Results: From 1642 differentially expressed genes in tumor samples, 3 clusters were identified. Cluster 1, enriched in protein folding/translation pathways, was associated with more advanced disease p-value=0.019) and Right-sided tumors(p-value=0.026). Cluster 2(DNA replication, mitotic nuclear division, chromosome organization and chromatid segregation pathways), as a possible proliferative subtype, with all cases in early stages (I-III:100%) and predominantly left-sided tumors (76.9%). Cluster 3(metabolic and oxidative response pathways), showed shortest RFS (p=0.026), while Cluster 1 had a shortest MFS follow by Cluster 3p=0.005). No statistically significant differences were observed in OS. 19 Hub genes associated with CRC progression were identified (including TMEM150A, HNF1A, SNTB1, CLOCK, CCND1, ITGA2).

Conclusions and perspectives: This first transcriptomic profiling of Colombian CRC patients reveals potential molecular subtypes associated with prognosis. These findings highlight potential biomarkers for personalized management and underscore the importance of including Latin American populations in CRC molecular studies to improve global equity in cancer care.

#7289 Activation of toll-like receptors promotes the expression of XBP1s in CLL cells.

Chih-Hang Anthony Tang, **Chih-Chi Andrew Hu**

Houston Methodist Research Institute, Houston, TX

Toll-like receptors (TLRs) are a family of transmembrane proteins found in nearly all immune cells and are responsible for recognizing a broad range of pathogenic molecular patterns, including DNA, RNA, sugars, and lipids. Mouse and human B cells express TLRs, contributing to activation of both the innate and adaptive immune responses. Several studies have shown crosstalk between TLR and B cell receptor (BCR) signaling, indicating an important role for TLRs in B cell survival, proliferation, and differentiation. Chronic lymphocytic leukemia (CLL) is the most common B-cell cancer in adults and is known for its variable clinical outcomes. CLL is defined by the accumulation of leukemic cells in the blood, spleens, lymph nodes, and bone marrow. Signals from the lymphoid microenvironment contribute to proliferation of malignant CLL clones, especially in those whose BCR signaling is more pronounced. TLR signaling may amplify BCR-induced cell proliferation and thus accelerate CLL progression. Spliced X-box binding protein 1 (XBP1s) is a transcription factor responsible for endoplasmic reticulum (ER) stress response. XBP1s is vital to plasma cell differentiation and antibody production. Previously, we observed that B cells produce XBP1s in response to treatment with TLR4 ligand lipopolysaccharide (LPS) and TLR9 ligand methylated CpG-DNA (CpG). It is possible that these and other TLR ligands may induce proliferation of specific CLL populations, illuminating the unique role of each TLR in the development of CLL. In this study, we showed that TLR agonists, other than LPS and CpG, were capable of mediating increased expression of XBP1s in mouse splenic B cells. Next, we utilized the Eμ-TCL1 mouse model to investigate the effects of TLR stimulation in CLL cells because CLL developed in these mice resembles the aggressive IGHV-unmutated type of human CLL. When compared to mouse B cells, mouse CLL cells were shown to drastically increase XBP1s expression after TLR stimulation. Consistently, when compared with precancerous B cells isolated from the same mouse, CLL cells expressed higher XBP1s levels in response to TLR ligands. Malignant CLL cells frequently downregulated their expression of stimulator of interferon genes (STING) protein, leading to increased surface expression of the BCR. CLL cells purified from $STING^{KO}$/Eμ-TCL1 mice indeed responded to TLR activation by expressing higher levels of XBP1s than those from their control littermates. We thus hypothesize that TLR-induced expression of XBP1s can further modulate BCR signaling in STING-deficient CLL cells to promote malignant progression.

#7290 Tumor treating fields (TTFields) enhance chemotherapy-induced proteotoxic stress in pancreatic cancer cells.

Ruben M. Munoz[1], Naama Flint-Brodsly[2], Yaara Porat[2], Daniel D. Von Hoff[1], Haiyong Han[1]

[1]TGen (The Translational Genomics Research Institute), Phoenix, AZ,[2]Novocure (Israel) Ltd, TIRAT CARMEL, Israel

Tumor Treating Fields (TTFields) have recently demonstrated a clinically meaningful survival benefit when added to first-line gemcitabine and nab-paclitaxel for unresectable, locally advanced pancreatic cancer (PANOVA-3). Pancreatic tumors are highly dependent on the unfolded protein response (UPR) to survive endoplasmic reticulum (ER) stress induced by hypoxia, nutrient deprivation, and cytotoxic chemotherapy. TTFields along with gemcitabine, nab-paclitaxel, and cisplatin (the Triple regimen) is under clinical investigation (NCT04605913) and may enhance antitumor efficacy by overwhelming the tumor's proteostasis mechanisms. In this study, we examined whether TTFields synergize with the Triple regimen to amplify ER stress and UPR signaling to trigger cell death in pancreatic cancer cells. TTFields showed frequency-dependent inhibition of cell proliferation (100-200 kHz) and significantly enhanced chemotherapy-induced cytotoxicity, with maximal effects at 150 kHz with a treatment duration of 72 hours. Western blot analysis revealed that both TTFields and the Triple regimen increased GRP78 expression, with significant greater induction observed when applied together, indicating augmented UPR activation. Immunofluorescence staining further demonstrated that TTFields elevated phospho-PERK and total PERK protein levels. In addition, RT-PCR analysis showed significant enhancement of XBP1 mRNA splicing by TTFields and chemotherapy. Collectively, these findings suggest that TTFields potentiate the antiproliferative effects of the Triple chemotherapy by amplifying UPR signaling through the IRE1α/XBP1 and PERK/eIF2 pathways. These results provide mechanistic insight into how TTFields may enhance the efficacy of chemotherapy in pancreatic cancer and support further clinical evaluation of this concomitant treatment approach.

#7291 Hypoxia selects for early PI3K pathway alterations and drives clonal complexity in HPV-positive oropharyngeal cancer.

Bill Diplas, Xin Pei, Yingjie Zhu, Shu Yazaki, Luc G.T. Morris, Richard J. Wong, Sean M. McBride, Heiko Schoder, Yao Yu, Alan L. Ho, Eric Sherman, Nora Katabi, Nancy Lee, Nadeem Riaz

Memorial Sloan Kettering Cancer Center, New York, NY

Purpose: Tumor hypoxia drives treatment resistance in head and neck cancer, yet its molecular determinants remain unclear. We previously demonstrated that HPV-related oropharyngeal cancer (OPC) exhibiting hypoxia is more aggressive necessitating escalated treatment. Here, we investigated the genetic drivers of tumor hypoxia and their impact on tumor evolution.
Methods: We analyzed 152 patients with early-stage HPV-related OPC from a prospective hypoxia-directed dose de-escalation trial (NCT03323463). Comprehensive genomic profiling included WES (n=122) and RNA-seq (n=91). Tumor hypoxia was assessed using 18F-FMISO PET with a standardized hybrid method incorporating qualitative assessment of four image characteristics and quantitative tumor-to-background ratios (TBR >1.3 considered hypoxic). Clonal architecture was reconstructed using PhylogicNDT. We validated molecular correlates of hypoxia in two independent cohorts of HPV-related oropharyngeal cancer from the TCGA and JAVELIN-HN. Hypoxia in validation cohorts was determined using three established mRNA-based hypoxia signatures (Buffa, Winter, Toustrup).
Results: Hypoxia as determined by FMISO PET was present in 72% of tumors at baseline, and correlated with well-established RNA-based signatures of hypoxia. Mutational profiling showed that hypoxic tumors were enriched for PI3K pathway alterations, most notably PIK3CA mutations (OR=5.45, adjusted p=0.05). Critically, this association was restricted to clonal PIK3CA mutations—subclonal mutations showed no hypoxia association, suggesting early selection under hypoxic conditions. This hypoxia-PI3K relationship was validated in independent cohorts of HPV-OPC (TCGA, JAVELIN-HN) using expression-based signatures of hypoxia (adjusted $p<0.05$ for Winter, Buffa and Toustrup hypoxia signatures). Lastly, clonal mapping further revealed that hypoxic tumors exhibited significantly greater clonal complexity ($p < 0.05$; Shannon diversity). Multi-region sequencing in a subset of 41 tumors confirmed extensive spatial heterogeneity, strongly linked to hypoxic tumors.
Conclusions: Our findings show that hypoxia drives early selection for PI3K pathway alterations and promotes clonal complexity, demonstrating how the microenvironment directs tumor evolution in HPV-related OPC.

#7292 Hypoxia-driven HIF-1α/YAP-AXL signaling drives adaptive resistance to TKIs in NSCLC.

Yuki Katayama[1], Tadaaki Yamada[2], Tomoko Yasuhiro[2], Ryohei Kozaki[3], Shigekuni Hosogi[2], Eishi Ashihara[4], Koichi Takayama[2]

[1]Department of Pulmonary Medicine, Kyoto Prefectural University of Medicine, Kyoto, Japan,[2]Kyoto Prefectural University of Medicine, Kyoto, Japan,[3]Ono Pharmaceutical Co., Ltd., Osaka, Japan,[4]Kyoto Pharmaceutical Univ., Kyoto, Japan

Background: Intratumoral hypoxia is a hallmark of solid cancers and promotes invasion, metastatic progression, and drug resistance. However, the mechanisms by which hypoxia contributes to resistance against tyrosine kinase inhibitors (TKIs) in driver-mutant non-small cell lung cancer (NSCLC) remain insufficiently defined. To address this gap, we systematically examined how hypoxic conditions reprogram signaling networks that undermine TKI responses.

Methods: EGFR-mutant PC-9 and HCC4011 and ALK-rearranged H2228 cells were cultured under normoxia (21% O_2) or hypoxia (1% O_2) and treated with osimertinib or brigatinib. Drug response and signaling were assessed by MTT assays, immunoblotting, and phospho-RTK arrays. Bulk RNA-seq (PC-9; normoxia vs hypoxia, 72 h) supported pathway-level analyses. Mechanistic perturbations included siRNA knockdown, co-immunoprecipitation, nuclear/cytoplasmic fractionation, and immunofluorescence. For spatial analysis of human tumors, multiplex immunofluorescence (HIF-1α, AXL, α-SMA, DAPI) was performed on FFPE EGFR-mutant lung adenocarcinoma specimens and quantified with whole-slide single-cell segmentation and tumor/cancer-associated fibroblast (CAF) classification; CytoMAP nearest-neighbor and 50-μm neighborhood metrics assessed CAF proximity to hypoxic tumor cells.

Results: Hypoxia reduced sensitivity to osimertinib in PC-9 and HCC4011 and to brigatinib in H2228. RNA-seq in PC-9 highlighted enrichment of hypoxia and PI3K/AKT pathways, indicating RTK network rewiring under hypoxia. Integrative phospho-RTK profiling and downstream validation pinpointed AXL as the dominant hypoxia-responsive node. AXL knockdown restored TKI growth inhibition and the suppression of downstream AKT signaling under hypoxia, and the AXL inhibitor ONO-7475 phenocopied these effects. Mechanistically, hypoxia decreased LATS1/YAP phosphorylation, promoted nuclear YAP, and enhanced HIF-1α-YAP interaction; silencing HIF-1α or YAP inhibited hypoxia-induced AXL expression. In patient specimens, HIF-1α-high tumor cells showed higher AXL intensity and closer proximity to α-SMA$^+$ CAFs within 50-μm neighborhoods, linking hypoxia, AXL upregulation, and CAF-enriched niches.

Conclusions: Hypoxia induces adaptive resistance to TKIs via HIF-1α/YAP-AXL signaling, linking oxygen stress to RTK reprogramming. Spatial analyses of patient tumors reveal CAF-proximal hypoxic niches with elevated AXL, providing tissue context for this mechanism. These findings support AXL inhibition as a rational combination partner to TKIs to suppress hypoxia-driven adaptive resistance in NSCLC, and motivate future studies to define the clinical conditions under which targeting this axis improves treatment durability.

#7293 The impact of oxygen exposure on clinical biomarkers - an underrecognized source of pre-analytic variability.

Ruizhong Wang, Adedeji Adebayo, Stephanie Adama, Steven M. Westphal, Hala Fatima, Carla S. Fisher, Hongyu Gao, Yunlong Liu, Ryla G. House, GEORGE SANDUSKY, Sean D. McCabe, Zhongping He, Jamunabai M. Prakash, Amber Roberts, Matt E. Thomas, Mohammad Al-Haddad, Sujani Yadlapati, Pam Rockey, William Berry, Mary B. James, Rana German, Emily M. G. Nelson, April M. Giron, Troy Moeller, Noah Xique, Kathy D. Miller, Harikrishna Nakshatri

Indiana University School of Medicine, Indianapolis, IN

When preclinical research fails to replicate human biology, scientific progress stalls, clinical trials falter, and patients continue to suffer. While many factors contribute to these failures, lack of attention to pre-analytic variability is a seminal issue. We recently reported that even short-term exposure to ambient air is sufficient to trigger signaling changes in tumor and non-malignant biospecimens. Those changes in turn alter their biology and responsiveness to targeted therapies. Thus, characterization of tumors collected and processed under physioxia (3% O_2) instead of current practice of collection and processing under ambient air (21% O_2) will help to identify clinically relevant biomarkers that are affected by O_2 tensions. This approach may help to reduce clinical trial failure rates and increase clinical translation of preclinical studies. Towards this goal, we collected human specimens (biopsies, ascites and pleural effusions from 94 donors) under physioxia, then divided the same specimen into two groups; one group maintained under physioxia, the other group exposed to ambient air. Both were for 45-60 minutes before fixing/processing. Samples were subjected to various biomarker analysis using IHC/IF, Western blotting to measure proteins, and nanopore sequencing for DNA methylation. We found the levels of pAKT, a clinically used biomarker of targeted therapy, were constantly higher in clinical samples under physioxia compared to ambient air. Similar effects of O_2 tension on pERK and MDM4 levels occurred in cells isolated from ascites or pleural effusion in a time-dependent manner. A significant decrease in pEGFR and p53 levels were observed in cells under physioxia. Moreover, O_2 tension-dependent differences extended to key epigenetic regulators including TET2. TET2 levels were lower under physioxia compared to ambient air. Consistently, nanopore sequencing revealed distinct differences in DNA methylation patterns under physioxia and ambient air. The observed differences in signaling pathways extended to cultured cells from ascites fluids and pleural effusions. However, there is a specificity in the effects of O_2 tensions on biomarkers as we did not observe significant differences in pPDGFR$_\beta$, ATE1 and many other biomarkers under two O_2 conditions. These results imply that the O_2 tension affects specific biomarkers and epigenome. Collectively, O_2 tension could result in dynamic and extensive changes in cell membrane, cytoplasmic and nuclear biomarkers. Observable changes of biomarkers could occur within an hour following exposure to ambient O_2, and some changes could last for prolonged period. Thus, our current study lays out a new physiologically relevant biomarker validation/discovery platform, which may accelerate evaluation of physiologically relevant signaling networks, new drug discovery, and enhance clinical translation of preclinical observations.

#7294 SDHA isoform expression modulates reverse electron flow during hypoxia.

Kaveri Goel, Katie Pepper Lee, Nicholas Hill, Weiqi Lee, Neil Pfister

Radiation Oncology, University of Alabama at Birmingham, Birmingham, AL

Succinate dehydrogenase (SDH, also known as complex II) is a mitochondrial enzyme complex that directly connects the TCA cycle to the electron transport chain (ETC) via reductions of succinate to fumarate, leading to the reduction of coenzyme Q to high energy UQH2. The SDH complex is composed of four different subunits. SDHA and SDHB are the enzymatic subunits of SDH that forms the mitochondrial matrix-facing hydrophilic head whereas SDHC and SDHD are the hydrophobic mitochondrial inner membrane anchor subunits. When oxygen is present, electrons flow through the ETC, generating ATP, with oxygen serving as the terminal electron acceptor. However, hypoxic niches exist during a variety of physiological states including cancer where fumarate acts as an additional electron acceptor to regenerate CoQ for additional biological processes including pyrimidine biosynthesis. When SDH is utilized in reverse to recapture electrons onto fumarate, succinate is regenerated, leading to succinate accumulation in cancer cells in hypoxic conditions. It has been previously discovered that some tissues favor forward SDH activity (heart, lung) whereas other tissues (brain, kidney) favor the reverse flow. We hypothesized that different isoforms of SDHA, which contains the active site for the succinate to fumarate enzymatic reaction, could favor or disfavor forward and reverse flow of electrons through SDH and serve as a mechanistic basis for the previously observed experimental findings. We analyzed human tissue datasets and identified 3 major SDHA isoforms. We found tissue-specific differences in SDHA isoform expression with high expression of SDHA isoforms in kidney tissue, and low expression of SDHA isoforms in heart tissue, consistent with our hypothesis. We overexpressed SDHA isoforms in cancer cell lines and analyzed 13C15N-glutamine tracing to provide experimental support of our hypothesis that specific SDHA isoforms prioritize reverse electron flow under hypoxic conditions. We are currently assessing how CRISPR-Cas9 engineered cells to expression only one SDHA isoform (rather than combination of wild-type and variant transcript) affect cell responses to cancer therapy under normal and hypoxic conditions including epigenetic regulation of gene expression via the fumarate and succinate oncometabolites. This study will help us in identifying how SDHA isoforms contribute to cancer initiation and treatment strategies for hypoxic tumors.

#7295 The role of PHD2 inhibition in melanoma progression, metabolic adaptation, and therapy resistance.

Claire Erdaje Palma, Stephen M. F. Jamieson, Tet-Woo Lee, Dean Singleton

Auckland Cancer Society Research Centre, University of Auckland, Auckland, New Zealand

Therapy-resistant melanoma poses significant challenges due to its diverse phenotypes and limited treatment options. A strong dependency of melanoma cells on *EGLN1*, which encodes prolyl hydroxylase domain protein 2 (PHD2)—a key regulator of HIF-α degradation— is evident in large-scale dependency datasets, prompting us to investigate *EGLN1*/PHD2 as a potential therapeutic vulnerability. Melanoma cell lines were engineered using CRISPR-Cas9 to generate knockout (KO) models of *EGLN1*, *HIF1A*, and *HIF1AN*. Pharmacologic assays were performed using the PHD inhibitor roxadustat and the FIH inhibitor tool compound DM-NOFD. Proliferation was assessed in short- and long-term assays. Protein expression was analyzed by immunoblotting, and transcriptional changes were evaluated by RT-qPCR. Metabolic consequences were assessed by measuring NADH/NAD$^+$ ratios. To model resistance to BRAF + MEK inhibition (BRAFi+MEKi), two systems were generated: (1) TGFβ1-induced adaptive resistance and (2) drug-acquired resistance following continuous BRAFi+MEKi exposure. Resistance was confirmed by phosphorylated ERK immunoblotting and IC_{50} analysis.*EGLN1* KO reduced melanoma proliferation by 70–80% relative to control cells ($p < 0.05$). Roxadustat inhibited growth in a HIF-1α–dependent manner, with IC_{50} values of 40–80 μM in wild-type cells versus >100 μM in *HIF1A* KO cells. Long-term treatment with 10–20 μM roxadustat reduced wild-type proliferation by 30–70%, but only 0–10% in *HIF1A* KO cells. Disruption of *HIF1AN* or treatment with DM-NOFD enhanced roxadustat sensitivity, decreasing proliferation by 40–60%, an effect absent in *HIF1A* KO models. Roxadustat increased PHD2 protein levels and induced *EGLN1* transcription in wild-type cells, accompanied by upregulation of canonical HIF-1 targets (*LDHA, PDK1, BNIP3*). A 20–50% increase in the NADH/NAD$^+$ ratio after 4 h of roxadustat treatment indicated a metabolic shift toward reductive stress. In BRAFi+MEKi-resistant models, roxadustat enhanced BRAFi+MEKi potency and inhibited ERK phosphorylation, reversing MAPK pathway reactivation in A375 acquired-resistant cells, but had no effect in A375 *HIF1A* KO resistant models, demonstrating a requirement for HIF-1α. In TGFβ1-induced adaptive resistance, *HIF1A* was necessary for the development and maintenance of resistance phenotypes, indicating that HIF-1α signaling contributes to early adaptive BRAFi+MEKi tolerance. These studies demonstrate that PHD2 inhibition suppresses melanoma growth through HIF-1α stabilization and can be enhanced by concurrent FIH inhibition. The requirement of HIF-1α for both adaptive and acquired BRAFi+MEKi resistance and for roxadustat-mediated re-sensitization highlights a functional link between hypoxia signaling and therapeutic tolerance. These findings support continued evaluation of PHD2-directed strategies, including combination approaches, in melanoma.

#7296 A KRAS G12V-mutant patient-derived organoid model of brain metastasis as a target discovery platform.

Dena Panovska[1], Yao Lulu Xing[2], Maria Dolan[3], Helena C. M. Oft[4], Alexa Gwyn[5], Emon Nasajpour[6], Michitaka Nakano[7], John Newman[8], Calvin Kuo[7], Pardes Habib[2], Claudia K. Petritsch[6]

[1]Neurology, Stanford University, Stanford, CA,[2]Neurosurgery, Stanford University, Stanford, CA,[3]University of Virginia, Charlottesville, VA,[4]Neurology, University of Pittsburgh, Pittsburgh, PA,[5]Vassar College, Poughkeepsie, NY,[6]Neurology and Stanford Cancer Model Development Center, Stanford University, Stanford, CA,[7]Medicine-Hematology, Stanford University, Stanford, CA,[8]Pathology, Stanford University, Stanford, CA

Brain metastasis (BM) is the most common brain tumor, with annual incidence rates ranging from 8 - 14 cases per 100,000 people. In the past decade, eligibility criteria have broadened, advancing treatments for BM with molecular targeted therapies and immune checkpoint inhibitors. Unfortunately, this progress has not yet reached patients with rare forms of BM, such as those originating from colorectal cancer (CRC), which is the second leading cause of cancer death worldwide. BM from CRC (BM-CRC) have the poorest prognosis amongst metastatic CRCs, due to their inherent resistance to chemotherapy and radiation, underscoring the need for new therapeutic approaches. Drug development faces in oncology faces significant challenges and has a high attrition rate, largely due to tumor diversity and the limitation of traditional models, such as 2D cell cultures and animal testing, which often fail to replicate human tumor behavior. Additionally, the small patient cohorts for BM-CRC impede molecular studies necessary for development of evidence-based therapies and clinical guidelines We recently identified elevated levels of transcriptomic signatures for unfolded protein response (UPR) in BM-CRC, by analyses of a public dataset of single cell RNA sequencing data from 8 patients with BM-CRC. CellChat performed with these single cell data revealed interaction between tumor and tumor microenvironment (TME), which underlined the dependency of the tumor on specific components of the TME. We confirmed that the UPR, activated by endoplasmatic reticulum (ER) stress in cancer cells, is upregulated in BM-CRC compared to parental CRC, using multi-omic analyses. To investigate the UPR as a potential therapeutic vulnerability in patients, we generated a novel patient-derived organoid (PDO) from a therapy-resistant KRAS G12V mutant BM-CRC. PDOs reliably forms intracranial tumors in xenografts models and mirror the phenotypic and genetic features of the original malignant tumor reliably BM-CRC. Our preclinical data showed that pharmacologic inhibition of an ER stress-related pathway more effectively reduced PDO viability than MAPK inhibition alone. We furthermore conducted molecular analyses how the upregulation of the UPR influences cell states of BM-CRC, correlating with their poor prognosis. Taken together, our new PDO model was generated as a platform for drug discovery and to evaluate targeted therapies for treatment-refractory BM-CRC. Our preclinical and multi-omics data puts forward UPR as a therapeutic vulnerability.

#7297 HIF-1α pathway is a therapeutic vulnerability in mucinous colorectal cancer.

Yoojeong Seo, Jinho Jang, Kyung-Pil Ko, Jie Zhang, Sohee Jun, Jae-Il Park

Experimental Radiation Oncology, UT MD Anderson Cancer Center, Houston, TX

Mucinous colorectal cancer (muCRC) represents an aggressive and histologically distinct subtype of CRC characterized by abundant extracellular mucin, right-sided predominance, and poor therapeutic response. Despite its clinical relevance, muCRC-specific therapeutic options are not available.Through comparative single-cell transcriptomic profiling of over 360,000 cells from muCRC and non-muCRC tumors, we identified a hypoxia-inducible factor-1α (HIF-1α)-centered regulatory program as a defining transcriptional hallmark of muCRC.Regulon reconstruction revealed that HIF-1α activity coincides with SPDEF- and TFF3-driven mucinous lineage programs, linking hypoxia signaling to secretory differentiation. Immunohistochemical and spatial transcriptomic analyses confirmed marked elevation of HIF-1α protein and target gene expression in murine and patient-derived mucinous CRC models compared to non-mucinous counterparts.Functionally, pharmacologic inhibition of HIF-1α using PX-478 completely prevented mucinous tumor formation in the genetically engineered mouse models, restoring normal crypt architecture and markedly extending survival. Likewise, PX-478 treatment abolished mucin accumulation and tumor growth in cecum orthotopic patient-derived organoid xenografts. Mechanistically, HIF-1α inhibition suppressed SPDEF and MUC2 expression, indicating that hypoxia signaling sustains mucinous differentiation and tumorigenic capacity. Collectively, these findings identify HIF-1α as a molecular dependency and therapeutic vulnerability in muCRC. Together, these results provide a strong translational rationale for HIF-targeted therapy in mucinous and related serrated CRC subtypes.

#7298 Extracellular acidosis modulates calcium signaling and adaptive resistance mechanisms in acute myeloid leukemia.

Eva Gez[1], Sofia Titah[1], Aurelie Guillemette[1], Celine Berthon[1], Laure Goursaud[1], Nathalie Jouy[2], Loic Lemonnier[3], Salomon Manier[1], Carine Brinster[1], Suman Mitra[1], Bruno Quesnel[1], Yasmine Touil[1]

[1]Univ. Lille, CNRS, Inserm, CHU Lille, Institut Pasteur de Lille, UMR9020-U1277-CANTHER-Cancer Heterogeneity Plasticity and Resistance to Therapies, F-59000 Lille, France., Lille, France,[2]Univ. Lille, CNRS, Inserm, CHU Lille, Institut Pasteur de Lille, US 41 - UAR 2014 - PLBS, F-59000 Lille, France, Lille, France,[3]Univ. Lille, Inserm, U1003 - PHYCELL - Physiologie Cellulaire, F-59000 Lille, France., Lille, France

Acute Myeloid Leukemia (AML) is a malignant hematological disease with a high relapse rate linked to multiple resistance mechanisms, including leukemic stem cells, apoptosis resistance, and efflux pump activation. Previous work in the host laboratory demonstrated that calcium signaling contributes to these resistance pathways**.** At the same time, the Warburg effect induces extracellular acidosis, a hallmark of aggressive cancer phenotypes. This study investigates whether an acidic extracellular pH alters calcium signaling and thus participates in AML resistance mechanisms.

The MOLM-13 AML cell line was exposed to acidic (pH 6.5) or neutral (pH 7.4) conditions for various durations (“real-time,” 24 h, and 72 h). Cell proliferation and cycle distribution (Ki-67/IP), viability and apoptosis (Annexin V/IP), leukemic stem-like subpopulations ($CD34^+/CD38^-$), and efflux pump activity (rhodamine exclusion) were analyzed by flow cytometry. Expression of genes regulating pH and calcium homeostasis (STIM, ORAI, SERCA, PMCA families) was quantified by qPCR, and intracellular pH and Ca^{2+} fluxes were assessed by flow cytometry using fluorescent probes.

Preliminary results show that exposure to pH 6.5 transiently slows proliferation and induces G_1 arrest without loss of viability or apoptosis. Acidic pH rapidly increases multidrug resistance (MDR) activity, suggesting an adaptive response, but does not enrich for $CD34^+$ stem-like cells. At the signaling level, acidity downregulates STIM2, SERCA2, ORAI1, and PMCA1 expression and transiently inhibits store-operated calcium entry (SOCE), an effect that diminishes after 72 h, indicating cellular adaptation to the acidic environment.

These findings demonstrate that extracellular acidosis reshapes calcium signaling and efflux activity, enabling rapid metabolic and signaling adaptation in AML cells. Future work will include precise intracellular pH measurements, exploration of TRP channels and STIM2 isoforms, and single-cell RNA-seq to map transcriptional heterogeneity in acidic conditions, using both cell lines and patient-derived PBMC samples.

#7299 A new approach to lung cancer treatment: Targeting endoplasmic reticulum stress.

Chang Zou, Huibin Song, Sixiao He

Shenzhen People's Hospital, Shenzhen, China

Endoplasmic reticulum stress plays a pivotal role in responding to external stimuli, which is closely involved in cancer cell survival. However, its upstream regulatory mechanism has not been well elucidated. Previously we have reported that the methyltransferase like protein METTL7B promoted lung adenocarcinoma progression and TKI resistance mainly via its regulation of ROS metabolism, which may related to its mRNA methylation function. However, whether METTL7B could work as a mRNA methylator remains not clear. Our latest data indicated that the expression of METTL7B in LUAD cell lines was significantly negatively correlated with GRP78, IRE1 and XBP-1s, which are key signaling cohort in endoplasmic reticulum stress and the sensitivity of cells to anticancer drugs. On the other hand, METTL7B can up-regulate the mRNA methylation level and reduce the mRNA stability of GRP78, IRE1 and XBP-1s. Moreover, we also identify Proflavine Hemisulfate, a clinically used preservative agent, as a novel METTL7B inhibitor that potently suppresses its m^6A methyltransferase activity and inhibit the proliferation of lung adenocarcinoma cells in a dose-dependent manner. These findings provide a scientific basis for elucidating the RNA methyltransferase activity of METTL7B and new therapeutic target for lung adenocarcinoma.

#7300 SMARCA4 loss in endometrial cancer induces cell fate chaos concomitant with the senescence associated secretory phenotype and aberrant regulation of mTOR.

Hannah Plummer-Doherty[1], Mackenzie Coatham[2], Julia Vassalakis[1], Farzaneh Afzali[1], Bianca Dauber[1], Einav Renert[1], Tyler Cooper[3], Ivan Topisirovic[4], Cheng Han-Lee[5], Lynne-Marie Postovit[1]

[1]Department of Biomedical and Molecular Sciences, Queen's Univ. Cancer Research Inst., Kingston, ON, Canada,[2]Department of Oncology, University of Alberta, Edmonton, AB, Canada,[3]Department of Obstetrics and Gynecology, Centre de recherche du Centre hospitalier de l'Universite de Montreal, Montreal, QC, Canada,[4]Assistant Professor, Dept. of Onc., McGill University Lady Davis Institute, Montreal, QC, Canada,[5]Department of Pathology and Laboratory Medicine, University of Alberta, Edmonton, AB, Canada

Endometrial cancer is the most common gynecological malignancy worldwide, and incidence has been steadily on the rise. While the prognosis for localized endometrial cancer is excellent, some patients develop dedifferentiated endometrial cancer (DDEC), wherein the five year survival rate is less than 25%. DDEC is an advanced, rare subtype of endometrial cancer characterized pathologically by the mix of dedifferentiated and well differentiated tissue. We have discovered that the loss of *SMARCA4*, the catalytic subunit in the SWI/SNF complex, causes well differentiated endometrial cancer cells to form histologically undifferentiated lesions. SWI/SNF is a critical epigenetic modifier, which remodels chromatin by sliding and evicting nucleosomes. Evidence from our lab suggests that SMARCA4 loss causes epigenomic dysfunction in endometrial cells, leading to cell state chaos and the emergence of tissue that appears dedifferentiated. Interestingly, this chaos occurs only upon passaging *in vivo*, following an initial period wherein cells manifest a senescent-like phenotype. This phenotype is indicated by reduced growth, expression of B-galactosidase, and manifestation of the Senescence Associated Secretory Phenotype (SASP). This suggests that features of the growing tumor, such as hypoxia, may enable cell state chaos and that the SASP may characterize a transitional cell state. The mTOR pathway, which regulates metabolism, survival, and mRNA translation, has been shown to promote the SASP and is normally inactivated in response to cell stress, such as hypoxia. We hypothesize that SMARCA4 loss promotes the senescent-like phenotype by altering mTOR signaling, and that by enabling adaptations in mRNA translation, aberrant mTOR signaling underpins the emergence of cell state chaos and disease progression. We have shown that, in contrast to other cell types, SMARCA4 deficient cells do not respond to hypoxia with a reduction in mTOR activity. SMARCA4 KO cells maintain high levels of phosphorylation of many key effectors, like 4EBP1, under hypoxia. Interestingly, phosphorylation of eIF4E (a cap binding protein involved in translation initiation) is significantly decreased with SMARCA4 KO, under hypoxia and in normoxia. These results suggest there may be modulation to the translational machinery upon SMARCA4 KO. Indeed, SMARCA4 deficient cells maintain high levels of protein synthesis in hypoxia, suggesting a strong resistance to stress-induced reductions in mRNA translation. In conclusion, our results suggest that dysregulated mTOR activity, leading to uncontrolled mRNA translation, may underpin the emergence of cell fate chaos an aggressive dedifferentiated histopathology in endometrial cancers.

#7301 Effect of chronic exposure to acidic pH on the MOLM-13 acute myeloid leukemia cell line.

Aurelie Guillemette[1], Eva Gez[1], Sofia Titah[1], Celine Berthon[1], Laure Goursaud[1], Nathalie Jouy[2], Loic Lemonnier[3], Salomon Manier[1], Carine Brinster[1], Suman Mitra[1], Bruno Quesnel[1], Yasmine TOUIL[1]

[1]University of Lille, CNRS, Inserm, CHU Lille, Institut Pasteur de Lille, UMR9020-U1277-CANTHER-Cancer Heterogeneity Plasticity and Resistance to Therapies, Lille, France,[2]University of Lille, CNRS, Inserm, CHU Lille, Institut Pasteur de Lille, US 41 - UAR 2014 - PLBS, Lille, France,[3]University of Lille, Inserm, U1003 - PHYCELL - Physiologie Cellulaire, Lille, France

Acidification of the extracellular microenvironment (pHe ≈ 6.4-6.8) constitutes a major metabolic stress in cancers, promoting immune evasion, tumor progression, and therapy resistance. In our laboratory, we previously demonstrated the pivotal role of calcium signaling in the resistance mechanisms of leukemic cells. Acute myeloid leukemia (AML), a malignant hematologic disorder with a high relapse rate, exemplifies this issue through the persistence of leukemic stem cells, resistance to apoptosis, and enhanced efflux pump activity. Furthermore, the Warburg effect drives extracellular acidosis, favouring the emergence of aggressive, therapy-resistant phenotypes and altering intracellular metabolic and signaling pathways that support survival and proliferation.

This study aimed to determine whether prolonged exposure to acidic extracellular pH modifies the calcium signature of leukemic cells and contributes to adaptive resistance mechanisms in AML. Experiments were conducted on the MOLM-13 cell line, derived from a relapse case harboring an FLT3 tandem duplication. Cells were cultured for three weeks at acidic (pHe ≈ 6.5) or neutral (pHe ≈ 7.4) pH conditions to induce phenotypic adaptation. Flow cytometry analyses assessed viability and apoptosis (Annexin V/IP), cell-cycle distribution (Ki67/IP), and the leukemic stem cell fraction ($CD34^+/CD38^-$). Intracellular calcium dynamics and intracellular pH were monitored in real time using specific fluorescent probes, while efflux pump activity was quantified by rhodamine exclusion. Gene expression related to calcium homeostasis and pH regulation was evaluated by qPCR to assess transcriptional adaptations to chronic acid stress.

Preliminary results indicate that chronic exposure to acidic pH does not impair viability nor induce apoptosis or necrosis. Cell-cycle analysis shows increased G_0 and S phases with G_1 predominance, accompanied by a reduction in the stem-like fraction. Intracellular pH, calcium stores, and capacitive calcium influx are reduced, whereas efflux pump activity declines by approximately 10%. At the transcriptional level, NFATc1, STIM2, and PMCA4 are downregulated, whereas ORAI1 is overexpressed, suggesting the activation of adaptive or resistance mechanisms in response to sustained acidosis, which may support the survival of residual leukemic cells under metabolic stress.

Although preliminary, these findings highlight the significant impact of chronic extracellular acidification on calcium signaling and the adaptive capacities of leukemic cells. Further investigations, including precise intracellular pH quantification, extended acid exposure, and analyses of primary AML samples from diverse mutational backgrounds, will refine these observations and may ultimately facilitate the identification of novel calcium-related functional biomarkers and potential therapeutic targets to overcome resistance in AML.

#7302 Critical involvement of PRELID2 in the regulation of mitochondrial homeostasis in renal carcinogenesis.

Renpei Kato[1], Daiki Ikarashi[1], Shigekatsu Maekawa[1], Mitsugu Kanehira[1], Yosuke Matsushita[2], Tetsuro Yoshimaru[2], Tomoya Fukawa[3], Toyomasa Katagiri[2], Wataru Obara[1]

[1]Iwate Medical Univ., Iwate, Japan,[2]Laboratory of Biofunctional Molecular Medicine, National Institute of Biomedical Innovation, National Institutes of Biomedical Innovation, Health and Nutrition, Osaka, Japan,[3]Tokushima Univ., Tokushima, Japan

Background: Mitochondrial homeostasis is critical for tumor adaptation to oxidative stress in clear cell renal cell carcinoma (ccRCC). PRELID2, a mitochondrial intermembrane space protein involved in lipid trafficking, has not been studied in renal carcinogenesis. We identified PRELID2 as a novel regulator of mitochondrial function and potential therapeutic target in ccRCC.
Methods: RNA sequencing was performed on 178 ccRCC patient samples. In vitro and in vivo studies established PRELID2's functional roles in ccRCC proliferation and progression. Mitochondrial proteomics, lipidomics (LC-MS), oxidative stress assays, co-immunoprecipitation, and mass spectrometry were conducted for comprehensive analysis.
Results: PRELID2 was significantly elevated in ccRCC and correlated with poor prognosis in metastatic cases. Unlike other PRELI family proteins, PRELID2 specifically interacted with Prohibitin 2 (PHB2), a mitochondrial scaffolding protein. PRELID2 depletion increased mitochondrial oxidative stress, resulting in elevated oxidized peptides and reduced cytochrome c under stress conditions. Lipidomics revealed altered phosphatidylglycerol composition, a cardiolipin precursor. Xenograft experiments showed PRELID2 overexpression significantly enhanced tumor growth.
Conclusion: PRELID2 is a critical regulator of mitochondrial lipid homeostasis and oxidative stress resistance in ccRCC. The PRELID2-PHB2 interaction represents a potential therapeutic target for novel interventions in renal tumorigenesis.

#7303 Activation of HIF1α drives oxidative stress and promotes deep senescence in *EGFR*-mutant NSCLC drug tolerant persister cells.

Radhika Koranne[1], Avishai Wizel[2], Aimee J. Gleason[1], Justine Bellier[1], Heidie Cabanos[1], Sarah Reeves[1], Luke Boland[1], Yotam Drier[2], Aaron N. Hata[1]

[1]Krantz Family Center for Cancer Research, Mass General Brigham Cancer Institute, Boston, MA,[2]The Hebrew University of Jerusalem, Israel, Jerusalem, Israel

Non-small cell lung cancers with oncogenic mutations in EGFR (exon 19 deletions or L858R substitutions) are sensitive to EGFR tyrosine kinase inhibitors (TKIs), which induce deep and durable responses in the majority of patients. However, despite these responses, the development of acquired resistance to EGFR TKIs is inevitable. Preclinical studies have implicated a role for drug-tolerant persister (DTP) cells in the development of acquired drug resistance. DTPs are a subpopulation of cancer cells that survive initial TKI therapy by entering a reversible, slow-cycling or quiescent state. Mechanistically, DTPs leverage reversible, non-genomic mechanisms, including epigenetic plasticity, activation of survival signaling pathways, and lineage switching, to maintain a drug-tolerant state. Importantly, DTP cells can undergo further evolution and acquire mechanisms of drug resistance that drive disease relapse. To identify vulnerabilities of DTP cells, we characterized DTP cells in patient-derived xenograft models of *EGFR*-mutant NSCLC and malignant pleural effusions from patients treated with EGFR TKIs. We observed that HIF1-α (hypoxia-inducible factor 1 alpha) signaling was consistently downregulated in DTP cells across models and patients. Unexpectedly, stabilization and reactivation of HIF-1α with the prolyl hydroxylase inhibitor, resensitized DTP cells to EGFR TKIs and suppressed the emergence of drug-resistant clones. Mechanistically, HIF-1 αreactivation increases oxidative stress in DTPs and promotes entry to an irreversible deep senescence state. These results add to a growing body of evidence that mitigation of oxidative stress is critical for DTP survival and suggest that reactivation of HIF-1α signaling may provide a therapeutic strategy to prevent emergence of resistance in *EGFR*-mutant NSCLC.

#7304 Lactate mediated suppression of tumor intrinsic type I interferon response in luminal breast cancer cells.

Yaminisree Nagidi[1], Aidan Moriarty[1], Min Yu[2]

[1]University of Maryland School of Medicine, Baltimore, MD,[2]University of Maryland, Baltimore, MD

Tumor hypoxia significantly contributes to cancer development, promoting tumor growth and metastasis. Previous work in our lab has shown that long term hypoxia leads to a marked suppression of type I interferon (IFN) signaling within luminal breast tumor cells. Notably, this suppression was persistent even when hypoxic precultured cells were reoxygenated which is indicative of hypoxic memory. Understanding the basis of IFN pathway suppression is important, as diminished IFN signaling weakens antitumor immune response and can promote tumor cell proliferation and survival. Hypoxia is also known to induce metabolic reprogramming which results in lactate accumulation, acidifying the tumor microenvironment (TME), and function as a signaling metabolite that suppresses antitumor immunity. While lactate's role in inhibiting immune response within TME is well established, its role within tumor cells in regulating interferon signaling remains poorly understood. In this study, we aim to explore the mechanisms of lactate mediated suppression of type I IFN response in tumor intrinsic manner. We found that long term hypoxia increases lactate accumulation and reduced type I IFN signaling. We also observed that addition of extracellular lactate to cells cultured under normoxia is sufficient to suppress type I IFN signaling, whereas pharmacological inhibition of lactate dehydrogenase A (LDHA) activity restores IFN signaling in hypoxia. Recent discoveries show that lactate can directly alter gene expression through histone lactylation, a novel epigenetic modification. However, its role in breast cancer immune escape remains largely unexplored. We observed that increased lactate levels under hypoxia correlate with elevated histone lactylation. Determining whether histone lactylation alters gene expression that can enhance the activity of suppressors of type I IFN signaling would elucidate the mechanisms of how lactate mediate suppression of IFN signaling. By uncovering this mechanism, our findings may reveal new therapeutic strategies to restore interferon signaling and enhance immunotherapy efficacy in breast cancer.

#7305 Evaluating the unfolded protein response as a therapeutic target in clear cell renal cell carcinoma patients.

Lee Moffitt Cancer Center & Research Institute, Tampa, FL

Metastatic clear cell renal cell carcinoma (ccRCC) is an incurable and lethal disease. While treatment of ccRCC has shifted toward antiangiogenic and immunotherapy combinations, long-term response is rare, underscoring the urgent need for novel therapeutic targets. We previously demonstrated in a murine model that therapeutic targeting of the unfolded protein response (UPR) via the mediator PKR-like ER kinase (PERK) can reverse tumor progression, immune suppression, and resistance to immune checkpoint blockade (ICB) (Mandula et al. Cancer Cell. 2022). Early-phase clinical studies are now evaluating PERK inhibition as a therapeutic strategy in solid tumors, including ccRCC. Here, we performed a retrospective analysis of patients with ccRCC using an analytical framework to estimate PERK activity from transcriptome data. We evaluated three independent ccRCC patient data sets - iATLAS patients treated with ICB (n = 296), ORIEN AVATAR patients treated with ICB (n = 85), and a TCGA treatment-naive cohort (n = 534). Across these datasets, PERK expression was associated with increased progression risk and worse overall survival. To evaluate the role of PERK in the context of endoplasmic reticulum (ER) stress, we generated a PERK knockout model using CRISPR gRNA in ccRCC cell lines and then challenged the cells with an ER stressor, thapsigargin. Interestingly, we found cytoplasmic vacuolization reminiscent of an unresolved unfolded protein response, ER swelling, and proteostasis disruption. Moreover, joint treatment with the PERK inhibitor AMG44 and thapsigargin significantly reduced viability in ccRCC cells. To further assess the therapeutic potential of PERK inhibition during standard-of-care therapy, we evaluated its impact during VEGF blockade. We observed decreased cell viability in PERK-silenced cells following cabozantinib (VEGF inhibitor) exposure, either through drug inhibition or genetic deletion. In summary, as clinical interest in PERK inhibition (PERKi) grows across multiple solid tumors, our findings highlight PERK as a potential therapeutic target in ccRCC and identify associated biomarkers that may inform future clinical strategies.

#7306 Does ribosomal protein haploinsufficiency induce cell competition in mammalian epithelia?.

Neha Joshi[1], Nicholas Baker[2], Eyemen Kheir[1]

[1]School of Medicine - Microbiology and Molecular Genetics, Uc-Irvine, Irvine, CA,[2]Uc-Irvine, Irvine, CA

Cell competition is a mechanism in which cells can be eliminated by neighboring cells with higher cellular fitness. Cell competition was discovered in Drosophila where heterozygosity for Ribosomal protein (Rp) gene mutations leads to elimination by cell competition with wild type cells. Rp gene haploinsufficiency is a common feature of aneuploid cells, and in Drosophila is largely responsible for the elimination of sporadic aneuploid cells. In mammals, Rp gene haploinsufficiency activates p53 through the nucleolar stress pathway. Cells with higher relative p53 activity are eliminated from mammalian epithelia, and p53 is also required for the selective removal of aneuploid cells from embryos. It has yet to be determined whether Rp gene haploinsufficiency leads to cell competition in mammals, how this depends on p53, and whether this contributes to aneuploid cell surveillance or tumor suppression. It is also not certain how Rp gene haploinsufficiency affects cells, other than activating the nucleolar stress pathway. We seek, using Crispr-based modification, to investigate the cellular effects of Rp gene haploinsufficiency, and to use epithelioid culture of mouse esophageal epithelium to measure cell competition in mosaic epithelia. We expect to gain insight into the contribution of Rp gene haploinsufficiency to tumor development and or cell competition to tumor suppression.

#7307 Cyclin-dependent kinase 5 (CDK5) contributes to Bruton tyrosine kinase inhibitor (BTKI) resistance via IRE1α/Xbp1s axis in mantle cell lymphoma (MCL).

Sonia Rodriguez-Rodriguez, **Keika Yan**, Andrew Chen, Dan Voung, Carly Roleder, Haifeng Shen, Tycel Phillips, Alexey Danilov

City of Hope, Duarte, CA

Resistance to BTKI is inevitable in MCL. While it may be partially driven by BTK mutations, full mechanisms are not understood. Here we evaluated the role of CDK5 in acquired BTKI resistance. We generated ibrutinib-resistant (IR) MCL cell lines (JeKo and Mino). RNA-seq of JeKo-IR cells showed that CDK5 was one of the upregulated genes with a fold change of 2.15 vs. parental cells, and findings were confirmed by IB. CDK5 is a proline serine/threonine protein kinase that modulates cell cycle proteins in neuronal tissue, however its role in cancer is not known. We established CDK5 overexpression (OE; by sgRNA) in JeKo and Mino cells. CDK5-OE cells exhibited enhanced proliferation and partial resistance to ibrutinib. By contrast, knockdown (KD; shRNA) of CDK5 in JeKo-IR and Mino-IR cell lines re-sensitized cells to ibrutinib. Treatment with GFB-12811, a selective CDK5 inhibitor, reduced proliferation of IR and CDK5-OE MCL cell lines in a dose dependent manner. We next evaluated CDK5 expression following activation of B-cell receptor signaling. IgM and BAFF crosslinking resulted in rapid increase in BTK phosphorylation which was accompanied by upregulated CDK5 protein levels. Furthermore, primary MCL cells cultured in BAFF- or CD40L-expressing stromal conditions (which induce ibrutinib resistance) upregulated CDK5. NSG mice xenografted with CDK5-OE JeKo cells exhibited inferior survival compared with mice xenografted with control cells. Mass spectrometry analysis of cell lines with manipulated CDK5 revealed >1000 differentially expressed proteins and >300 phosphosites, with cell cycle and metabolism-related pathways affected by CDK5. Kinase activity profiling revealed that 29 kinases were differentially active in CDK5-altered cells. In particular, Src kinase activation directly correlated with CDK5 expression. These findings were supported by RNA-seq and validated by immunoblotting. Furthermore, GSEA analysis of RNA-Seq revealed upregulation of the Unfolded Protein Response (UPR), Inflammatory response, Myc targets, p53 pathway and OxPhos in JeKo-IR cells. We next focused on the UPR. Both IR and CDK5-OE JeKo and Mino cells exhibited increased phosphorylation of IRE1α at Ser724 residue and upregulation of Xbp1, compared with control cell lines. By contrast, both pIRE1α and Xbp1 were decreased following CDK5-KD. Immunoprecipitation demonstrated a novel direct interaction between CDK5 and IRE1α. Finally, Xbp1-KD in JeKo-IR and Mino-IR cells led to reduced proliferation and viability, comparable to cells with CDK5-KD. In sum, CDK5 is overexpressed in MCL cells with acquired resistance to BTKi. Genetic or pharmacologic targeting CDK5 partially abrogates ibrutinib resistance. CDK5 contributes to BTKi resistance via modulation of the XBP1/IRE1α axis of the UPR pathway. Thus, CDK5 is a potential therapeutic target in MCL.

#7308 Older statins reduce metastatic potential in ccRCC: Mechanistic validation of SIM (selective inhibitor of metastasis) development.

Lily Wu[1], Junhui Hu[2], Moe Ishihara[1], Glen Brodie[3], Aino Siltari[4], Jimin Kim[1], Stuart Conway[3], Robert Damoiseaux[5], Teemu J. Murtola[6], Michael E. Jung[3]

[1]Molecular & Medical Pharmacology, University of California, Los Angeles, Los Angeles, CA,[2]Molecular & Medical Pharmacology, University of Califonia, Los Angeles, Los Angeles, CA,[3]Chemistry, University of California, Los Angeles, Los Angeles, CA,[4]Tampere University, Helsinki, Finland,[5]Department of Molecular & Medical Pharmacology, University of California, Los Angeles, Los Angeles, CA,[6]University of Tampere, Tampere, Finland

Purpose: Metastasis is the primary cause of mortality in clear cell renal cell carcinoma (ccRCC), and no current therapy prevents metastatic progression. We sought to define mechanism driving metastasis and develop small molecules capable of blocking dissemination.

Methods: Co-culture assays and xenograft models demonstrated that metastasis are promoted by interactions between VHL-deficient HIF1α-high (VHL$^-$HIF1α+) and VHL-proficient (VHL+) ccRCC cells, with the VHL$^-$HIF1α+ cells driving the metastasis by inducing proliferative and migratory programs in neighboring VHL+ cells. A high-throughput screen of over 18,000 small molecule compounds was undertaken to identify drugs selectively toxic to VHL$^-$HIF1α+ cells. Amongst the 2500 FDA approved drugs, 7 hits were identified, with 4 of them being older statins. Fluvastatin, being the most potent, was further tested for metastasis prevention in vivo. Transcriptomic and proteomic analyses compared older versus newer statins to assess HIF1α-dependent mechanisms. A population-based study of 17,792 RCC patients from the Finnish Cancer Registry linked cancer records with prescription data (1998-2018). Statins were classified as older (fluvastatin, simvastatin, lovastatin) or newer (atorvastatin, pravastatin, rosuvastatin). Logistic regression evaluated odds of metastatic presentation, and time-dependent Cox models assessed RCC-specific mortality, adjusting for demographics, comorbidities, tumor extent, and treatments.

Results: Screening identified fluvastatin (SIM-1) as a selective inhibitor, and medicinal chemistry yielded SIM-2 with >4-fold higher potency. Pre-treatment with fluvastatin reduced metastatic burden in vivo. Older statins showed more potent selective cytotoxicity against VHL$^-$HIF1α+ ccRCC cells than newer statins despite lower HMGCR affinity. HIF1α knockout abrogated fluvastatin sensitivity, suggesting its HIF1α dependence. Population analysis showed that pre-diagnostic use of older statins was associated with reduced odds of metastatic RCC at diagnosis, while newer statins did not reduce the risk of metastasis.

Conclusions: Mechanistic, pharmacologic, and epidemiologic data converge to identify older statins as inhibitors of metastasis acting through the HIF1α pathway. These findings support further development of SIMs towards achieving metastasis-preventive therapy for ccRCC.

#7309 Chronic extracellular acidosis drives metabolic plasticity and adaptive survival in multiple myeloma.

Hua-Ling Chen[1], Pei-Chu Tsai[1], Sheng-Chieh Lin[1], Fang-Yu Tsai[1], Shih Sheng Jiang[1], Chieh-Lin J. Teng[2], **Wun-Shaing Wayne Chang**[1]

[1]National Institute of Cancer Research, National Health Research Institutes (NHRI), Zhunan, Taiwan,[2]Division of Hematology/Medical Oncology, Taichung Veterans General Hospital, Taichung, Taiwan

Multiple myeloma (MM) is a plasma cell malignancy that evolves within the complex bone marrow microenvironment, where persistent extracellular acidosis exerts significant biological influence but remains insufficiently investigated. To elucidate the long-term impact of acidotic stress, we developed MM cell models chronically cultured under mildly acidic conditions, mimicking the gradual acidification seen during disease progression. This approach revealed a biphasic MM cellular response: early acidic exposure impaired proliferation, triggered apoptosis, and disrupted metabolic activity, whereas prolonged acidification induced a dynamic, reversible state marked by metabolic recovery, mitochondrial remodeling, and restored growth. Further transcriptomic profiling uncovered distinct gene expression programs associated with this chronic adaptation, including a set of acid-acclimated genes strongly correlated with disease stage and overall survival in MM patients. These findings suggest that extracellular acidosis is not a passive consequence of tumor metabolism, but a key determinant of MM progression by promoting adaptive metabolic plasticity and clonal evolution.

#7310 Interplay between HIF-1α and HIF-2α modulates TNBC phenotypes.

Aleksandra K. Kurowska, Long Chi Nguyen, Madeline Henn Bungert, Marsha Rich Rosner

The University of Chicago, Chicago, IL

Hypoxia-driven adaptation is a central feature of triple-negative breast cancer (TNBC) and contributes to its aggressive behavior. TNBC lacks ER, PR, and HER2 expression, which limits targeted treatment options. Hypoxia-inducible factors (HIFs), particularly the HIF-1α and HIF-2α isoforms, orchestrate the transcriptional response to low oxygen to maintain survival and metabolic programs, making them attractive therapeutic targets. HIF-1α is the main hypoxic responder in TNBC, but efforts to target it have failed in the clinic. The FDA approval of the HIF-2α inhibitor belzutifan for kidney cancer makes it urgent to determine whether inhibition may be effective in other solid tumors. Although HIF-1α and HIF-2α share some targets, their functions vary by cancer type, and the significance of HIF-2α in TNBC remains unclear. To address this, we investigated the individual and combined contributions of HIF-1α and HIF-2α in TNBC. Here, we show that HIF-2α is an important regulator in TNBC, in part due to previously unrecognized redundant or compensatory interactions between the two isoforms. Dual knockout of HIF-1α and HIF-2α did not further inhibit tumor growth compared to single knockouts, indicating functional overlap. Notably, HIF-2α acted antagonistically to HIF-1α and limited pro-metastatic effects, as HIF-2α knockout tumors showed increased metastatic burden in a syngeneic mouse model. This phenotype was supported by scRNA-seq analysis, which revealed elevated EMT hallmark signatures in HIF-2α-deficient xenograft tumors, and by *in vitro* observations where HIF-2α-deficient cells displayed a more invasive morphology. Some HIF-2α functions are context-specific and further shaped by the tumor microenvironment. Together, our findings reveal that HIF-1α and HIF-2α engage in redundant, compensatory, or antagonistic interactions dependent on the specific pathway. Thus, both factors contribute to stress responses, but HIF-2α also exhibits cancer-intrinsic functions that may potentially counteract the pro-metastatic effects of HIF-1α. Overall, these findings reveal the nuanced roles of HIF isoforms in tumor progression and highlight the need for careful consideration of HIF-2α targeting in TNBC therapy.

#7311 Characterization of PERK-positive polyploid-like breast cancer cells and their association with unfolded protein response signatures.

LUIS DEL POZO-YAUNER[1], Veronica Ramirez-Alcantara[2], Elba A. Turbat-Herrera[3], Hector Chavarria Bernal[1], Maha Babker[1], **Huseyin Kilic**[1], Rosetta Campbell[1], Bahaaeldin Youssef[1], Ajay Singh[4], Julio Isael Perez-Carreon[5], Wei Yang[6], Guillermo A. Herrera[1]

[1]Pathology, University of South Alabama College of Medicine, Mobile, AL,[2]USA Health Mitchell Cancer Institute, Mobile, AL,[3]University of South Alabama College of Medicine, Mobile, AL,[4]SOM-Cell and Molecular Biology, University of Mississippi Medical Center and Cancer Center and Research Institute, Jackson, MS,[5]National Institute of Genomic Medicine, Mexico City, Mexico,[6]Bruker Spatial Biology, Seattle, WA

Endoplasmic reticulum stress activates the unfolded protein response (UPR), a pathway linked to breast cancer (BC) progression, chemoresistance, and the formation of polyploid giant cancer cells (PGCCs). In a preliminary study, we identified a small subpopulation of breast cancer cells that were strongly positive for the phospho-PERK antibody in immunohistochemistry (IHC), some of which showed atypical mitosis and PGCC-like morphology. Because PGCCs are associated with tumor aggressiveness and poor outcomes, we hypothesize that the strongly PERK-positive BC cells represent PGCCs or their precursors and are enriched in tumors with active unfolded protein response (UPR) signaling. This study aimed to define the frequency of PERK-positive BC cells in BC, assess their association with UPR activation, and identify transcriptomic and proteomic features linked to tumors containing these cells. FFPE tissues from 131 BC patients (96 TNBC, 35 non-TNBC) were analyzed by IHC using antibodies against phospho-PERK, ATF6, and phospho-IRE1. All samples were collected before treatment. PERK-positive BC cells were defined as tumor cells with strong (3+) cytoplasmic and nuclear phospho-PERK staining. The IHC indicates an association between PERK-positive BC cells and tumors with a TNBC phenotype. These cells represent an heterogeneous population with broad variation in cell morphology and size, and mitosis status. Based on IHC results, 21 tumors (13 TNBC, 8 non-TNBC) were selected for nCounter multiomics, using BC360 and MO protein panel for transcriptomic and proteomic analysis, respectively. Eleven tumors contained abundant PERK-positive BC cells, while ten had few or none. Three normal breast tissues were included as controls. When breast cancer tumors with abundant PERK-positive BC cells were compared with those without, 388 genes were differentially expressed (p-value threshold 0.05), of which 296 had p-values < 0.01. Of them, SLPI, S100A7, SERPINB5, KIT, and PHGDH showed the most significant increase in expression (log fold-change >2.0), while 132 genes, including TFF1, PIP, TFF3, CDCA8, PAX5, IL24, and VEGFD, showed the most significant decrease in expression (log fold-change <-2.0). When BC tumors with abundant PERK+ cells were compared with normal breast tissue, 315 genes were differentially expressed (p-value threshold 0.05), of which 184 had p-values < 0.01. Of them, 28, including SPP1, KIFC1, CDK1, TOP2A, RRM2, CENPF, and MYBL2 had a log fold-change >2.0, while 94 genes, including APOD, ZBTB16, PDK4, RELN, TFF3, TIMP4, EGF, and VEGFD had a log fold-change <-2.0. Tumors containing abundant PERK-positive BC cells show clear evidence of unfolded protein response activation and a transcriptomic profile associated with aggressive behavior, metabolic reprogramming, and loss of differentiation.

This study was funded by a grant from the Breast Cancer Research Foundation of Alabama (BCRFA) to LPY.

#7315 Polysulfides contribute to persulfidation of FSCN-1 to accelerate development of pancreatic ductal adenocarcinoma.

Makoto Suematsu[1], Takehiro Yamamoto[1], Minako Takizawa[1], Chiyoko Nishime[1], Masami Suzuki[1], Nobuyoshi Hiraoka[2]

[1]Central Institute for Experimental Medicine and Life Science, Kawasaki city, Japan,[2]Pathology, National Cancer Center Japan, Tokyo, Japan

We previously reported polysulfides (PS) are overgenerated in ovarian and breast cancers that contribute to worsening prognosis and chemoresistance (1, 2), while molecular mechanisms remain unknown. In this study, expression of PS-generating enzymes in post-operative pancreatic ductal adenocarcinoma (PDAC) tissues were examined immunohistochemically using FFPE samples from 120 Japanese patients. Analyses revealed that cystathionine γ-lyase (CSE) expressed in cancer-associated fibroblasts (CAF) serves as an independent factor worsening post-operative disease-free and overall survivals. CSE-positive CAF predominantly occurs in regions adjacent to cancer cells and activated glycolysis to deliver C1 units towards transsulfudation as judged by elevated methylation of PFKFB3 and PKM2 that activates the carbon delivery for serine-cysteine synthesis. Gold nanoparticle-based surface-enhanced Raman spectroscopy (SERS) imaging (3) using frozen PDAC tissues unveiled PS generation over the cancer tissues. PS renders cancer cells to induce site-specific persulfidation of fascin-actin-bundling protein (FSCN)-1 to stimulate the ability of cancer cells to migrate, while PS-degrading ambroxol or gemcitabine canceled the effects through their action to scavenge PS in vitro. These results suggest that PS serves as a marker inducing CAF-mediated cancer invasiveness.References

#7316 Targeting sulfatide metabolism as a therapeutic vulnerability in pancreatic pre-cancer lesions.

Riccardo Ballaro[1], Yihui Chen[1], Marta Sans[1], Fredrik Ivar Thege[1], Rongzhang Dou[1], Jimin Min[1], Michele Yip-Schneider[2], Jianjun Zhang[3], Ranran Wu[1], Ehsan Irajizad[1], Yuki Makino[1], Kimal Rajapakshe[1], Mark Hurd[1], Ricardo A. Leon-Letelier[1], Jody Vykoukal[1], Jennifer B. Dennison[1], Kim-Anh Do[1], Samir M. Hanash[1], Robert Wolff[1], Paola A. Guerrera[1], Michael Paul Kim[1], C. Max Schmidt[1], Anirban Maitra[1], Johannes Fahrmann[1]

[1]UT MD Anderson Cancer Center, Houston, TX,[2]Indiana University School of Medicine, Indianapolis, IN,[3]Indiana University, Indianapolis, IN

Asymptomatic precursor lesions that predate invasive pancreatic ductal adenocarcinoma (PDAC) by years provide a compelling opportunity for cancer interception. One such precursor is the intraductal papillary mucinous neoplasm (IPMN). Using Matrix-Assisted Laser Desorption/Ionization Mass Spectrometry (MALDI-MS) imaging and spatial transcriptomics, we discovered long-chain hydroxylated sulfatide species and their biosynthetic enzymes as selectively enriched in IPMN. Genetic ablation of UGT8 and Gal3st1, the key enzymes catalyzing the synthesis of the sulfatide precursor galactosylceramide (GalCer) and sulfatides, respectively, suppressed sulfatide production and triggered mitochondrial ceramide accumulation in mutant Kras;Gnas IPMN cells. These metabolic disruptions led to reduced proliferation and invasiveness, alongside increased caspase-dependent apoptosis. Pharmacologic UGT8 inhibition also caused profound impairments in mitochondrial function and morphology. Integrated lipidomic and proteomic analyses on mitochondrial fractions revealed remodeling of lipid composition and dysregulation of proteins involved in mitochondrial translation, oxidative phosphorylation, mitophagy and sphingolipid metabolism, corroborating the phenotypic changes observed in our functional studies. In vivo, UGT8 inhibition suppressed tumor growth in IPMN allograft models. Collectively, our findings identify enhanced sulfatide metabolism as an early metabolic alteration of cystic pre-cancerous lesions and demonstrate that targeting UGT8 perturbs mitochondrial homeostasis and function, revealing a potential strategy for pancreatic cancer interception.

#7317 Dual targeting of SLC6A14 and autophagy/macropinocytosis enhances therapeutic efficacy in pancreatic ductal adenocarcinoma.

Mosharaf Mahmud Syed[1], Devaraja Rajasekaran[1], Souad R. Sennoune[1], Tanima Sharker[1], Oscar Sanchez[1], Mary Katherine Jurek[2], Longfa Kou[3], Ruijie Chen[3], Vadivel Ganapathy[1], Yangzom D. Bhutia[1]

[1]Cell Biology and Biochemistry, Texas Tech University Health Sciences Center, Lubbock, TX,[2]Psychiatry, Tufts Medical Center, Boston, MA,[3]Pharmacy, Wenzhou Municipal Key Laboratory of Pediatric Pharmacy, The Second Affiliated Hospital and Yuying Children's Hospital of Wenzhou Medical University, Wenzhou, China

PDAC is highly desmoplastic and undergoes metabolic reprogramming to sustain their growth and proliferation. Our laboratory has identified SLC6A14, an amino acid transporter, as a novel drug target for PDAC. Genetic deletion of SLC6A14 or its pharmacological blockade with α-MLT attenuates PDAC growth by inducing amino acid deprivation. However, nutrient stress, particularly amino acid deprivation, can induce nutrient scavenging mechanisms like autophagy and macropinocytosis, thereby undermining the full anticancer potential of SLC6A14 blockade. To address this, the current work was conducted to test if SLC6A14 blockade induces autophagy and/or macropinocytosis and to further investigate if dual inhibition of SLC6A14 (α-MLT) and autophagy/macropinocytosis (HCQ) would yield a better therapeutic outcome in PDAC as opposed to targeting SLC6A14 alone. In vitro assays (MTT and colony formation) revealed that the combination treatment significantly reduced PDAC cell viability and clonogenic potential as opposed to monotherapy. Treatment model subcutaneous xenograft in athymic nude mice demonstrated a superior therapeutic outcome with the combination regimen. Collectively, our study demonstrates that the afore-described combination therapy creates a metabolic trap wherein α-MLT induces nutrient stress, while HCQ prevents autophagic and macropinocytosis compensation, thus culminating in a more potent tumor attenuation. This dual blockade represents a hitherto unexplored treatment strategy for PDAC.

#7318 Pancreatic ductal adenocarcinoma causes altered whole-body iron distribution.

Amit Roopan, Subin Pyo, Yichi Zhang, Anna Barbeau, ChiHin Feng, Matthew G. Vander Heiden

Koch Institute for Integrative Cancer Research at MIT, Cambridge, MA

Anemia of chronic disease is a prevalent form of anemia that occurs in patients with acute or chronic immune activation associated with multiple diseases, including cancer. A hallmark of anemia of chronic disease is disturbed iron homeostasis, where iron uptake and retention within the reticuloendothelial system and within peripheral tissues is increased to divert iron away from circulation and into storage sites, limiting availability for erythropoiesis. We observe in PDAC mice and patients that they exhibit anemia of chronic disease and find in different mouse models of PDAC that iron availability is decreased in circulation and that instead iron is being stored in peripheral tissues such as muscle, pancreas, liver, spleen, and many other organs and tissues. Our laboratory has shown that impaired exocrine function is a key driver of peripheral tissue wasting in PDAC and that decreased pancreatic enzyme secretion can be used for early diagnosis of PDAC. Therefore, we wondered whether intestinal iron absorption is decreased in PDAC and surprisingly found increased intestinal iron absorption in PDAC due to upregulation of the enterocyte iron importer DMT1 and iron exporter Ferroportin. Iron uptake from diet and iron sequestration into peripheral tissues can be studied through isotope tracing experiments. Fe56 is the predominant naturally abundant iron isotope so we used an Fe57-infused diet to study the kinetics of Fe57 intake and found that Fe57 is less abundant in the serum from PDAC mice compared to wildtype mice, suggesting that iron is quickly sequestered from circulation and into peripheral tissues. We are now focusing on identifying the regulators of increased intestinal iron absorption and iron sequestration in the context of PDAC.

#7319 Targeting HDAC1 activity presents vulnerabilities in pancreatic cancer metabolism.

Don-Gerard C. B. Conde[1], Evan J. Zhou[2], Soren Jensen[1], Maximillian Farma[2], Chiamaka Joy Ezeh[2], Alexander N. Behram[1], Phuong T. N. Pham[1], Nabila N. Binti[1], Laiba Shiekh[2], Matthew C. Cheung[2], Zeribe Nwosu[2]

[1]Molecular Biology and Genetics, Cornell University, Ithaca, NY,[2]Cornell University, Ithaca, NY

Pancreatic cancer is a lethal disease with significant metabolic reprogramming, which promotes tumor growth, therapy resistance, and adaptation to stress. These alterations are largely attributed to mutations in the KRAS oncogene but with limited progress in therapeutic discovery. Despite the recent focus on metabolism in pancreatic cancer, the major mediators of altered metabolism remain unknown. Our differential gene expression analyses in multiple patient cohorts' pancreatic tumors versus normal tissues identify histone deacetylase 1 (HDAC1) as a consistently upregulated epigenetic gene. HDAC1-high tumors correlate strongly with metabolic pathways, including glycolysis, redox metabolism, and nucleotide biosynthesis. Using CRISPR/Cas9 gene editing, we found that the deletion of HDAC1 in pancreatic cancer cell lines triggers metabolic shifts, notably in glucose metabolism, and led to a distinct growth phenotype in a cell context-dependent manner. Similarly, treatment with class I selective HDAC inhibitors was selectively effective in suppressing pancreatic cancer cell growth. Furthermore, our drug screenings demonstrate profound synergies that overlap across the HDAC1-deleted and HDACi treated cell lines that present under-explored avenues for therapeutics. Our data provides evidence of compensatory metabolic alterations upon HDAC1 inhibition, which could broaden the opportunities for therapeutic intervention in pancreatic cancer.

#7320 KRAS-PIP5K1A-SDC1 axis regulates nutrient scavenging in pancreatic cancer.

Sommer H. Ramos, Oisun Jung, Suyong Choi

Eppley Institute For Cancer Research, University of Nebraska Medical Center, Omaha, NE

Pancreatic ductal adenocarcinoma (PDAC) is a lethal malignancy with limited treatment options and a five-year survival rate of 13%. A defining characteristic of PDAC is its ability to survive and proliferate in nutrient-deprived environments. This is driven by metabolic reprogramming induced by mutant KRAS, which is present in over 90% of cases. However, the mechanism by which mutant KRAS coordinates the metabolic adaptation remains incompletely understood. We have discovered recently that mutant KRAS directly interacts with Phosphatidylinositol-4-Phosphate 5-Kinase Type I Alpha (PIP5K1A), a lipid kinase responsible for generating phosphoinositide phosphatidylinositol 4,5-bisphosphate ($PI4,5P_2$) and enhances its enzymatic activity. Upon activation by mutant KRAS, PIP5K1A generates elevated levels of $PI4,5P_2$ at the plasma membrane, allowing $PI4,5P_2$ to associate with Syndecan-1 (SDC1), a transmembrane heparan sulfate proteoglycan. The goal of this study is to define the roles of SDC1 and PIP5K1A in two major nutrient acquisition pathways: macropinocytosis-mediated uptake of extracellular proteins and SDC1-dependent regulation of Glucose Transporter 1 (GLUT1), to promote enhanced glucose uptake in pancreatic cancer cells. In CFPAC-II cells, we observed the co-localization of $PI4,5P_2$, PIP5K1A, KRAS, and SDC1 at membrane ruffles, consistent with macropinocytic structures. In-vitro binding assays demonstrated a direct interaction between the SDC1 extracellular domain and nutrient transporters GLUT1 and CD98. Additionally, glucose uptake assays showed that knockdown of either SDC1 or PIP5K1A significantly decreased glucose uptake in KPC cells. Together, these findings identify a novel KRAS-PIP5K1A-SDC1 signaling axis that regulates nutrient acquisition in PDAC, highlighting a potential therapeutic strategy to disrupt nutrient scavenging in KRAS-driven pancreatic cancer.

#7321 The link between metabolism and inflammation in Black African pancreatic ductal adenocarcinoma patients.

Nnenna Elebo[1], Dupe Ojo[2], Jones A.O. Omoshoro-Jones[1], Stefano Cacciatore[2], John Devar[1], Ekene E. Nweke[1]

[1]Surgery, University of Witwatersrand, Johannesburg, South Africa,[2]Bioinformatics, International Centre for Genetic Engineering and Biotechnology, Capetown, South Africa

Background: Pancreatic Ductal Adenocarcinoma (PDAC) remains one of the most lethal cancers globally, with increasing incidence among Black African populations. Emerging evidence suggests that the interplay between metabolic dysregulation and inflammation may play crucial roles in the pathogenesis and progression of PDAC. However, this relationship remains underexplored in African cohorts.

Methods: We conducted an untargeted metabolomics study using Nuclear Magnetic Resonance (NMR) spectroscopy on plasma samples obtained from consenting participants comprising 81 PDAC patients (57 resectable, 15 locally advanced, and 9 metastatic), 6 chronic pancreatitis patients, and 6 healthy controls. Reactive oxygen species (ROS) levels were quantified using the OxiSelect™ In Vitro ROS/RNS Assay Kit (Green Fluorescence). Group comparisons were performed using Wilcoxon and Kruskal-Wallis rank-sum tests, while Spearman's correlation and Kaplan-Meier analyses were applied for correlation and survival assessment. A p-value < 0.05 was considered statistically significant.

Results: Total bilirubin (p = 0.004), conjugated bilirubin (p = 0.003), alanine aminotransferases (p = 0.01) and aspartate aminotransferases (p = 0.03) levels were significantly altered across the groups. Metabolomic profiling revealed elevated levels of 2-hydroxybutyrate (2-HB, p = 0.004) and acetoacetate (p = 0.009) with advancing tumor stage. PDAC patients were stratified into "high" and "normal/low" 2-HB groups, with the top 25% representing the "high" group. Furthermore, lower 2-HB concentrations were associated with longer survival outcomes. Although not statistically significant, patients with high 2-HB exhibited increased ROS/RNS levels compared to those with low 2-HB. There was a positive correlation between 2-HB and inflammatory markers: GlycA (rho=0.07, p=0.64), GlycB (rho=0.07, p=0.66), CRP (rho=0.49, p=0.08) and White cell count (rho=0.48, p=0.08).

Conclusion: This study demonstrates a potential link between altered metabolic pathways and oxidative stress in Black African PDAC patients. Elevated 2-HB and acetoacetate may serve as metabolic indicators of tumor progression and poor prognosis. These findings highlight the importance of integrating metabolic and inflammatory profiling to better understand PDAC biology in African populations.

#7322 Vav1 promotes pancreatic tumor cell invasion via GLS1-dependent glutamine metabolism.

Mustafa Emre Gedik[1], Omar L. Gutierrez-Ruiz[2], Katherine M. Johnson[1], Ella Rose D. Chianis[1], Jing Chen[3], Alex Bittner[4], Adam Zahm[1], Ankit Chhoda[1], Taro Hitosugi[5], Mark A. McNiven[3], Gina Razidlo[1]

[1]Department of Biochemistry and Molecular Biology, Mayo Clinic, Rochester, MN,[2]Division of Hematology, Mayo Clinic, Rochester, MN,[3]Division of Gastroenterology and Hepatology, Mayo Clinic, Rochester, MN,[4]St. Olaf College, Northfield, MN,[5]Department of Oncology, Mayo Clinic, Rochester, MN

Pancreatic ductal adenocarcinoma (PDAC) is an aggressive malignancy due in part to metabolic rewiring and a high rate of metastasis. Pancreatic tumors are particularly dependent upon glutamine (Gln) as a nutrient source for multiple metabolic pathways. To adapt to low levels of glutamine, PDAC cells upregulate the Rac1 dependent process of macropinocytosis, which internalizes extracellular macromolecules to scavenge them as a glutamine source. The proto oncogene Vav1 is an activator of the potent Rac/Cdc42 signaling cascades that regulate actin dynamics. While Vav1 is normally restricted to hematopoietic cells, Vav1 expression is significantly increased in PDAC, with high Vav1 correlating with worse overall survival. Here we uncover a novel Vav1 mediated regulation of glutamine metabolism in PDAC cells. While Vav1 is a potent activator of Rac1, surprisingly, Vav1 expression inhibited macropinocytosis in PDAC cells. Intriguingly, genomic and metabolomic analysis revealed that high Vav1 expression correlates with increased dependence on glutamine and glutamate (Glu) metabolism. Indeed, Vav1 dependent macropinocytosis was rescued by cell permeable glutamate, confirming disrupted Gln/Glu balance in Vav1 knockdown cells. RPPA screening indicated a Vav1 dependent effect on glutaminase 1 (GLS1, KGA isoform), which converts glutamine to glutamate. Mechanistically, we discovered that Vav1 modulates GLS1 localization to the mitochondria through regulation of GLS1 posttranslational modification. Disrupting GLS1 localization by deleting its mitochondrial targeting motif phenocopied loss of Vav1 in reducing the invasive potential of tumor cells. Investigation of Vav1 dependent metabolic consequences showed that knockdown of Vav1 alters 13C Gln derived metabolic flux into the TCA cycle, as well as a deficiency in the level of the antioxidant glutathione (GSH), which utilizes glutamate for its synthesis. Consequently, targeting Vav1 resulted in increased levels of cellular and mitochondrial reactive oxygen species (ROS) and increased sensitivity to lipid peroxidation. Notably, dual targeting of both glucose and glutamine pathways showed significant synergistic effects on cellular viability in Vav1 expressing cells. Here we established a new tumor promoting role for Vav1 via Gln/Glu regulation and uncover a novel subcellular regulation of mitochondrial glutamine metabolism. Our findings establish Vav1 as a critical regulator of metabolic rewiring in PDAC and orchestrates glutamine metabolism by controlling the KGA isoform of GLS1 mitochondrial localization. Importantly, Vav1 functions as a signaling adapter in glutamine metabolism, providing a potential therapeutic vulnerabilities for PDAC patients with high Vav1 expression.

#7323 ACADS-dependent fatty acid oxidation drive mitochondrial remodeling in pancreatic cancer cells.

Madison Brown-Blackshear, Divine Asamoah, Nadiya Harris, Mengistu Lemecha

Hampton University, Hampton, VA

Pancreatic ductal adenocarcinoma (PDAC) is a highly aggressive cancer projected to become the second leading cause of cancer-related deaths by 2030. While PDAC cells rely primarily on glycolysis, emerging evidence indicates that mitochondrial metabolism also contributes to tumor survival. The metabolic impact of stromal fibroblasts on pancreatic cancer mitochondria, particularly through fatty acid oxidation (FAO), remains poorly understood. Here, we investigated whether fibroblast exposure alters mitochondrial remodeling in PDAC cells and if this remodeling depends on mitochondrial fatty Acyl-CoA Dehydrogenase (ACADS) mediated FAO. Mitochondrial changes were assessed in Panc1 cells cultured alone and co-cultured with 3T3-L1 fibroblasts. MitoTracker Red staining and confocal microscopy were used to visualize mitochondrial content. Mitochondrial and metabolic proteins were quantified with Western blotting. Carnitine Palmitoyltransferase 1 (CPT1) was inhibited using Etomoxir (5-100 μM, 24 hrs). Compared with fibroblasts grown separately, Panc1 cells showed lower baseline mitochondrial mass. However, when direct co-cultured, Panc1 cells exhibited increased mitochondrial content and elevated expression of ACADS and Mitochondrially Encoded Cytochrome c Oxidase (MTCO1), suggesting mitochondrial adaptation in response to fibroblast interaction. To test whether this remodeling required downstream short-chain FAO, we inhibited CPT1, the rate-limiting enzyme for mitochondrial fatty-acid import. Although CPT1 does not directly regulate ACADS, Etomoxir-mediated CPT1 inhibition significantly decreased ACADS levels, consistent with reduced FAO flux. CPT1 blockade also triggered metabolic stress, evidenced by increased phosphorylated AMP-activated protein kinase alpha (p-AMPKα), and resulted in a dose-dependent increase in Dynamin-Related Protein 1 (DRP1), indicating enhanced mitochondrial fission and dysfunction. Collectively, our preliminary data suggests that PDAC cells depend on intact fatty-acid oxidation to maintain mitochondrial integrity.

#7324 HER3 mediates metabolic reprogramming in metastatic colorectal and pancreatic cancer.

Moeez Ghani Rathore, Chao Wei, Kimberly Curry, Mehrdad Zarei, Zhenghe Wang, Jordan Winter, Rui Wang

Case Comprehensive Cancer Center, Cleveland, OH

Background: Liver metastasis occurs in ~80% of all metastatic colorectal cancer (mCRC) and metastatic pancreatic cancer (mPC), and the liver has a unique microenvironment that promotes cancer cell survival. Prior studies from our group and others have reported that the liver endothelium and hepatocytes secrete soluble factors (NRG1 and LRG1) that activate the cancer-associated HER3 signaling pathway and promote cancer growth. This study examines the impact of HER3 signaling on the metabolism of mCRC and mPC, aiming to identify a novel therapeutic approach.

Methods: We performed mass spectrometry to profile the metabolic changes in mCRC and mPC tumors with/without HER3 inhibition in a syngeneic, orthotopic mouse model with hepatic injection. We also performed in vitro metabolic assays to determine the effect of HER3 ligands on the metabolism of CRC and PC. To further define the role of HER3 in metabolic reprogramming, we used siRNA silencing of HER3 and pharmacological inhibition of HER3 downstream signaling proteins to identify the key mediator(s) of HER3-induced metabolic shift. We performed in vitro synergy studies combining HER3i (Sapitinib) with oxidative phosphorylation (OXPHOS) inhibitors (metformin and ivosedinib). To further determine the synergistic efficacy *in vivo*, we established syngeneic, orthotopic metastases of mCRC/mPC in the liver via hepatic injection and treated the mice with HER3 and OXPHOS inhibitors.

Results: We found that HER3 ligands increase cell acidification and lactate secretion (as measured by Seahorse FX and ELISA, established readouts of glycolysis) while simultaneously reducing oxygen consumption and mitochondrial membrane potential (as measured by Seahorse FX and TMRE, key indicators of oxidative phosphorylation metabolites, OXPHOS). We found that PFK2 is activated by HER3 signaling, as determined by phosphorylation, and that the HER3-AKT/RSK-PFK2 signaling axis is the key mediator of HER3-induced glycolysis. We then determined that HER3 inhibition decreased glycolysis readouts but induced an adaptive survival strategy by causing a metabolic shift towards OXPHOS. Thus, we found that simultaneous inhibition of HER3 and OXPHOS synergistically blocked the growth of cancer cells *in vitro* and led to an unprecedented 70% complete response in mouse models with orthotopic mCRC/mPC liver metastases.

Conclusions: We identified the HER3-AKT/RSK-PFK2 axis as a promoter of glycolysis and growth in CRC/PC liver metastases. Leveraging the discovery of metabolic shifting towards OXPHOS caused by HER3 inhibition, we identified a potential therapeutic strategy of combining HER3 inhibitors and OXPHOS inhibitors for treating patients with mCRC/mPC.

#7325 Cytosolic transport of citrate protects nutrient-austere pancreatic cancer from ferroptosis.

Adam Kneebone[1], Kailey Lindaur[1], Ata Abbas[2], Joel Cassel[3], Sarah Graff[4], Caudia Rose Keating[1], Gerard Abood[1], Xianzhong Ding[1], William Small[5], Clodia Osipo[1], Wei Qiu[1], Curtis Tatsuoka[6], Simone Sidoli[4], Costas Andreas Lyssiotis[7], Joseph M. Salvino[3], Ali Vaziri-Gohar[1]

[1]Loyola University Chicago Stritch School of Medicine, Maywood, IL,[2]Case Western Reserve University, Cleveland, OH,[3]The Wistar Institute, Philadelphia, PA,[4]Albert Einstein College of Medicine, New York, NY,[5]Professor, Loyola University Medical Center, Maywood, IL,[6]University of Maryland, Baltimore, MD,[7]University of Michigan, Ann Arbor, MI

Pancreatic cancer (PDAC) cells experience nutrient starvation in a poorly perfused tumor microenvironment. Metabolic dependencies that protect PDAC cells from detrimental oxidative stress in a nutrient-restricted niche represent as tumor-specific targets. While the role of mitochondria in supporting energy production and biosynthetic requirements of cells has been well investigated, their contribution to maintaining intracellular redox homeostasis when PDAC cells are exposed to nutrient deprivation is unknown. Our results demonstrate that cytosolic transport of citrate via SLC25A1 confers a survival advantage to PDAC cells by protecting them from ferroptosis, a well-established iron-dependent cell death mechanism, under nutrient-limited conditions. Employing selective SLC25A1 inhibitor or targeting mitochondrial OXPHOS dramatically reduced GPX4 expression and PDAC cell viability. Rescuing GPX4 expression with the products of both ACLY and ACO1-dependent pathways uncovered their critical role in conferring survival advantage under metabolic stress. Importantly, exogenous expression of GPX4 reversed redox imbalance and metabolic discordance resulting from the lack of SLC25A1 activity, indicating the requirement of citrate-induced GPX4 expression to support mitochondrial health and function. As observed with cultured cells under nutrient limitation, SLC25A1 function was revealed to be indispensable in pancreatic tumor microenvironment, and the reduced growth, due to the lack of SLC25A1 activity, was rescued with antioxidant NAC in preclinical models of PDAC. Lastly, SLC25A1 suppression was accompanied by elevated glutamine metabolism, and combination therapy with pharmacologic inhibitors of SLC25A1 and glutaminase inhibitor CB-839 dramatically suppressed tumor growth, highlighting this combinatorial approach as a potential therapeutic strategy in PDAC.

#7326 PU-H71 alters metabolism to suppress growth in pancreatic cancer.

Chiamaka J. Ezeh, Darren Binder, Leo Li, Zeribee C. Nwosu

Molecular Biology and Genetics, Cornell University, Ithaca, NY

Pancreatic ductal adenocarcinoma (PDAC) is a deadly cancer with limited therapeutic options. Oncogenic KRAS signaling, mainly via the mitogen-activated protein kinase (MAPK) pathway, is the key driver of PDAC. To sustain its growth and resist therapy, PDAC tumors continuously reprogram their metabolic activities. To identify therapeutic agents capable of disrupting these adaptive survival activities, we performed a high-throughput drug screen of >2,000 compounds in two PDAC cell lines. This screen identified PU-H71, a selective epichaperome and heat shock protein 90 inhibitor, as a potent suppressor of PDAC viability. PU-H71 reduced short-term cell growth and impaired clonogenic survival across multiple PDAC models. Metabolomics profiling revealed that treatment with PU-H71 consistently altered intracellular amino acid levels, metabolites in key biochemical pathways, and caused a significant shift in extracellular metabolites, suggesting coordinated changes in metabolite flux and utilization. Further, treatment of PDAC cells with PU-H71 reduced the phosphorylation of mTOR-associated signaling components and suppressed the MAPK signaling pathway. Together, these findings indicate that PU-H71 disrupts PDAC survival by simultaneously perturbing metabolic programming and growth signaling networks. Our results identify PU-H71 as a promising therapeutic agent for targeting the crosstalk between metabolism and signaling programs that promote PDAC growth and therapeutic resistance.

#7327 Dissecting lysosomal metabolic dependencies in pancreatic cancer through functional genomics.

Caleb Cheng[1], Ruya Pakkan[1], Jasmine Wisniewski[1], Sydney Peters[2], Yuanyuan Qiao[2], Costas Andreas Lyssiotis[1], Arul Chinnaiyan[1]

[1]University of Michigan, Ann Arbor, MI,[2]University of Michigan Medical School, Ann Arbor, MI

BACKGROUND:Lysosomal nutrient recycling and acquisition pathways employed at an elevated capacity in pancreatic cancer cells in response to the harsh metabolic microenvironment in which they subsist. We have others have previously studied autophagy or lysosomal inhibition strategies and identified the metabolic adaptations they effect on cancer cells. These studies have thus suggested that the lysosome plays a role in regulating iron, lipids, nucleotides, and amino acids, among other nutrients. However, these studies have differed in their experimental approaches, pharmacological agent, and molecular targets, and it is unclear whether these multiple conclusions are broadly generalizable across all autophagy or lysosome inhibition strategies.
METHODS AND RESULTS:To address these issues, here we perform parallel metabolism-focused CRISPR activation and knockout screens using 8 different autophagy or lysosome inhibitors in pancreatic cancer cell lines. From these, we determined that iron homeostasis is primarily affected by agents that affect lysosomal pH, such as bafilomycin A1 and Ammonium, but not by other inhibitors of lysosomal function such as apilimod, ESK981, or chloroquine, or by ULK1 inhibitors ULK101, SBI-0206965, or DCC-3116. Pairing the CRISPR screen data with transcriptomics, we further identified that lipid homeostasis was affected by all lysosome inhibitors but not ULK inhibitors. These multi-omics approaches specifically highlighted Farnesyl Diphosphate Synthase (FDPS), a gene involved in cholesterol synthesis as a prominent metabolic vulnerability revealed upon lysosome inhibition, whether with chloroquine, bafilomycin A1, or apilimod.
DISCUSSION:Our study demonstrates a clear metabolic distinction between inhibiting autophagy compared to inhibiting the lysosome. Our data further highlight that disturbances in lipid metabolism are a general effect of lysosome inhibition, while disruptions in iron homeostasis may primarily be due to disturbances in lysosomal pH.

#7328 EPR imaging of oxygen consumption driven by NQO1-activated compounds in FH-deficient renal tumors.

Yuki Shibata[1], Shun Kishimoto[2], Ye Yang[1], Ming-Hui Wei[1], Julia Medina-Velazquez[1], Burchelle Blackman[3], Jeeva Munasinghe[4], Viraj Chegu[1], Vaishnavi S. Srirama[1], Tyler A. On[1], Nallathamby Devasahayam[2], Chandramouli V. Gadisetti[5], Jeffrey R. Brender[6], Murali C. Krishna[2], **Daniel R. Crooks**[1], William Marston Linehan[7]

[1]Urologic Oncology Branch, National Cancer Institute, Bethesda, MD,[2]National Cancer Institute, Bethesda, MD,[3]Chemical Synthesis Center, National Heart Lung and Blood Institute, Bethesda, MD,[4]National Institute of Neurological Diseases and Stroke, Bethesda, MD,[5]President, GenEpria Consulting Inc., Columbia, MD,[6]Radiation Biology Branch, National Cancer Institute, Bethesda, MD,[7]National Cancer Institute, Berhesda, MD

Patients with hereditary leiomyomatosis and renal cell carcinoma (HLRCC), characterized by mutations in the *fumarate hydratase* (FH) gene, are at risk for development of aggressive FH-deficient RCCs. FH-deficient tumor cells undergo a pronounced and irreversible metabolic shift to lactate fermentation due in part to loss and mutation of mitochondrial DNA. Fumarate accumulation in FH-deficient tumor cells leads to increased expression of NAD(P)H-quinone oxidoreductase 1 (NQO1) through activation of the NRF2 transcription factor. Although several therapeutic agents have shown promise in the treatment of FH-deficient RCC, clinical outcomes in patients remain unsatisfactory. In this study, we examined the mechanism and therapeutic efficacy of isobutyl-deoxynyboquinone (IB-DNQ), which undergoes futile redox cycling in the presence of NQO1 and oxygen, leading to sustained generation of the highly reactive and toxic superoxide anion. First, we found that patient-derived FH-deficient tumor cells exhibit minimal oxygen consumption in vitro, and EPR oxygen mapping of FH-deficient tumor xenografts in vivo revealed that tumor oxygen levels were elevated relative to other genetically defined in vivo models of RCC. Infusion of IB-DNQ in tumor-bearing animals resulted in rapid and robust non-mitochondrial oxygen consumption in FH-deficient tumor xenografts as measured by both EPR oxygen imaging and photoacoustic mapping of tumor hemoglobin saturation. Repeated doses of IB-DNQ resulted in reduced tumor growth rates. Metabolomic analyses revealed that IB-DNQ treatment strongly suppressed glycolysis and reduced cellular ATP levels by rapidly depleting NADH and NADPH in FH-deficient tumor cells. Finally, [1-^{13}C]pyruvate hyperpolarized MR spectroscopy revealed decreased conversion of pyruvate to lactate in FH-deficient tumor xenografts following IB-DNQ treatment, providing a direct measurement of the impact of IB-DNQ on lactate fermentation in vivo. The combination of these in vivo imaging techniques and metabolite measurements demonstrate that NQO1-activated quinones can effectively target aerobic glycolysis in FH-deficient tumors which rely heavily on lactate fermentation for growth.

#7329 Host organ environment shapes clear cell renal cell carcinoma metastatic metabolism.

X. Alex Guo[1], Lina P. Calderon[2], Andrea L. Sanmiguel[2], Anirudh Sridharan[1], A. Ari Hakimi[2], Ed Reznik[1]

[1]Computational Oncology, Memorial Sloan Kettering Cancer Center, New York, NY,[2]Department of Urology, Memorial Sloan Kettering Cancer Center, New York, NY

Primary clear cell renal cell carcinoma (ccRCC) is characterized by profound metabolic rewiring which adapts as tumors evolve to become more aggressive, yet the evidence showing whether those programs are preserved versus reshaped at distant metastatic sites in humans remains limited. To investigate the determinants of ccRCC metastatic metabolism, we performed mass-spectrometry-based metabolomic profiling on quartets of primary tumor, adjacent normal kidney, distant metastasis, and normal adjacent to metastasis, from 14 patients with metachronous metastases. We find three key results. First, through unpaired comparisons of ccRCC metastases versus primaries, we observe decreases in glutathione metabolism in metastatic tissues. Second, using linear models, we find that metabolic profiles of metastatic tumors more closely resemble those of the normal tissue at the metastatic site than those of the patient's original kidney tumor. Third, we show that several metabolites in metastases can be approximated as simple mixtures of the primary tumor and the local normal tissue. Together, these results suggest that ccRCC metastases are strongly reshaped by the metabolic environment of the metastatic organ.

#7330 Hypoxia enhances sensitivity to RAS inhibition in PDAC.

Anna Shevzov-Zebrun[1], Darius Sinha[1], Muhammad Bin Munim[1], Keene Abbott[2], Matthew G. Vander Heiden[1]

[1]Koch Institute for Integrative Cancer Research at MIT, Cambridge, MA,[2]Dana Farber Cancer Institute, Boston, MA

Pancreatic ductal adenocarcinoma (PDAC) is one of the most lethal malignancies, in part due to acquired therapy resistance. As ~90% of PDAC tumors harbor activating *KRAS* mutations, direct inhibition of RAS has emerged as a promising therapeutic strategy. The RAS(ON) multi-selective inhibitor daraxonrasib has demonstrated clinical activity in PDAC and is currently being evaluated in Phase 3 trials; however, monotherapy resistance still emerges underscoring the need to identify biological processes that enable tumor cell survival following RAS inhibition. As RAS signaling regulates cancer metabolism, we hypothesized that metabolic remodeling contributes to RAS inhibitor sensitivity and resistance. To test this, we profiled polar metabolites in PDAC cells treated with RMC-7977, a tool RAS(ON) multi-selective inhibitor. RAS(ON) inhibition led to broad alterations in metabolite levels, including decreased levels of glycolytic and pentose phosphate pathway intermediates. In line with these findings, RMC-7977 treatment reduced glucose uptake and increased lactate secretion, suggesting that RMC-7977 treatment reduces glycolysis and promotes a shift toward increased oxidative metabolism. Given this shift toward oxidative metabolism, which requires mitochondrial respiration, we hypothesized that hypoxia, a hallmark of PDAC, may increase sensitivity to RAS inhibition. Indeed, PDAC cells exhibited enhanced growth inhibition in response to RMC-7977 in low oxygen conditions. RMC-7977 also suppressed glucose uptake and lactate secretion similarly under normoxic and hypoxic conditions. Pharmacologic inhibition of mitochondrial respiration under normoxia also enhanced RMC-7977 sensitivity. Together, these findings reveal that RMC-7977 reduces glucose uptake and shifts cells toward oxidative metabolism and uncovers a potential metabolic vulnerability involving the PDAC tumor microenvironment that has the potential to enhance the impact of RAS inhibition.

#7331 Hepatic proton conductance as a bioenergetic vulnerability and therapeutic target in MASH-associated HCC.

Elizabeth Rachel Marie Zunica[1], Kim Pedersen[2], Anan L. Cole[3], Analisa L. Taylor[3], Elizabeth C. Heintz[3], Megan D. Dousay[4], Bolormaa Vandanmagsar[3], Monika Sharma[5], Odinakhon Shamieva[6], Lucas Kniess Debarba[6], Marcus DaSilva Goncalves[7], Tomislav Jelesijevic[8], Rees G. Matthew[9], Jennifer A. Roth[9], Martin J. Ronis[2], Christopher L. Axelrod[3], John P. Kirwan[1]

[1]Pennington Biomedical Research Ctr., Baton Rouge, LA,[2]Department of Pharmacology and Experimental Therapeutics, School of Medicine, Louisiana State University Health Sciences Center New Orleans, New Orleans, LA,[3]Integrated Physiology and Molecular Medicine Laboratory, Pennington Biomedical Research Ctr., Baton Rouge, LA,[4]Integrated Physiology and Molecular Medicine Laboratory, Pennington Biomedical Research Center, Pennington Biomedical Research Ctr., Baton Rouge, LA,[5]OrsoBio Inc, Menlo Park, CA,[6]Department of Medicine, New York University Langone Health, New York City, NY,[7]NYU Langone Health, New York, NY,[8]School of Veterinary Medicine, Louisiana State University, Baton Rouge, LA,[9]Broad Institute of MIT and Harvard, Cambridge, MA

Metabolic dysfunction-associated steatohepatitis (MASH) is the fastest growing cause of hepatocellular carcinoma (HCC), yet the metabolic dependencies underlying MASH-HCC remain poorly defined. Here, we identify mitochondrial proton conductance as a central determinant of HCC progression and therapeutic vulnerability. Human HCC exhibited increased mitochondrial efficiency and glycolytic flux with reduced oxidative flux, consistent with large-scale HCC dependency datasets showing strong enrichment for downregulated mitochondrial pathways. To functionally interrogate this bioenergetic liability, we performed an unbiased PRISM barcoded-cell-line screen using the mitochondrial uncoupler BAM15. Lineage-level analysis revealed broad cytotoxicity with marked enrichment of sensitivity in HCC, which was validated in HepG2 cells, where BAM15 demonstrated greater potency than sorafenib, a frontline therapy for advanced HCC. We next evaluated mitochondrial uncoupling in vivo using two MASH-HCC models: (1) high-fat, fructose, and cholesterol diet with thermoneutral housing plus low-dose DEN, and (2) cocoa-butter diet plus DEN, each recapitulating metabolic injury and tumor development. In both models, BAM15 significantly reduced tumor burden and improved liver function. These effects persisted in PPARα-null mice, indicating that uncoupling exerts its efficacy through direct disruption of mitochondrial efficiency rather than secondary activation of fatty acid oxidation. To assess translational relevance, we tested the long-acting liver-targeted mitochondrial uncoupler TLC-1180, which similarly decreased tumor burden and improved hepatic function. Finally, liver-specific deletion of Ucp2 reduced hepatic proton conductance, increased tumorigenesis, and impaired liver function, establishing a mechanistic link between diminished uncoupling capacity and enhanced carcinogenic progression. Together, these data demonstrate that suppressed proton conductance is a fundamental metabolic adaptation that promotes HCC growth, and that enforced mitochondrial uncoupling directly counteracts this program. These findings position hepatic proton conductivity as a mechanistically grounded therapeutic target and support mitochondrial uncoupling, particularly liver-directed approaches, as a rational strategy for treating MASH-HCC.

#7332 Targeting a DYRK1A-regulated lipogenesis-STING axis alleviates hepatic metabolic dysfunction and lipotoxicity in metabolic steatohepatitis.

Wen Yan Huang[1], Kyunghee Noh[2]

[1]Bionanotechnology Research Center, Korea Research Institute of Bioscience and Biotechnology, Daejeon, Korea, Republic of,[2]Bionanotechnology Research Center; Department of Nanobiotechnology, Korea Research Institute of Bioscience and Biotechnology, Daejeon, Korea, Republic of

Background Metabolic dysfunction-associated steatohepatitis (MASH) is a progressive liver disease marked by lipid accumulation, inflammation, and fibrosis that can advance to hepatocellular carcinoma. While both *de novo* lipogenesis (DNL) and innate immune activation drive disease progression, their mechanistic connection remains unclear. Here, we identified DYRK1A as a novel kinase that activates STING-dependent inflammatory signaling and links metabolic and immune dysregulation in MASH.

MethodsMASH and fibrosis models were established in both cellular and animal systems. DYRK1A expression was modulated through knockdown, overexpression, and pharmacological inhibition. Lipogenesis, STING activation, lipotoxicity, and fibrosis were assessed using molecular assays, histopathology, and serum injury markers.

ResultsDYRK1A expression was elevated by approximately 40% in cellular models of MASH compared with controls. Further, we confirmed DYRK1A overexpression reduced phosphorylation of AMPK and ACC, enhancing lipogenic flux and elevating lipid accumulation, supporting its potential involvement in metabolic regulation. Conversely, DYRK1A silencing or inhibitor treatment suppressed DNL, destabilized STING, and mitigated lipotoxicity by reducing the phosphorylation of STING, TBK1 and IRF3, as confirmed by Oil Red O staining and immunoblotting. *In vivo*, DYRK1A was markedly elevated in MASH-associated fibrosis, whereas its inhibition reduced hepatic triglyceride deposition (~30%), collagen remodeling (~30%), and serum AST/ALT levels (~40%), indicating improved liver function. Consistent with *in vitro* results, inhibitor-treated livers exhibited diminished DNL- and STING-related proteins expression, underscoring DYRK1A as a newly identified key driver of metabolic inflammation and fibrosis.

ConclusionsThis study defines a novel DYRK1A-mediated lipogenic-inflammatory cascade linking metabolic stress to innate immune activation and fibrosis in MASH. Targeting DYRK1A may provide a therapeutic strategy to disrupt the lipogenesis-STING axis, alleviate chronic metabolic liver injury, and potentially prevent progression to hepatocellular carcinoma.

#7333 Disrupting tumor lipid homeostasis by MUFA depletion drives cell death in HCC.

Justyna J. Gleba, Victoria N. Rios, Brian M. Necela, Skyeler M. Klinge, Matt L. Pawlush, Mike J. Redig, Aylin Alasonyalilar-Demirer, Han W. Tun and John A. Copland III

Mayo Clinic Comprehensive Cancer Center, Jacksonville, FL

Background: The cellular balance between saturated and monounsaturated fatty acids is a defining feature of tumor lipid metabolism, with SCD1 functioning as a key modulator through the production of MUFAs. Elevated SCD1 activity and MUFA accumulation have been documented in hepatocellular carcinomas, although the consequences of restricting MUFA synthesis have not been fully clarified.
Methods: A selective SCD1 inhibitor, SSI-4, was evaluated across established human HCC cell lines and xenograft models. Measurements included cell viability, lipid compositional analyses, and characterization of stress response pathways at both molecular and biochemical levels. The effects of MUFA depletion were studied *in vitro* and *in vivo*, with attention to ER stress, apoptosis, ferroptosis markers, and autophagy induction.
Results: SSI-4 treatment led to marked reduction in cellular MUFA content and an increase in saturated fatty acid pools. The resulting metabolic stress correlated with activation of unfolded protein response components, caspase-mediated cell death, and the upregulation of ferroptosis-associated genes. Triglyceride and MUFA levels declined precipitously, as confirmed by mass spectrometry-based lipidomics. Tumor growth was suppressed in PDX models and evidence of autophagic flux was apparent in sensitive cell lines. Variability in response highlights metabolic heterogeneity in HCC.
Conclusions: Targeted disruption of MUFA biosynthesis inflicts metabolic vulnerability on HCC cells, precipitating membrane alterations and activation of multiple cell death programs. These findings recommend further investigation into metabolic interventions exploiting MUFA depletion, with consideration for stratifying patients according to lipid metabolic phenotypes.
Funding: This work is supported by Mayo Clinic Comprehensive Cancer Center and the Jay and Deanie Stein Career Development Award for Cancer Research at Mayo Clinic Jacksonville and the Mayo Clinic Translational Hepatobiliary Cancer SPORE P**50CA210964** Career Enhancement Program (CEP) and Florida Department of Health/Florida Cancer Innovation Fund C25C23.

#7334 Mitochondrial creatine kinase promotes hepatocellular carcinoma progression.

Nusrat Israr Khan, Luke Jordan, Olayinka David, Shreya Pattisapu, Kyle Schachtschneider, Kejia Cai, Ron Gaba, **Lobna Elkhadragy**

Radiology, University of Illinois at Chicago, Chicago, IL

Background: Hepatocellular carcinoma (HCC), the most common type of liver cancer, is an aggressive malignancy with limited therapeutic options and poor prognosis, underscoring the need for novel therapeutic targets. Emerging evidence implicates dysregulated creatine metabolism in HCC pathogenesis. Serum creatine levels inversely correlate with HCC progression and mitochondrial creatine kinase (MtCK), encoded by *CKMT1*, has been identified as a potential diagnostic biomarker. MtCK catalyzes the reversible transfer of a phosphate group from ATP to creatine to generate phosphocreatine, a key energy buffer that supports cellular bioenergetics. However, the functional role of *CKMT1* in HCC progression remains poorly understood.

Methods: We investigated the role of *CKMT1* in HCC progression using both human (Hep3B) and porcine (Oncopig A272) HCC cells. *CKMT1* overexpression was achieved by lentiviral transduction of human *CKMT1* followed by antibiotic selection, and *CKMT1* knockout (KO) clones were generated by CRISPR/Cas9 and single-cell clone isolation. Altered CKMT1 expression was confirmed by Western blotting. Cell proliferation and migration were assessed by MTS and wound-healing assays, respectively. Intracellular creatine levels were quantified using colorimetric method, and *in vivo* tumor growth was evaluated by subcutaneous injection into both flanks of SCID mice (n=6 mice/group).

Results: *CKMT1* overexpression significantly decreased intracellular creatine levels and increased Hep3B cell proliferation and migration. A272 cells, which exhibit higher endogenous *CKMT1* expression compared to Hep3b, did not show further increase in proliferation or migration upon overexpression. Conversely, A272 *CKMT1* KO clones exhibited significantly elevated intracellular creatine levels and reduced proliferation and migration. *In vivo,* xenografts derived from *CKMT1*-overexpressing A272 cells exhibited significantly increased tumor growth rate compared to parental controls ($p < 0.001$), whereas *CKMT1* KO tumors grew at rates comparable to the parental line.

Conclusions: These findings identify *CKMT1* as a promoter of HCC progression, linking altered creatine metabolism to HCC growth. Targeting mitochondrial creatine kinase or its metabolic network may represent a promising therapeutic strategy. Ongoing studies focus on developing porcine HCC models with modulated creatine metabolism to enable integrated metabolic and molecular imaging approaches for improved diagnosis, risk stratification, and treatment monitoring in a physiologically relevant large-animal model.

#7335 Spatio-temporal interactome of fructose-1,6-bisphosphate aldolase B in hepatocellular carcinoma.

XIANGNAN CHEN, Hongfei WANG, Shanshan Zhong, Huiyong YIN

Biomedical Engineering, City University of Hong Kong, Hong Kong, Hong Kong

Hepatocellular carcinoma (HCC) is a prevalent and aggressive form of malignancies with limited therapeutic options. Understanding the molecular mechanisms underlying HCC development and progression is crucial for the identification of novel therapeutic targets. Fructose-1,6-bisphosphate aldolase B (ALDOB) is a key enzyme in glycolysis which has been implicated in HCC pathogenesis. Metabolic reprogramming is a core hallmark of cancer, and downregulation of ALDOB in HCC leads to alterations in glucose metabolism. Our previous studies identified multiple enzymatic and non-enzymatic roles of ALDOB in HCC through protein-protein interactions in different cellular locations including cytosol and nucleus. In this study, to better understanding the precise role and the network of interacting proteins of ALDOB in HCC, we aim to reveal the potential regulatory mechanisms of ALDOB in HCC through a combination of proteomics and metabolomics. By performing subcellular proteome fractions and combine with APEX proximity labeling, we identified the ALDOB function in nuclear of different cell stage and conditions. To be more comprehensively understand the underlying pathway and mechanism, we possess RNA-seq to identify how ALDOB functional units associated pathways. We propose to perform comprehensive analyses to identify proteins that physically interact with ALDOB and their dynamic changes under various biological stimuli and across different stages of HCC, shedding light on its functional associations and molecular pathways in liver cancer in an attempt to enhance the understanding of HCC biology. This project will lay the ground for developing novel therapeutic strategies targeting ALDOB and its interactors in the fight against this deadly disease.

#7336 Harnessing lipid metabolism to treat drug-tolerant persister cells.

Mumina Sadullozoda, Patrick Jonker, Erin Szuromi, Asha Bozicevich, Alexander Muir

Ben May Department for Cancer Research, University of Chicago, Chicago, IL

Pancreatic ductal adenocarcinoma (PDAC) remains one of the most lethal cancers, with a five-year survival rate of only 13% and limited response to current therapies. A major contributor to treatment failure is the emergence of drug-tolerant persister cells (DTPs), a slow-cycling subpopulation that survives targeted and systemic therapy and drives relapse. Here, we aimed to determine whether the metabolic dependencies of DTPs could be exploited to eliminate these cells. Through analysis of publicly available transcriptomic datasets across multiple malignancies, including PDAC, colorectal, breast, and non-small cell lung cancers, we identified consistent downregulation of *SREBF1*, a master regulator of de novo lipid synthesis, in DTPs. We previously demonstrated that PDAC cells with impaired lipogenesis are selectively vulnerable to exogenous polyunsaturated fatty acids (PUFAs) due to their inability to balance saturated and monounsaturated fatty acid pools, resulting in ferroptotic death. Based on these findings, we hypothesized that DTPs can be targeted through PUFA overload. To test this, we induced DTPs in murine PDAC cell lines using the KRAS-targeted therapy RMC-7977 and treated them with PUFAs, including alpha-eleostearic acid (ESA). ESA supplementation was sufficient to eradicate PDAC DTPs at dietarily achievable concentrations. We are now evaluating whether this approach can limit relapse by targeting minimal residual disease in animal models of PDAC treated with KRAS inhibitors. These findings reveal a diet-based strategy that exploits metabolic vulnerabilities of therapy-persistent PDAC cells and may reduce the risk of disease recurrence.

#7337 Estrogen-related receptor gamma maintains oxidative metabolism via glutamine-derived anaplerosis.

Samantha A. McLaughlin[1], Zelia M. Correa[1], J. William Harbour[2], Daniel Pelaez[1]

[1]Bascom Palmer Eye Institute, University of Miami Miller School of Medicine, Miami, FL,[2]Ophthalmology, UT Southwestern Medical Center, Dallas, TX

Glutamine (Gln), traditionally considered a nonessential amino acid, becomes essential in cancer cells as the rate of Gln consumption exceeds that of endogenous biosynthesis. This metabolic dependency constitutes a unique “glutamine addiction”. Although many factors, both genetic and environmental, have been shown to contribute to the control of Gln metabolism, the precise regulation of Gln utilization in cancer still remains largely unclear. Here, we identify estrogen-related receptor gamma (ERRγ) as a critical regulator of glutaminolytic enzymes and cellular Gln utilization. RNA-sequencing of four primary retinoblastoma cells lines with or without shRNA-mediated ERRγ knockdown showed that, relative to shGFP controls, shERRγ downregulated genes were enriched for hypoxic adaptation and glycolysis pathways (*FDR < 0.05*), with no change in oxidative phosphorylation, indicating a shift toward lactate-producing glucose flux. Consistent with this, key genes in lactic acid fermentation (PDK1, LDH, MCT1) were significantly reduced ($p < 0.05$). shERRγ also decreased expression of glutaminolysis-related genes (*FDR < 0.05*), suggesting reliance on Gln-derived carbon to sustain TCA activity in a “Warburg-like” state. Functionally, RB006, a model cancer cell line with high basal ERRγ expression, requires exogenous Gln for viability, exhibiting marked cell death upon Gln withdrawal and a dose-dependent increase in proliferation, with ≥ 4mM required for maximal growth. Mesenchymal stem cells (MSCs), which express low ERRγ, were Gln-independent; however, ERRγ overexpression (MSC[ERRγ]), induced both Gln dependence and dose-responsive proliferation. To further assess Gln utilization, cells were supplemented with increasing Gln, and TCA intermediates (glutamate, α-KG, citrate, pyruvate, ATP) were quantified. All lines converted Gln to glutamate in a dose-dependent manner, but only RB006 and MSC[ERRγ] showed parallel increases in α-KG and citrate, consistent with ERRγ-mediated control of GLUD1/2 and downstream reductive carboxylation. High- ERRγ cells demonstrated strong correlations between Gln levels and all metabolites ($r > 0.9$), produced greater metabolite output per unit Gln than MSCs, and exhibited larger stepwise increases in Gln-derived flux, reflecting enhanced glutamine-handling capacity. Our results indicate ERRγ may be necessary to support oxidative phosphorylation via glutamine-derived anaplerosis. We provide evidence that ERRγ is required for glutaminolytic pathways, suggesting that ERRγ may be a key player in the metabolic adaptation of highly proliferative cell lines.

#7338 Elucidating the interplay between phospholipid biosynthesis and oxidative stress responses in the tumorigenesis of Clear Cell Renal Cell Carcinoma.

Rento Ito[1], Renpei Kato[1], Yosuke Matsushita[2], Toyomasa Katagiri[2], Wataru Obara[1]

[1]Iwate Medical Univ., Iwate, Japan,[2]Laboratory of Biofunctional Molecular Medicine, National Institute of Biomedical Innovation, National Institutes of Biomedical Innovation, Health and Nutrition, Osaka, Japan

Background: Phospholipids are essential components of biological membranes that regulate diverse cellular processes. Cardiolipin (CL) is a mitochondria-specific phospholipid crucial for maintaining mitochondrial structure and function. However, its role in clear cell renal cell carcinoma (ccRCC) remains unclear. **Methods:** Comprehensive phospholipidomic profiling of paired tumor and normal kidney tissues from ccRCC patients was performed using LC-TQMS. Quantitative data were integrated with immunoblotting, immunohistochemistry, and transcriptomic analyses from both TCGA and an institutional RNA-seq cohort. **Results:** CL levels were significantly reduced in tumor tissues compared with normal renal cortex, whereas other phospholipids (PA, PI, PS and PG) showed no significant differences. Reduced CL content paralleled decreased VDAC1 expression, indicating lower mitochondrial abundance. Lipidomic analysis revealed selective suppression of unsaturated CL species in tumors, suggesting mitochondrial membrane remodeling induced by oxidative stress. Analyses of gene expression showed a consistent increase in the expersiion of enzymes involved in CL synthesis and remodeling, namely TAMM41 and TAZ, in both TCGA and in-house datasets, with ACSL5 being the only gene that was significantly increased in fatty acid activation. **Conclusions:** ccRCC is characterized by quantitative and qualitative cardiolipin remodeling, reflecting mitochondrial reduction and adaptation to oxidative stress. Altered CL metabolism may represent a key mechanism of mitochondrial reprogramming in tumor cells and a potential therapeutic target in renal cancer.**Statement of significance:** This study identifies cardiolipin remodeling as a hallmark of mitochondrial reprogramming in clear cell renal cell carcinoma, revealing a potential therapeutic vulnerability in mitochondrial lipid metabolism.

#7339 Transcriptomic features associated with tumoral metabolites characterizing the immune microenvironment in clear cell renal cell carcinoma.

Sei Naito, Takafumi Narisawa, Hiromi Ito, Norihiko Tschiya

Urology, Yamagata University Faculty of Medicine, Yamagata, Japan

Abstract: Objectives: Previous studies have demonstrated that the metabolic milieu plays a pivotal role in shaping the immunological landscape of cancer tissues. This study aimed to characterize the immune microenvironment of clear cell renal cell carcinoma (ccRCC) in relation to intratumoral metabolite levels.

Methods: Metabolomic and transcriptomic analyses were performed on frozen tumor samples and their paired formalin-fixed paraffin-embedded (FFPE) specimens from 31 ccRCC surgical cases. Five metabolites previously implicated in immune modulation—lactate, glutamine, adenosine, arginine, and tryptophan—were quantified and compared against transcriptomic profiles using pre-ranked gene set enrichment analysis (GSEA). The analysis incorporated hallmark gene sets (h.all.v2025.1.Hs.symbols) and immune-related gene sets (c7.immunesigdb.v2025.1.Hs.symbols).

Results: Lactate levels positively correlated with gene sets related to *glycolysis*, *hypoxia*, *interferon gamma response*, and *unfolded protein response*, as well as immune signatures derived from monocytes and dendritic cells stimulated by influenza A virus and HPV antigens. Negative correlations were observed with *mitotic spindle* and *oxidative phosphorylation* pathways. Glutamine showed positive associations with *glycolysis*, *RORgammat-deficient CD4+ T cells under Th17-polarizing conditions*, *SPHK1 knockout inflammatory responses*, and *type I interferon-treated endothelial cells*, while negatively correlating with *coagulation*. Adenosine was positively linked to *glycolysis*, *hypoxia*, *xenobiotic metabolism*, *mTORC1 signaling*, and *reactive oxygen species pathways*, as well as immune signatures involving memory CD4+ T cells, IL-4 stimulation, and monocyte activation. Negative correlations included *mitotic spindle*, *FOXP3-mutant Tconv cells*, and *plasmacytoid dendritic cell responses*. Arginine was positively associated with gene sets reflecting monocyte culture dynamics, memory CD8+ T cell differentiation, and thymocyte maturation.

Conclusions: These findings highlight distinct transcriptomic programs associated with specific metabolites in ccRCC, suggesting that intratumoral metabolic states—particularly elevated lactate and adenosine—are linked to immunosuppressive and inflammatory transcriptional profiles. The enrichment of immune gene sets derived from viral stimulation contexts implies that tumor metabolism may mimic or modulate immune activation pathways typically seen in infection. Overall, this integrative metabolomic-transcriptomic approach provides insight into how metabolic reprogramming in ccRCC contributes to shaping the immune microenvironment, with potential implications for immunotherapeutic strategies and metabolic targeting.

#7340 Exploring the role of PNPLA3 I148M in cancer using the selective small molecule degrader NUV-244.

Katrin Juenemann, Patrick Steigemann, Ralf Lesche, Tamara Kanashova, Hanna Meyer, Claudia Noack, Barbara Nicke, Peter Staller, Charlotte Kopitz, **Martin Lange**

Nuvisan ICB GmbH, Berlin, Germany

The patatin-like phospholipase domain-containing protein 3 (PNPLA3) I148M variant is a well-established genetic determinant of fatty liver disease, yet emerging evidence suggests broader implications in cancer biology, particularly in hepatocellular carcinoma and metabolic reprogramming of tumor cells (Tavaglione et al., 2024). We recently identified NUV-244 as a potent and selective small-molecule degrader of PNPLA3 I148M (Steigemann et al., 2025). These findings provided the first pharmacological and molecular framework to directly interrogate PNPLA3 I148M´s function in liver cells. Building upon these insights, we sought to investigate the potential oncogenic or tumor-modulatory role of PNPLA3 I148M in cancer, and to evaluate how pharmacologic inhibition by NUV-244 influences cancer cell metabolism, proliferation, and survival. We performed a comparative analysis of cancer cell lines harboring endogenous PNPLA3 I148M mutations versus wild-type counterparts and generated isogenic cell line models using a PNPLA3 I148M overexpression approach. These models were used to assess transcriptomic and proteomic modulation, mitochondrial function and cell viability with and without NUV-244 treatment. Using these experimental systems, we aim to define how PNPLA3 I148M contributes to cancer cell metabolic plasticity and whether its pharmacologic inhibition creates selective vulnerabilities. In summary, these studies establish a mechanistic basis for PNPLA3 I148M´s potential role in tumor biology and highlight NUV-244 as a chemical tool to probe its function in cancer.

#7344 NRG1 knock out in cancer cell lines decreases their aggressiveness.

Marie Issenmann[1], Clarisse Thiollier-Schmitt[1], **Manon Barre**[1], Emeline Cros-Perrial[1], Michael Duruisseaux[2], Lars Petter Jordheim[1]

[1]Cancer Research Center of Lyon (CRCL), Lyon, France,[2]Hospices Civils de Lyon, Bron, France

Introduction Neuregulin-1 (NRG1) is a growth factor which can bind to the ErbB/human epidermal growth factor receptors (HERs), especially to HER3, and activate the downstream signalling pathways. The *NRG1* gene has the potential to form oncogenic gene fusions with diverse gene partners leading to the emergence of cancer. Several therapeutic approaches targeting more or less directly *NRG1*'s signalling pathway exist, but patients tend to respond poorly to treatments or rapidly develop resistances. A better understanding of the NRG1- and *NRG1*-fusion-dependent cell biology could allow us to propose new treatment options to these patients. Here our objective is to study NRG1-dependent cell biology parameters in various cancer cell lines, with or without genetic alterations of NRG1.

Methods A CRISPR-Cas9-based deletion of *NRG1* was obtained in the A549 and SW1573 Non-Small Cell Lung Cancer (NSCLC) cell lines which highly express wild type NRG1, in the HCC95 NSCLC cell line which has an amplification of *NRG1*, and in the MDA-MB-175 breast cancer cell line which bears a complex *PPP6R3-TENM4-NRG1* fusion. The modified cell lines were grown as either or both polyclonal and monoclonal populations and were characterized using classic cell biology techniques such as western blot and flow cytometry to monitor protein expression, confluence assay and Cell-Trace CFSE to study proliferative capacities, scratch wound assay and Boyden chamber to monitor migratory capacities, and soft agar and clonogenic assay to study stemness characteristics.

Results The NRG1-deficient A549 clones (n=5) clustered into two distinct behavioural groups. One of them showed a loss of HER3 expression, a 3-fold increased sensitivity to afatinib, and up to 2-fold decreased migratory capacities. As for the other group, there was an induced expression of mesenchymal markers and a loss of FGFR1 expression. For other parameters, all A549 clones behaved in a similar manner as control clones. Preliminary results in NRG1-deficient HCC95 (n=2) suggest they have slightly reduced proliferative capacities and NRG1-deficient MDA-MB-175 (n=2) have a 2-fold higher sensitivity to several treatments including afatinib. All clones for the SW1573 cell line (n=4) exhibited no difference within all performed experiments.

Conclusion Overall, NRG1-deficiency decreases cancer cells' aggressiveness, although in a cell-specific manner. Upcoming transcriptomic assay of our different models will give us a better insight in NRG1-related molecular modifications. Further analyses of all models are ongoing (clones of MDA-MB-175 and HCC95, 3D bioprinting experiments, *in vivo* tumour growth⋯) and results will be included in the poster.

#7345 Synergistic targeting of mSWI/SNF and UTX reveals a novel combination therapy in T-cell acute lymphoblastic leukemia.

Shi Hao Tan[1], Hyoju Kim[1], Ziyang Lee[1], Lee Hui Chua[1], Sanda Takaomi[2], Allen Eng Juh Yeoh[1]

[1]Cancer Science Institute of Singapore, Singapore, Singapore,[2]Nagoya City Univ. Medical School, Nagoya, Japan

Dysregulated expression of oncogenic transcription factors (TFs) is a critical hallmark of T-cell acute lymphoblastic leukemia (T-ALL). These aberrations disrupt the tightly regulated spatial-temporal expression of downstream target genes and rewire transcriptional programs, culminating in a state of “transcription addiction”. We show that oncogenic factors such as RUNX1 and NOTCH1 in T-ALL recruit the mSWI/SNF chromatin-remodeling complex to modulate chromatin accessibility at target gene loci to initiate and maintain oncogenic transcriptional networks. Inhibiting mSWI/SNF function with SMARCA2/4 ATPase inhibitors (FHD-286) or PROTAC degraders (ACBI-1) targeting the SMARCA protein induces apoptosis and impairs T-ALL cell growth. To further dissect the functional dependencies of T-ALL cells on the mSWI/SNF complex, we performed genome-wide CRISPR knockout (KO) screens in T-ALL cells treated with FHD-286 or ACBI-1. These screens revealed that multiple members of the Mediator complex were high-confidence targets whose individual knockout was sufficient to rescue T-ALL cells from inhibitor-induced cell death. In contrast, knockout of the histone demethylase UTX sensitized T-ALL cells to mSWI/SNF inhibition. Notably, the IC50 of FHD-286 treatment decreased significantly in UTX KO cells compared to wild-type (WT) controls. Furthermore, UTX KO T-ALL xenograft mice showed improved survival when treated with FHD-286 compared to FHD-286-treated WT xenografts. A synergistic effect emerged when T-ALL cells or patient-derived xenografts (PDXs) were co-treated with GSK-J4, a histone demethylase inhibitor, and FHD-286. Transcriptomic analyses indicated that genes promoting ribosomal and mitochondrial function were substantially downregulated in UTX KO T-ALL cells treated with FHD-286 but not in similarly treated WT cells, suggesting a previously unrecognized role of UTX in gene regulation. Overall, these findings demonstrate that simultaneously targeting the mSWI/SNF complex and UTX may represent an innovative combinatorial strategy for T-ALL treatment.

#7346 RNA-seq analysis confirms post-thaw transcriptomic stability in ThawReady (TM) THP-1 assay-ready cells.

Ajeet P. Singh, Utsav Sharma, Lucas Underwood, Noah Wax, Steve King, Nilay Chakraborty, Jonathan Jacobs

ATCC, Manassas, VA

Cryopreserved cell lines have become essential for high-throughput screening and assay development, offering convenience and consistency across experiments. However, the freeze-thaw process can induce cellular stress, potentially affecting gene expression and compromising functional reliability. To ensure consistent assay performance, it is crucial to verify that cryopreserved cells retain their transcriptomic and functional integrity after thawing. In this study, we evaluated the transcriptomic stability of ThawReady™ THP-1 (TIB-202-AR™) cells using RNA sequencing (RNA-seq). Cells were analyzed immediately after thawing (0-hour) and following 2-hour and 8-hour recovery intervals and were compared to freshly cultured THP-1 cells. Principal component and hierarchical clustering analyses revealed that post-thaw samples closely grouped with fresh controls, demonstrating preservation of cellular identity and global gene expression patterns. Gene expression profiles showed strong concordance across key immune and inflammatory pathways characteristic of THP-1 cells. Differential expression analysis identified 178 genes altered at 0 hours, 951 at 2 hours, and 713 at 8 hours post-thaw relative to fresh culture, using a threshold of absolute fold change >5 and FDR-adjusted p-value <0.05. Despite these transient changes, pathways related to cell survival and proliferation remained stable. Notably, phagosome formation was the top-enriched pathway, suggesting adaptive recovery responses that support cell viability. Overall, these results confirm that ThawReady™ THP-1 cells maintain robust transcriptomic integrity post-thaw, supporting their reliability and reproducibility for downstream immune and inflammation-related functional assays.

#7347 Leptin-driven transcriptional reprogramming in triple-negative breast cancer: Exploring biological drivers of racial disparities.

Sarabjeet Kour Sudan[1], Amod Sharma[1], Shashi Anand[1], Jasleen Kaur[2], Lavanya Challagundla[2], Ajay P Singh[1], Seema Singh[1]

[1]Cell and Molecular Biology, Cancer Center and Research Institute, University of Mississippi Medical Center, Jackson, MS,[2]Cell and Molecular Biology, University of Mississippi Medical Center, Jackson, MS

We recently demonstrated that obesity is a significant risk factor for breast cancer (BC) diagnosis with triple-negative and Luminal A subtypes, especially in Black women. Furthermore, obesity was linked to earlier disease onset in Black women, who also demonstrated elevated serum leptin levels, an obesity-associated hormone, that showed a similar epidemiologic association. In this study, we investigated leptin-induced transcriptomic alterations in two triple-negative breast cancer (TNBC) cell lines derived from White (MDA-MB-231) and Black (MDA-MB-468) patients by performing mRNA sequencing, followed by bioinformatic and pathway analyses to identify differentially-expressed genes (DEGs) and their impact on biological pathways. Leptin treatment resulted in widespread gene expression alterations, with 1,857 DEGs identified in MDA-MB-231 and 1,242 DEGs in MDA-MB-468 cells ($P < 0.05$). Of these DEGs, 1030 and 827 were upregulated, and 617 and 625 were downregulated in MDA-MB-231 and MDA-MB-468, respectively. A comparison of DEGs between MDA-MB-231 and MDA-MB-468 showed only 177 DEGs to be commonly altered, suggesting a diverse and cell line-specific transcriptional impact of leptin signaling. Interestingly, the comparison of sequencing reads from vehicle-treated MDA-MB-231 and MDA-MB-468 cells identified significant transcript-level differences between the two lines. In leptin-treated MDA-MB-231 cells, KEGG pathway analysis revealed enrichment of the spliceosome, steroid biosynthesis, protein export, and basal transcription factor pathways, accompanied by suppression of AMPK signaling, focal adhesion, longevity regulation, and insulin signaling. Conversely, in MDA-MB-468 cells, leptin induced the activation of the ECM-receptor interaction, Notch, PI3K-AKT, and transcriptional misregulation in cancer pathways, while downregulating oxidative phosphorylation, mRNA surveillance, the TCA cycle, and AMPK signaling. Together, these findings suggest that leptin induces distinct, cell line-specific transcriptional reprogramming in TNBC, engaging proliferative signaling pathways, while suppressing energy-sensing and metabolic regulatory networks. Overall, our study highlights that targeting leptin-driven pathways may offer novel therapeutic and preventive opportunities to mitigate the obesity-associated risk of early-onset aggressive breast cancer.

#7348 Chronic e-cigarette aerosol exposure dysregulates NF-kB signaling and alters IRF-dependent innate immune signaling in human lung epithelial cells.

Vengatesh Ganapathy[1], Sulfath Thottungal Parambil[1], Jimmy Manyanga[1], Gautham Chengizkhan[1], Mayilvanan Chinnaiyan[1], Adele Hammoudi[1], Balaji Sadhasivam[2], Ilangovan Ramachandran[3], David Rubenstein[4], Lurdes Queimado[1]

[1]Departments of Otolaryngology Head and Neck Surgery, The University of Oklahoma Health Sciences Center, Oklahoma City, OK,[2]Occupational and Environmental Health, The University of Oklahoma Health Sciences Center, Oklahoma City, OK,[3]University of Madras, Chennai, India,[4]Biomedical Engineering, Stony Brook University, Stony Brook, NY

Background: Although electronic cigarettes (e-cigarettes) are marketed as safer alternatives to combustible tobacco, accumulating evidence indicates that chronic use may impair respiratory health. E-cigarette aerosols contain harmful constituents, including nicotine, carbonyl compounds, metals, carcinogens, and reactive oxygen species (ROS). Excess ROS can overwhelm antioxidant defenses, driving oxidative stress and chronic inflammation. NF-κB is a central regulator of inflammation and antiviral immunity, yet its modulation by chronic exposure to e-cigarette aerosol remains poorly defined. **Objective:** To determine how chronic exposure to e-cigarette aerosols alters NF-κB signaling and downstream inflammatory and antiviral pathways in lung epithelial cells.
Methods: Normal human bronchial epithelial cells (NuLi-1) were exposed to aerosol extracts generated from two commercial tobacco-flavored e-cigarette products every other day for 2 weeks. Exposure delivered approximately 30 ng/ml of nicotine to mimic the median levels observed in the plasma of e-cigarette users. NF-κB mRNA levels were measured by real-time RT-qPCR. Protein expressions of NF-κB, TLR3, TLR4, IRF1, IRF3 and IRF7 were quantified by Western blotting. Statistical significance was evaluated by Student's *t*-test.
Results: Chronic e-cigarette aerosol exposure significantly upregulated NF-κB mRNA and protein levels. TLR3, TLR4, and IRF7 proteins were also elevated after chronic exposure to e-cigarette aerosols, indicating activation of stress- and pathogen-sensing pathways. In contrast, IRF1, and IRF3 protein expression were significantly decreased, consistent with suppression of key antiviral transcription factors. This pattern reflects an inflammatory shift characterized by NF-κB activation with concurrent impairment of IRF-dependent innate immune signaling.
Conclusion: Chronic e-cigarette aerosol exposure induces a dysregulated inflammatory phenotype in human lung epithelial cells, marked by NF-κB activation and suppression of IRF-mediated antiviral pathways. These findings suggest that chronic e-cigarette use may compromise epithelial innate immunity and increase susceptibility to respiratory infections and inflammatory disease.
Grant support: NIH/NCI (R01CA242168, Queimado); TSET HPRC (Ganapathy); NHI/NIGMS (U54GM104938-140).

