microenvironment.

Prerana Sensharma[1], Huidan Zuo[2], Melanie Dawe[3], Megan Hopkins[4], Zeynep Baskurt[5], Osvaldo Espin-Garcia[5], Philippe L. Bedard[6], Melanie Spears[4], Susan J. Done[2]

[1]Medical Biophysics, University of Toronto, Toronto, ON, Canada,[2]Laboratory Medicine and Pathobiology, University of Toronto, Toronto, ON, Canada,[3]Princess Margaret Cancer Center, Toronto, ON, Canada,[4]Ontario Institute for Cancer Research, Toronto, ON, Canada,[5]Department of Biostatistics, Princess Margaret Cancer Center, Toronto, ON, Canada,[6]UHN-Toronto General Hospital, Toronto, ON, Canada

Triple-negative breast cancer (TNBC), the breast cancer subtype defined by the absence of hormone receptors and no amplified HER2 receptors, is the most aggressive breast cancer subtype. Targeted treatment remains a challenge with TNBC. Non-targeted chemotherapy regimens have been the longstanding treatment modality, recently supplemented by immune checkpoint inhibitors (ICIs) targeting the PD-1/PDL1 pathway. TNBC's high tumor mutational burden, PD-1 expression, and immunogenicity make it a good candidate for immunotherapy. However, further studies are needed to determine the individuals that benefit most from this treatment. Factors like the spatial patterns of immune cell infiltration, immune-tumour cell and immune-immune cell relationships impact the immune microenvironment's anti-tumour response and ICI response. The high-plex spatial analysis of archival patient tissue samples—an abundant but underutilised resource for tumor characterization—has remained a challenge. However, using the GeoMx Digital Spatial Profiler (DSP), the spatial immune heterogeneity of 40 immune markers were quantified in a cohort of archival treatment-naïve TNBC tumours
(n=140). The heterogeneity of 40 immune markers identifying immune cell lineages and sub lineages, activation and exhaustion states was quantified across separate stromal spatial regions of immune infiltration (n=486 from 140 patients). Tumours with overall low immune cell infiltration were significantly associated with higher spatial immune heterogeneity. Notably, low immune infiltration was also associated with a significantly higher spatial immune heterogeneity and total expression of multiple immunosuppressive markers, some of which are ICI targets This suggests that immunosuppression is spatially localized in stromal niches, which would impact immunotherapy response. High spatial immune heterogeneity was also associated with a trend of poorer patient survival.

#0804 Distinct cellular phenotypes and spatial neighborhoods constitute the heterogeneous microenvironment of desmoplastic small round cell tumor.

Kevin A. Murgas[1], Jiaqian Fan[1], Diana Shamsutdinova[2], Khalida Wani[2], Davis R. Ingram[2], Alexander J. Lazar[2], Danh D. Truong[1], Joseph A. Ludwig[1]

[1]Sarcoma Medical Oncology, MD Anderson Cancer Center, Houston, TX,[2]Anatomical Pathology, MD Anderson Cancer Center, Houston, TX

Desmoplastic Small Round Cell Tumor (DSRCT) is an ultra-rare, aggressive sarcoma primarily affecting young adults. Characterized by a pathognomonic *EWSR1::WT1* gene fusion, DSRCT typically presents with extensive peritoneal metastasis and has a 5-year overall survival rate of 15-25%. Histologically, these tumors exhibit marked peritumoral desmoplasia and minimal immune infiltrate ("immune-cold"). However, substantial heterogeneity among and within tumors has hindered the identification of secondary molecular mechanisms and the discovery of novel therapeutic targets.

We constructed a first-of-its-kind DSRCT tissue microarray (TMA), comprising over 260 specimens from 63 patients spanning 13 years. We applied sequential multiplexed immunofluorescence imaging using a 20-antibody panel (selected based on prior studies) to map tumor, stroma, and immune cell components simultaneously. Our image analysis pipeline utilized tissue and cell segmentation to extract proteomic expression data from nuclear and cytoplasmic compartments of each cell. We applied Harmony batch correction and Leiden clustering to assign putative cell identities based on multi-marker expression.

Our analysis of over 800,000 cells revealed significant inter- and intra-tumoral heterogeneity. We observed a variety of tumor nest morphologies, including well-circumscribed and trabecular architectures, as well as a range of stromal densities. We observed distinct marker expression phenotypes, with some cores dominated by AR-positive, epithelial-like (Pan-Keratin+) cells, while others display prominent neural markers (NSE+/SYP+). Estimated TMA core compositions quantitatively confirmed a range of tumor phenotypes and highlighted variable stromal predominance and a sparse immune infiltrate. Spatial analysis revealed distinct cellular neighborhood patterns and spatial arrangements among the tumor, stromal, and immune components. Finally, we correlated spatial signatures with clinical outcomes.

Our work provides the first comprehensive spatial proteomic atlas of DSRCT at a single-cell resolution using a TMA. This foundational resource aims to elucidate the complex cellular environment of DSRCT, uncover novel biological insights into tumor-driving mechanisms, and ultimately identify new therapeutic vulnerabilities in DSRCT. Ongoing work will incorporate spatial transcriptomics to augment cell phenotyping and identify signalling pathways implicated in the tumor and microenvironment.

#0805 Fluorescence-guided multi-sampling and spatial multi-omics reveal functional lipid vulnerabilities in glioblastoma.

Adele-Asia Ponzoni[1], Evangelos Liapis[1], Lea Anne T. Maristela[1], Elizabeth E. Ginalis[2], Linda Szymanski[3], Kar Fai Chow[4], Kangmin Lee[5], George J. Kaptain[5], Claire L. Carter[6]

[1]Center for Discovery and Innovation, Hackensack Meridian Health, Nutley, NJ,[2]Department of Neurosurgery, Rutgers New Jersey Medical School, Newark, NJ,[3]Department of Pathology, Hackensack University Medical Center, Hackensack, NJ,[4]Biorepository, Hackensack University Medical Center, Hackensack, NJ,[5]Department of Neurosurgery, Hackensack University Medical Center, Hackensack, NJ,[6]Department of Pathology, Hackensack Meridian School of Medicine, Nutley, NJ

Background: Glioblastoma (GB) is the most common and aggressive primary brain tumor in adults. Tumor recurrence occurs in most cases, typically within 2 cm of the resection margin, despite chemo and radiotherapy. This highly invasive nature and the marked heterogeneity of the tumor microenvironment make it challenging to treat. Fluorescence-guided multiple sampling of patient samples is being used to study intra-tumor heterogeneity. In this study we combined mass spectrometry imaging (MSI) with multiplex immunofluorescence (mIF) and histology to identify new therapeutic vulnerabilities based on spatial tumor biology. We developed a same slide workflow applying all 3 technologies to the same section to identify functional lipids that can be manipulated as less toxic therapeutic options.
Methods: Twenty GB patients underwent craniotomies and tumor tissue was surgically resected from multiple different fluorescing and non-fluorescing brain locations. MSI was carried out using a Bruker Solarix FTICR mass spectrometer, the same section then underwent mIF for cell and organelle phenotyping, followed by H&E-staining for histopathology. The Leica Stellaris 5 and GT 450 slide scanner were used for confocal and histological image acquisition, respectively. Data analysis was carried out using the SciLs lab, Leica LAS X and Imaris software. Processed mIF, H&E and MSI data were integrated in SciLS Lab for multimodal analysis on the same section.
Results: Integration of spatial lipidomic, proteomics and histopathology identified functional lipids that correlated with different pathological presentations and cellular neighborhoods within each sample. We focused on two multifunctional lipids: cardiolipins (CLs) and gangliosides (GGs). CLs are unique mitochondrial lipids that contain four acyl chains, whose structure is known to regulate mitochondrial function. In GB, we detected differential accumulation based upon fatty acid residue composition, which correlated with mitochondrial numbers and phenotype. Peritumoral regions showed interconnected mitochondria, while tumor regions with vascular proliferations displayed abundant fragmented mitochondria, indicative of altered metabolism and dynamics. GGs are involved in cell-cell interaction, immune modulation, and tumor growth. Anti-GD2 immunotherapy is FDA-approved for neuroblastoma and in clinical trials for other solid tumors. In GB, we identified over 30 GGs species across the GM1-3, GD1-3 and GT1,3 series, which segmented with different pathological regions based on acyl chain and sialic acid composition.
Conclusions: We optimized a same section spatial multi-omics workflow that identified tumor-specific lipid pathways as therapeutic vulnerabilities in glioblastoma.
Ongoing studies are using patient-matched 3D models to determine the functional relevance of these findings and for drug screening studies.

#0806 Tumor microenvironment of ampulla of Vater cancer reveals distinct spatial niche of CAF, TIL, and TAM and their correlation with clinicopathologic features.

Yesul Jeong[1], Se Jun Park[2], Sung Hak Lee*[3], Younghoon Kim*[3]

[1]Department of Hospital Pathology, St. Vincent's Hospital, College of Medicine, The Catholic University of Korea, Seoul, Korea, Republic of,[2]Division of Medical Oncology, Department of Internal Medicine, Seoul St. Mary's Hospital, Seoul, Korea, Republic of,[3]Department of Hospital Pathology, Seoul St. Mary's Hospital, Seoul, Korea, Republic of

Background:
While the individual roles of cancer-associated fibroblasts (CAFs), tumor-infiltrating lymphocytes (TILs), and tumor-associated macrophages (TAMs) in the tumor microenvironment (TME) of ampulla of Vater (AoV) carcinomas are recognized, a detailed understanding of their collective interplay and its correlation with clinicopathologic features and patient survival is still lacking.
Methods:
A retrospective cohort of 87 patients with resected stage IB-III AoV adenocarcinoma (Seoul St. Mary's Hospital between 2007 and 2021) was selected. TMAs (2-mm cores) were constructed and immunostained for tumor cell markers (EGFR, HER2, and c-MET), TME markers (CD3, CD8, FOXP3, CD68, CD163, alpha-SMA, FAP, PDPN, and POSTN), and Masson's Trichrome (MT) staining for fibrosis. Multiplex IF was performed for high-plex spatial proteomic analysis (CellScape). All slides were digitized and analyzed to quantify the immune cell densities (cells/mm2), mesenchymal marker H-scores, and spatial relationships (cell-cell distance) to define the TME niches. The primary endpoints analyzed using R were disease-free survival (DFS) and overall survival (OS). A two-sided p-value of <0.05 was considered to be statistically significant.
Results:
TAM markers showed a significant positive correlation with T-cell markers but a negative association with CAF markers. FAP and POSTN were positively correlated with each other but negatively correlated with PDPN and IL6. ACTA2 and IL6 were negatively correlated with most other markers, while being positively correlated with each other. Univariate Cox regression for DFS identified high EGFR (HR=6.89, 95% CI: 2.94-16.20, p=0.026), FAP (HR=2.21, 95% CI: 1.27-3.86, p=0.027), and high fibrosis (MT) (HR=2.49, 95% CI: 1.42-4.37, p=0.008) as unfavorable prognostic factors. CD3 and POSTN showed a trend towards prognostic significance for OS (p=0.07 and p=0.06, respectively). In multiplex IF, spatial analysis revealed that TAMs (CD68 and CD163) were located closest to the tumor cells, followed sequentially by CAF markers (vimentin and SMA), Collagen IV, and TIL markers, which were the most distant.
Conclusions:
Our findings demonstrate that TME components in AoV carcinoma form distinct spatial niches, characterized by TAMs proximal to tumor cells and TILs in the distal region. This specific architecture, especially when dominated by high FAP and fibrosis, is significantly associated with poor survival, highlighting the importance of spatial TME analysis as a critical prognostic tool.

#0807 Integrated transcriptomic and proteomic characterization of the lung tumor microenvironment using BD®OMICS-One-Protein-Panels for CITE-seq.

Samuel X. Shi[1], Cynthia Sakofsky[2], Hye-won Song[1], Manish Thakran[2], Tamiyo Kobayashi[3], Aruna Ayer[2]

[1]BD Biosciences, San Diego, CA,[2]BD Biosciences, Milpitas, CA,[3]BD Biosciences, Chiba, Japan

The tumor microenvironment (TME) is a heterogeneous and continuously evolving system. It is composed of malignant cells, numerous infiltrating immune cells, stromal cells, blood vessels, and extracellular matrix. The interactions of tumor and non-tumor cells produce an immune-reactive milieu, altering cellular phenotypes and function, thus contributing to tumor growth and progression or antitumor immunity. Profiling the components and alterations in the TME at high resolution is crucial to identify factors influencing cancer progression or evaluating the efficacy of immunotherapies. Advancements of single cell multiomics techniques provide powerful means to scrutinize the tumor and TME at high resolution, shedding light on discrete cell subsets and their potential functions. Cellular Indexing of Transcriptomes and Epitopes by Sequencing (CITE-seq) enables concurrent single-cell RNA sequencing alongside surface protein profiling by using oligonucleotide-tagged antibodies. By combining proteomic and transcriptomic data from the same cell, CITE-seq is an especially powerful approach for phenotyping discrete cell populations, especially suitable for the TME.
Here we applied CITE-seq to clinically relevant human lung cancer samples. A single cel suspension was obtained with BD Horizon™ Dri Tumor & Tissue Dissociation Reagent and then frozen with BD®OG-Cryopreservation Buffer, a non-cross-linking buffer. At another location, CITE-seq was conducted on the samples with the BD OMICS-One™ WTA Next Assay as well as the BD®OMICS-One-Protein-Panels, which are lyophilized and pre-titrated oligonucleotide-tagged antibody panels. Non-supervised clustering of transcriptomic and proteomic data revealed 12 major cell clusters, including infiltrating lymphocytes (TILs), resident and infiltrating immune cells, as well as non-immune intrinsic tumor cells. Over 50 protein epitopes were detected and used to identify tumor intrinsic cells with their expression of well published protein signatures of non-small cell lung cancer. Differential gene and protein expression profiles distinguish distinct tissue-resident alveolar-macrophages from infiltrating hematogenous macrophages. Moreover, T cell gene sets of naive, activation/stimulation, and exhaustion states were used to identify the functional heterogeneity of TILs. We successfully detected over fifty epitopes in this sample, enabling the identification of cancer specific cellular states, varied immune functions and potential interactions with other cells, when integrated with transcriptomic data. We demonstrate an end-to-end workflow from sample collection, storage, single-cell capture, sequencing, and analysis to characterize TME heterogeneity and further understand tumor biology.

#0808 Single cell spatial multiomics of TCR and BCR repertoires using CosMx® SMI to characterize immune cell dynamics in PBMCs and tumors.

Margaret L. Hoang, Rachel Liu, Dan McGuire, Ashley Heck, Kimberly Young, Megan Vandenberg, Claire Williams, Martin Shelton, Prajan Divakar, Patrick Danaher, Erin Piazza, Joseph M. Beechem

Research and Development, Bruker Spatial Biology, Seattle, WA

Immune cell dynamics shape tumor responses to therapy. Peripheral blood mononuclear cells (PBMCs) offer a systemic view of adaptive immunity, yet conventional immune sequencing lacks the spatial resolution to contextualize these findings within tissue architecture. High resolution spatial mapping of tumor-infiltrating lymphocyte (TILs) reveals cell-to-cell interactions, illustrating how immune cells engage with tumor cells and the tumor microenvironment (TME) to influence immunotherapeutic outcomes.We present a spatial multiomics strategy using the CosMx Spatial Molecular Imaging (SMI) platform to simultaneously profile T-cell receptor (TCR) and B-cell receptor (BCR) repertoires within PBMCs and tumor tissues. Immune profiling incorporated the CosMx TCR Add-on panel covering V, J, and constant segments of α, β, γ, and δ chains, along with BCR heavy chain V and constant region. These assays were integrated with CosMx Whole Transcriptome (WTX) and the Human Immuno-Oncology 64-plex protein panel for comprehensive immune cell characterization in PBMCs. High-resolution subcellular CosMx SMI imaging of tumor FFPE sections, combined with advanced computational pipelines, enabled single cell spatial mapping of TILs, capturing TCR/BCR clonotype distributions and immune cell interactions with tumor cells and the extracellular matrix (ECM) components including cancer-associated fibroblasts (CAFs), fibronectin (FN1), α-smooth muscle actin (α-SMA).We uncovered distinct patterns of T- and B-cell phenotypes across PBMCs and tumors, including multiomics signatures of activation, exhaustion, and cytokine signaling. Spatial context revealed immune niches enriched for T and B cells, as well as regions of TIL exclusion associated with immunosuppressive ECM signals. By combining spatial multiomics with immune repertoire profiling, this approach uncovers critical immune dynamics across systemic and tumor compartments, informing biomarker discovery and immunotherapy strategies.

#0809 Spatially resolved multiomics profiling of glioblastoma reveals molecular signatures of neuropathology and immuno-oncology architecture using CosMx SMI.

Yi Cui, Claire Williams, Chia-Ying Lee, Chi Phan, Sierra Mckinzie, Shanshan He, Ashley Heck, Kimberley Young, Lidan Wu, John Lyssand, PRAJAN DIVAKAR, Joseph M. Beechem

Bruker Spatial Biology, Seattle, WA

Glioblastoma (GBM) is a highly heterogeneous and aggressive brain tumor with limited therapeutic success, underscoring the need for advanced approaches to decode its complex molecular landscape. Here, we employed the CosMx® Spatial Molecular Imager to perform same-cell spatial multiomics profiling on serial sections from a human GBM tissue block, integrating the whole-transcriptome RNA panel (~19,000 genes) with two high-plex protein panels encompassing 64 neuropathology or immuno-oncology markers. This comprehensive dataset enables correlative mapping of transcriptomic and proteomic features across tumor and peri-tumoral regions. We identified five GBM tumor cell subtypes - astrocyte-like, OPC-like, mesenchymal-like, stem-like, and proliferating cells - each exhibiting distinct spatial localization and transcriptional signatures. Concurrent protein profiling uncovered regionally enriched phospho-Tau variants (e.g., p-Tau S214, S396, S404), whose accumulation marked hypoxic and epithelial-mesenchymal transition (EMT) active tumor microenvironments. Spatial regression analyses linked elevated neighborhood p-Tau scores to coordinated upregulation of hypoxia-responsive genes (e.g., HIF1A, VEGFA) and metabolic stress pathways, revealing a localized molecular response to cellular stress. Integration of the immuno-oncology protein panel highlighted spatially restricted immune checkpoint expression, including PD-L1, B7-H3, and TIM-3, delineating immune-evasive niches within distinct tumor neighborhoods. Tumor niches driven by divergent subtype GBM cells adopted unique immune evasion strategies, suggesting microenvironment-specific mechanisms of immune suppression. Overall, this study demonstrates the power of spatially resolved, same-cell multiomics to dissect GBM's transcriptional and proteomic heterogeneity at unprecedented resolution. The findings establish a mechanistic link between phospho-Tau-associated stress adaptation, metabolic remodeling, and immune modulation in GBM. This scalable framework offers a blueprint for future multi-sample spatial oncology studies aimed at uncovering therapeutic vulnerabilities, stratifying tumors by microenvironmental features, and identifying biomarkers predictive of treatment response.

#0810 Multi-omic spatial analysis reveals a distinct pattern of cellular neighborhood in gastric cancer.

Takashi Semba, Huaitao Wang, Atsuko Yonemura, Yilin Tong, Takatsugu Ishimoto

Japanese Foundation for Cancer Research, Tokyo, Japan

The tumor microenvironment (TME) consists of diverse cells, and recent studies suggest that their spatial relationships may be crucial for cellular function. However, the spatial organization of the gastric cancer (GC) TME remains poorly understood. In this study, we performed spatial analysis of the GC TME using multiplex immunohistochemistry (IHC) and spatial transcriptomics on paraffin blocks from 10 advanced gastric cancer cases. From more than 30-plex IHC images obtained using the RePROBE method, which we recently developed, we annotated each cell as fibroblasts, immune cells, etc., based on marker expression levels. We then performed cellular neighborhood (CN) analysis based on the annotated cell location information. This resulted in the identification of eight distinct CN meta-clusters. Furthermore, spatial transcriptomics analysis revealed the intercellular interactions occurring within spots. For example, an intercellular communication analysis based on a ligand-receptor database showed that within the CN primarily composed of fibroblasts, signals related to collagen and the extracellular matrix were intensely active. We also identified the transforming growth factor beta (TGF-β) and mitogen-activated protein kinase (MAPK) pathways as the driving pathways for this activity. Moreover, when we scored gastric cancer cases from The Cancer Genome Atlas cohort using gene signatures derived from differentially expressed genes in each CN, we found that cases with high scores for the fibroblast-dominant CN showed significantly poorer prognosis. In addition, graph-based cell network analysis revealed that poor lymphocyte network formation was associated with fewer progenitor-like exhausted CD8 T cells, and fibrotic TME may inhibit the formation of lymphocyte networks. These results highlight the immunosuppressive role of fibrotic TME and its potential as a therapeutic target.

#0811 Novel tyramide signal amplification dyes optimized for the detection of IO markers and four-plex detection of heterogeneously expressed targets.

Marco T. Pinheiro[1], Paul Wood[1], Sean Goggins[1], Henry Lamparski[2], John Donaldson[2], Grant Esomonu[2], Renzo Adilardi[2], Emerald Doolittle[2], Rose Delvillar[2], Hannah Maple[1]

[1]Bio-Techne Corporation, Bristol, United Kingdom,[2]Advanced Cell Diagnostics, Newark, CA

Spatial biology techniques such as RNAscope™ and multi-omics in situ hybridization (ISH) offer critical insights into tumor biology and the tumor microenvironment by enabling spatially resolved gene expression analysis. However, conventional ISH methods often lack the sensitivity required to detect low-abundance transcripts, which can hold key mechanistic, prognostic, and therapeutic significance. In this study, we present an enhanced and optimised ISH approach that integrates a new specifically designed range of fluorophores for tyramide signal amplification (TSA) with RNAscope™ Multiplex Assay probes to improve the detection of immuno-oncology (IO)-related targets. These two new reagents targeted at 620nm and 690nm wavelengths increase the number of assessable targets and enable robust four-plex detection of heterogeneously expressed transcripts. Our findings demonstrate that the new bright TSA reagents significantly increase the sensitivity and dynamic range of transcript and protein detection, facilitating the reliable identification of targets across a spectrum of expression levels. The newly developed four-plex dye system further expands upon multiplexing capabilities, supporting comprehensive spatial profiling in complex tumor tissues.

#0812 Spatial architecture of head and neck squamous cell carcinoma (SCCHN): An IMMUcan/EORTC analysis.

Lucas Michon[1], Athenais van der Elst[2], Daniel Herrero-Saboya[3], Marie Morfouace[4], Preethi Devanand[5], Robin Liechti[6], Daniel Schulz[7], Maya Persoons[1], Sylvie Rusakiewicz[5], Nils Eling[8], Paul-Antoine Nicolas[3], Stephanie Renaud-Tissot[5], Bernd Bodenmiller[9], Henoch Hong[10], Rachel Galot[11], Paolo bossi[12], Julio Oliveira[13], Florian Estrade[14], Caroline Even[15], Sophie E. Lucas[16], Loredana Martignetti[3], Celine Lefebvre[17], jean-pascal Machiels[11], Pierre Saintigny[1]

[1]Ctr. Leon Berard, Lyon, France,[2]Institut de Recherche Clinique et Experimentale, Universite catholique de Louvain (UCLouvain), Brussels, Belgium,[3]Institut Curie, Paris, France,[4]Marie Morfouace (Individual), Villejuif, France,[5]Centre Hospitalier Universitaire Vaudois, Lausanne, Switzerland,[6]SIB Swiss Institute of Bioinformatics, Lausanne, Switzerland,[7]ETH Zurich, Switzerland,[8]Department of Quantitative Biomedicine, University of Zurich, Zurich, Switzerland,[9]University of Zurich, Zurich, Switzerland,[10]Merck KGaA, Darmstadt, Germany,[11]Universite catholique de Louvain, Brussels, Belgium,[12]Humanitas University,[13]Instituto Portugues de Oncologia de Porto Franscisco Gentil, Porto, Portugal,[14]Centre Eugene Marquis, Rennes, France,[15]Gustave Roussy, Villejuif, France,[16]Catholic University of Louvain, Brussels, Belgium,[17]Servier Research & Development, Saclay, France

Background: The association of spatial architecture of SCCHN with clinical and molecular characteristics is poorly understood.
Methods: 253 recurrent/metastatic (R/M) SCCHN, including 77 pre-immunotherapy (IO) samples, were analyzed by imaging mass cytometry to study cancer cells and 13 immune cell types (PMID **40930089)**. Global cell densities (cellD, n/mm^2) and cellular neighborhoods (CN) were analyzed. Local cellD (degree of immune infiltration/exclusion within cancer cells) and cell interaction coefficients between pair-wise phenotypes, both independent of global cellD, were computed. Weighted correlation network analysis was used to detect modules of cell interaction coefficients. TLS and cancer cells states [hypoxic, cell cycling, EMT, β2-microglobulin (β2m) loss] were explored. Data were correlated with IO primary vs. secondary resistance (R), HPV status, survival, DNA and RNA profiles.
Results: 8 CN were identified (pure cancer cells, internal and external (cancer/stroma) interfaces, aggregation of plasma cells, neutrophils (PMN), macrophages/mural cells, T-cells and macrophages/mural/T-cells). HPV+ tumors had decreased external interface. Refractory HNSCC had decreased interfaces and lower DC infiltration. Cancer cells were increasingly hypoxic or had decreasing β2m expression and decreasing EMT in external interface vs. internal interface vs. pure cancer cells CNs. Overall, cancer cell states had profound impact by either increasing (cycling cancer cells) or decreasing (hypoxic cancer cells) immune cells infiltration. We identified 3 clusters of SCCHN: C1 (45%) had high global immune cellD but low local cellD; C2 (40%) was desertic; C3 (15%) was highly infiltrated (high local cellD) and had the best survival in IO-treated pts. RNA-based 'Classical' SCCHN were almost exclusively C2. C3 was enriched in extracellular matrix organization, immune cell and migration. Specific TLS CN included B compartment, germinal center and plasma aggregation. HPV+ tumors had increased B compartment but decreased plasma aggregation. All 3 TLS CN were decreased in refractory SCCHN and in primary vs. secondary R. In IO-treated pts, TLS presence improved outcome and the closer TLS were to cancer cells, the better was the outcome. While the interaction between PMN and immune cells was associated with worse outcome, PMN infiltrating cancer cells was associated with improved survival together with T-cells interacting with cancer cells or with HLADR, MacCD163 and mural cells. Finally, mutations were generally associated with more exclusion of immune to cancer cells e.g. T-CD8 and PMN were more excluded in SCCHN mutated for RB1 and FAT4-PTPRT respectively; and BAP1 and HRAS mutations had exclusion of MacCD163-NK-mural-HLADR-plasma and B cells respectively.
Conclusion: we provide a comprehensive description and clinical/molecular correlatives of the spatial architecture of SCCHN.

#0813 Linking tumor-infiltrating immune cells from tissue and peritoneal cytology to molecular markers in endometrial cancer.

Seungmee Lee[1], Jin-Young Kim[2], Shin-Wha Lee[3], Eun Ji Nam[4], Ji Hae Seo[5], Sojin Shin[1]

[1]Gynecologic Oncology, Keimyung University School of Medicine, Daegu, Korea, Republic of,[2]Division of Hematology/Oncology, Department of Internal Medicine, Keimyung University School of Medicine, Daegu, Korea, Republic of,[3]Asan Medical Center, University of Ulsan, Seoul, Korea, Republic of,[4]Yonsei University College of Medicine, Seoul, Korea, Republic of,[5]Department of Biochemistry, Keimyung University School of Medicine, Daegu, Korea, Republic of

Background

The composition of tumor-infiltrating lymphocytes (TILs) in endometrial cancer may be linked to both clinicopathologic factors and underlying molecular alterations. We sought to characterize TIL subsets recovered from fresh tumor tissue and peritoneal washing cytology and to determine how these immune profiles relate to routinely used immunohistochemical markers.

Methods

Fresh surgical specimens and peritoneal washings were obtained from patients with endometrial cancer who provided informed consent. Mononuclear cells were isolated and analyzed by flow cytometry to quantify $CD3^{-}CD19^{+}$ B cells, $CD3^{-}CD16^{+}CD56^{+}$ natural killer (NK) cells, $CD4^{+}CD25^{+}$ regulatory T cells (Tregs), and $CD3^{+}CD8^{+}$ cytotoxic T cells. These populations were compared according to histopathologic features and immunohistochemical results, including lymphovascular space invasion (LVSI), PD-L1, estrogen receptor (ER), p53, HER2, mismatch repair proteins (MLH1, MSH2, MSH6, PMS2), and microsatellite instability (MSI) status.

Results

Sixty immune profiles derived from endometrial cancer specimens were evaluable. Higher proportions of $CD3^{-}CD19^{+}$ B cells were observed in LVSI-positive tumors, whereas ER-positive tumors showed lower levels of this subset (both $p<0.05$). $CD3^{-}CD16^{+}CD56^{+}$ NK cells were more prevalent in cases with deficient mismatch repair (dMMR). $CD4^{+}CD25^{+}$ Tregs were reduced in ER-positive tumors ($p<0.05$). $CD3^{+}CD8^{+}$ cytotoxic T cells were less frequent in HER2-positive tumors but increased in dMMR cases. No additional significant associations were detected between immune subsets and the other immunohistochemical markers examined.

Conclusions

Immune cell profiles obtained from endometrial tumor tissue and peritoneal washing cytology appear to capture key clinicopathologic and molecular features, particularly LVSI, ER, HER2, and mismatch repair status. Validation in larger cohorts with integrated oncologic outcome data is needed to clarify the prognostic and potential predictive relevance of these immune signatures.

#0814 Lymphatic exudate is a novel source of tumor-associated immune cells.

Seka Lazare[1], Michael A. Harmon[1], Ashley Tellis[1], Zachary Costliow[1], Zhuosheng Gu[1], Adam Benson[1], Samuel Espinoza[1], Abbey Crittenden[1], Megan Rivera[1], Michael Abern[2], Sunil Patel[3], Kamal Pohar[4], Gautum Agarwal[5], Rohann Correa[6], Wendy Winckler[1]

[1]Droplet Biosciences, Inc., Cambridge, MA,[2]Duke University Department of Urology and Duke Cancer Institute, Durham, NC,[3]Johns Hopkins, Caltimore, MD,[4]Ohio State University, Columbus, OH,[5]Mercy Clinic, St. Louis, MO,[6]London Health Sciences Centre, London, ON, Canada

Autologous tumor-infiltrating lymphocyte (TIL) therapy has demonstrated efficacy in multiple solid tumor types, but therapy requires surgery and extensive manufacturing. Lymphatic exudate (“lymph”) is routinely collected from surgical drains following tumor resection. Although usually discarded, we have shown that this novel proximal biofluid is rich in ctDNA and prognostic of recurrence in head and neck squamous carcinoma (HNSCC) patients. Here, we investigate lymph as a novel, accessible source of tumor-associated lymphocytes.

Lymph was collected 24 hours post-surgery from 11 HPV- HNSCC and 14 bladder cancer (BLC) patients in K_2EDTA blood collection tubes. Cells were isolated from lymph and immune populations were characterized by flow cytometry. Bulk T-cell receptor b (TCR-b) sequencing was performed on 17 patient sets with matched tumor (11 HNSCC, 6 BLC). Two BLC patients failed sequencing QC. TCR repertoires were compared between tumor and lymph and Simpsons clonality was used to assess clonal diversity.

Lymph cells displayed high viability (>85%). Immune subpopulations are described in Table 1. Both $CD4^+$ and $CD8^+$ T cells were detected with variable CD4/CD8 ratios (1.05-4.9 [HNSCC] and 0.11-8.869 [BLC]). Bulk TCR-b analysis showed substantial clonal overlap between lymph and tumor (HNSCC mean 13.1% [0-33.1%] and BLC 9.1% [0.3-23.8%]), exceeding typical overlap described for peripheral blood. Lymph TCRs exhibited clonal expansion (Simpsons clonality means: HNSCC = 0.58% and BLC = 0.64%). Based on surgical drainage rates (median 1-3.5 mL/hour) and median number of CD3+ cells per mL, an estimated 4.8×10^6 - 1.68×10^7 T cells could be recovered daily from drains.

Table 1. Mean cell frequencies by indication measured by FACS; immune subsets expressed as % of CD45

	HNSCC	**BLC**
CD45+	95.36%	85.85%
T cells	3.92%	15.08%
NKT cells	0.78%	2.63%
B cells	0.55%	3.60%
Monocytes	0.37%	7.90%

Post-surgical lymph contains viable immune populations with substantial TCR overlap with tumor infiltrating lymphocytes. Lymph could enable the isolation of tumor-associated T cells without the challenges around metastasectomy. Lymph T cells may represent a novel, abundant, low cost, and easily accessible source for adoptive cell therapy.

#0815 Simultaneous spatial transcriptome and epigenome profiling in fresh frozen and FFPE tissues with spatial CoPro.

Katelyn Noronha, Molly Wetzel, Abigail Chang, Jennifer M. Garbarino, Jiaying Chen, Jeffrey Sabina, Colin Ng

AtlasXomics Inc., New Haven, CT

Understanding how gene regulation drives tumor evolution and therapeutic response requires spatially resolved, multi-omic data from clinically relevant samples. Current approaches for mapping gene expression dynamics rely on pairing spatial ATAC-seq with separate spatial or single-cell transcriptomic assays performed on adjacent sections. This consumes precious tissue, requires cross-slide computational integration, and makes it difficult to capture the state of the same cells—often obscuring key regulatory relationships and cell states. Here we introduce Spatial CoPro, a multi-omics assay that captures open chromatin and unbiased whole-transcriptome states within the same section, preserving morphology and spatial context in both fresh frozen and FFPE tissues. Built on the Deterministic Barcoding in Tissue for Spatial Omics Sequencing (DBiT-seq) platform, the innovation centers on a random hexamer priming strategy for unbiased capture of coding and noncoding transcripts. Unlike poly(A)-based approaches that capture only polyadenylated transcripts and are not suitable for fragmented or degraded RNA, random priming recovers RNA fragments across the gene body, making it particularly effective for both Fresh Frozen and FFPE samples. This provides a more complete and less biased view of transcriptional states while directly pairing with high-resolution chromatin accessibility data. Our Spatial CoPro assay achieves >2,000 fragments (FRiP >20%) for chromatin accessibility and >500 UMIs with >300 detected genes for RNA capture per 10 µm × 10 µm spot, approaching single-nucleus resolution across a 5.5 mm × 5.5 mm region in mouse hippocampus and human prostate cancer. Transcriptome performance matches industry standard spatial transcriptomics assays, while chromatin accessibility matches single-modality spatial ATAC-seq. Matched fresh frozen and FFPE sections correlate strongly across modalities (R >0.7), ensuring robustness across clinical specimens. This unified and FFPE-compatible workflow enables analysis of spatially distinct regulatory programs, enhancer-gene interactions, and tumor cell states not detectable with single-omic assays. By extending multi-omic spatial profiling to clinical specimens, Spatial CoPro establishes a new standard for spatial epigenome-transcriptome integration, advancing studies of tumor heterogeneity, therapeutic resistance, and disease progression to accelerate precision oncology and biomarker discovery.

#0816 Spatial metabolic gradients drive epigenetic reprogramming in human glioblastoma.

Sankha Subhra Chakrabarty[1], Yilin Xu[1], Shannon Coy[1], Jia-Ren Lin[2], Dimitrius Tansini Pramio[3], Pilar Baldominos[4], Clement Bodineau[5], Nathalie Y. R. Agar[6], Judith Agudo[7], Marcos Simoes-Costa[8], Keith L. Ligon[9], Peter Karl Sorger[2], Sandro Santagata[1]

Onc., Dana-Farber Cancer Institute, Boston, MA

Human glioblastoma (GBM) contains sharp spatial transitions in oxygen tension, metabolism, and lineage organization, yet how these microenvironmental cues become epigenetically encoded at the chromatin level remains poorly understood. Using cyclic immunofluorescence (CyCIF) on human IDH-wildtype GBM specimens enriched for necrosis, we mapped tumor cell lineages and histone H3K18 lactylation (H3K18la) at single-cell resolution. Necrotic and hypoxic regions displayed distinct lineage organization and elevated H3K18la, consistent with increased glycolytic flux and lactate accumulation under oxygen deprivation. In patient-derived GBM cell lines, hypoxia-mimetic treatment with deferoxamine (DFX) recapitulated this epigenetic response. RNA-sequencing and CUT&RUN profiling revealed that H3K18la associates with activation of hypoxia and epithelial-to-mesenchymal transition-related transcriptional programs, along with repression of cell-cycle and mitotic regulators. Together, these findings demonstrate how spatial metabolic gradients shape chromatin states and transcriptional networks in GBM, highlighting lactylation as a mechanism by which microenvironmental stress becomes epigenetically encoded and manifested as lineage-specific transcriptional adaptation.

#0817 Spatial characterization, of T-cell receptors at subcellular resolution using in situ sequencing-by-synthesis and spatial protein detection on the same tissue section.

Hansueli Meyer[1], Robert Pinard[1], Ryan Hindman[2], Emily Neil[1], Chris Nehme[1], Sameh Soliman[1], Dongju Park[1], Rebecca C. Hennessey[1], Jinling Wang[1], Alex Makrigiorgos[1], John Lee[1], Seiyu Hosono[1], Matthias Wahl[3], Dominic Mangiardi[1], Mong Marma[1], Hsu-yi Lee[1], Andreas Bosio[3]

[1]Miltenyi Biotec, Waltham, MA,[2]Miltenyi Biotec, Gaithersburg, MD,[3]Miltenyi Biotec, Bergisch-Gladbach, Germany

Abstract: Analyzing the tumor microenvironment (TME) and its immune context based on protein and RNA expression, alongside RNA sequencing, offers a powerful approach to understand tumor biology, predict treatment response, and guide the development of personalized therapies. It provides a more comprehensive understanding of tumor biology and the interplay between genetic alterations, cellular environment, and immune response. Currently, commercially available spatial transcriptomics methods require cDNA barcoding on tissue and ex situ cDNA sequencing on a separate instrument which limits the ability to directly sequence known or unknown regions in situ, such as T-cell or B-cell receptor (TCR/BCR) complementarity determining regions. This limitation can impact the detailed analysis of immune responses within tissue. Advances in technology are needed to enable direct in situ sequencing for more comprehensive insights.

Here, we present a novel approach combining in situ sequencing-by-synthesis with high-plex protein detection (30+), H&E, and DAPI — all performed on the same formalin-fixed, paraffin-embedded section. The technology is based on iterative detection of rolling circle amplified RNAs detection probes, proteins with directly conjugated antibodies and is also capable of in situ four color-based sequencing-by-synthesis (SBS) analysis of known and unknown RNA sequences. The detection of known RNA transcripts and unknown RNA sequences can be combined with existing pre-tested, ready to use MICS antibodies by Miltenyi Biotec, to identify proteins on the same FFPE tissue section.

Using this novel approach we generated data that enabled detailed characterization of TCRs in their spatial context. Five to ten µm thick tumor FFPE sections were transferred to glass slides, followed by deparaffinization and antigen retrieval. In situ sequencing was concurrently combined with an extensive panel of Miltenyi Biotec's MICS antibodies and DAPI imaging, followed by H&E staining on the same FFPE tissue section**.**

We observed high diversity of clonotypes which were assigned to T-cell subtypes and used to generate clonotype maps. Co-localized alpha and beta chain receptors within the same cell were identified as well. We also further applied immune cell protein markers for segmentation and mapping in the complex tissue environment. Our approach enables researchers to identify and analyze the diversity of T-Cell populations based on their unique receptor sequences, while spatially mapping immune cell clonality directly on tissue. This nondestructive method preserves the tissue in its original context.

#0818 Simultaneous spatial transcriptome and methylation profiling in fresh frozen and FFPE tissues.

Katelyn Noronha, Molly Wetzel, Jennifer M. Garbarino, Jiaying Chen, Jeffrey Sabina, Colin Ng

AtlasXomics Inc., New Haven, CT

Epigenetic regulation via DNA cytosine methylation is a key determinant of transcriptional programs, lineage specification, and cancer evolution as well as a prognostic indicator for certain cancer types at well characterized loci. Although spatial transcriptomics and chromatin profiling have expanded our understanding of gene-regulatory microenvironments, direct spatial mapping of the methylome in intact tissues has remained elusive. Spatial co-profiling of the transcriptome and DNA methylome bridges this gap by directly linking transcriptional output to epigenetic regulation within the tissue microenvironment. The AtlasXomics platform, built on the Deterministic Barcoding in Tissue for Spatial Omics Sequencing (DBiT-seq) assay, enables simultaneous capture of the whole transcriptome and genomic DNA fragments within defined spatial pixels, termed Spatial-DMT. RNA is reverse-transcribed with barcoded primers, while genomic DNA is processed by an enzymatic methyl-seq workflow that detects native cytosine methylation without bisulfite degradation. The paired libraries yielded co-registered maps of gene expression and DNA methylation in human medullablastoma and glioblastoma at 10µm resolution. Integration of methylome and transcriptome data delineated tissue architecture, lineage trajectories, and region-specific epigenetic states undetectable by transcriptomics alone. Implemented on the commercial AtlasXomics spatial barcoding platform, Spatial-DMT offers a standardized, scalable workflow compatible with frozen and FFPE specimens. This adaptability positions the method for translational studies of tumor heterogeneity, epigenetic reprogramming, and therapy response. By integrating methylation and gene expression within intact tissue architecture, Spatial-DMT bridges discovery-stage research and clinical pathology. Spatial DNA methylation and whole transcriptome profiling establish a powerful tool for spatial cancer epigenomics, enabling discovery of spatial epigenetic biomarkers, tumor-stroma interactions, and therapeutic response patterns. By uniting spatial methylome and transcriptome in clinical specimens, this technology advances precision oncology and bridges molecular profiling with clinical pathology.

#0822 Netrin-1/UNC5B-TFF3 axis modulates cancer stem cells self-renewal and chemoresistance in metastatic colorectal cancer.

Morgan Brisset[1], Kristina Radkova[1], Andrea Paradisi[1], Lea Stephan[1], Robin Wagner[2], Cyril Degletagne[1], Fabien Luiggi[1], Lisa Frydman[1], Alexander Heriot[3], Corina Behrenbruch[4], Tamara Vu[4], Frederic Hollande[4], Patrick Mehlen[1]

[1]Cancer Research Center of Lyon (CRCL), Lyon, France,[2]The University of Melbourne Department of Clinical Pathology, Melbourne, Australia,[3]Department of Surgical Oncology, Peter MacCallum Cancer Centre, Melbourne, Australia,[4]The University of Melbourne, Melbourne, Australia

Purpose: Metastatic colorectal cancer (mCRC) exhibits poor outcomes due to recurrence and resistance to chemotherapy driven by cancer stem cells (CSCs). We investigated the role of the dependence receptor ligand netrin-1 and its receptor UNC5B in CSC self-renewal and evaluated therapeutic inhibition of netrin-1 using the anti-netrin-1 antibody NP137.
Experimental Procedures: Patient-derived organoids (PDOs) from colorectal liver metastases were treated with recombinant netrin-1, NP137, or controls. Self-renewal was quantified by extreme limiting dilution assays. UNC5B was silenced by CRISPR/Cas9 to determine receptor the implication of this Netrin-1 receptor. Single-cell RNA-sequencing elucidated signaling pathways affected by NP137. In vivo efficacy of NP137 alone or combined with FOLFOX chemotherapy was tested in PDO-xenografted mice, and paired tumor biopsies from an mCRC patient enrolled in an NP137 clinical trial were analyzed by RNA-seq.
Results: Netrin-1 enhanced CSC self-renewal and survival, effects abolished by NP137 or UNC5B knockout. NP137 treatment triggered CSC apoptosis, an effect reversed by caspase inhibition. Single-cell transcriptomics revealed that UNC5B-positive cells secreted trefoil factor 3 (TFF3), which acted paracrinally to maintain stemness gene expression (LGR5, SOX4, SMOC2, PROM1). NP137 suppressed TFF3 and stemness transcripts in both PDOs and a treated patient's tumor. Blocking TFF3 dimerization phenocopied NP137 activity, confirming TFF3 as a critical downstream effector. FOLFOX exposure upregulated netrin-1 and UNC5B, and combination therapy (FOLFOX + NP137) significantly reduced self-renewal and tumor growth in mice while decreasing intratumoral TFF3.
Conclusions: Netrin-1 sustains mCRC CSC self-renewal through an UNC5B-dependent, TFF3-mediated paracrine survival mechanism. Pharmacologic inhibition of netrin-1 with NP137 induces CSC apoptosis and enhances chemotherapy efficacy, identifying the netrin-1/UNC5B/TFF3 axis as a promising therapeutic target to overcome stemness-driven resistance in metastatic colorectal cancer.

#0824 PPARδ overexpression drives transformation of multiple gastric progenitor and stem cells and tumorigenesis in mice.

Xiangsheng Zuo[1], Yi Liu[1], DAOYAN WEI[1], James C. Yao[2], Imad Shureiqi[3]

[1]UT MD Anderson Cancer Center, Houston, TX,[2]Assistant Professor, Dept. of Gastrointestinal Medical Oncology, UT MD Anderson Cancer Ctr., Houston, TX,[3]University of Michigan, Ann Arbor, MI

Background Peroxisome proliferator-activated receptor delta (PPARδ) is upregulated in many types of human cancers, including gastric adenocarcinoma (GAC). Elevated PPARδ expression correlates positively with GAC grade and stage, and negatively with patient survival. Overexpression of PPARδ in villin-positive gastric progenitor cells (VGPCs) has been shown to spontaneously induce GAC in villin-PPARδ mice through CCR20/CCR6 axis-mediated remodeling of the gastric tumor microenvironment. Lgr5-positive gastric stem cells (LGSCs), located in the gastric antrum and corpus glands, have also been widely studied for their role in GAC initiation and progression. However, whether this PPARδ-driven GAC is specific to particular cell types or models remains largely unknown.

Methods A new conditional transgenic PPARδ overexpression mouse line (CAG-LSL-PPARδ) was generated and subsequently crossed with villin-Cre or Lgr5-EGFP-IRES-CreERT2 mice (Lgr5-CreERT2) to generate CAG-LSL-PPARδ; villin-Cre ($PPAR\delta^{villin\text{-}cre}$) or CAG-LSL-PPARδ; Lgr5-CreERT2 ($PPAR\delta^{lgr5\text{-}creERT2}$) mice, in which PPARδ was overexpressed in VGPCs or LGSCs following tamoxifen induction. $PPAR\delta^{villin\text{-}cre}$ mice (n=15) and their controls (villin-Cre, n=12) were followed up until 45 weeks of age, whereas $PPAR\delta^{lgr5\text{-}creERT2}$ (n=16) and their controls (Lgr5-CreERT2, n=14) were observed for 45 weeks post-tamoxifen induction. Additionally, villin-PPARδ mice were bred with CCR6 knockout (CCR6-KO) mice to generate villin-PPARδ; CCR6-KO mice, which along with villin-PPARδ mice, were monitored until 35 weeks of age. All mice were evaluated for tumor multiplicity and subjected to histopathological examination.

Results Gastric hyperplasia and/or low-grade dysplasia occurred in the corpus of 100% of $PPAR\delta^{villin\text{-}cre}$ and $PPAR\delta^{lgr5\text{-}creERT}$ mice. High-grade dysplasia and/or locally invasive GAC were found in the corpus of 27% (4/15) of $PPAR\delta^{villin\text{-}cre}$, in both the corpus and antrum of 13% (2/16), and in the corpus of 19% (3/16) of $PPAR\delta^{lgr5\text{-}creERT2}$, whereas none of the control mice developed these lesions. Chronic inflammation was present in gastric lesions and positively correlated with tumor progression from hyperplasia to locally invasive GAC. CCR6 KO markedly suppressed PPARδ overexpression in VGPCs-induced gastric inflammation and tumorigenesis.

Conclusions PPARδ overexpression in both VGPCs and LGSCs induces chronic gastric inflammation and tumor formation. PPARδ, CCR6, VGPCs, and LGSCs may represent potential therapeutic targets for GAC.

#0825 Bone marrow from acute myeloid leukemia (AML) and multiple myeloma (MM) patients can be used to evaluate target expression and on-target efficacy for novel antibody drug conjugates (ADCs).

Aisha Mergaert, **Coranna Akdemirbey**, Mariah Suchan, Tara Murray, Emer Clarke

Discovery Life Sciences, Seattle, WA

The clinical efficacy of an ADC is heavily influenced by its ability to selectively target its designated epitope, however ADCs exhibit high off-target toxicity to tissues without epitope expression, thus limiting clinical efficacy. We evaluated an *in-vitro* platform to characterize potential hematological toxicity (neutropenia) associated with ADCs in patients with AML and MM. ADCs may still cause hematotoxicity, for example Trastuzumab vedotin, which targets human epidermal growth factor receptor 2 (HER2) which is not present on hematopoietic cells. Gemtuzumab ozogamicin (Mylotarg), Belantamab Mofodotin (Blenrep) and Trastuzumab vedotin were evaluated for toxicity to hematopoietic progenitor cells using the colony forming cell assay (CFC) in diseased (on-target efficacy) and normal bone marrow (NBM) (off-target toxicity). Mylotarg, an ADC targeting CD33, was evaluated for on-target efficacy on AML bone marrow and for off-target toxicity on NBM. Blenrep, an ADC targeting B-cell maturation antigen (BCMA) in MM, was evaluated on MM and NBM. Trastuzumab vedotin was evaluated on AML, MM and NBM. Cells were pretreated with ADCs for 72 hours, and then transferred to methylcellulose containing appropriate cytokines (AML, NBM) or conditioned medium (MM) and placed in a humidified incubator for 14 days. CFU-GM, AML-blast CFC or MM-blast CFC were assessed microscopically and colony numbers enumerated. Additionally, flow cytometric analyses of CD33 and BCMA expression were performed on the relevant diseased and NBM. Mylotarg significantly inhibited AML- blast CFC with an average IC_{50} value of 0.008 µg/mL (on-target efficacy). The IC_{50} values for AML-blast inhibition were not associated with CD33 expression. Mylotarg additionally significantly inhibited NBM progenitors with an average IC_{50} value of 0.01 µg/mL (off-target toxicity) and once again, was not associated with the CD33 expression. There was no significant difference between the IC_{50} values on AML versus NBM clonal growth. Trastuzumab vedotin also demonstrated toxicity to NBM progenitors with a mean IC_{50} value of 3.8 µg/mL demonstrating off-target toxicity. Blenrep exhibited different effects to the disease progenitors as compared to the healthy donor progenitors. Blenrap in MM patient bone marrow had IC_{50} values which ranged from 4.4 to 46 µg/mL with an average IC_{50} value of 21 µg/mL, compared to evaluation in NBM which resulted in IC_{50} values > 30 µg/mL (highest tested concentration) and rarely had any impact on colony growth. These data suggest that the CFC assays with primary normal and diseased bone marrow cells may provide insight as to relative potency of an ADC on a disease-specific target as well as potential off-target toxicity to normal hematopoietic progenitors.

#0826 Investigating TWEAK-mediated regulation of ovarian cancer cell survival.

Harshada Sapre, Mikella Robinson, Carrie House

San Diego State University, San Diego, CA

High-Grade Serous Ovarian Cancer (HGSOC) remains a salient concern in women's health, with 90% of patients eventually experiencing resistance to standard-of-care chemotherapies. Research implicates a subpopulation of quiescent, multipotent cells termed Cancer Stem-like Cells (CSCs) in contributing to resistance and relapse. We previously identified Tumor Necrosis Factor-Like Weak Inducer of Apoptosis (TWEAK), a pro-inflammatory cytokine, as highly enriched in the tumor microenvironment following chemotherapy and a critical mediator of CSCs by activating NFkB signaling to increase survival. We also found that a subpopulation of cells without CSC features were more sensitized to chemotherapy in the presence of TWEAK, suggesting a dual role for TWEAK. Canonically, TWEAK influences cell differentiation; however, this role is ill-defined in ovarian cancer. We hypothesize that TWEAK induces chemosensitivity in non-CSCs and chemoresistance in CSCs in ovarian cancer. To study this signaling in an immunocompetent mouse model recapitulating the tumor microenvironment, the murine ovarian surface epithelial cell line ID8 (p53-mutant and p53-wild type) were used. Combination IC50 of Carboplatin and Paclitaxel was studied in both cell lines for accurate drug dosing. A panel of surface markers was assessed for baseline expression by flow cytometry, including the TWEAK receptor Fn14 (27%), and CSC markers LGR5 (3.19%), GRP78 (29%), CD117 (70%), and αVβ3(0.27%). GRP78 was identified as a promising CSC marker in the p53-mutant ID8 cell line, with baseline expression of 29% increasing significantly to 53% post-chemotherapy. FACS sorting of GRP78+ enriched fractions to have high baseline expression of stem genes SOX2,OCT4, and NANOG. To assess TWEAK induction of CSC features, pre-treatment of TWEAK in GRP78 + and GRP78- factions showed an overall increase in viability after chemotherapy treatment, suggesting TWEAK treatment before chemotherapy may provide an advantage in survival. Current work is investigating GRP78+ ID8 cells using in vitro assays for spheroid formation, extreme limiting dilution, and chemoresistance in response to TWEAK stimulation. An in vivo murine relapse model will be used to test the role of TWEAK in maintaining GRP78+ cells and relapse potential. Future studies will elucidate the role of TRAF proteins in directing the downstream effects of TWEAK-Fn14 activity. Together, these investigations provide valuable insights into the mechanisms underlying chemoresistance.

#0827 Actin cytoskeleton modulation reprograms resistant GBM spheroids and GSCs, enhancing response to IR and temozolomide in vitro and in vivo.

Yuli Thamires Magalhaes[1], Viktor Kalbermatter Boell[2], Leticia Ramos Molica[1], Donna Joe[1], Fabio Luis Forti[3]

[1]Biochemistry, University of Sao Paulo - Institute of Chemistry, Sao Paulo, Brazil,[2]IQ USP, Sao Paulo, Brazil,[3]University of Sao Paulo, Sao Paulo, Brazil

Actin cytoskeleton regulate essential processes in cancer progression, including cell division, migration, invasion, and genomic stability. Nuclear F-actin has emerged as a critical regulator of DNA repair, chromatin organization, and transcription, representing a potential therapeutic target. Glioblastoma (GBM), a highly aggressive tumor with strong resistance to ionizing radiation (IR) and temozolomide (TMZ), frequently relies on GBM stem-like cells (GSCs) to sustain recurrence. GSCs exhibit enhanced DNA repair, and their stemness is influenced by pathways linked to actin dynamics. We investigated whether targeting actin polymerization sensitizes GBM to therapy by modulating DNA damage response (DDR) and GSC phenotypes. IR- and TMZ-resistant U87-MG cells generated through cyclic treatments were grown as 3D spheroids. Resistant spheroids showed increased proliferation, faster cell-cycle progression, elevated cell death within the core, and markedly enhanced self-renewal, supporting a stem-like tumorigenic profile. Interestingly, resistant cells exhibited distinct invasion patterns: IR-resistant were more invasive, whereas TMZ-resistant were more migratory, consistent with pFAK and vimentin immunoblotting, indicating distinct GSC-like subtypes within each resistant population. Strikingly, spheroid assembly in the presence of F-actin-disrupting drugs (cytochalasin D/B or latrunculin B) reduced therapy resistance and diminished tumorigenicity. Zebrafish xenotransplantation confirmed the aggressive proliferation, mortality rates, and metastatic dissemination of resistant cells, all of which were significantly reduced upon actin-targeting treatments, resulting in increased animal survival. RNA-seq, qPCR, immunoblotting, and immunofluorescence revealed upregulation of GSC markers in resistant spheroids, while actin disruption markedly reduced their expression. We propose that nuclear F-actin regulates transcriptional circuits that maintain stemness and therapy resistance. Consistently, resistant cells exhibited elevated nuclear actin which was dynamically modulated by genotoxic stress or pharmacological actin disruption. Ongoing chromatin-fraction proteomics aim to identify nuclear F-actin-associated proteins under damage conditions. Finally, in PDX GSC23 cells, inhibition of F-actin polymerization reduced stemness markers under self-renewal conditions and prevented serum-induced differentiation. Cytochalasin D enhanced sensitivity of GSC23 to IR and TMZ, reducing proliferation, viability, and tumorigenicity. Collectively, these findings reveal actin cytoskeleton regulation, particularly nuclear F-actin, as a vulnerability that can be therapeutically exploited to overcome GBM resistance, supporting actin-modulating compounds as promising adjuvants for GBM therapy.

#0828 Investigation of developmental LIN28/*let-7*/SOX2/SOX9 feedback loop during cell migration and metastasis.

Indhujah Thevarajan, Maria Osuna, Bareun Kim, Jihan K. Osborne

Pharmacology, University of Texas Southwestern Medical Center, Dallas, TX

The RNA binding protein LIN28, and the microRNA (miRNA) *let-7* family represent an evolutionarily conserved developmental feedback loop that acts as a regulator of developmental timing in metazoans. We have recently published data demonstrating that in the developing lung and brain, Sox2 and Sox9 transcriptionally regulate *Lin28a/b*. Moreover, previous work from our lab show that Lin28a binds *Sox2* and *Sox9* mRNAs and regulates their stability and translation. Our hypothesis is that reactivation of an early developmental pathway governed by SOX9 and SOX2 lead to transcriptional upregulation of LIN28A/B at various times during tumorigenesis. Our goal is to understand why developmental pathways are re-expressed during tumorigenesis as well as find ways to specifically target these pathways to inhibit metastasis. We established transient SOX9 knockdown (KD) using siRNA and stable SOX9 KD using lenti-viral shRNA construct in normal and cancer cell lines of lung and pancreas. We performed migration assays in control and SOX9 KD cells to test protein expression of SOX9, SOX2, LIN28A, and LIN28B using immunoblot and immunofluorescence experiments at different migratory stages. We performed migration/invasion assays using the Incucyte SX5 live-cell imager via high throughput migration assays to test migratory potential of control and SOX9 KD cells. We have found that SOX9 expression becomes nuclear during migratory stages in normal and cancer cells indicating a potential transcriptional activation during cell migration. We noticed that SOX9 expression is increased at different migratory stages but decreased after wound closure. Interestingly, SOX2 expression is higher in cancer cell lines after wound closure when SOX9 expression is lower. LIN28A and LIN28B expression is increased at different migratory stages in lung and pancreatic cancer cell lines, but not in the normal cell lines. Importantly, we observed that in lung and pancreatic cancer cells migration, invasion and proliferation are slow after SOX9 KD. We will now investigate whether LIN28A/B are functional downstream targets of the SOX9/SOX2 axis during the pathophysiology of non-small cell lung cancer (NSCLC) and pancreatic cancer with specific focus on migration/invasion and metastasis.

#0829 Infiltration of hematopoietic stem cells (HSC) is associated inversely with cell proliferation, with better patient survival, and its reduction by neoadjuvant chemotherapy relates with poor survival in breast cancer.

Masanori Oshi[1], Rongrong Wu[1], Li Yan[1], Takashi Ishikawa[2], Itaru Endo[3], Kazuaki Takabe[1]

[1]Roswell Park Comprehensive Cancer Center, Buffalo, NY,[2]Breast Surgery, Tokyo Medical University, Tokyo, Japan,[3]Yokohama City University, Yokohama, Japan

Background: Hematopoietic stem cell (HSCs), also known as blood stem cells, are self-renewable cells that can develop into all types of blood cells. They are found in bone marrow and peripheral blood. However, the clinical relevance of HSCs in breast cancer (BC) tumor microenvironment (TME) remains unknown. The aim of this study was to elucidate the clinical significance of HSC infiltration in the TME of BC.

Methods: In silico analyses were conducted on 5,176 BC patients, including large independent cohorts; The Sweden Cancerome Analysis Network-Breast (SCAN-B) and the Molecular Taxonomy of Breast Cancer International Consortium (METABRIC), as well as multiple single-cell sequenced cohorts. HSC were identified through the xCell algorithm, and patients with high HSC levels were defined as those with HSC expression above the median in each cohort.

Results: Fraction of HSCs ranged from 0.04-0.50% of all cells in BC TME by single cell transcriptome analyses. HSC infiltration was not correlated with its lineage cells, common myeloid progenitor cells and common lymphoid progenitor cells, but was associated with high infiltration of dendritic cells and stromal-related cells and low infiltration of Myeloid-related cells; M1-macrophages, and eosinophils, and lymphoid-related cells; Th1 cells, Tregs, NK T cells, and memory B cells. HSC high BC enriched TGF-β signaling, myogenesis, coagulation, and angiogenesis gene sets. On the other hand, all the cell proliferation-related gene sets in Hallmark collection; E2F targets, G2M checkpoint, MYC targets-v2, and mitotic spindle, enriched to low HSC BC, and HSC infiltration was significantly lower in high histological grade BC and in Ki67 high expression BC. HSC high patients were significantly associated with better overall survival compared to low patients in ER+/HER2- (both $p<0.02$), but not in TNBC in both cohorts. Interestingly, there was no survival difference by HSC infiltration in ER+/HER2- when neoadjuvant chemotherapy (NAC) was used. Together with our finding that HSC in the TME markedly reduced by NAC, we cannot help but speculate that the loss of HSCs by NAC may have contributed to loss of their benefit in patient prognosis. Lastly, high levels of HSC were associated with significantly lower risk of lung metastasis and better survival, but not with brain and bone metastases.

Conclusions: This is the first report that quantified HSCs in TME using transcriptome and demonstrated that they are rare, associated inversely with cell proliferation and with better survival in ER+/HER2- BC patients. Survival benefit of HSC infiltration was lost with NAC that reduce its infiltration. HSC high BC was associated with lower risk of lung metastasis and with better survival, but not with brain nor bone metastasis.

#0831 The functional crosstalk between tissue transglutaminase (TG2) and CD24 enhances cancer stem cell traits and therapy resistance in high grade serous ovarian cancer.

Rohit Pravin Nagare[1], Habeebunnisa Begum[1], Ben Wamba[2], Jogender Tushir-Singh[2], Fabrizio Pin[3], Salvatore Condello[1]

[1]Indiana University School of Medicine, Indianapolis, IN,[2]Department of Medical Microbiology and Immunology, University of California Davis, California, CA,[3]Department of Cell Biology and Physiology, Indiana University School of Medicine, Indianapolis, IN

High-grade serous ovarian cancer (HGSOC) remains one of the most lethal gynecologic malignancies, largely due to persistent cancer stem cells (CSCs) that drive disease progression. Our data revealed that tissue transglutaminase 2 (TG2) is a central mediator of OCSC biology through its interaction with fibronectin (FN) and integrins, activating oncogenic pathways, including Wnt signaling, that promote stemness and platinum resistance. We further identified that TG2 cooperates with the immune-regulatory receptor CD24 to anchor OCSCs to peritoneal organs, facilitating early metastatic implantation and ascites formation. To therapeutically disrupt this axis, we synthesized a selective peptide inhibitor (BP) that blocks the TG2-FN interaction and developed a CD24-neutralizing antibody (CD24-Ab), each of which suppresses CSC function in preclinical models. We then combined these modalities into a single first-in-class antibody-peptide conjugate, APC (CD24-Ab-TG2-BP), designed to simultaneously disrupt CD24 signaling and TG2-mediated CSC-tumor microenvironment (TME) interactions. TCGA analysis of HGSOC revealed TG2 and CD24 *m*RNA amplification in 3% and 2% of cases, respectively. Flow cytometry confirmed robust TG2 (58%, 51%) and CD24 (98%, 100%) expression, with substantial co-expression (55%, 45%) in OVCAR4 and OVCAR5 cells, respectively. APC treatment significantly downregulated CSC-associated markers (NANOG, OCT4, SOX2, ALDH1A1) and disrupted spheroid architecture. Co-immunoprecipitation demonstrated a specific TG2-CD24 interaction in SKOV3 and OVCAR4 cells, while biochemical fractionation localized the complex to lipid raft microdomains, signaling platforms that integrate receptors and downstream oncogenic effectors. In OC xenograft models, treatment with APC significantly reduced tumor volume (0.22 ± 0.11 mm^3 vs. 1.7 ± 1.1 mm^3; N =5, $P < 0.001$), tumor weight (0.64 ± 0.21 gm vs. 1.53 ± 0.46 gm; N =5, $P < 0.01$), and metastasis (5.3 ± 3.6 vs. 10 ± 3.6; N =5, $P < 0.001$) when compared with IgG controls, thus demonstrating potent anti-tumor efficacy. Collectively, these findings identify a lipid raft-restricted TG2-CD24 complex as a novel driver of OCSC maintenance and chemoresistance in HGSOC. Targeting this interaction with APC effectively disrupts CSC-TME crosstalk and suppresses tumor progression, establishing TG2/CD24 axis as a novel therapeutic vulnerability for overcoming resistance and recurrence in HGSOC.

#0833 Desmoglein-2 carrying cancer stem cell-derived extracellular vesicles promote lung cancer aggressiveness.

Prita Pandya, Aamena Ahmed, Nayya Murray, Dania S. Al-Qasrawi, Anaya Y. Clarke, Reagan Carris, Verline Justilien

Mayo Clinic Florida, Jacksonville, FL

Lung cancer remains the leading cause of cancer-related deaths worldwide, with non-small cell lung cancer (NSCLC) accounting for approximately 85% of all cases. Despite advances in targeted and immuno-therapies, overall survival for NSCLC remains below 25%, due to late-stage detection and therapeutic resistance. Cancer stem cells (CSCs), a highly tumorigenic subpopulation within NSCLC, drive relapse, metastasis, and treatment failure. Understanding the mechanisms by which CSCs promote the aggressiveness of NSCLC may reveal new diagnostic and therapeutic opportunities. CSCs establish an intercellular communication network through the secretion of extracellular vesicles (EVs), membrane-bound nanoparticles that transport proteins, lipids, and nucleic acids that can influence recipient cell behavior. Our previous work demonstrated that CSCs secrete significantly more EVs compared to bulk cancer cells (BCCs) and induce an enhanced tumorigenic phenotype in BCCs. However, the EV protein cargo that mediates these CSC-driven phenotypes and the signaling they promote remain poorly understood. This study aimed to identify and characterize CSC-derived EV protein cargo that contributes to NSCLC growth and metastasis. CSC- and BCC-derived EVs were isolated using tangential flow filtration and characterized according to MISEV guidelines. Mass spectrometry and pathway analysis were performed to compare the proteome of CSC- and BCC-derived EVs, followed by functional characterization *in vitro* and *in vivo.* Our results showed that EVs exhibited expected morphological, biochemical, and physical properties. Pathway analyses showed that CSC-derived EVs were enriched in proteins that localize to exosomes and associate with metabolism and cell adhesion. Comparison of BCC and CSC-derived EVs revealed Desmoglein-2 (DSG2) as one of the proteins exclusively detected in CSC-derived EVs. shRNA-mediated knockdown of DSG2 significantly reduced invasion, clonal expansion, and transformed growth *in vitro* and decreased tumor growth and metastasis *in vivo*. Furthermore, DSG2-competent EVs partially rescued the effects of DSG2 knockdown on CSC tumor growth *in vivo*. Together, these findings identify DSG2 as a key CSC-specific EV protein cargo that promotes an enhanced tumorigenic phenotype and NSCLC tumor growth. This work highlights the role of CSC-derived EV proteins as mediators of NSCLC aggressiveness and as candidates for biomarker and therapeutic development.

#0834 Unveiling the association of cancer stem cell markers with survival in follicular lymphoma patients.

Xin Zhang[1], Olivia White[1], Daniel Ashley[2], Betty Chung[3], Li Li[4]

[1]Institute of Translational Research, Ochsner Health System, New Orleans, LA,[2]University of Queensland-Ochsner Clinical School, New Orleans, LA,[3]Department of Pathology, Ochsner Health System, New Orleans, LA,[4]Ochsner Health System, New Orleans, LA

Background: Follicular lymphoma (FL) is the second most prevalent subtype of non-Hodgkin's lymphoma characterized by a protracted waxing and waning clinical course. Despite advances in treatments, about half of FL patients experience relapse within five years and become refractory to treatment. Clinical risk factors such as FL International Prognostic Index (FLIP) have not been used to guide the selection of treatment strategies. So far there are no prognostic markers for FL patients or physicians to select their treatment or understand their treatment resistance as well as relapse courses. Here we identified the cancer stem cell (CSC) markers in tissue microarray slides (TMA) and determined their association with FL patient survival.

Methods: Total 105 FL pts with available lymph node biopsy blocks were identified by AI software Deep6 and Slicer Dicer for query building in EPIC (ICD-10 code: C82.9). Demographic and clinicopathological characteristics of these FL pts were collected. FL patients were divided in two groups: FL pts with short-term survival (less than 5 years) and long-term survival (more than 20 years). FFPE blocks from 59 FL pts lymph node biopsies were collected and used to create tissue microarray slides (TMA). H&E staining and IHC staining of FL cells (CD20) and CSCs (ABCG2, Ki67, and OCT3/4) were performed. Frequency of CSCs was analyzed using HALO® software. statistical analyses were performed using GraphPad prism 9. Two-sided p values <0.05 were considered statistically significance.

Results: Among 59 FL patients, 26 (44.1%) pts were short-term survival, and 33 (55.9%) FL pts were long-term survival. Although no difference in the frequencies of CD20+ cells between the short-term and long-term survival groups, significant increases in the frequencies of single CSC markers (ABCG2, Ki67, or OCT3/4) as well as CSC combination markers (ABCG2+, Ki67+, OCT3/4+) were found in the short-term survival group compared to the long-term group (p values <0.05).

Conclusion: Our results unveil phenotypically distinct CSC markers that are independence of existing prognostic markers and associated with short-term survival in FL pts, indicating their prognostic value in predicting FL patients' outcome. Evaluation of CSC markers may aid in identifying high-risk individuals and guiding personalized treatment in FL patients.

#0835 Modeling endometrial cancer using iPSC-derived endometrial organoids integrating genetic determinants of ethnicity.

Sueanne Chear[1], Simon Gayther[2], Kate Lawrenson[2]

[1]University of Texas Health Science Center San Antonio, San Antonio, TX,[2]Center for Inherited Oncogenesis, University of Texas Health Science Center at San Antonio, San Antonio, TX

BACKGROUND: Endometrial cancer is the most common gynecologic cancer in developed countries with an increasing incidence of 28.3 per 100,000 women per year in the United States alone. The cancer arises from the glandular epithelium of the endometrium and typically progresses by invading the stroma and myometrium. Development of endometrial cancer is influenced by genetic mutations (PTEN, TP53, mismatch repair genes), as well as ethnic, environmental, and hormonal factors. A scalable, physiologically relevant human model of endometrial cancer that captures these complex factors remains lacking.
METHODS & RESULTS: We have established human induced pluripotent stem cell **(**iPSC)-derived endometrial organoids as a platform for studying the early mechanisms of endometrial cancer, including cancer initiation and progression. We first used different protocols to create endometrial-like epithelium and stroma. Human iPSCs from a healthy individual were differentiated into epithelial organoids consisting of early-stage Müllerian duct-like cells (MDLCs) with an epithelial-mesenchymal hybrid phenotype (Pan-CK+/VIM+). To promote endometrial identity, epithelial organoids were co-cultured with endometrial stromal cells and treated with a single cycle of steroid hormones mimicking the human menstrual cycle. Immunofluorescence staining showed the organoids developed luminal epithelial and glandular-like structure (KRT8+/PAX8+/CDH1+), surrounded by VIM+ mesenchymal cells. Endometrial organoids are hormone responsive and express functional markers of uterine endometrium, including the secreted proteins, PRL and IGFBP1. By incorporating iPSCs from individuals of diverse ethnic backgrounds and introducing pathogenic genetic variants, we aim to uncover how genetic variation and population-specific factors contribute to endometrial cancer development and progression.
CONCLUSIONS: We anticipate this model will enable us to study the multifactorial contributors to endometrial cancer and support the identification of early disease events and therapeutic targets.

#0837 IDH mutations disable the tumor suppressive activity of GSX2 to promote gliomagenesis.

Yi Xiao[1], Diana D. Shi[2], Lei Guo[1], Ethan Neumann[1], Michael M. Levitt[1], Pranita Kaphle[1], Tracey Shipman[1], Haocheng Li[1], Feng Cai[1], Denise M. O. Ramirez[1], Lauren G. Zacharias[1], Zhenkang Chen[1], Mathew Lin[2], Vinesh T. Puliyappadamba[1], Tao Chen[1], Milan R. Savani[1], Salvador Pena[1], Janaka Wansapura[1], Thomas P. Mathews[1], Prashant Mishra[1], Yoon Jung Kim[1], Prithvi Raj[1], Timothy E. Richardson[3], Jian Xu[4], Stephen C. Mack[4], Gilbert J. Rahme[5], Bradley E. Bernstein[2], Ralph J. DeBerardinis[1], Itay Tirosh[6], Mario L. Suva[2], Lin Xu[1], Kalil G. Abdullah[7], Samuel K. McBrayer[1]

[1]UT Southwestern Medical Center, Dallas, TX,[2]Harvard Medical School, Boston, MA,[3]Icahn School of Medicine at Mount Sinai, New York, NY,[4]St. Jude Children's Research Hospital, Memphis, TN,[5]Renaissance School of Medicine at Stony Brook University, Stony Brook, NY,[6]Weizmann Institute of Science, Rehovot, Israel,[7]University of Pittsburgh Medical Center, Pittsburgh, PA

Isocitrate dehydrogenase (*IDH*) mutations arise early in glioma development and are associated with a defined neurodevelopmental cancer cell hierarchy. However, how mutant IDH contributes to this hierarchy and whether this interaction promotes gliomagenesis remain unclear. Progress in addressing these questions has been hindered by technical limitations. Patient-derived models rarely capture the biology of tumor initiation, as surgical specimens are obtained only after these phases of cancer evolution have passed. Moreover, the lack of faithful preclinical models of mutant IDH has constrained mechanistic investigation. To overcome these challenges, we developed a genetic mouse model of mutant IDH-driven gliomagenesis and IDH-wildtype companion models to enable direct testing of causal genotype-phenotype relationships involving the *Idh1-R132H* oncogene. We leveraged these models to survey IDH-mutant glioma initiation by performing time-resolved, joint single-cell RNA and ATAC sequencing analysis of engineered neural cells. Mutant IDH activates neural progenitor cells (NPCs) and drives NPC lineage switching. These actions expand oligodendrocyte precursor cells, the predominant cell-of-origin for these tumors, at the expense of interneurons, a lineage incompatible with mutant IDH-induced transformation. We further find that lineage switching is mediated by promoter hypermethylation and silencing of *Gsx2*, a homeobox gene required for neurogenesis. Critically, *Gsx2* ablation recapitulates NPC fate reprogramming by mutant IDH while restoring *Gsx2* expression in IDH-mutant neurosphere lines impairs their self-renewal and tumorigenic potential. Our work uncovers the molecular mechanisms by which mutant IDH reprograms neural lineage specification to promote cancer initiation, providing a new model of neural cell fate control by IDH oncogenes and insights into the developmental origins of glioma.

#0838 Single cell multiomic profiling of heterogenousPROCR+ cells in mouse mammary gland and its implication for breast cancer.

Jose Silva[1], Koon-Kiu Yan[2], Erin Nekritz[1], Jiyang Yu[2]

[1]Icahn School of Medicine at Mount Sinai, New York, NY,[2]St. Jude Children's Research Hospital, Memphis, TN

Introduction: The mammary gland is a dynamic organ that undergoes extensive tissue remodeling during the female lifetime. In all these stages, epithelial enlargement is supported by a population of adult mammary epithelial stem cells (MaSCs) residing at the apex of the hierarchy. MaSC homeostasis needs to be tightly regulated in time and space to ensure proper organ function and avoid pathological consequences. Thus, dysregulation of stem cell activity has been linked to tumor initiation, and aggressive breast cancers are frequently enriched in cells exhibiting stem cell like properties. Although MaSCs are fundamental to mammary gland development, their precise identity and defining characteristics remain poorly understood. Notably, protein C receptor (PROCR) marks a rare subset of mammary epithelial cells with stem-like properties, but their low abundance has hindered their characterization.
Methods: Here, we combine targeted FACS enrichment with single-cell RNA sequencing and chromatin accessibility profiling to generate a multimodal atlas of $PROCR^{+}$ mammary epithelial cells across developmental stages.
Summary of results: We uncover heterogeneity within this compartment and identify a previously unrecognized $Procr^{+}$, $Cdh5^{-}$, $Col1a1^{+}$ population that exhibits the highest developmental potency, strongest EMT-like signature, and earliest pseudotime position, consistent with a bona fide mammary stem cell (MaSC) state. Integration of scRNA-seq and scATAC-seq reveals the transcriptional regulatory architecture governing MaSC identity and basal versus luminal lineage commitment, including direct master regulators whose motif accessibility and activity shift along differentiation trajectories. Comparative analyses with human mammary epithelium identify analogous $PROCR^{+}$ subpopulations, and interrogation of breast cancer datasets demonstrates that the $Procr^{+}$, $Cdh5^{-}$, $Col1a1^{+}$ MaSC signature is selectively enriched in triple-negative and claudin-low tumors.
Conclusions: These findings refine the cellular hierarchy of the mammary epithelium, define regulatory programs underlying stemness and lineage bifurcation, and establish a molecular link between a distinct MaSC state and the biology of aggressive breast cancer subtypes.

#0839 Single cell cloning iPSCs with the Pala single cell sorter preserves colony stemness and cell viability for high-throughput cell line engineering workflows.

Bhamini Purandare, Francisco Ramirez, **Ryan McComb**, Chris Heger

Bio-Techne, San Jose, CA

Stable cell line development is a critical process for developing and manufacturing biologics, generating disease relevant cellular models, and creating the next generation of cell & gene therapies. The utility of new cell models (patient derived iPSCs), the development of new genome editing technologies (CRISPR) and the deployment of automation and AI for high-throughput screening are creating a greater demand for scaling cell line development capabilities and workflows. Bio-Techne has developed the Pala single cell sorter and dispenser that incorporates microfluidics, flow cytometry, and liquid dispensing in a portable, easy to use, and gentle device for generating high rates of single cell derived clones for enhancing cell line engineering workflows. Here, Pala is compared to traditional limiting dilution (LD) to dispense induced Pluripotent Stem Cells (iPSCs) for single cell cloning and colony outgrowth. Single dissociated iPSCs from two different lineages were dispensed in matrix coated 96-well plates or hand pipetted at 0.4 cells/well using LD. Colony health and stemness are compared between each method using clone area and TRA-1-60 immunofluorescence staining. Pala, on average, generated ~3-fold greater numbers of single cells deposited and colonies generated than LD. Additionally, colony health showed equivalence between the two methods demonstrating that Pala derived clones are as healthy as clones derived with LD. This work demonstrates the gentleness and efficiency of Pala for use in stem cell/gene editing workflows for enhancing throughput of single cell cloning.

#0840 Multi-tissue modeling of *BRCA* cancers using iPSC-derived organoids platform.

Nur Yucer[1], Alyssa Okimoto[2], Subash Dhungana[1], Dean Bacich[1], Rebecca Webster[1], Beatriz German Falcon[3], Michelle Jones[4], Sarah Parker[4], Bobbie Jo Rimel[5], Beth Y. Karlan[6], Leigh Ellis[3], Matthew Freedman[7], Robin J. Leach[8], Xiaojiang Cui[4], Kate Lawrenson[1], Simon Gayther[1]

[1]Medicine, Center for Inherited Oncogenesis, UT Health San Antonio, Long School of Medicine,, San Antonio, TX,[2]Center for Inherited Oncogenesis, UT Health San Antonio, Long School of Medicine,, San Antonio, TX,[3]Department of Surgery, Center for Prostate Disease Research, Murtha Cancer Center Research Program, Uniformed Services University of the Health Sciences,, Bethesda, MD,[4]Cedars-Sinai Medical Center, Los Angeles, CA,[5]University of Washington Department of Obstetrics and Gynecology, Seattle, WA,[6]UCLA David Geffen School of Medicine, Los Angeles, CA,[7]Department of Medical Oncology, Dana-Farber Cancer Institute, Harvard Medical School, Boston, MA,[8]UT Health Science Ctr. at San Antonio, San Antonio, TX

Germline pathogenic mutations in the BRCA1 and BRCA2 genes (BRCA1/2mut) are the strongest genetic risk factors for high-grade serous ovarian cancer, and estrogen receptor-positive (ER+) and triple-negative breast cancer (TNBC). Pathogenic variants in these genes are implicated in about 15% of women with heritable risks of these cancers. Moreover, BRCA2^{mut} are associated with increased risk of ER+ breast cancer and aggressive prostate cancer in men. Precise risk estimates for BRCA1/2^{mut} that affect different cancer types are crucial to evaluate treatments and enhance drug sensitivity. Patient-specific induced pluripotent stem cell (iPSC) methods create opportunities to model human diseases in vitro. iPSCs derived from patients with known genetic mutations carry the patient's unique genetic background, to provide platforms for studying the functional effects of specific genes. Several inherited disease models created from iPSCs have successfully replicated high-risk cancers. This study aimed to utilize iPSC-based modeling to investigate the functional impact of pathogenic BRCA1/2^{mut} on early-stage phenotypes and genomic alterations that contribute to cancer progression.

Methods: We generated iPSC from both BRCA1/2^{mut} carriers' women and BRCA2^{mut} carrier male. From female BRCA1/2^{mut}, we have established iPSC-derived organoid models of ovarian cancer -OC-(fallopian tube epithelium, FTE) and breast cancer -BC-(mammary gland epithelium, MGE) and from male BRCA2^{mut} prostate cancer-PC.

Results: Following differentiation into FT organoids, both heterozygous BRCA1/2^{mut} models show specific cellular abnormalities - neoplastic transformation, expression of cancer-specific biomarkers - compared to BRCA^{WT} controls. ER+ BC and TNBC models revealed that following differentiation into MG organoids: models from heterozygous BRCA1/2^{mut} carriers conferred a neoplastic phenotype reminiscent of a ductal carcinoma in situ (DCIS) compared to BRCA^{WT} controls. Notably, the development of DCIS in BRCA2^{mut} carriers was dependent on estrogen (E2) exposure, while in BRCA1^{mut} carriers, it was independent of hormonal influences; this may suggest that BRCA haploinsufficiency contributes to the observed phenotype. PC models from BRCA2^{mut} subjects exhibit abnormalities reminiscent of early-stage neoplastic development. Importantly, prostate organoids with combinations of BRCA2^{mut} and PTEN alterations exhibited more aggressive PC phenotypes compared to BRCA2^{mut} and BRCA^{WT} organoids alone, and shared genomic signatures with primary aggressive PC.

Conclusion and Impact. iPSC-derived multi-tissue organoid platform can accurately replicate BRCA1/2^{mut} and BRCA^{WT} precursor tissues. This allows cancer to evolve in a dish, making it an ideal model for mechanistic studies and screening approaches to identify novel drug targets.

#0841 Maternal obesity reprograms intestinal stem cells to elevate colorectal cancer risk in offspring.

Gourab Lahiri[1], Karla Mullen[1], Yesenia B. Millan[1], Swathi Sankar[1], Dominic R. Saiz[1], Thomas H. McDermott[1], Madeline Blatt[1], Abhigyan Shukla[1], Khashayarsha Khazaie[2], Miyeko D. Mana[1]

[1]School of Life Sciences, Arizona State University, Tempe, AZ,[2]Mayo Clinic, Phoenix, AZ

Maternal obesity has been epidemiologically linked to an increased risk of sporadic colorectal cancer (CRC) in offspring, the third most prevalent cancer worldwide. This association underscores the lasting influence of early-life exposures on long-term health and disease susceptibility. Intestinal stem cells (ISCs), the long-lived cells that sustain epithelial renewal and often serve as the origin of intestinal cancers, are thought to play a central role in mediating this elevated cancer risk. However, how maternal obesity shapes the early-life programming and maturation of ISCs in their offspring remains poorly understood. Using mouse models of diet-induced obesity, we show that offspring exposed to a maternal high-fat Western diet (HFD) during pre- and postnatal development exhibit increased colonic proliferation, enhanced stem cell self-renewal, and a hypermetabolic state that persists into adulthood, even after dietary normalization. Alongside changes in stem cell properties, we observe a significant shift in epithelial cell composition, characterized by an increase in cells of secretory lineage at the expense of absorptive enterocytes, and these changes endure into adult life. Additionally, these changes are accompanied by an increased tumor burden in the loss of Apc heterozygosity model. Our data indicate that IL-17a, a pro-inflammatory cytokine, is critical in mediating these changes. Specifically, receptor IL-17RA/C expression is significantly upregulated in ISCs and secretory cells in maternal HFD-exposed offspring. Administration of IL-17a to intestinal organoids demonstrates sufficiency by mimicking the maternal obesogenic phenotype, indicating that immune-epithelial interactions influence ISC function and may be a driver of durable molecular patterning. These findings emphasize the long-term consequences of maternal HFD exposure on intestinal stem cell activity and epithelial composition, and possibly contribute to a higher risk of CRC in offspring later in life.

#0843 Protection of human bone marrow MSC from room air oxygen during isolation accelerates cell growth.

Alicia D. Henn, Shannon L. Darou, Collins E. Gbegbeawu, Syed A. Mustafa

BioSpherix, LLC, Parish, NY

The role of mesenchymal stromal/stem cells (MSC) in the cancer microenvironment is of great interest, not only for the fundamental roles that MSC play in inflammation, organoids, and regenerative medicine, but also as producers of exosomes. These extracellular vesicles, which can deliver cargo to other cells, are gaining interest as tumor-homing vehicles for therapeutic agents. However, the solid tumor environment is hypoxic, and even normal tissues reside at oxygen levels far below that of room air, where MSC are grown for exosome production. Exposure to supraphysioxic room air changes MSC, modulating HIF-1a which is upstream of signaling pathways related to cell proliferation, differentiation, and cell death. We previously showed that eliminating exposure of human bone marrow MSC to room air during cell culture and handling can prevent HIF-1a modulation, improve cell division rates, and reduce cell senescence in later passages. Here we extend those findings, isolating cells from cadaver bones that were sourced from a licensed organ procurement agency, under constant physioxia (5%O2/ 5%CO2) in an Xvivo System. Flow cytometric analyses and differentiation of the plastic-adherent bone marrow cells into adipocytes, chondrocytes, and osteocytes confirmed the bone marrow MSC phenotype. Having never experienced room air, these MSC exhibited faster cell growth at passage 8 (mean doubling time 43.2 +/- 1.2 hrs, n = 3 separate cultures) than commercially sourced MSC that had been isolated, expanded, and cryopreserved under traditional laboratory conditions (mean doubling time 128 +/- 15.2 hrs, n = 2 separate cultures). We concluded that protecting MSC from room air exposure, even during isolation, can improve human bone marrow MSC growth kinetics for studies of the tumor microenvironment, inflammation, and tumor-homing exosomes.

#0844 Investigating the ability of *foxo1* to maintain stem cells.

Stella Aime Rios, Megan E. Keniry

College of Sciences, University of Texas Rio Grande Valley, Edinburg, TX

Background: Our group discovered that FOXO transcription factors drive stem gene expression in cancer to promote aggressiveness. Work by our group and others demonstrated that FOXO factors universally maintain stem cells including in cancer, embryonic, hematogenic and neuronal contents. Our current efforts are delineating the molecular underpinnings by which FOXO factors halt differentiation to maintain stem cells. In this project, we are employing myoblasts as a valuable model to examine how Foxo1 maintains stem cells. Foxo1-regulated genes in myoblasts closely parallel its targets in glioblastoma and basal breast cancer stem cells, including targets such as *Leukemia Inhibitory Factor*, *Lif,* encoding a cytokine that prevents differentiation. Understanding how Foxo1 maintains stem cells is crucial, as it holds the potential to uncover new therapeutic options that could target the fundamental biological processes involved in cancer progression and chemotherapeutic resistance.

Methods: RNAi was performed on C2C12 myoblasts cells to create *Foxo1* knockdown and control lines, followed by assessment of target genes involved in differentiation, proliferation, and muscle fiber types using qRT-PCR. Fluorescent microscopy was utilized to investigate the structural differences in actin filaments and nuclei between *Foxo1* knockout cells and the control group. Our initial work, including investigating candidate genes using qRT-PCR. We are currently taking genomics approaches to investigate the role of Foxo1 in myoblast/stem cell differentiation.

Results: In *Foxo1* knockout cells, there was a notable decrease in *Lif* expression, suggesting differentiation. Downregulation of genes like *Igfbp1*, *Socs1*, and *Socs2* indicates possible direct or indirect activation by *Foxo1*, with implications for cell growth and cytokine signaling. Additionally, downregulation of *Pepck* and the modulation of energy metabolism pathways suggest altered metabolic states. The downregulation of *Stat1* and *Wnt3* implies disruptions in pathways that promote proliferation to favor differentiation. This aligns with observations of increased nuclei and actin filament abundance in *Foxo1* knockout cells, reflecting enhanced muscle differentiation and myotube formation.

Conclusion: *Foxo1's* involvement in regulating cellular dynamics through gene expression is complex and dynamic, impacting differentiation and proliferation, with notable changes in the cytoskeleton facilitating myoblast fusion and differentiation. Gaining insights into the relationship between *Foxo1* and target genes will clarify potentially conserved roles that determine the differentiation status of stem and progenitor cells. We are anticipate that this model system will allow us to glean fundamental mechanisms that maintain stems cells to ultimately target cancer stem cells, which are known to trigger recurrence and chemotherapeutic resistance.

#0845 Tumor-associated mesenchymal stem cells accumulate in high oxidative phosphorylation regions of peritoneal dissemination in gastrointestinal cancers.

Nobuhiko Kanaya, Yu Mikane, Shinji Kuroda, Eri Takeda, Makoto Matsumoto, Kosuke Yunoki, Yudai Mimata, Hitoshi Minagi, Tetsuya Katayama, Daisuke Kadowaki, Masashi Hashimoto, Yoshihiko Kakiuchi, Shunsuke Kagawa, Hiroshi Tazawa, Toshiyoushi Fujiwara

Department of Gastroenterological Surgery, Okayama University Graduate School of Medicine, Dentistry and Pharmaceutical Sciences, Okayama, Japan

Peritoneal dissemination represents a lethal metastasis in gastrointestinal malignancies; however, cellular constituents that sculpt the metastatic niche remain poorly resolved. Recent studies reveal tumor associate mesenchymal stem/stromal cells (TA-MSCs) induce tumor migration and immune suppression in several tumors such as ovarian cancer. In this study, we focused on TA-MSCs as potential stromal drivers of metabolic adaptation within the peritoneal dissemination from gastrointestinal malignancies, especially colorectal cancer. First, public multi-omics datasets revealed tumor type-dependent variation in canonical MSC transcripts. Next, in surgical specimens of the peritoneal dissemination from patients with colorectal, gastric, and pancreatic cancer, the immunohistochemistry demonstrated marked elevation of CD90 and CD73 compared with non-tumor peritoneum, indicating robust stromal expansion. Single-cell transcriptomes from peritoneal lesions further identified a distinct MSC-like cluster enriched for THY1 (CD90) high cells, supporting an MSC-dominated stromal architecture in the peritoneal dissemination. To model this interaction in vivo, murine colorectal cancer bearing peritoneal dissemination mouse models exhibited a similar amplification of MSC markers compared to primary tumor controls. Notably, Oxidative Phosphorylation (OXPHOS) dominant metabolic signatures were prominent both in human metastatic peritoneum and in peritoneally adapted MC38 derivatives isolated from mice. Then, the correction between OXPHOS specific metabolism and localization of MSCs was assessed. Interestingly, the area of high OXPHOS expression into colorectal cancer derived peritoneal dissemination contained the higher MSCs infiltration using immunohistochemistry. These data proposes that MSC directed metabolic status, specifically toward oxidative phosphorylation constitutes a tractable vulnerability in peritoneal dissemination.

#0846 Evidence of functional cytotoxic T-cell responses to induced pluripotent stem cells (IPSCs): Paving the way for IPSC-derived cancer vaccines.

Valentine Feyants[1], Catherine Martel[2], Christophe Desterke[1], Mequa Maatoug[1], Diana Chaker[2], **Ali G. Turhan**[2], Annelise Bennaceur Griscelli[2], Frank Griscelli[3]

[1]INSERM U1310, Universite Paris-Saclay, Villejuif, France,[2]INSERM U1310, Universite Paris-Saclay CITHERA, Villejuif, France,[3]INSERM U1310, Gustave Roussy Cancer Center, Villejuif, France

Background: Recent studies have demonstrated that both allogeneic or autologous iPSC-based vaccines represent a promising new approach to preventive or curative cancer immunotherapy strategies particularly against aggressive tumors harboring stemness features with high risk of metastatic spread. We have previously demonstrated the in vivo efficacy of this cancer vaccine strategy in mice models (Kishi et al, Front Med, 2021) but the immunogenicity of iPSCs in the context of human cells remains unknown. Methods:To address this issue in human cells, we developed a Mixed Lymphocyte Reaction (MLR) bioassay from collected batches of peripheral blood mononuclear cells (PBMC) from HLA-A2+ donors. The assay was standardized by co-culturing CD8+ naïve T Cells and Dendritic Cells (DCs) derived from CD14+ monocytes which were loaded with iPSCs derived-lysates generated from several iPSCs lines. The primed CD8+ T cells with the lysates were assessed using proliferation assays, phenotypic profiling, and cytokine secretion. Cytotoxic function of the primed CD8+ T cells was assessed after co-culture with several HLA A2+ human cancer cell lines, including melanoma (SK-MEL5), triple negative breast carcinoma (MAD-MB-231) and human colorectal adenocarcinoma (SW-620). Results: After differentiation and maturation, DCs loaded with iPSC-derived lysates highly expressed CD80, CD11c, CD86, MHC class I and II. After co-culture with these DCs, in all tested conditions, primed CD8+T cells exhibited significantly enhanced lysis of the cancer cell lines as compared to control T lymphocytes. These activated T cells displayed an effector phenotype marked by CD137, CD107a, IFN-γ, and TNF-α expression suggesting that iPSCs were able to transmit a a broad array of immunogenic epitopes. We further analyzed the clonal diversity of the α/β TCR repertoire in CD8+T cells primed with different iPSCs using single-cell RNA sequencing. Sixteen distinct T cell clusters were identified, including a minor population of CD8+ Flt3+T cells and a dominant cluster of CD83+ CD8+T cells comprising over 1,000 unique α/β TCR clones. Single cell RNA sequence analyses of these T cells are in progress. Conclusions: Our results provide strong evidence that iPSCs can effectively activate DCs and induce the generation of phenotypically activated and functionally competent cytotoxic T cells. This strategy holds great potential for the development of off-the-shelf, IPSC-based cancer vaccines leveraging the broad antigenic repertoire of iPSC-derived cells able to generate immune response against cancer stem cell genes expressed in the most aggressive cancers such as non-small cell lung cancer, pancreas cancer and glioblastoma.

#0847 The role of tissue renewal in early-onset colorectal cancer.

Bruce M. Boman, Anh Nguyen, Chi Zhang

Helen F. Graham Cancer Center & Research Institute, Newark, DE

A genetic etiology hasn't been discovered yet for early-onset CRC (EOCRC). An essential question is why do somatic *APC* mutations occur at a relatively young age in EOCRC patients? Indeed, *APC* mutations are the initiating event in both EOCRC and later-onset CRC (LOCRC). Moreover, most other cancer types frequently have inactivated *APC* due to promoter hypermethylation. However, we didn't find that other early onset cancer types (age <50) have increased *APC* hypermethylation. So, for EOCRC, we surmise that something is retarding tissue renewal such that cells with acquired *APC* mutations are retained instead of being extruded during tissue turnover. We conjectured that EOCRC involves an essential nutrient required for tissue renewal. Accordingly, we investigated the seven essential vitamins that require adequate dietary intake. Indeed, these vitamins are essential for tissue homeostasis because germline mutations in their receptors cause birth defects. Our bioinformatics analysis shows a high frequency of somatic mutations (2x-fold) in receptors for vitamin A *(STRA6*), and retinoic acid (*RARG*, *PPARG*) in EOCRCs (<45) *vs*. LOCRCs. We also found *RARG* hypermethylation occurs frequently in EOCRCs ($p<0.05$). Moreover, population-based studies report relatively frequent vitamin A deficiency in pre-school-aged children. Consequently, young-aged individuals might be prone to any cancer-initiating effects of vitamin A deficient diets. Indeed, vitamin A plays a crucial role in cell differentiation, particularly in the differentiation of stem cells and during tissue regeneration. Thus, incomplete differentiation of crypt cells due to reduced retinoic acid signaling may provide a mechanism that explains how delayed tissue renewal causes retention of somatic *APC* mutations in colonic epithelium. Thus, we put forth the hypothesis that aberrant vitamin A (retinol) metabolism and *APC* mutation-induced activation of WNT signaling are co-factors in promoting EOCRC.

#0848 Redox regulation of breast cancer metastasis via phenotypic and metabolic adaptation.

Rachel Hazan[1], Viney Kumar[1], Outhiriaradjou Benard[1], premprashant chaudhary[2], mahaldeep kaur[2], Ian Myles , Bethesda[2], Larry Norton[3]

[1]Albert Einstein College of Medicine, Bronx, NY,[2]National Institutes of Health, Bethesda, MD,[3]Dep. Physician-In-Chief For Breast Cancer Prog., Memorial Sloan Kettering Cancer Center, New York, NY

Background: Tumor heterogeneity fuels breast cancer metastasis by selecting subpopulations withepithelial-mesenchymal (EMT) plasticity and stemness. Loss of the antioxidant enzyme glutathione peroxidase 2 (GPx2) in the PyMT mouse model promotes phenotypic and metabolic reprogramming through ΔNp63-regulated hybrid EMT and fatty acidoxidation (FAO)-driven metabolism.
Results: Using our newly engineered PyMT/GPx2 knockout (KO) transgenic mouse model, we observed a striking increase in reactive oxygen species (ROS), HIF1α stabilization, vascular malformation, proliferation (Ki67), stemness (organoid formation), and lung metastasis compared with control tumors. GPx2-deficient tumors were markedly enrichedfor hybrid EMT cells co-expressing p63, KRT8, and KRT14. Flow cytometry confirmed that ~85% of GPx2-KO tumor cells were hybrid ($CD104^+/CD44^+$), with only minor epithelial ($CD104^+/CD44^-$, ~4%) and mesenchymal ($CD104^-/CD44^+$, ~0.8%) fractions. Metabolic profiling revealed FAO as the dominant energy source in GPx2-KO tumors, supported by Seahorse assays showing elevated mitochondrial ATP production, a higherOCR/ECAR ratio, and enhanced palmitate oxidation. GPx2 loss increased p-AMPK,indicative of AMPK-mediated OXPHOS activation, and upregulated GLUT1 whilesuppressing de novo lipogenesis. These changes indicate dependence on exogenousfatty acids through CD36/CPT1-mediated β-oxidation. Notably, lung metastases derivedfrom GPx2-KO tumors showed a shift toward glycolytic metabolism, highlightingmetabolic plasticity during dissemination.
Conclusion: GPx2 loss integrates redox dysregulation with EMT and metabolic reprogramming, fostering hybrid E/M cells endowed with high metastatic potential and adaptive energymetabolism.
Clinical implications: Targeting ΔNp63 signaling or FAO pathways may selectively eliminate metabolically flexible, aggressive hybrid tumor populations, offering a potential strategy to mitigate breast cancer metastasis.

#0850 SOX9 and SEMA7A regulate epithelial cell plasticity in the postpartum mammary gland with implications for postpartum breast cancer.

Lauren M. Cozzens[1], Brendan Hinckley[1], Sonali Jindal[2], Virginia F. Borges[3], Pepper Schedin[4], **Traci Renae Lyons**[5]

[1]University of Colorado Anschutz Medical Campus, Aurora, CO,[2]UT MD Anderson Cancer Center, Houston, TX,[3]Associate Professor, Dept. of Medical Oncology, University of Colorado Denver, Denver, CO,[4]OHSU, Portland, OR,[5]Medicine/Medical Oncology, University of Colorado Anschutz, Aurora, CO

Postpartum breast cancers (PPBCs), defined as breast cancers diagnosed within ten years of childbirth, carry a significantly higher risk of metastasis and mortality compared to breast cancers diagnosed in nulliparous women. Preclinical studies implicate postpartum mammary gland involution, a period marked by extensive epithelial cell death, tissue remodeling, and inflammation, as a driver of this poor prognosis. However, the epithelial programs that govern cell survival, plasticity, and transformation susceptibility during the postpartum window remain incompletely understood. We have previously published that SEMA7A, which is linked to PPBC progression, is involved in the survival of luminal progenitor cells (LPCs) during postpartum involution. Thus, we utilized single-cell RNA sequencing to further define SEMA7A-expressing cells in mouse mammary glands during both lactation and involution to show that SEMA7A is primarily expressed on cells of the endothelium, including pericytes, but less so on mammary epithelial cells. We also revealed that Sox9, a transcription factor that is known to be expressed on mammary epithelial cells, is expressed on LPCs in the mammary gland during involution. Notably, LPCs have been suggested as key cells-of-origin for several mammary tumors. We describe the expression pattern of SOX9 throughout lactation and involution, showing that SOX9 expression changes over the course of involution in both mouse and human samples. Functional *in vitro* models of lactogenic differentiation and involution with immortalized mammary epithelial cells were utilized to define the relationship between SOX9 and SEMA7A in these epithelial states. We found that SEMA7A is low in these epithelial cells across the differentiation and involution process and that SOX9 knockdown in mammary epithelial cells results in increased SEMA7A expression and drives mesenchymal cell phenotypes, uncovering a regulatory axis in which SOX9 restrains SEMA7A-mediated cellular plasticity. Analysis of breast cancer datasets shows that dysregulation of this axis, resulting in co-expression of SOX9 and SEMA7A, correlates with metastatic risk. Together, these findings reveal a previously unrecognized SOX9-SEMA7A signaling axis in the postpartum mammary gland and highlight how studies of normal development can uncover mechanisms of PPBC progression and point toward new avenues for prevention.

#0851 BMP inhibition is an effective treatment for targeting stem-like glioblastoma cell states.