#7350 DPF3a-YY1 cooperation drivesimmunosuppression in renal cell carcinoma by activating CSF2 transcription.

Xin-Ru Yu, Haodong Liu, Zeyun Mi, **Kexin Chen**

Tianjin Medical Univ. Cancer Inst. & Hospital, Tianjin, China, Tianjin, China

Background: Renal cell carcinoma (RCC) is among the most aggressive and therapy-resistant malignancies, characterized by extensive vascularization and profound immune evasion. Genome-wide association studies have identified the SNP rs4903064 as a key variant regulating the expression of DPF3a, a chromatin remodeling factor that interacts with HIF signaling in RCC. Although the DPF3 gene encodes two isoforms (DPF3a and DPF3b), the biological significance of DPF3a in RCC initiation and progression remains largely unexplored.
Methods: The expression of DPF3 isoforms in RCC cell lines and clinical tumor specimens was examined by Western blotting (WB), quantitative PCR (qPCR), and immunohistochemistry (IHC). Multi-omics approach integrating RNA-seq, CUT&Tag, and ATAC-seq were applied to define DPF3a-dependent transcriptional and chromatin accessibility landscapes. TurboID-based proximity labeling assays were used to identify interactors of DPF3a,and co-immunoprecipitation (Co-IP) were performed to validate these interactions. Single-cell RNA sequencing (scRNA-seq) and flow cytometry were used to evaluate the impact of DPF3a on the tumor immune microenvironment.
Results: In this study, we found DPF3a, but not DPF3b, was markedly overexpressed in RCC tissues and cell lines. Integrated multi-omics analysis revealed that DPF3a binds to the promoter of the CSF2 gene and promotes its transcriptional activation, consequently leading to increased CSF2 secretion. Mechanistically, the PHD1/2 domains of DPF3a mediate its interaction with the transcription factor YY1, which collaboratively facilitates CSF2 transcription. Furthermore, single-cell RNA sequencing analysis indicated that DPF3a-driven CSF2 upregulation promotes neutrophil infiltration and $CD8^+$ T-cell exhaustion, thereby contributing to the suppression of anti-tumor immunity.
Conclusions: Our findings identify DPF3a as a previously unrecognized oncogenic isoform in RCC. By forming a complex with YY1 and activating CSF2 transcription, DPF3a drives neutrophil recruitment and $CD8^+$ T-cell exhaustion, thereby fostering an immunosuppressive microenvironment and promoting RCC progression.
Keywords: DPF3a; YY1; CSF2; Renal Cell Carcinoma; Tumor Immune Microenvironment

#7352 CYLD mediated non-canonical RelB NF-κB transcription axis in multiple myeloma.

Uday Aditya Sarkar[1], Lalit Kumar[2]

[1]National Institute of Immunology, New Delhi, India,[2]Department of Medical Oncology, All India Institute of Medical Sciences, New Delhi, India

Introduction: Multiple myeloma (MM), a plasma B cell neoplastic disease, has been studied widely for its dependency on NF-κB signaling, yet the crosstalk between canonical (RelA/p50) and non-canonical (RelB/p52) arms remains incompletely defined. Tumor suppressor protein CYLD, an established negative regulator of canonical NF-κB, emerged in our studies as an enforcer of RelB-driven transcription. We define a CYLD-mediated RelB enforced signaling that promotes the disease pathogenesis by supporting survival and migration in tumor cells.

Methods: Primary CD138+ plasma cells were isolated from bone marrow aspirates of 74 patients with MM using MACS based separation. Cells were used for NF-κB DNA binding assay (n=15) and quantitative RT-PCR based gene expression studies (n=42). For *in vitro* studies, patient derived MM cell lines (MMCLs) JIM3 and KP-6 were used for biochemical studies. CYLD deficient isogenic MMCLs were generated using CRISPR-Cas9 gene editing. The RNA-seq metadata available with the Multiple Myeloma Research Foundation (MMRF) database IA13a were used for *in silico* transcriptomic analyses.

Results: In our study, using primary myeloma cells, we established the presence of increased nuclear RelB (nRelB) activity in newly diagnosed patients with MM. This increased nRelB activity was shown to be positively correlated with high RelB expression. MMRF transcriptomic data allowed us to show association of high RelB expression with poor prognosis. With NEMO kinase activity assay and NF-κB DNA binding assay on MMCLs, we showed that CYLD deficient KP-6 has higher canonical NF-κB activity as compared to CYLD sufficient JIM3 cells. This absence of deubiquitinase CYLD was associated with high RelB mRNA and protein levels at basal state that were further augmented by stimulation with BAFF, a non-canonical NF-κB activating cytokine. The re-enforced RelB activity in the absence of CYLD also provided advantage to CYLD deficient cells in survival and migration activities. This phenotypic advantage was mapped onto RelB mediated transcription of pro-survival factors such as BCL2, BIRC2, BIRC3, TRAF1 & c-FLIP and pro-migratory chemokine receptors such as CXCR4 & CXCR7. Deletion of CYLD using CRISPR-Cas9 editing to generate JIM3^{sgCYLD} cells, provided the causal role of CYLD mediated RelB enforced transcriptional axis that supports survival and migration in these malignant plasma cells.

Conclusions: The tumor microenvironment and cancer-associated mutations activate both canonical and non-canonical NF-κB pathways in MM. More so, these NF-κB pathways are intimately interlinked via a number of biochemical mechanisms. Our data signifies that RelB plays a role in the survival and migration of myeloma cells and mutational inactivation of CYLD exacerbates this disease-associated RelB phenotype, thus suggesting that NF-κB crosstalk mechanisms may provide prognostic evidence and therapeutic opportunities in the future.

#7354 ETS1 orchestrates a hybrid EMT program to drive metastasis and immune evasion in UASCC.

Chehyun Nam[1], Talia Wenger[1], Benjamin Ziman[2], Daniel Arnaudov[1], Thomas Tilton[1], Ethan Pan[1], Young Min Park[3], Uttam K. Sinha[4], De-Chen Lin[1]

[1]University of Southern California, Los Angeles, CA,[2]Biocare Medical, LLC, Walnut Creek, CA,[3]Yonsei University of College of Medicine, Seoul, Korea, Republic of,[4]Keck School of Medicine at USC, Los Angeles, CA

Intratumoral transcriptional heterogeneity (ITH) is a defining feature of aggressive cancers, yet the mechanisms by which distinct ITH programs drive metastasis and immune escape in upper aerodigestive squamous cell carcinoma (UASCC) remain poorly understood. Using single-cell RNA sequencing of cancer cell lines and patient tumors, we identified a hybrid epithelial-mesenchymal transition (hEMT) program strongly associated with metastatic potential. We determined that the transcription factor ETS1 functions as a master regulator of this hEMT state, directly activating pro-invasive and pro-metastatic gene networks and promoting distant dissemination in vivo. Beyond its role in metastasis, ETS1 unexpectedly established an immune-cold microenvironment by transcriptionally inducing STAT1 and PD-L1 (CD274), leading to reduced T-cell infiltration and elevated immune checkpoint expression. Clinically, ETS1-high tumors were consistently linked to poor survival and diminished responses to immune checkpoint blockade across multiple independent cohorts. Through a focused drug screen, we found that ETS1-high cancers exhibit selective vulnerability to HSP90 inhibition (e.g., Alvespimycin), which reduces ETS1 expression via disruption of HIF1A-driven transcription. Together, these findings define ETS1 as a central driver of both metastatic progression and immune evasion in UASCC and nominate HSP90 inhibitors as a promising therapeutic strategy for ETS1-driven disease states.

#7355 Investigating the interplay of transcription factor, ERG, and TGF-beta signaling in cervical cancer cells.

Kaitlyn Marie Eidson, Hannah Mckinsey Fitzgibbons, Logan J. Baker, Benjamin M. Greulich

Biology, Mercer University, Macon, GA

In healthy cells, TGF-β signaling is crucial to the cell cycle. The pathway promotes apoptosis, suppresses cellular proliferation, and stimulates immune cell activation. In malignant cells, however, TGF-β signaling has been shown to drive the proliferation of cancer through migration and metastasis, immune evasion, and angiogenesis. The effects of TGF-β signaling shift from tumor-suppressing to tumor-promoting as cancer progresses. Using TCGA data, we identified genes coexpressed with TβRIII. After determining which genes had the highest correlation, we used Enrichr to conduct pathway analysis. Pathway analysis indicated a relationship with ERG, leading us to hypothesize that ERG regulates TβRIII and other related genes. ERG seems to share many cancer behaviors with TGF-β, such as proliferation, invasion, and overall cell survival in cervical cancer. Kaplan-Meier Survival plots of TCGA data support decreased survival rates with high ERG expression in several other cancers as well, for the scope of this study, cervical cancer specifically. However, ERG has not been extensively investigated in this context. Western Blot analysis confirmed the presence of ERG expression in HeLa cells. Functional assays demonstrated that manipulating HeLa cells to express a knockdown of ERG led to a significant decrease in cell migration. The addition of TGF-β to HeLa cells with ERG knockdown (shERG) partially restores migration, suggesting that TGF-β could potentially compensate for the loss of ERG expression. To further investigate the effects of ERG on TGF-β, galunisertib, a known inhibitor of TGF-β signaling, was used. Analysis of scratch assays showed that in control HeLa cells, migration rates significantly reduced when exposed to galunisertib. In HeLa-shERG cells, migration was reduced as well; however, galunisertib failed to have the same decreased migration pattern in HeLa-shERG cells, suggesting that ERG and TGF-β pathways may converge in some way. HeLa-shERG significantly reduced the expression of TGFβ-I as well as decreasing the activation of SMAD2, a transcription factor that plays a significant role in TGF-β signaling. Invasion assays exposed HeLa cells' ability to travel throughout the extracellular matrix when manipulating TGF-β and ERG to measure metastasis. ChIP-seq is being done to investigate the possible interactions between TGFB signaling and ERG occupancy on the genome in cervical cancer, which will be compared to ERG sites in extensively studied cancers. Together, these findings suggest that ERG promotes cervical cancer cell migration and invasion, at least in part by regulating TGF-β signaling.

#7358 MYB expression increases progressively in pancreatic cancer, correlating with advancing tumor grade, metastasis, and poor patient survival.

Shashi Anand[1], Kunwar Somesh Vikramdeo[1], Mohammad Aslam Khan[2], Lingling Xian[3], Paul M. Grandgenett[4], James Elliot Carter[5], Moh'd Khushman[6], Seema Singh[1], Ajay Pratap Singh[1]

[1]Department of Cell and Molecular Biology, Cancer Center and Research Institute, University of Mississippi Medical Center, Jackson, MS,[2]Department of Pharmacy and Pharmaceutical Sciences, St. Jude Children's Research Hospital, Memphis, TN,[3]Department of Pathology, Yale School of Medicine, New Haven, CT,[4]Eppley Institute for Research in Cancer and Allied Diseases, University of Nebraska Medical Center, Omaha, NE,[5]Department of Pathology, Frederick P. Whiddon College of Medicine, University of South Alabama, Mobile, AL,[6]Division of Hematology and Oncology, Washington University in St. Louis and Siteman Cancer Center, St. Louis, MO

The transcription factor MYB plays a pivotal role in regulating cell proliferation, differentiation, and survival. Although it is amplified in a subset of pancreatic cancers, emerging evidence indicates that MYB overexpression may also arise through diverse regulatory mechanisms. We have previously demonstrated multiple oncogenic roles of MYB in pancreatic cancer pathogenesis; however, the temporal dynamics of its dysregulation during tumor progression remain poorly understood. Here, we investigated MYB expression across a spectrum of tissue samples representing normal, precancerous, and malignant stages of the pancreas, as well as matched liver metastases, by performing immunohistochemical analysis. The differential expression of MYB and its correlation with advancing tumor grade and patient survival were assessed using appropriate statistical analyses. We observed negligible expression of MYB in the normal pancreas, and its aberrant expression became noticeable in precancerous lesions, increasing progressively as the disease advanced. A high expression of MYB was also reported in metastatic lesions. Elevated MYB levels were positively correlated with higher tumor grade and significantly associated with reduced survival of pancreatic cancer patients. Interestingly, functional enrichment analyses of genes regulated by MYB overexpression suggested its involvement in key oncogenic programs, including proliferation, survival, epithelial-mesenchymal transition, and metastatic signaling pathways. These findings demonstrate that MYB dysregulation occurs early in pancreatic tumorigenesis and intensifies with disease progression, underscoring its potential as a biomarker for tumor aggressiveness and a potential target for therapeutic intervention.

#7359 The role of USP21 in prostate cancer.

Cheng Zhang

University of Kentucky, Lexington, KY

The Ubiquitin-specific protease 21 (USP21) is a deubiquitinase with pro-carcinogenic effects in various cancers. While its role and molecular mechanism in prostate cancer remain elusive. To investigate the role of USP21 in promoting prostate cancer, we evaluated that USP21 shows the highest mRNA expression in prostate cancer patients, and high USP21 levels predicted a poor prognosis in patients with prostate cancer. Additionally, suppression of USP21 significantly inhibited prostate cancer cell proliferation. *In vivo*, USP21 depletion significantly suppressed tumor growth in xenograft models. Moreover, we identified the androgen receptor (AR) as a potential substrate of USP21 by tandem affinity purification. Mechanistically, i) USP21 directly interacted and stabilized AR by deubiquitinating its K48-linked polyubiquitination, which is a main driver for prostate cancer. Silencing of USP21 enhances polyubiquitination of AR, promotes its proteasomal degradation, and ultimately attenuates PSA, while these effects could be largely restored by reintroduction of AR. ii) USP21 regulates transcriptional activity of AR according to our RNA-seq studies, we revealed that siUSP21 decreases both androgen response and AR-induced pathways, and knockdown USP21 decreases mRNA level of AR target genes. In conclusion, our project gives insight into the mechanism underlying how USP21 regulates AR to promote the progression of prostate cancer , therefore providing a novel approach for prostate cancer treatment.

#7360 Side-by-side evaluation of STAT3 targeted agents in oncology.

Xiaolan Su, Yue Zhai, Zhu Meng, Mingying Li, Tanfeng Zhao, Zhaoxia Yin, Qian Wang, Yanan Zhao, Lili Chai, Qiang Xia, **Tj (Tiejun) Bing**

ICE Bioscience, Beijing, China

Signal transducer and activator of transcription 3 (STAT3) is a critical transcription factor, which is aberrant activated in hematological malignancies, including acute myeloid leukemia (AML) and chronic lymphocytic leukemia (CLL), as well as solid tumors of the lung, breast, and others. Yet no selective STAT3 inhibitor has reached the clinic owing to disparate chemical matter, binding sites (SH2, DBD, CCD), and mechanisms (pY705 blockade, dimer disruption, DNA binding inhibition, degradation). We established a standardized integrated analytics platform that directly compares 5-10 chemically diverse STAT3 agents—including covalent SH2 ligands, allosteric DBD antagonists and PROTAC degraders—using harmonized biochemical (FP, TR-FRET etc), biophysical (SPR, SPS etc), and cellular (pSTAT3, reporter gene, HiBiT, proliferation) assays. Family and species selectivity, together with resistance panels, reveal distinct vulnerability windows and mechanism-based liabilities for each modality. The same matrix is screened in combination with JAK, SRC, EGFR, and chemotherapy partners to quantify synergy landscapes; By providing a comprehensive molecular-evaluation platform, the program streamlines hit-to-lead decisions, propels STAT3-directed drug discovery and accelerates the path to the clinic.

#7364 Candidate identification for SBRT versus surgery in early-stage NSCLC with interlobar pleural involvement: A multicenter retrospective study.

Zhengkun Cai, Zhiyong Yuan, Yue Wang

Tianjin Medical Univ. Cancer Inst. & Hospital, Tianjin, China

Purpose: This study aimed to compare survival outcomes between surgery and stereotactic body radiation therapy (SBRT) for early-stage non-small cell lung cancer (ES-NSCLC) with interlobar pleural involvement (ILPI), and to further identify patients who benefit more from SBRT.

Methods: This retrospective study analyzed 573 ES-NSCLC patients with ILPI, treated with surgery (n=379) or SBRT (n=194) across four centers. Propensity score matching (PSM) was employed to minimize confounding factors between treatment groups. Survival outcomes, including cancer-specific survival (CSS), disease-free survival (DFS) were estimated using the Kaplan-Meier method and compared with the log-rank test. Subgroup analyses utilized Cox proportional hazards models. We also conducted a comparative analysis of treatment-related adverse events (TRAEs) and assessed health-related quality of life (HRQoL) using the EORTC QLQ-C30.

Results: In the entire cohort, 3-year CSS was comparable between surgery and SBRT (HR, 1.48, 95% CI, 1.0-2.3; $P = 0.075$). In the PSM-matched cohort, CSS and DFS showed no significant differences (CSS: HR, 1.02, 95% CI, 0.6-1.5; $P = 0.822$; DFS: HR, 1.38; 95% CI, 0.8-2.5; $P = 0.374$). Multivariate Cox analysis identified several independent prognostic factors for CSS, including IPI features (site: HR, 0.48, 95% CI, 0.3-0.8; $P = 0.009$; location: HR, 2.05, 95% CI, 1.2–3.6; $P = 0.014$; type: HR, 8.00, 95% CI, 1.8–35.1; $P = 0.006$) and patient characteristics (age: HR, 1.88, 95% CI, 1.1–3.3; $P = 0.027$; smoking history: HR, 2.28 95% CI, 1.4–3.7; $P = 0.001$). Crucially, in the subgroup of patients over 70 years of age, SBRT was associated with significantly superior CSS compared to surgery (HR, 0.37, 95% CI, 0.2-0.8; $P = 0.007$). Specifically, CSS was improved in SBRT patients over 70 years with ILPI characterized by: Abutment-type ILPI (HR, 0.36, 95% CI, 0.1-1.0; $P = 0.045$), left lung oblique fissure (OF) involvement (HR, 0.21, 95% CI, 0.1-0.7; $P = 0.011$), or central ILPI location (HR, 0.10, 95% CI, 0.0-0.6; $P = 0.012$). Conversely, surgery showed better DFS in patients < 70 years and those with peripheral ILPI or right OF involvement. Regarding TRAEs, surgery was predominantly associated with pain (28.5%), while the SBRT cohort experienced fatigue (22.7%). The HRQoL showed SBRT was associated with significantly better preservation of emotional function and avoided the worsening of pain observed after surgery, which showed greater improvements in role and social function.

Conclusions: SBRT offers survival outcomes comparable to surgery for ES-NSCLC with ILPI without increasing the burden of TRAEs or compromising HRQoL. Patient age and ILPI characteristics are critical factors in guiding treatment selection. SBRT is particularly beneficial for patients over 70 years, especially those presenting with abutment-type ILPI, left OF involvement, or central ILPI.

#7365 Potential role of Lipocalin 2 as a biomarker of radio resistance in head and neck squamous cell carcinoma (HNSCC).

Smriti Suri[1], Sushmita Ghoshal[2], Jaimanti Bakshi[3], Arnab Pal[1]

[1]Biochemistry, Postgraduate Institute of Medical Education & Research (PGIMER), Chandigarh, India,[2]Radiotherapy, Postgraduate Institute of Medical Education & Research (PGIMER), Chandigarh, India,[3]Otolaryngology and Head & Neck Surgery (ENT), Postgraduate Institute of Medical Education & Research (PGIMER), Chandigarh, India

Background: HNSCC has significant burden with high morbidity and mortality. Majority of the HNSCC patients receive Radiotherapy (RT), which is associated with development of radiation resistance and disease-recurrence, which needs in-depth evaluation. Lipocalin2(LCN2), found to be dysregulated in the saliva of HNSCC patients in our previous study using LC/MS shotgun proteomics, is also found associated with radio resistance (RR). To establish the potential role as a predictor of RR, we evaluated LCN2 in HNSCC patients.

Methodology: 356 biopsy-proven treatment-naïve HNSCC, 26 Oral Pre-Malignant Diseases (OPMDs) and 118 healthy subjects were recruited for the study. The patients were treated with curative intent with 66Gy of RT. 5ml of unstimulated saliva and 3ml of whole blood were collected at baseline and during follow-ups in No evidence of disease (NED) and Residual Disease (RD)patients post therapy completion. To evaluate the role LCN2 as a marker of RR, radioresistant cells were generated by repeated sub-lethal exposure of Cal27 cells to γ-rays from radioactive Co^{60}. The RR phenotype was confirmed by phosphorylated H2AX(γH2AX) expression using Western Blot (WB) and Immunofluorescence (IF). Various RR assays such as clonogenic survival assay, apoptosis assay and cell cycle analysis, were performed on the successfully generated RR cells, which were later analysed for the expression of LCN2.

Results: Significantly higher($p \leq 0.0001$) levels of LCN2 in saliva and serum (median- 609.15ng/ml & 186.18ng/ml) of patients compared to OPMD (median-358.47ng/ml & 124.05ng/ml) and healthy controls (median-95.70ng/ml & 85.53ng/ml) respectively. The increased level of these proteins also correlated with patients' response post therapy completion with significantly higher($p \leq 0.0001$) LCN2 in RD (median-1919.61ng/ml & 133.48ng/ml) group compared to NED (median-537.27ng/ml & 90.68ng/ml), indicating that the increased LCN2 level estimated after therapy completion is associated with therapy resistance. Poorly differentiated patients had significantly higher($p \leq 0.0001$) LCN2(H-score148.12) as compared to moderately(H-score34.04) and well differentiated(H-score17.12) on IHC analysis. In the generated RR cell line, on IF analysis γH2AX foci was significantly higher validated by western blot. Further using clonogenic survival assay, apoptosis and cell cycle analysis assay it was henceforth proven that the cell lines generated had RR characteristics. The proven RR cell lines were further checked for LCN2 expression, which had significantly higher (3.6 fold) expression as compared to wild type cell lines. The results were validated with western blot.

Conclusion: LCN2 is proposed as a predictive biomarker to prognosticate resistance to radiation in patients with HNSCC.

#7366 Survival outcomes with concurrent systemic therapy in patients with a medical contraindication to cisplatin in the non-operative management of locally advanced HNSCC, an NCDB Study.

Deniz C. Demircioglu[1], Sohil Singh[1], Johnny Belcher[1], Joseph Zenga[2], Stuart J. Wong[3], Musaddiq Awan[4]

[1]Medical College of Wisconsin, Wauwatosa, WI,[2]Department of Otolaryngology, Medical College of Wisconsin, Wauwatosa, WI,[3]Department of Medicine, Division of Hematology and Oncology, Medical College of Wisconsin, Wauwatosa, WI,[4]Department of Radiation Oncology, Medical College of Wisconsin, Wauwatosa, WI

Standard-of-care non-operative management for locally advanced head & neck squamous cell carcinoma (HNSCC) is definitive radiation with concurrent cisplatin. NRG-HN004 demonstrated the benefit of concurrent cetuximab in patients with a medical contraindication to cisplatin including those older than 70 with a Charleson-Deyo (CD) score ≥ 1 and those under 70 with a CD score ≥ 2. In these populations, the survival benefits of concurrent systemic therapies may be limited due to medical co-morbidities. We evaluated overall survival (OS) of these populations in the National Cancer Database (NCDB) comparing radiation-treated patients who received concurrent chemotherapy against concurrent immunotherapy (most likely cetuximab given it is the only FDA-approved immunotherapy for this indication). The NCDB was queried for data from 2015-2023 to include stage III, IVa, and IVb non-metastatic HNSCC patients that met the HN-004 criteria. Histological subtypes of squamous cell carcinoma (SCC) were identified using ICD-O-3 codes 8070-8078. Patients with clinical T3-T4 and/or clinically node-positive disease with a known primary were included. Patients who received less than 60 Gy were excluded. Groups were stratified based on radiation with chemotherapy (RT-C) or radiation with immunotherapy (RT-I) without overlap. Concurrent systemic therapy was defined as having started within 30 days of the initiation of radiation. OS was evaluated using Kaplan-Meier (KM) statistics and differences were evaluated using log-rank testing. A $p < 0.05$ was considered statistically significant. To minimize the effect of informative censoring, patients without documented follow-up after January 1, 2023 were counted as deaths unless they had greater than 5 years of observed follow-up. Additionally, KM estimates were capped at 5 years. A total of 6299 patients were identified: 5657 treated with RT-C and 642 treated with RT-I. 2-year OS was 65.0% (95% CI, 63.8-66.3) and 52.9% (95% CI, 49.2-57.0) for RT-C and RT-I, respectively. 5-year OS was 20.7% (95% CI, 19.6-21.9) and 21.8% (95% CI, 18.7-25.5) for RT-C and RT-I, respectively. KM analysis ultimately showed no significant difference between the two treatment cohorts (log-rank p=0.059). In a subgroup of patients with medical contraindications to cisplatin, there was no statistically significant improvement in OS with concurrent chemotherapy over concurrent immunotherapy (likely cetuximab) for locally advanced HNSCC in this real-world dataset. Critically, early survival benefits seen with concurrent chemotherapy dissipate with long-term follow-up possibly due to deaths from other causes in this population with extensive co-morbidity. Further prospective study is needed to evaluate the benefit of concurrent chemotherapy over cetuximab in this frail population.

#7367 Proton versus photon VMAT craniospinal irradiation for hematologic leptomeningeal disease: A comparative study.

Brianna Hostler[1], Gene Lamanilao[2], Tam Le[2], Tara Austin[3], Caitlin L. Costello[4], Ah-Reum Jeong[4], Kaitlyn Dykes[4], Ayad Hamdan[4], Nadeem Tabbara[4], Iain Macewan[2], Jona A. Hattangadi-Gluth[2], Parag Sanghvi[2], Kathryn R. Tringale[2]

[1]Department of Psychology, San Diego State University, San Diego, CA,[2]Department of Radiation Medicine and Applied Sciences, University of California San Diego, La Jolla, CA,[3]Department of Psychiatry, University of California San Diego, La Jolla, CA,[4]Department of Medicine, University of California San Diego, La Jolla, CA

Craniospinal irradiation (CSI) is an effective treatment option in the treatment of hematologic leptomeningeal disease (LMD), a challenging condition seen in a variety of hematologic malignancies. Comparative outcomes between CSI delivered with protons (“pCSI”) versus modern photon-based volumetric modulated arc therapy (VMAT, or “xCSI”) have not been described in hematologic LMD. It is hypothesized that pCSI may reduce hematologic toxicity compared to xCSI due to the more favorable dose distribution regarding bone marrow sparing. This study compares acute toxicities and survival between xCSI and pCSI, hypothesizing higher toxicity with xCSI but similar survival after adjusting for performance status. Adult hematologic LMD patients treated with CSI between 2020 and 2025 were identified. Acute hematologic toxicities were graded using CTCAE v.5.0 at baseline, during treatment, and at 1- and 3-months post-CSI. Overall survival (OS) and CNS progression-free survival (CNS-PFS) were evaluated from CSI end to death and progression event, respectively, using Kaplan-Meier. OS was further analyzed using Cox proportional hazards models adjusted for ECOG performance status. Of 34 patients (median age 38), 26 (76%) received xCSI and 8 (24%) received pCSI. The delivered radiation dose ranged from 7.2 Gy-30.6 Gy in 4-17 fractions. Baseline clinicodemographic variables were similar between pCSI and xCSI: most patients had an ECOG score of 1 (p=.802), and acute lymphoblastic leukemia (58.8%) and non-Hodgkin lymphoma (17.6%) were the most common histologies (p=.517). Grade ≥3 lymphopenia was significantly higher during xCSI (p=0.006) but resolved by the 1-month post-CSI follow-up (p=.202). No other significant differences in acute hematologic toxicities were observed. Median OS was 28.3 months and did not significantly differ between the groups (28.26m; 95%CI, 21.19-35.33; p=.228) and remained nonsignificant after adjustment for ECOG (HR 0.16; 95% CI, 0.02-1.45; p=.103). Median CNS-PFS was not reached (p=.212). pCSI and xCSI demonstrated similar survival and acute hematologic toxicity profiles in hematologic LMD, supporting the safety of VMAT xCSI. However, patients who received xCSI were more likely to have severe lymphopenia, which is a particularly relevant endpoint for patients with hematologic malignancies who often have vulnerable bone marrow. These data are important to add to the existing literature on CSI for solid tumor LMD, as hematologic malignancies are a particularly at-risk population. While this study is limited by small cohort size and patient selection, it is an important first step toward optimizing the management of hematologic LMD.

#7368 Dynamic molecular and immune characterization for personalized treatment in locally advanced rectal cancer.

Fiza Ishaqwala[1], Ashley McCulloch[1], Lily Hillson[1], Liang Tang[2], Leonor Schubert Santana[1], Chia Yew Kong[1], Ross McMahon[1], Lynsey Devlin[3], Walaiphorn Woraharn[1], Noori Maka[4], Timothy Mitchell[3], Sean O'Cathail[1], Jean Quinn[1], Simon WF Milling[1], Philip Dunne[5], Colin W. Steele[1], **Joanne Edwards**[1], Campbell S. Roxburgh[1]

[1]University of Glasgow, Glasgow, United Kingdom,[2]Varian Medical Systems, Salt lake city, UT,[3]NHS Greater galsggow and Clyde, Glasgow, United Kingdom,[4]Queen Elizabeth University Hospital, Glasgow, United Kingdom,[5]Queen's University Belfast, Belfast

Background: Locally advanced rectal cancer (LARC) shows highly variable responses to neoadjuvant radiotherapy with a minority of patients achieving complete tumor regression. Existing clinical tools cannot reliably predict responders using pre-treatment samples. Understanding the dynamic molecular and immune changes occurring during and after radiotherapy is initiated is therefore critical to guide personalized treatment strategies and improve outcomes.
Aims/Objectives: This study employed a serial rectal tumor sampling protocol during neoadjuvant treatment. We aim to characterize longitudinal transcriptomic changes in LARC tumors during radiotherapy and to identify early molecular and microenvironmental features associated with treatment response.
Methods/Results: Tumor biopsies were collected from 38 patients at baseline, week 2, week 6, and week 12 during short-course or long-course radiotherapy. Bulk RNA-seq was used to profile gene expression across time. PCA and differential expression analyses showed that most transcriptional reprogramming occurred between baseline and week 2, with minimal changes at later time points. Responders exhibited early downregulation of proliferation-related genes alongside sustained activation of immune pathways. Divergence from non-responders was most evident by week 2, highlighting a critical window for treatment response. Consensus Molecular Subtype (CMS) classification showed enrichment of CMS2 in non-responders and CMS4 in responders. Tissue composition further influenced transcriptional patterns, with stromal-rich samples in responders displaying stronger immune signatures. Based on Cell deconvolution tools, responders showed pronounced week-2 activation of myeloid and lymphoid populations, while non-responders exhibited delayed immune activation.
Conclusions: This study shows that radiotherapy response in LARC is determined early, with week 2 emerging as a key point where responders and non-responders clearly diverge. Responders rapidly suppress proliferation and activate strong immune programs, while non-responders show delayed or minimal immune engagement. These early molecular and microenvironmental shifts highlight an important role for early immune activation in directing successful RT responses. These features, present early during therapy suggest that on-treatment predictive biomarker development should be pursued to support development of adaptive, personalized treatment strategies.

#7369 Hypofractionated prostate and pelvic nodal radiotherapy with androgen deprivation therapy for high-risk prostate cancer: A retrospective analysis of oncologic outcomes and toxicity.

Eashwer Reddy[1], **Affan Ahmad Ansari**[2], Inamul Haque[1], Dunia Khaled[3], John Park[4]

[1]Medical/Radiation Oncology, Kansas City VA Medical Center, Kansas City, MO,[2]University of Missouri - Kansas City, Kansas City, MO,[3]Urology, Kansas City VA Medical Center, Kansas City, MO,[4]Radiation Oncology, North Kansas City Hospital, Kansas City, MO

Purpose: This study evaluated the clinical outcomes and toxicity of hypo-fractionated prostate radiotherapy combined with elective pelvic nodal irradiation and androgen deprivation therapy (ADT) in patients with unfavorable intermediate-risk, high-risk, and very high-risk localized prostate cancer.
Methods: A retrospective analysis was conducted on 152 consecutively treated patients from 2014 to 2024. After excluding 21 deaths unrelated to prostate cancer, 131 patients formed the study cohort. All patients received volumetric modulated arc therapy (VMAT) with daily cone-beam CT image guidance. Treatment consisted of prostate hypo-fractionation delivered with a simultaneous integrated boost and pelvic nodal irradiation to 46-50 Gy in 20-25 fractions. ADT was administered for 6-24 months according to disease risk. Patients were followed for biochemical relapse-free survival (bRFS), disease-free survival (DFS), overall survival (OS), and genitourinary (GU) and gastrointestinal (GI) toxicity.
Results: With a median follow-up of 55 months, the cohort demonstrated a DFS rate of 93.8% and an OS rate of 97.7%. Eight patients experienced progression, including five metastatic deaths and three biochemical failures. Cumulative grade III or higher GU toxicity was 3.8%, including one grade IV event; no grade III or higher GI toxicity occurred. Toxicity remained low despite pelvic treatment, likely attributable to modern VMAT planning, daily image guidance, and consistent bowel and bladder preparation.
Conclusions: Hypo-fractionated prostate radiotherapy with elective pelvic nodal coverage and ADT produced excellent long-term disease control with minimal severe toxicity in high-risk and very high-risk prostate cancer. These findings support the safety and effectiveness of elective pelvic nodal irradiation when delivered with contemporary image-guided radiotherapy techniques and reinforce its potential role in the modern management of high-risk disease.

#7370 End-to-end *in vitro* and *in vivo* evaluation of radiopharmaceuticals in patient-derived models.

Anita Liu[1], Bryan Miller[2], Antonella di Mambro[2], Prabhakar Panday[1], Rosemary Shoop[1], Esther Kingma[2], Chiara Da Pieve[1], Bhushan Rai[2], Juliana Maynard[1], Elisabet Fernandez-Potente[1], Tatiane Takahashi[1], Bram Herpers[2], Lucy Harris[2], Lynne Braidwood[1], Ludovic Bourre[2], **Benedetta Arno**[1]

[1]Medicines Discovery Catapult Limited, Macclesfield, United Kingdom,[2]Crown Bioscience Inc, San Diego, CA

Background & Rationale Targeted radionuclide therapy (TRT) using alpha- and beta-emitting agents offers a precision approach to cancers treatments, with improving outcomes while minimizing systemic toxicity. The development and clinical translation of novel radiopharmaceuticals depend on the integration of robust *in vitro* and *in vivo* assays throughout the drug discovery process, critical for assessing target specificity, pharmacokinetics, biodistribution, drug resistance mechanism and therapeutic index. 3D cell lines and cell line-derived xenograft (CDX) provide fast and cost-effective means to assess drug effects, whereas patient-derived (xenograft) organoid (PD(X)O) and patient-derived xenograft (PDX) models preserve heterogeneity, tumour architecture, and enable more clinically predictive assessment of therapeutic efficacy across diverse patient populations. In this study, the theranostic pairing of [^{68}Ga]Ga-PSMA-617 and [^{177}Lu]Lu-PSMA-617 were prepared and tested in 2D and 3D in vitro assays using CDX and PDXO, followed by *in vivo* testing in PDX models to evaluate target expression, therapeutic efficacy, and translational relevance across heterogeneous PSMA expression profiles.

Methods PSMA-617 was radiolabelled with ^{68}Ga and ^{177}Lu using standard manual procedures. The RCP was confirmed by RP-HPLC and TLC analysis. Viability was measured on prostate cancer models with differential PSMA expression levels upon treatment with [^{177}Lu]Lu-PSMA-617. DNA damage (γH2AX) was assessed by immunofluorescence to evaluate radiobiological effects. PDX mouse models were imaged with [^{68}Ga]Ga-PSMA-617 PET to assess target density and heterogeneity prior to therapy and monitor treatment response. Prostate PDX models received a single dose of 50 MBq [^{177}Lu]Lu-PSMA-617. Subcutaneous tumour growth, survival and body weight were monitored over time. CBC (WBC, RBC, platelets, neutrophils, lymphocytes) was analysed prior to treatment and regularly after treatment to assess bone marrow toxicity.

Results Radiolabelling of PSMA-617 with ^{68}Ga and ^{177}Lu yielded products with an RCP≥95%, as determined by HPLC analysis, with no further purification. The specific activities of [^{68}Ga]Ga-PSMA-617 and [^{177}Lu]Lu-PSMA-617 were 10 and 17.5 MBq/nmol, respectively. Both *in vitro* and *in vivo* findings demonstrate distinct responses to [^177Lu]Lu-PSMA-617 treatment, consistent with varying PSMA expression levels, evidenced by diagnostic PET imaging and comprehensive PDX models characterization.

Conclusions Our results highlight the importance of integrating radiochemistry expertise with clinically relevant patient-derived models to thoroughly characterize novel radiopharmaceuticals. This holistic approach enhances the predictive accuracy of preclinical studies and ensures that emerging therapeutic strategies are closely aligned with clinical demand.

#7371 High-definition spatial and single-cell multiomics reveal immunological remodeling and radiation resistance mechanisms in colorectal cancer.

Junbum Kim[1], Olivier Elemento[2], Christina Montagna[3], Nir Ben Chetrit[1], Silvia C. Formenti[1], Liron Yoffe[1]

[1]Weill Cornell Medicine, New York, NY,[2]Weill Cornell Medical College of Cornell Univ., New York, NY,[3]Radiation Oncology, Rutgers University, New Brunswick, NJ

Radiation therapy remains central to colorectal cancer care, yet many patients experience incomplete response or recurrence. Understanding why tumors adapt instead of regress requires mapping how radiation reshapes both local and systemic immunity. The ImmunoRad ROBIN initiative addresses this need by integrating high definition spatial and single cell profiling to identify biological processes that sustain radiation resistance.Our cohort included six patients sampled before treatment, after radiation, and at surgery across tumor, adjacent mucosa, and lymph nodes. Using VisiumHD at 2 × 2 µm resolution, we generated more than one and a half million spatial spots, providing a near cellular view of therapy induced remodeling. A dominant pattern emerged at the tumor stroma boundary, where radiation triggered extracellular matrix activation, fibroblast signaling, and wound repair programs. These regions were enriched for M2 like macrophages expressing profibrotic and angiogenic genes. Their expansion suggests that a macrophage dependent repair niche forms at the invasive front and creates conditions that support tumor persistence.These stromal changes aligned with localized epithelial stress responses, showing that adaptation occurs through coordinated tissue level remodeling. Epithelial compartments displayed DNA damage repair, interferon signaling, and partial plasticity, especially near M2 rich zones. Adjacent mucosa showed weaker shifts in antigen presentation and barrier pathways. These patterns indicate that radiation injury extends across tumor and non-tumor tissue, generating new gradients that may influence treatment outcome.To assess systemic adaptation, we performed single cell RNA sequencing on matched blood. Early after radiation, circulating lymphocytes and dendritic cells showed transient interferon signatures. By surgery, these activated populations contracted and were replaced by suppressive myeloid subsets with reduced cytotoxic T cells, suggesting that initial immune activation shifts into a suppressive state. Lymph nodes exhibited disrupted follicular structure, reduced germinal center polarity, and expansion of mantle zones. Integrated analysis showed enrichment of regulatory T cells and exhausted CD8 T cells, consistent with impaired antigen driven immunity.Together, these findings support a model in which radiation triggers acute injury and immune activation that rapidly transitions into macrophage driven repair and systemic immune suppression. This coupled remodeling allows tumor cells to survive therapy and regain growth potential. The ImmunoRad ROBIN framework offers a scalable strategy for decoding treatment induced ecosystem changes and highlights stromal remodeling and lymph node dysfunction as central contributors to radiation resistance in colorectal cancer.

#7372 HOXA1 promotes radioresistance via activation of the ERK/HIF1A signaling pathway.

Tae-Jun Kim, Hyun-Jin Shin, Jong Kuk Park

Korea Institute of Radiological & Medical Sciences (KIRAMS), Seoul, Korea, Republic of

Oral squamous cell carcinoma (OSCC), the most common subtype of head and neck squamous cell carcinoma (HNSCC), remains a major clinical challenge due to treatment resistance, particularly radioresistance. Despite advances in surgery, radiotherapy, chemotherapy, targeted therapy, and immunotherapy, the 5-year survival rate for HNSCC patients has improved only marginally. HOXA1, a member of the homeobox (HOX) gene family, has been implicated in tumor progression and prognosis across several cancer types. However, its specific role in OSCC and its potential involvement in radioresistance remain unclear. In this study, we analyzed HOXA1 expression in OSCC patient samples with diverse clinicopathological features and generated HOXA1-deficient OSCC cell lines using CRISPR/Cas9 technology. Following validation of stable knockout, we assessed the expression of genes associated with proliferation, migration, and invasion at both mRNA and protein levels. HOXA1-deficient cells exhibited markedly decreased colony formation and cell viability after irradiation compared with control cells, indicating that HOXA1 contributes to radioresistance. Transcriptomic enrichment analysis further revealed an upregulation of focal adhesion-related genes in HOXA1-deficient OSCC cells. Mechanistically, HOXA1 was found to activate a focal adhesion via the ERK/HIF1A signaling pathway, underscoring its pivotal role in OSCC progression and therapeutic response.

#7373 An integrated bioinformatic and experimental analysis of radiation-induced epigenetic reorganization in colorectal cancer.

Megan Tandar, Allison Pittman, Christine E. Eyler

Duke University, Durham, NC

Colorectal cancer is the second-leading cause of cancer-related deaths in the US. Resistance to radiation therapy - known as radioresistance - often develops during treatment, leading to metastases and death. Current research overlooks the dynamic epigenetic changes that occur during therapy, limiting the development of effective therapeutics.

My project aims to profile and interrogate these radiation-induced epigenetic alterations across multiple in vitro colorectal cancer models. To study this phenomenon across diverse colorectal cancer subtypes, I integrated high-throughput sequencing analyses with wet-lab CRISPR screens to identify radiotherapy-affected epigenetic regions and validate them in biologically relevant models.

I performed RNA Sequencing (RNA-Seq), Gene Set Enrichment Analysis (GSEA), and Assay for Transposase-Accessible Chromatin Sequencing (ATAC-Seq) on radiation-treated colorectal cancer cell lines to characterize radiation-induced epigenetic changes. I administered two courses of radiation treatments on HCT116, SW480, MDST8, and RKO lines to mimic clinically relevant radiation courses: (1) a single-dose treatment of 0, 2, or 5 Gy, and (2) a fractionated-dose treatment of 0 or 2 Gy administered daily for five consecutive days. To validate these bioinformatic analyses, I employed dual whole-genome-wide CRISPR knockout screens in both HCT116 and MDST8 colorectal cancer cell lines to experimentally identify radiation-induced epigenetic alterations, screening 180 million cells under 0 Gy control and 2 Gy multi-dose irradiation conditions.

RNA-Seq revealed consistent post-radiation transcriptional changes in all four cell lines. The 5 Gy-irradiated RKO lines showed regions of the genome that had increases in gene expression with increasing radiation treatment, suggesting a potential radiation-induced epigenetic regulatory mechanism. In multi-radiation dose experiments, volcano plot analysis revealed increased expression of immune-related genes such as IFIT1 in HCT116 cells and similar lines. I ran additional GSEA analyses, which confirmed alterations in immune-sensing pathways following radiation treatment and suggest a potential link among immune response, radiation treatment, and epigenetic regulation in colorectal cancer. I am currently analyzing CRISPR and ATAC-Seq data, but anticipate overlap in radiation-altered epigenetic regions between datasets.

We aim to integrate CRISPR-screen data with RNA-Seq, GSEA, and ATAC-Seq analyses. I expect these results to contribute to the novel characterization of key radiation-induced colorectal epigenetic alterations and provide a robust framework for studying radioresistance in colorectal cancer. Ultimately, we hope to use these results to develop personalized, time-sensitive therapies that may improve patient outcomes and quality of life.

#7374 Molecular imaging guided precision radiotherapy and quantitative assessment of metastatic colorectal cancer.

Yunwen Huang[1], Jiahao Chen[1], Ning Zhao[2], Yidong Yang[1]

[1]University of Science and Technology of China, Hefei, China,[2]Raycision Medical Technology Co. Ltd., Hefei, China

Early detection and intervention of metastasis remain challenging and contribute significantly to cancer mortality. This study developed a molecular image-guided precision radiotherapy system that can early detect, precisely irradiate, and quantitatively assess metastatic tumors. Using the highly aggressive orthotopic HCT116 colorectal cancer model, we validated the system's detection sensitivity for primary and metastatic tumors and the efficacy of BLT/CT-guided radiotherapy (32 Gy in 4 fractions). The system detected metastatic tumors as small as 300 μm, with BLT-derived tumor size strongly correlating with histopathology ($R^2 = 0.91$, $p < 0.001$). γ-H2AX immunofluorescence staining revealed DNA damage foci predominantly localized within the tumor volume, confirming precise targeting. At 23 days post-treatment, the irradiation group exhibited reduction in bioluminescence intensity to 0.61-fold and tumor volume to 0.57-fold of initial values, whereas the control group showed increases to 86.62-fold and 5.89-fold, respectively ($p < 0.001$). FITC-dextran permeability assay and histological analysis of the entire intestine confirmed preserved intestinal barrier function and structural integrity. With precise targeting and minimal toxicity, the radiation group achieved >2-fold prolonged survival. This multimodal image-guided system enables accurate localization, precise treatment, and quantitative assessment of early-stage and metastatic tumors, offering significant potential for malignancies within complex soft tissue environments or with disseminated spread.

#7375 Efficacy of irreversible electroporation as treatment for hepatocellular carcinoma based on liver explants.

Michael Lauricella, Gauri Kelekar, Olufoladare Olorunsola

California Pacific Medical Center, San Francisco, CA

Introduction: Hepatocellular carcinoma (HCC) commonly develops in the context of cirrhosis. In these patients, liver transplantation remains the therapeutic approach with the highest likelihood of achieving cure. Local treatments such as ablation may be used to control HCC in patients awaiting a suitable organ. Irreversible electroporation (IRE) is a nonthermal ablation modality often considered for tumors in locations not amenable to thermal ablation, such as those near bile ducts, bowel, and other vulnerable structures. Previous studies investigating IRE have assessed efficacy primarily based on surveillance imaging. To these authors' knowledge, this is the largest study to examine HCC response to IRE in liver explants.

Methods: This single-institution retrospective study includes 18 patients who received IRE for HCC between 2018 and 2025 and subsequently underwent liver transplantation. Among liver transplantation candidates with HCC requiring a bridging locoregional therapy, IRE was selected as the treatment modality for tumors less than 3 cm located within 1 cm of heat-vulnerable structures. IRE treatments were performed in a single session. Procedural complications were recorded and classified according to the Society of International Radiology (SIR) grading system. Surveillance imaging (CT or MRI) was obtained at one month post-IRE, and every three months subsequently. A board-certified radiologist specialized in abdominal imaging interpreted all surveillance imaging according to LI-RADS treatment response criteria, with binary categorization of the treated lesion as viable or nonviable. One of several board-certified pathologists evaluated each liver explant with respect to viability of the IRE-treated lesion.

Results: Mean patient age was 62 (SD: 54-70). 72% were male. Their race/ethnicity were 61% white, 27% hispanic, 5% asian, 5% black. The etiology of their cirrhosis was either hepatitis C (61%), hepatitis B (11%), or alcohol use disorder (27%). Barcelona Clinic Liver Cancer (BCLC) classification was either A (78%) or B (22%). Child-Pugh classification was either A (78%) or B (22%). The average pre-ablative alpha-fetoprotein (AFP) was 33 (SD: 0-100). Mean size of treated lesions was 2.3 cm (SD: 1.3-3.3). Mean time between IRE and liver transplantation was 540 days (SD: 300-780). Two patients had IRE procedural complications, one classified as SIR 1 and the other as SIR 2. 16 of the 18 patients (89%) had complete tumor necrosis of the treated lesion on pathological review of the explanted liver. There was 100% correlation between viability assessment on surveillance imaging and that on explant histopathology.

Conclusions: IRE is a safe and effective method for treating HCC in the pre-transplant setting. Surveillance imaging has high accuracy in assessing HCC response after IRE relative to histopathologic assessment.

#7376 HMGB2-mediated radioresistance of glioblastoma stem cells.

Sara Nalina Barcik Weissman[1], Cheol Park[1], Connor Mork[1], Khoi Huynh[1], Yingwen Ding[2], Ze-yan Zhang[2], Eric L. Chang[1], Erik P. Sulman[2], Aram S. Modrek[1]

[1]Radiation Oncology, Keck School of Medicine of USC, Los Angeles, CA,[2]Radiation Oncology, NYU School of Medicine, New York, NY

Glioblastoma (GBM) is the most common and deadly adult central nervous system cancer. Despite surgical resection combined with DNA-damaging radiation and chemotherapy, GBM almost invariably recurs, becoming more resistant to radiation. To investigate the drivers of this radioresistance, we conducted a knockout radiosensitization screen and identified the High Mobility Group B2 (HMGB2) protein as a potential contributor. To elucidate HMGB2's role in GBM radioresistance, we performed viability, clonogenic survival, extreme limiting dilution (ELDA), and deletion mutant assays on patient-derived glioblastoma stem cells (GSCs) treated with a combination of radiotherapy (RT) and either HMGB2 knockdown or inhibition using Inflachromene (ICM), a small molecule inhibitor of HMGB2. Without radiation, ICM showed IC-50 values ranging from 8.43 μM to 10 μM across three GSC lines. Both ICM treatment and HMGB2 knockdown significantly reduced neurosphere formation compared to cultures treated with only RT and vehicle. Knockdown of endogenous HMGB2 combined with overexpression of an Acidic Tail-deleted HMGB2 mutant produced distinct puncta under fluorescence microscopy, unlike other deletion mutants. These findings implicate HMGB2 in GBM radioresistance and suggest that the Acidic Tail region mediates chromatin binding, possibly playing a role in HMGB2's mechanism of action. Together, these results provide a foundation for clarifying HMGB2's role in GBM biology and it's potential relevance to improving therapeutic response.

#7377 Radiation-mediated complement cascade activation within the lung tumor microenvironment diminishes the efficacy of radiation therapy.

Harendra Shah[1], Minakshi Saikia[1], Xiaobo Wu[2], John P. Atkinson[2], Abhay K. Singh[2], **Vaishali Kapoor**[2]

[1]Department of Radiation Oncology, Washington University In St. Louis School of Medicine, St. Louis, MO,[2]Washington University In St. Louis School of Medicine, St. Louis, MO

Non-small cell lung cancer (NSCLC) is the primary cause of cancer-related mortality worldwide, necessitating novel interventions to improve survival rates. Current treatment modalities for locally advanced NSCLC involve cytotoxic chemotherapy with concurrent external beam radiation therapy (XRT), followed by immunotherapy. However, the impact of XRT on the complement system, a crucial component of innate immunity, remains unclear. The complement regulatory proteins (CRPs), including CD46, CD55, and CD59, tightly control complement activation mediated by the three pathways. In this study, we investigated the surface expression of CRPs in NSCLC cell lines *in vitro* and within the tumor microenvironment (TME) *in vivo*. We assessed the activation of the three complement pathways in the TME and monitored tumor growth and survival in C57BL/6 wild-type, $C3^{-/-}$, and $C3AR^{-/-}$ mice following XRT. Following XRT, NSCLC cell lines A549 and H460 exhibited a significant increase in the cell surface expression of CD46, CD59, and CD55 compared to controls ($p<0.05$), whereas normal lung epithelial cells (MRC5) did not display such upregulation. Irradiated Lewis lung carcinoma (LLC) tumors in wild-type mice demonstrated elevated levels of C3 and C5 mRNA and protein ($p=0.0013$). Also, C3AR and C5AR were significantly upregulated in the irradiated LLC tumor as compared to the sham. Additionally, the alternative complement pathway components, factor B and factor D, were significantly upregulated ($p<0.001$) in the LLC TME following XRT. However, the membrane attack complex (MAC) did not form in XRT-treated LLC tumors compared to sham. Deficiency of the central C3 and C3AR complement components in $C3^{-/-}$ and $C3AR^{-/-}$ mice delays LLC tumor growth in combination with XRT. Our findings suggest that XRT increases the expression of CRPs in NSCLC, potentially facilitating immune evasion by tumor cells. We also found activation of the alternative pathway of the complement system. Targeting C3 and C3AR effectively delayed tumor growth, highlighting the potential of complement pathway modulation to enhance the efficacy of XRT in NSCLC treatment. These results underscore the importance of elucidating the intricate interplay between radiation-induced complement activation and tumor survival for devising novel therapeutic strategies in NSCLC.

#7378 Prolonged radiation exposure alters cellular proteome network in human hepatocellular carcinoma cells.

Mohammed Sikander, Shabnam Malik, Rajasekhar Baru, Daniel Zubieta, Iris Enriquez, Mirza S. Baig, Murali M. Yallapu, Subhash C. Chauhan

The University of Texas Rio Grande Valley, Edinburg, TX

Background: Hepatocellular carcinoma (HCC), leading cause of cancer-related mortality globally, presents a major challenge as majority of patients are diagnosed at later stages, rendering them ineligible for effective interventions such as liver resection and transplantation. Radiation therapy (RT) is growing as a well-tolerated non-invasive local ablative treatment option; however, its effectiveness is restricted by therapy-induced radioresistance, resulting in tumor recurrence, enhanced invasion, and alterations in the extracellular matrix. This study aims to examine the impact of prolonged radiation exposure on the molecular dynamics and cellular behavior of HCC cells, with particular emphasis on the function of invadopodia in acquired resistance and increased invasiveness, to pave the way for development of novel therapeutic strategies for improved patient outcomes.
Methodology: Radioresistant HCC cell lines were created by exposing them to a cumulative dose of 20 Gy of radiation (2 Gy daily for ten-days) followed by functional assays to measure colony formation, invasion, and migration. LC-MS was used to identify and quantify proteins in both the radiation-treated and control groups. Western blotting and immunofluorescence analysis were carried out to verify the differentially expressed proteins.
Results: Functional assays showed a significant increase in colony formation which indicates radioresistant HCC cells had enhanced proliferation capabilities as compared to normal cancer cells. In addition, these cells demonstrated a significant increase in their invasive and migratory abilities, suggesting that radioresistant cells not only exhibit improved survival but also have a higher potential for metastatic spread. Proteomic profiling analysis showed a differential expression of proteins between the radiation-treated and control groups. When compared to the control group, which included 5,201 proteins, the radiation-treated cells contained a total of 5,342 proteins. Additionally, 5,007 proteins were found to be present in both groups. Significant differences were observed, especially in proteins related to cell proliferation, cellular organization, metabolism, stress response, signal transduction, and other biological processes. Drebrin, plectin, and filamin-A were selected for further analysis due to their considerable upregulation among the differentially expressed proteins. Microscopic investigation revealed the existence of invadopodia, actin-rich protrusions, in radioresistant cells compared to control HCC cells. F-actin staining demonstrated more prominent invadopodia structures in radioresistant specimens compared to the control group.
Conclusion: This study suggests that prolonged radiation exposure influences multiple cellular and proteome level changes to promote aggressive tumorigenic and metastatic behavior of HCC cells.

#7379 FDXR expression is a rectal cancer biomarker of radiation resistance and confers resistance through ferroptosis.

Sara Soltani Tehrani, May Zin Hlaing, Joseph Fedro, Rami-James Aoun, Karishma Kundu, Sylvain Ferrandon, Matthew F. Kalady

The Ohio State University College of Medicine, Columbus, OH

Purpose: Treatment of locally advanced rectal cancer is multimodal and includes total neoadjuvant therapy (TNT) with chemoradiation and chemotherapy. Response to TNT is highly variable and correlates with oncologic outcomes. There are limited biomarkers for rectal cancer radiation response, and there is also a critical need to identify potential therapeutic targets that could improve radiation sensitivity. The gene *FDXR* encodes a mitochondrial flavoprotein involved in electron transport, iron metabolism and ferroptosis. This study evaluates the role of *FDXR* in rectal cancer radiation response.

Methods: Pretreatment biopsies from 33 rectal cancer patients were analyzed previously, identifying *FDXR* as differentially expressed among different AJCC Tumor Regression Score (TRS). *FDXR* expression was examined in public datasets. FDXR expression was measured by RT-qPCR in ten colorectal cancer (CRC) cell lines and correlated with radiosensitivity parameters (IC50, D10, SF2). Stable *FDXR* knockdown lines (HCT116, SW480) were generated using lentiviral shRNA. Knockdown was confirmed by Western blot. To assess mitochondrial morphology and structural integrity, Transmission electron microscopy (TEM). Clonogenic survival after irradiation, viability (CCK-8), lipid peroxidation (Image-iT), mitochondrial iron (MitoFerroGreen), and ROS levels were assessed before and after irradiation.

Results: *FDXR* was significantly overexpressed in rectal tumors compared with normal tissue in TCGA and GSE87211. In our patient cohort, higher *FDXR* expression correlated with poorer response (TRS 2-3) and showed strong predictive ability (AUC=0.8577). Across CRC cell lines, *FDXR* expression correlated positively with IC50, D10, and SF2. *FDXR* knockdown caused loss of mitochondrial structural integrity on TEM and significantly reduced clonogenic survival while increasing radiation-induced cell death. Knockdown lines exhibited higher mitochondrial iron, increased ROS, and elevated lipid peroxidation.

Conclusions: *FDXR* is a strong biomarker of rectal cancer radiation response. Loss of *FDXR* enhances ferroptosis through iron accumulation, ROS generation, and lipid peroxidation, increasing radiosensitivity. These results suggest that targeting *FDXR* could enhance radiation efficacy, offering a novel strategy for radiosensitization in rectal cancer.

#7380 TP53 mutants cooperate with H3K27M to enhance survival after DNA damage and drive radioresistance in DIPG.

Karol A. Arizaca Maquera, Viral Oza, Andrew Gaines, Colin Williams, Jessica Blackburn

Molecular and Cellular Biochemistry, University of Kentucky, Lexington, KY

Diffuse intrinsic pontine glioma (DIPG) is driven by the H3K27M oncohistone and frequently co-occurs with TP53 mutations, a genetic combination closely associated with radiation failure. Because H3K27M globally reprograms chromatin and alters promoter accessibility, we hypothesized that it creates a permissive epigenetic environment that enhances the stability and activity of specific TP53 mutants to promote radioresistance. To test this, we expressed TP53 wild-type (WT) or DNA-binding-domain hotspot mutants, including contact mutants (R273C, R273H, R248W) and a conformational mutant (R175H), in TP53-knockout HEK293 cells with either H3.3 or H3K27M. Sequence-specific DNA binding was first assessed using a transcription factor assay. Several mutants (R273H, R273C) retained DNA-binding activity, which increased substantially in the H3K27M context, whereas R175H remained low. Because these results suggested enhanced promoter engagement after DNA damage, we next performed ChIP-qPCR after 8 Gy irradiation. In the presence of H3K27M, multiple mutants (R273H, R273C, R248W) maintained occupancy at p53 target genes (MDM2, CDKN1A/p21), in contrast to reduced binding when H3.3 WT was expressed. Western blot analysis further revealed that several TP53 mutants, including R175H, were selectively stabilized in H3K27M-expressing cells, while WT p53 levels and transcriptional output were unchanged. We then examined transcriptional programs influenced by H3K27M in each TP53 background. Although several chaperone and chromatin-remodeling genes (HSPA14, BRD4, KDM7A) showed modest changes in R273C_H3K27M cells, the most prominent alterations were in stress-signaling pathways, including induction of the NKG2D stress-ligand RAET1E (logFC = +1.14, p = 0.0627). These gene-level changes indicate that H3K27M rewires cellular programs that cooperate with mutant p53 under genotoxic stress. Finally, we tested whether these chromatin-driven molecular effects translate into a functional phenotype. H3K27M provided only a modest proliferative advantage to WT TP53 cells, but markedly increased the survival and regrowth of TP53-mutant cells over 24-72 hours after irradiation. Taken together, these findings support a model in which H3K27M enhances mutant p53 DNA binding, stabilizes mutant p53 proteins, and reprograms stress-responsive pathways to amplify pro-survival responses after DNA damage. This cooperation between H3K27M and specific TP53 mutants provides a mechanistic explanation for radioresistance in DIPG and underscores the importance of considering both TP53 genotype and histone context when designing targeted radiosensitization strategies.

: Functional and Spatial Regulation of Immune Evasion and Anti-Tumor Immunity
Poster Session

#7384 Electrical activity powered neural circuit sustains systemic immune evasion in gastric cancer.

Puran Zhang[1], Feijing Wu[2], Yi Zeng[2], Shuang Li[2], Jin Qian[2], Hualong Zheng[2], Biyun Zheng[2], Juli Lin[2], Hiroki Kobayashi[2], Junya Arai[2], Yosuke Ochiai[2], Masahiro Hata[2], Leah B. Zamechek[2], Timothy C. Wang[2]

[1]Herbert Irving Comprehensive Cancer Ctr., New York, NY,[2]Columbia University Irving Medical Center, New York, NY

Background: Nociceptive sensory nerves are emerging as active regulators of tumor progression and immune suppression within the tumor microenvironment (TME). We previously showed that gastric cancer cells establish a bi-directional electrical circuit with CGRP⁺ sensory neurons, in which cancer depolarization triggers neuronal firing and CGRP release. Given that sensory afferents serve as the afferent limb of the inflammatory reflex transmitting peripheral signals to the brainstem, we hypothesized that cancer may similarly exploit neural circuits and neuropeptide signaling to regulate systemic immunity.
Methods: A chemogenetic receptor (PSAM4-$5HT_3$) was introduced into a syngeneic murine (ACKP) gastric cancer cell line to evoke cancer depolarization in vivo. Cancer-activated neuronal projections were mapped in TRAP2 (Fos-CreERT2) mice using Cre-dependent AAV reporters. Immune profiling was performed to characterize antigen-experienced T cells in the tumor-draining lymph node (TDLN) and various CD8⁺ T-cell subsets within the TME. In vivo imaging was used to monitor T-cell motility dynamics, and GCaMP6s was expressed in immune cells to visualize neuron-triggered calcium flux.
Results: Cancer depolarization activated nociceptive sensory neurons, which established synapse-like contacts with CD8⁺ TILs preferentially at the perivascular niche and tertiary lymphoid structures. The cancer-coupled sensory nerves upregulated Cxcl10, attracting T cells toward their terminals to form these connections. In a 3-D co-culture system comprising cancer spheroids, dorsal root ganglia, and CD8⁺ TILs, optogenetic stimulation of cancer cells induced a calcium flux in sensory nerve-connected T cells, confirming functional transmission. Local activation of this cancer-nerve-T-cell circuit enhanced T-cell migration toward nerve terminals but diminished effector capacity, evidenced by reduced TNFα and IFNγ expression and limited infiltration into the tumor core. Sensory afferents relayed signals to higher brainstem areas, including the nucleus tractus solitarius (NTS) and rostral ventrolateral medulla (RVLM), eliciting sympathetic output to the TDLN. This afferent-brain-efferent loop retained and immobilized antigen-experienced CD44⁺PD-1⁺ T cells within the TDLN, thereby restraining systemic immunity in a norepinephrine-Adrb2-dependent manner. Anti-PD-1 therapy paradoxically strengthens the cancer-sensory nerve coupling. Ablatio of this cancer-evoked neural circuit restored T-cell effector function systemically and synergized with anti-PD-1 therapy.
Conclusions: These findings reveal that cancer depolarization activates CGRP⁺ sensory neurons to form synaptic contacts with CD8⁺ T cells, linking local peptidergic signaling to systemic immune suppression via the NTS-RVLM-TDLN axis. Disrupting this circuit restores T-cell function and enhances anti-PD-1 response.

#7385 Cholesterol-associated immune cell dysfunction across lung cancer progression.

Jiwon Hwang, Ajay Tosh, Satyanarayana Rachagani

University of Missouri, Columbia, MO

Lung cancer progression occurs through tumor microenvironment (TME) transformation, leading cells to modify their metabolic patterns to support tumor growth. Research has recently focused on cholesterol metabolism because it shows promise to affect tumor cell behavior and immune system responses. The TME contains elevated cholesterol levels which lead to $CD8^+$ T-cell exhaustion through a process that results in increased inhibitory receptor expression and decreased antitumor activity. Previous studies have produced conflicting results about cholesterol effects on T-cell function because some studies found cholesterol builds up in tumor-infiltrating T cells whereas others showed that low cholesterol levels can impair T-cell performance. The current understanding lacks information about how cholesterol-related genes change between different cell types and different stages of lung cancer development. In this study, we analyzed single-cell RNA-seq data from a GEO dataset representing multiple stages of lung cancer progression to characterize stage-specific changes in cholesterol-related gene expression across major cell populations. To understand how these metabolic shifts relate to $CD8^+$ T-cell exhaustion, this study investigates the progression of cholesterol metabolism during lung cancer and its potential influence on antitumor immunity.

#7386 Estradiol-responsive niches drive immune exclusion in the tumor microenvironment.

Minsung Kim[1], Kwanghwan Lee[2], Hyun Ju Kang[2], Jin-Ku Lee[1]

[1]Department of Biomedical Sciences, Seoul National University, Seoul, Korea, Republic of,[2]Genomic Medicine Institute, Medical Research Center, Seoul National University, Seoul, Korea, Republic of

Epithelial ovarian cancer (EOC) presents marked molecular diversity, which is largely influenced by the tumor microenvironment (TME). However, the specific factors driving this diversity remain unclear. We established a multi-omics platform integrating growth factor-omics profiling with transcriptomic analysis of patient-derived ovarian tumor tissues. Using samples from 31 EOC patients, we identified the responsiveness of 128 factor combinations and analyzed through integrated bulk and single-cell RNA sequencing. Two main clusters were identified, one responsive to estradiol and Wnt and the other to R-spondin. These results were further validated by a pan-cancer analysis of 11,000 TCGA tumors across 33 cancer types, confirming the conservativeness and clinical relevance of this response program. Estradiol exposure induced robust proliferation characterized by mesenchymal and stem cell-associated transcriptional signatures, leading to tumor growth. Single-cell analysis identified two estradiol-responsive niches: a malignant PDCD5+ subtype and a TNFSF10-expressing fibroblast population, both of which increased after estradiol stimulation. MAL.PDCD5 cells exhibited impaired antigen presentation and metabolic suppression via reduced oxidative phosphorylation, whereas FB.TNFSF10 fibroblasts exhibited increased TGF-beta and CAF.S1 signaling, consistent with immunosuppressive reprogramming. Spatial transcriptomic analysis revealed a distinct spatial segregation between FB.TNFSF10 fibroblasts and T/NK cells, providing direct evidence for hormone-induced immune exclusion. Across various tumor types, elevated FB.TNFSF10 expression correlated with elevated stromal cell and regulatory T cell scores and was an independent predictor of reduced response to immune checkpoint blockade, independent of PD-L1 expression or tumor mutation burden. These findings demonstrate a preserved estradiol-responsive architecture that remodels the tumor microenvironment, preventing immune infiltration. These findings suggest novel biomarkers and therapeutic targets that could enhance the efficacy of immunotherapy across diverse cancers.

#7388 Distinct immune crosstalk axes define the tumor microenvironment across EGFR mutation status in NSCLC by single-cell profiling.

Yoojin Kim[1], Hyunsu Kim[2], Kyungjong Lee[3], Bo Mi Ku[2], Hae-Ock Lee[4], Jinyong Kim[2], Hyun Ae Jung[2], Jong-Mu Sun[2], Se-Hoon Lee[2], Jin Seok Ahn[2], Myung-Ju Ahn[2], Sehhoon Park[2]

[1]Department of Health Sciences and Technology, Samsung Advanced Institute of Health Sciences and Technology, Sungkyunkwan University, Seoul, Korea, Republic of,[2]Division of Hematology-Oncology, Department of Medicine, Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, Korea, Republic of,[3]Division of Pulmonary and Critical Care Medicine, Department of Medicine, Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, Korea, Republic of,[4]Department of Biomedicine and Health Sciences, Graduate School, The Catholic University of Korea, Seoul, Korea, Republic of

Background: Epidermal growth factor receptor (EGFR) is a major oncogenic driver in non-small cell lung cancer (NSCLC). Patients with EGFR-mutant NSCLC show limited responses to immune checkpoint inhibitors (ICIs) compared with those with EGFR-wild-type tumors, as previously reported. The mechanisms underlying primary ICI resistance and distinct tumor microenvironment (TME) characteristics in EGFR-mutant NSCLC remain poorly understood.

Methods: We performed single-cell RNA sequencing of treatment-naïve NSCLC samples from 88 patients (31 EGFR-mutant, 57 EGFR-wild-type) to characterize TME. Data processing, normalization, dimensional reduction, and clustering were conducted with *Seurat* package. Cell types were annotated with canonical marker genes, and transitional epithelial populations were further identified through consensus non-negative matrix factorization (cNMF). Cell-cell communication networks were computationally inferred, and the identified interactions were supported through differential expression and pathway enrichment analyses.

Results: By profiling 241,333 high-quality single cells, we identified 33,628 epithelial cells. cNMF revealed an inflammatory transitional epithelial (Epi_inflammatory) subset based on interferon-driven immune programs. In EGFR-wild-type tumors, these Epi_inflammatory cells showed dominant interactions with CD8+ tissue-resident memory T (Trm) cells through MHC class I-CD8 signaling. The epithelial cells exhibited higher expression of key antigen-presentation genes (*B2M, TAP1, PSMB8/9*), while CD8+ Trm cells showed elevated expression of cytotoxic markers (*GZMB, PRF1, NKG7*) and differentially expressed TCR repertoire-associated genes, indicating enhanced T-cell activation. GSEA showed enrichment of the "*Cell killing*" pathway in CD8+ Trm cells and "*Antigen processing and presentation of endogenous peptide antigen*" in epithelial cells, supporting dominant MHC class I-mediated interaction in EGFR-wild-type tumors. In contrast, intensified crosstalk between tumor-associated macrophages (TAMs) and CD8+ Trm cells was inferred in EGFR-mutant tumors, predominantly driven by the SPP1-CD44 ligand-receptor axis. Hypoxic and STAB1+ TAMs displayed upregulated SPP1 levels and reduced antigen-presentation genes expression, while CD8+ Trm cells expressed higher CD44 levels. Notably, expression of SPP1 in macrophages positively correlated with the exhaustion score of CD8+ Trm cells ($p = 0.041$).

Conclusion: Our findings suggest distinct immune landscapes; EGFR-mutant tumors showed macrophage-driven immunosuppressive TME via SPP1-CD44 axis, leading to CD8+ Trm dysfunction, whereas EGFR-wild-type tumors exhibited epithelial-CD8+ Trm crosstalk, establishing a cytotoxic niche. This divergence may explain the limited benefit of ICI therapy in EGFR-mutant NSCLC.

#7389 Evaluation of tumor-infiltrating γδ T cells across solid tumor indications.

Shawn P. Fahl, Cavin Ott, Kerri Colwell, Kayla Williams, Audrey Kleeman, Jessica Maxwell

Discovery Life Sciences, Huntsville, AL

The tumor microenvironment is a complex heterogeneous cellular mixture containing not only tumor cells, but also immune cells, fibroblasts, and endothelial cells. Based on numerous factors, including cellular subtype and activation, these cell types can have both tumor-promoting and tumor-eradicating activities. We have previously analyzed both intra-tumoral αβ T cells and B cells using a combination of flow cytometry and single cell transcriptomics across solid tumor indications such as bladder, colorectal, endometrial, lung, ovarian, prostate, and renal cancer using human dissociated tumor cells (DTCs). αβ T cells represented the largest tumor-infiltrating lymphocyte (TIL) subset, and the majority of αβ T cells were in an exhausted state based on high surface expression of inhibitory receptors such as PD1 and TIGIT. Across all indications, B cells were the next most prevalent TIL subset, although indication-specific differences were observed. Overall, like αβ T cells, intra-tumoral B cells had an exhausted phenotype, and a high proportion of these B cells were plasmablasts.γδ T cells represent an attractive candidate for immunomodulation as they recognize their cognate antigens in an HLA-independent manner and have intrinsic cytotoxic potential. Previous studies utilized large scale bulk transcriptomics inferred a substantial percentage of γδ T cells across several solid tumor indications. Further studies in melanoma and colorectal cancer analyzed the activation status and Vδ1/2 usage of intra-tumoral γδ T cells; however, a fully comprehensive evaluation and comparison of γδ T cell activation status, Vγ/Vδ usage, and putative γδ T cell ligand expression across numerous indications remains unstudied. We have now utilized DTCs across twelve solid tumor indications to analyze the relative percentages of γδ T cells, including their Vγ chain and Vδ chain usage. The naïve versus memory phenotype of the γδ T cells and the surface expression of exhaustion and natural cytotoxicity receptors were also evaluated. Finally, the expression of γδ T cell ligands, such as stress receptors and butyrophilins, on the tumor cells was assessed. Collectively, these studies provide crucial insight into the indication-specific γδ T cell composition to inform future γδ T cell-mediated immunotherapies.

#7391 A pd-l1 acetylation switch coordinates chromosome cohesion and antitumor immunity.

Meijie Wang[1], Jia Yu[2], Liewei Wang[3]

[1]Molecular Pharmacology & Experimental Therapeutics, Mayo Clinic Hospital-Rochester, Rochester, MN,[2]Mayo Clinic, Rochester, MN,[3]Mayo Clinic College of Medicine, Rochester, MN

Background: PD-L1 is best known for suppressing antitumor immunity at the cell surface, yet emerging evidence suggests additional nuclear functions. Previous studies from our laboratory demonstrated that nuclear PD-L1 interacts with the cohesin complex to maintain chromosomal stability. However, the upstream regulatory mechanism governing this interaction and its immunological consequences remain unknown.
Methods and Results: Using acetylation-site prediction, mutagenesis, and structural modeling, we identified lysine 178 (human) / 177 (mouse) as a conserved acetylation switch regulating PD-L1 function. Deacetylation of PD-L1 (K178R/K177R) disrupted PD-L1-PDS5B/cohesin binding without affecting subcellular localization. This led to defective sister chromatid cohesion, micronuclei formation, and cytosolic DNA accumulation. RNA-seq, qPCR, and immunoblotting demonstrated robust activation of the cGAS-STING-IFN-γ signaling axis and enhanced MHC-I antigen-presentation machinery in PD-L1 K178R cells. Functionally, K178R cells proliferated more slowly and were highly susceptible to PBMC-mediated killing in co-culture assays, with further enhancement upon anti-PD-L1 antibody treatment. In xenograft models (NSG mice), tumors expressing PD-L1 K178R grew significantly slower than WT. In immunocompetent C57BL/6 syngeneic models, PD-L1 K177R tumors showed reduced growth and heightened responsiveness to PD-L1 blockade. Structural and biochemical analyses confirmed that PD-L1 acetylation at K178/K177 stabilizes its interaction with the cohesin complex, thereby preventing chromosomal instability-induced immune activation.
Conclusions: We identify a conserved PD-L1 acetylation switch that couples cohesin stability to innate immune activation. PD-L1 deacetylation promotes chromosomal instability, activates cGAS-STING-IFN-γ signaling, enhances antigen presentation, and sensitizes tumors to PD-L1 immunotherapy. These findings uncover a previously unrecognized regulatory axis linking tumor genomic integrity to immune recognition, providing a mechanistic foundation for targeting PD-L1 acetylation in cancer treatment.

#7392 A cancer cell-intrinsic PAR1/MALT1/PD-L1 signaling pathway drives immune evasion in triple-negative breast cancer.

[1]Department of Laboratory Medicine and Pathology, Mayo Clinic, Rochester, MN,[2]Department of Pediatrics, University of Pittsburgh School of Medicine, Pittsburgh, PA,[3]Department of Medicine, Harvard Medical School, Boston, MA,[4]Department of Pathology, University of Pittsburgh School of Medicine, Pittsburgh, PA,[5]Department of Cancer Biology, Mayo Clinic, Jacksonville, FL,[6]Tsinghua University School of Medicine, Beijing, China,[7]Laboratory Medicine and Pathology, Mayo Clinic, Rochester, MN,[8]Pathology, University of Pittsburgh School of Medicine, Pittsburgh, PA,[9]Cancer Biology, Mayo Clinic, Jacksonville, FL,[10]Department of Immunology, University of Pittsburgh School of Medicine, Pittsburgh, PA,[11]Department of Medicine, Tufts Medical Center, Boston,, MA,[12]Department of Medicinal Chemistry and Molecular Pharmacology, Purdue University, West Lafayette, IN,[13]Department of Biomedical Sciences, Cornell University College of Veterinary Medicine, Ithaca, NY,[14]Department of Pharmacology, University of Colorado Anschutz Medical Campus, Aurora, CO,[15]Institute of Biochemistry and Molecular Biology, China Medical University, Taichung, Taiwan,[16]Department of Pharmacology and Chemical Biology, University of Pittsburgh School of Medicine, Pittsburgh, PA,[17]Department of Pediatrics and Adolescent Medicine, Mayo Clinic Comprehensive Cancer Center, Mayo Clinic, Rochester, MN,[18]Department of Laboratory Medicine and Pathology, Mayo Clinic Comprehensive Cancer Center, Mayo Clinic, Rochester, MN

Background: Triple-negative breast cancer (TNBC) is the most aggressive subtype of breast cancer and remains difficult to treat due to the absence of targeted therapies. While recent advances in immunotherapy, particularly with immune checkpoint inhibitors (ICIs), have transformed the treatment landscape for many cancers, response rates to ICIs remain low for TNBC, largely due to tumor-intrinsic immune evasion mechanisms.

Objective: We identify and characterize a novel immune evasion pathway in TNBC driven by deregulation of cancer cell-intrinsic protease-activated receptor 1 (PAR1), a thrombin receptor frequently upregulated in aggressive tumors.

Methods and Results: Through integrative bioinformatic analyses, genetic perturbations, xenograft models (immunodeficient and immunocompetent), flow cytometry-based tumor immune profiling, and RNA-seq, we demonstrate that PAR1 activation enhances immune evasion in TNBC. Mechanistically, we show that the paracaspase MALT1 acts as a critical downstream effector of PAR1 signaling and promotes immune escape by driving PD-L1 expression in TNBC cells. Functional assays reveal that genetic depletion of MALT1 or PD-L1 increases TNBC cell susceptibility to T cell-mediated cytotoxicity *in vitro* and significantly suppresses tumor growth *in vivo*. Notably, through knock-in and rescue experiments using a catalytically inactive MALT1 mutant, we reveal that MALT1's scaffolding - rather than protease - function is essential for PD-L1 regulation. Immune cell depletion assays further identify CD4+ T cells, CD8+ T cells, and natural killer (NK) cells as key mediators of the anti-tumor immune response suppressed by the PAR1-MALT1 axis. These findings are supported by human TNBC specimen analyses, where MALT1 expression inversely correlates with T cell activation and positively associates with PD-L1 in PAR1-high, but not PAR1-low, tumors.

Conclusion: Our study reveals immune evasion as a novel mechanism of PAR1-driven breast cancer pathogenesis, mediated by a PAR1/MALT1/PD-L1 signaling cascade. These findings bridge a critical gap by positioning MALT1 at the interface between tumor-intrinsic signaling and the immune microenvironment - two areas of CARMA-BCL10-MALT1 (CBM) complex research that have largely evolved in parallel over the years. Importantly, targeting MALT1 may enhance immunotherapy efficacy in TNBC. Given the availability of MALT1 inhibitors in clinical development, our work supports combining MALT1 inhibition with ICIs or other immune-oncology agents as a promising strategy to overcome immune resistance in TNBC.

#7394 Cytokine-driven CD38$^+$HLA-DR$^+$ CD8$^+$ T cells define a bystander program predicting poor prognosis in hepatocellular carcinoma.

Wei-Ting Ku[1], Chien-Hao Huang[1], Cheng-Heng Wu[1], Wei Teng[1], Po Ting Lin[1], Tsung-Han Wu[2], Jian-He Fang[1], Chan-Keng Yang[3], Yen-Chun Liu[1], Wen-Juei Jeng[1], Yung-Chang Lin[3], Chun-Yen Lin[1]

[1]Department of Gastroenterology-Hepatology, Linkou Chang Gung Memorial Hospital, Taoyuan, Taiwan,[2]Department of General Surgery, Linkou Chanf Gung Memorial Hospital, Taoyuan, Taiwan,[3]Department of Hematology-Oncology, Linkou Chang Gung Memorial Hospital, Taoyuan, Taiwan

Hepatocellular carcinoma (HCC) exhibits poor immunotherapy responses despite CD8$^+$ T cell infiltration, suggesting critical gaps in understanding tumor-reactive versus bystander immunity. While CD8$^+$ T cells can mediate anti-tumor effects through TCR engagement, their effector function may be subverted by immunosuppressive programs. Here, we identified a distinct CD38$^+$HLA-DR$^+$ CD8$^+$ T cell population whose expansion associates with adverse HCC outcomes independent of tumor-specific immunity. We integrated data from ex vivo cytokine (IL-12/15/18)-stimulated CD8$^+$ T cells, bulk RNA-seq and CITE-seq of matched peripheral blood (PB), non-tumor liver (NT), and tumor (T), and TCR clonotype mapping from an HCC cohort. We further projected cytokine-driven versus mutation-associated neoantigen (MANA) signatures onto TCGA-LIHC and integrated these with clinical flow cytometry, serum cytokines, and survival modeling in this cohort. IL-12/15/18 maximally drove bystander CD8$^+$ proliferation and effector function. Bulk RNA-seq distinguished cytokine- from TCR-driven activation, with strong *MKI67* upregulation and lower exhaustion transcripts (*PDCD1, CTLA4, LAG3*) in the former. Co-expression of CD38 and HLA-DR reliably identified these IL-12/15/18-induced bystander-activated CD8$^+$ T cells. Comparative profiling indicated that cytokine-activated CD38$^+$HLA-DR$^+$ CD8$^+$ T cells adopt an NK-like killing program. CITE-seq across PB/NT/T confirmed an in-vivo CD38$^+$HLA-DR$^+$ subset, whose state shifts from circulating bystander-like to tumor-adapted effector; TCR mapping showed extensive PB-tumor clonotype sharing. Gene-set analyses revealed an E2F-dominated proliferation/DNA-repair program in CD38$^+$HLA-DR$^+$ CD8$^+$ T cells ("risk" genes), versus an IRF-driven TCR/IL2-STAT5/IFN-γ effector program in MANA-specific "protective" genes. In TCGA-LIHC, the CD38$^+$HLA-DR$^+$ signature associated with higher *IL12A/IL15/IL18* expression and immunosuppressive signatures (Foxp3^{high} Tregs, MDSCs), indicating a cytokine-rich suppressive milieu. Clinically, peripheral CD38$^+$HLA-DR$^+$ CD8$^+$ T cells were enriched in HCC versus healthy donors and were highest in tumors; concomitant elevation of serum IL-12p70, IL-15, and IL-18 tracked with increased CD38$^+$HLA-DR$^+$ frequencies. Higher peripheral CD38$^+$HLA-DR$^+$ proportions associated with worse survival and remained an independent prognostic factor after adjustment for tumor burden and liver function. Together, cytokine-driven bystander activation generates a transcriptionally and functionally distinct CD38$^+$HLA-DR$^+$ CD8$^+$ population with NK-like features. Unlike MANA-specific T cells linked to favorable outcomes, this cytokine-driven program aligns with proliferative, immunosuppressive networks, leading to poor prognosis and nominating CD38$^+$HLA-DR$^+$ CD8$^+$ T cells as a biomarker and potential therapeutic target in HCC.

#7396 Osteopetrosis-associated transmembrane protein1 modulates CD8⁺ T-cell responses during immunotherapy in hepatocellular carcinoma.

Yixin Chen, Jie Luo, Nanzhou Yu, Yu Zhang, Ming Zhu, Yuma Yang, Lanqi Gong, Xin-Yuan Guan

University of Hong Kong, Hong Kong, Hong Kong

Background: Hepatocellular carcinoma (HCC), the most common form of primary liver cancer, is the third leading cause of cancer-related deaths worldwide. Although atezolizumab plus bevacizumab (Atezo+Beva) has shown some efficacy in the treatment of advanced HCC, its therapeutic benefit remains limited. Systematically identifying these regulatory factors is crucial for recognizing predictive biomarkers and therapeutic targets in HCC.

Methods: An *in vivo* genome-wide CRISPR/Cas9 knockout screen was performed in a murine HCC model treated with anti-programmed death ligand 1 (anti-PD-L1) and anti-vascular endothelial growth factor a (anti-VEGFa) antibodies to identify key regulators of immunotherapy resistance. Osteopetrosis-associated transmembrane protein 1 (OSTM1), an uncharacterised oncogene, was identified as a leading candidate. It was subsequently validated through tumour-cell–specific knockout in both orthotopic and hydrodynamic tail-vein injection (HDTVi) mouse models. Bulk RNA sequencing was performed on tumour tissues from OSTM1-knockout and control groups.

Results: The screening nominated OSTM1 as a key mediator of resistance to anti-PD-L1 and anti-VEGFa. Knockout of OSTM1 in tumour cells improved response to therapy and reduced tumour growth in both orthotopic and HDTVi mice models. Clinically, elevated OSTM1 levels have been demonstrated to be associated with diminished survival rates in patients with HCC who have been treated with Atezo+Beva. Mechanistically, OSTM1 fostered an immunosuppressive microenvironment by impairing CD8⁺ T-cell infiltration and multiple effector functions, including Interferon gamma (IFN-γ) production, and by reducing markers of proliferation and cytotoxicity such as kiel 67 (KI67), granzyme b (GZMB), and Perforin. Moreover, we merged differentially expressed genes from both the orthotopic and HDTVi OSTM1-knockout models consistently revealed PRELI domain containing 2 (PRELID2) as a downstream gene suppressed by OSTM1. Given that PRELID2 is involved in mitochondrial regulation and there is a new link between mitochondrial function and immune cell activity, this finding suggests that OSTM1 may indirectly influence immune cell infiltration and function in the tumor microenvironment through a potential axis.

Conclusion: OSTM1 contributes to poor immunotherapy response in HCC, suggesting its utility as a biomarker and candidate therapeutic target during Atezo+Beva therapy. Future research will investigate how targeting OSTM1 may enhance CD8⁺ T-cell infiltration and function in the tumour microenvironment.

#7397 Intercellular transfer of hepatocellular carcinoma-derived RNAs via tunneling nanotubes educates macrophages and enhances antigen presentation.

Yutao He, Lin Wang, Zhitian Shi

The Second Affiliated Hospital of Kunming Medical University, Kunming, China

Despite significant progress in immunotherapy for hepatocellular carcinoma (HCC), effective therapeutic targets remain limited, highlighting the urgent need for novel immunotherapeutic strategies. Intercellular communication is fundamental for maintaining homeostasis and responding to external stimuli, and while various modes such as ligand-receptor interactions and extracellular vesicle transfer are known, the potential role of tunneling nanotubes (TNTs) in macrophage-HCC cell communication has been unclear. In this study, using peritoneal macrophages from C57BL/6J mice co-cultured with Hepa1-6 HCC cells in vitro, we observed via field emission scanning electron microscopy and confocal microscopy that macrophages and HCC cells form TNTs—slender, straight, and suspended structures with vesicle-like protrusions indicative of cargo transport, composed of F-actin, α-tubulin, and Sec5. By physically inhibiting TNT formation using 0.4 μm transwell inserts and applying single-cell RNA sequencing, we found that in the TNT system, the HCC cell phenotype did not change significantly, but the proportion of MHC II⁺ macrophages greatly increased, and OT-II T cell activation assays further demonstrated enhanced antigen presentation ability in macrophages. Using specific markers for proteins, mitochondria, DNA, and RNA (CellTracker Blue, MitoTracker, Hoechst 34580, Click-iT RNA) and corresponding inhibitors (metformin, DNase, RNase), we obtained direct evidence that HCC cell-derived RNAs are transferred via TNTs to
macrophages, leading to increased antigen presentation capability. Moreover, blocking macrophage RNA sensors with hydroxychloroquine suppressed the TNT-induced increase in MHC II⁺ macrophages, and in an orthotopic HCC mouse model, intratumoral injection of hydroxychloroquine-pretreated macrophages resulted in significantly larger tumor diameters by day 7 compared to the untreated group. In summary, our study reveals that macrophages and HCC cells establish a novel form of intercellular communication—TNTs—through which HCC cells transfer RNAs to macrophages, mediating an increase in MHC II⁺ macrophage proportion and enhanced antigen presentation capacity, thereby suppressing tumor progression. We propose that promoting efficient transfer of HCC-derived RNAs to macrophages by TNTs and enhancing macrophage recognition of these RNAs may provide novel insights and potential therapeutic targets for innovative anti-HCC treatments.

#7398 Senescent regulatory T cells retain potent suppressive function in clear cell renal cell carcinoma.

Temitope Mary Ogunmola[1], Myung-Chul Kim[2], Zeng Jin[1], Umasankar de[3], Lina Cui[4], Guangrong Zheng[4], Ryan Kolb[4], Weizhou Zhang[4]

[1]University of Florida College of Medicine, Gainesville, FL,[2]Kyungpook National University, Daegu, Korea, Republic of,[3]Pharmacy, Sungkyunkwan University (SKKU), Suwon, Korea, Republic of,[4]University of Florida, Gainesville, FL

Clear cell renal cell carcinoma (ccRCC) is an aging-associated malignancy characterized by a highly immunosuppressive, immune-rich tumor microenvironment and variable response to immune checkpoint blockade. Regulatory T cells (Tregs) are dominant orchestrators of immune suppression in ccRCC, yet the functional consequences of cellular senescence in these cells remain unknown and are widely presumed to be impairing. Single-cell RNA sequencing of treatment-naïve human ccRCC tumors revealed a distinct tumor-infiltrating Treg (TI-Treg) subpopulation co-expressing classic senescence markers (p16^INK4a, p21), senescence-associated β-galactosidase activity (SA-β-gal), BCL-xL, and robust immunosuppressive effector programs. Contrary to the prevailing view that senescence attenuates Treg function, we hypothesized that senescent TI-Tregs retain potent suppressive capacity. To functionally characterize these senescent TI-Treg subsets, we used a novel activity-based fluorescent senescence probe that labels SA-β-gal and employed p16-tdTomato reporter mice for the isolation of viable senescent TI-Tregs. Additionally, using an in vitro co-culture system in which naïve Tregs are driven into senescence by ccRCC cell-derived factors, suppression assays demonstrated that senescent Tregs maintain strong inhibitory activity against $CD4^+$ T-cell proliferation, comparable to non-senescent Tregs. Concomitant RNA sequencing confirmed persistence of canonical immunosuppressive pathways and acquisition of a senescence-reinforced suppressive transcriptome. These findings challenge the assumptions that senescence Tregs are dysfunctional in cancer and establish senescent Tregs as critical contributors to immunosuppression in aging-associated ccRCC. This work unravels senescent TI-Tregs as therapeutic targets/vulnerabilities for their selective elimination to restore antitumor immunity.

#7399 Eosinophils promote an immunosuppressive bone marrow microenvironment in multiple myeloma.

Haley du Bois[1], Alberto Chaves[2], Ryan Bishop[1], Dina Atta[3], Jeremy Steven Frieling[1], Karl Nyman[1], Tao Li[1], Mostafa Nasr[4], Conor C. Lynch[1]

[1]Moffitt Cancer Center, Tampa, FL,[2]College of Engineering, University of South Florida, Tampa, FL,[3]H. Lee Moffitt Cancer Center and Research Institute and the University of South Florida, Tampa, FL,[4]Tumor Microenvironment & Metastasis, Moffitt Cancer Center, Tampa, FL

Multiple Myeloma (MM) is an incurable malignancy characterized by the expansion of plasma cells within the bone marrow, leading to structural disruption, osteolytic lesions, and profound immune dysregulation. Although therapeutic advances have improved initial responses, nearly all patients eventually develop relapsed or refractory disease. Understanding the cellular mechanisms that drive tumor immune escape and MM progression remains a critical unmet need, particularly as patients become candidates for cellular therapies (CAR-T) or T-cell engagers (TCEs), which currently achieve a median progression-free survival of only ~1 year. This limited durability is largely attributed to the MM-induced immunosuppressive microenvironment and T-cell exhaustion. Identifying cellular mediators of immunosuppression within the bone marrow is therefore essential to improving the efficacy of immunotherapies.To address this gap in knowledge we leveraged spatial transcriptomics (10x Visium) to interrogate the MM bone marrow microenvironment in an unbiased manner and revealed that eosinophils are enriched within the tumor bed of MM-bearing mice. Eosinophils have not previously been investigated in MM and are underrepresented in scRNA-seq datasets due to their labile nature and high RNAase content. To test the functional role of eosinophils, we used a syngeneic MM model (5TGM1 cells in immunocompetent C57BL/6-KaLwRij mice) that recapitulates key features of human disease. We found that depletion of eosinophils (α-SiglecF antibody; IP) prior to the establishment of MM significantly reduces tumor growth *in vivo*. We then compared KaLwRij versus C57BL/6 RAG2 (B and T cell deficient) mice and observed that eosinophil-mediated MM progression requires an intact adaptive immune system. Using flow cytometry, we determined that eosinophil depletion decreases $CD8^+$ T-cell exhaustion ($TIM\text{-}3^+$ $PD\text{-}1^+$) while enhancing T-cell activation ($CD69^+$ $CD25^+$). *In vitro*, we used primary eosinophils and found that exposure to 5TGM1 MM cells is sufficient to induce eosinophil PD-L1 expression. We also observed that MM-educated eosinophils can induce exhaustion (PD1+ CTLA4+) in pre-activated CD8 T cells.Together, our findings identify eosinophils as previously unrecognized mediators of immunosuppression in the MM bone marrow microenvironment and highlight them as a potential therapeutic target to enhance the durability of existing immunotherapies.

#7400 UHRF1 as an epigenetic driver of tumorigenicity and immune evasion in triple negative breast cancer.

Marina Suarez Pizarro[1], Ahhyun Kim[2], Jaime-Jean De La Torre[1], Xiyu Chen[1], Roberto Tinoco[1], Claudia A. Benavente[1]

[1]University of California Irvine, Irvine, CA,[2]University of California San Diego, San Diego, CA

Ubiquitin-like with PHD and RING Finger Domains 1 (UHRF1) is a multidomain epigenetic regulator essential for the maintenance of DNA methylation and repressive histone marks during cell division. As a downstream effector of the RB/E2F pathway, frequently deregulated in cancer, UHRF1 is aberrantly overexpressed in several malignancies, including triple-negative breast cancer (TNBC). Clinical datasets reveal that high UHRF1expression correlates with poor overall survival in TNBC, underscoring its clinical relevance.Using CRISPR/Cas9-mediated gene editing, we demonstrate that UHRF1 loss significantly impairs TNBC cell tumorigenicity. UHRF1-deficient TNBC cells exhibited reduced clonogenicity, migration, and invasion in vitro. In orthotopic xenograft models, tumors with low UHRF1 expression displayed significantly reduced growth and metastatic potential compared to controls. Transcriptomic profiling revealed that UHRF1 loss led to widespread depression of immune-related genes, suggesting that UHRF1 orchestrates an epigenetically repressed, immune-evasive state. To validate these findings in an immunocompetent context, Uhrf1 knockout (KO) TNBC cell lines were generated from mouse 4T1 cells.Consistent with human models, Uhrf1 KO cells displayed reduced tumorigenic potential and formed significantly smaller tumors in Balb/cJ mice. Importantly, Uhrf1 KO tumors showed increased infiltration of activated cytotoxic T cells (CD8+ CD44hi) and plasmacytoid dendritic cells (pDCs), alongside a higher cytotoxic-to-regulatory T cell ration, indicating an enhanced anti-tumor immune landscape following loss of UHRF1-mediated repression.Together, these results establish UHRF1 as a master epigenetic regulator linking the RB/E2F axis to tumor progression and immune modulation in TNBC. Targeting UHRF1-dependent chromatin regulation may represent a promising strategy to simultaneously suppress tumor growth and overcome immune evasion in aggressive breast cancers.

#7401 STING proton channel function controls T cell survival and tumor immune evasion.

Cong Xing, Kun Song, Zhen Tang, Antonina Araszkiewicz, Nicole Dobbs, Wanwan Huai, Nan Yan

Department of Immunology, University of Texas Southwestern Medical Center, Dallas, TX

Background The cGAS-STING pathway is a central sensor of cytosolic DNA that activates type I interferon (IFN-I) responses. In cancer, cGAS-STING signaling can promote antitumor immunity by enhancing antigen presentation and T cell priming. However, intrinsic STING activation in T cells also triggers T cell death within the tumor microenvironment in an IFN-independent manner, thereby limiting antitumor T cell immunity. The precise mechanisms underlying this dichotomous behavior remain unknown. Recent work has revealed that, beyond its canonical role in IFN induction, STING also acts as a proton channel that mediates IFN-independent processes such as autophagy, lysosome biogenesis, and cell death. Yet the physiological relevance of STING proton channel in vivo—particularly in shaping T cell fate in tumors—has remained unclear due to the lack of genetic models that selectively disrupt it.

Methods We performed targeted mutagenesis of conserved residues in mouse and human STING to identify mutations that selectively abolish proton channel activity while preserving IFN-I signaling. The effects of the mutations on STING trafficking, signaling, autophagy induction, and antiviral responses were evaluated using biochemical assays, imaging, and flow cytometry. To define the physiological role of STING's proton channel in vivo, we generated a knock-in mouse model carrying the channel mutation. T cell death and antitumor function were assessed using syngeneic tumor models.

Results We identified a conserved STING mutation in mouse and human that eliminated proton channel activity and Golgi deacidification while preserving STING trafficking, TBK1-IRF3 activation, and IFN-I induction. Functional assays revealed that the channel mutation abolished STING-mediated autophagy, lysosome biogenesis, and impaired antiviral defense. Splenic T cells from the channel-deficient-STING knock-in mice lost channel-dependent activities and were resistant to STING-induced cell death in vitro. In vivo, STING channel deficiency protected $CD8^+$ T cells from STING-driven cell death in an IFN-independent manner. We further showed that STING channel deficiency enhanced T cell persistence in the tumor microenvironment and significantly reduced tumor growth in the MC38 colon adenocarcinoma model, demonstrating a previously unrecognized role for the STING proton channel in modulating T cell survival and antitumor immunity.

Conclusions We establish the first genetic model that selectively disrupts STING proton channel activity while preserving IFN-I signaling. This model uncovers a critical IFN-independent role for the STING proton channel in driving T cell death and promoting tumor immune evasion. Our findings demonstrate distinct, separable outputs of STING signaling and identify the proton channel activity of STING as a potential therapeutic target to improve T cell-mediated antitumor immunity.

#7402 Tumor-intrinsic miR-21a orchestrates Treg-mediated immunosuppression through Pag-1 repression.

Yufei Deng[1], Wenyan Han[2], Zhaoyang Jia[2], Lujing Wu[2], Na Li[2], Lingling Wang[2], Tariq M. Rana[2], Zhouting Zhu[3]

[1]Cancer and Cell Biology program, Graduate School of Biomedical Science, Baylor College of Medicine, Houston, TX,[2]Department of Cellular and Molecular Medicine, University of California San Diego, La Jolla, CA,[3]Graduate School of Biomedical Sciences, Sanford Burnham Prebys Institute, La Jolla, CA

Immune checkpoint blockades (ICBs) such as anti-PD-1 and anti-CTLA-4 achieve durable responses in some cancers but fail in many patients, highlighting the need for additional immune modulators. Through comparative small RNA profiling of ICB-treated mouse tumors, we identified miR-21a as highly upregulated during combination immunotherapy. To define its tumor-intrinsic function, we generated CRISPR-Cas9 miR-21a knockout (KO) models in melanoma (B16F10, YUMM1.7), colorectal (MC38, CT26), and triple-negative breast cancer (4T1). Despite unchanged in vitro proliferation, miR-21a KO tumors exhibited markedly reduced growth in vivo, even without anti-PD-1 therapy, demonstrating its broad pro-tumorigenic role across cancer types. Single-cell RNA sequencing of MC38 KO tumors revealed reprogramming of regulatory T cells (Tregs) toward a less suppressive phenotype. Mechanistically, Pag-1 (phosphoprotein associated with glycosphingolipid microdomains 1) was identified as a direct target of miR-21a, and its de-repression in KO tumors contributed to enhanced immune activation. These findings uncover miR-21a as a conserved tumor-intrinsic immune regulator that orchestrates Treg-mediated immunosuppression through Pag-1, providing a promising therapeutic axis to improve immunotherapy efficacy.

#7403 Clinical impact of intraepithelial versus stromal immune cells in kidney cancer.

Zhihao Huang[1], Jan H. Muller[1], Ronald Simon[1], Christian Bernreuther[1], Nina Schraps[2], Fiete Gehrisch[2], Natalia Gorbokon[1], Florian Viehweger[1], Frank Jacobsen[1], Guido Sauter[1], Katharina Moller[1], Andreas Lubke[1], Andrea Hinsch[1], Till S. Clauditz[1], Eike C. Burandt[1], Elena Bady[1]

Although renal cell carcinoma (RCC), has become an important target for immune checkpoint therapies, the role of specific immune cell populations and checkpoint expression within its tumor microenvironment remains poorly understood. To learn more on the role of different immune cell populations and their expression of checkpoint proteins, we analyzed a tissue microarray containing 646 RCC samples using a 14-marker multiplex immunohistochemistry approach. Immune cell composition, checkpoint expression, and spatial distribution (stromal vs. intraepithelial) were quantified across 55 spatial immune parameters and evaluated for associations with clinicopathological features. With respect to individual cell types, high densities of FOXP3$^+$ regulatory T-cells (Tregs) were significantly associated with advanced pT stage ($p < 0.001$), whereas other cell types or overall inflammatory infiltration showed no such association. Increased immune infiltration - specifically CD3$^+$ and CD4$^+$ T-cells - correlated with nodal metastasis ($p < 0.05$). Both associations were predominantly driven by stromal rather than intraepithelial immune cells. The expression of several checkpoint proteins in multiple cell types was associated with unfavorable tumor phenotype. Higher PD-1 expression on CD4$^+$ ($p < 0.001$) and CD8$^+$ T-cells ($p = 0.03$) and higher TIM-3 expression on FOXP3$^+$ T-cells ($p = 0.04$) and CD11c$^+$ dendritic cells ($p = 0.04$) were associated with advanced pT stage. High levels of PD-L1 expression on macrophages ($p = 0.008$), CTLA-4 expression on CD4$^+$ ($p = 0.04$) and CD8$^+$ ($p = 0.005$) T-cells, TIM-3 expression on FOXP3$^+$ T-cells ($p = 0.04$), and PD-1 expression on CD4$^+$ T-cells ($p = 0.04$) were linked to nodal metastasis. These immune checkpoint associations were likewise predominantly stromal in nature. It is concluded, that Immune cell composition and checkpoint pathway activity correlate with tumor progression and metastatic behavior in kidney cancer. These clinically relevant interactions arise primarily in the stromal compartment, highlighting the stroma as a key immune regulatory niche within the tumor microenvironment of kidney cancer.

#7404 MTAP loss reshapes the immune and proliferative landscape of pancreatic ductal adenocarcinoma.

Nicolaus F. Debatin[1], **Elena Bady**[2], Jan H. Muller[2], Ronald Simon[2], Christian Bernreuther[2], Nina Schraps[3], Fiete Gehrisch[3], Natalia Gorbokon[2], Florian Viehweger[2], Frank Jacobsen[2], Guido Sauter[2], Katharina Moller[2], Andreas Lubke[2], Andrea Hinsch[2], Till S. Clauditz[2], Eike C. Burandt[2], Zhihao Huang[2]

[1]Department of Otorhinolaryngology, University Hospital Hamburg-Eppendorf, Hamburg, Germany,[2]Institute of Pathology, University Medical Center Hamburg-Eppendorf, Hamburg, Germany,[3]General, Visceral and Thoracic Surgery Department and Clinic, University Medical Center Hamburg-Eppendorf, Hamburg, Germany

S-methyl-5′-thioadenosine phosphorylase (MTAP) is encoded by the MTAP gene located at 9p21 and is often homozygously co-deleted in cancer together with cyclin dependent kinase 2A (CDKN2A). As a result, MTAP deficiency results in a critical vulnerability of cancer cells towards drugs targeting multiple pathways. MTAP deficiency has also been found to predict poor response to immune checkpoint inhibitors. Ductal adenocarcinoma of the pancreas belongs to a group of tumors with a particularly high rate of MTAP deficiencies. To learn more on potential differences in the tumor-microenvironment and proliferative activity between MTAP deficient and proficient cancers, a tissue microarray containing 378 pancreatic ductal adenocarcinomas were analyzed by an 8-marker multiplex immunohistochemistry approach. With respect to innate immune infiltration, MTAP loss was associated with significantly higher densities of $CD68^+$ macrophages compared to MTAP-retained tumors ($p = 0.010$), an effect predominantly driven by stromal $CD68^+PanCK^-$ macrophages ($p = 0.005$). In contrast, total lymphocyte densities ($CD45^+CD68^-PanCK^-$) showed only a mild, non-significant increase in MTAP-loss tumors. However, proliferative lymphocytes within the tumor compartment ($CD45^+CD68^-MCM3^+Ki67^+PanCK^+$) were significantly enriched in MTAP-loss cases ($p = 0.018$), while proliferative intraepithelial lymphocytes lacking Ki67 ($CD45^+CD68^-MCM3^+PanCK^+$) showed a trend toward higher density ($p = 0.052$). Tumor cell proliferative activity was consistently elevated in MTAP-loss tumors, reflected by significantly increased labeling indices in very early ($Ki67^+MCM3^+$; $p = 0.004$), early ($MCM3^+$; $p = 0.007$), and intermediate ($Ki67^+MCM3^+$; $p = 0.030$) cell-cycle phases. Clinicopathological parameters further modulated these associations. Early-stage tumors (pT1-2) displayed higher lymphocyte densities than pT3-4 tumors ($p = 0.025$), particularly in MTAP-loss cases, whereas MTAP-retained tumors showed higher densities of proliferating macrophages in pT1-2 than in pT3-4 lesions ($p < 0.001$). Nodal-negative tumors (pN0) exhibited higher intraepithelial lymphocyte ($p = 0.044$) and proliferative lymphocyte ($p = 0.036$) densities than pN^+ tumors, most prominently in MTAP-retained cases. Similarly, lower-grade tumors (Grade 1-2) demonstrated significantly higher intraepithelial proliferative lymphocyte densities ($p < 0.005$) compared to Grade 3 tumors, again largely restricted to MTAP-retained cancers. It is concluded, that MTAP deficiency impacts the immune microenvironment of pancreatic ductal adenocarcinoma by promoting stromal macrophage accumulation and increased proliferation within immune and tumor compartments.

#7405 Targeting cysteine cathepsins to boost gemcitabine in PDAC.

Nika Mazej Jeram[1], Biljana Mileva Mileva Boshkoska[2], Ales Tomazič[3], Stanislav Gobec[4], Damijan Knez[4], Janko Kos[4], **Milica M. Perisic Nanut**[1]

[1]Biotechnology, Jozef Stefan Institute, Ljubljana, Slovenia,[2]Jozef Stefan Institute, Ljubljana, Slovenia,[3]Dept of Abdominal Surgery, Ljubljana University Medical Centre, Ljubljana, Slovenia,[4]Faculty of Pharmacy, University of Ljubljana, Ljubljana, Slovenia

Cysteine cathepsins are increasingly recognized as important regulators of lysosomal function and autophagy, two processes that help cancer cells survive under treatment-induced stress. In pancreatic ductal adenocarcinoma (PDAC), where gemcitabine is still widely used as first-line chemotherapy, growing evidence indicates that drug-induced autophagy contributes to the development of resistance. In this study, we asked whether autophagy triggered by gemcitabine depends on cysteine cathepsins and whether blocking these proteases can improve gemcitabine's antitumor activity. We focused on cathepsins L, B, and V, major lysosomal proteases with established roles in proteolysis and emerging functions in survival signalling. Using three PDAC cell lines with distinct genetic backgrounds and chemosensitivity (PANC1, Capan2, BxPC3), we treated cells with sublethal LC30 and LC60 concentrations of gemcitabine to trigger stress responses without inducing extensive cell death, thereby allowing us to dissect adaptive autophagy from direct cytotoxicity. Using western blot analysis and immunocytochemistry, we examined expression, processing, and subcellular localization of cathepsins and key autophagy markers, and we quantified autophagic flux and lysosomal function in the presence or absence of selective inhibitors of cathepsins V, L, and B. In parallel, cell viability and apoptosis assays were used to assess treatment responses, and 3D patient-derived organoids and NK cell co-culture systems were employed to validate our findings in more physiologically relevant models. Our results show that gemcitabine-induced autophagy is at least partly dependent on cysteine cathepsin activity, and that pharmacologic inhibition of these enzymes interferes with autophagic processing and makes PDAC cells more sensitive to gemcitabine. We confirmed these findings in patient-derived organoids, where the combination of gemcitabine and cathepsin inhibition reduced tumour cell viability more effectively than either treatment alone. In addition, we tested how this combination affects immune recognition and found that natural killer (NK) cell–mediated killing was increased in gemcitabine- and cathepsin inhibitor–treated tumour cells. Overall, our data identify cathepsins L, B, and V as key modulators of gemcitabine-induced autophagy and immune susceptibility in PDAC and support their further exploration as therapeutic targets to overcome chemoresistance and improve clinical responses.

#7406 FcRn and macropinocytosis promote albumin uptake in tumor-associated macrophages.

Huiyu Hu[1], Xinying Ge[1], Thomas Sc Ng[1], Ralph Weissleder[2], Christopher S. Garris[1], Miles Aaron Miller[3]

[1]Massachusetts General Hospital, Boston, MA,[2]Director, Ctr. for Systems Bio., Massachusetts General Hospital, Boston, MA,[3]Graduate Student, Biological Engineering, Massachusetts General Hospital, Boston, MA

Background: Serum albumin, the most abundant and long-circulating protein in serum, has been successfully used as a drug delivery vehicle for cancer therapy. We have previously demonstrated that albumin accumulates at high levels in tumors, including anaplastic thyroid cancer (ATC), pancreatic cancer and prostate cancer. Oncogene-driven macropinocytosis in cancer cells plays a major role in albumin uptake. However, little is known about the level of albumin uptake and the mechanisms that contribute to its accumulation in tumor-infiltrating immune cells. We hypothesized that tumor-infiltrating immune cells, particularly tumor-associated macrophages (TAMs), efficiently take up albumin via macropinocytosis and FcRn-mediated endocytosis.

Methods: We assessed the *in vivo* uptake of mouse serum albumin by fluorescent reflectance imaging, and cellular albumin uptake by flow cytometry in the immunocompetent ATC TBP3743 ($Braf^{V600E}$ $p53^{-/-}$) in B6129SF1/J mice and melanoma YUMM1.7 ($Braf^{V600E/wt}$ $Pten^{-/-}$ $Cdkn2^{-/-}$) in C57BL/6J mice. We further identified tumor and cellular albumin uptake in neonatal Fc receptor (FcRn)- and caveolin 1 (Cav1)-deficient mice. *In vitro* cellular uptake of serum albumin was quantified in bone marrow-derived macrophages (BMDM) isolated from wildtype, $FcRn^{-/-}$ ($Fcgrt^{-/-}$) and $Cav1^{-/-}$ mice. We further treated BMDM with Na+/H+ exchanger (NHE) inhibitor 5-(N-ethyl-N-isopropyl)amiloride (EIPA) to block macropinocytosis, and fucoidan to block scavenger receptor-mediated endocytosis.

Results: TBP3743 tumors and YUMM1.7 tumors accumulated serum albumin at 9%ID/g (% injected dose per gram tissue) and 11%ID/g, respectively, in mice 24 hrs after intravenous albumin administration. Although TAMs comprised only 4% of cells in ATC tumors and 5% in melanoma tumors, they accumulated a disproportionately high proportion (22% and 19%, respectively) of total fluorescent albumin in the tumor microenvironment. Tumors in $Cav1^{-/-}$ and $FcRn^{-/-}$ mice accumulated only 10% and 29%, respectively, of the albumin uptake observed in wildtype mice. The mean fluorescence intensity of the serum albumin in TAMs in $Cav1^{-/-}$ and $FcRn^{-/-}$ hosts was 78%and 32% of the level in wildtype hosts. *In vitro* $Cav1^{-/-}$ and $FcRn^{-/-}$ BMDM accumulated albumin 107% and 44% of wildtype BMDM. EIPA reduced albumin uptake by 68%, 76% and 84% in wildtype, $Cav1^{-/-}$ and $FcRn^{-/-}$ BMDM. Fucoidan didn't alter albumin uptake in either BMDM.

Conclusion: TAMs exhibit the highest albumin uptake, on a per-cell basis, among cells within ATC and melanoma tumor microenvironments. Importantly, our data show that macropinocytosis and FcRn-mediated endocytosis are responsible for albumin uptake in TAMs. Thus, albumin accumulates efficiently in TAMs via FcRn and macropinocytosis, providing rationale for albumin as a drug delivery vehicle for TAM-targeted therapeutics.

#7407 The NAT10-PBX1 ac4C axis disables MHC Class II antigen presentation to promote immune-cold cholangiocarcinoma.

Kai Luo[1], Yuhan Fang[2], Yinzhao Chen[2], Yuting Zhao[2], Jialin Qu[3], Dong Shang[3], **Caiming Xu**[4], Guixin Zhang[1]

[1]The Second Hospital of Dalian Medical University, Dalian, China,[2]Institute (College) of Integrative Medicine, Dalian Medical University, Dalian, China,[3]The First Affiliated Hospital of Dalian Medical University, Dalian, China,[4]Beckman Research Institute of The City of Hope, Monrovia, CA

Background: Intrahepatic cholangiocarcinoma (ICC) is an aggressive malignancy with poor prognosis, partly driven by an inherently immune-cold tumor microenvironment. N4-acetylcytidine (ac4C) is a conserved RNA modification that regulates RNA stability and translation, and NAT10-mediated ac4C remodeling has been implicated in tumor metastasis and immune cell infiltration. Here, we investigate how ac4C modification promotes ICC progression and immune evasion to identify potential therapeutic vulnerabilities.

Methods: We quantified ac4C modification and NAT10 expression in ICC using publicly available cohorts and clinical tissue samples, and performed single-cell transcriptomic profiling to investigate the impact of NAT10 expression on immune cell infiltration. CRISPR-Cas9-based genetic manipulation of NAT10 in ICC cell lines and mouse models enabled functional interrogation of its contribution to tumor initiation and progression. Mechanistic insights were obtained through an integrated multi-omics and molecular approach, including RNA-seq, acRIP-seq, CUT&Tag, RIP, ChIP, FISH, dual-luciferase reporter assays and RNA stability assays.

Results: We found that both ac4C modification and NAT10 expression were significantly elevated in ICC tissues compared with adjacent non-tumor tissues ($P < 0.05$). Clinically, high NAT10 expression was associated with shorter mOS (17.3 vs 26.7 months; log-rank $P = 0.021$). In cellular models, NAT10 knockdown reduced ac4C levels and ICC cell proliferation (EdU-positive HUCCT1 and RBE cells decreased by 11.7% and 15.6%, respectively) and impaired invasion and metastasis, with Transwell migration reduced by 45.2% and 38.7%. In vivo, NAT10 knockout suppressed tumor growth in murine xenografts; tumor volumes were reduced by 67% ($P < 0.05$). Mechanistically, NAT10 knockdown diminished ac4C modification on PBX1 mRNA, leading to reduced mRNA stability and downregulation of PBX1 protein. PBX1 was identified as a transcriptional repressor of CIITA: NAT10 silencing increased CIITA expression via PBX1 downregulation, subsequently elevating transcript and protein levels of MHC class II genes. Conversely, PBX1 overexpression reversed these effects. Single-cell transcriptomic analysis demonstrated that ICC tumors with high NAT10 expression exhibited reduced infiltration levels of $CD4^+$/$CD8^+$ T cells, which was validated by multiplex immunofluorescence and flow cytometry in murine models.

Conclusion: Our study reveals that NAT10 promotes ICC progression and immune exclusion by ac4C-modifying PBX1 to repress the CIITA-MHC class II pathway, thereby limiting T-cell infiltration. Targeting NAT10 may restore antigen presentation and improve immunotherapy responsiveness in ICC.

#7408 *Brca2*-deficiency promotes increased cGAS-STING pathway activation and an immunosuppressive tumor immune microenvironment in prostate cancer.

Kimberly A. Rickman[1], Irena Q. Sun[2], Ramya Parameswaran[1], Xuxu Gou[2], Morgan E. Diolaiti[2], Harish N. Vasudevan[3], Alan Ashworth[2]

[1]Divsion of Hematology and Oncology, Department of Medicine, University of California, UCSF Helen Diller Family Comprehensive Cancer Ctr., San Francisco, CA,[2]UCSF Helen Diller Family Comprehensive Cancer Ctr., San Francisco, CA,[3]Department of Radiation Oncology and Neurological Surgery, University of California, San Francisco, San Francisco, CA

Background: Combined germline and somatic tumor profiling of advanced metastatic prostate cancer has revealed that ~20% of metastatic tumors have mutations in DNA repair genes such as *BRCA2*. Germline variants in *BRCA2* predispose to aggressive high-risk prostate cancer and more advanced disease at diagnosis. BRCA2 is vital to the repair of DNA double-strand breaks (DSB) by homologous recombination (HR) and deficiency leads to genomic instability which has been shown to drive inflammation via the cGAS-STING pathway. The implications of loss of *BRCA2* function in prostate cancer on immune activation and the tumor microenvironment (TME) are unknown. This represents a significant knowledge gap towards devising therapies that effectively target the immunosuppressive TME of HR-deficient prostate cancer.

Methods: We have engineered an immunocompetent *Brca2*-deficient prostate cancer model with loss of function frame shift (fs) mutations (*Brca2*^{fs}) using CRISPR/Cas9 to address the critical gap in current preclinical models. We validated BRCA2 loss of function and characterized innate immune signaling through the cGAS-STING pathway. We performed spectral flow cytometry and single-cell RNA sequencing (scRNA-seq) on *Brca2*^{WT} and *Brca2*^{fs} tumors from immunocompetent mice to assess the TME. Mice bearing *Brca2*^{fs} tumors were treated with anti-CCR8 monoclonal antibodies with and without anti-PD-1 to test the effectiveness of targeting the CCR8-axis in *Brca2*-deficient prostate tumors.

Results: *Brca2*^{fs} cells show hallmarks of increased DNA damage and cGAS-STING pathway activation compared to *Brca2*^{WT} cells. Analysis of implanted *Brca2*^{fs} tumors demonstrated enrichment of CD4+ T cells and immunosuppressive CCR8+ regulatory T cells (Treg) compared to *Brca2*^{WT} tumors. scRNA-seq of *Brca2*^{fs} tumors implanted in immunocompetent mice showed a significant increase in the interferon expression signature that is likely the result of increased cGAS-STING pathway activation in tumor cells. Additionally, tumor associated macrophages (TAMs) from *Brca2*^{fs} tumors showed a greater immunosuppressive phenotype with an increase in M2 polarization (pro-tumor) and high expression of *Ccl8*, the CCR8 receptor ligand. Combination anti-CCR8 and anti-PD-1 therapy significantly reduced tumor growth in mice bearing *Brca2*^{fs} tumors.

Conclusions: Our analysis has revealed enrichment of immunosuppressive CCR8+ Tregs and *Ccl8*-high expressing TAMs in *Brca2*-deficient but not *Brca2*-proficient prostate cancer tumors. Anti-CCR8 therapy, to deplete CCR8+ Tregs, in combination with anti-PD-1 therapy significantly reduced *Brca2*^{fs} tumor growth in our immunocompetent mouse model. These findings present the exciting possibility of targeting the CCR8-axis in *BRCA2*-deficient prostate tumors to overcome these immunosuppressive mechanisms and enhance activity of tumor-reactive T cells.

#7409 CD4 T cells regulate B and plasma cells to restrict tumor growth in Medulloblastoma.

Tanja Eisemann[1], **Alexander Thomas Wenzel**[2], Jill P. Mesirov[2], Robert Wechsler-Reya[3]

[1]SBP Medical Discovery Institute, La Jolla, CA,[2]Medicine, University of California, San Diego, La Jolla, CA,[3]Neurology, Columbia University, New York, CA

Medulloblastoma is the most common pediatric brain cancer. While survival has improved in recent years, some subtypes, such as “Group 3”, still have a poor prognosis, and due to the lifelong side effects of standard chemotherapy and radiation, new treatments with less toxicity are greatly needed. Further, immunotherapy, while beneficial for other cancers, has not impacted brain cancer treatment, and immune system dynamics and interactions with tumor cells in the brain are poorly understood. We created a mouse model of Group 3 Medulloblastoma in which transformed, orthotopically transplanted neural stem cells form tumors in syngeneic, immune-competent mice, allowing us to study the effects of immune system modulation on Medulloblastoma tumor growth. Though they comprised a relatively small subpopulation of immune cells in the brain, depleting CD4+ T cells resulted in rapid tumor growth and worse survival. An analysis of tumor and control cells profiled with single cell RNA-sequencing (scRNA-seq) showed that, in addition to a loss of CD4+ T cells, B cells and plasma cells were also substantially reduced. In a pseudotemporal model of B cell to plasma cell differentiation, tumor cells from treated mice were absent from differentiated plasma cells and from a plasmablast population. These results indicate that brain-resident CD4+ T cells play a key role in controlling Medulloblastoma tumor growth by regulating B and plasma cells, and that immunotherapy may play a role in future Medulloblastoma treatments.

#7410 Antiviral therapy reverses CMV-induced oncogenic signaling and enhances NK cell cytotoxicity in glioblastoma with associated PD-L1 upregulation and ilmmune modulation.

Vida Tajiknia[1], Wafik S. El-Deiry[2], Connor Purcell[2], Sean E. Lawler[2]

[1]Legorreta Cancer Center,Brown University, Providence, RI,[2]Brown University, Providence, RI

Background: Cytomegalovirus (CMV) has been implicated in glioblastoma (GBM) pathogenesis by promoting stemness, angiogenesis&immune evasion. Clinical trials targeting CMV in GBM have shown preliminary promise, However, the molecular mechanisms remain unclear. We hypothesized that CMV enhances oncogenic signaling and immune resistance in GBM, and that antiviral therapy may reverse these effects and increase susceptibility to immune-mediated cytotoxicity

Materials and Methods: Human GBM cell lines (U251, U87, U138, T98G, LN229) & normal astrocytes were infected with a mCherry-human CMV TB40 strain (MOI 0.5). Phenotypic assays including spheroid & colony formation were performed. A 60-plex cytokine panel and Western blotting were used to evaluate cytokine profiles & signaling pathway activation (IL-6/STAT3, Akt, SOX2, Survivin, p-RB). Co-culture experiments with NK-92mi cells were conducted using CMFDA and Eth-homodimer dyes to assess cytotoxicity.

Results: CMV infection upregulated IL-6/STAT3, SOX2, Survivin, p-AKT, and p-RB, promoting GBM cell proliferation, stemness, and resistance to apoptosis. Infected cells exhibited a tumor-supportive cytokine profile and, after ganciclovir treatment, reduced VEGF and Angiopoietin-2 levels. CMV-infected astrocytes also showed increased oncogenic signaling and colony formation, suggesting a role in early transformation. Ganciclovir partially reversed these effects, shifting cytokine expression toward an immune-permissive state. While NK cells alone failed to lyse GBM cells, ganciclovir-treated, CMV-infected cells showed significantly enhanced NK-mediated cytotoxicity. PD-L1 expression increased after CMV infection and remained elevated post-treatment, indicating immune modulation and potential for checkpoint blockade.

Conclusions: CMV infection reprograms both glioblastoma cells and normal astrocytes toward a more aggressive, immune-evasive phenotype through activation of IL-6/STAT3, p-AKT, SOX2, and angiogenic pathways. Ganciclovir treatment partially reverses these effects, reducing VEGF and Angiopoietin-2 levels, shifting cytokine profiles, and—critically—enhancing NK cell-mediated cytotoxicity. Persistent PD-L1 upregulation following infection suggests a novel immune checkpoint vulnerability, opening the door for synergistic antiviral and immunotherapy approaches. These findings identify CMV not only as a driver of tumor progression but as a tractable therapeutic target in GBM.

#7411 Proteotranscriptomic dissection of breast cancer T cell states identifies CD103+ Tfh-derived cytotoxic CD4+ cells linked to immunotherapy response.

Ghamdan Al-Eryani[1], Sophie van der Leij[2], Etienne Masle-Farquhar[2], Alma Andersson[3], Kate Harvey[2], Sunny Wu[2], Tony Wang[2], John Reeves[2], Cindy Ma[2], Daniel L. Roden[2], Charles M. [1]Broad Institute, Cambridge, MA,[2]Garvan Institute of Medical Research, Darlinghurst, Australia,[3]Science for Life Laboratory, KTH Royal Institute of Technology, Stockholm, Sweden,[4]UNC Lineberger Comprehensive Cancer, Chapel Hill, NC,[5]Stockholm University, Stockholm, Sweden

While cancer immunotherapies have primarily focused on activation of cytotoxic CD8 killing, CD4 T cell activity is also associated with survival and immunotherapeutic response in numerous cancers. We applied integrated single-cell RNA sequencing and multiplexed protein epitope profiling to breast cancer samples to resolve the complexity of immune cell states within the tumor microenvironment. This approach enhanced phenotypic resolution, identifying three distinct states within the T follicular helper (Tfh) cell cluster. A CXCR4high progenitor state gave rise to two differentiated states: an IGFL2high subset resembling conventional Tfh cells and localised to B cell-rich lymphoid aggregates, and a CD103+ subset, exhibiting features of tissue residency, exhaustion, and cytotoxicity, which co-localised with tumor foci. CD103+ Tfh-like cells were found to interact with CXCL10+ macrophages through production of CCL chemokines and CSF1. A higher CD103+ Tfh to IGFL2high Tfh ratio correlated with improved patient survival and enhanced responses to anti-PD1 checkpoint blockade. These findings integrate Tfh and CD4 with cytotoxic potential in breast cancer, offering new insight into anti-tumor immunity and response to checkpoint blockade.

#7412 ANXA1 and MYADM regulate CD4$^+$T cell differentiation and exhaustion in non-small cell lung cancer (NSCLC).

Minyeop Kim[1], Youwon Lee[1], **Seung Yeon Oh**[2], Eun Ji Lee[1], Ji Ae Ko[1], Jihyoung Mun[1], Byoung Chul Cho[1], Mi Ran Yun[1]

[1]Yonsei University College of Medicine, Seoul, Korea, Republic of,[2]Yonsei University College of Medicine SBSI, Seoul, Korea, Republic of

Introduction: CD4$^+$ T cells have primarily been known for their helper function with the tumor microenvironment (TME), and recent studies have demonstrated their ability to directly exert cytotoxic activity against tumor cells. Despite this functional potential, their cytotoxic activity can be compromised by exhaustion within the immunosuppressive TME. Therefore, preventing CD4$^+$ T cell exhaustion may be critical for promoting an anti-tumor immune responses. In this study, we aimed to identify potential target that contribute to CD4$^+$ T cell exhaustion in the TME.

Method: To analyze CD4$^+$ T cell in NSCLC, we performed single-cell RNA sequencing (scRNA-seq) on samples from 83 lung adenocarcinoma (LUAD) patients using the 10X genomic platform. After excluding B cells, lymphoid populations were annotated by canonical marker genes as CD8$^+$ T cells, CD4$^+$ T cells, NK cells, and proliferating cells. Subsequently, CD4$^+$ T cells were re-clustered to identify functional subtypes. Differential gene expression and pathway analyses were than performed to characterize the molecular feature of each cluster.

Result: CD4$^+$ T cells were identified as 10 distinct clusters and further categorized into early, intermediate, and late states based on state-specific marker gene expression. Clusters within the same state showed high transcriptional similarity. Interestingly, the tissue-resident memory (TRM) cluster (intermediate state), and ITGAE$^+$ Tfh-like clusters (late state) exhibited notable transcriptional similarity despite representing different functional states. Pathway enrichment analysis revealed that both clusters share certain effector and adhesion-related features, with TRM displaying stronger effector functions. In contrast, ITGAE$^+$ Tfh-like cells appeared more exhausted. Consistent with this, TRM cells were enriched in normal tissues, whereas ITGAE$^+$ Tfh-like cells predominated in tumors, reflecting activation- versus suppression- associated profiles. Trajectory analysis further revealed differentiation pathway from TRM cells to ITGAE$^+$ Tfh-like T cells. This transition was accompanied by reduced inflammatory response and regulation of T cell proliferation pathways, indicating progression toward an exhausted state. Notably, ANXA1, SMAD7, and MYADM were identified as key genes potentially regulating these processes, with ANXA1 and MYADM especially showing positive correlations with the T cell activation pathway as well as with each other.

Conclusion: These findings suggest a potential differentiation of TRM into ITGAE$^+$ Tfh like T cells, accompanied by transcriptional and functional changes indicative of progressive exhaustion. Such alterations likely contribute to the formation of an immunosuppressive TME. ANXA1 and MYADM play pivotal roles in regulating this process and may serve as potential targets for modulating T cell function in the tissue microenvironment.

#7413 CD36 influences leukemia progression in MLL-AF9-driven AML by modulating the leukemia immune microenvironment.