Davey (Cheng Zhe) Li, Michael Luo, Phuong U. Le, Maryam Safisamghabadi, Tuong V. Kieu, Andy Nkili, Paul Wambo, Rozica Bolovan, Javad Nadaf, Kevin Petrecca

Department of Neurology and Neurosurgery, Montreal Neurological Insitute-Hospital, McGill University, Montreal, QC, Canada

Glioblastomas are an aggressive and incurable type of brain cancer with an estimated 250,000 people around the world receiving this devastating diagnosis every year. With a median survival of 14.6 months, standard of care (surgery, radiation, and chemotherapy) is ineffective as it fails to eliminate residual glioblastoma stem cells (GSCs), which cause cancer recurrence.
Previous work suggests that GSCs arise from aberrantly activated neural stem cells (NSCs) from the subventricular zone (SVZ). This unique brain region supports NSC growth and potentially subsequent glioblastomagenesis. Single-cell RNA sequencing (scRNA-seq) and MERFISH spatial transcriptomics of glioblastoma tumors and SVZ tissue from patients have allowed us to generate an atlas of 2 million cells to identify and spatially validate primordial developmental pathways that drive the malignant transformation of SVZ-NSCs and promote GSC survival. Cell-cell interaction, consensus non-negative matrix factorization (cNMF), spatial domain, and neighborhood enrichment analysis revealed bone morphogenetic protein (BMP) signaling as a key pathway maintaining stem-like glioblastoma cells. Thus, we tested LDN193189, a potent BMP signaling inhibitor that selectively blocks the BMP type I receptors ALK2/3.
Using patient-derived GSCs treated with LDN193189, we observe a robust reduction of cell viability at 24 and 48 hour timepoints. Daily treatment for 7 days with LDN193189 on GSCs in vitro displayed reduction in cell cycling, decreased astrocytic stemness markers and BMP downstream signaling, while ablating the oligodendrocytic lineage. Assessment of LDN193189 in a patient-derived ex vivo explant organoid model demonstrated a reduction of cycling cells and reduced BMP signaling. Multiplexed spatial proteomics were performed to further interrogate the glioblastoma explant microenvironment and characterize the treatment response to LDN193189. These results suggest that disrupting key developmental pathways exploited by GSCs can halt highly proliferative GSC stem cell states, thus allowing us to target glioblastoma at its origin to prevent recurrence. Based on these promising pre-clinical results, we are currently exploring launching a Phase 1/2 open-label clinical trial for treating glioblastoma patients with BMP inhibitors.

: Survivorship Research
Poster Session

#0855 A systematic analysis on patients with NSCLC transformation to SCLC.

Duo Xu[1], Xiaomei Wu[2], Bo Zhu[1]

[1]Liaoning Cancer Hospital & Institute, Shenyang, Liaoning, China,[2]The First Hospital of China Medical University, Shenyang, Liaoning, China

Background: Lung cancer is a leading cause of global cancer mortality. Histologic transformation to small-cell lung cancer (SCLC) is a clinically significant yet under-recognized resistance mechanism in non-small cell lung cancer (NSCLC). However, a systematic review encompassing all NSCLC subtypes is lacking. To address this gap, this study integrates published cases to define the clinicopathological features and prognosis of this transformation, thereby guiding clinical management.
Method: We systematically reviewed the published literatures from 2015 to the present using PubMed database to summarize the characteristics and prognosis of cases with transformation from NSCLC to SCLC, included keywords like "transition from NSCLC to SCLC" and "NSCLC conversion to SCLC."
Results: Analysis of 72 publications identified 82 T-SCLC patients (54.9% male; median age 61 (IQR: 52-68). Available data showed 53.97% were never-smokers (34/63) and 53.66% had stage IV disease (44/65). Initial histology was adenocarcinoma (87.80%). The EGFR mutation rate was 58.54% (48/53) pre-transformation, mostly exon 19 Del (40.24%), rising notably to 84.6% (11/13) post-transformation.For pre-transformation, the first-line treatment was targeted therapy (35.37%), combination therapy (29.3%), and chemotherapy (28.0%), with a median progression-free survival (PFS) of 12.1 months (7.0-24.0); the first-generation EGFR-TKIs (18.3%) were most common. Targeted agents were also the most frequent choice in second-line (50.9%). Post-transformation, the mPFS was 8.0 months (5.0-13.0) and platinum-etoposide was the backbone (70.8%). Subsequent lines saw increased targeted therapy use but a sharp patient decline beyond third-line.Survival data post-SCLC diagnosis was accessible for 53 patients. The median overall survival (mOS) was 47.0 months (95% CI, 30.0-66.0 months) . Longer survival was associated with male, adenocarcinoma, smoker, non-metastatic disease, and early-stage disease at initial diagnosis. The median time from the first diagnosis of NSCLC transforming to SCLC was 29.0 months(20.0-46.0). The mOS after the diagnosis of SCLC was 12.0 months (7.0-19.0). The mOS of never smoker was 36.0 months (20.0-78.0). In comparison to male, female had a shorter mOS after converting to SCLC (11 vs 12).
Conclusion:This review systematically summarizes the pathological features of the transformation from NSCLC to SCLC, which primarily occurs in adenocarcinomas harboring EGFR mutations. Despite the availability of platinum-based combination chemotherapy with etoposide tailored for SCLC, patient prognosis remains poor, highlighting a critical therapeutic challenge. This underscores the urgent need for prospective clinical trials and investigations into the mechanisms of resistance to improve patient outcomes.

#0856 Lymphedema symptom burden patterns and cancer recurrence worry among Hispanic breast cancer survivors: Latent profile analysis.

Eunkyung Lee[1], Brian D. Sukhu[1], Jaeyoung Park[2], Jennifer Crook[3], Jongik Chung[4], Victoria Loerzel[3]

[1]Health Sciences, University of Central Florida, Orlando, FL,[2]School of Global Health Management and Informatics, University of Central Florida, Orlando, FL,[3]Nursing Practice, University of Central Florida, Orlando, FL,[4]Statistics and Data Science, University of Central Florida, Orlando, FL

Background: Breast cancer survivors often experience persistent physical and psychosocial challenges, including lymphedema symptoms and unmet supportive care needs. Previous studies have noted that the simultaneous occurring of these burdens may compound their effects on psychological stress, such as recurrence worry. Hispanic populations may face unique survivorship challenges that limit access to healthcare and support.
Objective: This study examined latent profiles of burden from lymphedema symptoms and unmet support needs, and differences in recurrence worry across these profiles within Hispanic women with breast cancer.
Methods: Hispanic women aged 20 and older, previously diagnosed with breast cancer in Central Florida, were for a population-based study examining health-related quality of life from September 2023 to October 2025. Five lymphedema symptoms (pain, swelling, movement, numbness, stiffness) were assessed using the FACT-B+4 scale. The strength of 5 unmet need domains (information needs, care needs, quality of life needs, psychological needs, and practical needs) was assessed using the 35-item Cancer Survivors' Unmet Needs questionnaire. Latent profile analysis was conducted to identify the distinct latent burden patterns, and model performance was evaluated with BIC, AIC, and entropy. Multivariable linear regression compared differences in recurrence worry (frequency, mood impact, daily function interference), measured by the 3-item Lerman Breast Cancer Worry Scale, across the identified profiles.
Results: A total of 564 breast cancer survivors (mean age: 58.9 ± 11.9 years; mean time since diagnosis: 4.1 ± 2.0 years) were included in the latent profile analysis. The five-profile model was selected as the optimal model. The five distinct profiles include low symptoms and moderate needs (Profile 1: n = 72, 12.8%), high symptoms and moderate needs (Profile 2: n = 52, 9.2%), high symptoms and strong needs (Profile 3: n = 34, 6.0%), low symptom and low needs (Profile 4: n = 303, 53.7%), and moderate symptoms but low needs (Profile 5: n = 103, 18.3%). Profiles differed significantly in recurrence worry frequency, mood impact, daily activity interference (all $p < 0.001$). Survivors in Profiles 1, 2, and 3 reported more frequent worry, higher impact on mood, and higher interference with daily functioning than those in Profiles 4 and 5.
Conclusions: Distinct burden profiles highlight heterogeneity in the survivorship experience of Hispanic women with breast cancer. Particularly, survivors with moderate or strong unmet needs reported elevated recurrence worry. Investigating the barriers to symptom management and the strategies to address unmet support needs is crucial to reducing psychological stress and enhancing the quality of life among breast cancer survivors.
Funding: Florida Breast Cancer Foundation.

#0857 Impact of delayed screening/care and frequent mental distress during COVID-19 among SGM cancer survivors.

John A. Fuller, Jessica Wells

Nell Hodgson Woodruff School of Nursing, Emory University, Atlanta, GA

Purpose: Sexual and gender minority (SGM) survivors have a significantly higher risk of late-stage cancer diagnosis compared with cisgender-heterosexual survivors, possibly due to historical exclusion from screening and higher engagement in risk behaviors like smoking, binge drinking, and risky sexual practices. Discrimination, stigma, and minority stress in healthcare settings limit access to screening, care, and treatment and contribute to increasing mental distress. The link between delays and mental health is unclear. This study examines the association between delayed screening/care and frequent mental distress (FMD) during COVID-19 among SGM survivors.

Methods: We utilized secondary data from OUT: The National Cancer Survey, an online questionnaire administered to U.S. adult SGM cancer survivors from September 2020 to March 2021. Participants self-reported delayed screening/care (coded as “Yes,” “No,” or “No, not applicable”) and the number of poor mental health days (free-text response) in the past month. FMD was analyzed as a binary outcome using a Centers for Disease Control and Prevention (CDC)-validated cutoff (i.e., 14 or more PMHD in the last 30 days). Age was included as a covariate, given its established impact on mental health outcomes. Descriptive statistics, bivariate correlations, and logistic regression with sensitivity analyses were performed.

Results: On average, participants (N = 2,073) were aged 58.69 years (SD = 11.12). The number of poor mental health days reported ranged from 0 to 30, with an average of 9.88 days (SD = 10.75). Delayed screening/care was significantly associated with FMD. 37.5% of participants reported delayed screening/care experienced FMD, compared to 49.6% of those who did not ($p < 0.001$). Multivariable regression analysis revealed that delayed screening/care and age were significant predictors of FMD. Participants who reported delayed screening/care were 84% more likely to experience FMD compared to those who did not report delayed screening/care (OR = 1.84, 95% CI: 1.41-2.41, $p < 0.001$). Age was inversely associated with FMD, with each additional year of age reducing the odds of experiencing FMD by 4% (OR = 0.96, 95% CI: 0.95-0.97, $p < 0.001$).

Conclusion: This study highlights the social determinants of health contributing to delays in cancer screening, care, and treatment among SGM cancer survivors. Future research should focus on guiding oncology providers in developing targeted strategies to improve mental health outcomes among marginalized communities, especially during periods of increased healthcare disruption like the COVID-19 pandemic.

#0858 Patient navigation as an equity intervention in head and neck cancer: Perspectives from a geocoded EMR cohort and qualitative insights from frontline navigators.

Alexandra L. Lindgren, Diana L. Morales, Trista A. Beard, Alyssa F. Harlow, Chanita Hughes Halbert

Department of Population and Public Health Sciences, Keck School of Medicine of USC, Los Angeles, CA

Background: In head and neck cancer (HNC), shorter time from surgery to post-operative radiation therapy (PORT) is associated with survival and improved local control. However, delays are common and distributed unevenly, reflecting social determinants of health (SDOH) such as insurance, transportation, language, and housing and food instability. Patient Navigation has been demonstrated to improve screening, follow up, and appointment adherence in breast, lung, and colorectal cancers; however, rigorous evaluations specific to HNC patient navigation and PORT timelines remain extremely limited. This mixed methods study explores the lived experiences and perceived impact of navigators working within a tertiary academic Head and Neck surgical center.
Methods: This concurrent mixed method study includes a quantitative arm and a quantitative interview arm. The quantitative arm utilizes a curated dataset with prespecified inclusion/exclusion criteria with the primary aim of describing baseline disparities in PORT timeliness pre-and-post initiation of the Patient Navigation HNC program and the secondary aims assessing 90-day post-operative emergency room visits and one year survival. Multivariable regression and time-to-event analysis will adjust for clinical factors and SDOH covariates. The qualitative arm comprises semi-structured interviews with all employed Head and Neck Cancer Patient Navigators (PNs). Analysis was conducted utilizing an inductive thematic approach. Interviews were then appraised using a structured three-domain evaluation framework.
Results: Four overarching themes emerged from the conversations: (1) Relational coordination and patient advocacy (2) Incremental process improvement (3) Systematic Barriers and Resource Constraints (4) Vision for program growth. Navigator composite scores ranged from 6-8 of 9, reflecting strong engagement in patient-centered interventions and iterative workflow improvements. For the quantitative arm we will report (1) distributions of time to PORT across SDOH strata (2) adjusted effect estimates for PN on timeliness and adherence, and (3) themes mapping structural and process barriers to delays. Mixed methods integration will yield targets for intervention and measurable Patient Navigator performance indicators.
Conclusions: By pairing robust analytics with Patient Navigator perspectives, this study will clarify if and how patient navigation reduces PORT delays in HNC, define SDOH-responsive metrics for quality improvement of Patient Navigation programs, and inform scalable implementation to improve both oncologic and equity outcomes.

#0860 Development of and consensus building towards shared metrics, measures and benchmarks for the connecting patient populations to clinical trials (CP2CT).

Folakemi T. Odedina[1], Jennifer Le-Rademacher[2], Robert Freimuth[2], Cristina Orozco[1], Laura Lectora[1], Timethia Bonner[1], Holly Thorson[2], Connecting Patient Populations to Clinical Trials(CP2CT) Program Evaluation Work Group, Connecting Patient Populations to Clinical Trials(CP2CT) Steering Committee

[1]Mayo Clinic Florida, Jacksonville, FL,[2]Mayo Clinic Rochester, Rochester, MN

Background: Multidisciplinary research networks often face challenges in harmonizing metrics and measures across participating sites, limiting the ability to aggregate data and generate generalizable insights. To address this barrier within the Connecting Patient Populations to Clinical Trials (CP2CT) Network, the Data, Evaluation, and Coordinating Center (DECC) coordinated the establishment of a unified framework that supports comparable evaluation and enhances the scientific impact of network-wide activities.
Methods: Consensus was developed through a structured, iterative, and collaborative process: (1) drafting initial constructs, metrics, measures, and benchmarks informed by Network site materials and relevant literature; (2) soliciting qualitative and quantitative feedback from Network sites via Basecamp, an innovative online collaborative workspace for construct development; (3) conducting open dialogue sessions followed by systematic review and integration of site feedback; and (4) refining all elements through repeated feedback cycles until no further modifications were requested. Each iteration strengthened the clarity, coherence, and scientific precision of the final constructs.
Results: A total of seven constructs were incorporated into the consensus-development process: clinical trials referral, clinical trials accrual, participants' awareness of clinical trials, participants' knowledge of clinical trials, providers' awareness of NCI-supported clinical trials, providers' engagement with NCI-supported clinical trials, and providers' referral to NCI-supported clinical trials. For each construct, the Network established a conceptual definition (broad description of the construct), an operational definition (specification of how the construct is measured or observed), benchmarks (standards for assessing performance), metrics (quantitative indicators of performance), and measures (tools used to quantify inputs, processes, or outcomes). Common measures were developed for two constructs—clinical trials accrual and participants' knowledge of clinical trials. Although full consensus was not achieved across all four Network sites for every construct, at least three sites reached consensus for the remaining five constructs.
Conclusion: This consensus-building initiative resulted in the development of a unified, scientifically grounded framework. By harmonizing key elements related to clinical trial referral, accrual, awareness, knowledge, and provider engagement, the Network has established foundational tools that enable cross-site data comparability and facilitate more rigorous assessment of efforts to connect diverse patient populations to clinical trials. This framework positions the Network to inform strategies that improve equitable clinical trial participation.

#0861 Examining social determinants of health and clinical trial participation among cancer survivors: A multi-state cross-sectional study.

Amrita S. Mukunda[1], Hui Xie[2], Priyanka N. Srinivasan[1], Qian Wang[3]

[1]Case Western Reserve University School of Medicine, Cleveland, OH,[2]Joseph J. Zilber School of Public Health, University of Wisconsin-Milwaukee, Milwaukee, WI,[3]Seidman Cancer Center University Hospitals, Cleveland, OH

Introduction: Clinical trials are essential for advancing cancer treatment options and providing patients access to novel therapies, yet recruitment and participation among cancer patients remain low. This study examined whether social determinants of health (SDOH) were associated with clinical trial participation among cancer survivors.

Methods: This cross-sectional study analyzed Behavioral Risk Factor Surveillance System data from 2022 to 2024. The sample included cancer survivors aged 18 years or older from 15 states and 2 U.S. territories. An SDOH composite score (range 0-9) was calculated by summing binary responses across nine domains: life satisfaction, social/emotional support, loneliness/isolation, employment disruption, SNAP benefits, food insecurity, housing/utility payment difficulty, threats of utility service shut-off, and transportation barriers. A higher composite score indicated greater social disadvantage. Adjusted logistic regression models identified factors associated with clinical trial participation. All analyses were weighted.

Results: Of the 6,929 cancer survivors, 370 (5.34%) reported clinical trial participation as part of their treatment. Cancer survivors who participated in a clinical trial as part of their treatment were younger, more likely to be female, and from racial/ethnic minority groups compared to non-participants (all p-values <0.05). After adjusting for age, sex, race/ethnicity, marital status, income, comorbidity burden, and health insurance type, SDOH composite score was not associated with clinical trial participation.When examining individual SDOH factors, cancer survivors who had experienced threats of utility service shut-offs (electric, gas, oil, and/or water) in the past 12 months were less likely to have participated in clinical trials (aOR: 0.504, 95% CI: 0.257-0.989, p=0.046). Additionally, cancer survivors with private insurance (aOR: 1.62, 95% CI: 1.14-2.30, p=0.007) and Medicare beneficiaries (aOR: 1.69, 95% CI: 1.22-2.33, p=0.001) were more likely to participate in clinical trials compared to those with Medicaid.

Conclusion: Overall SDOH burden was not associated with clinical trial participation among cancer survivors; however, insurance type and individual determinants of financial vulnerability did have a significant impact. While privately insured survivors and Medicare beneficiaries showed higher participation, those experiencing utility shut-off threats had significantly reduced participation. These findings highlight the importance of addressing financial stressors to improve clinical trial access for patients with cancer.

#0862 Trends in disability among US adult cancer survivors, 2016-2024.

Junlan Pu, Hermine Poghosyan

Yale University, New Haven, CT

Background Cancer and its treatments often lead to physical and functional limitations, placing cancer survivors at increased risk for disability. Yet, there is a limited understanding of how the prevalence of disability has shifted in recent years. Thus, we estimated the trends in disability prevalence of cancer survivors aged ≥18 years overall and by age, sex, race and ethnicity groups.

Methods We used nationally representative data from 2016-2024 Behavioral Risk Factor Surveillance System, a series of cross-sectional and telephone-based surveys of the US noninstitutionalized adults (≥18 years). Adults with self-reported cancer history (except non-melanoma skin cancer) were included. Disability was defined as having difficulty in any of the six domains: hearing, vision, cognition, mobility, self-care, and independent living. We analyzed combined disability and each disability type separately. We used a multivariable logistic regression model to estimate disability prevalence over the years, adjusting for survey year and socio-demographic and health-related factors. Subgroup analyses were performed based on age, sex, race and ethnicity. Analyses accounted for sampling weights and complex survey design.

Results We included 311143 cancer survivors, representing an estimated 124.78 million survivors. Overall, 53.67% of survivors were aged ≥65 years, 57.44% were female and 35.6% had ≤high school education. The adjusted prevalence of disabilities among cancer survivors increased by 5.67% (95% CI: 4.20-7.12; *P* for trend<0.001), from 40.12% in 2016 to 45.78% in 2024. The steepest increase occurred between 2020 and 2021 (by 4.04%, 95% CI: 2.28-5.80). All six disability domains increased (*P* for trend<0.001), with mobility disability showing the most pronounced growth. In 2024, mobility issues were the most prevalent disability (28.73%, 95% CI: 27.77-29.69), followed by the cognition impairment (16.08%, 95% CI: 15.19-16.97), hearing disability (14.68%, 95% CI: 13.92-15.43), difficulty in independent living (13.64%, 95% CI: 12.85-14.42), vision disability (8.87%, 95% CI: 8.11-9.62) and self-care disability (7.56%, 95% CI: 6.90-8.23). The largest increase in disability occurred in 18-34-year age group (10.04%, 95% CI: 1.62-18.45), males (6.06%, 95% CI: 3.96-8.16), and other races and ethnicities (12.78%, 95% CI: 3.70-21.85). Cancer survivors with disability were more likely to be male, Non-Hispanic Black or Hispanic, less educated, unemployed, unmarried, have lower income, report poorer health, and delay medical care (*P*<0.05) than those without disability.

Conclusion Disability among cancer survivors increased steadily, particularly for mobility disability, yet this burden is not equally distributed across age, sex, and racial and ethnic groups. Early identification of disability and the integration of tailored care into survivorship plans are essential, especially for subgroups who experience an unequal burden.

#0863 Internal, external and structural barriers in cancer care faced by survivors from the caribcares study.

Nancy Raquel Cardona-Cordero[1], Ana Patricia Ortiz-Martinez[1], Claudia Boneu[1], Polaris Torres-Rodriguez[1], Marievelisse Soto-Salgado[2]

[1]University of Puerto Rico Comprehensive Cancer Center, San Juan, PR,[2]University of Puerto Rico - Medical Sciences Campus, San Juan, PR

Introduction. Timely diagnosis is a public health priority. However, a great proportion of the population is often diagnosed with advanced disease or as an emergency. The study aimed at examining factors contributing to diagnostic delays and inequalities in cancer care among a subset of cancer survivors in Puerto Rico.
Methods. The Caribbean Cancer Research Center on Environmental and Natural Hazards (CARIBCARES) has been recruiting cancer patients who are or have been in active treatment over the past 12 months since August 20, 2025, to assess the impact of extreme weather events on the quality of life of this population. We conducted a cross-sectional study among participants (n=135) from the ongoing research project of CARIBCARES. Trained research assistants interviewed eligible participants who completed the 60-minute survey. A with a $20.00 incentive was provided to each participant.
Results. Participants' median age was 60 years, and 41% were living below poverty level. Females were willing to participate than males accounting for 66.4% and 33.6% of the sample, respectively. Over half (53%) of participants had a localized stage at cancer diagnosis, while 35% had regional or distant cancer. Around 49.6% of participants reported delays in their diagnosis. The top reported challenges were problems with their health insurance (24%), financial problems (20%) and Lack of communication with health care providers (14%). Smaller groups of participants were affected due to absence of confirmatory or genetic tests (4.4%), while 3% were unable to attend a medical appointment due to damage to their home or neighborhood caused by an extreme weather event.
Discussion. This study highlights critical barriers in the cancer diagnostic and care continuum among survivors participating in the CARIBCARES study, revealing important inequities that disproportionately affect populations in Puerto Rico. These findings underscore systemic weaknesses in healthcare access and navigation that must be addressed to improve early detection and survival outcomes.

#0864 Association between emergency department (ED) involvement in cancer diagnosis and survival across cancer types in the Medicare population.

Shannon Heitkamp[1], Eric Olsen[2], Ali Tafazzoli[3], Bethany Houpt[1], Olivia Hunt[1], **Anuraag R. Kansal**[3], A. Mark Fendrick[4], Eric Klein[3]

[1]Avalere Health, Washington, DC,[2]Department of Emergency Medicine, UCHealth Poudre Valley Hospital, Fort Collins, CO,[3]GRAIL, Inc., Menlo Park, CA,[4]Department of Internal Medicine; Center for Value-Based Insurance Design, University of Michigan, Ann Arbor, MI

Background: A substantial proportion of cancers are diagnosed following an emergency presentation, a pathway consistently associated with advanced stage at diagnosis, poorer survival, and worse patient experience. We aimed to quantify the association between ED involvement in the diagnosis of cancer and overall survival across different cancer types in the Medicare population.
Methods: We conducted a retrospective cohort study of SEER-Medicare beneficiaries diagnosed with invasive cancer between 2010 and 2020 and followed for mortality until 12/31/2020, defining the earliest cancer-related claim as the index date. We excluded beneficiaries without at least 12 months of continuous Medicare Parts A/B/D enrollment before and 1 month after the index date or with a prior cancer diagnosis within one year. Patients with an ED visit within 30 days before the index date were classified as having ED involvement in their diagnosis. Overall survival was evaluated using 17 independent multivariate Cox proportional hazards models, each corresponding to a cancer grouping defined according to SEER major cancer sites with available AJCC staging data (breast, prostate, lung, colorectal, bladder/urothelial tract, uterine, kidney, lymphoma, pancreatic, oral, liver, stomach, ovarian, esophageal, cervical, anal). Covariates included age, sex, race/ethnicity, dual eligibility status, Charlson Comorbidity Index, year of diagnosis, and tumor stage. This analysis did not adjust for some potential confounders including differences in duration of symptoms, performance status, and therapy access or initiation which were not captured in the dataset.
Results: Among 818,120 beneficiaries newly diagnosed with cancer (mean age 74.4 years), 26.4% had ED involvement in their diagnosis. The proportion with ED involvement increased with advancing stage across all cancer types (stage I: 13.8%, II: 26.3%, III: 23.7%, IV: 47.3%) and varied across cancer types, ranging from 6.1% for breast cancer to 53.4% for pancreatic cancer. Mortality during the study period was 44.4% among patients with ED involvement versus 19% among those without, with 46% of cancer deaths following ED involvement. ED involvement was associated with significantly higher mortality across nearly all cancer types, except cervical cancer (HR 0.81; 95% CI 0.28-2.37), ranging from pancreatic (1.61; 1.54-1.67) and colorectal (1.88; 1.84-1.93) to esophageal (3.86; 2.25-6.62) and bladder (4.08; 3.23-5.18).
Conclusion: ED involvement was associated with a significant fraction of overall mortality in patients with cancer and was a strong independent predictor of mortality after adjustment for patient factors including socioeconomics, comorbidities, and cancer stage at diagnosis. These findings highlight the need for strategies that promote earlier, non-emergency diagnostic pathways and structured follow-up.

#0866 Chronic stressors, biological age and deficit accumulation frailty in black breast cancer survivors.

Jeanne S. Mandelblatt[1], Iwalola Awoyinka[2], Jamaica R. Robinson[3], Xingtao Zhou[1], Julie Ruterbusch[4], Jaeil Ahn[1], Lucile L. Adams-Campbell[5], Steven Cole[6], Ann G. Schwartz[3], Brent Small[7], Zhaoming Wang[8], Kelly Rentscher[9], Judith E. Carroll[6]

[1]Oncology, Lombardi Comprehensive Cancer Center, Georgetown University, Washington, DC,[2]Medical College of Wisconsin, Wauwatosa, WI,[3]Karmanos Cancer Institute, Detroit, MI,[4]Wayne State University, Detroit, MI,[5]Georgetown Lombardi Comprehensive Cancer Ctr., Washington, DC,[6]UCLA, Los Angeles, CA,[7]University of North Carolina, Chapel Hill, Chapel Hill, VA,[8]St. Jude Children's Research Hospital, Memphis, TN,[9]Oncology, Medical College of Wisconsin, Milwaukee, WI

Introduction: Chronic social stressors contribute to disparities in population morbidity and mortality. One putative mechanism for these patterns is that stressors, which are differentially experienced by population sub-groups, result in cumulative wear and tear that increases biological aging via sustained release of stress hormones. However, these relationships have not been well studied in cancer survivors.

Methods: This cross-sectional study included 258 Black women from the Detroit Research on Cancer Survivors study. Survivors were 12-60 months post-diagnosis of stage 1-3 breast cancer and had germline DNA available for methylation analyses. Biological age was assessed using the Illumina Infinium Methylation EPIC Array for GrimAge, PhenoAge, Extrinsic Age and Dunedin Pace of Aging. Social stressors included life stress (financial, housing and food insecurity, lack of transportation to medical care, area safety; 0-5 composite score), racial discrimination and neighborhood area deprivation. The outcome was a deficit accumulation frailty index score (0-1; <0.20=robust, 0.20-0.35=pre-frail and >0.35=frail; differences of 0.02-0.06 points are clinically meaningful). Separate linear regression models tested associations of each stressor and deficit accumulation, considering age, time from diagnosis and cytotoxic treatment (chemotherapy, radiotherapy). Mediation models explored whether the relationships between stressors and deficit accumulation were statistically mediated by biological age.

Results: Survivors were an average of 58.8 years (range 30-83), were 21.1 (SD 14.6) months from diagnosis and 69.6% were pre-frail or frail. Between 55-78% had biological age greater than chronological age on one or more epigenetic clock and 88% had a faster pace of aging than expected based on chronological age. For each 1-point increase in life stress there was a 0.06 point increase in adjusted deficit accumulation ($p<0.001$) and life stress accounted for 67% of the explained variance in deficit accumulation. Biological age measured by GrimAge mediated 11.8% of the association between life stress and deficit accumulation ($p<0.05$) and there was similar but non-significant mediation by other epigenetic measures. Living in the most vs. least deprived area was also associated a large clinically meaningful increase in adjusted deficit accumulation ($p=0.007$), but discrimination had a smaller, non-significant effect.

Conclusions: These findings demonstrate an association between experiencing social stressors and deficit accumulation frailty among Black breast cancer survivors and this association was partially driven by biological aging. Future studies are needed to identify aging pathways and possible modifiable factors that could be targeted by policy, behavioral and pharmacological interventions to reduce disparities and improve outcomes among cancer survivors.

#0867 Cancer treatment-related cardiotoxicity among survivors of childhood cancer: A comparative and integrated view of multiple measures of biological age acceleration.

Xiaoxi Meng[1], Tiffany Eulalio[1], Kwangyeon Oh[1], Noel-Marie Plonski[1], Kyla Shelton[1], Heather L. Mulder[1], John B. Easton[1], Jinghui Zhang[1], Emily Walker[1], Geoffrey A. Neale[1], Deo Kumar Srivastava[1], Rebecca M. Howell[2], Jeanne S. Mandelblatt[3], Bonnie Ky[4], Stephanie B. Dixon[1], Gregory T. Armstrong[1], Melissa Maria Hudson[1], Kirsten K. Ness[1], Zhaoming Wang[1]

[1]St. Jude Children's Research Hospital, Memphis, TN,[2]The University of Texas MD Anderson Cancer Center, Houston, TX,[3]Georgetown University, Washington, DC,[4]University of Pennsylvania, Philadelphia, PA

Introduction: Mounting evidence suggests that childhood cancer survivors experience biological age acceleration (BioAgeAccel) and are at increased risk for cardiovascular disease. We performed an integrated analysis of multiple BioAgeAccel measures to examine how aging relates to treatment-related toxicity and cardiovascular risk, and how biomarkers developed under different methodological schemes capture this pathway.

Methods: Cardiovascular disease (CVD) was defined as either cardiomyopathy or myocardial infarction (MI). DNA methylation (DNAm) profiles of peripheral-blood-mononuclear-cells from 2,941 St. Jude Lifetime Cohort participants were generated using Illumina EPIC BeadChips. Biological age was assessed using 43 DNAm-based biomarkers, including epigenetic clocks such as GrimAge, PhenoAge, and DunedinPACE, as well as molecular biomarkers such as C-reactive protein (DNAmCRP). BioAgeAccel was defined as residuals from regressing biological age on chronological age at DNAm blood draw (except DunedinPACE). Cardiotoxic treatment exposures included radiation potentially exposing the heart (heart-RT; mean dose >15 Gy considered high-dose) and anthracycline chemotherapy (cumulative dose ≥250 mg/m^2 doxorubicin equivalents considered high-dose). Multivariable logistic regression models evaluated the associations of each biomarker with CVD. BioAgeAccel was also evaluated as a mediator between heart-RT or anthracycline exposure and CVD to examine its role in the causal pathway. Mediation analyses were conducted for each biomarker individually and for a composite measure derived from principal component analysis.

Results: Median age at cancer diagnosis was 6.1 years (range 0-23.6; Q1-Q3: 2.8-12.6), and at DNAm blood draw was 30.1 years (range 0.2-66.6; Q1-Q3: 21.7-38.0). Overall, 9.4% developed cardiomyopathy (median onset 34.7 years), and 2.3% developed MI (median onset 40.7 years). Most BioAgeAccel measures were elevated after high-dose heart-RT, with fewer associations for high-dose anthracyclines. PC version of GrimAge showed the strongest association with MI (OR=1.85, 95%CI: 1.45-2.36; Bonferroni *P*=4.06E-05), and DNAmCRP showed the strongest association with cardiomyopathy (OR=1.31, 95%CI: 1.14-1.50; Bonferroni *P*=5.17E-03). Mediation estimates varied across biomarkers. A composite BioAgeAccel measure accounted for 31.6% of the heart-RT-MI association, 35.9% of the heart-RT-cardiomyopathy association, and 7.7% of the anthracycline-cardiomyopathy association.

Conclusions: BioAgeAccel measures vary in their associations with cardiotoxicities and treatment-related aging pathways. These findings support further refinement and validation of DNAm-based aging biomarkers to advance future risk stratification and targeted prevention of long-term CVD in survivors.

#0868 Survival outcomes associated with hypothyroidism following cancer therapies.

Harry D. Momo[1], Megan R. Haymart[2], Xu Shi[3], Alison M. Mondul[1]

[1]Department of Epidemiology, University of Michigan, Ann Arbor, MI,[2]Department of Internal Medicine, University of Michigan, Ann Arbor, MI,[3]Department of Biostatistics, University of Michigan, Ann Arbor, MI

Background: Hypothyroidism is a recognized adverse effect of cancer therapies such as immunotherapy (immune checkpoint inhibitors, ICIs), chemotherapy (tyrosine kinase inhibitors, TKIs), and radiotherapy. Although proposed as an indicator of treatment response, its prognostic significance across cancer types and therapies remains under-explored. This study evaluated survival outcomes associated with treatment-induced hypothyroidism.

Methods: We conducted a retrospective cohort study using de-identified electronic health record data from the University of Michigan between 2006 and 2023. Adults (≥18 years) receiving ICIs, TKIs, or radiotherapy, without prior thyroid disease or malignancy were included. We defined hypothyroidism by institutional laboratory criteria or thyroid hormone initiation. Time-dependent Cox models estimated hazard ratios (HRs) and 95% confidence intervals (CIs) for overall and cancer-specific survival, adjusting for demographic, clinical, and lifestyle factors. Analyses were stratified by treatment class and cancer site; sensitivity analyses assessed robustness.

Results: Among 9,909 patients (57,772 person-years; median follow-up 4.64 years), 2,177 (22.0%) developed hypothyroidism (median onset time: 5.04 months). Treatment-induced hypothyroidism was associated with improved overall (HR = 0.86 [0.79-0.93], $p < 0.001$) and cancer-specific survival (HR = 0.76 [0.70-0.84], $p < 0.001$). Stratified analyses showed significant survival benefits with hypothyroidism following immunotherapy (overall HR = 0.75 [0.61-0.92], $p = 0.01$; cancer-specific HR = 0.75 [0.66-0.94], $p = 0.01$) and radiotherapy (HR = 0.88 [0.81-0.96], $p = 0.01$; cancer-specific HR = 0.76 [0.68-0.84], $p <0.001$), but not for chemotherapy. Site specific survival benefits were observed in brain/CNS (HR = 0.39 [0.26-0.61], $p < 0.001$), lip/oral cavity/pharyngeal (HR = 0.77 [0.61-0.97], $p = 0.03$) and lung/bronchus cancers (HR = 0.80 [0.66-0.97], $p = 0.03$) but higher mortality in colon cancer (HR = 1.82 [1.10-3.02], $p = 0.02$). Results were consistent across sensitivity analyses.

Conclusion: Hypothyroidism after immunotherapy and radiotherapy was associated with improved survival, supporting its potential as a prognostic biomarker of therapeutic benefit. Future studies should investigate the underlying mechanisms and clinical implications.

#0869 Sleep duration predicts quality of life during colorectal cancer survivorship across age groups: Results from the ColoCare Study.

Victoria Damerell[1], Sheetal Hardikar[2], Apurva S. Medhe[3], Nathalie Nguyen[4], Christoph Kahlert[1], Christopher I. Li[5], David Shibata[6], Doratha A. Byrd[7], Cornelia M. Ulrich[2], Jane C. Figueiredo[4], Adetunji T. Toriola[3], Anita R. Peoples[8], Biljana Gigic[1]

[1]Department of General, Visceral and Transplantation Surgery, Heidelberg University Hospital, Heidelberg, Germany,[2]Huntsman Cancer Institute, Salt Lake City, UT,[3]Department of Surgery, Washington University St. Louis, St. Louis, MO,[4]Department of Medicine, Samuel Oschin Comprehensive Cancer Institute, Cedars-Sinai Medical Center, Los Angeles, CA,[5]Fred Hutchinson Cancer Center, Seattle, WA,[6]Department of Surgery, University of Tennessee Health Science Center, Memphis, TN,[7]Department of Cancer Epidemiology, Moffitt Cancer Center, Tampa, FL,[8]Department of Population Science, American Cancer Society, Atlanta, GA

Background Early-onset colorectal cancer (EO-CRC, <50 years) survivors often face unique quality of life (QoL) challenges compared with late-onset (LO-CRC, ≥50 years) patients. Sleep disturbances are common during and after cancer treatment and sleep duration of <7 hours may worsen physical and emotional symptoms, however, longitudinal evidence on QoL is limited. This study examined the influence of sleep duration on QoL trajectories over 24 months after primary tumor resection across EO- and LO-CRC patients.
Methods We used mixed-effects models to assess changes in functional and symptom-related QoL domains by age group and sleep duration in 905 CRC patients from three sites of international ColoCare Study: Heidelberg University Hospital, Washington University St. Louis and Cedars-Sinai Medical Center. We assessed sleep duration by the Pittsburgh Sleep Quality Index and QoL scales using the EORTC-QLQ-C30 at enrolment (baseline), and at 6, 12, and 24 months. Time (baseline, 6, 12, 24 months), age group (EO-CRC vs. LO-CRC), and sleep duration (<7 vs. ≥7 hours/night) were included as fixed effects, while QoL scores were used as random effects. Interactions between time, age group, and sleep duration were tested.
Results Functional QoL scores improved over time, with higher global and emotional functioning at 12 and 24 months ($p < 0.01$), while cognitive and role functioning remained stable. Symptom-related QoL fluctuated, with higher dyspnea at 6 months that generally improved by 12 and 24 months. Sleeping fewer than seven hours per night was consistently associated with lower global, social, role, and cognitive functioning as well as greater fatigue, insomnia, nausea, pain, constipation, and appetite loss at baseline ($p < 0.01$). EO-CRC patients reported higher physical but lower social and role functioning as well as higher fatigue, nausea and financial difficulties at baseline ($p < 0.01$) with improvements across most domains over time. EO-CRC patients with short sleep duration experienced lower insomnia at 12 months compared to LO-CRC patients sleeping ≥7 hours ($p < 0.05$). Three-way interactions were limited, suggesting the effects of insufficient sleep on QoL were broadly similar across age groups.
Discussion Sleep duration is a predictor of QoL in CRC survivors, independent of age. EO-CRC patients exhibited distinct baseline deficits in social and role functioning, yet short sleep adversely affected all groups. These findings highlight the potential benefit of interventions targeting sleep to improve both functional and symptom-specific QoL throughout CRC survivorship. Integrating sleep screening and management into routine follow-up could further enhance QoL.

#0870 Neighborhood disparities and treatment outcomes in pediatric acute lymphoblastic leukemia (ALL): A report from the REDIAL Consortium.

Rutu Rathod[1], Amy E. Hughes[2], Pagna Sok[3], Karen Rabin[4], Sandi L. Pruitt[5], Philip J. Lupo[6], Michael E. Scheurer[6], Jeremy M. Schraw[7]

[1]Epidemiology, University of Arkansas for Medical Sciences, Little Rock, AR,[2]University of Texas Southwestern Medical Center, Dallas, TX,[3]Baylor College of Medicine, Houston, TX,[4]Pediatrics, University of California, San Francisco, CA,[5]UT Southwestern Medical Center, Dallas, TX,[6]Pediatrics, Emory University School of Medicine, Atlanta, GA,[7]Pediatrics, Baylor College of Medicine, Houston, TX

Introduction- Acute lymphoblastic leukemia (ALL), the most common pediatric cancer, shows persistent outcomes disparities among socioeconomically disadvantaged and Hispanic children. Structural factors such as neighborhood socioeconomic status (nSES) and residence in Hispanic enclaves - culturally distinct neighborhoods with high concentrations of Hispanic residents, linguistically isolated households, and ethnic resources - may influence cancer outcomes, yet their impact on pediatric ALL remains unclear. We examined associations of nSES and Hispanic enclave residence with treatment outcomes in children with ALL.

Methods- The REducing Disparities in Acute Leukemia (REDIAL) Consortium includes six pediatric cancer centers across Texas. We included children (0-24 years) diagnosed with ALL between 2005-2017 and treated at centers in Houston, Fort Worth, and McAllen. Census tract Hispanic enclave and nSES (Yost) indices were computed from U.S. Census and American Community Survey data. We defined Hispanic enclaves as tracts in the highest quintile (Q5) or Q4 adjacent to Q5 with >250 Hispanic residents, and low nSES as tracts in the lowest two quintiles of statewide distribution, using patient addresses at the time of diagnosis. Outcomes included end-of-induction (EOI) minimal residual disease (MRD) positivity (≥0.01%), relapse, event-free survival (EFS), and overall survival (OS). Associations were evaluated using logistic and Cox regression models adjusted for sex, age at diagnosis, race/ethnicity, NCI risk group, ALL immunophenotype, cytogenetic subtype, and treating institution.

Results- Among 1,348 patients, 41% resided in low nSES tracts and 42% in Hispanic enclaves; 59% were Hispanic and 90% had B-ALL. Median follow-up was 5.6 years for EFS and 5.2 years for OS. In adjusted analyses, neither enclave residence (aOR= 1.22; 95% CI= 0.82, 1.80) nor low nSES (aOR= 1.06; 95% CI= 0.73, 1.55) were associated with EOI MRD positivity; similar null associations were observed for relapse (enclave: aOR= 0.88; 95% CI= 0.52, 1.49; low nSES: aOR= 1.04; 95% CI= 0.66, 1.64), EFS (enclave: aHR= 0.81; 95% CI= 0.52, 1.26; low nSES: aHR= 1.04; 95% CI= 0.71, 1.54), and OS (enclave: aHR= 1.07; 95% CI= 0.59, 1.94; low nSES: aHR= 0.89, 95% CI= 0.53, 1.51). Although unadjusted analyses indicated slightly poorer 5-year EFS for low nSES areas (81% vs. 85%, p=0.04), this difference attenuated after adjustment.

Conclusions- In this large, multi-center, and diverse cohort of children with ALL, neighborhood socioeconomic disadvantage and residence in Hispanic enclaves were not independently associated with treatment outcomes after accounting for clinical and cytogenetic features. Future studies should examine other social determinants and the influence of neighborhood context on disease characteristics, survivorship, and late effects.

#0871 Surgical approach and five year survival in early stage cervical cancer: A national cancer database analysis.

Vishruti Pandya[1], Marguerite R. Irvin[2], Sharad Ghamande[3], Charles A. Leath[1], Chenguang Wang[4], Steve Coughlin[5], Warner K. Huh[1], **Sejong Bae**[5]

[1]Obstetrics and Gynecology, University of Alabama at Birmingham, Birmingham, AL,[2]Epidemiology, University of Alabama at Birmingham, Birmingham, AL,[3]Obstetrics and Gynecology, Augusta University, Augusta, GA,[4]Statistical Innovation Biostatistics and Data Management, Regeneron, Basking Ridge, NJ,[5]Biostatistics, Data Science, and Epidemiology, Augusta University, Augusta, GA

Background: The optimal surgical approach for early-stage cervical cancer remains debated, especially after the Laparoscopic Approach to Cervical Cancer (LACC) trial raised concerns about minimally invasive surgery (MIS). This study evaluates the association between surgical approach (robotic/MIS vs. open surgery) and five-year survival, accounting for demographic, facility, and clinical factors.

Methods: We analyzed data from the National Cancer Database (NCDB) for patients diagnosed with AJCC stage I-IIA cervical cancer from 2004-2022 who underwent surgery. Patients were classified as cases (died within five years) or controls (alive at five years). Multivariable logistic regression assessed the association between surgical approach and five-year mortality, adjusting for age, race, insurance, facility type, geographic region, distance traveled, tumor grade, comorbidity, adjuvant therapy, length of stay, and 30-day readmission.

Results: Among 18,849 patients, 2,263 (12.0%) died within five years. Robotic/MIS was associated with lower five-year mortality compared to open surgery (adjusted OR: 0.86; 95% CI: 0.76-0.99). Higher mortality was independently associated with receipt of adjuvant therapy (aOR: 1.79), older age (aOR per year: 1.05), Black race (aOR: 1.40), public insurance (aOR: 1.41), treatment at comprehensive community cancer centers (aOR: 1.38), travel >50 miles (aOR: 1.35), higher tumor grade (aOR: 2.66), and greater comorbidity burden (aOR: 2.30). Readmission rates did not differ significantly by surgical approach.

Conclusions: Robotic/MIS was significantly associated with improved five-year survival compared to open surgery in early-stage cervical cancer. However, demographic, facility, and clinical factors, including race, insurance, facility type, and comorbidities, were also strong predictors of mortality, highlighting persistent disparities. These findings underscore the need to address healthcare inequities and optimize care delivery. Future research should further explore how patient and systemic factors modify survival outcomes.

#0872 Trajectories of body image distress among diverse young adult cancer survivors.

Mariah Bianca Echeverria[1], Dayanara Ruiz[1], Julia Stla[2], Maureen Cairns[1], Priscilla Marin[1], Jonathan Kaslander[1], Kimberly A. Miller[1]

[1]Department of Population and Public Health Science, Keck School of Medicine of USC, Los Angeles, CA,[2]Department of Medical Oncology, Division of Population Sciences, Dana-Farber Cancer Institute, Boston, MA

Introduction: Body image distress (BID) is a psychological stressor for young adult cancer survivors (YACS), but its trajectory over time remains underexplored due to limited longitudinal data among this population. We examined how BID trajectories evolve as YACS progress throughout survivorship and assessed differences by Hispanic/Latino (H/L) ethnicity.

Methods: YACS aged 18-39 years were recruited within 3 months of a de novo cancer diagnosis from two comprehensive cancer centers and a safety-net hospital, across all cancer stages. The 9-item Body Image Scale (BIS) assesses cancer-specific BID on a 5-point Likert scale, ranging from “not at all” to “very much”. The BIS was administered at three time points (baseline, 3 months, and 12 months); mean scores ≥ 10 were considered clinically meaningful. Latent Growth Curve Modeling (LGCM) was used to model and estimate longitudinal BID trajectories, with an unconditional model (model 1) for the overall trajectory and a conditional model (model 2) for ethnicity that included covariates of gender, socioeconomic status (SES), age at diagnosis, and education. Model fit indices evaluated the models.

Results: Among the sample of 119 YACS, 56.3% were of H/L origin, 67.2% female, 44.5% were of low SES (<$40k), and 47.9% were college graduates or higher; participants had a mean age at diagnosis of 32.0 (*SD*: 5.45). BID trajectories were slightly above the clinical threshold at all timepoints (baseline = 10.7; 3-month = 10.9; 12-month = 10.6; $p > .10$), suggesting that BID did not improve over time. Model 1 fit well (CFI = 1.00), the slope was non-significant ($p = .89$), and the intercept showed significant variability ($p < .001$), indicating individual differences in BID severity. Model 2 also fit well (CFI = 1.00); gender predicted higher BID, as females had significantly greater BID across all time points ($p < .001$). By ethnicity, non-H/L YACS showed a gradual rise in BID over time, while H/L YACS had a slight decrease in BID over time, suggesting a protective trend; however, this trend was not significant ($p = .87$). No relationship was found between SES, education, and age at diagnosis.

Conclusion: Among YACS in this cohort, clinically significant BID persisted throughout the first year of survivorship and did not improve over time. Findings reveal a need for longitudinal monitoring of BID and the need for gender-specific interventions to mitigate BID throughout survivorship. Though non-significant, divergent directional trends by ethnicity suggest possible culturally informed protective factors that warrant further evaluation in larger samples.

#0873 Factors associated with functional status among older women with ovarian cancer.

Minh Tung Phung[1], Lisa M. Barroilhet[2], Neil Binkley[3], Ronald E. Gangnon[4], Janelle Sobecki[2], Britton Trabert[5], Amy Trentham-Dietz[1]

[1]Department of Population Health Sciences & Carbone Cancer Center, University of Wisconsin-Madison, Madison, WI,[2]Department of Obstetrics and Gynecology & Carbon Cancer Center, University of Wisconsin-Madison, Madison, WI,[3]Department of Geriatrics and Endocrinology, University of Wisconsin-Madison, Madison, WI,[4]Department of Biostatistics and Medical Informatics, University of Wisconsin-Madison, Madison, WI,[5]Department of Obstetrics and Gynecology & Huntsman Cancer Institute, University of Utah, Salt Lake, UT

Background: Women aged 65+ account for nearly half of new ovarian cancer diagnoses. This patient group faces a substantial risk of declining functional status, i.e., the capability to carry out essential daily activities necessary for basic needs and health, such as dressing, bathing, toilet use, and eating. For this patient group, maintaining functional independence is a top priority. However, factors influencing functional status in older women with ovarian cancer remain poorly understood. This study aimed to identify demographic and clinical factors associated with functional status in this vulnerable population.

Methods: We utilized data from the Minimum Data Set (MDS), which provides standardized functional assessments for U.S. nursing home residents. MDS data were linked with SEER-Medicare to capture cancer diagnoses and medical histories. The cohort included 6,257 women with primary invasive epithelial ovarian cancer diagnosed at age 65+ between 2000-2019. Functional status was quantified using a validated Activities of Daily Living (ADL) scale ranging from 0-28, with higher scores indicating greater dependency. A linear mixed-effect model was fit to identify factors associated with functional status during the first year after diagnosis, while accounting for repeated measures. Variables included age at diagnosis, Charlson Comorbidity Index, tumor stage, histotype, race/ethnicity, and Medicaid enrollment (as a proxy for socioeconomic status).

Results: Median age at diagnosis was 79 years (interquartile range 74-84 years) with most diagnosed at distant stage (74%). Older age was associated with higher ADL scores (mean difference [MD]=0.07 per one year increase in age, 95% confidence interval [CI] 0.05-0.09, $p<0.01$). Other factors associated with higher ADL scores included: higher comorbidity (MD=0.41 per unit increase in Charlson Comorbidity Index, 95% CI 0.33-0.50, $p<0.01$), later tumor stage (distant vs. localized stages: MD=1.38, 95% CI 0.80-1.95, $p<0.01$) and non-serous histotype (non-serous vs. serous: MD=0.90, 95% CI 0.63-1.18, $p<0.01$). Higher ADL scores were also observed for non-White vs. White women (MD=1.95, 1.45, 1.14 for Black, Hispanic, and Asian/Pacific Islander, respectively, all $p<0.01$) and Medicaid-enrolled patients vs. non-enrolled (MD=0.65, 95% CI 0.11-1.18, $p=0.02$).

Conclusions: Older age, higher comorbidity, later tumor stage, non-serous histotype, non-White race/ethnicity, and Medicaid enrollment are independently associated with increased functional dependency in older women with ovarian cancer. These findings suggest both biological and socioeconomic drivers of functional decline. Targeted supportive care is needed to mitigate functional decline, particularly for women with advanced disease, comorbidities, minority backgrounds, and low socioeconomic status.

#0874 Maintenance therapy in first remission for advanced fibrolamellar carcinoma.

Laura Golian[1], Paul M. Kent[2], Tom Stockwell[1]

[1]FibroFighters Foundation, Temecula, CA,[2]FibroFighters Foundation, River Forest, IL

Background: Fibrolamellar carcinoma (FLC) is a rare primary liver malignancy affecting predominantly adolescents and young adults, with high recurrence rates even after complete macroscopic resection. Traditionally, surgical intervention alone was largely considered the only curative strategy. Research in recent years suggests the role of systemic therapy, however no consensus guidelines currently exist. This study evaluates progression-free survival (PFS) and overall survival (OS) after surgery, while incorporating stage, type of therapy, and resection margin status as prognostic factors. This is the first study to evaluate outcomes associated with maintenance/adjuvant therapy following surgical resection in a real-world FLC cohort.