Yiting Meng, Wenda Zhu, Mateusz Pospiech, Long Huynh, Kalyani Divgi, Yiyu Xiao, Qianqian Peng, Nicholas A. Graham, **Houda Alachkar**

USC - University of Southern California, Los Angeles, CA

CD36, a fatty acid translocase, is recognized as a potential therapeutic target in acute myeloid leukemia (AML), where its overexpression is associated with disease progression, yet its role in leukemogenesis remains to be elucidated. This study investigates the role of CD36 in leukemia initiation using the MLL-AF9 mouse model, where hematopoietic stem progenitor cells (HSPCs) from Cd36 knockout (KO) or wild-type (WT) mice were transduced with MLL-AF9 virus and evaluated for leukemogenic potential through in vitro and in vivo assays, and comprehensive transcriptomic, metabolomic, and immune profiling. Both Cd36KO and Cd36WT HSPCs transformed into leukemic cells, but Cd36 deletion led to a less aggressive leukemia phenotype, with reduced leukemia burden and extended median survival in sublethaly irradiated mice (15 vs. 22 days, P = 0.001). Leukemia engraftment was significantly higher in Cd36WT-MA9 compared with Cd36KO-MA9 transplanted mice in spleen (74.99% vs. 38.67%, P = 0.008) and blood (85.49% vs. 26.84%, P < 0.001) relative to bone marrow (BM). Increased CD4 (13.93% vs. 36.78%, P = 0.025) and CD8 T cells (7.62% vs. 16.06%, P = 0.02) and less CD4CD25 T cells (34.53% vs. 19.24%, P = 0.006) were observed in mice engrafted with Cd36KO-MA9 cells compared with Cd36WT-MA9 mice. qPCR analysis shows elevated *Gzmb* (2.43-fold, P < 0.001), and *Tim3* (5.88-fold, P = 0.002) mRNA expression in Cd36WT-MA9 compared with Cd36KO-MA9 mice, while *Foxp3*, *Lag3*, and *Pd1* showed no significant differences. A more pronounced phenotypic was observed in immunocompetent, non-irradiated mice; Cd36WT-MA9 cells displayed significantly greater leukemia engraftment (BM: 98.58% vs. 0.73%, P < 0.0001; spleen: 64.60% vs. 0.79%, P < 0.001, and blood: 89.08% vs. 10.20%, P = 0.014) compared with Cd36KO-MA9 cells. Cd36KO-MA9 mice showed enhanced immune responses with higher CD3+ (10.87% vs. 37.82%, P < 0.001), CD4 (27.77% vs. 55.19%, P = 0.008), CD8 T cells (17.84% vs. 31.24%, P < 0.001), and NK1.1 cells (14.47% vs. 29.83%, P < 0.0001), but lower CD4CD25 (11.11% vs. 5.55%, P = 0.045), DN-T cells (51.95% vs. 10.46%, P < 0.001), and CD25 DN T cells (17.77% vs. 4.00%, P < 0.001) compared with Cd36WT-MA9 mice, suggesting Cd36 deletion reduces leukemia progression by enhancing anti-leukemic immunity. RNA-sequencing and gene set enrichment analysis indicated enrichment of inflammatory (TNFA, FDR < 0.001) and metabolic pathways (oxidative phosphorylation, FDR < 0.001) in Cd36WT-MA9 cells compared with Cd36KO-MA9 mice. Metabolomic analysis identified 124 metabolites, with Cd36KO-MA9 cells showing a significant increase in asparagine (10.00-fold, unadj P = 0.009) and a decrease in purine (7.68-fold, unadj P < 0.0001) compared with Cd36WT-MA9 cells. While Cd36 deletion does not prevent leukemogenesis, it alters the leukemia immune microenvironment and slows leukemia progression, highlighting its role in modulating leukemia development.

#7417 Immune system state shapes clinical response to CAR-T therapy in mantle cell lymphoma.

Vivian Jiang, Qingsong Cai, Hong Kim, Lei Nie, Chengtai Yu, Yang Liu, Yijing Li, Jovanny Vargas, Michael Wang

UT MD Anderson Cancer Center, Houston, TX

Background:
CAR-T therapy has transformed treatment for relapsed/refractory mantle cell lymphoma (MCL), yet a significant subset of patients relapses or fails to respond. The biological mechanisms driving relapse and refractoriness remain poorly defined, particularly the influence of systemic immune dynamics in shaping CAR-T efficacy.
Methods:
Single-cell RNA sequencing (scRNA-seq) was performed on 56 blood samples from 44 MCL patients treated with brexucabtagene autoleucel, including 24 long-term responders (pre-CAR-T samples), 17 relapsed patients (13 with paired pre-CAR-T and post-relapse samples), and 3 refractory patients (paired pre- and post-CAR-T samples). Integrative computational analysis was conducted to define immune system state (ISS) at single-cell resolution and correlate them with clinical outcomes. An AI-assisted predictive model is under development for clinical application.
Results:
scRNA-seq analysis of 156,852 cells in total revealed three major ISS categories strongly associated with clinical outcomes: immune surveillance (low-risk), immune equilibrium (intermediate-risk), and immune suppression (high-risk), based on cytotoxicity and immunosuppressive profiles. Low-risk patients exhibited robust cytotoxic activity and durable remission, whereas relapse involved evolution to high-risk states characterized by T-cell and NK-cell exhaustion and monocyte enrichment. All refractory patients displayed high-risk ISS prior to CAR-T. Exhaustion scores and checkpoint expression (e.g. TIGIT, LAG3) were elevated in T-cell subsets (CTL, Tex, TCM) and NK cells post-relapse or in refractory cases. These findings establish ISS as a predictive framework for CAR-T response and relapse risk in MCL.
Conclusions:
ISS provides a clinically actionable framework for predicting CAR-T response in MCL by capturing systemic immune dynamics. ISS-guided risk stratification may inform CAR-T optimization and rational combination strategies in MCL.

#7418 Evaluation of chemo-radiation therapy's effect on the senescence status of tumor microenvironment of HNSCC.

Lan Gao[1], Alanna Sun[1], Ruomin Xin[1], Daniel John[1], Wei Tse Li[2], Weg M. Ongkeko[1]

[1]University of California San Diego, San Diego, CA,[2]University of California San Francisco, San Francisco, CA

Background: Cellular senescence is a stress-induced, irreversible arrest of cell proliferation accompanied by a senescence-associated secretory phenotype (SASP), which may impair the immune system's ability to detect and eliminate cancer cells. Chemotherapy and radiation therapy (RT) are standard treatments for head and neck squamous cell carcinoma (HNSCC) by inducing DNA damage. Despite their therapeutic utility, studies have shown that chemotherapy and RT-induced DNA damage may also cause immune cell senescence in other cancers. The effect of these therapies on the senescence state of the tumor microenvironment (TME) in HNSCC has not been elucidated. We hypothesized that chemoradiation treatment results in the immunosenescence of TME in HNSCC. In this study, we analyzed how chemotherapy and radiation therapy influence the senescence-associated gene programs in the TME of HNSCC.

Methods: Bulk immune-targeted RNA sequencing data were obtained from 30 HNSCC patients before and after chemoradiotherapy (GSE193445 from GEO). Single-cell RNA sequencing data were obtained from oral cancer tumor samples of 4 patients with HNSCC (GSE280982) at 3 time points of RT treatment. Filtering, normalization, integration, and clustering were performed on the sequencing data. Generative AI was used for assistance in debugging analyses.

Results: Gene Set Enrichment Analysis (GSEA) of bulk RNA-seq data shows that, post-chemoradiation, myeloid cell activation involved in immune response was upregulated (NES = +1.93, padj = 0.0056), while cytokinesis was downregulated (NES = -2.32, padj = 0.0037). Differential expression analysis identified interferon-stimulated genes ISG15 (log2FC = -1.48, padj = 4.9e-07) and IFI6 (log2FC = -1.46, padj = 2.2e-07) were strongly downregulated after chemoradiation. Additional immune-modulatory genes expression such as IGFBP3 (log2FC = -1.56, padj = 6.0e-08) and GAGE family genes (log2FC = -1.79, padj = 0.022) also decreased post-treatment. Single-cell RNA-Seq data show that in individual cell clusters after RT, in CD8+ T cells, the p53 pathway was upregulated (NES = 1.8, padj = 0.0038) and IL-2/STAT5 signaling pathway was suppressed (NES = -1.8, padj = 0.02). In B cells, TNFα signaling (NES = 2.6, padj = 4.1e-07) and apoptosis pathway (NES = 1.66, padj = 0.03) is upregulated. In Tregs, oxidative phosphorylation (NES = 2.6, padj = 6.1e-05) and MYC signaling is upregulated in Tregs (NES = 3.2, padj = 2.5e-08).

Conclusion: Preliminary data suggest that innate immune pathways in the TME of HNSCC were suppressed after chemoradiation therapy; the proliferative and survival pathways of CD8+ T cells, B cells, and Tregs are altered as a response to RT.

#7419 Comprehensive profiling of primary and metastatic prostate tumors reveals distinct tumor and fibroblast cell states associated with androgen resistance.

Aleksandar Obradovic[1], Kwangmin Yoo[2], Chang Liu[3], Patrick McCann[4], Casey R. Ager[5], Matthew C. Dallos[4], Samir Zaidi[6]

[1]Columbia University, New York, NY,[2]Korea University College of Medicine, Seoul, Korea, Republic of,[3]Columbia University Irving Medical Center,[4]Memorial Sloan Kettering, New York, NY,[5]Mayo Clinic, Phoenix, AZ,[6]Yale University, New Haven, CT

Prostate cancer requires continual escape from immune surveillance, but mechanisms underlying this escape in the transition from androgen sensitivity to resistance and metastasis remain incompletely understood. Androgen-deprivation therapy (ADT)—the treatment backbone—induces tumor cell apoptosis but also remodels the tumor microenvironment (TME). We have assembled a single-cell RNA-seq atlas from >800,000 cells across 68 patients treated at Columbia University and Memorial Sloan Kettering. The resource includes 33 primary tumors (16 treatment-naïve, 17 post-ADT) annotated with time to PSA recurrence, and 31 metastases, including longitudinal pre- and post-ADT data in 14 castration-sensitive tumors (CSPC), 17 castration-resistant tumors (CRPC), and 4 neuroendocrine tumors (NEPC). This dataset spans the spectrum of prostate cancer disease progression.Using ARACNe and VIPER to infer activity of transcriptional regulatory and signaling proteins, we detect conserved cell state programs while minimizing batch effects. Several significant features emerged. Immune infiltration—both lymphoid and myeloid—is significantly higher in CSPC metastases than in primary or CRPC tumors and increases further after ADT. T cells constitute ~15% of cells in primary tumors versus 30% in treatment-naive CSPC (40% post-ADT), falling to 13% in CRPC and <1% in NEPC ($p<1e-32$), consistent with an initially "hot" CSPC TME that progressively excludes T cells with disease progression.Among ~350,000 epithelial/tumor cells, trajectory analysis reveals two differentiation pathways from normal epithelium. Pathway 1—dominant in primary tumors—shows androgen receptor (AR) activity with three sub-phenotypes (T1-T3): T1 exclusive to primary tumors; T2 shared by primary and CSPC; and T3 restricted to CRPC, with high ERG expression, and very strong AR activity. Pathway 2 (clusters T4-T6), present in NEPC and a subset of CRPC, lacks AR activity and displays SOX2, FOXA2, PRKD1. These aggressive states uniformly overexpress AURKA, RET, and TOP2A, suggesting druggable targets for combination therapy.We further define five cancer-associated fibroblast (CAF) subtypes. CAF1-3 track with advanced, treatment-resistant disease—enriched in NEPC versus CRPC (25% vs 18% of CAFs) and in CRPC versus CSPC (18% vs 11%)—while CAF4-5 predominate in primary tumors. We identify druggable proteins and receptor-ligand interactions linking CAF1-3 with T4-T6 tumor states; in vivo perturbations are underway.This atlas provides a resource profiling tumor and immune ecosystems across prostate cancer progression. It highlights MR programs and stromal-tumor-immune interactions that underlie immune evasion and ADT resistance, yielding actionable targets and combination-therapy hypotheses for aggressive disease.

#7420 Mechanistic study of CX3CL1 promoting T cell exhaustion in ESCC via the JAK/STAT3 axis.

Jiayi Huang[1], Beilei Liu[2], Licheng Tan[1], Hongyu Zhou[3], Bowen Yao[1], Shuang Zhang[1], Xin-Yuan Guan[1]

[1]Clinical Oncology, The University of Hong Kong, Hong Kong, Hong Kong,[2]City University of Hong Kong, Hong Kong, Hong Kong,[3]Shanghai Cancer Center, Shanghai, China

Despite the transformative impact of T cell therapy on hematologic cancers, its efficacy in solid tumors such as esophageal squamous cell carcinoma (ESCC) is hampered by T cell exhaustion and poor tumor infiltration. By establishing an immunocompetent ESCC mouse model and conducting single-cell RNA sequencing (scRNA-seq), we have generated a dynamic single-cell atlas of tumor evolution across four distinct phases: immune surveillance, immune equilibrium, immune suppression, and immune escape. We found that CX3CL1 is highly enriched in the immune suppression stage and associated with T cell exhaustion. Further GO analysis demonstrated that CX3CL1$^+$ tumor cells activate the JAK/STAT3 signaling pathway. Both in vitro co-culture systems and in vivo studies showed that treatment with CX3CL1-neutralizing antibodies and JAK inhibitors effectively enhances T cell cytotoxicity and promotes tumor cell apoptosis. Combined therapy with PD-1 inhibitors and CX3CL1-neutralizing antibodies/JAK inhibitors significantly suppressed the growth of subcutaneous ESCC tumors in mice. Our findings indicate that CX3CL1 is a potential therapeutic target in ESCC, and targeting the CX3CL1/JAK/STAT3 axis in combination with immune checkpoint inhibitors may confer potential benefits to ESCC patients.

#7421 Palmatine modulates tumor microenvironment and improves gemcitabine efficacy in PDAC via HOXA10-STAT3 axis suppression.

Pancreatic ductal adenocarcinoma (PDAC) is a highly aggressive malignancy with a five-yearsurvival below 12%. This poor prognosis stems from the late diagnosis, intrinsicchemoresistance, immunosuppression, and a dense desmoplastic stroma that promotes tumorprogression and therapeutic resistance. Current first-line treatments, including gemcitabine/nab-paclitaxel and FOLFIRINOX, are limited due to patient-specific responses, highlighting the needfor broadly effective therapies. Our previous work identified palmatine, a naturally occurringisoquinoline alkaloid, as a potent inhibitor of pancreatic stellate cells (PSCs) and PDAC cellgrowth. In this study, we evaluated the therapeutic efficacy of palmatine in combination withgemcitabine using an orthotopic KPC syngeneic mouse model. Combination treatmentsignificantly reduced tumor volume compared to vehicle or gemcitabine alone. Spatial immuneprofiling and transcriptomics of excised tumors revealed that combination treatment wasassociated with marked reduction in macrophage density, whereas gemcitabine alone displayedclear presence of macrophage-enriched immune neighborhoods not distinctly observed in thecombination group. Additionally, gemcitabine treated tissues exhibited a higher frequency ofneutrophil and dendritic cell-rich aggregates. Notably, the predominant immunemicroenvironment in combination-treated samples demonstrated a reduction in dendritic cellpopulations, alongside modest increases in $CD4^+$ and $CD8^+$ T cell subsets. Integration of bulkRNA-sequencing and spatial transcriptomics identified elevated *Hoxa10* expression andactivation of the IL-6/STAT3 signaling axis in mesenchymal cells. CyTOF analysesdemonstrated increased HOXA10, phosphorylated STAT3, and epithelial-mesenchymaltransition (EMT)-associated proteins in PSCs co-cultured with PANC-1 cells, which wereattenuated by combination treatment. Functional assays, including colony formation, confirmedthat combination therapy was more effective in suppressing clonogenic growth than gemcitabinealone. ChIP-seq data with HOXA10 pull-down from ENCODE project identified STAT3 as apotential HOXA10 target. These findings suggest that palmatine enhances gemcitabine efficacyby mitigating the immunosuppressive tumor microenvironment by targeting the HOXA10-STAT3 axis, and disrupting EMT programs. This combination represents a promising strategy toovercome PDAC chemoresistance and improve therapeutic outcomes. Supported in part throughZachry Endowment and VA Merit Award BX003876 (APK).

#7422 Investigation of acquired resistance to atezolizumab-bevacizumab in hepatocellular carcinoma: Paired tumor microenvironment analysis in a mouse model and human subjects.

Tsung-Hao Liu[1], Li-Chun Lu[1], Yu-Yun Shao[2], Shu-Han Yang[1], Chi-Yuan Yao[1], Chia-Lang Hsu[3], Ying-Chun Shen[4], Ann-Lii A. Cheng[5], Chih-Hung Hsu[1]

[1]National Taiwan University Hospital, Taipei, Taiwan,[2]National Taiwan University, Taipei, Taiwan,[3]Department of Medical Research, National Taiwan University Hospital, Taipei, Taiwan,[4]National Taiwan University Cancer Center (NTUCC), Taipei, Taiwan,[5]Professor, Dept. of Internal Medicine, National Taiwan University Hospital, Taipei, Taiwan

Background Immunotherapy combinations are the standard first-line treatment for advanced hepatocellular carcinoma (HCC), yet most responders eventually develop resistance. No standard second-line therapy exists post-progression, and elucidating mechanisms of acquired resistance is essential to guide future strategies.

Methods Hep53.4 murine HCC cells were subcutaneously implanted into C57BL/6 mice and treated with anti-programmed death-ligand 1 (PD-L1) monoclonal antibody (mAb) (clone 6E11, 5 mg/kg) and anti-vascular endothelial growth factor (VEGF) mAb (clone B20-4.1.1, 5 mg/kg). Tumors were harvested at baseline, responding, and resistant phase (n=6 per group) for analysis using NanoString nCounter® Pan-Cancer IO 360™, bulk RNA sequencing (RNA-seq), and immunohistochemistry (IHC) staining. Paired human tumor samples (n=4) at pre- and post-progression on atezolizumab-bevacizumab were analyzed with RNAseq. Immune cell fractions were estimated using CIBERSORT.

Results NanoString analysis of different response phases - baseline, responding, and resistant phase of murine Hep53.4 HCC tumors treated with anti-PD-L1 and anti-VEGF mAb revealed distinct tumor-immune microenvironment (TME) changes. Total tumor-infiltrating lymphocytes and cytotoxic T cells increased in responding tumors but declined in resistant ones, whereas exhausted and regulatory T cells showed the opposite trend. No significant changes were observed in B cells or dendritic cells. Notably, mast cells decreased in responding tumors but increased significantly in resistant ones. RNA-seq with CIBERSORT and IHC validated immune dynamics, including mast cell fluctuations, in murine tumors. Paired human tumors also showed mast cell enrichment at progression versus baseline.

Conclusion TME profiling of a murine HCC model treated with anti-PD-L1/VEGF mAbs demonstrated a dynamic shift in immune contexture, mirroring the immune response-resistance phenomenon. Mast cells decreased in response but increased upon resistance—a trend confirmed in human samples. Further investigation of the role of mast cells in acquired resistance is warranted.

#7423 Longitudinal tumor microenvironment analysis to predict immunochemotherapy response in salivary duct carcinoma.

Boseung Choi[1], Hyunsu Kim[2], Dongryul Oh[3], Myung-Ju Ahn[2], Hyun Ae Jung[2], Junhun Cho[4], Han-Sin Jeong[5], Se-Hoon Lee[2], Kyungmi Yang[3], Nayeon Choi[5], Eun-hye Kim[5], Sehhoon Park[2]

Background:
Salivary duct carcinoma (SDC) is a rare but highly aggressive malignancy. Although neoadjuvant cytotoxic chemotherapy followed by surgery is standard for locally advanced high-grade SDC, recent studies suggest potential benefit from immune checkpoint inhibitors (ICIs) in the perioperative setting. To characterize treatment-related tumor microenvironment (TME) features, we analyzed paired pre- and post-immunochemotherapy samples from a perioperative clinical trial (ONO-4538-X78).
Method:
A total of 42 tumor samples from 30 SDC patients were analyzed using whole-transcriptome sequencing (WTS). Samples were collected at diagnosis (T1) and at surgery (T2) after three cycles of immunochemotherapy. Patients with <10% residual viable tumor were classified as major pathologic responders (MPR). Samples were classified into T1 non-MPR (n=7), T1 MPR (n=15), T2 non-MPR (n=11), and T2 MPR (n=9), and TMEs were compared across time points and response groups.
Result:
To characterize TME differences, we inferred cell states for each response group. At baseline (T1), non-MPR tumors exhibited a pro-angiogenic TME driven by malignant epithelial cells, consistent with EMT and angiogenesis pathways. In contrast, T1 MPR tumors showed a more immune-infiltrated TME with interferon-related signaling.
From the surgical samples (T2), direct comparison of MPR and non-MPR revealed distinct antitumor immune patterns, indicating robust T- and B-cell-mediated adaptive immunity in MPR, whereas non-MPR displayed chronic inflammatory signatures rather than effective antitumor responses. ssGSEA using core enrichment genes from T- and B-cell-related GOBP pathways confirmed significantly higher immune activation in the T2 MPR group compared with T2 non-MPR (p=0.001).
Longitudinal comparison further highlighted divergent trajectories. In non-MPR tumors, T2 non-MPR tumors were inferred to retain malignant epithelial features with minimal immune cells; DEG analysis supported this with inflammatory responses at T2 and EMT programs at T1.Conversely, T2 MPR tumors were inferred to lose malignant epithelial signatures and show immune activation, consistent with T cell-mediated adaptive responses pathways, whereas T1 MPR displayed epithelial cell-cycle pathways.
Conclusion:
In this study, we found that MPR tumors exhibited a pre-existing interferon-activated tumor microenvironment at baseline, which transitioned into an adaptive immune response after immunochemotherapy. These findings suggest that an interferon-primed TME is a prerequisite for effective post-treatment immune activation and may serve as a predictive biomarker for immunochemotherapy responsiveness.

#7424 Longitudinal and spatial heterogeneity of intra-tumoral TCR repertoires during immunotherapy in metastatic cancers.

Asimina Zoitou[1], Stefan Velculescu[2], Gavin Pereira[3], Archana Balan[3], Mimi Najjar[3], Amna Jamali[3], James R. White[3], Rachel Karchin[3], Noushin Niknafs[3], Hyunseok Kang[4], Patrick M. Forde[3], Christine L. Hann[3], Jody E. Hooper[5], Julie R. Brahmer[3], Valsamo (Elsa) Anagnostou[3]

[1]Department of Biomedical Engineering, Johns Hopkins University, Baltimore, MD,[2]Department of Chemistry, Princeton University, Princeton, NJ,[3]Department of Oncology, Johns Hopkins University, Baltimore, MD,[4]Stanford University, Palo Alto, CA,[5]Department of Pathology, Stanford University, Palo Alto, CA

Introduction: Spatial and temporal heterogeneity and evolution of the T cell receptor (TCR) landscape may influence immunotherapy outcomes. Studying TCR repertoires and their antigen specificities, together with T cell dynamics, could provide important insights into the quality of anti-tumor immune responses and their impact on cancer immunotherapy effectiveness.
Methods: We performed serial and multi-region sampling at critical timepoints (n=52 samples) during the clinical course of 7 patients with metastatic lung and head and neck cancer, who received immunotherapy-containing regimens. To study the TCR repertoire, we performed bulk TCR sequencing of TCR-β CDR3 regions and recovered 69,135 unique productive clones (ImmunoSeq assay, Adaptive Biotechnologies). To determine differential responses to immunotherapy across tumor sites and patients, we evaluated TCR repertoire similarity using Morisita's overlap index (MI) based on clonotype frequency and identity. Next, we clustered TCR clones of similar antigen specificities using GIANA (15,476 clusters) and performed differential T cell abundance analyses at the clone- and cluster-level to assess T cell dynamics. Statistically significant TCR expansions and regressions were determined using Fisher's exact test ($p \leq 0.05$). We used the VDJDB and CEDAR databases to de-orphanize 2,019 TCR clusters, mapping to TCRs with known antigen specificities.
Results: We found significant TCR repertoire heterogeneity between patients ($MI_{between\ patients} \approx 0$), suggesting private TCR landscapes at a patient level. In individual patients, a higher heterogeneity was noted between primary and metastatic sites ($MI_{baseline\text{-}metastatic} = 0.01 - 0.34$) while TCR repertoires of metastatic sites from proximal anatomic locations shared similarities ($MI_{proximal\ metastasis} = 0.47 - 0.96$). Despite the largely private expanded clusters and clones in each patient, similar dynamics were observed in regressing compared to progressing tumors in the context of immunotherapy, while at the autopsy sites, significantly expanded clusters dominated their respective TCR repertoires (14-28% abundance). TCR sequences recognizing viral antigen epitopes, such as GLCTLVAML (EBV), KLGGALQAK (CMV) and RAKFKQLL (EBV) were identified across patients and were part of the significantly expanded clusters in progressing metastatic sites. Several significantly expanding TCR clusters (FDR $p \leq 0.05$) were detected; while these had unmapped antigen specificity, they could recognize tumor antigens and mutation-associated neoantigens relevant for mounting anti-tumor immune responses.
Conclusions: Spatial and temporal TCR repertoire analyses provided a better understanding of the patients' immune landscape during therapy and offered insights that can be used to further dissect the heterogeneity of adaptive immune responses in the context of immunotherapy.

#7425 Histologic and tumor microenvironmental features as prognostic markers in mantle cell lymphoma: A digital pathology-based study.

Hyungjin Kim[1], Sei Na[1], Jeong-Ok Lee[2], Ji Yun Lee[2], Sang-A Kim[2], Jin Ho Paik[1]

[1]Department of Pathology, Seoul National University Bundang Hospital, Seongnam-si, Korea, Republic of,[2]Department of Internal Medicine, Seoul National University Bundang Hospital, Seongnam-si, Korea, Republic of

Mantle cell lymphoma (MCL) is a mature B-cell non-Hodgkin lymphoma with limited histopathologic markers for prognostication. We aimed to characterize histologic pattern and tumor microenvironment (TME) of MCL and evaluate their prognostic significance. A total of 33 cases of MCL (17 excisional biopsy and 16 needle biopsy specimens) were reviewed with pathologic slides and medical records. Survival outcomes including overall survival (OS) and progression-free survival (PFS) were calculated for 28 patients. CD4+, CD8+, and FoxP3+ T-lymphocytes, oncogene p53 expression patterns and Ki-67 proliferative index were assessed by immunohistochemistry, and quantified using Qupath digital image analysis. The median age of patients with MCL (n=33) was 69 years (range, 47-84), and 25 cases were male (75.8%). The majority of cases presented with advanced Ann Arbor stage (III-IV; 24/29, 82.8%). According to the Mantle Cell Lymphoma International Prognostic Index (MIPI), patients were categorized into low-risk (n=14, 46.7%), intermediate-risk (n=9, 30.0%), and high-risk (n=7, 23.3%) groups. Histologic patterns were evaluable in 30 cases, with 16 cases (53.3%) exhibiting a diffuse histologic pattern and 14 cases (46.7%) showing multinodular/mantle zone patterns. The diffuse histologic pattern was significantly associated with inferior PFS (p=0.011) and higher Ki-67 index (>30%, p=0.022). CD3+ cell density, defined as the number of CD3+ cells per square millimeter (cells/mm2), ranged from 576.2/mm2 to 8104.4/mm2 (median=1829.6/mm2). Higher CD3+ cell density was associated with worse OS (p=0.018). CD4+ cell density ranged from 0/mm2 to 6169.7/mm2 (median=508.5/mm2), and lower CD4+ cell density correlated with aberrant p53 expression, higher Ki-67 index and high-risk MIPI (p=0.012, 0.027 and 0.009, respectively). FoxP3+ cell ratio, defined as the proportion of FoxP3+ cells among total nucleated cells, ranged from 0% to 7.62% (median=1.20%). Higher FoxP3+ cell infiltration trended toward better PFS, without reaching statistical significance (p=0.099). Aberrant p53 expression (null/overexpression patterns; 5/33, 15.2%) was correlated with worse OS and PFS (p=0.005 and 0.038, respectively), and also with higher Ki-67 index (p=<0.001). CD4+/CD8+ cell ratio was highly variable (range, 0.01-7.53; median=0.77). In excisional biopsy specimens, cases with bone marrow involvement (4/17, 23.5%) exhibited higher CD4+/CD8+ cell ratio (p=0.028). Histologic pattern, tumor immune microenvironment and p53 expression pattern appear to have prognostic value in MCL. Quantitative assessment of TME using digital pathology methods may provide additional tools for predicting clinical behavior of MCL.

#7427 Genomic analysis of microenvironment composition by breast cancer molecular subtype using an integrated single-cell RNA sequencing cohort.

Constandina (Dina) E. O'Connell[1], Alexander V. Lobanov[2], Kevin R. Mott[3], Daniel P. Hollern[4], Brian C. Miller[5], Charles M. Perou[3]

[1]Department of Pathology and Laboratory Medicine, University of North Carolina at Chapel Hill, Chapel Hill, NC,[2]Department of Genetics, University of North Carolina at Chapel Hill, Chapel Hill, NC,[3]Lineberger Comprehensive Cancer Center, University of North Carolina at Chapel Hill, Chapel Hill, NC,[4]Salk Institute Cancer Center, La Jolla, CA,[5]Division of Oncology, University of North Carolina at Chapel Hill, Chapel Hill, NC

Breast cancer is a heterogeneous disease clinically classified by expression of three key biomarkers, namely ER, PR, and HER2. Between clinical subtypes, the prognostic value of immune cell infiltration varies significantly. In triple-negative/basal-like tumors, tumor infiltrating lymphocytes (TILs) are positively prognostic, while in ER+/luminal tumors, TILs are less prognostic and sometimes associated with worse outcomes. This opposing, subtype-specific behavior suggests different roles for the immune system and is important to understand as immunomodulatory treatments are increasingly tested and utilized across breast cancer subtypes. Previous work using TCGA Breast Cancer bulk RNA sequencing data determined that among highly immune infiltrated tumors, there is significant variation in the immune microenvironment according to PAM50 molecular subtype. High-TIL luminal tumors were enriched for innate immune features, while high-TIL HER2-enriched and basal-like tumors had elevated expression of B and T cell features, respectively. To extend these findings, we curated an integrated dataset of single-cell RNA sequencing from 115 human breast tumors and 17 normal tissue specimens. Samples spanning all clinical subtypes came from four publicly available datasets, and common bioinformatic approaches were used to guide cell type annotation. Cell type frequencies in each sample were calculated and compared by PAM50 subtype. Basal-like tumors were enriched for multiple effector T cell and macrophage populations, while HER2-enriched exhibited increased frequency of IgG-secreting plasma cells. Conversely, luminal A tumors were enriched for various stromal cell types, including fibroblasts, endothelial cells, and perivascular-like cells; interestingly, a macrophage subset expressing the immunosuppressive marker TREM2 was also more abundant in luminal A. We identified highly immune infiltrated tumors from our cohort and compared cell type frequencies in these tumors by PAM50, finding that many baseline differences in microenvironment composition by subtype persist into the immune-high setting. Finally, we analyzed a subset of tumors from Bassez *et al.* (PMID: 33958794) that included T cell expansion data as a proxy for anti-PD1 immunotherapy response. In pre-treatment basal-like tumors, increased proportions of plasma cells, effector T cells, and regulatory T cells were associated with T cell expansion following anti-PD1. Ongoing work is exploring tumor-microenvironment crosstalk using ligand-receptor interaction prediction, with a focus on stromal cells in luminal tumors and B cell-T cell crosstalk in basal-like; for the latter, CD40-CD40LG interaction has emerged in preliminary analysis as a potential target for clinical intervention to improve patient outcomes and is currently being tested in mouse model systems.

#7428 Tumors induce a NR4A1 transcriptional program in dendritic cells leading to immune tolerance and cancer progression.

Michael P. Plebanek, Mahere Rezazade Bazaz, Y-Van Nguyen, Balamayooran Theivanthiran, Brent A. Hanks

UNC Lineberger Comprehensive Cancer Center, Chapel Hill, NC

The induction of effective anti-tumor immune responses is reliant upon efficient dendritic cell (DC)-mediated activation of T cells. Furthermore, DCs are necessary for the efficacy of checkpoint inhibitors. However, during tumor progression, transcriptional reprogramming of DCs occurs leading to the development of dysfunctional DCs which potentiates tolerance within the tumor microenvironment (TME). This process is facilitated by the release of metabolites and soluble factors by tumor cells leading to the activation of transcriptional states that suppress the capacity of DCs to stimulate T cells. In prior studies, we have demonstrated that tumor-derived lactate activates SREBP2 in DCs within the TME, promoting the development of pro-tolerogenic mature regulatory DCs (mregDCs) that can inhibit antigen cross-presentation and facilitate tumor progression. Despite this work, our understanding of the exact transcriptional programs that govern the development of immunotolerant DC states, the mechanisms driving the suppressive functions of DCs, and the importance of intersecting transcription factor networks remain unclear. Insights into these mechanisms hold great promise for the development of novel immunotherapeutic strategies. In this project, we investigated DC regulatory programs that are induced during tumor progression using transgenic mouse models of melanoma. Single cell assay for transposase accessible chromatin sequencing (scATACseq) and transcription factor binding motif analysis of DCs isolated from the tumor-draining lymph nodes (TDLNs) of $BRAF^{V600E}PTEN^{-/-}$ transgenic melanoma mice revealed an enrichment in the accessibility of NR4A1 transcription factor motifs in mregDCs relative to other conventional DC populations. *Nr4a1*-GFP reporter mice show increased expression of *Nr4a1* in cDCs of tumor bearing mice, particularly in mregDCs that have developed from cDC1s. We proceeded to characterize the role of DC-expressed NR4A1 in regulating anti-tumor immunity using both *in vitro* and *in vivo* models. Zbtb46-restricted *Nr4a1* knockout mice show that loss of *Nr4a1* in DCs suppresses tumor progression and promotes $CD8^+$ T cell tumor infiltration. Furthermore, we determined that lactic acid released by tumor cells via monocarboxylate transporter 1 (MCT1) induces DC *Nr4a1* gene expression in a SREBP2-dependent manner. We went on to verify that SREBP2 binds to the *Nr4a1* promoter using ChIP-qPCR. Additional studies found NR4A1 inhibition to suppress DC expression of *Ido1* and *Il4i1* while also inhibiting mregDC-dependent $FoxP3^+$ regulatory T cell development and activation. Collectively, this data demonstrates a previously unknown role for NR4A1 in DCs. Ultimately, we have identified a DC regulatory program centered around a lactate-SREBP2-NR4A1 signaling axis that represents a promising strategy for overcoming anti-PD-1 resistance in treatment refractory tumors.

#7429 Characterizing the spatial tumor microenvironments of therapy-induced and hereditary mismatch-repair-deficient hypermutated gliomas.

Chae Yun (Kate) Cho[1], Bo Zhao[1], Lingqun Ye[1], Ines Martin-Barrio[1], Yonathan Lissanu[2], Kadir C. Akdemir[1]

[1]Department of Neurosurgery, UT MD Anderson Cancer Center, Houston, TX,[2]Department of Thoracic and Cardiovascular Surgery, UT MD Anderson Cancer Center, Houston, TX

Hypermutation in gliomas is observed in some recurrent tumors and hereditary cancer syndromes; however, the extent to which elevated tumor mutational burden influences the tumor microenvironment and contributes to a more aggressive clinical phenotype remains unclear. We comprehensively define the spatial tumor microenvironments in 49 glioma tissues from 32 patients by mapping the transcriptional and spatial organization of 2.3 million single cells *in situ*. Longitudinal analyses reveal an enrichment of proliferating, stem-cell-like malignant states in both therapy-induced and hereditary mismatch-repair (MMR)-deficient hypermutated tumors, consistent with the increased proliferative activity observed with hypermutation. Additionally, despite a shared MMR-deficiency, malignant cells from chemotherapy-induced and hereditary origin hypermutated tumors exhibit distinct transcriptional programs, underscoring the influence of mutation etiology on malignant cell states. Hypermutation at recurrence does not consistently correlate with increased lymphocytic infiltration or response to immune checkpoint blockade, despite clear transcriptional changes. Together, our single-cell spatial maps illustrate how hypermutation of distinct origins drives divergent cellular transcriptional programs and tissue architecture in gliomas, highlighting the role of tumor-immune microenvironment in shaping cancer evolution and informing therapeutic strategies.

#7430 Transcriptional programs of precursor-exhausted CD8$^+$ T cells associated with checkpoint blockade response in NSCLC.

Ethan Daniel Littlestone, Md Roungu Ahmmad, **Xiaoli Zhang**

University of South Florida, Tampa, FL

Immune checkpoint blockade (ICB) benefits only a subset of patients with non-small cell lung cancer (NSCLC), and the immune determinants of major pathologic response (MPR) remain incompletely defined. Recent studies suggest that precursor-exhausted CD8$^+$ T cells (Tpex) are critical for sustaining anti-tumor immunity and generating the effector pool reinvigorated by PD-1 blockade. Although Tpex cells tend to be enriched in responders, the mechanisms by which they contribute to improved therapeutic outcomes remain unclear. In this study, we profiled Tpex transcriptional states in patients with MPR versus non-responders using a publicly available single-cell RNA-sequencing dataset (GSE243013). Differential gene expression analysis revealed that Tpex cells from responders showed upregulated expression of genes involved in metal-ion homeostasis (e.g., MT2A) and adaptive stress tolerance (e.g., MTRNR2L12, SLPI, ITGA6). In contrast, Tpex cells from non-responders preferentially expressed interferon-stimulated and proliferative-stress programs (e.g., TYMS, HMOX1, LINC01480). Pathway enrichment analysis supported these findings, identifying metallothionein-associated processes in responders and enriched cytokine/interferon signaling in non-responders. Cox proportional hazard regression modeling of Tpex differentially expressed genes further demonstrated that MYB proto-oncogene like 2 (MYBL2), which was upregulated in non-responders, was associated with poorer recurrence-free survival (HR ≈ 1.28; 95% CI: 1.12-1.44; adjusted P = 0.016). Additional genes linked to proliferative or interferon-driven dysfunction (RRM2, GEM, PKMYT1, ISG15) showed nominal associations with adverse outcomes, reinforcing the presence of a cycling, IFN-high, shift towards terminal exhaustion in patients who experienced recurrence. Taken together, our study provides important information for linking Tpex functional states to therapeutic response and disease recurrence, with potential implications for refining immunotherapy strategies in NSCLC. Generative AI assistance was used and limited to improving clarity of methodological descriptions.

#7431 Metabolic correlates of measurable residual disease following high dose melphalan conditioning for autologous stem cell transplant in multiple myeloma.

Qualia Hooker, Timothy Triche

Van Andel Institute (VAI), Grand Rapids, MI

In Multiple Myeloma (MM) high dose melphalan (HDM) conditioning followed by autologous stem cell transplant (ASCT) yields durable remissions, but measurable residual disease (MRD) is the strongest predictor of early relapse. Metabolic plasticity of malignant plasma cells and immune subsets are emerging as key determinants of MRD, potentially contributing to differences in transplant outcomes. However, the metabolic programs that separate MRD+ from MRD- patients remain poorly understood. As an alkylator, HDM induces oxidative stress and DNA damage that selects for malignant plasma cells with enhanced metabolic features, while simultaneously impairing reconstitution of protective T-cell subsets. Importantly, germline genetic variation may prime for distinct metabolic fates and immune reconstitution post-ASCT. Thus, we posit that MRD reflects the dual pressure of metabolically adapted MM clones and impaired immune recovery. We performed a retrospective analysis of paired 5′ scRNA-seq and TCR-seq from CD138- bone marrow aspirates of 28 MM patients (progressors n=13 vs. non-progressors n=15 and MRD-positive n=17 vs. MRD-negative n=11) collected pre- and post-ASCT. MRD status was independent of progression. BCR analysis revealed clonal restriction patterns in plasmablasts consistent with biochemical relapse. We used METAflux to analyze B-cell flux activities and determined that MRD is correlated with oxidative stress (OR:1.62, 95% CI:1.06-2.48), while progression was linked to upregulation of oxidative and biosynthetic metabolism pathways. Plasmablasts from MRD+ progressors exhibited enhanced proliferative metabolism signatures consistent with active MM clones. Progression in the T cell compartment was strongly linked to oxidative phosphorylation (OR:2.46, 95% CI:1.44-4.20), while there were no significant MRD associations. However, MRD+ progressors displayed clonal restriction patterns in CD8+ T cells signifying defective immune reconstitution. This study identifies cell-type specific metabolic alterations distinguishing MRD-positive from MRD-negative patients post-ASCT. Enrichment of antioxidant metabolism in B-cells coupled with altered T-cell metabolism and recovery demonstrates dual vulnerabilities: metabolic plasticity and immune deficits. These results identify potential immunometabolic dependencies that may serve as therapeutic targets that can be used to eliminate MRD and improve transplant outcomes.

#7432 Spatial protein profiling of irradiated ER positive breast cancer lymph nodes suggests nodal irradiation modulates immune function.

Stephanie O. Dudzinski[1], **Elizve N. Barrientos-Toro**[2], Benjamin D. Smith[3], Simona F. Shaitelman[4], Sharia Hernandez[2], Alejandra Serrano[2], Khan Khaja[2], Larisa Kostousov[2], Wei Lu[2], Rensi Zacharia[1], Nathan Comeaux[1], Solis M. Luisa[2], Aysegul A. Sahin[4], Maria Gabriela Raso[2], Jing Wang[5], Karen Hoffman[3], Wendy A. Woodward[3]

[1]Radiation Oncology, UT MD Anderson Cancer Center, Houston, TX,[2]Translational Molecular Pathology, UT MD Anderson Cancer Center, Houston, TX,[3]Breast Radiation Oncology, UT MD Anderson Cancer Center, Houston, TX,[4]UT MD Anderson Cancer Center, Houston, TX,[5]Bioinformatics & Comp Biology, UT MD Anderson Cancer Center, Houston, TX

Background: We hypothesized that the systemic benefit of regional nodal irradiation (RNI) for breast cancer derives from immune stimulation in involved nodes. We compared involved lymph nodes (ILN) from patients treated on a prospective trial of pre-operative and post-operative conventional (2 Gy/fx) versus hypofractionated (2.67 Gy/fx) RNI regimens (SAPHIRE NCT02912312).
Methods: 17 patients ILNs with ER+, pN+ BC were Digitally Spatially Profiled with immune-related proteins. 6 post-op cases had no neoadjuvant chemotherapy (NACT) (untreated controls). All others had NACT +/- RNI. 4 pre-operative RNI short-course (RNI_NACT-2.67Gy/fx); 5 pre-op standard RNI (RNI_NACT-2 Gy/fx); 3 post-op RNI after NACT. 5 Regions of Interest (ROIs) were selected and categorized as “Tumor” (PanCK+) or “Immune” (CD45+) compartments. Cell density and spatial analysis were assessed in selected cases. Pearson’s correlations, T-Test and KS tests were performed on protein expression in all ROIs, FDR < 0.1, P value < 0.05. Signals with Log2 differences between -1 and 1 were analyzed using adjusted LMM for patient-level variation, and PCA of ROIs by compartment was performed.
Results: Nearest neighbor analysis shows increasing median distance between tumor and immune cells from untreated, to NACT, and NACT+RNI, and no differences between short and standard pre-operative RNI. Proximity analysis reveals the distribution of CD3+ cells from the CK+ cells changes with increasing therapy, favoring frequency of closer immune cells, although the average number of cells around each CK+ cell diminishes with increasing therapies. CK+ cell density remains stable, suggesting migration rather than cell death. Differences in expression profiles of immune ROIs suggest more immune signaling in pre-op short. Considering all RT, 27 differentially expressed proteins (DEP) were significantly upregulated in Post tumor ROIs. None were significantly downregulated. After correction by LMM, 11 markers were up in Post cases and none downregulated. We found lower expression of SMA , CD4, CD45RO, CD14, CD11c, TIM-3, and B7-H3 in the Pre nodes. No significant DEPs remain in immune ROIs after LMM correction. The first two principal components accounted for 45.8% of the total variance, with PC1 largely separating samples based on Pre RNI. Pre-short vs Pre-standard showed 9 increased and 0 decreased proteins in Pre-short including CD27, Sting, CD40, CD11c, CD25.
Conclusions: Pre-operative radiation contributes to Immune microenvironment remodeling, complementing neoadjuvant chemotherapy in ILN, without altering immune cell density. Different immune signals in irradiated ILN suggest a less immunosuppressive phenotype in RNI, and potential immune activation in Pre-short RNI. Small sample size limits conclusions, immune studies will follow to optimize radiation regimens.

#7433 Dual stromal and tumoral origins of TWEAK drive CSC maintenance in ovarian cancer relapse.

Mikella Robinson, Luisjesus S. Cruz, Carrie House

San Diego State University, San Diego, CA

Serous ovarian cancer (OC) has one of the highest relapse rates of all cancers, with around 85% of patients relapsing following chemotherapy. Evidence suggests that cancer stem-like cells (CSCs) exhibit chemoresistance, sustained self-renewal, and tumor-initiating potential to drive recurrence. We have previously identified TWEAK, an inflammatory cytokine enriched in OC tumors post-chemotherapy, promotes CSC maintenance and survival. Furthermore, antagonism of TWEAK-Fn14 signaling following chemotherapy in a murine relapse model significantly prolonged survival. Because Fn14 is broadly expressed within the tumor microenvironment, we sought to identify sources of TWEAK. Conventionally, TWEAK is secreted by macrophages, and although single cell sequencing of treatment-naive human OC tumors suggests that infiltrating tumor associated macrophages (TAMs) primarily express TWEAK, recent work in relapsing pancreatic cancer identified cancer cells as an additional source of TWEAK. We therefore hypothesized that TWEAK in ovarian cancer is derived from multiple sources, including macrophages and cancer cells. Since macrophages are the predominant immune cell type found in OC tumors, we used an interperitoneal xenograft nude mouse bearing human CAOV4 OC cells to model relapse. Inhibition of macrophage recruitment using a CSF-R1 inhibitor BLZ945 during chemotherapy significantly reduced CSC expression and improved survival, compared to chemotherapy alone. Using a 14-marker flow cytometry panel, we profiled TWEAK expression in relapsed tumors across macrophage (CD45, F4-80, CD11b, LyVe1, CD80, CD206, CD273, MHC Class II), endothelial (CD31), fibroblast (PDGFRa), and CSCs (CD117) populations. We identified 12 distinct cell populations, representing four TAM (CD45+/F4-80+/CD11b+) clusters including two high in MHC Class II, one tissue-resident macrophage (TRM) cluster (CD45+/F4-80+/LyVe1+), two fibroblast clusters, one endothelial cluster, and four cancer cell clusters. Four clusters expressed TWEAK, included one TAM, TRM, fibroblast, and OC cluster. The highest baseline TWEAK expression was in the TAM and TRM clusters; however, these decreased after chemotherapy. The OC cluster, comprised of CSCs, significantly increased (twofold) TWEAK expression following chemotherapy and were BLZ945 responsive, suggesting their chemotherapy-dependent TWEAK expression was also macrophage-dependent. Preliminary in vitro studies of gene expression, imaging, and flow cytometry further indicate that OC-derived TWEAK increases in response to chemotherapy. Future studies will investigate how macrophages regulate OC-derived TWEAK and the contribution of this signaling to relapse. Defining the stromal and tumoral cell sources of TWEAK and delineating their roles in TWEAK-Fn14 mediated tumor recurrence may facilitate development of targeted therapies for patients at risk of recurrence.

#7434 Metabolic dependence of prostate cancer subtypes and its association with the tumor-immune microenvironment.

Tonatiuh A. Gonzalez[1], Anisha Tehim[2], Inna Serganova[1], Roberta Zappasodi[3], Ekta Khurana[3]

[1]Weill Cornell Grad. School of Medical Sci., New York, NY,[2]Cornell University, Ithaca, NY,[3]Weill Cornell Medicine, New York, NY

Due to the rising use of androgen deprivation therapy (ADT) and AR signaling inhibitors (ARSIs), metastatic castration-resistant prostate cancer is expanding and although it is known that its subtypes provide predictive utility, their individual tumor-immune microenvironments are woefully underexplored mechanistically. Careful investigation of these subtypes of mCRPC may provide insights into therapeutic resistance beyond mCRPC. Using both publicly available and in-house single-cell RNA-sequencing and spatial transcriptomics datasets, we have characterized mCRPC cells and their accompanying tumor-immune microenvironment using established marker genes and verified their identity using inferred copy-number variation status. Firstly, we have explored metabolic profiles of the various cell-types in our samples by calculating scores based on transcription of genes involved in metabolic processes. We have performed ligand-receptor pair analysis to predict which cell types are interacting and through which inflammatory and metabolic axes these interactions are occurring. Finally, we have demonstrated interaction feasibility by measuring distance in space via our spatial transcriptomics data. Our preliminary results indicate that these subtypes have significantly different metabolic profiles. Additionally, the immune cells near to these different subtypes have shown differential immunosuppressive programs and metabolic reprogramming. These findings suggest the potential role of tumor metabolic forces in the induction of an immunosuppressive tumor microenvironment and point to a promising utility of metabolic perturbations in mCRPC as a neoadjuvant to enhance response to immune checkpoint blockade (ICB). This work highlights novel lenses in which to analyze tumors in the hopes of suggesting combination therapies that may overcome treatment obstacles.

#7435 Spatial transcriptomics unveils tumor microenvironment changes in murine glioblastoma upon EGFRvIII suppression.

Fabio de Mello[1], David Eisenbarth[1], Feng Guo[1], Yamei Chen[2], Kun Huang[2], Chunhai Hao[3], Y. Alan Wang[1]

[1]Brown Center for Immunotherapy, IU Simon Comprehensive Cancer Center, Indianapolis, IN,[2]Department of Biostatistics & Health Data Science, Indiana University School of Medicine, Indianapolis, IN,[3]Indiana University School of Medicine, Indianapolis, IN

EGFRvIII, a tumor-specific in-frame deletion of exons 2-7 that generates a constitutively active EGFR mutant, drives potent oncogenic signaling in a molecularly defined subset of glioblastoma (GBM) and is implicated in altered invasion, therapy resistance and immune modulation; because EGFRvIII occurs in a substantial fraction of GBMs we asked how suppression of this mutation in established tumors reshapes tumor cells and immune microenvironment in order to reveal treatment opportunities. We used an inducible EGFRvIII GBM mouse model to perform single-cell RNA sequencing and spatial transcriptomics on established with and without transcriptional suppression of EGFRvIII. Findings were validated in spatial transcriptomic profiles from human GBM specimens stratified by EGFR status. EGFRvIII suppression increases infiltration of myeloid and lymphoid cells into core tumor regions, slowing most tumor growth and increasing mouse survival. However, it also promotes invasion and proliferation in EGFRvIII-independent tumor-subpopulations, due to loss of EGFRvIII-driven communication between EGFRvIII-positive and -negative subpopulations. These observations are consistent with prior literature knowledge that direct EGFR inhibition often leads to resistance by vIII-negative populations, and complements it with insights into its mechanistic bases. Overall, our data argue for approaches that exploit the immune microenvironment changes to enhance direct EGFRvIII-targeted strategies for vIII-positive GBM.

#7436 Dissecting the spatial architecture of plasmacytoid urothelial carcinoma to inform therapeutic strategies.

Kathryn H. Gessner, Jeffrey S. Damrauer, Siyao Liu, Mi Zhou, David Corcoran, Sara E. Wobker, William Kim

UNC Lineberger Comprehensive Cancer Center, Chapel Hill, NC

Plasmacytoid urothelial carcinoma (PUC) is an aggressive histologic subtype of bladder cancer that frequently co-exists with conventional urothelial carcinoma (CUC). Patients with PUC have worse response to cisplatin-based neoadjuvant chemotherapy and worse outcomes than patients with CUC, emphasizing the importance of therapeutic development. Elucidating the biology of plasmacytoid urothelial carcinoma (PUC) may reveal therapeutic vulnerabilities specific to this variant. PUC is defined by loss of E-cadherin protein expression, and evidence from other cancer types suggests a complex relationship between E-cadherin signaling, epithelial-to-mesenchymal transition (EMT), tumor microenvironment (TME) remodeling, and responsiveness to immune checkpoint blockade. This study seeks to understand the impact of E-cadherin loss on TME composition in PUC and the crosstalk between cell types. Archival formalin-fixed paraffin embedded tissue samples from patients with urothelial carcinoma who underwent surgical intervention was obtained. Hematoxylin and eosin stains were performed and reviewed by a GU pathologist to identify areas of histology consistent with conventional or plasmacytoid UC. Immunohistochemistry for E-cadherin confirmed loss of E-cadherin in histologic areas of PUC. The 10X Genomics Xenium In Situ assay was utilized to perform spatial transcriptomics. The expression of 477 genes was profiled in situ using a combination of the 10X Genomics Human Multi-Tissue and Cancer panel and a custom 100-gene panel, designed to evaluate the expression of bladder cancer specific genes. Xenium data analysis was performed using a combination of the 10X Genomics Xenium Explorer and R-based packages, including Seurat and HoodScanR. Analysis focused on a mixed histology tumor with histologic areas of PUC and CUC. Within areas of PUC histology, CDH1 (gene encoding E-cadherin) RNA expression was absent, and genes associated with EMT signaling (Snail, vimentin) were upregulated. Relative proportions of immune cells were characterized and PUC-specific cellular neighborhoods were identified. In the area of PUC histology, increased infiltration of macrophages was identified, with different macrophage phenotypes identified between PUC and CUC areas. Using spatial transcriptomics at single cell resolution, this study delineates PUC architecture and demonstrates the interplay between E-cadherin loss, EMT, and macrophage activation. Further characterization of PUC-specific expression and TME components will identify potential therapeutic vulnerabilities.

#7437 Decoding tumor microenvironment heterogeneity through spatial microdomains and network biology to predict immunotherapy outcomes.

A. Burak Tosun[1], Raymond Yan[1], Brian Falkenstein[1], Filippo Pullara[1], S. Chakra Chennubhotla[2]

[1]PredxBio, Inc., Pittsburgh, PA,[2]PredxBio, Inc. / University of Pittsburgh, Pittsburgh, PA

Background: Spatial niches, often quantified through the co-occurrence or colocalization of various cell types, are a common measure of tissue organization in health and disease. However, a clear link is missing between how these spatial measures quantify tissue heterogeneity, how that heterogeneity relates to functional organization within the tissue, and how the functional organization impacts patient outcomes.
Methods: The SpaceIQ™ multi-omics analysis platform addresses tissue heterogeneity through a formal analysis of spatial cell-cell communication from a mutual information perspective. This methodology allows for the virtual dissection of tissue into distinct tumor microenvironment (TME) programs. Inter-patient heterogeneity is then revealed by clustering these spatial TME programs based on their compositional fractions, a process independent of patient outcomes. Crucially, these spatial TME programs serve as highly effective "microdomains" that provide critical local context for cell-to-cell interactions and spatially modulated "network biology," demonstrating strong predictive power for patient outcomes.
Results: We analyzed a publicly available 51-plex immunofluorescence based spatial proteomics data (CODEX platform) from checkpoint-treated cutaneous T-cell lymphoma patients, using spatial analysis based on microdomains and network biology. Our findings demonstrate that: (i) checkpoint expressions alone are poor predictors of patient response; (ii) spatial interactions between different cell types moderately improve prediction accuracy compared to multi-marker phenotypes; and (iii) microdomains significantly outperform non-spatial methods and checkpoint expression-based approaches in predicting response.
Conclusions: Spatial analysis leveraging microdomains and network biology significantly enhance prediction accuracy compared to non-spatial or checkpoint expression-based methods. This advancement enables improved biomarker-driven patient selection and targeted therapy optimization.

#7438 Residual disease on a dish: A practical approach to deep intrinsic resistance in melanoma.

Balraj Singh, Vanessa N. Sarli, Nikil Erry, Anthony Lucci

UT MD Anderson Cancer Center, Houston, TX

Cancer is an evolution like process; wherein genetically abnormal cells persist despite a variety of mechanisms designed to kill such cells. Immune checkpoint and targeted therapies have significantly improved outcomes in melanoma. However, residual disease remaining after treatment, as indicated by a lack of complete pathological response or as detected by other sensitive methods, often evolves further leading to recurrence/metastasis. Thus, there is a need to inhibit or eradicate residual disease to prevent recurrence. In this regard, there is a lack of good preclinical models of residual disease, particularly for testing new therapies that would inhibit quiescent or slow-growing melanoma cells. This is important since opportunistically switching to quiescence and to survive in deep quiescence are major hurdles in improving outcomes. Our approach to a cell culture model of residual disease aligns with the idea that selection pressures are important in enforcing cancer cell quiescence. A selection pressure involving a severe and extended metabolic change, such as a lack of glutamine in culture medium, is an excellent choice for eliminating bulk of sensitive cells that proliferate in artificially rich medium. We subjected two highly metastatic melanoma cell lines, A375SM (representing undifferentiated melanoma with a common BRAF V600E mutation and homozygous CDKN2A deletion) and B16-BL6 (suitable for syngeneic mouse model), to glutamine deficiency in two ways: 1) culture in Gln-free medium (with low 27 μM Gln coming from serum, instead of 4 mM Gln in complete medium), and 2) culture in stringent Gln-free medium (near zero Gln with the use of dialyzed serum in medium). More than 99% cells died in Gln-free medium; rare cells survived in deep quiescence, and then gradually exited quiescence after 4-5 weeks and proliferated indefinitely. We extended the quiescence to 7 weeks and beyond by culturing A375SM cells in stringent Gln-free medium. In these experiments, we replaced medium with fresh medium every 2-3 weeks. Interestingly, if we did not replace medium for an extended period (50 days), we found that A375SM cells did not exit quiescence. We interpret that rare cells surviving in deep quiescence gradually develop an ability to exit quiescence; however, this exit or/and proliferation requires some glutamine. By not changing medium for an extended period, low level of Gln got exhausted, and cells stayed quiescent. We refer to the cells selected in this manner as metabolically adaptable (MA); they are broadly adaptable. The MA cells were much more resistant to paclitaxel than were their parental cell lines. Our results support the feasibility of the approach for modeling residual disease. In conclusion, when we approach deep intrinsic resistance in melanoma with a new perspective (abnormal quiescence besides abnormal proliferation leading to recurrence), new insights and fresh solutions are likely to emerge.

#7439 SPP1 positive macrophage spatial feature correlation to stage III-IV colon cancer multiple pathology parameters.

Shaojun Xu[1], Hongzhe Sun[2], Shuo Han[2], Lin Zhu[2], Yan Wu[1], Qisong Zhang[1], Aiwen Wu[1], Zhifu Zhang[2], Enkai Zhang[3], Na Li[3], **Zhongwu Li**[1]

[1]Key Laboratory of Carcinogenesis and Translational Research (Ministry of Education), Department of Pathology, Peking University Cancer Hospital & Institute, Beijing, China,[2]Beijing PhenoVision Bio Co., ltd, Beijing, China,[3]Hangzhou PhenoVision Bio Co., ltd, Hangzhou, China

Colorectal cancer (CRC) is a frequent gastrointestinal malignancy with high rates of morbidity and mortality. Our previous studies have shown macrophages exhibited significant variations in stage III-IV colon cancer compared to other immune cells. Current study reviewed 11 stage III-IV CRC patient archived FFPE samples carried varied pathology and treatment conditions to investigate macrophage cell features. IHC control, multiplex immunofluorescence (mIF) panel control and the followed mIF staining were conducted using PN 7-Plex Detection Kit (PhenoVision Bio Co., ltd) targeted CD68, CD163, HLA-DR, panCK, SPP1 and PD-L1. The QC procedures made sure each marker from mIF results exhibited identical location and density of the same marker from IHC staining. The 11 staining slides were scanned, tumor areas were lined out by pathologist based on H&E staining from the serial section of each sample. Non-tumor region, tumor parenchyma and tumor stromal region were analyzed using PhenoVision mIF AI analysis system trained from Oncotopix Discovery system (Visiopharm). Positive cell percentage were analyzed in 11 samples. Statistical analysis exhibited correlation of CD68+/SPP1+ co-positive cell to the pathology parameter of PCR/non-PCR (p=0.05), dMMR/pMMR (p=0.024), with or without mucin pool (p=0.022) in tumor stromal region based on binary logistic regression. PD-L1 correlated to dMMR/pMMR in tumor parenchyma region. The co-positive marker did not show correlation to treatment (p=0.069) and necrosis (p=0.313) groups. There was lower CD68+/SPP1+ cell percentage in tumor stromal region in PCR *vs.* non-PCR group (0.46% *vs.* 2.01%, p=0.049) and non-cellular mucin pool group *vs.* with cellular mucin pool group (0.47% vs. 2.39%, p=0.022). Interestingly, there were more CD68+/SPP1+ cells in pMMR *vs.* dMMR group (1.94% *vs.* 0.24%, p=0.027). CD68+/SPP1+ co-positive cell distribution did not exhibit variations among necrosis groups (with *vs.* without necrosis, p=0.254), different treatment strategies (Chemoradiotherapy + Immunotherapy *vs.* Immunotherapy, p=0.066) and pathology stages (III *vs.* IV, p=0.460) in tumor, stromal, and normal region. Besides CD68+/SPP1+ co-positive marker in tumor stromal region, PD-L1 positive cell percentages were higher in tumor parenchyma region of dMMR patient samples compared to pMMR samples (10.09% *vs.* 1.04%, p=0.024). Current study indicates that CD68+/SPP1+ cell spatial feature correlates to PCR stage, MMR stage and mucin pool conditions of stage III-IV colon cancers. Increased sample number may lead to correlation of the marker to treatment variation which suggests the marker distribution characteristics may be utilized for stage III to IV CRCs patients' health monitoring plans.

#7440 Characterization of the metastatic TIME via spatial transcriptomics reveals unique cellular phenotypes post anti-CSF-1R and immuno-chemotherapy.

Diego Armando Pedroza[1], Sung Wook Kang[1], Xiang H.-F. Zhang[1], Bora Lim[2], Hyun-Sung Lee[1], Jeffrey M. Rosen[1]

[1]Baylor College of Medicine, Houston, TX,[2]UT MD Anderson Cancer Center, Houston, TX

Metastatic breast cancer is the main cause of breast cancer related deaths amongst diagnosed women. Current standard-of-care therapies with chemotherapy (CTX) and T cell activating immune checkpoint inhibitors (ICIs) are limited against metastatic disease. Clinical trials have revealed that the tumor immune microenvironments (TIME) with high levels of tumor associated macrophages (TAMs) are associated with ICI treatment failure. We have developed and extensively characterized several genetically engineered mouse models that lack the p53 gene that is most frequently altered in TNBC. These “claudin low” models closely phenocopy the high EMT/TAM subtype observed in patients. We previously showed that TAM ablation by anti-CSF1R mAb therapy coupled with CTX alters the TIME of multiple p53 null GEMMs. This new immunologically “hot” environment displayed elevated levels of IL-17, IL-5 and type II interferon response with residual inflamed- MHCII+ macrophages. A long-term anti-tumor adaptive immune response was accompanied by the infiltration of CD4+/CD8+ T and B cells. However, in lung metastases adjacent micro-metastases persisted and continued to display a “cold” TIME now with elevated PD-L1 indicative of intra-tumoral heterogeneity (ITH). The addition of ICB to SNDX-ms6352 and CTX resulted in sustained loss of TAMs, tumor cells, decreased PD-L1/PD-1 expression and was accompanied by B- and T cell infiltrations in both lung and liver tissues. To understand the differences within the metastatic TIME between single agent and combination treatments, we applied Vizgen’s MERSCOPE platform that encompasses Multiplex Error-Robust Fluorescence in situ Hybridization (MERFISH) technology. Using a unique 500 gene mouse specific immuno-oncology panel we conducted spatial transcriptomics (SP) on lung and liver tissues from mice treated with IgG, SNDX-ms6352, CTX, CTX+SNDX-ms6352+/-aPD1. To study the TIME in depth we have pre-selected up to 8 regions of interest (ROIs) from each tissue, spanning both tumor macro- and micro-metastases, stromal and normal tissue. Collectively across 5 tissues we have been able to capture approximately 2 million single cells that have been identified as cancer, immune and stromal. With uniform manifold approximation and projection (UMAP) uncovering up to 60 cellular phenotypes. Strikingly the combination groups illustrate loss of *Trem2, Arg1, Mcr1*- TAMs with dense accumulation of *Cd19*- B, and activated *Gzma*, *Nkg7*-NK and *Gzmb*, *Cd3g*-T cells compared to single agent treatment. Lymphoid, stromal and CAFs where spatially closer to tumor cells within combination treated neighborhoods. Thus, this novel combination treatment turns immunologically “cold” lung and liver metastases “hot”. We will compare our mouse SP to spatially resolved datasets from the NewSTART Clinical trial (NCT06959537).

#7441 Mapping immune clonotypes in prostate cancer using spatial V(D)J to resolve cancer vaccine response.

Eirik Hoye[1], Karishma Sajnani[2], Reetta Natkin[2], Sini Hakkola[2], Antti Kiviaho[2], Thomas Cecchetto[2], Anthony Mathelier[1], Matti Nykter[2], Wolfgang Lilleby[3], Sini Eerola[2], Alfonso Urbanucci[2], Tapio Visakorpi[2], Heini Kallio[2]

[1]Norwegian Centre for Molecular Biosciences and Medicine (NCMBM), Nordic EMBL Partnership, University of Oslo, Oslo, Norway,[2]Faculty of Medicine and Health Technology, Tampere University and Tampere University Hospital Cancer Center, Tampere, Finland,[3]Department of Oncology, Oslo University Hospital, Oslo, Norway

Purpose: The prostate tumor microenvironment (TME) is immunologically “cold,” limiting the efficacy of immunotherapy. Vaccine-induced immune activation has shown promise, but the spatial distribution and function of immune clones within the TME remain poorly understood.
Methods: We applied spatial V(D)J sequencing, combining long- and short-read analysis of the CDR3 region, to map T and B cell clonotypes alongside gene expression signatures directly in prostate tissue while preserving spatial context. Prior data from a phase 1/2a clinical trial (NCT01784913) of the telomerase (hTERT) peptide vaccine UV1, administered in combination with radiation therapy, used TCRseq to investigate changes in the TME and T cell repertoires before and after vaccination, as well as factors distinguishing the cancer vaccine non-responders from the responders who had a very favourable outcome.
Results: TCRseq data revealed distinct profiles in tissue prior to vaccination that differentiated responders from non-responders. Notably, a T cell receptor motif signature in pre-vaccination tissue was associated with patients who mounted an early immune response to the vaccine. Differences in transcriptomic profiles and T cell repertoires were observed among patients with early, late, or no immune response, linking immune contexture to clinical outcomes.
Conclusions: Our findings provide high-resolution insights into immune-tumor interactions in prostate cancer, demonstrating that specific immune clonotypes underlie effective vaccine responses and may inform future immunotherapy strategies, and that spatial V(D)J analysis can be leveraged to explore the spatial contexture of the prostate cancer tumor microenvironment.

#7442 Cancer chemotherapy-induced accelerated aging is mitigated by activation of the altruistic stem cell defense response.

Lekhika Pathak[1], Partha Jyoti Saikia[1], Upasha Sarmah[2], Rupam Das[3], Chayanika Das[3], Tulika Sarma[3], Bikul Das[1]

[1]Department of Cancer and Stem Cell Biology, KaviKrishna Laboratory, Guwahati, India,[2]Department of Stem Cell and Infectious Diseases, KaviKrishna Laboratory, Guwahati, India,[3]KaviKrishna Telemedicine Care, Sualkuchi, India

Introduction: Accelerated biological aging (ABA) is increasingly recognised as a driver of poor survivorship outcomes in cancer. Conventional aging biomarkers including epigenetic clocks, inflammatory signatures, and frailty scales are descriptive and lack mechanistic specificity. We hypothesized that the Altruistic Stem Cell (ASC) Defense (ASD) response (1) of mesenchymal stem cells (MSCs) represents protective pathway against chemotherapy and tumor-induced ABA at both systemic and tumor-microenvironment (TME) levels.

Methods: A cisplatin-induced accelerated aging mouse model (2) was used to evaluate whether activation of the ASD response mitigates ABA. MCF-7 breast cancer-bearing mice received cisplatin with or without squalene supplementation, a nutritional geroprotectant predicted to enhance ASD activity. ABA was quantified in BM-derived MSCs ($CD271+/CD45^-$ progenitors) and tumor-derived $CD271^+$ MSCs using two canonical aging hallmarks: DNA double-strand breaks (γH2AX) and heterochromatin loss (H3K9Me3). The ASC phenotype of MSCs were measured as described (1). 20 PBMC samples from breast, lung, and ovarian cancer patients (N=10) treated with cisplatin (KaviKrishna HealArt cohort) were analyzed. $CD45^-$ MSCs were isolated and expanded under naïve MSC conditions (3). The ASD response was measured by quantifying the ASC phenotype of the CD45- MSCs (3).

Results: Cisplatin induced a robust accelerated aging phenotype in tumor-bearing mice, characterized by elevated γH2AX and reduced H3K9Me3 in BM-derived MSCs. Notably, TME-derived $CD271^+$ MSCs also exhibited pronounced aging features, indicating that chemotherapy accelerates aging locally within the tumor niche. This aging TME correlated with increased tumor burden in cisplatin-treated mice. Although the ASD was activated, it was not sustained. Squalene supplementation sustained the ASD response, evidenced by the mobilization of ASCs to the circulation. Activation of ASD reversed aging hallmarks in both BM-MSCs and tumor-derived $CD271^+$ MSCs, reducing DNA damage and restoring heterochromatin integrity. Importantly, squalene-treated mice displayed reduced tumor growth, suggesting that preventing aging of the TME suppresses tumor-supportive signals. In the human study, we identified a subset of patients (n=4) with ASD-positive MSCs showed significantly lower γH2AX ($p < 0.05$) and higher H3K9Me3 CTCF values compared to patients (n=6) having ASD-negative MSCs.

Conclusion: Chemotherapy accelerates aging in circulating progenitors and in tumor-derived $CD271^+$ MSCs, creating an aging TME that may foster tumor progression. Clinically, ASD can be quantified from PBMC-derived MSCs and may serve as a biomarker to stratify patients at highest risk of ABA.

#7443 Low hypoxia microenvironment and impaired T cell maturation drive immunotherapy resistance in premenopausal triple negative breast cancer.

Vidya Prasad Nimbalkar[1], Snijesh V P[1], Anupama CE[1], Mahalakshmi S[1], Annie Alexander[1], Rakesh Ramesh[2], Srinath BS[3], Jyothi S. Prabhu[1]

[1]Division of Molecular Medicine, St. John's Research Institute, Bangalore, India,[2]Department of Surgical Oncology, St. John's Medical College and Hospital, Bangalore, India,[3]Department of Surgical Oncology, Sri Shankara Cancer Hospital and Research Centre, Bangalore, India

Purpose: Triple-negative breast cancer (TNBC) often show limited response to immune checkpoint blockade (ICB) therapy, but the mechanisms underlying this resistance remain unclear. This study aimed to investigate how menopausal status associated changes in the tumor microenvironment influence antitumor immunity, particularly T-cell differentiation and activation, and how these factors may contribute to ICB resistance.

Methods: Spatial transcriptomic profiling (NanoString GeoMx DSP) was performed on 19 TNBC tumors across 59 tumor and immune regions. These data were integrated with publicly available bulk RNA seq datasets from METABRIC and SCAN-B, as well as single-cell RNA seq data (GSE176078) including pre and postmenopausal TNBC samples. Gene Set Enrichment Analysis (GSEA) was used to identify pathway-level differences, and T-cell subtypes from the single-cell dataset were assessed for distribution and functional state. Findings were further investigated using immunotherapy response data from the I-SPY2 clinical trial.

Results: Premenopausal TNBC tumors showed consistent downregulation of hypoxia and angiogenesis pathways across both spatial and bulk transcriptomic datasets. These pathways were positively correlated ($r = 0.61$, $p = 5.8e-05$) and associated with reduced immune signaling. Single-cell profiling showed an enrichment of naïve and progenitor-like $CD8^+$ T cells in premenopausal tumors, lacking exhaustion markers such *as PDCD1, TOX,* and *TIGIT*. In contrast, postmenopausal tumors contained more cytotoxic $CD8^+$ T cells expressing granzyme and perforin, indicative of enhanced effector activity. Although premenopausal tumors had higher proportions of M1 macrophages and follicular helper T cells, these populations did not appear to drive effective cytotoxic responses. Importantly, the hypoxia-low transcriptional profile of premenopausal TNBC resembled that of ICB non-responders in the I-SPY2 trial.

Conclusions: Reduced hypoxia-related signaling and impaired maturation of cytotoxic T-cell responses may contribute to weak antitumor immunity and poor ICB efficacy in premenopausal TNBC. These findings point to the need for tailored therapeutic strategies to improve immunotherapy responses in premenopausal TNBC.

#7444 Tetraspanin-driven metabolic plasticity and chemoresistance in disseminated breast cancer cells.

Alexia Brunel*[1], Kristin Decker*[2], Suvendu Das[1], Praveen Neel[1], Asad Ullah[1], Jasmin Meier[2], Ganesan Ramamoorthi[3], Flavio Palma[4], Jacob Torrez[5], Duy Nguyen[5], Marcelo Bonini[4], Brian Czerniecki[3], Thordur Oskarsson[1]

[1]Department of Molecular Oncology, Moffitt Cancer Center, Tampa, FL,[2]Heidelberg Institute for Stem Cell Technology and Experimental Medicine (HI-STEM), Heidelberg, Germany,[3]Department of Breast Oncology, Moffitt Cancer Center, Tampa, FL,[4]Department of Metabolism and Physiology, Moffitt Cancer Center, Tampa, FL,[5]Department of Bioengineering, Moffitt Cancer Center, Tampa, FL

Breast cancer (BC) is a major cause of cancer-related death in women, largely due to metastasis. Therapy-resistant Disseminated Cancer Cells (DCCs) can persist in a dormant state for long periods and serve as latent seeds of relapse. Their ability to evade detection and withstand treatment, such as chemotherapy, underscores the need to better understand DCC biology and to develop strategies to eliminate them before metastatic outgrowth.

Across multiple orthotopic BC mouse models, including cell-line based or patient-derived xenografts, we observed extensive dissemination of tumor cells to multiple organs. DCCs persisted in a quiescent state for weeks yet retained metastatic capacity. Notably, whereas primary tumors and growing lung metastases responded to chemotherapy, DCCs remained resistant, indicating distinct survival mechanisms.

To investigate the molecular properties of DCCs, we isolated the cells from secondary organs by flow cytometry and subjected them to transcriptomic profiling to uncover mechanisms underlying their biological function and resistance to chemotherapeutics. DCCs were analyzed across multiple secondary sites, including bone, kidney, and pancreas. This revealed specific differences between DCCs and mammary tumor cells, as well as remarkably conserved adaptive programs among DCCs from distinct organs, highlighting common survival strategies that may represent shared therapeutic targets. Gene signature analysis identified various cellular functions altered in DCCs. We observed reduced apoptotic responses, accompanied by enhanced DNA repair and striking metabolic rewiring as hallmarks of DCC persistence. Specifically, DCCs repressed glycolysis while inducing oxidative phosphorylation and fatty acid metabolism to establish a bioenergetic state that supports survival under therapeutic stress.

Among the most highly upregulated genes in DCCs, we identified TSPAN8 and TSPAN1, which emerged as essential mediators of DCC metabolic adaptation and chemoresistance. These two members of the tetraspanin superfamily are transmembrane proteins that lack intrinsic enzymatic activity but organize membrane microdomains via interactions with partner receptors and signaling molecules. Their expression was strongly correlated in DCCs, suggesting a shared regulatory mechanism. Functional studies *in vitro* and *in vivo* demonstrated that ectopic TSPAN1/8 expression promotes metabolic adaptation and chemoresistance, whereas their knockdown disrupts the rewired metabolic network and sensitizes DCCs to chemotherapy.

Collectively, our study establishes TSPAN1 and TSPAN8 as mediators of metabolic plasticity and chemoresistance in dormant DCCs. These findings provide a rationale to investigate combinatorial therapies integrating metabolic inhibitors with standard-of-care chemotherapy to eradicate dormant DCCs, the root drivers of metastatic recurrence.

#7445 Effector regulatory T-cell infiltration, ARID1A status, and *Ex Vivo* anti-PD-1 response in ovarian clear cell carcinoma: Insights from a comparative high-grade serous ovarian cancer cohort.

Junsik Park[1], Eun Kyung Kim[2], Jung Chul Kim[1], Nari Kim[3], JooHyang Lee[3], Sunghoon Kim[3], Sang Wun Kim[3], Yong Jae Lee[3], Jung-Yun Lee[3]

[1]Department of Obstetrics and Gynecology, Soonchunhyang University Hospital Bucheon, Bucheon, Korea, Republic of,[2]Department of Pathology, National Health Insurance Service Ilsan Hosp., Goyang, Korea, Republic of,[3]Department of Obstetrics and Gynecology, Yonsei University College of Medicine, Seoul, Korea, Republic of

Recent trials suggest potential benefit of immune checkpoint blockade (ICB) in ovarian clear cell carcinoma (OCCC), but the immune contexture and biomarkers that modulate ICB response remain poorly understood. We characterized tumor-infiltrating lymphocytes (TILs) in OCCC and explored associations with clinical features, ex vivo anti-PD-1-based ICB responsiveness, and biomarker expression. Peripheral blood mononuclear cells (PBMCs) and TILs were obtained from patients with OCCC (n=55). Immune checkpoint receptor and transcription factor expression were analyzed by multicolor flow cytometry. TILs were stimulated ex vivo with anti-CD3 plus anti-PD-1 with or without anti-CTLA-4, and proliferation was assessed by T-cell division. HER2, ARID1A, and L1CAM expression were evaluated by immunohistochemistry on tumor tissue. Twenty of 55 patients had stage III/IV or recurrent disease, and most tumors were grade 3. Among evaluable tumors, 9/38 exhibited HER2 2+/3+, 24/41 showed loss of ARID1A, and 29/41 showed high L1CAM expression. In flow cytometric analysis, CD8 T cells and regulatory T cells (Tregs) were enriched in tumors compared with peripheral blood. $CD8^+$ TILs showed a profoundly exhausted phenotype, with higher PD-1, CTLA-4, and TOX and lower TCF-1 expression than $CD8^+$ T cells in blood, while tumor-reactive $CD39^+CD103^+$ CD8 TILs were also more enriched. Tregs exhibited highly suppressive features with increased immune checkpoint receptors, CD39, and CCR8, and effector Tregs ($CD45RA^-$FoxP3high) were more abundant in stage III/IV or recurrent tumors than in stage I/II disease. In ex vivo assays, CD8 TILs from a subset of patients showed robust anti-PD-1-induced proliferation, and effector Treg frequency was inversely associated with anti-PD-1-induced CD8 T-cell reinvigoration. ARID1A-deficient tumors exhibited significantly lower effector Treg infiltration, whereas HER2 and L1CAM expression were not clearly associated with T-cell phenotypes or anti-PD-1 response. When compared with our previously reported cohort of advanced-stage high-grade serous ovarian cancer (HGSOC), the percentage of tumor-infiltrating Tregs, particularly $4\text{-}1BB^+$ Tregs, was lower in advanced/recurrent OCCC than in HGSOC. In conclusion, OCCC exhibits profound exhaustion of CD8 TILs alongside infiltration of highly suppressive Tregs. Effector Treg frequency was inversely associated with anti-PD-1-induced CD8 T-cell reinvigoration, and ARID1A loss may be linked to a tumor microenvironment more permissive to anti-PD-1-based immune checkpoint blockade. This hypothesis may help explain the high ICB response rate reported in OCCC compared with HGSOC and requires confirmation in larger clinical cohorts and mechanistic studies elucidating how ARID1A loss in OCCC reprograms the tumor immune microenvironment.

#7446 Inflammation and chemotherapy induce immune mimicry in PDAC and promote crosstalk between fibroblasts and tumor cells.

Carson Cable[1], Qinlin Jiang[2], Kourosh Kouhmareh[3], Richard L. Klemke[4], Ryan Matthew Shepard[5], Alejandro D. Campos[4], Sara M. Weis[5], David A. Cheresh[5]

[1]Pathology, University of California, San Diego, La Jolla, CA,[2]University of California, San Diego, La Jolla, CA,[3]UC San Diego School of Medicine, La Jolla, CA,[4]UCSD Moores Cancer Center, La Jolla, CA,[5]UCSD Medical Ctr., San Diego, CA

Pancreatic ductal adenocarcinoma (PDAC) is a leading cause of cancer-related mortality partly due to refractory responses to chemotherapeutics. Factors secreted by immune cells and cancer-associated fibroblasts (CAFs) like interleukin (IL)-6 family members can activate Signal transducer and activator of transcription 3 (STAT3) in PDAC cells, driving drug resistance. We developed a STAT3 effector gene signature induced by inflammatory mediators that strongly correlates with poor relapse-free survival in PDAC. One of the signature genes, *IL7R*, encoding interleukin-7 receptor alpha (IL7Rα), is commonly associated with lymphoid cells. Importantly, we observed *IL7R* enrichment in tumor cells from chemotherapy-treated patients compared to treatment-naïve patients that correlates with an increased epithelial-to-mesenchymal transition (EMT) score. Furthermore, we identified high expression of the IL7Rα ligand thymic stromal lymphopoietin (TSLP) primarily restricted to CAFs from PDAC patients. PDAC cells exposed to an IL-6 family member gained IL7Rα expression leading to hyperactivation of the tumor-promoting transcription factors, STAT1, STAT3, and STAT5 in response to TSLP. We contend that *IL7R* expression represents an “immune mimicry” response leveraged by tumor cells to gain stress tolerance, drug resistance, and EMT through crosstalk with CAFs, leading to an aggressive cancer phenotype.

Poster Session

#7450 TGF-β heterogeneity in cancer cells might be associated with tumor progression in gastric cancer.

Daiki Imanishi[1], Masakazu Yashiro[1], Hinano Nishikubo[1], Tomoya Sano[1], Dongheng Ma[1], Canfeng Fan[1], Takashi Sakuma[1], Yurie Yamamoto[1], Kiyoshi Maeda[2]

[1]Department of Molecular Oncology and Therapeutics, Osaka Metropolitan Univ. Graduate School of Med., Osaka, Japan,[2]Department of Gastroenterological Surgery, Osaka Metropolitan Univ. Graduate School of Med., Osaka, Japan

Background: It has been reported that tumor heterogeneity is frequently found in various types of human carcinomas. Tumor heterogeneity may exist in not only human tumors but also cancer cell lines. Analysis of tumor heterogeneity might be useful to understand the mechanisms of tumor development. In this study, we examined the heterogeneity of gastric cancer using a gastric cancer cell line and human gastric tumor samples.
Materials and Methods: A gastric cancer cell line OCUM-12 and a total of 530 gastric cancers were used in this study. The heterogeneity of cancer cell line was examined after subcloning of OCUM-12 cells using limiting dilution. mRNA expression levels of *TGF-β1* and *TGF-β2* in each subclone cell were examined by RT-PCR. Next, we performed immunohistochemical study of TGF-β using 530 gastric cancers specimens. TGF-β expression was evaluated both at cancer cells and at cancer-associated fibroblasts (CAFs). Immunohistochemical staining level was evaluated by not only manual but also using digital QuPath. Correlation between TGF-β1 expression and clinicopathological features were analyzed.
Results: mRNA expression levels of *TGF-β1* and *TGF-β2* was different among 12 OCUM-12 subclones. Immunohistochemical staining level of TGF-β was also different among tumor specimens. Five-year recurrence-free survival rate of high TGF-β expression group tended to be a poor prognosis ($p = 0.0913$) in Stage 2, while the survival rate showed a better prognosis in Stage 3.
Conclusion: TGF-β heterogeneity in cancer cells might be associated with tumor progression in gastric cancer.

#7451 Integrated bulk and single cell transcriptomics reveal *PARL* as a mitochondrial regulator associated with immunometabolic reprogramming and favorable prognosis in lung squamous cell carcinoma.

Jaber H. Jaradat[1], Zaid Alwarawrah[2], Laith Alomari[3], Anwaar Saeed[4], Azhar Saeed[5]

[1]Faculty of Medicine, Mutah University, Al-Karak, Jordan,[2]Griffin Hospital, Derby, CT,[3]Department of Medicine, Jefferson Einstein Philadelphia Hospital, Philadelphia, PA,[4]UPMC Hillman Cancer Center, Pittsburgh, PA,[5]University of Vermont Medical Center, Colchester, VT

Background: Lung squamous cell carcinoma (LUSC) lacks reliable prognostic biomarkers. Given the growing recognition of mitochondrial dysfunction as a driver of cancer metabolism and immune regulation, we investigated the mitochondrial protease presenilin-associated rhomboid-like (PARL) gene expression as a potential modulator of tumor progression and immune microenvironment in LUSC.
Methods: TCGA-LUSC bulk RNA-seq was analyzed with DESeq2 to evaluate PARL differential expression. Univariate and multivariate Cox models were performed to evaluate association with overall survival (OS). Limma was used to assess pathway-level differences using Hallmark MSigDB gene sets. Functional enrichment was performed using GO and GSEA. CIBERSORTx was utilized to assess immune infiltration. Single-cell analysis of the 10x Genomics NSCLC Tumor 1 dataset included quality control, normalization, clustering, automated annotation (SingleR), and pseudotime trajectory analysis to examine lineage-specific PARL patterns.
Results: Low *PARL* expression correlated with shorter OS (median OS: 39 vs. 61 months; log-rank $p = 0.008$) and remained an independent favorable prognostic factor (HR = 0.75, $p = 0.003$). The survival benefit of high *PARL* expression persisted across early and late disease stages. Functional enrichment analysis indicated that high-*PARL* tumors were enriched for mitochondrial organization, oxidative phosphorylation, and apoptotic regulation, whereas *PARL*-low tumors favored proliferative and cell cycle pathways. Key pathways downregulated in high-*PARL* tumors included KRAS signaling, complement, IL6/JAK/STAT3, and TGF-β signaling, while DNA repair, MYC targets, Oxidative Phosphorylation, and G2M checkpoint pathways were upregulated, suggesting enhanced metabolic activity and cell cycle regulation. Furthermore, Pearson's chi-squared test showed a significant association between *PARL* expression and TP53 mutations ($\chi^2 = 8.04$, $p = 0.0046$). CIBERSORTx analysis revealed that *PARL*-high tumors exhibited lower infiltration of immunosuppressive and pro-inflammatory cells, including Tregs, M2 macrophages, and neutrophils suggesting a role for *PARL* in shaping a less suppressive immune microenvironment. Single-cell trajectory analysis revealed *PARL* expression peaked in progenitor and stromal populations, implying an early role in mitochondrial quality control and immune differentiation, influencing tumor-immune dynamics and clinical outcomes.
Conclusions: *PARL* emerges as a candidate gene expression-based biomarker associated with mitochondrial homeostasis, reduced immunosuppression and favorable prognosis in LUSC. These findings highlight a potential role of *PARL* in immune metabolic adaptation and support further validation to establish its clinical relevance.

#7452 Claudin 18.2 targeted proapoptotic peptide for early pancreatic diagnosis and tumor-target killing.

Poongkavithai Vadevoo Sri Murugan[1], Gunassekaran Gowri Rangaswamy[2], Byungheon Lee[1]

[1]Kyungpook National University, Daegu, Korea, Republic of,[2]Biochemistry and Cell Biology, Kyungpook National University, Daegu, Korea, Republic of

Pancreatic adenocarcinoma is a lethal condition with a rising incidence, predicted to become the second leading cause of cancer-related deaths worldwide by 2030. One major hurdle in the treatment of this disease is the predominantly elderly patient population and clinically silent and aggressive nature. Early detection of pancreatic neoplasms and novel treatment for highly aggressive and metastatic conditions is of great need in pancreatic tumor therapy.Claudins are crucial components of tight junctions. They are transmembrane proteins and are the keeper of the “fence function”. Claudins in tumor are like the fall of the soldiers entrusted to protect the gate. Claudin 18.2 is a member of the claudin family, commonly expressed in multiple cancers, including Gastric cancer and Pancreatic cancer. Claudin-18.2 expression on cancer cells is increased and exposed on surface of the cells. The development of malignant tumors leads to the disruption of tight junctions, exposing the Claudin 18.2 epitope on the surface of tumor cells as a specific target. Also, claudin 18.2 is transcriptionally upregulated with the binding of cyclic AMP-responsive element binding protein to the methylated CLDN18.2 promoter region. Claudin 18.2 is considered an early stage marker of pancreatic carcinogenesis. Claudin 18.2 is considered a ‘dark horse’ in anti-tumor therapy. Thus, Claudin 18.2 could be a good “target” for early detection and target-specific treatment of pancreatic tumor.Construction of phage peptide library and bio panning for claudin18.2-binding peptides using claudin18.2 overexpressing cells : After five rounds of screening, phage titers that bind to transfected cells were enriched higher-fold compared to phage titers isolated in the first round. 2 phage clones displaying peptides that selectively bound to transfected cells were chosen and sequenced for further study. The two peptides showed selective binding to claudin 18.2 expressing cells as analyzed by Immunofluorescence. Pull down assay further confirmed selective binding of peptide to claudin 18.2. Bioaccumulation study in vivo showed significant accumulation of peptide in tumor tissue. Treatment of KPC transgenic pancreatic tumor bearing mice with claudin 18.2 peptide conjugated to proapoptotic peptide enhanced the survival of the mice. In summary, Claudin 18.2 peptide can specifically target the tumor cells and conjugation with proapoptotic peptide can induce tumor targeted apoptosis with increased survival in pancreatic tumor bearing mice. Claudin 18.2 targeted tumor killing can be a promising approach for pancreatic tumor treatment.

#7456 PCSK1 and PCSK7 orchestrate immune checkpoints to amplify anti-tumor immunity.

Marta Martin-Bornez[1], Chloe Porcheron[1], Geraldine Siegfried[1], Serge Evrard[2], John Creemers[3], Nabil Seidah[4], Simon Pernot[2], **Abdel-Majid Khatib**[1]

[1]INSERM, Bordeaux, France,[2]Bergonie, Bordeaux, France,[3]KU Leuven, Leuven, Belgium,[4]IRCM, Montreal, QC, Canada

Background: Immune-checkpoint receptors (ICPs) such as PD-1, CTLA-4, and TIGIT restrain T-cell activation and enable tumor immune evasion. Although ICP-targeting antibodies have transformed cancer therapy, many patients exhibit incomplete or transient responses, underscoring the need to identify upstream regulators that control ICP expression and function. Proprotein convertases (PCSKs) have recently emerged as modulators of immunity, but their roles in T-cell checkpoint regulation remain poorly defined.
Methods: We investigated the functions of Furin and PCSK7 using CRISPR/Cas9-mediated gene deletion, antisense oligonucleotides (ASOs), overexpression systems, mouse knockout models, patient-derived tumor samples, paired PBMCs, and ex vivo T-cell activation assays. Immune-checkpoint expression and trafficking were assessed using flow cytometry, transcriptomic profiling, and imaging. Functional consequences were evaluated through cytokine secretion, proliferation assays, cytotoxicity measurements, chemotaxis analyses, and tumor-organoid co-culture systems.
Results: Furin and PCSK7 emerged as complementary and essential regulators of ICP biology in T cells. Furin controls ICP expression at the transcriptional level, reducing mRNA abundance of PD-1, CTLA-4, and TIGIT upon deletion. In contrast, PCSK7 functions as a non-enzymatic chaperone, stabilizing newly synthesized ICPs and directing them to the cell surface. Loss of either convertase significantly diminished surface checkpoint levels and reduced the fraction of T cells co-expressing multiple inhibitory receptors. In human tumors and corresponding PBMC-derived T cells, decreased Furin or PCSK7 expression correlated with enhanced T-cell proliferation, cytokine release, and cytotoxic function. Organoid models, ex vivo patient tumor assays, and tumor-bearing mouse models demonstrated that targeting Furin and PCSK7 enhances the efficacy of chemotherapy and immunotherapy.
Conclusions: Furin and PCSK7 constitute key upstream regulators of immune checkpoints, controlling both transcriptional abundance and cell-surface availability through distinct mechanisms. Their inhibition enhances T-cell activation and anti-tumor function, representing a promising therapeutic strategy to potentiate immune responses and overcome resistance to current checkpoint-blocking therapies.

#7457 IL-33-mediated control of myeloid immunity in glioblastoma progression.

Tala-Maria Mouannes, Shyam V. Menon, Peipei Zeng, Jianbo Zhang, Isabelle Carrier, Eduardo Diez, Stephen M. Robbins, Donna L. Senger

Lady Davis Institute at Jewish General Hospital, Montreal, QC, Canada

Glioblastoma (GB) is the most lethal primary brain cancer in adults, characterized by a profoundly immunosuppressive microenvironment dominated by tumor-associated macrophages and microglia (TAMs). We previously identified Interleukin-33 (IL-33), a dual-function cytokine with nuclear and extracellular roles, as a key modulator of this innate immune landscape. While full-length IL-33 accelerates GB progression by recruiting immunosuppressive myeloid cells, a nuclear-deficient variant lacking the nuclear localization sequence (ND-IL-33) potently halts tumor growth and prolongs survival. This growth-restrictive state is marked by the emergence of a distinct pro-inflammatory, anti-tumor myeloid population. Secretome profiling reveals that ND-IL-33-expressing glioma cells produce a unique repertoire of immune-stimulatory factors, consistent with enhanced innate immune activation, suggesting that loss of IL-33 nuclear activity reshapes tumor-intrinsic signaling to drive myeloid reprogramming. The clinical relevance of this biology is supported in patient-derived GB specimens, where high IL-33 expression is associated with increased immunosuppressive TAM infiltration and reduced overall survival. Ongoing bulk and single-cell RNA sequencing, integrated with functional co-culture assays, aims to define the transcriptional programs that distinguish tumor-inhibiting from tumor-promoting myeloid populations and to uncover therapeutic pathways capable of inducing this anti-tumor state. Together, these findings position IL-33 activity as a targetable regulator of myeloid plasticity in GB and offers a promising avenue to leverage innate immunity for improved therapeutic outcomes in glioblastoma.

#7458 Examining OST4's impact on tumorigenesis and immune microenvironment in ovarian cancer.

Mengyi Gu[1], Michelle K.y. Siu[1], Ruiqian Zhang[2], Luqi CHEN[1], Ling Shan HUNG[3], Kui Liu[1], Yuen Sheung Hextan Ngan[4], Haonan Lu[1], Annie NY Cheung[5], Karen K.l. Chan[1]

[1]University of Hong Kong, Hong Kong SAR, China,[2]University of Hong Kong, The - Li Ka Shing Faculty of Medicine, Pok Fu Lam, China,[3]Universtiy of Hong Kong, Hong Kong SAR, China,[4]University of Hong Kong, Hong Kong, SAR, China,[5]Clinical Professor, Dept. of Pathology, University of Hong Kong, Pokfulam, China

IntroductionOvarian cancer remains one of the deadliest malignancies in gynecology, characterized by a high tendency for metastasis, strong drug resistance, and limited response to immunotherapy. Protein glycosylation plays a critical role in these processes, making it an attractive target for therapeutic development. The oligosaccharidyltransferase (OST) complex, which catalyzes a central step in N-linked glycosylation, is of particular importance. Among OST subunits, OST4 serves as a key regulatory element. Previous studies indicate that OST4 expression modulates the efficiency of protein N-glycosylation and has been recognized as a prognostic marker in head and neck cancers, with connections to PD-L1 expression. However, the role of glycosylation-related genes such as OST4 in ovarian cancer development and immune cell activity within the tumor microenvironment remains unclear. This study explores the function of OST4 in ovarian cancer and assesses its potential as a therapeutic target.MethodsWe employed comprehensive data mining of The Cancer Genome Atlas (TCGA) and single-cell RNA sequencing datasets to identify pathways linked to OST4 in ovarian cancer and its immune-related effects. OST4 expression was knocked down in ovarian cancer cell lines (OVCAR4 and OVCAR8) using siRNA. Cell migration and invasion were measured to evaluate metastatic potential, and proliferation was assessed via XTT assays. Western blot analysis was performed to examine associated signaling pathways and downstream effectors. Tumor Conditioned Medium (TCM) was collected from ovarian cancer cells transfected with OST4 siRNA and scRNA, incubated in complete medium for 48 hours. The transwell migration assay was used to determine the infiltration of T cells cultured with the TCM. ResultsOST4 was found to be highly expressed in ovarian cancer. Patient stratification based on OST4 expression levels revealed associations with macrophage and T-cell infiltration. Pathway analysis indicated that OST4 may regulate the unfolded protein response (UPR). Silencing OST4 suppressed ovarian cancer cell migration, invasion, and proliferation. Western blot analysis further demonstrated that OST4 knockdown decreased the expression of IRE1α, a central component of the UPR pathway. The number of infiltrated $CD8^+$ T cells increased in the presence of TCM derived from OST4-silenced OC cells compared to control TCM.ConclusionIn conclusion, OST4 influences ovarian cancer progression and $CD8^+$ T cell infiltration, potentially through activation of the UPR pathway. Targeting OST4 may offer a promising therapeutic approach for ovarian cancer.

#7459 Localized co-delivery of hyaluronidase enhances CSPG4 CAR-T cells cytotoxicity against chordoma.

Maoyang Qi[1], Giulia Cattaneo[2], Zan Chen[3], Cristina Ferrone[2], Joseph Schwab[1]

[1]The Department of Orthopaedics, Cedars-Sinai Medical Center, Los Angeles, CA,[2]The Department of Surgery, Cedars-Sinai Medical Center, Los Angeles, CA,[3]The Department of Neurosurgery, Xuanwu Hospital, Beijing, China

Background: Chordoma is a rare malignant bone tumor characterized by a dense extracellular matrix (ECM) and an immunologically “cold” microenvironment that limits immune cell infiltration and therapeutic efficacy. Chondroitin sulfate proteoglycan 4 (CSPG4) has emerged as a promising tumor-associated antigen in chordoma. However, the hyaluronan-rich ECM forms a physical and biochemical barrier that hampers CAR-T cell trafficking and function. We hypothesized that localized co-delivery of hyaluronidase (PH20) could remodel the ECM and enhance the cytotoxic activity of CSPG4-directed CAR-T cells.
Methods: CSPG4 CAR-T cells were generated using a third-generation lentiviral construct containing CD28-Ox40-CD3ζ signaling domains. Human chordoma cell lines and patient-derived 3D organoids were used to evaluate cytotoxicity and infiltration. Electrical impedance assays were applied to monitor real-time changes in surface charge and cell-matrix interactions following PH20 treatment. Transwell migration assays and 3D organoid co-cultures were used to assess CAR-T infiltration, and cytokine secretion was quantified by ELISA. In vivo efficacy and safety were examined in xenograft models following localized co-delivery of PH20 and CAR-T cells.
Results: CSPG4 CAR-T cells exhibited antigen-specific cytolytic activity against chordoma cells, but their infiltration was markedly restricted in hyaluronan-rich environments. Electrical impedance analysis revealed that PH20-mediated ECM degradation significantly altered the charge distribution and impedance profile, indicating reduced matrix density and improved accessibility for CAR-T cells. In Transwell assays, PH20 enhanced CSPG4 CAR-T transmigration across hyaluronan-containing barriers. Similarly, in 3D chordoma organoids, PH20 co-treatment promoted deeper CAR-T infiltration and led to greater cytotoxicity with elevated IFN-γ and Granzyme B production. Consistent findings were observed across multiple patient-derived organoid models. In xenograft studies, localized co-delivery of PH20 with CSPG4 CAR-T cells resulted in stronger tumor regression and prolonged survival compared with CAR-T monotherapy ($p < 0.01$), without observable systemic toxicity.
Conclusion: ECM degradation through localized hyaluronidase co-delivery effectively enhances CSPG4 CAR-T cell infiltration and cytotoxicity against chordoma. This combinatorial approach overcomes stromal barriers, reshapes the tumor microenvironment, and represents a feasible strategy to improve CAR-T efficacy in solid tumors with dense ECM architecture.

#7460 Logic-gated T cell engager linked with mutant IL-2 for safer and better effective solid tumor immunotherapy.

Yang-Xin Fu

tsinghua University, Beijing, China

T cell engagers (TCEs) have achieved transformative success in B-cell malignancies but show limited efficacy in solid tumors with severe toxicity. Here, we identify insufficient IL-2 signaling as a key bottleneck for sustaining TCE-induced T-cell function. Although exogenous IL-2 enhances TCE efficacy, its systemic administration causes more severe toxicity. To overcome this limitation, we engineered a protease-activatable dual-variable-domain (DVD) as Pro-TCE to reduce its off-tumor toxicity. Furthermore, we designed a mutant IL-2 (3E) with markedly reduced receptor affinity that is inactive in periphery. The construct (DVD-3E) remains inert in circulation and becomes locally activated only upon tumor-specific protease cleavage, coupling T-cell engagement with cis IL-2 signaling. This logic-gated design restricts both TCE and cytokine activity to the tumor microenvironment (TME), enabling potent antitumor responses without systemic toxicity. Mechanistically, DVD-3E enhances the persistence and effector function of preexisting intratumoral T cells, expands $TCF1^{+}$ progenitor and antigen-specific T cells populations, mitigates exhaustion, and establishes durable immune memory. Notably, DVD-3E treatment increased the frequency of antigen-specific T cells in draining lymph nodes, which were capable of controlling distant tumors and mediating effective tumor regression upon adoptive transfer. These findings define a new design principle for logic gated TCEs that achieve a favorable balance between safety and efficacy, offering a strategy to overcome current therapeutic resistant.

#7461 Inhibitory effects of induction of massive apoptosis (PRIMA-1^{MET}) on tumorigenic chemokines in ovarian cancer cells.

Audene B. Wilkinson, Deok-Soo Son

Department of Biochemistry and Cancer Biology, Meharry Medical College, Nashville, TN

Background/Purpose: Ovarian cancer is the most lethal gynecologic malignancy, with TP53 mutations present in >95% of high-grade serous cases, representing a prime molecular target for therapy. In addition to disrupted p53 signaling, elevated pro-inflammatory chemokines drive tumor progression by enhancing proliferation and distant metastasis. This study investigates the therapeutic potential of PRIMA-1^{MET}, a small-molecule reactivator of mutant p53, to suppress tumorigenic chemokine production in ovarian cancer cells.

Methods: OVCAR3 cells (harboring TP53^{R248Q} mutation) were cultured under standard conditions. Cell viability was quantified by MTT assay to determine IC50 values. Protein levels and phosphorylation status were assessed by Western blotting. The transcriptional activity of p53 was measured in cells transiently transfected with p53-responsive luciferase reporter plasmids ± wild-type and mutant p53 expression vectors, followed by measurement of luciferase activity. Chemokine profiling was performed using a Human XL Cytokine Array.

Results: PRIMA-1^{MET} reduced OVCAR3 viability in a dose-dependent manner (IC50 ≈ 30 μM), and significantly down-regulated chemokines CXCL1, CXCL8, and CCL20, indicating attenuated pro-inflammatory and pro-metastatic signaling. PRIMA-1^{MET} markedly decreased phosphorylated NF-κB, implicating suppression of this master regulator of chemokine transcription. Consistent with p53 reactivation, PRIMA-1^{MET} enhanced p53-driven luciferase reporter activity while concomitantly inhibiting CXCL8 promoter activity—containing an NF-κB binding site—at both basal and IL-1β-induced levels.

Conclusion: PRIMA-1^{MET} restores mutant p53 function and inhibits NF-κB-driven chemokine signaling, thereby restraining ovarian cancer progression and metastasis. These findings highlight its promise as targeted therapy.

#7462 DAPK3-DCAF1 pathway regulates ZBP1 protein stability to orchestrate innate immune responses and PANoptosis.

Zhiqi Liao[1], Linghui Wang[1], Wenjian Gong[1], Ziyan Zhang[1], Gordon B. Mills[2], Ding Ma[1], Guangnian Zhao[1], Qinglei Gao[1], Yong Fang[1]

[1]Department of Gynecological Oncology, Tongji Hospital, Tongji Medical College, Huazhong University of Science and Technology, Wuhan, China,[2]OHSU Knight Cancer Institute, Portland, OR

Background: Z-DNA binding protein 1 (ZBP1) is an interferons (IFN)-stimulated cytosolic sensor of Z-nucleic acids (Z-NA) that regulates PANoptosis (pyroptosis, apoptosis, and/or necroptosis) and thereby drives potent anti-tumor immune responses. However, the mechanisms controlling ZBP1 protein stability in tumors—and whether they can be therapeutically manipulated to induce ICD—remain unclear. We sought to define regulatory pathways that govern ZBP1 abundance in ovarian cancer and to test strategies that exploit ZBP1 activation for antitumor therapy.

Methods & Results: Here we demonstrate that the reduced ZBP1 expression in ovarian cancer and correlated with poorer survival. Type I IFN (IFN-β) rapidly increased ZBP1 levels by inhibiting its proteasome-dependent ubiquitination. Proximity labeling and biochemical assays identified DCAF1 as a key interactor that mediates ZBP1 ubiquitination and degradation. Furthermore, IP-MS and LC-MS/MS identified DAPK3 as an IFN-induced DCAF1 kinase, which phosphorylates DCAF1-pS1328 to promote its turnover, thereby stabilizing ZBP1. Genetic ablation of DCAF1 impaired tumor cell proliferation *in vitro*, reduced tumor burden and promoted anti-tumor immunity *in vivo*. Pharmacological targeting of this pathway using the DCAF1 inhibitor B32B3 and—when combined with the Z-NA activator CBL0137—effectively reactivated ZBP1 signaling, promoted PANoptosis, and enhanced antitumor immunity, thereby suppressing tumor growth in two chemotherapy-resistant ovarian cancer patient-derived xenograft (PDX) models and providing a promising therapeutic strategy for refractory malignancies.

Conclusion: Overall, this study delineates a novel DAPK3-DCAF1 signaling axis that governs ZBP1 stability, unveiling an integrated regulatory framework that connects interferon signaling, post-translational modification, and immunogenic cell death. Combining DCAF1 blockade with Z-NA activation elicits ZBP1-mediated PANoptosis and augments anti-tumor immunity, representing a promising therapeutic approach for refractory ovarian cancer.

#7463 Targeting S100A7/RAGE-driven Stat3/Serpin-E1 signaling for immunotherapy in metastatic breast cancer.

Pratyusha Ghanta[1], Ajeet K. Verma[1], Cho-Hao Lin[1], Manish Charan[1], Ganesh R. Koshre[2], Tanisha Mukherjee[1], Wayne O. Miles[2], Sanjay Mishra[1], Ramesh Ganju[1]

[1]Pathology, Ohio State University, Columbus, OH,[2]Cancer Biology and Genetics, Ohio State University, Columbus, OH

Background: Triple-negative breast cancer (TNBC) is an aggressive type that lacks targeted therapies, with immunosuppressive variants resistant to checkpoint blockade. Elevated S100A7 expression is reported in these immune-ignored, anti-PD1-refractory tumors; yet S100A7 mechanisms, which shape the immune tumor microenvironment (iTME), remain unclear. Here, we investigated how S100A7 activates the RAGE/Stat3 axis to induce Serpin-E1, reshaping the iTME, and assessed therapeutic potential in immunosuppressive TNBC.

Method: Expressions of S100A7, RAGE, Stat3, and Serpin-E1 were analyzed in TNBC cells by Western blotting, cytokine arrays, and ELISA. Functional assays evaluated the impact of S100A7 overexpression (OE) or knockdown (KD) and pharmacologic inhibition of RAGE and Stat3, alone or combined, on viability, migration, and colony formation. Pre-clinical models, including doxycycline (DOX)-inducible mammary gland-specific S100A7-OE bitransgenic mice treated with RAGE and Stat3 inhibitors ± Serpin-E1 neutralizing antibody (nAb) were utilized for *in-vivo* studies. Multi-color flow cytometry determined macrophage polarization and T-cell activation. CD4/CD8 depletion assays and *in-silico* analyses evaluated T-cell dependency and prognostic significance.

Results: S100A7 upregulation enhanced phosphorylation of Stat3 (Ser727) and Serpin-E1 expression, whereas its downregulation suppressed pStat3/Serpin-E1. Dual inhibition of RAGE and Stat3 produced synergistic suppression of TNBC cell viability, migration, and colony formation and markedly inhibited downstream pStat3 signaling. Mechanistic studies revealed that S100A7/RAGE signaling activates Stat3, which binds to the Serpin-E1 promoter and enhances its transcription. *In-vitro* assays demonstrated a potential role for Serpin-E1 in modulating macrophage polarization. Next, *in-vivo* treatment of RAGE and Stat3 inhibitors ± Serpin E1 nAb led to significant reductions in primary tumor growth and distant metastasis in female NSG mice. Significantly decreased tumor burden in S100A7-OE mice treated with the combination of RAGE/Stat3 inhibitors was observed compared to alone treatment groups alone. Additional immune profiling within tumor tissues revealed a significant abundance of antitumor iNOS and $MHCII^{high}$ TAMs and increased activation of CD4+ and CD8+ T cells with elevated effector markers in combinatorial treatment compared to a single regimen. These effects were abrogated by CD4/CD8 depletion. Clinically, high co-expression of S100A7 and Serpin-E1 correlated with poorer outcomes, particularly in basal and immunomodulatory TNBC subtypes.

Conclusions: This study identifies the S100A7/RAGE/Stat3/Serpin-E1 axis as a key regulator of tumor growth and iTME suppression in TNBC and its potential for a targeted therapeutic strategy for immune-ignored TNBC subtypes.

#7464 Inhibiting interferon-gamma-stimulated melanoma progression by disrupting the crosstalk between nNOS/NO and COX-2.

Anika Patel[1], Kate Alison Lozada[1], Moom Roosan[1], Basir Syed[1], Jennifer Totonchy[1], Amardeep Awasthi[2], Richard B. Silverman[2], **Sun Yang**[1]

[1]Chapman University, Irvine, CA,[2]Northwestern University, Evanston, IL

Interferon gamma (IFN-γ) in the melanoma tumor microenvironment plays opposing roles, orchestrating both pro-tumorigenic activity and anticancer immune responses. Our previous studies demonstrated the role of neuronal nitric oxide synthase (nNOS) in IFN-γ-stimulated melanoma progression. However, the underlying mechanism has not been well defined. Bioinformatic analysis of patient and cellular proteomic data was conducted to identify proteins of interest associated with IFN-γ treatment in melanoma. Our omics analysis revealed that the induction of COX-2 was significantly predictive of IFN-γ treatment in melanoma cells. In the presence of IFN-γ, PGE_2 further enhanced PD-L1 expression and amplified the induction of nNOS, which increased intracellular NO levels. Cotreatment with celecoxib, a selective COX-2 inhibitor, effectively diminished these changes induced by PGE_2. nNOS blockade using a selective small molecule inhibitor (HH044) efficiently inhibited IFN-γ-Induced PGE_2 production and COX-2 expression in melanoma cells. STAT3 inhibitor napabucasin also inhibited COX-2 expression both in the presence and absence of IFN-γ. *In vivo*, HH044 treatment significantly reduced tumor PGE_2 levels in a human melanoma xenograft mouse model (A375/Nu/Nu). Combination treatment with HH044 and celecoxib yielded the greatest tumor suppression in the syngeneic murine melanoma model (Cloudman S91/DBA/2), reducing tumor volume to 19% of control, compared to 38% and 52% with HH044 or celecoxib alone, respectively. Furthermore, transcriptomic analysis revealed significant changes in genes involved in matrix remodeling and metastasis after HH044 treatment. *Ex vivo* co-culturing human PBMCs with melanoma cells inhibited T cell activation, decreasing IL-2-secreting T cells in the presence and absence of IFN-γ. PBMCs from a significant portion of donors (64%) were reactivated by HH044 pretreatment, displaying a significant increase in IL-2+ T cells after coincubation with melanoma cells.Our study reveals a positive feedback loop linking nNOS-mediated NO signaling to the COX-2/PGE_2 signaling axis in melanoma, thereby further enhancing the pro-tumorigenic activity of IFN-γ. Disrupting crosstalk between nNOS/NO and COX-2 with selective inhibitors effectively suppressed melanoma tumor growth, possibly by modulating the tumor immune microenvironment.

#7465 Chemically regulated STING-activating prodrugs of deoxyribose cyclic dinucleotides elicit robust immune activation and durable antitumor immunity.

Huimin Liu, Zhiqiang Xie, Kejia Xu, Rong Xiang, Shibo Li, Zhen Xi

Nankai University, Tianjin, China

Background: Prodrugs derived from deoxyribose cyclic dinucleotides (dCDNs) exhibit enhanced cellular permeability, stability, and sustained STING activation. However, the impact of phosphotriester chirality on their bioactivity remains underexplored. This study systematically evaluates the stereochemistry-dependent pharmacology of alkyne-conjugated, esterase-sensitive dCDN prodrugs in vitro and in vivo. Methods: Three diastereoisomers of the dCDN prodrug: (Rp,Rp)-10, (Sp,Sp)-10, and (Rp,Sp)-10—were synthesized, purified by chiral HPLC, and confirmed by NMR and HRMS. Cellular uptake and stability were assessed in THP1-Lucia ISG cells. STING pathway activation was measured by IFN-β reporter assays and phospho-TBK1/IRF3 immunoblots. In vivo efficacy was evaluated in CT26 colon carcinoma-bearing BALB/c mice following intravenous administration. Immune memory was assessed by tumor rechallenge. Results: Among the isomers, (Rp,Rp)-10 exhibited the most potent STING activation (EC50 = 1.7 nM), superior cellular uptake, and prolonged TBK1/IRF3 signaling. In mice, all three prodrugs induced stronger systemic cytokine responses than ADU-S100 or the parent CDN 3′,3′-c-di-dAMP. In the CT26 model, (Rp,Rp)-10 achieved complete tumor regression in 9/10 mice (90% CR), significantly improved survival ($p < 0.001$), and established long-term immunological memory with 100% rejection upon rechallenge. No overt toxicity was observed. Conclusion: Phosphotriester chirality is a critical determinant of dCDN prodrug activity. (Rp,Rp)-10 represents a promising next-generation STING agonist with potent systemic antitumor immunity and durable therapeutic effects. These findings underscore the importance of stereochemical control in the rational design of STING-targeted cancer immunotherapies.

#7466 Epiregulin drives immunosuppressive TAM programming and is negatively regulated by miR-19a-3p in colorectal cancer.

Ah Ran Yu[1], Ju Yeon Park[1], Jeong Eun Kang[1], Sang Hyuk Moon[2], Hey Kyung Hong[3], **Yong Beom Cho**[4]

[1]Institute for Future Medicine, Samsung Medical Center, SEOUL, Korea, Republic of,[2]Department of Biopharmaceutical Convergence, SEOUL, Korea, Republic of,[3]Samsung Medical Center, SEOUL, Korea, Republic of,[4]Department of Health Sciences and Technology, SAIHST, Sunkyunkwan University, Seoul, Korea, Republic of

Colorectal cancer (CRC) is one of the most prevalent malignancies worldwide and remains a leading cause of cancer-related mortality. Its clinical challenge is compounded by the presence of a highly immunosuppressive tumor microenvironment (TME), which not only facilitates tumor growth and metastasis but also contributes to poor responses to immunotherapy. Among the cellular components of the TME, tumor-associated macrophages (TAMs) play a central role in supporting tumor progression, largely through their polarization into an M2-like, immunosuppressive phenotype. Despite their importance, the upstream regulators and downstream signaling pathways that maintain the tumor-promoting state of TAMs in CRC remain insufficiently defined. We performed single-cell RNA sequencing and transcriptomic profiling of CRC patient samples, which led to the identification of epiregulin (EREG) as a TAM-enriched gene, with predominant expression in SPP1^{+} macrophage clusters. Functional studies using EREG knockdown in murine CT26-derived TAMs and human M2-polarized macrophages demonstrated that EREG promotes M2-like polarization, elevates the secretion of pro-tumoral cytokines and enhances the proliferation and migration of co-cultured CRC cells. Mechanistically, we found that EREG signals through the JAK/STAT3 pathway, as its silencing led to reduced STAT3 phosphorylation and downregulation of associated target genes involved in immune suppression and tumor progression. Furthermore, miRNA screening and validation assays revealed that miR-19a-3p directly binds to the 3′UTR of EREG mRNA, as confirmed by RIP (Ago2) enrichment analysis. Introduction of miR-19a-3p mimics led to a significant reduction in EREG expression, suppression of JAK/STAT3 signaling, and reprogramming of TAMs toward an M1-like, anti-tumor phenotype. Collectively, our findings uncover the miR-19a-3p–EREG–JAK/STAT3 axis as a critical regulatory mechanism of TAM programming in colorectal cancer and highlight its potential as a therapeutic target for reprogramming the immunosuppressive tumor microenvironment.

#7467 Real-time detection of ADC internalization kinetics using a pH-sensitive fluorescent dye.

An Ouyang[1], Linlin Ma[2], Di Shi[2], Siwen Wang[1], Tianfu Zhang[2], Zhicheng Dong[2], YuehChun Hsieh[2]

[1]ACROBiosystems Inc., Newark, DE,[2]ACROBiosystems Co., Ltd., Beijing, China

BACKGROUND Monitoring antibody-drug conjugate (ADC) internalization demands highly sensitive and specific methods to differentiate surface-bound from internalized molecules. To address this need, we developed an internalization detection reagent based on pH-sensitive fluorescent dyes that enable real-time visualization of endocytosis events in live cells. This assay allows quantitative monitoring of dynamic parameters such as initiation rate, uptake duration, and total internalization, providing critical insights for understanding ADC mechanisms of action, optimizing dosing regimens, and refining administration strategies.

METHOD AND MATERIALS The primary antibody (2 μg/mL) and Internalization Detection reagent (1μg/mL) were prepared in cell culture medium, mixed, and incubated at room temperature for 10 min to form the labeling complex. For suspension cells, 50 μL of cell suspension (1×10^6 cells/mL) was seeded into each well of a 96-well plate and combined with 50 μL of the labeling complex. For adherent cells, 5,000-10,000 cells were plated per well and allow to attach. The medium was then replaced with 50 μL of fresh medium prior to the addition of 50 μL of the labeling complex. Cells were incubated with the labeling complex for 0.5-24 h, followed by analysis via flow cytometry or high-content imaging at designated time points.

RESULTS SK-BR-3 (HER2+) cells were incubated with various Anti-HER2 mAbs and our internalization detection reagent. Throughout the incubation period, there was a time-dependent increase in fluorescence across all tested primary antibodies, with signal intensity gradually increasing over time. In contrast, no positive signal was detected in the negative control cell line MDA-MB-468(HER2-). SK-BR-3(HER2+) cells were also incubated with anti-HER2 mAbs and their corresponding ADC drugs in presence of the internalization detection reagent. The intensity of the internalization detection signal showed a dose-dependent upward trend with increasing reagent concentration. The internalization detection signal for anti-HER2 antibody in SK-BR-3 cells increased gradually over the initial 7 hours, then the signal reached a plateau and maintained stable for up to 18 hours. Upon removal of the reagent and antibody mixture at the 7-hour mark, the internalization signal in the 2 nM anti-HER2 antibody group showed a gradual decline over the next 24 hours.

CONCLUSION The developed internalization detection reagent enables real-time, quantitative monitoring of antibody and ADC internalization kinetics with high sensitivity, reproducibility, and specificity. The reagent demonstrates consistent performance across different targets such as HER2 and CD20, offering a robust and versatile platform for studying endocytosis mechanisms, comparing candidate antibodies, and accelerating ADC development and optimization.

#7468 Calcium homeostasis modulator GRIN2D activates cancer-associated fibroblast for desmoplasia and promotes neutrophil infiltration for neutrophil extracellular trap formation in pancreatic ductal adenocarcinoma.

Chi Hin Wong[1], Yip Kan Kwan[1], Ka-Fai To[2], Yangchao Chen[1]

[1]School of Biomedical Sciences, The Chinese University of Hong Kong, Shatin, Hong Kong,[2]Department of Anatomical and Cellular Pathology, The Chinese University of Hong Kong, Shatin, Hong Kong

Pancreatic ductal adenocarcinoma (PDAC) is recognized as a “cold tumor” due to its poor response to immunotherapy, which is greatly contributed by the dense and complicated tumor microenvironment. Calcium ions (Ca^{2+}) are important signaling molecules for various biological processes. Dysregulated calcium channels and transporters greatly contribute to abnormal calcium homeostasis and, in turn, promote cancer progression. However, its roles in the PDAC tumor microenvironment and therapeutic resistance are still largely unknown. We previously demonstrated the importance of calcium transporters glutamate ionotropic receptor NMDA type subunit 2D (GRIN2D) in promoting PDAC tumor growth and liver metastasis. Here, we studied the importance of GRIN2D in the tumor microenvironment and therapeutic resistance. The upregulated GRIN2D activated cancer-associated fibroblast (CAF) and promoted neutrophil infiltration, contributing to an oncogenic tumor microenvironment. Mechanistically, transcriptome profiling after GRIN2D knockdown in PDAC cells identified fibronectin 1 (FN1) and interleukin-1 beta (IL-1β) as GRIN2D downstream targets under calcium signaling. The GRIN2D-FN1 pathway activated CAF for tumor desmoplasia, while the GRIN2D-IL-1β pathway promoted neutrophil infiltration and neutrophil extracellular traps formation. Furthermore, we revealed the epigenetic mechanism leading to the upregulation of GRIN2D in PDAC. We identified a hypermethylated Exon-CpG island at GRIN2D, promoting GRIN2D expression in PDAC tumors. Targeting GRIN2D in the tumor microenvironment enhances the efficacy of both chemotherapies and immunotherapies in inhibiting tumor growth and metastasis. Knowledge gained from this project uncovers the importance of GRIN2D and calcium homeostasis in PDAC progression and contributes to novel therapeutic targets in PDAC.

#7469 Targeting the tumor immune microenvironment to promote efficacy of chemo agents against breast cancer.

Alexander J. Krusell[1], Yi Le[2], William G. Richards[3], Deborah A. Dillon[4], Zhenglun Zhu[2]

[1]Massachusetts Institute of Technology, Cambridge, MA,[2]Department of Medicine, Brigham and Women's Hospital, Boston, MA,[3]Department of Surgery, Brigham and Women's Hospital, Boston, MA,[4]Department of Pathology, Brigham and Women's Hospital, Boston, MA

Breast cancer (BC) is the most common cancer worldwide and the second leading cause of cancer related death for women in the US. Despite significant advances in mechanistic exploration and therapeutic intervention, improving the overall survival rate (OS), treating metastatic breast cancer remains an urgent challenge. Estrogen, progesterone and human epidermal growth factor 2 (HER2) receptor triple negative BC (TNBC), for example, has a 5-year OS of 11% and a median OS of only 11 to 13 months. Due to the lack of a feasible target or biomarkers for targeted therapy, chemo agents serve as a limited therapeutic option for metastatic TNBC. Currently, clinical application of chemotherapy has been significantly limited by age-related and dosage-dependent cytotoxicity of chemo agents. While recent studies have suggested that the tumor immune microenvironment (TIME) plays an important role in chemoresistance, how to target the TIME to improve the efficacy of chemotherapy against TNBC has remained largely unknown. In this study, we characterized the immune cell profile in the TIME of BC and found that the expression level of the homeobox protein VentX, a transcription factor implicated in macrophage plasticity, is significantly downregulated in BC tumor associated macrophages (TAMs). We found that down-regulated VentX expression in BC-TAMs is associated with their pro-tumor M2-like phenotype and is accompanied by the increased population of immune suppressive T_{reg} cells in the BC-TIME. We also demonstrated that ectopic expression of VentX in BC-TAMs converted its pro-tumor M2-like phenotype into an anti-tumor M1 phenotype. Using an *ex-vivo* TIME enabling model system (TIME-EMS) developed in the lab, we showed that elevated expression of VentX in BC-TAMs led to transformation of the BC-TIME from an immune suppressive state into an immune activated state. Using the TIME-EMS models of BC, we explored the effects of chemo agents on cancer cells in BC-TIME. We discovered that conversion of BC-TIME from an immune suppressive state into an immune activated state drastically increased the sensitivity of cancer cells to the chemotherapeutic agent paclitaxel. Besides TNBC, we showed that reversal of immune suppression of BC-TIME also improves chemosensitivity of paclitaxel on other sub-groups of BC. We also demonstrated that elevated expression of VentX in BC-TAMs did not increase the cytotoxicity of paclitaxel on normal breast epithelial cells. In summary, our work demonstrates the utility of the TIME-EMS models as an *ex-vivo* model system to explore treatment options for BC in the context of the TIME. Our results suggest that VentX may serve as a potential therapeutic target to improve the efficacy of chemo agents against BC and improve prognosis of TNBC patients who have limited therapeutic options.

#7470 Uncovering the role of XPO6 in nasopharyngeal carcinoma.

Ziye Lu[1], Ziyang Qi[1], Lanqi Gong[2], Yuma Yang[1], Jie Luo[2], Qin Liu[2], Xin-Yuan Guan[2]

[1]The University of Hong Kong, Shenzhen Hospital, Shenzhen Shi, China,[2]The University of Hong Kong, Hong Kong, Hong Kong

Nasopharyngeal carcinoma (NPC) is a geographically prevalent malignancy, especially in southern China and Southeast Asia, with over 95% of cases in endemic regions linked to Epstein-Barr virus (EBV) infection. Despite advances in screening and chemoradiotherapy, advanced and treatment-resistant NPC remains a significant clinical challenge, characterized by high recurrence rates and limited therapeutic options. While immunotherapy, including anti-PD-1/PD-L1 agents, has been proposed to address this unmet need, responses are often suboptimal, underscoring the need to understand EBV-specific immune evasion mechanisms intrinsic to tumor cells.

Our study focuses on Exportin-6 (XPO6), a nuclear export protein identified as a candidate mediator of immune resistance in EBV-positive NPC through a comprehensive CRISPR-Cas9 screen. The screen targeted 19,114 genes in the EBV-positive C666 NPC cell line and the EBV-negative HK1 NPC cell line. Both cell lines were subjected to cytotoxic pressure from NY-ESO-1-specific TCR-engineered T cells, a model that recapitulates antigen-specific antitumor immune responses. Analysis with MAGeCK highlighted XPO6 as an EBV-positive NPC-specific regulator, with its deletion significantly sensitizing tumor cells to T cell-mediated killing. To validate these findings, we generated XPO6 knockout (KO) and overexpression (OE) derivatives of the C666 cell line. Functional co-culture assays confirmed that XPO6 KO markedly reduced NPC cell viability in the presence of TCR-engineered T cells, directly demonstrating enhanced susceptibility to T cell-mediated cytotoxicity. Consistent with this, XPO6 KO C666 cells also exhibited increased secretion of T cell-derived proinflammatory cytokines, including IFN-gamma and TNF-alpha, indicating that XPO6 deletion amplifies the anti-tumor immune response beyond direct cytotoxicity. Conversely, XPO6 OE in C666 cells conferred increased resistance to T cell killing, confirming that XPO6 expression is sufficient to drive immune evasion in EBV-positive NPC. The precise molecular mechanism by which XPO6 mediates these effects remains to be fully elucidated and warrants further investigation.

This study identifies XPO6 as a pivotal regulator of immune resistance specifically in EBV-positive NPC. Targeting XPO6 not only enhances tumor cell sensitivity to T cell cytotoxicity but also promotes a more robust T cell cytokine response, highlighting its potential as a therapeutic target to improve immunotherapeutic outcomes. Further exploration of the underlying molecular pathways through which XPO6 enables immune escape will be undertaken in the future.

#7471 Identification and characterization of compounds that block heterocellular adhesion between diffuse-type gastric cancer cells and cancer-associated fibroblasts.

Hideki Yamaguchi[1], Yuko Nagamura[1], Makoto Miyazaki[2]

[1]Department of Cancer Cell Biology, Sasaki Institute, Sasaki Foundation, Tokyo, Japan,[2]Laboratory of Pediatric and Refractory Cancer, Chiba Cancer Center Research Institute, Chiba, Japan

The phenotypes of cancer cells are profoundly influenced by reciprocal interaction with the tumor stroma within the tumor microenvironment. Among stromal components, cancer-associated fibroblasts (CAFs) are the most abundant and play pivotal roles in shaping the tumor milieu. CAFs promote cancer progression through the secretion of pro-tumorigenic factors and remodeling of the extracellular matrix. In addition to these paracrine effects, recent studies have emphasized the critical role of direct heterocellular adhesion between cancer cells and CAFs in tumor progression. Diffuse-type gastric cancer (DGC) is the most aggressive subtype of gastric cancer with an extremely poor prognosis. DGC is characterized by rapid infiltrative growth and frequent peritoneal metastasis. DGC is commonly accompanied by desmoplastic stroma, which results from the extensive proliferation of CAFs. We previously demonstrated that direct interactions with CAFs are essential for the invasion and peritoneal metastasis of DGC cells. To further elucidate the biological significance of this interaction, we established a high-throughput screening system to identify molecules that disrupt DGC cell-CAF adhesion. Using this screening system, we successfully obtained monoclonal antibodies that block this heterocellular adhesion and suppress peritoneal metastasis of DGC in vivo. In the present study, we aimed to identify small-molecule compounds that inhibit heterocellular adhesion between DGC cells and CAFs. High-throughput screening of a chemical library led to the identification of several hit compounds. Notably, one compound not only inhibited DGC cell-CAF adhesion but also suppressed the proliferation of DGC cells. Furthermore, this compound markedly reduced peritoneal metastasis of DGC in a mouse xenograft model. These findings suggest that targeting the heterocellular adhesion between cancer cells and CAFs represents a promising therapeutic strategy, and that small molecules disrupting this interaction may serve as novel anti-cancer agents.

#7472 Taraxasterol suppresses *H. pylori*-induced gastritis and gastric cancer by targetingPTP1B/PKM2/NF-κB signaling pathway.

Liting Zhou

Zhengzhou University, Zhengzhou, China

Chronic *Helicobacter pylori* infection is a primary cause of gastritis, peptic ulcers, and gastric cancer (GC), creating a demand for novel therapeutic agents that address both inflammation and tumor progression. Taraxasterol (TAX) has demonstrated significant therapeutic potential against both gastritis and gastric cancer (GC). *In vitro*, TAX effectively alleviated H. pylori-induced gastritis by reducing intracellular bacterial load and attenuating the inflammatory response, specifically by decreasing TNF-α levels and reactive oxygen species, and inhibiting the NF-κB signaling pathway (IKKα and P65 phosphorylation). TAX did not directly inhibit H. pylori growth, suggesting its mechanism is primarily anti-inflammatory. Beyond gastritis, TAX exhibited potent anti-cancer effects on GC cell lines (AGS and MGC803), dose-dependently inhibiting their proliferation and colony formation. Mechanistically, computational and experimental analyses (SPR, DARTS, CETSA) identified Protein Tyrosine Phosphatase 1B (PTP1B) as a direct target of TAX. PTP1B, found to be highly expressed in gastritis and GC tissues and associated with poor prognosis, had its phosphatase activity inhibited by TAX. Further studies showed that PTP1B knockdown inhibited GC cell proliferation and that TAX's anti-proliferative effects were partially mediated through PTP1B, modulating the PTP1B/PKM2/NF-κB signaling pathway. *In vivo*, TAX successfully inhibited H. pylori and/or alcohol-induced gastritis in mice, reducing inflammation, lymphocyte infiltration, and cytokine levels. Crucially, TAX also suppressed tumor growth in gastric cancer patient-derived xenograft (PDX) models. These findings collectively highlight TAX as a promising therapeutic agent for both gastritis and gastric cancer, primarily through its anti-inflammatory properties and its targeted inhibition of PTP1B.

#7473 A novel dual-target strategy against TNBC: Combining EZH2 inhibition and dopamine D1 receptor activation to restore immune balance.