Methods: We analyzed 207 patients with FLC who underwent surgical resection in a retrospective multicenter dataset. Adjuvant systemic therapy was categorized as “none,” “chemotherapy,” or “immunotherapy.” Endpoints included PFS and OS calculated from date of surgery. Kaplan-Meier estimates and log-rank tests assessed unadjusted differences. Multivariable Cox proportional hazards models evaluated the independent effects of therapy type, stage (Localized = Stage 1, Regional = Stages 2 & 3, Metastatic = Stage 4), and margin status (R0 = NED, R1 =Microscopic Disease, R2 = Gross Disease Remains).

Results: A total of 200 patients were evaluable for PFS (163 progression events) and 199 for OS (75 deaths). Stage was the strongest predictor of outcome: metastatic disease was associated with an 8.6-fold higher hazard of progression and a 47.7-fold higher hazard of death relative to localized disease. Margin status was prognostic, with R2 resections conferring a significantly increased hazard of death (HR 2.87, 95% CI 1.50-5.47).Adjuvant systemic therapy was independently associated with prolonged PFS after adjusting for stage and margin. Compared with no therapy, chemotherapy (HR 0.44, 95% CI 0.25-0.75) and immunotherapy (HR 0.41, 95% CI 0.26-0.66) both benefitted metastatic patients. Although there was no statistical significance in OS for chemotherapy or immunotherapy, this is likely the result of other factors and suggests need for additional study.

Conclusions: In this large real-world surgical cohort of FLC patients, postoperative chemotherapy and immunotherapy were independently associated with reduced risk of progression, with the most pronounced benefit in metastatic disease. OS was driven primarily by disease stage and margin status. These findings suggest a potential role for postoperative systemic therapy in patients with advanced FLC and highlight the critical importance of achieving negative surgical margins. Prospective studies are needed to validate these results and define evidence-based guidelines.

#0875 Identifying novel therapeutic targets for cancer-related fatigue in colorectal cancer patients using lipidomics: Results from the ColoCare Study.

Nicole C. Lorona[1], Mary C. Playdon[2], James E. Cox[3], Alan Maschek[4], Xiaoyin Li[5], Aasha I. Hoogland[5], Maria F. Gomez[5], Patricia A. Erickson[2], Mmadili N. Ilozumba[2], Victoria Damerell[6], Ildiko Strehli[2], Megan Mclaws[2], Lyen C. Huang[2], Paul Stewart[2], Sheetal Hardikar[2], Jennifer Ose[7], Anita R. Peoples[2], Brent Small[8], David Shibata[9], Doratha A. Byrd[5], Adetunji T. Toriola[10], Christopher I. Li[11], Cornelia M. Ulrich[2], Biljana Gigic[6], Heather S. L. Jim[5], Jane C. Figueiredo[1]

[1]Department of Medicine, Samuel Oschin Comprehensive Cancer Institute, Cedars-Sinai Medical Center, Los Angeles, CA,[2]Huntsman Cancer Institute, University of Utah, Salt Lake City, UT,[3]Department of Biochemistry, University of Utah, Salt Lake City,, UT,[4]Department of Nutrition and Integrative Physiology and the Diabetes and Metabolism Research Center, University of Utah, Salt Lake City, UT,[5]Department of Health Outcomes and Behavior, H. Lee Moffitt Cancer Center and Research Institute, Tampa, FL,[6]Heidelberg University Hospital (UKHD), Heidelberg, Germany,[7]Department of Information and Communication, University of Applied Sciences and Arts, Hanover, Germany,[8]School of Nursing, The University of North Carolina at Chapel Hill, Chapel Hill, NC,[9]University of Tennessee Health Science Center - Memphis, Memphis, TN,[10]Washington University School of Medicine in St. Louis, Saint Louis, MO,[11]Fred Hutchinson Cancer Center, Seattle, WA

Background: Cancer-related fatigue (CRF) is the most frequently reported symptom among patients with colorectal cancer (CRC), with limited therapeutic options. Alterations in metabolic pathways related to lipid metabolism have been shown to play a role in non-cancer fatigue-associated diseases, and are hypothesized to influence CRF. The purpose of the present study was to investigate serum lipidomic biomarkers to identify longitudinal predictors of CRF in a prospective cohort of patients with CRC.
Methods: The ColoCare Study enrolled men and women ages 18 to 89 with newly diagnosed primary stage I-IV CRC at six U.S. sites and one German site. CRF was measured using the fatigue subscale of the European Organization for Research and Treatment of Cancer Quality of Life Questionnaire C30 (EORTC QLQ-C30) at T0 (CRC surgery/baseline), T1 (6 months post-surgery), T2 (12 months), and T3 (24 months). Using blood collected at each time point, we performed targeted lipidomics following comprehensive protocols for measurement and quality control. For the present study, participants with stage I-III disease and at least one measurement of CRF and lipidomic profiling (N=863) were included. Using linear mixed effects models with an interaction term with time point and subject-specific random intercepts, we assessed associations between individual lipids and CRF at each time point. We adjusted for multiple testing using the Benjamini-Hochberg correction for false-discovery rate. Models also adjusted for age, sex, tumor site, stage, body mass index, chemotherapy, radiation, and study site. We used elastic net regression on a training subset (n=176) to identify lipids at T1 (when first-line treatment was nearing completion) that were predictive of fatigue at T2. Further analyses validating prediction models and using metabolic pathway analyses are ongoing.
Results: Mean age was 61.6 years (SD: 12.7). N=305 total lipids were identified. In linear mixed effects models, no lipids were associated with CRF at T0 or T1. At T2 and T3, higher levels of ceramides (20), monohexosylceramides (11), gangliosides (4), trihexosylceramides (1), and sphingomyelins (16) were associated with lower CRF after adjustment for multiple testing. Predictive modeling identified higher levels of three sphingolipids at T1 associated with lower CRF at T2 and higher levels of two lipids (one diglyceride and one ceramide) at T1 associated with higher CRF at T2.
Conclusions: Specific sphingolipids, including ceramides, monohexosylceramides, and sphingomyelins, were inversely associated with CRF, suggesting a protective role. Predictive modeling supports their potential as targetable biomarkers of fatigue. These findings highlight lipid metabolism as a promising target for understanding and mitigating fatigue in cancer survivors, warranting external validation and mechanistic research.

#0876 Medication adherence and contributing factors among cancer survivors with cardiovascular disease.

Hyunjung Lee, Lynda Waku Kouomou, Farhad Islami

Surveillance & Health Equity Science Department, American Cancer Society, Atlanta, GA

Background Cardiovascular disease (CVD) is the leading cause of non-cancer mortality among cancer survivors. CVD incidence is about twice as high in cancer survivors as in the general population, likely driven by cardiotoxic cancer therapies and shared risk factors like smoking and obesity. Among those with known CVD, adherence to CVD medications often declines following a cancer diagnosis. Previous studies found higher non-adherence in younger ages, females, and those with high copayment insurance but reported mixed findings for other sociodemographic factors and comorbidity burden. This study investigates determinants of suboptimal adherence to CVD medications among cancer survivors with CVD.

Method We used nationally representative data from the pooled 2010-2022 Medical Expenditure Panel Survey. The primary outcome was CVD medication adherence, defined as the proportion of days covered ([total days supplied ÷365]×100) of ≥80%. Logistic regression was used to estimate associations between medication adherence and individual sociodemographic, access to medication, and health-related factors, adjusting for potential confounders.

Results Approximately 70% of cancer survivors aged ≥18 years had CVD (N=18,461). In adjusted models, CVD medication adherence among cancer survivors was lower in ages 18-44 (adjusted OR [AOR]=0.51, 95%CI=0.37,0.71) and 45-64 (AOR=0.79, 95%CI=0.70,0.90) than ages ≥65 years; females (AOR=0.79, 95%CI=0.70,0.88) than males; and those with a high school diploma (AOR=0.80, 95%CI=0.70,0.92), some college education (AOR=0.78, 95%CI=0.67,0.90), or a bachelor's or higher degree (AOR=0.72, 95%CI=0.62,0.84) than those with less than high school education. Adherence was also lower among cancer survivors who only used community pharmacies (AOR=0.82, 95%CI=0.69,0.98) than those who have ever used mail order or online pharmacies. Adherence was higher among cancer survivors in the Midwest (AOR=1.27, 95%CI=1.10,1.47) and South (AOR=1.23, 95%CI=1.08,1.40) than West; those with comorbidity score of 3 (AOR=1.23, 95%CI=1.02,1.48) than comorbidity score of zero; and those taking ≥5 medications (AOR=2.32, 95%CI=2.07,2.59) than taking <5 medications. Other factors including race and ethnicity, marital status, income, employment status, health insurance, activity limitation, self-reported health status, and type of cancer were not associated with adherence in adjusted models.

Conclusions CVD medication adherence among cancer survivors was lower among young adults; women; individuals with higher education, multiple chronic conditions, limited access to mail-order or online pharmacies, or managing multiple medications; and in the Midwest and South regions. Targeted interventions are needed to improve cardiovascular medication adherence and long-term health outcomes in cancer survivors.

#0877 Optimal post-diagnostic dietary patterns for prevention of frailty among men with prostate cancer.

Chaoran Ma[1], Yuanyuan Deng[1], Li-Wei Wu[2], Jane Bailey Vaselkiv[3], Colleen B. McGrath[3], Caroline Himbert[4], Lorelei A. Mucci[3], Edward L. Giovannucci[5]

[1]University of Massachusetts - Amherst, Amherst, MA,[2]National Defense Medical Center Taipei Taiwan, Taipei, Taiwan,[3]Harvard T.H. Chan School of Public Health, Boston, MA,[4]University of Utah, Salt Lake, UT,[5]Professor of Nutrition & Epidem., Harvard TH Chan School of Public Health, Boston, MA

Background. Frailty has been associated with poor prognosis in prostate cancer patients. Diets with a focus on plant-based foods associated with a lower risk of frailty, but few studies have examined these diets on frailty among prostate cancer survivors. We thus prospectively assessed various dietary patterns after prostate cancer diagnosis in relation to risk of frailty in a large U.S. prospective cohort.

Methods. We included 5,191 males who were not frail prior to their prostate cancer diagnosis between 1986 and 2018 from the Health Professional Follow-up Study and assessed post-diagnostic dietary patterns based on general dietary recommendations. Incident frailty was defined as having ≥3 out of five criteria (fatigue, reduced resistance, reduced aerobic capacity, having several illnesses, and a significant weight loss during the previous year) in the FRAIL scale through 2020. We used left-truncated Cox proportional hazards regression models to estimate hazard ratios and 95% confidence intervals for frailty across quartiles of dietary scores adjusting for potential confounders.

Results. During a median follow-up of 12 years, we observed 1,433 events of frailty among 5,191 men with prostate cancer. Participants with better adherence to the post-diagnostic diets were more likely to have a lower BMI, be more physically active, to use multivitamins, and less likely to smoke. In models adjusting for age, lifestyle factors, clinical characteristics, treatments, and other health conditions, comparing extreme quartiles, adherence to the Diabetes Risk Reduction Diet (DRRD, HR = 0.81, 95% CI = 0.76, 0.86), Dietary Approaches to Stop Hypertension score (HR = 0.84, 0.79, 0.90), Alternative Healthy Eating Index-2010 (HR = 0.85, 0.79, 0.91), and Alternate Mediterranean Diet (HR=0.92, 0.87, 0.98) were associated with a lower risk of frailty (P for trend < 0.01 for all), while no association was found for the World Cancer Research Fund/American Institute for Cancer Research diet, healthful plant-based diet, empirical dietary index for hyperinsulinemia (EDIH), and empirical dietary inflammation pattern. The inverse associations between dietary patterns and frailty persisted in subgroups, and were generally stronger in men who were younger, overweight or obese, engaged in vigorous physical activity, never smoked, with lower alcohol consumption, with higher Gleason score, and ever received androgen deprivation therapy. The associations between dietary patterns and frailty were similar in the 4-year lagged analysis. When excluding prostate cancer cases diagnosed before 2008, a more pronounced trend was observed for the DRRD (HR=0.62, 0.42, 0.91) and reversed EDIH (HR=0.51, 0.34, 0.78).

Conclusions. Adherence to healthy dietary patterns after prostate cancer diagnosis were associated with lower risk of frailty, which may inform on future dietary guidelines for prostate cancer survivors.

#0878 Long-term physical quality of life in survivors of adolescent and young adult Hodgkin lymphoma: Risk factors and associations with adverse health outcomes.

Carlos Cruz[1], Amanda Warner[1], Adiya Rahman[1], Bryce West[1], Mia Brumlow[1], Qian Xiao[2], Karen Albritton[3], Gregory Aune[4], Karen Eshelman-Kent[4], Sairah Ahmed[1], Kelly Merriman[1], Susan Peterson[1], Michael Roth[1], Michelle A. T. Hildebrandt[1]

[1]UT MD Anderson Cancer Center, Houston, TX,[2]UTHealth School of Public Health, Houston, TX,[3]Cook Children's Medical Center, Fort Worth, TX,[4]UTHealth San Antonio/Mays Cancer Center, San Antonio, TX

Purpose: Few studies characterize patient-reported outcomes in long-term survivors of adolescent and young adult (AYA, age 15-39 years at diagnosis) Hodgkin Lymphoma (HL). The present study aims to describe long-term health outcomes of survivors and identify the impact of cancer diagnosis and treatment exposures on health and quality of life (QoL).

Methods: This study included AYA HL survivors (N=264) previously treated at MD Anderson Cancer Center who were at least 5 years post diagnosis. At time of study enrollment, participants completed a comprehensive health questionnaire, which included the SF-36 QoL questionnaire. The SF-36 was used to calculate Physical Component Summary (PCS) and Mental Component Summary (MCS) scores. A subset of HL patients (N=44) had also previously completed the SF-12 questionnaire within 6 weeks of diagnosis. In parallel, 67 siblings of cancer survivors completed the same health questionnaire. Clinical characteristics and treatment information were obtained from the medical record. Area deprivation index (ADI) was calculated based on zip code at time of questionnaire completion.

Results: The median age at HL diagnosis and questionnaire completion of 26.0 and 41.8 years, respectively. Survivors had a significantly poorer PCS compared to siblings (45.3 vs 47.5, p=0.03), as well as a greater proportion of individuals with extremely poor PCS scores (scores ≤40; 16% vs 10%). Among HL survivors, no difference in PCS was observed by race/ethnicity (p=0.82). However, survivors who resided in neighborhoods with increased deprivation had significantly lower PCS compared to those in the highest resource neighborhoods (p=0.003). Treatment exposures and clinical characteristics were also related to PCS, in which survivors who received radiation treatment and had HL relapse were linked to lower PCS scores compared to survivors who did not (44.5 vs 46.7, p=0.03 and 43.5 vs 45.9, p=0.04). Survivors with extremely poor PCS reported increased prevalence of adverse health outcomes, such as diagnoses impacting cardiovascular, respiratory, and nervous systems (p<0.001 for each) compared to survivors with a PCS >40. These patients also reported increased cholesterol, pain, and depression medication use (p<0.001 for each). No differences in mental QoL defined by the MCS were observed between survivors and siblings.

Conclusion: HL is characterized by long-term survival, making health outcomes and QoL integral aspects of their cancer experience. This study showed that long-term survivors of HL experience reduced physical QoL. Moreover, this reduction is related to adverse health outcomes, underscoring the necessity of long-term support and clinical interventions to improve physical health for HL survivors.

#0879 Utilization of pelvic floor therapy after a colorectal cancer diagnosis in a universal-access health system.

Kimberly R. Robins[1], Yvonne Eaglehouse[2], Craig D. Shriver[3], Kangmin Zhu[4]

[1]Murtha Cancer Center Research Program, Uniformed Services University, Henry M. Jackson Foundation, Bethesda, MD,[2]Murtha Cancer Center Research Program, Uniformed Services University Walter Reed Surgery, Henry M. J, Bethesda, MD,[3]Uniformed Services University, Bethesda, MD,[4]Professor, Walter Reed National Military Medical Center, Rockville, MD

Background: About 70-90% of patients with colorectal cancer experience declined bowel function after treatment. Pelvic floor therapy (PFT) can improve bowel function and quality of life, yet access to PFT remains limited and factors associated with its use are understudied. Conducting this research within the U.S. Military Health System, a universal healthcare system, allows a clearer assessment of demographic, clinical, and system-level factors associated with receiving PFT while minimizing the effects of affordability and access on the results.

Methods: We conducted a nested case-control study of adults (≥18 years) with stage I-III colorectal cancer who had surgery within 6 months of diagnosis (2001-2014) in the MilCanEpi database. PFT recipients (cases) and non-recipients (controls) were matched by diagnosis month/year with a 1:1 ratio. Patients with non-TRICARE insurance (except Medicare which is part of coverage for all patients aged ≥65 years with TRICRE for Life) were excluded. Stepwise multivariable logistic regression was used to calculate adjusted odds ratios (aORs) with 95% confidence intervals (CIs) and identify factors associated with PFT use. To assess potential effect modification by sex, results from the overall adjusted model were compared with a men-only analysis.

Results: PFT recipients (n=679) were older (median [min-max]: 60 [21-94] vs 55 [23-88]) and more likely to be male (64% vs 58%), unmarried (24% vs 19%), have ≥1 comorbidity (43% vs 32%), and receive care at a military treatment facility (MTF; 37% vs 29%) than non-recipients (n=679). In the fully adjusted model, the use of PFT was more likely among patients with increased age (aOR=1.03, 95% CI: 1.01, 1.04), males (aOR=1.34, 95% CI: 1.02, 1.77), ≥3 comorbidities (aOR=2.13, 95% CI: 1.34, 3.38), active-duty status (aOR=1.67, 95% CI: 1.09, 2.55), and among those receiving care at a MTF compared to the private-sector (aOR=1.91, 95% CI: 1.39, 2.61). Among men, older age (aOR=1.04, 95% CI: 1.02, 1.06), total (vs partial) colectomy and/or proctectomy (aOR=4.97, 95% CI: 1.52, 16.27) and receiving care at a MTF compared to the private-sector (aOR=3.08, 95% CI: 1.60, 5.91) were associated with higher PFT use.

Conclusion: Within the MHS, fully adjusted analyses showed that PFT utilization after colorectal cancer surgery was higher among older patients, males, those with ≥3 comorbidities, active-duty service members, and patients receiving care at a MTF compared to the private-sector, highlighting the influence of demographic, clinical, and healthcare system factors on PFT use. In men, total (vs partial) surgery was the only factor additionally associated with higher PFT use. These findings suggest that targeted strategies may be needed to increase PFT utilization among groups of patients with a lower likelihood of use in the MHS, such as among younger patients and females.

#0881 Association of social support patterns on health-related quality of life among Hispanic breast cancer survivors .

Brian D. Sukhu[1], Jongik Chung[2], Leslie Palomino[1], B'Ellana Schlosser[1], Angello Pena[1], Eunkyung Lee[1]

[1]Health Sciences, University of Central Florida, Orlando, FL,[2]Statistics and Data Science, University of Central Florida, Orlando, FL

Objectives: Social support influences health-related quality of life (HRQoL) among Hispanic breast cancer survivors, but prior research has not examined which combination of dimensions of social support shapes HRQoL. Thus, we examined the association of social support profiles with HRQoL among Hispanic breast cancer survivors.
Methods: Hispanic women aged 20 and older, diagnosed with breast cancer at least six months earlier, residing in Central Florida, and able to read or speak English or Spanish were recruited via the Florida Cancer Registry's recruitment procedure for a population-based study examining intra-Hispanic disparities in HRQoL. Social support was assessed using the 19-item Medical Outcomes Study questionnaire. Latent Profile Analysis was conducted to explore distinct social support patterns with the four (emotional, tangible, affective, social network) domains as profile indicators. Model fit was determined using AIC and BIC. Functional Assessment of Cancer Therapy - Breast (FACT-B) assessed HRQoL. A multivariable regression model compared FACT-B scores across the identified profiles.
Results: Among 583 women recruited during September 2023 to October 2025, 560 women who completed the social support and HRQoL assessments were included in the analysis. Mean age was 58.9 ±11.9 years, and mean time since diagnosis was 4.1 ±2.0 years. Five support profiles emerged: low support across domains (8.0%), average support (16.6%), above average support (18.4%), high in affection/social support but low tangible support (7.1%), and moderately high support (49.8%). After controlling for age at diagnosis, Hispanic origin, BMI, race, multimorbidity, income, education, functionality, years living in the USA, and current age, we found that women in Profile 4 ($\beta = 15.34$, $p = 0.001$) and Profile 5 ($\beta = 19.19$, $p < 0.001$) had significantly higher FACT-B scores compared to those in Profile 1. Profiles 2 and 3 did not differ significantly from Profile 1.
Conclusions: This study identified five distinct social support profiles among Hispanic women with breast cancer and demonstrated that higher levels of affective and social support are associated with better HRQoL, underscoring the critical role of social resources in survivorship outcomes. These findings highlight the need for culturally tailored interventions that strengthen emotional and social networks to improve quality of life. Funding: Florida Breast Cancer Foundation Scientific Research Grant.

#0882 Cardiovascular disease mortality among breast cancer survivors in Puerto Rico: A population-based competing risk analysis.

Genesis Rodriguez-Ortiz[1], Barbara Segarra-Vasquez, DHSc[2], Francisco Cordova-Perez[3], Vivian Colon-Lopez[1], Cynthia M. Perez[4], Carola T. Sanchez-Diaz[1]

[1]Division of Cancer Control and Population Sciences, University of Puerto Rico Comprehensive Cancer Center, San Juan, PR,[2]School of Health Professions - Clinical Laboratory Science Program, University of Puerto Rico Medical Sciences Campus, San Juan, PR,[3]Section of Cardiology, Veterans Affairs Medical Center, San Juan, PR,[4]Professor/Biostatistics and Epidemiology, University of Puerto Rico Med. Sciences Campus, San Juan, PR

Purpose: Cardiovascular disease (CVD) is an increasingly important cause of death among breast cancer (BC) survivors, yet competing mortality risks remain understudied in Puerto Rico. This study estimated the cumulative incidence of BC-specific and CVD-specific mortality and identified associated risk factors among Puerto Rican BC survivors using competing risk methodology.
Methods: Data were analyzed from 17,430 female BC patients recorded in the Puerto Rico Central Cancer Registry (2004-2019) who survived at least 1 year post-diagnosis and were followed through 2021. Deaths were categorized as BC- or CVD-related. Fine-Gray competing risk models estimated subdistribution hazard ratios (HRs) with 95% confidence intervals, stratified by age group (18-64, 65-79, 80+), to evaluate demographic and clinical correlates of BC and CVD mortality at 5, 10, and 15 years post-diagnosis.
Results: Among 17,430 survivors, 6,881 (39.5%) died during follow-up. BC was the leading cause of death (3,636 deaths; 52.8%), while 470 (6.8%) were due to CVD. Median survival was longer among those who died from CVD (5.5 years (IQR: 3.1, 8.7)) than from BC (3.6 years (IQR: 2.2, 5.9)). By 15 years post-diagnosis, CVD had become a major competing risk: among women aged 80+, the cumulative incidence of CVD mortality reached 14.5% (95% CI: 9.3, 19.4), approaching the BC mortality risk of 16.6% (95% CI: 12.4, 20.6). In younger survivors (ages 18-64), comorbidity significantly increased CVD mortality risk (HR=2.7, 95% CI: 1.5, 4.8) but was not associated with BC mortality (HR=1.0, 95% CI: 0.9, 1.2). Advanced stage and aggressive treatment modalities were consistently associated with greater BC mortality across age groups, while comorbidity and older age were key drivers of CVD mortality.
Conclusions: While BC remains the primary cause of death among survivors, CVD emerges as a substantial competing risk, especially in older women with extended survivorship. Distinct risk profiles, such as the strong influence of comorbidities on CVD mortality in younger survivors and the narrowing difference between BC and CVD mortality in the 80+ age group, underscore the need for survivorship care models that integrate cancer surveillance and cardiovascular management.

#0883 Parental concerns about hereditary risk in adolescent and young adult cancer survivors.

Dayanara Ruiz[1], Kimberly A. Miller[1], Jonathan Kaslander[1], Julia Stal[2], Mariah Bianca Echeverria[1], Charite N. Ricker[1], Andrea C. Betts[3], David Freyer[4], Michael Roth[5], Jessica L. Corredor[6]

[1]Keck School of Medicine of USC, Los Angeles, CA,[2]Dana Farber Cancer-Institute, Boston, CA,[3]UTHealth Houston, Houston, TX,[4]Children's Hospital Los Angeles, Los Angeles, CA,[5]The University of Texas MD Anderson Cancer Center,[6]UT MD Anderson Cancer Center, Houston, TX

Background: Adolescent and young adult cancer survivors (AYAs; diagnosed between ages 15-39) report worries regarding the health of their children, particularly regarding their chance of developing cancer. This study describes the frequency of reproductive health concerns among ethnically diverse survivors of AYA cancer and examines how genetic counseling impacts these concerns.
Methods: AYAs between 18-39 years at diagnosis were recruited from two NCI-designated comprehensive cancer centers and a safety-net hospital. Concerns regarding the health of future children were evaluated using the three-item Child's Health Subscale (CHS), a subset of the Reproductive Concerns after Cancer Scale. Receipt of genetic counseling was self-reported. Descriptive statistics and mean overall score comparisons were examined, stratified by ethnicity and receipt of counseling.
Results: The sample included 58 AYAs (48% Hispanic, 79% female) diagnosed at a mean age of 36 years (SD=5). The most common cancer types were breast (22%) and brain/spinal cord (19%). Additional cancer types included in our sample were cervical, uterine, ovarian, Hodgkin lymphoma, non-Hodgkin lymphoma, colorectal, melanoma, sarcoma, and ovarian. Overall, 56% (n=32) of AYAs reported they did not receive any form of counseling. AYAs had a mean CHS score of 2.11 (SD=0.8; range 1-3, where higher scores reflect greater concern), indicating moderate concern about their future child's health. Mean CHS scores did not differ significantly for those who had received counseling versus those who had not (2.3 [SD=.7] vs 2.1 [SD=.9], p=.2, respectively). No significant differences were found between mean overall CHS scores and ethnicity.
Conclusion: In this study, AYAs expressed moderate concerns about their future child's health regardless of whether they received genetic counseling, suggesting that current counseling practices may not fully address the factors driving these concerns. Moreover, high concern levels among AYAs who did not receive counseling (presumably those not identified as having an indication for it) highlight potential gaps in how risk information and reassurance are conveyed within survivorship care. These findings indicate the need to strengthen reproductive health and genetic risk discussions across the survivorship continuum, ensuring both indicated and non-indicated survivors receive appropriate guidance, reassurance, and support.

#0884 Waist-hip ratio (WHR) defined obesity phenotype and risk of diabetes in cancer survivor women from Sister Study.

Mahfuja Luna[1], Hazel B. Nichols[2], Katie M. O'Brien[3], Michael G. Fradley[4], Mario Schootman[5], Michael R. Thomsen[6], Benjamin C. Amick III[1], Clarice R. Weinberg[7], Dale P. Sandler[8], Yong-Moon (Mark) Park[1]

[1]Department of Epidemiology, Fay W. Boozman College of Public Health, University of Arkansas for Medical Sciences, Little Rock, AR,[2]Department of Epidemiology, University of North Carolina, Chapel Hill, NC,[3]Epidemiology Branch, National Institute of Environmental Health Sciences,, Research Triangle Park, NC, NC,[4]Cardio-Oncology Program, Division of Cardiology, Department of Internal Medicine, University of Pennsylvania, Philadelphia, PA,[5]Department of Internal Medicine, College of Medicine, University of Arkansas for Medical Sciences Northwest, Springdale, AR,[6]Department of Health Policy and Management, Fay W. Boozman College of Public Health, University of Arkansas for Medical Sciences, Little Rock, AR,[7]Biostatistics and Computational Biology Branch, National Institute of Environmental Health Sciences, Research Triangle Park, NC, NC,[8]Epidemiology Branch, National Institute of Environmental Health Sciences, Research Triangle Park, NC, NC

Introduction: Cancer survivors are at elevated risk of developing diabetes and often experience treatment-related changes in body composition and insulin sensitivity. However, few studies have evaluated whether general and central obesity, independently and jointly, are associated with diabetes risk in long-term cancer survivors. We examined whether obesity phenotype (general, central, or combined) is associated with incident diabetes among women cancer survivors.

Methods: We included 1,924 women (aged 35 to 74 years) from the Sister Study (enrolled 2003-2009) who reported a history of cancer other than breast or non-melanoma skin cancer and had no diabetes at baseline. We excluded participants diagnosed <1 year before enrollment (median time since diagnosis: 11.6 years). Participants were followed through September 2021. General obesity was defined as examiner-measured body mass index (BMI)≥30 kg/m^2, and central obesity as waist-hip ratio (WHR)≥0.85. Participants were categorized as: no obesity (BMI<30, WHR<0.85), central-only (WHR≥ 0.85, BMI<30), general-only (BMI ≥30, WHR<0.85), and combined obesity (BMI≥30 and WHR ≥0.85). Incident diabetes was identified by self-reported new physician diagnosis during follow-up. Multivariable Cox proportional hazards models were used to estimate hazard ratios (HRs) and 95% confidence intervals (CIs) for incident diabetes across obesity phenotypes.

Results: At baseline 16.5% of participants had central-only obesity, 14.0% had general-only obesity, and 13.3% had combined obesity. Over a median follow-up of 12.9 years, 157 women (8.2%) developed incident diabetes. After adjusting for potential confounders, central obesity alone was associated with more than 2-fold higher diabetes incidence (HR 2.14, 95% CI 1.25-3.68), and general obesity alone showed a similar >2-fold association (HR 2.33, 95% CI 1.38-3.92), each compared with no obesity. The combined obesity phenotype was associated with the highest incidence, showing a more than 6-fold risk (HR 6.48, 95% CI 4.13-10.19) with a significant multiplicative interaction between general and central obesity (p for interaction <0.0001). Alternative central obesity parameters (waist circumference ≥88 cm and waist-height ratio ≥0.50) showed similar associations. Associations were generally consistent across categories of time since cancer diagnosis (<5 years, 5-<15 years, and ≥15 years). These associations also were seen among women with prevalent hypertension, dyslipidemia, or cardiovascular disease.

Conclusion: Our findings suggest that central and general obesity, especially in combination, are strongly positively associated with diabetes incidence in cancer survivors. Incorporating WHR-based obesity assessment into survivorship care may help identify women cancer survivors who would benefit from targeted diabetes prevention and monitoring.

#0888 Impact of neighborhood disadvantage, travel distance, and travel time on clinical outcomes of multiple myeloma patients treated with idecabtagene vicleucel.

Alicia R. Richards, Jessica Y. Islam, Yu Chen Lin, Ariel F. Grajales-Cruz, Guillermo Gonzalez-Calderon, Melanie Buhlmann, Gabe DeAvila, David Scheiber-Camoretti, Vivien Yin, Brandon Blue, Laura B. Oswald, Brandon Kale, David Kaldas, Ken Harada, Rebecca Gonzalez, Ciara L. Freeman, Hien Liu, Fabiana Perna, Taiga Nishihori, Rachid Baz, Kenneth H. Shain, Melissa Alsina, Frederick L. Locke, Omar Castaneda Puglianini, Doris K. Hansen, Lauren C. Peres

Moffitt Cancer Center, Tampa, FL

Purpose: To examine the association of neighborhood disadvantage and travel distance (TD)/time (TT) with clinical outcomes in multiple myeloma (MM) patients treated with the first chimeric antigen receptor T-cell therapy (CAR T) for MM, idecabtagene vicleucel (ide-cel).
Methods: MM patients who received ide-cel at Moffitt Cancer Center by July 2024 were included. Neighborhood disadvantage was defined using the Area Deprivation Index (ADI), Social Deprivation Index (SDI), and Social Vulnerability Index (SVI), with higher values indicating more disadvantaged neighborhoods (DN). TD/TT from patients' residence to Moffitt were calculated via Google Directions API. Chi-squared, log-rank tests, and Kaplan-Meier curves were used to compare patient characteristics, safety, and efficacy by each index and TD/TT using the upper quartile as the cut-point. Multivariable logistic and Cox regression were used to examine the association of each index and TD/TT with ide-cel response and survival, respectively, adjusting for relevant covariates.
Results: Among 173 MM patients treated with ide-cel, most were male (54%), non-Hispanic White (73%), and >60 years (75%). Median follow-up was 12.6 months (range 0.1-38.4). Median ADI was 42 (range 1-96), SDI was 38 (range 1-100), and SVI was 0.7 (range 0.1-1.0). Patients living in more vs less DN were younger (all indices, $p<0.05$), more likely to be Black (SDI: 37% vs 10%, $p<0.001$), had a prior autologous stem cell transplant (ADI: 80% vs 61%, $p=0.02$), and extramedullary disease (ADI: 32% vs 14%, $p=0.01$). Patients with higher SVI were more likely to develop infections (44% vs 25%, $p=0.02$) and less likely to achieve a complete response (CR) or better (44% vs 63%, $p=0.03$). Patients living in more vs less DN had inferior overall survival (OS; SDI: median 27 months vs not reached, $p=0.04$; SVI: median 18 months vs not reached, $p=0.01$). In multivariable models, patients living in more vs less DN were less likely to have a CR or better response (SDI: odds ratio [OR]=0.39, 95% confidence interval [CI]=0.16-0.91; SVI: OR=0.40, 95% CI=0.17-0.90) and had worse OS (SDI: hazard ratio [HR]=1.78, 95% CI=0.97-3.28; SVI: HR=2.14, 95% CI=1.16-3.95). No other differences in outcomes were observed by DN. Median TD and TT were 76.5 miles (range 2.5-1079.6) and 90 minutes (range 10-1022), respectively. No differences in patient characteristics or clinical outcomes by TD/TT were noted except patients with a longer TD/TT were more likely to have high-risk cytogenetics (58% vs 28%, $p<0.001$). Patients from more DN had shorter TD/TT (all indices, $p<0.05$).
Conclusion: In MM patients treated with ide-cel, most lived in less DN yet faced significant TD/TT. The marked travel burden overall and the worse responses and inferior OS in patients living in more DN highlight the need to address systemic barriers to improve CAR T access and outcomes.

#0889 Assessment of disparities in breast reconstruction following breast cancer surgery at a Central Illinois Breast Cancer Program.

Hajar Amina El Amri[1], Kathy Robinson[2], Shreya Arikati[3], Kristin Delfino[4], Ricardo Cossyleon[5], Krishna A. Rao[6]

[1]Internal Medicine, Southern Illinois University School of Medicine, Springfield, IL,[2]Hematology and Oncology, Simmons Cancer Institute at Southern Illinois University School of Medicine, Springfield, IL,[3]University of Illinois Urbana-Champaign, Champaign, IL,[4]Department of Surgery, Southern Illinois University School of Medicine, Springfield, IL,[5]Simmons Cancer Institute at Southern Illinois University School of Medicine, Springfield, IL,[6]Assistant Professor, Internal Med., Southern Illinois University School of Medicine, Springfield, IL

Introduction: Despite increases in reconstruction rates and legislative efforts to improve access, disparities in post-mastectomy breast reconstruction persist. Prior studies have shown lower reconstruction rates among racial and ethnic minorities, patients with lower socioeconomic status, those insured with Medicare/Medicaid, older patients, and individuals living in rural areas.
Methods: We performed a retrospective cohort study of 99 patients (>18 years) who underwent total/simple, skin-sparing, nipple-sparing, or modified radical mastectomy for breast cancer between January 2020 and December 2022 at our institution. Patients who underwent partial mastectomy/lumpectomy were excluded. Clinical, demographic, socioeconomic, and operative data were extracted from the electronic medical record and managed in REDCap. Rural vs. urban residence was determined using RUCC codes (1-3 urban; 4-9 non-urban).The primary outcome was receipt of post-mastectomy breast reconstruction.
Results: The majority of patients in the cohort were Caucasian (87%), with racial and ethnic minority groups representing a smaller proportion. Race was not significantly associated with receipt of breast reconstruction. Patients who underwent reconstruction were significantly younger than those who did not (50.4 ± 11.7 vs. 61.6 ± 12.3 years, $p < 0.0001$). Geographic residence(urban vs. non-urban), smoking status, and comorbidities, including type 2 diabetes, congestive heart failure, and COPD were not associated with reconstruction. Cancer stage and receipt of adjuvant chemotherapy or radiation therapy also did not significantly influence reconstruction rates. Patients who underwent contralateral prophylactic mastectomy were significantly more likely to receive reconstruction ($p = 0.00005$); of these, only 3 patients had a BRCA mutation, while the remainder opted for the procedure by personal choice.
Conclusion: In our cohort, younger age and undergoing contralateral prophylactic mastectomy were the strongest predictors of post-mastectomy reconstruction. Other demographic and clinical factors, including race, geographic residence, and adjuvant treatment, did not affect reconstruction. Standardizing patient education and early referral to plastic surgery may help reduce variation and support more equitable care.

#0890 Addressing heterogeneity in breast cancer outcomes and patterns of care among Asian Americans in Los Angeles: the AMBER-LA Study..

Junrui Lyu[1], Kelsey Lam[1], Grace Guo[1], Andrei Mikhael Galura[2], Emily Kumagai[1], Bodour Salhia[1], Evanthia T. Roussos Torres[1], Chanita Hughes-Halbert[1], Veronica Wendy Setiawan[1], Jennifer Tsui[1]

[1]Keck School of Medicine of USC, Los Angeles, CA,[2]Dornsife College of Letters, Arts and Sciences, University of Southern California, Los Angeles, CA

Background: Breast cancer (BC) is the most diagnosed cancer among Asian American (AA) women, and its incidence continues to rise rapidly. Although emerging evidence suggests variation in cancer outcomes across AA groups, most studies have aggregated Asians into one category. To address this gap, we aimed to build a cohort of diverse AA BC patients to characterize ethnic group-specific patterns of care and cancer outcomes.
Methods: The Asian American Breast Cancer Research in Los Angeles (AMBER-LA) is an exploratory study assessing the feasibility of recruiting AA BC patients to identify multilevel factors associated with care and disease prognosis. Chinese, Korean, and Filipino women aged 21-75 years, residing in Los Angeles County, and diagnosed with invasive BC since January 2021, were recruited from a large academic health center and community outreach events. Data on demographics, cancer diagnosis, and patterns of care were collected through surveys and medical record abstractions. Differences across AA groups were examined using Fisher's exact test.
Findings: Among the 51 participants enrolled to date, including 19 Chinese, 11 Filipino and 21 Korean women, most (94.1%) were recruited from telephone and in-person outreach within clinic settings, and 88.2% were born outside the US. Although 72.5% completed the survey in English, only 17.6% prefer English in their daily life. The mean age at diagnosis was 53.0 years (SD: 10.8). Although not statistically significant, Filipino participants in this sample were more likely to be diagnosed before the age 50, compared with other groups. Modes of diagnosis were similar across groups, with half being detected through routine screening and half after seeking care for symptoms. The median time from abnormal results to seeing a specialist was 21 days (IQR: 10-32). Compared with other groups, Korean participants were more likely to be referred within two weeks, although the differences were not significant. Although 98.0% of participants reported being insured, 15.7% of them reported delaying or not receiving care due to cost in the past year. Alarmingly, experience of discrimination during care was reported by 68.4% of Chinese, 36.4% of Filipino and 42.9% of Korean participants. The most frequently reported experience differed by AA groups: Chinese participants reported not being listened to, Filipino participants reported being treated with less courtesy, and Korean participants described feeling inferior.
Conclusion: Recruiting AA BC patients was challenging, however, engagement with healthcare providers made it feasible. Preliminary evidence of younger age at diagnosis, variation in referral interval, and differential experience of discrimination highlight the need for culturally relevant, group-specific care strategies to improve patient experience and quality of care for AA women.

#0891 A comparison of black and white women with breast cancer in the Deep South and their experiences utilizing theAoUdataset.

Lauren K. Evans[1], Ivan T. Jubilee[2], Layja J. L. Grant[3], Nelson R. Lemieux[4], KiTani Parker Lemieux[5]

[1]Basic Pharmaceutical Sciences, Xavier University of Louisiana, College of Pharmacy, New Orleans, LA,[2]Division of Basic Pharmaceutical Sciences, Xavier University of Louisiana - College of Pharmacy, New Orleans, LA,[3]Public Health, Xavier University of Louisiana, New Orleans, LA,[4]Seven Star Academy, Inc, New Orleans, LA,[5]Xavier University of Louisiana - College of Pharmacy, New Orleans, LA

Purpose: In 2024, Black women had a 38% higher breast cancer mortality rate than their white counterparts, despite a lower incidence. The impact of the social determinants of health (SDoH) within this disparity remains unclear. The Deep South, an area associated with poorer health outcomes, hosts the highest cancer-related death rates nationwide. As such, evaluation of women with breast cancer in this region may influence the understanding of socioeconomic burden. This research examines and compares perceptions of healthcare interactions, access to infrastructure, and community dynamics to contribute to the understanding of social determinants in a black, southern population living with breast cancer.

Methods: Participant and survey data were derived from the All of Us Research Program (AoURP) workbench and SDOH survey. The AoURP is an initiative focused on improving health outcomes through a diverse research database. Inclusion criteria consisted of adult women with breast cancer who self-identified as White or Black/African American and lived in the Deep South (Alabama, Georgia, Louisiana, and Mississippi). Selected survey questions addressed neighborhood perspectives, access to neighborhood resources, and discriminatory experiences in healthcare settings. Black and white participants were identified via the cohort selection tool and further subdivided based on 3-digit zip code values. Using Python in Jupyter Notebook, participant responses were extracted and quantified to allow comparison.

Results: Inclusion criteria were met by 457 black women and 587 white women. Response counts per survey question varied. Black women were significantly more likely to express that their neighborhoods were noisy, unsafe, and unclean. Additionally, black women felt less listened to during health care experiences ($p = 0.0068$) and as if they were treated with less courtesy ($p = 0.0001$). Most questions addressing infrastructure did not result in statistically significant differences. Low-cost recreational facilities and shops were not within walking distance for the majority of both black and white respondents.

Conclusion: These results indicate that black women with breast cancer are impacted by aspects of the SDoH more than their white counterparts. Negative neighborhood dynamics, as well as feelings of less respect and courtesy, may impact prognosis and rates of early diagnosis. Additionally, both cohorts indicated a disparity in infrastructure, which aligns with the predominantly rural composition of the Deep South.

#0892 Distance and deprivation: geographic and contextual influences on pediatric cancer outcomes.

Emma Hymel[1], Kendra L. Ratnapradipa[1], Cheng Zheng[2], Edward S. Peters[1], Jenna Allison[3], Sarah H. Nash[4], Mei-Chin Hsieh[5], Shinobu Watanabe-Galloway[1]

[1]Epidemiology, University of Nebraska Medical Center, Omaha, NE,[2]Biostatistics, University of Nebraska Medical Center, Omaha, NE,[3]Pediatrics, University of Nebraska Medical Center, Omaha, NE,[4]Epidemiology, University of Iowa, Iowa City, IA,[5]Epidemiology and Population Health, LSU Health Sciences Center, New Orleans, LA

Introduction: Cancer is the number one cause of death by disease in children in the US and while survival rates have improved significantly, differences persist in pediatric cancer outcomes by a number of factors. The objective of this study was to demonstrate how cancer registry data can be used to assess social and geospatial predictors of pediatric cancer mortality and their combined effects.

Methods: This population-based longitudinal study used data from the Louisiana Tumor Registry and Iowa Cancer Registry and included all individuals aged 0-19 at primary cancer diagnosis from 2000 to 2020. Travel distance was estimated using the great-circle distance method in ArcGIS Pro, neighborhood deprivation was characterized with the Area Deprivation Index, and rurality was measured at the census tract level with Rural Urban Commuting Area codes. Cox regression models were used to assess the association between social and geospatial predictors and pediatric cancer mortality, adjusting for confounding variables identified through a directed acyclic graph.

Results: Of the 6,982 children with cancer identified from the two states, 4,871 had complete information on home addresses at diagnosis and treatment facilities and were included in the final analysis. Of the cases from Iowa, 40.31% resided in rural census tracts, compared to 15.00% of cases from Louisiana. Five-year survival was higher for children in Iowa (86.63%, 95% CI: 85.19-88.14%) than Louisiana (83.41%, 95% CI: 82.00-84.88%). Compared to children with low travel distances and low neighborhood deprivation, those experiencing both high travel distance (distance in the fourth quartile) and high neighborhood deprivation (ADI in top 50%) have an 82% high hazard of cancer mortality (95% CI: 1.43-2.32). When looking at the combined effects of rurality and travel distance, mortality differences appeared to be driven more by distance than rurality. Interestingly, compared to children in urban areas with a low travel distance to treatment, the hazard of death was highest for children with high travel distances residing in urban areas (aHR=1.41, 95% CI: 1.17-1.71), followed by children with high travel distances in rural areas (aHR=1.28, 95% CI: 1.01-1.62).

Conclusions: By integrating cancer registry data with geospatial and neighborhood social and economic indicators, we identified that children facing both long travel distances and high neighborhood deprivation experience significantly elevated hazards of mortality. Importantly, geography and context are not just a backdrop, but a determinant of survival. These findings highlight the need for multilevel interventions that target individual, hospital, neighborhood, and policy drivers of differences in cancer outcomes for children.

#0893 Real-world bladder cancer survival across the immunotherapy era: Persistent age-, stage-, and race-ethnicity disparities demand precision oncology strategies..

Maria Ivette Lopez Martinez, Bharat Peddinani, Aura Calderon, Everardo Cobos, Diane NGUYEN

The University of Texas Rio Grande Valley, Edinburg, TX

Background: Bladder cancer represents 5% of U.S. malignancies, with 82,000 new cases and 17,000 deaths annually. Most tumors are non-muscle invasive, yet recurrence is common and requires long-term surveillance. Five-year survival is high for non-invasive and localized disease (96% and 70%) but drops sharply for regional (34%) and metastatic stages (5%). Despite advances with platinum regimens and, more recently, immune checkpoint inhibitors (ICIs), mortality gaps persist, especially among older adults, Black patients, and those with advanced diseases.

Methods: We assessed relative survival for invasive and in situ bladder cancer using SEER-21 data (2000-2021), stratified by race/ethnicity, age, and SEER summary stage. Hispanic origin followed the NAACCR Hispanic Algorithm; AI/AN estimates were limited to PRCDA regions. Survival from 1-10 years after diagnosis was calculated using expected-survival life tables.

Results: Overall five-year survival was 78%. Persistent disparities were noted: • Non-Hispanic White: 79.1%• Hispanic: 74.0% • Asian/Pacific Islander: 77.0% • AI/AN: 70.7% • Non-Hispanic Black: 65.0% Age and stage influenced outcomes, with survival ranging from 86.8% (<50 yrs) to 75.3% (≥65 yrs), and from 71.3% (localized) to 7.5% (distant). Since 2016, ICIs—including atezolizumab, pembrolizumab, nivolumab, durvalumab, and avelumab—have improved response durability, achieving complete responses in ~6% and a median OS of ~15 months in selected patients.

Conclusions: Although immunotherapy has expanded options for metastatic urothelial carcinoma, its real-world impact remains uneven. Survival gains are modest, and demographic inequities persist across age, race/ethnicity, and stage. Black and AI/AN patients continue to face the highest mortality, and older adults—who represent most cases—often benefit less due to cisplatin ineligibility, comorbidities, and variable ICI responsiveness. These patterns show that therapeutic advances alone are insufficient; strategies integrating biomarker-based selection, optimized sequencing, and multimodal approaches are urgently needed. Without targeted action, current progress risks widening long-standing disparities in bladder cancer survival.

Impact: Closing these gaps requires precision-guided care and equitable access to emerging therapies to ensure survival gains are shared by all patient groups.

#0894 Prostate cancer outcomes in Hispanic/Latino ethnic enclaves: Results from the California Cancer Registry and American Community Survey.

Diego Alvarez-Lopez, Joel Sanchez Mendez, Michelle Tran, Laura Thompson, Lihua Liu, Myles Cockburn, Mariana C. Stern

Department of Population and Public Health Sciences, Keck School of Medicine, USC - University of Southern California, Los Angeles, CA

Introduction: Prostate cancer (PCa) is the most commonly diagnosed cancer among Hispanic/Latino (H/L) men and the fourth leading cause of cancer-related death. We and others have shown that nativity influences patterns of PCa treatment and survival among H/L men. Here, we examined whether these associations were modified by residence in H/L ethnic enclaves.
Methods: We conducted a retrospective, population-based study of primary PCa cases diagnosed from 2005-2021 in the California Cancer Registry, linked to census tract characteristics from the American Community Survey (2010, 2015, 2020). A composite H/L Enclave Index (HEI) was created using the proportions of H/L residents, non-US-born H/L residents, H/L individuals with limited English proficiency, and linguistically isolated households, with principal components analysis applied to all census tracts to derive the first component. Enclave residence was defined as living in a census tract in the 5th quintile of HEI with ≥ 250 H/L residents or in an adjacent 4th-quintile tract meeting the same threshold. We examined enclave residence as a main exposure in the full cohort and, among H/L patients, as a potential modifier of nativity-outcome associations. Multivariable mixed-effects logistic regression models estimated associations with high-grade disease (Gleason ≥ 8), treatment receipt and treatment delay (≥3 months), including nativity-enclave interaction terms. Prostate-specific survival was evaluated using a covariate-adjusted mixed-effects Weibull model. All models included random intercepts to account for census tract clustering.
Results: A total of 249,860 prostate cancer cases were included (29,159 H/L), of which 75,496 (30.2%) had ever resided in an H/L ethnic enclave: 17.1% NHW men, 50.1% US-born and 71.8% of non-US-born H/L men (pairwise $p<0.01$). Living in an H/L ethnic enclave was associated with 4% higher odds of presenting with high-grade disease (OR= 1.04; 95% CI: 1.02-1.07) and 15% higher hazard of mortality (HR= 1.15; 95% CI: 1.08-1.22). Among H/L men living outside enclaves, non-US-born men had lower odds of high-grade disease compared with US-born men (OR=0.90; 95% CI: 0.83, 0.97); however, we found no evidence of effect modification (interaction $p = 0.17$). Similarly, we found no evidence that enclave residence modified nativity differences in treatment receipt (interaction $p = 0.22$), treatment delay (interaction $p = 0.66$), or survival (interaction $p = 0.08$).
Conclusions: Our analyses show that residence in an H/L ethnic enclave is associated with higher risk of high-grade PCa and mortality. Ethnic enclave residence had limited influence on differences in prostate cancer stage, treatment, or survival among H/L patients by nativity. Our findings suggest that neighborhood ethnic composition alone may not drive our previously observed disparities in prostate cancer outcomes by nativity.

#0895 Impact of immigration and acculturation on mortality in Asian American women with breast cancer.

Alfredo V. Chua[1], Rabsa Sikder[1], Luna Gao[2], Julie Von Behren[2], Janise M. Roh[3], Esperanza Castillo[2], Isaac J. Ergas[3], Iona Cheng[2], Marilyn L. Kwan[3], Salma Shariff-Marco[2], Mi-Ok Kim[2], Katherine Lin[2], Brittany N. Morey[4], Anna H. Wu[5], Esther M. John[6], Lenora W. M. Loo[7], Allison W. Kurian[6], Christine B. Ambrosone[1], Lawrence H. Kushi[3], Scarlett L. Gomez[2], Song Yao[1]

[1]Department of Cancer Prevention & Control, Roswell Park Comprehensive Cancer Center, Buffalo, NY,[2]Department of Epidemiology & Biostatistics, University of California, San Francisco, CA,[3]Division of Research, Kaiser Permanente Northern California, Pleasanton, CA,[4]Department of Health, Society & Behavior, Wen School of Population & Public Health, University of California, Irvine, CA,[5]Division of Epidemiology, Keck School of Medicine, University of Southern California, Los Angeles, CA,[6]Department of Epidemiology & Population Health, Stanford University School of Medicine, Stanford, CA,[7]Department of Epidemiology, University of Hawai'i Cancer Center, Honolulu, HI

Purpose: Immigration/acculturation may affect breast cancer outcomes among minoritized racial and ethnic populations. Limited data exist on how these factors influence survival in Asian American women with breast cancer. We investigated associations of immigration/acculturation with all-cause (ACM) and breast cancer-specific mortality (BCSM) in this population.
Methods: 3971 Asian American women with breast cancer were included from the Asian American Resiliency and Cancer Disparities (ARC) Study. Measures of immigration/acculturation included nativity (born in the US vs. outside the US), number of years (y) and percent (%) of life lived in the US, age at immigration, Asian country of birth, and preferred language at interview. Primary outcomes were ACM and BCSM. Cox proportional hazards were used to estimate hazard ratios (HRs) for ACM and Fine and Gray competing risk models for BSCM, adjusted for clinical, demographic, socioeconomic, reproductive, and lifestyle factors. Analyses were stratified by follow-up duration (≤10 y and >10 y).
Results: Women born outside the US had lower ACM compared with women born in the US at 10 y (HR 0.72, 95% CI 0.61-0.85, p<0.001) and beyond 10 y (HR 0.72, 95% CI 0.63-0.82, p<0.001) follow-up. No statistically significant differences by nativity in BCSM were observed overall; however, higher BCSM in women born outside the US after 15 y of follow-up was suggested. Among women born outside the US, living longer in the US was associated with higher ACM, particularly beyond 40 and 50 y (HR 1.49, 95% CI 1.05-2.10, p=0.02; HR 1.94, 95% CI 1.34-2.81, p<0.001, respectively), which became non-significant after adjustment. Earlier age at immigration was associated with lower ACM and BCSM, and immigration in late adulthood (≥55 y) with higher ACM (<10-y HR 2.04, 95% CI 1.09-3.80, p=0.02; >10-y HR 2.05, 95% CI 1.23-3.41, p=0.006). However, after adjustment, associations with ACM remained significant only for immigration in adolescence (13-17 y) (<10-y HR 0.56, 95% CI: 0.36-0.88, p=0.01) and early adulthood (25-34 y) (>10-y HR 0.75, 95% CI: 0.59-0.96, p=0.02). For BCSM, associations were seen for immigration in adolescence (<10-y HR 0.56, 95% CI: 0.34-0.92, p=0.02), adult transition (18-24 y) (>10-y HR 0.71, 95% CI: 0.52-0.97, p=0.03) and middle adulthood (35-54 y) (<10-y HR 0.62, 95% CI: 0.39-0.97, p=0.04; >10-y HR 0.60, 95% CI: 0.40-0.88, p=0.01). No significant associations were observed between % of life in the US, Asian country of birth, or preferred language at interview, and ACM or BCSM.
Conclusions: Immigration factors may influence long-term mortality in Asian American women with breast cancer. Women born outside the US demonstrated lower ACM, but the length of stay in the US and age at immigration may have influenced this association. This highlights the need for culturally tailored survivorship and public health interventions that promote native cultural behaviors in this population.

#0896 Age-based left-digit bias in the treatment of pancreatic adenocarcinoma.

Qianyun Luo, Bethel Ozed-Williams, David Brauer, Bryan Trottier, Todd Tuttle, Jane Hui, Eric H. Jensen, Jacob Ankeny, Christopher J. LaRocca, Schelomo Marmor

University of Minnesota, Minneapolis, MN

Purpose: Left digit bias, where the left-most digit disproportionately influences decision-making, can impact treatment decisions and patient outcomes. This study examines how such bias may affect treatment decisions for patients with pancreatic adenocarcinoma (PDAC), focusing on differences between patients aged 79 and 80.

Method: A retrospective cohort study using the National Cancer Database (2004-2020) analyzed patients with PDAC aged 79 and 80. The primary exposure was age-based left-digit bias. The main outcomes measured included differences in treatment received and overall survival. Statistical analyses included chi-square tests, multivariate analysis, Kaplan-Meier survival curves, and Cox proportional hazards models.

Results: Among 5,304 patients (2,718 aged 79, 2,586 aged 80), chemotherapy use was higher in 79-year-olds (50.3%) than 80-year-olds (45.1%) (OR 0.79, 95% CI 0.70-0.89, $p<0.01$). No significant differences were found in surgery or radiation. Chemotherapy was associated with lower mortality risk (HR 0.85, 95% CI 0.79-0.92, $p<0.01$). Adjusted overall survival was similar between groups (HR 1.00, 95% CI 0.93-1.07, $p=0.91$).

Conclusion: Left digit bias was observed in the treatment of PDAC, with a tendency to favor chemotherapy for patients aged 79 over 80. This highlights the need for age-neutral decision-making in treatment planning to avoid biases that could impact patient care and outcomes.

#0897 Missed opportunity or standard of care.

Lilia Olsen, Antonio Logan, Paul Kent

FibroFighters, Temecula, CA

Fibrolamellar Carcinoma (FLC) is a rare cancer that primarily affects children and young adults and is easily confused with the common Focal Nodular Hyperplasia (FNH) on imaging. Often, a biopsy is not performed at initial presentation and the opportunity for an early diagnosis of FLC can be missed. Our study aims to evaluate the effects of delayed diagnosis, and based on those results propose an addendum to the current HCC liver biopsy guidelines. We reviewed all FLC patients diagnosed in the last 10 years that had complete records in our database. This was a retrospective observation study that initially looked at 216 patients. We excluded patients who did not have a reference to benign tumors or FNH, or who did not have a pathological diagnosis of FLC. After exclusion we had a cohort of 35 patients. We compared this cohort to 95 patients who had complete records and were not assumed to have FNH at time of diagnosis. A Mann-Whitney U test was performed to compare the time delay between first images and pathological diagnosis between females and males. The analysis shows a significant result between delay and sex, U=59.00, Z= -2.189 p= 0.028. The average diagnostic delay in females was 347.85 days SD= 571.686 and the average diagnostic delay was 41.22 days SD= 31.630 in males. A Mann-Whitney U test showed a significant result between delay in those assumed to have FNH and delay in those who did not, U = 647.500, Z= -5.591, p= <0.001. Based on these results we are suggesting an addendum to the current recommendations. 1. Give FLC its own section separate from HCC 2. Biopsy should be used to confirm diagnosis of FLC or FNH 3. Recommend that a biopsy should be considered when a unique patient population is identified. 4. Close and reliable follow-up for all patients 5. If the neoplasm is in a surgically complicated area, where tumor growth could significantly affect prognosis or possibility of resection, a biopsy should be considered 6. Acquire B12 levels, if they are >2000pg/mL a biopsy should be recommended. 7.A chest x-ray should be acquired to assess possible lung nodules. Due to the gap in guidelines, 70% of our patients experienced a delay in diagnosis. We believe that adding a separate section in the current liver biopsy guidelines for FLC with seven stipulations could help amend this gap in care.

#0898 HER2 as a therapeutic target in prostate cancer: Multi-omic and spatial insights across genetic ancestries.

Nicole Mavingire[1], **Abdulrahman M. Dwead**[1], Joy Solomon[2], Janelle Moore[1], Moyinoluwa Adeniyi[2], Odunayo Oluokun[2], Jabril R. Johnson[1], Estefania Labanca[3], Peter Shepherd[3], Mya Walker[4], Isaiah Sailors[4], Serene Dowiri[4], Greisha L. Ortiz Hernandez[4], Jillian C. McDonough[4], Diana LeVasseur[1], Jazlyn Farlough[1], Justin Tran[4], Frank Myers[4], Fornati Bedell[4], Zhirong Yin[4], Rachel Martini[1], Melissa B. Davis[1], Clayton C. Yates[5], K. Sean Kimbro[1], Rick A. Kittles[1], Tanya Dorff[4], Cristina Magi-Galluzzi[6], Soroush Rais-Bahrami[7], Firas Kobeissy[1], Yehia Mechref[2], Leanne Woods-Burnham[1]

[1]Morehouse School of Medicine, Atlanta, GA,[2]Texas Tech University, Lubbock, TX,[3]UT MD Anderson Cancer Center, Houston, TX,[4]City of Hope National Medical Center, Duarte, CA,[5]Sidney Kimmel Comprehensive Cancer Center, Baltimore, MD,[6]The University of Alabama at Birmingham, Birmingham, AL,[7]Wake Forest University School of Medicine, Winston-Salem, NC

INTRODUCTION: Patients with prostate cancer (PC) initially respond to androgen deprivation therapy. However, relapse is lethal. For this reason, inhibiting androgen-independent signaling pathways—such as human epidermal growth factor receptor 2 (HER2)—is a promising area of investigation. HER2 overexpression in PC tumors correlates with worse prognosis, but has not been sufficiently evaluated in Black men. We hypothesize that unique ancestry-associated multi-omic molecular signatures are modulated with anti-HER2 drug targeting.

METHODS: Using RNA sequencing, we quantified *HER2/ERBB2* in primary patient tissue and correlated with quantified ancestry estimates. IHC staining was used to detect HER2 expression in primary prostate tissue. We quantified transcript and protein levels of HER levels in PC cell lines by qPCR and ELISA. CellTiter-Glo® assessed cell viability in PC cells treated with anti-HER2 drug. We performed multi-omic analyses using LC-tandem mass spectrometry and LC-PRM mass spectrometry. Biological pathway and network analysis was performed using Qiagen's Ingenuity Pathway Analysis. We validated significantly modulated genes with qPCR. We performed immunofluorescence staining of HER2 and androgen receptor (AR) in treated vs. untreated PC cell lines. To resolve the spatial dynamics of *ERBB2* and *AR* in ancestry genotyped patient-derived xenografts (PDXs), we utilized the 10x Genomics Xenium *In Situ* spatial transcriptomics platform.

RESULTS: We detected moderate correlation with *HER2/ERBB2* and West African genetic ancestry (WAA) in primary prostate tissue in a cohort of Black men (n=36). We detected HER2-positive scores in 70% of primary PC tissue in a separate cohort of Black men (n=10). Transcript and protein levels of HER2 were confirmed in PC cells. We observed significantly reduced viability only in HER2-targeted PC cells from Black patients. Systems biology revealed differential pathway and network expression in HER2-targeted PC cells derived from Black men compared with white men. Common significantly modulated genes *ERBB2, MYC, MYCN,* and *TP63* were validated. HER2 and AR immunofluorescence staining diminished with HER2 drug targeting. Spatial transcriptomic analysis revealed that the *ERBB2* and *AR* transcript burden per tumor area were significantly higher in a PDX developed from a Black patient (58% WAA) compared to a PDX developed from a white patient (0% WAA).

CONCLUSIONS: Thorough evaluation of the molecular mechanisms by which HER2 overexpression confers tumor progression and treatment-resistance will provide the foundation to address high-risk PC with precision medicine. By leveraging the unique characteristics of HER2-positive tumors, an additional oncogenic pathway can be therapeutically targeted which will have a major impact in reducing progression to metastasis and reducing mortality.

#0899 Building a national network coordination center for clinical trials: Early implementation outcomes from the CP2CT DECC.

Laura E. Lectora[1], Cristina J. Orozco[1], Holly A. Thorson[2], Timethia Bonner[1], Robert R. Freimuth[2], Jennifer G. Le-Rademacher[2], Folakemi T. Odedina[1]

[1]Mayo Clinic, Jacksonville, FL,[2]Mayo Clinic, Rochester, MN

Background: Despite the decline in overall mortality and incidence of cancer in the US population, the burden of cancer is still high, especially in underserved and under-researched populations. A major contributor to poor cancer outcomes is the absence of dedicated efforts utilizing scientifically rigorous approaches and implementation strategies to optimize participant enrollment and accrual in clinical trials. The Connecting Patient Populations to Clinical Trials (CP2CT) program implements innovative multilevel interventions to enhance clinical trial awareness and optimize referral pathways that facilitate patient enrollment. The CP2CT Data, Evaluation, and Coordinating Center (DECC) supports its data and evaluation activities, and coordinates a learning collaborative towards mitigating the key barriers of cancer burden in all populations.
Methods: Using an implementation science-informed approach, the DECC deployed coordinated strategies over three years: (1) administrative structuring through streamlined governance, centralized reporting, and stakeholder integration; (2) data standardization via Common Data Elements (CDEs), a cross-network REDCap system, and a multi-institution Data Transfer Agreement (DTA); (3) evaluation infrastructure through a Network Logic Model, evaluation plan, standardized constructs, and a Process Evaluation Plan with tools; (4) learning supports through an internal website and expanded Speaker Series; and (5) site-level implementation facilitation through structured visits.
Results: In collaboration with the CP2CT Network and NCI, the DECC's achievements span four domains: (1) Administrative: built infrastructure, deployed centralized reporting platforms, coordinated key meetings, and strengthened community integration. (2) Data: standardized collection, secured network-wide data sharing through the DTA, enabled harmonized multi-site reporting, and advanced groundwork for interoperability and scientific value. (3) Program Evaluation: linked CP2CT activities to measurable outcomes through a Network-wide Logic Model, guided evaluation, established shared evaluation language, and launched a transferable Process Evaluation framework. (4) Learning Collaborative: developed a centralized resource hub, expanded the Speaker Series, and advanced authorship transparency with the CP2CT Publication Policy. <
Conclusion: The CP2CT DECC has established a sustainable, scalable infrastructure that integrates administrative coordination, standardized data collection, robust program evaluation, and a collaborative learning environment. These efforts enhance clinical trial awareness, optimize referral pathways, and provide a transferable model for improving participant enrollment and scientific rigor across national research networks, ultimately addressing disparities in cancer outcomes.

#0900 Risk of second cancer in survivors of early-onset colorectal cancer: racial and ethnic differences in a population-based study.

Aniruddha B. Rathod[1], Caitlin C. Murphy[2], Sandi L. Pruitt[3]

[1]Epidemiology, University of Arkansas for Medical Sciences, Little Rock, AR,[2]Pediatrics, University of Chicago, Chicago, IL,[3]UT Southwestern Medical Center, Dallas, TX

Introduction: Early-onset colorectal cancer (EOCRC) incidence is rising sharply in the US, yet the long-term survivorship experience of this population remains poorly defined particularly among groups experiencing unequal cancer burden. Because racial and ethnic disparities persist in cancer-related exposures, treatment experiences, and survivorship care, the long-term probability of developing a second primary cancer (SPC) after EOCRC may also vary across population groups. We estimated risk of SPC by race and ethnicity to improve understanding of long-term survivorship following EOCRC.
Methods: We used SEER 12 registry data to identify adults aged 18-49 years with stage 0-III EOCRC between 1992-2021. SPC was defined as any new primary cancer diagnosed ≥6 months after EOCRC. Accounting for competing risk of death, we estimated cumulative incidence of 1) any SPC and 2) second CRC by calendar time and attained age. Standardized incidence ratios (SIRs) compared risk to the general population. Analyses were stratified by sex and racial/ethnic groups.
Results: Among 29,115 EOCRC survivors, 53.5% were male, and the racial/ethnic distribution was non-Hispanic White (NHW: 54%), non-Hispanic Black (NHB: 10.9%), Hispanic White (HW: 16.7%), Asian/Pacific Islander (API: 15%), and other (3.4%). Overall, 8.4% developed any SPC and 2.8% developed a second CRC. Cumulative incidence of any SPC did not differ significantly by race/ethnicity for men and women. Among men, SIRs for any SPC were 1.4 (95% CI: 1.3-1.5) for NHW, 1.4 (1.2-1.6) for NHB, 1.8 (1.5-2.1) for HW, and 2.4 (2.0-2.8) for API. Among women, SIRs were 1.3 (1.2-1.4) for NHW, 1.6 (1.3-1.9) for NHB, 1.6 (1.4-1.9) for HW, and 1.8 (1.6-2.1) for API. Cumulative incidence of second CRC differed significantly by race/ethnicity for men and women. At 25 years after diagnosis, cumulative incidence of second CRC was 2.8% (95% CI: 2.3-3.5) for NHW women; 4.6% (3.9-5.4) for NHW men; 5.5% (4.0-7.4) for NHB women; 4.0% (2.8-5.5) for NHB men; 5.9% (4.2-8.0) for HW women; 7.0% (5.3-9.1) for HW men; 4.0% (2.9-5.5) for API women; and 6.6% (4.8-8.9) for API men. By age 70, estimates were 2.9% (2.3-3.6) for NHW women, 4.7% (4.0-5.5) for NHW men, 5.6% (3.9-7.8) for NHB women, 4.6% (3.1-6.4) for NHB men, 4.9% (3.6-6.5) HW women, 6.7% (5.1-8.6) for HW men, 4.5% (3.1-6.3) for API women, and 6.1% (4.5-8.1) for API men. Second CRC SIRs showed similar patterns, with highest risks in HW men (SIR: 8.0; 95% CI: 6.3-10.0) and HW women (SIR: 7.1; 95% CI: 5.2-9.5).
Conclusion: Despite no statistical differences in risk of any SPC, second CRC risk differed significantly by racial and ethnicity. HW men and women showed higher cumulative incidence over time, partly reflecting younger age at diagnosis and longer time at risk. Additional genetic, lifestyle, and care-related factors may contribute and warrant study to guide prevention and early detection in EOCRC survivors.

#0901 Disparities in gastric cancer treatment and related adverse events in older adults.

Nana Owusu[1], Jennifer Ferris[2], Ji Yoon Yoon[3], Jeong Yun Yang[2], Josephine Soddano[2], Sophie Wagner[2], Chin Hur[2]

[1]Columbia Univ. Vagelos College of Physicians & Surgeons, New York, NY,[2]Department of Medicine, Columbia University Irving Medical Center, New York, NY,[3]Department of Gastroenterology, Icahn School of Medicine at Mount Sinai, New York, NY

Background: Disparities in treatment-related adverse events (AEs) may contribute to racial differences in cancer outcomes. In this study, we performed a comprehensive analysis of treatment patterns and related AEs between non-Hispanic White (NHW) and non-Hispanic Black (NHB) gastric cancer (GC) patients.

Methods: We queried SEER-Medicare (2000-2017) for NHW and NHB patients aged ≥66 years with histologically confirmed GC. Inpatient and outpatient claims within 1 year of diagnosis were collected for chemotherapy, surgery, and radiation treatments. Chemotherapy treatments were classified as 'NCCN' if consistent with first/second-line regimens per 2025 NCCN GC guidelines, and 'non-NCCN' otherwise. Chemotherapy-related AEs were identified using hospitalization claims for hematologic, gastrointestinal, infectious, and metabolic toxicities within 21 days of treatment consistent with prior SEER-Medicare studies. Cohort differences were tested with χ^2 or t-tests. To control for repeated observations (e.g., treatment cycles) per patient, we used multivariable Generalized Estimating Equations to measure associations between race and AEs.

Results: The cohort included 18,089 patients (15,824 NHW; 2,265 NHB). SEER stage distribution was consistent across both NHW and NHB cohorts (33% vs. 34% metastatic disease, P=0.32). NHW patients were more often male (64% vs. 55%, P<0.01) and had more cardia primaries (59.9% vs. 37.0%, P<0.01), while NHBs had higher comorbidities (mean NCI Index 0.64 vs. 0.50, P<0.01). NHBs were less likely to receive chemotherapy (aOR 0.80, 95% CI 0.71-0.89) or radiation (aOR 0.76, 95% CI 0.66-0.86), and had longer mean time to treatment initiation (chemotherapy: 82 vs. 73 days; radiation: 100 vs. 85 days; both P<0.01) than NHWs. Among 5,748 chemotherapy recipients (5,147 NHW; 601 NHB), mean treatment cycles did not differ between NHWs and NHBs (5.0 vs. 5.2, P=0.19). However, NHBs had higher AE risk (aOR 1.15, 95% CI 1.02-1.30) per treatment than NHWs. Metastatic disease (aOR 1.49, 95% CI 1.39-1.59) and non-NCCN regimens (aOR 1.31, 95% CI 1.22-1.40) were also associated with elevated AE risk. Further sub-group analyses showed higher AE risk for NHBs relative to NHWs in the non-NCCN cohort (aOR 1.35, 95% CI 1.10-1.65) but not in the NCCN cohort (aOR 1.11, 95% CI 0.95-1.28).

Conclusions: NHB patients with GC were less likely to receive chemotherapy or radiotherapy and experienced longer treatment delays than NHW patients. NHB patients also had greater risk of chemotherapy-related AEs, particularly when using non-NCCN regimens. These findings highlight persistent inequities in GC care and support further investigation into structural and biological drivers of AE disparities.

#0902 Characterizing barriers and facilitators to healthcare access among female breast cancer patients in The Gambia.

Anjali Gupta[1], Jen Gathings[2], Ami Mejia[2], Ramatoulie Jobe[3], Anna Korrea[3], Abdul K. Fye[3], Joseph W. Jatta[3], Ashwini Joshi[4], Ousman Sanyang[3], Alagie Manneh[3], Charles A. P. Roberts[3], Lamin Jaiteh[3], Gabriel O. Ogun[3], Tomi F. Akinyemiju[4]

[1]School of Medicine, Stanford University, Stanford, CA,[2]ETR Services, LLC, Durham, CA,[3]School of Medicine & Allied Health Sciences, University of The Gambia, Banjul, Gambia,[4]School of Medicine, Duke University, Durham, NC

Background: The Gambia, the smallest country within mainland Africa, is estimated to have one of the lowest cancer survival rates of countries in Africa, Asia, and Central America. Although poor access to healthcare contributes to low breast cancer survival rates in The Gambia, little is known about patient experiences across multiple healthcare access domains. The purpose of this study was to characterize healthcare access barriers and facilitators to breast cancer care.
Methods: Twenty-three breast cancer patients from the Edward Francis Small Teaching Hospital (EFSTH; largest referral center in the country) in Banjul, The Gambia participated in semi-structured interviews from June-December 2023. Interviews were conducted in Wolof, Mandinka and/or English as appropriate. Topics included patient experiences and pathways to diagnosis, prior knowledge and beliefs about breast cancer, barriers to accessing care, and cultural factors impacting the treatment journey. Analysis coupling an inductive approach with an initial deductive approach following Penchansky and Thomas's (1981) theoretical framework of healthcare access resulted in a final set of codes.
Results: Of the 21 participants with available age data, the mean (SD) age was 44 (10) years. Most participants had little to no knowledge of breast cancer prior to their diagnosis. The time from symptom onset to diagnosis ranged widely from a few weeks to months or years. Seven participants (30%) reported using traditional medicine prior to visiting a healthcare professional. Affordability of diagnostic procedures and treatments was the most frequently mentioned barrier (91% of participants), followed by availability of services (e.g., providers, working equipment, facilities' capacities to perform procedures, medications, etc.; 83%), accessibility (distance and travel) of providers (74%), accommodation (health system organization) in relation to the preferences of the patients (43%), and acceptability (quality of patient-provider interaction; 9%). Family, peers, and faith were important sources of support and comfort during the cancer journey.
Conclusions: Our results highlight major barriers to healthcare access among breast cancer patients in The Gambia, leading to delays in diagnosis and treatment. Multi-level initiatives to address these barriers will be crucial to reducing the breast cancer burden within the country.

#0903 Socioeconomic and system-level factors influencing receipt of advanced NSCLC surgery..

Nimish Valvi[1], Francesca Kowalik[1], Dejana Braithwaite[2], Mihika Shinde[2], Hiren Mehta[3], **Shama Karanth**[2]

[1]Ball State Univ., Muncie, IN,[2]Department of Surgery, University of Florida, Gainesville, FL,[3]Department of Medicine, University of Florida, Gainesville, FL

Background: Lung cancer is a major contributor to cancer-related morbidity and mortality in the United States. Although advances in medical and surgical treatment have improved outcomes, economically disadvantaged patients, particularly those living in rural areas or lacking health insurance, continue to experience substantial treatment disparities. These disparities are exacerbated by the introduction of newer surgical technologies, as underserved patients often have limited access to these modern treatments.
Objective: To evaluate the association between area-level socioeconomic status (SES) and type of surgery received, robotic-assisted thoracic surgery (RATS), video-assisted thoracic surgery (VATS), and open lobectomy among patients with non-small-cell lung cancer (NSCLC).
Methods: Data were drawn from the 2015-2022 National Cancer Database and included patients diagnosed with Stage 0-IIIa NSCLC. The primary exposure was area-level income, defined by quartiles of median household income in the patient's zip code. Multinomial logistic regression was used to estimate adjusted odds ratios (aORs) and 95% confidence intervals (CIs) for the association between income quartiles and surgical approach, using open surgery as the reference group. Models were adjusted for patient, clinical, hospital, and socioeconomic characteristics. All comparisons were considered statistically significant with $p < .05$.
Results: The study included 84,931 patients with NSCLC, with a mean age of 67.8 ±8.5 years. Patients were identified as having undergone either an open lobectomy (38.4%), VATS (33.3%), or RATS (28.2%) during the study period. Most patients were older, White, and Medicare-insured, with care predominantly at academic metropolitan centers. In the adjusted models, low-income (<$46,277) patients were less likely to undergo RATS (aOR: 0.81, 95% CI: 0.76-0.87) or VATS (aOR: 0.82, 95% CI: 0.77-0.87) versus open lobectomy compared to patients from high-income (≥$74,063) areas. Compared to academic hospitals, community centers were 67% less likely to receive RATS (aOR: 0.33, 95% CI: 0.30-0.37) and 39% less likely to receive VATS (aOR: 0.61, 95% CI: 0.57-0.67). Additionally, males were less likely than females to receive RATS or VATS.
Conclusions: The findings indicate that patients with NSCLC from low SES areas have reduced access to advanced, minimally invasive surgical techniques (RATS and VATS). Targeted efforts to ensure access to modern surgical care are warranted to reduce and mitigate treatment disparities and improve patient outcomes.

#0904 Developing a polysocial risk score for prostate cancer patients treated with radical prostatectomy.

Kelsie Campbell, Dayoung Bae, Chanita Hughes-Halbert

Population and Public Health Sciences, USC Keck School of Medicine, Los Angeles, CA

Introduction: Prostate cancer is the leading cause of cancer morbidity and mortality among men in the United States, with stark racial disparities. Black men experience both higher incidence and worse outcomes compared to White men, even after accounting for clinical stage and treatment. Social determinants of health (SDOH) are increasingly recognized as critical drivers of these disparities, influencing care across the prostate cancer continuum—from screening to survivorship. We developed a novel polysocial risk score that integrates multiple psychosocial and socioeconomic factors to quantify cumulative SDOH burden, and evaluated its associations with race, clinical characteristics, and neighborhood context in a prostate cancer cohort.

Methods: We retrospectively identified 126 prostate cancer patients who underwent radical prostatectomy between 2011 and 2019 at a single academic cancer center. Eleven candidate variables—capturing perceived stress, loneliness, financial strain, and socioeconomic status (education, income, employment)—were included in an exploratory factor analysis. A 7-item unidimensional composite (1 stress item, 3 loneliness items, 1 financial strain item, 2 SES items) was retained based on factor loadings and showed acceptable internal consistency (Cronbach's $\alpha = 0.74$). We compared polysocial risk scores by self-reported race (Black vs. White) and examined associations with tumor stage, prostate-specific antigen (PSA), the Social Deprivation Index (SDI), and neighborhood collective efficacy.

Results: The final score accounted for 39.6% of variance in the item set, reflecting a cohesive social risk construct. Black patients had significantly higher scores than White patients (mean 2.79 vs. -1.08, $p < .001$), indicating greater cumulative social adversity. The score was not associated with tumor stage ($p = .89$), suggesting social risk burden was independent of disease severity. However, higher scores were correlated with neighborhood disadvantage (SDI, $r = 0.52$, $p < .001$) and lower collective efficacy (trust; $r = -0.20$, $p = .03$).

Conclusion: This composite measure of psychosocial and socioeconomic adversity revealed markedly higher cumulative social risk among Black prostate cancer patients, despite similar clinical profiles. The polysocial risk score may aid in identifying patients with unmet social needs who could benefit from targeted supportive interventions. Integrating social risk assessment into prostate cancer care may promote health equity by addressing upstream determinants of disparate outcomes.

#0905 Racial disparities in geographic access to uterine cancer clinical trials across U.S. counties.

Caitlin E. Meade[1], Jennifer A. Sinnott[2], Simran A. Kanal[1], Laura M. Chambers[3], **Ashley S. Felix**[1]

[1]College of Public Health, Ohio State University, Columbus, OH,[2]College of Arts and Sciences, Ohio State University, Columbus, OH,[3]College of Medicine, Ohio State University, Columbus, OH

Purpose: Uterine cancer mortality is rising, disproportionately affecting racially and socioeconomically marginalized populations. Clinical trials improve access to novel therapies and outcomes, yet racial disparities in trial enrollment persist. Because the geographic distribution of trials shapes opportunities for enrollment, we examined associations between race and county-level availability of interventional uterine cancer trials, and whether this relationship varies by neighborhood vulnerability.

Methods: We identified US-based uterine cancer interventional trials from the Aggregate Analysis of ClinicalTrials.gov database (2008-2021) and aggregated site ZIP codes to counties, counting multiple sites per county as one trial. County-level trial availability was linked to the CDC Social Vulnerability Index (SVI; range 0-1, higher scores = greater vulnerability) and uterine cancer cases in SEER (2008-2021). Multivariable logistic regression estimated associations between race/ethnicity (American Indian/Alaska Native, Asian, Black, Hispanic, Native Hawaiian/Pacific Islander, and White) and county-level trial availability, adjusting for clinical characteristics and county size. Effect modification by SVI [high (≥90th percentile) vs. low (<90th percentile) was assessed.

Results: We included 151,610 uterine cancer cases (mean [SD] age at diagnosis, 61.7 [11.7] years) diagnosed between 2008 and 2021. Two-hundred and twenty-five unique interventional uterine cancer clinical trials were open in the year of diagnosis and county of residence for these cases; 78% lived in a county with at least one open interventional trial. Compared to White women, Asian, Black, and Native Hawaiian/Pacific Islander women had higher odds of trial availability, whereas American Indian/Alaska Native and Hispanic women had lower odds. We observed effect modification by SVI (p-interaction <0.001): in areas of high vulnerability, Black compared to White women had higher odds of trial availability (OR=1.31, 95% CI=1.08-1.60).

Conclusions: Our findings highlight racial disparities in geographic access to uterine cancer clinical trials - an essential prerequisite for enrollment. Among residents of more socially vulnerable areas, trial availability was higher for Black than White women, contrasting with prior research showing lower enrollment among Black patients. This suggests structural barriers beyond proximity continue to limit equitable participation, even where trials are accessible.

#0906 Sex-based differences in lung cancer survival: A competing risks model using the PLCO trial.

Veer N. Shah[1], Grace Mhango[1], Darshi Shah[2], Paolo Boffetta[3], Juan P. Wisnivesky[1]

[1]Icahn School of Medicine at Mount Sinai, New York, NY,[2]Stony Brook University, Renaissance School of Medicine, Stony Brook, NY,[3]Stony Brook University, Stony Brook, NY

Purpose:Lung cancer causes more than 130,000 deaths each year in the United States. Although females with non-small cell lung cancer (NSCLC) appear to have better survival than males, many prior studies did not fully account for key confounders, including smoking history and competing causes of mortality. Moreover, large cohort analyses often relied on Cox models, which may overestimate cause-specific risks when competing mortality is substantial. Hence, in this study, we assessed whether sex-based survival differences in NSCLC persist after adjusting for these confounders and applied competing risk regression to adequately account for competing causes of death and more accurately quantify lung cancer-specific mortality.
Methods:Using data from the Prostate, Lung, Colorectal, and Ovarian (PLCO) trial, we selected patients whose first-ever malignancy was primary NSCLC, excluding anyone with a prior other cancer diagnosis or secondary/metastatic lung tumors. Lung cancer-specific survival for females versus males was evaluated using Fine and Gray competing risk models, adjusting for sociodemographic factors, cancer location, histology, treatment, smoking status, and comorbidities. Because patients with NSCLC experience substantial mortality from non-cancer-related causes, we applied a competing risk model to accurately account for this. This approach avoids the more than twofold (2.25-fold) overestimation of cause-specific risk that can occur when Cox models are used in elderly populations. All analyses were performed using SAS 9.4.
Results:Among 2,793 patients (59% male, 41% female), 2,006 (72%) experienced lung cancer-related death, 531 (19%) died from other causes, and 256 (9%) were alive at last follow-up. Female patients were more likely to be never smokers (14% vs 5%, $p<0.0001$), have adenocarcinoma (55% vs 42%, $p<0.0001$), and less likely to have cardiovascular disease (heart failure: 7% vs 18%, $p<0.0001$). Unadjusted Fine and Gray models showed (hazard ratio [HR]: 0.81, 95% confidence interval [CI]: 0.74-0.88) lower lung cancer-specific mortality among women. Adjusted analyses demonstrated that female sex (HR: 0.85, 95% CI: 0.74-0.98) was associated with decreased risk of lung cancer-specific death. A significant interaction between female sex and stage IV disease (b coefficient: 0.18, 95% CI: 0.99-1.45) showed that lung cancer-specific survival of women and men was similar among patients with advanced disease.
Conclusions:Females with NSCLC demonstrate reduced lung cancer-specific mortality after adjustment for competing risks and confounders. These results could be suggestive of sex-based disparities in inherent biological differences in tumor biology, natural disease progression, or overall increased life expectancy in females, further supporting investigating molecular pathways including hormonal signaling and immune responses to guide optimal treatment strategies.

#0907 Impact of socioeconomic status and travel distance on treatment outcomes in soft tissue sarcoma: A retrospective analysis from a high volume tertiary care center.

Cordero Lee McCall[1], Janelle Cordero[2], Meena Bedi[1], David King[3]

[1]Medical College of Wisconsin, Wauwatosa, WI,[2]Fordham University, Bronx, NY,[3]Orthopedic Surgery, Medical College of Wisconsin, Milwaukee, WI

Introduction: Soft tissue sarcomas (STS) are rare mesenchymal tumors with substantial clinical complexity. Although tumor size, grade, and histology are established prognostic factors, socioeconomic status (SES) and geographic access to specialized care may also influence outcomes. Prior studies in multiple cancers show that socioeconomic disadvantage and longer travel distances can delay treatment and worsen prognosis. High-volume sarcoma centers offer multidisciplinary management that improves survival, yet SES-related barriers may still affect access. This study evaluates the impact of SES, travel distance, treatment patterns, and survival outcomes among STS patients treated at a high-volume tertiary center.

Methods: A retrospective cohort of 364 patients with primary STS treated over 20 years at a single tertiary center was analyzed. Patients with metastatic disease at diagnosis, incomplete treatment data, or inadequate follow-up were excluded, leaving 357 eligible patients. SES was measured using the Area Deprivation Index (ADI) and classified as high (ADI 8-10) or low (0-7) deprivation. Travel distance was calculated using the Haversine formula. Kaplan-Meier analyses assessed overall survival (OS), progression-free survival (PFS), and distant metastasis-free survival (DMFS). Logistic regression evaluated factors associated with wound complications.

Results: No significant differences were found in OS (p=0.2), PFS (p=0.3), DMFS, or wound complications (p=0.1) between high- and low-ADI groups. Treatment patterns were similar, including adjuvant chemotherapy (8.9% vs. 8.7%, p=1.000) and radiation (10.7% vs. 11.8%, p=1.000). High-ADI patients traveled slightly farther (median 24.8 vs. 18.5 miles), but this modest increase was not associated with differences in treatment delivery or outcomes. On multivariate analysis, tumor grade, age, and Karnofsky Performance Status predicted OS.

Conclusion: Despite marginally longer travel distances, socioeconomically disadvantaged patients had comparable treatment patterns and survival outcomes to more advantaged patients. The small travel difference did not impede access to multidisciplinary sarcoma care. High-volume tertiary centers may help mitigate SES-related disparities by providing equitable, standardized treatment across diverse populations.

#0908 An intersectional analysis of physical and mental health-related quality of life among LGBTQ+ patients with cancer.

Rolando F. Trejos, Shahrzad Zamani, Matthew B. Schabath

Department of Cancer Epidemiology, Moffitt Cancer Center, Tampa, FL

Background: Prior studies report that LGBTQ+ patients with cancer report poorer health-related quality of life (HRQOL), but very little is known about how their LGBTQ+ identity intersects with their race and ethnicity. Guided by Intersectionality and Minorities' Diminished Returns theories, this study sought to explore the impact of the intersection of these identities on cancer patients' HRQOL. We hypothesize that ethnoracially diverse LGBTQ+ cancer patients will have poorer HRQOL.
Methods: Self-reported data were obtained from 97,346 patients, of whom 3,353 self-identified as LGBTQ+, who completed a standard-of-care electronic questionnaire including demographics, psychosocial measures, and the validated Short Form Health Survey-12. Sexual orientation (SO) and gender identity (GI) were used to identify sexual minorities, gender minorities, and cisgender heterosexual persons. SF-12 scores were used to calculate the Physical Component Summary (PCS) and Mental Component Summary (MCS). Age-adjusted generalized linear models estimate mean MCS and PCS for intersectional identities using SAS (version 9.4). For the SO analyses, the reference group was non-Hispanic White heterosexual patients; while for GI analyses, it was non-Hispanic White cisgender male patients.
Results: For the intersectional analyses by SO, 39 identities were analyzed. Twenty identities were associated with lower MCS, of which White Heterosexual and Hispanic multiracial lesbian/gay patients had statistically significantly lower scores. For PCS, 23 identities were associated with lower scores, but only while multiracial non-Hispanics with unspecified SO had significantly lower PCS. PCS was significantly higher among Black Hispanic patients who did not disclose their sexual orientation. For the intersectional analyses by GI, 26 of 43 identities were associated with lower MCS, of which White Hispanic transgender, White cisgender females, and Non-Hispanic Asian patients had significantly lower scores. For PCS, 26 identities were associated with lower scores, but only Hispanic Native Hawaiian or other PI Cisgender males had significantly lower PCS. When SO+GI were combined with non-Hispanic White straight cisgender males as the reference, 20 identities had significantly lower MCS, including non-Hispanic Asian straight transgender males and non-Hispanic multiracial genderqueer patients. For PCS, 24 groups had significantly lower scores, including Hispanic American Indian/AN cisgender males and non-Hispanic multiracial bisexuals with other GI.
Conclusions: This analysis of intersectional identities by LGBTQ+ status, race, and ethnicity highlights the importance of collecting detailed demographics to reveal cancer-related disparities and underscores the need for personalized care and the delivery of supportive services to populations disproportionately experiencing worse HRQOL.

#0909 Disparate access and outcomes of immunotherapy treatment in patients with head and neck cancer.

Morgan C. Byrd[1], Tariq M. Omer[2], Alexandra Hunter[2], Rong Jiang[3], Aleksandr R. Bukatko[4], Oyomoare L. Osazuwa-Peters[3], Tammara L. Watts[3], Nosa Osazuwa-Peters[2]

[1]Head and Neck Surgery & Communication Sciences, Duke University School of Medicine, Durham, NC,[2]Duke University School of Medicine, Durham, NC,[3]Duke Cancer Institute, Durham, NC,[4]St. Louis University School of Medicine, St. Louis, MO

Introduction: Head and neck cancers (HNC) are often treated with surgery, radiation, and chemotherapy which can cause significant morbidity. Immune checkpoint inhibitors activate the immune system to target cancer cells and may reduce treatment-related complications. We examined clinical and sociodemographic factors associated with first-line immunotherapy receipt and timing, and assessed survival impacts in a hospital-based cohort.

Methods: Adults with advanced stage (III-IV) HNC (n=414,380) from the National Cancer Database (2004-2022) were analyzed. Multivariable regression estimated differences in time to immunotherapy and adjusted odds ratios (aORs) for receipt, adjusting for age, sex, race, tumor site, insurance, Charlson-Deyo comorbidity (CDCC), income, and education. Overall survival was evaluated using Cox models comparing immunotherapy timing relative to surgery (immunotherapy only, neoadjuvant, or adjuvant) versus no immunotherapy, adjusting for the same covariates plus radiation and chemotherapy. A secondary model among immunotherapy recipients evaluated survival by sociodemographic factors.

Results: The cohort was 74.2% male, mean age 62.5 years, 85.6% White; 4.7% had immunotherapy. Black patients (ß 11.06, 95% CI 5.12-16.99), females (ß 6.24, 95% CI 1.99-10.50), and tumors in the mouth/oral cavity (ß 10.95, 95% CI 6.42-15.49) or nasopharynx/nasal cavity/sinus (ß 13.96, 95% CI 5.75-22.18) had longer times to immunotherapy compared to oropharynx. Areas with higher low-education also had delays. Older age was associated with shorter delays; insurance and income showed no differences. Females (aOR 0.83, 95% CI 0.80-0.86) and tumors in the mouth/oral cavity (aOR 0.78, 95% CI 0.75-0.81), larynx/hypopharynx (aOR 0.73, 95% CI 0.70-0.77), and nasopharynx/nasal cavity/sinus (aOR 0.6, 95% CI 0.63-0.73) had lower odds of receipt than oropharynx. Higher comorbidity, Medicaid/Medicare, and higher income were associated with increased odds of receipt. Adjuvant immunotherapy improved survival (aHR 0.95, 95% CI 0.90-0.99), while immunotherapy alone (aHR 1.25, 95% CI 1.22-1.29) and neoadjuvant therapy (aHR 1.12, 95% CI 1.04-1.20) were linked to worse survival compared to no immunotherapy. Older age, Black race, non-oropharynx tumors, higher comorbidity burden, lower income, and residence in areas with lower educational attainment were each independently associated with higher mortality. Among immunotherapy recipients only, Black race (aHR 1.23, 95% CI 1.14-1.31) and increasing CDCC scores predicted worse survival, while private insurance was protective (aHR 0.64, 95% CI 0.57-0.72).

Conclusion: Differential access to immunotherapy and survival outcomes in HNC disproportionately affects racial minorities and socioeconomically disadvantaged populations, underscoring multifactorial determinants of survival and the need for equitable cancer care interventions.

#0910 Disparities in 5-year relative survival rates of cervical cancer by age and stage at diagnosis between African Americans and Whites, in the USA, from 2016 to 2022.

Milahni Wilkerson[1], John Heath[2], **Ehsan Abdalla**[1]

[1]Tuskegee University College of Veterinary Medicine (TUCVM), Tuskegee, AL,[2]CBR/RCMI, Tuskegee University, Tuskegee, AL

BACKGROUND: The overall five-year relative survival rates (RSRs) for cervical cancer in the USA are about 67%, varying significantly by stage at diagnosis. Localized cervical cancer has a higher survival rate, approximately 91%, while later stages (regional or distant) have lower rates, with the regional stage it is 62% and the distant stage it is 19%.
OBJECTIVE: To compare differences in cervical cancer RSRs by age and stage at diagnosis between African Americans and Whites in the U.S.
METHODS: Using data from the 2016 to 2022 SEER (Surveillance, Epidemiology, and End Results) database, we analyzed 356 African Americans and 4,612 Whites diagnosed with cervical cancer. RSRs compared African Americans and Whites by age and stage at diagnosis using SEER*Stat software.
RESULTS: At the localized stage, Whites aged 15-44 had an RSR of 97.1% (95% CI, 95.5-98.2), consistently higher than African Americans, except those aged 45-54 and 55-64, who had slightly higher RSRs at 94.6% and 91.6% (95% CIs: 77.0-98.8 and 65.2-98.2), respectively. At the regional stage, Whites had better survival overall, with an RSR of 60.7% (95% CI, 50.3-69.5). The exception was African Americans aged 75 and older, who had a higher RSR of 56.2% (95% CI, 0.2-94.9) than Whites in the same age group. At the distant stage, both African Americans and Whites aged 15-44 had similar lower RSRs of 31.5% (95% CI, 19.8-30.1). African Americans aged 55-64 and 65-74 had higher RSRs of 22.6% and 25.3% (95% CIs: 9.10-39.7 and 6.2-50.6) than their White counterparts. Among those aged 75 and older, Whites had a higher RSR (7.4%, 95% CI: 1.9-17.9). For cases with an unknown stage, Whites aged 15-44 had an RSR of 91% (95% CI, 73.5-97.2), again higher than African Americans. However, African Americans aged 45-54 had a higher RSR of 67.3% (95% CI, 5.1-94.9) compared to Whites in the same age group.
DISCUSSION/CONCLUSION: Significant disparities in cervical cancer RSRs exist by race, age, and stage. Overall, African Americans had lower RSRs than Whites, underscoring persistent disparities in cervical cancer outcomes among these two groups.

#0911 Racial and ethnic differences in cardiovascular disease mortality among women diagnosed with ductal carcinoma *in situ* in the United States.

Yancen Pan[1], Ziad Zakaria[1], Jessica Li[1], Lene HS Viega[2], Amy Berrington de Gonzalez[3], Geetanjali Datta[1], Jacqueline B. Vo[2], Cody Ramin[1]

[1]Samuel Oschin Comprehensive Cancer Institute, Cedars-Sinai Medical Center, Los Angeles, CA,[2]Division of Cancer Epidemiology and Genetics, National Cancer Institute, Bethesda, MD,[3]Division of Genetics and Epidemiology, The Institute of Cancer Research, London, United Kingdom

Background: Ductal carcinoma *in situ* (DCIS) is associated with an elevated risk of cardiovascular disease (CVD) mortality, which may be due to comorbidities or cancer treatment, yet prior studies examining racial and ethnic differences are limited. The aim of this study is to investigate the association between race, ethnicity and CVD mortality among women diagnosed with DCIS in the United States.
Methods: We included women diagnosed with a first primary DCIS aged 20-84 between 2000 to 2017 in the U.S. Surveillance, Epidemiology, and End Results, and followed for more than one year. Fine and Gray regression was used to estimate sub-distribution hazard ratios (HRs) for CVD mortality by race and ethnicity (Hispanic, non-Hispanic Asian American (NH-AA), NH-Black, NH-Native Hawaiian and other Pacific Islander (NH-NHPI), and NH-White), adjusting for age at diagnosis, year of diagnosis, surgery type, and radiotherapy, and accounting for competing risks of non-CVD death. Models were further stratified by DCIS diagnosis age (<50 and ≥ 50) and year (2000-2004, 2005-2009, and 2010-2017). Cumulative incidence of CVD mortality was also assessed by race and ethnicity, accounting for competing risks.
Results: Among 158,072 women diagnosed with DCIS (median follow-up=6.80 years; mean age=58.47 years), 4,504 CVD deaths were identified (3,190 heart disease, 964 cerebrovascular disease, and 350 other CVD deaths). Compared to NH-White women, NH-Black and NH-NHPI women had a higher risk of CVD mortality ($HR_{NH\text{-}Black}$ = 1.61, 95%CI=1.48-1.76; $HR_{NH\text{-}NHPI}$ = 1.80, 95%CI=1.22-2.65) while NH-AA women had a lower risk of CVD mortality ($HR_{NH\text{-}AA}$ = 0.68, 95%CI=0.60-0.79). There was no significant association of CVD mortality for Hispanic women compared NH-White women ($HR_{Hispanic}$ = 0.91, 95%CI=0.80-1.03). Although the increased risk of CVD mortality remained higher in NH-Black and NH-NHPI women regardless of age at DCIS diagnosis, younger women (<50 years) had greater relative risk compared to older women (≥50 years) in stratified analyses ($HR_{NH\text{-}Black,\ <50}$ = 3.93, 95%CI=2.62-5.90, $HR_{NH\text{-}Black,\ \geq 50}$ = 1.56, 95%CI=1.43-1.71; $HR_{NH\text{-}NHPI,<50}$ = 4.19, 95%CI=1.04-16.97, $HR_{NH\text{-}NHPI,\ \geq 50}$ = 1.73, 95%CI=1.16-2.59). Risk of CVD mortality increased by year of diagnosis, especially among NH-Black and NH-NHPI women. NH-Black and NH-NHPI women had the highest cumulative incidence of CVD mortality at 5-years (1.51%, 95%CI=1.33%-1.72% and 1.53% 95%CI=0.81%-2.66% respectively) and 10-years (4.29%, 95%CI=3.90%-4.70% and 4.17% 95%CI=2.62%-6.26% respectively) post DCIS diagnosis.
Conclusions: NH-Black and NH-NHPI women diagnosed with DCIS had higher CVD mortality compared to NH-White women, especially among younger women and those diagnosed in recent years. Further studies are needed to understand multi-level factors driving the increased risk of CVD mortality in NH-Black and NH-NHPI women with DCIS.

#0912 Non-Hodgkin's lymphoma survival by neighborhood disinvestment and socioeconomic composition.

Jesse J. Plascak, Elizabeth Ghias, Daniel C. Trotier, James L. Fisher, Kami J. Maddocks, Jennifer A. Woyach

The Ohio State University Comprehensive Cancer Center, Columbus, OH

Background: Socioeconomic factors have been associated with adverse survival from non-Hodgkin's Lymphoma (NHL), but few studies have considered the role of neighborhood disinvestment. This study investigated associations among neighborhood socioeconomic composition, disinvestment (e.g., disrepair and deterioration), stage at diagnosis, and NHL survival.
Methods: Age, sex, marital status, race-ethnicity, diagnosis date, residence at diagnosis, health insurance, stage at diagnosis (localized, regional, distant), and histologic subtype (Diffuse large B-Cell lymphoma, follicular, Chronic lymphocytic leukemia / small lymphocytic lymphoma, other B-cell, and T-cell) were from 1209 Franklin County, Ohio residents diagnosed with non-Hodgkins lymphoma between 2010 and 2019 as recorded in the Ohio Cancer Incidence Surveillance System. Neighborhood disinvestment was from a virtual neighborhood audit of 6 indicators - garbage, graffiti, dumpsters, building conditions, yard conditions, abandoned buildings - within 5,000+ Franklin County Google Streetview location-dates estimated at residential addresses and diagnosis dates using spatio-temporal models. Census tract-level, neighborhood socioeconomic composition was measured by the Yost index - a validated composite of seven socioeconomic factors annually assessed from the US American Community Survey - and linked to each NHL case by residential census tract and year of diagnosis. We fitted accelerated failure time models of all-cause and NHL-specific survival time as functions of neighborhood socioeconomics, disinvestment, and stage, adjusted for covariates. Survival time was right-censored at the earliest of death from other causes, loss to follow-up, or end of follow-up (12/31/2020).
Results: Across 5308 person years, there were 362 all-cause and 163 NHL-specific deaths. Disinvestment and stage statistically interacted in models of all-cause but not NHL-specific deaths. Among those diagnosed regional stage, all-cause survival time decreased by 35% (95% CI: 7%, 55%), with each standard deviation increase in disinvestment after adjustment for covariates. There was no evidence of associations between disinvestment and all-cause survival among localized and distant stages, disinvestment and NHL-specific survival, and socioeconomic composition and NHL-specific survival.
Conclusion: Both neighborhood socioeconomic composition and disinvestment among those diagnosed at regional stage are independently associated with shorter all-cause, but not NHL-specific, survival among NHL cases within a Midwestern Metropolis.

#0913 Acuity circles policy and persistent socioeconomic disparities in liver transplantation.