Rajni Kant Shukla[1], Kate Ormiston[2], Gautam Sarathy[2], Shivani Dhekne[2], Dionisia Marie Quiroga[2], Sanjay Gupta[3], Daniel G. Stover[4], Pierre Giglio[5], Christian Rolfo[2], **Eswar Shankar**[2]

[1]Oklahoma State Health Science Center, Oklahoma, OK,[2]Division of Medical Oncology, Department of Internal Medicine, Wexner Medical Center, The Ohio State University, Columbus, OH,[3]Department of Urology, School of Medicine, Case Western Reserve University School of Medicine, Cleveland, OH,[4]OSUCCC - James, Columbus, OH,[5]Department of Neurology, School of Medicine, Wexner Medical Center, The Ohio State University, Columbus, OH

Triple-negative breast cancer (TNBC) remains one of the most aggressive and therapeutically challenging breast cancer subtypes, characterized by high heterogeneity, intrinsic resistance, and poor immune infiltration. There is a critical unmet need for less toxic approaches that can both suppress tumor growth and remodel the tumor microenvironment (TME). EZH2, a histone methyltransferase, is frequently overexpressed in TNBC, associated with immunosuppression, and disease progression. We previously reported combining GSK126 (an EZH2 inhibitor) with A77636 (a dopamine D1 receptor [DRD1] agonist) produced superior antitumor effects compared to monotherapies. We hypothesized synergistic targeting of EZH2 and DRD1 would convert the immunologically “cold” TNBC microenvironment into a “hot,” immune-permissive state, thereby enhancing therapeutic efficacy and overcoming resistance mechanisms. Female NSG mice (4-6 weeks old) were orthotopically implanted with MDA-MB-231 cells, randomized into four treatment groups (n=8): vehicle, GSK126 (2 mg/kg), A77636 (50 mg/kg), or combination. Treatments were administered intraperitoneally weekly for four weeks. Tumor volume was measured weekly and at endpoint. Tumors and immune tissues were analyzed by flow cytometry. Combination therapy significantly reduced tumor weight (mean difference = 0.278g, 95% CI: 0.109-0.446, p=0.0018) and volume (mean difference = 101 mm³, 95% CI: 51.7-151, p<0.0001) compared with vehicle and single agents. Notably, the combination markedly decreased monocyte populations in both blood and tumor tissue and downregulated EZH2 expression in tumor-associated monocytes and neutrophils. Kinetic profiling revealed a biphasic monocyte response-initial Ly6C^hi recruitment followed by Ly6C^lo transition. The combination suppressed Ly6C^hi infiltration (0.32 vs. 0.92; 65% decrease, p=0.0138) while promoting Ly6C^lo accumulation (2.5 vs. 1.5; 1.67-fold increase, p=0.5126). By using a combinational treatment strategy to redirect monocyte phenotypes, we were able to suppress the pro-inflammatory IL-1β environment while simultaneously enhancing anti-inflammatory IL-10 signaling-ultimately creating a tumor-suppressive immune milieu. In summary, dual modulation of EZH2 and DRD1 effectively halts TNBC progression by reshaping the immunological landscape. These findings uncover a distinctive therapeutic avenue that integrates epigenetic regulation with dopaminergic activation to restore immune responsiveness in TNBC. *(This work was supported by DOD W81XWH2010065 to Eswar Shankar).*

#7474 M4N as a potential anti-inflammatory therapy for KDM6A-deficient bladder cancer.

Nobuhito Muramoto[1], Masayuki Iwasaki[1], Yasuyuki Sera[1], Kohei Kobatake[2], Kyosuke Iwane[2], Tsuyoshi Fukushima[3], Kotohiko Kimura[4], Ru Chih C. Huang[4], Hiroaki Honda[1]

[1]Tokyo Women's Medical University, Tokyo, Japan,[2]Hiroshima University, Hiroshima, Japan,[3]Assistant Professor, Dept. of Pathology, University of Miyazaki, Miyazaki, Japan,[4]Johns Hopkins University, Baltimore, MD

Introduction and Objective: Histone modifications are important for tissue homeostasis, and their mutations are involved in carcinogenesis. Mutations in an X-linked histone demethylase KDM6A are most frequently observed in bladder cancer (BCa) among human malignancies. We previously demonstrated that loss-of-function of KDM6A contributes to BCa development by promoting inflammation through activating the JAK-STAT pathway. Tetra-O-methyl-nordihydroguaiaretic acid (M_4N), a methylated derivative of nordihydroguaiaretic acid, inhibits transcription factor Hypoxia-Inducible Factor (HIF) and Specificity protein 1 (Sp1) and exerts anti-inflammatory activities through inhibiting the JAK-STAT pathway. Here, we investigated the therapeutic efficacy of M_4N against KDM6A-deficient BCa using a subcutaneous syngeneic model.

Methods: To investigate the anti-proliferative effect of M_4N on KDM6A-deficient BCa, we used CRISPR-Cas9 genome editing and established *Kdm6a*-deficient sublines from mice BCa cell lines, MB49 and MBT2. *Kdm6a*-deficient and *control parental* cells were subcutaneously implanted into syngeneic mice and tumor growth on the recipients fed either a normal diet and an M_4N-supplemented diet was continuously monitored. Resected tumors were subjected to pathological, molecular, and cellular analyses using real-time PCR and immunohistochemical staining.

Results: In subcutaneous syngeneic models, *Kdm6a*-deficient cells formed significantly larger tumors compared to *control* cells. M_4N efficiently suppressed tumor growth of *Kdm6a*-deficient cells but showed no effect on tumors of *control* cells. By performing RNA sequencing and pathway analyses using resected tumors, we found that M_4N suppressed inflammatory pathways such as chemokine signaling and JAK-STAT pathways. In *Kdm6a*-deficient tumors, M_4N significantly suppressed the expression of pro-inflammatory cytokines and chemokines, such as *Il-6* and *Ccl2*, and also reduced the expression of *Vegfa* and *Nampt*, the downstream targets of Sp1 and HIF, involved in inflammatory pathways. Moreover, immunostaining of the tumors with F4/80, a macrophage marker, and with p-STAT, a JAK-STAT pathway marker, revealed significant macrophage accumulation and activation of the JAK-STAT pathway, specifically in tumors lacking *Kdm6a*, which was efficiently suppressed by M_4N.

Conclusions: M_4N may serve as a novel therapeutic approach for patients with BCa bearing *Kdm6a* mutations by suppressing inflammation.

#7475 Combinations of grape seed procyanidin extract and milk thistle silymarin extract additively decrease recruitment of THP-1 derived M2 macrophages into the lung tumor microenvironment..

Jenny T. Mao[1], Diego Oliva[1], Jessica Schilter[1], Lauren Rollin[1], Lily Jih[2]

[1]Pulmonary, Critical Care & Sleep Medicine, VA Medical Center, San Diego/UCSD, San Diego, CA,[2]Pathology and Laboratory Medicine, VA Medical Center, San Diego/UCSD, San Diego, CA

Introduction: Grape seed procyanidin extract (GSE) and milk thistle silymarin extract (MTE) are widely used as health food supplements to promote cardiovascular and hepatobiliary health, respectively. Both GSE and MTE contain high levels of structurally distinct polyphenols and each agent has been shown to exert antineoplastic effects against lung cancer. Previously we have shown that the combinations of GSE and MTE decreased production of the tumor promoting, M2 macrophage polarizing CCL2 chemokine by lung cancer cells. CCL2 is a key chemokine in the tumor microenvironment that facilitates recruitment and polarization of macrophages toward the tumor promoting M2c phenotype, which promotes tumor progression by creating a pro-tumorigenic environment. Targeting recruitment to and M2c macrophage polarization in the lung tumor microenvironment with GSE + MTE may represent a novel immunotherapeutic strategy against lung cancer.
Methods:THP-1 cells were differentiated into M0 cells with phorbol-12-myristate-13-acetate (PMA), then to M2c macrophages using interleukin (IL)-10 priming as previously described. M2c phenotype was then confirmed using qPCR profiling with CD163 and CD206 primers. The effects of GSE and MTE conditioning, alone or in combination, on the ability of A549 cells to recruit M2c cells were assessed using co-culture migration/invasion assay of THP-1 derived M0 and M2c macrophages with A549 cells and conditioned cell culture supernatants, simulating the lung tumor microenvironment.
Results: Conditioning of A549 cells with GSE and MTE additively reduced CCL2 production by A549 cells and co-culture with GSE $\pm$ MTE conditioned A549 cells/supernatants additively decreased migration/invasion of M2c cells.
Conclusions: In the present study, we report on the additive effects of GSE and MTE on reducing the migration/invasion of tumor promoting M2c cells in the lung tumor microenvironment. Our findings illustrate a potential novel immunomodulatory mechanism of GSE combined with MTE against lung cancer and support the continued investigation of the combinations for lung cancer prevention and treatment.

#7476 Role of AOC1 in modulating the ovarian cancer tumor microenvironment and malignant phenotype.

Sammy Ferri-Borgogno, Chun Wai (Oscar) Ng, Basant T. Gamal, Erin H. Seeley, Yadira Pacheco, Christopher D. Pacheco, Jared K. Burks, Samuel Mok

UT MD Anderson Cancer Center, Houston, TX

Ovarian cancer can be subdivided into different histologic types. Among them, clear cell ovarian cancer (CCOC), which constitutes 8% of ovarian cancer, differs from the other types with respect to its clinical characteristics. Most of CCOC frequently presents at an early stage compared to high-grade serous ovarian cancer (HGSOC), with most cases diagnosed at Stage I or II, which offers a favorable prognosis. However, those diagnosed with advanced disease experience poorer clinical outcomes compared to those with HGSOC, since CCOC is usually more resistant to systemic chemotherapy than other types. Despite multiple studies showing promise of immune checkpoint inhibitors (ICIs) treatment in patients with CCOC, the molecular mechanisms by which CCOC confers improved response to ICIs, and biomarkers that can predict treatment response to these ICIs in CCOC have not been thoroughly explored. In addition, it remains unclear whether the immune microenvironment plays a role in the early presentation and in metastatic potential of CCOC.Recent spatial transcriptomics (ST) analyses demonstrated that increased AOC1 expression was found in the epithelial cell cluster of early stage CCOC than in HGSOC, which was subsequently validated by sequential immunofluorescence (seqIF) analysis on 17 CCOC and 34 HGSOC patient samples. Increased AOC1 expression is associated with improved overall survival in HGSOC patients. Functional studies showed that despite the lack of a direct effect on the growth of ovarian cancer (OC) cells, syngeneic mouse cells transfected with full-length AOC1 had significantly lower tumor burden than the control mice, suggesting that the tumor microenvironment (TME) mediates the effect of AOC1 on tumor growth. Integrating ST and mass spectrometry imaging (MSI) revealed significantly inverse correlation between AOC1, and histamine and cell membrane VISTA expression levels in cancer cells and/or macrophages in the TME of CCOC and HGSOC, which was confirmed by seqIF. These findings suggest that histamine and VISTA mediate the tumor suppressive effect of AOC1. Indeed, our in vitro studies demonstrated that AOC1 abrogates the growth promoting effect of histamine in OC cells expressing high levels of histamine receptor HRH1, and AOC1 attenuates histamine induced OC proliferation and enhance T cell-mediated anti-tumor immunity via the histamine/HRH1/VISTA axis. Further studies demonstrated that in addition to VISTA, histamine can upregulate PD-L1 in both macrophages and OC cells. AOC1 may increase immune surveillance through attenuating histamine-induced VISTA and PD-L1 expression in the OC TME. Studies to further delineate the immune modulation role of AOC1 and exploring whether enhancing circulating AOC1 levels or targeting histamine with repurposed drugs to improve the efficacy of ICIs as a new strategy in the treatment of OC patients are warranted.

#7477 Angiogenic profile associated with KRAS dependency upon modulation of TIMP1.

Ilamathi M-Thirusenthilarasan[1], Pankaj Kumar Ahluwalia[2], Bilal Siddiqui[3], Ravindra Kolhe[2], Amyn M. Rojiani[4], Mumtaz V. Rojiani[5]

[1]Pathology, Penn State College of Medicine/Penn State Cancer Institute, Hershey, PA,[2]Pathology, Medical College of Georgia/Augusta University, Augusta, GA,[3]Pathology, Penn State College of Medicine, Hershey, PA,[4]Pathology, Penn State College of Medicine/Penn State Health Hershey Medical Center, Hershey, PA,[5]Pathology, and Neuroscience and Experimental Therapeutics, Penn State College of Medicine/Penn State Cancer Institute, Hershey, PA

Non-small cell lung carcinoma (NSCLC) remains a leading cause of cancer-related deaths, with KRAS mutations conferring oncogene addiction and chemoresistance to therapy. Our previous work demonstrated that Tissue Inhibitor of Metalloproteinase-1 (TIMP-1) inversely correlates with KRAS dependency and promotes epithelial-mesenchymal transition (EMT). Given the role of TIMP-1 in tumor progression, we investigated how TIMP-1 modulation impacts the expression of angiogenic mediators in NSCLC cells.KRAS-dependent (H441) and KRAS-independent (H460) NSCLC cell lines were modulated to overexpress (OE) or knock down (KD) TIMP-1, respectively. Serum free conditioned media from these cells was analyzed using angiogenesis proteome profiler array (R&D systems). We found that the levels of pro-angiogenic factors VEGF1 and CXCL8 increased upon TIMP1 overexpression and decreased upon knocking down TIMP1. On the other hand, Thrombospondin-1, an angiogenic inhibitor was downregulated when TIMP1 was over-expressed and upregulated when TIMP1 was knocked down. Additionally, TIMP-1 overexpression in H441 cells increased Angiogenin and decreased Endostatin, Angiostatin, Serpin E1, and Platelet Factor 4 (PF4). Conversely, TIMP-1 knockdown in H460 cells showed the opposite trend, indicating that TIMP1 is pro-angiogenic. RNA-seq data analysis across five NSCLC lines revealed a reciprocal TIMP1:THBS1 expression pattern with strong CXCL8 induction under TIMP1 overexpression, most pronounced in H441. The TIMP1-THBS1 inverse relationship supports a CXCL8-dominant angiogenic axis.As studies have shown that KRAS dependency is associated with upregulation of c-Myc and ERK, leading to a decrease in TSP-1 levels, we assessed c-Myc levels in the lysates using Western blot. We found that the levels of c-MYC were high in KRAS-dependent parental cells and further increased upon TIMP-1 overexpression. In KRAS-independent cells however, TIMP-1 knockdown did not significantly alter c-MYC levels. Ongoing studies continue to evaluate the effects of TIMP-1 modulation on angiogenic responses under normoxic and hypoxic conditions.Our findings highlight TIMP-1 as a potential regulator of tumor angiogenesis in NSCLC in a KRAS dependency specific manner, incorporating a CXCL8-dominant axis.

#7478 Targeting the extracellular matrix in Wilms tumor.

Wilson Yeung[1], Hripsime Chomoyan[1], Matthew E. Thornton[2], David S. Koos[1], Valentina Villani[1], Justin Sunwoo[1], Brendan H. Grubbs[2], Roger E. De Filippo[3], Laura Perin[3], Astgik Petrosyan[3]

[1]Children's Hospital Los Angeles, Los Angeles, CA,[2]Keck School of Medicine of USC, Los Angeles, CA,[3]Children's Hospital Los Angeles/Keck School of Medicine of USC, Los Angeles, CA

Introduction: Wilms tumor (WT) represents approximately 90% of pediatric renal malignancies. While standard treatments are effective for many patients, those with relapse or unfavorable histopathology experience poor survival and severe long-term toxicities. The extracellular matrix (ECM) plays a critical role in driving cancer progression and drug resistance. Our comprehensive profiling of WT revealed type II collagen alpha 1 (COL2A1), absent in normal kidney, to be highly expressed in high-risk tumors, highlighting its potential as a novel biomarker and therapeutic target.
Methods: We utilized WT cancer stem cell (CSC)-like progenitors, 3D cultures, and patient-derived xenografts (PDXs) with metastatic and chemoresistant phenotypes to investigate COL2A1-mediated signaling. Comparative transcriptomics were performed on WT CSCs cultured on WT-versus normal kidney-derived decellularized ECM. Functional assays assessed epithelial-mesenchymal transition (EMT), tumor suppressor expression, and chemotherapy response following COL2A1 inhibition.
Results: COL2A1-enriched substrates activated AKT signaling, induced EMT, downregulated tumor suppressors, and promoted chemoresistance. Transcriptomic analysis revealed COL2A1 upregulation alongside its transcriptional regulator SP1, correlating with enhanced tumorigenic pathways and reduced drug sensitivity. Notably, COL2A1 blockade using a specific antibody reversed EMT (i.e., increased cytokeratin and decreased vimentin), restored tumor suppressor expression, and enhanced chemotherapy response.
Conclusions: COL2A1 is a critical ECM component driving therapy resistance in WT. Targeting COL2A1 offers a promising ECM-directed strategy to overcome treatment resistance and improve outcomes in high-risk WT patients. These findings highlight ECM-directed interventions as a new frontier in the treatment of pediatric kidney cancer.

#7479 A CCL20-high chemokine program defines a CCR6⁺ immune-myeloid niche in gastric cancer.

Kurtay Ozuner[1], Jaewon Kim[2], Sandra W. Ryeom[3]

[1]Herbert Irving Comprehensive Cancer Ctr., New York, NY,[2]Albert Einstein College of Medicine, New York, NY,[3]Columbia University Irving Medical Center, New York, NY

Introduction: Gastric cancer remains one of the leading causes of cancer mortality worldwide and is characterized by an aggressive clinical course and a profoundly immunosuppressive tumor microenvironment with limited therapeutic options. Chemokine signaling has emerged as an important regulator of gastric tumor progression, and among these pathways, the CCL20-CCR6 axis is a validated driver of epithelial to mesenchymal transition, invasion, and metastasis, and is associated with poor patient survival. However, the upstream signals that generate high levels of CCL20 within gastric tumors, and the specific CCR6⁺ immune compartment that respond to this signal remain poorly understood. Understanding the source and downstream signaling for this axis may offer novel therapeutic options for gastric cancer. Here, we identify a previously unrecognized CCL20 high chemokine signature and a dynamically regulated CCR6⁺ immune and myeloid niche in gastric cancer.

Methods:

Chemokine profiling of murine gastric cancer cell lines, multiplex immunohistochemistry of gastric tumors isolated from preclinical models of gastric cancer, and integration with human gastric single-cell RNA-seq confirmed CCL20 expression by gastric cancer cells and CCR6 expression in myeloid and B lineage clusters in the gastric tumor microenvironment.

Results:

Gastric cancer murine organoids exhibited a distinct chemokine signature marked by high CCL20 together with CCL22 and M-CSF. Confocal imaging confirmed abundant CCL20 protein within gastric tumors and organoids. Analysis of TCGA stomach adenocarcinoma data demonstrated that high CCR6 expression correlates with reduced overall survival. Multiplex immunohistochemistry revealed that substantial CCR6 positive CD11c⁺ MHCII⁺ immune cells infiltrate into the gastric cancer tumor microenvironment, including B220⁺ plasmacytoid DC-like (pDC-like) subset. pDC-like cells increased with tumor burden and was modulated by anti-PD-1 and 5-fluorouracil treatment, indicating dynamic regulation of CCR6⁺ myeloid subsets. Human gastric single-cell RNA-seq datasets identified CCR6 expression on myeloid clusters capable of responding to CCL20 through the CCR6 receptor.

Conclusions:

These findings define a previously unrecognized CCL20-high, CCR6⁺ immune-myeloid population in gastric cancer that offers insight into the source of chemokines that drive recruitment of immune cells into the gastric cancer tumor microenvironment. Targeting this axis may reveal actionable vulnerabilities in gastric cancer progression.

#7483 Adhesion plasticity and bidirectional paracrine signaling cooperatively drive glioblastoma invasion.

Abhinaba Banerjee[1], Audrey Iwashita[1], Afsheen Banisadr[2], Frank Furnari[3], Adam Engler[1]

[1]Bioengineering, University of California San Diego, San Diego, CA,[2]Biomedical Sciences Program, University of California San Diego, San Diego, CA,[3]Department of Medicine, University of California San Diego, San Diego, CA

Glioblastoma (GBM) lethality stems from diffuse invasion beyond surgical margins. EGFR amplification is frequent, and constitutively active mutant EGFRvIII co-exists with wild-type EGFR (wtEGFR) cells in ~50% of tumors, yet cell-intrinsic and extrinsic mechanisms coupling this heterogeneity to invasion remain unresolved. Murine astrocytes engineered with wtEGFR or EGFRvIII expression were interrogated across complementary 2-D, 3-D, and in-vivo platforms. Here, we found that EGFRvIII cells were ~40% less adherent, enabling faster migration than their wtEGFR counterparts. EGFRvIII conditioned media reduced adhesion strength of wtEGFR cells, but direct co-culture showed bidirectional signaling, with both populations experiencing a two-fold decrease in adhesion strength. Cooperative adhesion reduction was induced by a secretome unique to co-cultured cells, further suggesting bidirectional communication. Adhesion changes also cause post-"education" differences in invasion mode; EGFRvIII cells alone disseminate in a follow-the-leader mode but switch to single cell scattering when co-cultured with wtEGFR (and similar to the wt cells only condition). In addition to mode, the extent of migration is impacted by co-culture; mixed co-culture spheroids invade the matrix more extensively (>2-fold) than spheroids of either population alone, mirroring how patient tumors heterogeneity scales with invasiveness and prognosis. Moreover, RNA-seq, cytokine-arrays, and intracranially injected in vivo mouse models identified transcriptional and signaling alterations that could drive GBM adhesion. Heterotypic interaction between wtEGFR and EGFRvIII induces remodeling of focal adhesions through a distinct paracrine program, highlighting cooperative invasion. Targeting this adhesion-modulating axis offers a strategy to limit diffuse GBM spread. Together, these data show that both intrinsic and extrinsic signaling propel glioma migration and nominate new therapeutic entry points to improve patient outcomes.

#7484 Self-made matrix: Tumor-derived Laminin-α5 supports pancreatic cancer cell survival and metastatic persistence.

Annant Bir Kaur, Nivedeta Krishna Kumar, Pratima Raut, Kirtana Arikath, Venkatesh Varadharaj, Zahraa Wajih Alsafwani, Jesse Cox, Poompozhil Mathivanan, Surindar K. Batra, Moorthy P Ponnusamy

University of Nebraska Medical Center, Omaha, NE

This study investigates how pancreatic cancer cells utilize LAMA5 to build an autonomous niche that promotes survival and metastasis, revealing novel therapeutic vulnerabilities. A stiff and fibrotic extracellular matrix (ECM) is a defining feature of pancreatic ductal adenocarcinoma (PDAC). This dense microenvironment impedes drug penetration, contributing to pronounced therapeutic refractoriness and poor patient survival. While stromal cells are classically regarded as the primary source of ECM, recent evidence suggests that tumor cells themselves can generate matrix components, establishing an autonomous survival niche. Laminin-α5 (LAMA5), a key basement membrane protein, regulates epithelial adhesion, polarity, and migration, yet its tumor-intrinsic role in PDAC remains unexplored. Our comprehensive interrogation of bulk, single-cell RNA sequencing, and spatial transcriptomics datasets revealed selective enrichment of LAMA5 within malignant epithelial cells rather than the stromal compartment. In a clinical context, immunohistochemistry of human PDAC patient samples showed marked upregulation compared with adjacent normal pancreas, and further elevation in metastatic cell clusters in the liver. Next, in murine PDAC progression models (KC: *Kras; PdxCre* and KPC: *Kras; p53; PdxCre*), the ductal cell-derived contribution of LAMA5 increased progressively with disease severity, surpassing stromal expression. KPC-derived organoids similarly exhibited enhanced luminal LAMA5 expression compared with normal ducts, as confirmed by multiplex immunofluorescence, indicating robust secretion by tumor ductal epithelium. Long-term LAMA5 depletion in primary and metastatic human PDAC cell lines impaired proliferation, cell adhesion, anchorage-independent growth, and survival under non-adherent conditions, indicating a role in protecting against anoikis (apoptosis due to loss of attachment to ECM). Interestingly, supplementation with extracellular LAMA5 restored these phenotypes, establishing LAMA5 as a key mediator of adhesion-dependent survival. Tumor cells also exhibited elevated expression of LAMA5-binding receptors ITGA6, ITGB4, and BCAM, supporting an autocrine survival loop that reinforces epithelial adhesion and stress tolerance. To uncover therapeutic vulnerabilities, connectivity mapping through the iLINCS platform identified an FDA-approved compound, Lomustine, which reduced LAMA5 expression and markedly inhibited the growth of mouse and human PDAC organoids. Our findings collectively show that PDAC cells secrete LAMA5 to build a self-made matrix microenvironment that supports survival, adhesion, and metastatic persistence. Tumor-intrinsic LAMA5 redefines the tumor-stroma paradigm, enabling microenvironmental autonomy and anoikis-resistance, and highlights potential targets for intervention in PDAC.

#7485 RNA modification control of platinum sensitivity via ADAM23-dependent pathway.

Hao Huang[1], Ujin Kim[1], junzui li[2], Daniela E. Matei[3]

[1]Department of Obstetrics and Gynecology, Feinberg School of Medicine, Northwestern University, Chicago, IL,[2]Northwestern Univ. Feinberg School of Medicine, Chicago, IL,[3]Northwestern University - Chicago, Chicago, IL

N6-methyladenosine (m6A) is the most common modification involved in post-transcriptional regulation of RNA, affecting stability, splicing, and translation. M^{6}A modifications are regulated by methyltransferases (“writers”) and demethylases (“erasers”). Methyltransferase-like 3 (METTL3) is one of the m^{6}A writer complexes, catalyzing the m6A modification by transferring a methyl group to the N6 position of adenosine. METTL3 has been implicated in tumor development by modulating m^{6}A distribution and promoting the translation of oncogenic transcripts. Overcoming platinum resistance in ovarian cancer is a significant clinical challenge; therefore, we hypothesized that METTL3-mediated m^{6}A methylation contributes to resistance by altering cellular response to platinum drugs. We assessed m^{6}A and METTL3 expression after cisplatin treatment using RT-qPCR and western blotting. To evaluate their functional role, we measured the IC_{50} of cisplatin in ovarian cancer cell lines with METTL3 overexpression or knockdown. Additionally, the METTL3 inhibitor STM2457 was utilized to investigate the role of METTL3 in ovarian cancer, both in vitro and in vivo. Cisplatin treatment upregulated m^{6}A and METTL3 levels. METTL3 overexpression enhanced platinum resistance. Conversely, METTL3 knockdown or STM2457 treatment sensitized cells to cisplatin. RNA-seq analysis identified ADAM23 as a downstream target of METTL3. ADAM23 is a member of the ADAM (a disintegrin and metalloprotease) family involved in cell adhesion and extracellular matrix interactions. The protease is silenced in various tumors, including breast, gastric, pancreatic cancers, and gliomas. In ovarian cancer cell lines, ADAM23 expression was inversely correlated with METTL3 levels, showing decreased expression upon METTL3 overexpression and increased expression following METTL3 knockdown. Notably, cisplatin treatment led to reduced ADAM23 expression through METTL3 upregulation. Further analysis using SRAMP identified several very high confidence m6A modification sites on ADAM23 mRNA in human. These findings suggest that METTL3-mediated m^{6}A modifications, through regulation of ADAM23, may represent a novel therapeutic target in ovarian cancer.

#7486 SORL1 promotes mesothelial clearance and migration of ovarian cancer cells through regulating integrin trafficking.

Jasmine Jathan, Viktoriia Kolesnyk, Samantha Goncalves Novo, Miranda Mansolf, Yang Yang-Hartwich

Yale School of Medicine, New Haven, CT

Background: Peritoneal dissemination is a hallmark of advanced ovarian cancer and leading cause of poor patient prognosis. Ovarian cancer metastasis involves adhesion, invasion, and dynamic remodeling of cell-matrix interactions, where integrin trafficking plays a central role. The intracellular sorting receptor, SORL1 regulates receptor recycling and intracellular trafficking, with evidence linking its activity to oncogenic signaling in various cancers. Building on our prior findings that SORL1 modulates endosomal trafficking and recycling of EGFR1 and FGFR4 in ovarian cancer, this study aimed to investigate how SORL1 regulates ovarian cancer invasion and metastasis by modulating integrin trafficking and endosomal recycling. The therapeutic potential of inhibiting tumor peritoneal dissemination and metastasis in recurrent ovarian cancer by targeting SORL1 was also evaluated.
Methods:SORL1 expression was knocked down in patient-derived ovarian cancer cells using siRNA/shRNA. Tumor spheroid co-cultured with mesothelial cells were used to quantify cancer cell clearance efficiency. Integrin localization was examined by immunofluorescence co-staining with endosomal markers and confocal microscope imaging. Flow cytometry measured cell surface integrin levels with and without activation by fibronectin as an extracellular matrix ligand. Co-immunoprecipitation and proximity assays assessed SORL1-dependent interactions between integrins α3/β1 and the trafficking adaptor GGA1. Finally, the activity of a SORL1-blocking protein on inhibition of ovarian cancer migration and mesothelial clearance was evaluated.
Results:SORL1 knockdown significantly reduced ovarian cancer invasion and mesothelial clearance. Immunofluorescence staining analysis revealed enhanced internalization of integrin-a3 upon SORL1 inhibition, showing a shift from the plasma membrane to intracellular endosomal compartments. Consistently, the decreased surface levels of integrins after fibronectin activation in SORL1-knockdown cells indicated impaired integrin recycling. Increased interaction of integrins with GGA1 in SORL1 knockdown cells suggested accumulation in early and recycling endosomes. SORL1-blocking antibody inhibited ovarian cancer migration and mesothelial clearance. These findings demonstrate that loss of SORL1 disrupts integrin trafficking and surface expression, thereby impairing integrin-mediated adhesion and invasion in ovarian cancer.
Conclusion:SORL1 regulates integrin trafficking and recycling to maintain integrin-mediated adhesion and invasion in ovarian cancer cells. Loss of SORL1 disrupts these processes, limiting peritoneal dissemination. Targeting SORL1-dependent trafficking pathways may offer therapeutic potential to inhibit ovarian cancer metastasis.

#7488 C-Met and Integrin-αV regulated the response of desmoid cells to sorafenib.

Tianjie Pu[1], Jia Hu[1], Vladislav Tsiperson[2], Lakshana Senthilkumar[3], Narasimhan P. Agaram[1], Marco Vincenzo Russo[1], Ralph Garippa[1], Samuel Singer[1], Meera Hameed[1], Aimee Marie Crago[1]

[1]Memorial Sloan Kettering Cancer Center, New York, NY,[2]SUNY Downstate Health Sciences University, New York, NY,[3]Metropolitan Hospital Center, New York, NY

Background: The basis of sorafenib activity in desmoid tumors (DT) is poorly understood and predictive markers have not been defined. Activation of β-catenin transcription target c-ABL by PDGFRβ is associated with accumulation of EGR1 and increased sorafenib sensitivity in vitro, but in tumors, elevated EGR1 is associated with sorafenib resistance. Here we evaluate whether environmental signaling pathways outside of PDGFRβ modify EGR1 levels in DT and regulate sorafenib response.

Methods: A lentiviral shRNA screen targeting genes highly expressed in DT was performed in primary DT cell line (DES9525T). Potentially mitogenic genes encoding cell surface receptors were validated in DES8163T. Following treatment with drugs, shRNA directed at MET/ITGAV, HGF or vitronectin, cell proliferation, gene expression and protein analysis were assayed using CyQuant, RT-PCR and immunoblot, respectively. Synergy to drug treatments was assessed using Synergyfinder web (v3.0).

Results: The custom screen identified both MET and ITGAV as affecting DT cell proliferation (35 and 31% decrease in knock-downs [KDs], respectively, $p \leq 0.01$). Supplementation of DT cell cultures with HGF or vitronectin conversely promoted desmoid proliferation (1.9 and 1.7-fold, respectively, $p \leq 0.01$) and increased the IC_{50} of sorafenib in DT cells (from 5.2 and 5.7μM to 7.3 and 7.6μM). Growth of DT cells on vitronectin-coated plates was associated with increased phosphorylation of FAK but also PDGFRβ, ERK1/2 and the canonical c-ABL target CrkL; vitronectin exposure led to EGR1 accumulation in cells. ITGAV KD or treatment of cells with the FAK inhibitor defactinib abrogated this response and increased cell sensitivity to sorafenib with combined sorafenib/defactinib treatment having a synergistic effect on DT proliferation (HAS synergy score 19). Stimulation of cells with HGF also resulted in phosphorylation of c-MET, AKT, ERK1/2, and CrkL, led to EGR1 accumulation and increased FAK phosphorylation consistent with reported HGF/c-MET role in integrin signaling regulation; this was inhibited by MET KD. Treatment of DT cells with MET inhibitor tivantinib was additive with sorafenib while HGF supplementation was associated with increased synergy score when assessing combined sorafenib and FAK inhibitor defactinib (HAS synergy score 12 vs. 15).

Conclusions: Together, these findings demonstrate that HGF/MET and integrin-αV/FAK signaling each promote DT proliferation and sorafenib resistance. This is likely related to activation of downstream ERK/EGR1 in a manner not targetable by the PDGFRβ inhibitor. C-MET and integrin signaling pathway components may represent appropriate molecules to assess as markers predictive of sorafenib response in DT patients.

#7489 Unraveling a new ECM stiffening function of the axon guidance molecule Netrin-1.

Gaetan THIVOLLE LIOUX, Laurent Fattet, PATRICK MEHLEN

Cancer Research Center of Lyon, Lyon, France

State of the art The extracellular matrix (ECM) is a complex and dynamic network composed of core structural proteins and matrisome-associated components. Under physiological conditions, ECM homeostasis contributes to the maintenance of natural tissue stiffness. However, disruption of this balance can lead to abnormal stiffening, a hallmark observed in various pathological conditions, including fibrosis and cancer. Our laboratory investigates the role of the dependence receptor ligand Netrin-1 (NTN1), a neuronal guidance protein predominantly expressed during early developmental stages. Intriguingly, NTN1 is frequently re-expressed in tumors, where its presence has been correlated with increased ECM stiffness. As such, our research aims to elucidate the role of NTN1 in ECM remodelling and stiffening.
Methodology and resultsUsing atomic force microscopy (AFM) on inert Matrigel matrices, we observed a marked increase in stiffness upon supplementation with recombinant Netrin-1 (rNTN1). This stiffening effect was reversed by NP137, a monoclonal antibody targeting NTN1. Structural analyses via immunofluorescence staining for laminin-111 and rNTN1, alongside scanning electron microscopy (SEM), revealed a significant reduction in pore size in the presence of rNTN1. Complementary in silico analysis using PEPPI software indicated strong interactions between NTN1 and key ECM components such as Nidogen and Laminin.
PerspectivesTo validate these predicted interactions, we performed biolayer interferometry with various ECM proteins. Furthermore, 3D cultures models of MCF10A normal mammary epithelial cells exposed to NTN1 displayed a phenotypic transition toward a more mesenchymal and invasive state. Interestingly, knockdown of NTN1 receptors did not prevent this phenotypic shift, suggesting a novel receptor-independent function for NTN1 in promoting cell invasiveness through direct modulation of ECM stiffness. Ongoing structural analyses are being conducted on fibroblast-derived matrices, with and without endogenous Netrin-1 expression, to evaluate its potential remodeling effects on collagen IV and fibronectin networks. In parallel, these matrices are utilized in functional assays to investigate how Netrin-1 ECM impact, influences cellular behaviours and transcriptional activity, using a range of experimental approaches.

#7490 MYBBP1A is part of a mechanically modulated system that alters breast cancer metastatic potential by regulating focal adhesion.

Xi Chen, Kent W. Hunter

National Cancer Institute, Bethesda, MD

MYB binding protein 1a (MYBBP1A) was first identified for its ability to bind and repress the proto-oncogene c-MYB. Most research focuses on its role in regulating ribosomal RNA (rRNA) transcription; However, its impact on metastasis remains unclear. Analysis of TCGA breast cancer patient data reveals higher MYBBP1A levels are associated with shorter survival times in breast cancer patients, while a Mybbp1a knockdown (KD) gene signature, generated by machine learning, indicates significantly improved patient survival outcomes. Using mouse spontaneous metastasis model, we confirmed that MYBBP1A loss suppresses breast cancer cell metastasis. Further analysis revealed that Mybbp1a KD cells exhibit robust abnormalities in cell morphology, which is associated with reduced cell invasion and disrupted F-actin organization. Cell morphological changes are partially rescued in type I collagen-coated high stiffness extracellular matrix (ECM) culture, indicating MYBBP1A could be part of a mechanically modulated system that alters breast cancer metastatic potential. This is supported by the observation that MYBBP1A levels exhibit a gradually increase in response to the increases of ECM stiffness, which is coupled with increased cell invasion capacity. Mechanical stimuli from the tumor microenvironment play an important role in mediating breast cancer metastasis. The pathways that cancer cells use to sense and leverage mechanical cues are largely driven by the assembly and disassembly of focal adhesions, which regulate the dynamics of F-actin stress fibers and couple F-actin with the extracellular matrix (ECM) to transduce mechano-signaling to nucleus and regulate cell motility. Focal adhesion can be visualized by immunofluorescence (IF) staining of phospho-FAK (focal adhesion kinase) plaques at the points of F-actin filaments and be measured by FAK level. Our data shows focal adhesion is reduced in Mybbp1a KD cells, evidenced by weakened level and number of phospho-FAK clustering at the points of F-actin. In parallel, overexpression of FAK rescues breast cancer cell phenotypes and partially restores the reduced cell metastasis capacity observed in Mybbp1a KD. In exploring the function of MYBBP1A in regulating mechanosignal transduction, we found that SUN2, an important component of the Linker of Nucleoskeleton to the Cytoskeleton (LINC) complex, was stripped from nuclear envelop and relocated to heterochromatin dense areas, upon Mybbp1a KD. That breaks the connection between nucleus and cytoskeleton and could explain the reduced focal adhesion assembly following Mybbp1a KD. In the future, we will keep studyingFuture work will focus on the role of MYBBP1A as part of a mechanically modulated complex that is important in promoting breast cancer metastasis.

#7492 Preclinical osimertinib-resistant mouse models for advancing third-generation EGFR-TKI drug development.

Hongyan Sun, Yinuo Wang, Shiying Guo, Yujing Zhang, Huixin Yang, Xiang Gao

GemPharmatech Co., Ltd., Nanjing, China

The efficacy of Osimertinib, a third-generation EGFR tyrosine kinase inhibitor used in non-small cell lung cancer (NSCLC), is well established through clinical trials showing prolonged patient survival with EGFR-TKI therapy. However, a key clinical challenge arises from acquired resistance, frequently mediated by EGFR C797 mutations—notably the triple mutations Del19/T790M/C797S and L858R/T790M/C797S. To systematically investigate Osimertinib resistance and enable the testing of new therapeutic candidates, we have developed a panel of resistant models in both in vitro and in vivo settings. Using the human lung adenocarcinoma NCI-H1975 cell line—which carries the dual EGFR L858R/T790M mutations, we employed precise gene editing to introduce the C797S mutation, generating an isogenic triple-mutant subline (H1975 L858R/T790M/C797S). This model recapitulates the genetic profile of patients who have developed resistance following Osimertinib treatment. In addition to C797S-mediated resistance, we applied prolonged in vitro exposure of multiple cell lines to escalating Osimertinib concentrations, inducing acquired resistance independent of C797 mutations. Resistance was quantitatively confirmed through IC50 assays, which revealed a marked increase in Osimertinib tolerance. These models were further validated in vivo for tumor growth and drug response, confirming their functional resistance. We now possess well-characterized Osimertinib-resistant cell lines, including triple-mutant NCI-H1975 and PC-14 variants, providing essential platforms for dissecting resistance mechanisms and accelerating the development of next-generation treatments.

#7493 Novel preclinical models for evaluating checkpoint inhibitor resistance.

Hongyan Sun, Yan Wang, Fang Zhu, Yujing Zhang, Huixin Yang, Xiang Gao

GemPharmatech Co., Ltd., Nanjing, China

Cancer immunotherapy targeting the PD-1/PD-L1 axis has revolutionized oncology, producing durable responses in a range of malignancies. However, a significant number of patients either fail to respond or develop resistance following initial success. There is a critical need for robust preclinical models of anti-PD-1 resistance to elucidate underlying mechanisms and inform new therapeutic strategies. Known resistance mechanisms include impaired tumor antigen presentation, downregulation of MHC class I molecules, alterations in IFN-γ signaling, and an immunosuppressive tumor microenvironment. To address this need, GemPharmatech has developed three distinct preclinical models of anti-PD-1 resistance:

Drug-Induced Resistance Model: CT26 tumors were engrafted in BALB/c-hPD-1 mice and subjected to repeated cycles of anti-PD-1 treatment (KEYTRUDA®) and re-implantation of non-responding tumors. This iterative in vivo selection pressure generated a stable anti-PD-1 resistant model.

Genetically Engineered Model: Isogenic anti-PD-1 resistant models were created by knocking out genes associated with resistance (B2Mor STK11) in the CT26 cell line.

Primary Resistance Model. Characterization of the drug-induced model confirmed a stable resistant phenotype in vivo, with resistant CT26 cells exhibiting accelerated tumor growth compared to parental cells. RNA sequencing identified differentially expressed genes, offering insights into potential resistance pathways. In the engineered STK11knockout model, loss of STK11 abrogated the response to anti-PD-1 therapy. This was associated with a reduced infiltration of CD8+ T cells, a significant accumulation of myeloid-derived suppressor cells (MDSCs) in the tumor microenvironment, and decreased PD-L1 expression on tumor cells, implicating immunosuppressive mechanisms in the resistance phenotype. In summary, these validated preclinical models of anti-PD-1 resistance serve as powerful tools for deconstructing resistance mechanisms, facilitating biomarker identification, and guiding the development of novel combination therapies.

#7494 Development of enhanced enhertu-resistant HER2-positive breast cancer models for ADC resistance research.

Hongyan Sun, Yuan Fang, Fang Zhu, Yujing Zhang, Huixin Yang, Xiang Gao

GemPharmatech Co., Ltd., Nanjing, China

Antibody-drug conjugates (ADCs) combine the precision of a monoclonal antibody with a potent cytotoxic payload to selectively target cancer cells and represent a promising strategy for targeted cancer therapy. Enhertu (trastuzumab deruxtecan, DS-8201), an ADC targeting HER2-positive cancers, has achieved remarkable clinical efficacy and set a new benchmark for anti-HER2 ADCs, yet acquired resistance remains a major challenge. To elucidate resistance mechanisms and support development of next-generation ADCs, we established a stepwise preclinical platform for Enhertu resistance using the HER2-positive breast cancer cell line JIMT-1. JIMT-1 tumor bearing mice were first subjected to repeated *in vivo* Enhertu dosing, and subsequent residual tumors were harvested to derive a resistant cell line. This resistant cell line exhibited stable resistance to Enhertu both *in vitro* and *in vivo. In vitro*, resistant cells showed a right-shifted IC50 to the DXd payload, while flow cytometry and immunohistochemistry demonstrated the line maintained HER2 expression. RNA sequencing and whole-exome sequencing revealed upregulation of ABCG2 and other transporters, indicating a payload-centric resistance mechanism driven by altered payload sensitivity and enhanced drug efflux rather than target downregulation. To generate a more stringent model that better reflects long-term, high-intensity clinical exposure, the resistant cell line was re-implanted and serially passaged *in vivo* under high-dose Enhertu treatment, yielding an “enhanced” high-dose resistant tumor model. These enhanced tumors remained HER2-positive by IHC and displayed transcriptional changes similar to the resistant cell line, including pronounced ABCG2 upregulation and broader alterations in genes related to drug transport and cell-cycle regulation. Together, these Enhertu-resistant models offer a practical system to investigate resistance mechanisms that may not yet be evident in clinical samples and to identify candidate biomarkers and therapeutic targets. These cell lines also enable preclinical testing of biomarker-guided combination therapies and next-generation ADCs designed to overcome Enhertu resistance in HER2-positive malignancies.

#7495 Modeling of de novo and experimentally induced acquired resistance to trastuzumab deruxtecan in HER2-positive patient-derived xenografts.

Hongyan Sun, Xiaoliu Yang, Shiying Guo, Yujing Zhang, Huixin Yang, Xiang Gao

GemPharmatech Co., Ltd., Nanjing, China

Trastuzumab Deruxtecan (T-DXd) has improved outcomes for HER2-positive cancers, yet intrinsic and acquired resistance present significant clinical hurdles. The mechanisms of resistance are diverse and incompletely understood, and optimal subsequent therapies for T-DXd-resistant patients remain undefined. To address this, we established a matched pair of patient-derived xenograft (PDX) models that recapitulate these critical clinical scenarios. Through in vivo efficacy screening of our HER2-positive PDX bank, we identified a unique model demonstrating de novo resistance to T-DXd, showing minimal tumor regression upon treatment. Separately, we generated a model of acquired resistance by subjecting an initially sensitive HER2-positive PDX to repeated cycles of T-DXd in vivo. This model recapitulated the clinical progression from initial response to treatment failure. This paired set of models provides a powerful, controlled system for a direct comparative analysis of resistance mechanisms. These well-characterized PDX models represent a critical resource for the oncology community. They enable the direct comparison of molecular mechanisms driving both intrinsic and treatment-induced resistance in a controlled, in vivo setting. This platform is immediately applicable for investigating alterations in HER2 biology, payload delivery, and bypass signaling pathways, and is ideally suited for evaluating novel therapeutic strategies aimed at overcoming T-DXd resistance.

#7499 Genetic evolution of sarcomatoid/rhabdoid de differentiation in renal cancers..

Natalie R. Abuelsamen, Kate I. Glennon, Mustafa Soytas, Madeleine Arseneault, Peixi Liu, eleonora scarlata, fadi brimo, Simon Tanguay, Yasser Riazalhosseini

Human Genetics, McGill University, Montreal, QC, Canada

Background: The presence of sarcomatoid and rhabdoid (SR) differentiation is associated withpoor prognosis in renal cell carcinomas (RCCs), yet molecular underpinnings of SR patterns areunderstudied. While advances in cancer genomics have shed light on substantial intratumoralheterogeneity (ITH) in RCC, the evolutionary dynamics fueling disease progression, andemergence of SR dedifferentiation has remained poorly understood.
Methods: We conducted multi-region whole-exome sequencing (WES) of 156 tumor samples,representing S/R histological features and matched clear-cell or papillary tumor areas from 46RCC patients. Somatic variant and copy number analysis was performed to identify distinctsubclonal populations within each sample. Using PyClone and ClonEvol, we modeled thetrajectories of subclonal evolution within each patient, capturing the emergence and progressionof shared and site-specific subclones across tumor regions and metastatic sites.
Results: We observed significant ITH across RCC subtypes. Each individual sample exhibitedseveral cell populations with distinct profiles of subclonal somatic mutations. Temporal orderingof subclones revealed the emergence of new subclonal cell populations during the transition to S/Rdifferentiation. We constructed phylogenetic trees for each individual patient, in which theemergence of subclones driving S/R features exhibited both monoclonal and polyclonal seedingpatterns, suggesting that there may be several evolutionary routes to these changes.
Significance: Monoclonal tumors showed a more uniform path of evolution, while polyclonaltumors exhibited greater genetic complexity, reflecting the diversity of tumor progressionpatterns. These findings underscore the importance of targeting truncal mutations in early-stagetumors and monitoring subclonal evolution in aggressive phenotypes.
Disclosures: The authors have no conflicts to disclose.

#7500 Dependent lineage regulatory programs in TP53-mutated acute myeloid leukemia revealed through deep single-cell multi-omic profiling of patient samples.

Felix A. Radtke[1], Bijay S. Jaiswal[2], Gonzalo Lopez[3], Junfei Zhao[4], Sagnik Banerjee[5], Daiane Hemerich Brennan[4], Yilin Zhao[6], Verena Korber[1], Marlen Metzner[1], Rachel Moore[1], Bilyana Stoilova[1], Batchimeg Usukhbayar[1], David Cruz Hernandez[1], Maria Ortiz Estevez[7], Aimee O'Donohue[8], Daniel Lopes de Menezes[2], Rajasekhar NVS Suragani[9], Anita K. Gandhi[8], Paresh Vyas[1]

[1]MRC Molecular Haematology Unit, Radcliffe Department of Medicine, Weatherall Institute of Medicine, University of Oxford, Oxford, United Kingdom,[2]Translational Development, Bristol Myers Squibb, Brisbane, CA,[3]Informatics and Predictive Sciences, Bristol Myers Squibb, Cambridge, MA,[4]Informatics and Predictive Sciences, Bristol Myers Squibb, Summit, NJ,[5]Informatics and Predictive Sciences, Bristol Myers Squibb, San Diego, CA,[6]Informatics and Predictive Sciences, Bristol Myers Squibb, Seattle, WA,[7]Informatics and Predictive Sciences, Bristol Myers Squibb, Sevilla, Spain,[8]Translational Development, Bristol Myers Squibb, Summit, NJ,[9]Translational Development, Bristol Myers Squibb, Cambridge, MA

TP53-mutated (*TP53*m) Acute myeloid leukemia (AML) represents a clinically intractable and biologically distinct disease. To study the molecular basis of this disease through hemopoiesis, we integrated single-cell RNA-seq (10x and long-read Oxford Nanopore sequencing) with open chromatin profiles (scATAC-seq), whole-genome (WGS) to capture structural variants and copy number alterations, and deep panel DNA sequencing from bone marrow samples taken from a cohort of 49 *TP53*m AML patients, 7 *TP53* wild type (WT) AML patients, and 4 healthy donors.

Phased genotyping plus WGS revealed biallelic loss to be associated with intrachromosomal breakage, whereas monoallelic loss favored numerical chromosomal alterations. *TP53*m clones pervaded stem/progenitors and myeloerythroid lineages but were proportionally depleted in mature lymphocytes. While co-occurring AML driver mutations influence the lineage biases of *TP53m* clones, we observed expansion of HSC/MPP, LMPP, and late erythroid compartments.

In HSC/MPP dominant disease, *TP53m* cells displayed suppression of translational and mitochondrial-respiratory programs, with enrichment of a “p53-LSC” signature linked to chronic inflammatory stress. This suggests adaptation through metabolic quiescence, conferring persistence under inflammatory pressure. In LMPP-dominant expansion, we observed enriched MYC/E2F targets. Transcriptomic neighborhood analysis with pseudotime showed the erythroid compartment to be heterogeneous, with less mature basophilic cells enriched for *TP53*m clones, whereas more mature orthochromatic cells were enriched for *TP53*wt clones, nominating this transition as a tipping point for differentiation delay/arrest. Consistently, in erythroid dominant patients, late-stage erythroid cells demonstrated impaired GATA-1 and KLF1 (erythroid TFs) activities, and *TP53*m clones showed heightened GATA2, SPI1, and CEBPD regulon activity. *TP53*m versus *TP53*wt clones in erythroid differentiation showed heightened transcriptional activity of the EIF2AK1(HRI)→eIF2α mediated integrated stress response (ISR). Differential expression analysis within the aforementioned erythroid compartment showed ISR activation in *TP53m* clones; *SESN2*, *DDIT4*, and *DDIT3*/CHOP significantly up, with *ATF3*, and *XBP1*, up-trending, together with increased *GATA2*. Replication/mitochondrial-handling components (*GINS2*, *RPA3*, *ABCB8*) were significantly downregulated. These data together support a model in which deficient GATA-1/KLF1 function underpins the intra erythroid arrest of *TP53*m clones possibly due to activated HRI-ISR circuitry.

These detailed molecular differentiation stage specific analyses of *TP53*m AML provide mechanistic insights and a platform for functional and synthetic lethal studies to specifically target *TP53*m leukemic cells.

#7502 Spindle assembly checkpoint integrity determines sensitivity to KIF18A inhibition in small-cell lung cancer.

Chiori Tabe, Rajesh Kumar, Yang Zhang, Yue Huang, Ajit Kumar Sharma, Roshan L. Shrestha, Anish Thomas

National Cancer Institute, National Institutes of Health, Bethesda, MD

Small-cell lung cancer (SCLC) is characterized by extensive chromosomal instability (CIN) and rapid proliferative turnover, yet the cellular vulnerabilities arising from these features remain insufficiently defined. KIF18A, a kinesin-8 family motor protein that regulates microtubule plus-end dynamics and facilitates chromosome alignment at metaphase, has been recently emerged as a selective dependency in CIN-high tumors. Here, we investigated the role of KIF18A in SCLC, a prototypical CIN-high malignancy. Transcriptomic analyses revealed that KIF18A expression was markedly higher in SCLC compared with non-small-cell lung cancer (NSCLC) subtypes and positively correlated with CIN-related gene signatures (CES, CIN70) and proliferation markers such as MKI67 and PCNA. However, neither KIF18A transcript nor protein levels were predictive of responsiveness to the selective KIF18A inhibitor AM-9022 across a diverse panel of SCLC cell lines, indicating that dependency is not governed by expression levels. Comparative RNA-sequencing of AM-9022-sensitive and -resistant SCLC cell lines demonstrated distinct mitotic gene-expression programs. Sensitive cells showed enrichment of pathways associated with mitotic spindle assembly kinetochore organization, and spindle assembly checkpoint (SAC) activation. Consistently, immunofluorescence analysis revealed that resistant cells exhibited diminished expression and impaired kinetochore localization of the SAC components MAD1 and BUBR1, indicative of defective SAC signaling. Live-cell imaging confirmed that KIF18A inhibition induced pronounced mitotic arrest and apoptotic cell death in SAC-proficient cells, whereas SAC-deficient lines bypassed prolonged arrest and proceeded through aberrant mitosis with chromosome segregation errors, thereby escaping cell death. Collectively, these findings establish SAC competency as a critical determinant of vulnerability to KIF18A inhibition in SCLC. KIF18A blockade triggers catastrophic mitotic arrest and apoptosis in SAC-proficient, CIN-high SCLC cells, while SAC deficient counterparts tolerate spindle perturbations and continue proliferating despite persistent chromosomal errors. This study defines mitotic checkpoint integrity as both a mechanistic basis and a predictive biomarker for therapeutic response to KIF18A inhibition, providing a conceptual framework for exploiting mitotic control in chromosomally unstable SCLC.

#7503 Spatio-temporal analysis of EGFR inhibitor resistant tumor epithelial clusters.

Shuichi Watanabe[1], Yoshiyuki Suehara[1], Masachika Ikegami[1], Soohwan Park[1], Yo Kimura[1], Toshihide Ueno[1], Takuo Hayashi[2], Hiroyuki Mano[3], Kazuya Takamochi[4], Shinji Kohsaka[1]

[1]Division of Cellular Signaling, National Cancer Center Japan, Tokyo, Japan,[2]Department of Diagnostic Pathology, Juntendo University Hospital, Tokyo, Japan,[3]National Cancer Center Japan, Tokyo, Japan,[4]General Thoracic Surgery, Juntendo University Hospital, Tokyo, Japan

[Background]Drug-tolerant persister (DTP) cells are a reversible drug-insensitive tumor subpopulation implicated in minimal residual disease (MRD) and recurrence. However, their emergence mechanisms and therapeutic vulnerabilities remain unclear. We previously tracked clonal dynamics in vivo using genetic barcodes and showed that expansion of specific clones contributes to the resistance of EGFR inhibitors. Here, we analyzed non-small cell lung cancer treated with EGFR inhibitors to (1) identify treatment-resistant tumor cell populations and (2) elucidate spatial mechanisms underlying DTP cell emergence.
[Methods]Tumor samples from the PIT3 trial (UMIN000026197) were analyzed before and after the neoadjuvant EGFR inhibitor therapy. Single-cell (sc) RNA-seq (n = 8) and Visium HD spatial transcriptomics (n = 10) were performed. Spatial datasets were processed using HueTracer (https://github.com/MANO-B/HueTracer), enabling extraction of single-cell-level expression profiles and integration with scRNA-seq.
[Results]Integrated scRNA-seq analysis (8 specimens, 16,419 cells) identified multiple tumor epithelial clusters, including an EGFR-resistant subcluster enriched in poor responders. This subcluster showed a higher proportion of G1-phase cells, reduced EGFR, and elevated EMT-related genes, suggesting treatment-resistant phenotypes. Rare cells with similar transcriptional features were also detected in responders, indicating the presence of surviving DTP-like cells.
Spatial transcriptomic analysis (20 specimens, 2,415,876 cells) identified tumor clusters and treatment-responsive regions characterized by island-like residual lesions with necrosis and desmoplasia. Small numbers of surviving cells were designated as DTP candidates and compared with other tumor epithelial cells. Across five cases, meta-analysis of differentially expressed genes revealed consistent upregulation of inflammation- and plasticity-related genes, including *ILR-X*, *TF-X*, *LAMB3*, and *TXLNB* (FDR < 0.05). GSEA showed enrichment of TNF-α/NFκB signaling, interferon response, EMT, and tissue remodeling pathways, indicating a shared inflammatory and plasticity-enhanced state in DTP candidates.
[Conclusion]Single-cell and spatial analyses demonstrate that DTP-like cells persisting after EGFR inhibitor therapy exhibit a shared molecular phenotype characterized by heightened inflammation and epithelial plasticity. These features may underlie microscopic residual disease capable of driving post-treatment recurrence, supporting the concept of DTP cells as a potential therapeutic target.

#7504 Do secondary MSH3/MSH6 alterations define an immune-modulatory subtype of MSI gastric cancer?.

Marika Milan[1], Daniela Conticelli[1], Marco Volante[2], Claudia Orru[2], Emanuela Boccuni[2], Simona Corso[2], Silvia Giordano[2]

[1]Candiolo Cancer Institute-IRCCS, Candiolo, Italy,[2]University of Turin, Turin, Italy

Gastric cancer (GC) is one of the leading causes of cancer-related morbidity and mortality worldwide. Molecular classification stratifies GC into four major subtypes: Epstein-Barr virus-positive, microsatellite instability (MSI), genomically stable, and chromosomal instability. Among these, MSI GC—representing approximately 8-25% of cases—is characterized by high mutational burden resulting from defects in the mismatch repair (MMR) system. For early-stage cancer the main therapeutic approaches include surgery, along with chemotherapy. Recently, immune checkpoint inhibitors, administered alone or in combination with other treatments, have demonstrated potent antitumoral activity in some subgroups of GC; among the responders are MSI tumors, which are associated with a better clinical prognosis compared with microsatellite-stable (MSS) ones. However, only around 50% of MSI GC obtain a benefit from immunotherapy. This study aims to elucidate the molecular mechanisms underlying the different ability of MSI CG to respond to immunotherapy, focusing on how alterations in mismatch repair genes can contribute to mutational burden, neoantigen formation, and immune activation. Taking advantage from our molecularly annotated platform including around 1000 primary tumors and 250 patient-derived xenografts (PDXs), we performed a multilevel molecular characterization to define MMR status and to functionally evaluate how specific MMR alterations influence immune responsiveness in vivo. Our preliminary data indicate that gastric cancers are characterized by intratumoral heterogeneity of the MMR, which may manifest as primary heterogeneity, defined by the coexistence of MSS and MSI regions, or as secondary heterogeneity, where MLH1 silencing is frequently accompanied by the additional loss of another MMR component, typically MSH3 or MSH6.This loss often results from frameshift mutations at mononucleotide repeat hotspots. These alterations, potentially reversible, have been linked to immune evasion. Notably, our findings indicate that secondary MSH3 and MSH6 mutations represent a frequent event in gastric MSI tumors (56% of MSI GCs display MSH3/MSH6 frameshift mutations), and we aim to explore their potential clinical implications. Future directions include dissecting the molecular pathways through which alterations in MMR genes generate subclonal neoantigenic diversity, ultimately shaping tumor-immune system interactions. A deeper understanding of these processes may inform the development and refinement of immunotherapeutic strategies for MSI gastric cancer.

#7505 Single-cell transcriptomics identifies distinct EPCAM-low and EPCAM-negative epithelial populations with aggressive phenotypes in hormone-receptor positive breast cancer.

Elise Di Lena[1], Alyssa Victoria Francis[2], Atilla Omeroglu[1], Sarkis Meterissian[1], Luke McCaffrey[1]

[1]McGill University, Montreal, QC, Canada,[2]Medicine, McGill Univ. Goodman Cancer Ctr., Montreal, QC, Canada

The intra-tumoral heterogeneity of hormone-receptor positive (HR+) breast cancers is incompletely known. The purpose of this study was to perform an unbiased characterization of the epithelial landscape in untreated, early-stage hormone-receptor positive (HR+) breast cancers. We performed single-cell RNA sequencing on over 60,000 unsorted cells from 6 primary HR+ tumors. A standardized bioinformatic pipeline was used for clustering, differential gene expression, and pathway analysis. Key findings were validated spatially using multiplexed immunofluorescence and Imaging Mass Cytometry. Our unbiased analysis revealed a complex epithelial landscape. The EPCAM-high cells, representing the largest luminal compartment, were highly heterogeneous and clustered into multiple patient-specific ("private") phenotypes that were strongly ER-positive and made up a tumor fingerprint unique to each patient. In contrast, we identified two distinct "public" phenotypes, present across multiple patients, with significantly reduced or absent EPCAM expression. The first population (EPCAM-low) expressed a unique pro-inflammatory signature enriched for interferon-gamma response and KRAS signaling pathways. The second population (EPCAM-negative) clustered distantly from all other epithelial cells and was enriched for aggressive, stem-like pathways, including TNF-alpha signaling via NF-kB and Hedgehog signaling. Both EPCAM-low/negative populations were hormone-receptor low. The EPCAM-high compartment is a heterogeneous mix of patient-specific populations, while the EPCAM-low/negative compartment contains distinct, shared populations with aggressive, non-targetable phenotypes. These findings reveal a pre-existing cellular reservoir that may drive de novo resistance to endocrine therapy and contribute to late recurrence. This work also highlights that common marker-based epithelial sorting methods may fail to capture the full heterogeneity of HR+ breast cancer.

#7506 CEACAM1-dominant molecular program drives immune escape in EGFR-mutant lung adenocarcinoma.

Jianyu Li, Qinglin Wang, Tongyan Liu, Siwei Wang, Rong Yin

Department of Thoracic Surgery, Jiangsu Cancer Hospital, The Affiliated Cancer Hospital of Nanjing Medical University, Nanjing, China

Background: In East Asian populations, EGFR-mutant lung adenocarcinoma (LUAD) represents the predominant molecular subtype, yet even the two most common variants, exon 19 deletions (19del) and L858R, exhibit substantial molecular and clinical heterogeneity whose determinants of malignant progression remain poorly defined. A subset of EGFR-mutant LUADs exhibits an immune-escape phenotype with poor tyrosine kinase inhibitor (TKI) response, highlighting the need to define EGFR-driven malignant programs and intercellular mechanistic crosstalk.

Methods: We performed single-cell RNA sequencing (scRNA-seq) on $EGFR^{19del}$ and $EGFR^{L858R}$ genetically engineered mouse models (GEMMs; n = 20) and on an in-house human EGFR-mutant LUAD cohort spanning early to advanced stages (n = 33), of which a subset had paired spatial transcriptomics (n = 8). Consensus non-negative matrix factorization (cNMF) was applied to derive metaprograms, which were correlated with immune composition, spatial niches, and clinical outcomes. Mechanistic and therapeutic relevance were evaluated using organoid co-cultures, blocking CEACAM1, and *in vivo* studies combining the anti-CEACAM1 antibody CM24 with TKIs and immune checkpoint inhibitors in TKI-resistant models.

Results: Analyses revealed immune-related malignant programs and a proliferation-associated program. Intriguingly, a CEACAM1-dominant metaprogram, termed CEACAM1-MP, emerged as an invasive subtype indicator independent of EGFR mutant status and was consistently associated with early progression and immune escape. A high CEACAM1-MP score correlated with worse overall survival (HR = 2.39, $P < 0.001$) in multiple datasets. CEACAM1-MP^{high} tumor cells showed reduced effector $CD8^+$ T-cell infiltration but strong interactions with $SPP1^+TIM3^+$ tumor-associated macrophages (TAMs), predominantly via CEACAM1-TIM3. Spatial transcriptomics revealed that CEACAM1-MP^{high} tumor cells localized to perivascular regions where they co-accumulated with $SPP1^+TIM3^+$ TAMs, forming an immunosuppressive niche that promoted M2-like polarization. The anti-CEACAM1 antibody CM24 impaired CEACAM1-MP^{high} tumor cell proliferation. In TKI-resistant models, CM24 combined with TKIs and PD-1 blockade significantly delayed tumor growth, with a tumor growth inhibition rate of 68% ($P < 0.01$).

Conclusions: This study identifies a CEACAM1-MP as an important driver of early invasion and immune escape in EGFR-mutant LUAD, defined by a perivascular niche and tight crosstalk with $SPP1^+TIM3^+$ TAMs. CEACAM1-MP provides a novel indicator to identify high-risk EGFR-mutant patients, while targeting CEACAM1 represents a promising strategy for refractory lung cancer.

#7507 Genomic evolution and heterogeneity of von Hippel-Lindau (VHL)-associated clear cell renal cell carcinoma revealed by multi-region whole-genome sequencing.

Francesca Corea[1], Husayn A. Pallikonda[2], Scott T. C. Shepherd[2], Isaline Rowe[3], Alessandro Larcher[3], Andrea Salonia[1], Samra Turajlic[2], Thomas J. Mitchell[4], Rosa Bernardi[5], Umberto Capitanio[3]

[1]Universita Vita-Salute San Raffaele, Milano, Italy,[2]The Francis Crick Institute, London, United Kingdom,[3]Comprehensive Cancer Center/Unit of Urology; URI, IRCCS San Raffaele Hospital, Milano, Italy,[4]Early Cancer Institute, University of Cambridge, Cambridge, United Kingdom,[5]Comprehensive Cancer Center, IRCCS San Raffaele Hospital, Milano, Italy

Intra-tumor heterogeneity (ITH) of somatic mutations is a hallmark of sporadic clear cell renal cell carcinoma (ccRCC). In contrast, the extent and nature of ITH in hereditary (VHL-associated) ccRCC remain poorly characterised, primarily due to the rarity of these tumors. This study aims to comprehensively characterise this heterogeneity and elucidate its evolutionary dynamics and biological relevance. To investigate intra- and inter-tumor heterogeneity in VHL-associated ccRCC, we performed multi-region whole-genome sequencing (WGS) of 23 primary tumor biopsies obtained from four spatially distinct regions of six small (≤3 cm) renal tumors across two patients carrying pathogenic germline *VHL* mutations. Somatic single-nucleotide variants (SNVs) and copy number alterations (CNAs) were analysed to reconstruct the genomic histories of these tumors. We found that all tumors were clonally independent, each harboring distinct sets of somatic variants and chromosomal copy number alterations, including the characteristic chromosome 3p loss. Within individual tumors, copy number profiles were homogeneous across regions, suggesting early acquisition of these events. Subclonal diversification of somatic SNVs was detected in all tumors. Notably, in one patient, two of the three analysed tumors displayed pronounced ITH, with most mutations being unique to a single region. Moreover, markedly distinct patient-specific molecular profiles emerged, characterised by divergent driver events and copy number landscapes that correlated with differences in their clinical grades. Although preliminary, these findings provide new insights into the genomic heterogeneity of VHL-associated ccRCC, advancing our understanding of how inherited kidney cancers develop and diversify, and potentially informing improved clinical management of patients with VHL disease.

#7509 A spatiotemporal cancer cell trajectory underlies glioblastoma heterogeneity.

Grant De Jong[1], Fani Memi[1], Tannia Gracia[1], Olga Lazareva[2], Richard Mair[3], Sam Behjati[1], Oliver Stegle[2], **Omer Bayraktar**[1]

[1]Wellcome Sanger Institute, Cambridge, United Kingdom,[2]German Cancer Resarch Centre, Heidelberg, Germany,[3]Cancer Research UK Cambridge Institute, Cambrige, United Kingdom

Cancer cells display highly heterogeneous and plastic states in glioblastoma, an incurable brain tumour. However, how these malignant states arise and whether they follow defined cellular trajectories across tumours is poorly understood. Here, we generated a deep single cell and spatial multi-omic atlas of human glioblastoma that pairs transcriptomic, epigenomic and genomic profiling of 12 tumours across multiple regions. We identify that glioblastoma heterogeneity is driven by spatially-patterned transitions of cancer cells from developmental-like states towards those defined by a glial injury response and hypoxia. This cellular trajectory regionalises tumours into distinct tissue niches and manifests in a molecularly conserved manner across tumours as well as genetically distinct tumour subclones. Moreover, using a new deep learning framework to map cancer cell states jointly with clones in situ, we show that tumour subclones are finely spatially intermixed through glioblastoma tissue niches. Finally, we show that this cancer cell trajectory is intimately linked to myeloid heterogeneity and unfolds across regionalised myeloid signalling environments. Our findings define a stereotyped trajectory of cancer cells in glioblastoma and unify glioblastoma tumour heterogeneity into a tractable cellular and tissue framework.

#7510 Molecular and clinical correlates of extrachromosomal DNA in oral squamous cell carcinoma.

Lucas Penny[1], Hugh Kim[2], Jeffrey Bruce[1], Matthew Waas[1], Meinusha Govindarajan[1], Christopher Yao[2], Thomas Kislinger[1], Laurie Ailles[1], Scott V. Bratmn[1]

[1]Department of Medical Biophysics, University of Toronto, Toronto, ON, Canada,[2]Department of Otolaryngology, University of Toronto, Toronto, ON, Canada

Introduction: Extrachromosomal DNA (ecDNA) consists of circularized chromosomal fragments generated through structural instability. In solid tumors, ecDNA amplifies oncogenes, reshapes cis-regulatory architecture, and alters therapeutic response. Its role in HPV-negative oral cavity squamous cell carcinoma (OSCC) remains poorly defined, with only limited tumor-specific analyses to date. Clarifying its contribution to transcriptional dysregulation and tumor phenotypes may identify drivers of carcinogenesis of OSCC.

Methods: We evaluated OSCC cases from Canada's Marathon of Hope Cancer Centres Network (MOHCCN). Whole-genome (~80X depth) and bulk whole-transcriptome sequencing (~80M reads) were performed on 131 primary tumors. ecDNA architecture was resolved using AmpliconArchitect and AmpliconClassifier. Differential gene expression was performed by DESeq2, and immune cell type deconvolution was performed by Cibersort. Matched patient-derived xenografts (PDXs) were generated to assess downstream functional effects.

Results: All OSCC cases were surgically treated with 16% stage I-II and 84% stage III-IVB. ecDNA was detected in 33 of 131 (25.2%) tumors. ecDNA positivity showed a significantly different subsite distribution compared with ecDNA-negative cases, with ecDNA positivity enriched in floor-of-mouth and tongue tumors (Fisher's exact $p = 1.7\times10^{-4}$). Smoking status, drinking history, and stage were not significantly associated with ecDNA burden. Recurrent ecDNA structures harbored key oncogenes and co-amplified partners, including CCND1, FGF19, FGF3, FGF4, MYEOV, PPFIA1, CTTN, and ANO1, with the highest enrichment on chromosomes 11 (n=14) and 7 (n=9). Transcriptomic analysis demonstrated marked up-regulation of ecDNA-enriched genes, with expression levels elevated by approximately six-fold relative to non-ecDNA counterparts (Wilcoxon test, $p < 1\times10^{-16}$). Correlation of ecDNA copy number with RNA expression supported direct dosage effects and regulatory augmentation; promoter-like element density showed a positive association with expression ($R=0.36$, $p=0.046$). Immune deconvolution demonstrated a significant reduction in resting natural killer cells in ecDNA-positive tumors (FDR < 0.05), while M1 macrophages (FDR = 0.065) and CD8 T cells (FDR = 0.096) showed similar downward trends. Additionally, matched PDX models were generated and profiled for transcriptome and proteome on 88 of the 131 patients; 26/88 (29.5%) tumors were ecDNA positive.

Conclusion: This work delineates the landscape and functional impact of ecDNA in OSCC, linked to transcriptional amplification, regulatory element activity, and shifts in immune contexture. These findings establish ecDNA as a correlate of tumor biology and a potential therapeutic target.

#7511 Extrachromosomal *MDM2* amplifications define an ecDNA-permissive tumor cell state that impacts intercellular tumor heterogeneity and treatment response across cancers.

Rachel Schmargon[1], Giulia Montuori[1], Elias Rodriguez-Fos[1], Lotte Bruckner[1], Dennis Gurgen[2], Anton George Henssen[1], Jan-Rafael Dorr[1]

[1]Department of Pediatric Oncology/Hematology, Charite-Universitatsmedizin Berlin, corporate member of Freie Universitat Berlin and Humboldt Universitat zu Berlin, Berlin, Germany, Berlin, Germany,[2]Experimental Pharmacology and Oncology Berlin-Buch GmbH, Berlin, Germany

Extrachromosomal DNA (ecDNA) amplifies oncogenes with high copy-number variability, promoting heterogeneity, rapid tumor evolution and treatment failure. MDM2, a key negative regulator of TP53, is frequently amplified on ecDNA, yet its impact on ecDNA dynamics and ecDNA dosage-driven treatment responses remains unclear. We integrated pan-cancer ecDNA reconstructions (TCGA + PCAWG), single-cell DNA FISH and ImmunoFISH, scRNA-seq, scG&T-seq from cell lines and PDX models with acute drug perturbations to analyze the impact of extrachromosomal *MDM2* amplifications on ecDNA maintenance, TP53 function and treatment response. Consistent with prior work, our analysis of pan-cancer ecDNA reconstructions (TCGA + PCAWG) revealed that *MDM2* is the most frequently amplified oncogene on ecDNA and is predominantly amplified extrachromosomally rather than on homogeneously staining regions (HSRs). Among over 100 recurrently amplified oncogenes, we found *MDM2* to be one of the strongest ecDNA-biased drivers and to be associated with increased amplicon size and complexity. In contrast to *MDM2* amplifications on HSR, *MDM2* ecDNA almost exclusively arose in *TP53*-wildtype tumors and frequently co-occurred with additional ecDNA oncogenes, suggesting that *MDM2* ecDNA creates a phenotypically *TP53*-deficient state that supports ecDNA maintenance and diversification. In neuroblastoma and astrocytoma models, *MDM2* ecDNA copy number tightly correlated with protein and transcript abundance, generating pronounced single-cell heterogeneity. In this way *MDM2* copy number determined TP53 activity and differentially affected treatment outcome in response to cytotoxic or targeted therapies at single-cell level as determined by combined fluorescence-in-situ hybridization and immunofluorescence (FISH/IF) and G&T sequencing data. Whereas chemotherapy rapidly enriched for ecDNA-high cells with reduced TP53 signaling, pharmacologic MDM2 inhibition (Nutlin-3a/Idasanutlin) selectively eliminated ecDNA-high subclones through TP53-dependent apoptosis. Similarly, MDM2 inhibition also reduced *MYCN* copy numbers in neuroblastoma cell lines and PDX with *MYCN* amplification, indicating that TP53 activation disrupts ecDNA-permissive states across different oncogenes. Our study demonstrates that *MDM2* ecDNA is the predominant ecDNA oncogene in human cancers and defines an ecDNA-permissive state in *TP53*-wildtype tumors which facilitates rapid adaptation to different therapeutic pressures. These results identify *MDM2* ecDNA copy number variation as a functional determinant of acute treatment responses and reveal MDM2-regulated TP53 function as a vulnerability in ecDNA-carrying cancers that may be exploited through rational treatment sequencing.

#7513 Integrated clonal and single-cell analyses uncover progenitor-driven tumor diversification in early-stage endometrioid endometrial carcinoma.

Suguru Miyata[1], Hiroshi Yoshida[2], Toyoyuki Hanazawa[3], Masahito Kawazu[4]

[1]Chiba Cancer Center, Chiba, Japan,[2]Gastrointestinal Oncology Division, National Cancer Center Hospital, Tokyo, Japan,[3]Chiba University, Chiba, Japan,[4]Chiba Cancer Center Research Institute, Chiba-shi, Japan

Background and Objectives

The normal endometrium undergoes cyclical regeneration and frequently contains somatic mutations, yet the earliest steps of endometrioid endometrial carcinoma (EEC) development remain poorly defined. Although tumor heterogeneity arises from both genomic evolution and diversity in epithelial cell states, how these two axes interact during early tumorigenesis is not well understood. To address this question, we focused on early-stage EEC and performed an integrative analysis linking clonal architecture with cell-state heterogeneity.

Methods

We performed multi-region whole-exome sequencing (WES) of uterine samples from 37 patients with early-stage EEC to map the anatomical distribution of tumor clones. Representative cases covering POLE-mutated, microsatellite instability-high, and copy-number-low subtypes underwent single-cell RNA sequencing to characterize epithelial differentiation states and reconstruct lineage relationships. Somatic mutations identified by WES were used to infer clonal structures at single-cell resolution. Patient-derived organoids were established to functionally evaluate distinct progenitor-like tumor populations.

Results

Single-cell RNA sequencing revealed a spectrum of epithelial differentiation, ranging from mature ciliated and secretory cells to undifferentiated progenitor-like tumor cells. The proportions of these states varied widely not only between patients but also across regions within the same uterus. By integrating WES-derived mutations with single-cell profiles, we showed that individual tumor clones contained both progenitor-like and differentiated cells, recapitulating a hierarchical epithelial organization reminiscent of the normal endometrium.

Subclonal populations differed markedly in epithelial composition and proliferative activity, indicating that clone-specific genomic alterations influence cell-state output. Notably, we identified two transcriptionally and functionally distinct progenitor-like tumor cell types, suggesting multiple differentiation routes in early tumor evolution.

Conclusions

Early-stage EEC exhibits coordinated heterogeneity at genetic and cellular levels. The discovery of two progenitor-like tumor populations provides evidence for parallel differentiation programs that drive early tumor diversification. By integrating clonal evolution driven by genetic alterations with single-cell phenotypes, this study refines current EEC classification frameworks such as ProMisE and offers new biological insights into the origins, propagation, and therapeutic vulnerabilities of early-stage endometrial cancer.

#7514 Spatial multimodal and functional dissection reveal a UCHL1-driven malignant program in clear cell renal cell carcinoma.

Yize Li[1], Wagma Caravan[1], Xiyi Wei[1], Kapur B. Dhami[1], Kazuhito Sato[1], Xiangwei Fang[1], Preet Lal[1], Hongyi Liu[2], Lijun Chen[2], Cody Weimholt[1], Hui Zhang[2], Li Ding[1], Feng Chen[1]

[1]Washington University in St. Louis, Saint Louis, MO,[2]Johns Hopkins University, Baltimore, MD

Clear cell renal cell carcinoma (ccRCC), the most common subtype of kidney cancer, exhibits substantial molecular and spatial heterogeneity that contributes to therapeutic resistance and poor clinical outcomes. Our previous work identified UCHL1 as a marker of aggressive ccRCC, but its mechanistic role in tumor progression remained unclear. To further elucidate UCHL1 function, we integrated single-nucleus RNA sequencing (snRNA-seq) from 67 tumors with bulk proteogenomics and spatial assays addressing molecular coverage and spatial specificity. Our refined tumor-intrinsic UCHL1 classification identified a distinct ccRCC subgroup characterized by elevated UCHL1 mRNA and protein abundance. The UCHL1-high subgroup, comprising 19% of tumors in this cohort, was significantly associated with BAP1 mutants, immune infiltration, and poor prognosis. The spatial mapping in Xenium indicated UCHL1-high tumors displayed enhanced interactions with an immune-inflamed tumor microenvironment (TME), whereas UCHL1-low tumors were enriched for immune-desert regions dominated by endothelium and VEGF signaling. Furthermore, we observed spatial dynamics in UCHL1 expression arising from distinct subclones within the same tumor, reflecting the intratumoral heterogeneity in the UCHL1-high subgroup. Our functional studies demonstrated that UCHL1 knockout and downregulation markedly suppressed ccRCC cell proliferation and tumorigenicity in vitro and in cell line-derived xenograft (CDX) models. Pharmacological inhibition of UCHL1 consistently reduced tumor growth in ccRCC cell lines. The corresponding cell line proteomics and post-translational modification profiling, including phosphorylation and ubiquitination, delineated that UCHL1 regulated key tumor-promoting pathways of inflammation and epithelial-mesenchymal transition (EMT) through NF-κB activation. Notably, the RESL9 patient-derived xenograft (PDX) model responded robustly to the UCHL1 inhibitor, exhibiting pronounced tumor growth suppression. Collectively, these findings establish UCHL1 as a critical molecular driver and therapeutic target in ccRCC, supporting the potential of UCHL1-directed monotherapies or combination regimens to improve outcomes for patients with advanced ccRCC.

#7515 Uncovering transdifferentiation mechanisms underlying heterogeneity in neuroblastoma.

Michele Tomanelli[1], Jennifer Hoti[2], Ilaria Medici[2], Chaimae Sellak[2], Tullio Florio[3], Aldo Pagano[4]

[1]Department of Experimental Medicine, University of Genoa, Genoa, Italy,[2]University of Genoa, Genoa, Italy,[3]Department of Internal Medicine, University of Genoa, Genoa, Italy,[4]IRCCS Ospedale Policlinico San Martino, Genoa, Italy

Neuroblastoma is the most prevalent extracranial tumor in newborns and originates from neural crest-derived cells. Using selected Neuroblastoma cell lines, we generated clones engineered to express the non-coding RNA NDM29. This approach allowed us to investigate the function of NDM29 in tumor cell differentiation and to identify potential new therapeutic targets aimed at limiting tumor aggressiveness. Additional analyses, including single-cell sequencing, revealed the existence of distinct cellular subpopulations within this model. These subsets were subsequently separated through FACS sorting. The cellular heterogeneity observed in this system mirrors the complexity found in neuroblastoma patient samples. The clonal nature of our model and the presence of multiple subpopulations suggest that the observed heterogeneity arises from transdifferentiation processes. The plasticity of these subpopulations is a central focus of our study. The ability of cancer cells to undergo transdifferentiation is a key aspect in cancer research. In our model, we identified a subpopulation capable of responding to VEGF signaling and potentially able to regulate the angiogenic process within the tumor nodule. Understanding the plasticity mechanisms involved in this model, which lead to the generation of this and other subpopulations, may enable us to develop targeted therapeutic strategies aimed at counteracting tumor cell transdifferentiation.

#7520 Developing patient-derived organoid and xenograft models for preclinical assessment in ovarian cancer.

Choong-Jae Lee[1], Jubi Heo[1], Joo Hang Jeong[1], Ha-eun Lee[1], Jinyoung Park[1], Wonyoung Choi[2], Sang Yoon Park[3], Yo Han Woo[3], Myong Cheol Lim[3], Sun-Young Kong[1]

[1]Targeted Therapy Branch, National Cancer Center - Korea, Goyang-si, Gyeonggi-do, Korea, Republic of,[2]Department of Cancer biomedical science, National Cancer Center - Korea, Goyang-si, Gyeonggi-do, Korea, Republic of,[3]Center for Gynecologic Cancer, National Cancer Center - Korea, Goyang-si, Gyeonggi-do, Korea, Republic of

Background: Ovarian cancer (OC) is a highly lethal malignancy, characterized by late-stage diagnosis, marked tumor heterogeneity, and poor overall prognosis. Preclinical models of OCs, including patient-derived organoids (PDO) and xenografts (PDX), has been investigated for drug development and precision medicine. In this study, we established OC PDOs and PDX models
Methods: Tumor tissue were collected from multiple sites (ovary, omentum, diaphragm, and peritoneum) or ascites during surgery. After tissue dissociation, single cells were embedded in basement membrane extract for PDO culture and injected either intrabursally or subcutaneously into immunodeficient mice (NOD/Shi-scid IL-2Rv^{null}) to generate PDXs. PDOs were successfully cultured beyond five passage, and drug screening across 14 drugs including platinum-based agents, taxanes, topoisomerase inhibitors, and PARP inhibitors was performed using the CellTiter-Glo 3D viability assay. PDXs tumor growth were monitored three times a week, and analyzed the time points to reach 100 mm^3.
Results: A total of 18 PDOs were successfully established from 14 advanced-stage OC patients with diverse histological and genetical characteristics. Drug screening demonstrated a variable range of responses with the area under the curve ranging from 0.29 to 1.00, especially to platinum-based drugs and PARP inhibitors. The OC PDX model was successfully established in 9 (26.5%) out of 34 patients. Overall, the duration until 100 mm^3 tumor growth was shorter in intrabursal models compared to subcutaneous models with mean times of 90.3 days (n = 4) and 149.8 days (n = 9), respectively. Notably, tumor formation accelerated with successive passages, suggesting enhanced engraftment efficiency and growth kinetics in later generations.
Conclusions: We successfully developed OC PDO and PDX models that preserve tumor heterogeneity. These models enable detailed investigation of tumor biology offering critical insights for the development of novel treatment strategies. This research was supported by the Bio&Medical Technology Development Program of the National Research Foundation (NRF) funded by the Korean government (MSIT): RS-2025-19542979, RS-2025-25437292

#7521 Optimization of tumor tissue enzymatic dissociation for rapid and viable tumoroid generation.

Colin D. Paul, Anthony Chatman, **Logan Wilson**, Chris Yankaskas, Pradip Shahi Thakuri, Matt Dallas, David Kuninger

Thermo Fisher Scientific, Frederick, MD

Patient-derived tumoroids, or 3D organoid cultures from dissociated tumor tissue, are a powerful translational tool that bridge molecular profiling with functional drug testing. However, the success of tumoroid derivation is critically dependent on preanalytical variables—tissue handling, transport, and enzymatic dissociation—that influence viable cell recovery and culture performance. Here, we report an optimized workflow and enzyme formulations to maximize cell yield and fitness for downstream tumoroid culture and functional assays.Fresh surgical resections from colorectal, endometrial, breast, lung, and head and neck cancers were processed to assess the impact of dissociation on downstream culture. Tissues were collected in Hibernate™-A-based transport buffer supplemented with GlutaMAX™ and B-27™ supplements, antibiotics, and the ROCK inhibitor Y-27632, to ensure stability during overnight transport on ice. Upon receipt, samples were washed in Advanced DMEM/F-12-based tissue processing buffer and mechanically minced before enzymatic dissociation. A designed experimental framework evaluated enzyme type, concentration, and interactions across donors, measuring outcomes of viable cell yield (cells/mg tissue) and tumoroid formation at day 7 post-plating in OncoPro™ Tumoroid Culture Medium.Optimization revealed that initial viable cell yield was not predictive of subsequent culture success, necessitating dual metrics of viability and tumoroid growth. Collagenases, DNase, dispase, and hyaluronidase were beneficial depending on tissue type. While higher yields were obtained in some dissociation conditions, tumoroid formation was compromised, demonstrating a trade-off between digestion of tissue and stress on cells. Approximately 90% of dissociated samples generated tumoroids within 7 days, demonstrating both speed and reproducibility of the optimized workflow. Next-generation sequencing of paired solid tissue, dissociated cells, and day 7 tumoroids revealed >85% correlation in cancer-related gene expression and >95% overlap in single nucleotide variants, confirming preservation of tumor identity throughout processing. We further explored whether long-term tumoroid derivation success could be improved by spike-in of additional supplements and growth factors to OncoPro medium and identified several candidates that potentially contribute to line establishment. This integrated workflow of tumor transport, dissociation, and culture led to optimal viable cell recovery and tumoroid formation efficiency across multiple cancer indications. These results establish a practical and scalable framework for generating high-quality patient-derived tumoroids.

#7522 Ex vivo drug sensitivity and in silico evaluation of phytochemicals in gynaecological cancers.

Maria Nomusa Sikhakhane[1], Deepak Govindaraj[2], Mutsa Monica Takundwa[2], Xavier Siwe Noundou[1]

[1]Pharmaceutical Sciences, Sefako Makgatho Health Sciences University, Pretoria, South Africa,[2]CSIR South Africa, Pretoria, South Africa

Background: Gynaecological cancers—including cervical, ovarian, endometrial, and vulvar cancers—pose significant therapeutic challenges due to late-stage diagnosis, therapeutic resistance, and the presence of cancer stem cells. Dietary phytochemicals are emerging as potential modulators of cancer-related pathways, but their clinical utility is often limited by poor pharmacokinetics. Integrating in silico ADMET (Absorption, Distribution, Metabolism, Excretion, and Toxicity) profiling, molecular docking, and ex vivo drug sensitivity screening may facilitate the identification of effective therapies.
Methods: Primary tumor cells were isolated from 22 patients (age range 29-83 years) undergoing surgery for cervical (n=13), ovarian (n=2), endometrial/uterine (n=4), and vulvar (n=3) cancers. Cell yields ranged from 15.9×10^6 to 3.05×10^9 with viability between 14-99%. Cells were cryopreserved for downstream assays. Six dietary phytochemicals (quercetin, curcumin, resveratrol, EGCG, genistein, ursolic acid) were evaluated using SwissADME and pkCSM to predict pharmacokinetic and toxicity profiles. Boiled-egg plots assessed gastrointestinal absorption and blood-brain barrier permeability. Molecular docking was performed against key enzymes implicated in gynecological cancer pathways (EGFR, VEGFR-2, PI3K, TOP2A) using AutoDock Vina. Ex vivo drug sensitivity screening compared FDA-approved chemotherapeutics with the selected phytochemicals to identify compounds with higher cytotoxic potential.
Results: ADMET profiling revealed high gastrointestinal absorption for quercetin, curcumin, resveratrol, and genistein (HIA 77-93%), with limited BBB penetration except for resveratrol. Ursolic acid and EGCG demonstrated poor absorption. P-glycoprotein efflux and CYP inhibition were minimal for most compounds, though EGCG showed hERG II inhibition, and ursolic acid presented hepatotoxicity risk. Molecular docking showed favorable binding of EGCG to EGFR (-9.3 kcal/mol), curcumin to VEGFR-2 (-9.4 kcal/mol), and ursolic acid to TOP2A (-9.1 kcal/mol), comparable to FDA-approved inhibitors. Preliminary ex vivo drug screening indicated that FDA-approved chemotherapeutics exhibited higher cytotoxicity across patient-derived cells compared to the dietary phytochemicals.
Conclusions and Future Directions: Our integrated approach demonstrates that ex vivo drug sensitivity screening complements in silico ADMET and molecular docking, providing a platform to prioritize therapeutic candidates. Preliminary data suggest FDA-approved chemotherapeutics outperform dietary phytochemicals in patient-derived models. Future work will incorporate biostatistical and genomic analyses to predict optimal drug combinations for individualized therapy, potentially enabling precision oncology strategies for gynecological cancers.

#7523 A vascularized glioblastoma tumor spheroid model for studying tumor invasion and therapeutic response.

Anagha Shreesha[1], Sheridan Ke-Wing Fok[2], Brendan Harley[3]

[1]Bioengineering, University of Illinois, Urbana-Champaign, Urbana, IL,[2]University of Illinois at Urbana-Champaign, Champaign, IL,[3]University of Illinois at Urbana-Champaign, Urbana, IL

Introduction: GBM is characterized by its extensive invasiveness; its highly infiltrative cells penetrate surrounding brain tissue and often cannot be completely removed through surgery, leading to tumor recurrence and poor survival. The extent of vascularization directly correlates with GBM malignancy. Previous studies have demonstrated that sequentially adding fibroblasts to a pre-formed spheroid resulted in their peripheral concentration and enhanced vascularization in a SN12C kidney cancer model. We are interested in investigating whether sequentially adding fibroblasts promote vasculature formation in vitro and induces angiogenesis in the presence of endothelial cells. The objective of this experiment is to develop a representative model of the GBM tumor spheroid, with a focus on how vascularization and stromal cell populations could affect invasion and therapeutic response.

Materials & Methods: Sequential spheroids are synthesized by adding $2.5x10^3$ U87-MG cells to an ultra-low attachment plate and incubated at 37°C for 24 hours to allow spheroid aggregation. After 24 hours, an equal amount of NHLFs are added to the preformed spheroids at a 1:1 ratio. Cells were incubated at 37°C for an additional 24 hours to allow complete spheroid formation. Co-mixed spheroids are synthesized using a similar method but adding U87-MG and NHLFs concurrently. NHLF and HUVECs were resuspended in 5% GelMA solution at a ratio of 2: 1 ($2x10^6$ NHLF:$1x10^6$ HUVEC). Individual spheroids were pipetted into each well of a 20 µL hydrogel mold and polymerized using UV radiation.

Results: We observed distinct patterns in fibroblast distribution and spheroid behavior. In sequential spheroids, fibroblasts localized primarily at the periphery, whereas the co-mixed method produced a more uniform distribution throughout the spheroid. When sequential and co-mixed spheroids are encapsulated with endothelial cells (HUVECs) and NHLFs, sequential spheroids demonstrated more vessel formation around the spheroids, while limited network development occurred around co-mixed spheroids. Additionally, AlamarBlue data confirmed significant higher metabolic activity in hydrogels containing sequential spheroid on Day 5. We also observed that sequential spheroid outgrowth correlated to fibroblast density, while co-mixed spheroid outgrowth was more evenly distributed around the spheroid. Temozolomide treated sequential spheroids showed no significant difference compared to untreated controls, suggesting a reduced response to TMZ.

Conclusion: Future work will focus on understanding how spheroid organization influences population dynamics. We plan to track changes in cellular populations and investigate whether spheroid organization affects cytokine release in a 3D model. Finally, we aim to validate the effects of fibroblasts on tumor invasion using different cancer cell lines.

#7524 Genetically defined organoid systems uncover PIK3CA-mediated suppression of an oral-immune program during early squamous neoplastic evolution.

Hua Zhao[1], Young Min Park[2], Yueyuan Zheng[3], Qiong Mao[1], Hao Wu[1], Fanyi Mo[1], Uttam K. Sinha[1], Parish Sedghizadeh[1], De-Chen Lin[1]

[1]USC - University of Southern California, Los Angeles, CA,[2]Yonsei University Health System, Seoul, Korea, Republic of,[3]Hong Kong University of Science and Technology, Hong Kong, Hong Kong

Head and neck squamous cell carcinoma (HNSCC) is an aggressive and lethal neoplasm, yet its early neoplastic transformation mechanisms remain poorly defined. Despite extensive genomic characterization, translation of these molecular insights into clinical practice has been limited. A critical barrier has been the absence of physiologically relevant human models capable of faithfully recapitulating the stepwise progression from precursor lesions to invasive tumors while enabling rigorous interrogation of genotype-phenotype relationships. Here, we developed two complementary, cross-species, genetically defined organoid systems—a genome-sequenced patient-derived platform spanning normal tissue, precursor lesions, and tumors, and a CRISPR/Cas9-engineered human and mouse organoid platform targeting key HNSCC drivers (*TP53*, *CDKN2A*, *PIK3CA*) to reconstruct the continuum of squamous malignant transformation. Using these models, we uncovered critical insights into early neoplastic evolution. *TP53*/*CDKN2A* double-knockout (DKO) organoids exhibited morphological dysplasia, hyperproliferation, loss of squamous differentiation, and tumorigenicity—phenotypes further exacerbated by introducing mutant *PIK3CA*^{E545K} (DKOP). Single-cell RNA sequencing of DKO and DKOP organoids revealed expansion of quiescent basal and proliferative squamous populations and depletion of differentiated cells. Notably, an Oral-Immune transcriptional program characteristic of normal squamous epithelium was attenuated in DKO organoids and further diminished in DKOP. The Oral-Immune program was strongly correlated with intratumoral T-cell infiltration in HNSCC, marked by enrichment of cytotoxic and proliferative CD8$^+$ subsets and upregulation of IFN-pathway and cytotoxic effector genes. Strikingly, across 46 ICB-treated cohorts, its strongest association with therapeutic response occurred in an HNSCC cohort, where it outperformed 17 established immune gene-expression signatures, including *IFNG* and *PD-L1*. Both CD8$^+$ T-cell scores and the Oral-Immune score were inversely correlated with PIK3CA mutation status. Mutant *PIK3CA*^{E545K} suppressed Oral-Immune program genes in HNSCC, and this effect was reversible with PI3K inhibition. Functionally, *PIK3CA* mutations reduced CD8$^+$ T-cell infiltration in both in vitro CD8$^+$ T cell-organoid coculture assays and in vivo orthotopic allograft models. Together, these findings identify the Oral-Immune program as a key determinant of immune-inflamed tumor states, reveal *PIK3CA* mutations as drivers of immune evasion and diminished immunotherapy responsiveness through suppression of this program, and underscore the power of genetically defined organoid models for dissecting early cancer evolution.

#7525 Drug screening using patient-derived tumoroids harboring diverse mutations to identify effective therapeutics for metastatic cancer patients.

Seyoum Ayehunie[1], Dylan Bryda[1], Alex armento[1], Groves Megan[2], Anthony Tolcher[2]

[1]Sartorius, Ashland, MA,[2]NextOncology, San Antonio, TX

Patient-derived primary tumors (PDPTs) are emerging as physiologically relevant and translational in vitro models for predicting human responses to cancer therapeutics. Compared to conventional 2D cell lines, PDPTs more accurately recapitulate the tumor microenvironment, enable high-throughput drug screening, and support precision medicine. However, widespread adoption has been limited by challenges in large-scale expansion without phenotypic changes. We developed a novel system for in vitro expansion and biobanking of colorectal cancer tumoroids derived from four metastatic donors with distinct mutations. Our approach integrates matrix-coated plates with microwell technology to scale up tumoroid growth. Two assay platforms were established: (a) Tumoroids generated by seeding 5000 single tumor cells as a stand-alone model, and (b) Complex 3D tissues created by co-seeding 500 tumor cells with fibroblasts, endothelial cells, and immune cells to mimic the tumor microenvironment (TME). Tumoroids were treated with five chemotherapeutic agents—Cisplatin, Doxorubicin, Oxaliplatin, Fluorouracil, and Cetuximab—at six concentrations over a 7-day period (three doses). For tumoroids grown in TME, microscopic and histological analyses confirmed uniform-sized tumoroids and glandular-like structures. Epithelial origin and fibroblast presence were validated by CK19+ and vimentin staining, respectively. Live/dead staining using calcein AM and PI revealed dose- and time-dependent drug responses in both platforms. Notably, Doxorubicin, previously unused in these patients, demonstrated significant activity—highlighting the assay's potential to identify drugs for precision therapy and enable patient-specific drug ranking. In summary, scalable PDPT expansion combined with physiologically relevant assay systems offers a cost-effective, predictive, and non-animal approach for metastatic cancer drug screening, advancing the concept of precision medicine.

#7526 Breast cancer organoids as a complementary preclinical model to PDX, enabling immunotherapy evaluation.

Olivier Deas[1], Emilie Indersie[1], Amandine Prioux-Quartier[2], Philippe Lluel[2], **Emilie Decaup**[2]

[1]Xentech, Evry-Courcouronnes, France,[2]Urosphere, Toulouse, France

Background : Breast cancer (BC) remains a major global health challenge, with increasing incidence and mortality rates. Given the genetic, pathological, and clinical heterogeneity of BC subtypes, preclinical models that accurately reproduce tumor complexity are essential. To address this need, we established patient-derived xenograft (PDX) models alongside matched organoids (PDXO). This study aimed to demonstrate the high degree of similarity between PDX and their corresponding PDXO models in genomics and pharmacology. We validated organoids as a relevant platform for immunotherapy assessment, illustrated by the evaluation of trastuzumab, monoclonal antibody directed against HER2, in a co-culture system with immune cells.

Methods: PDX models were generated by xenografting patient's tumors tissues in immunodeficient mice and serially passages into mice after the first engraftment. To generate matched PDXO models, PDX tumors were minced and enzymatically digested before murine cells depletion. Then, human epithelial isolated cells were seeded in Matrigel® and cultured in optimized medium. Molecular characterization was performed by whole exome and transcriptome sequencing. PDXs and PDXOs were subjected to equivalent pharmacological treatments. For trastuzumab efficacy evaluation, organoids were co-cultured with activated peripheral blood mononuclear cells (PBMCs) from healthy donors at several Effector:Target ratios. Organoid viability was evaluated after 72 hours of treatment.

Results : PDXs and their corresponding PDXOs exhibited comparable responses to standard chemotherapies. Omics analyses revealed a high degree of mutational concordance between paired models, including shared oncogenic driver mutations such as TP53 and ATM. We further evaluated responses to HER2-targeted therapies using trastuzumab-emtansine (T-DM1) in two pairs of PDX and PDXO models differing in HER2 expression. T-DM1 demonstrated efficacy in both a HER2-positive PDX and its matched PDXO, resulting in tumor growth inhibition and organoid mortality. Furthermore, using a co-culture system of PBMCs and HER2-expressing organoids, we assessed the activity of trastuzumab. The antibody showed a clear antibody-dependent cell-mediated cytotoxicity effect against HER2-positive organoids, confirming the relevance of these models for evaluating immunotherapeutic responses.

Conclusion: The establishment of a mirror biobank comprising matched PDX and PDXO models enables acceleration of early-stage drug screening and seamless in vivo validation using corresponding PDXs. Beyond pharmacological testing, organoids offer an advantage by facilitating the evaluation of immunotherapeutic strategies. Together, these complementary models provide powerful translational tools for the development of novel breast cancer therapies and open new avenues for advancing immunotherapy research.

#7527 Sequential 3D functional profiling shows preserved drug resistance and sensitivity profiles after neoadjuvant treatment in an ovarian cancer patient.

Chiara Maestri, Ivan Trus, Rajeshwar Nitiyanandan, Ricardo J. Parker, Chris Apfel

SageMedic Corp., Redwood City, CA

Background
Despite standard platinum-based doublet therapy, most patients with advanced ovarian cancer do eventually relapse[1], and subsequent therapies exhibit variable benefit. Functional precision assays can guide treatment selection and reduce exposure to ineffective therapies. Here we used a multiplexed 3D functional profiling platform on specimens collected before and after neoadjuvant treatment, capturing evolving cytotoxic and antiproliferative responses and identifying effective treatment options.
Methods
Fresh specimens were obtained from a patient with high-grade serous ovarian carcinoma: a baseline ascites sample from stage III disease, and a surgical biopsy sample collected at stage IV disease after neoadjuvant carboplatin-paclitaxel treatment. Specimens were processed to obtain ex-vivo microtumors[2] and exposed to NCCN-recommended therapies. After 4 days of drug exposure, multiplexed viability and proliferation profiling was performed[3]. Four-parameter logistic dose-response curves were fitted, and differences (Δ) in cytotoxic and antiproliferative efficacies at standardized drug concentrations between the baseline and post-treatment samples were calculated.
Results
The carboplatin paclitaxel combination showed moderate cytotoxic (0.37, estimated 95% CI [0.34-0.41]) and antiproliferative effects (0.37 [0.36-0.39]) before and after neo-adjuvant treatment (0.30 [0.25-0.36] and 0.33 [0.31-0.36]), aligning with the limited objective tumor response. VAC (vincristine, actinomycin, and cyclophosphamide) demonstrated high cytotoxic and antiproliferative efficacy before (0.85, [0.75-0.90], and 0.97 [0.92-0.99]) and after therapy (0.73 [0.64-0.78], and 0.99 [0.94-1.00]). Interestingly, the PARP-inhibitors olaparib and rucaparib showed limited cytotoxicity (0.10 [0.08-0.12] and 0 [0-0.08]) but pronounced antiproliferation (0.60 [0.53-0.70] and 0.58 [0.49-0.74]) before the treatment with no material change after it.
Conclusions
Sequential ex-vivo multiplexed profiling of this advanced ovarian cancer revealed that neoadjuvant carboplatin paclitaxel minimally altered cytotoxic and antiproliferative drug response sensitivity and resistance patterns to VAC and PARP inhibitors. Thus, pre-treatment functional profiling, when tumor tissue is readily available, might provide useful follow-on treatment options to avoid exposure to ineffective regimens in the future.

#7528 Utilizing confocal live-cell imaging for evaluating therapeutic efficacy and toxicity in complex oncology models.

John Rauch[1], Jasmine Trigg[2], Kirsty McBain[2], Jonathan Bezenah[1], Libuse Oupicka[1], Richard Lister[1], Laura Skerlos[1]

[1]Sartorius, Ann Arbor, MI,[2]Sartorius, Royston, United Kingdom

Oncology research continues to progress towards utilizing more complex, translational cellular models to improve clinical outcomes. The need for complementary bioanalytical tools to enable clear insights from increasingly complex data has evolved in parallel. The Incucyte® CX3 enables multiplane, spinning disk confocal imaging of complex tumor models and organoids under physiologically relevant conditions. This poster will highlight the application of this technology, paired with integrated analysis tools, to evaluate the efficacy and off-target toxicity of therapeutic compounds. The effects of chemotherapeutic compounds were first evaluated in solid tumor models. For example, MCF7 cells stably expressing a nuclear-restricted green fluorescent protein were embedded in extracellular matrix and plated in the presence of a fluorescent dye to monitor apoptosis. Spheroid formation was monitored for 3 days, then the effects of camptothecin (0.3 - 10 µM) or cisplatin (3 - 100 µM) were tested. Automated analysis performed on confocal max projection images revealed a concentration-dependent decrease in spheroid growth and complementary increase in apoptosis. Many chemotherapeutic agents have been observed to induce hepatotoxicity in clinical cases. Therefore, the effects of compounds were also measured in a model of liver toxicity. Mouse hepatic organoids stably expressing a nuclear-restricted orange fluorescent protein were plated in a similar manner to cancer spheroids. Confocal multiplane images were acquired every 8 hours during formation (1 day) and for an additional four days following drug treatment. Camptothecin and cisplatin induced a concentration-dependent decrease in growth over time, with high concentrations (5-10 µM or 50-100 µM, respectively) inducing apoptosis. Importantly, fluorescent readouts of toxicity enabled by confocal imaging were more sensitive, as cellular debris can be difficult to distinguish from healthy organoids via brightfield readouts. Immune- and cancer-cell coculture models were also evaluated. SKOV-3 Nuclight Orange spheroids were seeded with a density range of activated (10 ng/mL CD3/CD28 for 72 hours) or non-activated PBMCs in the presence of Fabfluor-488-CD45 or Fabfluour-488-IgG1 and optigreen background suppressor. Co-cultures were imaged over 6 days using confocal multiplane acquisition. The results showed a density-dependent decrease in orange area with increasing PBMC density for activated PBMCs, indicating target cell death. Additionally, following immune-mediated tumor killing, we observed a density-depending increase in green area with PBMCs expansion. Taken together, these data highlight the ability of multiparameter, multiplane confocal live cell analysis to provide clear, rapid insights from a variety of complex pre-clinical models, including immuno-oncology and organoid-based toxicity readouts.

#7529 Reproducible 3D bioprinting of patient-derived tumors enables high-fidelity preclinical drug testing.

H. Nikki March, Ben Kennedy, Olivia Matthews, Andrew McCormack, Abby McSorley, Laura Nixon, Lorna Ewart

Carcinotech Ltd., Edinburgh, United Kingdom

Traditional 2D cancer cell culture systems have substantially advanced our understanding of tumor biology but fail to recapitulate the architectural organization, ECM composition, and spatial nutrient and oxygen gradients present in vivo. Consequently, they show weak correlation between in vitro drug sensitivity and clinical response. This translational gap contributes to high attrition in cancer drug development, with many therapies performing well preclinically but failing clinically due to the insufficient predictive power of early models, including in vivo systems that lack patient-specific biology and exhibit species-specific differences. Developments in 3D bioprinting enable reconstruction of tumor tissues containing epithelial, stromal, and immune populations embedded within physiological matrix analogs, more accurately reproducing the tumor microenvironment and retaining cell-cell and cell-matrix interactions. Bioprinting allows standardized, scalable tumor models while maintaining biologically relevant complexity. Early studies established feasibility, but systemic validation using fresh human tumor tissue, including compositional and functional fidelity, remains incomplete. We demonstrate that patient-derived ovarian and HER2+ breast tumors can be dissociated, bioprinted, and maintained in 3D culture while preserving key cellular populations and functional behaviors, and that treatment responses in these models correlate with known patient outcomes and standard-of-care drug efficacy. Constructs were generated using biomimetic hydrogels supplemented with ECM-derived proteins and primary tumor cells, and evaluated for viability, structural stability, and microarchitecture by live/dead imaging, histology, flow cytometry, and quantitative microscopy. Drug-response assays with standard-of-care chemotherapies and targeted anti-HER2 agents were performed. Optimized initial cell density supported sustained survival, proliferation, and hierarchical reorganization. Evaluation of our printing strategy showed we can achieve constructs with coefficients of variation below 10% for both bioprint structural integrity and cell viability at one day post-print and that this could be maintained over prolonged culture. This degree of reproducibility permitted attribution of drug responses to the treatment and supported investigation of optimal pre-treatment culture duration. Drug-response profiles differed from those in 2D cultures, indicating greater physiological relevance. Collectively, these findings highlight the predictive validity of bioprinted tumor constructs as a promising tool for preclinical efficacy assessment. Ongoing work will expand multicellular complexity, incorporate immune components, and benchmark against clinical datasets.

#7530 Comparative analysis of therapy responses and stem cell marker expression in glioblastoma neurospheres verus monolayer cultures using imaging, cytotoxicity assays, and flow cytometry.

Daniel S. Costa, **Joseph P. Kolb**, Olivia Mankos, Karsten E. Fynboe, Stephanie M. Fogerson, William D. Culp, Kathryn R. Meshaw

Powered Research LLC, Durham, NC

Background: Glioblastoma (GBM) is an aggressive and lethal primary brain tumor that is resistant to conventional therapies. Despite advances in treatment strategies, the standard of care and median patient survival have remained largely unchanged for nearly two decades. One major obstacle to therapeutic progress is the complexity of the GBM tumor microenvironment, which is poorly recapitulated by most GBM cell lines when used in animal models and in vitro screening assays. Three-dimensional (3D) neurosphere cultures of GBM cell lines are thought to improve model performance over traditional two-dimensional (2D) monolayer systems by enriching for glioblastoma stem-like cells (GSC), which, when implanted orthotopically, produce tumors that more closely resemble human disease. Consequently, in vitro drug screens using neurospheres more accurately reflect the spatial architecture, cell-cell interactions, and diffusion gradients improving predictive values of these types of studies. Here, we sought to further characterize the phenotype of U-87 MG-Luc2 cells grown in 2D or as neurospheres and to assess their drug sensitivity in vitro and as xenografts.
Methods: U-87 MG-Luc2 cells grown in 2D or as neurospheres were treated with temozolomide, lomustine, and bortezomib, individually and in combination, to assess drug sensitivity in vitro. In addition, these cells were stained for the GSC markers CD133, CD15, CD49f, and CD44 and analyzed by flow cytometry before and after intracranial implant. Orthotopic cell growth was tracked by IVIS imaging.
Results: Cytotoxicity assays revealed that neurospheres were significantly less sensitive to treatment compared to monolayers, consistent with enhanced resistance mechanisms supported by 3D architecture and GSC. Flow cytometry indicated differences in cell size, granularity, and GSC markers between the two models. Importantly, both culture types successfully engrafted and proliferated as murine orthotopic xenografts.
Conclusion: These findings suggest that 3D neurosphere models more accurately reflect the in vivo tumor environment and drug response, while 2D monolayers remain a valuable tool for initial therapeutic screening. Neurosphere culture conditions impacted U-87 MG-Luc2 GSC surface marker expression. Tracking changes in frequency and expression of GSC markers after drug treatment may be useful for selecting promising drug candidates. Head-to-head comparisons underscore the importance of model selection in preclinical GBM research.

#7531 Autoimmunity in a Dish: A 3D human orbital fibroblast platform for inflammatory biomarker discovery and fibrotic stromal biology.

Mengling Liu, Gene Lin, Noel Derecki, Lily Li, Paula Pellon, Calvin Ha

Immunology and Biomarker, EnquBio, San Diego, CA

Thyroid eye disease (TED) is an autoimmune inflammatory disorder and the most common cause of orbital disease in adults. Often associated with Graves' disease, TED can lead to debilitating visual impairment due to bulging of the eyes (proptosis) from severe swelling of the extraocular muscles and orbital tissues. The pathophysiology of TED is thought to involve activation of periorbital fibroblasts, triggering an inflammatory cascade that results in local accumulation of lipids and glycosaminoglycans and, ultimately, fibrosis. Fibroblast-driven extracellular matrix remodeling and fibrosis are also hallmarks of the stromal compartment in many solid tumors, linking TED biology to broader questions in tumor microenvironment research. To better understand the mechanistic pathophysiology of TED and to support discovery of agents that target fibrotic stroma, we have developed an in vitro 3D culture model using primary human orbital fibroblasts. In this system, fibroblasts form spheroidal 3D structures that provide a more physiologically relevant context than conventional monolayer culture. Using this platform as a bridge between clinic and bench, we assay surface, intracellular, and secreted inflammatory biomarkers following IGF-1 stimulation—a signaling axis with established roles in both autoimmunity and cancer—using ELISA, MSD, JESS, and flow cytometry. Endpoint data are integrated through a bespoke AI- and machine-learning-based pipeline to identify and rank multidimensional biomarker signatures. Taken together, these data strongly validate our 3D human orbital fibroblast culture as a useful model to investigate the molecular mechanisms underlying the pathogenesis of TED and to screen potential therapeutics via assays developed in-house with clients and partners in the autoimmune space. More broadly, this IGF-1-responsive 3D human stromal platform provides a tractable model of fibrotic, inflammatory fibroblast biology that is directly relevant to the tumor microenvironment and can be extended to future co-culture studies with tumor and immune cells to support preclinical oncology drug discovery.

#7532 Multi-cancer patient-derived organoid platform for translational cancer research.

JUBI HEO[1], Choong-Jae LEE[1], Eun Joo LEE[1], Sung Weon Choi[2], Sang-Jae Park[3], Sang Myung Woo[3], Sang Yoon Park[4], Myong Cheol Lim[4], So-Youn Jung[5], Bo Hyun Kim[3], Jung Won Chun[3], Joohyun Hong[6], Wonyoung Choi[1], Sun-Young Kong[1]

[1]Targeted Therapy Branch, National Cancer Center(NCC), Goyang, Korea, Republic of,[2]Department of Oral and Maxilofacial Surgery, National Cancer Center(NCC), Goyang, Korea, Republic of,[3]Center for Liver and Pancreatobiliary Cancer, National Cancer Center(NCC), Goyang, Korea, Republic of,[4]Center for Gynecologic Cancer, National Cancer Center(NCC), Goyang, Korea, Republic of,[5]Center for Breast Cancer, National Cancer Center(NCC), Goyang, Korea, Republic of,[6]Center for Colorectal Cancer, National Cancer Center(NCC), Goyang, Korea, Republic of

Purpose Patient-derived organoids (PDOs) are useful cancer models because they reflect important features of each patient's tumor. In Korea, however, researchers have not had enough PDO samples with clear clinical information. To improve this situation, the National Cancer Center created a platform to collect organoids from different cancers and provide reliable models that can be used for research.
Methods Tumor specimens were obtained through surgical resection, image-guided biopsy, and malignant body fluids. All samples were processed using a unified workflow covering tissue handling, enzymatic dissociation, organoid culture, and criteria for long-term growth. PDOs that continued to grow for more than five passages were classified as successfully established. Quality checks included STR profiling, mycoplasma testing, and histologic and genomic evaluation to ensure accuracy and safety. Clinical and pathological information was linked to each PDO, and biobanking procedures were used for long-term storage. Selected models were evaluated in drug-response assays using a 384-well screening format.
Results The platform currently maintains 122 PDO models across multiple cancer types, including oral (n = 33), pancreatic (n = 20), tongue (n = 16), gastric (n = 16), ovarian (n = 9), gallbladder (n = 8), biliary tract (n = 8), breast (n = 5), liver (n = 4), and colorectal cancers (n = 3). These PDOs preserved key histopathologic, genetic, and phenotypic characteristics of their matched tumors and were successfully cryopreserved for long-term use. Drug-response profiling of 42 PDOs with 46 therapeutic agents revealed substantial inter-tumoral variability, and several investigational compounds demonstrated notable antitumor activity. In representative cases, ex vivo cytotoxic responses corresponded with clinical treatment outcomes, underscoring the translational relevance of the platform.
Conclusions This PDO platform provides a centralized and high-quality resource that reflects the biological and clinical diversity of human cancers. By supporting systematic drug screening, mechanistic studies, and biomarker-based precision approaches, the platform offers essential infrastructure to advance translational oncology research and promote the development of personalized therapeutic strategies in Korea. This research was supported by the Bio&Medical Technology Development Program of the National Research Foundation (NRF) funded by the Korean government (MSIT) (No. RS-2025-19542979)

#7533 The protease MALT1 is required for chronic lymphocytic leukemia genesis in Eμ-TCL1 mice.

Delia Carlino[1], Julia Boehling[1], Terri Rasmussen[2], Van Hoang[1], Carole Bitar[3], Matthew Burow[1], Nakhle Saba[1]

[1]Hematology/Oncology, Tulane School of Medicine, New Orleans, LA,[2]Tulane School of Medicine, New Orleans, LA,[3]Dermatology and Dermatopathology, Tulane School of Medicine, New Orleans, LA

The Bruton's Tyrosine Kinase inhibitors, such as ibrutinib, acalabrutinib, and zanubrutinib, are leading the frontline treatment in Chronic lymphocytic leukemia (CLL), but acquired resistance represents a significant clinical challenge. Our group has previously shown that targeting Mucosa-Associated Lymphoid Tissue 1 (*MALT1*) *in vitro* induces apoptosis in ibrutinib-sensitive and -resistant CLL cells, suggesting the involvement of the MALT1 axis in CLL progression and survival. Here, we generated a mouse model crossbreeding the Eμ-*TCL1* transgenic C57BL/6 system of spontaneous CLL with CRISPR-mediated *MALT1* knockout (KO) mice to test the requirement for *MALT1* in CLL development. Through genotyping, we established four cohorts with at least 25 mice per cohort: Eμ-TCL1^{wt}/*MALT1*^{wt}, Eμ-TCL1^{wt}/*MALT1*$^{+/-}$, Eμ-TCL1^{wt}/*MALT1*$^{-/-}$, and Eμ-TCL1$^{-/-}$/*MALT1*$^{-/-}$. We measured leukemia burden in these groups by measuring splenomegaly and collecting cells from the bone marrow, spleen, and peritoneal fluid following euthanasia and analyzed cell populations using flow cytometry. Our results show low/negligible CLL burden in the Eμ-TCL1$^{-/-}$/*MALT1*$^{-/-}$ and Eμ-TCL1^{wt}/*MALT1*$^{-/-}$ cohorts. Conversely, the Eμ-TCL1^{wt}/*MALT1*^{wt} and Eμ-TCL1^{wt}/*MALT1*$^{+/-}$ groups showed higher levels of CLL cell populations in each compartment. The largest median number of cells that were positive for CLL markers were in the peritoneal fluid and were 43% and 53% respectively. There was no statistical significance between the Eμ-TCL1^{wt}/*MALT1*^{wt} and Eμ-TCL1^{wt}/*MALT1*$^{+/-}$ cohorts in terms of CLL positive cells or levels of splenomegaly. There were significant differences between the Eμ-TCL1$^{-/-}$/*MALT1*$^{-/-}$ and Eμ-TCL1^{wt}/*MALT1*$^{-/-}$ cohorts versus the Eμ-TCL1^{wt}/*MALT1*^{wt} cohort in both the peritoneal fluid (p-value = 0.0162 and 0.0161 respectively) and the bone marrow (p-value = 0.0016 and 0.0017 respectively), but not the spleen. Using the Kaplan-Meier method to compare overall survival of the four groups, we showed that all cohorts survived longer than the Eμ-TCL1^{wt}/*MALT1*^{wt} cohort. The majority of mice in the Eμ-TCL1$^{-/-}$/*MALT1*$^{-/-}$ and Eμ-TCL1^{wt}/*MALT1*$^{-/-}$ cohorts expired due to non-CLL-related complications, namely the development of dermatological lesions and ocular ulcers. These complications led to the Eμ-TCL1wt/MALT1+/- cohort having the largest median survival at 435 days. Therefore, we were able to show that MALT1 knockout mice experienced lower leukemia burden, as defined by positive CLL cells and splenomegaly. Our data concerning the dermatopathological complications associated with the Eμ-TCL1$^{-/-}$/*MALT1*$^{-/-}$ and Eμ-TCL1^{wt}/*MALT1*$^{-/-}$ cohorts highlights potential side effects of MALT1 inhibition and are of note due to the frequent clinical presentation of cutaneous lesions in CLL patients. Overall, our data suggest that MALT1 is required for CLL leukemogenesis and may represent a critical component in therapeutic targeting.

#7534 Novel mouse models for cancer research.

Jason Beckwith, Jen Merriam, Darcy Pomerleau, Crystal Davis, Jennifer Kelmenson, Hiroaki Onda

The Jackson Laboratory, Bar Harbor, ME

The Jackson Laboratory (JAX) is a centralized resource of genetically defined mutant and transgenic mice to support the scientific research community. This poster will highlight new models available for specific cancers, xenograft recipients, immunodeficient platforms for PDX studies and multi-purpose tool strains having CRISPR utility, conditional/inducible expression (Cre-lox, FLP-frt, Tet-On/-Off), optogenetic function and calcium-sensing technologies. The NSG (NOD scid IL2rγc-/-) portfolio of strains for transplantation/engraftment and humanized mouse research continues to grow, with recent humanized alleles (*e.g.*, IL6, TSLP) expanding the options for immune-oncology studies. New mouse lines for cancer immunology and antibody therapeutic studies combine humanized FCGRT and ALB alleles for human preclinical pharmacokinetics (HuPK), as well as humanized PD-1 and PD-L1 alleles. Novel fluorescent strains include Gene Editing Reporters for visualizing homology-directed repair (HDR) and non-homologous end joining (NHEJ) repair events, as well as several CRISPR Editing, Bxb1 Integrase Editing, Base Editor, Prime Editor and DNA repair pathway tools. In addition to cryopreserving each strain, JAX employs a genetic quality control program that confirms mutation identity and genetic background, and screens for common unwanted alleles (via testing for neo, Cre, FLP, GFP, RFP, etc.). Cancer researchers are encouraged to query the collection of innovative mouse models using the JAX Mouse Search website (mice.jax.org). This resource includes models created by many generous donating institutions. Researchers are encouraged to donate their mouse lines via a very short Strain Submission form (jax.org/donate-a-mouse). Please also visit the JAX Oncology webpage for cancer research related strains and resources (jax.org/jax-mice-and-services/solutions-by-therapeutic-area/oncology). JAX is supported by the NIH, The Howard Hughes Medical Institute and other private charitable foundations.

#7535 Over 800! Establishment of an ADC payload efficacy database across diverse tumor cell lines: Foundation for optimized in vitro ADC evaluation and drug development.

Guoqian Wang, Yao Tang, Jingxiao Xu, Tingduo Lv, jinying ning, **Feng Hao**

Kyinno Biotechnology Co., LTD, Beijing, China

Ever since the first antibody-drug conjugate (ADC), Mylotarg, received approval back in 2000, the ADC market has expanded to include 15 approved products so far, while more than 210 others are currently in clinical trials. This indicates that ADC drug development has stepped into a thriving phase—especially when targeting molecules like HER2, EGFR, Trop2, CLDN18.2, and Nectin-4, ADCs have demonstrated notable efficacy and favorable safety profiles. As such, ADC therapy holds extremely broad application prospects in the field of cancer treatment.Antibody-drug conjugates (ADCs) consist of three core components: a monoclonal antibody, a linker, and a toxin. Among these, the ADC toxin—also referred to as the ADC payload—is a critical element of ADC drugs, as it serves as the key factor determining the drug's potency. The payloads used in approved ADCs are highly toxic; major examples include MMAE/MMAF, calicheamicin, DM1/DM4, and SN38/Dxd. Compared with traditional chemotherapy drugs, these payloads are 1 to 2 orders of magnitude more toxic, and some even reach toxicity levels in the picomolar (pM) range. For payloads currently under development, their mechanisms of action mainly fall into four categories: DNA alkylating agents, DNA topoisomerase inhibitors, microtubule disruptors, and RNApolII inhibitors.We have established an extensive cell bank, which houses over 800 human tumor cell lines and 100 animal tumor cell lines, covering all types of cancers. Leveraging this rich cell resource, we are constructing an ADC screening platform. Through comprehensive testing, we collect efficacy data of different ADC payloads across various cell lines—this data then guides us in selecting appropriate cell lines for in vitro ADC evaluation. Up to now, we have already finished over 700 commonly used cell lines using several ADC payloads, such as MMAE, SN38, Dxd, and exatecan. As a large-scale initiative, the ADC screening platform is expected to play a positive and supportive role in the screening and evaluation of ADC drugs.

#7536 In vitro and in vivo screening platform for discovery of JAK2 inhibitors.

Na Li, Hao Huang, Xinyu Zhong, Guoqian Wang, Xuyang Duan, Yue Huang, Jinying Ning, **Feng Hao**

Kyinno Biotechnology Co., LTD, Beijing, China

Background: The JAK-STAT signaling pathway, activated by cytokine receptors, plays a central role in regulating cell proliferation, differentiation, apoptosis, and immune responses. JAK2, a key kinase in this pathway, transduces signals from hematopoietic growth factor receptors such as thrombopoietin (TPO), erythropoietin (EPO), and granulocyte-macrophage colony-stimulating factor (GM-CSF). Dysregulation of JAK2 is implicated in the pathogenesis of myeloproliferative neoplasms (MPNs), including polycythemia vera (PV), myelofibrosis (MF), and essential thrombocythemia (ET).
Objectives: This study aimed to evaluate the efficacy of JAK2 inhibitors, elucidate their mechanisms of action, and identify optimal dosing strategies to maximize therapeutic benefit while minimizing adverse effects.
Method: An *In vivo*, a murine model of JAK2-driven myeloproliferative disease was established by intravenous transplantation of JAK2-activated cell lines into BALB/c nude mice. Disease progression was monitored using bioluminescent imaging. Terminal analyses included evaluation of splenomegaly, serum biochemistry (ALT and AST), and splenic histopathology (hematoxylin and eosin staining).For *in vitro* analysis, a panel of cell lines was treated with increasing concentrations of JAK inhibitors (Ruxolitinib, Fedratinib, and Tofacitinib) to evaluate compound efficacy. Inhibition of downstream JAK2-STAT5 signaling was quantified using an α-LISA for phosphorylated STAT5 (p-STAT5). Dose-response profiles were generated, and IC_{50} values were calculated to determine the relative sensitivity of the cells to each agent.
Results:*In vivo*, our model mice displayed progressive increases in bioluminescent signal, marked splenomegaly and hepatomegaly, decreased survival, and elevated serum ALT/AST levels. Ruxolitinib treatment significantly suppressed bioluminescent signal progression, reduced hepatic and splenic tumor burden, and extended survival.*In vitro*, Ruxolitinib potently and dose-dependently inhibited JAK2-STAT5 signaling, with IC_{50} values confirming target sensitivity. The cell lines exhibited differential sensitivity to the JAK2 inhibitors Ruxolitinib, Fedratinib, and Tofacitinib.
Conclusion: We established integrated *in vivo* and *in vitro* screening platforms for the discovery and evaluation JAK2 inhibitors. This model provides a valuable tool for optimizing treatment regimens against JAK2-driven pathologies.

#7537 From BTK in-situ mutation (C481S, A428D, etc.) to in vivo screening: A comprehensive platform to address drug resistance in BTK-targeted therapy.

Yao Tang, Guoqian Wang, Hao Huang, Yue Huang, Jinying Ning, **Feng Hao**

Kyinno Biotechnology Co., LTD, Beijing, China

Bruton's tyrosine kinase (BTK) is a core regulatory molecule in the B-cell receptor (BCR) signaling pathway. It is constitutively expressed in myeloid and lymphoid cells and plays a decisive role in the proliferation, survival, differentiation, activation, and apoptosis of B cells. Abnormal activation of BTK is closely associated with B-cell malignancies such as chronic lymphocytic leukemia (CLL) and mantle cell lymphoma (MCL). In hematologic tumors, BTK inhibitors block key steps in the BCR signaling pathway, thereby inhibiting the proliferation and survival of tumor cells. Ibrutinib is the first effective covalent Bruton's tyrosine kinase inhibitor (BTKi), approved by the U.S. Food and Drug Administration (FDA) in 2013, ushering in an era of chemotherapy-free treatment for B-cell malignancies. Second-generation covalent BTK inhibitors, including acalabrutinib, zanubrutinib, and orelabrutinib, have also been approved for marketing in China. The advent of BTK inhibitors has had profound significance for the treatment of B-cell malignancies, improving the treatment modalities and prognosis for patients with B-cell lymphoma. However, traditional BTK inhibitors exhibit poor kinase selectivity and a high incidence of off-target adverse reactions. Moreover, in recent years, although BTK inhibitors (such as ibrutinib and acalabrutinib) have significantly improved patient survival, the issue of drug resistance has become increasingly prominent—approximately 30% of patients develop resistance due to BTK gene mutations (e.g., C481S, T474I, L528W, etc.), limiting therapeutic efficacy. Through breakthroughs in in-situ mutation technology, kyinno has precisely introduced specific BTK mutations directly into the genome of TMD8 cells, preserving the natural expression regulatory mechanisms. This provides a more clinically relevant "touchstone" for analyzing BTK resistance mechanisms and developing targeted therapies. Kyinno has developed over 20 BTK in-situ mutant cell lines (including single mutations such as C481S, T474I, A428D, L528W, and compound mutations). These novel cell models, based on in-situ mutation technology, enable systematic evaluation of the dynamic impact of different mutations on drug binding and guide the structural optimization of next-generation inhibitors. Additionally, we have developed in vitro and in vivo screening platforms based on these mutant cell lines, enabling rapid validation of lead compounds from the molecular to the organism level, thereby accelerating BTK inhibitor development.

#7538 Establishment of a translational research ecosystem: A globally networked PDX model platform to accelerate oncology drug development.

Alyssa Simonson[1], Anna Stackpole[1], Amy Fredrickson[1], Johnnie Mitchell[1], Jennifer Garcia[1], Natalia Banos Herraiz[1], Jim Lund[1], Ashley Jamison[1], Andrew Cunningham[1], Kyriakos P. Papadopoulos[2], Victor Moreno Garcia[3], Emiliano Calvo[3], Chris Takimoto[2], Michael J. Wick[2]

[1]The START Center for Cancer Research- XenoSTART, San Antonio, TX,[2]The START Center for Cancer Research, San Antonio, TX,[3]The START Center for Cancer Research- Madrid, Madrid, Spain

Background: Patient-derived xenograft (PDX) models continue to play a critical role in translating novel oncology drug innovation from discovery through late-stage development. The START Center for Cancer Research is a global translational and clinical trials oncology network that includes XenoSTART, a PDX development and testing division. XenoSTART offers end-to-end capabilities, beginning with the establishment of PDX models directly from conventional and trial patients across diverse indications, reflecting current treatment landscapes with the added ability to support a full suite of in vivo study capabilities, provide models and data under license, and tailored model development. Strategic partnerships allow for extended service capabilities which include orthotopic imaging, radioligand therapy (RLT), and humanized systems capabilities, enabling mechanistic depth and modality-specific translational insights rarely available through a single platform.

Methods: XenoSTART PDX (XPDX) models are collected from primary or metastatic patient tumor samples and engrafted into immunocompromised mice under standardized workflows; a curated extraction of clinical details and treatment histories from donor patients ranging from newly diagnosed through heavily pretreated is performed for all collected samples. Resulting models are serially passaged and further developed until growth stabilization. Established models are profiled using integrated molecular and pathological analysis including WES and RNAseq, receptor expression, and advanced bioinformatics to support biomarker discovery or mechanistic insights and further characterized through in vivo responses to standard-of-care and emerging therapies. Bioinformatic analyses are conducted using validated pipelines to evaluate molecular signatures and biomarker associations. In vivo studies following harmonized protocols align with clinically relevant dosing schedules.