Sungsu Park[1], Junho Song[2], Hyungjune Ku[3], Tehyun Phillip Eom[4], Sunghan Kim[4], Changmin Jo[5], Minkwan Kim[6], Amy Choi[7], Dongyeol Lee[8], Sangsoo Lee[3], Jihyun Park[9], Hyewon Kim[10], Seoyeong Ku[11], Heekyoo Kim[3]

[1]Daegu Catholic University School of Medicine, Daegu, Korea, Republic of,[2]Northwestern University - Chicago, Hershey, PA,[3]Kosin University College of Medicine, Busan, Korea, Republic of,[4]CHA University School of Medicine, Seongnam-si, Korea, Republic of,[5]Chung-Ang University College of Medicine, Seoul, Korea, Republic of,[6]Independent researcher, Gwangmyeong-si, Korea, Republic of,[7]Department of Medicine, Penn State College of Medicine, Hershey, PA,[8]Department of Medicine, Penn State College of Medicine, Chicago, IL,[9]Montini Catholic High School, Lombard, IL,[10]Hanyang University College of Natural Sciences, Seoul, Korea, Republic of,[11]Seoul Women's University, Seoul, Korea, Republic of

Background: The Acuity Circles policy, implemented by UNOS on April 2, 2020, aimed to improve geographic equity in liver transplantation by prioritizing local candidates with high medical acuity. However, concerns remain about whether this policy adequately addresses persistent socioeconomic disparities in transplant access. We evaluated the impact of Acuity Circles on disparities in deceased donor liver transplant (DDLT) rates across socioeconomic factors including race/ethnicity, insurance status, education, employment, citizenship, and geographic region.

Methods: Using UNOS data from adult HCC patients listed for liver transplant, we analyzed 13,589 patients in the 21-month periods before (n=7,380) and after (n=6,209) Acuity Circles implementation. We employed competing risks analysis with Aalen-Johansen cumulative incidence functions to estimate DDLT rates, accounting for death/deterioration as competing events. Socioeconomic disparities were assessed using Gray's test for equality of cumulative incidence functions. Time origin was listing date with era-specific censoring.

Results: Overall DDLT rates were comparable between the pre- and post-policy eras: 49.5% at 12 months pre-policy vs. 48.1% post-policy (Gray's test p=0.93). Regarding race/ethnicity, pre-policy, Asian patients had DDLT rates of 44.0% vs. 50.0% for White patients (reference) and 54.9% for Black patients. Post-policy, Asian rates remained lower at 44.9% vs. 49.0% for White patients, with Black patients at 52.7% (Gray's test: pre $p<0.001$, post $p<0.001$). By insurance status, private insurance patients maintained higher DDLT access compared to public insurance patients in both eras (Gray's test: pre p=0.002, post p=0.012). For education, patients with less than college education had slightly different DDLT rates compared to college graduates in both periods (49.4% vs. 48.0% pre-policy, 47.3% vs. 47.5% post-policy; Gray's test $p<0.001$ both eras). Additionally, US citizens had higher access than non-US citizens (p=0.001 pre, p=0.009 post), employed patients had better access than unemployed ($p<0.001$ both eras), and significant regional variation remained ($p<0.001$ both eras). Gender differences were not significant.

Conclusions: The Acuity Circles policy did not significantly alter overall DDLT rates or reduce existing socioeconomic disparities in liver transplantation. Despite its goal of improving geographic equity, race/ethnicity, insurance, employment, citizenship, and regional disparities persisted at similar magnitudes before and after implementation. These findings highlight the need for complementary policy interventions that directly address socioeconomic determinants of transplant access beyond geographic redistribution of organs.

#0914 Racial disparities in immune-related adverse events with immune checkpoint inhibitors: A systematic review and meta-analysis.

Toshiaki Takahashi[1], Yu Fujiwara[2], Ahmad Bouhuwaish[3], Kohei Chida[2], Rodrigo Paredes[4], Sarbajit Mukherjee[5]

[1]Department of Medicine, John A. Burns Sch. of Med. Univ. of Hawaii at Manoa, Honolulu, HI,[2]Department of Medicine, Roswell Park Comprehensive Cancer Center, Buffalo, NY,[3]Department of Public Health, Sechenov University, Moscow, Russian Federation,[4]Department of Medicine, Icahn School of Medicine at Mount Sinai, Mount Sinai West/Morningside, New York, NY,[5]Miami Cancer Institute | Baptist Health South Florida, Miami, FL

Background: There is insufficient data on whether immune-related adverse events (irAEs) from immune checkpoint inhibitors (ICIs) differ by race/ethnicity. The objective of our study was to systematically evaluate the incidence of irAEs by race to inform equitable treatment approaches.

Methods: We searched PubMed/MEDLINE and Embase from inception through December 16, 2024 for randomized trials and cohort studies in adults receiving ICIs. Race-specific incidence was pooled using a generalized linear mixed-effects proportional meta-analysis. Within-study odds ratios (ORs) versus White were pooled with random-effects inverse-variance models; heterogeneity was summarized with I^2 and inspected with leave-one-out analyses. Subgroup analyses were conducted based on ICI class (PD-1 monotherapy and dual PD-1/CTLA-4 therapy), tumor type (lung cancer), and study design (excluding organ-specific irAE reports and excluding registry-based database studies).

Results: Of the 3,397 records screened, 510 full-text articles were assessed for eligibility, and 24 studies comprising 109,902 patients were included in the analysis. In the overall population, the pooled incidence of irAEs was 13.7% (95% CI, 2.7-47.5) in Asian, 20.6% (8.6-41.7) in Black, 16.0% (5.1-40.5) in Hispanic, and 20.5% (11.1-34.8) in White patients, with substantial heterogeneity (I^2=85.7-99.8%). Pooled ORs versus White were not statistically significant: non-White 1.28 (95% CI 0.82-1.98), Asian 1.67 (0.76-3.70), Black 1.37 (0.83-2.27), and Hispanic 0.89 (0.55-1.42); all p>0.05. Findings showed a consistent trend across the ICI-class subgroups, the lung-cancer subgroup, and the subgroup excluding registry-based studies.

Conclusion: No significant differences in irAEs were observed among races. These findings support equitable access to ICI therapy and culturally competent toxicity monitoring.

Pooled incidence of irAEs and odds ratios (ORs) by race. Abbreviation: NA, not applicable

	Overall population					**Sensitivity analysis, excluding studies reporting only organ-specific irAEs**

#0915 Disparities and underutilization of MyChart among patients with pancreatic ductal adenocarcinoma.

Anjani D. Kapadia[1], Yijia He[2], Samantha Kwock[3], Bradford Chong[4]

[1]Internal Medicine and Pediatrics, University of Chicago, Chicago, IL,[2]Center for Health and the Social Sciences, University of Chicago, Chicago, IL,[3]Pritzker School of Medicine, University of Chicago, Chicago, IL,[4]SectionSection of Gastroenterology, Hepatology, and Nutrition, Department of Medicine, University of Chicago, Chicago, IL

Background: Electronic health record portals such as MyChart support patient engagement, communication, and access to medical information. Although engagement may vary across demographic and socioeconomic groups, the relationship between portal utilization and clinical characteristics in oncology populations is poorly understood. In pancreatic ductal adenocarcinoma (PDAC), where timely diagnosis and treatment are critical, it is essential to understand how portal engagement relates to health outcomes.
Objective: We aimed to determine predictors of MyChart utilization among patients with PDAC and associations between portal engagement and stage at diagnosis. We hypothesized that greater portal use is protective against advanced stage diagnosis.
Methods: We conducted a retrospective cohort study of patients diagnosed with PDAC at the University of Chicago between 2012-2022. MyChart activity was abstracted and categorized into appointment/scheduling, health maintenance/test results, clinical messaging/document viewing, eCheck-in/eVisit, medication-related actions, and other categories. Demographic variables included age, sex, race, ethnicity, and Area Deprivation Index (ADI). Clinical variables included stage at diagnosis. We used multivariable logistic models for MyChart use and for pre-diagnosis use predicting stage, and multivariable linear regression for post-diagnosis engagement, modeling log-transformed session counts by stage.
Results: Among 1,463 patients with PDAC, 478 used MyChart after diagnosis. Black patients had lower odds of MyChart use compared with white patients (OR 0.66, p = 0.014), and those in the highest-deprivation neighborhoods (ADI 75-100) had substantially lower engagement (OR 0.52, p = 0.006). Age, sex, and ethnicity were not significant predictors of utilization. Higher MyChart utilization after diagnosis was associated with lower odds of advanced-stage disease (OR = 0.82, p = 0.007), and each category of activity showed significant or near-significant inverse associations with advanced stage. High clinic-hours use showed a stronger inverse association with advanced stage (OR 0.78, p = 0.001) than after-hours use (OR 0.86, p = 0.033). Pre-diagnosis MyChart use (n = 101) was also associated with lower odds of advanced-stage presentation (OR 0.59, p = 0.026), though intensity of pre-diagnosis activity was not significantly associated with stage.
Conclusions: Our findings highlight clear disparities in MyChart engagement among vulnerable populations. MyChart is underutilized in patients with advanced stage PDAC, both before and after diagnosis. These patterns suggest that patients who interact more frequently with digital health tools may enter the care pathway earlier or maintain stronger connectivity to healthcare services. Addressing disparities in digital engagement may support earlier diagnosis and streamlined cancer care.

#0916 Prevalence of screen-detectable cancers among adults aged 18-49 years: Findings from HINTS-SEER.

Gaurav Y. Kulkarni[1], Matthew Untalan[1], Wayne R. Lawrence[2], Ami E. Sedani[3], Subhankar Chakraborty[4], Dede K. Teteh-Brooks[5], **Aldenise P. Ewing**[6]

[1]The Ohio State University, Columbus, OH,[2]National Institutes of Health, Betheseda, MD,[3]School of Public Health, UT Health Houston, Houston, TX,[4]College of Medicine, The Ohio State University, Columbus, OH,[5]MD Anderson Cancer Center, Houston, TX,[6]College of Public Health, The Ohio State University, Columbus, OH

Background/Purpose: Over the past two decades, the incidence of cancers diagnosed among adults younger than age 50 (e.g., early-onset cancer) has risen globally. Emerging evidence indicates these trends span multiple cancer types, disproportionately burdening women, and racially and ethnically minoritized populations. However, population-level estimates of the burden of screen-detectable cancers among younger adults remain poorly characterized, limiting efforts to inform public health strategies. This study aims to quantify the prevalence and distribution of screen-detectable cancers among adults diagnosed before age 50.
Methods: We utilized 2022 data from Health Information National Trends Survey-Surveillance, Epidemiology, and End Results (HINTS-SEER), a registry-linked national survey of cancer survivors. Weighted prevalence estimates of cancers survivors among adults aged 18-49 were calculated to describe screen-detectable cancers among adults diagnosed before age 50. Cancer sites were categorized as breast, colorectal, cervical, lung, prostate, and non-melanoma skin. Weighted estimates accounted for complex survey design. Findings were stratified by birth sex, race and ethnicity.
Results: The analytic sample included 298 respondents (weighted N ≈ 119,131). Screen-detectable cancers accounted for 60.0% of diagnoses. By site, prevalence estimates were breast (29.0%), non-melanoma skin (16.1%), colorectal (7.2%), prostate (4.3%), lung (2.3%), and cervical (1.0%). Mean age varied by site, from 28.2 years for cervical cancer to 43.0 years for colorectal cancer. The sample was predominantly female (67.6%) and included respondents who were non-Hispanic White (73.6%), Hispanic (13.4%), non-Hispanic Asian (7.6%), non-Hispanic Black (3.2%), and non-Hispanic other (2.2%). Most participants (87.3%) reported at least one first- or second-degree relative with cancer, and one-third (31.6%) reported undergoing genetic testing.
Conclusions (Interpretation/Implications): Screen-detectable cancers represent a substantial proportion of early-onset cancers, driven primarily by breast and non-melanoma skin cancers, with meaningful contributions from colorectal, prostate, lung, and cervical cancers. These findings highlight critical opportunities to refine screening initiation ages, improve awareness, and implement risk-based screening strategies for younger populations. Although subgroup estimates were limited by small sample sizes, overall patterns underscore the urgency of targeted prevention and early detection efforts. Registry-linked national surveys such as HINTS-SEER provide essential context to guide policy and resource allocation tin response to the growing burden of early-onset cancers.

#0919 Provider communication strategies that promote HPV vaccination in adults 27-45 years for oropharyngeal cancer prevention: A call to action.

Lauryn Trisha Kibugi[1], Yaeli Greenblum[1], Isabella Banan[1], Iris Chang[1], Edward Rego[1], Samantha Kaplan[2], Vincent D'Anniballe[3], Nosa Osazuwa-Peters[4]

[1]Duke University, Durham, NC,[2]Medical Center Library & Archives, Duke University, Durham, NC,[3]Medical Scientist Training Program, Duke University, Durham, NC,[4]Duke University School of Medicine, Durham, NC

Background: At least 21,000 oropharyngeal cancer (OPC) cases are diagnosed annually, with an estimated 70% attributable to Human papillomavirus (HPV) infection. Unlike cervical cancer, there are no established screening tools for early OPC detection, making vaccination the only proven method of prevention. In 2018, the FDA expanded HPV vaccine eligibility to adults up to age 45. This expansion heightens the need for effective shared decision-making between providers and patients. We conducted a scoping review to examine the landscape of provider communication strategies aimed at promoting HPV vaccine uptake in adults aged 27-45, with a focus on OPC prevention.
Methods: A medical librarian with expertise in systematic searching developed a comprehensive strategy using keywords to capture the concepts of HPV vaccination, patient-provider communication, vaccine uptake, and OPC. The databases MEDLINE, Embase, and the Web of Science were searched from inception to September 4, 2025. All results were compiled in EndNote and imported into Covidence for deduplication and screening.
Results: Of the 325 studies reviewed, 43 met the criteria for full-text screening and 9 were included in the analysis. Concerningly, only one study included otolaryngologists, who are critical in managing OPC. Eight studies consisted primarily of cross-sectional studies, surveys, and interviews with dental providers. Few evidence-based communication strategies specific to head and neck cancer prevention were identified. One promising approach was a dialogue tool that facilitated conversations about the HPV vaccine between dental providers and patients. However, significant barriers to uptake were identified: only half of dental providers believed it was their role to recommend the HPV vaccine, and only 18% of providers actually made recommendations. Only 16% of referred patients received their first dose within 6 weeks. Additional barriers included limited time, hesitancy, inadequate training, and cost. Limitations: Many dental providers indicated that they lacked sufficient training to counsel patients about HPV vaccination and oropharyngeal cancer prevention.
Conclusions: Across the literature, one study evaluated communication strategies among otolaryngologists—despite their direct involvement in the management of HPV-related OPC. This near-total absence of ENT-focused communication research signals a missed opportunity for specialty engagement. Given the expanded adult HPV vaccine indication and the rising incidence of HPV-related OPC, the field urgently needs targeted provider-facing communication tools to promote vaccination in adults aged 27-45. This review serves as a call to action for otolaryngology, dentistry, and primary care alike to fill this gap develop evidence-based communication strategies that support mid-adult HPV vaccine promotion.

#0922 Expanding HPV-related cancer awareness through multichannel communication among youth and young adults living in Los Angeles.

Samantha B. Verganza[1], Patricia Escobedo[2], Rosa Barahona[3], Letech Caldera-Huerta[3], Lourdes Baezconde-Garbanati[2]

[1]USC Norris Comprehensive Cancer Center, Los Angeles, CA,[2]Keck School of Medicine of USC, Los Angeles, CA,[3]USC, Los Angeles, Los Angeles, CA

Background: In Los Angeles County, HPV prevention remains challenging due to social media misinformation and limited audience-segmented materials. Most campaigns target parents of adolescents rather than youth and young adults, who face the highest risk for new infections. HPV communication has also focused primarily on women and cervical cancer, overlooking other HPV-related cancers that affect people of all genders. Using a community-driven audience segmentation approach, we developed multi-media HPV informational materials to raise awareness among youth and young adults across Los Angeles County.
Methods: From 2024-2025, seven listening sessions and three focus groups with LA County youth and young adults identified preferred communication channels, messaging, and information gaps. From July 2024-November 2025, the USC MICEO campaign disseminated tailored materials through social media, community partners, and cancer wellness hubs. The USC Norris Cancer Center Office of Community Outreach and Engagement and other partners supported distribution. Community health worker trainings on HPV-related cancers and prevention strategies were also conducted.
Results: Youth and young adults were reached through Instagram, YouTube, billboards, and community outreach. The campaign produced seven informational videos, eleven educational posts, and five billboard variations in Spanish, English, and Simplified Chinese. Two informational handouts on cervical cancer and HPV-related cancers supported outreach efforts. Thirty-six community health workers were trained and received two toolkits to guide dissemination. Messaging improved visibility of HPV, affected populations, HPV-related cancers, and recommended protective behaviors. Preliminary analytics show more than 8,162 social media views and over 926 in-person interactions during community outreach.
Conclusion: MICEO delivered audience-segmented HPV-related cancer information through diverse communication channels to address persistent information gaps among youth and young adults. Ongoing pre- and post-surveys are assessing changes in knowledge, attitudes, behaviors, and beliefs to inform future HPV prevention campaigns aimed at reducing cancer burden in LA County communities.

#0923 Preliminary results of a community-based randomized controlled trial to raise colorectal cancer awareness: The Community Genetic Navigation Engagement Specialist (CoGENES) Program.

Bianca Rosales[1], **Diego Alvarez-Lopez**[2], Janet Rodriguez[3], Joel Sanchez Mendez[2], Charite N. Ricker[4], Rosa Barahona[2], Heinz Josef Lenz[4], Lourdes Baezconde-Garbanati[4], Mariana C. Stern[5]

[1]USC Norris Westside Cancer Ctr., Inglewood, CA,[2]USC - University of Southern California, Los Angeles, CA,[3]USC Norris Comprehensive Cancer Center, Los Angeles, CA,[4]Keck School of Medicine of USC, Los Angeles, CA,[5]Associate Professor, Dept. of Prev. Medicine, USC Norris Comprehensive Cancer Center, Los Angeles, CA

Introduction: Knowledge and awareness of colorectal cancer (CRC) prevention and genetic testing remain limited in many Los Angeles County (LAC) communities. To address this, we trained 42 CRC-specialized community health workers (CoGENES) through a train-the-trainer program. We present preliminary results of a community-based randomized controlled trial (RCT) to evaluate the impact of materials and training delivered by CoGENES as part of an NCI funded PE-CGS network program at USC.
Methods: A two-armed, single blinded RCT was launched in August 2024. Participants are ≥ 18 years of age and residents of LAC. The intervention included the delivery of an educational session by CoGENES and an *a priori* developed educational handbook. The control group received standard CRC and genetic testing materials. Data on demographics, acculturation, cultural values and fatalism, health literacy, numeracy, generalized self-efficacy (GSE), genomic knowledge, cancer prevention behaviors and attitudes, were collected at baseline with validated or team-developed surveys. Follow-up surveys at 6-12 weeks and 6-8 months after intervention receipt evaluate changes in GSE, genomic knowledge, and cancer prevention behaviors. Paired dietary changes were evaluated using McNemar's test. Paired t-tests and independent t-tests were used to compare baseline and follow-up results within and between arms, respectively.
Results: A total of 138 participants (mean age = 48.8 years, SD = 13.6) were randomized to the intervention (n = 72) or control (n = 66) arm, with no baseline differences. All were Hispanic/Latine, most were female (83%), Mexican (64%), Catholic (61%), married (50%), completed ≤11th grade education (51%), and spoke primarily Spanish (69%). Interim analyses showed that by 6-8 weeks, participants in the intervention arm demonstrated improved dietary behaviors, with a higher proportion limiting processed food intake (rarely or never: 48.6% at baseline vs 69.8% at follow-up; $p < 0.05$). We observed significant improvements in cancer genetic knowledge within the intervention arm at 6-12 weeks, with more correct answers (mean difference = 4.32; $p < 0.01$), and fewer "don't know" responses (mean difference = -5.40; $p<0.01$). These improvements were greater than in the control arm: 2.7 more correct answers ($p<0.01$) and 3.25 fewer "don't know" responses ($p<0.01$). Genetic literacy and comprehension scores also improved (mean difference = 11.38; $p < 0.01$), though not significantly more than in the control group (difference-in-differences = 2.20; $p = 0.43$).
Conclusion: We present preliminary evidence that deploying CRC prevention trained educators in a community setting, may improve CRC genetic knowledge, and highlights opportunities and willingness to improve lifestyle and dietary patterns to reduce CRC incidence.

#0924 Association between proxy markers of insulin resistance and colorectal cancer risk: results from a large scale prospective cohort of Korean adults.

Sukhong Min[1], Hyobin Lee[1], Sinyoung Cho[2], So-Yoon Lee[1], Jeongheon Kim[1], Ji-Yeob Choi[3], Daehee Kang[1]

[1]Department of Preventive Medicine, Seoul National University College of Medicine, Seoul, Korea, Republic of,[2]Department of Family Medicine, Seoul National University Hospital, Seoul, Korea, Republic of,[3]Department of Biomedical Sciences, Seoul National University College of Medicine, Seoul, Korea, Republic of

Background: Colorectal cancer (CRC) remains one of the most common cancers in Korea, underscoring the importance of identifying modifiable risk factors. Although insulin resistance has been implicated in CRC development, existing evidence remains inconsistent, and direct measures of insulin resistance are not routinely collected in clinical practice. This limitation highlights the potential utility of simple proxy markers of insulin resistance in epidemiologic and clinical settings. In this study, we investigated the associations between several proxy insulin resistance markers and CRC risk among Korean adults.

Methods: Using data from the Korean Genome and Epidemiology Study Health Examinee cohort, we evaluated the associations between several proxy markers of insulin resistance, including the TG/HDL ratio, triglyceride-glucose index (TyG), TyG-BMI index, TyG-waist circumference index (TyG-WC), TyG-waist-to-height ratio index (TyG-WHTR), and the metabolic score for insulin resistance (METS-IR), and CRC risk using Cox regression models. Subgroup analyses were stratified by sex, age, diabetes status, and prior screening experience, and sensitivity analyses were conducted based on varying follow-up durations.

Results: During a median follow-up period of 9.3 years, 795 new CRC cases were observed among 106,965 Koreans aged 40-69 years (36,899 men and 70,066 women). For the TG/HDL ratio, individuals in the highest quartile had a significantly elevated CRC risk compared with the lowest quartile (HR: 1.23, 95% CI: 1.00-1.53). A similar pattern was observed for the TyG and TyG-WC indices, where quartile 4 was associated with increased CRC incidence (TyG Q4 HR: 1.30, 95% CI: 1.04-1.63; TyG-WC Q4 HR: 1.36, 95% CI: 1.01-1.83). Finally, the METS-IR index showed a graded association, and the highest quartile was significantly associated with CRC incidence (Q4 HR: 1.26, 95% CI: 1.02-1.57).

Conclusions: In this large population-based cohort, multiple surrogate markers of insulin resistance were independently associated with an increased risk of colorectal cancer, with the strongest effects observed in the highest quartiles. These findings indicate that metabolic dysregulation related to insulin resistance contributes to colorectal carcinogenesis and that simple lipid-glucose-anthropometric markers may help identify individuals at elevated risk.

#0925 Examining trends of public interest in fasting and cancer-fasting clinical trials in the U.S..

Alanna Burwell[1], Maria Mogollon[2], Alexander Hernandez[2], Nadine Friedrich[2], Pao-hwa Lin[3], Stephen J. Freedland[2]

[1]North Carolina Institute for Medical Research, Durham, NC,[2]Department of Urology, Samuel Oschin Comprehensive Cancer Institute, Cedars-Sinai Medical Center, Los Angeles, CA,[3]Department of Medicine, Duke University School of Medicine, Durham, NC

Background: Interest in fasting related to cancer has increased as evidence suggests fasting may have anti-cancer benefits. Fasting has been shown to deprive cancer cells of nutrients, thereby inhibiting their growth and proliferation and making them more sensitive to chemotherapy in preclinical studies. Clinical trials incorporating fasting have grown over the years; however, recruiting participants remains challenging due to eligibility criteria, protocol complexities, and public interest. Identifying public interest in fasting and cancer, as well as in cancer-fasting clinical trials could help improve methods to raise awareness of the importance of fasting clinical trials and increase the number of trials to improve cancer.
Objective: To determine if public interest in fasting and cancer corresponds with cancer fasting clinical trials.
Methods: U.S. Google Trends data were queried by region from January 2004 to October 2025 to identify public interest in fasting overall (across all categories) and by cancer. Data are presented using relative search interest (RSI) ranging from 0 to 100, with 100 indicating the most searched, 50 representing half as many searches, and zero or null indicating insufficient data. Data from clinicaltrials.gov and Surveillance, Epidemiology, and End Results (SEER) Program were queried and used for trend analysis.
Results: Public interest in fasting in general, not restricted to cancer, across all categories was low prior to 2011 (RSI generally <20). RSI began to increase slightly after 2011 and grew to 30 by 2016. There was a sharper increase after 2016 with interest peaking in November 2019 (RSI=100) but has remained consistently high since (RSI range 50-80 since 2019). When examining only cancer interest, fasting related to cancer remained low with occasional spikes, but began to increase after 2016, in-line with the increased interest in fasting not limited to cancer. Indeed, interest in fasting and cancer largely mirrored general interest in fasting trends. Among all states with data, most had an RSI of 75 or higher for fasting across all categories. From 1991 to the present, 255 clinical trials have been initiated on fasting and cancer. The number of new trials per year slightly rose from 2000 to 2008, then dipped a bit, and then grew again slightly from 2013 (15 new trials in 2013) to 2025 (18 new cancer-fasting trials in 2025).
Conclusions: Public interest in fasting and cancer in the past ~12 years has grown 2-3-fold and been sustained at a high level over the past ~8 years. In contrast, the number of new trials started per year has barely changed over this time. While the reasons fasting trial numbers have lagged public interest are unknown, we speculate challenges enrolling and receiving funding for dietary trials may play a role. Given promising preclinical data coupled with public health interest, there should be increased funding and support for fasting trials in patients with cancer.

#0926 Prolonged high fat dietary intake increases pancreatic intraepithelial neoplasia to cancer progression.

Urvinder Kaur Sardarni[1], Erika Y. Faraoni[2], Alyssa Waller[1], Lincoln Strickland[1], Baylee O'Brien[3], Jesse Cox[1], Florencia McAllister[2], Jennifer Bailey-Lundberg[1]

[1]University of Nebraska Medical Center, Omaha, NE,[2]UT MD Anderson Cancer Center, Houston, TX,[3]Texas A&M Medical School, College Station, TX

Background: Emerging evidence implicates dietary macronutrient composition as a key modulator of pancreatic tumorigenesis. While the high-fat diet (HFD) drives acinar-to-ductal metaplasia (ADM) and pancreatic intraepithelial neoplasia (PanIN) progression in *Kras*^{G12D} mice, the impact of ketogenic diet (KD) remains controversial. To determine how KD affects early *Kras*-driven neoplasia, we investigated the effects of KD, HFD, and low-fat diet (LFD) on pancreatic disease initiation and progression using the *Ptf1a*^{CreERT2} *Kras*^{G12V} *(KC*^{Acinar}*)* mouse model.

Methods: Six- to eight-week-old *KC*^{Acinar} and wild-type (WT) mice were maintained on standard chow (SD) or switched to LFD, HFD, or KD for four weeks before tamoxifen-induced *Kras*^{G12V} activation. Mice were monitored for survival, body weight, and glucose tolerance. Pancreatic tissues were collected for histopathological evaluation, trichrome staining, and immunohistochemistry. Reverse-phase protein array (RPPA) of pancreatic lysates and serum cytokine profiling were performed to assess signaling and systemic changes.

Results: KD-fed *KC*^{Acinar} mice showed the shortest survival (median 26 ± 7 days) compared with SD (87 ± 29; p = 0.02) and LFD (57 ± 27; p = 0.02), while HFD also reduced survival compared with SD (35 ± 25; p = 0.05). KD feeding induced glucose intolerance in both WT and *KC*^{Acinar} mice. Histological analysis revealed that both KD- and HFD-fed *KC*^{Acinar} mice developed a higher incidence of invasive PDAC with fibrosis, accompanied by reduced CD8^{+} T-cell infiltration and increased stromal CD39 expression relative to tumor compartments. Proteomic profiling showed increased Akt, phospho-S6, Paxillin, and YTHDF2, and decreased PUMA, STAT5A, PHGDH, FASN, and ASNS expression in KD- and HFD-fed *KC*^{Acinar} mice. Pathway enrichment analysis identified upregulation of EGFR tyrosine kinase inhibitor resistance, chemokine, PI3K-Akt-mTOR, Rap1, and VEGF signaling pathways. Serum cytokine profiling further revealed elevated systemic levels of Ang-2, CCL6, LDLR MMP-9, PAI-1, PTX3, TNFSF13B, and OPG in KD-fed *KC*^{Acinar} mice.

Conclusions: Dietary lipid content before oncogenic *Kras* activation critically shapes pancreatic cancer development. Both ketogenic and high-fat diets accelerated progression from PanIN to invasive PDAC, accompanied by fibrosis, immune suppression, and activation of PI3K-Akt-mTOR and EGFR signaling. These findings reveal that lipid-rich diets can potentiate oncogenic and inflammatory pathways in the pancreas and caution against the use of ketogenic diets in prevention settings or early stages of pancreatic cancer.

#0927 Impact of loneliness on dietary habits of individuals with or without cancer history.

Sayantani Sarkar

Center for Information Technology Research in the Interest of Society and the Banatao Institute, University of California Berkeley, Berkeley, CA

Introduction Loneliness is a widespread health concern that affects health behaviors, lifestyle, physical health, psychological well-being, and overall quality of life of individuals. Limited literature exists about how loneliness impacts healthy dietary habits among individuals with and without a cancer history. Hence, the purpose of our study is to investigate the association between self-reported loneliness and daily dietary consumption habits.

Method Secondary analysis of the cross-sectional data collected via the Health Information National Trends Survey-HINTS-7 (2024), comprising US adults with or without a cancer history. Final analysis includes 5,597 individuals with (n=844) and without (n=4,753) cancer history. The predictor was loneliness, measured with four items on a 5-point scale, with a total score ranging from 4 to 20 (Never=4, Mild=5-8, Moderate=9-12, Severe=13- 20). The outcome variables were the amounts of daily fruit and vegetable consumption (<2 or≥2 cups per day). Descriptive statistics and multivariable logistic regression were conducted using statistical software STATA.

ResultsAmong cancer survivors, the majority were white (75.4%), male (55.7%), aged ≥75 years (32.16%), and college-educated (79.4%). Of those without a history of cancer, 60.7% were white, 51.4% were male, 5.0% were aged ≥75 years, and 73.6% were college educated. About 37% of cancer survivors and 35% of those without cancer reported obesity. Among cancer survivors, 30.8% reported consuming ≥2 cups of vegetables and 23.6% consuming ≥2 cups of fruits per day. Among individuals without a history of cancer, 27.5% reported consuming ≥2 cups of vegetables and 19.4% consuming ≥2 cups of fruits per day. More than 62% cancer survivors suffer from some degree of loneliness, including 10.7% reporting severe loneliness. Among those without cancer, 64.8% reported loneliness, including 13.7% stating severe loneliness. In the regression model, a one-unit increase in loneliness score is associated with 3% lower odds of consuming vegetables (OR = 0.97, 95% CI = 0.95-0.99, p = 0.007). There was no statistically significant association between loneliness and fruit intake (OR=0.98, 95% CI 0.95-1.02, p=0.271). After incorporating the interaction term into the model, we found that the relationship between loneliness and vegetable or fruit intake does not differ significantly between the two groups.

Conclusion Loneliness impacts vegetable consumption, highlighting the importance of screening for loneliness, regardless of oncologic status, to maintain a healthy dietary intake.

#0928 Variability in anthocyanin content among commercial blueberries and implications for dietary cancer prevention.

Noemi Y. Li, Lane Firestone, William W. Li, Vincent W. Li

The Angiogenesis Foundation, Cambridge, MA

Early intervention through dietary cancer prevention may reduce tumor risk, as supported by experimental models and epidemiologic studies linking diet to lower cancer incidence. Mechanisms of cancer prevention for many edible fruits are mediated by bioactive phytonutrients. For example, consumption of two servings of blueberries per week was associated with a 25% lower cancer mortality among breast cancer patients in the Nurses' Health Study, and anthocyanin consumption was linked to a 22% reduced risk of colorectal cancer in a meta-analysis. Anthocyanins, a major class of bioactive flavonoids in blueberries, modulate endothelial growth and inhibit VEGF-driven angiogenesis in preclinical models, suggesting that differences in anthocyanin concentration across blueberry cultivars may influence their anticancer potential. Commercially grown blueberries are available in a variety of cultivars and regions, potentially resulting in substantial variability in anthocyanin content and bioactivity. To investigate this and identify candidates for mechanistic studies, blueberries were collected from 11 commercially available sources. Samples were frozen at -20°C, pulverized, solvent-extracted, and analyzed by high-performance liquid chromatography (HPLC) in triplicate, using cyanidin-3-0-glucoside (C3G) as a validated standard. Anthocyanin concentrations ranged from 0.204 to 4.244mg/g wet weight (C3G equivalents). Wild lowbush Maine blueberries contained the highest anthocyanin concentrations and had a distinct chromatographic profile, while highbush cultivars, which dominate U.S. commercial blueberry production, showed more variable levels, with several also ranking relatively high. Overall, these findings demonstrate that anthocyanin content differs significantly among blueberry types and provide a rationale for selecting specific cultivars for mechanistic studies of dietary angioprevention. Based on these results, representative extracts (high and low anthocyanin content) were selected for subsequent in vitro studies of endothelial tube formation. Such comparative biochemical characterization is essential to optimize the design of future investigations into the cancer-preventive potential of blueberry-derived anthocyanins.

#0929 High red meat diet promotes colorectal tumorigenesis via gut microbiota mediated Th17/Treg imbalance.

Yamei Hu[1], Yating Wei[2], Runjie Song[3], Yilin Tang[2], Dongli Pei[2], Zigang Dong[2]

[1]Department of Pathology, The Third Affiliated Hospital of Zhengzhou University, Zhengzhou University, Zhengzhou, China,[2]Department of Pathophysiology, School of Basic Medical Sciences, Zhengzhou University, Zhengzhou, China,[3]School of Life Sciences, Zhengzhou University, Zhengzhou, China

Background: Excess red and processed meat consumption is a known risk factor for colorectal cancer (CRC), but the underlying mechanisms remain unclear. Given that dietary components reshape gut microbial ecology and mucosal immunity, we hypothesized that high red meat consumption promotes CRC by disrupting microbiota-immune crosstalk that maintains intestinal homeostasis.
Methods: The C57BL/6 mice were fed isocaloric diets with increasing proportions of red meat-derived protein (20%, 50%, 100%) compared with a 20% casein control. Tumorigenesis was assessed in azoxymethane (AOM)/dextran sulfate sodium (DSS)-induced mouse and $Apc^{Min/+}$ mouse models, complemented by orthotopic MC38-Luc-implantated mouse models as well as AOM/DSS-induced $Lgr5^{GFP\text{-}Slp\text{-}mCherry}$ transgenic mouse engineered to trace intestinal stem cells ($GFP^{+}mCherry^{-}$) and tumor microenvironmental cells ($GFP^{-}mCherry^{+}$). Colonic tumors were subjected to single-cell RNA sequencing to delineate immune landscape shifts, while fecal samples were analyzed by metagenomics and metabolomics to profile microbiota and microbial metabolites.
Results: Higher dietary red meat led to significantly increased colonic tumor burden in a dose-dependent manner. scRNA-seq revealed a progressive shift toward a pro-inflammatory T cell milieu with escalating Th17/Treg ratios: 0.26 (control diet), 0.44 (20% red meat diet), 0.61 (50% red meat diet) and 0.71 (100% red meat diet). Th17 transcriptional signature including IL17A and RORγt as well as IL-6/STAT3 signaling was enhanced in tumors from red meat-fed mouse, consistent with amplified Th17 responses. Metagenomic profiling identified the depletion of a commensal consortium “PFIO” comprising *Parasutterella excrementihominis*, *Faecalibaculum rodentium*, *Ileibacterium valens* and *Oscillospiraceae* species linked to short-chain fatty acid synthesis and bile acid homeostasis. Metabolomic data confirmed reduced SCFA and secondary bile acids levels, consistent with an inflammatory gut environment conducive to Th17 polarization.
Conclusions: These findings define a microbiota-Th17/Treg axis that mechanistically links red meat consumption to colorectal tumorigenesis. Disruption of SCFA-producing commensals amplifies Th17 dominance, driving tumor-promoting inflammation. Therapeutically restoring microbiota composition or Th17/Treg balance may offer preventive strategies for red meat diet associated CRC.

#0930 Mediterranean versus Western diet - preventative and interventional effects of dietary lipids on colorectal tumor growth and biology.

Cara C. Wallingford[1], Anindita Mahanty[1], Revan Hammontree[1], Alexa Magstadt[2], Jennifer Davis[1]

[1]Cancer Biology, University of Kansas Medical Center, Kansas City, KS,[2]University of Kansas, Lawrence, KS

The purpose of this study was to examine the preventative and interventional effects of different fat sources (lard verses olive oil) and their respective lipid components in a Western-style high-fat diet and Mediterranean-style high-fat diet on tumor biology *in vivo* in a Cre-lox mouse model called iKAP (inducible Kras, Apc, p53) of colorectal cancer (Boutin et al, *Genes & Development* 2017, 31:370).
Experimental Procedures: At 8-11 weeks of age, mice are randomized to a control lard-based 10% fat diet with high fiber (low-fat diet, LFD), a lard-based 45% fat diet with low fiber (high-fat diet, HFD) or olive oil-based 43% fat Mediterranean diet (MD) with the fiber matched to the LFD control. To measure diet-induced metabolic dysfunction, body composition and glucose tolerance are measured with EchoMRI and glucose tolerance tests (GTT) every three and six weeks, respectively. After 12 weeks post-randomization on diet, mice undergo a submucosal induction with 4-hydroxytamoxifen (4-OHT), which deletes loxP conditional *Apc* and *Trp53* in intestinal cells expressing the Villain promoter, thus causing tumorigenesis. Endoscopies are done every two weeks and tumor growth is measured by percent luminal occlusion - or the percent of the lumen taken up by the tumor over time - until end-of-study (one year or mortality due to tumor burden). In addition to understanding how the two diets affect tumor growth when given before tumor development, an arm of the study aims to understand the effects of an interventional diet post-tumor initiation. To accomplish this, a proportion of mice on LFD or HFD will be assigned to MD two weeks after induction with tamoxifen.
Results: At 12 weeks post-randomization with diet, mice on both HFD and MD show evidence of metabolic dysfunction (higher body weight, high fat mass and glucose intolerance) compared to LFD. In addition, mice on HFD and MD consume more chow. Interestingly, preliminary data suggests that systemic cholesterol levels in MD and LFD mice are at similar levels and significantly lower than that of HFD mice. Orthogonal *in vitro* studies using immunofluorescence, fatty acid oxidation assays and molecular profiling of protein pathways involved in lipogenesis (SREBP1/2, FASN, ABCA1) and cancer cell growth/metabolism (AKT, PI3K, mTOR) are ongoing to understand the influence of different dietary fatty acids (oleic and palmitic acids) and cholesterol/phytosterols in the context of tumorigenesis.
Conclusion: Based on preliminary findings, both the Western HFD and MD effectively induce metabolic dysfunction in an iKAP murine model. However, the lipid components of the diets are significantly different; thus, differences in tumor metabolism and growth remain a pertinent question.

#0931 Air pollutants remodel mutant epithelia toward a convergent lung adenocarcinoma progenitor state.

Michelle M. Leung[1], Maria Zagorulya[2], Tej Pandya[2], Marcellus Augustine[2], Anthony J. Griffen[3], Alix Le Marois[2], Sophia Ward[2], Hubert Slawinski[2], Alejandro Suarez-Bonnet[4], Simon L. Priestnall[4], Alexandros Hardas[4], Erik Sahai[2], Lindsay M. LaFave[3], Eva Gronroos[2], Nicholas McGranahan[1], William Hill[2], Clare Weeden[2], Charles Swanton[2]

[1]University College London (UCL) Cancer Institute, London, United Kingdom,[2]The Francis Crick Institute, London, United Kingdom,[3]Albert Einstein College of Medicine, New York, NY,[4]Royal Veterinary College, London, United Kingdom

The lung epithelium harbours progenitor populations, including basal, club, neuroendocrine, and alveolar type I/II (AT1/AT2) cells. A highly plastic Krt8+ alveolar intermediate cell state (KAC) arises in *Kras*-driven tumorigenesis and in lung injury models. Environmental particulate matter (PM) exposure promotes lung tumorigenesis through macrophage-derived interleukin-1β (IL-1β). How *EGFR* mutations (EGFRm), the most common genomic driver of lung cancer in never-smokers, and tumour promotion drive lung adenocarcinoma (LUAD) at the single cell level from diverse lung epithelial lineages remains unclear. Understanding this will aid development of molecularly targeted prevention approaches, particularly in never-smokers.

We generated mouse models of lineage-specific activation of *EGFR-L858R* within basal, club, neuroendocrine, and AT2 lineages. LUAD development and lineage convergence were assessed using histology and snRNA-seq across 37,627 cells from 100 mice. For PM effects, *EGFR-L858R* induction in AT2 cells was achieved via Ad5-Spc-Cre intratracheal instillation, followed by PM or PBS exposure. 10X multiome snRNA-seq (34,459 AT2-lineage cells) and snATAC-seq were used to profile transcriptional and epigenetic changes. EGFRm precision-cut lung slices (PCLS) were exposed to PM *ex vivo* in presence of IgG or anti- IL-1β blocking antibodies.

Our analysis revealed that LUAD arises from basal, club, neuroendocrine, and AT2 lineages — all converging on an alveolar-like state, mirroring the trajectory observed in KRAS-driven LUAD. Notably, alveolar KACs were detected in EGFRm cells derived from basal, club, and AT2 lineages, indicating a conserved transitional state during early tumorigenesis. EGFRm activation also induced KAC-signature genes while preserving lineage-specific markers, reflecting a dual programme of lineage convergence and memory. Upon PM exposure, EGFRm KACs exhibited pronounced upregulation of stress-responsive and inflammation-induced epithelial genes. Compared with wild-type AT2 controls, PM-exposed EGFRm KACs exhibited strong enrichment of LUAD-associated transcripts, with over 30% overlap encompassing 1,298 genes. This highlights the synergy between EGFRm and environment-induced injury. Furthermore, we identified epigenetic rewiring of KACs, marked by activation of transcription factors linked to the IL-1β pathway upon PM. Functionally, blocking IL-1β in PCLS effectively inhibited KAC formation, establishing a mechanistic link between inflammatory signalling and early tumour cell fate.

In conclusion, we showed that epithelial lineages converge on KACs en-route to *EGFR*-driven LUAD, which expands and undergoes transcriptional and epigenetic remodelling upon PM-exposure. Future studies defining key regulators of KAC expansion and its IL-1β dependency could inform novel therapeutic avenues for molecular cancer prevention.

#0932 High sucrose intake amplifies and independently promotes anthracycline-induced cardiac dysfunction and senescence in juvenile mouse models.

Alaina L. Poche[1], Huaxian Ma[1], Prince Jeyabal[1], Fei Wang[1], Efstratios Koutroumpakis[2], Eugenie S. Kleinerman[1], Joya Chandra[1]

[1]Department of Pediatrics Research, The University of Texas MD Anderson Cancer Center, Houston, TX,[2]Department of Cardiology, The University of Texas MD Anderson Cancer Center, Houston, TX

Anthracyclines such as doxorubicin (dox) are effective chemotherapeutic agents frequently used in adolescents and young adults (AYAs) with cancer but are associated with cardiotoxicity. Mitigation of cardiac late effects through modifiable behaviors has global and cost-effective benefits, but parameters influencing potential benefit remain unclear. Here, we investigated the impact of sucrose consumption on dox-induced cardiotoxicity and senescence in vivo. Male and female p16/3MR transgenic mice were provided normal (NSW, 0%) or high (HSW, 45%) sucrose water and treated with dox (2.5 mg/kg, tail vein ×4 doses). Cardiac function was assessed by echocardiography to measure ejection fraction (EF) and fractional shortening (FS). Cardiac miR-1a and miR-499 expression were quantified by qRT-PCR, and senescent cell accumulation was visualized in heart tissue by red fluorescent protein (RFP) signal. High sucrose intake worsened dox-associated reductions in ejection fraction, with the HSW + dox group showing the greatest functional decline, a pattern that was statistically significant at 4 weeks ($p = 0.0187$) and 6 weeks ($p = 0.0353$) post-treatment. Notably, high sucrose alone reduced EF relative to NSW controls, indicating diet-induced impairment of cardiac function. Dox treatment elevated biomarkers of myocardial stress (miR-1a and miR-499) in cardiac tissue, and high sucrose alone produced comparable upregulation. Senescence, as measured by RFP fluorescence, increased in both dox- and sucrose-exposed hearts. Interestingly, the HSW + dox group demonstrated the highest RFP signal, compared to both dox and diet controls, indicating a synergistic enhancement of senescence, suggesting that molecular senescence markers may capture early injury preceding functional decline. High dietary sucrose both amplifies and independently impairs cardiac function and increases senescence, with combined sucrose and dox exposure promoting the strongest EF reduction and senescence elevation. These findings underscore the contribution of sucrose consumption to anthracycline-associated cardiac injury and support the investigation of dietary modulation as a potential strategy to mitigate long-term cardiac damage.

#0933 PHGG supplementation modulates gut microbiome metabolites and breast cancer progression.

Sercan Kenanoglu, Fabia de Oliveira Andrade, Leena Hilakivi-Clarke

The Hormel Institute, University of Minnesota, Austin, MN

Short-chain fatty acids (SCFAs) are linked to improved anti-tumor immune responses and reduced breast cancer risk. Isoflavones in soybean-based (SB) high fiber diets may block fiber's advantages by triggering immunosuppression. We investigated the effect of SB diet, combined with partially hydrolyzed guar gum (PHGG) supplementation, on triple negative E0771 mammary tumor growth in mice fed AIN93G control or SB diet. Some SB-fed mice received PHGG or maltodextrin (MDX) control in drinking water. We found that SB diet increased tumor burden, and both MDX and PHGG revered the increase. Fecal microbiota transplants (FMTs) were prepared from the AIN93G, SB, SB+PHGG, and SB+MDX fed mice, and transferred to antibiotic-treated hosts fed AIN93G diet. Tumor burden was similar in hosts receiving FMT from AIN93G, SB, or SB+MDX donors, suggesting that SB diet did not increase mammary tumorigenesis through changes in the gut microbiome but perhaps directly by affecting immune cells in the tumor microenvironment. Mice receiving FMT from SB+PHGG fed donors exhibited significantly reduced tumor burden. To further investigate whether cellulose in AIN93G diet affected PHGG's ability to reduce mammary tumorigenesis, compared with MDX, we fed mice cellulose-free AIN93G diet. In this setting, PHGG reduced tumorigenesis compared with MDX. However, PHGG increased fecal SCFAs both in cellulose containing and cellulose-free AIN93G diet fed mice. Further, PHGG-supplemented mice exhibited significantly increased FFAR3 expression in CD4+ T cells in the spleen. Our findings indicate that PHGG reduces mammary tumorigenesis in mice fed fiber-deficient diet, and the effect is likely mediated through the gut microbiome.

#0934 Comparison of colonoscopy using a multipurpose rigid endoscope with postmortem detection of polyp in Pirc rat model of familial adenomatous polyposis.

Ishan T. Narkar[1], Vesna Tumbas Saponjac[2], Ming Hu[2], Rashim Singh[2]

[1]Michael E. DeBakey High School for Health Professions, Houston, TX,[2]University of Houston, College of Pharmacy, Houston, TX

Background: Familial adenomatous polyposis (FAP) is a rare disease affecting ~1 in 10,000 individuals and accounts for <1% of colorectal cancer cases. Untreated FAP carries a nearly 100% lifetime risk of colorectal cancer, typically manifesting by age 40 and is treated by colon resection between 15-25 of age. The Pirc (polyposis in rat colon) model of FAP harbors an *Apc* gene mutation analogous to that in humans. This model develops multiple polyps in the colon and duodenum with age and is widely used to test preventive interventions and in mechanistic studies. Longitudinal monitoring of polyp number, size, and grade is essential for preclinical testing of efficacy of preventive interventions and can be achieved through colonoscopy. In this study, we compared rigid endoscope-enabled colonoscopy with postmortem analysis of polyps in Pirc rats.

Methods: Colons of 16-week-old male and female Pirc rats (n=8) were examined using a rigid endoscope (Small Coloview scope, 10 cm, Karl Storz, Tuttingen, Germany). Before colonoscopy, rats were anesthetized with isoflurane, colons were flushed with warm water to remove fecal matter. In the video review, polyps were graded based on the degree of lumen obstruction: G1: barely detectable; G2: ≥ barely detectable to <1/8th of lumen; G3: ≥1/8 to <1/4 of lumen; G4: ≥1/4 to <1/2 of lumen; and G5: ≥1/2 of lumen to complete blockade. Animals were then euthanized, and colons were excised to determine polyp number and diameter measured with digital caliper (General® Ultratech, CA, USA). Total and detectable polyp counts were compared between the two methods using Wilcoxon matched-pairs signed rank test. Mean ± standard deviation (SD) of polyp diameter for each polyp grade was reported. Statistical analyses were performed using GraphPad Prism v.10.

Results: The median total polyps count was 2 (range: 0-5) using the endoscope and 3 (range: 1-12) postmortem, with no statistically significant difference (p= 0.09). Because the rigid endoscope visualizes only the distal 10 cm of rat colon, detectable polyps were compared. The median detectable polyps count was 2.5 (range: 0-7) postmortem and was not significantly different from colonoscopy (p= 0.5). The mean ± SD of the polyp diameter was as follows: G2: 2.9±0.7 mm, G3: 3.4±0.5 mm, G4: 3.6±0.6 mm, and G5: 3.6±0.7. Limitations of colonoscopy included incomplete visualization of the entire colon, difficulty distinguishing adjacent polyps, and challenges in detecting rectal polyps.

Conclusion: Polyp detection using a rigid endoscope is feasible and comparable to postmortem evaluation, supporting its use for longitudinal monitoring in preclinical prevention studies. Flexible and extendable endoscopes may enhance polyp detection and monitoring. **Acknowledgements:** This research was funded by CPRIT RP240401. Dr. Rashim Singh is supported by the NCATS/NIH under award number K12TR004522.

#0935 Nutritional disruption of folate homeostasis triggers an endogenous genotoxic carcinogen.

Christopher Mellor[1], Saeideh Azad[1], Nicholas Cheng[1], Brandon James[1], Vicky A. Simon[1], Olga V. Malysheva[1], Guillermo Burgos Barragan[2], John Blenis[3], Martha S. Field[1], **Meng Wang**[1]

[1]Division of Nutritional Sciences, Cornell University, Ithaca, NY,[2]Weill Cornell Medical College, New York, NY,[3]Professor of Pharmacology, Weill Cornell Medical College, New York, NY

Background: Formaldehyde, a human carcinogen found in industrial chemicals, is also produced by mammalian metabolism. The toxicity of endogenous formaldehyde is most severe in children with inborn errors in formaldehyde detoxification enzymes (ALDH2/ADH5), causing early-onset bone marrow failure and leukemia through formaldehyde-DNA damage. While endogenous formaldehyde exists in all healthy tissues, the nutritional and metabolic factors controlling its production remain unknown. Prior in vitro studies showed folate can spontaneously decompose to release formaldehyde. However, folate metabolism's contribution to endogenous formaldehyde in vivo has never been studied. Given widespread folate supplementation and the 2 billion people with folate insufficiency worldwide, we investigated how folate excess and deficiency affect endogenous formaldehyde in mouse models.