Results: The XenoSTART platform generates a diverse and deeply characterized XPDX repository reflecting contemporary treatment landscapes, with high rates of molecular and phenotypic fidelity. Treatment benchmarking replicates known clinical response patterns to standard-of-care agents. Integrated clinical and molecular datasets revealed biomarkers associated with treatment sensitivity and resistance. Specialized collaborations enable innovative translational studies including orthotopic imaging, RLT, and humanized immune-oncology evaluation.

Conclusion: XenoSTART's globally connected PDX ecosystem provides a clinically focused, best-in-class translational resource that enhances predictive accuracy, informs patient-stratification strategies, and drives more confident decision-making from early discovery through late-stage clinical development.

#7539 *In vivo* metastatic prostate tumor model development and follow-up progression using *in vivo* bioluminescence imaging.

Vincent Faugeroux, Nicolas Hoffmann, Sarah Belderbos, Maeva Albanese, Kenny Herry, Nicolas Ancellin, Caroline Mignard, **Marc Hilairet de Boisferon**

Oncodesign Services, Dijon, France

Prostate cancer is the most frequently diagnosed malignancy in men and the second leading cause of cancer-related death after lung cancer. Its incidence is highest in high-income regions. Although widespread screening allows approximately 80% of cases to be detected while still organ-confined, 15–20% of patients present with locoregional or distant metastases. In the United States, the proportion of men diagnosed with metastatic disease has been rising in recent years, particularly among younger patients. Clinical outcome strongly correlates with tumor grade and stage at diagnosis; men with metastatic disease have significantly reduced overall survival compared with those with localized tumors. The primary metastatic sites are lymph nodes and bone, followed by liver and lung. However, few preclinical models effectively recapitulate these advanced stages, creating a critical gap for evaluating novel therapeutics.

Here, we describe the establishment of liver and lung metastases in immunodeficient male mice using 22Rv1-Luc-mCherry prostate cancer cells delivered via intratibial or intra-arterial injection. Mice were monitored three times per week for clinical condition and body weight. Tumor progression was assessed by in vivo bioluminescence imaging once per week for five weeks. At euthanasia, major organs were collected for ex vivo imaging to confirm metastatic localization.

Following intratibial inoculation, bioluminescence increased initially at the injection site during the first two weeks, then predominantly in the liver and lungs from days 15 to 42. These findings were confirmed by ex vivo imaging. After intra-arterial inoculation, early bioluminescence was detected primarily in bone through day 28, followed by a marked increase in the liver between days 28 and 35. Ex vivo imaging verified metastatic dissemination to the liver, limb bones, spinal column, and seminal vesicles.

In summary, we report a reproducible metastatic prostate cancer model that mimics key features of late-stage disease, providing a valuable platform for preclinical evaluation of new therapeutic compounds

#7540 Integrated multi-omics analysis reveals conserved tumor-associated antigens (TAAs) profiles in PDX and organoid models for advancing ADC development.

Xiaolong Tu[1], Likun Zhang[1], Jie Lin[1], Hengyuan Liu[1], Jun Zhou[1], Marrit Putker[2], Ludovic Bourre[2], Julie Myer[2]

[1]Crown Bioscience, Taicang, China,[2]Crown Bioscience, Inc., San Diego, CA

Introduction The development of antibody-drug conjugates (ADCs) requires reliable tumor-associated antigens (TAAs) expression for efficacy, necessitating predictive preclinical models. Patient-derived xenografts (PDXs) preserve patient tumor characteristics, which serve as a mainstay in translational oncology research, while patient-derived organoids (PDOs) and PDX-derived organoids (PDXOs) have recently emerged as powerful *in vitro* 3D systems that offer enhanced scalability while retaining key biological features of the original tissue. However, their fidelity in maintaining TAA profiles requires multi-omics validation. This study evaluates TAA consistency across platforms and between PDXs and matched organoids.

Methods We analyzed 18 clinically relevant TAAs using IHC on ~1000 PDX models across 18 cancer types. IHC quantification was analyzed using HALO AI platform to generate H-Score, this data was integrated with RNA-seq and MS-mass spectra-proteomics from Crown Bioscience's database to determine the correlation coefficients. To assess model translatability, a focused panel of 10 key TAAs was selected for IHC assessment between a subset of ~400 characterized PDXs and their paired PDOs/PDXOs, enabling a cross-model comparison.

Results Our integrated multi-omics analysis within the extensive PDXs cohort demonstrated a high degree of concordance between protein expression (H-Score) and both transcriptomics and proteomics data for the 18 investigated TAAs, including HER2(R_{RNAseq}=0.871,$R_{Proteomics}$=0.765), TROP2(R_{RNAseq}=0.852, $R_{Proteomics}$=0.775), Nectin-4(R_{RNAseq}=0.679, $R_{Proteomics}$=0.861), DLL3(R_{RNAseq}=0.75, $R_{Proteomics}$=0.698), CEACAM5(R_{RNAseq}=0.799, $R_{Proteomics}$=0.743). Critically, a remarkably high degree of concordance was observed in TAAs protein expression patterns between PDXs and their paired PDOs/PDXOs models, including TROP2(R=0.946, P<0.0001), Nectin-4(R=0.772, P<0.0001), DLL3(R=0.819, P<0.0001), HER3(R=0.659, P<0.0001), Claudin 18.2(R=0.775, P<0.0001). The consistency of IHC intensity and heterogeneity characteristics between organoids and their in vivo counterparts further supports this molecular fidelity.

Conclusion This study validated TAAs expression concordance across multi-omics platforms in a large PDX cohort. More significantly, we deliver compelling evidence that PDOs/PDXOs models exhibit exceptional fidelity in maintaining the TAA expression landscape of their corresponding PDX tumors, demonstrating PDOs/PDXOs as highly reliable and invaluable tools from initial target validation and lead antibody characterization to the formulation of biomarker-driven patient selection strategies in clinical trials.

#7541 Comprehensive preclinical *in vivo* oncology platform for rational drug candidate nomination.

Amandine Alard, Marie Lafitte, Nizar Serhan, Giuseppina Claps, Frederique Dol-Gleizes, Pascale Lejeune

Evotec, Toulouse, France

Introduction: Robust in vivo pharmacology is critical to de-risk oncology drug candidates and guide translational decision-making. Evotec's integrated preclinical platform combines scientific and animal welfare expertise with AAALAC and My Green Lab accreditations to accelerate candidate nomination.
Methods and Results: Leveraging multidisciplinary capabilities such as chemistry, early formulation, ADME/DMPK (LC-MS/MS), in vitro biology, and translational biomarker analysis is essential to support projects at any stage of drug discovery and whatever the therapeutic modality: small molecules, degraders, ADCs, antibodies, oligonucleotides, cell therapies, vaccines, and oncolytic viruses. Our extensive tumor model repertoire covers multiple cancer indications and includes CDX and syngeneic models implanted SC, orthotopically or as metastatic model in a variety of mice backgrounds, immunocompetent, immunosuppressed or humanized for the immune system. We describe here case studies illustrating flexible study designs that include:•Target validation with engineered cancer cells•PK/PD studies (single/repeated dosing)•Tolerability for chronic dosing derisking•Efficacy studies assessing anti-tumor activityReadouts encompass tumor growth inhibition, PK/PD correlation, target engagement, transcriptomics, proteomics, metabolomics, and tumor microenvironment characterization.In addition, deciphering the relationship between PK, PD markers modulation and antitumor efficacy is of great value to model and predict human dose. Experts at Evotec have access to several modeling and simulation softwares from PK, PK/PD, PBPK, statistical and mathematical analysis to optimize dosing for best efficacy while minimizing toxicity.
Conclusion: Our platform enables tailored strategies that integrate PK/PD and biomarker-driven endpoints to optimize dosing and predict efficacy. Over 5 years, our multidisciplinary expertise delivered comprehensive in vivo solutions that accelerated oncology drug discovery with the nomination of nine preclinical drug candidates progressing in the clinic.

#7542 *In vitro* and *in vivo* evaluation of bortezomib using the 5TGM1 cell line and a syngeneic mouse model of multiple myeloma.

Mari I. Suominen, Katja M. Fagerlund, Justyna Zdrojewska, Jukka P. Rissanen, Jenni H. E. Maki-Jouppila

Pharmatest Services Ltd., Turku, Finland

Multiple myeloma (MM) is the second most prevalent hematologic cancer, originating from plasma cells (differentiated B-cells) and accounting for approximately 2% of cancer-related deaths. Clinical manifestations often include bone pain due to osteolytic lesions, pathologic fractures, and hypercalcemia. MM typically exhibits a low proliferative index and relies heavily on its surrounding microenvironment, making it resistant to conventional chemotherapy. However, these same characteristics present opportunities for emerging therapies, such as stroma-targeting agents and immunotherapies. The success of these novel strategies depends on robust preclinical models that accurately reflect both immune function and the tumor microenvironment. To support the relevance of the syngeneic 5TGM1 murine model in drug development, we evaluated the sensitivity of 5TGM1 cells to bortezomib both *in vitro* and *in vivo*.

In vitro, 5TGM1 cells were cultured for six days, and cell viability was assessed using the CellTiter-Glo assay on days 0, 3, and 6. The EC50 value for bortezomib was determined, confirming its cytotoxic effect on 5TGM1 cells. *In vivo*, female C57Bl/KaLwRij mice (6-8 weeks old) were intravenously inoculated with 5TGM1 cells. Bortezomib treatment was initiated one day post-inoculation and administered intraperitoneally. The study included an untreated control group, a group receiving bortezomib twice weekly, and a group receiving bortezomib thrice weekly. Additionally, untreated satellite animals were included to evaluate disease progression and were sacrificed on day 35, prior to the termination of the main study. Mice were monitored daily for clinical condition, with body weight recorded twice a week. Sacrifice criteria included ≥20% weight loss or paraplegia. Serum IgG2b levels, which indicate disease progression, were measured from samples collected before inoculation, on day 21, day 35, and at sacrifice. Gross necropsy was performed to assess metastases, and *ex vivo* microCT scans of both tibias were conducted to analyze osteolytic lesions.

Bortezomib was well tolerated, with no significant differences in body weight between groups. The termination day was determined based on disease progression in the vehicle control group; 40% of the vehicle group was sacrificed on day 41, and the remaining animals were sacrificed the following day. IgG2b levels were reduced in treated groups, particularly in the thrice-weekly regimen. However, bortezomib did not prevent the progression of bone lesions, which increased notably in the final week of the study.

These findings support the use of bortezomib as a reference compound *in vitro* and *in vivo* in the 5TGM1 model, demonstrating its efficacy in reducing tumor burden as indicated by IgG2b levels. However, its protective effect on bone integrity remains limited.

#7544 Validation of a bone metastasis technology platform against clinically used standard-of-care therapies.

Tiina E. Kahkonen[1], Jie Wen[2], Ru Yang[2], Jussi M. Halleen[1]

[1]OncoBone Ltd, Kiviniemi, Finland,[2]PharmaLegacy LLC, Shanghai, China

Bone metastases are a significant clinical problem in many major cancers, especially in breast and prostate cancer where 70-90% of advanced patients develop bone metastases. Myeloma bone disease is associated with similar clinical problems than bone metastases. Current cancer therapies can only partially decrease tumor growth in bone, resulting in only 5% of bone metastatic patients being alive 5 years after the diagnosis. Bone metastases decrease the quality of life of patients due to cancer-induced bone loss that leads to increased risk of fractures and bone pain. Bone metastases are therefore a high unmet medical need with a high demand for effective therapies.

Lack of appropriate preclinical bone metastasis models that would exhibit the same clinical features and responses to therapies that are observed in bone metastatic patients has made it difficult to advance therapy development at early stages. In this study, we validated our previously established Bone Metastasis Technology Platform (BMTP©) against standard-of-care (SOC) therapies in triple-negative breast cancer (TNBC) and castration-resistant prostate cancer (CRPC) bone metastasis models, and in a multiple myeloma (MM) bone disease model.

In this study, we used the following cell lines and mouse strains: 4T1 mouse TNBC cells in BALB/c mice, RM-1 mouse CRPC cells in C57BL/6 mice, and human RPMI 8226 MM cells in immunodeficient NPG mice. Intratibial inoculation into the bone marrow was used to model tumor growth in bone. Tumor growth was monitored by bioluminescence imaging, cancer-induced bone changes by X-ray imaging, and bone pain by Von Frey filaments (mechanical allodynia). SOC treatments included doxorubicin (4 mg/kg, ip, BIW) in the TNBC model, docetaxel (10 mg/kg, ip, BIW) in the CRPC model, bortezomib (0.5 mg/kg, ip, BIW) in the MM model, and zoledronic acid (0.1 mg/kg, QW) in all models as an inhibitor of cancer-induced bone loss.

In the TNBC model, doxorubicin decreased tumor growth and both doxorubicin and zoledronic acid decreased bone loss. Neither therapy was effective in reducing bone pain. In the CRPC model, docetaxel decreased tumor growth and zoledronic acid decreased bone loss, but no effects were observed on bone pain. In the MM model, bortezomib decreased tumor growth and zoledronic acid decreased bone loss.

These results demonstrate that BMTP shows the same clinical features and responses to therapies that are observed in patients with TNBC, CRPC and MM. We conclude that BMTP is a clinically relevant translational tool for evaluating efficacy of cancer therapies on bone metastasizing cancers.

#7548 Mechanistic insights into reactive oxygen species (ROS) homeostasis in ovarian cancer chemoresistance.

Minjun HE[1], Michelle K.Y. SIU[1], Mingo M.H. YUNG[1], Crystal TANG[1], Ruiqian ZHANG[1], Cui CAN[1], Xiaoyan ZHONG[1], Haonan LU[1], Kui LIU[1], Annie N.Y. CHEUNG[2], Hextan Y.S. NGAN[1], David W. CHAN[1], Karen K.L. CHAN[1]

[1]Department of Obstetrics & Gynaecology, The University of Hong Kong, Hong Kong SAR, China,[2]Department of Pathology, The University of Hong Kong, Hong Kong SAR, China

Background: Ovarian cancer remains one of the most lethal gynecologic malignancies, with disease recurrence and platinum resistance representing major therapeutic challenges. Reactive oxygen species (ROS) homeostasis and cancer stem cells (CSC) contribute critically to chemoresistance; however, the molecular mechanisms that sustain CSC expansion under oxidative stress remain insufficiently defined. This study investigated how ROS regulation in ovarian cancer spheroids engages NOTCH1/HES1 and IL11/STAT5-mediated signaling to drive stemness and resistance to cisplatin.

Methods: Ovarian cancer cell-derived spheroids and/or patinum-resistant patient-derived organoids were used to evaluate ROS homeostasis, antioxidant enzyme expression, and CSC phenotypes. ROS levels and MnSOD/HO-1 expression were assessed by fluorescence detection and immunoblotting. Expression, promoter activity and/or activation of P38/NRF2, NOTCH1/HES1, and IL11/STAT5 signaling were examined by qPCR, Western blotting, and reporter assays. Gene silencing of MnSOD, HO-1, HES1 or NRF2 was achieved using siRNA. Pharmacologic inhibition was performed using GSI-MK0752 (NOTCH1/HES1) and CYT387 (JAK2/STAT5). CSC activity was quantified by ALDH assays, CD44 expression, and spheroid formation capacity. An orthotopic ovarian cancer xenograft model was used to evaluate therapeutic efficacy of cisplatin given alone or in combination with pathway inhibitors.

Results: Ovarian cancer spheroids maintained a low-ROS environment through induction of key antioxidants MnSOD and HO-1. Cisplatin activated spheroids P38/NRF2 signaling, which consequently upregulated NOTCH1/HES1 signaling. Silencing of MnSOD, HO-1, or NRF2 impaired spheroids NOTCH1/HES1 activation. Pharmacologic inhibition of either NOTCH1/HES1 or IL11/STAT5 signaling confirmed the NOTCH1/HES1 and IL11/STAT5 signaling axis and decreased spheroids CSC markers and $ALDH^+/CD44^+$ CSC subpopulations, while dual inhibition produced synergistic effects. Moreover, CSC subpopulations enhanced cisplatin responsiveness. Cisplatin induced organoids NOTCH1 activation and promoted STAT5 signaling and expanded $ALDH^+/CD44^+$ CSC subpopulations. In vivo, combined pathway blockade with cisplatin significantly reduced tumor burden and ascites formation compared with monotherapies.

Conclusion: A ROS-responsive NOTCH1/HES1 and IL11/STAT5 signaling axis plays a central role in maintaining CSC populations and promoting platinum resistance in ovarian cancer. Dual targeting of these signaling pathways disrupts the redox-regulated circuit and enhances cisplatin efficacy, supporting further investigation of this combinatorial strategy as a potential therapeutic approach for platinum-resistant ovarian cancer.

#7549 Development of personalized medicine strategies for rectal cancer.

Kiki Lianos[1], Kelly Olsen[1], Aleksandra Edmundson[2], Danielle Siganto[2], Matthew Burge[3], David Clark[2], Vicki Whitehall[1]

[1]Conjoint Gastroenterology Laboratory, QIMR Berghofer, Brisbane, Australia,[2]The Department of General Surgery, Royal Brisbane and Women's Hospital, Brisbane, Australia,[3]The Department of Medical Oncology, Royal Brisbane and Women's Hospital, Brisbane, Australia

Background: Standard of care treatment for patients with locally-advanced rectal cancer includes neoadjuvant chemoradiotherapy followed by surgery. However, this treatment is toxic affecting the patient's quality of life. Additionally, 20% of patients achieve a complete response, 15% show no response and 30-40% may develop metastasis post treatment. Therefore, predicting patient response to treatment would be beneficial to inform clinicians if treatment is not optimal. 3D patient-derived tumor organoids (PDTOs) have been used to predict patient response to treatment due to their ability to replicate the biology and drug responsiveness of the original tumor. My project aims to use rectal cancer PDTOs to develop a personalized medicine strategy to accurately predict patient clinical response prior to therapy to inform clinicians of their treatment options. Patient-derived normal organoids (PDNOs) will also be used for toxicity assessment.

Methods: Rectal cancer patients that meet the required criteria were recruited. Biopsies were collected via flexible-sigmoidoscopy and processed immediately in the laboratory for PDO establishment. Post establishment, patient-derived organoids (PDOs) were tested using a chemoradiation assay to determine sensitive, partial and resistant responders. On day 0, PDOs were seeded on a 384 well plate in 5% matrigel. On day 2, PDOs were exposed to Fluorouracil (0.412uM) followed by radiation (2 and 4 Grays). On day 7, live cells were measured using CellTiter Glo 3D Cell Viability Assay (Promega) on the Cytation 5 multiplate reader. Treatment sensitivity was investigated by calculating 50% growth rate (GR50) using Graphpad Prism.

Results: To date, 14 patients have been recruited and 11 (78.5%) patient biopsy samples have been collected. Out of the collected biopsy samples, 7 out of 10 (70%) have been established with one currently in progress. Chemoradiation assays have been completed for 5 of the 7 established PDOs (RC-001, RC-003, RC-006, RC-008 and RC-010). RC-001 PDTOs exhibited a cytotoxic effect indicating complete response to treatment. The remaining PDTOs illustrated a partial effect indicating partial response to treatment. RC-001, 003, 008 and 010 PDNOs achieved GR50 at 4Gy whereas RC-006 PDNOs achieved GR50 at 2.2Gy. These results indicate that the complete responder could potentially benefit from chemoradiation treatment and the partial responders and could potentially benefit from additional treatment strategies with one partial responder potentially more susceptible to adverse treatment effects.

Conclusion: This project is the first of its kind in Australia to predict patient response to chemoradiotherapy using PDOs. We demonstrate varied patient response to treatment and the important information that could potentially be garnered. Our work has the potential to inform selection of optimal therapy for patients and improve rectal cancer outcomes.

#7553 Digital access, health literacy, and cancer beliefs: Findings from a multi-region community survey.

Tingyu Zou[1], Monica L. Albertie[1], Emelina Asto-Flores[1], Manisha Salinas[1], Farhia Omar[2], Adeline Abbenyi[3], Noreen Stephenson[1], Nuwanthi Heendeniya[2], James R. Cerhan[4], Kathleen J. Yost[3], Folakemi T. Odedina[1]

[1]Mayo Clinic, Jacksonville, FL,[2]Mayo Clinic, Phoenix, AZ,[3]Mayo Clinic, Rochester, MN,[4]Mayo Clinic College of Medicine and Science, Rochester, MN

Background: Digital access, health literacy, and confidence in obtaining cancer information are well-known factors that influence cancer beliefs and behaviors. However, less is understood about whether these information-related factors vary across regions within a cancer center's catchment area and how they collectively relate to cancer beliefs in large community samples. This study investigated regional differences in digital access, health literacy, and confidence in seeking information, and examined the connections between these factors and cancer risk perceptions, fatalistic beliefs, prevention confusion, and willingness to participate in cancer clinical trials.
Methods: Data (N=2,334) from the 2023 Mayo Clinic Comprehensive Cancer Center's Cancer-Focused Needs Assessment, conducted across catchment areas in Arizona, Florida, and the Midwest (Minnesota, Wisconsin, Iowa). Regional differences in digital access (Internet use and device ownership), health literacy, and confidence in obtaining cancer information were analyzed using multivariable ANCOVAs and logistic regressions, adjusting for sociodemographic covariates. Follow-up models examined whether these information precursors are associated with perceived cancer risk, fatalistic beliefs, confusion about recommendations, and willingness to participate in cancer clinical trials, adjusting for the same covariates.
Results: Regions showed minimal differences in digital access and health literacy. Health literacy was instead associated with ethnicity, age, gender, and education (all $p<.001$). Confidence in obtaining cancer information followed similar trends, with significant influences of ethnicity and gender ($p<.01$). Internet use was strongly associated with sociodemographic factors (all $p<.01$). Additionally, the information precursors consistently correlated with cancer beliefs across the full sample: Higher health literacy and greater confidence in obtaining cancer information were associated with increased perceived cancer risk, reduced cancer fatalism, and less confusion regarding prevention guidelines (ps $< .001$). Internet use and device access were significantly related to a greater willingness to participate in clinical trials (ps $< .01$). These relationships persisted even after controlling for sociodemographic covariates.
Conclusions: Regional differences in digital access and health literacy were minimal, indicating a consistent information environment. Within this context, individual sociodemographic and information-related factors played a larger role, strongly shaping cancer beliefs. These findings underscore technology access and information empowerment as key targets for enhancing cancer prevention knowledge and research engagement, and indicate that the effects of information empowerment are primarily driven at the individual rather than the geographic level.

#7554 Strengthening the future cancer workforce: Factors influencing STEM career interest among high school students in Puerto Rico.

Natalie Alamo- Rodriguez[1], Jacquelinee Rojas-Livia[1], Xavier Lopez-Leon[2], Vivian Colon- Lopez[1]

[1]Cancer Control and Population Sciences, University of Puerto Rico Comprehensive Cancer Center, San Juan, PR,[2]Community Outreach and Engagement Office, University of Puerto Rico Comprehensive Cancer Center, San Juan, PR

Introduction: National data indicate a decline in student interest in science and biomedical research, posing risks to the future research and clinical workforce. This is especially concerning in cancer, given the rising incidence of the disease and the growing population of survivors.
Objective: This study aimed to evaluate among public high school students in Puerto Rico, the factors associated with the interest in pursuing careers in STEM. Methods: Two public high schools were randomly selected from among the seven educational regions defined by the Puerto Rico Department of Education (n=14). Following school authorization, teachers distributed parental consent forms and invited students in grades 9-12 to participate in the study. After parental informed consent received, students completed a survey via REDCap. The instrument assessed five domains: sociodemographic characteristics, academic self-efficacy, school climate, perceived social support, and science career motivation. Main dependent variable was students' interest in pursuing careers in STEM, dichotomized as (1) students who intend to or may consider following STEM careers, and (2) students who are not interested or reported not having sufficient knowledge about STEM careers. Student's t-test, Wilcoxon rank-sum test, and Pearson's Chi-square test examined associations between student interest in STEM and potential covariates. Logistic regression was used to estimate odds ratios (OR) and 95% CI. Model selection based on Akaike Information Criterions, Bayesian Information Criterions and likelihood ratio tests.
Results: A total of 197 students were recruited, the majority (62.1%) identified as female and 65% expressed interest in or were considering pursuing a STEM career. In the best-fitting logistic model, higher levels of academic self-efficacy and greater science career motivation significantly increased the odds of students being interested in pursuing STEM careers (OR = 1.71, 95% CI: 1.09-2.80; OR = 2.66, 95% CI: 1.55-4.89, respectively), after adjusting for science self-determination and use of tutoring services.
Conclusions: Our findings show that academic self-efficacy and science career motivation are key drivers of STEM interest among Puerto Rican high school students. Understanding these factors can inform the design of targeted programs that provide early exposure to engaging science experiences, while strengthening students' confidence in their academic abilities, ultimately supporting the development of a skilled workforce capable of meeting the growing demands of cancer research and care. Funding: This work was supported by the NIH (R25MD007607). Ethical approval for the study was secured from the UPR-CCC IRB (20503011465). Declaration of Generative AI and AI-assisted technologies in the writing process: During the preparation of this work the authors used AI for editing.

#7555 Association of political ideology and fatalistic cancer beliefs.

Chinenye M. Okafor[1], Chinenye C. Egwuonwu[2], Onyema Chido-Amajuoyi[3], Henry Onyeaka[4]

[1]The Medical University of South Carolina (MUSC), Florence, SC,[2]Piedmont Athens Regional, Athens, GA,[3]Fred Hutchinson Cancer Center, Seattle, WA,[4]Geisinger Health, Moosic, PA

Introduction: Cancer fatalism is linked to lower adherence to cancer screening and poor preventive health behaviors. Race, health information and social factors have been associated with cancer fatalism, however there is limited research on association with political orientation.

Methods: Data from the National Cancer Institute's Health Information National Trends Survey (HINTS) 7, conducted from March 25 - September 16, 2024, was used. This is a publicly available, de-identified, nationally representative survey of non-institutionalized civilian US adults and is thus exempt from institutional review board review. Survey response rate was 27.3%, with over 86% responding to the specific questions on fatalistic cancer beliefs and political ideology. Primary outcome was fatalistic cancer beliefs assessed using four items in the HINTS survey, each re-coded into a dichotomous variable of strongly agree/somewhat agree vs. strongly disagree/somewhat disagree for this study. Political ideology and race were self-reported. Multivariable logistic regression (adjusted for age, sex, race/ethnicity, educational level, household income, personal cancer history and rural-urban residence) was carried out for each fatalistic belief and political ideology. Statistical analyses were performed using Stata 18.0 software (StataCorp LLC) with 2-sided significance at $p < .05$

Results: The study sample included 6267 adults [3708 (48.3%) women, 3386 non-Hispanic White (61%), and 5400 (87.2%) urban residents. 2033 (31.9%) self-reported as conservative, 2232 (37.5%) as moderate, and 2002 (30.6%) as liberal. Adjusted logistic regression models showed that conservative participants, compared with liberals and moderates were more likely to say they strongly agree/somewhat agree that it seems everything causes cancer [adjusted odds ratio (aOR), 1.47; 95% CI, 1.27-1.69 and 1.29; 95% CI, 1.12-1.49 respectively]. Similarly, when statements on "there is not much you can do to lower your chances of getting cancer" and "there are so many different recommendations about preventing cancer, it's hard to know which ones to follow" were analyzed, conservative participants were more likely to strongly agree/somewhat agree compared with liberal participants [aOR 1.46; 95% CI, 1.26-1.70 and 1.51; 95% CI, 1.32-1.78 respectively] and moderate participants [aOR 1.41; 95% CI, 1.22-1.63 and 1.57; 95% CI, 1.36-1.81 respectively]. There was no significant difference in the statement "When I think about cancer, I automatically think about death" across political ideologies.

Conclusions: In this nationally representative survey of US adults, significant association exists between political ideology and cancer fatalism statements. Given that cancer fatalism has been linked to decrease in screening uptake and health behaviors, political ideologies should be considered as a factor for culturally appropriate interventions, and health promotion strategies.

#7556 Association between health literacy and cancer history with medical trust among adults in the United States.

Huda Haque[1], Morgan Byrd[2], Joab O. Odera[1], Nosa Osazuwa-Peters[2]

[1]Duke University, Durham, NC,[2]Duke University School of Medicine, Durham, NC

Introduction: Health literacy, or the ability to understand health information, shapes health-seeking behaviors. Among those with a history of cancer, low health literacy is associated with poor outcomes. In an era of disinformation, examining how health literacy and cancer history interact with trust in sources of health information can elucidate individuals' health decisions.
Methods: We analyzed data from the Health Information National Trends Survey (HINTS), a nationally representative dataset, for the 2014, 2018, 2020, 2022, and 2024 cycles. Health literacy (Low: never, rarely, sometimes; High: always), personal cancer history (ever vs. never), and age (18-39, 40-64, 65+) were examined in relation to trust in doctors, family, and religious organizations for health information (Low: not at all, a little, some; High: a lot). All variables were self-reported. Survey-weighted logistic regression models accounted for complex sampling and replicate weights using the jackknife method in R. Models included health literacy, cancer history, age category, and survey cycle as predictors. Interactions between age and health literacy, and age and cancer history were tested using Rao-Scott likelihood ratio tests; significant interactions were explored with stratified odds ratios.
Results: Higher health literacy was significantly associated with greater trust in doctors for health information (aOR 4.50, 95% CI 3.61-5.60). When stratified by age, the association varied (ages 18-39: aOR 4.78, 95% CI 2.89-7.91; ages 40-64: aOR 4.00, 95% CI 2.91-5.50; ages 65+: aOR 5.34, 95% CI 3.68-7.75). Cancer history was not associated with doctor trust (aOR 1.17, 95% CI 0.91-1.51), and trust did not vary meaningfully by cycle. For trust in family for health information, the association with health literacy differed by age (interaction p = 0.03). In stratified analyses, higher health literacy showed a trend towards greater trust among younger adults (ages 18-39: aOR 2.02, 95% CI 0.91-4.51), while associations were weaker for middle-aged (ages 40-64: aOR 0.71, 95% CI 0.43-1.16) and older adults (65+: aOR 1.02, 95% CI 0.56-1.87). Cancer history was not associated with family trust, but trust was lower in later cycles (2022 vs. 2017 aOR 0.58, 95% CI 0.42-0.81; 2024 vs. 2014 AOR 0.56, 95% CI 0.41-0.76), suggesting shifting trust in family after the COVID-19 pandemic. Trust in religious organizations for health information was higher in older adults (ages 40-64 vs. 18-39 aOR: 1.95, 95% CI 1.36-2.79; 65+ vs. 18-39 aOR: 1.55, 95% CI 1.13-2.15) and lower among cancer survivors (aOR 0.61, 95% CI 0.43-0.87). Health literacy was not associated with trust in religious organizations and trust remained stable across cycles.
Conclusion: These findings emphasize the importance of targeted outreach for different patient and trust contexts to promote informed health decisions, especially for older adults and cancer survivors.

#7557 Perceived stress and immigration-related demands in a Haitian immigrant community: Descriptive findings from a cancer disparity registry.

Jovanka Ravix[1], Maurice Chery[1], Sandy St. Hilaire[1], Mame Dioum[1], Lauren Smith[1], Twyla Murphy[1], Ivana Saborit[1], Johnathon Penso[1], Nadege Jacques[2], Sonide Cherise[2], Loukencia Jean[2], Priscila Barreto Coelho[1], Rimsky Denis[2], Sophia Hl George[3]

[1]University of Miami, Miller School of Medicine, Miami, FL,[2]Center for Haitian Studies, Miami, FL,[3]Univ. of Miami Sylvester Comprehensive Cancer Ctr., Miami, FL

Introduction: Psychosocial stress plays a critical role in shaping cancer-related outcomes, influencing both health behaviors and biological processes such as inflammation and immune function. Among immigrant populations, stress is often compounded by migration-related challenges and structural barriers. This study provides a descriptive profile of perceived stress and immigration-related demands among Haitian adults participating in the Florida Cancer Health Disparity Registry.

Methods: Seventy-five Haitian adults residing in South Florida completed a cross-sectional survey. The Perceived Stress Scale (PSS-10) was used to assess global stress levels, while the Immigration Demand Scale captured migration-related stressors. Participants also provided sociodemographic data, including age, education, income, employment status, and family history of cancer. Descriptive statistics were used to summarize responses.

Results: The mean age was 43.45 years (±13.47), with the majority aged 31-45 (40.0%) and 46-60 (29.3%). Most participants reported low income (66.7% earning < $10,000/year), and 56.8% were not employed. Only 19.7% reported a family history of cancer. On the Immigration Demand Scale (0-3 scale), the most strongly endorsed stressors included “Job market disadvantage” (1.96 ±0.21), “Missing people from country of origin” (1.92±0.31), and “Not feeling accepted” (1.81±0.16), with additional concerns about accent discrimination and language barriers. On the PSS-10, the mean stress score was 2.26 (±0.50). The most frequently reported experiences were feeling “nervous and stressed” (2.82 ± 0.89), being “upset by something unexpected” (2.47±1.10), and feeling “unable to control important things” (2.33±1.13). Positively framed items such as “Felt things were going your way” (1.47 ± 1.12) and “Felt on top of things” (1.80 ± 1.04) scored lowest, suggesting limited perceived control and optimism.

Conclusions and Implications: Participants reported high levels of perceived stress and immigration-related adversity, highlighting the psychosocial burden faced by Haitian immigrants. These stress exposures are important to understand in the context of cancer outcomes, as they may influence healthcare engagement, risk perception, and biological vulnerability. Future analyses will explore the relationship between stress and other cancer-relevant outcomes, including potential impacts on immune and inflammatory biomarkers, to inform culturally grounded prevention strategies.

#7558 Burden of non-vaccine high-risk oral HPV in updated cohort of people with HIV: Implications for public health strategies.

Jurelis Torres-Reyes[1], Juliana Mary Serrano-Rodriguez[2], Gabriel Borges-Velez[1], Jeannette L. Salgado Montilla[1], Maria M. Sanchez-Vazquez[1], Magaly Martinez-Ferrer[3], Ramon F. Gonzalez-Garcia[3], Josue Perez-Santiago[1]

[1]Comprehensive Cancer Center of University of Puerto Rico, San Juan, Puerto Rico,[2]University of Puerto Rico - Rio Piedras, San Juan, PR,[3]University of Puerto Rico School of Medicine, San Juan, Puerto Rico

Introduction/Background: Human papillomavirus (HPV) is the most common sexually transmitted infection and is considered the second infectious agent related to cancer. People with HIV (PWH) are at a higher risk of acquiring oral HPV infection, despite antiretroviral therapy, increasing their risk for oropharyngeal cancer (OPC). While there are more than 200 HPV genotypes, about 15 of them are classified as high-risk (hr) and responsible for HPV-related cancers. Currently, a nine-valent HPV vaccine is recommended in the US, providing protection against (6,11,16,18,31,33,45,52,58) HPV types. HPV vaccination is recommended for females, and males aged 13-26 years; for adults ages 27-45 years might get the HPV vaccination based on discussion with their clinician. In 2023, HPV vaccination rates among US Hispanics were 60%, but in Puerto Rico (PR) remain limited, particularly among PWH. Here, we described the prevalence of oral HPV infection by HPV genotypes among PWH, investigated HPV vaccination rates, and nonmedical factors associated with HPV infection.

Methods: We evaluated 184 sexually active PWH with a median age of 48 years. Oral rinse samples were collected and analyzed for HPV and genotyped using the DNA ELISA kit HPV SPF10 and RHA kit HPV SPF10-LiPA25. An administered questionnaire collected sociodemographic characteristics and lifestyle variables. Statistical analyses were performed in R-statistical software.

Results: The prevalence of oral HPV infection was 33%, of which 62% were hr genotypes, with HPV-18 being the most abundant (30%). Also, the prevalence of other hr HPV was 14% (HPV-35), 11% (HPV-33, HPV-16), 5% (HPV-39, HPV-51, HPV-53, HPV-56, HPV-59, HPV-74), and 3% (HPV-44, HPV-43, HPV-70). The prevalence of hr HPV genotypes not covered by the current nine-valent vaccine were more prevalent (57%) than vaccine covered hr genotypes (41%). There are not significantly difference between hr HPV, and socio-behavioral factors as current smokers (p=0.35), more than fifty sexual partners in lifetime (p=0.40), and education level (p=0.53).

Conclusion: PWH exhibited an elevated prevalence of oral HPV infection, with rates higher than those previously documented in PR. Although current HPV vaccines offer broad protection to some hr HPV oncogenic genotypes, limited vaccination rates may contribute to the persistence of oral HPV infection. Additionally, we have observed several other hr HPV oncogenic genotypes which are not currently covered by the existing vaccines, highlight the need for novel improved HPV vaccines.

#7559 Implementation of an interactive clinical trials education and decision tool for Florida cancer patients at an NCI Center.

Susan T. Vadaparampil, Lindsay N. Fuzzell, Elliott S. Tapia-Kwan, Yayi Zhao, Rossybelle Amorrortu, Dana Rollison, **Margaret Byrne**

Moffitt Cancer Center, Tampa, FL

Background: CHOICES Decision Aid (DA) is an evidence-based, interactive, education and decision-making support tool (available in English and Spanish) for cancer patients about participation in cancer clinical trials (CCTs). As part of the ACT WONDERS study, a multi-level intervention aimed at increasing referral and enrollment of diverse patients to CCTs, the website was made accessible to new Moffitt Cancer Center patients residing in seven geographically defined study intervention zones in the catchment area. CHOICES DA features education content such as facts about CCTs, values clarification tools on CCT participation, and patient narratives about CCT participation.
Method: Eligible patients were able to access the site via patient portal and received an email with a description and website link. Upon site exit, patients were asked to complete an optional 5-item survey about subjective CCT knowledge (1-7 scale), preparedness to talk with providers about CCTs (1-7), CCT decision readiness (1-7), and usefulness (1-10), and satisfaction with the site (1-10). Mean scores were re-scaled to 100% for comparison. Usage metrics were continuously monitored.
Results: In the first year following intervention launch (September 17, 2024 - October 2, 2025), 550 of 2,340 eligible patients (24%) visited CHOICES DA. Of 550 eligible patients who viewed the site, race demographics were: white 37% (n=203); Black 4% (n=27); other race 4% (n=23); not reported 54% (n=297). Ethnicity was 11% (n=61) Hispanic/Latino, 33% (n=181) non-Hispanic/Latino, and 56% (n=308) unknown. Mean age was 65 (range 56-73). 10% of users returned to the site at least once. 13% of patients viewed the Spanish site. 45 (8%) patients completed the survey. Mean self-rated CCT knowledge was 84%, readiness to decide about CCTs was 83%, and readiness to discuss CCTs with a doctor was 88.6%. Mean website usefulness and satisfaction were 86% and 85%, respectively.
Conclusion: Findings suggest CHOICES DA could be readily implemented in a high-volume oncology care setting leveraging existing communication channels available to patients. Survey completers gave high ratings to their CCT knowledge and readiness to discuss and make decisions about participation in CCTs, as well as website satisfaction and usefulness. CHOICES DA will also be evaluated at the two-year post-implementation time point, and future analyses will examine the impact on CCT enrollment at the cancer center.

#7561 Understanding beliefs about hereditary susceptibility for cancer: An analysis of HINTS 2020.

Ashley Hatch[1], Heidy N. Medina[2], Nicholas A. Borja[2], Matthew Schlumbrecht[3], Patricia I. Moreno[2]

[1]Department of Public Health Sciences, University of Miami, Miami, FL,[2]University of Miami, Miami, FL,[3]Miller School of Medicine - University of Miami, Miami, FL

Purpose: Cancer is driven by a complex interplay of genes and environment. However, little is known about the public's beliefs about hereditary susceptibility to cancer. This study characterized beliefs about hereditary susceptibility to cancer in a nationally representative survey of US adults. We also identified who is more likely to want to know if they had a genetic predisposition to cancer.**Procedures:** We analyzed data from the NCI Health Information National Trends Survey (HINTS) 2020 Cycle 5 Wave 4 using SAS 9.4 for weighted survey analysis. Adjusted linear regression models assessed predictors of (1) how much respondents believe genes that are inherited determine whether or not a person will develop cancer and (2) how much respondents would want to know if they had a genetic change that increases their chance of getting cancer (these items were reverse coded). Individuals with a previous cancer diagnosis were excluded.**Results:** Most respondents (N=3,253) were female (46.9%), non-Hispanic White (57.4%), married (44.4%), and were 46.6 years old (SE=.58). On average, respondents endorsed between "somewhat" and "a lot" for how much hereditary susceptibility determines a person's cancer risk and their desire to know if they had a genetic predisposition to cancer. Respondents believed that hereditary susceptibility to cancer (M=1.8, SE=.02), cardiovascular disease (M=1.8, SE=.02), and diabetes (M=1.8, SE=.02) were similar (p's >.6), but believed hereditary susceptibility to obesity was significantly lower (M=2.2, SE =.02, p<.0001). Individuals with health insurance (versus those who were uninsured, β = –.42 - –.37, p = .017 - .021) and those who had previously sought cancer information (β = –.19, p < .001) were more likely to believe that hereditary susceptibility determines a person's cancer risk. Individuals who believe in greater hereditary susceptibility to cancer were more likely to want to know if they had a genetic predisposition to cancer (β = .14, p = .001). Hispanic (β = –.25, p = .0098) and non-Hispanic Black (β = –.47, p < .0001) respondents, and individuals with a family history of cancer (β = –.20, p = .0051), who previously sought cancer information (β = –.19, p = .0019), and were less fatalistic (β = –.08, p = .036) were also more likely to want to know about their genetic predisposition to cancer. **Conclusions:** Individuals who believe in greater hereditary susceptibility to cancer are more likely to want to be informed if they have a genetic predisposition to cancer. Importantly, Hispanic and Black individuals were more likely than non-Hispanic Whites to want to know about their genetic risk to cancer, which highlights the critical need to overcome barriers related to access and cost and ensure equitable access to genetic testing. Outreach and educational efforts are needed to address fatalistic beliefs and lack of information or misinformation.

#7562 Evaluating the effectiveness of the C.H.A.N.G.E. training: A community-based tobacco cessation program for community health workers.

Andres Mauricio Garcia-Sierra, Victoria Nassar Abuabara, Tianqu Lu, Cynthia Tang, Anna Veluz-Wilkins, Marcia Tan

University of Chicago, Chicago, IL

Background: Commercial tobacco use drives approximately 30% of cancer-related deaths and remains disproportionately high among low-socioeconomic-status (SES) populations. Community health workers (CHWs) are uniquely positioned to promote tobacco cessation within this communities. The C.H.A.N.G.E. (Community Health Allies Nicotine Guidance Education) training was developed to enhance CHWs' capacity to deliver culturally responsive cessation counseling. This study evaluated its effectiveness in improving CHWs' tobacco-related knowledge, motivation, readiness, and confidence.
Methods: We conducted a secondary analysis of pre-, post-, and six-month follow-up data from CHWs (N=155) in Chicago, IL, recruited through a public health department, community-based organizations, and a CHW degree program. Of these, 144 completed post-training and 98 completed six-month assessments. The participatory curriculum, adapted from the WHO 5A's and 5R's Toolkit, emphasized motivational interviewing (MI), culturally tailored communication, and the social determinants of tobacco use. Changes across time points were analyzed using paired-sample t-tests.
Results: Significant improvements were observed from pre- to post-training (all $p<.05$): knowledge (Mean=4.89 to 7.91 out of 10), motivation (Mean=7.81 to 8.71 out of 10), readiness (Mean=6.09 to 8.25 out of 10), confidence in delivering cessation support (Mean=6.48 to 8.39 out of 10), and MI confidence (Mean=6.96 to 8.57 out of 10). At six months, all mean scores declined relative to post-training ($p\leq.05$) but remained significantly higher than pre-training for all domains except motivation ($p\leq.05$).
Conclusions: The C.H.A.N.G.E. training effectively improved CHWs' competence and self-efficacy in delivering tobacco cessation counseling. Findings support community-driven, culturally adapted models to extend evidence-based cessation interventions beyond clinical settings. Ongoing booster sessions and train-the-trainer approaches may enhance long-term skill retention and contribute to reducing tobacco-related cancer disparities in low-SES populations.

#7565 Psychological distress, antidepressants, and sympathetic-immune profiles in cancer survivors.

Ji E. Park[1], Andrew Ray[1], Rikki Cannioto[1], Kathryn Glaser[1], Han Yu[2], Karen Hulme[1], Susan LaValley[1], Orla Maguire[3], Hans Minderman[3], Krystin Mantione[4], Nicolas Schlecht[1], Shipra Gandhi[5], Elizabeth Bouchard[1], Elizabeth Repasky[6], Christine Ambrosone[1], Chi-Chen Hong[1]

[1]Cancer Prevention and Control, Roswell Park Comprehensive Cancer Center, Buffalo, NY,[2]Biostatistics and Bioinformatics, Roswell Park Comprehensive Cancer Center, Buffalo, NY,[3]Flow and Immune Analysis Shared Resource, Roswell Park Comprehensive Cancer Center, Buffalo, NY,[4]Pharmacology and Therapeutics, Roswell Park Comprehensive Cancer Center, Buffalo, NY,[5]Medicine, Winship Cancer Institute of Emory University, Atlanta, GA,[6]Immunology, Roswell Park Comprehensive Cancer Center, Buffalo, NY

Background: Psychological distress, including perceived stress, anxiety, and depression, can activate the sympathetic nervous system and increase norepinephrine (NE) and epinephrine (E). These catecholamines may impair anti-tumor immunity through β2-adrenergic effects on CD8+ T-cells and myeloid-derived suppressor cells (MDSCs). Antidepressants that alter NE reuptake may further modify sympathetic signaling and immune regulation in cancer survivors.

Methods: This analysis included 152 cancer survivors who completed the Perceived Stress Scale (PSS), PROMIS Anxiety (PROMIS), and Center for Epidemiological Studies Depression (CES-D) surveys and reported clinical diagnosis of anxiety or depression and current antidepressant use. Plasma NE, E, 3,4-dihydroxyphenylglycol (3,4-DHPG), and dopamine (DA) were quantified by LC-MS/MS, and CD8+ T-cell and MDSC subsets were assessed by flow cytometry as percent cell-subset events over total cell type events. Antidepressant use was classified as none (N=120), selective serotonin reuptake inhibitor (SSRI, N=11), or serotonin-NE or NE-DA reuptake inhibitors (SNRI/NDRI, N=21); five clinically diagnosed individuals not taking antidepressants were excluded. Associations of distress measures, clinical diagnoses, and medication class with catecholamines and immune profiles were evaluated using ANCOVA adjusted for age, education, and smoking history, with reciprocal adjustment for PROMIS or CES-D in clinical diagnosis models.

Results: Catecholamine levels were not associated with PSS, PROMIS, or CES-D. Higher perceived stress was associated with altered CD8+ T-cell distributions: naïve CD8+ T-cells were 30.7% higher in the highest vs lowest quartile (62.2 vs 47.6%, p=0.03), while memory CD8+ T-cells were 28.5% lower (36.6 vs 51.2%, p=0.01). Clinical anxiety (N=23) was not related to catecholamine levels, but clinical depression (N=24) was associated with higher NE (22.2%; 663.0 vs 542.2 pg/mL, p=0.01) and DA (41.8%, 20.5 vs 14.5 pg/mL, p=0.002). Neither diagnosis was associated with CD8+ T-cells or MDSCs. Antidepressant class showed expected physiologic patterns: SNRI/NDRI users had higher NE (37.7%; 485.3 vs 352.4, p=0.04), lower 3,4-DHPG (19.9%; 912.7 vs 1139.4 pg/mL, p=0.0004), and higher DA (64.5%, 16.1 vs 9.8 pg/mL, p=0.001) than SSRI users. PMN-MDSCs trended 32.2% higher (1.15 vs 0.87%, p=0.11) and M-MDSCs 54.8% higher (4.32 vs 2.79%, p=0.09) among SNRI/NDRI users vs SSRI users, consistent with increased adrenergic-linked immunosuppressive myeloid activity.

Conclusion: Clinical depression was associated with higher sympathetic catecholamines, and NE-reuptake-inhibiting antidepressants produced expected catecholamine shifts. Corresponding increases in PMN-MDSC and M-MDSC among SNRI/NDRI users suggest adrenergic signaling may contribute to immunosuppressive myeloid abundance in cancer survivors.

#7566 Use of supportive care medications is associated with pancreatic cancer tumor location at diagnosis.

Hussein Khalil[1], Kourtney A. D. Byrd[1], Yi Guo[2], Shuang Yang[3], Xiwei Lou[3], Lisa Scarton[4], Sherise C. Rodgers[5], Diana J. Wilke[4], John M. Allen[1]

[1]Purdue University, West Lafayette, IN,[2]University of Florida College of Medicine, Gainesville, FL,[3]College of Medicine, University of Florida, Gainesville, FL,[4]University of Florida, Gainesville, FL,[5]Brown University, Providence, RI

Background: Pancreatic cancer (PC) often presents with non-specific symptoms that vary by tumor location. Tumors in the body and tail often present later and are more commonly associated with pain, nausea, or cachexia. Supportive care medications (SCMs) such as psychotropics, pain relief medications, antinausea agents, and appetite stimulants ae commonly used to manage these symptoms yet little is known about whether prescribing patterns differ by tumor location. We evaluated whether pancreatic tumor location at diagnosis is associated with subsequent use of SCMs among older adults with pancreatic cancer.
Methods: We conducted a retrospective cohort study using Surveillance, Epidemiology, and End Results (SEER)-Medicare data (2007-2019). The study included patients aged ≥65 years old with incident pancreatic cancer and continuous Medicare parts A, B, and D coverage for 3 months before diagnosis. Patients with another cancer diagnosis within 6 months or missing baseline data were excluded. Pre-diagnosis SCM use was ascertained from Medicare Part D prescription claims. Tumor location at diagnosis were categorized as pancreatic head (C250), body (C251), tail (C252), or other (C253, C254, C257, C258, C679). We used multivariable logistic regression to evaluate the association between SCM use and tumor location adjusting potential confounders.
Results: Compared to tumors in the pancreatic head, tumors in the body were associated with higher odds of receiving most SCM classes including psychotropic medications (OR for any psychotropic: 1.13; 95% CI: 1.08-1.19), pain medications (OR for any pain medication: 1.25; 95% CI: 1.19-1.31), anti-nausea agents (OR: 1.08; 95% CI: 1.03-1.13), appetite stimulants (OR: 1.16; 95% CI: 1.11-1.21). Tail tumors were associated with increased use of anxiolytics (OR: 1.07; 95% CI: 1.00 - 1.14) and non-opioid analgesics (OR: 1.25; 95% CI: 1.15-1.37), but lower odds of anti-nausea use (OR: 0.85; 95% CI: 0.81-0.89). Tumors in other locations generally had lower odds of SCM use across nearly all categories.
Conclusion: Pancreatic cancer tumor location at diagnosis is associated with distinct patterns of supportive care medication use. Patients with tumors in the body of the pancreas were more likely to receive symptom-directed therapies than those with head tumors while those with tail or other locations had more variable patterns. These findings suggest that tumor location may influence supportive care needs and should be considered when tailoring symptom management strategies.

#7567 Predictors of antidepressant use in older adults after pancreatic cancer diagnosis: A SEER-Medicare analysis.

Hussein Khalil[1], Kourtney A. D. Byrd[1], Yi Guo[2], Shuang Yang[3], Lisa Scarton[3], Xiwei Lou[3], Diana J. Wilkie[4], Sherise C. Rodgers[5], John M. Allen[1]

[1]Purdue University, West Lafayette, IN,[2]University of Florida College of Medicine, Gainesville, FL,[3]Department of Health Outcomes & Biomedical Informatics, University of Florida, Gainesville, FL,[4]Biobehavioral Nursing Science, University of Florida, Gainesville, FL,[5]Brown University Warren Alpert Medical School, Providence, RI

Depression is highly prevalent among patients with pancreatic cancer (PC), driven by both the biological effects and the profound psychosocial burden of the diagnosis. Untreated depression contributes to poorer quality of life, reduced treatment adherence, increased symptom burden, and worse survival. Prior work suggests sociodemographic inequities may shape access to supportive care medications, yet little is known about how these factors operate specifically within older adults with PC. We aimed to characterize predictors of antidepressant use following pancreatic cancer diagnosis, with the goal of identifying inequities and informing patient-centered approaches to supportive care delivery in this high-risk population.

We conducted a retrospective cohort study using SEER-Medicare data among patients aged ≥65 years diagnosed with primary PC between 2007 and 2019. Antidepressant use was identified from Medicare Part D claims up to 24 months post-diagnosis. We compared patient characteristics by antidepressant use status. Multivariable logistic regression models estimated adjusted odds ratios (ORs) and 95% confidence intervals (CIs).

Among 81,535 patients with PC, 23.5% (N=19,181) received antidepressants post-diagnosis. Compared with those living in the highest-SES neighborhoods, patients in the lowest SES quintile had 19% lower odds of receiving antidepressants (aOR: 0.81; 95% CI 0.74-0.88). Increasing age was strongly associated with reduced use (≥80 vs. 65-69 years: aOR:0.60; 95% CI 0.57-0.63), while female sex was associated with higher odds (aOR:1.19; 95% CI 1.15-1.23). Marked racial/ethnic disparities were observed: non-Hispanic Black (aOR:0.63; 95% CI 0.59-0.67) and Asian (aOR:0.60; 95% CI 0.56-0.65) patients were substantially less likely to receive antidepressants compared with non-Hispanic White patients. Higher comorbidity modestly increased use (CCI per point: aOR:1.07; 95% CI 1.06-1.08). Strong associations were observed for prior supportive care medication use (aOR: 2.02; 95% CI 1.94-2.09) and hospice enrollment (aOR: 1.73; 95% CI 1.67-1.80).

In our study, nearly a quarter of older adults with PC received antidepressants, with substantial variation by socioeconomic status, race/ethnicity, age. The markedly lower use among racial/ethnic minority and lower-SES patients indicates potential inequities in mental health treatment access and potential cultural influences. Increased use among those with higher comorbidity burden and hospice enrollment suggests that antidepressants are more often introduced in the context of advanced symptom burden or end-of-life care rather than early in the cancer course. These findings underscore the need for systematic depression screening across all demographic groups and proactive integration of mental health services into routine pancreatic cancer care.

#7568 The STANDOUT program: A model for undergraduate training and career development in behavioral cancer prevention and control.

Joel Erblich[1], Jennifer S. Ford[1], Guy H. Montgomery[2]

[1]Department of Psychology and Center for Cancer Health Disparities Research, Hunter College, New York, NY,[2]Center for Behavioral Oncology, Icahn School of Medicine at Mount Sinai, New York, NY

The potential for behavioral science to make meaningful strides in cancer prevention and control is significant, yet more behavioral scientists focused on cancer prevention and control are desperately needed to achieve this end. Unfortunately, progress in behavioral cancer prevention and control (BCPC) research is hampered by several key barriers. These include: 1) the relatively small fraction of scientists who focus on BCPC, 2) limited awareness of BCPC career opportunities when college students consider their advanced educational options, 3) limited opportunities to receive formal early training in BCPC research, and 4) a lack of stewardship of outstanding college students to transition from research labs to successful graduate education. The objective of STANDOUT (Summer Training Accelerating and Nurturing the Development of Outstanding Undergraduate Trainees; R25CA260125) is to address institutional challenges head-on, by providing multifaceted, immersive summer training and career development opportunities to talented undergraduates attending Hunter College, a large diverse urban university in New York City. Now in its third year, we report on trainee outcomes to date. Undergraduate Trainees (n=41, 16-18/cohort) completed a 10-week summer research internship program. The program includes: 1) formal mentored BCPC research training with scientists at either Hunter College of the City University of New York or the Center for Behavioral Oncology at the Icahn School of Medicine at Mount Sinai, 2) biweekly research and career development seminars, 3) research and networking conferences, and 4) continued outreach and mentoring as students advance in their education and training. We conducted pre-post assessments of key outcomes, as well as program satisfaction, and annual follow-ups to track student advancement and accomplishments. Findings indicated that trainees consistently endorsed high levels of satisfaction across multiple program elements, including mentor quality, research experience, and seminars and conferences. Trainees also exhibited significant increases in a number of key research-related skills, including conducting literature reviews, writing, generating and refining hypotheses, conducting quantitative analyses, and presenting research. Notably, trainees' interest in pursuing cancer research increased significantly following the program. Finally, annual follow-up data revealed continued interest in BCPC research, increases in related professional activities, presentations, publications, attendance at scientific conferences, and career and academic advancement (e.g., successful application to graduate programs). STANDOUT is an example of a program that can both train and inspire students early in their academic trajectories to pursue careers aimed at advancing research in behavioral cancer prevention and control.

#7569 Health literacy and beliefs about cancer causation and prevention in a Haitian immigrant population.

Maurice J Chery[1], Jovanka Ravix[1], Sandy St. Hilaire[1], Mame Dioum[1], Lauren Smith[1], Twyla Murphy[1], Ivana Saborit[1], Johnathon Penso[1], Nadege Jacques[2], Sonide Cherise[2], Loukencia Jean[2], Priscila Barreto Coelho[1], Rimsky Denis[2], Sophia Hl George[3]

[1]University of Miami Miller School of Medicine, Miami, FL,[2]Center for Haitian Studies, Miami, FL,[3]Univ. of Miami Sylvester Comprehensive Cancer Ctr., Miami, FL

Introduction: Cancer prevention efforts are influenced by individuals' beliefs about disease causation and their ability to access, understand, and use health information. This descriptive study presents interim findings on health literacy, cancer causal beliefs, and cancer prevention attitudes among Haitian immigrants. The data come from a subsample in the Florida Cancer Health Disparity Registry.
Methods: We conducted a cross-sectional survey among 75 Haitian adults residing in South FL. Health literacy was assessed using the HLS19-Q12 and the BRIEF HL Screening Tool. Additional items evaluated beliefs about the causes and preventability of cancer. Descriptive statistics summarized sociodemographic data, literacy levels, and thematic patterns in belief systems. No inferential testing was performed at this stage.
Results: Mean age of participants was 43.45 years (+/-13.47). Over half (52.7%) had never been married. Educational attainment varied, 44.0% having intermediate education, 32.0% low, and 24.0% high. Two-third reported earning less than $10,000 annually, and 56.8% were unemployed. Family history of cancer was reported by 19.7% of respondents. On the HL, 44.1% of participants had inadequate HL, and 33.9% had problematic HL, totaling 78% with suboptimal skills. On the BRIEF, 82.0% had trouble learning from written health materials, 80.3% struggled to understand spoken explanations, and 77.1% required help reading hospital materials. Only 53.2% felt confident completing forms, while 46.8% lacked confidence. Overall, 60.7% demonstrated “not sufficient” health literacy. Regarding cancer causation, participants listed 188 beliefs, the most frequent being diet and nutrition (35.1%), referencing processed foods, sugar, red meat, and chemical additives. Other belief categories included environmental exposures (14.4%), genetic/biological factors (12.8%), behavioral factors (11.7%), infections (10.6%), physical causes (8.0%), and cosmetic products (4.3%). When analyzed by controllability, 47% listed three controllable causes, and 36% listed two, suggesting widespread belief in individual agency over cancer risk. In terms of prevention beliefs, 76.6% disagreed with the statement "Everything causes cancer," and 65.6% disagreed with "Not much you can do to prevent cancer," reflecting positive attitudes toward preventability. However, 40.6% agreed that cancer means death, and 54.8% found cancer prevention recommendations confusing.
Conclusions: Our results highlight limited health literacy alongside strong beliefs in cancer preventability and personal control over risk among Haitian immigrants. Findings support the need for tailored education addressing literacy gaps and cancer-related misconceptions. Further analyses will examine associations between literacy, beliefs, and sociodemographic factors to guide targeted intervention development.

#7570 Expanding digital access to cancer immunotherapy trials: Nationwide engagement and high match rates among 21,000 patients.

Cynthia L. Neben, Wendy Weise, Samik Upadhaya, Alicia Y. Zhou

Cancer Research Institute, New York, NY

Clinical trials are essential to advancing cancer care and precision medicine. They provide access to innovative treatments and are fundamental to validating new therapies, generating evidence for regulatory approval and improved care. Yet participation remains limited - only 9% of U.S. patients report being invited to a clinical trial, and one in five adult cancer trials fail to finish due to low enrollment. Increasing patient and provider awareness and helping patients navigate their best options are key to closing this gap.

To help address these barriers, the Cancer Research Institute (CRI) provides a free, online Clinical Trial Finder designed to connect patients with cancer immunotherapy trials. The tool uses a short survey to match users to open studies based on cancer type, location, and other eligibility criteria. Users can access the full portfolio of clinical trials sourced from the ClinicalTrials.gov and search by cancer type, drug type, trial phase, and sponsor. Additional one-on-one trial navigation support is available by phone or email.

Over nine months, more than 21,300 individuals visited the CRI Clinical Trial Finder webpage (https://cri.careboxhealth.com/en-US/). Nearly all individuals who completed the survey did so online (95.6%, 3,651) rather than by phone or email (169, 4.4%). Survey completion rates were also higher for online users (2,510, 68.7%) versus phone or email (87, 5.1%). Among all individuals who completed the survey (n=2,597), 97.2% matched to at least one open clinical trial. This match rate is substantially higher than published reports and may reflect broad eligibility of cancer-type-agnostic and genomically-driven immunotherapy trials.

Users came from 49 U.S. states and the District of Columbia, with the largest numbers in California (157), Texas (74), and Florida (74) (n=1,036 who provided location); there were no users in Wyoming. These data mirror general U.S. population distribution and demonstrate nation-wide reach.

About one-third (1,210) of users reported a diagnosis of pancreatic, breast, or ovarian cancer. While breast cancer is the most commonly diagnosed cancer among women in the U.S., pancreatic and ovarian cancers are lower incidence and often detected in later stages, with fewer treatment options, making clinical trials particularly relevant for these patients. Individuals with sarcoma (118), kidney (66), skin (16), thyroid (8), or testicular (4) cancer had a 100% match rate. Melanoma had the lowest (87.3%, 48).

Our findings demonstrate how online, patient-friendly tools supplemented with personalized navigational support can help bridge the gap between patients and cancer research. By lowering barriers to access and empowering patients, digital trial-matching services can help advance clinical trial participation and make more life-saving immunotherapies available to more people.

AI was used to review abstract text.

#7571 Health literacy and colorectal cancer: A targeted review of screening, outcomes, and challenges in vulnerable populations.

Nijole P. Tjader[1], Brigette Waldrup[2], Hyoshin Kim[1], **Enrique I. Velazquez Villarreal**[2]

[1]Biomedical Informatics, The Ohio State University Wexner Medical Center College of Medicine, Columbus, OH,[2]Integrative Translational Science, City of Hope, Duarte, CA

Health literacy is increasingly recognized as a critical determinant of cancer prevention, treatment adherence, and survivorship outcomes. In colorectal cancer (CRC), its importance is pronounced, in part because early detection through screening can significantly reduce incidence and mortality. Persistent disparities in CRC-related health literacy may contribute to lower screening uptake, suboptimal treatment decisions, and reduced quality of life, especially among populations experiencing disproportionate health burdens. To characterize the scope and impact of health literacy in CRC, we conducted a targeted literature review examining its relationship with clinical, behavioral, and psychosocial outcomes across the CRC care continuum. Using PubMed, we identified peer-reviewed studies that evaluated associations between health literacy and outcomes such as screening participation, treatment adherence, patient-reported experiences, and quality of life. Studies were included if they addressed CRC and incorporated measurable health literacy constructs. Thirty-nine studies met inclusion criteria. We synthesized approaches and key findings, with particular attention to implications for disproportionately affected populations. Across diverse geographic and clinical settings, limited health literacy was consistently associated with lower CRC screening rates, reduced knowledge of guideline recommendations, greater perceived barriers, and more fatalistic beliefs. Among individuals diagnosed with CRC, lower health literacy was linked to poorer treatment adherence, reduced health-related quality of life, and increased mortality, with especially strong effects in early-stage disease. Challenges were amplified among individuals with both limited literacy and limited English proficiency. Interventional studies demonstrated the promise of culturally-tailored interventions, including educational materials, patient navigation, and community-based outreach, in mitigating literacy-related disparities. Recent studies identified the influence of health literacy on financial toxicity, communication preferences, and care satisfaction, particularly among rural, immigrant, and low-income populations. Overall, this review identified key ways that health literacy is a significant, modifiable determinant of CRC outcomes and a contributor to persistent disparities. Targeted interventions to address literacy gaps, especially among vulnerable populations, should be prioritized in CRC across prevention, diagnosis, and survivorship. Future research should focus on scalable, culturally and linguistically appropriate strategies, including the integration of artificial intelligence and digital health tools, to strengthen informed decision-making and improve outcomes across all populations throughout the CRC care continuum.

#7572 Personalized counseling on cancer prevention at the National Cancer Prevention Center's Prevention clinic: Bridging the gap between research, application, and individual implementation.
Ursula Melanie Christel Will

DKFZ German Cancer Research Center, Heidelberg, Germany

The prevention of non-communicable diseases is becoming an increasingly important focus of modern health systems. In addition to population-based strategies, approaches that consider genetic, biological, and lifestyle-related risk factors are becoming important for individualized prevention. The National Cancer Prevention Center (NCPC) is being established in Germany through a long-term strategic partnership between the German Cancer Research Center (DKFZ) and the German Cancer Aid. The NCPC brings together all key components of cancer prevention under one roof: from fundamental research and prevention trials to evidence-based counseling for the public and training for prevention specialists and multipliers. A central element is the Prevention Outpatient Clinic (POC), a unique model facility in Germany that maximizes the potential of cancer prevention and makes it accessible to everyone. In the POC, risk profiles are systematically created based on identified cancer risk factors, including family history, genetic predispositions, lifestyle factors, previous illnesses, and medication use. With these risk profiles, we create individualized prevention pathways that link health promotion counseling with recommendations for early detection and lifestyle changes. There is a strong focus on health literacy and sustainable behavior change because prevention only works when it is feasible in everyday life. Thus, the POC serves as an active partner in behavior modification. At the same time, the POC functions as a research platform for epidemiological, implementation, and translational trials. Standardized data on risk profiles, adherence, effectiveness, and acceptance of preventive measures provides insight into the success factors and barriers of cancer prevention. Linking research and application creates a bidirectional knowledge loop in which findings from science are translated into practice and re-translated from application to new research questions. Additionally, the POC fosters interdisciplinary collaboration among oncology, human genetics, nutrition and sports medicine, psychology, and public health. Digital tools and AI-supported algorithms offer new perspectives for more precise risk assessment and personalized prevention planning for specific risk reduction. The POC exemplifies a paradigm shift in oncology, moving away from solely treating disease and toward a proactive, personalized, and accessible health strategy nationwide. The POC combines research and application, strengthens health literacy and self-efficacy, and establishes prevention as an integral part of modern society.

#7573 Evaluation of a training intervention for primary care providers to prepare patients for cancer discussions with their oncologists.

Carma Bylund[1], Alyssa Crowe[1], Margo Michaels[2], Domenic Durante[1], Maria Sae-Hau[3], Andrea Cassells[4], Jason Arnold[1], Ana Natale-Pereira[5], Raymond Mailhot Vega[6], Zhongyue Zhang[1], Ji-Hyun Lee[1], Elisa S. Weiss[3]

[1]University of Florida, Gainesville, FL,[2]Health Care Access & Action, Boston, MA,[3]Blood Cancer United, Rye Brook, NY,[4]Clinical Directors Network, New York, NY,[5]Rutgers New Jersey Medical School, Newark, NJ,[6]University of Florida, Jacksonville, FL

We examined the impact of an online training intervention, “Preparing Patients for Cancer Treatment Discussions,” on primary care providers’ knowledge, attitudes/beliefs, and communication/referral behavior.

We partnered with Clinical Directors Network (CDN), Florida Academy of Family Physicians, and U.S. Residency Program Directors to recruit primary care providers (MDs, DOs, NPs, and PAs), Family Medicine residents, Internal Medicine residents and Geriatric fellows. The 1-hour, asynchronous online training was hosted by three faculty members: a primary care provider, radiation oncologist, and cancer clinical trials expert. Participants engaged in simulated patient and clinical scenarios to practice communication about oncology referrals and cancer clinical trials. Pre- and post-training surveys measured knowledge, attitudes, beliefs, and willingness to discuss trials. Further, a 3-month follow-up survey measured the sustained impact of the training on communication behavior about clinical trial referrals.

135 primary care providers (91 residents, 44 practicing clinicians) participated in the training intervention (84% retention at 3-month follow-up). Knowledge improved from a mean of 51.8% to 82.4% correct (p<.001) immediately after training and was sustained with a mean score of 77.7% correct (p<.001) at 3-month follow-up. Mean belief scores concerning the primary care provider's role in assisting patients with decisions about clinical trials increased from 4.1 to 4.6 (1-5 scale; p<.001) immediately following training. This improvement was sustained at a score of 4.5 (p<.001) during the 3-month follow-up. Additionally, mean scores for the willingness to communicate about clinical trials increased from 4.3 to 4.6 (1-5 scale; p<.001) immediately after training. This improvement was sustained at a score 4.5 (p<.001) during the 3-month follow-up. Behavior measures increased significantly at 3-month follow-up. Providers were asked the percentage of patients they educated about receiving treatment with a cancer clinical trial and encouraged to inquire about receiving treatment from a cancer clinical trial prior to making a referral. Education (15.1% to 52.9%) and inquiry encouragement (17.6% to 62.4%) both increased (p<0.001). Providers were asked the same questions regarding patients that returned after their oncology visit to discuss treatment options. Education (13.9% to 49.5%) and inquiry encouragement (20.7% to 47.8%) both increased significantly (p<0.001).

Significant improvements in knowledge, attitudes, beliefs, communication and referral behavior demonstrate the online course was effective. Future plans for dissemination and sustainability include integrating the online course into curricula for medical and nursing education.

#7574 A single arm clinical trial evaluating the impact of patient education on cancer clinical trials knowledge and beliefs.

Diana Laura Morales, Trista A. Beard, Chanita Hughes Halbert

Population and Public Health Sciences, Keck School of Medicine of USC, Los Angeles, CA

Background: Racial and ethnic minorities remain underrepresented in cancer clinical trials (CCTs), limiting the generalizability of findings and equitable access to new therapies. Barriers include limited trial access in diverse communities, low referral rates among medically underserved groups, and lack of awareness or understanding of CCTs. Educational interventions may help address these gaps by improving knowledge and engagement among disparity populations.

Objective: Evaluate patient knowledge and beliefs of CCTs after an education intervention at an NCI-designated cancer center.

Methods: Patients being treated for any type of cancer were invited (by mailer and posted pamphlets) to participate in a Clinical Trial Social Determinants Survey to characterize their social determinants of health and preferences for clinical trials education. A secondary validated instrument (CHEKS) evaluated patients' knowledge and beliefs about CCTs, before and after exposure to educational stimuli (written and video) detailing the purpose and characteristics of CCTs.

Results: A total of 51 cancer patients observed the educational stimuli and completed pre and post surveys. The mean score for positive '*knowledge and beliefs*' (out of 100) increased from 86.1 pre-intervention to 90.9 post-intervention. The sample was 60.8% female and 39.2% male. One third (33%) reported prior enrollment in a CCT; 47.1% reported annual household income <$75K and 51% reported >$75K; 78% reported education as some college or beyond and 21.6% reported a high school degree or lower; and 62% reported being in a domestic partnership and 37.3% were single. Because 65% of patients were White, and other groups were represented in small numbers, no results by race/ethnicity are reported. For every subgroup (male/female, education low/high, income low/high, previous CT yes/no, coupled yes/no), the educational intervention showed a positive effect, meaning the knowledge score increased post stimuli. Males' knowledge (mean) score increased +5.75 points, while females increased +4.2; married or coupled patients' score increased significantly (+6.59) while single persons had the lowest increase of all subgroups (+1.79). The highest increase in knowledge scores was the high-income group (+6.8), and the low-income group increase was +2.83; high school graduate or less increased +4.09, some college and beyond increased +5; for those who have previously enrolled in a clinical trial the score increased +4.59, and those with no clinical trial experience increased +4.91.

Conclusions: Specific and high quality CCT educational material that explains the purpose and phases of CCTs, the need for diverse populations, safety protocols, costs, and patient rights can impact patients' views and understanding of CCTs. By reducing the knowledge barrier, we hope to improve enrollment of underrepresented groups in CCTs.

#7575 Characterizing radiation oncologist work patterns with a time-motion study.

Sophie C. Chang, Kenya Ochoa, Maryum Haidari, Van Nguyen, Johan Carrascoza-Bolanos, Phillip Schofield, Melody K. Schiaffino

UC San Diego School of Medicine, La Jolla, CA

Oncologists face increased demands in their workload from growing administrative and technology-related burdens such as charting and responding to messages. In radiation oncology, where care involves multiple multidisciplinary care touchpoints, these tasks can detract from patient-facing time needed for essential assessments of increasingly complex patients. Pressure to multitask will likely increase without effective workflow optimization. While previous literature has explored system- or process-level workflows in radiation oncology, we sought to characterize physician work patterns in an ambulatory setting to support improved workflow management and patient care. We used an observational time-motion study design to characterize the work patterns of seven attending radiation oncologists and two PGY5 residents at a large urban academic medical center. Each physician was observed for at least nine hours by a trained observer across two to three shifts for a total of 90 hours of observation. Observers recorded the number and type of activities performed within each five-minute interval. Intervals with more than one recorded activity were considered instances of multitasking. To estimate the total amount of time spent performing each activity, we divided the duration of each five-minute interval equally among its recorded activities. Patient visit duration was calculated as the length of an uninterrupted block of patient-facing time. On average, radiation oncologists spent 37.4 ± 9.5% of their time directly interfacing with patients, 39.9 ± 7.4% on patient-adjacent tasks, 10.6 ± 7.9% on administrative work, 2.6 ± 2.2% on personal time, and 9.5 ± 5.4% on tasks categorized as research/other. Patient-adjacent tasks included computer-based work such as charting and responding to messages (18.5 ± 5.1%), interacting with clinical staff (11.3 ± 4.7%), making consults (8.0 ± 6.9%), and interfacing with medical physicists (1.6 ± 2.1%). Physicians multitasked in 53.7% of five-minute intervals. Patient-adjacent tasks contributed to 85.9% of instances of multitasking. Durations of 121 patient visits ranged from 5 to 65 minutes (median 15 minutes). Visits with at least one family member present (n=53) were significantly longer than visits without (n=68) (median 20 vs 10 minutes, $p < 0.01$, Mann-Whitney U). This preliminary time-motion study reveals a significant burden of patient-adjacent tasks in radiation oncologist workflow. Physicians spent more time on these tasks than on direct patient interactions on average and multitasked in more than half of the observed time intervals. Longer patient visit durations in the presence of family underscore the need to optimize patient-adjacent workload to support complex visits, improve efficiency, and reduce physician burden.

#7576 Evaluating a community-focused approach to increase representation of understudied populations in clinical studies.

Kimlin Ashing[1], Virginia Savage[1], Diana Tam[1], Gaole Song[1], Brenda Gascon[1], Alyssa Cardenas[2], Sophia Yeung[1]

[1]City of Hope National Medical Center, Duarte, CA,[2]TGen, Phoenix, AZ

Background: Our Community Scientist Advocate (CSA) program aimed to address the critical underrepresentation of ethnic minority populations in cancer-focused clinical trials by preparing health leaders to promote clinical research engagement in their communities. We developed and implemented an evidence-based training curriculum with six modules that discussed the role and benefit of clinical studies, research ethics, barriers to participation, social drivers of health, cancer care, and research engagement promotion strategies.

Methods: CSAs are community health leaders and educators recruited via community health services or advocacy organizations. We delivered modules through Zoom and Teams with six CSA cohorts serving diverse communities in California. CSAs were encouraged to conduct community science and clinical study dissemination and log their activities. We assessed CSA preparedness to promote clinical research engagement through analysis of 12 items gathered in pre- and post-surveys. We evaluated the scope and reach of participants' community outreach activities, as well as barriers to study participation, through analysis of activity tracking forms and surveys.

Results: A total of 103 participants, 83% female and 14% male, completed pre- and post-program surveys (n=103). Participants represented diverse communities, with 50% self-identifying as Latinx, 37% as Asian, 12% as African American/Black, and 2% as Pacific Islander. The mean score of participant preparedness increased from 24.7 at baseline to 31.3 post-intervention. 72 community outreach activities were reported through tracking forms and were estimated to serve more than 1662 community members. Activities consisted of 40 informal health research education and 32 formal health research education events such as community presentations, health fairs, etc. Participants noted that ongoing barriers to clinical study participation include concerns about research or health system trustworthiness; concerns about privacy or data use; language barriers; lack of information tailored to communities, cost barriers, lack of doctor referral, and embarrassment/cultural stigma.

Conclusions: The CSA program offered an impactful approach to increase representation in clinical research through advocacy development. Further efforts are needed to continue building trust between clinical researchers and underrepresented communities, develop close partnerships between multisectoral stakeholders, and address structural barriers to research participation.

#7577 Advancing the science, practice and impact of COE.

Kimlin Ashing[1], CHARNITA ZEIGLER-JOHNSON[2], Hayley S. Thompson[3], Kim Rhoads[4], Nadine Barrett[5], Lisa Carter Bawa[6], Timiya S. Nolan[7], Monica Baskin[8], Vanessa B. Sheppard[9], Marvella E. Ford[10], Erica Phillips[11], Lorna H. McNeill[12], Folakemi T. Odedina[13]

[1]City of Hope National Medical Center, Duarte, CA,[2]Fox Chase Cancer Center, Philadelphia, PA,[3]Wayne State University School of Medicine, Huntington Woods, MI,[4]University of San Francisco, San Francisco, CA,[5]Wake Forest University, Winston-Salem, NC,[6]Georgetown University, Washington DC, WA,[7]University of Alabama at Birmingham, Birmingham, AL,[8]UPMC Hillman Cancer Center, Pittsburgh, PA,[9]Virginia Commonwealth University, Richmond, VA,[10]Associate Director of Cancer Disparities, Medical University of SC Hollings Cancer Center, Charleston, SC,[11]Division of General Internal Medicine, Weill Cornell Medicine, New York, NY,[12]UT MD Anderson Cancer Center, Houston, TX,[13]Mayo Clinic Florida, Jacksonville, FL

Introduction: COE has become the gold standard in addressing health disparities. COE's value is emphasized by NIH and leading cancer-related organizations e.g., AACR. The Alliance for COE (The Alliance) mission is to advance the art, science, and impact of COE; promote community health and wellness; and reduce cancer burden and disparities. Methods: This abstract builds on the Alliance's Science of Community Outreach and Engagement (SoCOE) Conference a NCI R13 funded series. SoCOE Conference is organized by 10 NCI-designated Cancer Centers to provide a platform for COE academic-clinical-policy-community stakeholders to share best practices for solution-focused community responsive cancer prevention, diagnostics, therapeutics and survivorship research and practice. Results: > 500 researchers, clinicians, policymakers, healthcare administrators, with >12% being survivors and/or advocates, participated in our SoCOE Conferences. The delegates' recommendations are:

Decentralize who/entities that hold all the power in science and clinical research (trials). Communities hold valuable, necessary wisdom and resources to inform and guide science

Include multisectoral partners early and always

Community capacity building and compensation with gratitude

Mentoring of junior COE researchers, clinicians, policymakers, healthcare administrators, survivors and advocates with humility is a must

Develop virtual communities to share best practices across cancer centers and within regions

Develop working groups to identify and explore commonalities across COE work in rural/urban, diverse/homogenous spaces

Publish Science of COE papers on various topics related to COE Frameworks and evidenced-solutions

Provide community reports on best practice guide that can be widely available to be shared locally and in-person, and digitally

Partner and learn from COE teams working with other cultural/ethnic groups

Attend to, measure and remedy societal/social drivers of health disparities that mirror barriers to care, and research engagement and participation.

Discussion: Informed by our community advisory boards and the findings for our SoCOE Conferences, we present the pillars of the Alliance to tackle population cancer burden and disparities: Training future COE leaders/advocates, Advocating for public health policies/guidelines, Increasing access to cancer prevention and care that will also increase access to studies, Engaging and partnering with multisectoral stakeholders and communities, Building community capacity, Advancing COE science through catchment-relevant research, and Leading bi-directional communication and information and resource sharing between catchment area communities and cancer centers. The expectation and impact of COE can only be achieved if COE teams are valued, supported cancer center members with community advisory boards and community as cancer centers' priority population.

: Risk Prediction Modeling, Screening, Early Detection, and Preneoplastic and Tumor Markers
Poster Session

#7581 Loss of the duffy antigen receptor for chemokines (DARC/ACKR1) expression in ductal carcinoma in situ is associated with immune dysregulation and progression to invasive ductal carcinoma.

Dana Franklin[1], Ni-Chun Tsai[2], Hyejin Cho[3], Yate-Ching Yuan[2], Yuqi Zhao[3], Padmashree Rida[4], Nikita Jinna[1]

[1]Population Sciences, City of Hope Comprehensive Cancer Ctr., Duarte, CA,[2]Computational and Quantitative Medicine, City of Hope Comprehensive Cancer Ctr., Duarte, CA,[3]Integrative Genomics, City of Hope Comprehensive Cancer Ctr., Duarte, CA,[4]Science, Rowland Halll, Salt Lake City, UT

Ductal carcinoma in situ (DCIS) is a non-invasive precursor of breast cancer, characterized by malignant epithelial proliferation confined within the ducts. DCIS accounts for 20-25% of all breast cancer cases. Majority of DCIS lesions are treated with highly invasive surgeries and cytotoxic radiotherapy. Left untreated, 25-60% of DCIS lesions progress to invasive ductal carcinoma (IDC). Discerning which DCIS lesions will progress to IDC, to circumvent over- or under- treatment, remains a major clinical challenge. Accumulating evidence suggests that immune dysregulation within the tumor microenvironment (TME) plays a pivotal role in DCIS progression. Altered immune composition—reduced antigen presentation, T cell activation, and immune surveillance—can create a permissive environment that supports tumor growth and invasion. The Duffy Antigen Receptor for Chemokines (DARC/ACKR1), a decoy chemokine receptor expressed on erythrocytes, binds and sequesters pro-inflammatory chemokines for lysosomal degradation to maintain tissue immune homeostasis. Thus, ACKR1 regulates TME immune cell infiltration and the immune response. Loss of ACKR1 expression may disrupt chemokine gradients and impair immune cell recruitment to the TME, contributing to tumor immune evasion and progression. We hypothesize that ACKR1 influences DCIS progression by modulating immune cell composition and activation within the breast TME. We analyzed the influence of ACKR1 on the tumor immune response and DCIS TME in RNA-seq data derived from breast cancer patients in multiple independent publicly-available gene-expression datasets (GEO, Oncohuman, METABRIC) via the OmicSoft platform. We observed significant downregulation of ACKR1 expression from DCIS to IDC lesions in both the Oncohuman and METABRIC datasets, and this loss correlated with loss of E-cadherin expression in DCIS lesions. GEO analysis uncovered significant differences in a chemokine signaling network and cytokine expression profiles between ACKR1-low and ACKR1-high DCIS cases. CIBERSORT immune cell deconvolution revealed that relative to ACKR1-high lesions, ACKR1-low lesions exhibit significantly reduced proportions of naïve B cells, activated dendritic cells, $CD4^+$ memory-activated T cells, and T follicular helper cells in DCIS. Our findings support the role of ACKR1 in shaping immune signaling within the DCIS TME by demonstrating distinct immune response profiles based on ACKR1 status. Our work suggests that loss of ACKR1 expression in DCIS supports an “immune-cold” TME, further highlighting its role as a suppressor of tumor invasion and potential biomarker of disease progression. Thus, ACKR1 may improve clinical decision making and DCIS patient management by providing insight into patient immune response profiles and predisposition for progression.

#7584 Tumor microRNA expressions associated with prostate cancer aggressiveness across independent cohorts.

Huiyi Lin[1], Jong Y. Park[2], Masuma Mannan[1]

[1]Lousiana State Univ. Health Ctr., New Orleans, LA,[2]Moffitt Cancer Center, Tampa, FL

Introduction: Tumor microRNAs (miRNAs) play a critical role in prostate cancer (PCa) biology and may serve as biomarkers for disease aggressiveness. However, robust identification and validation of tumor miRNA expressions across independent datasets remain challenging. This study aimed to discover and validate miRNAs associated with PCa aggressiveness using three independent cohorts.
Methods: We analyzed tumor miRNA expression profiles from three datasets: our cohort (discovery set, 268 Whites), TCGA-PRAD (406 Whites), and GSE135535 (GSE, 320 men). In our cohort, we identified the top 25 miRNAs significantly associated with PCa aggressiveness ($p < 0.01$) using univariate logistic models. Using these 25 miRNAs, stepwise selection was performed in the 1,000 bootstrap samples based on our cohort. Among the 9 miRNAs selected in >20% of 1000 bootstrap runs, many miRNA expressions are highly correlated. Therefore, we further performed stepwise selection to identify the most informative miRNAs associated with PCa aggressiveness. Then, the selected miRNAs were tested in the other two validation sets.
Results: Two tumor miRNA expressions were significantly associated with PCa aggressiveness in our cohort (hsa-miR-145-5p, $p<0.001$, and hsa-miR-182-5p, $p = 0.001$, AUC=0.74). In the GSE135535 cohort, the p-values were 0.003 and 0.099 for hsa-miR-145-5p and hsa-miR-182-5p, respectively (AUC=0.621). In the TCGA set, the p-values were 0.024 and 0.059 for hsa-miR-145-5p and hsa-miR-182-5p, respectively (AUC=0.591). Thus, these two miRNAs represent distinct biological clusters, suggesting complementary roles in PCa aggressiveness.
Conclusion: Our multi-cohort analysis identified and validated two miRNAs associated with PCa aggressiveness. Other previous studies have supported the biological function of these two miRNAs. It has been shown that hsa-miR-145-5p significantly inhibits PCa cell growth and metastasis by negatively regulating metadherin (MTDH) expression and acts as a tumor suppressor. hsa-miR-182-5p acts as an oncogenic miRNA to contribute to poor prognosis for PCa patients. Up-regulation of miR-182 is significantly associated with PCa risk, progression, and treatment response. Functional enrichment analysis in previous studies revealed a significant association between miR-182 and its target genes, MITF (melanocyte inducing transcription factor) with epithelial-to-mesenchymal transition (EMT). Our findings support their potential utility as prognostic biomarkers and warrant further functional studies to elucidate underlying biological mechanisms.

#7585 Fatty liver index and AST/ALT ratio for hepatocellular carcinoma prediction in low-risk Korean men: Results from the HEXA-G cohort.

So Yoon Lee[1], Hyobin Lee[1], Sukhong Min[1], Sinyoung Cho[2], Jeongheon Kim[1], Ji-Yeob Choi[3], Daehee Kang[4]

[1]Seoul National University, Seoul, Korea, Republic of,[2]Seoul National University Hospital, Seoul, Korea, Republic of,[3]Assistant Professor, Seoul National Univ. College of Medicine, Seoul, Korea, Republic of,[4]Dean, Professor, Dept. of Molecular Medicine And Biopharmaceutical Sciences, Seoul National University, Seoul, Korea, Republic of

Background: The prognostic utility of the fatty liver index (FLI, a steatosis index derived from BMI, waist circumference, triglycerides, and GGT) and AST/ALT (De Ritis) ratio for hepatocellular carcinoma (HCC) risk in low-risk Asian populations is not well defined. We evaluated their independent and incremental predictive value in a large Korean cohort.
Methods: We analyzed 43,981 Korean men (376 HCC cases) from the Health Examinees-Gem (HEXA-G) cohort (2004-2013). A low-risk subcohort (n = 39,033) was defined by excluding individuals with diabetes or chronic hepatitis. Multivariable Cox models assessed associations with log-transformed FLI and the AST/ALT ratio after adjusting for demographic, lifestyle, socioeconomic, and metabolic factors. Incremental predictive value was evaluated using likelihood ratio tests (LRTs), changes in C-statistics, and Bayesian Information Criterion (BIC). Sensitivity analyses using penalized regression produced similar results.
Results: In univariable analyses, the AST/ALT ratio showed crude associations with HCC, whereas FLI did not. After adjustment, this pattern reversed: the AST/ALT ratio became non-predictive—consistent with confounding by age, alcohol consumption, smoking, and metabolic factors—while log(FLI) emerged as a modest independent predictor in the low-risk subcohort (adjusted HR 1.08; 95% CI, 1.01-1.16; p = 0.04). Discrimination improved minimally (C-statistic 0.715 to 0.719), and conventional FLI categories failed to stratify risk. In the full cohort, log(FLI) remained independently associated with HCC (adjusted HR 1.11; 95% CI, 1.03-1.20; p = 0.009) and modestly improved model fit (LRT p = 0.011) without meaningfully improving discrimination (C-statistic 0.795 to 0.797). The De Ritis ratio added no independent or incremental value in any model.
Conclusions: Across low-risk and mixed-risk Korean men, FLI remained an independent predictor of HCC after adjustment, although the effect size was modest. In contrast, the AST/ALT ratio lost all prognostic value after accounting for demographic, lifestyle, and metabolic confounding. The reversal of crude versus adjusted associations underscores substantial confounding for AST/ALT and a small, metabolically related signal for FLI. Overall, these findings highlight that FLI provides some independent information in low-risk settings, but substantial improvement in HCC risk prediction will require more robust biomarkers.

#7586 The impact of COVID-19 on sexual minority women seeking breast cancer screenings and treatment: An analysis of the OUT national cancer survey data.

Kristi Tredway[1], Melissa S. Camp[2], Vered Stearns[3]

[1]Cancer Population Science, OHSU Knight Cancer Institute, Portland, OR,[2]Sidney Kimmel Comprehensive Cancer Center, Johns Hopkins University, Baltimore, MD,[3]Oncology, Weill Cornell Medicine, New York, NY

Breast cancer is the most frequently diagnosed female cancer in the U.S. and now globally. Early detection of breast cancer through screening is well established to reduce mortality. Despite the substantial benefits, sexual minority women (e.g., lesbians and bisexual women) are significantly less likely to access breast cancer screenings, have lower lifetime prevalence of screening mammography, and undergo less timely screening as compared to sexual majority women (i.e., heterosexual women). Some reasons for the low utilization of screenings include negative beliefs about care, lower perceived severity, lack of health insurance, costs of care, and perceptions of heterosexism and homophobia among providers. Hesitancy in breast cancer screenings for sexual minority women is compounded by culturally-specific risk factors that place many sexual minority women at higher risk for breast cancer. Risk factors identified as those sexual minority women are more subject to include: tobacco use and smoking, higher alcohol consumption, drug use, obesity, low levels of physical activity, less likely to undergo routine preventive screenings, less likely to have insurance coverage, less satisfaction with medical interactions, higher rates of psychological distress (likely due to the fear of homophobia and bias), and nulliparity or not bearing offspring. Hesitancy and delays were increased during the COVID-19 era even with the temporary transition to telehealth (online, virtual) appointments with healthcare practioners. Using data from the National LGBT Cancer Network's OUT National Cancer Survey, this study analyzes the experiences of sexual minority women who faced breast cancer diagnoses. This dataset is the first large, nationwide sample to target LGBTQ+ populations regarding their cancer diagnoses. Survey items included demographics, behavioral questions about cancer treatment and social support, and structural and psychosocial barriers to or facilitators of seeking care. A total of 2,700 respondents completed the National LGBT Cancer Network survey. Of those 2,700 respondents, 503 had had breast cancer diagnoses. The sample for this study included the 490 females (since birth), 359 were lesbian or gay and 62 were bisexual, of those 503 respondents. Findings highlight experiences with social isolation, levels of optimism versus pessimism, whether doctors or medical clinics delayed cancer screenings, experiences and satisfaction with telemedicine, and other impacts of COVID-19.

#7587 Cervical cancer screening and prevention among Latinas in the U.S. among a network of community health centers.

Selena Rushton[1], Tahlia Hodes[2], Jennifer A. Lucas[2], John Heintzman[2], Cirila Estela Vasquez Guzman[3]

[1]ASHA-American Sexual Health Association, Lacey, WA,[2]OHSU, Portland, OR,[3]OHSU Knight Cancer Institute, Portland, OR

Introduction: Timely cervical cancer screenings are critical for middle to older aged Latinas, who have high morbidity and mortality from cervical cancer, but we currently know less about screening in this population. Efforts to engage middle to older-age Latina immigrants need to be tailored to recognize their distinct experiences with coming to the US that may set them apart from other groups. Latinas tend to receive disproportionate care in Community Health Centers (CHCs) and CHCs are a vital component for cancer screening and prevention. This study leverages a national network of CHCs to assess disparities in and utilization of cervical cancer screening among middle to older age Latinas.
Methods: Retrospective analysis of electronic health record data from a multistate network of CHCs across the United States. Data were extracted on Latina and non-Hispanic White (NHW) women age >45 with known birth country and at least one in-person primary care visit in a CHC between January 1, 2014, and September 14, 2022, across 527 community-based primary care clinics in 15 states. To examine the receipt of at least one Pap Smear and/or Human papilloma Varus (HPV) test ever during the study period, generalized estimating equations (GEE) logistic regression were conducted, overall and disaggregated by country of origin.
Results: Among 34,135 patients, we found that all Latina groups aside from US born Latinas and those from other countries with sample sizes too small to analyze individually had higher odds of receiving either an HPV or Pap test compared to non-Hispanic Whites. When disaggregated by country of origin, all Latina groups born in Central America have higher odds than non-Hispanic Whites. All three of the models showed that Latinas had higher odds of receiving either an HPV or Pap test at least once during the study period compared to non-Hispanic White patients.
Conclusion: CHCs may have unique strengths to address diverse and underserved populations such as Latinas; however, rates remain less than optimal, and work is still needed

#7588 Addressing the immigrant screening gap: A systematic review on interventions to increase colorectal cancer screening among immigrants in the United States.

Taylor McCready[1], Ethan Cohen[2], Delaney Gordon[3], Perla Chebli[4], Peter S. Liang[4], Audrey Renson[1]

[1]Department of Population Health, NYU Grossman School of Medicine, New York, NY,[2]Allegheny Health Network, Pittsburgh, PA,[3]Bucknell University, Lewisburg, PA,[4]NYU Langone Health, New York, NY

Introduction Colorectal cancer (CRC) screening rates are lower among immigrants in the United States (US) than the general population. Immigrant communities face structural barriers that disincentivize engagement in CRC screening. A growing body of literature has evaluated the effects of interventions aimed at increasing CRC screening engagement among immigrants, but findings have not been systematically synthesized. We systematically evaluated quantitative studies of interventions to increase CRC screening among immigrants in the US.

Methods We searched English-language peer-reviewed and grey literature on interventions to improve CRC screening rates among immigrants, published between January 1, 2000 and April 30, 2025 in seven databases: PubMed, Cochrane Library, CINAHL (EBSCO), ClinicalTrials.gov, Embase, Scopus, and Web of Science and imported into Covidence. Two reviewers independently screened records and extracted data. Risk of bias was assessed using the Cochrane Risk of Bias 2 (ROB2) tool for randomized controlled trials, and the Risk of Bias in Non-Randomized Studies of Interventions (ROBINS-I) tool for other study designs. Quantitative synthesis was restricted to studies that explicitly defined immigrants in their population. The protocol was registered in PROSPERO (CRD42023488183) and published in PLOS One.

Results The primary outcome was CRC screening completion. Of 1,824 unique records screened, 45 studies were included (39 randomized trials, 6 non-randomized studies), representing over 21,000 participants. Individualized education (n=12), navigation-based interventions (n=17; including patient navigation alone and navigation plus culturally targeted materials), and non-individualized educational campaigns (n=7) were the most evaluated strategies, alongside mailed outreach with fecal tests and telephone reminders (n=4). Across trials reporting screening outcomes for both intervention and control arms (n=19), interventions increased screening by an average of 20% compared with control, with culturally tailored navigation-based approaches generally yielding the largest gains. Substantial heterogeneity in immigrant group definitions, settings, and outcome measures, coupled with limited and inconsistently collected immigration-related variables, constrained cross-population comparisons and precluded a formal meta-analysis.

Conclusions Culturally and linguistically tailored patient navigation emerged as the most effective approach. Limited and inconsistently collected immigration-related information and heterogeneity across immigrant groups restricted inference but the findings still offer concrete guidance for practitioners and policymakers developing tailored programs and policies to improve CRC screening uptake among immigrant populations in the US.

#7589 On the road to early detection: A survey of barriers and facilitators to community participation in mobile lung cancer screening.

Cherell Cottrell-Daniels[1], Najy Sadig[2], Sofia Haddan[2], Sashanna Roman[2], Vani N. Simmons[2], **Matthew B. Schabath**[2]

[1]Health Choice Network, Miami, FL,[2]Moffitt Cancer Center, Tampa, FL

Introduction: Mobile screening units (MSUs) are an innovative strategy to mitigate barriers to community access to cancer screening modalities. A pivotal step in implementing an MSU is identifying potential barriers that may impact community utilization. Therefore, the goal of this study was to conduct a community-wide cross-sectional survey to assess barriers and facilitators to mobile lung cancer screening using validated survey measures.

Methods: Patient eligibility included have undergone any cancer screening at Moffitt Cancer Center (MCC) between Jan 1, 2023 and Dec 1, 2024, or patients who visited MCC during the same time and met current lung cancer screening guidelines. The web-based survey was administered from May 2025 to June 2025 and included items derived from validated measures, existing literature, and questions developed by the study team. The survey collected data on health behaviors, barriers, facilitators, screening preferences, and demographics. Participants were offered a $10 Amazon gift card upon survey completion. Descriptive statistics and exploratory stratified analyses were used to quantify survey responses.

Results: Among the 218 participants who completed the survey, 33% reported a prior clinician discussion about lung cancer screening. Most participants (73.4%) reported no concerns about getting screened in a mobile screening unit, but 67.9% reported concerned about the cost or if insurance covered mobile lung cancer screening, and 84.4% reported they would be screened if a voucher or insurance would pay for it. Regarding preferences, 54.1% reported no preference for the time of year for a mobile screening event, 59.6% reported they will be willing to wait up to 30 minutes to get screened, 44% would travel more than 20 minutes to get screened, and 44% preferred only Monday-Friday 9 am to 5 pm to get screened in a mobile unit. There were only few statistically significant differences found in stratified analyses by smoking status (ever vs. never), race/ethnicity (non-Hispanic Whites vs. all other groups), age (<67 vs. ≥67), and veteran status (former/active vs. no).

Conclusions: In this community-wide survey study, mobile lung cancer screening was broadly acceptable. Actionable preferences included: daytime weekday events, indoor waiting, short waits, proximity to home, clear cost coverage, and streamlined clinician recommendation. Implementation strategies that focus on provider prompts/referrals, financial transparency (vouchers/coverage), and hybrid workflows (vouchers/coverage) may enhance uptake.

#7590 Calibration of the US breast cancer risk assessment tool in 114,533 Mexican women: Evidence from the Mexican Teachers' Cohort.

Liliana Gomez-Flores-Ramos[1], Mario Arturo Aguilar[2], Dalia Stern[1], Adrian Cortes-Valencia[2], Marion Brochier[2], Ariadna Gutierrez[2], Gabriela Torres-Mejia[2], Salvador Zamora[3], Pabel Miranda-Aguirre[4], Patricia Perez-Escobedo[5], Alejandro Mohar[6], Ruth Pfeiffer[7], Martin Lajous[8]

[1]Secihti, National Institute of Public Health of Mexico, Mexico City, Mexico,[2]National Institute of Public Health of Mexico, Mexico City, Mexico,[3]UNAM, Mexico City, Mexico,[4]ISSSTE, Mexico City, Mexico,[5]Direccion medica, ISSSTE, Mexico City, Mexico,[6]Instituto de Investigaciones Biomedicas, UNAM, Mexico City, Mexico,[7]National Cancer Institute, NIH, Bethesda, MD,[8]National Institute of Public Health, Harvard T.H. Chan School of Public Health,, Bethesda, MD

Background: Breast cancer risk prediction models are increasingly used to identify women for risk-based screening and chemoprevention. The US Breast Cancer Risk Assessment Tool (NCI-BCRAT/Gail) is a widely used model, yet its performance in Mexican women is unknown. The Mexican Teachers' Cohort (MTC), a prospective cancer cohort in Mexico, is a unique resource that can be leveraged to assess the usefulness of breast cancer risk models in this understudied population. Thus, we evaluated calibration and discrimination of this model in a large, diverse cohort of Mexican women.

Methods: Absolute invasive breast cancer risk was calculated from enrollment to December 31, 2019, in 114,533 cancer-free women aged 25-80 years. Missing model predictors were assigned to the lowest-risk category. We compared expected and observed cases overall and by 5-year age groups and Indigenous ethnicity using expected-to-observed (E/O) ratios with 95% confidence intervals (95% CI). Discrimination was assessed with the area under the ROC curve (AUC). We quantified the proportion of women with a predicted risk above the 5-year high-risk threshold among those who developed and those who did not develop breast cancer.

Results: Over a mean follow-up period of 11.2 years, we identified 1,490 women with invasive breast cancer among cohort participants. The NCI-BCRAT/Gail model predicted that 2,115 women would develop breast cancer, leading to an expected-to-observed (E/O) ratio of 1.40 (95% CI 1.35-1.49). Overestimation was most pronounced in the 50-54 age group (E/O = 1.62; 95% CI 1.41-1.87). Among Indigenous women, 79 developed breast cancer compared to 135 women who were predicted to develop the disease (E/O = 1.71;95% CI 1.35-1.49), and for age 50-54 E/O ratio was 2.71 (95% CI 1.29-5.86). The model's discriminatory accuracy was 63% (95% CI, 62%-65%). Yet, 82% of women who developed breast cancer did not reach the 5-year high-risk threshold. Also, 7% of non-cases had a predicted risk above the 5-year high-risk threshold. Further, results using different breast cancer incidence estimates for Mexico and 5-year high-risk thresholds will also be presented.

Conclusions. The NCI-BCRAT/Gail model overestimated invasive breast cancer risk in Mexican women from the MTC. Overestimation was particularly salient in older women and Indigenous women. Using this model "as is", most women who developed breast cancer would have been classified as average risk. These findings suggest that the NCI-BCRAT/Gail should be recalibrated and validated before clinical use in this population.

#7591 Identification of a multi-protein signature to predict 5-year stomach cancer risk using high-throughput proteomics and machine learning.

Jessica Chadwick[1], Clare Paterson[1], Sama Shrestha[1], Hannah Biegel[1], Jessica Kuzma[2], Stephen Williams[2], In collaboration with the EPIC - Proteomic investigators

[1]Illumina, San Diego, CA,[2]SomaLogic, Boulder, CO

Introduction: Stomach cancer is the fifth most common cancer worldwide, and the fourth leading cause of cancer death, with an average 5-year relative survival rate of only 20%-30%. This low survival rate is largely due to late diagnosis, which often occurs after the cancer has spread and is more difficult to treat. There is currently no guidance from the US Preventive Services Task Force around screening for stomach cancer or *Helicobacter pylori* (*H pylori*) infection, a primary risk factor for stomach cancer. This study investigated whether high-throughput proteomics could be used to develop a stomach cancer susceptibility model that may help stratify individual risk and direct screening procedures.

Methods: Samples from the European Prospective Investigation into Cancer and Nutrition study were assayed using modified-aptamer proteomics technology (SomaScan™ 7K assay). Following data QC, 14,787 citrate plasma samples had clinical and proteomic data (totaling ~103 million protein measurements), which included n=56 and n=219 stomach cancer diagnosis within 5 years and over 20-year follow-up period, respectively. Machine learning techniques were used to identify a model that predicts risk of stomach cancer diagnosis within 5 years of blood draw using an 80% training split of the data. Discrimination was assessed via C-index and 5-year AUC. A post-hoc subset analysis was performed in individuals with H pylori infection status (n=286).

Results: An abundance of proteomic signal was detected with 922 proteins significantly associated with incident stomach cancer at FDR <0.1. An 8-protein accelerated failure time model was identified that accurately predicted stomach cancer risk with a 5-year AUC of 0.742 and C-Index of 0.697 in the hold-out validation dataset. Performance of the protein model was higher than the average performance of the Polygenic Risk Score-based models used to predict lifetime stomach cancer risk. The model included proteins known to be up or downregulated in stomach cancer (75%), although only a subset of these proteins (37.5%) are predictive of stomach cancer risk, and novel proteins (25%). In the subset of individuals positive for H pylori infection (n=214), the stomach cancer risk model had a 5-year AUC = 0.698 and C-Index of 0.599 suggesting the model can still accurately predict risk in individuals with H pylori infection.

Conclusions: We successfully developed a multi-protein model to predict 5-year risk of stomach cancer in individuals with and without H pylori infection, highlighting the potential utility of high-throughput proteomics as a novel screening tool for assessing cancer risk.

#7592 Machine learning enables accurate prediction of patient outcomes for immune checkpoint blockade using real-world clinical data.

Alyssa Pybus[1], Isis Yanina Narvaez-Bandera[2], Tosin Jolaogun[1], PAULO CILAS MORAIS LYRA JR[2], Khai Dang[2], Jeremy Goecks[2]

[1]Machine Learning, H. Lee Moffitt Cancer Center, Tampa, FL,[2]H. Lee Moffitt Cancer Center, Tampa, FL

Background: While immune checkpoint blockade (ICB) therapy can produce durable clinical responses and substantially improve patient outcomes, accurate predictors of outcomes are critical as up to half of patients with advanced disease derive limited or no benefit. Accurate ICB outcome prediction will improve treatment stratification, reduce unnecessary toxicity, and enhance outcomes for cancer patients.
Methods: We used state-of-the-art machine learning survival models to accurately predict patient survival after ICB therapy in our large multi-cancer institutional cohort. This retrospective study included 2,090 patients with advanced melanoma (n=908), advanced non-small cell lung cancer (NSCLC, n=878), or metastatic renal cell carcinoma (RCC, n=304) who underwent anti-PD-1/PD-L1 and/or anti-CTLA-4 ICB therapy at Moffitt Cancer Center from 2011-2025. Over 50 pre-treatment clinical and laboratory features were abstracted from electronic health records and analyzed against overall and progression-free survival. We trained and tested survival support vector machine models to predict patient outcomes with a 75/25 random split.
Results: Cox PH analysis identified 11-44 statistically significant features per data set for inclusion into each model, including serum albumin, neutrophil-to-lymphocyte ratio, blood pressure, heart rate, and ECOG scores. Our models achieved AUC values of up to 0.83 in melanoma, 0.80 in NSCLC, and 0.85 in RCC, with enhanced performance in progression models trained on multi-cancer data. Our models outperformed PD-L1 and TMB at each time point where data is available.
Conclusions: Our work demonstrates the promise of machine learning with accessible clinical and laboratory features to predict ICB patient outcomes with improved performance versus current biomarkers.

#7593 Personalized risk assessment of breast cancer using administrative health data.

Fidela Mushashi[1], Shi-ang Qi[2], Parveen Bhatti[3], Andrew Roth[1], Russell Greiner[2], Rachel A. Murphy[4]

[1]University of British Columbia, Vancouver, BC, Canada,[2]University of Alberta, Edmonton, AB, Canada,[3]British Columbia Institute of Cancer Research, Vancouver, BC, Canada,[4]School of Population and Public Health, University of British Columbia, Vancouver, BC, Canada

Breast cancer screening programs are one-size-fits-most approaches with suboptimal participation rates. Population-level administrative health databases provide a unique opportunity to build scalable, data-driven risk assessment tools capable of identifying women who may benefit from more personalized screening strategies. We assembled nearly two decades of longitudinal health data, including mammographic screening history, medication use, physician visits, and hospital discharge abstracts, for 1.74 million women in British Columbia, among whom 39,211 incident breast cancers were diagnosed. Our team is developing new breast cancer risk assessment models to predict each woman's individual time until Breast Cancer Onset (BCo) using administrative health data from Canada's publicly funded healthcare system. We are applying machine learning Individual Survival Distribution (ISD) models, which identify each subject x with a distribution S (t | x), showing the probability that x's time until BCo is at least t more years, for all t > 0. We can then use these models to estimate each woman's expected time until BCo, as well as her risk score. In preliminary models using 25 features with known/suspected links to breast cancer, random survival forest (RSF) achieved the highest concordance index (CI = 58.9%), while multitask logistic regression (MTLR) achieved a competitive 5-year Brier score (BS = 0.0068) and a low mean absolute error (MAE = 30.4 months). These early results demonstrate the feasibility of leveraging administrative health data for personalized breast cancer risk prediction. Ongoing work will substantially expand the feature sets to improve model discrimination.

#7594 Combining electronic health records, environmental, and genomics data for lung cancer risk prediction in Southern California.

Gianni Pucillo[1], Sanye Naqvi[2], Allison Jue[3], Chandler Law[3], Sandip Patel[2], Uduak Z. George[1]

[1]Computational Science Research Center, San Diego State University, San Diego, CA,[2]UC San Diego, San Diego, CA,[3]San Diego State University, San Diego, CA

Background: Lung cancer risk reflects intersecting clinical, environmental, and genomic factors, yet these data types are rarely integrated at the individual level. We assembled an EHR-based cohort in Southern California to build a predictive model of incident lung cancer diagnosis and to characterize the clinical, genomic, and neighborhood features that drive risk.
Methods: We constructed a retrospective cohort of 7,151 adults from UC San Diego Health electronic health records (50.4% female, 65% ≥ 65 years) and linked approximately 40 clinical features to census-tract-level environmental and socioeconomic indicators from CalEnviroScreen, as well as genomic mutation status for ALK and EGFR. We compared 14 classifiers (logistic regression, random forest, XGBoost, and 11 PyTorch neural networks) using stratified five-fold cross-validation to predict lung cancer diagnosis. Hyperparameters for top performing models were optimized using Bayesian search in Optuna. Model performance was summarized using AUROC, accuracy, precision, recall, and F1, and feature importance was assessed using Shapley (SHAP) values.
Results: Optimized XGBoost achieved the best cross-validated discrimination (AUROC 0.879), with accuracy 0.802, precision 0.744, and F1 0.694, outperforming linear and deep-learning baselines. Top-ranked features by SHAP included smoking intensity, cardiometabolic comorbidity, and age, with neighborhood unemployment, pesticide burden, and ozone levels contributing additional, though smaller, predictive signal, reinforcing the contribution of neighborhood disadvantage and pollution to lung cancer vulnerability in this regional cohort. Among genomically profiled patients, ALK-positive cases were diagnosed at a significantly younger age than ALK-wildtype cases (mean 56 vs 71 years, p=0.016), underscoring biologically distinct disease courses.
Conclusion: An integrated gradient-boosting model leveraging EHR, environmental, and genomic data can meaningfully stratify individual lung cancer risk in a diverse regional cohort and elevate both clinical and neighborhood drivers of vulnerability. These findings support the use of routinely collected health and environmental data to guide targeted lung cancer screening and prevention efforts and motivate future work on external validation, time-varying exposures, and explicit fairness constraints across racial and socioeconomic groups.

#7595 Survival outcomes in chemotherapy patients using a multi-institutional risk model. A retrospective analysis.

Aswanth Reddy[1], Arpana Ashok[1], Yang Wang[2], Jay Carlson[2]

[1]Mercy Hospital, Fort Smtih, AR,[2]Mercy Hospital, St. Louis, MO

Background: Patients with cancer who are receiving chemotherapy have a high risk of complications due to the disease and from adverse events due to therapy. The Chen Model, a proprietary risk stratification tool (multivariable analysis) developed by Mercy Health, St. Louis, identifies chemotherapy patients at risk for adverse outcomes. The Chen Model stratifies patients into high risk (score>=90), moderate high risk (80 to 89), and low risk groups (<80). From our multi-institutional analysis, we aim to identify the 6- and 12-month mortality rates among adult chemotherapy patients (non-leukemia, age >18) stratified by the Chen model.
Methods: We conducted a retrospective analysis of 18,854 chemotherapy patients treated between July 2023 and August 2025 at the Mercy Hospital system, which includes multiple hospital sites and oncology practices across three states (Missouri, Arkansas, and Oklahoma). Patients were assigned to cohorts based on their maximum Chen model score during the 7-day post-chemotherapy period. A total of 2139 patients were in the high-risk group, 2449 in moderate high-risk, and 14266 in the low-risk group. Kaplan-Meier estimates and Cox proportional hazards models were used to assess 6- and 12-month mortality, with hazard ratios (HR) and 95% confidence intervals (CI) calculated.
Results: Six-month mortality rates were 39.96% (95% CI: 37.85%-42.14%) for the high-risk group, 22.59% (95% CI: 20.91%-24.40%) for the moderate high-risk group, and 11.65% (95% CI: 11.12%-12.21%) for the low-risk group. Twelve-month mortality rates were 51.63% (95% CI: 49.31%-54.00%), 31.44% (95% CI: 29.36%-33.62%), and 19.54% (95% CI: 18.84%-20.26%), respectively. Cox models showed significantly elevated hazard of death for high-risk (HR=4.4 at 6 months, HR=3.7 at 12 months; $p<0.005$) and moderate high-risk (HR=1.5 at 6 months, HR=1.4 at 12 months; $p<0.005$) groups compared to the low-risk group. Further analysis on composite palliative care and hospice services utilization was identified to be 23.2% in high risk and 15.6% in moderate high-risk groups.
Conclusions: The Chen model effectively stratifies chemotherapy patients by mortality risk, with high-risk patients facing substantially worse outcomes at 6 and 12 months. We also identified a lower palliative care utility in the higher-risk groups. These findings support the model's utility in identifying patients who may benefit from intensified monitoring and early involvement of supportive services, particularly palliative care services. Further studies are needed to validate these results and assess the impact of targeted interventions.

#7596 Risk factors and prediction models for colorectal cancer in older US individuals.

Chen Yuan[1], Qiao-Li Wang[2], Sara K. Char[3], Wenjie Ma[4], Brian M. Wolpin[3], Jeffrey A. Meyerhardt[3], Shuji Ogino[5], Mingyang Song[6], Andrew T. Chan[4], Edward L. Giovannucci[6], Kimmie Ng[3]

[1]Cedars-Sinai Medical Center, Los Angeles, CA,[2]Lund University, Malmo, Sweden,[3]Dana-Farber Cancer Institute, Boston, MA,[4]Massachusetts General Hospital, Boston, MA,[5]Brigham and Women's Hospital, Boston, MA,[6]Harvard T.H. Chan School of Public Health, Boston, MA

Background: Colorectal cancer (CRC) has high incidence and mortality in older adults, yet routine screening after age 75 is generally not recommended and current guidelines are limited. Risk factors for CRC diagnosed after age 75 and the subgroups of older individuals at highest risk are not well defined.
Methods: We conducted a prospective cohort analysis within the Nurses' Health Study and the Health Professionals Follow-Up Study among participants free of CRC through age 75. Established CRC risk factors were assessed up to age 75, with modifiable factors averaged across repeated questionnaires. We calculated age- and sex-standardized incidence rates (standardized to the 2000 US standard population) and used Cox proportional hazards regression to estimate associations and build a risk prediction model. Model discrimination was evaluated using the C-statistic.
Results: Among 92,773 participants, 848 developed CRC after age 75. A history of lower endoscopy by age 75 was associated with substantially lower CRC risk (incidence, 113 vs 237 per 100,000), and this association was consistent regardless of indication (screening or symptoms). When considering endoscopy timing by age 75, participants whose last endoscopy occurred between ages 66 and 75 had lower CRC incidence than those whose last endoscopy was before age 66 (i.e., missing at least one recommended endoscopy; 102 vs 163 per 100,000). Risk was higher in men and in those with a family history of CRC. Modifiable factors showed positive associations for heavy smoking, alcohol consumption, body mass index (BMI), and processed meat intake. Some subgroups had incidence rates comparable to those without prior endoscopy, such as individuals with ≥2 affected first-degree relatives, >2 alcoholic drinks/day, and BMI ≥35 kg/m^2 (210 to 243 per 100,000). No significant associations were observed for height, waist circumference, history of diabetes, physical activity, unprocessed red meat, dietary fiber, or whole grain intake. Compared to a model including only prior lower endoscopy, adding last-endoscopy timing, sex, family history, and modifiable factors significantly improved discrimination (C-statistic from 0.55 to 0.66; $p < 0.001$).
Conclusion: In two large prospective cohorts, lower endoscopy by age 75, particularly between ages 66 and 75, was associated with substantially lower CRC incidence after age 75, and family history and modifiable factors further stratify risk. Incorporating these factors improved risk prediction and may guide individualized prevention beyond age 75.

#7599 HOUSES as a screening tool for cancer screening: Patient-level housing-based socioeconomic status and breast and cervical cancer screening adherence.

Eunice Y. Park[1], Madison Beenken[2], Dave Watson[2], Chung Il Wi[3], Tufia Haddad[4], Gladys Asiedu[5], Karla BALLMAN[2], James R. Cerhan[2], Carolyn Flock[6], Brian Lynch[3], Folakemi T. Odedina[4], Scott H. Okuno[4], Young J Juhn[3]

[1]Radiation Oncology, Mayo Clinic, Rochester, MN,[2]Quantitative Health Sciences, Mayo Clinic, Rochester, MN,[3]Pediatric and Adolescent Medicine, Mayo Clinic, Rochester, MN,[4]Oncology, Mayo Clinic, Rochester, MN,[5]Kern Center for the Science of Health Care Delivery, Mayo Clinic, Rochester, MN,[6]Mayo Clinic Health System Research, Mayo Clinic, Rochester, MN

Introduction: The National Cancer Institute estimated almost 317,000 new breast cancer and over 13,000 new cervical cancer cases in 2025. While the National Breast and Cervical Cancer Early Detection Program has served millions of women over the past two decades, inequities in cancer screening, subsequently delayed diagnosis, and timely and appropriate treatment remain a public health challenge in the United States. Despite the substantial impact of social determinants of health (SDOH) on cancer screening, few studies have accounted for SDOH at the individual level when assessing breast and cervical cancer screening adherence. The primary objective of this study is to examine whether the individual-level SDOH, measured using HOUsing-based SocioEconomic Status (HOUSES) index, is associated with breast and cervical cancer screening non-adherence (not current on respective USPSTF recommendations for age and frequency).

Methods: In this retrospective study, patients were identified as those receiving primary care in the Mayo Clinic Health System and Mayo Clinic (Rochester, MN). The Midwest Quality Metrics panel was then used to assess patients due for screening for breast or cervical cancer in July 2023. The HOUSES, using home address and publicly available data on the residence which measures and categorizes housing status into quartiles, was obtained using the electronic health records (EHRs)-linkable patient-level information. Logistic regression analyses were conducted, controlling for Census block group-level adverse social exposome from the Area Deprivation Index, age, and comorbidities. Results are presented as odds ratios (OR) with corresponding 95% confidence intervals (CI).

Results: For breast cancer, among 128,462 eligible patients, 20.1% (n= 25,857) were non-adherent. Compared to the highest HOUSES quartile (Q4), lower HOUSES groups showed significantly higher odds of non-adherence: Q3 OR=1.20 (95% CI=1.15, 1.25), Q2 OR=1.45; (95% CI=1.40, 1.53), and Q1 OR=1.90 (95% CI=1.81, 1.99). For cervical cancer, among 175,712 eligible patients, 29.9% (n=52,533) were non-adherent. Compared to the highest HOUSES quartile (Q4), lower HOUSES groups showed significantly higher odds of non-adherence: Q3 OR=1.07 (95% CI=1.03, 1.10), Q2 OR=1.16; (95% CI=1.12, 1.20), and Q1 OR=1.36 (95% CI=1.31, 1.41).

Conclusions: A clinically meaningful association between the HOUSES index and cancer screening adherence was observed. A lower HOUSES index was associated with higher odds of non-adherence for both breast and cervical cancer screening, even after accounting for neighborhood-level risk, age, and comorbidities. Incorporating HOUSES into EHRs can be a practical “screening-for-screening” tool that enables close monitoring of higher-risk patients without additional burden of surveys.

#7600 Thirty years of breast cancer screening and socioeconomic inequalities: A national register-based study in Finland.

Peng Li[1], Pekka Martikainen[2], Mikko Myrskyla[1]

[1]Population Health, Max Planck Institute for Demographic Research, Rostock, Germany,[2]Population Research Unit, University of Helsinki, Helsinki, Finland

Background: The national wide Finnish breast cancer screening program has operated since 1992, yet the long-term effects of screening and socioeconomic inequalities remain incompletely characterized. This study examines 30 years of screening invitations, participation, diagnostic stage, and mortality, with a focus on educational disparities.

Methods: We used data from the Mass Screening Registry, which contains more than 8 million screening invitations issued to 1.2 million women aged 50-69 during 1992-2022. These data were linked with demographic information from Statistics Finland and cancer diagnosis records from the Finnish Cancer Registry. All invited individuals and participation were stratified by education. Survival differences by educational level and screening participation status were assessed using Kaplan-Meier survival curves. Overall mortality was analyzed using Cox proportional hazards models adjusted for education, marital status, urbanization level of residence, and stage at diagnosis. Effects of screening and education on early-stage detection (stage I-II vs. III-IV) were assessed using logistic regression models.

Results: Screening participation displayed a clear socioeconomic gradient (low education 80.2%, medium 84.7%, high 85.7%) and slightly decreased by year. Mean age at death was higher among screened than unscreened women overall (+2.65 years, 81.73 vs. 79.08), and the survival advantage was largest in the lower-educated group (+3.51 years, 81.12 vs. 77.61) than in the higher-educated group (+1.56 years, 82.38 vs. 80.82). Screening participation was associated with a 54% reduction in mortality (HR = 0.46, 95% CI 0.45-0.46) after full adjustment. Screened women had more than double the odds of early-stage diagnosis (OR = 2.31, 95% CI 2.00-2.68). Higher-educated women were more likely to receive an early-stage diagnosis (OR = 1.80, 95% CI 1.52-2.13) than lower-educated women.

Conclusions: Participation in the national breast cancer screening program is strongly associated with improved survival, markedly earlier detection, and substantially reduced mortality risk. Although women with lower education gain the largest absolute survival benefit when they attend screening, their lower participation rates contribute to persistent socioeconomic inequalities. Targeted efforts to increase screening uptake among disadvantaged groups may reduce these disparities.

Main messages: Overall, the national breast cancer screening program demonstrates strong effectiveness in improving survival and promoting earlier detection, while highlighting persistent socioeconomic inequalities that require targeted attention.

#7602 Effectiveness of initiating FIT screening at age 45: Comparative yield with adults aged 50-54 years.

Le Wang[1], Chen Zhu[1], Yu Qiu[1], Weimiao Wu[1], Dong Hang[2], Ni Li[3], Partha Basu[4], Lingbin Du[1]

[1]Zhejiang Cancer Hospital, Hangzhou Institute of Medicine (HIM), Chinese Academy of Sciences, Hangzhou, China,[2]Nanjing Medical University, Nanjing, China,[3]National Cancer Center/National Clinical Research Center for Cancer/Cancer Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing, China,[4]International Agency for Research on Cancer (WHO), Lyon, France

Background and aim: Over the past two decades, the incidence of early-onset colorectal cancer (CRC) has risen in several high-income countries. To address this trend, the United States Preventative Services Task Force recommended lowering the starting age for CRC screening from 50 to 45 years based on estimates from microsimulation models. However, real-world evidence on the screening yield across diverse populations remains limited.

Methods: A population-based CRC screening program has been implemented since 2020 in a region with high CRC incidence (Zhejiang Province, China). The program primarily targeted individuals aged 50-74 years but also included those aged 40-49 years. Screening consisted of two-sample fecal immunochemical testing (FIT), with colonoscopy offered to individuals testing positive on either sample. We compared screening outcomes between participants aged 45-49 years and 50-54 years, including: (1) FIT positivity (threshold of 20 μg hemoglobin per gram of feces); (2) colonoscopy completion; and (3) positive predictive values (PPV, cases detected among those with a positive FIT and available colonoscopy) for neoplasia. Advanced neoplasia included CRC, advanced adenoma and advanced serrated lesion. Variables with standardized mean differences greater than 0.1, including sex, fruit intake, and year of participation, were included in the propensity score model for 1:1 matching between age groups. Risk ratios (RRs) were estimated using a Poisson mixed-effects model.

Results: After propensity score matching, 89 446 subjects aged 45-49 and 89446 subjects aged 50-54 who completed the FIT test were selected, with comparable baseline characteristics. The FIT positivity in the 45-49 age group was 10.61%, which was lower than 11.02% in the 50-54 age group (RR, 0.96; 95% CI, 0.94-0.99), with similar colonoscopy adherence (46.75% vs 47.43%; RR, 0.99; 95% CI, 0.95-1.03). Compared with the 50-54 age group, the 45-49 age group had significantly lower PPVs for any adenoma (15.82% vs 19.91%; RR, 0.79; 95% CI, 0.72-0.88) and advanced neoplasia (6.06% vs 8.25%; RR, 0.73; 95% CI, 0.63-0.86).In subgroup analyses of 45-49 age group, the PPVs for advanced neoplasia among participants with smoking, BMI ≥28 kg/m^2, frequent alcohol drinking, personal history of adenoma or a family history of CRC exceeded that observed in the 50-54 age group.

Conclusions: Individuals aged 45-49 years had comparable colonoscopy adherence to those aged 50-54 years but a lower yield for adenomas and advanced neoplasia. Higher yields among younger individuals with risk factors highlight the potential of risk-stratified approaches. These findings contribute population-specific evidence to inform ongoing discussions on optimal screening initiation age, but further longitudinal, cost-effectiveness, and programmatic evaluations are warranted.

#7603 Type-2 Diabetes, medications, and risk of multiple colorectal polyps: A colonoscopy-based study using natural language processing.

Jessica van Onselen[1], Ryzen Benson[2], Stephanie Richardson[3], Maci Winn[1], Candace Winterton[3], Svenja Pauleck[3], Ainhoa Gomez-Lumbreras[3], Polly A. Newcomb[4], Cornelia M. Ulrich[1], John Inadomi[5], Sheetal Hardikar[1]

[1]University of Utah Huntsman Cancer Institute, Salt Lake City, UT,[2]Department of Radiation Oncology, University of California, San Fransico, San Francisco, CA,[3]Huntsman Cancer Institute, Salt Lake City, UT,[4]Fred Hutchinson Cancer Center, Seattle, WA,[5]Department of Internal Medicine, University of Utah, Salt Lake City, UT

Introduction: Colorectal polyps are known precursors to colorectal cancer (CRC), and a higher polyp count is associated with an increased CRC risk. This study aimed to investigate the impact of type-2 diabetes (T2D) and its treatments on polyp count.

Methods: We leveraged pathology reports from the University of Utah (UofU) Enterprise Data Warehouse (EDW) to develop a rule-based natural language processing pipeline, to extract polyp diagnoses and features (site, count) for 38,038 patients who underwent colonoscopy at the UofU Gastroenterology clinic from 2011-2020. We identified 6,556 patients with T2D via ICD codes and anti-diabetes medication prescriptions. Patient characteristics were extracted from the EDW, including age, sex, race, smoking, BMI, anti-inflammatory medication use, and active prescriptions for insulin, metformin, sulfonylureas, GLP-1 agonists, and DPP-4 inhibitors. Polyp count was categorized as none, one, or multiple. Adjusted odds ratios (OR) and 95% confidence intervals (CI) for polyp counts were calculated using multinomial logistic regression.

Results: Patients were on average 56 years old, 84% White, 51% female, with a mean BMI of 30 kg/m^2. 73% of patients with T2D used anti-diabetes medications. T2D alone was not associated with multiple polyps, but patients with T2D taking anti-diabetes medications had a lower risk of polyps overall, irrespective of polyp count. Insulin use was associated with an increased risk of one or multiple polyps [OR(95%CI)=1.29(1.08-1.54) and 1.40(1.18-1.66), respectively], compared to other medications. Metformin and GLP-1 agonists were both associated with a decreased risk of one [Metformin OR(95% CI)=0.71(0.59-0.85), GLP-1=0.79(0.64-0.99)] or multiple polyps [Metformin OR(95% CI)=0.71(0.52-0.73), GLP-1=0.63(0.51-0.77)], compared to patients taking medications other than metformin or GLP-1 agonists, respectively. Compared to patients taking no anti-diabetes medications, those on insulin, metformin, DPP-4 inhibitors, or sulfonylureas had an increased risk of at least one polyp, while patients taking GLP-1 agonists had a lower risk of multiple polyps [OR(95%CI)=0.81(0.63-1.03)]. DPP-4 inhibitors and sulfonylureas also had a lower risk of multiple polyps [OR(95%CI)=0.79(0.64-0.97) and 0.80(0.68, 0.96), respectively].

Conclusion: Overall, T2D alone was not associated with polyp count, but medication use modified this relationship. Insulin use was associated with increased risk, whereas the use of metformin, GLP-1 agonists, DPP-4 inhibitors, and sulfonylureas was associated with decreased risk of one or multiple polyps, compared to patients taking other anti-diabetes medications. These results highlight the potential role of T2D medication choice in altering colorectal polyp risk, underscoring the need for more research into underlying mechanisms to guide potential interventions.

#7604 Disaggregating Latino nativity using machine learning on electronic health records: Insights for colorectal cancer screening disparities.

Miguel Marino[1], Jun Hwang[1], Jennifer A. Lucas[1], Wyatt Bensken[2], Matthew P. Banegas[3], John D. Heintzman[1]

[1]Oregon Health & Science University, Portland, OR,[2]OCHIN Inc., Portland, OR,[3]Cancer Prevention Fellow, UC San Diego, San Diego, CA

Background: Advancements in colorectal cancer (CRC) prevention have not been equitable with studies showing reduced CRC screening rates and later-stage diagnoses among Latino patients. Latino subgroups vary in their cancer-related risk factors but also differ widely in their sociodemographic characteristics, migration histories, insurance coverage, and health care access patterns that may impact cancer prevention. However, large-scale datasets seldom contain granular data needed to study Latino subgroup-specific differences in cancer risk and outcomes. This study evaluated a machine learning approach designed to infer nativity and country of birth and advance cancer prevention research to better evaluate health equity among Latinos.

Methods: We used comprehensive electronic health record data from 1,500,191 Latino patients receiving care at 1,876 community health centers across 28 states, along with geocoded census-tract-level neighborhood composition data, and surname-based data to develop machine learning models of Latino subgroups. Multiple supervised learning algorithms were trained and tested to predict nativity and country of birth. Model predictive performance was evaluated using area under the receiver operating curve (AUC). As a case example, we used model-predicted probabilities of Latino subgroups and nativity to evaluate CRC screening disparities by foreign-born status, both known and predicted.

Results: Among 1,500,191 Latinos in the network, country of birth was self-reported by Latino patients for only 173,278 (11.6%), underscoring the challenges of using existing EHR data for studying Latino heterogeneity. Prediction models for nativity showed excellent discriminatory prediction performance across all groups (US-born vs. foreign-born: AUC=0.90; Mexican vs. non-Mexican: AUC=0.87; Guatemalan vs. non-Guatemalan: AUC=0.84; Cuban vs. non-Cuban: AUC=0.84). In our case example, using known foreign-born status of Latino patients, we observed that US-born Latinos had lower odds of CRC screening compared to foreign-born Latinos (OR=0.55, 95% CI=0.50-0.617). We observed high concordance between known and model-predicted estimates of CRC screening odds ratios.