Methods: For folate excess, wildtype and *Adh5*$^{-/-}$ mice received high-folate diet (10x recommended daily allowance) for 8 weeks. For deficiency: 1) SLC46A1 deletion causing folate malabsorption, and 2) folate-depleted diet for 8-12 weeks. We developed ultra-sensitive mass spectrometry to quantify formaldehyde-DNA adducts as biomarkers of tissue formaldehyde exposure.

Results: Contrary to in vitro predictions, tissue folate accumulation did not elevate endogenous formaldehyde. Strikingly, folate deficiency significantly increased formaldehyde in liver, spleen, and bone marrow. In folate-deficient *Adh5*$^{-/-}$ mice with impaired formaldehyde clearance, hepatic formaldehyde increased 35-fold with elevated DNA damage, severe anemia (50% reduction in red cells), and hematopoietic stem cell loss. Metabolomics revealed folate-deficient livers upregulated choline oxidation to generate one-carbon units, a pathway that produces formaldehyde as a toxic byproduct.

Conclusions: We establish folate metabolism as a critical safeguard against endogenous formaldehyde accumulation, with deficiency triggering formaldehyde production through compensatory choline oxidation. Our findings have three major implications: First, they validate the safety of folate supplementation, used by millions for prenatal care and cancer treatment, by proving excess folate does not generate formaldehyde. Second, we hypothesize a mechanism underlying cancer risk in folate-deficient individuals worldwide, particularly the 500 million with ALDH2 deficiency who cannot detoxify formaldehyde. Third, we identify choline as an unexpected endogenous formaldehyde source, highlighting the need for caution with choline supplementation during low-folate status. These findings support targeted folate supplementation as a cancer prevention strategy for high-risk populations with ALDH2 deficiency

#0936 Temporal dependency of STAT3 signaling dictates hepatocarcinogenesis in metabolic dysfunction-associated steatohepatitis.

Jie Qing Eu[1], Nur Afiqah Binte Mohamed Salleh[2], Ming Yee Sim[2], Zi Swan Tan[2], Daniel Q. Huang[3], Tuan Zea Tan[4], Boon Cher Goh[4], **Li Ren Kong**[1]

[1]Nanyang Technological University Singapore, Singapore, Singapore,[2]National University of Singapore, Singapore, Singapore,[3]Dept. of Medicine, NUS Yong Loo Lin School of Medicine, Singapore,[4]Cancer Science Institute of Singapore, Singapore, Singapore

Background: Metabolic dysfunction-associated steatohepatitis (MASH) is rapidly surpassing viral and alcoholic etiologies as the leading cause of hepatocellular carcinoma (HCC). Despite so, the molecular checkpoints governing the transition from metabolic injury to malignancy remain poorly understood. Hyperactivated STAT3 has been implicated in lipid dysregulation, inflammation, fibrosis, and oncogenic signaling. However, its dynamic regulation during MASH-to-HCC progression remains undefined.
Methods: We performed longitudinal profiling of diseased mouse and human liver tissues to map STAT3 signaling dynamics across disease stages. Using the STAM model, we administered a hepatocyte-targeting, GalNAc-conjugated Dicer-substrate siRNA (GalNAc-STAT3) to selectively silence STAT3 at distinct disease phases: (i) early MASH and (ii) post-tumor initiation. Disease outcomes were evaluated using histopathology and serum proteomics. Spatial transcriptomics and immune phenotyping were used to resolve microenvironment- and subtype-specific responses.
Results: STAT3 suppression exhibited striking stage-specific effects. Early intervention prior to malignant transformation substantially reduced HCC initiation and tumor burden despite persistent steatosis, demonstrating that lipid accumulation alone is insufficient to drive carcinogenesis. Multi-omics analyses identified a STAT3-dependent, TGF-β1-associated fibrogenic and inflammatory program in peritumoral regions that acted as a key molecular driver for malignant progression. In contrast, late intervention failed to reduce tumor nodule formation despite effect STAT3 inhibition, indicating loss of STAT3 dependency following malignant transformation. Spatial interrogation further revealed subtype-specific adaptive remodeling through metabolic re-differentiation in glutamine synthetase (GS)-positive nodule, and activated stress tolerance transcriptional programs in GS-negative tumors.
Conclusions: This work uncovers a previously unrecognized temporal dependency of STAT3 during MASH-associated hepatocarcinogenesis. STAT3 is essential as an early driver in establishing pro-tumorigenic niche, but is dispensable once malignant cell states emerge. These discoveries redefine the therapeutic window for STAT3 inhibition, positioning it as an early stage interception strategy rather that treatment for advanced tumors.

#0937 Breast cancer risk prediction model for racially diverse women with benign breast disease.

Alzina Koric, Yikyung Park, Shu Jiang, Fouad Boulos, Debbie L. Bennett, Graham A. Colditz

Washington University School of Medicine in St. Louis, St. Louis, MO

Purpose: Existing breast cancer risk prediction models are ineffective for women with benign breast disease (BBD) and do not stratify risk by key histologic subtypes, especially in racially and ethnically diverse populations. Although BBD and breast cancer share several risk factors, women with BBD have a higher underlying risk due to accumulated changes in benign breast tissue compared to the general population. The magnitude of risk varies by morphologic subtype—modestly increased for proliferative disease without atypia (PDWA), and highest for atypical hyperplasia (AH). We aimed to refine a prediction model for breast cancer through risk stratification by PDWA and AH subtypes, using data from a contemporary and racially diverse cohort of women.
Methods: 8,870 women diagnosed with histologically confirmed benign lesions were identified at the Siteman Cancer Center in St. Louis from 2010-2023 (followed until June 10, 2025). Risk modeling was performed with Cox regression and internally validated through a bootstrap resampling method (i.e., corrected for overfitting). Model discrimination was estimated with Harrell's C-index. Model calibration was assessed by the 5-year observed-to-expected (O/E) ratio. Positive and negative predictive values (PPV/NPV) were estimated for a 3% 5-year risk threshold per national guidelines to define increased risk.
Results: Among the 8,870 women with BBD, there were 362 subsequent breast cancers at least 6 months following a benign biopsy. 11.2% were triple negative tumors (ER-PR-HER2-); 73.8% were invasive breast cancers. The cohort is 64.3% White, 32.5% Black, and 3.2% Asian. On average, women were 50 (SD=13) years of age at biopsy. Average age at menarche was 13 (SD=1.8) and average BMI 29.6 kg/m2 (SD=7.7). Harrell’s C-index was 0.68 (95% CI: 0.65-0.71) in the original sample and 0.67 (95% CI: 0.65-0.70) in the bootstrap sample. At 5 years, the overall model calibration was 0.99 (95% CI: 0.86-1.13). Women predicted to be in the high-risk group (≥3%, 5y) included those with atypia and half of those with proliferative disease without atypia. Of these women, 7.0% developed breast cancer, and in the average-risk group, 97.5% did not in the 5 years following a benign biopsy.
Conclusion: Our model demonstrates sound discriminatory ability in the internal validation within a racially diverse cohort of women followed after benign biopsy. With a 5-year PPV of 7%, the model effectively flags women at high-risk (≥3%, 5y), providing a meaningful basis for intensified surveillance or preventive measures for early detection after benign biopsy showing proliferative disease with or without atypia.

#0939 Patient and oncologist factors associated with trastuzumab drug choice and administration route.

Derek Hsu[1], Liam Schmitt[2], Austin Wesevich[3]

[1]University of Chicago, Chicago, IL,[2]Center for Personalized Therapeutics, University of Chicago, Chicago, IL,[3]Section of Hematology/Oncology, University of Chicago, Chicago, IL

Background: As biosimilars and subcutaneous (SQ) formulations of intravenous (IV) biologics enter the market, it is unclear how prescribers determine which formulation to give a patient. While patients may generally prefer SQ administration, IV biosimilars may be less expensive than newer SQ formulations. We focused on trastuzumab, which has name-brand SQ, name-brand IV, and biosimilar IV formulations, to assess potential association of patient and oncologist factors with drug choice and administration route.
Methods: This cross-sectional study included patients with HER2+ breast or gastrointestinal (GI) cancer who received trastuzumab at the UChicago from 1/1/2021 to 12/31/2024. Patient factors, trastuzumab formulation and administration route, and prescriber were extracted from the electronic medical record. Prescriber demographics were obtained using public data from the Centers for Medicare & Medicaid Services. Multilevel multivariable logistic regression models assessed associations of patient and oncologist factors with IV vs SQ trastuzumab and brand-name IV vs biosimilar, nesting doses within patients and patients within oncologists. Models adjusted for patient insurance, age, race, sex, SVM quartile, ECOG score, BMI, cancer stage, and oncologist sex and years since graduation. The name-brand IV vs biosimilar model also adjusted for cancer type. The SQ vs IV model only included those with breast cancer as SQ trastuzumab is not approved for GI cancer, and it also accounted for concurrent IV chemotherapy administration.
Results: A total of 35 oncologists and 368 patients were included, of which 319 (87%) had HER2+ breast cancer and 49 (13%) had HER2+ GI cancer. Most patients had private (47%) or Medicare (41%) primary insurance, and oncologists had a mean of 22 years of experience. IV biosimilars were given to 89% of patients. Patients with Medicaid had lower odds of receiving a biosimilar than patients with private insurance (aOR 0.11, 95% CI 0.04-0.34). No patients with GI cancer and 69 (22%) of patients with breast cancer received SQ. Patients with Medicare had lower odds of receiving SQ than those with private insurance (aOR 0.18, 95% CI 0.04-0.75). Except for concurrent IV chemotherapy administration in the SQ vs. IV model, no other patient factors beyond insurance and no oncologist factors were significantly associated with drug formulation or administration route.
Conclusions: Drug choice and administration route were significantly associated with patient insurance. While administration route may be driven by the logistics of giving IV trastuzumab along with concurrent IV chemotherapy, no patient or oncologist factors were identified in prescribers' decision-making about drug choice or administration route beyond insurance. It may be difficult to incorporate patient preferences or cost-saving measures into prescribing patterns if insurance does not allow for drug choice.

#0942 Target validation and high-throughput screening assay development for natural product discovery for cancer prevention and interception.

Yurong Song[1], Brandon Somerville[1], Kajal Biswas[2], Karim Baktiar[1], Liankun Song[3], Sara Sanders[4], Tanja Grkovic[5], Ligia A. Pinto[1], Ana Catarina Menezes[6], Paul P. Liu[6], Matthew J. Hart[7], Chinthalapally V. Rao[7], Shugeng Cao[8], Xin Chen[8], Xu Wu[9], Xiaolin Zi[3], Mark J. Henderson[4], Barry R. O'Keefe[5], Altaf Mohammed[2], Robert H. Shoemaker[2]

[1]Frederick National Laboratory for Cancer Research, Frederick, MD,[2]Division of Cancer Prevention, National Cancer Institute, Bethesda, MD,[3]Department of Urology, University of California, Irvine, CA,[4]National Center for Advancing Translational Science, Rockville, MD,[5]National Cancer Institute at Frederick, Frederick, MD,[6]National Human Genome Research Institute, Bethesda, MD,[7]University of Oklahoma Health Sciences Center, Oklahoma City, OK,[8]University of Hawai'i at Hilo, Hilo, HI,[9]Massachusetts General Hospital and Harvard Medical School, Charlestown, MA

Background Natural products (NPs) represent a rich source of bioactive compounds with cancer prevention/interception potential. NPs offer unique chemical diversity and a history of safe human use, making them attractive candidates for long-term use. High-throughput screening and mechanistic studies are key to discovering promising leads and translating them into effective and safe cancer prevention and interception strategies. To support the Discovery and Development of Natural Products for Cancer Interception and Prevention (DDNP-CIP) Initiative, we aimed to validate potentially clinically relevant molecular targets (SKP2, TEAD2, 5-LOX and RUNX1) and establish and optimize assays to enable high-throughput NPs library screening for cancer prevention.
Methods Target validation was performed using tissue microarrays. SKP2, a component of the SKP2-SCF E3 ligase complex, and TEAD2, a DNA-binding transcription factor, were evaluated for their expression levels in TMAs of prostate and liver cancer, respectively. In addition, cell-based platforms were developed or adapted to identify NPs exhibiting immune-modulating activity or targeting either 5-LOX, a lipid-peroxidizing enzyme, or RUNX1, a transcription factor critical for hematopoietic differentiation and frequently mutated in hematologic malignancies. These assays utilized stably expressing reporter cell lines.
Results SKP2 was significantly over expressed in 68.6% of prostate hyperplasia, 97.6% of prostate intraepithelial neoplasia, and 81.9% of adenocarcinoma compared with normal tissue. TEAD2 was highly expressed in liver hyperplasia and significantly upregulated in hepatitis ($p = 0.0041$), hepatocellular carcinoma ($p = 0.0012$), and intrahepatic cholangiocarcinoma ($p < 0.0001$). To identify NPs with immune-modulating activity, an assay using the THP-1 ISRE FRET reporter cell line was adapted and optimized. Reference compounds and initial challenge plates were tested, with several samples eliciting positive responses. A cell line expressing 5-LOX was generated and validated. An inhibition assay using a positive compound nordihydroguaiaretic acid demonstrated dose-dependent inhibition (29% at 0.1uM to 92% at 1uM) upon arachidonic acid treatment without toxicity. To screen NPs for splicing modulating activity, nano-luciferase reporter cell lines with RUNX1 mutations identified in patients with familial platelet disorder with associated myeloid malignancy were generated. Several reference compounds showed positive responses in selected mutations.
Summary Validated targets and assay platforms establish a foundation for high-throughput NPs screening. These efforts advance the DDNP-CIP's mission to identify and develop NPs for cancer prevention and interception. Funded partly by the National Cancer Institute under Contract No. HHSN261201500003I

#0943 Chemoprevention of hepatocellular carcinoma by next-generation antipsychotic aripiprazole.

Nevena Slović[1], Sumit Mishra[2], Subhojit Paul[2], Marine A. Oudot[1], Frank Juhling[1], Hiroaki Kanzaki[2], Julien Moehlin[1], Margaux Denos[1], Anouk Charlot[1], Sarah C. Durand[1], Courtney Katz[2], Cloe Gadenne[1], Emanuele Felli[3], Joachim Lupberger[1], **Emilie Crouchet**[1], Yujin Hoshida[2], Thomas F. Baumert[1]

[1]Institute for Translational Medicine and Liver Disease (ITM), University of Strasbourg/Inserm U1110, Strasbourg, France,[2]Department of Internal Medicine, University of Texas Southwestern Medical Center, Dallas, TX,[3]Hospital Group Saint Vincent, Strasbourg, France

Hepatocellular carcinoma (HCC) is the most common form of liver cancer and is a major global health burden, ranking sixth in incidence and third in cancer-related mortality. Despite therapeutic advances, treatment options for advanced liver disease and HCC are limited and strategies to prevent HCC development are lacking. To address the urgent need for chemopreventive strategies, we identified Aripiprazole, an oral atypical antipsychotic, as a candidate for HCC chemoprevention. Transcriptomic analyses of clinical liver tissues showed an association of Aripiprazole target gene expression with fibrotic liver diseases severity. In a rat model of MASH-induced HCC induced by choline-deficient L-amino acid-defined and high-fat diet, Aripiprazole prevented liver disease progression toward HCC development by modulating fibrogenesis, inflammation, and immunity-related pathways. Moreover, Aripiprazole exhibits an antifibrotic effect and reverses the high-risk status of the prognosis liver signature (PLS), a signature associated with disease progression and HCC risk in patients, in multiple human liver cell-based models. Mechanistic studies demonstrated that Aripiprazole exerts antifibrogenic, and anti-proliferative effects via suppression of TGF-β, NF-kB, cMet-ERK, and PI3K/AKT signaling in liver epithelial cells and myofibroblasts. Finaly, perturbation studies in patient-derived cell lines and patient-derived tumorspheroid system showed that Aripiprazole has a direct anticancer effect, by modulating the tumor microenvironment and suppressing tumor cell survival and invasion. Collectively, these findings suggest that treatment with aripiprazole is a clinically relevant approach for HCC chemoprevention.

#0944 The combination of EPA and Naproxen prevents iCAF polarization and attenuates inflammation associated with Pirc tumor development.

Niti Jani[1], Ryan Beach[1], Michael Martinez[1], Shizuko Sei[2], Vignesh Gunasekharan[2], Daniel W. Rosenberg[3]

[1]University of Connecticut Health Center, Farmington, CT,[2]Division of Cancer Prevention, National Cancer Institute, Rockville, MD,[3]Professor of Med. & Co-Director, Colon Cancer Prev. Prog., University of Connecticut Health Center, Farmington, CT

We recently reported that eicosapentaenoic free fatty acid (EPA-FFA) or a chemically stable EPA analog (TP-252), when combined in the diet with naproxen, reduces colon tumor development by up to 98% in the highly penetrant Pirc rat model. Cancer suppression is dependent, in part, upon modifications of eicosanoid biosynthesis. The following study expands upon these initial findings using genome-wide RNA-sequencing (RNA-seq) analysis to identify specific molecular pathways in Pirc tumors affected by drug treatment. Colon tumors isolated from untreated control Pirc rats maintained on AIN93G diet exhibited gene expression profiles associated with the presence of inflammatory cancer-associated fibroblasts (iCAFs). Following a twenty-week treatment with a combination diet of EPA-FFA (2% w/w) and naproxen (200 ppm), there was a marked reduction in inflammatory and proliferative gene signatures. Further analysis of these drug combination-treated tumors showed expression profiles resembling a less inflammatory fibroblast phenotype, suggesting the presence of myofibroblasts (myCAFs). To further establish potential mechanisms, we isolated CAFs from colon tumors of untreated Pirc rats. CAFs were then stimulated for 12 hours with individual cytokines (TNF-a, IL-1β or IL-6) to promote iCAF activation. The secretion of a panel of inflammatory cytokines (IL-6, Cxcl2, Csf3 and Nos2) determined in IL-1β activated CAFs were similar to those found by RNA-seq analysis of colon tumors from untreated Pirc diet controls. In addition, the combination treatment of EPA-FFA and naproxen attenuated polarization of CAFs towards an iCAF phenotype upon IL-1β stimulation. The present work contributes further to our understanding of intestinal tumor protection afforded by a combination of dietary EPA and naproxen. These findings further uncover potential mechanisms that can be exploited in future clinical chemoprevention studies.

#0945 Chemoprevention of triple-negative breast cancer originating from cancer stem cells using OXPHOS inhibitors.

Esra Akkus[1], Cemile Uslu[2], Mert Gungor[1], Beyza Şimbil[3], Elif Uzun[4], Etna Abad[5], Alex Lyakhovich[6]

[1]Molecular Biology, Genetics and Bioengineering, Sabanci Universitesi, Istanbul (Anatolia), Turkey,[2]Sabanci Universitesi, Istanbul,[3]Molecular and Cellular Biology, Heidelberg University, Heidelberg, Germany,[4]Regenerative Biology and Medicine, Technical University of Dresden, Dresden, Germany,[5]Vall d'Hebron Institute of Oncology (VHIO), Barcelona, Spain,[6]Molecular Biology, Genetics and Bioengineering, Sabanci Universitesi, İstanbul, Turkey

We and other researchers have recently demonstrated in vitro that chemoresistant and stem-like triple-negative breast cancer cells preferentially obtain energy through mitochondrial oxidative phosphorylation (OXPHOS) compared to their chemosensitive counterparts, which undergo glycolysis. Proteomic profiling revealed several possible survival mechanisms for the resistant phenotype, including OXPHOS-associated pathways. Since metastasis and poor clinical prognosis are often associated with the dormant subset of slow-growing cancer stem cells (CSCs), we treated tumor models derived from mammospheres with pre-selected bactericidal antibiotics—OXPHOS inhibitors - AMX, FSS and others. Our results demonstrate significant inhibition of tumor growth in the inhibitor-treated groups compared to the placebo-treated group. Furthermore, this inhibition was more pronounced in tumors derived from CSCs than in tumors derived from chemosensitive cancer cells prone to glycolysis, further emphasizing the role of OXPHOS in CSCs. Since CSCs are often associated with a pool of chemoresistant OXPHOS-dependent cells, we conducted a chemoprevention experiment in which nude mice were given the above-mentioned inhibitors for several weeks, followed by injection with CSC-like cells (mammospheres) to create tumors. Our results showed a slowdown in tumor growth in the group of mice that had previously received these inhibitors, compared to mice that received a placebo. Thus, our experiments may be of interest for modeling the prevention of OXPHOS-dependent breast tumors.

#0946 Liposomes encapsulated chloroform fraction of *Cassia fistula* L. bark enhances anticancer efficacy in ehrlich ascites carcinoma mice model.

Satwinderjeet Kaur, Rasdeep Kour

Department of Botanical and Environmental Sciences, Guru Nanak Dev University, Amritsar, India

Cancer remains one of the eminent causes of mortality and a major health concern profoundly influencing life expectancy worldwide. *Cassia fistula* L. commonly known as 'Golden shower' finds its application in the Ayurveda and Chinese traditional medicines. The phytoconstituents from the bark powder were obtained using organic solvents in the increasing order of polarity viz. *CaMH* (hexane fraction), *CaMC* (chloroform fraction), *CaME* (ethyl acetate fraction) and *CaMM* (methanol fraction). These bark fractions were tested for their cytotoxic potential in HeLa (cervical cancer), MCF-7 (breast cancer), LN-18 (brain glioblastoma), MG-63 (osteosarcoma), A431 (skin cancer), MIA PaCa-2 (pancreatic cancer) and normal cell line L929 (human fibroblast cells) using MTT assay. Among all the tested fractions, *CaMC* fraction shows highest selective cytotoxicity against HeLa cells with GI_{50} value of 41.53 µg/mL. Silica gel column chromatography of *CaMC* fraction yielded *Cf-1* fraction spectroscopically deciphered as Piperine. It showed significant cytotoxicity against HeLa, MG-63 and MCF-7 cell line with GI_{50} of 0.10 mM, 0.37mM, 0.56 mM respectively. *CaMC* and *Cf-1* fractions treated HeLa cells showed significant manifestations of apoptosis in morphological and flow cytometric investigations. These induced cell cycle arrest at G_0/G_1 phase in concentration-dependent manner. Molecular mechanistic studies of *CaMC* and *Cf-1* fraction depicted upregulation of apoptotic markers including p53, caspase 3 and 9, and downregulation of Bcl-2. Furthermore, the *in-vivo* studies evaluated in Ehrlich Ascites Carcinoma-bearing Swiss albino mice showed that liposomal encapsulated *CaMC* fraction (*CaMC-LP*) resulted in 82.23% tumor growth inhibition in contrast to *CaMC* fraction with 60.81% tumor inhibition, comparable to 86.39% inhibition by 5-Fluorouracil. The use of liposomal encapsulation enhanced the anticancer efficacy *in vitro,* and *in vivo* showing significant tumor inhibition in EAC- bearing mice without inducing toxicity. These findings suggest that *C. fistula* L. bark constituents have cancer chemopreventive and chemotherapeutic potential which can further be exploited for the benefit of mankind.

#0947 Mammary gland architectural modulation with a natural galactagogue *Asparagus racemosus* (Shatavari root extract) and its impact against triple negative breast cancer (TNBC) tumorigenesis.

Md. Imtiazul Kabir, Robin Kumar, Lakshmi Sai Pratyusha Bugata, **Komal Raina**

Dept. of Pharmaceutical Sciences, South Dakota State University, Brookings, SD

The roots of *Asparagus Racemosus Willd.* (Shatavari) are known for its galactagogue properties and often used as a traditional/ alternative way to increase milk production during lactation and for breast size augmentation. There is also supporting evidence that it has anti-cancer properties against various cancers including carcinogen-induced breast cancer in pre-clinical *in vivo* studies and against ER positive breast cancer cell lines. In the present study we investigated the anti-cancer potential of standard extract of roots of *Asparagus Racemosus* (AR^{RE}) against triple negative breast cancer (TNBC). We conducted orthotopic tumorigenesis studies in C57Bl/6 female mice. Five weeks old C57Bl/6 female mice (Jackson Labs), were maintained on control AIN-76A diet from Envigo diets, Inc. After 1 week of acclimatization mammary tumors were induced by orthotopic injection of $2x10^6$ PY230 breast cancer cells in the 4^{th} mammary fat pad (either left or right) on day 0. n=7 mice per group were treated with or without AR^{RE} as an oral intervention agent (including with and without tumor inoculation). The dose of AR^{RE} was 250 mg/kg body weight/day (volume 200µl sterile distilled water)-prepared fresh daily. Study end point was 8 weeks following cell inoculations. At study end, tumor tissues, tumor adjacent breast fat pad was harvested from mice and processed for pathological/ molecular analysis. AR^{RE} treatment caused an increase in latency time (time taken for appearance of palpable TNBC tumors) indicating its preventive benefits. AR^{RE} treatment did not have any significant impact on TNBC tumorigenesis; however, tumors had the appearance of differentiated lobular/glandular formation in AR^{RE} - fed groups compared to undifferentiated tumor cells in the controls. Proteomic profiling of mammary gland tissues indicated there were 43 differentially expressed biomarkers after AR^{RE} intervention. Out of the 43 differentially expressed biomarkers, there were 2 molecules [Methylenetetrahydrofolate dehydrogenase 1 (MTHFD1) and Mitogen-activated protein kinase kinase kinase kinase 4 (MAP4K4) that were significantly decreased in the AR^{RE} control (treated tissue). Importantly, these two molecules are reported to be overexpressed in breast cancer and implicated in the growth and progression of breast cancer. Overall, the results indicated that AR^{RE} intervention results in modulation of signaling pathways (that are associated with breast cancer growth and progression) and had the potential to induce differentiation in TNBC tumors, which could possibly be a novel approach to target TNBC malignancy. Taken together, the study outcomes favor the use of AR^{RE} as a preventive or therapeutic modality against TNBC but warrants further investigation.

#0948 TRAIL inducing drug, ONC201 prevents adenocarcinoma in transgenic KRAS^{G12V} mouse lung cancer model.

Karthikkumar Venkatachalam[1], Gopal Pathuri[1], Nicole Stratton[1], Anil Singh[1], Nandini Kumar[1], Shizuko Sei[2], Vignesh Gunasekharan[2], Chinthalapally V. Rao[1], Venkateshwar Madka[1]

[1]Center for Cancer Prevention and Drug Development, Stephenson Cancer Center, Department of Medicine, University of Oklahoma HSC, Oklahoma City, OK,[2]Division of Cancer Prevention, National Cancer Institue, Rockville, MD

Lung cancer is one of the leading cancers worldwide. Around 226,000 people will be diagnosed with lung cancer in the US during 2025. Almost one-fourth of all lung cancers are KRAS-mutated tumors, which are very challenging to treat and have poor prognosis. Interception of lung cancer is of utmost importance to reduce the burden and mortality. However, there are currently no interception agents approved by FDA. TCGA database revealed that the apoptosis mediating TRAIL expression is lost during the progression of lung tumor stages. ONC201 (Dordaviprone) is an orally active TRAIL inducing small molecule compound with proven preclinical efficacy and is being clinically evaluated against multiple cancers. Previously we reported the cancer prevention potential of ONC201 in an NNK-induced lung cancer model in A/J mice. Here, we evaluated the efficacy of ONC201 in an aggressive KRAS^{G12V} lung tumor mouse model. Male and female KRAS^{G12V} mice were generated by inhouse breeding. Six-week aged mice were randomized (n=20/sex) into placebo and interception groups. Beginning at 8 weeks of age (early adenoma stage) mice were gavaged one of the doses of ONC201 (0, 25, 50, 100mg/kg in PBS vehicle) twice weekly for 28 weeks. All mice were euthanized at 36 weeks of age, and lungs were evaluated to determine tumor incidence and multiplicity. Both the male and female KRAS^{G12V} mice in placebo group developed lung tumors (~100% incidence) with average tumor multiplicity of 12.2±1.5 (male) and 11.7±0.8 (female) per mouse. ONC201 treatment resulted in significant reduction in total lung tumors multiplicity in both male (34%-63% less; $p<0.05$-$p<0.0001$) and female (33%-55% less; $p<0.001$-$p<0.0001$) mice in a dose dependent-manner as compared to their control group. H&E stained lung tumor sections were histologically classified as adenomas (AD), and adenocarcinomas (ADCA). Placebo mice showed multiplicity of 9.3±1.3 ADCA, and 12±1.2 AD+ADCA in male; 8.3±0.6 ADCA, and 11.61±0.87 AD+ADCA in female mice. Histopathology results indicated dose-dependent reduction in ADCA multiplicity in ONC201 treated mice in male (53%-86%; $p<0.001$ - $p<0.0001$) and female mice (54%-79%; $p<0.0001$) when compared to their respective control mice. There was no clinical sign of toxicities observed in all three doses tested in both male and female mice. Immunoblotting and IHC results revealed that TRAIL inducing ONC201 triggering the downstream signaling molecules (TRAIL, DR5, FADD, Apaf1), elevated apoptosis markers (Caspases), concurrently reduces the proliferation markers (PCNA, Cyclin D1, EGFR, Ki67). In conclusion, ONC201 demonstrated strong efficacy in preventing lung cancer in two preclinical mouse models and warrants further clinical development for the prevention of lung tumor in high risk populations.
(Project funded 100% with Federal funds from NCI, NIH, DHHS, under Contract 75N91019D00020_75N91022F00003)

#0949 Prevention of insulin receptor isoform A formation inhibits MASH-driven hepatocellular carcinoma.

Yanting Wang, Manasi Das, Panyisha Wu, Yunpeng Yang, Isabella Maranan, Liping Zeng, Yichun Ji, Deepak Kumar, Nicholas Webster

University of California San Diego, San Diego, CA

Introduction: Metabolic dysfunction-associated steatohepatitis (MASH) has emerged as a leading driver of hepatocellular carcinoma (HCC). Our previous work identified that the loss of the RNA splicing factor SRSF3 is an early event in chronic liver disease. This loss leads to the aberrant skipping of exon 11 in the insulin receptor (*INSR*) gene, shifting the isoform expression from the normal hepatic IR-B to the fetal IR-A isoform. Unlike IR-B, IR-A binds insulin-like growth factor 2 (IGF2) with high affinity, potentially establishing a mitogenic autocrine loop. We hypothesized that this specific splicing switch is a critical driver of hepatocarcinogenesis and that preventing it could inhibit tumor formation.

Methods: To test this hypothesis, we generated a novel "Exon 11+" mouse model in which *Insr* exon 11 inclusion is genetically enforced, thereby preventing the production of the IR-A isoform. We subjected Exon 11+ mice and wild-type (WT) littermates to a chemical-dietary carcinogenesis protocol. Mice received a single injection of diethylnitrosamine (DEN) at 2 weeks of age, followed by chronic administration of thioacetamide (TAA) and a Western diet (MASH conditions) for 24 weeks to induce HCC. Tumor burden was assessed by surface counting and measuring. Liver tissues were analyzed via histology (H&E, Sirius Red, Reticulin), immunohistochemistry (Ki67, CD45), and qPCR.

Results: WT mice developed extensive liver tumors accompanied by severe fibrosis and inflammation. In striking contrast, Exon 11+ mice were significantly protected against tumorigenesis, exhibiting a profound reduction in both the number (decrease >80%, $p<0.001$) and size ($p<0.05$) of surface tumors. Histological analysis confirmed that Exon 11+ mice had significantly reduced liver fibrosis (Sirius Red, $p<0.001$) and immune cell infiltration (CD45, $p<0.01$) compared to WT controls. Notably, Reticulin staining revealed that Exon 11+ livers maintained normal hepatic plate architecture (1-2 cell thickness), whereas WT livers displayed disorganization and thickening characteristic of HCC. Furthermore, enforcing IR-B expression significantly suppressed hepatocyte proliferation (Ki67, $p<0.0001$) and downregulated the expression of key proinflammatory (Tnf, Il6, Ccl2) and profibrogenic (Col1a1, Col3a1) genes (all $p<0.05$).

Conclusions: Our data provide the first *in vivo* genetic evidence that the alternative splicing switch of the insulin receptor from IR-B to IR-A is a necessary event for MASH-driven HCC progression. Blocking this specific splicing error is sufficient to suppress inflammation, fibrosis, and tumor development in a harsh carcinogenic environment. These findings suggest that targeting the IGF2/IR-A signaling axis or correcting *INSR* splicing represents a potent therapeutic strategy for preventing MASH-associated liver cancer.

#0950 Efficacy of androgen receptor inhibitor, Apalutamide, in intercepting bladder cancer in a BBN-induced rat bladder tumor model.

Venkateshwar Madka[1], Gopal Pathuri[1], Anil Singh[1], Surya P. Singh[1], Anh Bao[1], Nicole Stratton[1], Shizuko Sei[2], John Clifford[2], Chinthalapally V. Rao[1]

[1]Center for Cancer Prevention and Drug Development, Stephenson Cancer Center, Department of Medicine, University of Oklahoma HSC, Oklahoma City, OK,[2]Division of Cancer Prevention, National Cancer Institute, Rockville, MD

Bladder cancer (BC) is the second-most diagnosed genitourinary cancer. Most tumors are detected at the non-muscle invasive (NMIBC) stage and treated; however high recurrence rate, treatment resistance, tumor progression and metastasis contribute to significant mortality annually. Many studies have indicated significantly higher incidence rates and BC progression to be more predominant in men. Experimental data have also showed strong association of BC tumorigenesis with androgen receptor (AR) signaling , making AR a promising target for cancer interception. In this study, AR antagonist, apalutamide (APA) was evaluated for BC preventive efficacy in a N-butyl-N-(4-hydroxyl)-nitrosamine (BBN)-rat BC model. Male and female Fischer rats were randomized into placebo and intervention groups (30 rats/group/sex: 24 BBN+6 Saline). At 8 weeks of age, rats in carcinogen groups received BBN by oral gavage (150mg/dose; 2x/week for 8 weeks) to induce BC. APA was given to rats in intervention groups at 7.5, 15, or 30mg/kg body weight by oral gavage (5x/week) until termination. Early intervention with APA started at carcinogenesis stage i.e., a week after last BBN, while delayed intervention began at papilloma stage i.e., ~10 weeks after last BBN. Bladder tumors were assessed at 40 and 50 weeks of age in male and female rats respectively. APA did not cause any overt-toxicities. BBN treatment induced bladder tumors in all rats, resulting in significantly larger bladders in placebo group compared to normal bladders in saline group. Importantly, APA significantly reduced bladder weights suggesting tumor growth inhibition in intervention groups compared to placebo. With early intervention, bladder weights were reduced by 60%-65% in male rats ($p<0.05$) and by 54%-63% in female rats ($p<0.05$) when compared to the placebo group. Incidence of large bladder tumors was also significantly decreased with APA treatment by 30%-47% in males ($p<0.05$-$p<0.01$) and by 32%-50% in females ($p<0.05$) in a dose dependent manner. Delayed intervention also resulted in 21%-53% ($p<0.01$) reduction of bladder weights and 28%-66% less incidence of large tumors in male rats only. Histopathological analysis of the tumor sections demonstrated suppression of tumor progression in APA treated rats as indicated by the significant decrease in multiplicity of papillomas, NMIBC, and MIBC when compared to placebo. Biomarker and gene expression analysis suggested modulation of critical tumor promoting pathways with APA treatment. In summary, this preclinical study demonstrated that an AR antagonist, apalutamide, can intercept bladder tumor growth and progression and warrants further investigation in clinical trials. (Project funded in whole with Federal funds from the NCI-NIH, DHHS, under Contract No. 75N91019D00020 - 75N91022F00002).

#0951 STAT3 inhibitor TTI-101 effectively intercepts bladder cancer in a carcinogen-induced rat bladder tumor model.

Venkateshwar Madka[1], Gopal Pathuri[1], Anil Singh[1], Nicole Stratton[1], Anh Bao[1], David J. Tweardy[2], Shizuko Sei[3], Vignesh Gunasekharan[3], Chinthalapally V. Rao[1]

[1]Center for Cancer Prevention and Drug Development, Stephenson Cancer Center, Department of Medicine, University of Oklahoma HSC, Oklahoma City, OK,[2]Division of Internal Medicine, The University of Texas MD Anderson Cancer Center, Houston, TX,[3]Division of Cancer Prevention, National Cancer Institute, Rockville, MD

Bladder cancer (BC) is the 9th most common cancer worldwide. Most bladder tumors are detected and treated at the non-muscle invasive (NMIBC) stage. However, tumors recur frequently, many progress to MIBC and metastasize contributing to significant mortality. Rising incidence and mortality in BC underscore the need to develop new regimen for its management. Transcriptional factor Signal transducer and activator of transcription 3 (STAT3) regulates cell proliferation through inflammation and immune responses. Its activation is highly regulated in normal cells but in cancers including BC, it is constitutively active. Expression of dominant-negative STAT3 was shown to inhibit tumor formation in nude mice. Earlier we and others reported that STAT3 inhibitors reduces BC cell survival and proliferation. In the present study, we determined pharmacodynamic pSTAT3 inhibitory effect of STAT3 inhibiting small molecules (GLG-302, SH5-07, TTI-101) *in-vitro* BC cells and *in-vivo* rat tumors. TTI-101 was further evaluated for its potential to intercept BC in a N-butyl-N-(4-hydroxyl)-nitrosamine (BBN)-rat BC model. Female F344 rats were randomized into a placebo, STAT3 (n=24) and Sulindac (n=18) intervention groups. Eight-weeks of age, rats were given BBN by oral gavage (150mg/dose; 2x/week for 8 weeks). Drug treatment was initiated at papilloma stage i.e., ~10 weeks after last BBN. Rats in intervention groups received TTI-101 at 25 or 75mg/kg body weight by oral gavage (5x/week) for 20 weeks. Sulindac was administered at 10mg/kg BW as a comparator. All drugs were formulated using 60% labrasol:40% PEG400. Bladder tumors were assessed at ~45 weeks of age. TTI-101 did not cause any overt-toxicities. BBN-induced bladder tumors in all rats, resulting in larger bladders in placebo group (0.31±0.06g; Mean±SEM). Importantly, bladder weights in TT1-101 25mg/kg and 75mg/kg groups were 0.21±0.06mg (32% inhibition; $p>0.05$) and 0.13±0.01g (58% inhibition; $p<0.01$) when compared to the placebo. Sulindac treatment had non-significant 46% inhibition (0.17±0.02g; $p=0.07$). In the placebo group, about half of all rats developed large bladder tumors (>200mg; 50% incidence). Interestingly, significantly fewer rats developed such tumors with TTI-101 25-mg/kg (17% incidence; $p<0.05$) and at 75mg/kg BW dose (8% incidence; $p<0.005$) in a dose dependent manner (67%-83% less respectively). Thus, STAT3 inhibition with TTI-101 resulted in a dose dependent inhibition of bladder tumors growth. Biomarker and gene expression analysis suggested modulation of critical tumor promoting pathways with decrease in pSTAT3 expression. Collectively, our study demonstrated that STAT3 inhibition using TTI-101 can intercept bladder tumor growth and warrants further investigation in clinical trials. (Project funded in whole with Federal funds from the NCI-NIH, DHHS, under Contract No. 75N91019D00020-75N91020F00005).

#0952 Silibinin induced mast cell regulation: Potential immunomodulation via ODC1 in pancreatic cancer prevention and therapy.

Neha Mishra[1], Sandeep Paudel[1], Komal Raina[2], Chapla Agarwal[1], **Rajesh Agarwal**[1]

[1]University of Colorado Anschutz Medical Campus, Aurora, CO,[2]San Diego State University, San Diego, CA

It has been estimated by the American Cancer Society that in the US in 2025, ~67,440 people (34,950 men; 32,490 women) will be diagnosed with, and ~51,980 people (27,050 men; 24,930 women) will die of pancreatic cancer (PC). Additionally, the average lifetime risk of developing PC has been estimated to be ~1 in 56 in men and ~1 in 60 in women. PC has been reported to be the 4th leading cause of cancer deaths in the US with a <5% overall 5-year survival rate. The role of immune system, particularly the primary cellular responders, the mast cells (MCs), in PC remains obscure. The natural flavonolignan silibinin (SB), has been effective in preclinical models of PC; however, its role in the immune modulation in PC has not been reported, to our knowledge, particularly with respect to MCs. We previously reported immunomodulation by SB in basal cell carcinoma, prostate cancer, colon cancer, and hepatocellular carcinoma. Thus, mechanistic aspects of SB treatment on MCs in PC were determined, leveraging bone marrow MCs (BMMCs) derived from C57BL/6 mice, in the presence of IL-3 and SCF (confirmed using flow cytometry [cKit/Fc€RI dual staining]). BMMCs were exposed to different doses of SB (25-100 μM) and two concentrations (25 μM; SB 25 and 100 μM; SB 100) were selected for further experiments. BMMCs treated with SB 25, SB 100, and untreated (control) were subjected to proteomics (LCMS on Fusion Lumos mass spectrometer); 3575 proteins were identified using the annotated mouse proteome. Statistical analysis (ANOVA followed by Fisher's posthoc analysis; $p<0.05$, FDR<0.01) and 166 proteins were found to have statistically significant differential expressions amongst the three groups (n=4/group). These 166 proteins were selected for further pathway analysis using Ingenuity Pathway Analysis (IPA; Qiagen). Only pathways specifically demonstrated experimentally in immune cells/cell lines in PC were selected for further analysis. Top canonical pathways associated with SB treatment of immune cell regulation via MCs were found to be folate signaling pathway, senescence-associated secretory phenotype, cyclins and cell cycle regulation, transcriptional regulation by RUNX2, as senescence pathway. Important upstream regulators were found to be ODC1, CDKN1A, SMAD2, PLAC8, TP53. Important nodes determined were KRAS, GLI1, and ODC1, with the main causal network implicated being polyamine synthesis, hinged on ornithine decarboxylase 1 (ODC1). ODC1 inhibition is proposed to be a potential therapeutic strategy, as pancreatic tumors particularly those resistant to conventional treatments are highly dependent on this enzyme for tumor progression. Thus, SB may play an important immunomodulatory role in PC via regulation of MCs and ODC1. Further studies are warranted to delineate these mechanisms leveraging SB in the form of a preventive or treatment option (supported by R01 CA140368).

#0953 Chemopreventive effects of *Rheum webbianum* against colorectal cancer via modulation of Wnt/β-catenin and TGF-β signaling: Insights from in-vitro and in-vivo studies.

Umer Majeed Khaja[1], Reena Singh[1], Showkat Ahmad Ganie[2]

[1]Bioengineering and Biosciences, Lovely Professional University, Phagwara, Punjab, India,[2]Department of Clinical Biochemistry, University of Kashmir, Srinagar, Jammu and Kashmir, India

Background: Colorectal cancer (CRC) is one of the most prevalent malignancies worldwide, largely influenced by lifestyle and environmental factors. The search for safe, natural chemopreventive agents remains a key research priority. *Rheum webbianum* Royle (RW), a Himalayan medicinal plant with notable ethnopharmacological significance, has shown promising anticarcinogenic activity in prior studies. Building on our earlier findings demonstrating its protective effects against DMH-induced colon carcinogenesis, the present study further explores the anticancer potential of RW ethanolic extract, focusing on its influence on molecular pathways and rectal tissue morphology.

Methods: The ethanolic extract of RW was assessed using both *in-vitro* and *in-vivo* approaches. In HT-29 colorectal adenocarcinoma cells, cytotoxicity and wound-healing assays were used to examine antiproliferative and antimigratory effects. Western blotting analyzed alterations in β-catenin and TGF-β1 expression. In-vivo evaluation was performed using a 1,2-dimethylhydrazine (DMH)-induced CRC rat model to investigate molecular modulation and histopathological alterations in rectal tissues.

Results: *In-vitro*, RW extract markedly reduced HT-29 cell viability in a dose- and time-dependent manner, reaching approximately 80% inhibition at 200 µg/mL, and significantly impaired cancer cell migration. *In-vivo*, RW treatment downregulated β-catenin and TGF-β1 expression, indicating inhibition of oncogenic and pro-metastatic signaling.Histopathology: Microscopic examination revealed marked restoration of rectal tissue architecture in RW-treated groups compared to DMH-only rats. RW-treated animals showed reduced epithelial disruption, congestion, inflammatory infiltration, crypt abscesses, and dysplasia, while DMH-only groups exhibited severe mucosal damage, irregular glandular organization, and extensive inflammatory lesions with crypt abscesses and dysplasia. These findings suggest the protective efficacy of RW extracts in preventing DMH-induced colorectal tissue degeneration.

Conclusion: The ethanolic extract of *Rheum webbianum* demonstrates strong chemopreventive potential against colorectal carcinogenesis by suppressing tumor cell proliferation, migration, and aberrant activation of Wnt/β-catenin and TGF-β signaling pathways, along with restoring rectal tissue integrity. These outcomes support RW as a promising natural candidate for colorectal cancer prevention and integrative therapeutic development.

#0954 Dabigatran etexilate potentiates the anti-tumor effects of anti-CTLA4 antibody through remodeling the immune microenvironment in a syngeneic mouse model of MyC-CaP cells.

Liankun Song, Matthew Gozon, Andrewtrung Le, Jun Xie, Xiaolin Zi

UC Irvine, Irvine, CA

Dabigatran etexilate, an FDA approved thrombin inhibitor, has been used for treatment of venous thromboembolism for many years in cancer patients, including prostate cancer patients. Beyond its anticoagulant properties, the anti-prostate cancer properties and immunomodulatory capacity of dabigatran etexilate remain largely uncharacterized. Therefore, this study aims to determine the anti-tumor effects of dabigatran etexilate alone and its combination with anti-CTLA4 antibody in a syngeneic mouse model of MyC-CaP cells. Mice bearing MyC-CaP xenograft tumors received dabigatran etexilate daily via oral gavage and/or anti-CTLA4 antibody treatments every other day through intraperitoneal injection for 14 days. Tumor volumes were monitored throughout the treatments, after which fresh tumor tissues were dissected for flow cytometric characterization of tumor-infiltrating lymphocytes (TILs). The combination of dabigatran etexilate and murine anti-CTLA4 blocking antibody resulted in significantly enhanced anti-tumor efficacy, achieving 18% greater tumor growth inhibition compared to anti-CTLA4 monotherapy alone, and markedly prolonged overall survival of tumor bearing mice. Flow cytometry analysis revealed that dabigatran etexilate in combination with anti-CTLA4 antibody significantly increased effector T cell (Teff) populations while reducing regulatory T cells (Tregs). Notably, granzyme B-positive cytotoxic CD8+ T cells increased by 1.6 folds in the combination group compared to anti-CTLA4 monotherapy. In addition, granulocytic myeloid-derived suppressor cells (Gr-MDSCs) were significantly reduced in the combination group. Furthermore, single-cell analysis of tumor-infiltrating lymphocytes revealed that dabigatran etexilate and anti-CTLA4 combination therapy markedly increased cytotoxic natural killer (NK) cell infiltration while decreasing suppressive and exhausted NK cell populations. Taken together, our data has shown that dabigatran etexilate potentiates anti-CTLA4 therapy by activating cytotoxic T and NK cells while suppressing immunosuppressive Tregs and Gr-MDSCs. These results suggest that dabigatran etexilate deserves further investigation as a new immunomodulatory agent for prostate cancer prevention and treatment.

#0955 Development of HiBiT tagged high-throughput screening assay for the discovery of SKP2 targeting degraders in prostate cancer.

Liankun Song, Merry Chai, Matthew Gozon, Jun Xie, Saiyang Zhang, Xiaolin Zi

University of California, Irvine, Irvine, CA

S-phase kinase associated protein 2 (SKP2), an E3 ubiquitin ligase for protein degradation and regulating the cell cycle, is overexpressed in high-grade prostatic intraepithelial neoplasia and prostate adenocarcinoma compared to normal prostate tissues, and its higher mRNA levels in prostate tumor tissues are significantly associated with poorer survival of prostate cancer patients. Therefore, identifying novel molecules that promote SKP2 degradation represents a promising strategy for intercepting prostate cancer. We have generated the CRISPR/Cas9 knock-in (KI) of the HiBiT tag at the endogenous *SKP2* locus in the 22Rv1 prostate cancer cell line with *SKP2* gene amplification to enable high-throughput screening of SKP2 protein degraders. Sanger sequencing, western blot and luminescence imaging were performed to confirm the successful expression of the endogenous SKP2-HiBiT in 22Rv1 cells. Screening conditions adapted with nano-Glo® HiBiT lytic detection assay were well established in a 384 well plate format, yielding a high signal-to-background ratio of 69. We have further validated the screening assay with SKP2 C1 inhibitor and Flavokawain A, a naturally occurring chalcone from the Kava plants. Flavokawain A (degrading SKP2 protein) but not C1 (a SKP2 enzyme inhibitor) inhibited the HiBiT luminescence signal, confirming the specificity of the assay. In addition, we have synthesized a small library of chalcone derivatives and by screening them in SKP2-HiBiT-KI 22Rv1 cells, three new SKP2 degraders with improved efficacy have been identified. To avoid false positives due to assay artifacts, compounds that significantly inhibit luminescence within 5 minutes of treatment are excluded from the hits list. The screening assay exhibited robust performance with Z′ factors exceeding 0.6. These three SKP2 degraders significantly reduced the HiBiT luminescent signal at low micromolar concentrations after 8 hours of treatment compared to vehicle control treatment, with minimal effects on cell viability. Western blot analyses further confirmed that these three hits downregulated the protein levels of SKP2 in a dose and time dependent manner. In addition, PC3 cells overexpressing SKP2 are more sensitive to the growth inhibitory effects of these three degraders than SKP2 non-overexpressing PC3 control cells, suggesting the specificity of these degraders for targeting SKP2 overexpressing prostate cancer cells. In conclusion, we successfully established and validated the SKP2-HiBiT-KI 22Rv1screening platform that enables the identification of highly potent, low-toxicity SKP2 degraders for prostate cancer interception.

#0956 The repurpose of dabigatran etexilate for improving prostate cancer prevention and treatment through down-regulating Myc and E2F target genes and inducing autophagic apoptosis.

Guanxing Zhai, Vinh Le, **Liankun Song**, Yixi "Michael" Wu, Xiaolin Zi

UC Irvine, Irvine, CA

Dabigatran etexilate (DAB), an FDA-approved oral anticoagulant drug, has been safely used in cancer patients. While it has been concurrently administered with anti-androgens like enzalutamide in some prostate cancer patients, the potential interactions between DAB and enzalutamide and their effects on prostate cancer cells remain unknown. In this study, we have shown that DAB selectively inhibited prostate cancer cell growth with minimal growth inhibitory effects on normal prostate epithelial cells. Dabigatran induced autophagic apoptosis as evidenced by LC3B/Caspase 3 cleavages and increased autophagic vesicles. Oral administration of DAB significantly inhibited in vivo tumor growth in a xenograft model of 22Rv1 cells and reduced AR and Ki67 expression levels in tumor tissues. A systematic transcriptome analysis of gene expression regulation in DAB treated 22Rv1 cells revealed that the DAB regulated genes were significantly enriched in c-Myc and E2F targets and apoptosis and G2M checkpoint related genes. In addition, DAB acted synergistically with enzalutamide to reduce cell viabilities of prostate cancer cell lines: 22Rv1 and MyC-CaP. Our results indicate that DAB deserves further investigation as a novel anti-cancer agent, for prostate cancer prevention and for treatment of prostate cancer in combination with the main clinically used drug enzalutamide.