Conclusion: National calls for data disaggregation, including among Latinos, have numerous challenges. We developed and validated novel prediction models to infer Latino nativity and country of birth for use in population-based cancer disparities research. These methods present an opportunity to evaluate cancer disparities in data where Latino nativity is not collected.

#7605 Multilevel determinants of hepatocellular carcinoma surveillance in eligible Hispanic and Asian American patients: Language concordance and ethnic enclaves.

Caroline A. Thompson[1], Enyao Zhang[1], Mindy C. Hebert-DeRouen[2], Alison J. Canchola[2], Alyssa Cortella[2], Terri Rice[2], Pushkar P. Inamdar[2], Mai Vu[3], Pragati Kenkare[3], Janet N. Chu[4], Anna D. Rubinsky[5], Chanda Ho[6], Su-Ying Liang[3], Hashem B. El-Serag[7], Michele M. Tana[4], Ma Somsouk[4], Mark Segal[2], Mi-Ok Kim[2], Iona C. Cheng[2], Scarlett L. Gomez[5], Salma Shariff-Marco[2]

[1]Epidemiology, University of North Carolina at Chapel Hill, Chapel Hill, NC,[2]Epidemiology and Biostatistics, University of California San Francisco, San Francisco, CA,[3]Palo Alto Medical Foundation Research Institute, Palo Alto, CA,[4]Medicine, University of California San Francisco, San Francisco, CA,[5]University of California San Francisco, San Francisco, CA,[6]California Pacific Medical Center, San Francisco, CA,[7]Baylor College of Medicine, Houston, TX

Low hepatocellular carcinoma (HCC) surveillance uptake among high-risk Hispanic and Asian American populations may be influenced by provider communication and/or neighborhood context. We investigated associations between patient-provider language concordance, neighborhood ethnic enclave and HCC surveillance in a large, diverse California health system. We analyzed electronic health record data from Sutter Health (2000-2016) appended to census tract-level ethnic enclave indices (% recent immigrants, Spanish/Asian language-speaking households and limited English proficiency, % Hispanic/Asian residents). Eligible adults had an assigned primary care provider (PCP), ≥1 encounter, valid address, no liver cancer history, surveillance indication (cirrhosis or chronic hepatitis B/C), ≥18 months follow-up, and self-identified as Hispanic (HA) or Asian American (AA). Surveillance was ultrasound every 6 months and/or contrast-enhanced CT/MRI (with/without alpha-fetoprotein). We defined uptake as ≥1 test and adherence as percent time up-to-date (PTUDS) among those surveilled. We assessed language concordance (PCP spoke patient's non-English language) and ethnic enclave (quintiles; Q5=highest). Hierarchical logistic/linear regression with facility clustering estimated ORs (uptake) and betas (PTUDS), adjusting for demographics, follow-up time, utilization. N=11,311 patients were included (3,444 HA, 7,867 AA); 19% of HAs and 28% of AAs were non-English speakers; 38% of HAs and 55% of AAs lived in Q5 enclaves. Overall, 36% of HAs and 43% of AAs were surveilled (median PTUDS: 0.16 HA, 0.15 AA). Among AAs, compared to English speakers, language-concordant non-English speakers had higher uptake (OR=1.35, 95%CI 1.12-1.62) and adherence (beta=0.024, 95%CI 0.009-0.039), while non-concordant non-English speakers had similar uptake (OR=1.01, 95%CI 0.88-1.16) but higher adherence (beta=0.020, 95%CI 0.008-0.032). Among HAs, language-concordant non-English speakers showed similar uptake/adherence to English speakers, but non-concordant non-English speakers had higher uptake (OR=1.43, 95%CI 1.16-1.76). Ethnic enclave showed no AA association (p-trend=0.46) but HA uptake was inversely associated with enclave (OR=0.79 comparing Q1 vs. Q5, 95%CI 0.59-1.07, p-trend=0.01). Adherence was not associated with enclave. Patient-provider language concordance and neighborhood ethnic enclave influenced HCC surveillance differently by race/ethnicity. AA surveillance was associated with language-concordant providers but not enclave; HA surveillance was associated with enclave but not provider language. These differential patterns suggest tailored intervention targets: multilingual provider recruitment for Asian languages, and community-based outreach leveraging existing networks in Hispanic neighborhoods.

#7606 Tumor and Host Determinants of the Breast Tumor Immune Microenvironment in Kenyan Breast Cancer Women.

Li Feng[1], Amber N. Hurson[1], Shahin Sayed[2], Hela Koka[1], Viviane Oluoch[2], Veronica Ngundo[2], Alfred Mburu Githuka[2], Zaitun Ajuoga[2], Shaoqi Fan[1], Kristine Jones[3], Belynda Hicks[3], Amy Hutchinson[3], Maria Brown[3], Petra Lenz[3], Aaron M. Rozeboom[3], Difei Wang[3], Francis Makokha[4], Stefan Ambs[5], Jonine D. Figueroa[1], Ruth M. Pfeiffer[1], Xiaohong Rose Yang[1]

[1]Division of Cancer Epidemiology and Genetics, National Cancer Institute, Bethesda, MD,[2]Aga Khan University Hospital, Nairobi, Kenya,[3]Cancer Genomics Research Laboratory, Frederick National Laboratory for Cancer Research, Frederick, MD,[4]Mount Kenya University, Nairobi, Kenya,[5]Center for Cancer Research, National Cancer Institute, Bethesda, MD

Background: The tumor immune microenvironment (TIME) reflects both tumor-intrinsic biology and host-modifiable factors. Characterizing how tumor features, body mass index (BMI), and reproductive history relate to immune activity may help explain heterogeneity in breast cancer and inform precision prevention and survivorship strategies.**Methods:** We analyzed 461 invasive breast tumors from Kenyan patients using a custom NanoString nCounter® immune-focused gene panel. Intrinsic subtypes were assigned with PAM50, and immune cell composition (relative proportions for 22 immune cells) was estimated by CIBERSORTx. Composite immune activity scores were derived to represent functional modules: *z_hot* (CD8+, M1 macrophages, NK activated, T follicular helper) and *z_suppression* (Treg + M2 macrophages) from CIBERSORTx; *z_cytotoxic (GZMB, PRF1), z_exhaustion (PDCD1, LAG3, CTLA4)*, and *z_checkpoint* (*PDCD1, PDCD1LG2, CTLA4, LAG3*) from GSVA signatures. Associations between immune scores and tumor features (PAM50 subtypes, risk of recurrence (ROR), RNA-based TP53 status, tumor grade) or host factors (BMI, menopausal status, parity, breastfeeding) were evaluated in age-adjusted linear regression models. Independent effects of host factors were further examined in multivariable regression models adjusted for tumor characteristics and lifestyle covariates. Multiple testing was accommodated using a false discovery rate adjusted *p*-values.**Results:** Participants had a mean age of 50.3 years; 43.8% of tumors were luminal A and 21.5% basal-like. Most women were overweight/obese (BMI ≥ 25, 73.1%) and 65.7% had ≥ 3 children. High-grade, basal-like, high-ROR, and TP53 mutant-like tumors showed strong evidence of elevated *z_hot*, *z_cytotoxic*, *z_checkpoint*, and *z_exhaustion* scores (BH-adjusted $p < 0.001$), along with modestly lower *z_suppression* in basal-like and TP53 mutant-like tumors ($p < 0.05$), indicating an active TIME characteristic of aggressive tumors. In contrast, established BC risk factors showed weaker influence on TIME. Overweight/obese patients were more likely to have cold TIME (lower CD8 ($p = 0.09$), T follicular helper ($p < 0.05$), and *z_hot* score ($p < 0.05$)), while patients with longer duration of breastfeeding had more active TIME (higher T follicular helper and *z_cytotoxicity;* lower M2 macrophages and *z_suppression* (all $p < 0.05$)).**Conclusions:** Tumor-intrinsic subtype classification remains the dominant determinant of immune heterogeneity, while established BC risk factors (BMI and reproductive risk factors) may modulate immune responsiveness. Integrating tumor, reproductive, and lifestyle data can help clarify immune variation across diverse populations.

#7607 CT-assessed body composition and tumor immunologic characteristics in patients with endometrial cancer.

Yidan Zhang[1], Cuthbert Mario Mahenge[1], Jordan Krull[2], Rand Talal Akasheh[1], Laura Chambers[3], Xuan Nguyen[4], Ting-Yuan David Cheng[1]

[1]Department of Internal Medicine, The Ohio State University Wexner Medical Center, Columbus, OH,[2]Pelotonia Institute for Immuno-Oncology, The Ohio State University Comprehensive Cancer Center, Columbus, OH,[3]Division of Gynecologic Oncology, The Ohio State University Comprehensive Cancer Center - James Cancer Hospital and Solove Research Institute, Columbus, OH,[4]Department of Radiology, The Ohio State University College of Medicine, Columbus, OH

Background: Variations in the body composition, specifically fat and muscle mass, may influence tissue immune infiltration. However, the relationships between these components and the tumor immune microenvironment in endometrial cancer remain poorly defined. We aimed to investigate whether CT-assessed body composition is associated with tumor immune cell infiltration in endometrial cancer.
Methods: We analyzed 63 patients with endometrial cancer from The Cancer Genome Atlas (TCGA) and the Clinical Proteomic Tumor Analysis Consortium (CPTAC) who had pre-treatment CT body composition measurements at the L3 vertebral level and bulk RNA-seq-based immune deconvolution. Approximately 75% of these patients had endometrioid adenocarcinoma. Immune cell abundances for 22 CIBERSORTx-derived subsets were estimated in absolute mode; subsets with ≥75% zero values were excluded, leaving 14 immune cell types plus the CIBERSORT total immune score for analysis. Eight CT-derived body composition metrics were evaluated, including visceral adipose tissue (VAT), subcutaneous adipose tissue (SAT), intermuscular adipose tissue (IMAT), skeletal muscle areas, and corresponding Hounsfield unit (HU)-based density measures. Linear regression models assessed associations between body composition metrics and log1p-transformed immune abundances. Analyses were conducted using univariable and multivariable models adjusting for age and cohort. P-values were corrected for multiple testing using the Benjamini-Hochberg false discovery rate (FDR).
Results: Immune cell abundances were generally low (median<0.10 for most subsets). In univariable models, higher VAT was nominally associated with lower total immune score and reduced abundances of several innate immune subsets, including NK-cell (resting and activated), and macrophage (M0/M1) (all $p<0.05$). In contrast, several HU-based density metrics, including SATHU and IMATHU, showed nominal positive associations with CD8 T cells. However, no associations remained statistically significant after FDR correction (all FDR ≥0.32). Multivariable models adjusting for age and cohort yielded similar patterns.
Conclusion: In this exploratory cohort, CT-derived body composition metrics showed heterogeneous associations with immune cell infiltration. Visceral adiposity showed potential inverse associations with innate immune infiltration, whereas higher subcutaneous adipose tissue showed potential positive associations with CD8 T-cells. These heterogeneous innate and adaptive immune patterns suggest potential differences in how body composition relates to immune infiltration, warranting further investigation in larger cohorts.

#7608 Characterizing myoepithelial marker loss in young-onset DCIS through integrated mouse and human studies.

Zhenzhen Zhang[1], Tanya Russell[2], Elizabeth Elizabeth Mitchell[1], SONALI JINDAL[1], Solange Bassale[1], Jayasri Narasimhan[1], Emily Guinto[3], Alison Fraser[3], Ken Smith[3], Pepper Schedin[1]

[1]Knight Cancer Institute, Oregon Health & Science University, Portland, OR,[2]University of Colorado, Aurora, CO,[3]Pedigree and Population Resource, Population Sciences, Huntsman Cancer Institute, Salt Lake City, UT

INTRODUCTION: Postpartum breast cancer (PPBC), diagnosed within 5-10 years after recent childbirth, is associated with increased metastasis, but postpartum status's impact on mortality among young women diagnosed with Ductal Carcinoma in Situ (DCIS) remains unclear. This study investigates how the postpartum environment may influence DCIS behavior in young women (≤45 years) diagnosed with DCIS and explores biological mechanisms through myoepithelial markers that could promote postpartum DCIS progression.

METHODS: Young women diagnosed with DCIS and invasive breast cancer were identified through the statewide Utah Population Database (UPDB) and SEER Utah Cancer Registry data (diagnosis year 1996-2017 with a median follow-up of 12.5 years, and mortality outcomes were evaluated in relation to DCIS diagnosis time since recent childbirth. Patterns of postpartum status among women diagnosed with DCIS versus invasive breast cancer were compared. To identify underlying biological mechanisms, we examined myoepithelial integrity in normal human breast tissues collected at defined post-weaning intervals and used mouse models of DCIS to evaluate how postpartum mammary gland involution influences tumor progression.

RESULTS: Of 597 women with DCIS, 23 deaths occurred during follow-up. DCIS was less frequent in the <5-year postpartum group (12.4%) compared to nulliparous (17.6%) and 5-<10 years group (17.6%), and invasive BC more frequent in the <5-year group. ER-negative DCIS was higher in the <5-year group (18%) compared to other groups (7%, 6%, 9%). Mortality outcomes were similar between postpartum and nulliparous women, with no clear evidence of increased all-cause mortality associated with recent childbirth. In normal human breast, postpartum breast involution is associated with reduced expression of the myoepithelial markers p63 and calponin, hallmarks of DCIS-to-invasive transition. Mouse models of postpartum DCIS confirmed increased tumor progression in involuting glands compared to nulliparous controls. Moreover, calponin loss in murine mammary myoepithelium correlated with increased tumor dissemination.

CONCLUSION: In young onset DCIS patients, BC-specific mortality was very low during the follow-up, implicating standard care as largely curative. We observed lower frequency of DCIS in the <5-year postpartum group suggesting potential progression of DCIS to invasive carcinoma during the early postpartum period. We find that recent childbirth, specifically weaning, reduces myoepithelial cell calponin expression, potentially facilitating DCIS progression to invasive disease. Calponin loss in a DCIS mouse model confers tumor advantage. These results highlight the importance of reproductive history and the postpartum breast microenvironment in early breast cancer prognosis and may inform risk-stratified management strategies for young women with DCIS.

#7609 Emotional functioning and NR3C1 and FKBP5 expression in multiple myeloma.

Mark Aaron Fiala[1], Steven Cole[2], Judith E. Carroll[2]

[1]Washington Univeristy School of Medicine, St. Louis, MO,[2]UCLA - University of California Los Angeles, Los Angeles, CA

Introduction: Emotional distress is common following a cancer diagnosis, and for some cancers it has also been associated with worse outcomes. However, the impact of emotional distress in patients with multiple myeloma (MM) remains relatively understudied. Methods: This study utilized data from CoMMpass (IA22), a longitudinal study of over 1000 patients who provided biospecimens, clinical data, patient reported outcomes (PROs). In this analysis, we aimed to determine if patient-reported and/or biomarker-based indicators of emotional distress at MM diagnosis were associated with patient outcomes. Patients completed the EORTC QLQ-C30 at diagnosis. The emotional functioning subscale was calculated, with scores ranging 0-100 and lower scores indicating higher distress. CoMMpass lacks data on common biomarkers for distress such as cortisol and cytokines. Therefore, we used mRNA expression (mRNA-seq on CD138-enriched MM cells) of two genes that play an important role in stress response and are dysregulated in people with emotional distress, NR3C1 and FKBP5.

Analysis: Patient reported emotional functioning and NR3C1 and FKBP5 expression were classified into quartiles. Patients in the lowest quartile of emotional functioning were classified as having emotional distress. Associations between emotional functioning, stress biomarkers, and relevant clinical factors were assessed using ANOVA and x^2. Associations with progression-free and overall survival were assessed using Cox Regression and adjusted for patient age, sex, race, and stage (International Staging System [ISS]). Results: 572 patients had baseline PROs and mRNA-seq data. The median age was 64 [IQR 57-71], 59% were male, 78% were White, 15% were Black, and 7% were another race. The median emotional functioning score was 75 [IQR 58.3-91.7]. There was an association between patient reported emotional functioning and higher FKBP5 expression ($p = 0.043$), but not NR3C1 ($p = 0.932$), despite a strong positive association between FKBP5 and NR3C1 ($p < 0.001$). Emotional functioning was also associated with age ($p = 0.023$), sex ($p = 0.006$), and race ($p = 0.003$), but not ISS stage ($p = 0.980$). In multivariable models, both emotional distress and FKBP5 expression were independently associated with prognosis. Patients with emotional distress had a 39% increase in hazard for progression (aHR 1.39; 95% CI 1.07-1.79; $p = 0.012$), but emotional distress was not associated with overall survival. Patients in the highest quartile of FKBP5 expression had a 53% increase in hazard for progression (aHR 1.53; 95% CI 1.16-2.03; $p = 0.003$) and 64% increase in hazard for death (aHR 1.64; 95% CI 1.14-2.36; $p = 0.007$).

Conclusion: Emotional Functioning and FKBP5 expression are both independently associated with MM prognosis. In further analyses, we aim explore the mechanisms underlying these associations and to evaluate potential interventions to mitigate the adverse effects on MM outcomes.

#7610 Tumor-intrinsic programs of epithelial-mesenchymal transition and immune deregulation are linked to disease recurrence in papillary thyroid carcinoma.

Emma Su[1], Amanda E. Garza[1], Jihye Park[1], Himanshu Patankar[2], Brendan Reardon[1], Yutaro Tanaka[1], Jingxin Fu[1], Sabrina Y. Camp[1], Erica Maria Pimenta[1], Helena Jun[1], Josephine Yates[1], Gerard Doherty[3], Justine Barletta[4], Erik Alexander[4], Eliezer M. Van Allen[1], **Theodora Pappa**[5]

[1]Dana-Farber Cancer Institute, Boston, MA,[2]Mass General Hospital, Boston, MA,[3]Surgery, Mass General Brigham, Boston, MA,[4]Mass General Brigham, Boston, MA,[5]Mass General Brigham and Dana-Farber Cancer Institute, Boston, MA

Introduction: Papillary thyroid carcinoma (PTC) is the most common subtype of differentiated thyroid cancer, predominantly affecting females and young adults. Current clinical models fail to capture its marked molecular heterogeneity and integrate this information into prognostic algorithms that would enable personalized care plans. Here, we identify tumor-intrinsic molecular programs contributing to thyroid cancer progression that may inform risk stratification.

Methods: We performed single nuclei multiome (RNA and ATAC) sequencing of 16 fresh frozen samples from a PTC clinical cohort with varying risks of disease recurrence, as determined by the 2025 American Thyroid Association guidelines. Programs with distinct cellular activity were identified with consensus non-negative matrix factorization (cNMF). Cell-cell communication between the tumor and its microenvironment was assessed with MultiNicheNET. Active regulons within cell types of interest were identified using SCENIC. Chromatin accessibility analysis was performed using Signac.

Results: We identified a novel, tumor-specific transcriptional program, defined by composite upregulation of epithelial-to-mesenchymal-transition (EMT) and TNF-alpha signaling, that was enriched in high-risk PTC. Top active regulons in this program included molecules involved in inflammatory response and immune modulation. Chromatin accessibility analysis revealed a significantly differentially accessible peak near CCL20, previously shown to promote thyroid cancer invasion via NF-kB signaling, in tumor cells with highest expression of the program. In thyroid cancer lines from the Broad Institute's Cancer Cell Line Encyclopedia (CCLE), expression of this program was significantly higher in the presence of BRAFV600E mutation ($p<0.001$). Similarly, when projecting this program onto the Thyroid Cancer Genome Atlas (TCGA) database of 496 PTC samples, we observed a significant association between usage of this transcriptional program and both higher risk of recurrence and presence of BRAFV600E mutation ($p<0.001$). This association remained independent in a multiple linear regression model and after adjusting for sex and tumor purity. Cell-cell interaction analyses demonstrated increased activity of thrombospondin-1, a key EMT mediator, signaling from cancer associated fibroblasts to tumor cells, that was unique to high-risk PTC samples.

Conclusions: We identified a new, tumor-intrinsic transcriptional program through integrative multi-omic analysis that is characterized by EMT and immune deregulation, enriched in high-risk PTC, and validated its clinical relevance in TCGA. Evaluating the performance of this program in larger thyroid cancer cohorts will be essential to establish its prognostic value and potential to incorporate into clinical risk stratification models.

#7614 Early cancer detection using early-access Illumina protein prep 6K assay and machine learning.

KAMEL LAHOUEL, **Mete Mulazimoglu**, Kameron Bates, Candice Wike, Kunjur Manasa Upadhyaya, Victoria Zismann, Kamawela Leka, Payton Smith, Gracyn Benck, Kianna Martos Rupp, Chaney Jambor, Matteo Munini, Sophie Penisson, Stephanie Pond, Jeffrey Trent, Patrick Pirrotte, Cristian Tomasetti

TGen (The Translational Genomics Research Institute), Phoenix, AZ

Background:
Studies in cancer early detection have revealed circulating proteins to be powerful and informative biomarkers. We further aimed to develop a machine-learning framework robust to batch effects across independently processed datasets and to identify a subset of proteins capable of detecting cancer at its earliest stages. In this study, we sought to evaluate the early-access Illumina protein prep proteomic assay not only for its technical reproducibility but also for its ability to yield biologically informative protein signatures relevant to cancer early detection.
Experimental Procedures:
Proteomic profiles from six plates were analyzed, encompassing approximately 217 normal and 206 cancer plasma samples. The first four plates contained samples collected from Eastern European sources and were used for model training and feature selection, while the remaining two plates contained samples collected in the United States from populations with diverse ancestry backgrounds and served as an external test set. These two plates included samples from bladder, breast, gastric, and lung cancers, representing diverse biological and technical conditions.
Feature selection was performed using the Minimum Redundancy-Maximum Relevance (MRMR) method, which ranks proteins by maximizing mutual information with cancer status while minimizing redundancy. The top 200 proteins were used to train a Support Vector Machine (SVM) classifier with a radial-basis kernel.
Results:
The model achieved a mean AUC of 0.89 across the two independent test plates, demonstrating strong cross-batch and cross-ancestry reproducibility and confirming that informative, generalizable protein features can be extracted from the Illumina platform. At 95% specificity, the classifier achieved an overall sensitivity of 65% (95% CI: 51-77%), with particularly strong performance in Stage II cancers at 82% (95% CI: 52-95%), underscoring its potential utility for early detection. Performance was consistent across cancer types, with highest sensitivities observed in lung. Importantly, a six-fold leave-one-plate out cross-validation yielded an average sensitivity of 82% at 99% specificity, demonstrating that integrating diverse data sources will likely strengthen model generalizability.
Conclusions:
A machine-learning framework applied to large-scale proteomic data identifies a compact and biologically meaningful subset of proteins capable of early cancer detection. The results highlight the robustness of the Illumina Protein Prep, 6K assay, and the feasibility of developing batch-insensitive protein classifiers for population-scale cancer screening.

#7615 Multiplex detection of BCR-ABL1 fusion transcripts in a streamlined single-tube workflow using PCR-based single molecule counting.

Vladyslava Ratushna, Jung won Keum, Christina Fan

R&D, Countable Labs, Palo Alto, CA

Accurate quantification of *BCR-ABL1* fusion transcripts is essential for monitoring minimal residual disease (MRD) in chronic myeloid leukemia (CML), where distinguishing between isoforms (p210, p230, p190) is clinically important for diagnosis, prognosis, and treatment monitoring. Traditional detection methods rely on two-step workflows involving reverse transcription (RT) followed by PCR amplification, either via qPCR or digital PCR (dPCR). While dPCR enables absolute quantification without standard curves, its limited dynamic range and multi-step workflow present challenges for streamlined isoform detection. We developed a one-step multiplex RNA assay for the direct detection and molecular counting of p210, p230, and p190 isoforms, even amid abundant wild-type *ABL1* molecules, within a single tube. The entire workflow, including RT-PCR and counting, occurs without sample transfers, reducing hands-on time and contamination risk. Using 3D light-sheet microscopy, molecules are directly counted by imaging the complete 50 µL reaction volume, eliminating dead volume and partitioning statistics. When *BCR-ABL1* RNA containing each isoform was serially diluted into wild-type *ABL1* background at varying ratios, wild-type *ABL1* counts remained stable, near one million molecules, while *BCR-ABL1* counts decreased proportionally with dilution.This highlights the highly sensitive and specific detection of RNA isoforms across a 6-log dynamic range with low variance (<10% CV), enabling monitoring of both abundant and rare transcripts within a single tube. This single-tube approach provides a streamlined alternative for sensitive detection of all *BCR-ABL1* isoforms in one multiplexed reaction, with potential applications in clinical assessment and therapeutic decision-making in CML.

#7616 Early detection of pancreatic cancer with a multi-omic liquid biopsy.

James M. Cameron, Holly J. Butler, David S. Palmer, Rose G. McHardy, Matthew J. Baker

Dxcover Ltd., Glasgow, United Kingdom

Background: Early diagnosis is the central challenge in pancreatic ductal adenocarcinoma (PDAC) and the successful development of an early detection biomarker test would revolutionize the field. PDAC is the 3rd leading cause of cancer-related deaths in the United States with 66,400 new diagnoses in 2024. The five-year survival is only 12.8% because 80% of patients are diagnosed in advanced stages limiting the potential for curative surgical resection. There is an urgent need to facilitate the triage of high-risk groups into the diagnostic pathway, particularly those with pancreatic cysts, chronic pancreatitis and new-onset diabetes over the age of 50. However, the incidence of PDAC in these at-risk populations is ~1% over the next 3 years. Imaging modalities, such as CT/MRI and endoscopic ultrasound with fine-needle aspiration, are too expensive and invasive to serve as primary screening tools.

Methods: Here the ability of a spectroscopic blood test as an alternative strategy for PDAC detection is assessed. The technology utilizes infrared (IR) spectroscopy, and interrogates a blood sample with IR light to produce a distinctive signature that is sensitive to the hallmarks of cancer. When combined with machine learning, the test detects PDAC by monitoring of all biomolecular components of the sample. In this proof-of-concept study, 166 PDAC patients were classified against 459 symptomatic patients with a non-cancer diagnosis.

Results: The receiver operating characteristic (ROC) curve reported an area under the curve (AUC) value of 0.84. The diagnostic algorithm reported 92% sensitivity with 52% specificity. Importantly, the model did not seem to be affected by cancer stage. The detection rates with the sensitivity-tuned model were 88% stage I, 94% stage II, 99% stage III and 95% stage IV.

Conclusions: The detection of PDAC in early stages would improve prognosis and survival rates of affected patients. Advancements in genetic sequencing have opened opportunities for tumor-derived biomarkers, using genomics, epigenomics, and transcriptomics to isolate circulating tumor DNA, exosomes, and/or microRNA. However, these biomarkers are limited in PDAC at early stages due low release and near-undetectable signals. A spectroscopy-based multi-omic blood test represents an alternative strategy, particularly for high-risk populations, that may address the gap in PDAC diagnostics.

#7617 A multi-omic liquid biopsy for the earlier detection of ovarian cancer.

James M. Cameron, Holly Butler, David Palmer, Rose McHardy, Matthew Baker

Dxcover Ltd., Glasgow, United Kingdom

Background: Ovarian cancer has one of the highest mortality rates among gynecologic cancers, largely because more than 70% of cases are diagnosed at more advanced stages. Early-stage ovarian cancer, by contrast, has a five-year survival rate above 90%. Currently, there are no approved population-wide screening tests for ovarian cancer, due to ineffective testing options highlighting the urgent need for better early detection tools. Novel liquid biopsy technologies offer a promising path to identify ovarian cancer early, when treatment is far more effective.
Methods: This study explored the ability of a multi-omic liquid biopsy as an alternative strategy for ovarian cancer detection. The technology utilizes infrared (IR) spectroscopy and interrogates a blood sample with IR light to produce a distinctive signature that is sensitive to the signals of cancer. In this proof-of-concept study, 125 ovarian cancer patients were classified against 260 female symptomatic patients with a non-cancer diagnosis. Blood was obtained from patients before surgical resection or the start of other anti-cancer therapies. Blood serum samples were analyzed by the Dxcover® Liquid Biopsy Platform and classified with machine learning algorithms. These trained algorithms are then independently tested on an additional clinical dataset.
Results: The receiver operating characteristic (ROC) curve reported an area under the curve (AUC) value of 0.86. The sensitivity-tuned algorithm reported 92% sensitivity with 54% specificity, and the specificity-tuned model reported 58% sensitivity with 90% specificity. Importantly, the diagnostic algorithm was unaffected by cancer stage. The detection rates were 97% stage I, 86% stage II, 92% stage III and 100% stage IV, for the high sensitivity model. Validation testing provided additional confirmation of diagnostic ability in the intended use population.
Conclusions: Detecting ovarian cancer earlier improves prognosis and survival rates of affected patients. There is a low barrier to integrating the blood test into existing diagnostic pathways since the technology is simple to use, minute sample volumes are required, and results can be provided rapidly. This liquid biopsy represents an alternative strategy, particularly for high-risk populations, that may address the gap in ovarian cancer diagnostics.

#7619 PanGIA Analysis System, a novel machine learning platform for non-invasive diagnosis of oral cancer through an oral sample.

Francis Lim, Abhignyan Nagesetti, Nick Gonzalez, Miguel Javiel, Pablo Hernandez, Kyle Ambert, Robert Cardwell, **Obdulio Piloto**

PanGIA Biotech Inc., Miami, FL

The PanGIA Analysis System (PAS) is an advanced diagnostic platform designed to characterize complex biological systems through machine learning-assisted biochemical profiling. Powered by trained algorithms and proprietary hydrogel microarrays known as NuTec Slides, PAS enables unbiased capture and analysis of biomolecular signatures from diverse biofluids. Oral samples represent a particularly valuable yet underexplored matrix for noninvasive disease assessment, offering insight into both local and systemic health conditions. In this study, a commercialization-ready PAS prototype was evaluated for its capacity to differentiate between cancer-spiked and unspiked oral samples. Oral fluid from healthy volunteers was pooled with TruSample Oral Buffer Cell and spiked with literature-validated analyte panels representative of oral cancer. Following incubation of NuTec Slides with both spiked and unspiked control samples, heat-based signal development and high-resolution scanning were performed. Extracted image feature data were analyzed by principal component analysis (PCA). This proof-of-concept study indicates that PAS can distinguish between control and spiked human oral samples containing literature supported oral cancer analytes. Conclusion: These findings establish proof-of-concept for the use of PAS in noninvasive cancer detection through oral fluid profiling. Further clinical validation is warranted to expand its diagnostic applications across additional cancer types and to explore its potential in longitudinal monitoring, risk stratification, and personalized medicine.

#7620 PanGIA Analysis System, a novel machine learning platform for non-invasive diagnosis of multiple cancers through urine.

Abhignyan Nagesetti, Francis Lim, Nick Gonzalez, Miguel Javiel, Pablo Hernandez, Kyle Ambert, Robert Cardwell, **Obdulio Piloto**

PanGIA Biotech Inc., Miami, FL

The PanGIA Analysis System (PAS) represents a novel machine learning-driven platform for the interrogation of complex biological systems through biochemical signature profiling. Analogous to advanced language models such as Google Gemini or ChatGPT, PAS employs trained algorithms to interpret multidimensional data derived from biological samples. The system utilizes proprietary hydrogel-based microarray substrates, termed NuTec Slides, designed to capture unbiased biomolecular profiles from diverse liquid matrices. Among these, urine offers a particularly informative yet underutilized medium for assessing physiological and pathological states. In this study, a commercialization-ready prototype of PAS was evaluated for its ability to discriminate urine samples containing cancer-associated analytes from non-spiked controls. First-morning urine from healthy volunteers was pooled and spiked with literature-validated analyte panels representing hematological cancers, breast, bone, and brain cancers. Following incubation of NuTec Slides with both spiked and unspiked samples, heat-based signal development, and scanning, extracted image feature data were analyzed by principal component analysis (PCA). This proof-of-concept study indicates that PAS can distinguish between control and spiked human urine samples containing literature supported analytes. Furthermore, we observe distinct clustering between individual cancers. Conclusion: These findings demonstrate the feasibility of PAS as a non-invasive diagnostic tool for cancer detection using urine-based biomolecular profiling. Continued clinical validation is warranted to establish its broader utility in diagnostics, prognostics, companion diagnostics, and monitoring of minimal residual disease.

#7621 Early-onset colorectal cancer detection through a non-invasive label-free electrochemical immunosensor probe.

Ruma Paul[1], Md Zahirul Islam Khan[2], Soumya Nair[2], Alicia I Loya[1], Sourav Roy[2], Carlos R. Cabrera[1]

[1]Chemistry and Biochemistry, The University of Texas at El Paso, El Paso, TX,[2]The University of Texas at El Paso, El Paso, TX

Early-onset colorectal cancer (CRC; <50 years) is rapidly increasing in the United States and disproportionately affects Hispanic and African American patients. Since survival rates are positively associated with early detection, the absence of reliable and accessible screening tools for younger adults remains a significant unmet need. Liquid-biopsy diagnostics offer a practical alternative to invasive tests; however, the risk of false negatives is too high. Using gene-expression datasets, cDNA arrays, tissue-microarrays, and tissues from CRC patients, we have identified and validated the elevated expressions of CCNB1 and MCM10, at the transcript and protein levels, in Hispanic early-onset CRC patients when compared to their Non-Hispanic White counterparts. We are developing a label-free electrochemical immunosensor for point-of-care (POC) detection of these early-onset CRC biomarkers. As a prototype, we designed a sensor targeting the early CRC biomarker CCSP-2. A gold working electrode (Au) was functionalized with cysteine-modified recombinant Protein G, which selectively binds the Fc region of hIgG to achieve controlled orientation of CCSP-2 antibodies (Ab) on the Au surface. After Ab immobilization, bovine serum albumin (BSA) was used as a blocker, and each modification step was characterized by cyclic voltammetry and electrochemical impedance spectroscopy (EIS). EIS quantified CCSP-2 antigen (Ag) through changes in relative charge-transfer resistance ($\Delta R_{ct}/R_{ctl}$). The resulting calibration curve ($\Delta R_{ct}/R_{ctl}$ vs Ag) demonstrated strong linearity (R^2 = 0.95) from 10-100 ng/µL, with a detection limit of 0.71 ng/µL.

To further enhance stability and antifouling performance in complex biofluids, we are integrating a porous BSA-glutaraldehyde-gold nanowire (BSA-GA-AuNW) hydrogel onto Au interdigitated microelectrodes, followed by antibody immobilization and testing of early-onset CRC biomarkers. This conductive, hydrophilic matrix is expected to improve sensitivity and specificity while enabling reliable blood-based measurements. This non-invasive, low-cost electrochemical probe has strong potential to expand screening and improve early detection of CRC, especially among younger and underserved populations, thereby improving the survival rates.

#7622 Breaking barriers to scalable multi-cancer early detection (MCED).

Bahram G. Kermani

Crystal Genetics, Inc., Los Altos, CA

In recent years, MCED via liquid biopsy has risen to prominence for its potential to shift the paradigm of cancer detection from one to many, and from late to early stages. Yet, realizing this promise requires addressing several fundamental challenges, without which MCED risks remaining confined to expensive niche markets rather than becoming a broadly practical clinical tool. These challenges comprise technical, methodological, psychological, and economic factors. While detection at all early stages is challenging, detecting solid cancers at Stage I is significantly more demanding compared to Stage II. For the four most common solid cancers, volumetric measurements suggest that Stage I is roughly 5 to 30 times harder to detect than Stage II. This nonlinear challenge, compounded by the inherent nature of some cancer types, highlights the demanding sensitivity requirements of a true early detection scheme and the limitations faced by many advanced molecular platforms. Specificity poses a parallel challenge. Maintaining high specificity while simultaneously preserving strong Stage I sensitivity is intrinsically difficult because early cancer signals can closely resemble healthy baselines. A compromise in Stage I sensitivity, for instance, could translate to apparent increased specificity. This, in turn, could lead to a perceived exaggeration of the positive predictive value (PPV) if not interpreted with caution. Rigorous cohort design is essential to prevent distortion of accuracy. Careful consideration of age, comorbidities, and related variables is crucial to avoid significant consequences. For example, an older-skewed cohort could falsely inflate the perceived PPV. Similarly, age differences between cancer and healthy groups can mislead metrics, as older individuals' non-cancer signals may falsely raise apparent sensitivity. Psychological factors can hinder cancer screening, with fear and anxiety particularly high in MCED, which targets multiple cancers simultaneously. Employing MCED as a triage rather than a definitive screening test can reduce these concerns, as positive results prompt confirmatory screening. However, while this approach makes MCED an accessible entry point, it would demand high sensitivity, particularly at the earliest cancer stages. Lastly, cost remains a critical consideration. For MCED to achieve widespread adoption, it must be economically viable, ensuring cost-effectiveness, accessible reimbursement pathways, and consequently affordability at the population level. These economic factors will be key to its real-world feasibility. In this work, we present a low-cost, high-sensitivity/specificity MCED leveraging proteomics and machine intelligence, initially targeting breast, lung, prostate, and colon cancers. By addressing the key challenges, we demonstrate how MCED can evolve from a costly niche market to a clinically actionable tool for large-scale early cancer detection.

#7623 Non-invasive detection of early colorectal neoplasia using red blood cell DNA profiling: a prospective clinical validation.

Chengcheng Liu[1], Xingyun Yao[2], Haobo Sun[2], Yurong Jiao[1], Xiangxing Kong[1], Jie Jin[3], Kefeng Ding[1], Jun Li[1], Xiaofei Gao[4]

[1]Department of Colorectal Surgery and Oncology, Key Laboratory of Cancer Prevention and Intervention, Ministry of Education, The Second Affiliated Hospital, Zhejiang University School of Medicine, Hangzhou, China,[2]Westlake University, Hangzhou, China,[3]Timing Biotech, Hangzhou, China,[4]Research Center for Industries of the Future and School of Life Sciences, Westlake University, Hangzhou, China

Background: Colorectal cancer (CRC) is a major cause of cancer mortality, yet early detection markedly improves outcomes. Current screening tools like colonoscopy and fecal immunochemical test (FIT) face limitations in accessibility, participation, and sensitivity, particularly for advanced adenomas (AA). Emerging evidence indicates that tumor-derived systemic stress can induce genomic and epigenetic abnormalities in bone marrow, thereby remotely reprogramming hematopoiesis. Consistent with this phenomenon, our previous work revealed that colorectal tumors remotely disrupt the genomic integrity of hematopoietic stem and progenitor cells, and that these alterations presist through erythroid differentiation to generate distinct DNA signatures in mature red blood cells (rbcDNA). Leveraging these rbcDNA signatures, we developed a CRC-rbcDNA based classifier for early detection of CRC and AA. Following multi-center validation, this study presents the first prospective clinical evaluation of the classifier and a head-to-head comparison with quantitative FIT (qFIT), aiming to assess its performance in detecting both early CRC and AA.

Methods: We conduct a prospective cohort clinical study (NCT05875584) designed to validate the locked rbcDNA classifier and to benchmark its performance against qFIT. A total of 598 individuals were enrolled, of which 585 samples were available for analysis. These comprised 299 non-CRC controls (non-neoplastic findings, non-advanced adenomas, and limited non-CRC malignancies), 206 AAs (high-grade dysplasia, villous features, or lesions ≥10 mm), and 80 CRCs. All samples underwent rbcDNA isolation, purification, and low-coverage whole-genome sequencing to generate rbcDNA profiles. For each participant, the locked classifier generated an rbcDNA-based predictive score, and qFIT results were collected in parallel.

Results: Using the predefined threshold, the rbcDNA assay reached 90% sensitivity for CRC, including over 90% of stage I-II tumors, and detected 60% of AA cases. Among 299 controls, specificity was 90% and remained consistent across clinical subgroups. Performance in the prospective cohort closely matched that of the multi-center validation set and remained consistent across demographic, clinical, and pathological characteristics. Compared with qFIT, the rbcDNA assay achieved similar CRC sensitivity (90% vs. 88%) but substantially improved AA sensitivity (60% vs. 18%). Overall, the rbcDNA assay showed substantially higher sensitivity than qFIT for early-stage CRC and AA, which typically present with low tumor burden, while maintaining similar specificity.

Conclusions: This prospective clinical study demonstrated rbcDNA can be a highly sensitive and non-invasive method for early detection of colorectal neoplasia, supporting its promise for integration into clinical screening practice.

#7624 Liquid biopsy MCED enabled by a novel 800K-locus bimodal amplicon sequencing technology.

Kamel Lahouel, **Kameron Bates**, Victoria Zismann, Candice Wike, Kunjur Manasa Upadhyaya, Matteo Munini, Mete Mulazimoglu, Gracyn Benck, Kianna Martos Rupp, Payton Smith, Chaney Jambor, Sophie Penisson, Stephanie Pond, Jeffrey Trent, Cristian Tomasetti

TGen (The Translational Genomics Research Institute), Phoenix, AZ

Background:
Multi-cancer early detection (MCED) from plasma liquid biopsy has advanced rapidly, demonstrating that diverse cfDNA features can reveal early tumor signals. Most current assays rely on whole-genome or methylation sequencing, which are costly and require deep coverage. EarlySeek is a novel, highly multiplexed cfDNA amplicon-based alternative that targets ~800,000 SINE-enriched loci using long and short amplicons, generating a bimodal insert-size distribution and requiring as little as 0.25 ng of DNA input. This design captures complementary signals such as fragmentation, aneuploidy, genomic abundance shifts, and sequence motif patterns. We evaluated a multi-signal framework integrating these features using artificial intelligence and machine learning.
Methods:
Three datasets were analyzed: a training set (237 cancers, 463 normals), a calibration set (72 cancers, 140 normals), and an independent test set with tissues present in training (78 cancers, 192 normals). EarlySeek output yields six biological scores: fragment length, two aneuploidy scores, two coverage/abundance scores, and a 6-mer motif score. Scores were generated using representation and deep learning architectures, including autoencoders that compress amplicon-level and binned genomic information into informative latent features, combined with machine learning classifiers such as support vector machines and gradient-boosted trees. Each score was calibrated via quantile-to-quantile regression, and a predefined multi-signal rule was applied to generate final scores for the test cohort.
Results:
Across 270 independent test samples, the combined six-score framework achieved 51% sensitivity at 99% specificity (95% CI: 40%-62%). Sensitivity by stage showed meaningful early detection: 45% for stage I (CI 26%-66%), 58% for stage II (CI 39%-74%), 57% for stage III (CI 37%-67%), and 100% for stage IV (2/2; CI 34%-100%). Performance varied by cancer type, with strongest detection in colorectal (61%), gastric (71%), liver (80%), ovarian (75%), and pancreatic cancer (64%). Lower sensitivities in breast, and prostate cancers reflected known low cfDNA shedding.
Conclusions:
EarlySeek's bimodal amplicon design enables extraction of diverse cfDNA signals from a single sequencing assay. Integrating these orthogonal features through artificial intelligence and machine learning supports high-specificity MCED detection and yields meaningful early-stage performance. This approach offers a scalable, cost-effective MCED test, a desirable feature for population-level cancer screening.

#7625 Development of a blood-based tumor hypoxia detection assay.

Azemat Jamshidi-Parsian[1], Ruud Petrus Dings[1], Rajshekar A. Kore[1], Narasimhan Rajaram[2], Varsha Karunakaran[3], **Robert J. Griffin**[1]

[1]University of Arkansas for Med Sci, Little Rock, AR,[2]Biomedical Engineering, University of Arkansas, Fayetteville, AR,[3]University of Arkansas, Fayetteville, AR

We have developed a method designed for detection of hypoxia-based markers in the vesicles shed from tumor cells in vitro and in vivo to non-invasively assess the degree of hypoxia present in a patient (patent pending). Our initial studies indicated that vesicle proteins can be labeled by various nitroimidazoles and detected by western blotting of exosome lysates from blood samples or tissue culture. In addition, vesicles secreted from 4T1 murine breast tumor cells incubated with pimonidazole in hypoxia (0.5% O_2) could be detected using flow cytometry or plate-reader fluorescence quantification of purified exosome samples assayed with a fluorescent anti-pimonidazole primary antibody. There was a 2.4-fold elevation in binding signal in exosomes sampled from hypoxic vs oxic culture. Recently, we have also studied the production of pimonidazole-labeled exosomes in the U118 human brain tumor cell line and found a marked difference in signal between exosomes isolated from aerobic culture vs. exosomes isolated in hypoxic culture. In 4T1 tumor tissue lysates, hypoxia induced a maximum over 8-fold increase in pimonidazole adducts by day 11 of tumor growth. However, at day 4 of tumor growth there was a maximum of 3.95-fold increase in adducts from exosomes isolated from a blood sample, and the signal decreased, yet remained elevated compared to samples from non-tumor bearing mice, in blood samples taken at day 7, 11 or 14 or tumor growth. We theorized that the more advanced the tumor becomes, the less blood circulation and more necrosis are present which prevents hypoxic exosomes from entering the circulation. In U118 brain tumor cell exosomes from in vitro culture, there were similar distinct signal enhancements found, where there was a 3.8 fold enhancement of pimonidazole adduct bands in exosomes harvested from U118 cells cultured in 0.5% O_2 overnight compared to exosomes from cells cultured in normoxia. We have most recently investigated a click-chemistry based detection of nitroimidazoles in biological samples, thereby avoiding the need for antibody detection and thus improving the sensitivity and specificity. We have observed marked hypoxia-specific binding of the click-compatible dye in cells cultured in hypoxia and found a distinct reduced azido-aza associated peak using Raman spectroscopy, which could be a more efficient and rapid test for clinically obtained samples. Finally, a dot blot approach we developed has demonstrated that vesicles obtained from the blood of tumor bearing mice indicate an average signal increase of 40% in tumor-bearing mouse exosomes vs. animals without tumor. We surmise that the detection of vesicles being shed from a hypoxic niche could lead to a non-invasive blood test for tumor or ischemia presence, as well as a surrogate marker for treatment success or tumor recurrence. Efforts to correlate individual tumor hypoxic fraction and the exosome signal are ongoing to verify the specificity of the approach.

#7626 A gene expression classifier to predict progression risk of ductal carcinoma in situ to invasive breast cancer.

William Joseph Harley[1], Maria Roman-Escorza[2], Jelle Wesseling[3], Elinor Sawyer[2], Renee X. de Menezes[4], Esther Lips[3]

[1]The Netherlands Cancer Institute, Amsterdam, Netherlands,[2]King's College London, London, United Kingdom,[3]Moleculaire Pathologie / Molecular Pathology, The Netherlands Cancer Institute, Amsterdam, Netherlands,[4]Biostatistics Center, The Netherlands Cancer Institute, Amsterdam, Netherlands

Background: Ductal carcinoma in situ (DCIS) is a non-obligate precursor to invasive ductal carcinoma. A minority of DCIS cases will ever progress to ipsilateral invasive breast cancer (iIBC), but almost all are treated with breast-conserving surgery and radiotherapy. Reliable biomarkers of progression risk are needed to prevent overtreatment of low-risk lesions. We present a DCIS gene expression classifier to predict the risk of iIBC occurring within the first 5 years of diagnosis.
Methods: The model was trained on a dataset of pure primary DCIS RNA-seq samples from a Dutch population-based cohort collected from 1989 to 2005. Samples from 188 patients treated with breast-conserving surgery only were retained for the training data to remove radiotherapy as a confounding factor in iIBC risk. The classifier is a logistic regression model with elastic net penalization, trained in a nested 5x5 cross-validation scheme. The final model was validated on an external, independent dataset of 91 British DCIS samples from the NHS Sloane project.
Results: The classifier achieved an overall AUC of 0.642 on the outer loop test sets in the Dutch training set, and 0.694 in the Sloane independent validation set. The classifier risk score is shown in a logistic model to be associated with an increased risk of iIBC within 5 years in the Sloane validation dataset [OR: 1.16; CI: 1.05-1.27; p = 0.0496] where HER2 status, ER status, histopathological grade and age at diagnosis were not. A threshold to categorize risk scores into low- and high-risk categories was chosen on the training set by selecting the cut-point that maximized balanced accuracy. Gene set enrichment analysis showed enrichment of cell cycle and proliferation gene sets in the high-risk category (HALLMARK_E2F_TARGETS, HALLMARK_G2M_CHECKPOINT, GNF2_MKI67).
Discussion: The performance of this classifier on an external, independent validation dataset shows that signals of risk of developing iIBC within 5 years of diagnosis can be detected within the gene expression profile of pure primary DCIS lesions. That the classifier was trained and validated on samples from patients who received the least aggressive treatment available without the confounding factors of radiotherapy or mastectomy brings us closer to an understanding of the biology underlying the risk of progression to iIBC in DCIS untreated at diagnosis. Such an understanding could be valuable information for including DCIS patients in active surveillance trials, and a step forward in preventing women having to undergo unnecessary surgery and radiotherapy.

#7627 Multi-omics integration reveals evening circadian preference as a causal risk factor for cancer-depression comorbidity through shared neuro-endocrine-immune pathways.

Liansha Tang, Wenbo He, Handan Hu, Jiayao Wang, Jiyan Liu

West China Hospital of Sichuan University, Chengdu City, China

Background: The comorbidity of cancer and depression leads to substantially poor prognosis, yet its shared mechanisms remain elusive. Circadian disruption, particularly evening circadian preference, is a plausible link but its role and underlying pathways in comorbidity warrant further investigation.

Methods: We conducted an integrative multi-omics analysis. Utilizing prospective UK Biobank data (N=299155), we assessed the association of evening chronotype with cancer-depression comorbidity risk across distinct transition pathways (baseline to comorbidity, cancer to comorbidity, depression to comorbidity). Mendelian randomization (MR) and polygenic risk scores (PRS) for morning chronotype were performed for causal inference and genetic stratification. To uncover molecular mechanisms, we integrated summary-data-based MR (SMR) and colocalization analyses using GWAS and eQTL data to identify circadian clock-related genes (CRGs) consistently associated with breast (BCa), prostate (PCa), colorectal cancer (CRC), and depression. Pathway enrichment analysis and immune cell infiltration analysis were also conducted to investigate shared mechanisms.

Results: Evening chronotype significantly increased the risk of transitioning from a healthy baseline state to comorbidity for overall cancer, CRC, and BCa (fully adjusted HRs = 1.30, 1.55, and 1.43, respectively), and on the transition from cancer to comorbidity (HRs=1.29, 1.50, and 1.34, respectively). The effect was more pronounced in subgroups such as women, smokers, individuals with higher levels of education, and those with a lower socioeconomic status. Genetically, morning chronotype PRS showed protective effects, and individuals with both evening chronotype and low PRS constituted the highest-risk subgroup. Two-sample MR confirmed a causal protective effect of morning chronotype on BCa, CRC, and depression. Multi-omics integration identified five key CRGs (GAL, ALAS1, SUCNR1, PTK2, DDIT3) with consistent causal effects on both cancer and depression. Pathway enrichment analysis revealed that these genes were significantly clustered in neuroendocrine regulation and metabolic pathways. GAL and SUCNR1/PTK2 were significantly correlated with mast cells and CD8+ T cells infiltration, respectively, revealing a pathway from circadian disruption to comorbidity through neuro-endocrine-immune dysregulation.

Conclusion: Our study elucidates evening chronotype as a significant and modifiable risk factor for cancer-depression comorbidity. We identify a high-risk genetic subgroup and delineate shared biological mechanisms, providing a foundational framework for targeted circadian-based interventions to mitigate comorbidity risk.

#7628 Sensitive detection of microRNAs from human melanoma cell lines and FFPE tissue using fluorescent nitrogen-vacancy center nanodiamonds.

Isaac Rampersaud[1], Charles Fletcher[1], Colin Angell[2], William E. Carson[3], **Arfaan Rampersaud**[1]

[1]Columbus NanoWorks, Inc., Columbus, OH,[2]The Ohio State University, Columbus, OH,[3]Professor of Surgery, The Ohio State University, Columbus, OH

Diamond magnetometry (DM), using fluorescent nitrogen-vacancy center nanodiamonds (FND), is an enzyme-free, quantum-based platform that can detect and monitor cancer biomarkers, such as microRNAs. Fluorescence is due to the nitrogen vacancy center (NV-center), a crystallographic defect where a nitrogen atom is adjacent to a vacant (empty) site within the diamond lattice. Importantly, NV-center fluorescence can be optically manipulated and is sensitive to nanoscale magnetic fields. In the present study, we used diamond magnetometry to rapidly detect picomolar amounts of microRNAs in human melanoma cell lines without requiring the Polymerase Chain Reaction (PCR) or amplification or preamplification steps. Method. FNDs and magnetic nanoparticles were functionalized with biomolecules to create NV-Biosensors for miR-486-5p, miR-363-3p, miR-196-5p, miR-135b-5p, and miR-21-5p. Synthetic RNA and DNA oligonucleotides were synthesized by IDT and quantified on a Nanodrop spectrophotometer. Total RNA was prepared from the melanoma cell lines A375, MEL-39, CHL-1 HT-144, 18105 Mel, and MEL1174. Following isolation, nucleic acid sensors were mixed with 2 µL of total RNA in TBS reaction buffer containing 0.05% SDS, 5 mM $MgCl_2$, and 1 nM of a random 50-mer DNA sequence. Reactions were run for 15 minutes, then spotted onto a glass coverslip, gently rinsed, then mounted on a widefield fluorescence microscope set-up, and analyzed by a technique called optically detected magnetic resonance (ODMR). In the absence of a microRNA target, the FND and magnetic particle are associated with DNA hybridization and show low ODMR contrast. If a microRNA target is present, it displaces the FND-MNP hybrid, and the FND shows increased ODMR contrast. Results were collected in a few minutes at room temperature, with between 200 and 600 independent ODMR data points recorded for each sample. The large number of data points allowed robust data analysis. Results. We demonstrated the specific detection of synthetic RNA and DNA oligonucleotides for miR-21-5p and miR-486-5p down to a concentration of 1 pmole. Our NV-Biosensors also detected miR target molecules in total RNA preparations from cell lines. We could not detect miR-486-5p in total RNA from HT-144 and this was consistent with Reverse Transcription-Polymerase Chain Reaction (RT-PCR) results. We used total RNA from HT-144 in spiking studies to demonstrate specific detection of miR-486-5p. Finally, we benchmarked our technology against the gold standard, RT-PCR, and showed that DM was as sensitive as RT-PCR for microRNA detection. DM has the advantage of using single microliter sample volumes and is a simple, accurate assay that can be performed in a fraction of the time needed for RT-PCR

#7630 Shear wave elastography and photoacoustic imaging to non-invasively identify resistant regions in the tumor microenvironment.

Sarah K. Burris[1], Caroline O'Riordan[2], Peter Kesa[2], Philippe Trochet[2], Dieter Fuchs[2]

[1]FUJIFILM VisualSonics Inc., Toronto, ON, Canada,[2]FUJIFILM VisualSonics Inc., Amsterdam, Netherlands

Increased stiffness is a hallmark of malignant tumors and can impede chemotherapy delivery due to elevated interstitial pressure. Clinically, tumor stiffness is assessed using Shear Wave Elastography (SWE); however, small animal imaging systems combining SWE with anatomical, functional, and molecular information have been lacking. Here, we present, for the first time, high-frequency ultrasound with ultrafast plane wave acquisition combined with assessments of capillary function and tumor oxygenation, offering non-invasive, detailed insight into the tumor microenvironment.CT26 murine colorectal carcinoma cells were implanted subcutaneously into the flanks of Balb/C mice to establish solid tumors. Two weeks later, tumor imaging was performed using the Vevo® F2 LAZR-X system. During a single imaging session, tumor structure, vascularization (after intravenous injection of the MicroMarker contrast agent), oxygenation/hypoxia (via photoacoustic imaging), and stiffness (via SWE) were evaluated without moving the animals. An oxygen challenge identified regions responsive to changing conditions (potentially treatable “responder” regions), which were compared with SWE-measured stiffness and vascular data.Our results demonstrate that combining SWE with ultrasound and photoacoustic imaging provides real-time, non-invasive insights into the tumor microenvironment. Regions of high stiffness, identified by SWE, are linked to increased interstitial pressure, which may restrict drug delivery and affect treatment efficacy. By mapping vascular and hypoxic features alongside stiffness, this multimodal approach revealed intra- and inter-tumor heterogeneity. Areas with higher stiffness correlated with non-responsive oxygen regions and lower vascular density, providing a non-invasive representation of evolving tumor characteristics.This study establishes SWE as a powerful tool for non-invasively assessing tumor stiffness and its relationship with hypoxia and vascularity. Integrating SWE with photoacoustic and ultrasound imaging provides a comprehensive, multidimensional method to characterize the tumor microenvironment, moving beyond traditional measures based solely on tumor volume. This advancement enhances understanding of tumor heterogeneity and supports the development of personalized therapeutic strategies, ultimately improving treatment planning and outcomes

#7631 Predicting and preventing cancer stemness in low Earth orbit.

Jessica Pham[1], Wenxue Ma[1], Claire Engstrom[1], Patrick Chang[2], Shuvro P. Nandi[3], Inge van der Werf[1], Emma Klacking[1], Teresa Sposito[1], Kendale Wirtjes[1], Thomas Frias[1], Antonio Ruiz[1], Jane Isquith[2], Luisa Ladel[1], Christina N. Wu[1], Jana Stoudemire[2], Pinar Mesci[4], Kay T. Yeung[5], Rebecca A. Shatsky[5], Anna A. Khachatrian[6], James J. La Clair[7], Michael D. Burkart[7], Peggy Wentworth[2], Curtis L. [1]Department of Medicine, Division of Regenerative Medicine, UC San Diego, La Jolla, CA,[2]Sanford Stem Cell Institute, UC San Diego, La Jolla, CA,[3]Department of Cellular and Molecular Medicine, Department of Bioengineering, UC San Diego, La Jolla, CA,[4]Axiom Space, Houston, TX,[5]Department of Medicine, UC San Diego, La Jolla, CA,[6]Scripps Health, La Jolla, CA,[7]Department of Chemistry and Biochemistry, UC San Diego, La Jolla, CA,[8]Aspera Biomedicines, La Jolla, CA,[9]Center for Computational Biology and Bioinformatics, UC San Diego, La Jolla, CA,[10]Sanford Stem Cell Institute, Dept. of Cellular and Molecular Medicine, Depart. of Bioengineering, UC San Diego, La Jolla, CA

Cancer stemness properties, including enhanced survival, malignant regeneration, telomere deregulation, genomic and epitranscriptomic instability, fuel metastases, and have been linked to stress, retrotransposon and inflammatory cytokine activation, which can occur in low earth orbit (LEO). In NASA Axiom 1, 2 and 3 missions to the ISS, confocal imaging, WGS, RNA-seq and scRNA-seq of lentiviral FUCCI2BL cell cycle and ADAR1-GFP reporter transduced erythroleukemia (TF-1a), colorectal (Caco-2) and metastatic breast cancer (MBC; MDA-MB-231 and patient samples) revealed proliferation, significant genomic instability, HERV and LINE-1 retrotransposon deregulation, and APOBEC3C and ADAR1 activation. Moreover, in Axiom 2 and 3 missions with ADAR1-reporter expressing MBC organoids and in humanized MBC mouse models, an ADAR1p150 splicing modulator, rebecsinib (IND 153126), prevented tumor propagation. Thus, cancer studies in LEO may accelerate the development of innovative cancer therapeutics and countermeasures for long-term spaceflight.

#7632 Plasma proteomics for risk prediction of lung cancer.

[1]Francis Crick Institute, London, United Kingdom,[2]University College London, London, United Kingdom,[3]Centre for Prevention, Detection and Early Diagnosis, Wolfson Institute of Population Health, Queen Mary, University of London, London, United Kingdom,[4]Novartis (Cambridge, MA), Cambridge, MA,[5]Johns Hopkins Bloomberg Sch. of Public Health, Baltimore, MD,[6]Nuffield Department of Population Health, University of Oxford, Oxford, United Kingdom,[7]Department of Epidemiology and Biostatistics, School of Public Health, Imperial College London, London, United Kingdom.[8]University of Oxford, Oxford, United Kingdom,[9]Cancer Epidemiology and Prevention Research Unit, School of Public Health, Imperial College London, London, United Kingdom,[10]University of Oxford, Cancer Epidemiology Unit, United Kingdom,[11]UCL London Cancer Institute, London, United Kingdom

Background: Current lung cancer screening programs rely heavily on age and smoking history, excluding never-smokers and those with minimal smoking exposure. Such criteria have a low positive predictive value (PPV), limiting molecular prevention strategies. Our previous work identified interleukin-1β (IL-1β) as a mediator of lung cancer initiation through environmental particulate matter (PM) exposure, suggesting potential targets for therapeutic cancer prevention. Here, we sought to identify circulating signals predictive of lung cancer prior to clinical diagnosis and determine if they were useful for clinical trial stratification of IL-1β therapy.
Methods: Using human plasma proteomic data from the UK Biobank (n=48,099 individuals; 375 lung cancer cases), we developed a machine-learning framework to identify proteins predictive of lung cancer diagnosis. We validated this model in eight independent human cohorts (2,176 cases, 54,324 controls). We further analysed plasma proteomic murine data from EGFR-mutant mice exposed to PM as well as from baseline samples from the CANTOS trial which previously had demonstrated reduction of lung cancer incidence with IL-1β inhibition.
Results: Our machine-learning approach identified a plasma signature of 14 proteins, predictive of lung cancer diagnosis up to 6 years before clinical detection, significantly outperforming current lung cancer risk models ($p<0.01$ by de Long's test). Validation across eight external human cohorts confirmed consistent associations for all proteins. Mouse experiments demonstrated a sustained increase in circulating signature proteins following PM exposure specifically in EGFR-mutant mice, linking environmental PM exposure directly to the alveolar niche as an early tumour-promoting microenvironment. Retrospective analysis of the CANTOS trial showed the protein signature stratified individuals deriving benefit from IL-1β inhibition, reducing the number needed to treat from 1516 to 55.
Discussion: Our findings indicate that a circulating plasma signature derived from alveolar niche remodelling and induced by PM and EGFR-driven oncogenesis can effectively identify individuals at high risk of lung cancer two years before clinical onset. The identified proteins may enable targeted stratification for molecular prevention trials. Future research should focus on extending this approach and developing absolute quantification assays to for clinical translation.

#7633 Dynamic monitoring and identification of reliable biomarkers to predict efficacy of bireociclib and fulvestrant: An exploratory ctDNA analysis of the BRIGHT-2 study.

Yan Wang[1], Hangcheng Xu[1], Yiran Zhou[1], Liang Cui[2], Qiang Sa[1], Hong Cheng[1], Renchi Gao[1], Qingyuan Zhang[3], HHiping Li[4], Zhongsheng Tong[5], Quchang Ouyang[6], Xinxin Tan[7], Jing Bai[2], Li Wang[8], Xianghui Duan[8], Fan Yang[8], Jiayu Wang[1], Binghe Xu[1]

[1]Cancer Hospital Chinese Academy of Medical Sciences, Beijing, China,[2]Geneplus-Beijing Institute, Beijing, China,[3]Harbin Medical University Cancer Hospital, Harbin, China,[4]Beijing Cancer Hospital, Beijing, China,[5]Tianjin Medical University Cancer Institute and Hospital, Tianjin, China,[6]Hunan Cancer Hospital, Hunan, China,[7]Geneplus-Shenzhen Clinical Laboratory, Shenzhen, China,[8]Xuanzhu Biopharmaceutical Co.Ltd., Beijing, China

Background Although the novel cyclin-dependent kinase 4 and 6 (CDK4/6) inhibitor bireociclib demonstrated potent efficacy for hormone receptor -positive, human epidermal growth factor receptor 2 (HER2)-negative advanced breast cancer in the BRIGHT-2 study (NCT05077449), patient exhibited substantial heterogeneity in therapeutic efficacy—some demonstrated high sensitivity, while others rapidly developed resistance. Consequently, a critical research aim is to ascertain sensitivity before treatment initiation and define biomarkers that can dynamically detect therapeutic outcomes earlier than imaging.

Methods Based on the BRIGHT-2 study, longitudinal circulating tumor DNA (ctDNA) analysis was performed using a 1021-gene panel at baseline, on-treatment, and end-of-treatment timepoints. Somatic mutations were identified and molecular tumor burden index (mTBI) was calculated. Survival analyses employed Kaplan-Meier curves with log-rank tests and Cox proportional hazards models, while the interaction analysis between treatment and gene alternations were conducted using False Discovery Rate (FDR) method. All the analyses were performed using R software, with statistical significance set at $p<0.05$.

Results The bireociclib group collected 197, 139, and 86 ctDNA samples from three timepoints, compared with 79, 46, and 49 from placebo group. The most frequently mutated genes were *PIK3CA* (48%), *TP53* (37%), and *ESR1* (23%). Patients with ctDNA-positive or high mTBI had conspicuously shorter progression-free survival (PFS) and overall survival (OS) than those with ctDNA-negative or low mTBI. The gene alterations in CCND1 and FGF19 were associated with a greater PFS benefit with bireociclib versus placebo (FDR-adjusted P values of 0.030 and 0.002, respectively). The *gBRCA* and homologous recombination repair genes mutation indicated poorer prognosis compared to wild-type in bireociclib group. Dynamic clearance of ctDNA or specific gene mutations was correlated with improved efficacy and survival outcomes for CDK4/6 inhibitor.

Conclusions Both baseline and dynamic monitoring of ctDNA demonstrated salient predictive value for treatment response and survival outcomes in hormone receptor-positive, HER2-negative breast cancer patients receiving bireociclib plus fulvestrant. These potential biomarkers warrant further validation through larger clinical trials and basic researches.

Key words: CDK4/6 inhibitor, advanced breast cancer, biomarkers, bireociclib, prognosis.

#7635 Elucidating the molecular interaction between RELT and Filamin A and the physiological role of this interaction in breast cancer cells.

Samantha Wong[1], Ashley Ko[1], Yashar Pourmoghadam[1], Hunter Hudgins[1], Maryann Batiste[1], Bethany Joy[1], Ashley Christensen[1], Eslam Mohamed[2], John K. Cusick[3]

[1]College of Medicine, California Northstate University, Elk Grove, CA,[2]California Northstate University, Elk Grove, CA,[3]Department of Medical Education, University of California, Merced, Merced, CA

Receptor Expressed in Lymphoid Tissues (RELT) is a member of the Tumor Necrosis Factor Receptor Superfamily that was previously shown to be upregulated in breast cancer. A proteomic screen identified Filamin A (FLNA), an actin-binding scaffold protein involved in various cell processes, including DNA repair, signal transduction, and cell migration, as a potential RELT-interacting partner. FLNA is implicated to play a vital role in breast cancer, as its expression correlates with tumor grade and stage, and it has been shown to bind both BRCA1 and BRCA2. This study aimed to further explore the novel interaction between RELT and FLNA and to characterize its physiological significance.

A yeast two-hybrid screen was utilized to identify a carboxy-terminal fragment of FLNA (C-FLNA) as a potential RELT-binding partner. Transient overexpression of C-FLNA and deletion mutants of RELT in HEK-293 cells, followed by co-immunoprecipitation (co-IP) and western blotting, was performed to identify the binding site on RELT for FLNA. Immunofluorescence (IF) microscopy was used to evaluate RELT-FLNA subcellular colocalization in MDA-MB-231 (231) breast cancer cells. To examine the impact of C-FLNA on RELT's ability to induce cell death, 231 cells, a model for triple-negative breast cancer, were transiently transfected with varying combinations of RELT, FLNA mutants, and empty vector control plasmids. Consequently, these cells were analyzed for apoptosis via flow cytometry, using Annexin V/Propidium Iodide (AV/PI) staining.

Co-IP experiments performed with deletion mutants demonstrated that C-FLNA binds within amino acids 340-400 of RELT's intracellular domain. IF studies confirmed cytosolic colocalization of RELT and FLNA, supporting a direct interaction between these two proteins. Flow cytometry data revealed that co-expression of RELT and C-FLNA induced significantly higher AV/PI staining in 231 cells, indicating greater levels of apoptosis, compared to cells expressing either protein alone.

These findings define an intracellular binding region on RELT for FLNA binding. Furthermore, co-expression of RELT and C-FLNA resulted in significantly enhanced apoptosis in breast cancer cells, suggesting a potentially synergistic effect. Current studies are examining whether RELT expression influences breast cancer cell migration given FLNA's established role in cytoskeletal dynamics and motility. Collectively, these results enhance our understanding of the interaction between RELT, a protein that is upregulated in breast cancer, and FLNA, a protein whose importance for breast cancer has been well established.

#7636 A rare multipotent peg-like epithelial cell is a candidate cell-of-origin for high-grade serous ovarian cancer.

Megan L. Ritting[1], Wenmei Yang[2], Syed Mohammed Musheer Aalam[2], Hui Zhao[2], Liang Feng[2], Jianning Song[2], Mihai G. Dumbrava[1], Wazim M. Ismail[3], Kenneth Schaufelberger[2], S. John Weroha[4], Scott H. Kaufmann[5], Alexandre Gaspar-Maia[3], Mark E. Sherman[6], Jamie N. Bakkum-Gamez[7], Nagarajan Kannan[2]

[1]Mayo Clinic College of Medicine and Science, Rochester, MN,[2]Department of Laboratory Medicine and Pathology, Mayo Clinic, Rochester, MN,[3]Center for Individualized Medicine, Mayo Clinic, Rochester, MN,[4]Department of Medical Oncology, Mayo Clinic, Rochester, MN,[5]Department of Oncology, Mayo Clinic, Rochester, MN,[6]Quantitative Health Sciences, Mayo Clinic, Jacksonville, FL,[7]Department of Obstetrics and Gynecology, Mayo Clinic, Rochester, MN

High-grade serous ovarian cancer (HGSOC), the most prevalent and lethal ovarian cancer subtype, is typically diagnosed at an advanced stage due to the absence of effective early detection strategies. Mounting evidence indicates that HGSOC originates from the fallopian tube (FT), particularly from secretory epithelial cells in the fimbria. However, incomplete understanding of the cellular and molecular origins of HGSOC continues to hinder early interception efforts. To address this, we established a clinically and genetically annotated living FT organoid biobank at Mayo Clinic, representing over 200 patient donors. Using optimized enrichment protocols, we isolated FT epithelial stem/progenitor cells from tissue and Tao brushings, generating organoids independent of anatomical site or laterality that recapitulate native FT epithelial architecture and lineage differentiation. We applied integrated multi-omic analyses, including single-cell RNA sequencing, single-nucleus RNA/ATAC sequencing, and bulk RNA-seq, across fresh cells and organoids. Integration with public datasets produced the largest single-cell atlas of normal and high-risk FTs to date. This analysis defined high-specificity gene signatures for secretory and multiciliated lineages that outperform canonical lineage markers (e.g. *PAX8, FOXJ1*), identified lineage-defining transcription factors and regulatory networks, and showed concordant protein expression in the human FT epithelium. Notably, subcluster-level analysis revealed a rare hybrid epithelial-mesenchymal population transcriptionally and proteomically aligned with the mesenchymal-like subtype of HGSOC. Spatial immunoprofiling demonstrated that these cells express multiple defining markers and reside above the basement membrane, intercalated between epithelial cells and lack luminal contact, reminiscent of the histologically described peg cell population. Comparative analyses with fetal mesonephric tissues uncovered developmental parallels, and this population was stably maintained in 3D organoid cultures, providing a robust *ex-vivo* model to study early transformation. Together, our findings identify a rare, multipotent epithelial population with mesenchymal features as a candidate origin for mesenchymal-like HGSOC and establish the FT organoid biobank as a powerful platform for mechanistic and translational studies in ovarian carcinogenesis.

#7637 Genome-wide CRISPR screening reveals a PKA-driven resistance mechanism to metformin for oral cancer prevention that can be exploited by combination with NSAIDs.

Thomas S. Hoang[1], Farhoud Faraji[2], Amaya Mendez-Molina[1], Sendi R. Adame-Garcia[1], Kuniaki Sato[1], Tomohiko Ishikawa[1], Pham Thuy Vo[1], Sydney Ramirez[3], Paola Y. [1]Pharmacology, UCSD Moores Cancer Center, La Jolla, CA,[2]Otolaryngology-Head and Neck Surgery, UCSD, La Jolla, CA,[3]La Jolla Institute for Immunology, La Jolla, CA,[4]Pathology, UCSD Moores Cancer Center, La Jolla, CA,[5]UCSD Moores Cancer Center, La Jolla, CA,[6]UCSD, La Jolla, CA

Head and neck squamous cell carcinoma (HNSCC) is among the ten most common cancers worldwide and is associated with high morbidity and poor survival. Diminished HNSCC outcomes are often related to delayed diagnosis and treatment of occult progression of premalignant lesions, underscoring the need for effective and low risk chemoprevention strategies. In this regard, metformin has shown promising clinical activity for HNSCC prevention. Here, we performed a genome-wide CRISPR/Cas9 screen of metformin-treated HNSCC cells and identified activation of PKA signaling as the top resistance pathway. We show that metformin mediates PKA activation in HNSCC cells, and that PKA inhibition (PKAi) when combined with metformin treatment synergistically inhibits HNSCC growth. We found that metformin-induced PKA activation is mediated by a prostaglandin E2 (PGE2) autocrine loop, which can be blocked using cyclooxygenase-2 (COX2) inhibitors. Importantly, COX2 inhibition using non-steroidal anti-inflammatory drugs (NSAIDs) combined with metformin treatment synergistically inhibits of HNSCC cell growth and prevents progression of oral premalignant lesions (OPLs) into invasive HNSCC in a model of tobacco driven oral carcinogenesis. Together, these findings demonstrate that metformin and NSAID combination therapy may represent a promising therapeutic strategy for HNSCC chemoprevention.

#7639 Primate comparative oncology reveal humans' unique cancer susceptibility.

[1]University of Arizona Cancer Center, Tucson, AZ,[2]University of Arizona College of Medicine - Phoenix, Phoenix, AZ,[3]University of Utah Huntsman Cancer Institute, Salt Lake City, UT,[4]North Carolina State College of Veterinary Medicine, Raleigh, NC,[5]Peel Therapeutics, Inc, Salt Lake City, UT,[6]UCSF Medical Ctr., Goleta, CA,[7]Arizona State Univ. Biodesign Institute, Tempe, AZ

Studying cancer from an evolutionary perspective can yield important theoretical and applied insights; however, little is known about the prevalence of cancer among non-human primates. Non-human primates are our closest living relatives, yet the primate lineage is phenotypically diverse, exhibiting wide variation in evolutionary and life-history characteristics. By integrating comparative phenotypic data with prevalence records of neoplastic disease, we assembled a dataset of 2,095 individuals from 36 species across nine primate families to examine cross-species cancer risk. Additionally, functional in vitro studies using isolated and cultured primary fibroblast cell lines from representative species show that resistance to cellular death correlates with certain life-history traits. Comparative phylogenetic modeling of human cancer risk, situated within the broader primate phylogeny, demonstrates a drastic reduction in cancer risk even among primates most closely related to humans (e.g., the great apes). Together, large-scale cancer prevalence records and functional assays provide valuable insights into the ecological and cellular dynamics of cancer in our closest living relatives—and in ourselves.

#7640 Ciliated cells drive critical STING-mediated tumor suppression in fallopian tube epithelium.

Mitigating DNA damage in the fallopian tube epithelium (FTE) is essential for preventing tubo-ovarian high-grade serous carcinoma (HGSC). Here we demonstrate that STING is abundantly expressed in the ciliated cells of the FTE and functions as a critical immune-independent tumor suppressor. Using patient samples, mouse models, and organoid systems, we demonstrate that ciliated cells mount a dual protective response to ovulation-associated genotoxic stress: intrinsic STING-driven apoptosis and extrinsic clearance of neighboring damaged secretory cells via TNFα secretion. This surveillance mechanism markedly limits DNA damage accumulation within the epithelial microenvironment. Crucially, while these mechanisms are vital for maintaining homeostasis and reducing genomic instability, they fail to impact p53-deficient precursor lesions as both intrinsic and extrinsic pro-apoptotic processes rely on functional p53 signaling. This study uncovers a previously unrecognized, immune-independent role for STING-high ciliated fallopian tube cells as active guardians of genomic integrity, whose loss creates a permissive niche for HGSC initiation.

#7641 Decoding the spatial architecture of the immune microenvironment in mismatch repair-deficient colorectal carcinogenesis.

Abel Martel-Martel[1], Nan Deng[1], Melissa W. Taggart[2], Araceli Garcia-Gonzalez[1], Jacklyn V. Thompson[1], Luigi Ricciardiello[3], Y. Nancy You[4], Selvi Thirumurthi[4], Krishna M. Sinha[1], Eduardo Vilar[1]

[1]Clinical Cancer Prevention, The University of Texas MD Anderson Cancer Center, Houston, TX,[2]Pathology, The University of Texas MD Anderson Cancer Center, Houston, TX,[3]Gastroenterology, Hepatology and Nutrition, The University of Texas MD Anderson Cancer Center, Houston, TX,[4]Colorectal Surgery, The University of Texas MD Anderson Cancer Center, Houston, TX

Introduction: Lynch Syndrome (LS) is the most common hereditary colorectal cancer syndrome and is secondary to germline mutations in the mismatch repair (MMR) genes. Upon acquiring a second somatic hit, epithelial cells become MMR-deficient (MMRd) and accumulate high number of indel mutations in microsatellite loci, generating frameshift peptides (mutated neo-antigens). These neo-antigens activate robust immune responses and promote the expansion of specific T-cell clonotypes. However, the spatial organization of immune-epithelial compartments, and how MMR loss shapes early immune surveillance and escape, remains unclear.

Methods: We dissected the immune microenvironment across the LS carcinogenesis axis using spatial transcriptomics to interrogate over 5,000 genes and 27 LS neoantigen-specific TCR clonotypes from our LS cohort at MD Anderson. We studied a total of 41 colorectal biopsies from 23 LS and 15 sporadic cases that were arranged in tissue microarrays and analyzed according to MMR status and malignancy, thus representing the largest spatial transcriptomic dataset generate to date in the context of LS.

Results: Spatial profiling using Xenium platform identified distinct epithelial, immune, and stromal domains across LS and sporadic samples. Relative to normal mucosa, adenomas showed expansion of proliferating transit-amplifying epithelium, cancer stem-like cells, REG4^{+} epithelia, and a shift toward M2b-enriched macrophages, consistent with signs of early immune modulation. Neo-antigen-specific TCRs increased along the pathology axis and localized near dysplastic glands. MMRd adenomas displayed enrichment of activated monocytes/macrophages, plasma cells, inflammatory epithelium, and broad induction of interferon-responsive and cytokine-mediated pathways, thus reflecting strong innate and adaptative immunity. CD8^{+} T cells in MMRd lesions also expressed higher CTLA-4 levels, indicating activation-induced inhibitory signaling and early exhaustion. Compared to sporadic samples, LS tissues showed stronger immune activation, larger inflammatory and remodeling neighborhoods, and increased macrophage and plasma-cell infiltration. Multiple neo-antigen-specific TCR clones appeared exclusively in LS lesions, supporting enhanced immune surveillance.

Conclusions: Spatial transcriptomics reveals coordinated remodeling of epithelial, immune, and stromal neighborhoods driven by pathology progression, MMR loss, and LS background. These spatial patterns provide insights into immune-epithelial interactions during LS neoplasm progression, establishing spatial biomarkers that may inform surveillance and immune interception strategies in hereditary gastrointestinal syndromes, such neo-antigen-based vaccination for boosting the expansion, infiltration, and effector function of tumor-specific T cells in MMRd cancers.

#7642 Nicotine dependence partially mediates the association between *IP6K3* genetic variation and risk of lung squamous cell carcinoma among smokers.

Jing Jin[1], Yasir Rahmatallah[2], Horacio Gomez-Acevedo[2], Yong-Moon (Mark) Park[3], David Ussery[2], Mohammed Orloff[3]

[1]Biostatistics, University of Arkansas for Medical Sciences, Little Rock, AR,[2]Biomedical Informatics, University of Arkansas for Medical Sciences, Little Rock, AR,[3]Epidemiology, University of Arkansas for Medical Sciences, Little Rock, AR

INTRODUCTION: Nicotine dependence is a heritable trait that may mediate genetic susceptibility to lung cancer. Building on a prior integrative genomic study that identified significant SNPs and their annotated genes located within tracts of homozygosity (TOH) overlapping differentially methylated regions (DMRs) in lung tissue, we investigated whether these SNPs and haplotypes within these methylation-driven genes were associated with Non-Small Cell Lung Cancer (NSCLC) risk through pathways involving nicotine dependence among smokers.

METHODS: The study included individuals with lung adenocarcinoma (LUAD), lung squamous cell carcinoma (LUSC), and population-based controls from a genome-wide association study (GWAS). Genes exhibiting differential expression with an absolute $\log_2$ fold-change ≥2 between tumor and adjacent normal tissues were retained as candidate loci for SNP- and haplotype-based mediation models. Within candidate genes, linkage disequilibrium blocks were defined to construct haplotypes. Multivariable logistic regression models adjusted for age and sex were used to estimate SNP- and haplotype-level associations with NSCLC risk by subtypes. Individuals carrying a significant haplotype were coded as exposed. Causal mediation analyses were used to estimate the proportion of each SNP or haplotype's effect on NSCLC risk that was mediated by nicotine dependence, measured by the Fagerström Test for Nicotine Dependence (FTND). Structural equation modeling (SEM) further quantified direct and indirect associations among age, sex, cancer status, smoking cessation status, smoking pack years, nicotine dependence (FTND), and carrier status for the significant haplotypes.

RESULTS: The *IP6K3* haplotype "GTGTG" (rs649775-rs2966-10947433-rs4713668-rs6457740) was inversely associated with LUSC risk, with approximately 39% of its protective association mediated by nicotine dependence (average causal mediation effect [ACME]=-0.023, 95% CI: -0.039, -0.010). Consistent with this pattern, *IP6K3* rs2966 (TT vs CC; CT vs CC) and rs4713668 (TT vs CC; CT vs CC) exhibited significant indirect effects via nicotine dependence (ACME ranges from -0.023 to -0.027; *p*-values between 0.004 and 0.024), accounting for 33-38% of their total protective effects on LUSC risk.

CONCLUSION: These findings identify *IP6K3* as a potential candidate gene in nicotine-related lung carcinogenesis and highlight the relevance of neurobiological dependence pathways in personalized smoking cessation and lung cancer prevention strategies.

#7643 A novel pH-sensitive probe to quantify autophagy on high throughput/content imaging platforms.

Giuseppe D. Ciccotosto[1], Lorenzo Lorenzo[2], David L. Hare[3], **Peter J. Wookey**[1]

[1]Medicine-Austin, University of Melbourne, Heidelberg, Australia,[2]Fox Chase Cancer Center, Philadelphia, PA,[3]University of Melbourne, Melbourne, Australia

Autophagy is deregulated in various pathological conditions including cardiovascular, neurological, neoplastic, autoimmune and degenerative disorders. However, clinically relevant pharmacological modulators of autophagy remain elusive, calling for the development of novel screening approaches, amenable to high throughput/content applications. Cellular responses were imaged with the novel CalRexin^{TM}:pHrodo^{TM} Red (CalRexin^{TM}, Apop Biosciences Pty Ltd) reagent on the Operetta high content screening platform. Human cervical carcinoma HeLa cells, and mutants *RB1CC1-/- (FIP200)* and *ATG5-/-* were induced for autophagy with rapamycin, torin-1 and serum deprivation and inhibited with 3-methyladenine, MRT68921, chloroquine and bafilomycin A1. The co-localisation with pixel definition between CalRexin^{TM}:pHrodo^{TM} Red and markers of early and late endosomes and autolysosomes was studied with high resolution confocal microscopy and Fiji software. Pixel co-localization analysis demonstrated significant overlap between CalRexin^{TM}:pHrodo^{TM} Red and markers of early and late endosomes, as well as LysoTracker^{TM}, a marker of autolysosomes.CalRexin^{TM}:pHrodo^{TM} Red is accumulated via the endosome-amphisome-autolysosome (low pH ~4.5) pathway, thus connecting to canonical autophagy and yielding a bright fluorescent signal. CalRexin^{TM}:pHrodo^{TM} Red provides a novel approach for imaging autophagy on high throughput/content platforms and is adaptable for screening large chemical libraries for the identification of novel autophagy-modulators as potential drugs for treatment of chronic diseases.

#7647 Ecotype-guided multi-omics profiling identifies potential cell-surface therapeutic targets in gastric cancer.

Yuefan Wang[1], Lindsey K. Olsen[2], Hui Zhang[1], Bing Zhang[2], Clinical Proteomic Tumor Analysis Consortium (CPTAC)

[1]Pathology, Johns Hopkins University, Baltimore, MD,[2]Baylor College of Medicine, Houston, TX

Gastric cancer (GC) exhibits marked heterogeneity, complex molecular alterations, and limited therapeutic options. To comprehensively define its biology and vulnerabilities, we performed 15-layer multi-omics profiling of 159 gastric adenocarcinomas and 30 matched normal adjacent tissues, encompassing genomics, epigenomics, transcriptomics, proteomics, post-translational modifications, protein–protein interactions, metabolomics, and microbiome analyses, yielding more than 385,000 features. By integrating cell-state deconvolution, we defined gastric tumor ecotypes based on cellular states, providing a new framework for multi-omics integration. These ecotypes captured distinct tumor ecosystems and stromal–immune compositions and offered deeper mechanistic insight than conventional genomic or histologic classifications.Leveraging machine learning and large-scale AI models, we identified ecotype-specific molecular features and linked them to clinical outcome. To prioritize therapeutic opportunities, we applied high-outlier analysis to proteins and glycoproteins. Multiple cell-surface–associated targets showed strong high-outlier expression, including several known or emerging therapeutic candidates. Extracellular matrix (ECM) components were significantly enriched among high-outlier proteins, underscoring their central role in tumor growth, invasion, and potential therapeutic targeting. We further characterized altered cell-surface glycosylation patterns in high-outlier glycoproteins, revealing changes in immune regulation and ECM engagement. Phosphosite-resolved analysis identified key signaling signatures associated with aggressive tumor behavior.Importantly, embedding these high-outlier events within ecotype and genomic subtype frameworks revealed distinct, ecotype-specific patterns that were not apparent from genomic classification alone. Single-cell analyses localized many targets to specific stromal compartments, particularly fibroblast-rich ecosystems, suggesting that targeting fibroblast-driven niches may provide new therapeutic strategies for aggressive GC subsets. Overall, this study establishes an ecotype-guided proteogenomic approach to nominate cell-surface proteins, glycoproteins, and signaling nodes as precision therapy candidates in gastric cancer, and offers a broadly applicable model for dissecting heterogeneity in other complex malignancies.

#7648 Plasma proteo-transcriptomic integration identifies molecular signatures and circulating biomarkers in ependymomas.

Rafat Malik[1], Ritu Kulshreshtha[2], Amandeep Kumar[3], Vaishali Suri[1], Mehar Chand Sharma[1]

[1]Neuropathology, Neurosciences Centre, All India Institute of Medical Sciences (AIIMS), New Delhi, India,[2]Department of Biochemical Engineering and Biotechnology, Indian Institute of Technology Delhi, New Delhi, India,[3]Neurosurgery, All India Institute of Medical Sciences (AIIMS), New Delhi, India

Background: Ependymomas (EPNs) are heterogeneous central nervous system (CNS) tumors that lack reliable blood-based biomarkers for diagnosis, prognosis, treatment monitoring, and recurrence detection. We generated the first plasma proteo-transcriptomic atlas of pediatric EPN to define circulating signatures across tumor subtypes, grades, treatment states and recurrence.
Methods: Plasma from 33 EPN patients and seven controls was analyzed using quantitative label-free untargeted LC-MS/MS and integrated with 44 tumor Total RNA sequencing and six control (differentially expressed genes (DEGs); $|\log_2 FC| \geq 1$, FDR < 0.05). Differentially expressed proteins ($|\log_2 FC| \geq 0.58$, FDR < 0.05) were examined via GO/KEGG/Reactome enrichment, STRING protein-interaction networks, and multi-omics concordance analyses. Biomarkers correlated with Cyclin D1 positivity, 1q gain, ZFTA-RELA fusion, and CDKN2A loss. CancerMine contextualizes known oncogenic roles.
Results: We identified 270 dysregulated plasma proteins that delineated a systemic pattern of ECM activation, coagulation complementation, lipid metabolic reprogramming, and humoral immune suppression. FN1 was the top marker, elevated 26.36-fold in subependymoma, 7.66-fold in supratentorial, and 6.37-fold in posterior fossa tumors, sharply decreasing post-treatment (1.64-fold), reflecting tumor dynamics. APOE (3.29-fold), APOD, APOH, APOA4, and TMEM198 (2.12-fold) were consistently elevated and decreased after therapy. Immune suppression was evident, with JCHAIN reduced to 0.32-fold, immunoglobulins (IGHD 0.07-fold), and complement proteins (C1QB, C4A/B) downregulated. IGHV3-35 was elevated pre-treatment (2.03-fold) and at recurrence, serving as a dual biomarker. LPA and SERPINF1 were recurrence-specific, and CD5L was supratentorial-specific. Transcriptomics identified 1,286 DEGs, of which 132 mapped to plasma proteins (57 upregulated, 75 downregulated). FN1, TMEM198, and IGKC showed RNA-protein concordance, whereas APOE, APOD, and JCHAIN showed secretion-driven discordance. STRING analysis revealed dense ECM and coagulation-lipid interaction hubs (PPI $p < 1 \times 10^{-16}$). CancerMine validated oncogenic roles of FN1, APOE/APOD, JCHAIN, C1QB, and TTR in other cancers, novel to EPN. Biomarkers were strongly correlated with aggressive genotypes.
Conclusion: This plasma proteo-transcriptomic atlas revealed a robust systemic signature in pediatric EPN, defined by ECM remodeling, coagulation dominance, metabolic rewiring, and immune suppression. Key biomarkers, such as FN1, TMEM198, APOE/APOD, IGHV3-35, JCHAIN, LPA, and SERPINF1, offer strong potential for non-invasive diagnosis, stratification, therapy monitoring, and early recurrence detection, establishing plasma proteomics as a transformative precision oncology platform.

#7649 Urinary arsenic speciation and metabolic indices associate with exposure chemistry and prostate cancer aggressiveness.

Sithembiso S. Msibi[1], MinJae Lee[2], Ping-Ching Hsu[3], L. Joseph Su[1]

[1]UT Southwestern Medical Center, Dallas, TX,[2]UT Health, Houston, TX,[3]University of Arkansas for Medical Sciences, Little Rock, AR

Background: Prostate cancer (PCa) is the second most common type of cancer among men worldwide. Environmental exposure to arsenic has been implicated in PCa carcinogenesis and progression through various pathways. This study assessed arsenic species and methylation indices and their association with aggressive PCa.

Methods: We analyzed data from 1,497 men (722 Black and 775 White) enrolled in the North Carolina-Louisiana Prostate Cancer Project (PCaP), including 396 with high and 1,101 with low aggressive PCa. Urinary arsenic species concentrations were quantified using HPLC-ICPMS and adjusted for urine dilution using creatinine. We assessed the arsenic species including inorganic arsenic (iAs), monomethylarsonate (MMA), and dimethylarsinate (DMA) and methylation indices (Primary Methylation Index and Secondary Methylation Index) between low vs. high aggressive groups using univariable tests. We also performed multivariable logistic regression models, adjusting for screening history, waist-to-hip ratio (WHR), age, smoking status, study site and race.

Results: Univariable comparisons showed no significant difference in individual arsenic species and methylation indices with low vs. high aggressive PCa (all p>0.10). However, median concentrations of total inorganic arsenic (iAs+DMA+MMA) showed a marginal difference between low vs. high aggressive PCa (1.34[0.39-2.68] vs. 1.49[0.62-3.02], p=0.06). When comparing race, Black and White men had similar levels of total iAs (1.35[0.42-2.86] vs. 1.39[0.46-2.68]; p=0.83). Multivariable logistic regression models showed overall positive association with elevated arsenic concentrations, with tertile 2 and 3 showing significantly higher odds of aggressive PCa (OR: 1.39, 95% CI: 1.01-1.91, p = 0.04 and OR: 1.45, 95%CI: 1.07-1.97, p = 0.02, respectively). A significant linear trend was also observed across increasing total iAs tertiles (p-trend=0.02). Race-stratified models showed significant association for White men (OR: 1.68, 95% CI: 1.05-2.67, p = 0.03) and not statistically significant association for Black men (OR: 1.34, 95% CI: 0.89-2.03, p = 0.16). Race did not modify the association between total iAs and aggressive PCa (p-interaction = 0.76). PMI and SMI were not significantly associated with aggressive PCa in adjusted models (OR: 1.01, 95% CI: 0.81-1.25, p = 0.91; and OR: 1.13, 95% CI: 0.96-1.33, p = 0.14).

Conclusions: Our findings show that elevated urinary inorganic arsenic levels are associated with increased odds of aggressive prostate cancer, independent of race and methylation efficiency. The results point to inorganic arsenic, rather than its methylated metabolites, as the key chemical driver of prostate cancer progression. This connection between arsenic speciation and prostate cancer aggressiveness underscores the translational importance of environmental chemistry in cancer prevention.

#7650 High-resolution detection of post-translational modifications using single-molecule protein sequencing.

Natchanon Sittipongpittaya[1], Khanh (Kendrick) Dinh Quoc Nguyen[2], Andrey Reshetnyak[3], Muriel Priault[4], Ajay Vashisht[5], John Vieceli[5], **Meredith Carpenter**[5], Nidhi Sahni[6], Gloria Sheynkman[1]

[1]Molecular Physiology and Biological Physics, University of Virginia, Charlottesville, VA,[2]Quantum-Si, San Diego, CA,[3]Structural Biology, St. Jude Children's Hospital, Memphis, TN,[4]IBGC, University of Bordeaux, Bordeaux, France,[5]Quantum-Si, Branford, CT,[6]Neurosurgery, Baylor College of Medicine, Temple, TX

Post-translational modifications (PTMs) play a critical role in regulating protein function and cellular processes. However, due to the diversity and complexity of the proteome, detecting and quantifying PTMs remains challenging. While conventional mass spectrometry and antibody-based methods provide valuable information, they are limited in their capacity to resolve and quantify PTMs at the amino acid level, particularly for PTMs with minimal differences in mass. The Quantum-Si Platinum® and Platinum® Pro sequencers are benchtop instruments designed for high-resolution, single-molecule protein sequencing. These instruments use engineered N-terminal amino acid recognizers to accurately determine the sequence composition of proteins, enabling the detection of PTMs and making advanced proteomic analysis accessible in a standard laboratory setting. In addition to leveraging the recognizer binding patterns, the recent development of PTM-specific binders further enhances the instrument's ability to detect and quantify PTMs by selectively targeting modified residues. This combined approach improves sensitivity and specificity, allowing researchers to quantify PTMs and obtain even more detailed PTM profiles on a single run. In this study, we investigated the application of single-molecule protein sequencing on Platinum Pro to detect and quantify multiple PTMs across diverse protein types. We demonstrate the detection of phosphorylation order at several sites within the anaplastic lymphoma kinase (ALK) protein, citrullination events on vimentin, asparagine deamidation as a marker of molecular ageing, and the identification and differentiation of aspartic acid stereoisomers in calmodulin sequences. This is the first study demonstrating the ability to resolve and quantify multiple PTMs on the Platinum Pro, enabling differentiation of chemical changes and stereochemical variants that, while subtle, can nevertheless have significant biological impacts. Platinum Pro can also be used to add proteoform characterization to biomarker studies, providing additional resolution not readily available in broad biomarker screening panels. We expect this technology to democratize advanced protein characterization, making the high-resolution detection of PTMs available to a broader scientific community.

#7652 Two-way proteogenomics identifies tumor-specific, immune-visible peptides for immunotherapy development in triple-negative breast cancer.

Moran Chen, Jong Min Choi, Zhiao Shi, Wenrong Chen, Bing Zhang

Baylor College of Medicine, Houston, TX

Introduction: Triple-negative breast cancer (TNBC) is an aggressive disease with limited treatment options. Despite its frequently inflamed tumor microenvironment, TNBC exhibits poor and inconsistent responses to immunotherapy, highlighting the need for alternative strategies, such as TCR-based therapy and cancer vaccines. These approaches depend on robust identification of HLA-presented, tumor-specific peptides that are visible to the immune system. To address this need, we applied immunopeptidomics together with a new proteogenomic integration framework to a panel of TNBC cell lines to establish a foundation for a comprehensive antigen resource to support peptide-based immunotherapy development.

Methods: Five TNBC cell lines were profiled with and without IFN-γ stimulation. Whole-genome sequencing, whole-exome sequencing, RNA-seq, Ribo-seq, and immunopeptidomic data were jointly analyzed using NeoFlow2, a next-generation two-way proteogenomics framework. In addition to the conventional forward approach, in which genomic and transcriptomic data inform proteogenomic database searches, NeoFlow2 introduces a reverse direction by mapping de novo-sequenced peptides back to the transcriptome to reveal unannotated translation events. NeoFlow2 further assesses tumor specificity using PepQueryMHC, which evaluates peptide-level transcript support in tumor versus normal RNA-seq data across TCGA and GTEx cohorts.

Results: NeoFlow2 revealed a markedly expanded repertoire of both canonical and non-canonical peptides across the profiled TNBC cell lines, with IFN-γ stimulation further enhancing antigen diversity. Among these, the pipeline identified hundreds of non-reference peptides arising from diverse genomic and transcriptomic origins, including missense mutations, frameshifts, alternative splicing, UTRs, intron retention, non-coding RNAs, and alternative ORFs. Leveraging TCGA and GTEx datasets, we prioritized peptides presented in TNBC tumors but absent from normal tissues, yielding a focused set of TNBC-specific antigens with strong immunotherapeutic potential.

Conclusions: NeoFlow2 provides an effective framework for integrating multi-omics and immunopeptidomic data to systematically identify canonical and non-canonical tumor antigens. In TNBC cell lines, this framework revealed a set of TNBC-specific antigens with potential relevance for peptide-based cancer immunotherapy.

#7653 Novel therapeutic opportunities in POU2F3 transcription factor-driven small cell lung cancer.

Lily L. R. Rix[1], Hayley D. Ackerman[1], Nicole R. Hackel[1], Xueli Li[1], Rachel Leigh O'Rourke[2], Juhyeon Son[1], Michelle A. Reiser[1], Arianna Nenci[1], Bin Fang[1], Eric A. Welsh[1], Brandon J. C. Klein[1], John M. Koomen[1], Eric B. Haura[1], Florian Karreth[1], Amanda Garner[2], Elsa R. Flores[1], **Uwe Rix**[1]

[1]H. Lee Moffitt Cancer Center & Research Institute, Tampa, FL,[2]University of Michigan, Ann Arbor, MI

Small cell lung cancer (SCLC) is a recalcitrant cancer characterized by loss of *TP53* and *RB1*. POU2F3+ SCLC cells are uniquely dependent on IGF1R signaling although this has not yet led to clinical translation. We therefore aimed to identify efficacious pharmacological targeting approaches for POU2F3+ SCLC and elucidate the underlying mechanisms.Cell viability was measured by CellTiter-Glo and soft agar assays. Drug targets and signaling pathways were identified by quantitative mass spectrometry-based proteomics and validated by Western blot. POU2F3 mutants were cloned to determine the kinase responsible for phosphorylation of POU2F3 the cellular effects of POU2F3 phosphorylation. Loss- and gain-of-function experiments were done using CRISPR, RNAi, chemical probes, or protein expression. Xenograft tumors were obtained by subcutaneous injection of POU2F3+ H526 cells into athymic nude mice. *POU2F3* overexpressing, transgenic $Rb1^{fl/fl}Trp53^{fl/fl}(Myc^{LSL/LSL})$ (RP/RPM) mice are being generated by genetic engineering and transfer of embryonic stem cells.Combination drug screening identified synergistic combinations between ALK-inhibitors with cross-reactivity for IGF1R and WEE1 inhibitors abrogating cell growth *in vitro* and in *in vivo*. Efficacy differences between the IGF1R inhibitors suggested the presence of additional druggable targets. Merging proteome-wide drug targets with changes in protein signaling and expression highlighted mTOR and cell cycle pathways and RSK1/2 as a relevant off-target. Interestingly, changes in both POU2F3 phosphorylation itself and expression of downstream POU2F3 transcriptional targets were identified upon individual or combination drug treatment and confirmed by immunoblotting. Rescue by overexpression of POU2F3 phospho-mutants upon CRISPR knockout of endogenous POU2F3 suggest an inhibitory function for pPOU2F3. Brigatinib and ceritinib, two potent FDA approved ALK/IGF1R inhibitors, were found to synergize with WEE1 inhibitors, in POU2F3+ SCLC. Quantitative, global chemical proteomics analysis found overlapping target profiles indicating favorable polypharmacology beyond IGF1R inhibition. Furthermore, quantitative phospho- and expression proteomics and subsequent genetic validation identified a novel regulatory mechanism of the oncogenic transcription factor POU2F3 by loss-of-function phosphorylation, which is strongly induced by drug combination treatment. This modification may indicate a new actionable vulnerability, which could be targeted to benefit the greatly underserved SCLC patient population.

#7654 Unique oncogenic mechanisms of ultrahigh-frequency mutant PTEN^{R130G}in endometrial cancer.

Xiangyi Kong[1], Li Wang[2], Md Kamrul Hasan Khan[2], Jidong Wang[3], Huaijun Zhou[1], Xinyan Wu[2]

[1]Nanjing Drum Tower Hospital Affiliated to Nanjing University Medical School, Nanjing, China,[2]Mayo Clinic Cancer Center Minnesota, Rochester, MN,[3]Jinan Central Hospital Affiliated to Shandong University, Jinan, China

Phosphatase and Tensin Homolog (PTEN) is a critical tumor suppressor frequently mutated in cancers, notably endometrial cancer (EC), where it drives early carcinogenesis. PTEN mutations disrupt lipid phosphatase activity, causing PI3K/AKT/mTOR pathway hyperactivation. However, clinical trials targeting this pathway in advanced EC yield suboptimal outcomes, with PTEN loss showing poorly predictive value for therapeutic response, indicating other mechanisms are involved. TCGA Pan-Cancer Atlas data show a 39.1% co-mutation rate of PTEN and PIK3CA in EC, much higher than the 3.6% pan-cancer rate, challenging the idea of mutual exclusivity in driver mutations within the same pathway. PTEN missense mutations are most common in EC (41.44%), with R130 as a hotspot, especially among PIK3CA-mutant patients (45.28%), while other cancers with frequent PTEN mutations show much lower R130 rates. These findings suggest PTEN R130 missense mutants undergo positive selection and may have unique oncogenic effects in EC.To characterize these mutants, a Tet-on inducible system in PTEN-null SPAC-1-S EC cells compared wild-type PTEN (PTEN^{WT}), loss of function mutant PTEN^{R173C}, and ultrahigh frequency mutant PTEN^{R130G}. PTEN^{WT} suppressed proliferation, PTEN^{R173C} showed reduced tumor suppressive activity, while PTEN^{R130G} increased proliferation, indicating a PTEN^{WT}-independent tumor-promoting function. In MFE 296 cells with PTEN $^{R130Q/N332fs}$ mutations, knockdown of PTEN^{R130Q} suppressed proliferation, providing functional evidence that PTEN^{R130G} has PTEN^{WT}-independent oncogenic activity in EC.

To elucidate the underlying mechanisms, we performed quantitative proteomic and BioSITe analyses in SPAC-1-S cells inducibly expressing PTEN^{WT} or PTEN^{R130G}, enabling comprehensive mapping of the unique signaling alterations specific to this ultrahigh-frequency PTEN^{R130G} mutant. Our initial analysis revealed that PTEN^{WT} induction caused broad transcriptional suppression of oncogenic and structural pathways, including MAPK/ERBB, focal adhesion, ECM-receptor interaction, and lysosomal function, consistent with restored tumor-suppressive activity. In contrast, PTEN^{R130G} induction led to a distinct transcriptional response; while partially repressing lysosomal and adhesion pathways, stress-adaptive and metabolic programs like TGF-β signaling and glutathione metabolism remained active or were reactivated. These results suggest PTEN^{R130G} not only loses PTEN's inhibitory functions but may gain new transcriptional and metabolic activities that promote cell survival and tumor progression. Overall, our analysis indicates wildtype PTEN restores signaling restraint, while PTEN^{R130G} reprograms the transcriptome toward a pro-cancer, stress-resilient state, suggesting a gain-of-function oncogenic role.

#7655 Defining molecular interfaces of glyco-immune checkpoint ligands using tandem mass spectrometry and ion-ion reactions.

Tim S. Veth, Haley M. Schramm, **Nicholas M. Riley**

Chemistry, University of Washington, Seattle, WA

The Siglec (sialic acid-binding immunoglobulin-like lectin) family of glycan-binding immune receptors are emerging as attractive targets for cancer immunotherapy. Siglecs recognize cell surface glycoproteins through complex interactions with various glycans containing sialic acid residues, which are upregulated in numerous malignancies. Engagement of Siglecs by their sialoglyco-ligands elicits an inhibitory signaling cascade using the same immunoreceptor tyrosine-based inhibitory motif (ITIM) signaling domains shared by established immune checkpoint receptors (e.g., PD-1, CTLA-4, and SIRPα). Our understanding of the mechanisms behind Siglec-mediated immune evasion has been rapidly improving, largely due to efforts to define transcriptional and metabolic programs that promote Siglec ligand expression. Even so, unknown combinations of glycan and protein epitopes (i.e., the glycocode) that guide Siglec ligand recognition are a major hurdle for exploiting Siglecs as therapeutic targets. Molecular details of specific glycocode patterns that contribute to Siglec ligand recognition are needed to target immune modulatory glycoforms in tumor-specific microenvironments while minimizing off-target effects, but these heterogenous modifications states challenge traditional analytical approaches. Here, we describe our efforts to develop cutting-edge mass spectrometry (MS) data acquisition technologies that incorporate electron transfer dissociation (ETD) and proton transfer charge reduction (PTCR) ion-ion reactions to profile highly complex Siglec ligand glycoproteins. We use online and offline MS workflows in combination with bottom-up glycoproteomics to profile highly heterogeneous intact glycoproteoforms of Siglec ligands that have emerged as attractive targets for next-generation glyco-immunotherapies. PTCR readily isolated and charge-reduced proteoforms of interest, generating pseudo-native spectra. PTCR scans of interest were identified, and spectra were cleaned using in-house software, PTCRcleaner. Analysis of both intact approaches was supported by bottom-up mass spectrometry data collected using a sceHCD-pd-EThcD approach. We also applied this workflow to characterize other glycosylated immune checkpoint ligands, e.g., PD-L1. Altogether, our novel tandem MS approaches that uniquely leverage ion-ion reactions enable the characterization of highly heterogeneous glycoproteoform repertoires, contributing to a deeper understanding of the complexity of the glycocode and how these proteins contribute to heterogeneity in the tumor-immune synapse.

#7656 Comprehensive investigation of stool metaproteomes among patients with precancerous lesions and colorectal cancer.

Emmalee J. Northrop-Albrecht, Vinod K. Gupta, William R. Taylor, Jason P. Sinnwell, Doug W. Mahoney, Patrick H. Foote, Kelli N. Burger, Jaeyun Sung, John B. Kisiel

Mayo Clinic, Rochester, MN

INTRODUCTION: Colorectal cancer (CRC) is the 2nd most fatal cancer in the U.S.; most benefits of CRC screening are from detection of advanced pre-cancerous lesions (APLs). With a goal to improve non-invasive stool test APL sensitivity, we sought novel APL signatures in stool metaproteomes (host- and gut microbiome-derived proteins) among cancer-free controls (CTRL), APL, and CRC patients. Since dysbiosis in gut microbiota is associated with CRC initiation, we also examined the microbial source of differentially expressed proteins (DEPs).
METHODS: Mass spectrometry was performed on archival stool supernatants (n=63 patients; 15 CTRL, 32 APL [16 adenomas & 16 sessile serrated lesions], 16 CRC). A sectioning and database-enrichment strategy was applied for peptide-spectrum matching. Microbial and human-derived proteins were searched against the Integrated Gene Catalogue (IGC) and UniProt human reference proteome. DEPs were identified using thresholds of $P < 0.05$ and fold-change ≥ 1.5. Pathway annotation of human DEPs was performed with the REVIGO webserver, while gut microbial DEPs were functionally categorized using the KEGG Automatic Annotation Server (KAAS). To assess the taxonomic distribution of microbial DEPs, sequences were aligned against the NCBI non-redundant database using BLASTP.
RESULTS: Mass spectrometry detected 879 human and 32,514 microbiome-derived proteins. When limiting detection to proteins present in ≥ 75% of patients, only 117 human and 204 microbial proteins remained. There were 17 (4,875), 288 (9,638), and 63 (3,053) unique human (microbial) proteins detected in CTRL, APL, and CRC groups, respectively. When the protein presence cutoff was set at >30% of patients, there were 52 (13 human [11 upregulated, 2 downregulated], 39 microbial [28 upregulated, 11 downregulated]) DEPs detected for the CRC + APL vs CTRL comparison. Some pathways associated with upregulated human DEPs included: inflammatory response, cellular response to iron, and endothelial cell migration. The top upregulated microbial DEPs were derived from the Phocaeicola, Lachnospiraceae, and Oscillospiraceae genera. The top downregulated microbial DEPs belonged to the Bacteroides, Eubacterium, Agathobacter, Coprococcus, and Blautia genera.
CONCLUSION: This work highlights the biological diversity and molecular heterogeneity of the stool proteome. We identified several host and microbial protein markers that differentiate APLs and early CRC from controls. These results provide a foundation for future validation studies, which are necessary to determine the clinical utility of these protein biomarkers prior to their integration into a noninvasive stool test.

#7657 An AFA assisted workflow for mass-spectrometry based proteomics of FFPE samples.

Dong-Gi Mun[1], Kiran Mangalaparthi[1], Daigo Gunji[2], Amy J. French[1], Raghavendra Pasupuleti[3], Cristine Charlesworth[1], Sameer Vasantgadkar[4], DEB BHATTACHARYYA[4], Akhilesh Pandey[5]

[1]Mayo Clinic, Rochester, MN,[2]Mayo Clinic Cancer Center Minnesota, Rochester, MN,[3]Mayo CLinic, Rochester, MN,[4]Covaris, Woburn, MA,[5]Mayo Clinic, Rochseter, MN

Introduction: The intricate cellular structure is a constantly evolving environment where cells interact, communicate, and adapt to their surroundings. The fate, role, and actions of each cell are shaped by its specific location within the tissue. Therefore, studying the spatial proteome is crucial for gaining a deeper understanding of physiological or pathological processes. With significant advancements in microscopy and mass spectrometry, it has become feasible to explore the cellular proteome at low or even single cell numbers. However, spatial proteomics is an evolving field with scope for newer sample preparation and data analysis techniques. Our objective was to develop a sample preparation workflow for analyzing proteome from limited cells extracted from formalin fixed paraffin embedded (FFPE) tissue using laser capture microdissection (LCM).

Methods: One hundred cells from the FFPE normal colon tissue were extracted by LCM and collected into an AFA-compatible 96-well plate. Decrosslinking was performed at 90ºC for 50 minutes followed by lysis in a buffer composed of 100 mM triethylammonium bicarbonate and 0.1% n-dodecyl-β-D-maltoside using adaptive focused acoustic (AFA) energetics in scanning mode for 5 minutes. After lysis, the proteins were digested using Trypsin/Lys-C mix using AFA energetics for 1 hour. The resulting peptides were acidified with trifluoroacetic acid and analyzed on a timsTOF Ultra 2 mass spectrometer coupled to a nanoElute 2 liquid chromatography system using a 15 cm (75 µm) IonOpticks column, in DDA-PASEF mode for a total run time of 34 minutes. The data were searched against the UniProt Human Reviewed protein database using MSFragger.

Results: We utilized AFA energetics to extract and digest proteins from a limited number of cells isolated from FFPE tissue using LCM. This experiment was conducted with technical replicates to ensure accuracy and reliability. A total of 3,723 proteins were identified across the three replicates, with replicate 1 identifying 3,895 proteins, replicate 2 identifying 3,754 proteins, and replicate 3 identifying 3,519 proteins. In total, we identified 21,005 peptides, with replicate 1 identifying 22,896 peptides, replicate 2 identifying 22,377 peptides, and replicate 3 identifying 17,741 peptides from 100 colon cells. Notably, we observed a 70% overlap in the proteins identified across the three replicates, which highlights the reproducibility of the approach.

Conclusion: The entire sample preparation process, after cell collection, was completed within a concise four-hour timeframe, demonstrating the efficiency of this methodology for analyzing protein profiles from small cell populations. Further, this approach is highly adaptable to automation and high-throughput applications. Its adaptability and scalability make it a promising strategy for spatial proteomics applications.

#7658 Mapping mutation-specific interaction and signalling networks across FGFR1-4 to understand cancer-associated rewiring.

Iftekhar Mahmud Chowdhury, Xiaonan Liu, Markku Varjosalo

University of Helsinki, Helsinki, Finland

Fibroblast growth factor receptors (FGFR1-4) are essential receptor tyrosine kinases that play a crucial role in controlling cellular fate, guiding tissue development, and maintaining physiological balance. Cancer-driving mutations in FGFRs are found in many tumour types, but exactly how each mutation alters receptor behaviour, protein interactions, and signalling pathways is still not fully understood. In this study, we systematically analysed wild-type, kinase-dead, and two cancer driver mutants for each FGFR paralogue by generating stable, isogenic Flp-In™ T-REx™ 293 cell lines which were engineered under inducible expression for each FGFR variant. We performed affinity purification-mass spectrometry (AP-MS) and proximity-dependent biotinylation (BioID) to generate high-confidence mutation-level map of FGFR interactomes, integrating both stable and transient protein associations. To understand the functional implications of the altered interactome we performed phosphoproteomics on both global lysates and affinity-purified complexes. This enabled quantification of pathway-specific signalling changes and differentiation between the catalytic and scaffolding roles of mutant receptors. Distinct signalling rewiring patterns were observed between wild-type and mutant FGFRs such as preferred activation of MAPK versus PI3K-AKT signalling pathway and revealed mutation-specific signalling biases consistent with recent models of RTK signalling divergence. Functional assays in NIH3T3 and U2OS cells, including colony formation, immunofluorescence, cell cycle profiling, and reporter assays, validated the differential oncogenic potential and subcellular localisation of each variant. We further evaluated the effects of clinically relevant FGFR inhibitors on the viability and signalling pathway activity across all mutants, identifying both drug-sensitive and drug-resistant classes linked to specific mutations, including gatekeeper substitutions (e.g., FGFR4-V550L) and extracellular loop alterations (e.g., FGFR2-S252W). Together, our findings establish the first paralogue-wide, mutation-resolved signalling atlas of the FGFR family. This integrative approach of structural, functional and pharmacological analysis provides systematic insight into oncogenic mechanism and therapeutic sensitivity and establishes a broadly applicable framework for the functional annotation of kinase driver mutations in cancer.

#7660 Altered cell surface N-glycosylation implicates hypersialylation in breast cancer brain metastasis.

Judith Nwaiwu, Wenjing Peng, Akhila Reddy, Xue Dong, Parisa Ahmadi, Jingfu Zhao, Yifan Huang, Peilin Jiang, Waziha Purba, Oluwatosin Daramola, Yehia Mechref

Department of Chemistry and Biochemistry, Texas Tech University, Lubbock, TX

Breast cancer is the second most common cause of brain metastasis, often in advanced-stage disease. The mechanisms underlying breast cancer brain metastasis (BCBM), particularly how tumor cells cross the blood-brain barrier and adapt to the brain environment, remain unclear. Cell surface glycosylation plays diverse roles, and its dysregulation in cancer can disrupt signaling and promote metastasis. We investigated how changes in cell surface N-glycans contribute to BCBM by analyzing N-glycans released from human breast cancer cell lines (MDA-MB-231, MDA-MB-361, HTB-131, HTB-22), a brain-seeking variant (MDA-MB-231BR), and glioblastoma cells (CRL-1620) using nano liquid chromatography-tandem mass spectrometry (LC-MS/MS). Surface N-glycans were enzymatically released from live cells with PNGase F without compromising membrane integrity. Results showed the 231BR cell line expressed higher levels of sialylated N-glycans than other cells, with N-glycan 4502 as the most abundant. Four sialylated structures (4501, 4502, 3501, 5602) were significantly elevated in 231BR, suggesting a role in brain metastasis. This study expands understanding of altered N-glycan profiles in BCBM and highlights potential molecular features linked to brain colonization. Further research on these N-glycans could clarify their function in mediating metastasis and identifying therapeutic targets.

#7661 Integrated multiomics profiling of lysates using nCounter® protein and RNA panels for comprehensive oncology insights.

Brian Filanoski, Lori Hamanishi, Giang Ong, Terence C. Theisen, Erin Piazza, Christina Bailey, Prajan Divakar, Margaret L. Hoang, Joseph M. Beechem

Research and Development, Bruker Spatial Biology, Seattle, WA

Multiomic approaches combining transcriptomic and proteomic data are critical for understanding complex biological systems in oncology. The nCounter® platform enables simultaneous quantification of RNA and protein targets from the same sample, reducing variability and maximizing biological insight. This innovation builds upon the demonstrated clinical utility of classic nCounter mRNA assays in translational and clinical research, including Prosigna®(FDA-cleared), Lymph2Cx, and Merck's Tumor Inflammation Signature (TIS). Lysates were prepared from eight different cancer cell lines (HT-29, Daudi, PC-3, U-937, LNCaP, HeLa, PANC-1, MCF-7) following optimized protocols for nCounter multiomics. Protein targets were profiled using the new nCounter Tumor Signaling Panel plus Immune Pathways (500+ Abcam RabMab monoclonal antibodies) and combined with IO360 gene expression panel for integrated analysis. Using 5,000 - 20,000 lysed cells, we find high reproducibility between replicate lysate, with low coefficient of variation (CV) for RNA and protein across replicates. Sensitivity of detection was maintained down to 50 ng of RNA and 200 ng protein per lysate. As expected median Pearson correlation between RNA and protein expression for overlapping markers was $R < 0.5$, highlighting the high multiomics assay information content. In addition, integrated analysis of transcript and protein levels uncovered concordant activated pathways, including key post-translational modifications (PTMs). This study demonstrates the feasibility and utility of lysate-based multiomics using nCounter panels for oncology research. The approach provides a streamlined workflow for comprehensive molecular profiling, supporting translational studies and biomarker discovery.

#7662 A high-throughput, automated, and reproducible mIF workflow for spatial biology enabled by ZEISS slide stream and Vizgen's InSituPlex® assays.

Cassandra Kysilovsky[1], Kevin Hwang[1], Susanne Pfeifenbring[2], Michael Downing[1], Sherry Derakhshani[2], Moritz Widmaier[2], Jiang He[1], Angela Vasaturo[1]

[1]Vizgen, Cambridge, MA,[2]Zeiss, Jena, Germany

Multiplex immunofluorescence (mIF) has become a cornerstone technique in spatial biology for investigating the tumor microenvironment. Despite its widespread use, existing mIF workflows are often hindered by variability in image acquisition and dependence on labor-intensive manual steps. To overcome these limitations, we developed a fully integrated, high-throughput spatial biology workflow combining the highly standardized and automated ZEISS spatial biology platform with Vizgen's pre-optimized InSituPlex assay. Together, these deliver high-throughput, fully automated, and reproducible biomarker detection across a broad dynamic range, enhancing both efficiency and scalability. To validate these claims, we conducted a multisite verification study. A 4-plex OmniVUE panel including CD3, Ki67, Granzyme-B and CK/Sox10 was utilized to stain multiple tissue indications on formalin-fixed paraffin-embedded (FFPE) sections. On all sites, the slides underwent the same predefined and automated routine for staining using Leica Bond RX instruments and imaging using ZEISS Axioscan 7 spatial biology slide scanners. Acquired images were seamlessly uploaded to Mindpeak and analyzed with integrated STARVUE algorithms optimized for Vizgen InSituPlex assays imaged on Axioscan scanners, providing quantitative analysis for densities and fluorescence intensities of positive cells. Analysis of the results demonstrated excellent concordance between sites, confirming the precision and accuracy of the combined workflow across multiple operators and instruments. Qualitatively, staining was highly comparable across all sites, and the limited variations in fluorescence signal and background did not affect the accuracy of the STARVUE™ AI algorithms. Quantitatively, the presented workflow exhibits high reproducibility and repeatability of results across locations, providing a reliable solution for translational research with amplified speed and quality of data generation. As a result, it offers significant potential to advance spatial biology from translational research to clinical applications

#7663 Discovery of tumor-specific and neoantigenic peptides in cancer tissue samples using mass spectrometry-based immunopeptidomic.

Cameron Ellis[1], Arhur Viode[2], Anamarija Pfeiffer[2], Lucy Yang[2], Monika Pepelnjak[2], George Rosenberger[2], Polina Shichkova[2], Kristina Marx[3], Christopher Below[2], Roland Bruderer[2]

[1]PreOmics Inc., Billerica, MA,[2]Biognosys AG, Schlieren, Switzerland,[3]Bruker Daltonics GmbH & Co. KG, Bremen, Germany

Therapeutic peptide-based vaccination is a promising strategy for cancer immunotherapies. The identification of tumor-specific antigens is key to developing therapies. Mass spectrometry has emerged as the primary technique for the identification of peptides presented on human leukocyte antigen (HLA), i.e., immunopeptides. While tremendous progress has been made, the analysis of immunopeptides remains challenging. This is especially true for scarce clinical tissue, with amounts below 20mg. Here, we present a robust and scalable workflow utilizing the BeatBox tissue homogenizer that enables deep immunopeptidomics profiling of clinically relevant samples, facilitating the discovery of tumor-specific and neoantigenic peptides for therapeutic development. A total of 33 tissue samples from 11 donors are homogenized under native conditions with the BeatBox tissue homogenizer using the BeatBox Tissue Kit 24x kit (PreOmics). Immunopeptides are isolated using a pan anti-HLA class 1 antibody (W6/32) coupled to magnetic protein A beads in a semi-automated manner on the KingFisher (Thermo Fisher). Peptides are eluted under acidic conditions and filtered using a 10kDa MWCO plate. The immunopeptides are loaded onto Evotips (Evosep) for analysis using the Whisper Zoom method from Evosep coupled to a timsUltra AIP (Bruker) mass spectrometer. Data analysis is performed using Spectronaut 20 (Biognosys) using directDIA. For the RNA sequencing, total RNA was extracted from fresh frozen tissue samples and sequenced using Illumina 2×150 bp paired-end reads (~100M reads per sample). We analyzed matched tissue samples from 11 HLA-typed colorectal cancer donors, including healthy tumor-adjacent tissue, primary tumors, and metastatic tumors (n = 33). We profiled over 80,000 peptides with an average of 10,000 per sample using directDIA. Overall, more than 70% of the peptides were predicted to be binders (MHCFlurry). Integration of MS-based immunopeptidomics data with RNA sequencing enabled the identification of key antigens that could be used for the development of immunotherapy. We identified neoepitopes shared between tumors and metastatic tumors within patients as well as unique neoepitopes in tumors. Amongst detected neoepitopes, multiple patented or previously established immunotherapy targets were observed. Taken together, we have developed a robust workflow for the immunopeptidome profiling of clinically relevant samples and identification of neoepitopes. These findings demonstrate the potential of this workflow to support personalized cancer vaccine development and advance precision immunotherapy strategies.

#7664 An automated sequential protein/DNA/RNA extraction workflow for comprehensive multiomics analysis from cells and tissue.

Laure Jobert[1], Charmaine Hinahon[2], Leigh Foster[3], Marie Holter-Sorensen[1], Samri Michael[1], Iwona Grad[1], Lina Zheng[4], Berit Reed[1]

[1]Thermo Fisher Scientific, Oslo, Norway,[2]Thermo Fisher Scientific, Austin, TX,[3]Thermo Fisher Scientific, Rockford, IL,[4]Thermo Fisher Scientific, Carlsbad, CA

Introduction: The integration of proteomics, genomics, and transcriptomics is crucial for comprehensive biological insights. We have developed an automated sequential Protein/DNA/RNA workflow designed to reproducibly isolate high-quality protein, DNA, and RNA from the same sample using the KingFisher™ SamplePrep Purification System, enhancing the efficiency, through-put and depth of multiomics studies.
Methods: Our sequential Protein/DNA/RNA extraction workflow utilizes a magnetic bead-based approach, leveraging the well renowned Dynabeads™ and MagMAX™ magnetic beads technologies. This enables efficient isolation of protein, DNA, and RNA from as few as 1,000 cells or 1 mg of tissue. The workflow is compatible with both manual and automated processing on the KingFisher™ sample purification system, accommodating a wide range of sample numbers from low to high throughput.
Results:

- Mass Spectrometry (MS): The workflow produces high-quality proteins suitable for MS analysis. Comparative studies with the EasyPep™ MS Sample Prep Kit show similar chromatograms, peptide properties, and distribution profiles among biological processes and cellular components, as well as absence of incompatible reagents.
- Next-Generation Sequencing (NGS): The workflow yields high-quality nucleic acids compatible with NGS. Whole genome sequencing and rRNA depletion sequencing demonstrate excellent molecular depth, coverage and uniformity, with robust QC metrics across various sample types.

Conclusion: The sequential Protein/DNA/RNA workflow offers a versatile and efficient solution for multiomics research, providing high-quality analytes compatible with both MS and NGS. This magnetic bead-based workflow, utilizing Dynabeads™ and MagMAX™ magnetic beads, is ideal for precious and small samples, enabling reproducible data and high throughput capabilities. For Research Use Only. Not for use in diagnostic procedures.

#7665 Multi-step antibody validation for nCounter high-plex multiomics panels.

Giang Ong, Terence C. Theisen, Brian Filanoski, Lori Hamanishi, Erin Piazza, Christina Bailey, Prajan Divakar, Margaret L. Hoang, Joseph M. Beechem

Research and Development, Bruker Spatial Biology, Seattle, WA

Expanded development on the nCounter® Analysis System now enables simultaneous quantification of over 500 proteins and up to 800 transcripts from a single FFPE tissue sample. With the introduction of two high-plex protein panels used in combination with any prebuilt nCounter® RNA Panel this new capability brings a novel non-destructive FFPE assay with new depth, simplicity and reliability for immuno-oncology multiomics research. The nCounter® platform has long been known as the gold standard for oncology and immunology studies including diagnostic development. Confirming performance in support of translational and clinical applications is essential part of this capabilityTo ensure high data integrity in this complex environment, we developed a rigorous multi-step antibody validation pipeline. The process begins with an initial IHC screening, performed by our antibody partner AbCam, to confirm specificity in known positive and negative tissues. These single-plex IHC validated antibodies are individually conjugated to nCounter-compatible UV-cleavable oligonucleotides. Functional performance of the high-plex protein panels was assessed using more than 90 cell lines and more than 100 tissue cores from over 30 tissue types featuring cancerous and healthy FFPE samples. Sensitivity and specificity are benchmarked against available orthogonal RNA-Seq and mass spectrometry datasets for the cell lines. The specificity of phospho-specific antibodies was also tested in a phosphatase treatment assay, confirming that >90% of signal is reduced with treatment.To demonstrate the compatibility of these antibodies in a high-plex panel, we show antibody performance remains robust when our protein panels are stacked together or run independently. Finally, reproducibility is confirmed across users and runs. This validation framework ensures high specificity, sensitivity, and reproducibility, enabling confident multiomic profiling of complex tissue samples and accelerating translational insights in cancer biology.

#7666 Comprehensive surfaceome profiling reveals tumor specific targets in osteosarcoma.

Snehal D. Ganjave[1], Kevin K. Leung[1], Leanne C. Sayles[2], Alejandro Sweet-Cordero[1], James A. Wells[3]

[1]UCSF - University of California San Francisco, San Francisco, CA,[2]Lab Manager, Pediatrics Cancer Biology, University of California, San Francisco, CA,[3]UCSF Comprehensive Cancer Ctr., San Francisco, CA

Osteosarcoma (OS) is an aggressive bone cancer characterized by significant genomic alterations. Despite recent efforts to study OS, the extracellular proteins driving tumorigenesis and metastasis in xenograft models remain understudied due to technical limitations in enriching low-abundance surface proteins. Here, we employed quantitative surfaceome profiling via Wheat Germ Agglutinin (WGA)-HRP mediated cell surface protein enrichment to map the dynamic surface protein landscape of primary and metastatic OS, uncovering clinically actionable targets. We applied an integrated proteomics approach combining WGA-HRP-based cell surface capture and deep offline peptide fractionation coupled with DIA-PASEF mass spectrometry to achieve deep and accurate surfaceome coverage. Primary and metastatic OS cell lines (n = 9) and PDX tumors (n = 4-5), along with controls (n = 3), were analyzed using WGA-HRP mediated surface enrichment followed by Neutravidin based pulldown. PDX tumors were mechanically dissociated to obtain single suspensions. Enriched proteins were fractionated offline, and a deep spectral library was generated using high-pH fractionation and DDA-PASEF, enabling high-resolution, quantitative mapping of the OS surfaceome across diverse samples. The optimized workflow identified ~6,000 total proteins, of which over 600 were validated as druggable surface proteins through Surfy database (FDR < 0.01). PCA revealed clear separation of samples by disease state and phenotype, demonstrating the high reproducibility and biological fidelity of the surfaceome profiles. Comparative analysis of all metastatic OS cell lines vs. controls identified numerous highly dysregulated surface proteins ($log_2FC \geq 5$). The surfaceome profile revealed both reported & novel targets, including a pronounced and coordinated upregulation of proteins critically involved in enhanced nutrient transport and metabolic reprogramming, key cell-cell adhesion and structural maintenance molecules, and prominent growth signaling receptors. These upregulated functional classes are critically implicated in enhanced metastatic capacity and aggressive tumor progression. These findings provide a comprehensive surfaceome map of OS remodelling, revealing interconnected, tumor-specific dysregulation and actionable surface targets. The identified protein classes highlight potential biomarkers for early diagnosis, prognosis, and monitoring therapeutic response, and can guide the rational development of targeted biologics and immunotherapies to improve outcomes for OS patients.

#7667 Integrating multi-omics and AI-driven approaches into STEMM education to advance cancer research training.

Shixia Huang

Baylor College of Medicine, Houston, TX

Preparing future scientists to address the complexity of cancer requires early exposure to advanced analytical methods and transdisciplinary thinking. We developed scalable STEMM education programs that integrate multi-omics and artificial intelligence into cancer research training across multiple learner levels. Central to this effort is the Biotechnology Research Incubator for Teachers (BRITE), an NIH R25 Science Education Partnership Award program providing secondary-school teachers with hands-on multi-omics training rooted in cancer biology. By incorporating genomics, proteomics, and data-driven interpretation, BRITE equips teachers to translate authentic cancer research practices into classroom learning. Building on this foundation, the NCI-funded P20 Cancer Research Education Program (C-REP) engages undergraduate and graduate/PharmD trainees in multi-omics workflows, tumor signaling pathways, and computational analyses. We also established the IMPACT Medical Scholar Program, which introduces medical students to cancer research methodologies, advanced analytics, and patient-centered communication. To broaden the early pipeline, we created high-school programs that use AI-assisted adapted primary literature and culminate in a student research symposium. Collectively, these programs provide a scalable model for integrating advanced technologies into STEMM education to strengthen participation in cancer research.

#7668 Characterization of outer membrane vesicles (OMVs) from *pks+*NC101 and *pks-*DH10B *E. coli* strands.

Lissette Marie Perez-Rovira[1], Grace Enid Velez Crespo[2], Luis A. Prieto-Costas[2], Jeremy J. Colon-Morales[2], Abel Baerga-Ortiz[2]

[1]University of Puerto Rico Comprehensive Cancer Center, San Juan, PR,[2]UPR Molecular Science Research Center, San Juan, Puerto Rico

Background & Objectives: Colibactin is a genotoxin encoded by the *pks* genomic island in pathogenic Gram-negative bacteria and has been implicated in colorectal cancer. Colibactin synthesis and activation occur in a two-step process in which pre-colibactin is produced in the bacterial cytoplasm and subsequently activated into colibactin within the periplasmic space. However, the mechanism by which *pks*$^+$ bacteria export colibactin to host cells remains unclear. We hypothesize that outer membrane vesicles (OMVs), nanosized proteoliposomes released by Gram-negative bacteria capable of transporting diverse biomolecules, serve as a delivery system for this toxin to host cells.

Methods: To investigate this, OMVs were isolated from *pks*$^+$ NC101 and *pks*$^-$ DH10B *E. coli* strains using the exoEasy Maxi Kit and quantified with a BSA-based protein assay on a Synergy H1 microplate reader.

Results: Yielding concentrations consistent with typical OMV preparations. The stability and morphological characteristics of the extracted OMVs will be evaluated using dynamic light scattering (DLS). Metabolites extracted from OMVs will be examined via mass spectrometry to confirm the presence of known colibactin-related intermediates. Additionally, OMVs will undergo proteomic analysis to identify proteins involved in OMV-host interaction mechanisms. Finally, we aim to assess the effects of OMV exposure on large intestinal epithelial cells to better understand their contribution to colibactin-associated toxicity and colorectal cancer development.

Conclusion: Ultimately, this research seeks to clarify how OMVs mediate colibactin transport and cytotoxicity, providing new insights into bacterial factors that promote colorectal carcinogenesis.

Acknowledgements: This research was funded by the National Institute of Allergy and Infectious Diseases (NIAID) Grant #5R25AI183304-02.

#7669 Automated multiplex profiling of human cytokines and autoantibodies using an Automated Assay Workstation.

Wen-Rong Lie, Brooke Gilliam, Laura Marquardt, Mark Pawlicki, Ernest Mueller, Xiuyuan Zhang, Nathanael Ellis, Todd Hendrich, Linda Meeh, Scott Keefer, Qiang Xiao

MilliporeSigma, Burlington, MA

Automated multiplex bead-based immunoassays were performed using an AAW™ Automated Assay Workstation for high-throughput profiling of immune factors and cancer autoantibodies. Human serum cytokine analysis was conducted with MILLIPLEX Human Cytokine Panel A and Panel B kits (48-plex, overnight protocol), and across cytokines spanning a broad dynamic range, automated-to-manual correlation coefficients (R^2) were greater than 0.95 with regression slopes between 0.80 and 1.20. Cancer autoantibody profiling used a 15-plex antigen-coated bead multiplex panel on sera from various cancer types and healthy donors (n=96 total samples). The AAW™ workstation automates all critical liquid handling, standard curve preparation, sample transfer, reagent dispensing (matrix solution, Assay Buffer, Standards, QCs, samples, and Beads), and plate setup with robotic lidding. Assay plates were washed off-deck on an automatic plate washer and analyzed with a Luminex instrument. The automated protocol enabled processing of 2-3 plates daily, with streamlined setup which significantly reduce hands-on time. Minimizing manual interventions reduced opportunities for human errors, resulting in greater reliability and efficiency for high-throughput applications. The AAW™ performance confirms robust, reproducible, and scalable multiplex analysis for cancer and immunology research.

#7670 Integrated mass spectrometric workflows enabling next-generation conjugate therapeutics in cancer research.

Min Fang, Nilesh Sonawane, Wenchuan Ma, Benjamin Wei, Qingcong Lin

Medicilon, Lexington, MA

Antibody-drug conjugates (ADCs) and the broader class of Antibody-X Conjugates (AXCs)—including emerging Antibody-Oligonucleotide Conjugates (AOCs)—are rapidly advancing as therapeutic modalities in oncology and autoimmunity. Their expanding impact increases the need for robust bioanalytical strategies capable of quantifying total and conjugated antibodies, released payloads, and associated biotransformation pathways.LC-MS/MS has become an essential platform for addressing the analytical complexity of AXCs, supporting hybrid LBA-LC-MS workflows for total and conjugated antibodies, as well as direct measurement of free payloads and payload metabolites. Click-chemistry-enabled drug systems, designed for tumor-selective activation, present similar analytical challenges that require high sensitivity and specificity. The platform described here meets these demands through enhanced sensitivity, selectivity, and comprehensive biotransformation characterization.We developed an integrated LC-MS/MS workflow tailored for ADC, AXC, and AOC programs. Optimized controlled-reduction and selective-extraction methods enabled accurate quantification of diverse payload classes—including auristatins (MMAE/MMAF), topoisomerase-I inhibitors (DXd, SN-38, exatecan), and associated linker-drug species—while minimizing artificial payload release. These assays demonstrated high sensitivity, linearity, and matrix robustness across plasma, tumor, tissue, and cell-based systems, supporting reliable pharmacokinetic, stability, and biotransformation assessments.A complementary bioorthogonal click-chemistry workflow using azide-alkyne and TCO-tetrazine reactions was also established to selectively tag precursor and product species, enhancing MS detectability and enabling quantitative analysis of activation behavior.Together, these LC-MS/MS-based approaches provide a unified analytical solution for ADCs, AOCs, AXCs, and click-activated therapeutics. The platform supports comprehensive in vitro, ex vivo, and in vivo pharmacokinetic studies across plasma and tissue matrices, facilitating robust PK/PD correlation and exposure profiling for these emerging modalities.

#7671 Integrated proteogenomics of primary tumoroid models for precision oncology.

Shawn P. Fahl, Audrey Kleeman, Jessica Maxwell, Yukta Bhurke, Jessica Moore, Jaison Arivalagan, Kerri Colwell, Cavin Ott, Kayla Williams, Danielle Gutierrez

Discovery Life Sciences, Huntsville, AL

The availability of scalable primary oncology models remains an impediment to preclinical evaluation of new therapeutic strategies. Recently, primary tumoroid models have been developed to aid in early-phase evaluation of drug compounds. These models are generated from dissociated primary tumors and can be expanded through numerous passages, from a conventional, embedded dome stage through a suspension state, which allows for the generation of a large number of tumoroids for comprehensive studies. The tumoroid lines maintain the underlying genomic and transcriptomic signatures of the parent tumor from the initial, early-passage embedded stage to later-passage suspension cultures. These models are highly amendable to in vitro evaluation of cell-intrinsic therapeutic interventions, as well as cell-extrinsic modalities, since tumor-resident immune and stromal cells from the parent tissue are preserved in the cryopreserved dissociated tissue. Proteogenomics is the integration of genomic, transcriptomic, and proteomic datasets to uncover novel biological insights that cannot be uncovered with a single data set alone. Tumoroids represent the most physiologically relevant oncology models to understand the relationship between DNA variants, RNA expression, and protein expression. Mass spectrometry-based proteomic data were generated from the tumoroid models and searched against sample-specific databases generated from whole exome sequencing as well as whole transcriptome data for a comprehensive overview of the biology of the tumoroids. This robust analysis was further supported by drug response data of the tumoroids exposed to a standard set of classical chemotherapeutic compounds and small-molecule inhibitors. We identified a colorectal cancer tumor model with a pathogenic KRAS-G12C mutation, and how treatment with the clinical KRAS-G12C inhibitor sotorasib altered global protein expression was further evaluated. Additionally, high mutational burden tumoroids generated from deficient DNA mismatch repair endometrial tumors were analyzed to better understand how DNA hypermutation affects global protein expression. Collectively, these studies establish a pipeline to generate a holistic view of tumor cell biology, enabling for the discovery of new biomarkers and drug targets.

#7672 Automated, flexible multiplex immunofluorescence for tumor microenvironment profiling using HCR™ Gold IF and clinically-relevant antibody clones.

Wudy Yang[1], Randy Chen[1], Harry Choi[1], Aneesh Acharya[1], Anne Hellebust[2], Will Howat[3]

[1]Molecular Instruments, Inc., Los Angeles, CA,[2]Indica Labs, Albuquerque, NM,[3]Abcam, Cambridge, United Kingdom

Background: Multiplexed immunofluorescence (mIF) is central to oncology research but is often limited by fixed panels, antibody modification requirements, harsh stripping, and workflows that risk epitope damage. HCR™ Gold IF enabled by HCR™ HiFi Encoders addresses these constraints by providing enzyme-free amplification with universal compatibility to unmodified rabbit IgG and mouse IgG1 primaries. Here, we evaluated a complete, interoperable workflow combining automated HCR™ Gold IF on Leica Biosystems' BOND RX staining instrument, validated Abcam antibodies, and quantitative image analysis using Indica Lab's HALO platform for tumor microenvironment (TME) profiling.

Methods: FFPE tissue sections from healthy tissues and tumors were stained via HCR™ Gold IF on the BOND RX staining instrument. Panels included epithelial, proliferation, immune, and checkpoint markers (e.g., panCK, Ki67, CD3, CD8, CD68, PD-1, PD-L1). All primary antibodies were obtained from Abcam and qualified in a single-plex experiment prior to multiplex assembly. Slides were imaged with whole-slide scanners and analyzed in the HALO® platform to quantify biomarker expression and interrogate spatial relationships between cell populations.

Results: The automated, protease-free workflow generated high signal-to-background with crisp subcellular localization and clean channel separation across tissues and targets. Universal compatibility with unmodified Abcam antibodies streamlined panel design and minimized assay development time. Single-plex to multiplex concordance met predefined acceptance criteria, indicating minimal epitope masking or channel cross-talk. Across tumor cohorts, we observed expected and quantifiable TME shifts versus matched healthy tissues, including elevated PD-L1 on tumor/myeloid compartments and increased CD8+ and CD68+ densities at tumor-stroma interfaces.

Conclusions: Integrating HCR™ Gold IF, powered by the HiFi Encoders, on the BOND RX staining instrument and analyzing in the HALO platform delivers an automated, plug-and-play mIF solution that couples superior, enzyme-free amplification with true bring-your-own-antibody flexibility. This end-to-end workflow lowers barriers to custom, high-plex TME studies, preserves tissue integrity, and enables standardized generation of spatial biomarkers to inform immune-oncology research and patient stratification. The approach is readily extensible to larger panels and to combined RNA/protein co-detection for deeper, multi-omic context. For Research Use Only. Not for use in diagnostic procedures.

#7673 9-channel spatial co-detection of clinically relevant protein and RNA targets in FFPE tumors with HCR™ Gold and MoxiePlex.

Wudy Yang[1], Randy Chen[1], Harry Choi[1], Aneesh Acharya[1], Minakshi Singh[2], Quyen Vu[3]

[1]Molecular Instruments, Inc., Los Angeles, CA,[2]Hamamatsu Photonics Europe GmbH, Herrsching am Ammersee, Germany,[3]Hamamatsu Corporation, Bridgewater, NJ

Background: High-plex spatial profiling of protein & RNA in FFPE tumors is increasingly important for characterizing tumor-immune interactions, but existing methods often limit exploration to predefined antibody panels, harsh stripping/eluting steps, and iterative cycles that compromise sample and target integrity and make assay development and validation burdensome. HCR™ Gold IF, enabled by the HiFi Encoder, supports enzyme-free fluorescent detection using unmodified, user-supplied primary antibodies and operates on the same amplification platform as HCR™ Gold RNA-FISH. Combined with the Hamamatsu MoxiePlex multispectral tissue imaging platform, which enables whole-slide single-round imaging of 7-9-plex panels without the need for cyclic-staining, this workflow offers a practical route to flexible, 7-9-plex protein and RNA co-detection in FFPE specimens.

Methods: FFPE human tumor sections were stained with HCR™ Gold IF using encoded, clinically validated primary antibodies alongside HCR™ HiFi Probes. Two parallel multiplex configurations were tested on the MoxiePlex:1. 7-plex panel: DAPI, 425, 488, 546, 594, 700, 7502. 9-plex panel: DAPI, 425, 488, 514, 546, 594, 633, 700, 750Panels incorporated antibodies specific to cancer-relevant proteins (e.g., pan-CK, Ki-67, PD-L1, CD8, CD68) & RNA targets representing tumor and immune biology (e.g., EPCAM, CXCL9, CD274). For each fluorophore-target combination, single-stain reference slides were generated to establish exposure settings, verify filter performance, and quantify spectral bleed-through to enable spectral unmxing. Multiplex slides were imaged in a single acquisition round, and data were evaluated for signal intensity, channel crosstalk, expected biological localization, and concordance with single-stain references. Spectral unmixing was carried out automatically for the whole- slide image, following acquisition, as part of the imaging process.

Results: HCR™ Gold IF & HCR™ Gold RNA-FISH produced bright, robust signals with preserved tissue architecture. In whole- slide multiplex imaging, protein and RNA targets localized to expected tumor and stroma regions highlighting immune infliltration in the tumor microenvironment, the expression of which. closely matched single-stain reference patterns. The MoxiePlex platform delivered consistent, whole-slide imaging performance with reproducible acquisition settings appropriate for routine 7-9-plex scanning.

Conclusions: HCR™ Gold IF & HCR™ Gold RNA-FISH can be combined in a single-round workflow on the MoxiePlex to achieve up to 9-plex imaging of clinically relevant protein and RNA targets in FFPE tissue. This approach avoids stripping or photobleaching, maintains compatibility with validated antibodies and standard filter sets, and provides a practical path for flexible, 7-9-plex spatial assays in translational and clinical research.

#7674 Formaldehyde-free fixation for safe, scalable and flexible single-cell multiomics studies.

Joseph Olives, Hongduan Huang, Zhiqi Zhang, Lin Chen, Rosary Nguyen, Hye-won Song, Aruna Ayer

Single Cell Multiomics, Becton Dickinson Biosciences, San Diego, CA

The development and commercialization of flexible single-cell multiomics methods has allowed for investigator selection and implementation of assays which provide the desired biological depth and context for their disease model of interest. Multiomic methods generally achieve best results with fresh, high-quality samples for efficient recovery of the native biological state. These dynamic samples, however, pose logistical challenges for larger clinical studies, limiting scope and reproducibility. Formaldehyde (PFA) fixation has been the standard for tissue preservation, due to its accessibility and stability enabling simplified clinical sample preparation and biobanking from large patient cohorts. The implementation of PFA, however, predates common knowledge of its carcinogenicity and nucleic acid crosslinking, limiting future transcriptomic and genomic study. Unlike tissue, fixation of single cell suspensions has not yet been standardized to this extent, offering a valuable opportunity to survey more safe and flexible solutions for sample preservation. To address this, we evaluated fixatives that have increasingly been investigated for these advantages over PFA with the goal of suggesting an alternative single-cell fixative solution for further investigation. We optimized each alternative fixation solution using various cellular and molecular analysis tools suggesting broad multiomic and clinical compatibility. Optimal formulations were used to treat peripheral blood monocytes (PBMCs) and their nuclei and analyzed by genetic (ATAC-seq), transcriptomic (WTA) and proteomic (CITE-seq) assays for multiomic evaluation against live and PFA controls. Our data identified a safe and stable novel fixative formulation for preserving PBMC samples throughout a mock biobanking process and gave broad multiomic compatibility comparable or exceeding that of PFA.This alternative and its novel preparation are underrepresented in academic and industry studies on single-cell fixation solutions at a critical time for large cohort studies. Further development, optimization and demonstration of this safer alternative is needed as these large single cell atlas and clinical studies become increasingly common. Such studies' data are shaping new virtual cell models and clinical standard operating procedures foundational to this field and necessitate further review of safer alternatives with more flexible assay compatibility.

#7677 High-throughput plasma proteomics enables sarcopenia stratification and identifies the IGFBP axis as a key mediator of muscle impairment in cancer patients.

Filippo Gustavo Dall'Olio[1], Wael Salem Zrafi[1], Xinran Song[1], Littisha Lawrance[1], Fei Chen[1], Pierre Busson[1], Catherine Brenner[1], Rebecca Ibrahim[1], Marie Guinhut[1], Caroline Even[1], Nathalie Lassau[1], Diana Cardenas-Braz[1], Fabrice Barlesi[2], Yohann Loriot[1], Fabrice Andre[1], Mariam Jamal-Hanjani[3], Antoine Italiano[1], Yegor Vassetzky[1], Benjamin Besse[1]

[1]Gustave Roussy, Villejuif, France,[2]Gustave Roussy, villejuif, France,[3]University College London (UCL) Cancer Institute, London, United Kingdom

Background: Cancer-related sarcopenia, defined by progressive loss of skeletal muscle mass and function, worsens outcomes but lacks a single universally accepted diagnostic criteria. Current assessments are time-consuming. We aimed to identify a plasma proteomic signature of sarcopenia and uncover soluble mediators involved in muscle decline.
Methods: Two MATCH-R cohorts (NCT2517892) were analyzed: advanced cancers treated with immunotherapy (training) and metastatic castration-resistant prostate cancer (mCRPC) treated with enzalutamide (validation). An external validation cohort came from TRACERx (NCT01888601, resected and relapsed NSCLC). In MATCH-R, skeletal muscle index (SMI) at L3 level was measured on CT/PET within 42 days of blood draw; ECOG PS was used as a surrogate for muscle function. Plasma proteomics was performed using Olink Explore 1536/3072. Bulk and, for selected cases, single-cell RNA-seq were available for paired biopsies. In TRACERx, skeletal muscle area (SKM) was quantified via an automated deep-learning pipeline (PMID: 37045997). An XGBoost classifier was trained on high-contrast cases (low sarcopenia, LS: high SMI, ECOG 0; high sarcopenia, HS: low SMI, ECOG ≥2) using neuromuscular-related proteins enriched in LS. The model generated sarcopenia probability (SP, 0-100%) applied to all cohorts.
Results: The training cohort included 99 patients (36 high-contrast: 21 HS, 15 LS). Using a 50% SP cutoff, the model showed an accuracy of 0.889 in 18 high-contrast validation cases. SP correlated with ECOG PS when available ($p < 0.001$) and SMI in training and mCRPC cohorts (training: $\rho = -0.39$, $p = 0.004$ for male and ρ -0.42 for female; mCRPC: $\rho = -0.41$, $p = 0.008$), with SKM in TRACERx baseline ($\rho = -0.29$, p 0.01 and ρ -0.24 p 0.07 for male and female), recurrence $\rho = -0.42$, p 0.002 and ρ -0.36 p 0.04 for male and female). A change in SP was associated with a corresponding changement in SKM in paired samples (ρ -0.32 , $p=0.006$). SP > 50% was associated with poorer survival across datasets (training: OS 5 vs 25.8 months, $p < 0.0001$; mCRPC: 8.9 vs 21.9 months, $p < 0.0001$; TRACERx baseline: DFS 10.7 vs 20.2 months, $p = 0.007$; OS 25 vs 48 months, $p < 0.001$; TRACERx recurrence: OS 44 vs 30.5, $p = 0.043$). Transcriptomic analyses in both training and mCRPC cohorts showed convergent upregulation of inflammatory pathways and suppression of muscle-related programs in patients with high SP. Across all cohorts, amongst others, plasma IGFBP1, IGFBP2, and IL6 were consistently higher in sarcopenic patients. Functional assays showed that IGFBP1/2 (1µg/mL) markedly impaired human myoblast differentiation (reduced fusion index and decreased MHC/β-actin expression)
Conclusions: Plasma proteomics offers a scalable, imaging-free diagnostic for sarcopenia and identifies IGFBP1/2 as actionable drivers of cancer-associated muscle dysfunction

#7678 Ultra-low-abundance cancer biomarker discovery: Multiplexed protein profiling with attomolar sensitivity.

Malcolm MacKenzie[1], Ilya Alexandrov[2], Matthew Preimesberger[2]

[1]ActivSignal, Natick, MA,[2]ActivSignal, NATICK, MA

Introduction: There is a great potential for utilizing ultra-low-abundance biomarkers in numerous applications across oncology research. These biomarkers, including many cancer-related signaling proteins and their post-translationally modified (PTM) isoforms, may provide key biological indicators, yet remain technically challenging to measure, particularly in multiplex. The leading discovery platforms available in the market lack the necessary sensitivity to reliably detect sub-fM biomarkers, and, therefore, do not include PTM isoforms in their panels. Based on published third-party assessments, 1,000+ plex platforms can return non-detects on over half of the targets in their panels for a given sample, due to insufficient sensitivity. **Methods and Results:** We have developed and validated a multiplex protein profiling technology, BlueSCAI™ (Background Lowering using Serial-Capture, Adapter-Insertion), which can increase technical sensitivity down to the attomolar level. BlueSCAI is a proximity-based platform with a capture-release-recapture mechanism. We conducted a head-to-head comparison with an industry leading proximity profiling platform, encompassing an overlap of 21 randomly selected biomarkers, for which there were i. published LODs available for other commercial platform; and ii. the required reagents, and iii. the target antigens, were readily available from vetted vendors**.** Across numerous protein targets, BlueSCAI demonstrated limits of detection that are several logs lower than those of high plex protein platforms, representing a substantial improvement in analytical sensitivity. In addition, in comparisons with commercial ELISA assays, using the same antibody pairs, BlueSCAI demonstrated LODs almost 1,000 fold lower for multiple biomarkers. For example, BlueSCAI's integrated CA19-9 biomarker has an improved sensitivity of ~ 3 logs compared to CA19-9 measured using a leading clinical lab platform (<0.0001 U/mL vs 0.6 U/mL). Analysis of dose-response curves indicated that almost half of the target panel exhibited 4+ logs of linear dynamic range, with an equal fraction showing maximal signal above background of greater than 10,000. Cross-reactivity (1-signal specificity) was measured with a leave-out mixed antigen pool approach. Signal specificities exceeded 99.9% across ¾ of the target panel, and over 98% specific on the remaining 25% of targets.**Conclusion:** BlueSCAI's specific, high sensitivity, multiplex detection shows great promise for profiling new oncology-related, biologically informative, ultra-low-abundance biomarkers, which includes cancer signaling proteins, PTM isoforms, and extracellular vesicle cargo, across diverse cancer research applications.

#7679 Advanced proteomic profiling of patient-derived tumor models reveals high cross-model concordance and improved translational fidelity.

Jia Xue[1], Hengyuan Liu[1], Xiaobo Chen[2], Sheng Guo[1]

[1]Crown Bioscience, Inc., Suzhou, China,[2]Crown Bioscience, Inc., Beijing, China

Introduction: High-throughput proteomic profiling of preclinical tumor models is increasingly critical in oncology studies and translational research for anti-cancer drug development. However, the murine stromal compartment in patient-derived xenografts (PDXs) confounds accurate proteomic quantification, as previously demonstrated. For instance, 30% of PDX tumor samples contain over 25% mouse stromal cells, which causes false results in downstream proteomic analysis.
Methods: To overcome this issue, we developed an optimized "separate-then-run" methodology that effectively separates human and mouse cells before proteomics profiling by mass spectrometry, thus enabling the acquisition of precise human tumor proteomic signatures from PDX samples. For organoid models, no mouse cell removal was performed before the mass spectrometry experiment.
Results: Using an optimized data-analysis pipeline, we profiled 418 PDX models and 89 organoids, including 59 patient-derived organoid (PDO) and 30 PDX-derived organoid (PDXO) models, quantifying a median of 9,916 human proteins per sample (range: 8,514-11,206) with high reproducibility after batch correction and normalization (Pearson correlation coefficient range: 0.93-0.98). To evaluate cross-platform fidelity, we also start to perform proteomic profiling of paired *in vivo* and *in vitro* tumor models; preliminary results show high consistency of proteome expression between paired models. For example, Pearson correlation coefficients are 0.93-0.96 for 3 PDO-PDOX pairs and 0.91-0.96 for 7 PDX-PDXO pairs; both are much higher than inter-model correlation within PDO, PDOX, PDX, and PDXO (Wilcox test p-value < 0.01). Further ongoing studies will provide more evidence on within/between tumor model proteome similarity.
Conclusions: In summary, we have established an advanced proteomic profiling platform that significantly enhances protein detection coverage in preclinical tumor models over conventional methods and validates the high concordance of protein expression between paired *in vitro* and *in vivo* tumor models.

#7680 Pre-diagnostic plasma proteomic signatures associated with early-onset colorectal cancer in two large prospective cohorts.

Mengyao Shi[1], Xiaoyu Zong[1], Ruiyi Tian[2], Daniel Hong[3], Xinyuan (Cindy) Zhang[4], Yichen Sun[1], A. Heather Eliassen[5], Edward L. Giovannucci[6], Gong Yang[7], Andrew T. Chan[8], Wei Zheng[7], Yin Cao[9]

[1]Washington University School of Medicine, St. Louis, MO,[2]Washington University In St. Louis, St. Louis, MO,[3]Washington University School of Medicine in St. Louis,[4]Brigham and Women's Hospital and Harvard Medical School, Boston, MA,[5]Assistant Professor, Harvard University, Boston, MA,[6]Professor of Nutrition & Epidem., Harvard TH Chan School of Public Health, Boston, MA,[7]Vanderbilt University Medical Center, Nashville, TN,[8]Massachusetts General Hospital, Boston, MA,[9]Washington University in St. Louis, St Louis, MO

Objective: Early-onset colorectal cancer (EOCRC) has been rising globally, yet its molecular pathways and mechanisms have not been fully explored. Large-scale proteomic studies suggest circulating proteins can illuminate key biological pathways and early markers of carcinogenesis, but robust evidence on pre-diagnostic protein biomarkers specific to EOCRC is still scarce.
Design: We measured 3,072 pre-diagnostic plasma proteins using the Olink Explore platform in EOCRC (<age 55 at diagnosis) cases and matched controls, in two prospective studies, the Nurses' Health Study II (NHSII, 1989-2015; 43 pairs; 98.8% White) and Southern Community Cohort Study (SCCS, 2002-2015; 109 pairs; 78.9% Black), as well as 59 pairs of advanced adenoma (<age 50) in NHSII. Controls were matched on age and year at blood draw, sex, and race. Cohort-specific multivariable logistic regression models were used to estimate odds ratios (ORs) and 95% confidence intervals (CIs) per standard deviation (SD) increase by protein. Inverse variance-weighted fixed-effect meta-analyses estimated pooled ORs. We additionally generated plasma protein-based estimates of organ-specific biological aging to assess differences in accelerated aging between cases and controls.
Results: The mean (SD) age at blood draw was 43.7 (4.7) years in NHSII and 45.5 (3.6) years in SCCS. Meta-analysis identified 13 proteins associated with EOCRC that met replication criteria (consistent effect direction, $I^2 \leq 40\%$, FDR < 0.25). Top replicated proteins implicate immune regulation (IL7 [OR per SD increase: 1.67; 95% CI 1.25-2.25; ANK2 [1.35; 1.02-1.80]; PTX3 [1.33; 1.03-1.72]), cellular structural pathways (PRSS53 [1.31; 1.00-1.71]; FSTL1 [0.67; 0.50-0.92]; MMP13 [0.75; 0.56-0.99]), and metabolic pathways (GHRL [1.33; 1.02-1.74]; GIPR [0.73; 0.55-0.96]). Cohort-specific analyses revealed additional distinct protein associations. In NHSII, TLR4, VEGFA, PGLYRP2, PXDNL, KRT17, and HRC were associated with EOCRC risk, implicating disrupted host-microbiome interactions, angiogenic signaling and altered epithelial biology as potential pathways. Some associations (KRT17 and HRC) were also observed in advanced adenoma compared with controls, highlighting their potential roles in initiation of precancerous changes. In SCCS, proteins positively associated with EOCRC risk suggested alterations in matrix and cytoskeletal remodeling (AFAP1, CORO6, ARAF) and immune activation (WAS). Organ-specific aging analyses suggested higher accelerated aging levels in EOCRC cases for multiple organs, including brain, the immune system, and intestine.
Conclusion: In this prospective, multi-cohort proteomic profiling study, we identified pre-diagnostic circulating proteins associated with EOCRC risk, highlighting immune and inflammatory signaling, and metabolic dysregulation as key biological pathways.

#7681 Chemical proteomics identifies a transcription-related network of proteins that interact with the next-generation poly(ADP-ribose) polymerase inhibitor saruparib.

Rachael H. Martin[1], Lindsey Nguy[2], Thales Da Costa Nepomuceno[2], Ou Deng[2], John M. Koomen[2], Uwe Rix[2], Alvaro N. Monteiro[2]

[1]Moffitt Cancer Center/University of South Florida, Tampa, FL,[2]Moffitt Cancer Center, Tampa, FL

Introduction: Ovarian cancer is one of the leading causes of gynecological-related mortality rates, often due to late-stage diagnosis. Poly(ADP-ribose) polymerase 1 inhibitors (PARPi) have been FDA approved for treatment in ovarian, breast, pancreatic, and prostate cancers. PARPi's lead to synthetic lethality in cells deficient in homologous recombination repair. Although PARPi's are a promising cancer therapeutic, drug resistance as well as side effects like hematological toxicity remain unmet clinical challenges.

Methods: In this study we utilized *PARP1*-proficient and generated CRISPR *PARP1*-deficient isogenic HEYA8 and HAP1 cell lines to perform chemical proteomics using derivatized Olaparib and a next-generation PARPi, Saruparib. Proteins and protein complexes engaged with the drug were pulled down after click chemistry in cell lysates, followed by LC-MS/MS to identify new targets of Saruparib.

Results: The subsequent analysis revealed a statistically significant set (p-value ≤ 0.03) of 247 unique proteins that were ≥2-fold enriched when compared to the unmodified PARPi competition. Within those 247 proteins, we compared the different conditions in both cell lines to identify proteins that interacted with Saruparib as well as its canonical target, PARP1. 182 were found exclusively in the Saruparib pulldown, 192 were found only in PARP1-proficient conditions regardless of drug, and 159 were found in both the Saruparib pulldown and PARP1-proficient conditions. Several proteins associated with the TFIID complex, composed of pre-initiation transcription factors, were shown to be enriched only in the Saruparib pulldown regardless of PARP1-proficiency, indicating a potential deregulation of the transcriptional machinery. However, one protein of the TFIID complex, BRD2, was shown to have enrichment dependent on PARP1-proficiency, indicating both potential drug and PARP specificity. BRD2 is a member of the BET family of proteins, which plays a role in transcriptional regulation and gene expression. We further validated the interaction between endogenous BRD2 and PARP1 through co-immunoprecipitation experiments with HEK293T whole cell lysates.

Conclusions: Our findings have uncovered a novel landscape of transcription-related proteins, including BRD2, that might provide targets for combination therapy with the PARPi Saruparib.

#7682 Integrative Blood Proteomics Reveals the HuBP Atlas of over 10,000 Proteins Informing Human Physiology and Disease..

Zhenyu Sun, Tung-Shing M. Lih, Yuanyu Huang, Yingwei Hu, Yuefan Wang, Hui Zhang

Department of Pathology, Johns Hopkins University School of Medicine, Baltimore, MD

Blood provides a rich and accessible source of clinical information, yet no centralized resource systematically documents which proteins are detectable across blood sample types, analytical workflows, and disease states. To address these needs, we developed the Human Blood Proteome (HuBP) database that links protein detectability, abundance, and reproducibility across analytical workflows, sample types, and disease contexts.Using data-independent acquisition, we profiled healthy plasma with complementary workflows, including direct analysis, high-abundance protein depletion, low-abundance protein enrichment, and extracellular vesicle enrichment and identified 9,965 proteins in total. HuBP enables users to query protein detectability across methods and provides standardized performance metrics and detailed standard operating procedures (SOPs) to support reproducibility and cross-laboratory implementation.To characterize disease-associated alterations, we further analyzed 140 pancreatic ductal adenocarcinoma (PDAC), 111 clear cell renal cell carcinoma (ccRCC), and 82 lung adenocarcinoma (LUAD) whole-blood samples, identifying 8,002, 8,006, and 8,009 proteins, respectively. Across these cancers, 8,021 proteins were detected, including 498 proteins absent in healthy controls, highlighting disease-specific blood proteomic signatures.In total, HuBP assembles 10,463 nonredundant blood proteins, representing the most comprehensive blood proteome resource to date. By providing an integrated and quantitative atlas across workflows, sample types, and disease contexts, HuBP offers a valuable platform for optimizing experimental designs in both large-scale blood proteomics studies and targeted analyses of disease-specific proteins, ultimately supporting the discovery of non-invasive biomarkers and the advancement of precision medicine.

#7683 A proteomic analysis of differential protein expression between platinum-sensitive and platinum-resistant high grade serous ovarian cancer.

Nujsaubnusi Cassandra Vue[1], Kyla Frenia[2], Xi Peng[3], Eirwen Miller[1], John Nakayama[1], Sharon Liang[1], Sarah Crafton[1], Alyssa Wield[1], Christopher Morse[1], Thomas Krivak[1], Qiangmin Zheng[3], Kunhong Xiao[3]

[1]Western Pennsylvania Hospital, Pittsburgh, PA,[2]University of Pittsburgh, Pittsburgh, PA,[3]Allegheny Health Network, Pittsburgh, PA

Introduction: Ovarian cancer is the most lethal gynecologic malignancy. Platinum-based therapy is the mainstay of treatment, with 70% chance of treatment sensitivity. Resistance to platinum therapy is the leading cause of mortality in advanced ovarian cancer. There are limited studies using proteomics to evaluate platinum resistance in ovarian cancer. This study aims to perform proteomic evaluation of treatment naive tissue from high grade serous ovarian cancer (HGSOC) tumors that are platinum-sensitive (PS) versus resistant (PR).
Methods: Formalin-fixed paraffin-embedded (FFPE) tumor tissue collected from 63 patients with HGSOC were analyzed, including 40 PS & 23 PR. Platinum sensitivity was defined as disease response without evidence of recurrence after 6 months of treatment. Samples were analyzed using a high-throughput liquid chromatography-tandem mass spectrometry (LC-MS/MS) protocol. Differential expression (DE) analysis was performed to identify proteins distinguishing between the two groups. Unsupervised machine learning techniques such as least absolute shrinkage and selection operator (LASSO) regression analysis, linear discriminant analysis (LDA), and weighted gene co-expression network analysis (WCGNA) were employed to create a differentially expressed protein profile between PS and PR.
Results: Among 4048 proteins identified, 1,604 met quality thresholds for further analysis, appearing in >50% of samples. Thirty-seven proteins were significantly differentially expressed with four upregulated in PS and 33 upregulated in PR. With LASSO regression analysis, an additional 61 DE proteins were identified. LDA revealed 7 proteins (DPM1, INF2, ISYNA1, RBM12B, ATP5F1C, GNL1, UBA7) to have a predictive potential with 85% sensitivity and 100% specificity. Functional enrichment analysis implicated pathways related to RNA binding, epigenetic regulation, spliceosome activity, glutathione metabolism, and metabolic reprogramming in platinum sensitivity.
Conclusion: With the combination of traditional statistics and unsupervised machine learning, this study generated a list of DE proteins and facilitated a 7-protein panel that can be used to further investigate and understand the complex tumor dynamics behind platinum sensitivity and resistance.

#7684 Absolute quantification of 400 plasma proteins using a novel NGS-based immunoassay: Analytical validation and biomarker discovery in breast cancer.

David Aaron Routenberg[1], Evan A. Gizzie[1], Annamaria Szabolics[1], Lucie Hebert[1], Somnath Paul[2], Anthony Williams[2], Richard J. Cote[2], Jacob N. Wohlstadter[1]

[1]Meso Scale Diagnostics, LLC, Gaithersburg, MD,[2]Washington University in St. Louis School of Medicine, St. Louis, MO

Next generation sequencing (NGS)-based immunoassays have enabled multiplex, sensitive, wide dynamic range protein measurements, but existing platforms lack absolute quantitation and a clear path for translating proteomic hits into focused assay panels on platforms suitable for down-stream studies. We introduce a novel high multiplex immunoassay platform from ProteinXI, a division of Meso Scale Diagnostics, LLC. (MSD), with accurate and reproducible absolute quantification, and demonstrate simultaneous measurement of hundreds of targets in human biofluids. We also show strong concordance with analogous assays on MSD's high-throughput electrochemiluminescence (ECL) platform, providing an efficient route to focused validation panels. The ProteinXI Discovery 400 panel was evaluated for analytical sensitivity, precision, reproducibility and dilution linearity using a set of 40 commercially sourced plasma samples from healthy donors. Concordance with well-established commercial immunoassays was assessed for over one hundred analytes by measuring the same sample set using MSD V-PLEX or U-PLEX assays. To assess translational relevance, we measured plasma samples from a cohort of 387 subjects with breast cancer of varying stages and molecular subtypes monitored during neoadjuvant therapy (NAT). Samples were collected at baseline (pre-treatment), on day 1 of the second therapy cycle (C2D1), and prior to surgery. Tumor and lymph node biopsies were obtained before and after NAT, and treatment response was evaluated using the MD Anderson Residual Cancer Burden (RCB) score. The platform showed high dynamic range, with 90% of assays spanning at least 4 logs between lower limit of detection (LLOD) and upper limit of quantitation (ULOQ). Analytical sensitivity exceeded 1 fg/mL for some assays, with a median LLOD of 0.48 pg/mL. Most (80%) analytes were within the quantifiable range in at least 75% of healthy plasma samples. Dilution linearity was between 70% and 130% for 85% of quantifiable analytes. Median intraplate CVs of calculated concentrations across all quantifiable samples and analytes was 6.8% (IQR=3.1%-13.3%). Median Interplate and inter-run CVs of calculated concentrations were 10.3 and 11.7% respectively. Concordance with U-PLEX and V-PLEX immunoassays was high with Pearson correlations >0.8 for 84% of assays. In breast cancer samples, classical markers CA15-3, CEA, CA125 and Cytokeratin 8 were elevated relative to healthy controls and correlated with tumor stage, as did VEGF-A, VCAM-1, MMP-7 and Osteopontin. High baseline Ki67 and Leptin levels were associated with lower RCB score. PDGF-AA and PDGF-AB both decreased with NAT, while BAFF and GDF-15 increased. These results demonstrate the ProteinXI platform's robust analytical performance and ability to reproduce expected biological patterns, supporting its translational utility.

#7685 Absolute quantification of aqueous humor proteins for prognostic stratification in uveal melanoma.

Donny Liang[1], Elaine Huang[1], Yilin Chen[2], Chen-Ching (Patrick) Peng[3], Jesse Berry[3], Liya Xu[3]

[1]USC - University of Southern California, Los Angeles, CA,[2]Children's Hospital Los Angeles,[3]Children's Hospital Los Angeles, Los Angeles, CA

Background: Uveal melanoma (UM) is the most common primary intraocular malignancy in adults and carries a high risk of metastatic progression, particularly in tumors with high-risk gene expression profiles or advanced clinical stage. Direct tumor biopsy provides valuable prognostic information but carries procedural risk, highlighting the need for minimally invasive approaches to capture tumor-derived biomarkers. Aqueous humor (AH) contains detectable molecular material released by intraocular tumors, yet absolute quantification of protein biomarkers has not previously been performed. This study aims to establish the first calibrated AH proteome map for UM and to identify protein biomarkers associated with molecular classification and disease stage.
Methods: AH samples from 70 UM eyes were collected before plaque brachytherapy. Fine needle tumor aspiration provided gene expression profiling (GEP1, GEP2) and PRAME status. All samples underwent NGS based high-plex proximity extension assay (PEA), and 27 samples with remaining volume underwent qPCR-based PEA targeting 92 proteins. Regression models derived from 66 overlapping proteins enabled extrapolation of absolute pg/mL concentrations across the full cohort. Proteins with median concentrations >5 pg/mL were assessed for differences by GEP class, PRAME status, and AJCC stage. Pathway enrichment and upstream regulators were identified using Ingenuity Pathway Analysis.
Results: Twenty-three proteins were present at clinically quantifiable concentrations. The lowest protein levels were observed in GEP1/PRAME- tumors, with progressive increases seen across advanced AJCC stages. Significant elevations were noted in Stage IV disease for CXCL8 ($p=0.00024$), IL10 ($p=0.00049$), and PDCD1 ($p=0.00094$). Pathway analysis demonstrated enrichment in immune and tumor-associated signaling pathways. VEGFA ($z=3.1$) and CCL2 ($z=1.7$) were identified as predicted upstream regulators and were elevated in advanced-stage tumors.
Conclusions: This study provides the first absolute quantitative map of AH proteins in UM and identifies a panel of 23 clinically detectable biomarkers associated with tumor biology, molecular classification, and stage. These findings position AH proteomics as a minimally invasive liquid biopsy platform capable of capturing stage-linked immune activity in UM and supporting the development of standardized biomarkers for prognostic stratification.

#7686 Identification of a first-in-class therapeutic target using machine learning enabled translational-optimized proteomics system (TPS).

Catherine Wong[1], Ning Li[2], Shuaixin Gao[1], Nan Zhang[1], Jiming Yin[2], Yonghong Zhang[2]

[1]Foreseen Biotechnology (Beijing) Co., Ltd., Beijing, China,[2]Beijing You-An Hospital, Capital Medical University, Beijing, China

Background:
At Foreseen, we built a translational-optimized proteomics system (TPS) and assembled a vast collection of well-characterized human clinical samples. Our platform can extract actionable insights from complex proteomics and clinical datasets to accelerate the discovery of clinically relevant targets for drug discovery and for diagnostic applications.
Methods:
Chronic hepatitis B (CHB) infection may lead to progressive liver diseases including fibrosis, cirrhosis, and ultimately hepatocellular carcinoma (HCC). An optimized plasma proteomics analysis using parallel accumulation-serial fragmentation combined with data-independent acquisition (DIA-PASEF) on a large liver cohort was performed. This cohort (N=340) consists of healthy individuals (n = 48), patients with either CHB (n = 39), liver fibrosis (n = 47), liver cirrhosis (LC, n = 56), and HCC (4 subgroups based on TNM staging system: HCC1-4; n = 36, 38, 39, and 37). Highly abundant proteins were removed from plasma prior to proteomic preparation. Samples were processed and analyzed using DIA-MS for high-throughput protein quantification. Our TPS can identify potential biomarkers and stage-specific molecular drivers associated with liver disease and liver cancer progression. Expression analysis using tissue microarrays (TMA), followed by validation through in vitro (cell lines) and in vivo (cell-derived xenograft models) studies were conducted on selected candidate targets.
Results:
Integrin alpha-2 (ITGA2) was among the seven tumor-associated antigens (TAAs) identified in hepatocellular carcinoma (HCC) we selected as final drug candidates after screening. It is a cell surface membrane receptor and may function as a regulatory factor in cancer, responsible for driving tumorigenesis, inducing chemoresistance, regulating genomic instability and remodeling the tumor microenvironment. In this study we demonstrated that the protein expression of ITGA2 is low in patients' groups of CHB, fibrosis and cirrhosis, but significantly upregulated in HCC. Furthermore, ITGA2 is overexpressed in multiple solid tumors, including pancreatic, gastric, and colorectal cancers using TMA analyses. We discovered and developed an antibody targeting ITGA2 with nM binding affinity and good internalization properties. We advanced FS001(IPN60300) into the final stages of preclinical development. This a first-in-class antibody drug conjugate comprised of (i) Foreseen's proprietary antibody targeting ITGA2 and (ii) linker-payload with excellent pharmaceutical features developed by Shanghai Escugen Biotechnology. Foreseen has granted an exclusive worldwide license of FS001(IPN60300) to Ipsen in July 2024.
Conclusion:
Our translational-optimized proteomics system (TPS) has led to the discovery of ITGA2, a novel tumor-associated antigen (TAA) and enabled the development of FS001(IPN60300).

#7688 Blood-based proteomic profiling reveals novel biomarkers of neuroendocrine prostate cancer.

Tatiana Erazo[1], Ethan S. Barnett[1], Amanda Weaver[2], A. Zara Herskovits[1], Alisa Valentino[1], Howard I. Scher[1], Gary A. Pestano[2]

[1]Memorial Sloan Kettering Cancer Center, New York, NY,[2]Biodesix, Inc., Broomfield, CO

Neuroendocrine prostate cancer (NEPC) is an aggressive, AR-indifferent subtype of metastatic prostate cancer, with a median survival of 7-15 months. Trans-differentiation from prostate adenocarcinoma to NEPC occurs through a mechanism termed lineage plasticity. Diagnosing NEPC remains a major clinical challenge due to the lack of robust biomarkers and pronounced spatial and temporal heterogeneity. There is an urgent need for diagnostic biomarkers of NEPC before clinical manifestation. To characterize the proteomic landscape of NEPC, we first performed a bottom-up proteomic analysis using LC-MS/MS in NEPC (H660) and adenocarcinoma (VCaP) cell lines. An average of 10,230 proteins were identified in both cell lines, with over 1,300 proteins significantly enriched in NEPC compared to VCaP. NCAM1, a clinical marker of NEPC, was among the significantly enriched proteins (*adjusted p*=0.004; Log2FC=6.5), supporting the biological significance of our findings. Pathway analysis revealed enrichment in E2F, EMT, and p53 signaling pathways, consistent with established mechanisms of lineage plasticity. Next, we conducted a prospective pilot study using plasma from patients with pathologically confirmed NEPC or concurrent *RB1/TP53* loss (n=21) and from patients with *RB1/TP53wt* prostate adenocarcinoma without evidence of histological transformation (n=20). To enhance the detection of low-abundance proteins, we applied sequential enrichment and elution (SEER) followed by Proteograph XT digestion and high-resolution mass spectrometry. Putative proteoforms were identified using data-independent acquisition-neural network (DIA-NN) processing. A total of 6,619 proteins were identified in both cohorts, 93 of which were significantly enriched in the NEPC samples, including NCAM1, validating the approach in plasma. In addition, potential new markers were detected such as methionine adenosyltransferase 2A (MAT2A) (*adjusted p*=2.59E-09; Log2FC=2.8), a critical metabolic driver of androgen-independent cellular state. Neuronal-specific enolase (NSE/ENO2), a glycolytic enzyme associated with poor prognosis and tumor dedifferentiation in prostate cancer, was exclusively expressed in H660 cells and NEPC patient samples. Pathway analysis revealed co-enrichment of neuroendocrine and mitotic germ cell-associated programs, reflecting extensive phenotypic reprogramming that enhances metastatic capacity during lineage plasticity. These findings demonstrate the utility of blood proteomic profiling for the discovery of prognostic and predictive NEPC biomarkers. These markers may help elucidate molecular mechanisms underlying lineage plasticity. Furthermore, high-resolution plasma proteomics offers a promising approach to overcome the limitations of tissue biopsy, which is often restricted by high intra-tumoral heterogeneity and the lack of specificity of current pathological markers.

#7689 Absolute quantification by targeted proteomics identifies BRCA1 hypomorphs and other PARP inhibitor resistance mechanisms in patient-derived xenografts.

Beom-Jun Kim[1], Alba Llop-Guevara[2], Steve M. Sweet[1], Camille Lombard-Banek[1], Robert Hanson[3], Chris Richardson[1], Violeta Serra[2], Elizabeth A. Harrington[3], Josep Forment[3], Yeoun Jin Kim[1]

[1]Cancer Biomarker Development, AstraZeneca, Gaithersburg, MD,[2]Translational Medicine, AstraZeneca, Barcelona, Spain,[3]Translational Medicine, AstraZeneca, Cambridge, United Kingdom

Introduction: BRCA1 is a tumor suppressor required for homologous recombination repair (HRR) of DNA double-strand breaks. BRCA1 loss-of-function mutations cause HRR deficiency and sensitize tumors to platinum-based chemotherapy and PARP inhibitors (PARPi). Standard gene-level testing may miss other mechanisms affecting BRCA1 protein functionality, such as BRCA1 promoter methylation, or other PARPi response molecular determinants, such as hypomorphic protein expression that partially restores HRR, leading to PARPi resistance. Current standard assays suitable for formalin-fixed paraffin-embedded (FFPE) tissue, such as immunohistochemistry, are limited in their ability to characterize BRCA1 protein levels - highlighting the need for new approaches for protein-level quantification.
Methods: Targeted proteomics was performed on an Orbitrap Exploris 480 mass spectrometer coupled to an Evosep One nanoLC to quantify BRCA1 peptides spanning the N-terminal RING domain, Exon 11 and C-terminal BRCT domain, enabling BRCA1 hypomorph detection based on domain-specific peptide abundance. The targeted panel assay also included additional DNA repair proteins. This assay was applied to 56 FFPE tumors from 26 patient-derived xenografts (PDX), including 7 samples collected at acquired olaparib resistance.
Results: PDX tumours from BRCA1 wild-type, BRCA2-mutant, or PALB2-mutant models (n=10), had a median BRCA1 peptide expression level of 45.8 amol/µg (range 20.7-120.9), consistent with a normal-expression reference range. In contrast, PDX tumors with BRCA1 promoter hypermethylation (n=4) exhibited low BRCA1 peptide levels (< 1.8 amol/µg). At acquired olaparib resistance, tumours from the same models showed a ~25-fold BRCA1 protein increase, consistent with demethylation and restored BRCA1 expression. Among BRCA1-mutant PDX models (n=15), most models exhibited low expression, consistent with loss-of-function mutations (n=8 with < 5 amol/µg). Targeted proteomics further identified seven candidate BRCA1-mutant PDX hypomorphic cases in which at least one BRCA1 domain peptide exceeded the ~5 amol/µg threshold; their BRCA1 peptide levels ranged from 6.2 to 31.7 amol/µg. Six out of seven hypomorph cases (86%) were PARPi resistant. Low 53BP1 expression was observed in four PARPi-resistant PDX models; three of these had known 53BP1 dysregulation or mutation. However, one model showed low 53BP1 despite the absence of a known TP53BP1 mutation, implicating 53BP1 loss as a plausible contributor to resistance.
Conclusion: These data support this targeted proteomic assay as a practical approach to distinguish normal from low BRCA1 expression at the protein level, nominate hypomorphic BRCA1 variants linked to PARPi resistance, and identify deficiency in additional resistance biomarkers.

#7690 Extracellular kinome network reveals secretory kinase FAM20C as a key driver of recurrence in oral squamous cell carcinoma.

Mi Rim Lee[1], Yu-Sun Lee[1], Sumin Kang[1], Jiyoung Lee[1], Hye Won Shon[1], Sun Il Choi[1], Gyeongmin Kang[1], Kyung-Hee Kim[2], Jong-Ho Lee[3], Ik-Jae Kwon[4], Sung Woen Choi[3], Yun-Hee Kim[1]

[1]Research Institute of National Cancer Center, Goyang-si, Gyeonggi-do, Korea, Republic of,[2]Kookmin University, Seoul, Korea, Republic of,[3]National Cancer Center, Goyang-si, Gyeonggi-do, Korea, Republic of,[4]Seoul National University Dental Hospital, Seoul, Korea, Republic of

Oral squamous cell carcinoma (OSCC) is a highly aggressive malignancy with a recurrence rate of 40-60%, frequently exhibiting locoregional relapse and lymph node metastasis even after definitive treatment. Tumor progression and recurrence are driven not only by intrinsic characteristics of cancer cells but also by complex interactions with the surrounding tumor microenvironment (TME). To explore recurrence-associated regulatory pathways, we performed LC-MS/MS-based phosphoproteomic profiling of plasma from 34 OSCC patients and identified 113 phosphoproteins harboring 261 phosphosites enriched in lipid binding, complement activation, extracellular matrix (ECM) organization, and calcium-binding functions. Principal component and correlation analyses distinguished patients with recurrence from those without, and consensus clustering revealed three phospho-secretory subtypes. Notably, the subtype with the poor prognosis exhibited a enrichment of phospho-serine within the S-x-E motif. This pattern suggested activation of the secreted serine kinase FAM20C, which phosphorylates ER/Golgi-localized secretory proteins and membrane ectodomain substrates. Public datasets confirmed that high FAM20C expression correlates with increased recurrence risk and reduced overall and progression-free survival. To validate these findings, we examined patient-derived organoids (PDOs) and cancer-associated fibroblasts (CAFs) established from our cohort. Both FAM20C expression and secretion were markedly elevated in PDOs derived from recurrent tumors, and CAFs from recurrent patients also exhibited increased FAM20C secretion. Functionally, FAM20C overexpression enhanced invasion, ECM remodeling, and EMT activation, while FAM20C knockdown suppressed mesenchymal markers, reduced TGF-β-SMAD2/3 signaling, and suppressed stemness-associated genes including SOX2, OCT4, CD44, NANOG, MYC, and CD133. Together, these findings identify FAM20C as a key regulator of recurrence-associated extracellular signaling and highlight its potential as a prognostic biomarker for recurrence in OSCC.

#7691 A magnetic bead-based workflow for streamlined and quantitative mass spectrometry sample preparation in cancer proteomics.

Mike Rosenblatt[1], Zhiyang Zeng[2], Atul Deshpande[3], Marjeta Urh[4], **Wenhui Zhou**[5]

[1]Research & Development, Promega Corporation, Fitchburg, WI,[2]Research and Development, Promega Corporation, San Luis Obispo, CA,[3]Marketing, Promega Corporation, Fitchburg, WI,[4]Research and Development, Promega Corporation, Fitchburg, WI,[5]Research and Development, Promega, San Luis Obispo, CA

Background: Efficient and reproducible sample preparation is essential for robust mass spectrometry (MS)-based proteomics, particularly in oncology applications where input materials can be limited. We developed a Magnetic Particle-based Sample Preparation (MPSP) platform leveraging magnetic bead-based protein capture from diverse lysis conditions, enabling integration with automated workflows and downstream proteomic analysis.

Methods: Human K562 cells and other cancer cell lines were lysed using various buffers. Proteins were captured via magnetic beads and organic solvent-induced precipitation, followed by on-bead digestion with optimized protease combinations (e.g., trypsin, Lys-C, Arg-C). Peptide recovery and digestion efficiency were benchmarked against precipitation and filter-based methods. The workflow was automated using an Agilent AssayMAP Bravo system, and performance was assessed using LC-MS/MS, SDS-PAGE, and high-pH reversed-phase HPLC fractionation. Application-specific adaptations included quantitative PROTAC analysis and phospho/enrichment strategies.

Results: MPSP enabled efficient surfactant removal with minimal protein loss, achieving higher protein identifications (5,794 proteins) than precipitation (5,413) or filter-based (5,567) methods. The approach was compatible across bead surface chemistries and cell lines (HEK, HeLa, K562) and demonstrated scalability to low-input samples (<10,000 cells). Digestion optimization via Design of Experiments (DOE) established ideal parameters: 1:16 enzyme-to-substrate ratio, 16-hour digestion at 40°C, yielding improved peptide recovery (94% digestion efficiency). MPSP reduced sample prep time by ≥1 day and supported quantitative accuracy in PROTAC screens, enabling BRD4 ubiquitination detection and enhanced peptide enrichment using K-ε-GG, pY antibodies, and IMAC/TiO_2. Automated exosome processing using MPSP identified 697 proteins versus 256 by manual methods, with a 2,861-protein overlap.

Conclusions: MPSP offers a scalable, automation-compatible solution for cancer proteomics sample preparation. It supports robust quantitation, high sensitivity, and reproducibility across diverse sample types and workflows. This platform is positioned to enhance throughput and analytical depth in translational and discovery oncology research.

#7692 Proteomic analysis of immune synapses by high-precision microscopy-guided photo-biotinylation.

Jung-Chi Liao, Chantal Hoi Yin Cheung, Weng-Man Chong, Harry Huang, Hsiao-Jen Chang, Chia-Wen Chung

Syncell Inc., Taipei City, Taiwan

An immune synapse (IS) is essential for lymphocyte recognition and cytotoxic response against tumor cells. Although numerous proteins involved in IS formation, stability, and signaling pathways have been characterized, the complete proteomic composition of the synapse remains unknown. A significant challenge involves the purification of proteins at a nanoscale organization with adequate specificity and sensitivity. In this context, we employed an integrated workflow using Syncell's Microscoop® Mint platform, an advanced technology integrating microscopy-guided automated photo-biotinylation, pulldown, and mass spectrometry to isolate and identify proteins localized between T-lymphocytes (Jurkat) and B cells (Raji B). IS formation between T-B cells was recognized using a convolutional neural network-based deep learning algorithm based on CD3 (T-lymphocyte surface marker) signal at the T-B cell synapses. Automated photo-induced biotinylation was performed across thousands of fields of view so that sufficient proteins were biotinylated for the subsequent pulldown and LC-MS/MS-based proteome identification. We precisely identified canonical proteins linked to critical components of T-cell receptor (TCR) signaling pathways, including the TCR/CD3 complex, Src and Tec family tyrosine kinases, and essential NF-kB signaling molecules, thereby validating the specificity of our spatial proteomics methodology. Furthermore, we observed enrichment of proteins not previously associated with the T-B cell immune generating testable hypotheses for advancing the functional dissection of the immunological synapse. Microscoop couples optics and proteomics to enable the precise enrichment of the IS proteins at the Raji-Jurkat interface, and can be readily applied to studies of other types of ISs or ISs from patient tissue samples. Together, these data demonstrate that resolving the nanoscale proteomic architecture of the IS is essential for uncovering how lymphocytes recognize and sometimes fail to recognize tumor cells. By enabling precise, unbiased enrichment of IS proteins, this approach opens new avenues to identify immune-evasion mechanisms and novel therapeutic targets in cancer.

#7693 Unlocking the surfaceome: Nanoscale spatial proteomics for biomarker and target discovery using Synlight-Rich and Synlight-Pure.

Jung-Chi Liao[1], Po-Chao Chan[1], Weng-Man Chong[1], Hsiao-Jen Chang[2], Michelli Faria de Oliveira[3], Elate Huang[1], Daniel Dlugolenski[3]

[1]Syncell Inc., Taipei City, Taiwan,[2]Syncell Inc, Taipei City, Taiwan,[3]Syncell Inc., Livermore, CA

Cell surface proteins mediate essential signaling, trafficking, and cell-cell interactions, representing key biomarker and drug target classes. Yet, comprehensive characterization of human cells surfaceome remains challenging due to the limited spatial precision and labeling specificity of existing proteomic methods. We present an integrated workflow using Syncell's Microscoop® Mint platform in combination with Synlight-Rich and Synlight-Pure reagents to achieve nanometer-scale, unbiased surfaceome discovery with exceptionally high specificity. Synlight-Rich employs two-photon photo-biotinylation to covalently tag proteins within user-defined microscopy regions of interest (ROI) at ~350 nm lateral resolution, enabling deep proteomic interrogation of subcellular domains with high spatial control. Labeled proteins are recovered via the Synpull kit and analyzed by LC-MS/MS. Building on this, Synlight-Pure introduces antibody-mediated proximity labeling, restricting biotinylation to within ~25-50 nm of the target structure. This dual-precision approach—image-guided and chemistry-confined—enables selective, high-specificity enrichment of membrane-associated and interaction-proximal proteins. In HeLa cells, Microscoop with Synlight-Rich identified >3,500 proteins, including >1,000 known plasma-membrane proteins, with >50% showing ≥1.5-fold enrichment ($P < 0.05$) over unlabeled controls. Gene Ontology analysis revealed that ~55% of the top 200 enriched proteins localized to plasma-membrane compartments. Integration of Synlight-Pure increased membrane-specific identifications to ~70% within the same enrichment group, highlighting substantial improvement in labeling specificity and the discovery of previously uncharacterized surface components involved in receptor- and transporter-mediated signaling. By extending spatial proteomics from the micrometer to nanometer scale, Synlight-Rich and Synlight-Pure together unify unbiased discovery and targeted molecular precision within a single workflow. This platform enables comprehensive cell surfaceome mapping with unparalleled specificity, accelerating biomarker and therapeutic target identification across oncology, neurodegeneration, and immunology.

#7694 Proteomic analysis of BRAF-V600E mutant metastatic colorectal cancer FFPE tissues reveals potential involvement of WEE1 expression in therapeutic resistance.

Shotaro Yamaguchi[1], Satoshi Muraoka[2], Yosui Nojima[3], Toshiharu Hirose[1], Hidekazu Hirano[1], Natsuko Okita[1], Atsuo Takashima[1], Jun Adachi[2], Hirokazu Shoji[1], Ken Kato[4]

[1]Gastrointestinal Medical Oncology, National Cancer Center Hospital, Tokyo, Japan,[2]Laboratory of Proteomics for Drug Discovery, Center for Drug Design Research, National Institute of Biomedical Innovation, Health and Nutrition, Osaka, Japan,[3]Center for Mathematical Modeling and Data Science, The University of Osaka, Osaka, Japan,[4]Head and Neck, Esophageal Medical Oncology / Department of Gastrointestinal Medical Oncology, National Cancer Center Hospital, Tokyo, Japan

Background and Aims: Approximately 10% of metastatic colorectal cancers (mCRC) harbor the *BRAF*-V600E mutation. Although targeted therapies such as encorafenib plus cetuximab with or without binimetinib (BEACON regimen) have been developed for this subtype, clinical outcomes remain poor, and overcoming therapeutic resistance represents a critical unmet need. To elucidate the molecular mechanisms underlying this resistance, we performed a proteomic analysis using formalin-fixed paraffin-embedded (FFPE) tissues obtained from patients with *BRAF*-V600E mutant mCRC. The aim of this study was to identify proteins potentially associated with resistance to *BRAF*-targeted therapy and to explore therapeutic targets for this population.

Methods: FFPE tumor samples were collected from patients with *BRAF*-V600E mutant mCRC prior to any systemic treatment. Sections (5 μm thick) were mounted on PEN glass slides, and macro-dissected tumor areas (12-130 mm^2 per sample) were processed for protein extraction. Proteins were purified and digested using the Single-pot, solid-phase-enhanced sample preparation (SP3) protocol, followed by mass spectrometric analysis on an Orbitrap Exploris 480. Furthermore, we retrospectively analyzed clinical data from patients who received the BEACON regimen as second-line treatment for mCRC at our hospital between December 2020 and April 2024. Correlations between quantitative protein expression and clinical outcomes, including progression-free survival (PFS), were assessed using the log-rank test.

Results: A total of 15 patients were included, and protein quantification was successfully achieved in samples of 12 patients. Across these samples, 9,078 proteins were quantitatively profiled, and correlations between protein expression and PFS were examined. The median PFS (mPFS) for patients who received the BEACON regimen as second-line therapy was 6.9 months (95% CI, 2.6-11.0). Among the quantified proteins, 13 proteins showed a negative correlation with PFS (correlation coefficient [r] < -0.8), with WEE1 demonstrating the strongest correlation (r = -0.94). In contrast, no significant correlation was observed between WEE1 expression and PFS during first-line treatment (r = -0.48). When patients were stratified by WEE1 expression levels for the second-line setting, the high-WEE1 group exhibited significantly shorter PFS than the low-WEE1 group (mPFS: 3.6 months vs 10.8 months [HR, 21.88, 95% CI, 3.84-124.6]; $p = 0.0005$).

Conclusion: Our proteomic analysis identified WEE1 expression as a potential biomarker associated with poor clinical outcomes in patients with *BRAF*-V600E mutant mCRC treated with the BEACON regimen. These findings suggest a context-dependent resistance mechanism as a promising therapeutic target warranting further investigation in preclinical and clinical settings.

#7695 Blood-based proteomics analysis for uveal melanoma prognosis.

Abarajithan Chandrasekaran[1], Nikhil Nayee[2], Jerome Lacombe[1], Timothy Karr[3], Frederic Zenhausern[4], Justin Moser[5]

[1]University of Arizona College of Medicine - Phoenix, Phoenix, AZ,[2]Department of Medical Oncology, HonorHealth Research Institute, Scottsdale, AZ,[3]Biosciences Mass Spec/Proteomics Core, ASU-Banner Neurodegenerative Disease Research Center, Phoenix, AZ,[4]Center for Applied NanoBioscience and Medicine, University of Arizona College of Medicine - Phoenix, Phoenix, AZ,[5]HonorHealth Research Institute, Scottsdale, AZ

Background: Uveal melanoma (UM) is the most common intraocular tumor of the eye in adults. About 50% of cases become metastatic, indicating poorer prognosis and survivability. There is currently no well-established blood-based method to accurately predict the risk of metastasis and disease progression of UM using proteomic analysis. This study aimed to test the efficacy and utility of proteomics in the risk assessment of UM.

Methods: Proteomic analysis from serum and extracellular vesicles (EV) of 49 samples from 27 unique patients was performed to classify metastatic and non-metastatic disease. Controls were taken from 5 patients with cutaneous melanoma. Initial serum depletion was completed using the ProteoSpin Abundant Serum Protein Depletion Kit. EVs were extracted via the qEV Concentration Kit IZON system. Proteins from depleted serum and EVs were analyzed via Mass Spectrometry (MS) using a standard trypsin-based workflow. A data-dependent MS^2 method on Thermo Fisher Orbitrap Lumos generated MS data. Orbitrap MS^1 spectra was followed by MS^2 fragmentation via ion trap using collision-induced dissociation. Machine learning was used to develop a predictive proteomic signature for metastasis. Models were trained with 3052 EV and serum protein levels and 906 serum only levels. Model sensitivity and positive predictive value (PPV) were calculated using out-of-bag bootstrap sampling conducted 500 times. Candidate models for classification of disease vs controls were used to classify holdout surveillance samples from 9 unique patients. Additionally, differential abundance analysis of each sample classification used the log(2) ratio of protein abundances with a cut off >1 and <-1, indicating increased and decreased abundance, respectively. Statistical significance of abundance was set at $p<0.05$.

Results: Machine learning models revealed EVs showed higher sensitivity and PPV than serum. EV proteins with the strongest signals for disease (primary, surveillance, metastatic) vs controls include immunoglobulin (Ig) lambda variable 3-10, Ig mu heavy chain, 14-3-3 protein zeta/delta, heat shock cognate 71 kDa protein, and fibrinogen beta chain. Serum proteins include trypsin-3, mitochondrial ATP synthase complex subunit C1, type 2 cytoskeletal keratin, and polymeric Ig receptor. Dopamine beta-hydroxylase was most prominent in metastatic vs non-metastatic (primary, surveillance) in serum. Differential expression analysis of EV and serum revealed significant abundance of proteins related to metabolism, cellular organization and biogenesis, and cell proliferation in disease groups vs controls.

Conclusion: This preliminary analysis demonstrates that blood-based proteomic analysis of various UM stages can be useful in providing diagnosis or prognosis of disease course for such patients. Further work with a larger sample size and repeated sampling at different disease progression stages is warranted to advance this work.

#7696 Quantitative plasma proteomics on stellar MS enables discovery of clinically relevant cancer biomarkers.

Stephanie Samra, Qingling Li, Cristina Jacob, Philip Remes, Jared Deyarmin

Thermo Fisher Scientific, San Jose, CA

Quantitative plasma proteomics is essential for discovering circulating biomarkers that enable early cancer detection and patient stratification. However, existing assays often lack the scalability, reproducibility, and sensitivity required for large clinical studies. To overcome these limitations, we developed a high-throughput targeted proteomics workflow on the Thermo Scientific™ Stellar™ mass spectrometer, enabling rapid and precise quantification of plasma proteins. The platform's fast acquisition speed and robust retention time stability allow comprehensive analysis of hundreds of peptides within a 30-minute gradient, while MS^3 fragmentation enhances selectivity for low-abundance targets. Using the Biognosys PQ500 reference peptide kit, we quantified 804 peptides representing 322 plasma proteins, including 57 FDA-approved biomarkers, in plasma from patients with colorectal and lung cancer and healthy donors. More than 94% of peptides showed coefficients of variation below 25%, with linear responses across six orders of magnitude and limits of quantitation down to the attomole range. In colorectal cancer plasma, 29 proteins were significantly altered (adjusted $p < 0.05$, > 2-fold change) compared with controls. Notably, serum amyloid A2 (SAA2), alpha-2-glycoprotein-like (A2GL), and complement component C9 (CO9) were elevated—proteins implicated in inflammatory and immune pathways driving tumor progression. This study demonstrates that quantitative plasma proteomics on Stellar MS provides the sensitivity, reproducibility, and throughput needed to identify clinically relevant biomarker signatures in cancer. The workflow offers a robust and scalable foundation for translational proteomics and precision oncology applications, bridging the gap between discovery and clinical validation.

#7697 Machine learning-based plasma proteomic signatures for diagnosis and prognosis of cholangiocarcinoma.

Chongming Zheng[1], Yi Wang[2], Gang Chen[1]

[1]The First Affiliated Hospital of Wenzhou Medical University, Wenzhou, China,[2]Wenzhou Medical University, Wenzhou, China

Background: Cholangiocarcinoma (CCA) lacks reliable non-invasive biomarkers for early diagnosis and individualized prognostic assessment. Circulating proteomic profiling offers an opportunity to develop clinically actionable molecular signatures.Methods: A total of 320 plasma samples were collected across two centers, including patients with CCA, benign biliary disease, and healthy controls. Proteins were quantified using the Olink Explore Oncology II panel. Machine-learning pipelines integrating LASSO feature selection and ensemble classifiers were used to construct diagnostic and prognostic models. Model robustness and discrimination were evaluated in independent test cohorts. Integration with bulk RNA sequencing and single-cell datasets was performed to determine the cellular origins and tumor microenvironment context of candidate proteins.Results: A five-protein diagnostic classifier (5-PCM) accurately distinguished CCA from non-CCA controls, achieving AUCs of 0.917-0.930 across cohorts and outperforming conventional serum biomarkers. A seven-protein prognostic model (7-PPC) stratified overall survival with concordance indices of 0.726 and 0.853 in the derivation and validation cohorts, respectively. Multi-omics analyses demonstrated that these diagnostic and prognostic proteins were enriched in malignant epithelial cells, immune subsets, or stromal compartments, supporting their biological relevance in CCA.Conclusions: Plasma proteomics combined with machine learning enables accurate, non-invasive diagnosis and prognostic stratification of CCA. These protein signatures show strong translational potential for early detection and precision clinical management of cholangiocarcinoma.

#7698 Advancing plasma proteomics: A next-generation nanoparticle enrichment workflow for deep and quantitative biomarker discovery in colorectal cancer.

Cameron Ellis[1], Katharina Limm[2], Sandra Schar[3], Roland Bruderer[3], Nils Kulak[2]

[1]PreOmics Inc., Billerica, MA,[2]PreOmics GmbH, Planegg/Martinsried, Germany,[3]Biognosys AG, Zurich, Switzerland

Human plasma provides a minimally invasive source of circulating cancer biomarkers, yet its extreme protein dynamic range and interindividual heterogeneity hinder the detection of low-abundance, tumor-derived markers. In colorectal cancer (CRC), where early detection, risk stratification, and therapy monitoring remain major unmet needs, these analytical barriers limit clinical translation. Here, we present a single-particle enrichment workflow that combines P2 nanoparticles with iST sample preparation and Spectronaut® 20 DIA analysis to enable deeper proteome coverage, improved quantitative precision, and enhanced biological insights in human EDTA-plasma biomarker discovery. Human EDTA-plasma samples from a pilot study of CRC and healthy specimens (n = 6 per group) were processed using the P2-iST Plasma workflow (PreOmics), employing proprietary nanoparticles that selectively capture low-abundance proteins while depleting high-abundance species. Enriched samples were subsequently digested and purified using the optimized iST technology (PreOmics), ensuring standardized peptide generation. Peptides were analyzed on a timsTOF HT (Bruker) operated in dia-PASEF® mode and data processed in Spectronaut® 20 (Biognosys) using the directDIA+ framework for deep, quantitative profiling. Compared with non-enriched plasma samples, the integrated workflow yielded deeper proteome coverage and high quantitative precision (median protein-level CV <15% across replicates). Principal-component and hierarchical clustering analyses demonstrated clear discrimination between CRC and control samples. Functional enrichment revealed distinct biological pathways differentiating disease from control groups, highlighting the sensitivity and discriminative potential of the workflow. The P2-iST Plasma workflow integrates nanoparticle-based enrichment, standardized digestion, and advanced DIA analysis to generate deep, precise, and reproducible plasma proteomes that reflect disease-relevant biology in colorectal cancer. By unlocking new possibilities in circulating biomarker discovery, it supports research in early detection, molecular subtyping, prognosis, and treatment monitoring. Its scalable, automation-friendly design further enables large-cohort validation and longitudinal studies in colorectal and other cancers.

#7699 Quantitative TMT-based proteomic profiling reveals stage-specific protein dysregulation in colorectal cancer.

Camille N. Zenon Melendez, Gabriel Borges Velez, Josue Perez-Santiago, Yakshi Ortiz Maldonado, Liliana Castro Jimenez, Hilmaris Centeno Girona, Sheila N. Lopez Acevedo, Elba V. Caraballo

University of Puerto Rico Comprehensive Cancer Center, San Juan, Puerto Rico

Background: Colorectal cancer (CRC) is a leading cause of cancer-related deaths in the U.S. and its territories, with incidence increasing particularly early-onset CRC, and is often diagnosed at advanced stages. Quantitative proteomics using Tandem Mass Tag (TMT) provides an opportunity to characterize stage-associated molecular alterations. This study aimed to profile the proteomic landscape of CRC in a cohort of Hispanics living in Puerto Rico (HPR) and identify molecular differences across disease stages.
Methods: Tissue samples from healthy controls (n=21), early-stage CRC (n=11), and advanced-stage CRC (n=12) were obtained from the Puerto Rico Familial Colorectal Cancer Registry (PURIFICAR). Samples underwent TMT-based quantitative proteomics followed by liquid chromatography- tandem mass spectrometry (LC-MS/MS). Normalized protein abundance was processed in MetaboAnalyst 5.0. Compositional differences across study groups were evaluated using principal component analyses (PCAs) and PERMANOVA permutation testing for statistical evaluation. Differential protein abundance was assessed using a one-factor analysis with |fold change| ≥1.5 and p≤0.05. Dysregulated proteins were annotated using UniProt and Ingenuity Pathway Analysis (IPA).
Results: PCA showed significant proteomic differentiation among all pairwise comparisons, confirmed by PERMANOVA testing: early-stage CRC versus healthy controls (p=0.001), advanced-stage CRC versus healthy controls (p=0.001), and advanced versus early-stage CRC (p=0.021). Early-stage CRC had 203 differentially abundant proteins relative to healthy controls (72 upregulated, 131 downregulated), with 55.2% unique to this stage. Advanced-stage CRC showed 131 (77 upregulated, 54 downregulated), of which 33.6% were unique. Only twenty-eight (28) proteins were differentially abundant between advanced and early-stages. Venn diagram revealed no proteins common to all three contrasts (0 in the three-way intersection). Early-stage CRC showed dysregulation of DEF1, AZU1, and FCGBP, while advanced-stage CRC demonstrated changes in MMP9, ANXA3, and DEF1. Pathway analysis of classified dysregulated proteins predominantly as enzymes, transporters, and membrane-associated proteins.
Conclusion: Quantitative proteomic profiling identified distinct proteomic profiles associated with CRC stage within this HPR cohort. Early- and advanced-stage CRC demonstrated different dysregulation patterns, with early-stage disease showing greater overall proteomic remodeling and a unique protein composition compared with advanced-stage disease. These stage-associated differences warrant further validation to determine their relevance for early CRC detection and biological characterization.

#7700 Secretomic profiling of triple-negative breast cancer media using Mag-Net™ HP.

Antolize Deetlefs[1], Charne Scully[1], Hafiza Parkar[1], Andrea Ellero[1], Amy van Graan[2], Melissa Vorster[2], Justin Jordaan[2], **Previn Naicker**[2]

[1]Department of Pharmacology, University of Pretoria, Pretoria, South Africa,[2]ReSyn Biosciences, Pretoria, South Africa

Introduction: Secretomics provides a real-time view of tumor biology by profiling proteins that cancer cells release into their microenvironment and circulation. In breast and other cancers, secreted factors can serve as predictive and prognostic markers of disease state and treatment response. However, conventional mass-spectrometry workflows often miss low-abundance cytokines, growth factors, and signalling mediators masked by highly abundant plasma proteins. *Ex vivo* secretome analyses in controlled culture conditions allow reproducible characterization of secreted proteomic signatures, which can then guide targeted validation in larger clinical cohorts. Mag-Net™ enrichment, as demonstrated by Wu et al., offers cost-effective capture of extracellular vesicle-linked, low-abundance proteins from plasma and other biofluids, enhancing downstream MS sensitivity. Here, we present Mag-Net™ HP enabled secretome profiling to sensitively track dose responses to doxorubicin in an *in vitro* model of triple-negative breast cancer (TNBC).

Methods: BT-20 cells (1×10^5 cells/well) were cultured in 24-well plates and treated in triplicate with doxorubicin (0.1, 0.3, 0.7 or 1.5 µM), or DMSO. After 72 h, conditioned media were collected and incubated with Mag-Net™ HP beads for secretome enrichment. Vesicle capture, clean up and digestion was performed in a semi-automated manner on a KingFisher™ Flex using the Mag-Net™ HP kit. Peptides were loaded onto Evotips and analysed using an Evosep One coupled to a Bruker timsTOF HT system.

Results: Mag-Net™ HP yielded substantial improvements in secretomic proteome coverage compared with conventional methods i.e. ~4-fold improvement compared to protein aggregation capture. Approximately 300 proteins were significantly (FDR<0.05) changed proportional to dose—mostly decreasing, negative correlations and others increasing, positive correlations. Gene set enrichment analyses of proteins positively correlated with dose showed, consistent with doxorubicin's mechanism of action, induction of pathways related to DNA damage, p53-related and checkpoint networks (via ATM/ATR, RB1, and MECP2 pathways) potentially indicative of cell-cycle arrest and apoptosis initiation. Together, these results show that Mag-Net™ HP -enhanced secretome profiling enables coherent, reproducible, and biologically interpretable proteomic readouts of drug response that may warrant further investigation in clinical applications.

Conclusion: Mag-Net™ HP enrichment markedly improves detection of low-abundance secretome proteins in doxorubicin-treated TNBC cells in which doxorubicin drives a clear, dose-graded shift in the secretome. This streamlined approach enhances MS-based secretome workflows and supports discovery of clinically relevant biomarkers. Ongoing studies extend this pipeline to additional cell lines and patient-derived organoids.

#7701 Potential clinical utility of small extracellular vesicles derived from head and neck tumors.

Abolfazl Jangholi[1], B. W. M. Thilini Basnayake[1], Omar Breik[2], Liz Kenny[3], Sarju Vasani[2], Riccardo Dolcetti[4], **Chamindie Puyadeera**[1]

[1]Griffith University, Nathan, Australia,[2]Royal Brisbane and Women's Hospital, Brisbane, Australia,[3]The University of Queensland, Brisbane, Australia,[4]University of Melbourne, Melbourne, Australia

Small extracellular vesicles (EVs) carry selective protein cargo that reflect the physiological state of their parent tumor cells, making them a promising source of biomarkers for head and neck cancer (HNC). HNC-derived small EVs are known to contribute to key pathological processes, including immunosuppression, therapy resistance, and metastatic potential. Saliva and plasma, as accessible and minimally invasive biofluids, represent surrogates for tumor-derived biomarkers to enhance clinical monitoring. However, it remains unclear whether small EVs enriched from these fluids accurately represent tumor-derived EVs. This study optimised small EV isolation from HNC tumor tissue and evaluated proteomic overlap between tumor-, saliva-, and plasma-derived EVs.

Small EVs were isolated from tumor tissue and saliva by ultracentrifugation and from plasma using size exclusion chromatography. The morphology, size and concentration of small EVs were assessed by cryogenic Transmission electron microscopy (cryo-TEM) and nanoparticle tracking analysis (NTA). The proteome of small EVs was profiled and quantified using SWATH mass spectrometry. Functional analysis of overlapping and unique proteins was performed to determine their biological relevance.

Small EVs isolated from tumor tissue, saliva and plasma exhibited typical lipid bilayer morphology with sizes ranging from 40 to 200 nm. More than 60% of the identified protein cargoes were shared across all three sources. These shared proteins were significantly enriched in pathways associated with cancer progression, including mTORC1 signalling, coagulation, complement, epithelial-mesenchymal transition, and PI3K/AKT/mTOR signalling. To support the reliability of the proteomic results, a subset of proteins was further validated by immunoblotting.

The substantial proteomic overlap between small EVs from tumor tissue, saliva, and plasma supports the feasibility of using biofluid EVs as surrogates for tumor EVs. Saliva and plasma, being easily accessible, represent viable, non-invasive sources for biomarker discovery and clinical monitoring. These findings provide a strong foundation for advancing liquid biopsy approaches in HNC.

#7702 Integrin αvβ3-driven secretome remodeling uncovers THBS1 as a potential prognostic mediator in cutaneous T-cell lymphoma.

Maria Mercedes Debernardi[1], Lucero Alvarado[1], Ingrid Souza[2], Alejandro Cagnoni[3], Karina Formoso[1], Graciela Cremaschi[1], Alejandro Correa Dominguez[2], Florencia Cayrol[1]

[1]Instituto de Investigaciones Biomedicas (BIOMED-UCA-CONICET), Buenos Aires, Argentina,[2]Instituto Carlos Chagas, Curitiba, Brazil,[3]IBYME-CONICET (Institute of Biology and Experimental Medicine), CABA, Argentina

Cutaneous T-cell lymphomas (CTCL) are a heterogeneous group of T-cell non-Hodgkin lymphomas whose progression depends on dynamic interactions with the tumor microenvironment. Thyroid hormones (THs), at physiological concentrations, act through the membrane receptor integrin αvβ3 to activate oncogenic signaling such as MAPK and JAK/STAT, promoting proliferation and dissemination in T-cell lymphomas. However, the impact of this pathway on the CTCL secretome and its contribution to disease progression remain poorly characterized. Here, we analyzed how integrin αvβ3 activation modulates the CTCL secretome using Mycosis Fungoides (MJ) and Sézary Syndrome (HuT78) cell lines treated with THs (T4=100 nM, T3=1 nM) with or without the αvβ3 inhibitor cilengitide (1.5 µM). Proteins secreted into supernatants were analyzed by LC–MS/MS, and differential expression was evaluated using *limma* and ShinyGO. Under basal conditions, HuT78 secretome displayed a more aggressive profile, enriched in angiogenesis, metabolic reprogramming, and immune evasion pathways compared to MJ. TH treatment significantly altered the secretome composition in both models, with 66 proteins upregulated and 54 downregulated in HuT78 (FDR <0.1). Enriched pathways included VEGFA–VEGFR2, focal adhesion, and TGF-β signaling, all of which are associated with tumor dissemination and immunosuppressive remodeling. THBS1, FN1, FLNA, FLNB, and TLN1 were among the top upregulated proteins and are functionally related to extracellular matrix organization, endothelial activation, and inhibition of antitumor immunity. Importantly, integrin αvβ3 blockade with cilengitide reversed the TH-induced upregulation of these proteins, demonstrating integrin dependence. Transcriptomic analysis of CTCL patient datasets (GSE113113, GSE168508) revealed that the expression of protein THBS1 positively correlates with ITGB3 ($p<0.05$) and is significantly increased in advanced disease stages, consistent with poorer survival. Together, our results show that physiological activation of integrin αvβ3 by THs reshapes the CTCL secretome toward a pro-tumorigenic and immunosuppressive state. THBS1 emerges as a potential prognostic mediator within this network, underscoring how systemic factors like hormones can influence lymphoma progression and revealing new molecular targets with diagnostic and therapeutic relevance.

#7703 Proteomic profiling of Neem (Azadirachta indica) leaves.

Abigail Kahsay, Basir Syed, Dorna Davani, Aftab Ahmed

Pharmaceutical science, Chapman University, Irvine, CA

Modern scientific studies have contributed largely to creating well -validated research data for the holistically rooted use of the Neem *(Azadirachta Indica)* tree in disease management. Neem's astonishing historical and modern relevance reveal more evidence as to why Neem is the target of our study.Valuable studies have shown that the whole parts of the Neem tree are are markable natural source of more than 130 bioactive compounds, which are highly responsible for many therapeutic applications. Historically, Neem has been used as a source of complementary and traditional medicine Ayurvedic and Unani medicine for over 4,500 years. The mystical tree Neem originated from southern Asian countries. This research focuses on the proteomic profiling of Neem leaves and tests their anticancer potential on breast cancer cells. Recent Cancer studies have ranked breast cancer among the most rapidly increasing cancer types in women. Despite consistent advancements in therapies, breast cancer remains a concerning health issue and a deadly disease among women. Many of the existing and emerging Cancer therapies come with numerous drawbacks, increasing the thirst to find better the rapeutics from plant sources with safer and efficacious outcomes. Neem has shown a remarkable potential against cancer due to its wide range of biologically active compounds, including proteins. Studies on the proteins present in Neem remain largely unexplored. The reviewed SwissProt database in UniprotKB shows only three proteins reported from the Neem tree.Therefore, this study has great potential to explore the global proteomic profiling of Neem leaves. Further analysis has also evaluated the cytotoxic potential of proteins from Neem leaves against MDA-MB 231 breast cancer cell lines. The defatted Neem leaves were extracted in n -hexane, followed by extraction in a 20 mM Tris/HCl buffer, pH 8, and then precipitated using 80% ammonium sulfate. The crude extract was dialyzed in water using a 3.5MWCO dialysis tubing and then lyophilized. The anticancer assay of Neem leaves Crude protein at different concentrations was evaluated against MDA-MB-231 cells by using MTS assay, where cells were incubated for 24hours, followed by the treatment with Crude protein for 48 hours, and absorbance was measured at 490 nm. Concentration ranges (6.4- 0.2 mg/mL) showed inhibitory effects on MDA - MB 231 cells. Further, the downstream proteomics was achieved by purification of Crude using gel filtration chromatography first on Hiload Superdex-200 column. The electrophoretic profile was developed by SDS-PAGE electrophoresis using a 10% Tris/Glycine gel, confirmed the presence of proteins with MW ranging from 10 to 37 kDa. The Proteomic profiles were established by peptide mass fingerprinting using Q-tof LC-MS/MS. The bioinformatic analysis using PEAKS Studio X and the UniProtKB TrEMBL Viridiplantae database revealed 17 proteins in 11 groups at an FDR ≤ 1% with a minimum of two unique peptide matches.

#7704 Proteome-wide high throughput perturbation screening of microglial response to oncologic compounds reveals distinct immunomodulation and toxicity profiles.

Alyssa Rosenbloom, Kiran Edwardson, Nathaniel Robichaud, Narges Rashidi, Milad Dagher

Nomic Bio, Montreal, QC, Canada

Microglia are critical for maintaining neural homeostasis. However, under pathological conditions, they can adopt a pro-inflammatory M1 phenotype characterized by the release of IL12, IL1β, TNFα, and IL6. Chronically, the M1 state contributes to neurodegenerative diseases including Alzheimer's, Parkinson's, and multiple sclerosis (MS). M1-polarized microglia are of particular interest in glioblastoma (GBM) because their pro-inflammatory cytokine programs can both suppress antitumor immunity and promote tumor growth; influencing disease progression and shaping effectiveness of emerging therapeutic strategies. Identifying potential therapies requires capturing the breath of inflammatory proteins produced by microglia, and signals of potential toxicities to minimize adverse events (AEs).

The high cost of capturing these diverse signals at scale limits typical drug discovery efforts to simple low-plex readouts. To address this, we previously described the Nomic platform, a proteomics tool capable of quantifying >1000 proteins simultaneously. Here, we leverage Nomic's Omni 1000 to screen 510 bioactive small molecules in microglia stimulated with LPS to mimic a pro-inflammatory state., generating >6,500 samples and >6.5 million data points.

LPS led to expected increased expression of TNFα, IL1β, and IL6, as well as ISG15 and IL12 p40, indicators of chronic inflammation associated with neurodegenerative diseases. Approximately 1/3 of the compounds screened blocked inflammation, of which ¼ presented clear signs of toxicity, characterized by leaking of intracellular content into the supernatant. To further assess potential toxicities, we treated cardiomyocytes and hepatocytes with these compounds, identifying expected and novel drugs with promising properties. For example, Berberine (BBR) is being developed to revert M1 microglia to M2 by blocking NF-κB signaling. We observed significantly reduced IL12 p40, IL10, and CXCL6 upon addition of BBR, with minimal signs of toxicities. Methylprednisolone (MP), a synthetic glucocorticoid, is used for inflammatory flares in MS. Here, MP significantly reduced TNFα, IL6, IL1β, and IL12 p40 in LPS-treated microglia. However, in hepatocytes, MP led to increased SAA, and IL6, consistent with clinical reports of hepatic AEs with high MP exposure. In addition, several compounds under clinical investigation for GBM, including proteasome inhibitors (Bortezomib), and topoisomerase inhibitors (Doxorubicin, Camptothecin derivatives), showed distinct immunomodulatory and toxicity profiles, revealing microglial cytokine programs that may inform potential therapeutic outcomes or combinatorial strategies

Our results demonstrate the value of high-throughput proteomics to simultaneously identify immunomodulatory compounds and characterize their efficacy and safety profile.

#7705 Simultaneous quantitation and discovery of cancer-related proteins in plasma using a fast, high-resolution accurate mass spectrometry-based assay provides insight into precision oncology and drug discovery.

Dominique Figueroa[1], Qingling Li[1], Jared Deyarmin[1], Sophia Steigerwald[2], Matthew R. Dallas[3], Stephanie Samra[1]

[1]Thermo Fisher Scientific, San Jose, CA,[2]Thermo Fisher Scientific, Bremen, Germany,[3]Thermo Fisher Scientific, Frederick, MD

The inherent heterogeneity of cancer has spurred significant technological advancements to enhance the detailed study required to characterize this complex disease, predominantly defined by uncontrolled changes. Efforts to address and treat this multi-faceted variability are executed as investigation of plasma - a readily accessible biological fluid rich in information regarding physiological states. This work seeks to present robust and standardized methods for the quantitation and discovery of known cancer-related proteins found in plasma. Specifically, our methods aim to reduce variability and labor across workflows and spur the adoption of next-generation plasma proteomic and mass spectrometry methods in discovery and development research. PQ500 peptides were prepared per manufacturer instructions, and human plasma samples from BioIVT Inc were digested using the AccelerOme automated platform and pooled as the sample matrix. Two experiments evaluated hybrid-DIA performance. The first tested different targeted peptide numbers (30-300) in SureQuant and tMS2 hybrid-DIA methods using PQ500 peptides spiked into pooled plasma. The second assessed linearity, limit of detection, and limit of quantification using serial dilutions analyzed on the Orbitrap Astral Zoom MS. LC-MS analysis was performed on a Vanquish Neo UHPLC with an EASY-Spray column and optimized gradients, with samples analyzed using both hybrid-DIA methods on the Orbitrap Astral Zoom mass spectrometer. This analysis spans 144 proteins identified as cancer-associated. Key tumor suppressors include TP53 and PTEN, while major oncogenic drivers such as EGFR, ERBB2, KIT, and SHH promote cell proliferation and survival. Proteins like VEGFA, MMP2, and MMP9 regulate angiogenesis and metastasis, and immune modulators such as PVR, VTCN1, and B2M support tumor immune evasion. Metabolic and redox enzymes including PKM2, LDHA, and TXN drive cancer cell metabolism and stress adaptation. Clinically relevant biomarkers—CEACAM5 (CEA), KLK3 (PSA), MUC16 (CA125), WFDC2 (HE4), and MSLN—aid in diagnosis and monitoring. Overall, these proteins cover major cancer hallmarks including proliferation, angiogenesis, immune escape, invasion, and metabolic reprogramming, representing both established and emerging therapeutic targets. Future directions will leverage the unique capabilities of mass spectrometry-based proteomics to investigate post-translational modifications, including phosphorylation and glycosylation, which are crucial in signaling and cancer. By integrating plasma proteomics studies, quantifiable reference peptides, and the Orbitrap Astral Zoom mass spectrometer, we aim to streamline precision oncology and drug discovery by minimizing variability in these dynamic models.

#7706 Phase-separated RTK fusion condensates orchestrate oncogenic signaling through extensive protein recruitment and RTK crosstalk.

Wei Yang[1], Thomas C. Whisenant[2], Daniel J. Donoghue[1]

[1]Chemistry and Biochemistry, University of California San Diego, La Jolla, CA,[2]Center for Computational Biology and Bioinformatics, University of California San Diego, La Jolla, CA

Liquid-liquid phase-separated RTK (Receptor Tyrosine Kinase) fusion condensates represent a newly identified category of biomolecular assemblies that play a key role in driving the oncogenic functions of RTK fusion proteins. In this study, we isolated the NACC2-NTRK2 (Nucleus Accumbens-Associated Protein 2 - Neurotrophic Receptor Tyrosine Kinase 2) fusion condensate and applied LC-MS/MS along with IMAC (Immobilized Metal Affinity Chromatography) to profile its total proteome and phospho-proteome. Our analyses revealed that the condensate selectively recruits 190 proteins via kinase activation, impacting essential cellular pathways such as signal transduction, transcriptional regulation, cell division, cell-cycle progression, and metabolic control. Fluorescence microscopy further demonstrated that proteins with distinct cellular roles interact with the condensates in different ways. Phospho-proteomic profiling showed that the kinase active condensates bring phosphorylation to 1,399 proteins and facilitate RTK crosstalk, particularly with ephrin receptor tyrosine kinases, enabling ligand-independent activation of EPHA2 (Ephrin Receptor A2) and EPHB4 (Ephrin Receptor B4).

#7710 Extracellular vesicle immunopeptidomics recovers immunogenic neoantigen peptides from cancer patient plasma.

Todd Hembrough[1], Alan Mark Ezrin[1], Zackary Opheim[1], Cheryl Bandoski[1], Sarah Bennett[2], Kate Fagan-Solis[2], Benjamin G. Vincent[3], William Hoos[2]

[1]Nexosome Oncology, Durham, NC,[2]Pathfinder Oncology, Chapel Hill, NC,[3]University of North Carolina at Chapel Hill, Chapel Hill, NC

Personalized immunotherapy using patient-specific neoantigens is a critical strategy in immuno-oncology. DNA/RNA sequencing and MHC affinity modeling are used to select optimal neoantigen peptides for development. Tissue-based peptide-MHC (pMHC) mass spectrometry (MS) immunopeptidomics studies have been used to confirm MHC presentation of neoantigen peptides. Since these pMHC analyses are tissue intensive, novel ways to identify MHC presentation of patient-specific neoantigen peptides are needed. Extracellular vesicles (EV) are constitutively expressed by all tumor and immune cells and represent a potential plasma source of patient specific pMHC complexes. Using a proprietary EV purification method, we report detection and characterization of patient specific neoantigen pMHC complexes from very small volumes of patient plasma using targeted proteomics. Methods: Consented patient plasma was used in this study, and patient metadata (DNA/RNA sequencing, HLA haplotyping, and neoantigen peptide binding predictions) was used to define potential neoantigens. EV were purified from plasma (0.5 mL) using proprietary size exclusion chromatography (SEC) methods. Class I MHC-presented peptides were enriched from samples using a pan-MHC antibody column, and enriched peptides were analyzed by high-resolution targeted LC-MS/MS with heavy peptide standards**.** Single chain trimers (SCT) for pMHC complexes were used to evaluate neoantigen-specific T cell frequencies in the peripheral blood, sort T cells for TCR sequencing, and engineer TCR-T cells for further neoantigen characterization. Results: EVs purified from patient plasma using proprietary SEC methods surprisingly yielded ~20 greater amounts of total class I MHC protein based on ELISA than standard EV preps, illustrating a potential for pMHC detection. Plasma enriched EVs from two patients (advanced CRC and osteosarcoma (OST)) were used in subsequent experiments. Multiple patient-specific pMHC were recovered from each patient, 3 peptides from OST and 5 peptides from CRC. Expression of multiple pMHC were confirmed in tumor tissue by MS. Peptides represent candidate neoantigens based upon expression and MHC presentation. Immunogenicity was confirmed for multiple peptides (4 CRC/ 2 OST) by identification of neoantigen-specific CD8+ T cells in peripheral blood using SCT staining and flow cytometry. Subsequent studies will be reported with engineered TCR-T's. Conclusions: Identification of patient-specific tumor antigens is a prerequisite for personalized immunotherapy. We have developed a workflow for Extracellular Vesicle Immunopeptidomics (EV-IMPX) to validate neoantigen presentation using small-volume patient plasma samples. We expect that peptide selection based on EV-IMPX will enhance immunotherapy by narrowing neoantigen selection to MHC-presented peptides with the highest likelihood of tumor killing.

#7712 Wnt-driven chromosomal instability as a biomarker for PORCN inhibition.

Diego Garcia-Lopez[1], Azedine Zoufir[1], Hector De Galard Terraube[1], Laura Madrid[1], Amy Cullen[1], Ania Piskorz[1], Nicola Wallis[1], Ruth Plummer[2], Steven Jackson[3], Jackie Walling[1], James D. Brenton[4], Florian M. Markowetz[5], Jason Yip[1], Jose Teles[1], **Geoff Macintyre**[6]

[1]Tailor Bio Ltd, Cambridge, United Kingdom,[2]Newcastle University, Newcastle, United Kingdom,[3]Cancer Research UK Cambridge Insitute, University of Cambridge, Cambridge, United Kingdom,[4]University of Cambridge, Cambridge, United Kingdom,[5]University of Cambridge, CRUK Cambridge Institute, Cambridge, United Kingdom,[6]Spanish National Cancer Research Ctr. (CNIO), Madrid, Spain

Targeting Porcupine (PORCN), a key regulator of the WNT-signalling pathway, has shown therapeutic potential in multiple cancers. However, clinical responses to PORCN inhibitors have so far been limited despite strong target engagement data and a favourable safety profile. Given that Wnt signaling can drive tumorigenesis by inducing chromosomal instability (CIN), we hypothesised that CIN signatures might serve as a novel predictive biomarker to improve PORCN inhibitor response rates. Using a combination of CIN signatures capturing diverse Wnt-driven CIN processes including replication stress, error-prone non-homologous end joining repair, and whole genome duplication, we established proof-of-concept of a biomarker predictive of PORCN inhibition response. We found that CIN signature activity significantly correlated with both knockdown and pharmacological inhibition of PORCN across 180 and 24 cancer cell lines, respectively (Kendall's Tau=-0.16, P-value=0.001,Tau=-0.22, P-value=0.065). We performed a meta-analysis of 25 studies of in vivo patient-derived or cell-line xenografts treated with PORCN inhibitors, and found that biomarker activity was quantitatively associated with response to PORCN inhibition, (CIN signature activity versus tumour over control ratio, Pearson's R=-0.66, P-value=0.009). Using these data to determine an optimised threshold for clinical application (specificity=100%, 95%CI:54.07%-100% and sensitivity=100%, 95%CI:29.24%-100%), we showed concordance between predicted and observed efficacy in previous PORCN inhibitor clinical trials. The quantitative nature of the CIN signature biomarker offers an opportunity to widen the therapeutic index of existing clinical stage PORCN inhibitors and analysis of biomarker prevalence across 6,335 patient tumours from The Cancer Genome Atlas study identifies esophageal and gastric cancers as optimal indications for future clinical development.

#7713 Biomarker-guided treatment approach For advanced bladder cancer.

Dhasarathan Ganesan[1], Karina Aguilar[1], Tianyu yang[1], Bal L. Lokeshwar[1], Vinata B. Lokeshwar[2]

[1]Augusta University, Augusta, GA,[2]Associate Professor, Dept. of Urology, University of Miami, Miller School of Medicine, Augusta, GA

INTRODUCTION AND OBJECTIVE: We previously discovered a first-in-class human Chondroitinase (Chase) that degrades chondroitin sulfate. This Chase is a splice variant of HYAL4 (V1) and promotes a malignant phenotype and chemoresistance in bladder cancer (BC) cells. We evaluated the diagnostic and prognostic potential of V1-Chase and its functions in driving treatment resistant BC in preclinical models.
METHODS: Efficacy of the V1 (qPCR) and Chase (ELISA-like assay) was evaluated in three test and validation cohorts (total n = 925; BC=239; non-BC = 686). 40 cystectomy specimens from MIBC patients who received adjuvant Gemcitabine plus cisplatin (G+C) treatment. V1 was expressed in BC cell lines or silenced and the transfectants were analyzed for sensitivity to Gemcitabine (Gem) and Cisplatin. The mechanism of Gem resistance was evaluated in preclinical *in vitro* and *in vivo* models.
RESULTS: Chase levels were 7-10-fold elevated in patients with BC compared to patients with benign genitourinary conditions, history of BC, or other cancers. In all three cohorts, Chase test detected BC with > 92% sensitivity and > 85% specificity. Chase test correctly diagnosed atypical cytology inferences. V1 induced an invasive stem cell phenotype. V1's Chase activity induced Gem resistance in BC cells by cleaving CD44 and promoting intracellular JAK2/Stat3 signaling which caused up-regulation of cytidine deaminase (CDA). CDA induces Gem metabolism and efflux of dFdU, an inactive Gem metabolite. In patients with MIBC, V1/p-JAK2/CDA signature predicted failure to G+C adjuvant/salvage treatment (P<0.0001). STAT3 and CDA inhibitors re-sensitized V1-expressing cells to Gem. Transcriptome and gene enrichment analyses showed V1 induces JAK-Stat3, inflammatory and invasion/metastasis gene signatures, which were validated in clinical specimens. V1-expressing tumors were Gem resistant but were re-sensitized to Gem treatment in combination with a CDA inhibitor.
CONCLUSION: V1/Chase is a potential diagnostic and prognostic biomarker for bladder cancer and drives muscle-invasion, metastasis, and Gem resistance in BC. Inhibitors of the Chase signaling pathway overcome V1-induced Gem resistance, suggesting a precision-based treatment approach to improve treatment response.

#7714 Extracellular vesicle glycosylation profilepredictsand affectstherapeutic outcomes ofCLDN18.2-targeted CAR-T cell therapyagainst gastrointestinal cancers.

Wenran Li, Min Tao, Changsong Qi, Lin Shen, Cheng Zhang

Department of Gastrointestinal Oncology, Peking University Cancer Hospital & Institute, Beijing, China

CLDN18.2-targeted CAR-T cell therapy has shown promising potential against gastrointestinal cancers (GIC). However, biomarkers for its patient selection and outcome prediction are urgently needed. This study aims to analyze plasma extracellular vesicle (EV) glycosylation profile and select key features to predict and monitor survival outcomes and therapeutic response of CLDN18.2-targeted CAR-T cell therapy and further investigate the underlying potential mechanisms. We depicted EV glycosylation profile via a 56-lectin array in 91 dynamic plasma samples from 53 GI cancer patients received CLDN18.2-CAR-T therapy (CT041-CG4006 trial). Based on the baseline EV glycosylation profile, we found that GalNAc/Gal related glycosylation on total EVs correlated with patients' survival outcomes. We selected the binding intensity of plasma total EVs to four key lectin features using machine learning methods which simultaneously predicted progression-free survival (PFS), overall survival (OS) and therapeutic response at baseline and all specifically recognized GalNAc/Gal. Besides the baseline analysis, dynamic changes in the binding intensity of key lectins were also related to treatment response and survival outcomes. Furthermore, high binding intensity of the key lectins to total EVs and high expression of genes mediating GalNAc/Gal glycosylation were associated with weaker anti-tumor immunity represented by fewer circulating CD8+CD28+ T cells, and correlated with poorer tumor progression indicated by elevated expression of abdominal tumor biomarkers. Mechanistically, decreasing the level of GalNAc on the surface of EVs and tumor cells could strengthen killing capability of CAR-T cells in vitro. Collectively, our work provided novel biomarkers for GIC patients undergoing CLDN18.2 CAR-T cell therapy in view of plasma EV glycosylation and revealed the potential mechanism by which the EV glycosylation affects the efficacy of CAR-T therapy.

#7715 Elevated baseline DKK1 plasma is a biomarker for sirexatamab treated colorectal cancer patients.

Zongzhong Tong[1], Scott Patton[1], Patty Ormonde-Hanson[1], Calvin Jia[2], Cyndi Sirard[2], Jay Baum[2], **Mike Kagey**[2]

[1]ARUP Laboratories, Salt Lake City, UT,[2]Leap Therapeutics, Cambridge, MA

Sirexatamab is an IgG4 monoclonal antibody that potently neutralizes dickkopf-related protein 1 (DKK1). DKK1 is a secreted protein that has been implicated as a poor prognostic marker and as an oncogenic driver for colorectal cancer (CRC). The DeFianCe (NCT05480306) Phase 2 randomized, global, open-label, multicenter study was conducted to evaluate the efficacy and safety of sirexatamab plus the current standard of care (SOC) treatment regimen (FOLFIRI/FOLFOX and bevacizumab) versus SOC as second-line treatment for participants with advanced CRC (n=188). A retrospective analysis of baseline plasma levels of DKK1 using a research assay identified a significant improvement in progression free and overall survival favoring the experimental arm in patients with elevated levels of DKK1. In order to enable future prospective patient selection, an optimized DKK1 assay using the Meso Scale Discovery (MSD) platform was developed and underwent feasibility at a central laboratory. DeFianCe samples were retested with the optimized assay. Consistent with the research assay, patients whose DKK1 levels were above the median showed improved clinical outcomes in the experimental arm compared to SOC. Furthermore, approximately 500 commercial CRC plasma samples were evaluated to determine the prevalence of patients with elevated DKK1 in a real-world data set and understand the association between demographics and DKK1 levels. Future work will include completing the development and validation of the assay as a potential companion diagnostic and determining the appropriate threshold of DKK1 plasma levels for CRC patients who would be most likely to derive clinical benefit from a sirexatamab-based therapy.

#7716 Tumor-intrinsic MHC-II activation in pancreatic ductal adenocarcinoma enhances immune response and treatment efficacy.

Canping Chen[1], Kyle P. Gribbin[2], Xi Li[3], Tugba Ozmen[4], Furkan Ozmen[4], Shamilene Sivagnanam[2], James Kim[2], Katie E. Blise[5], Xinxing Yang[1], Yi Zhang[2], Dove Keith[5], Mara H. Sherman[6], Mushui Dai[7], Lisa M. Coussens[8], Charles D. Lopez[9], Rosalie C. Sears[7], Gordon B. Mills[10], Katelyn T. Byrne[7], Zheng Xia[10]

[1]Biomedical Engineer, Oregon Health & Science University, Portland, OR,[2]Department of Cell, Developmental and Cancer Biology, Oregon Health & Science University, Portland, OR,[3]Medical, Huazhong University of Science and Technology, Wuhan, China,[4]Division of Oncological Sciences, Knight Cancer Institute, Oregon Health & Science University, Portland, OR,[5]Brenden-Colson Center for Pancreatic Care, Oregon Health & Science University, Portland, OR,[6]Memorial Sloan Kettering Cancer Center, New York, NY,[7]OHSU, Portland, OR,[8]OHSU Knight Cancer Institute, Lake Oswego, OR,[9]Assoc. Professor, Div. of Hemat./Onc., Oregon Health & Science University, Portland, OR,[10]OHSU Knight Cancer Institute, Portland, OR

Pancreatic ductal adenocarcinoma (PDAC) is characterized by an immunosuppressivetumor microenvironment (TME) and poor prognosis. While major histocompatibility complexclass II (MHC-II) expression is traditionally associated with professional antigen-presentingcells, its role in PDAC malignant cells remains underexplored. Herein, we utilized single-cellRNA sequencing (scRNA-seq), spatial transcriptomics, bulk RNA sequencing, multipleximmunohistochemistry (mIHC) and ex vivo studies in culture with both human and murinemodels to investigate the prognostic relevance of MHC-II expression in malignant PDACcells. Elevated MHC-II expression in malignant cells was strongly associated with increasedinfiltration of CD4+ T and CD8+ T cells in human PDAC, and pronounced co-localization withplasma cells, indicative of an antigen-activated immune microenvironment. In the KPCmouse model of PDAC, pharmacologic induction of MHC-II expression by cobimetinibtreatment in malignant epithelial cells significantly enhanced the therapeutic response toimmune checkpoint blockade (ICB). These findings highlight the role of malignant cell-intrinsic MHC-II expression in promoting antigen presentation and fostering an anti-tumorimmune microenvironment. Our results position MHC-II as a promising prognostic biomarkerand therapeutic target in PDAC, paving the way for novel immunomodulatory strategies.

#7717 TRPM4 expression predicts Acetalax sensitivity in prostate cancer.

Yuka Hoshi[1], William C. Reinhold[1], Daiki Taniyama[1], Yoshitaka Inoue[2], Augustin Luna[1], Suresh Kumar[1], NAI-YUN SUN[3], Yoo Sun Kim[1], Yin Juanjuan[1], Nitin Roper[1], Adam G. Sowalsky[1], Naoko Takebe[4], Yves Pommier[1]

[1]National Cancer Institute, Bethesda, MD,[2]Library of Medicine, National Institute of Health, Bethesda, MD,[3]Graduate Institute of Oncology, National Taiwan University, Taipei, Taiwan,[4]Stephenson Cancer Center at the University of Oklahoma, Oklahoma, OK

Background: Advanced and treatment-refractory prostate cancer, including castration-resistant disease, highlights the need for new therapeutic strategies exploiting targetable vulnerabilities. TRPM4, a calcium-activated monovalent cation channel, regulates cell volume and promotes cancer progression. Our research showed that Acetalax induces selective oncosis-like cell death in TRPM4-positive triple-negative breast cancer, suggesting TRPM4-dependent susceptibility. Targeting TRPM4 may offer advantages over existing therapies by disrupting ion-transport and volume-regulatory mechanisms not addressed by current treatments. We examined TRPM4 expression and Acetalax activity in prostate cancer.
Methods: We assessed Acetalax sensitivity in prostate cancer cell lines with high or low TRPM4, including androgen-dependent (LNCaP) and castration-resistant models (PC3, DU145, 22Rv1). TRPM4 dynamics, cellular swelling, and oncosis-associated phenotypes were evaluated by Western blotting and immunofluorescence. Resistant clones were developed by continuous drug exposure. TRPM4 expression in patient samples was analyzed using tissue microarrays (TMAs) and TCGA. Transcriptomic changes following TRPM4 loss were examined by RNA sequencing. Antitumor activity and tolerability were tested in TRPM4-positive PDX models.
Results: TRPM4-high prostate cancer cells exhibited rapid swelling, membrane blebbing, and TRPM4 degradation after Acetalax, whereas TRPM4-low cells and resistant clones lacking TRPM4 were unaffected. Resistant clones showed TRPM4 depletion, confirming TRPM4 is required for responsiveness. In patient samples, TRPM4 protein was higher in adenocarcinoma than benign hyperplasia, and TCGA datasets confirmed increased TRPM4 transcripts in tumors relative to normal tissue, with minimal differences across stage or Gleason grade. Transcriptomic profiling revealed gene-expression changes associated with TRPM4 loss, including alterations in ion transport, cytoskeletal organization, and cell-death-related pathways, with a shift toward proliferative programs and reduced stress and inflammatory signaling consistent with disrupted volume-regulatory networks. In vivo, Acetalax significantly suppressed growth of TRPM4-positive PDX tumors in a dose-dependent manner without systemic toxicity.
Conclusions: TRPM4 functions as a target and predictive biomarker for Acetalax response in prostate cancer. These findings highlight a TRPM4-dependent therapeutic vulnerability and support biomarker-guided development of Acetalax for TRPM4-expressing, treatment-refractory prostate cancer, including CRPC.

#7718 Stearic acid-macrophage crosstalk identifies MIF-CD44 signaling as a therapeutic target in lung cancer initiation.

Amrita Roy[1], Greta Forbes[1], Dikshaya Prabhakara[1], Tyler Faith[2], Apurva Mallisetty[3], Samuel Weinberg[4], Alicia Hulbert[2], Frank D. Weinberg[5]

[1]Department of Medicine, University of Illinois at Chicago, Chicago, IL,[2]University of Illinois at Chicago, Chicago, IL,[3]University of Illinois, Chicago, IL,[4]Northwestern University, Chicago, IL,[5]University of Illinois Cancer Center, Chicago, IL

Background: Lung cancer (LC) is the leading cause of cancer-related mortality, yet the process of tumor initiation is poorly understood. Prior work from our group indicated that biomolecules like stearic acid (SA) and proinflammatory cytokines like MIP1α and MIP1β were selectively elevated in the tumor bearing lung lobes of early-stage LC patients. Hence, we hypothesized that a SA-macrophage (MΦ) inflammatory axis contributes to neoplastic transformation in lung epithelium.

Method: Plasma cytokine profiles were compared between early-stage LC patients (n=5) and healthy controls (n=6). Cytokine production following SA exposure at transcriptional and translational level were assessed in PBMC-derived MΦs and human monocytic cell lines (U937) to establish synchrony between two systems. Conditioned media (CM) from SA-treated MΦs (SA-CM) was applied to BEAS2B epithelial cells (non-transformed lung epithelial cells), with transformation measured by soft agar and spheroid assays. Receptor expression for MIP1α (CCR5) and MIF (CD44) was quantified by mRNA/protein analyses. Functional blockades of CCR5 and CD44 were performed using small-molecule antagonists (Maraviroc and Verbascoside respectively) to identify critical cytokine driving transformation.

Results: Elevated MIP1α were observed in plasma samples from early-stage LC patients compared to healthy individuals. SA treatment augmented MIP1α and MIF expression from both PBMC and U937 derived MΦs. Simultaneously, SA-CM from both PBMC and U937 derived MΦs induced significantly greater colony formation in soft agar matrix and robust spheroid growth under low-attachment conditions, indicating neoplastic transformation. Receptor analysis revealed abundant CD44 but limited CCR5 expression on BEAS2B cells. Blockade of CD44 with Verbascoside abrogated SA-CM-induced spheroid formation, whereas CCR5 inhibition had no effect.

Conclusion: Based on these observations we conclude that SA reprograms MΦ transcriptional states promoting a MΦ driven proinflammatory environment that induces MIF-CD44-dependent neoplastic transformation of lung epithelial cells. These findings implicate a novel immunometabolic axis involved in the early oncogenic events of LC initiation and support therapeutic targeting of SA-MIF-CD44 signaling as a potential preventive strategy.

#7719 Exploring biomarker predictors of response to nintedanib and bevacizumab combination therapy in advanced cancer patients: Correlative studies from Phase 1b study.

Ravi Kumar Paluri[1], Anup Kasi[2], Francisco Robert[1], Gagan Deep[3], Ashish Manne[4]

[1]Wake Forest Baptist Health, Winston Salem, NC,[2]The University of Kansas Cancer Center, Kansas City, KS,[3]Wake Forest University School of Medicine, Winston-Salem, NC,[4]Ohio State University, Columbus, OH

Background: Bevacizumab and other VEGF inhibitors provide clinical benefit across multiple cancers but are limited by resistance driven largely by revascularization through alternate pro-angiogenic pathways, including PDGFR and FGFR. Nintedanib, a triple kinase inhibitor targeting VEGFR, PDGFR, and FGFR, may overcome these escape mechanisms. The safety and efficacy of nintedanib plus bevacizumab was previously explored in our phase 1B study and published. We are presenting correlative biomarker studies on the plasma samples acquired at prespecified endpoints.
Methods: Plasma samples were obtained from patients enrolled in a phase 1 dose-escalation study evaluating nintedanib in combination with bevacizumab for advanced solid tumors (lung n=9, colon n=8, cervical n=1). Baseline plasma biomarkers—including IL-8, ICAM-1, Angiopoietin-2, KDR/VEGFR2, E-selectin, VEGF, and SDF-1α—were analyzed and correlated with clinical outcomes. Biomarker quantification was performed using multiplex bead-based immunoassays (Luminex), with select analytes validated by ELISA.
Results: Nintedanib 200 mg twice daily was well tolerated with no dose-limiting toxicities. . Among bevacizumab-pretreated patients, 55% achieved durable disease control, including one complete response and four stable diseases. Higher baseline levels of KDR/VEGFR2 and E-selectin and lower SDF-1α were associated with improved outcomes. ANOVA identified several biomarkers significantly linked to disease control, including KDR/VEGFR2 ($p=0.004$), PDGF-AA ($p=0.037$), and Endoglin ($p=0.020$).
Conclusion: Nintedanib combined with bevacizumab was safe, well tolerated, and demonstrated meaningful clinical activity in heavily pretreated patients. Baseline KDR/VEGFR2, E-selectin, and SDF-1α emerged as potential predictive biomarkers. These data support further validation in larger cohort as a strategy to refine biomarker-driven patient selection for treatments in lung and colorectal cancers.

#7720 Differences in FGFR2 fusion detection between DNA and RNA NGS in a large Chinese lung cancer cohort.

Wenxue Chen[1], Xinlin Yu[1], Lipeng Bai[1], Can Wen[1], Wennan Zhang[1], Wanwan Zou[1], Zhiliang Liu[1], Ruijia Sun[2], Mengli Huang[2]

[1]Jiangxi Key Laboratory of Translational Cancer Research Jiangxi Cancer Hospital, Nanchang, China,[2]Department of Medical Affairs, 3D Medicines Inc., Shanghai, China

Background: Fibroblast growth factor receptor 2 (FGFR2) fusions are rare driver gene alterations in non-small cell lung cancer (NSCLC), with an overall incidence of approximately 0.02%. FGFR2 fusion breakpoints typically occur within exons 17-19, and numerous fusion partner genes have been identified. While next-generation sequencing (NGS) is the primary method for fusion detection, the differences in the detection spectrum between DNA- and RNA-based NGS for FGFR2 fusions remain inadequately characterized in large-scale cohorts.
Methods: This retrospective study analyzed a large Chinese lung cancer cohort comprising 12,974 tumor samples. Among these, 3,578 samples were tested by DNA-NGS for fusion detection, and 9,396 samples were tested using RNA-NGS. Only FGFR2 fusions classified as pathogenic or likely pathogenic were included in the final analysis.
Results: A total of 18 FGFR2 fusion events were identified, yielding an overall detection rate of 0.14%. The patient cohort was predominantly male (72.22%), with a median age of 65 years (range: 52-78). Histologically, most cases were diagnosed as lung adenocarcinoma (44.44%) and lung squamous cell carcinoma (38.89%), with 3 cases of undetermined pathology. All FGFR2 fusions were characterized by 5'-3' rearrangements. DNA-NGS identified 5 FGFR2 fusions (0.14%), all in lung adenocarcinoma, with heterogenous fusion partners including FGFR2-INPP5F, FGFR2-TACC2 (non-canonical breakpoints: exon 6), FGFR2-PCAT2, FGFR2-KCNH5, and one complex fusion involving FGFR2-NME9 and NME9-FGFR2. Meanwhile, RNA-NGS detected 13 FGFR2 fusions (0.14%), with a partner distribution distinct from DNA-NGS: 11 cases of FGFR2-ATE1 (84.62%) involving non-canonical breakpoints (exon2/5/6/9), as well as FGFR2-BICC1 and FGFR2-TACC2. All FGFR2-ATE1 fusion patients were male, and 7 of the 8 cases with specified pathology were lung squamous cell carcinomas, indicating a potential enrichment. Importantly, the FGFR2-ATE1 fusion lacked the FGFR2 kinase domain, and the vast majority (90.91%) had supporting reads <100, suggesting low expression levels. These features imply that FGFR2-ATE1 may exert oncogenic effects via kinase-independent mechanisms, and such fusions are unlikely to respond well to FGFR kinase inhibitors. The pathogenicity of atypical, low-expressed fusion transcripts requires cautious evaluation and reclassification.
Conclusions: This study reveals distinct FGFR2 fusion detection patterns between DNA and RNA NGS. When interpreting complex or atypical fusions for targeted therapy guidance, integrating results from both DNA and RNA NGS is recommended to optimize patient stratification and treatment decisions.

#7721 Correlation between PD-L1, desmocollin 3, and stromal lymphocytes in recurrent head and neck squamous cell carcinomas.

Vedanti Newaskar[1], Shivani Sharma[1], **Bakulesh M. Khamar**[2]

[1]Core Diagnostics, Delhi, India,[2]Cadila Pharmaceuticals, Ahmedabad, India

Introduction: Immune checkpoint inhibitors has improved outcome of recurrent /metastatic head and cancer (rmHNSCC) . Benefit is seen in around 20% pf patients and is proportionate to PD-L1 expression. We evaluated correlation between PD-L1, Desmocollin-3 (DSC3) and stromal tumor infiltrating lymphocytes (TIL) to explore possibility of using DSC3 specific therapy along rmHNSCC . DSC3 is a predictive biomarker for an investigational product CADI-05.

Methods: Samples from patients with rmHNSCC were evaluated PD-L1 expression using standard protocol and expressed as combined proportion score (CPS) and tumor proportion score (TPS) . DSC3 expression was evaluated as tumor proportion score (TPS) by immunohistochemistry, using mouse anti-DSC3 monoclonal antibody (Progen, Heidelberg, Germany Cat#61093 dilution: 1:50) following removal of paffinization of formalin-fixed, paraffin-embedded tissue. TIL was evaluated after staining with hematoxylin and eosin and expressed as a percentage of total cells. All evaluated samples were received after informed consent of patients.

Results: Total of seventy (70) samples were evaluated between September 2023 to May 2025 for PD-L1, DSC3 and TIL. PD-L1 expression as CPS and TPS was observed in 77% and 51% of samples. PD-L1 values ranged from 0-95% (CPS) and 0-95%(TPS). DSC3 expression was observed in 93% of samples. DSC3 (TPS) values ranged from 0-80%. No correlation was found between PD-L1(CPS) and DSC3 expression (Spearman correlation coefficient r = -0.1432, p = 0.3846; 95% Confidence interval = -0.4389 to 0.1805). There was a moderate negative correlation (r= -0.3) between PD-L1(TPS) and DSC3. All PD-L1 negative samples expressed DSC3.Mean and median DSC3 expression values were not different between PD-L1 positive and negative samples. Based on expression level TIL were grouped as samples having TIL ≥ 10% and <10%. TIL ≥ 10% were observed in 40% of evaluated samples. All samples expressing PD-L1(CPS and TPS) as well as DSC3 had TIL ≥ 10% . TIL were absent in five samples and all expressed DSC3 from 10-40%.

Conclusion: DSC3 is expressed in 93% of rmHNSCC , irrespective of PD-L1 and TIL expression suggesting DSC3 specific therapy may be useful in management of patients with rmHNSCC with absent/low PD-L1 and or TIL .

#7722 Biomarkers of nelmastobart efficacy: BTN1A1 expression and tumor microenvironment dynamics in colorectal cancer.

Bong-Ki Hong[1], Soohyeon Lee[2], Andrew H. Park[1], Young-Seung Kim[1], Chunai Wu[1], Seung-Hoon Lee[1], Jong-Su Park[1], **Stephen S. Yoo**[1]

[1]STCube Pharmaceuticals Inc., Rockville, MD,[2]Korea Univ. Medical Center, Seoul, Korea, Republic of

Background: Butyrophilin 1A1 (BTN1A1) is an immune regulatory protein expressed in various tumors and immune cell populations, playing a role in shaping the tumor microenvironment (TME). Our previous tissue microarray (TMA) analysis demonstrated that high BTN1A1 expression in colorectal cancer is associated with reduced intratumoral $CD8^+$ T-cell infiltration, suggesting BTN1A1's role in promoting an immunosuppressive TME. The Phase 1 clinical study of Nelmastobart, a BTN1A1-targeting antibody, showed acceptable safety and preliminary antitumor activity. Additionally, early findings from the ongoing STCUBE-IIT Phase 1b/2 trial (ClinicalTrials.gov: NCT05990543) suggest a potential link between BTN1A1 expression and therapeutic response. To further investigate the biological significance of BTN1A1 and identify reliable biomarkers predictive of Nelmastobart efficacy, we conducted a deep, multiplexed tissue analysis using the CellDIVE platform on baseline tumor specimens from patients enrolled in the STCUBE-IIT Phase 1b/2 clinical trial.
Methods: Baseline colorectal tumor tissues were analyzed using the CellDIVE multiplex imaging system. Quantitative profiling included BTN1A1, CD8, FoxP3, and additional TME- and tumor-intrinsic markers. TME composition and spatial organization were compared between responders and non-responders. Baseline BTN1A1 expression and pathway activity scores were integrated to assess correlations with objective response rate (ORR) and progression-free survival (PFS). The primary endpoint was the association between BTN1A1 expression and immune cell composition; the secondary endpoint examined composite molecular features predictive of response to Nelmastobart.
Results: High BTN1A1 expression was associated with lower intratumoral $CD8^+$ T-cell infiltration and increased immunosuppressive cellular populations. Integrated analyses revealed that combining exhausted $CD8^+$ T-cell abundance and spatial distribution with tumor-intrinsic DNA damage repair activity more strongly correlated with treatment response than BTN1A1 expression alone.
Conclusions: BTN1A1 expression is linked to key immunological alterations in the colorectal cancer TME. A composite biomarker incorporating exhausted $CD8^+$ T-cell features and tumor DNA damage-related repair activity provides superior predictive value for Nelmastobart response compared with BTN1A1 alone. These findings support a multidimensional biomarker strategy for optimizing BTN1A1-targeted therapies and warrant validation in larger clinical cohorts.

#7723 Implementation of a novel immune monitoring strategy for multicenter clinical trials to enable equity in cancer prognosis for individuals from remote settings of Australia.

Natalie J. Smith[1], Michael Cohen[2], Lauren J. Tracey[2], Julie Alipaz[3], Christina Loh[3], David A. King[4], Neha Pulyani[5], Rebecca Auzins[5], Elin S. Gray[6], Sandra Taylor[7], Rajat Rai[7], Steven Kao[8], Barbara Fazekas de St Groth[1], **Helen McGuire**[1]

[1]The University of Sydney, Sydney, Australia,[2]Standard BioTools, Markham, ON, Canada,[3]Standard BioTools, San Francisco, CA,[4]Standard BioTools, South San Francisco, CA,[5]Edith Cowan University, WA, Australia,[6]Edith Cowan University, Joondalup, Australia,[7]Dubbo Base Hospital, Dubbo, Australia,[8]Chris O'Brien Lifehouse, Sydney, Australia

Improved cancer prognosis begins with the collection of high-quality data from clinical trials. However, execution of longitudinal immune phenotyping studies by flow cytometry is complex due to logistical challenges that could affect data quality. The challenges of immune monitoring are exacerbated when considering remote and rural communities in Australia, which are burdened by both an increased prevalence and worse prognosis of cancer. Paradoxically, these communities are often underrepresented in clinical trials. Our group has developed a novel blood-based “immune signature” that robustly predicts failure to make a clinical response to checkpoint therapies targeting the PD-1/PD-L1 pathway in melanoma and lung cancer. We have now taken these groundbreaking findings to implement in remote clinical settings, along with an expanded CyTOF™ panel for 50-plus-parameter analysis of cancer patient peripheral blood samples. Recent developments in CyTOF technology facilitate a highly simplified workflow of asynchronous sample collection and staining, compatible with current hospital laboratories, which typically run on unpredictable schedules, to remote settings, which are resource-poor and have limited clinical trial infrastructure. This is uniquely enabled by using a stable, dried-down cocktail of CyTOF antibodies and an easy-to-follow protocol that yields reproducible staining while minimizing sample required. Furthermore, this unique mass cytometry workflow provides flexibility and minimizes technical variation via sample barcoding and freezing of stained samples for shipment to a central site for batch acquisition. As such, this study is designed to demonstrate both clinical impact of the large panel and utility of CyTOF technology for a highly simplified and robust workflow for multi-site clinical trials. Here we present findings from the implementation of this novel workflow through a 100-sample pilot study at three sites across Australia, in a variety of clinical implementation setups. Remote asynchronous sample collection was performed to compare two surface staining approaches on i) PBMC versus ii) plasma-depleted whole blood to suit settings where centrifugation access was readily available or not, respectively. Stained samples were shipped to a central lab for processing. In the case of cryopreserved whole blood, bead-based granulocyte depletion was first performed, with all samples subsequently multiplex barcoded together for intracellular antibody staining of key functional markers. Analysis harmonization was achieved across sample collection sites and staining approaches. Overall, this workflow enables access to underserved communities, facilitating for the first time equity and scalability of immune phenotyping studies to harness truly geographically dispersed clinical centers.

#7724 A circulating GPNMB-based multimodal model integrates tumor-immune crosstalk to predict immunotherapy response in esophageal cancer.

Liang Zhu[1], Xiaoyuan Wang[2], Guoyu Cheng[1], Yancheng Lai[1], Lan Lan[1], Zhenghao Dong[1], Zhixuan You[1], Xinjie Chen[1], Ziyi He[1], Xinyi Xiao[1], Lingxuan Zhu[1], Rucheng Liu[1], Shaosen Zhang[1], Dongxin Lin[1], **Chen Wu**[1], Jiang Chang[3]

[1]Cancer Hospital Chinese Academy of Medical Sciences, Beijing, China,[2]Harbin Medical University Cancer Hospital, Harbin, China,[3]Department of Epidemiology and Biostatistics, Huazhong University of Science & Technology, Wuhan, China

Neoadjuvant immunotherapy improves outcomes in esophageal squamous cell carcinoma (ESCC), yet ~70% of patients fail to respond. Pretreatment biopsies and plasma thus provide critical opportunities for biomarker discovery. Here, we performed plasma proteomic profiling and identified soluble glycoprotein non-metastatic melanoma protein B (sGPNMB) as the most elevated circulating protein in non-responders. Mechanistically, tumor cell-derived sGPNMB suppressed $CD8^+$ T cell receptor (TCR) signaling to induce functional exhaustion, with secretion being required for its immunosuppressive activity. Cancer-associated fibroblast-epithelial (CAF-Epi) niches promoted SOX2 upregulation in tumor cells, transcriptionally activating GPNMB expression. In humanized PDX models, plasma GPNMB levels predicted response to PD-1 blockade, and GPNMB inhibition synergised with therapy. Across retrospective cohorts and a prospective clinical trial, a multimodal model combining plasma GPNMB levels, CAF-Epi niche detection, and clinical-pathological features achieved robust predictive accuracy for immunotherapy response and survival. These findings establish a mechanistically grounded, spatial-circulating biomarker framework for precision immunotherapy in ESCC.

#7725 Integrative molecular profiling identifies predictors of response to sacituzumab govitecan in advanced prostate cancer.

Jacque Lyman[1], Todd Knutson[2], Allison Haaning[2], Braedan M. McCluskey[2], Yingming Li[1], Jamie M. Sperger[3], Rendong Yang[4], Christos Kyriakopolous[5], Susan F. Slovin[6], Scott T. Tagawa[7], Joshua M. Lang[3], Scott M. Dehm[1]

[1]Masonic Cancer Center, Minneapolis, MN,[2]Minnesota Supercomputing Institute, University of Minnesota, Minneapolis, MN,[3]University of Wisconsin-Madison, Madison, WI,[4]Feinberg School of Medicine, Northwestern University, Chicago, IL,[5]University of Wisconsin, Madison, WI,[6]Associate Professor of Medicine, Memorial Sloan Kettering Cancer Center, New York, NY,[7]Weill Cornell Medicine, New York, NY

Prostate cancer is the second leading cause of cancer related death in men. Potent therapies that inhibit the androgen receptor (AR) transcription factor have improved survival of patients with prostate cancer, however many cases progress to lethal castration resistant prostate cancer (CRPC). Resistance to AR-targeted therapies is frequently mediated by reactivation of AR signaling or transition to AR-independent, non-luminal subtypes. Identifying new treatment strategies for patients with CRPC who are resistant to available therapies is critical for improving survival outcomes. One promising therapeutic target for CRPC is the trophoblastic cell surface antigen (Trop-2). Found to be highly expressed in many solid tumors, Trop-2 has oncogenic activities implicated in CRPC progression and could provide a target for treatment of prostate cancer resistant to AR targeted therapies. Sacituzumab Govitecan (SG) is an anti-Trop-2 antibody drug conjugate that provides targeted delivery of the topoisomerase I inhibitor SN-38. As part of a completed phase II clinical trial assessing the efficacy of SG in CRPC, we performed integrative whole exome DNA-seq and RNA-seq on metastatic biopsies obtained from 29 patients at baseline (pre-treatment with SG) and during treatment with SG. We characterized the gene expression profiles and mutational landscapes to evaluate the prognostic value of gene signatures and acquired genetic alterations. Baseline biopsies from patients that responded to SG displayed enrichment for gene signatures that define basal subtypes of CRPC and inflammatory response. Conversely, baseline biopsies from patients that did not respond to SG displayed enrichment for pathways related to high proliferation and AR activity. These findings provide a framework for interpreting response to SG that may inform future clinical development as well as selection of laboratory models to enhance mechanistic knowledge of SG response and resistance.