#0958 Novel syngeneic models for evaluating therapies targeting $EGFR^{L858R/T790M}$ and $EGFR^{L858R/T790M/C979S}$ resistance mutations in NSCLC.

Lei Ci, Kai Zhou, Jiangyan Liu, Ruilin Sun

GenoBioTX LLC, Suger Land, TX

Both the first and second-generation EGFR-TKIs drugs have markedly improved the survival of NSCLC patients with activating EGFR mutations. However a secondary T790M mutation rapidly drives resistance towards these drugs. Third-generation EGFR-TKIs potently suppress the T790M mutant, but the subsequent C797S mutation abolishes their covalent binding, leaving no currently approved targeted options. Therefore, our laboratory generated conditional knock-in C57BL/6 mice harboring human $EGFR^{L858R/T790M}$ or $EGFR^{L858R/T790M/C979S}$, which quickly develop spontaneous NSCLC and yield primary tumor cell lines.In syngeneic, immune-competent C57BL/6 hosts, the fourth-generation TKI under research, BLU-945, markedly inhibited both $EGFR^{L858R/T790M}$ and $EGFR^{L858R/T790M/C979S}$ tumor growth. In contrast, osimertinib was effective only against $EGFR^{L858R/T790M}$, but failing against the $EGFR^{L858R/T790M/C979S}$ mutation. This demonstrates how our novel mouse models faithfully recapitulate and allow the reversal of osimertinib resistance *in vivo*.

#0959 Harnessing Id1 as a Biomarker in a Plasmid Reporter System for Cervical Cancer.

Abbigael V. Eli, Benjamin B. Kasten, Yolanda Hartman, Rebecca C. Arend, Jason M. Warram

University of Alabama at Birmingham (UAB), Birmingham, AL

Introduction: Ten-year cervical cancer (CC) incidence in the U.S. has remained stable despite screening advancements such as HPV testing, suggesting that new CC screening technologies are needed to address stagnant rates. We proposed a diagnostic plasmid for screening that induces expression of a reporter enzyme (secreted embryonic alkaline phosphatase, SEAP) through the control of the cancer-specific inhibitor of differentiation 1 (Id1) promoter sequence. The resulting plasmid (pId1-SEAP) was used to transfect CC cells in vitro and characterize reporter SEAP production based on Id1 expression. Methods and Results: Western Blot and immunohistochemistry were used to establish Id1 expression in cell models and human tissues. Timed transfections in various conditions were used to correlate Id1 and SEAP expression. CC cell lines (HeLa 3.0±0.13, SiHa 2.9±0.27, CaSki 3.1±0.19, all $P<0.0001$) expressed increased normalized baseline Id1 compared to non-cancer 3T3 fibroblasts (1.0±0.0). In a microarray of CC tissues, normal samples had mean Id1 staining value of 3E4±3E4, while early- and late-stage cancers had increased mean Id1 staining (3E5±1E5 $P<0.0001$ and 2E5±1E5 $P=0.0002$, respectively). HeLa and SiHa lines produced increased normalized SEAP amounts with pId1-SEAP (0.63±0.25 and 0.50±0.10, $P<0.05$) compared to 3T3 cells with pId1-SEAP (0.16±0.058). Id1 and SEAP expression were strongly correlated (Pearson's $r=0.99$, $P=0.012$). As few as 12,500 pId1-SEAP plasmid-exposed HeLa cells co-cultured with naïve cells resulted in an increased SEAP value (3E4±3E3 $P=0.004$) compared to background level (1E4±4E2). Conclusions and Future Directions: pId1-SEAP can transfect CC cells to produce SEAP proportionally to endogenous Id1 expression, demonstrating its potential for future diagnostic tests for CC. These data support further studies to characterize pId1-SEAP function in 3-D tissue models and in vivo animal models, towards the development of a home-based approach to screen for cervical cancer using Id1 expression as a biomarker.

#0960 Dysregulation of the islet hormone cholecystokinin drives obesity-associated pancreatic cancer.

Daniel C. McQuaid[1], Cathy C. Garcia[1], Aarthi Venkat[1], Christian F. Ruiz[1], Christy Zheng[1], Smita Krishnaswamy[2], Mandar Deepak Muzumdar[3]

[1]Yale School of Medicine, New Haven, CT,[2]Yale University, New Haven, CT,[3]Fellow, Medical Oncology, Yale University, New Haven, CT

Pancreatic ductal adenocarcinoma (PDAC) is the third-leading cause of cancer death in the United States with a 5-year survival rate of ~13%. Obesity is a key PDAC risk factor associated with increased incidence and decreased survival, but the mechanisms by which obesity promotes PDAC development and progression remain unclear. To study how obesity drives PDAC, our lab developed a novel genetically engineered mouse model of obesity-associated PDAC and found that obese mice had significantly increased disease burden relative to lean controls, a phenotype which was abrogated by early induced weight loss. Molecular analyses of the pancreata from obese mice showed marked upregulation of the peptide hormone cholecystokinin (CCK) in β cells of the endocrine pancreas due to stress-responsive JNK/cJun signaling. CCK canonically promotes digestive enzyme release in exocrine acinar cells, the putative PDAC cell-of-origin, and acts as a survival factor in endocrine β cells under conditions of increased insulin demand, such as obesity. Exogenous CCK stimulates acinar cell proliferation and ductal metaplasia, early prerequisite steps in PDAC development. Strikingly, we found that β cell CCK overexpression was sufficient to enhance exocrine tumorigenesis in lean mice, phenocopying the effects of obesity and validating β cell CCK as an independent driver of PDAC development. Conversely, pancreas-specific CCK knockout significantly abrogated exocrine tumorigenesis in obese mice similar to levels seen in lean mice. Critically, tumor burden was significantly positively associated with pancreatic CCK expression and negatively correlated with endogenous insulin production, suggesting that CCK, rather than insulin, drives obesity-associated tumorigenesis. Finally, treatment of obese mice with GLP-1 receptor agonists (GLP-1RAs), which augment glucose-stimulated insulin secretion and improve β cell health, enhanced β cell function and significantly decreased pancreatic CCK expression. Together, this work has established endocrine-exocrine CCK - rather than insulin - as a critical previously unappreciated mediator of obesity-driven PDAC and enabled the identification of novel translational approaches, including GLP-1RAs, to intercept obesity-associated PDAC development.

#0961 HSC-humanized mouse model: Invivo CAR-T mediated B-cell depletion and application in targeted drug screening.

Xiaolei Qiu, Lei Ci, Ruilin Sun

GenoBioTX LLC, Sugar Land, TX

Background: In the research of targeted therapy for B-cell related malignant tumors and autoimmune diseases, traditional animal models have limitations such as significant species differences and inadequate mimicry of human immune function, which hinder the efficiency of drug development. Hematopoietic Stem Cell (HSC)-humanized mice can reconstitute a functional human immune system, providing an ideal in vivo research platform to address these issues. Their application value in the evaluation of in vivo CAR-T (Invivo CAR-T) therapy and screening of innovative drugs urgently needs to be verified.

Methods: A standardized protocol was used to construct the HSC-humanized mouse model: Severe immunodeficient NMG mice were preconditioned with sublethal dose irradiation (1.2 Gy) to disrupt the endogenous hematopoietic system and create space for human HSC engraftment. Subsequently, 1.5×10^5 sorted and purified human umbilical cord blood-derived $CD34^+$ HSCs per mouse were transplanted via tail vein injection. After stable model reconstitution (peripheral blood $hCD45^+$ cell ratio ≥25%), the CD19-targeted Invivo CAR-T system was used for intervention. CAR gene/mRNA was delivered via viral vectors (e.g., lentivirus, adeno-associated virus) or targeted lipid nanoparticles (tLNP). Following a single administration, the B-cell depletion efficiency in peripheral blood and spleen, as well as the CAR transfection positive rates in $CD4^+$ T cells and $CD8^+$ T cells, were detected simultaneously.

Results: After transplantation, $CD34^+$ HSCs successfully engrafted in the bone marrow of HSC-humanized mice and achieved multi-lineage differentiation, forming a stable population of human immune cells. The immune reconstitution exhibited a time-dependent characteristic: T cells accounted for 40%-50% at 14-20 weeks, B cells were the dominant population in the early stage, accompanied by low-proportion reconstitution of myeloid cells such as NK cells (average proportion ~2%) and monocytes. Human immune checkpoint molecules were expressed on the surface of immune cells. After Invivo CAR-T intervention, autologous B cells in the peripheral blood and spleen of mice were significantly depleted with a near-complete clearance efficiency, and positive CAR expression was detected in both $CD4^+$ T cells and $CD8^+$ T cells. Further analysis showed that B-cell reconstitution was dominated by naive B cells after depletion, suggesting functional resetting of the immune system. By synchronously monitoring CAR transfection efficiency and target cell clearance effect, it provides crucial technical support for the efficacy screening, dosage optimization, and safety evaluation of innovative drugs targeting B cells.

#0962 Phenylacetaldehyde induces apoptosis through endoplasmic reticulum stress and potentiates the effect of 5-FU treatment in colorectal cancer.

Sylvain Ferrandon[1], Cheng Kong[2], sara soltani tehrani[1], Joseph Fedro[1], Rami-James Aoun[1], Zeneng Wang[3], Chureeporn Chitchumroonchokchai[1], Huanlong Qin[4], Steve Clinton[1], Matthew F. Kalady[1]

[1]The Ohio State University College of Medicine, Columbus, OH,[2]Fudan University Shanghai Cancer Center, Shanghai, China,[3]The Lerner Research Institute - Cleveland Clinic, Cleveland, OH,[4]Shanghai Tenth People's Hospital, Shanghai, China

Introduction: Phenylacetaldehyde (PAA), a product of phenylalanine metabolism, is generated by microbiota and has demonstrated anticancer properties in breast cancer. As intestinal homeostasis is influenced by the gut microbiome, we investigated the effect of PAA on colorectal cancer (CRC).

Methods: Serum PAA levels and feces microbiota from a test cohort of 30 CRC patients and 30 healthy control patients were analyzed by targeted GC-MS/MS and metagenomic sequencing. A validation cohort of 75 CRC patients and 53 healthy control patients was analyzed for PAA levels in serum. CRC cell lines and CRC-patient-derived organoids were cultured and treated with PAA alone or in combination with 5-fluorouracil (5-FU), then evaluated for viability, proliferation, , and cell death *in vitro*. The effect of PAA alone or in combination with 5-FU on tumor growth was also tested *in vivo*. We identified the mechanisms induced by PAA treatment using RNA sequencing, western blot, immunostaining, ROS quantification assay, cysteine and glutathione quantification.

Results: PAA levels were significantly decreased in the circulation of CRC patients compared to healthy controls in our study population and the validation cohort. Metagenomic sequencing indicated the bacteria that positively correlated with PAA levels were significantly more abundant in healthy controls; while bacteria that negatively correlated with PAA were more abundant in CRC. *In vitro*, PAA inhibited the viability and colony formation of CRC cell lines as well as human-derived organoids in a concentration-dependent manner. Mechanistically, PAA treatment induced generation of ROS leading to cysteine and reduced glutathione depletion. An investigation by RNA sequencing and immunoblotting showed that PAA inhibits CRC by inducing endoplasmic reticulum stress-induced autophagy accompanied by downregulation in PI3K/AKT/mTOR and ERK pathways. When combined with 5-FU, PAA enhanced the potency of 5-FU on viability, cell death, DNA damage and tumor growth.

Conclusions: The bacteria metabolite PAA increased CRC cell death by endoplasmic reticulum stress-induced autophagy and downregulation of the PI3K/AKT/mTOR and ERK pathways. PAA also potentiated the chemotherapeutic efficacy of 5-FU through induction of DNA damages. These findings warrant further exploration of PAA as a potential CRC biomarker and novel therapeutic agent.

#0963 Preclinical testing of A_{2B} adenosine receptor inhibitor PSB1115 for pancreatic cancer immunoprevention.

Alyssa M. Waller[1], Lincoln Strickland[1], MacKenzie Demmel[1], Erika Y. Faraoni[2], Michelle I. Savage[3], Shizuko Sei[4], John L. Clifford[4], Powel H. Brown[5], Eduardo Vilar-Sanchez[5], Florencia McAllister[5], Jennifer Bailey-Lundberg[1]

[1]University of Nebraska Medical Center, Omaha, NE,[2]Department of Genetics, The University of Texas MD Anderson Cancer Center, Houston, TX,[3]Department of Clinical Cancer Prevention, The University of Texas MD Anderson Cancer Center, Houston, TX,[4]Division of Cancer Prevention, Chemopreventative Agent Development Research Group, National Cancer Institute, Rockville, MD,[5]UT MD Anderson Cancer Center, Houston, TX

Introduction: Pancreatic ductal adenocarcinoma (PDAC) is an aggressive malignancy with very poor prognosis due to low efficacy of current treatments and late-stage diagnosis. PDAC is characterized by a profoundly immunosuppressive tumor microenvironment (TME), with the adenosine signaling pathway acting as an important mediator of immune suppression. In this pathway, adenosine (an immunosuppressive metabolite) signals via adenosine receptors, including the A_{2B} receptor. The goal of this study is to test immunopreventative strategies that target the A_{2B} adenosine receptor to reduce intratumoral adenosine and prevent immune suppression. We hypothesize that the use of small molecule A_{2B} inhibitors will prevent the progression of PDAC by shifting the immune microenvironment and promoting anti-tumor immunity.

Methods: A syngeneic model of PDAC was used with tumor cells derived from $Kras^{G12D}$; $Trp53^{R172H}$/+; Pdx1:Cre (KPC) mice. Tumor cells were implanted subcutaneously in the flanks of immunocompetent C57BL/6 mice. Oral gavage delivery of PSB1115 (small molecule A_{2B} inhibitor) began 14 days after KPC implantation, when tumors were palpable. Mice were treated either three days/week or seven days/week at 0.7mg/kg, and tumor sizes were measured twice weekly. After two weeks of treatment, mice were euthanized. Blood and tumors were collected at the time of euthanasia. Histology was analyzed and 10 fields per mouse were quantified using ImageJ.

Results: Oral gavage delivery of PSB1115 reduced the growth rate of KPC subcutaneous tumors in the syngeneic model. While mice treated with PSB1115 trended to have smaller final tumor volumes when compared to vehicle controls in both the 3 and 7 days a week treatment groups, these changes were more pronounced in the 7 days/week group (three-fold reduction; $p=0.07$) as compared to the 3 days/week group (two-fold reduction; $p=0.1$). Immunohistochemical staining of tumors showed that treatment with PSB1115 induced significant $CD8^+$ T-cell infiltration ($p=0.0174$) and increased Granzyme B expression ($p<0.0001$), indicating an activated cytotoxic immune response. There was no significant increase in the amount of NIMPR14+ cells when comparing the vehicle control and PSB1115 treated tumors ($p=0.1565$). When compared to vehicle controls, tumors treated with PSB1115 had significantly increased levels of CD68 ($p<0.0001$), with no significant increase in CD163 levels ($p=0.1174$), indicating infiltration of anti-tumor M1-like macrophages.

Conclusions: Oral gavage delivery of PSB1115 and targeting of the adenosine A_{2B} receptor alters the immune landscape in subcutaneous PDAC tumors, promoting $CD8^+$ T-cell and M1-like macrophage infiltration through reduced A_{2B} receptor signaling. Small molecule inhibitors targeting the A_{2B} adenosine receptor are promising candidates for immunoprevention in PDAC. [Supported by NCI 75N91019D00021/75N91023F00003]

#0964 Accelerated Pirc rat model for animal efficacy trials for prevention and treatment of colorectal cancer.

Rashim Singh, Vesna Tumbas Saponjac, Trang Le Nu Huyen, Jie Yang, Jie Chen, Taijun Yin, Songpol Srinual, Ming Hu

Pharmacological and Pharmaceutical Sciences, University of Houston, College of Pharmacy, Houston, TX

PURPOSE: The Pirc rat (F344/NTac-Apc^{am1137}) model has played a critical role in advancing our understanding of colorectal cancer (CRC) pathogenesis and in evaluating preventive/therapeutic strategies. The objective of this study was to establish an inflammation-driven accelerated model of colon polyp growth in Pirc rats. This model replicates chronic epithelial barrier disruption and low-grade gut inflammation, thereby reflecting real-world scenarios of lifestyle and environmental factors combined with genetic predisposition towards CRC development.

METHODS: Dextran sodium sulfate/DSS (in drinking water) and/or high-fat diet/HFD (60 kcal% as fat) treatment was given to Pirc rats, whereas control rats received a regular rodent diet with no DSS. Two cycles (5 days ON, 9 days OFF, and 3 days ON) of DSS treatment (1-2% w/v) were administered starting at 6.5 weeks of age to accelerate colon polyp development without causing colitis. The effects of HFD treatment alone (6.5-16.5 weeks) and in combination with 2%DSS treatment were established. 2%DSS+HFD-treated rats received Celecoxib (70 mg/Kg/day, p.o. from 10.5-16.5 weeks) to confirm the response of the model to the anti-inflammatory agent. The colon polyp burden was determined after euthanizing rats at Week 16.5.

RESULTS: No colitis was observed in animals during 1% or 2%DSS treatment, whereas consumption of HFD caused constipation. Minor body weight loss (<5%) was observed during DSS treatment. Administration of 2%DSS but not 1%DSS or HFD alone increased the polyp burden (n=2/group). However, the addition of HFD to 2%DSS treatment dramatically increased colon polyp number (9.7-fold, $p<0.001$) and volume (12.7-fold, $p<0.01$) in treated female rats (n=10) as compared to control rats (n=10), with larger size (>6 mm in diameter) polyps observed in the treated group only. In male rats, 2% DSS alone (n=4) or in combination with HFD (n=7) led to higher polyp numbers (2.6-2.8-fold), volumes (1.8-3.5-fold), and larger size compared to control (n=7). Celecoxib treatment reduced the polyp growth in male and female rats treated with 2%DSS+HFD (n=7), though statistical significance was not achieved.

CONCLUSION: We successfully established an accelerated polyp development Pirc rat model, providing a better platform for high-throughput screening of pharmacological and dietary interventions for CRC chemoprevention in FAP and other high-risk populations, with greater translational potential. A single anti-inflammatory agent was ineffective at preventing aggressive polyp growth in this model, suggesting that combination therapies targeting multiple targets may be required. The mechanism of action underlying CRC development in this model is being investigated to identify new pharmacological targets and combinations.

ACKNOWLEDGEMENTS: This research was funded by CPRIT RP240401. Rashim Singh is supported by the NCATS under award number K12TR004522.

#0965 A novel agonist of CD137, SA-4-1BBL, as a single agent halts spontaneous breast cancer progression.

Yongyong Li[1], Sarita Rani[1], Feyza Nur Arguc[1], Yichen Wang[1], Daniel Davis[2], Esma S. Yolcu[3], Haval Shirwan[4]

[1]Molecular Microbiology and Immunology, NextGen Precision Health, University of Missouri-Columbia, Columbia, MO,[2]Pathobiology and Integrative Biomedical Sciences, University of Missouri-Columbia, Columbia, MO,[3]Molecular Microbiology and Immunology, Pediatrics, NextGen Precision Health, University of Missouri-Columbia, Columbia, MO,[4]Molecular Microbiology and Immunology, NextGen Precision Health, School of Medicine, University of Missouri-Columbia, Columbia, MO

Introduction: Breast cancer is the most commonly diagnosed cancer among women globally, and early immunologic intervention could reduce disease burden and improve long-term outcomes. Immunotherapy has demonstrated encouraging efficacy and an acceptable safety profile in both early-stage and metastatic triple-negative breast cancer. However, currently approved immunotherapies such as PD-1/PD-L1 blockade, HER2-targeted antibodies, and tumor vaccines exhibit highly variable responses due to tumor-intrinsic factors and the immunosuppressive tumor microenvironment. A novel CD137 agonist, SA-4-1BBL, as a single agent, prevents the development of various transplantable tumor types as well as a tobacco carcinogen, NNK, induced spontaneous lung cancer in preclinical models with an excellent safety profile. Here, we evaluated the immunoprevention efficacy of SA-4-1BBL in a mouse model of spontaneous breast cancer, MMTV-PyMT, which recapitulates the progression of human breast cancer.
Study design: Female MMTV-PyMT C57BL/6J mice, aged 5 (n=12) or 8 (n=17) weeks, were assigned to either the SA-4-1BBL or saline (n=19) treatment groups. SA-4-1BBL was administered every two weeks for a total of four doses. Tumor growth was monitored twice weekly for 120 days, at which time animals were euthanized to collect tumors, tumor-draining lymph nodes, and spleen for tumor weight measurement, histology, and deep immunophenotyping.
Results: SA-4-1BBL significantly delayed the onset of tumors and inhibited their progression in both the 5-week and 8-week treatment cohorts. Median tumor appearance was observed at 13 weeks in PBS controls, compared to 16.5 weeks for the 5-week cohort and 15 weeks for the 8-week cohort. Tumor growth was markedly reduced in both SA-4-1BBL-treated groups ($p < 0.0001$). As compared to saline controls, both SA-4-1BBL treatment groups showed a significant reduction in tumor weight by ~76% and a decrease in the number of tumor-bearing mammary glands by ~50%. Deep immunophenotyping of tumor-draining lymph nodes showed substantial increases in multiple immune cell subsets, including NK cells, $CD4^+$ T cells, and $CD8^+$ T cells, demonstrating enhanced antitumor immunity.
Conclusion: SA-4-1BBL, as a single agent, effectively suppresses spontaneous breast tumor development and progression in the MMTV-PyMT model. These findings support its potential as a promising biologic for breast cancer immunoprevention. Elucidation of the underlying mechanisms will further guide the optimization and clinical translation of this protocol for immunoprevention of cancer in high-risk individuals.

#0966 Development of a humanized IL-17A/IL-17F mouse model for preclinical efficacy studies of IL-17-related diseases.

Huacheng He, Ailin Yang, Shuang Li, Qingqing Qi, Yi Li, Ruilin Sun

GenoBioTX LLC, Sugar Land, TX

Background: IL-17 cytokine family members exert diverse biological functions, promoting protective immunity against many pathogens while also driving inflammatory pathology in infection and autoimmunity. The IL-17 pathway has therefore become a major therapeutic target in autoimmune and chronic inflammatory disorders such as rheumatoid arthritis, multiple sclerosis, and psoriasis. Therapeutic monoclonal antibodies targeting IL-17A, IL-17A/IL-17F, the IL-17 receptor, or IL-23 have demonstrated substantial clinical efficacy in several of these conditions. In this study, we developed a novel humanized IL-17A/IL-17F mouse model and established an imiquimod (IMQ) -induced psoriasis model to evaluate the preclinical efficacy of bimekizumab and other test articles.
Methods: The hIL-17A/hIL-17F dual knockin mice were generated by homologous recombination, replacing the entire coding sequences of mouse *Il-17a* and *Il-17f* with their human counterparts while preserving the endogenous murine signal peptides. Human IL-17A and IL-17F mRNA transcription was validated by qRT-PCR, and corresponding serum protein levels were quantified by ELISA. Finally, topical IMQ application was used to trigger psoriasiform dermatitis on the back and ear skin of the hIL-17A/hIL-17F dual knockin mice. Bimekizumab and additional test agents were administered, and in vivo efficacy was assessed by H&E staining, pathological scoring, and cytokine profiling.
Results and Conclusion: IMQ treatment induced a psoriasis-like phenotype in hIL-17A/hIL-17F mice and resulted in high expression of human IL-17F. Bimekizumab and the test articles markedly improved histopathological features and reduced the levels of IL-17F in our mice. Overall, these findings demonstrate that the hIL-17A/hIL-17F dual humanized mouse provides an advanced tool for preclinical efficacy studies of IL-17-related therapeutics.

#0967 Prevention and interception of triple-negative breast cancer and its metastasis to the brain with brain-permeant L024.

Atieh Hajirahimkhan[1], Alexander D. Eremin[1], Elizabeth Bartom[2], Saktimayee M. Roy[1], Daniel M. Watterson[1], Susan E. Clare[3], Seema A. Khan[4]

[1]Northwestern University - Chicago, Chicago, IL,[2]Northwestern University, Evansville, IL,[3]Associate Professor, Surgery, Northwestern University Feinberg School of Medicine, Chicago, IL,[4]Professor of Surgery & Bluhm Family Professor of Cancer Research, Robert H. Lurie Comp. Cancer Center of Northwestern University, Chicago, IL

Introduction: Estrogen receptor-negative (ER-neg) breast cancer (BC) disproportionatelyaffects younger women, women of African descent, and underserved populations. Nopreventive agents are approved for this subtype. ER-neg BCs, including triple-negative (TNBC)and HER2+ tumors, often metastasize to the brain early, yet remain undetected until neurologicsymptoms emerge, when prognosis is poor. Current therapies, including ER-neg adjuvantagents, offer limited brain efficacy due to poor blood-brain barrier penetration. Radio-surgicalinterventions for brain metastases have severe side effects with no survival benefit. There is acritical need for safe, risk-reducing therapies that prevent both ER-neg BC and braindissemination.We identified L024, a first-in-class agent with efficacy against ER-neg BC. Mechanistically, L024inhibits SREBP1-driven lipogenesis, suppresses the PI3K-AKT axis, and downregulates NF-κB-mediated inflammation, key pathways in ER-neg progression. We have demonstrated that L024suppresses tumor growth and we hypothesize that it will intercept early brain metastasis, offering a novel preventive and interceptive approach.
Methods: We assessed L024's antiproliferative activity in six ER-neg BC lines: MDA-MB-231,HCC-1937, HCC-3153, 4T1, 4T1-BM2, and MDA-MB-231-Br using IncuCyte live cell imaging. Xenografts were developed using MDA-MB-231 cells in nude mice; L024 (80 mg/kg/day) was administered when tumors reached threshold size. Tumor growth was monitored over 28 days;RNA-seq was performed on excised tumors. Transwell assays with/without matrix assessedinvasion/migration of brain-tropic cells after a sublethal L024 dose (2.5-5 μM). Western blotswere performed after 24 h L024 (5 μM) exposure to assess downstream effectors. ADMEproperties were evaluated in silico (ACD Lab). PK was analyzed in female CD-1 mice dosed with L024 (50 mg/kg), with drug levels in plasma, mammary, and brain measured with LC-MS/MS, and modeled using SAAM II.
Results: L024 significantly inhibited TNBC proliferation in a dose-dependent manner, with sustained effects six days post-treatment. It reduced tumor growth and epithelial-to-mesenchymal transition in the xenografts. Sublethal doses impaired invasion and migration ofbrain-tropic cells. Western blots showed reduced PI3K, AKT, and pAKT (Ser473). In silicoprofiling predicted CNS permeability: molecular weight <400 Da, LogP = 3.9, TPSA = 66.76 Å^2,and no P-gp/BCRP efflux. In vivo PK confirmed high brain exposure (Kp >1 between 1-8 h),cleared by 24 h, supporting prevention/therapy potential.
Conclusions: L024 reprograms metabolic pathways essential for ER-neg BC progression,specifically targeting multiple steps of the metastatic cascade. CNS PK supports furtherevaluation in immunocompetent TNBC models with brain metastatic potential.

#0968 Fully human anti-PD-L1 antibodies with tumor cytotoxicity: Screening in SmocMab mice.

Ningning Ge, Huacheng He, Lei Ci, Ruilin Sun, Dongxiao Feng

GenoBioTX LLC, Sugar Land, TX

PD-L1 is highly expressed across a broad spectrum of tumor cells and negatively regulates the tumor cytotoxicity of T cells. Herein, we generated multiple fully human anti-PD-L1 antibodies with high binding affinity through single B cell screening, utilizing SmocMab mice humanized for the variable regions of immunoglobulin heavy and light chains. These antibodies effectively blocked the PD-1/PD-L1 interaction *in vitro* and exhibited potent endocytic activity. In *in vivo* studies, monotherapy with the anti-PD-L1 antibodies demonstrated significant tumor-suppressive effects in hPD1 C57BL/6 mice. Furthermore, PD-L1 antibody-drug conjugates (ADCs) constructed based on these anti-PD-L1 antibodies substantially enhanced tumor-killing efficacy. Collectively, these findings validate that SmocMab mice serve as a robust platform for the screening of fully human antibodies with promising therapeutic potential.

#0969 Humanized TFR1 knock-in mice: A powerful platform for evaluating TFR1-targeting brain shuttles.

Liping Feng, Shuang Li, Zixuan Cao, Yi Li, Dongxiao Feng, Ruilin Sun

GenoBioTX LLC, Sugar Land, TX

Background: The development of therapeutic antibodies and antibody-based diagnostics for the neurological disorders and gliomas is largely hampered by the presence of blood-brain barrier (BBB). While the BBB restricts most large molecules, it permits the transport of essential nutrients through selective transport mechanisms, creating opportunities to delivery drugs into the central nervous system using brain shuttle technologies. Transferrin receptor 1 (TFR1), which is expressed on brain endothelial cells (BECs), is one of the most extensively studied targets for receptor-mediated transcytosis (RMT) and has been validated as a gateway for brain drug delivery. To support the development of TFR1-targeting antibody or peptide-based brain shuttles, we generated a humanized TFR1 knock-in mouse model (hTFR1), serving as a robust preclinical platform for evaluating the efficacy, safety, and PK/PD profiles of TFR1-targeted therapeutics.

Methods: The hTFR1 knock-in mouse model was generated by inserting the full-length human TFR1 coding sequence plus WPRE/polyA stop cassette into mouse *Cd71* gene locus in C57BL/6 background via ES cell-based gene targeting, in which full-length human TFR1 proteins are expressed on the surface of targeted cells. To characterize the human TFR1 expression in the hTFR1 knockin mice, we assessed its localization on the brain endothelial cells by immunofluorescence (IF) staining and performed flow cytometry analysis to characterize its expression on activated T cells. Finally, we administered Trontinemab and the anti-human TFR1 antibodies generated via our SmocMab platform to hTFR1 mice through *i.v.* injection to evaluate th PK characteristics and brain uptake capability across the BBB.

Results: Human TFR1 expression in hTFR1 mice was confirmed in brain microvessels and was upregulated on activated T lymphocytes. For PK analysis, brain tissues and serum samples were collected 24 hours after a single intravenous dose (10 mg/kg) of the human-specific TFR1 antibodies or a control antibody. Antibody concentrations were quantified by ELISA. The human-specific TFR1-binding antibody showed accelerated serum clearance and increased brain uptake compared with the control antibody, demonstrating its enhanced ability to penetrate the BBB.

Conclusions: Our humanized TFR1 knockin mice provides a powerful tool for preclinical evaluation of TFR1-targeting therapeutic antibodies.

#0970 A Jak2-V617F knock-in mouse model for assessing therapeutic efficacy in myeloproliferative neoplasms.

Ailin Yang, Shuang Li, Qingqing Qi, Yi Li, Ruilin Sun

GenoBioTX LLC, Sugar Land, TX

Background: Myeloproliferative neoplasms (MPN) are a group of malignant hematological disorders characterized by excessive proliferation of blood cells and are often accompanied by splenomegaly, thrombosis, and bleeding tendencies. The main subtypes of MPN include polycythemia vera (PV), essential thrombocythemia (ET), and primary myelofibrosis (PMF). The acquired somatic JAK2-V617F mutation occurs in approximately 95% of PV cases and in about 50% of ET or PMF patients. This mutation results in constitutive activation of the JAK2 kinase signaling pathway, establishing it as a critical therapeutic target in MPNs. Therefore, to enable preclinical evaluation of therapies targeting this mutation, we developed a novel Jak2-V617F knock-in mouse model.
Method: Firstly, we generated Jak2-Flox-V617F mice by inserting the inverted exon 14 cassette (carrying the c.1849 G>T, p. V617F mutation) flanked by antiparallel loxp sites into the endogenous *Jak2* exon14 locus via ES cell-based gene targeting. These mice were then crossed with Vav1-Cre mice to obtain heterozygous Jak2-Flox-V617F/Vav1-Cre offspring (Jak2-V617F mice), in which Cre-mediated recombination induces Jak2-V617F expression specifically in the hematopoietic cells. The mutant mice were phenotyped using blood routine analysis, flow cytometry, H&E staining and pathology analysis. Finally, we tested the JAK inhibitor Ruxolitinib, a clinical agent for myelofibrosis, for its efficacy in this model.
Results: Compared with wild-type mice, Jak2-V617F mice exhibited significantly elevated hemoglobin and hematocrit levels, marked thrombocytosis, increased neutrophils, alopecia and splenomegaly at 8 weeks. By 28 weeks, pathology analysis revealed megakaryocyte hyperplasia and extramedullary hematopoiesis in bone marrow, spleen, and liver in Jak2-V617F mice. Notably, these hematological abnormalities and splenomegaly were significantly mitigated by oral administration of Ruxolitinib.
Conclusion: Taken together, our Jak2-V617F mouse model provides a unique platform for studying the mutation of Jak2 in the hematopoietic cells and evaluating the efficacy of potential therapeutic targets in preclinical studies.

#0974 AI-driven- structure-based drug discovery and validation of novel compounds as CTLA-4/B7 inhibitors.

Poonam Kalhotra[1], Tzayhri Gallardo-Velazquez[2], Guillermo Osorio-Revilla[3], Veera Chandra Sekhar Reddy Chittepu[4]

[1]Medical Oncology, Jerome Lipper Multiple Myeloma Disease Center, Dana-Farber Cancer Institute, Harvard Medical School, Boston,, MA,[2]Departamento de Biofisica, Escuela Nacional de Ciencias Biologicas, Instituto Politecnico Nacional, Mexico City, Mexico,[3]Departamento de Ingenieria Bioquimica, Escuela Nacional de Ciencias Biologicas, Instituto Politecnico Nacional,, Mexico City, Mexico,[4]Harvard Medical School/Brigham and Women's Hospital, Boston, MA

In recent years, CTLA-4/B7 immune checkpoints have been well known to suppress T-cell activation, with implications for patient survival under targeted therapeutics. Monoclonal antibodies targeting this immune checkpoint pathway have proven effective, and the use of recently FDA-approved antibodies clearly demonstrates their clinical and therapeutic value, showing promise across solid and hematologic cancers. However, the potential of small molecules derived from nature as future CTLA-4/B7 inhibitors remains largely unexplored. Naturally occurring compounds, as sources of chemical diversity, could yield novel leads for immune checkpoint inhibition. This approach may serve as one of the core strategies in modern immuno-oncology, complementing antibody-based therapies to improve patient outcomes in clinical settings.
In this study, we developed CTLA-4/B7-specific machine learning (ML) and artificial intelligence (AI) models, along with 3D-QSAR models, to assist in ligand discovery as CTLA-4/B7 inhibitors. Structure-based virtual screening of compounds arising from natural sources was performed. Any compound predicted by our AI models as positive served as a candidate for subsequent structural biology studies. Protein-ligand interactions were investigated using molecular docking simulations, and the stability of resulting CTLA-4-inhibitor-B7 complexes was assessed using molecular dynamics simulations.To study biological relevance, we employed a PBMC-based functional assay and a tumor-relevant co-culture model (PBMC-B7 + tumor cells) to determine whether discovered leads could restore T-cell cytokine responses suppressed through CTLA-4/B7 engagement, complementing binding studies.
Our ML/AI models prioritized flavones as new potential CTLA-4/B7 inhibitors, predicting binding affinity and favorable IC_{50} values. Molecular dynamics simulations further confirmed the stability of protein-flavone interactions. Experimentally, we selected chrysin, naringenin, and morin as representative molecules to validate that our workflow has potential to aid in the discovery of CTLA-4/B7 inhibitors. Functional assays revealed that flavones restored cytokine production suppressed as a result of CTLA-4/B7 engagement, thereby validating their immunological activity.Overall, our approach broadens therapeutic possibilities beyond antibody-based blockade, offering benefits in combination with existing therapeutics. The leads discovered may serve as starting points to develop derivatives that could advance next-generation immuno-oncology therapeutics to improve cancer care.

#0975 Deep learning-based screening and design of novel therapeutics that reverse cancer-associated transcriptional phenotypes.

Jing Xing[1], Mingdian Tan[2], Dmitry Leshchiner[1], Mengying Sun[3], Shreya Paithankar[1], Rama Shankar[1], Erika Lisabeth[3], Bilal Aleiwi[3], Ruoqiao Chen[3], Matthew Giletto[3], Richard Neubig[3], Samuel So[2], Edmund Ellsworth[3], Mei-Sze Chua[2], Jiayu Zhou[4], **Bin Chen**[1]

[1]Michigan State University, Grand Rapids, MI,[2]Stanford University, Palo Alto, CA,[3]Michigan State University, East Lansing, MI,[4]University of Michigan, Ann Arbor, MI

Identifying drugs that reverse expression of disease-associated transcriptomic features has been widely explored as a strategy for discovering drug repurposing candidates, but its potential for novel compound discovery and optimization remains largely underexplored. Here, we present a deep learning-based drug discovery platform, guided by transcriptomic features, that screens large compound libraries and optimizes lead compounds. We first develop a model that predicts gene expression changes solely from chemical structures and deploy it to infer the expression changes induced by compounds in large screening libraries. We then refine compound scoring and employ a Monte Carlo Tree Search method for multi-objective optimization. By incorporating Structure-Gene-Activity Relationships, we uncover drug mechanisms directly from transcriptomic data. To demonstrate the utility of the system, we identify and validate compounds for hepatocellular carcinoma (HCC). In HCC, we design a novel compound that improves the IC_{50} from 4 μM to 0.5 μM, with increased *in vitro* selectivity, favorable pharmacokinetics and *in vivo* activity.

#0976 FGFR3-TACC3 fusion: multi-omics and machine learning characterization across tumor types.

Manuel Pedregal[1], Esther Cabanas Morafraile[2], Balazs Győrffy[3], Ester Garcia[4], Miriam Dorta[4], Bernard Gaston Doger de Speville[4], Emiliano Calvo[5], Alberto Ocana[6], Victor Moreno Garcia[4]

[1]START - Madrid, Madrid, Spain,[2]Center for Biological Research Margarita Salas (CIB-CSIC), Spanish National Research Council, Madrid, Spain,[3]Institute of Transdisciplinary Discoveries, Medical School, University of Pecs, H-7624, Pecs, Hungary, Budapest, Hungary,[4]START - Madrid - FJD, Madrid, Spain,[5]START Madrid CIOCC - Catedra Intheos-START-CEU, Madrid, Spain,[6]Catedra INTHEOS-START-CEU, Madrid, Spain

Background: The FGFR3-TACC3 (FGFR3-TACC3) fusion is a recurrent oncogenic alteration observed in gliomas, urothelial, and head and neck cancers. This fusion drives constitutive FGFR3 kinase activation and disrupts mitotic spindle organization through TACC3, leading to uncontrolled proliferation and transcriptional reprogramming. To elucidate the molecular landscape and therapeutic vulnerabilities of FGFR3-TACC3-positive tumors, we integrated genomic, transcriptomic, and computational analyses.
Methods: Transcriptomic data from TCGA cohorts were analyzed to compare FGFR3-TACC3-positive and wild-type tumors. Differentially expressed genes (fold change > 2 or < -2) were intersected with druggability databases to identify actionable targets. In parallel, we analyzed 58 FGFR3-TACC3 fusion samples and 9,642 non-fusion cases to determine recurrently mutated genes and enriched Gene Ontology (GO) terms. A combined neural network and random forest classifier was trained on mutational and functional features to discriminate fusion from non-fusion profiles.
Results: FGFR3-TACC3 fusion tumors exhibited a distinct transcriptional and mutational signature, including 1,984 upregulated and 2,504 downregulated genes, with enrichment in RTK/MAPK signaling, mitotic spindle assembly, and vesicle transport pathways. Integration with pharmacologic databases revealed 48 co-expressed druggable genes, encompassing oncogenic kinases (FGFR3, EGFR, CDK4, PDGFRA, NTRK3) and neurotransmission-associated receptors (OXTR, ADORA1, GRIA3/4). Machine-learning analysis identified 9 recurrently mutated genes and 69 informative GO terms, achieving an AUC of 0.85 and accuracy of 0.79, highlighting a robust functional signature of FGFR3-TACC3 fusion tumors.
Conclusions: This integrated multi-omics and machine-learning study suggests a functional, transcriptional, and pharmacologic landscape of FGFR3-TACC3 fusion-driven cancers. The combined mutation-GO-transcriptome framework uncovers potential druggable co-dependencies and provides hypotheses for rational combination strategies and precision therapies for FGFR3-TACC3-positive tumors that warrant experimental validation.

#0977 VINI: A multimodal *in silico* platform for discovering rational drug combinations in KRAS-mutant pancreatic cancer.
Drasko Tomic

Ruđer Bosković Institute, Zagreb, Croatia

Rational combination therapies are urgently needed for aggressive KRAS-mutant cancers such as pancreatic ductal adenocarcinoma (PDAC), which has a 5-year survival rate below 10%. VINI is a multimodal *in silico* platform that integrates AI, quantum-informed algorithms, pathway modeling, and structural data to accelerate the discovery of effective drug combinations. Its foundation is based on KEGG cancer pathways, with gene expression and mutation data from the Cancer Cell Line Encyclopedia (CCLE), molecular structures from PubChem and DrugBank, three-dimensional protein structures from RCSB PDB or AlphaFold predictions, and protein sequences from UniProt and DrugBank (for monoclonal antibodies), capturing disease-specific biology.
VINI uses AI and semi-empirical quantum-informed virtual screening (planned for implementation in the upcoming Horizon project) to predict intracellular drug efficacy and multi-drug synergy. Classical computational chemistry tools, including Rosetta, AutoDock Vina, UCSF Chimera, and Scripps MGLTools, are used by VINI to generate high-quality predictions, with high-performance computing enabling rapid evaluation.
Proof-of-concept studies demonstrated VINI's ability to predict novel triple-drug combinations targeting ALK, BCL-2, mTOR, DNA repair, and androgen pathways in hormone-sensitive prostate cancer, achieving 79.3% agreement with clinical outcomes across 16 cancer types and 100% for DU-145 and PC3 lines. VINI has also been applied to SARS-CoV-2 drug combinations, illustrating its broad applicability.
In the upcoming EU Horizon project, VINI will be instrumental in identifying effective three-drug combinations against KRAS-mutant PDAC: (1) novel KRAS inhibitors developed at the University of Toronto, (2) DNMT1 inhibitors discovered at RBI, and (3) targeted monoclonal antibodies against PDAC hallmarks, also identified at RBI using VINI. Through this multinational consortium - including the University of Toronto, Lund University, Fraunhofer, EPFL, and seven other leading institutions - VINI will integrate AI, structural modeling, and computational chemistry to provide actionable insights for treatment-resistant cancers and guide future preclinical validation.

#0978 Deep learning frameworks for translating cancer drug response from cell-level to patient-level by modeling transcriptome.

Sun Kim[1], Bonil Koo[1], Dongmin Bang[2], Inyoung Sung[1], Changyun Cho[2], Sangseon Lee[3], Kyoung Jae Won[4]

[1]Seoul National University, Seoul, Korea, Republic of,[2]AIGENDRUG Co. Ltd., Seoul, Korea, Republic of,[3]Inha University, Incheon,[4]Cedars-Sinai Medical Center, Los Angeles, CA

Introduction: Measuring perturbations of the transcriptome upon drug treatment can be highly informative, yet perturbed transcriptome profiles are often unavailable at both the cell-level and the patient-level. A key challenge, therefore, is how to infer such unobserved drug responses. Because drug treatment perturbs not only individual gene expression levels but also the underlying gene-gene interactions, the major challenge is how to model perturbations of these gene-gene interactions at the gene-level in LINCS so that unobserved drug responses of cancer cells and patients can be inferred.
Methods: To predict unobserved perturbation of transcriptome after drug treatment, we have developed a deep learning model that captures perturbations of gene-gene interactions in LINCS, Condition-Specific Gene-Gene Attention (CSG2A, *Bioinformatics/ISMB* 2024). CSG2A models dosage- and time-dependent transcriptome perturbation and serves as as *perturbation-based* pretrained model. As change in transcriptome can be also seen as transcriptomic cellular state change, we used an existing pre-trained *rank-based* model (Geneformer, *Nature* 2024). Given these models of transcriptomic changes, we model the cancer patient in two different approaches in terms of transcriptome profiles. In the first approach, a deep learning model, called THERAPI, embeds a tumor by combining arbitrary sets of cancer cells in GDSC, after which perturbations of gene-gene interactions are predicted with the *perturbation-based* and *rank-based* models. In the second approach, we proposed PREDIKTOR, which uses a network-based representation of the patient transcriptome with DysRegNet (*British Journal of Pharmacology* 2024), and then predicts drug-induced perturbations of gene-gene interactions using the *perturbation-based* pre-trained model.
Results: We developed two computational frameworks for predicting patient-level drug response from cell-line response, THERAPI and PREDIKTOR. Both THERAPI and PREDIKTOR outperformed existing deep learning models with significant margin up to 8.5% improvement in experiment with TCGA data and the I-SPY2 patient cohort.
Conclusion: These two frameworks are being deployed on the Amazon cloud as “DrugVLAB^{TM} response” so that any researchers around the world can utilize for drug response prediction. Our systems can evolve with upcoming deep learning models, propriety or public, for more accurate drug response prediction.

#0979 DrugVLAB for oncogenic kinase inhibitor generation.

Sun Kim[1], hyerin kim[2], Bokyung Park[2], Joonho Seong[2], kim youngkuk[1], Seokchol Hong[2], Changyun Cho[2], Heejoon Chae[3], Kyoung Jae Won[4]

[1]Seoul National University, Seoul, Korea, Republic of,[2]AIGENDRUG Co. Ltd.,, Seoul, Korea, Republic of,[3]Sookmyung Women's University, Seoul, Korea, Republic of,[4]Cedars-Sinai Medical Center

Introduction: The dysregulation of kinases is a major mechanism for cancer development and progression. Rapid advances in generative deep learning technologies now allow models to generate candidate kinase inhibitors. However, with over 500 human kinases, the major challenge is to design inhibitors that are highly selective for the oncogenic kinase without blocking other essential ones. Thus, all generated molecules need to be tested rigorously for interactions with specific residues and overall affinity to pockets of both target and off-target kinases. This task requires orchestrating multiple AI tools in a well-defined workflow, which is not trivial to researchers.

Methods: To address the challenges, we developed DrugVLAB for Kinase Inhibitor Generation, a comprehensive Amazon cloud-based workflow, built through our collaboration, that enables human-in-the-loop search.*Workflow*: The workflow consists of more than 20 cutting edge AI tools. It begins with in-house fragment-based molecule generations (ICLR 2025). Users can specify requirements such as residue-atom interactions and drug-likeness filters using in-house tools (JCIM 2025, ICML 2025, ISMB 2025). Candidate molecules then undergo docking simulations with Autodock Vina, followed by additional filtering based on residue-atom interactions while considering docking pose. Finally, drug target affinity (DTA) can be rigorously checked using in-house tools (ICLR 2025, ISMB 2025). At this stage, molecules are ranked by DTA values for synthesis and evaluation. As molecules are generated with fragments, most of them are synthesizable. This will conclude the execution of one round of DrugVLAB^{TM} for Kinase. A unique and notable feature of our cloud system is to incorporate assay results of newly synthesized and evaluated molecules. Our system identifies fragments or substructures enriched in active and inactive molecules. With these new fragment sets, itinitiates the next round of assay-guided molecule generation. Our experience is that better, more active molecules are generated as the round goes on.

Results: DrugVLAB can generate 3000 molecules on Amazon cloud in 2.5 hours and a complete round of evaluation can be done in 2.5 hours for a target kinase and five off-targets.

Conclusion: Our system is implemented on Amazon cloud, enabling researchers around the world to generate and evaluate molecules as kinase inhibitors. DrugVLAB for kinase is designed in a modular way so that any newly developed AI tools can be incorporated easily and timely.

#0980 Multimodal chemogenomic modeling-based drug repurposing for targeted therapy of PDAC.

Adil Ibrahim Mohammed[1], Zhaowei Han[2], Yuanhao Huang[2], Zihe Meng[3], Jie Liu[2], Shuibing Chen[3]

[1]Cornell University/Weill Cornell Medicine, Ithaca, NY,[2]University of Michigan, Ann Arbor, MI,[3]Weill Cornell Medicine, New York, NY

Pancreatic Ductal Adenocarcinoma (PDAC) is a disease with a high mortality rate primarily due to its aggressive nature, late-stage prognosis, and limited effective treatment regimens. Current standard-of-care drugs for treatment include Gemcitabine and the combination drug FOLFIRINOX. However, precision and personalized treatment for PDAC is still missing. Mutations of *KRAS*, *TP53*, and *SMAD4* are the most common and highly effective genetic mutations in PDAC, resulting in the initiation, proliferation, and therapy resistance of tumor cells. Though drug candidates and inhibitors of $KRAS^{G12D}$, the most prevalent *KRAS* mutation, are being tested in clinical trials but mutations of $TP53^{R172H}$ and *SMAD4*, seen in 70% and 50% of PDAC cases respectively, remain to be effectively targeted because precision therapy is restricted. To address this challenge, we propose a precision medicine-based drug repurposing strategy to identify and prioritize mutation-specific drug candidates and their combinations for PDAC treatment. Using an isogenic murine organoid platform developed by our lab, we integrate multimodality data, including in house Whole Genome Sequencing (WGS), single cell RNA-seq (scRNAseq) and a preliminary drug screening library. We first compute Differentially Expressed Genes (DEGs) from scRNAseq data and a list of acquired gene mutations from WES data for each of the isogenic organoids lines and then query these gene signatures to computationally screen for potential drug compounds against the Connectivity Map touchstone dataset by computing a similarity based enrichment score. Next, using the chemical screening library of ~5000 compounds, we perform molecular docking simulations against the target proteins associated with the three driver mutations and run a Quantitative Structure Activity Relationship (QSAR) analysis to pinpoint chemical scaffolds and functional groups associated with stronger activity, thereby refining candidate hits from the Connectivity Map analysis. We also use the docking scores to perform an in-silico perturbation screen to capture downstream shifts in order to synergize target identification and engagement. We finally present high confidence drug candidates to target $KRAS^{G12D}$, $TP53^{R172H}$ and *SMAD4* identified through an integrated chemo-omics analysis. Ongoing work includes computational validation to top hits using Cancer Drug Response models and in vitro validation of selected drugs and combinations.

#0981 MTA-DTA: A multi-token attention framework for drug-target binding affinity prediction.

Il-san Jeong, Seung-Woo Baek, Jee-Woo Seo, Yeo-Gyeong Yoon, Jae-Yoon Kim, Seon-Young Kim, Seon-Kyu Kim

Genomic Medicine Research Center, Korea Research Institute of Bioscience and Biotechnology, Daejeon-city, Korea, Republic of

Backgrounds: Accurate prediction of drug-target affinity (DTA) is a key step in drug discovery, but experimental measurement remains costly and time-consuming. Deep learning-based approaches have recently shown strong performance using sequence- or graph-level representations of drugs and proteins, and attention mechanisms provide interpretability by highlighting key molecular subsequences. However, conventional attention computes dependencies between single token pairs, which cannot fully capture the cooperative and multi-residue binding behaviors that characterize real protein-ligand interactions.
Methods: We propose a Multi-Token Attention (MTA)-based DTA model that models both global and local interaction contexts between drug and target proteins. The model was trained and evaluated on the widely used Davis and KIBA benchmark datasets for binding affinity prediction. Protein sequences and drug SMILES were both embedded using pretrained models - ESM2 (esm2_t33_650M_UR50D) for proteins and ChemBERTA (ChemBERTAa-77M-MTR) for compounds. The MTA module incorporates key-wise convolution to aggregate local token neighborhoods before attention calculation and head-mixing convolution to fuse inter head information, allowing multi-token contextual dependencies.