#7726 Expression profile of therapeutic target CDH17 in gastric cancer.

Fei Chu[1], Jiaxing Zhao[2], Dan Huang[1], Hao Luo[1], Aaron Hong[1], Ye Tian[2], Chang Liu[2], David Chu[3], Jim Lu[1]

[1]Gopath Diagnostics, LLC, Buffulo Grove, IL,[2]Celnovte Biotech, Rockville, MA,[3]Fetchflow Inc, San Francisco, CA

Background:
CDH17 has recently gained attention as a promising therapeutic target in gastric cancer (GC), driven by advances in antibody-drug conjugates and other targeted modalities designed to exploit its highly restricted expression in gastrointestinal tissues. Despite growing therapeutic interest, the real-world prevalence and staining characteristics of CDH17 in clinical GC samples are not well established. A clearer understanding of CDH17 expression patterns may help refine patient selection strategies, guide the development of CDH17-directed therapies, and support biomarker-driven clinical decision-making.
Methods:
Tissue microarrays from 73 patients with histologically confirmed gastric cancer were evaluated by immunohistochemistry (IHC). CDH17 staining was performed using the Celnovte IHC platform with CNT-PolyStacker secondary antibodies (clone C5A5), which enables high-specificity visualization of membrane-associated and cytoplasmic expression. Staining intensity was scored semi-quantitatively, and CDH17 positivity was defined as ≥50% of tumor cells demonstrating 2+ or 3+ intensity. All slides were reviewed independently by board-certified pathologists to ensure consistent interpretation.
Results:
CDH17 expression was identified in 15.1% (11/73) of gastric cancer cases. Positive tumors demonstrated strong, well-defined membranous and cytoplasmic staining, consistent with the known biology of CDH17 as an intestine-specific adhesion molecule. Within this cohort, CDH17-positive cases appeared across both intestinal and diffuse histologic subtypes, and no clear relationship with tumor differentiation, sample location, or patient demographic factors was observed. The overall expression rate aligns with reported ranges from prior smaller studies, suggesting that CDH17 may define a distinct molecular subset of GC patients potentially suitable for targeted therapeutic approaches.
Conclusions:
CDH17 expression was detected in approximately 15% of gastric cancer cases in this real-world cohort, reinforcing the relevance of CDH17 as a potential biomarker for targeted therapy development. As CDH17-directed agents continue to advance in early-phase clinical trials, reliable biomarker prevalence data will be essential for refining clinical trial eligibility criteria and informing market-wide testing strategies. Additional studies with larger and more diverse patient populations are warranted to validate the prevalence, biological implications, and potential predictive value of CDH17 expression in gastric cancer.

#7727 Integrated FHIT and IDH2 biomarkers predict synthetic lethal response to DCPS inhibition in acute myeloid leukemia.

Madhurendra Singh[1], Francesca Grassi[1], Lisa Bast[2], Vladimir Talibov[1], Camilla Silvander[1], Simon Moussaud[1], Matthieu Desroses[1], Angelo De-Milito[1], Julian Walfridsson[2], Andreas Hoglund[1], Martin Andersson[1]

[1]Tumor Biology, Sprint Bioscience AB, Stockholm, Sweden,[2]Karolinska Institutet, Stockholm, Sweden

DCPS (Decapping Scavenger Enzyme) is a critical regulator of RNA metabolism that clears cap structures generated during mRNA decay. At Sprint Bioscience, in the frame of our efforts to develop new modalities in oncology, we have generated, among others, novel selective DCPS inhibitors (DCPSi) with sub-nanomolar activity in cells using our fragment- and structure-based drug discovery platform. Using the clinically validated DCPSi RG3039 across a panel of AML cell models, we identified a synthetic lethal interaction between DCPS and the cap-degrading enzyme Fragile Histidine Triad (FHIT), which shares overlapping substrate specificity. In both *in vivo* and *ex vivo* systems, low FHIT expression emerged as a strong predictive biomarker of therapeutic response to DCPSi, while hydroxyurea pretreatment was identified as a negative confounding factor. Mechanistically, FHIT loss preserves the therapeutic effects of DCPSi, including release of differentiation blockade, induction of cell-cycle arrest, and apoptosis—key vulnerabilities in AML. Interrogation of AML databases (cBioPortal OHSU 2022, total 942 samples) and primary patient samples (Champions Oncology, 30 *ex vivo unpassaged primary AML*) further revealed that IDH2 mutation status correlates with both FHIT expression (FDR=0.002) and sensitivity to DCPSi (p=0.042), identifying IDH2 as an additional predictive biomarker. Primary AML specimens harboring IDH2 mutations demonstrated increased susceptibility to RG3039, consistent with this molecular association. Together, these findings establish DCPS as a safe and efficacious therapeutic target in AML. We propose that FHIT expression, frequently reduced in cancer, provides a biomarker-driven strategy for patient stratification, and that IDH2 mutation status further refines prediction of response to DCPS-targeted therapy.

#7728 Glycogen branching enzyme 1 as a metabolic determinant and prognostic driver of the CMS4 subtype in colorectal cancer.

Fang-Chi Hsu[1], Leila Su[1], Frank Luh[1], Yi-Fan Chen[2], Xin Wang[1], Yun Yen[3]

[1]Sino-American Cancer Foundation, Covina, CA,[2]International Master Program for Translational Science, Taipei Medical University, Taipei, Taiwan,[3]Sino-American Cancer Foundation, Arcadia, CA

Colorectal cancer (CRC) continues to impose a substantial global health burden, ranking among the top causes of cancer incidence and mortality. Despite meaningful advances in screening, surgical techniques, and systemic therapy, patients with biologically aggressive molecular subtypes—particularly consensus molecular subtype 4 (CMS4)—experience limited therapeutic benefit and disproportionately poor outcomes. CMS4 tumors are characterized by a mesenchymal phenotype, pronounced hypoxic signaling, activation of Wnt-driven transcriptional programs, and a proliferative state that contributes to treatment resistance. Identifying actionable metabolic determinants of this phenotype remains an unmet clinical need.Through integrative multi-omics profiling across independent CRC cohorts, we identified glycogen branching enzyme 1 (GBE1) as a central metabolic regulator closely aligned with the CMS4 transcriptional landscape. GBE1 expression is significantly enriched in CMS4 tumors and demonstrates a strong, inverse association with overall survival, underscoring its potential as a subtype-specific prognostic biomarker. Transcriptomic analyses further reveal that GBE1 and its downstream glycogen-synthesis pathways are selectively activated in CMS4 tumors, achieving robust statistical significance.Mechanistically, GBE1 operates as a hypoxia-induced effector downstream of HIF-1α, reshaping carbohydrate metabolism in a manner that reinforces the metabolic rigidity of CMS4 disease. Beyond its canonical enzymatic role, GBE1 influences broader glycosylation and glycosyltransferase networks, and modulates lipid biosynthetic programs through the PPARγ/Wnt/β-catenin axis. This dual control of carbohydrate and lipid metabolism endows CMS4 tumors with a pronounced growth advantage. Functional studies using CRISPR-mediated GBE1 knockout demonstrate marked suppression of tumor cell proliferation and attenuation of Wnt/β-catenin signaling, confirming its mechanistic role in sustaining the pro-invasive CMS4 phenotype.Together, these findings identify GBE1 as a clinically meaningful metabolic vulnerability that defines the CMS4 subtype. GBE1 emerges as both a prognostic marker and a tractable therapeutic target, providing a precision oncology framework for the management of high-risk CRC patients with metabolically and immunologically dysregulated diseases.

#7729 Phosphorylated FRS2 (pFRS2) as a biomarker for FGFR mutation or fusion activity assessment in formalin-fixed paraffin-embedded tumor sections.

Peter Feiszt, Kristopher A. Lofgren, **Paraic A. Kenny**

Gundersen Medical Foundation, La Crosse, WI

Genes encoding the Fibroblast Growth Factor Receptor family (FGFR1, FGFR2, FGFR3 and FGFR4) are a recurrent target of genomic alterations in several solid tumor types. Alteration types include gene amplification, gene fusion and point mutations which can affect both extracellular and intracellular domains. The FGFR inhibitors, pemigatinib, erdafitinib and futibatinib, have FDA approvals to treat selected solid tumors with FGFR pathway alterations. Because FRS2 is a common substrate for each of these kinases, we investigated whether the level and subcellular localization of phosphorylated FRS2 (pFRS2) would be an effective biomarker to read out pathway activity in clinical FFPE tumor specimens.

The Gundersen Precision Oncology Cohort includes 1,046 patients who received next-generation sequencing at Gundersen Health System during their cancer care. A total of 29 patients had FGFR alterations (13 x FGFR1, 9 x FGFR2 and 7 x FGFR3) with fusions, point mutations and gene amplifications represented. The most common tumor types were urothelial (7), lung (7) and biliary tract (6).

Here we report a pFRS2 immunofluorescence assay that permits high-resolution readout of both the level and subcellular localization of the activity of genetically altered FGFRs. This enables quantitative distinction between specimens with high pathway activity (including fusions and some point mutations) from specimens with lower pathway activity (some amplifications), suggesting utility as a companion diagnostic for identification of likely responders to currently approved and newly emerging FGFR therapies. In particular, the ability to determine subcellular localization of pathway activity may prove useful for trials of both antibody-drug conjugates and bispecific antibodies which might be expected to be less effective in tumors where the oncogenic FGFR activity is primarily internal and not cell-surface associated.

#7730 A novel ultra-sensitive qPCR-based liquid biopsy assay: ESR1 mutation detection in peripheral plasma derived cfDNA.

Fei Ma[1], Haili Qian[1], Wenna Wang[1], **Yongpan Yan**[2], Bowen Ji[2], Yuwei Pei[2]

[1]State Key Laboratory of Molecular Oncology, National Cancer Center/Cancer Hospital, Chinese Academy of Medical Sciences & Peking Union Medical College, Beijing, China,[2]RayBio Inc, Beijing, China

Background: ESR1 mutations are a leading cause of acquired resistance to endocrine therapy in HR+/HER2- metastatic breast cancer (mBC). Monitoring of ESR1 mutations' dynamic accumulations is critical for patients to quickly switch to effective selective estrogen receptor degrader (SERD) treatment. Therefore, a rapid and cost-effective assay for ESR1 mutations status monitoring is in urgent demand in clinical practice.
Methods: ESR1 sequence with consecutive mutations poses a major hurdle for conventional qPCR assay development. Here an Innovative Suppression Probe PCR was designed and assay was successfully developed (Eq-PCR). Genomic cell-free DNA samples which were extracted from ESR1 mutated breast cancer cell lines (n=47) and patient-derived peripheral blood samples (n=25) were subjected to Eq-PCR, ddPCR (digital droplet PCR) and Next generation sequencing (NGS covering 78 genes).
Results: Our Eq-PCR assay has a limit of detection of 0.5% mutation frequency for major ESR1 mutations. For 47 cell lines samples (10ng DNA input), overall agreement between Eq-PCR and ddPCR is 100%. For 25 samples collected from mBC patients(cfDNA concentration ranged from 0.2ng-0.8ng/μl), overall agreement between Eq-PCR and NGS is 100.0% of PPV (5 positive samples) and 85.0% of NPV (20 negative samples).
Conclusion: A novel, cost-effective qPCR-based assay for major ESR1 mutations was developed with top accuracy and quick turn-around time. This assay provides an urgently needed clinical tool to monitor critical ESR1 mutation in HR+/HER2- mBC patients in a convenient, timely and cost-effective fashion.

#7731 Tumor immune microenvironment features associated with response to neoadjuvant durvalumab plus gemcitabine, cisplatin, and nab-paclitaxel (DURGAP) in resectable biliary tract cancer.

Huiying Yan[1], Wenxin Li[2], **Linze Xu**[1], Rentao Li[2], Linlin Fu[2], Qi Qi[2], Xihao Zhang[2], Jihui Hao[3], Huikai Li[2], Yang Liu[1]

[1]Department of Hepatobilay Cancer, Liver Cancer Center, Tianjin Medical University Cancer Institute & Hospital, National Clinical Research Center for Cancer, Key Laboratory of Cancer Prevention and Therapy, Tianjin's Clinical Research Center for Cancer, Tianjin, China,[2]Department of Hepatobiliary and Pancreatic Oncology, Tianjin Cancer Hospital Airport Hospital, Tianjin, China,[3]The Pancreas Center, Tianjin Medical University Cancer Institute & Hospital, National Clinical Research Center for Cancer, Tianjin Key Laboratory of Digestive Cancer, Tianjin's Clinical Research Center for Cancer, Tianjin, China

Background: Neoadjuvant DurGAP therapy has shown promising efficacy in resectable biliary tract cancer (BTC). In an updated cohort of 30 patients (2025 The Lancet Summit: Cancer Control in China, Abstract #TLSU2025_0087; NCT05640791), the objective response rate (ORR) was 60%, disease control rate (DCR) 86.7%, and R0 resection rate among resected patients 93.8%. However, mechanisms underlying variable response remain unclear. This study explored the tumor immune microenvironment (TIME) associated with differential tumor regression grades (TRG).

Methods: Four TRG1 (major response) and four TRG3 (minimal response) patients from the DurGAP cohort were analyzed. Multiplex immunofluorescence quantified $CD8^+$ T cells, $CD4^+$ T cells, and regulatory T cells (Tregs). One representative case per group underwent spatial transcriptomic sequencing to assess cellular composition and spatial distribution. Immunofluorescence data were compared using Mann-Whitney U test. Spatial transcriptomic data were processed with the Seurat and sctransform pipelines, normalized and batch-corrected via Harmony, followed by PCA and UMAP-based clustering. Spatial domains were annotated using FindAllMarkers to identify domain-specific genes. Differentially expressed genes ($p<0.05$, $|\log_2 FC|>\log_2 1.5$) were subjected to GO and KEGG pathway enrichment analysis.

Results: TRG1 tumors displayed significantly higher infiltration of $CD8^+$ and $CD4^+$ T cells compared with TRG3, while Tregs were enriched in TRG3. Spatial transcriptomics confirmed these findings, revealing greater T and B lymphocyte density and fewer malignant cells in TRG1, whereas TRG3 exhibited higher tumor cell proportions and reduced effector infiltration. Subset analysis showed that the proportion of Tregs among total T cells was markedly higher in TRG3, while the $CD8^+$/Treg ratio was substantially greater in TRG1. Functional enrichment highlighted immune activation and antigen presentation pathways in TRG1, contrasting with metabolic and proliferative signaling enrichment in TRG3. These spatial and transcriptional patterns indicate that robust effector T-cell infiltration and coordinated immune architecture underlie effective tumor regression, whereas immunosuppressive microenvironments limit therapeutic benefit.

Conclusions: Distinct TIME profiles distinguish responders from non-responders to neoadjuvant DurGAP in BTC. Higher effector T-cell infiltration, an increased $CD8^+$/Treg ratio, and immune-enriched spatial domains are linked to major tumor regression, whereas Treg-dominant microenvironments correspond to poor response. These findings highlight potential immune biomarkers to refine patient selection and improve future therapeutic strategies.

#7732 A stromal-immune spatial transcriptomic signature associated with MUC4 identifies potential biomarkers of trastuzumab resistance in HER2-positive breast cancer.

Maria F. Mercogliano[1], Nadine Schrode[2], Kristin Beaumont[3], Roxana Schillaci[4]

[1]Laboratorio de Inmunologia Tumoral, Instituto de Biologia y Medicina Experimental, Buenos Aires, Argentina,[2]Center for Advanced Genomics Technology, Icahn School of Medicine at Mount Sinai, New York, NY,[3]Icahn School of Medicine at Mount Sinai, New York, NY,[4]Laboratorio de Inmunologia Tumoral, Instituto de Biologia y Medicina Experimental, Buenos Aires, Argentina

Trastuzumab-based therapies are the standard of care treatment for HER2-positive breast cancer. We previously demonstrated that mucin 4 (MUC4) expression is associated with trastuzumab resistance and is an independent biomarker of poor clinical response. The aim of this work was to refine the prognostic and predictive value of MUC4.Five HER2-positive breast cancer samples obtained at diagnosis and classified as either MUC4-positive/non-responder or MUC4-negative/responder to trastuzumab were used to analyze spatial expression of transcripts using the Visium platform from 10X Genomics. Libraries were sequenced on a NextSeq 550 and data were processed with Cell Ranger. To minimize batch effects and to optimize noise-to-signal ratio, data were integrated using different approaches: reciprocal PCA, canonical correlation analysis and Harmony. RPCA was selected for optimal batch correction and preservation of biological heterogeneity.Cell annotation included three approaches: manual annotation using cell specific markers, automated prediction using data from other five spatial transcriptomic experiments and a semi-automated method using Unicell. Cells were annotated when at least two of these methods coincided in cell annotation. Differential gene expression was performed with Seurat and limma, accounting for donor and cell type composition. Notably, downregulated genes included multiple immunoglobulin-related transcripts consistent with previously reported trastuzumab response signatures such as HER2DX.To reduce false positives arising from gene list variability, we applied an elastic net penalized logistic regression which refined the initial set of 267 MUC4-associated genes to 37 high confidence candidates. For each gene, we analyzed structural features, biological function, protein-protein interactions and relevance in cancer using resources such as The Human Protein Atlas, Gene Cards, UniProt and PubMed. The analyzed gene set showed strong enrichment for Gene Ontology Biological Process categories related to extracellular matrix remodeling, stromal activation, epithelial-to-mesenchymal transition, angiogenesis, cell invasion and migration, immune modulation and metabolic reprogramming. Spatial transcriptomics therefore identified 37 differentially expressed genes in MUC4-positive breast cancer associated with stromal and immune transcriptional programs that may contribute to trastuzumab resistance and refine MUC4 predictive and prognostic value improving the identification of patients most likely to benefit from trastuzumab treatment.

#7733 Reliable antibodies for cancer research: TROP2 as a case study of Abcam's enhanced validation framework.

Caroline S. Hirst, JK Tanjore Ramanathan, Nadine Nelson, Antonella Galli, Will Howat, Silvia Sbacchi

Abcam Limited, Cambridge, United Kingdom

Reliable antibody performance is essential for cancer research, particularly when investigating disease-associated targets such as TROP2. Conventional antibody validation methods often fall short in addressing the complexity of human tissue expression and disease heterogeneity. To overcome these limitations, an enhanced validation framework was developed that integrates disease-relevant tissue profiling. This approach combines multiple validation steps, including knock out validation testing and generating detailed IHC expression profiles in selected formalin-fixed paraffin-embedded (FFPE) human tissue microarrays (TMA) using automated immunohistochemistry (IHC) platforms. As a case study, a recombinant rabbit monoclonal antibody (RabMab®) targeting TROP2, clone EPR20043 (ab214488) was validated across multiple IHC automated platforms. The antibody demonstrated high specificity, with no TROP2 detected by IHC in FFPE cell pellets prepared from TACSTD2 knockout MCF7 cells (ab286330). Furthermore, AI-driven expression profiling of multi-cancer TMAs (breast, lung, ovarian and endometrial cancer) revealed high sensitivity for detecting diverse protein expression levels, supporting its potential for biomarker assessment, patient stratification and diagnostic applications across varied disease settings. This study highlights the value of enhanced antibody validation in de-risking reagent selection and ensuring robust, reproducible results in cancer research. The TROP2 case exemplifies how rigorous Abcam's antibody validation can accelerate discovery and translational applications in the oncology research.

#7734 The gap score: A functional biomarker of drug sensitivity.

Sharon B. Cantor, Jenna Whalen, Tokio Sano

MCCB, UMass Chan Medical School, Worcester, MA

Accurate identification of tumors most likely to benefit from DNA damage response (DDR)-targeted therapies remains a major clinical challenge. Current biomarkers, including genomic instability assays and multi-gene HRD panels, rely on “genomic scarring” to infer homologous recombination repair (HRR) defects. While informative, these static measurements capture historical DNA repair events and fail to provide a real-time functional assessment of DDR pathway activity. RAD51 foci assays offer dynamic evaluation but remain intrinsically tied to HDR capacity, thereby overlooking non-HR mechanisms that drive therapeutic vulnerability.Here, we present single-stranded DNA (ssDNA) gaps as a mechanistically grounded and clinically actionable biomarker that reflects the common denominator of DDR dysfunction across tumor types. We developed a robust, scalable ssDNA gap detection assay optimized for clinical specimens, enabling real-time quantification of endogenous replication-associated gaps without prior drug exposure. Using this platform, we demonstrate that ssDNA gaps are intrinsically elevated in BRCA-deficient cancers, independent of genotoxic stress, revealing a native replication vulnerability not captured by HRD scores.AI-assisted imaging analysis enabled fully automated and unbiased quantification of gap burden across tumor sections and xenograft samples. ssDNA gap levels strongly correlated with sensitivity to PARP inhibitors and other replication-perturbing agents, outperforming HRD-score and RAD51-based assays in predicting therapeutic response. Mechanistically, gap formation in BRCA-deficient tumors arises during replication through combined contributions of abasic site accumulation, PrimPol-mediated repriming, and aberrant nuclease processing. These findings establish ssDNA gaps as the functional consequence of impaired genome maintenance, integrating multiple upstream DDR alterations into a single measurable phenotype.Collectively, our data position ssDNA gap burden as a rapid, reliable, and more biologically faithful biomarker than traditional HRD metrics for stratifying patients likely to benefit from DDR-targeted therapies. By shifting biomarker development from HR deficiency to replication gap biology, this approach enables improved patient selection in clinical trials and supports the implementation of precision medicine strategies that directly measure tumor vulnerability rather than relying on genomic proxies.

#7735 *HER2* expression and tumor-infiltrating lymphocytes predict response to tucatinib plus trastuzumab in *HER2*-positive metastatic colorectal cancer (MOUNTAINEER): Exploratory analysis of a multicenter, Phase II trial.

Mitsuho Imai[1], John H. Strickler[2], Woochan Hwang[3], Kara Bonneau[4], Andrew B. Nixon[5], Jongchan Park[3], Chang Ho Ahn[3], Tanios Bekaii-Saab[6], Takayuki Yoshino[7]

[1]National Cancer Center Hospital East, Kashiwa, Japan,[2]Medicine, Duke University Medical Center, Durham, NC,[3]Lunit.Inc, Seoul, Korea, Republic of,[4]Duke University Medical Center, Durham, NC,[5]Duke Univ. Medical Ctr., Durham, NC,[6]Mayo Clinic Arizona, Scottsdale, AZ,[7]National Cancer Center Hospital East, Kashiwa City, Chiba, Japan

Introduction: The HER2-targeted doublet, tucatinib and trastuzumab, recently received FDA approval for previously treated HER2-positive metastatic colorectal cancer (mCRC). While the intensity of HER2 IHC staining and ERBB2 amplification have been proposed as potential markers of response, our understanding of the role of the tumor microenvironment remains limited.
Methods: The phase II MOUNTAINEER Trial (NCT03043313) enrolled patients for tucatinib plus trastuzumab based on HER2 positivity (IHC or NGS amplification). Patients from cohort A with available HER2 IHC and H&E slides were included in this analysis. Previously validated AI-based models (Lunit SCOPE uIHC and SCOPE IO) were used to quantify the percentage of HER2 3+ stained tumor cells (AI-H3+) and the densities of tumor infiltrating lymphocytes (TILs) in the cancer epithelium (iTIL) and stroma (sTIL).
Results: The analyzed cohort (N=30) had an objective response rate (ORR) of 43.4% and median progression-free survival (PFS) of 8.0 months. AI-H3+ percentage showed a strong, dose-dependent association with an ORR of 57.1%, 66.6%, and 80.0% for tumors with AI-H3+ ≥10% (n=14), ≥25% (n=12), and ≥50% (n=10), respectively. This benefit extended to PFS, with the ≥50% cohort reporting a PFS HR of 0.17 (P=0.002) compared to tumors with AI-H3+ <50%. Tumors with below median iTIL or sTIL had significantly shorter PFS. Notably, tumors with sTIL density in the bottom quantile had an ORR of 0% and PFS HR of 4.40 (P=0.002) despite including cases with high AI-H3+. TIL densities and AI-H3+ percentage were not correlated.
Conclusion: These findings confirm AI-quantified HER2 intensity as a marker of response and suggests the importance of TILs, which may have a role through immunogenic cell death. Stratification by HER2 and TIL may be an approach to consider as this regimen progresses into the first-line setting.

	Overall	OverallHigh AI-H3+ percentage			Low iTIL density	Low sTIL density	
Cutoff	n/a	≧ 10%	≧ 25%	≧ 50%	< 2.6 cells/mm^2 (median)	< 131.8 cells/mm^2 (median)	< 52.1 cells/mm^2 (25% quantile)
N	30	14	12	10	15	15	8
ORR	43.4%	57.1%	66.6%	80.0%	26.7%	26.7%	0.0%
PFS	n/a	HR 0.44 [95% CI 0.18-1.10], P=0.071	HR 0.31 [95% CI 0.11-0.85], P=0.017	HR 0.17 [95% CI: 0.05-0.59], P=0.002	HR 3.14 [95% CI: 1.27-7.73], P=0.010	HR 3.57 [95% CI: 1.42-9.00], P=0.005	HR 4.40 [95% CI: 1.55-10.51], P=0.002

#7736 Rare *EGFR* cis compound L833V/H835L mutation in non-small cell lung cancer is oncogenic and a therapeutic target of EGFR tyrosine kinase inhibitors.

Yo Han Jeon[1], **Ahjin Lim**[2], Myung Kyung Choi[3], Hee Seong Choi[3], Yurimi Lee[4], Hyunju Song[2], Hyun-Soo Cho[3], Jeonghee Cho[2], Yoon-La Choi[4]

[1]Kosin University, Busan, Korea, Republic of,[2]Dankook University, Cheonan, Korea, Republic of,[3]Yonsei University, Seoul, Korea, Republic of,[4]Sungkyunkwan University, Seoul, Korea, Republic of

Non-small cell lung cancer (NSCLC) with *EGFR* L833V/H835L in cis mutation remains poorly understood. We retrospectively reviewed the clinicopathologic features NSCLC with either *EGFR* L833V or H835L mutation. The study population includes NSCLC patients (n=3835) at Samsung Medical Center, Seoul, Korea. A total of 8 patients with *EGFR* L833V/H835L in cis mutation were identified. Poorly differentiated histology (either micropapillary or solid patterns) presented in 4 of 5 resected cases. Four patients received EGFR tyrosine kinase inhibitors (TKIs) and achieved a median progression-free survival of 13 months. The oncogenic and therapeutic properties of the mutation were investigated through a combination of functional and biochemical analyses, utilizing both in vitro and in vivo models, and structural modeling. The L833V/H835L mutant exhibited oncogenic potential, transforming NIH-3T3 cells and promoting IL3-independent growth in Ba/F3 cells. Furthermore, EGFR TKIs effectively suppressed the mutant's oncogenic activity in both in vitro and in vivo studies. These phenomena are further supported by its increased kinase activity in structural modeling. Although rare, *EGFR* L833V/H835L in cis mutation, represents a biologically oncogenic and clinically actionable variant in NSCLC.

#7737 Baseline CD16$^+$ NK cells are associated with clinical outcome of nivolumab plus ipilimumab immunotherapy in advanced hepatocellular carcinoma.

Hongjae Chon[1], Narim Lee[2], Hannah Yang[1], Junho Kang[3], Won Suk Lee[1], So Jung Kong[1], Beodeul Kang[1], Jung Sun Kim[1], Ho Yeong Lim[1], Jung Kyoon Choi[3], Chan Kim[1]

[1]CHA Bundang Medical Center, Seongnam, Korea, Republic of,[2]CHA University, Seongnam, Korea, Republic of,[3]Department of Bio and Brain Engineering, KAIST, Daejeon, Korea, Republic of

Background: Combination immunotherapy of nivolumab plus ipilimumab (Nivo/Ipi) has shown durable responses in advanced hepatocellular carcinoma (HCC). However, reliable biomarkers predicting clinical benefit remain limited. CD16$^+$ (FcγRIIIa) NK cells mediate antibody-dependent cellular cytotoxicity (ADCC) and may influence the efficacy of Ipi, a human IgG1 monoclonal antibody. We investigated whether baseline peripheral CD16$^+$ NK cell levels correlate with clinical outcomes in advanced HCC patients receiving Nivo/Ipi.

Method: Patients with advanced HCC were prospectively enrolled from 4 tertiary cancer centers in Korea from Mar 2020 to Aug 2023. Patients received Nivo 1 mg/kg plus Ipi 3 mg/kg every 3 weeks (4 cycles) followed by Nivo maintenance (240 mg every 2 weeks). Peripheral blood mononuclear cell samples were collected at baseline and on day 22 (Cycle 2 Day 1 [C2D1]) and analyzed by flow cytometry. Patients were classified into high and low CD16$^+$ NK groups based on a cut-point determined by maximally selected rank statistics. Single-cell RNA sequencing from 10 responders and 20 non-responders was performed to identify transcriptional correlates of treatment response.

Results: 55 patients were enrolled and analyzed. Most patients were male (82%) with Hepatitis B virus infection (81.8%), and preserved liver function (Child-Pugh A 78.2%, B 21.8%). 74.5% had received ≥2 prior systemic therapies, and 23.6% were immunotherapy naïve. The median follow-up duration was 38.7 months (range, 18.3-50.1). Median progression-free survival (PFS) was 1.3 months (95% CI, 1.2-1.7), and median overall survival (OS) was 4.7 months (95% CI, 3.8-9.1). Although there were no differences in total NK cell numbers between responders and non-responders (p = 0.139), baseline CD16$^+$ NK cells were significantly higher in responders. The high CD16$^+$ NK group showed superior objective response rate (60% vs 17.8%, p = 0.012), disease control rate (70% vs 26.7%, p = 0.023), and longer PFS (14.4 months, 95% CI 1.4-not reached [NR], p = 0.017) and OS (14.7 months, 95% CI 1.4-NR, p = 0.079). High baseline CD16$^+$ NK cell proportion were associated with the decline of regulatory T cells at C2D1, suggesting enhanced ADCC by Ipi. Consistently, single cell analysis also revealed higher baseline CD16$^+$ expression in NK cells at baseline in responders than non-responders. Independent validation of these findings is ongoing.

Conclusion: Baseline peripheral CD16$^+$ NK cell levels were significantly associated with improved clinical outcomes in advanced HCC patients treated with Nivo/Ipi. High CD16$^+$ NK cell frequency correlated with higher response rates and prolonged survival, potentially through enhanced ADCC and suppression of regulatory T cells. These findings suggest that baseline CD16$^+$ NK cells may serve as a predictive biomarker for Nivo/Ipi in HCC, warranting further validation cohorts.

#7741 AI-designed personalized neoantigen vaccine, EVX-01, induces durable *de novo* T-cell responses in advanced melanoma patients.

Mads Lausen[1], Michail Angelos Pavlidis[1], Ohrt Andersen Rasmus[1], Thuesen Nikolas[1], Nadia Viborg[1], Georgina V. Long[2], Adnan Khattak[3], Paolo A Ascierto[4], Carolina Cimminiello[5], Thomas Trolle[1], Christian Garde[1], Michael J. Chisamore[6], Benjamin Wolthers[1], Stine Friis Thorsen[1], Birgitte Rono[1], Daniela Kleine-Kohlbrecher[1]

[1]Evaxion A/S, Hoersholm, Denmark,[2]Melanoma Institute Australia, The University of Sydney, and Mater and Royal North Shore Hospitals, Sydney, NSW, Australia,[3]One Clinical Research, Hollywood Private Hospital & Edith Cowan University, Perth, WA, Australia,[4]Melanoma, Cancer Immunotherapy & Developmental Therapeutics, Istituto Nazionale Tumori - IRCCS - Fondazione Pascale, Neaples, Italy,[5]Divisione di Oncologia Medica del Melanoma, Sarcoma e Tumori Rari, IEO - Istituto Europeo di Oncologia IRCCS, Milano, Italy,[6]Merck & Co., Inc., Wheaton, IL

Cancer vaccines have recently emerged as promising anti-cancer therapies that complement immune checkpoint blockade by stimulating targeted anti-tumor immunity. Their efficacy critically depends on including tumor antigens that can elicit a potent, cancer-specific T-cell response. To achieve this, Evaxion developed the proprietary AI-Immunology™ platform to identify highly immunogenic tumor antigens and design personalized cancer vaccines based on patient-specific sequencing data, optimized for maximal immune activation.The AI-platform identifies somatic mutations and indels in the tumor mutanome, considering tumor expression, clonality and HLA loss to select neoantigens with highest immunogenic potential. EVX-01, the first vaccine candidate generated from this AI-platform, was evaluated in a phase 2 clinical study (NCT05309421) in advanced melanoma. EVX-01 was administered in combination with pembrolizumab, following a 12-week run-in period with pembrolizumab as monotherapy. Patients received in total 10 EVX-01 doses, split into 6 priming and 4 booster immunizations. Primary endpoint was RECIST 1.1-based response improvement of the objective response rate (ORR). For immunogenicity and biomarker analysis peripheral blood was collected before, during and after treatment and processed to peripheral blood mononuclear cells (PBMC). Vaccine-specific T-cell responses were assessed by Interferon-gamma ELISpot and intracellular cytokine staining and flow cytometry, both *ex vivo* and after *in vitro* stimulation. Non-vaccine antigens were tested to investigate potential epitope spreading. At the two-year read out, the ORR was 75% (12/16) in the overall cohort. Of the responders, 92% (11/12) continued to respond at 24 month follow up. The treatment was well-tolerated, and the manufacturing success rate was 100%. Additionally, of 13 patients with stable disease (SD) or partial response (PR) after a the 12-week pembrolizumab induction, 54% (7/13) deepened the response upon initiation of EVX-01. The final immunogenicity analysis showed that EVX-01 priming induced strong vaccine-specific T-cell responses in the 15 assessable patients, with booster doses sustaining response magnitudes until last assessment at week 102. Both CD4+ and CD8+ T cells contributed to the response, with CD4+ T cells predominating. 84% of tested neoantigens elicited a specific immune response and AI-Immunology™ platform-assigned immunogenicity scores correlated with the magnitude of T-cell reactivity. In conclusion, the AI-Immunology™ platform can effectively identify highly immunogenic neoantigens, design manufacturable and safe personalized cancer vaccines with pharmacodynamic activity. Combined with PD-1 blockade, EVX-01 achieves a 75% ORR and induces durable, vaccine-specific T-cell immunity in all treated patients, validating the platforms predictive precision.

#7742 Intratumoral effector T-cells and macrophages underlie prolonged survival after PD-1 axis blockade in metastatic non-small cell lung cancer (mNSCLC).

Daniel Boiarsky[1], Thazin Nwe Aung[2], Anna Wurtz[3], Jianlei Gu[4], Benjamin Y. Lu[5], David L. Rimm[2], Arutha Kulasinghe[6], Katerina A. Politi[7], Scott Gettinger[8], Kurt Alex Schalper[9]

[1]Department of Medicine (Medical Oncology and Hematology), Yale School of Medicine, New Haven, CT,[2]Yale School of Medicine, New Haven, CT,[3]Yale Cancer Center, Yale School of Medicine, New Haven, CT,[4]Department of Pathology, Yale School of Medicine, New Haven, CT,[5]Department of Medicine (Medical Oncology and Hematology), Yale New Haven Hospital, New Haven, CT,[6]University of Queensland, Woolloongabba, Australia,[7]Yale Cancer Center, New Haven, CT,[8]Yale Univ., New Haven, CT,[9]Yale University, Branford, CT

Background: Although PD-1 axis inhibitors have improved outcomes in patients with mNSCLC, only a subset of patients derives long-term benefit. Most studies assessing determinants of sensitivity have relied on short-term endpoints such as response, potentially overlooking biological features underlying durable tumor control. We hypothesized that patients achieving prolonged response after PD-1 axis blockade exhibit distinct tumor microenvironment (TME) features compared with those with primary resistance or limited response.

Methods: We assembled a retrospective cohort of bulk whole-transcriptome data from 342 pretreatment tumor samples from patients with mNSCLC treated with PD-1 axis blockade alone or in combination with anti-CTLA-4 therapy from Yale (n=31), Stand Up To Cancer (n=73), and Samsung Medical Center (n=278). Patients were classified as having primary progression (PP; PFS <3 mo; n=200), non-exceptional response (NER; PFS 6-36 mo; n=116), and prolonged survival (PS; PFS >36 mo; n=26). After batch correction, differential expression (limma) and CIBERSORT were used to identify genes and immune cells associated with PS. Single-cell RNA sequencing from a publicly-available lung cancer immune cell atlas (n=234) was used to refine immune cell signatures and assess their association with outcomes via ssGSEA. Spatial proteomics (Phenocycler-Fusion) performed on baseline samples from patients treated with PD-1 axis blockade (n=55; PP=21, NER=26, PS=8) at Yale and the University of Queensland was used for validation.

Results: Tumors from PP, NER, and PS demonstrated a stepwise increase in HLA class I antigen-presentation machinery (APM) transcripts (PSMB9, ERAP2), memory T-cell markers (CXCR6), and $CD8^+$ T-cell infiltration. PD-L1 expression was markedly higher in NER than PP, but similar between NER and PS. The most significantly enriched genes in PS relative to NER were macrophage-related, with higher absolute M1 (Cliff's δ=0.34, p=0.007) and M2 (δ=0.29, p=0.023) tumor-associated macrophage (TAM) scores. This difference was not observed between NER and PP. Four percent of patients with low (≤ median) calculated $CD8^+$ T-cell and TAM levels were PS, compared with 15% of those with high $CD8^+$/TAM levels (odds ratio=4.5, p=0.0083). Single-cell analysis identified 15 TAM subsets, several enriched in PS but none in PP. Spatial proteomics confirmed an increase in the proportion of stromal TAMs in PS (PS vs NER: δ=0.62, p=0.0079; PS vs PP: δ=0.58, p=0.016) and revealed a stepwise decrease in the proportion SMA^+ fibroblasts across clinical benefit groups.

Conclusion: Prolonged survival after PD-1 blockade in mNSCLC is associated with distinct TME features including increased expression of APM components, and increased CD8 T-cells and TAMs. These insights may inform the development of predictive biomarkers and novel therapeutic strategies.

#7743 Pre-existing T cells drive durable anti-tumor immunity after oncolytic virus therapy in glioblastoma.

Maxime Meylan[1], Ye Tian[1], Lijian Wu[1], Alexander L. Ling[2], Daniel Kovarsky[3], Graham L. Barlow[1], Linh D. Nguyen[1], Jason Pyrdol[1], Lucas Westphal[1], Michel Julius[1], Nicolas L. Gonzalez Castro[4], Sydney D. Dumont[4], Andres Santos[2], Itay Tirosh[3], Mario L. Suva[4], E Antonio Chiocca[2], Kai W. Wucherpfennig[1]

[1]Cancer Immunology and Virology, Dana-Farber Cancer Institute, Boston, MA,[2]Harvey Cushing Neuro-oncology Laboratories, Department of Neurosurgery and Center for Tumors of the, Mass General Brigham Cancer Institute, Boston, MA,[3]Department of Molecular Cell Biology, Weizmann Institute of Science, Rehovot, Israel,[4]Department of Pathology and Krantz Family Center for Cancer Research, Massachusetts General Hospital, Boston, MA

Background: Recurrent glioblastoma (rGBM) remains refractory to immunotherapy due to sparse and suppressed T cell infiltration. We recently reported that survival correlated with immune activation signatures in rGBM patients receiving the oncolytic HSV-1 (oHSV) rQNestin34.5v.2 (CAN-3110). Here, we provide in-situ and molecular evidence that a single oncolytic virus injection can induce durable, tumor-reactive T cell immunity in rGBM.

Methods: We integrated highly multiplexed spatial proteomics (CODEX), spatial transcriptomics (Xenium) with custom probes for viral, immune and TCR targets, and bulk TCR-sequencing on paired pre- and post-treatment specimens from a phase 1 clinical trial (NCT03152318).

Results: T cell densities strongly increased after treatment, with deep infiltration into viable tumor regions persisting up to two years after a single intratumoral oHSV injection. Cytotoxic GZMB+ T cells were located in close proximity with cleaved-caspase 3+ apoptotic tumor cells, and shorter T cell-tumor distance correlated with longer-progression free survival, demonstrating ongoing anti-tumor immunity. Spatial transcriptomics identified CD8+ T cells states expressing early TCR activation (NR4A1, CD69) and tissue residency (ZNF683 [HOBIT], ITGAE [CD103]) programs enriched in the tumor bed while stem-like T cells localized within lymphoid aggregates. Bulk and spatial TCR analyses revealed in-situ expansion of pre-existing tumoral T cell clones whose amplification correlated with survival. Expanded clones featured tissue resident phenotypes and were positioned closer to tumor cells than non-expanded T cells. Viral remnants were limited to necrotic regions and did not co-localize with T cells, suggesting persistent tumor recognition rather than viral antigen.

Conclusion: These results provide in-situ evidence that a single intratumoral oncolytic virus injection can amplify pre-existing T cells clones and induce sustained T cell mediated tumor cytotoxicity even after virus clearance. This suggests that oncolytic virotherapy is as potent T cell activating strategy in rGBM.

#7744 Single-cell and spatial profiling reveal tumor-immune features underlying pathologic complete response to neoadjuvant anti-PD-L1 and chemoradiotherapy in NSCLC.

Jii Bum (Joy) Lee[1], Sang Hoon Lee[2], Haangik Park[2], Seul Lee[3], **Dong Kwon Kim**[2], Jae-Hwan Kim[4], Ju-Hyeon Lee[2], Jaeho Cho[5], Chang Geol Lee[5], Chang Young Lee[6], Jin Gu Lee[6], Dae Joon Kim[6], Hyo Sup Shim[7], Sun Min Lim[8], Hye Ryun Kim[8], Byoung Chul Cho[9]

[1]Yonsei University, Seoul City, Korea, Republic of,[2]Severance Biomedical Science Institute, Seoul, Korea, Republic of,[3]Yonsei University College of Medicine,[4]Yonsei University Hospital Cancer Center, Seoul, Korea, Republic of,[5]Department of Radiation Oncology, Yonsei Cancer Center, Seoul, Korea, Republic of,[6]Department of Thoracic and Cardiovascular Surgery, Seoul, Korea, Republic of,[7]Department of Pathology, Severance Hospital, Seoul, Korea, Republic of,[8]Division of Medical Oncology, Department of Internal Medicine, Seoul, Korea, Republic of,[9]Yonsei University College of Medicine, Seoul

Background: Perioperative chemoimmunotherapy has become standard for resectable non-small cell lung cancer (NSCLC), yet how neoadjuvant anti-PD-L1 and chemoradiotherapy remodel the tumor microenvironment (TME) remains poorly defined.

Methods: Tumors from patients with stage III NSCLC treated with neoadjuvant durvalumab plus concurrent chemoradiotherapy in the NCT03694236 trial were analyzed using single-cell RNA sequencing (scRNA-seq), T cell receptor sequencing (TCR-seq), and spatial transcriptomics to delineate cellular and molecular programs associated with pathologic response.

Results: Neoadjuvant durvalumab combined with concurrent chemoradiotherapy was administered to 30 patients with resectable stage III NSCLC. All patients completed therapy without surgical delay, achieving a major pathologic response (MPR) rate of 74% and a pathologic complete response (pCR) rate of 41%, with R0 resection in all surgical cases. Integrated scRNA-seq, TCR-seq, and spatial analyses of 19 tumors revealed distinct immune architectures between pCR and non-pCR groups. pCR tumors exhibited expansion and spatial clustering of clonally enriched CD8$^+$ effector-memory (T_{EM}) and progenitor-exhausted (T_{PEX}) cells forming a $T_{EM}\rightarrow T_{PEX}\rightarrow T_{EX}$ trajectory with cytotoxic and antigen-processing programs localized adjacent to tumor nests. In contrast, non-pCR tumors accumulated TNFα-producing OLR1$^+$ monocytes and FOLR2$^+$macrophages that promoted TNFR2$^+$ regulatory T cell (Treg) differentiation through TNF-TNFR2 signaling, reinforcing immunosuppression. Chemokine-receptor mapping demonstrated divergent recruitment patterns: antigen-presenting CAFs (apCAFs) and myeloid cells in pCR expressed CCL5 and CCL3, recruiting T_{PEX} cells via CCR5, whereas CCL20-CCR6/CCR4 signaling in non-pCR favored Treg attraction. apCAFs in pCR upregulated antigen-presentation and cytotoxicity-related genes while losing immunosuppressive traits, facilitating CD8$^+$ T cell infiltration and spatial organization of an inflamed TME. Collectively, these findings delineate opposing immune circuits-cytotoxic CD8$^+$ T_{PEX}/T_{EX} activation in pCR versus TNF-TNFR2-driven myeloid-Treg suppression in non-pCR tumors.

Conclusion: Neoadjuvant durvalumab-based chemoradiotherapy reprograms the stage III NSCLC TME toward clonally expanded, cytotoxic CD8$^+$ T cell immunity in pCR, while persistent TNF-TNFR2-Treg signaling sustains immune resistance in non-pCR tumors. Targeting TNFR2 signaling, modulating myeloid polarization, or enhancing CCL5-CCR5-mediated T cell recruitment may further potentiate antitumor efficacy. These findings provide a mechanistic rationale for integrating TNFR2 blockade or chemokine-axis modulation with neoadjuvant immunotherapy to improve pathologic response and long-term outcomes.

#7745 EGFR-TKI enhances anti-CD47 antibody-mediated macrophage phagocytosis in EGFR-mutant non-small cell lung cancer.

Myungja Ro[1], Seung Min Yang[2], **Youngtaek Kim**[3], Min-Hak Lee[4], Eun Ji Lee[3], JuHyeon Lee[2], Mi Ran Yun[1], Ji-Eun Park[5], Jiyea Choi[5], Hyesun Lee[5], Sung Ho Kim[5], Heung Tae Kim[5], Byoung Chul Cho[1]

[1]Yonsei New Il Han Institute for Integrative Lung Cancer Research, Seoul, Korea, Republic of,[2]Department of Research, Yonsei Biomedical Research Institute, Seoul, Korea, Republic of,[3]Yonsei University College of Medicine, Seoul, Korea, Republic of,[4]JEUK Institute for Cancer Research, JEUK Co., Gumi, Korea, Republic of,[5]ImmuneOncia Therapeutics, Inc., Gyeonggi-do, Korea, Republic of

Background: CD47, a “don’t eat me” signal, enables tumor cells to evade macrophage-mediated clearance. EGFR-mutant non-small cell lung cancer (NSCLC) exhibits increased CD47 expression, facilitating immune evasion by inhibiting phagocytosis. Preclinical studies suggest that combining third-generation EGFR TKIs with CD47 blockade can enhance antitumor immunity. Here, we investigated the therapeutic potential of combining the anti-CD47 antibody IMC-002 with lazertinib to enhance macrophage phagocytosis.
Methods: EGFR-mutant and wild-type NSCLC cell lines, patient-derived cells (PDCs), and TKI-resistant derivatives were analyzed for CD47 expression by qPCR, immunoblotting, and flow cytometry. Cells were treated with lazertinib and IMC-002 individually or in combination across a concentration range. Macrophage phagocytosis was quantified by flow cytometry and live-cell imaging (Incucyte). Single-cell RNA sequencing (scRNA-seq) datasets from EGFR-mutant NSCLC patients before and after TKI treatment were analyzed to characterize changes in CD47 expression and resistance-associated pathways.
Results: EGFR-mutant cell lines showed overall higher baseline CD47 expression compared to wild-type controls. Lazertinib treatment induced a dose-dependent increase in surface CD47 expression in H1975 cells. Co-treatment with lazertinib and IMC-002 led to additive to synergistic increases in macrophage-mediated phagocytosis in multiple EGFR-mutant cell lines and in PDCs. In cell lines where lazertinib upregulated surface CD47, IMC-002 blockade elicited substantially greater phagocytosis than lazertinib alone, suggesting that TKI exposure increases target availability and that subsequent antibody blockade acts synergistically by abrogating CD47-SIRPα signaling and promoting macrophage-mediated engulfment. scRNA-seq analyses of EGFR-mutant NSCLC patients before and after third-generation EGFR TKI treatment revealed increased CD47 expression within tumor clusters enriched for drug-tolerant persister signatures, including TGF-β, Wnt, and YAP pathways, providing additional explanations for enhanced anti-CD47 antibody accessibility and phagocytic clearance following combination treatment. Collectively, EGFR-TKI exposure can increase the abundance and accessibility of CD47 on tumor cells, and anti-CD47 antibody treatment synergizes with lazertinib to amplify macrophage-mediated clearance, supporting a rationale for a combination strategy to improve antitumor immunity in EGFR-mutant NSCLC.
Conclusion: Lazertinib induces CD47 upregulation and synergizes with IMC-002 to enhance macrophage-mediated clearance of EGFR-mutant NSCLC cells. These findings provide a mechanistic rationale for clinical evaluation of EGFR-TKI and anti-CD47 combination strategies to improve therapeutic efficacy in EGFR-mutant lung cancer.

#7746 CEACAM5/6+ cancer cell and IL1B+ macrophage-mediated resistance in anti-PD-1 treated gastric cancer.

Liudeng Zhang[1], Jian Chen[2], Yikai Luo[1], Lie Wang[2], Han Liang[1]

[1]Bioinformatics and Computational Biology, UT MD Anderson Cancer Center, Houston, TX,[2]Zhejiang University, Hangzhou, China

Immune checkpoint blockade therapy has shown limited efficacy in gastric cancer, with most patients developing resistance through mechanisms that remain incompletely defined. Here, we generate a comprehensive single-cell RNA sequencing atlas of 526,583 cells from gastric cancer patients treated with anti-PD-1 plus chemotherapy, analyzing paired pre- and post-treatment samples to capture dynamic resistance mechanisms. We identify two distinct resistance pathways that emerge during treatment. First, CEACAM5/6+ cancer cells are markedly enriched in pre-treatment non-responders and predict treatment failure. These CEACAM5/6+ epithelial cells show the highest tumor scores and correlate with increased regulatory T cell infiltration expressing CEACAM1, establishing an alternative checkpoint axis that bypasses PD-1/PD-L1 blockade. External validation in independent cohorts confirms CEACAM5/6 expression as a robust predictor of anti-PD-1 resistance. Second, we uncover a macrophage-driven inflammatory cascade central to treatment resistance. IL-1β+ macrophages serve as the primary source of NF-κB pathway activation across the tumor microenvironment, triggering downstream IL-6 production, Th17 cell differentiation, chronic inflammation and epithelial-mesenchymal transition. This macrophage module is significantly enriched in post-treatment non-responders, with TNF-high expressing monocyte-macrophages absent in responders but prevalent in resistant tumors. The resulting inflammatory milieu drives PD-L1 upregulation across multiple cell types, creating a self-reinforcing immunosuppressive niche. Collectively, these findings nominate CEACAM5/6$^+$ epithelial cells and IL-1β$^+$ inflammatory macrophages as actionable therapeutic targets for overcoming anti-PD-1 resistance in gastric cancer, providing a mechanistic framework and rational blueprint for next-generation combination immunotherapy strategies.

#7747 Comparison of T-cell activation status in patients treated with retifanlimab in combination with anti-LAG3/Anti-TIM3 vs retifanlimab alone.

Robert I. Haddad[1], Denis Soulieres[2], Prakash Neupane[3], Amaury Daste[4], **Zhiwan Dong**[5], Jin Lu[5], Michelle Kinder[5], Jeff Jackson[5], Richard Schaub[5], Nawel Bourayou[5], John Janik[5], Christophe Le Tourneau[6]

[1]Dana-Farber Cancer Institute, Brigham and Women's Hospital, Harvard Medical School, Boston, MA,[2]Centre Hospitalier de l'Universite de Montreal, Montreal, QC, Canada,[3]The University of Kansas Medical Center, Kansas City, KS,[4]Hopital Saint-Andre, CHU Bordeaux-University of Bordeaux, Bordeaux, France,[5]Incyte, Wilmington, DE,[6]DITEP, Gustave Roussy, Villejuif, France

PD-1/PD-L1-targeting antibodies have revolutionized cancer treatment but most pts fail to respond (primary resistance) or lose response (secondary resistance). Anti-PD-1 therapy resistance mechanisms are poorly understood; other checkpoint inhibitor pathways are important investigational targets based on animal model studies. Co-expression of PD-1, LAG3, and TIM3 is associated with functional T-cell exhaustion and may contribute to resistance. Antibodies targeting LAG3 and TIM3 are potential candidates for overcoming anti-PD-1 resistance; LAG3 is also clinically supported as a target for resistance in pts with melanoma. INCAGN2385-203 is a randomized, phase 2 study to evaluate the efficacy and safety of retifanlimab (anti-PD-1) + INCAGN02385 (anti-LAG3) and retifanlimab + INCAGN02385 + INCAGN02390 (anti-TIM3) combinations vs retifanlimab alone in immunotherapy naïve PD-L1-positive (CPS ≥1) recurrent/metastatic SCCHN. Objective response rate was numerically higher in anti-LAG3-containing arms (~30%) vs the retifanlimab monotherapy arm (20%). Median progression-free survival was similar in all 3 arms. To evaluate pharmacodynamic biomarkers associated with LAG3 and/or TIM3 blockade in the context of PD-1 inhibition, flow cytometry was used to evaluate frequency changes of CD4 and CD8 T cells, regulatory T cells, and memory T cells, as well as activation and proliferation markers in whole blood samples. T-cell proliferation and activation were observed in all 3 arms. T-cell proliferation (CD4 and CD8) measured by frequency change of Ki67-positive T cells and HLA-DR expression was more pronounced in both anti-LAG3-containing arms vs the retifanlimab alone arm. No significant difference in regulatory T cells was observed between the 3 arms. Naïve CD4 and CD8 T cells decreased at similar levels at cycle 1, day 8 across all arms. A steady decrease of central memory CD4 and CD8 T cells up to cycle 4, day 1 was observed with retifanlimab alone, whereas retifanlimab + anti-LAG3 showed elevation of central memory T-cell frequencies in both CD4 and CD8 T cells up to cycle 1, day 15, before decreasing steadily up to cycle 4, day 1; there was no obvious change from baseline to cycle 4, day 1 in the triplet arm. Opposite trends were observed in effector memory CD4 and CD8 T cells. Retifanlimab alone produced a steady increase, whereas retifanlimab + anti-LAG3 showed decreases in CD4 (up to cycle 1, day 15) and CD8 (up to cycle 2, day 1) effector memory T cells before increasing steadily. These preliminary results suggest that LAG3 and/or TIM3 blockade may have unique effects on T-cell function. LAG3 with PD-1 blockade may overstimulate T cells and lead to T-cell elimination, highlighting the need for dose optimization. Further evaluation of T-cell responses of PD-1/PD-L1 blockade with other checkpoint inhibitors, including those targeting LAG3 and TIM3, is warranted.

#7748 Immune-related RNA-seq biomarker-based clustering reveals heterogeneous immunotherapy responses and guides subtype-specific strategies in metastatic NSCLC.

Jiyon Lyu[1], Sebastia Franch-Exposito[2], **Sanghwa Kim**[1], Liam Il-Young Chung[1], Ronald Min[1], Sung Hwan Lee[3], Shinkyo Yoon[1], Michelle M. Stein[2], JACOB MERCER[2], Paul Fields[2], Bella Kim[4], Young Kwang Chae[1]

[1]Department of Medicine, Northwestern University Feinberg School of Medicine, Chicago, IL,[2]Tempus AI, Chicago, IL,[3]Department of Surgery, CHA Bundang Medical Center, Seongnam, Korea, Republic of,[4]Northwestern University, Chicago, IL

Metastatic non-small cell lung cancer (mNSCLC) represents a highly heterogeneous disease with variable clinical outcomes under first-line immunotherapy plus chemotherapy. To better understand immune landscape features associated with heterogeneous response to immunotherapy, we performed biomarker-driven RNA-seq molecular clustering using known immune-related markers *TIGIT, FOXP3, CD274* (*PD-L1*), and tumor-associated macrophage (TAM) score.

We analyzed a real-world cohort of 2,235 mNSCLC patients with pre-treatment tumor biopsies in the de-identified Tempus database treated with first-line PD-(L)1 plus chemotherapy. Unsupervised clustering of RNA-seq data defined four distinct immune subtypes. Real-world overall survival (rwOS) and progression-free survival (rwPFS) were assessed via Kaplan-Meier analysis with a log-rank test. Pathway enrichment using hallmark gene sets, tumor mutational burden (TMB), and immune cell composition using QuantiSeq were analyzed.

Expression levels of RNA-seq biomarkers and TAM score were significantly different across identified clusters (ANOVA; p <0.001). These clusters also showed significantly differential prevalence of TMB-high and PD-L1-positive (IHC) (Chi-squared; p < 0.001, respectively), as well as characteristic pathway enrichment and immune profiles. Non-squamous/Never smoker were more frequent in Cluster 2, whereas Squamous/Current smoker were predominant in Cluster 1 (Chi-squared; Histology/Smoking, p <0.05, respectively). Survival differed significantly, being poorest in Cluster 1 and best in Cluster 3 (rwOS/rwPFS, p <0.001) (Table 1).

This biomarker-driven RNA-seq analysis identified four immune clusters of mNSCLC with differential survival outcomes. This study provides a foundation for understanding tumor heterogeneity and supports the use of immune biomarkers to enable patient stratification for therapeutic combinations.

Table 1.

	Cluster 1 (Immune-desert) N=713	**Cluster 2 (TAM-enriched) N=402**	**Cluster 3 (Immune-hot) N=813**	**Cluster 4 (Myeloid-inflamed, PD-L1-high) N=302**	***p*-value**
Median Survival Time (Months) rwOS/rwPFS	11.5/5.95 mo	14.8/7.33 mo	18.1/8.15 mo	16.7/6.84 mo	Log-rank test; p <0.001
RNA-Seq Biomarkers (TIGIT, FOXP3, CD274 (PD-L1)) and TAM Score	Uniformly low expression of all markers	High TAM but low TIGIT/FOXP3/PD-L1	High TIGIT/FOXP3/PD-L1 with elevated TAM	High PD-L1 with low TIGIT/FOXP3	ANOVA test; p <0.001
Pathway Enrichment TME: tumor microenvironment	↑ Oncogenic signalings and proliferation ↓ Immune -related pathways	↑ TME remodeling pathways	↑ Immune/inflammatory signaling (e.g., IFNγ) and TME remodeling pathways	↑ Proliferation and DNA-repair pathways	Welch ANOVA + Games-Howell or Kruskal-Wallis and Dunn (BH) test; adjusted p <0.05
Immune Cell Composition	↓ Lymphoid and myeloid cell infiltration	↑ M1/M2 macrophage	Broad infiltration (↑ CD8, CD4, Treg, B, NK)	↑ Myeloid cell infiltration	Kruskal-Wallis and Dunn (BH) test; adjusted p <0.05
TMB-High (TMB ≥10 mut/Mb)	283 (34%)	92 (20%)	254 (26%)	124 (35%)	Chi-squared test; p <0.001
PD-L1-Positive (IHC; TPS ≥ 1%)	203 (36%)	174 (54%)	421 (68%)	213 (94%)	Chi-squared test; p <0.001
Tumor Histology					Chi-squared test; p <0.001
Squamous	232 (33%)	73 (18%)	221 (27%)	84 (28%)	
Non-Squamous	444 (62%)	315 (78%)	555 (68%)	201 (67%)	
NOS	37 (5.2%)	14 (3.5%)	37 (4.6%)	17 (5.6%)	
Smoking Status					Chi-squared test; p <0.05
Current Smoker	118 (62%)	44 (46%)	113 (55%)	48 (59%)

#7749 Increased immune activity in patients with high-grade serious ovarian cancer after combination PARPi + ATRi therapy.

Elias Pavlatos[1], Benjamin Tate[1], Austin Nguyen[1], Ian S. Heller[2], Dimitrios Nasioudis[2], Janos L. Tanyi[3], Drew A. Torigian[4], Diego Rodriguez[2], Susan M. Domchek[4], Ronny I. Drapkin[2], Eric J. Brown[5], Gordon B. Mills[6], Fiona Simpkins[2]

[1]Immune Monitoring and Cancer Omics Services, OHSU Knight Cancer Institute, Portland, OR,[2]Division of Gynecologic Oncology, Department of Gynecology and Obstetrics, University of Pennsylvania, University School of Medicine, Philadelphia, PA,[3]Division of Medical Oncology, Perelman School of Medicine at the University of Pennsylvania, Philadelphia, PA,[4]Department of Radiology, Perelman School of Medicine at the University of Pennsylvania, Philadelphia, PA,[5]Department of Cancer Biology & Abramson Family Cancer Research Institute, Perelman School of Medicine at the University of Pennsylvania, Philadelphia, PA,[6]OHSU Knight Cancer Institute, Portland, OR

Introduction: Complete responses to PARP inhibitor (PARPi) monotherapy in recurrent high-grade serous ovarian cancer (HGSOC) are rare. However, preclinical data have demonstrated promising synergy between PARP and ATR inhibitors. Characterizing the immune contexture of the tumor microenvironment and the surrounding stroma during treatment may provide valuable biological insights into the efficacy of this combination therapy and inform future combinations.

Methods: Patients with recurrent HGSOC received ceralasertib 160mg orally daily, days 1-7 and olaparib 300mg twice daily, days 1-28 of a 28-day cycle. 18 tissue samples were collected across archival (resection) and pre-treatment and on-treatment timepoints (core biopsies). Each sample was analyzed using a 25-plex multiplex immunohistochemistry (mIHC) assay, which interrogates cell composition and functional states of neoplastic and immune cell types, including all major lymphoid and myeloid populations. Segmented cells were assigned to either a tumor or stroma compartment using a PanCK mask that was uniformly expanded by 25µm, and average cell densities were calculated for each compartment.

Results: Samples obtained during combination PARPi + ATRi treatment demonstrated widespread increases in immune cell densities including T cells (CD8+, Tregs, and Th1-like cells), B cells, dendritic cells, macrophages, and monocytes. Among the T-cell populations, higher densities of Granzyme B and PD-1 were observed, indicating enhanced cytotoxic activity and immune engagement. Concurrently, there was a decrease in proliferating neoplastic cells (PanCK$^+$Ki67$^+$), consistent with reduced tumor cell proliferation during treatment. Using the PanCK tumor mask, we observed that CD8$^+$ T cells, Th1-like cells, B cells, and dendritic cells increased more prominently within the tumor compartment compared to the surrounding stroma. Samples obtained prior to treatment from patients with stable or progressive disease (SD/PD) exhibited higher macrophage densities, primarily attributable to elevated levels of M2-like (immunosuppressive) macrophages.

Conclusions: The increased immune cell densities measured by mIHC indicate overall activation of the immune system following PARPi + ATRi treatment. Elevated levels of PD-1$^+$ and Granzyme B$^+$ T cells suggest enhanced immune activation and cytotoxic potential, while comparative analysis of the tumor versus stroma compartments demonstrates improved immune cell infiltration into the tumor. Notably, higher baseline densities of M2-like macrophages may influence or limit response to therapy. Collectively, these findings provide evidence that PARPi + ATRi combination therapy promotes anti-tumor immune activity. However, additional data is needed to correlate these immune changes with clinical outcomes.

#7750 Integration of spatial single cell proteomics and spatial metabolomics reveals tumor microenvironment predictive of immunotherapy response in mucosal melanoma.

Jun Wang[1], Priyadharsini Nagarajan[2], Sungnam Cho[3], Yunhe Liu[1], Erin H. Seeley[4], Yibo Dai[1], Yang Liu[1], Jared K. Burks[3], Jennifer L. McQuade[5], Adi Diab[5], Linghua Wang[6], Suhendan Ekmekcioglu[5]

[1]Department of Genomic Medicine, UT MD Anderson Cancer Center, Houston, TX,[2]Department of Pathology, UT MD Anderson Cancer Center, Houston, TX,[3]Hematopoietic Biology & Malignancy, UT MD Anderson Cancer Center, Houston, TX,[4]Mass Spectrometry Imaging Core Facility, UT MD Anderson Cancer Center, Houston, TX,[5]Department of Melanoma Medical Oncology, UT MD Anderson Cancer Center, Houston, TX,[6]UT MD Anderson Cancer Center, Houston, TX

Background: Mucosal melanoma (MuM) is a rare melanoma subtype, accounting for only 1-2% of all melanoma cases, yet is highly aggressive, demonstrating poorer responsiveness to immune checkpoint blockade than the more common cutaneous melanoma. However, the biological mechanisms driving therapeutic resistance in MuM remain poorly understood. This study aims to uncover spatial and molecular mechanisms underlying response and resistance of MuM to immune checkpoint blockade therapies.

Study Design and Methods: An integrative spatial multi-omics framework was applied, which combined single-cell spatial proteomics using COMET platform with high mass resolution spatial metabolomics using imaging mass spectrometry (MALDI-IMS). We comprehensively profiled cellular compositions and spatially defined cellular neighborhoods (CNs) across 97 FFPE tissue cores from 26 MuM patients treated with PD-1/PD-L1 or CTLA-4 inhibitors. Spatial organization, cell-cell interactions, proteomic profiles and metabolomic features of CNs were further compared across responders and non-responders.

Results: The comprehensive approach enabled spatially resolved profiling of 695,444 single cells, which were categorized into 25 cellular phenotypes spanning 9 major cell lineages. Spatial cellar neighborhood analysis revealed 15 biologically distinct CNs that differed in their composition and spatial distribution of tumor, immune, and stromal cell compartments. In patients who responded to immunotherapy, three tumor-associated CNs—the central tumor, invasive tumor, and tumor boundary CNs—were significantly enriched and collectively formed unique spatial organization patterns. Notably, the invasive tumor CN and tumor boundary CN were characterized by spatial proximity among Ki67$^+$ tumor cells, CD163$^+$ macrophages, and CD11c$^+$ dendritic cells. These CD163$^+$ macrophages exhibited reduced expression of IRF4 and Arg1, consistent with lower immunosuppressive activity. Conversely, non-responders exhibited a stromal-dominant CN composed primarily of SMA$^-$ stromal cells and demonstrated reduced immune infiltration in both pre-treatment and post-treatment samples. Spatial metabolomic profiling further revealed a pronounced reduction of tryptophan-derived indole metabolites in responders, which significantly correlated with CD11c and CD163 expression, indicating coordinated immunometabolic remodeling within the tumor microenvironment.

Conclusions: These findings highlight that spatial tumor-immune architecture, stromal exclusion, and metabolic rewiring collectively shape immunotherapy response in MuM. The identified spatially resolved tryptophan-derived metabolite signatures offer promising biomarkers and potential therapeutic targets to improve treatment outcomes in this clinically challenging melanoma subtype.

#7751 Integrative multi-omics and spatial transcriptomics reveal novel immunotherapy targets in hepatocellular carcinoma.

Zihui Zhao[1], Xiaohang Long[2], Siyuan HUANG[2], Yan Liu[3], Alfred S. l. Cheng[4]

[1]School of Biomedical Science, Chinese University of Hong Kong (CUHK), Hong Kong, Hong Kong,[2]CUHK, NT, Hong Kong,[3]The Chinese University of Hong Kong, Shatin, NT,[4]Chinese University of Hong Kong (CUHK), Hong Kong, Hong Kong

Background: Immunotherapy has transformed the management of hepatocellular carcinoma (HCC), yet most patients fail to achieve durable responses. The underlying single-cell-level gene-regulatory mechanisms shaping immune evasion remain poorly understood. To uncover previously unknown therapeutic vulnerabilities, we integrated single-cell multiomic profiling with spatial transcriptomics in a 25-patient HCC immunotherapy cohort.

Methods: Tumor samples underwent 10x multiome sequencing, enabling simultaneous scATAC-seq and scRNA-seq from the *same cells* using shared barcodes. This allowed cell-resolved mapping of chromatin accessibility, transcriptional states, and gene-regulatory relationships. We identified differentially accessible regions and gene-expression changes associated with clinical immunotherapy outcomes. To contextualize these regulatory programs in situ, spatial transcriptomic profiling was performed to map target-gene expression and immune-cell localization within the tumor microenvironment.

Results: Joint scATAC-scRNA integration revealed previously unrecognized regulatory circuits distinguishing responders from non-responders, including chromatin-primed dysfunctional $CD8^+$ T cells and TREM2+ macrophage programs not detectable by single-modality assays. Multiomic analysis identified novel candidate immune-regulatory targets, defined by coordinated shifts in chromatin accessibility and transcriptional activation at the single-cell level. Spatial mapping demonstrated that these targets are enriched in discrete immune-excluded regions and at tumor-myeloid interfaces, revealing new spatially orchestrated mechanisms of immune suppression. Several ligand-receptor pairs and non-canonical transcriptional regulators emerged as high-confidence targets for therapeutic intervention.

Conclusions: By combining shared-barcode single-cell multiomics with spatial transcriptomics, we provide a comprehensive, mechanistic view of gene-regulatory changes driving immunotherapy resistance in HCC. This study uncovers novel, spatially validated immune-regulatory targets and highlights previously unknown cell-state transitions that may be leveraged to improve immunotherapy efficacy. #7752 Targeting SOAT1 to Boost NK Cell Mediated Cytotoxicity in High Grade Serous Ovarian Cancer.

Luqi Chen[1], Michelle K.y. Siu[1], Ruiqian Zhang[1], Ling Shan Hung[1], Mengyi Gu[1], Dickson Ngan[1], Xin He[1], Haonan Lu[1], Hextan Y.s. Ngan[1], Kui Liu[1], Annie Ny Cheung[2], Karen K.l. Chan[1]

[1]Department of Obstetrics & Gynaecology, The University of Hong Kong, Hong Kong, China,[2]Clinical Professor, Dept. of Pathology, University of Hong Kong, Pokfulam, China

Rationale: Despite advances in surgery and chemotherapy, high-grade serous ovarian cancer (HGSOC) still carries poor long-term survival, and most patients with advanced disease suffer relapse. Tumor cells exploit cholesterol metabolism, and the enzyme sterol O-acyltransferase 1 (SOAT1/ACAT1), which converts free cholesterol to cholesteryl esters, has emerged as a potential driver of tumor progression and immune evasion. NK cell degranulation, widely monitored via CD107a surface expression, provides a readout of NK cytotoxicity. We sought to identify genes whose loss enhances NK-mediated killing of HGSOC cells.
Methods: We implemented a whole-genome CRISPR/Cas9 screen in OVCAR8 HGSOC cells challenged with allogeneic primary NK cells at an effector:target ratio. Relative guide RNA abundance was measured by next-generation sequencing before and after co-culture to identify genes whose disruption decreased tumor cell survival. Candidate negative genes were prioritized using filters: (1) ovarian cancer DepMap CERES score > -0.3 to avoid highly fitness-essential genes; (2) removal of curated core-essential genes; (3) at least three effective sgRNAs exhibiting consistent depletion; and (4) higher expression in ovarian cancer compared with normal ovary in public transcriptomic cohorts. SOAT1 emerged from this pipeline and was taken forward. OVCAR8 cells were transfected with SOAT1 siRNA and then co-cultured with NK92 cells. Tumor viability was quantified using metabolic/viability assay, while NK92 activation was evaluated by CD107a staining and flow cytometry. To assess clinical relevance, we interrogated independent ovarian cancer datasets (GSE118828, GSE26712) for relationships between SOAT1 expression, NK-related transcriptional signatures, and overall survival.
Results: The CRISPR screen pinpointed SOAT1 as a top metabolic modifier of NK-mediated tumor clearance. SOAT1 silencing produced mRNA knockdown in OVCAR8 and significantly reduced tumor cell survival under NK92 attack, with median viability falling to 50-60% of control conditions. NK92 cells co-cultured with SOAT1-deficient OVCAR8 exhibited increased CD107a surface expression, indicating augmented degranulation and effector activity. Across public datasets, SOAT1 expression was elevated in ovarian tumors versus normal and adjacent tissues and aligned positively with transcriptional scores of NK infiltration and cytotoxic function. Notably, in cases with high NK infiltration, patients with higher SOAT1 expression experienced worse overall survival.
Conclusions: By integrating genome-wide CRISPR screening with functional and bioinformatic analyses, we identify SOAT1 as a cholesterol-metabolic regulator that attenuates NK cell cytotoxicity in ovarian cancer. These findings nominate SOAT1 inhibition as an approach to metabolically reprogram HGSOC and improve the efficacy of NK-directed immunotherapies.

#7753 Circulating thymidine kinase activity (TKa) as a predictive and dynamic biomarker in the metastatic non-small cell lung cancer (NSCLC): Immunoblood study.

Maristella Giammaruco[1], Lorenza Landi[2], **Mattias Bergqvist**[3], Gabriele Minuti[2], Silvia Carpano[1], Francesca Fusco[1], Martina Brandi[1], Fabiana Letizia Cecere[1], Vincenzo Pio Di Noia[1], Livia Tosetto[1], Andrea Torchia[1], Corrado Orciuolo[1], Daniele Marinelli[1], Grisel Maver Militello[1], Diana Giannarelli[4], Federico Cappuzzo[1]

[1]Medical Oncology 2, IRCCS Regina Elena National Cancer Institute, Rome, Italy,[2]Clinical Trials Unit: Phase 1 and Precision Medicine, IRCCS Regina Elena National Cancer Institute, Rome, Italy,[3]Biovica International AB, Uppsala, Sweden,[4]Epidemiology and Biostatistics, Gemelli University Hospital Foundation, IRCCS, Rome, Italy

Introduction: Despite major advances with immune checkpoint inhibitors (ICIs) in treatment of metastatic NSCLC, reliable biomarkers to predict who will benefit from therapy and monitor early treatment response remain limited. Thymidine kinase is an enzyme fundamental in the DNA synthesis, its activity reflects tumor cell proliferation and tumor aggressiveness. This study (NCT06823401) is the first to evaluate plasma TKa levels in NSCLC patients receiving immunotherapy (IT) or chemotherapy-IT (CHT-IT). The objectives were to determine whether baseline TKa levels can predict efficacy of IT and if early on-treatment changes in TKa levels reflect treatment response, thereby supporting TKa as a minimally invasive biomarker for patient therapy selection and early efficacy assessment. The capacity of TKa to evaluate cell proliferation is expected to reflect and predict successful T-cell activation of IT and prolonged efficacy.

Methods: 94 patients (50 males, 44 females) with metastatic NSCLC, had plasma samples collected at baseline (pre-treatment) and at second treatment cycle of whom 93 received first-line systemic therapy. Circulating TKa was measured using the FDA cleared and CE marked DiviTum® TKa assay (Biovica, Sweden), with values reported in DiviTum units of activity (DuA). Analysis was performed blinded to clinical outcomes. TKa was evaluated for its association with response rate (RR), progression-free survival (PFS), overall survival (OS) and was also correlated to other biomarkers, including PD-L1 expression.

Results: 65 pts (70%) received first-line CHT-IT, while 28 pts (30%) received IT alone. PD-L1 expression was <1% in 37 pts (40%), 1-49% in 17 pts (18%), ≥50% in 34 pts (36%), and unknown in 6 pts (6%). The median baseline TKa level was 203 DuA. The RR in the low (<203 DuA) and high-TKa group was 52% and 32% respectively ($p = 0.80$) while the mPFS was not reached in the low TKa group versus 7.3 mos in high TKa group ($p = 0.13$). The 1-year OS rate was similar between the two groups (69.9% vs 62.4%, $p = 0.34$). Using a TKa cutoff of 326 DuA, we observed a statistically significant difference in mPFS; 13.8 months in the low-TKa group (65 pts) versus 3.3 months in the high-TKa group (23 pts) ($p = 0.004$). The 1-year OS rate was 65.6% vs 53.3%, respectively ($p = 0.18$). Further data on patients treated with IT alone and with CHT-IT will be presented at the meeting.

Conclusions: Our study shows a possible association between high plasma TKa levels and shorter PFS and OS in advanced NSCLC treated with first-line IT alone or combined with CHT, supporting the potential role in guiding treatment choice. Further studies are needed to validate the prognostic and predictive value of TKa in this setting.

#7754 Peripheral immune signatures associated with peptide receptor radionuclide therapy in neuroendocrine tumors.

Eriko Katsuta[1], Takuto Nobuhiro[1], Masaru Takeuchi[1], Satoshi Matsui[1], Asano Daisuke[1], Ishikawa Yoshiya[1], Hiroki Ueda[1], Keiichi Akahoshi[1], Noritoshi Kobayashi[2], Yasushi Ichikawa[2], Daisuke Ban[1]

[1]Institute of Science Tokyo, Tokyo, Japan,[2]Yokohama City University, Yokohama, Japan

Background: Peptide receptor radionuclide therapy (PRRT) is an internal radiotherapy for somatostatin receptor (SSTR)-positive neuroendocrine tumor (NET). The tumor microenvironment, particularly cytotoxic T lymphocyte (CTL), is a key determinant of tumor behavior, treatment response, and prognosis, but NET typically shows a “cold” immune microenvironment with sparse immune-cell infiltration, which may contribute to the limited efficacy of ICI-based therapies. External beam radiotherapy can activate systemic antitumor immunity and occasionally induce abscopal effects, in which irradiation of a primary lesion leads to shrinkage of both irradiated and distant metastatic sites; however, the influence of PRRT on systemic immunity has scarcely been studied. We hypothesized that PRRT modulates systemic immunity in NET patients and investigated changes in circulating cytokines.
Methods: We analyzed changes in serum cytokine levels in NET patients treated with PRRT at Yokohama City University. Twelve paired serum samples from 9 patients were collected before and after PRRT and analyzed with a 36-plex cytokine array.
Results: Of the 9 patients, 7 were undergoing their first PRRT course and 2 a second course (retreatment after a prior four-administration PRRT course that had achieved at least partial response with ≥1.5 year of disease control). Primary sites were pancreas (n=6), rectum (n=1), lung (n=1), and thymus (n=1), and target lesions were in the liver (n=7), bone (n=2), primary site (n=1), lymph node (n=1), and peritoneum (n=1). Twelve serum pairs comprised 10 pre- and post-individual PRRT administrations and 2 pre- and post-full-course pairs. Of the 36 examined cytokines, only 12 were detectable. Among these, CD154 showed more than 2-fold changes in 7 pairs, with 6 showing downregulation and 1 showing upregulation after PRRT. IL-1ra was also upregulated in 3 pairs.
Conclusion: We found that PRRT is associated with systemic changes in circulating cytokines in NET patients, notably modulation of CD154 and IL-1ra. These data suggest that PRRT may influence host antitumor immunity; larger studies are required to elucidate the mechanisms and clinical significance of these immune changes.

#7755 Precision immune therapies for cancer developed through understanding the role of myeloid checkpoints as key mediators of adaptive resistance in T-cell checkpoint inhibitor resistant patients.
Ronan O'Hagan, Magali Perderzoli-Ribeil

Bectas Therapeutics, Houston, TX

Background: T-cell immune checkpoint inhibitor (ICI) therapies can deliver cures to cancer patients. However, about 80% of patients show only transient responses or outright resistance to these therapies. Thus, ICI resistance is a major unmet medical need. A key challenge is the lack of precise understanding of which specific resistance mechanism is operative in which specific subset of patients. Moreover, previous studies have demonstrated that molecular signals for clinical response or resistance to ICI therapies are evident only after initiation of treatment and that pre-treatment molecular profiles are poorly predictive. Hence, a precision strategy that accounts for the homeostatic nature of the immune response and the resulting adaptive nature of ICI resistance is key to successfully developing new ICI monotherapy or combination approaches.
Methods: To elucidate adaptive mechanisms of resistance to ICI's and precisely determine which resistance mechanism was relevant in each patient we applied defined machine learning models to analyze serial longitudinal clinical and molecular data from over 400 cancer patients undergoing aPD1/aCTLA4 treatment. This led to the definition of a blood-based biomarker predictive of non-response and the identification of dynamically regulated drivers of resistance that represent targets for precision drug discovery. The newly established links between druggable adaptive resistance targets in ICI resistant patients and blood-based patient selection biomarkers can guide clinical development of agents directed to these targets.
Results: Myeloid driven immune suppression was identified as the dominant mechanism of adaptive resistance in patients treated with ICI's. Specific myeloid checkpoints that drive resistance were indentified in subsets of patients that could be defined by protein signatures detectable in blood. These precision biomarkers identified patients across multiple indications in which ICI resistance is driven by a targetable myeloid checkpoint. Bectas has now developed monoclonal antibody therapies to a series of myeloid checkpoint targets identified through this approach. In each case, the antibody therapy is accompanied by a precision biomarker to enable patient selection.
Conclusions: Our unique multi-dimensional blood-based biomarker strategy enables early detection of resistance to ICI treatment, and identifies specific myeloid checkpoints driving resistance in specific patients. This precision approach, coupled with first in class antibody therapies directed to these myeloid checkpoints has the potential to significantly accelerate the development of new therapeutic regimes to address the 80% of cancer patients who do not benefit currently from immune-based therapies.

#7756 A tumor-targeting IL-12 immunocytokine therapy increases peripheral natural killer (NK) cells with phenotypes associated with increased tumor cell lysis in patients with advanced solid tumors.
Stephanie C. Pitts, Nicole J. Toney, Jennifer L. Marte, James L. Gulley, Jeffrey Schlom, Renee N. Donahue

National Cancer Institute, Bethesda, MD

Background: PDS01ADC (previously designated NHS-IL12) is a tumor-targeting immunocytokine with promising preclinical activity. A first-in-human clinical trial (NCT01417546) showed PDS01ADC monotherapy to be safe and well tolerated in patients with advanced solid malignancies, and preliminary signs of clinical activity (stable disease in 50% of evaluable patients) were observed. Here, we investigate peripheral blood natural killer (NK) cell phenotypes that associate with tumor cell lysis in ex-vivo assays, and evaluate patients treated with PDS01ADC for changes in these NK phenotypes and for correlations with clinical response.
Methods: Healthy donor NK cells (n=12) were evaluated in lysis assays with human SW620 colorectal and H69 small cell lung cancer tumor cells and assessed by flow cytometry. Peripheral blood collected from patients with advanced malignancies before and after 2 and 4 weeks of PDS01ADC treatment (n=28) was also assessed for changes in NK cell phenotypes and for correlations with response.
Results: Total NK cells were not changed upon PDS01ADC treatment; however, several NK cell phenotypes that positively associated with NK cytotoxicity were increased after treatment. For example, Granzyme B^+ NK cells positively correlated with NK cell lysis of SW620 tumor cells ($p=0.0299$, $r=0.6364$) and were increased with PDS01ADC treatment ($p<0.0001$). A more refined phenotype of NK cells, co-expressing both cytotoxic molecules and activating receptors (Granzyme B^+Perforin$^+$NKG2D$^+$NKp46$^+$), showed a stronger correlation with NK cell lysis ($p=0.0002$, $r=0.9021$), and was both increased in patients upon PDS01ADC treatment and associated with clinical response ($p=0.0688$). Other refined NK subsets expressing inhibitory receptors, such as NKG2A$^+$TIGIT$^+$Perforin$^+$ NK cells, negatively correlated with lysis ($p=0.0078$, $r=-0.7413$), and were decreased with PDS01ADC, with greater decreases associated with improved clinical response ($p=0.0224$).
Conclusions: PDS01ADC increased peripheral NK cells with specific phenotypes that positively associated with tumor cell lysis, with increases in some cases correlating with clinical response. These findings highlight the importance of deep interrogation of the peripheral immunome and demonstrate the role of NK cells in the biologic activity of PDS01ADC. Studies combining PDS01ADC with other agents to synergize with these NK cell changes are warranted.

#7757 Investigating the mechanisms underlying regulatory T cell dysfunction in ICI-induced colitis.

Emily Schahrer, Paul Ngai, Mehdi Benjelloun Zahar, Christopher R. Weber, David Zemmour

University of Chicago, Chicago, IL

Immune checkpoint inhibitors (ICIs) have revolutionized cancer therapy but can trigger immune-related adverse events such as colitis. The mechanisms driving these toxicities remain poorly understood. In this study, we analyzed colon biopsies from a patient cohort with ICI-induced colitis using integrated single-cell RNA sequencing and paired spatial transcriptomics and proteomics to define disease mechanisms and model human autoimmunity.Transcriptomic mapping revealed accumulation of proliferative cytotoxic T cells in the colon, suggesting failure of regulatory T cells (Tregs) to restrain effector responses. Tregs displayed upregulation of Th1- and IFN-response genes, including *IL12RB2, IFI6*, and *CXCL9*, distinguishing ICI colitis from patterns observed in Th17-driven inflammatory bowel disease.Within the $CD8^+$ T cell compartment, combined single-cell and TCR analyses identified tissue-resident memory (Trm) cells as key targets of ICIs driving colonic inflammation. Activated $CD8^+$ Trm cells displayed a cytotoxic, IFN-γ-rich profile enriched for granzymes, chemokines, and effector transcriptional modules characteristic of human ICI colitis. Spatial mapping will confirm the co-localization of Trm cell activation, Treg dysfunction, and IFN-driven microenvironments within epithelial and mucosal niches.Together, these results define a pathogenic circuit in which Trm activation, Treg destabilization, and Th1-skewed inflammation converge to drive ICI-induced colitis. This work provides a mechanistic framework for understanding ICI-associated autoimmunity and may guide development of targeted therapeutic strategies that preserve antitumor immunity while limiting tissue toxicity.

#7758 Prediction of pharmacokinetics and pharmacodynamics profile for a fixed dosing and body weight-based dosing of GI-102 based on cell-level pharmacodynamics-mediated drug disposition model in patients with advanced or metastatic solid tumors.

Suemin Park[1], Seung Chan Choi[1], Kwang-Soo Shin[2], Nari Yun[2], **Myoung Ho Jang**[2], Hyeong-Seok Lim[1]

[1]Department of Clinical Pharmacology and Therapeutics, Asan Medical Center, University of Ulsan College of Medicine, Seoul, Korea, Republic of,[2]Clinical development, GI Innovation, Seoul, Korea, Republic of

GI-102 (CD80/IL2v3) is designed to direct IL-2 variant to immune cells and tumor cells, and to block CTLA-4 via CD80. Proliferation of cytotoxic T (T_c) cells and natural killer (NK) cells is enhanced through selective binding to IL-2Rβγ. CD80-CTLA4 binding further inhibits immunosuppressive function of regulatory T (T_{reg}) cells. Based on GI-102 monotherapy dose-escalation data of the phase 1/2 first-in-human study (KEYNOTE-G08), a cell-level pharmacodynamics-mediated drug disposition (PDMDD) model was constructed to assess the relationship between drug exposure, target receptor occupancy, and pharmacodynamic (PD) effect. Historically, IL-2 therapies relied on body-weight-based dosing due to narrow therapeutic windows and high interpatient variability. Leveraging GI-102 safety and tolerability in humans, model-informed simulations compared overall pharmacokinetic (PK) and PD profiles of fixed-dose versus weight-based dosing.The model was constructed by simultaneously fitting drug concentrations (n=1185) and total lymphocyte (n=826), T_c cell, NK cell, and T_{reg} cell counts (n=529 each) from 54 patients with advanced or metastatic solid tumors who received GI-102 intravenously every three weeks at doses of 0.06-0.45 mg/kg. The target-mediated drug disposition (TMDD) model incorporated time-varying PD-mediated disposition at the cellular level. Lymphocyte diapedesis after treatment was described empirically, and time delay between drug concentrations and lymphocyte increase driven by GI-102-IL-2Rβγ stimulation was captured by an indirect response model with the operational model of agonism. Following model diagnostics, Monte-Carlo simulations with 1000 replicates were performed for each scenario using the final model. Modeling was conducted using NONMEM® v7.5.0, and data processing and plotting using R v4.3.3. The two-compartment, cell-level PDMDD model adequately described central tendency of observed PK/PD data. Simulations showed a clear exposure-response relationship across doses. At 0.24-0.45 mg/kg, total lymphocytes and T_c cells, accounting for diapedesis, reached levels around 3640-4136 cells/μL and 515-572 cells/μL, respectively. At the same range, NK cells were predicted to exceed 1000 cell/μL, indicating robust expansion at receptor occupancy < 50%. In addition, simulations for fixed-dose regimen of 10, 20, and 30 mg showed increased immune cell proliferation, largely comparable to corresponding weight-based doses of 0.12, 0.24, and 0.35 mg/kg, respectively. Our modeling and simulation provides preliminary prediction of PD effect at tested doses and fixed-dose regimens, serving as reference for determining optimal dose and dosing regimen.

#7759 Construction of a novel immune gene signature to distinguish immunotherapy responders and non-responders.

Moonyoung Lee[1], Yona Kim[2], Sangjeong Ahn[2], Sung Hak Lee[1]

[1]Department of Hospital Pathology, Seoul St. Mary's Hospital, College of Medicine, The Catholic University of Korea, Seoul, Korea, Republic of,[2]Department of Pathology, Korea University Anam Hospital, College of Medicine, Korea University, Seoul, Korea, Republic of

Introduction: Immune checkpoint therapies (ICT) restore the immune system's ability to fight cancer by blocking inhibitory signals of T cell activation, allowing them to recognize and attack tumor cells. Representative examples include drugs targeting PD-1, PD-L1, and CTLA-4 proteins. Despite active research into ICT, many patients remain untreated. The response to ICT vary across cancer types and even within cancer types, depending on immune subtype. Therefore, we aimed to define a new immune signature to identify responders and non-responders in individual cancer types. We developed a model using data from 11 cancer types from the TCGA as a training dataset and validated this model with other data sets.

Methods: Using TCGA data for 11 cancer types (BLCA, BRCA, COAD, UCEC, ESCA, HNSC, KIRC, LIHC, LUAD, SKCM, STAD), we divided them into immunologically hot group, cold group, and intermediate group, according to the expected effects of ICT. To divide the data into three groups, we used immune-related pathways, immune markers from literature, Cibersort, Ecotype, and Methylation data as features. Lasso was used to select important features, and Kmeans was used for clustering. To test the results, Silhouette score, CH index, and Dunn index were used. The results of these coefficients decreased further when methylation data and ecotype features were added, so these two features were finally removed and clustered. We then created a new gene set signature using leading edge genes/markers that overlapped across these features. We tested this gene set signature on melanoma data and confirmed that it effectively distinguished responders from non-responders.

Results: A total of 5,089 samples corresponding to 11 cancer types were selected, and 38 pathways were selected as features, and it was confirmed through a heatmap that they were well divided into 3 groups. A new signature was discovered with a total of 84 genes, including leading edge genes that appear repeatedly in this pathway and markers corresponding to the signature. This confirmed that the discovered gene set was well-separated across each cancer type. For further validation, we used the GSE91061 dataset to examine whether the new gene set differed between the responder and non-responder groups using a NES plot. The positive enrichment score was biased toward the responder group, and the padj value was significant at 0.028, consistent with the pattern observed in TCGA. When ORA was used with Reactome and GOBP, immune-related pathways were also significantly identified.

Conclusion: Given the close connection between ICT and immunity, we believe this new gene set signature will be helpful in distinguishing between ICT-responsive and non-responsive groups. We plan to conduct validation tests using other cancer type data and WSI on immunologically hot and cold tumor groups to further improve accuracy.

#7761 Tertiary lymphoid structure (TLS) representative cells elicit response to anti-PD-1$^+$ therapy in a cold tumor.

Satish Sankaran[1], Priyanka Chevour[1], Kowshik Jaganathan[1], Biswajit Das[1], Moumita Nath[1], Abdul Haseeb[1], Jobin K Paul[1], Vasanthakumar A[1], Oliyarasi M[1], Rajashekar M[1], Jayaprakash C[2], Venkatesh T[2], MS Ganesh[3], Amritha Prabha[3], Prakash BV[4], Upendra K[1], Mehul Kapur[1], Ritu Malhotra[1], Govindaraj K[1], Pavithira .[1], Mohit Malhotra[1]

[1]Farcast Biosciences India Pvt. Ltd., Bangalore, Bangalore, India,[2]DBR & SK Super Speciality Hospital, Tirupati, Tirupati, India,[3]Vydehi Institute of Medical Sciences and Research Centre, Bangalore, Bangalore, India,[4]Sri Lakshmi Multi Speciality Hospital, Bangalore, Bangalore, India

The composition and activation phenotype of immune cells within the tumor microenvironment (TME) can significantly influence therapeutic response to PD-1 based immunotherapy. Using the Farcast TruTumor histoculture platform, we investigated potential factors contributing to the unexpected anti-PD-1 responsiveness in an immune cold TME. Freshly resected Head and Neck Squamous Cell Carcinoma (HNSCC) samples (n=5) and matched blood were collected from consented patients. Explants were generated from the tumors and treated in culture with anti PD-1 (Nivolumab132 µg/ml) for 72 h. The response was evaluated using histopathology and flow cytometry readouts. Among the five samples analysed, one responder (S2) exhibited elevated cleaved caspase-3 expression (2.5-fold increase) in the tumor relative to the control. Interestingly, this sample (immune content <2%), exhibited a cold tumor immune microenvironment compared with the four non-responder (NR) samples (mean immune content = 4.5%). To investigate factors underlying the observed response, we evaluated the baseline immune profile. Sample S2 exhibited a more heterogenous Lo-SSC compartment compared to NR samples. This was characterized by a high proportion of CD23$^+$ follicular B cells (3.9-fold increase), CD11c$^+$ dendritic cells (1.5-fold increase), and DC-LAMP$^+$ expressing mature dendritic cells (2.9-fold increase) compared to NR samples. These sub-populations are indicative of immune cell subsets typically present in or associated with TLS. Although the responder sample contained a relatively low overall proportion of CD8$^+$T cells, it exhibited 15 fold lower proportions of both early (CD8$^+$PD-1$^+$) and late (CD8$^+$CD39$^+$) exhausted T-cells, while displaying a 12-fold increase in stem-like (CD8$^+$TCF1$^+$) T cells. Upon ex vivo culture of tumor explants on TruTumor platform, the responder sample showed a distinct increase of 1.8-fold in pro-inflammatory M1 macrophages in the treated relative to the untreated control, whereas no appreciable change was observed in the non-responder samples. Interestingly, anti PD-1 treatment led to the emergence of an NKT-cell population (CD3$^+$CD56$^+$) and an increase in NK cells expressing Granzyme B (CD3$^-$CD56$^+$Granzyme B$^+$). In summary, our data reveals that response to anti-PD-1 is not solely dependent on the abundance of CD8$^+$ T cells but also involves substantial contributions from TLS representative immune sub-populations within the TME. Specifically, the presence of follicular B cells, stem-like CD8$^+$ T cells, CD11c$^+$ cells, and DC-LAMP$^+$ dendritic cells may contribute to treatment responsiveness, even in the context of an otherwise immune-poor phenotype. The TruTumor histoculture platform provides a translational model to study tumor response to immunotherapy with insights into how tumor responsiveness, transcends beyond mere presence of CD8$^+$ T cells in the TME.

#7762 PD-L1-dependent 4-1BB costimulation enhances anti-tumor efficacy and T cell persistence as monotherapy or in combination with tarlatamab.

Felipe Vences Catalan[1], Willy Tsai[1], Wendy Chen[1], Anja Henn[2], Kevin Cook[1], Maryam Yousefi[3], Tanya Vagner[3], Andrew Jimena[1], Khushboo Sharma[4], Deepali Sawant[1], Jason DeVoss[1], Matthias Friedrich[2], Mithun Khattar[1], Julie Bailis[1], Andrew Rankin[1], **Sungeun Kim**[1]

[1]Amgen Research, Amgen, Inc., South San Francisco, CA,[2]Amgen Research, Amgen, Inc., Munich, Germany,[3]Research biomarkers, Amgen, Inc., South San Francisco, CA,[4]Precision Medicine, Amgen, Inc., South San Francisco, CA

Bispecific T-cell engagers (TCEs) have demonstrated transformative clinical efficacy by redirecting T cells to eliminate tumor cells. However, clinical outcomes highlight opportunities to further enhance therapeutic benefits, particularly by improving overall response rates and durability of responses. Sustained CD3 engagement by TCEs can lead to T cell exhaustion, resulting in diminished effector function and reduced persistence. To address these challenges, we developed AMG 728, a PD-L1-targeted 4-1BB bispecific molecule designed to enhance T cell anti-tumor activity and persistence. AMG 728 simultaneously blocks PD-1/PD-L1 inhibitory signaling and activates 4-1BB costimulatory signaling in a PD-L1-dependent manner. This dual mechanism is intended to enhance T cell activation and persistence while minimizing the risk of immune activation and off-tumor toxicity associated with systemic 4-1BB agonism. By combining the CD3-mediated signaling from TCEs with 4-1BB costimulation provided by AMG 728, we aimed to fully activate T cells, thereby promoting cytolytic effector differentiation, improving survival, and expanding memory T cell populations. A mouse surrogate PD-L1-4-1BB bispecific molecule demonstrated dose-dependent anti-tumor efficacy as a monotherapy in a human PD-L1/4-1BB double knock-in mouse model bearing syngeneic, human PD-L1-expressing tumors. Mechanistic characterization of this surrogate molecule further revealed several potential pharmacodynamic biomarkers *in vivo*, including increased $CD8^+$ T cell proliferation, expansion of central memory T cells in draining lymph nodes, enhanced cytolytic effector T cell differentiation within tumors, and elevated levels of soluble 4-1BB. Furthermore, AMG 728 was evaluated for its potential to improve the efficacy of tarlatamab, a DLL3-targeted bispecific TCE *in vitro* and in a T cell humanized small cell lung cancer (SCLC) preclinical mouse model. Selective 4-1BB agonism on PD-L1-positive tumors enhanced the cytotoxic activity of tarlatamab *in vitro*. In the human PD-L1-overexpressing SHP-77 SCLC xenograft implanted in NSG mice, combination treatment with AMG 728 and tarlatamab at suboptimal doses resulted in significantly greater tumor growth inhibition, extended survival, and a higher frequency of complete responses, compared with either monotherapy. Notably, AMG 728 treatment led to a significant increase in central memory T cells in the tumors from tarlatamab-treated mice. Collectively, these findings suggest that the addition of AMG 728 to tarlatamab represents a rational combination strategy that enhances T cell activation and longevity, resulting in improved antitumor activity and survival.

#7763 FOXA1 in ovarian cancer: Therapeutic target and immunotherapy enhancer.

Taewan Kim, Baek MooJun, HyoWook Gil, Eunjung Yang, Kwangseock Kim, jaesung Ryu, Kong Hyejeong, Beamjun Park, **Seob Jeon**

Soonchunhyang University Cheonan Hospital, Cheonan, Korea, Republic of

OBJECTIVE
This study aimed to elucidate the oncogenic role of FOXA1 (Forkhead Box A1) in ovarian cancer and to evaluate its potential as both a therapeutic target and a diagnostic biomarker. We further investigated whether FOXA1 inhibition could enhance responsiveness to immune checkpoint blockade and overcome chemoresistance.
METHODS
A total of 76 ovarian tissue samples were analyzed, including 9 normal, 34 benign, and 33 malignant specimens. Immunohistochemical (IHC) staining was performed to assess FOXA1 expression and its correlation with tumor stage. Functional studies were conducted using FOXA1 siRNA in SK-OV3 and HEYA8 cell lines. Changes in cell proliferation, migration, invasion, and wound-healing ability were evaluated following FOXA1 silencing. Quantitative RT-PCR was used to measure FOXA1 and epithelial-mesenchymal transition (EMT)-related gene expression. In addition, the effects of FOXA1 inhibition on sensitivity to carboplatin and the immune checkpoint inhibitor atezolizumab were assessed.
RESULTS
IHC analysis revealed significant differences in FOXA1 expression among normal, benign, and malignant tissues, with expression levels correlating with tumor stage. FOXA1 silencing significantly reduced cell proliferation and decreased migration and invasion by 60-80%. EMT-related genes were markedly downregulated after FOXA1 knockdown. Moreover, FOXA1 inhibition enhanced atezolizumab responsiveness and reduced carboplatin resistance in ovarian cancer cells.
CONCLUSION
FOXA1 acts as an oncogenic driver in ovarian cancer, promoting proliferation, invasion, and EMT activation. Its overexpression correlates with disease progression, supporting its role as a diagnostic and prognostic biomarker. Targeting FOXA1 may enhance immunotherapy efficacy and overcome chemoresistance in ovarian cancer.

#7764 Modeling CRS in humanized immune system mice.

Audrey Wetzel[1], Anais Meynet-Cordonnier[1], Clothilde Philouze[1], Charline Boulot[1], Emilie Bayon[1], Sebastien Tabruyn[2], **Dan Georgess**[1]

[1]TransCure bioServices, Archamps, France,[2]TransCure, Archamp, France

Cytokine release syndrome (CRS) is a major risk during treatment with CAR-T cells, T-cell engagers, and, occasionally, checkpoint inhibitors. Because humanized immune-system mice are frequently used for the preclinical development of such therapies, we sought to provide a platform to derisk CRS before the clinical stage. We therefore characterized CRS induction, immune dynamics, and clinical manifestation in two different humanized mouse models. We humanized the immune system of initially immunodeficient mice by engrafting them either PBMCs or CD34+ hematopoietic stem cells. In the PBMC model, T cells were the only engrafted human immune population and exhibited a chronically induced, partially exhausted (TIM3+, LAG3+, PD1-) phenotype at baseline. At one week post-PBMC engraftment, circulating T-cells were at approximately at 1000 cells per mL, and OKT3 injection depleted them, thereby failing to induce CRS. At three weeks post-engraftment, however, circulating T-cell counts reached one million cells per mL and were no longer depleted by OKT3, which instead induced severe CRS and mortality within 24 hours. CRS induction in PBMC mice was accompanied by increases in circulating TNF-α, IFN-γ, and IL-2, as well as transient (≤6 hours) T-cell proliferation. In contrast, in the CD34 model, a more complete human immune system developed after engraftment, including myeloid, NK, dendritic, B, and non-exhausted T cells. This broader immune reconstitution enabled OKT3 to induce CRS with as few as 10,000 circulating T cells. Although clinical CRS symptoms were milder than those observed in PBMC-engrafted mice, the CRS cytokine signature in the CD34 model included not only the IFN-γ, TNF-α, and IL-2 surges observed in PBMC mice but also substantial increases in hallmark myeloid-derived CRS cytokines such as IL-6, CXCL10, and CCL2. Likewise, the cellular signature of CRS was more complete in CD34 mice, with induction of T-cell activation (CD69+, CD38+, HLA-DR+), exhaustion (PD1+, TIM3+), and proliferation (Ki67) markers, along with increased monocyte mobilization into the blood. In summary, our results demonstrate that the CD34 model displays mild-to-moderate clinical symptoms while more comprehensively recapitulating the hallmark cellular and molecular features of CRS.

#7766 Single-dose neoadjuvant atezolizumab in resectable stage IA-IIIA non-N2 NSCLC: Tumor infiltrate analysis from the PRINCEPS trial.

Antonio Nuccio[1], Lydie Cassard[2], Nathalie Cozic[3], Malek Ben Salah[4], Vesna Lukic[4], Julien Adam[5], Wael Salem Zrafi[3], David Planchard[6], Jordi Remon[7], Pernelle Lavaud[7], Anas Gazzah[8], Vincent Thomas de Montpreville[9], Maria Rosa Ghigna[10], Patrick Dumont[11], Elie Fadel[12], Fabrice Barlesi[1], Caroline Caramella[13], Filippo Gustavo Dall'Olio[6], Olaf Mercier[12], Paul-Henry Cournede[4], Nathalie Chaput[14], Benjamin Besse[1]

[1]Inserm, U981, F-94805, Universite Paris-Saclay, Gustave Roussy, Villejuif, France,[2], INSERM US23, Laboratoire d'immunomonitoring en Oncologie, F-94805,, Universite Paris-Saclay, Gustave Roussy, Villejuif, France,[3]Service de Biostatistique et d'Epidemiologie, Gustave Roussy, Universite Paris-Saclay, Villejuif, France,[4]Lab of Mathematics and Computer Science (MICS), Universite Paris-Saclay, CentraleSupelec, Paris, France,[5]Pathology, Hopital Paris Saint-Joseph, Paris, France,[6]Medical Oncology, Institut Gustave Roussy, Villejuif, France,[7]Institut Gustave Roussy, Villejuif, France,[8]DITEP, F-94805, Universite Paris-Saclay, Gustave Roussy, Villejuif, France,[9]Pathology, Hospital Marie Lannelongue, Le Plessis Robinson, Paris, France,[10]BIOPATH, F-94805, Universite Paris-Saclay, Gustave Roussy, Villejuif, France,[11]Centre Hospitalier de Chauny, Chauny, France,[12]Department of Thoracic Surgery & Heart-Lung Transplantation, Universite Paris-Saclay, Hopital Marie Lannelongue, Paris, France,[13]Radiology Department, Groupe Hospitalier Paris Saint Joseph, Hopital Marie Lannelongue, Paris, France,[14]INSERM US23, Laboratoire d'immunomonitoring en Oncologie, F-94805, Universite Paris-Saclay, Gustave Roussy, Villejuif, France

Phase 2 PRINCEPS trial (NCT02994576) showed that single dose neoadjuvant Atezolizumab (A, 1200 mg IV) was feasible in 30 stage IA-IIIA non-N2 NSCLC patients (treated arm, T). A comparative arm (C) was later added. We report tumor immune profiles and updated survival for T and C arms.
C arm included untreated resected stage IA-IIIA non-N2 NSCLC patients. Surgery samples were profiled for residual viable tumor (RVT) and immune infiltrates. RVT cutoffs were defined with Maximally Selected Rank Test for DFS/OS (Table1). Immune infiltrates (N=316) were compared across groups by Mann Whitney U test.
From 9/2019 to 8/2022, 30 patients were enrolled in C (2 non-NSCLC excluded). Mean age was 64 vs 66, squamous histology 13% vs 26%, PD-L1 neg 63% vs 46%, adjuvant ChT 20% vs 50% (T vs C).
T arm tumors were enriched in CD45+ leukocytes, CD8+ T cells, HLA-DR+ CD163+ myeloids; C arm tumors showed CD115+ CD163+ macrophages and CD16Low immature neutrophils suggesting an immunosuppressive TME.
In T arm, Responders (RVT≤60%) had higher lymphocyte, activated/exhausted PD-1+/TIGIT+ T cell and mature/activated CD16+ CD11bHigh neutrophil rates; Non-Responders (RVT>60%) showed more senescent CD57+ T cells and immunosuppressive (CD16-, CD163+) myeloids.
In C arm, Spontaneous Regressors (RVT≤95%) had proliferating Ki67+ OX40+ T cells, CD69+ NK, exhausted CTLA4+ TIGIT+ T cells and pro-inflammatory CD16+ macrophages vs Non-Spontaneous Regressors (RVT>95%), enriched in highly activated Treg.
In conclusion, neoadjuvant single dose A induced a CD8+/activated-myeloid profile that could relate to durable survival benefit. In T arm Responders showed activated/exhausted T cells and mature pro-inflammatory neutrophils, similar to Spontaneous Regressors in C arm; Non-Responders were enriched in senescent T cells and immunosuppressive myeloids. These results may indicate PD-1+/TIGIT+ exhausted T cells and pro-inflammatory myeloids as predictive biomarkers of A activity.

Table 1. DFS: Disease-free Survival; OS: Overall Survival; MaxStat: Maximally Selected Rank Test

#7767 Spatial profiling of the tumor immune microenvironment following oncolytic herpes simplex virus treatment in glioblastoma.

Sophia A. Paxton[1], Corinne H. Strawser[1], Lakshmi Prakruthi Rao Venkata[1], Elizabeth A. R. Garfinkle[1], James M. Markert[2], Katherine E. Miller[1], Kevin A. Cassady[3], Elaine R. Mardis[1]

[1]The Steve and Cindy Rasmussen Institute for Genomic Medicine, The Abigail Wexner Research Institute at Nationwide Children's Hospital, Columbus, OH, [2]Department of Neurosurgery, University of Alabama at Birmingham, Birmingham, AL,[3]Center for Childhood Cancer Research, The Abigail Wexner Research Institute at Nationwide Children's Hospital, Columbus, OH

Glioblastoma (GBM) is the most common and aggressive malignant brain tumor in adults, with an extremely low 5-year survival rate of ~5%. Despite established surgery and chemoradiotherapy treatments, outcomes remain poor due to GBM's profound heterogeneity and highly immunosuppressive tumor immune microenvironment (TIME). Emerging immunotherapies offer new opportunities to overcome these barriers. Among them, oncolytic herpes simplex viruses (oHSVs) stand out for their dual ability to selectively lyse tumor cells while stimulating robust anti-tumor immune responses. Preclinical and early clinical studies demonstrate that oHSVs can profoundly remodel immune cell expression within tumors, but these analyses lack spatial insight. Spatial multi-omics technologies now enable precise mapping of such immune transcriptome and proteome changes, answering how immune reorganization shapes the GBM TIME. The present study utilized 10x Genomics Visium spatial multi-omics to comprehensively map oHSV-induced immune responses in human GBM and explore their association with patient outcomes. Brain tumor samples were obtained from a Phase IA dose-escalation oHSV trial for recurrent glioma, with tissue collected both before treatment and at post-treatment resection. Across four patients, a total of seventeen formalin-fixed, paraffin-embedded samples were profiled using the Visium Spatial Gene Expression (Whole Transcriptome) and Visium Immune Profiling (Protein) panels. Spatial multi-omic data were analyzed in Seurat, leveraging a human brain immune reference integrated with our oHSV single-cell RNA-sequencing data to enhance cell type identification for spatial deconvolution. We characterized key immune cell populations, evaluating how their localization, abundance, and expression varied across treatment status (pre- vs. post-oHSV), spatial context (tumor bed vs. periphery), and clinical response (responders vs. non-responders). We also explored the use of custom viral RNA probes to detect viral presence within tissue; while signal detection was limited, these efforts informed future optimization of viral localization methods. By comparing spatial immune architectures between responders and non-responders, we identified trends that illuminate how immune cell organization shapes therapeutic efficacy. Furthermore, the observed concordance between spatial gene and protein expression of key immune markers reinforces the biological validity of these signatures and suggests their possible association with treatment response. Ultimately, elucidating the mechanisms by which oHSV modulates the GBM TIME advances our understanding of its anti-tumor effect and provides a rationale for its continued clinical development.

#7768 Biological pathways of response to neoadjuvant chemo-immunotherapy in triple-negative breast cancer (TNBC).

Nickolas Stabellini[1], Perrana B. Parthasarathy[2], Iluja Gautam[3], Patricia A. Rayman[2], Monaben Patel[2], Paul G. Pavicic Jr[2], Adam Moen[2], Brian Race[2], Eden Mundell[2], Amanda Trevino[2], Jennifer Powers[2], Tyler Joseph Alban[2], Jennifer Ko[2], Bahar Moftakhar[4], Takae Mizukami[5], Cynthia Owusu[5], Timothy A. Chan[6], Alberto J. Montero[5], C. Marcela Diaz-Montero[2]

[1]Case Western Reserve University School of Medicine, Cleveland, OH,[2]Cleveland Clinic, Cleveland, OH,[3]Cleveland Clinic Lerner College of Medicine, Cleveland, OH,[4]University Hospitals Seidman Cancer Center, Cleveland, OH,[5]University Hospitals Cleveland Medical Center, Cleveland, OH,[6]The Cleveland Clinic, Taussig Cancer Institute, Cleveland, OH

Background: KEYNOTE-522 established neoadjuvant pembrolizumab plus chemotherapy as standard care for early-stage TNBC, improving pathological complete response (pCR) rates. However, up to 45% of patients (pts) do not achieve pCR, and mechanisms driving differential responses are unclear. This study aimed to identify biological pathways distinguishing pCR from non-pCR pts at baseline (BL) and to characterize how these pathways evolve during treatment (DT) and post-surgery (PS).
Methods: Blood samples from TNBC pts were collected at BL, DT, and PS. Peripheral blood mononuclear cells (PBMCs) were isolated by density gradient centrifugation. Single-cell RNA sequencing was performed using the Parse Biosciences platform. Gene Set Enrichment Analysis identified enriched pathways using the Molecular Signatures Database (MSigDB) hallmark (50 gene sets) and Reactome (1,787 gene sets) collections. Comparisons were made between pCR and non-pCR patients at each timepoint and within groups (DT vs. BL).
Results: Among 18 sequenced pts, 11 achieved pCR. A total of 883,183 cells across 17 cell types were analyzed. At BL, responders showed elevated interferon (IFN) and cytokine signaling, mainly from lymphocytes, along with chemokine upregulation in classical monocytes (CM) and increased DAP12 expression in CD8+ T cells. During treatment, responders demonstrated a myeloid-driven TNFα/NFκB inflammatory response and upregulated GPCR signaling in CM. In contrast, non-responders exhibited ineffective myeloid IFN signaling and downregulated TNFα/NFκB activity across all cell types DT.
Conclusions: pCR is distinguished by a coordinated lymphocyte and myeloid immune activation. Non-responders exhibit ineffective signaling and suppressed inflammatory pathways. These divergent mechanisms highlight potential biomarkers to guide patient stratification and therapeutic optimization in TNBC.

Table 1. Most prominent pathways differing between responders and non-responders

Pathway	MSigDB Gene set	Cell Type	Baseline (responders vs non-responders)	On treatment (responders vs non-responders)	Post-Surgery (responders vs non-responders)

#7769 IL-12/anti-PD-1 armored oncolytic HSV-1 reprograms CNS immunity: Integrated longitudinal immune, genomic, and metabolic CSF profiling in the MVR-C5252 PuMP Trial.

Elizabeth Owens, Kelly Hotchkiss, Stevie Threatt, Justin T. Low, Monika Anand, Julia Louw, Melody Goldston, Margaret O. Johnson, Claire Bradbury, James E. Herndon, Gerry A. Grant, David M. Ashley, Anoop P. Patel, Annik Desjardins, Michael C. Brown, Mustafa Khasraw

Duke University School of Medicine, Durham, NC

Introduction/Rationale: Glioblastoma (GBM) remains refractory to immunotherapy and exhibits low basal IL-12 and IFN-γ levels relative to other solid tumors, reflecting an immunologically quiescent microenvironment. MVR-C5252 is a replication-competent HSV-1 engineered to deliver IL-12 and an anti-PD-1 antibody fragment, coupling oncolysis with Th1 polarization and localized checkpoint blockade to overcome this resistance.
Methods: Stage 1 of PuMP (NCT06126744) assessed safety in six adults with recurrent IDH-wildtype GBM treated with a single convection-enhanced intratumoral infusion (5×10^8 or 1×10^9 PFU). An Ommaya reservoir enabled CSF sampling at baseline, 1 hour, and 28 days. Serial CSF single-cell RNA sequencing (scRNA-seq) assessed immune cells, and whole-genome sequencing (WGS) quantified ctDNA and viral kinetics. Liquid chromatography-mass spectrometry (LC-MS)-based metabolomics interrogated IFN-γ-linked tryptophan/kynurenine and arginine/NO pathways. Stage 2 (ongoing) incorporates repeat dosing via an implanted pump, and Stage 3 delivers 12 doses in a Bayesian Optimal Interval (BOIN) dose-escalation design, with the selected dose and schedule planned for expansion in Stage 4.
Results: Six patients (3M/3F; 50-59 years; KPS 90 in 5, 80 in 1; MGMT unmethylated in 5) were treated in Stage 1. Median PFS was three months and median OS was 6.1 months, with two patients alive at last follow-up. MVR-C5252 was well tolerated (grade 1-2 only) with no PCR-detectable shedding in urine or saliva. scRNA-seq in four patients with CSF from all three timepoints yielded 14,049 high-quality cells and diverse T-cell and myeloid populations. $CD8^+$ subsets included cytotoxic and exhausted states, while $CD4^+$ subsets spanned naïve, memory, effector, and regulatory states. TAM-like microglia and macrophages were also identified. Rapid early IFN-driven activation and monocyte/dendritic-cell recruitment were observed, followed by sustained cytotoxic and myeloid remodeling at 28 days. $CD8^+$ populations showed increased effector states and fewer exhausted cells, while $CD4^+$ T-cell states spanned naïve and helper lineages. Tumor and viral genome kinetics were characterized by WGS, immune-metabolic pathways were quantified by LC-MS-based metabolomics, and integrated CSF-tumor-blood analyses will be presented.
Conclusions: Stage 1 demonstrates safety and immunobiological activity of MVR-C5252, with a single infusion inducing immune remodeling that was not sustained. Meaningful antitumor activity is expected to require repeated intratumoral dosing, as planned in Stages 2-4. These findings establish a mechanistic human model in which localized IL-12/anti-PD-1 virotherapy shifts the tumor microenvironment from a quiescent to a Th1-polarized, cytotoxic state, providing a foundation for next-phase efficacy evaluation.

#7773 Continuation of immune checkpoint inhibitor therapy after progression in head and neck squamous cell carcinoma: A multicenter study.

Hyun Ae Jung[1], Young Kim[2], Ross Merkin[3], Thomas Roberts[3], Manisha Patel[3], Boram Park[4], Jinyong Kim[1], Sehhoon Park[1], Jong-Mu Sun[1], Se-Hoon Lee[1], Jin Seok Ahn[1], Myung-Ju Ahn[1], Lori J. Wirth[3], Jong Chul Park[3]

[1]Samsung Medical Center, Seoul, Korea, Republic of,[2]New York Medical College, Valhalla, NY,[3]Massachusetts General Hospital, Boston, MA,[4]College of Medicine, Inha University, Incheon, Korea, Republic of

Background: Immune checkpoint inhibitors (ICIs) have significantly improved survival outcomes in recurrent or metastatic head and neck squamous cell carcinoma (HNSCC). However, disease progression after first-line ICI therapy remains a major clinical challenge, and the benefit of ICI continuation or rechallenge after progression has not been fully elucidated.
Methods: In this multicenter retrospective study, we included patients diagnosed with HNSCC between 2016 and May 2025 at Samsung Medical Center and Massachusetts General Hospital. This study included patients who received first-line ICI therapy with or without other agents. Overall survival (OS) was compared between patients who received second-line ICI continuation (ICI-based regimens) and those who received non-ICI treatments.
Results: A total of 278 patients received first-line ICI therapy with or without chemotherapy, including 85 (30.6%) with HPV-positive HNSCC, 133 (47.8%) with HPV-negative disease, and 60 (21.6%) with unknown HPV status. Among them, 242 patients (87.0%) experienced disease progression after first-line ICI ± chemotherapy, and 210 proceeded to second-line treatment. Of these 210 patients, 73(34.8%) received ICI-based therapy — while the remaining 137 (65.2%) received cytotoxic chemotherapy or other non-ICI regimens. The median OS from the start of first-line therapy was 17.0 months (95% CI, 14.5-19.5). Median OS was 21.1 months for patients who received second-line ICI continuation and 14.3 months for those who received non-ICI treatments (HR 0.61, 95% CI 0.43-0.85, P = 0.004). The median OS from the start of second-line therapy was 12.2 months for patients who received ICI with or without other agents and 8.0 months for those who received chemotherapy (P = 0.003). In subgroup analyses stratified by first-line ICI efficacy, patients with a first-line treatment duration of < 6 months showed a modest OS advantage with ICI-based second-line therapy compared with non-ICI regimens (11.2 vs. 8.0 months; P = 0.042). In patients whose first-line treatment duration was ≥ 6 months, the difference was substantially more pronounced, with ICI-based therapy demonstrating a markedly longer OS compared with non-ICI treatment (12.7 vs. 7.8 months; P = 0.035).
Conclusions: ICI continuation was associated with a significant OS benefit compared with non-ICI regimens in patients with recurrent or metastatic HNSCC who progressed after first-line ICIs. These findings indicate that continuing ICI-based treatment may be a feasible option regardless of the duration of first-line PFS, with a more pronounced benefit in patients who initially achieved durable disease control with first-line ICI therapy.

#7774 Blockade of cell-ECM interaction with an oncolytic virus suppresses tumoral STING activation while inducing antitumor immunity.

Upasana Sahu[1], Matthew Mullarkey[2], Kimberly Rivera Caraballo[1], Sergie Bombin[1], Adam Chadli[1], Ravindra Kolhe[3], James M. Markert[4], Bangxing Hong[1], Balveen Kaur[1]

[1]Augusta University, Augusta, GA,[2]The University of Texas Health Science Center At Houston, Houston, TX,[3]Pathology, Medical College of Georgia, Augusta, GA,[4]University of Alabama at Birmingham (UAB), Birmingham, AL

Oncolytic HSV (oHSV) therapy is an emerging immunotherapeutic modality currently approved for melanoma in USA and EU and conditionally approved for recurrent brain tumors in Japan. Several clinical trials are investigating the utility of this approach in patients. To investigate ways to improve its therapeutic index, we analyzed the transcriptomic changes in patients with recurrent brain tumor pre and post CAN-3110 treatment (NCT03152318). Gene set enrichment analysis showed significant enrichment in the pathways of extracellular matrix (ECM) interactions and glycosaminoglycan (GAG) synthesis post virotherapy. CD44, a cell surface receptor, plays a crucial role in cell-cell and cell-ECM interactions. Apart from engaging with ECM components like hyaluronic acid (HA), collagens, fibronectin, osteopontin, matrix metalloproteinases (MMPs), etc., it also partners with several cell surface receptors like growth factor receptor family and integrins to guide cellular responses to ECM and growth factor stimulation. Here we investigated the role of CD44 signaling in regulation of both anti-viral innate immunity and anticancer adaptive immunity by creating an oHSV that encodes for the secreted extracellular portion of CD44 (OV-x44). Our results indicated that OV-x44 destabilized xCT and disrupted cellular redox homeostasis. Increased oxidative stress resulted in tumor selective STING carbonylation, and reduced TBK1 activation, thereby enhancing virus replication. On the contrary, single-cell RNA sequencing uncovered enhanced innate immune responses in immune cells with TLR7 driven activation in T cells in the tumor microenvironment (TME). To our knowledge, this is the first report to describe an oHSV that can inhibit innate intracellular anti-viral immunity in tumor cells and can also stimulate innate immune responses in the TME to guide antitumor immunity. Collectively, this study uncovers the significance of OV-x44 as a potent immune stimulating anticancer therapeutic.

#7775 Pharmacodynamic biomarkers of TGFβR2xPD-1 bispecific antibody INCA33890 in patients with MSS metastatic colorectal cancer (mCRC).

Michelle Kinder[1], Rui Hong[1], Chifei Sun[1], Yunlan Fang[1], **Michael Smith**[1], Cynthia Timmers[1], Chiara Greggio[1], Jordi Rodon Ahnert[2]

[1]Incyte Corporation, Wilmington, DE,[2]The University of Texas MD Anderson Cancer Center, Houston, TX

INCA33890 is an TGFβR2xPD-1 bispecific antibody designed to antagonize TGFβR2/PD-1 signaling in immune cells co-expressing both targets. In the INCA 33890-101 study (NCT05836324) part 1A, 48 patients (pts) across 10 tumor types were evaluated with 7 dose levels (100, 300, 600, 900, 1200, 1500 mg Q2W and 900 mg Q4W). In part 1B, 94 pts with MSS mCRC were treated across 3 dose levels (300, 600, and 900 mg Q2W). During part 1B dose expansion, fresh or archival (≤3 years of first dose) baseline biopsies and on-treatment biopsies (Cycle 2, Day 15 [C2D15] up to Cycle 2, Day 28) were required. We present pharmacodynamic biomarker analyses from pts in part 1A and part 1B with MSS mCRC. Peripheral blood from pts was analyzed by flow cytometry for receptor occupancy, anti-idiotype binding, and T-cell activation (Ki67 and HLA-DR). Cytokines (CXCL9, CXCL10, IFNγ) were measured in plasma using a 4-Plex ELLA or proinflammatory MSD assay. Intratumoral T-cell infiltration was measured at baseline and C2D15 using multiplex immunohistochemistry, which included CD8, Granzyme B, and FOXP3. Multiplex immunofluorescence staining for phosphorylated SMAD (pSMAD) and spatial transcriptomics using the Xenium immuno-oncology panel were also performed. Following INCA33890 treatment, PD-1 competitive binding decreased, demonstrating target engagement. Anti-idiotype binding of INCA33890 increased in both PD-1^{+} effector memory T cells and PD-1^{-} naïve T cells, demonstrating dose-dependent engagement of TGFβR2 at the highest dose levels. At all doses, INCA33890 induced T-cell activation, evidenced by increased Ki67 and HLA-DR expression on peripheral T cells, and increased proinflammatory cytokines IFNγ, CXCL9, and CXCL10. In pts with MSS mCRC, intra-tumoral CD8^{+} T-cell density was significantly increased in matched post-treatment tumor biopsies. pSMAD and T cell TGFβR2 response signatures were decreased in PD-1^{+} T cells in post-treatment biopsies of responding patients. In the INCA 33890-101 study, treatment with INCA33890 resulted in activation of peripheral CD4^{+} and CD8^{+} T cells, and increased T-cell infiltration within the tumor microenvironment. At the recommended doses for expansion, INCA33890 binding was specific for PD-1^{+} T cells, as evidenced by low anti-idiotype binding on naïve T cells, which do not express PD-1. Decreases in pSMAD and T-cell TGFβR2 response signature in intratumoral T cells demonstrated the inhibition of TGFβR2 by INCA33890.

#7776 An exopolysaccharide-containing yogurt preserves CCR6$^+$ CD4$^+$ T Cells: Th7R, and may enhance immunotherapy responses in lung cancer patients.

Hiroshi Kagamu[1], Ayako Shiono[1], Hisao Imai[1], Atsuto Mouri[1], Ou Yamaguchi[1], Kosuke Hashimoto[1], Shota Takei[1], Hirotaka Kawanabe-Matsuda[2], Kyoichi Kaira[1]

[1]Saitama Medical University International Medical Center, Hidaka, Japan,[2]Meiji Holdings Co., Ltd., Hachioji, Japan

Background: Anti-tumor T-cell immunity is strongly influenced by the host immune state, known as the cancer-immune set point, in which gut immunity plays an essential role. Kawanabe-Matsuda et al. demonstrated in tumor-bearing mice that oral intake of purified exopolysaccharides derived from *Lactobacillus delbrueckii ssp. bulgaricus* OLL1073R-1 (R-1 EPS) induces CCR6$^+$ T cells in Peyer's patches and enhances the antitumor efficacy of immune checkpoint inhibitors. A randomized controlled study also reported that 4-week continuous consumption of yogurt containing R-1 EPS increases CCR6$^+$ T-cell subsets in the peripheral blood of healthy volunteers. We previously identified a novel CCR4$^-$CCR6$^+$ CD4$^+$ T-cell cluster, Th7R, enriched in advanced non-small cell lung cancer (NSCLC) patients who responded to PD-1 blockade therapy. Pre-treatment Th7R predicted ICI efficacy, and long-term survivors maintained a high proportion of Th7R after therapy.

Objective: To analyze longitudinal changes in T-cell subsets in patients with histologically confirmed lung cancer who consumed yogurt fermented by *L. bulgaricus* OLL1073R-1 containing R-1 EPS.

Methods: Peripheral blood was collected before intake, after 4 weeks of yogurt consumption, and 4 weeks after discontinuation. Changes in T-cell immune markers were evaluated using the Welch test and correlation analyses. Adverse events and the influence of concurrent cancer treatments were assessed.

Results: By August 15, 2025, 91 NSCLC patients were enrolled (median age 73 years; 70 males). Participants included stage II-III patients who received neoadjuvant therapy plus surgery or chemoradiotherapy, and patients with advanced or recurrent disease receiving systemic therapy. Treatments included targeted therapy (n=5), pembrolizumab (n=15), ipilimumab plus nivolumab (n=51), cytotoxic agents plus pembrolizumab (n=2), chemoradiotherapy (n=3), and neoadjuvant cytotoxic therapy plus nivolumab (n=9). In the PD-1 inhibitor group, an increase in peripheral GZMB$^+$ CD8$^+$ T cells was observed. Moreover, compared with historical data, the pembrolizumab-induced reduction of Th7R cells was attenuated. In the pembrolizumab subgroup with PD-L1 TPS ≥50%, treatment efficacy was favorable relative to historical controls (ORR 58.3%; DCR 91.7%). Notably, the neoadjuvant cohort achieved a 100% response rate.

Conclusion: Intake of yogurt containing R-1 EPS may enhance the efficacy of immuno-oncology therapies by suppressing the decline of Th7R cells.

#7777 Direct *in vivo* activation and functional reprogramming of human TILs using a multifunctional nanoengager in humanized renal carcinoma.

Man Wang[1], Lifu Ruan[1], Xin Wen[2], Tian Zhang[1], Andrew Z. Wang[1]

[1]University of Texas Southwestern Medical Center, Dallas, TX,[2]Xuzhou Medical University, Xuzhou, China

INTRODUCTION: Tumor-infiltrating lymphocytes (TILs) therapy has demonstrated remarkable clinical success in melanoma. However, its application in other cancers has been limited by high manufacturing cost and toxic conditioning regimen. To overcome these limitations, we aimed to develop a novel strategy to directly activate and expand TILs in vivo using a multifunctional nanoengager (TIL-NPs). In this study, we report the validation of TIL-NPs using mouse models of cancer, including a humanized renal carcinoma model that closely recapitulates human immune-tumor interactions.
METHODS: TIL-NPs were generated by conjugating azide-functionalized PEG-PLGA nanoparticles with DBCO-modified anti-CD3, anti-4-1BB, and IL-2. Their ability to activate and expand TILs was assessed using both MC38 and 786-O models. For the MC38 study, mice bearing bilateral tumors received intratumoral TIL-NPs in the right flank tumor only, and TIL activation was further evaluated using isolated MC38 TILs co-cultured with MC38 cells in vitro. To assess human relevance, TIL-NP-mediated expansion of human TILs was tested using renal cell carcinoma (RCC) patient samples, and a humanized RCC model was established by inoculating 786-O cells into NSG mice engrafted with human PBMCs.
RESULTS: We engineered multifunctional nanoparticles (TIL-NPs) displaying anti-CD3, anti-4-1BB, and IL-2, measuring ~126 nm with ~50 μg of immune agonists conjugated per mg NP. In vitro, MC38 tumor-derived TILs stimulated with TIL-NPs showed markedly enhanced cytotoxicity against MC38 cells and produced the highest IFN-γ levels compared with free antibodies or unstimulated TILs. In vivo, intratumoral delivery of TIL-NPs in a bilateral MC38 model induced complete regression of all injected tumors and generated a strong systemic response, with substantial regression of contralateral tumors and improved survival. Using RCC patient-derived TILs, TIL-NPs also enhanced cytotoxicity against 786-O and ACHN cells relative to free antibodies. In a humanized RCC model, TIL-NPs produced near-complete regression of treated tumors and markedly suppressed contralateral tumor growth. Immunohistochemistry confirmed dense $CD8^+$ T-cell infiltration in TIL-NP-treated tumors, indicating enhanced activation and recruitment of cytotoxic T cells. Overall, TIL-NPs strengthened T-cell signaling through receptor clustering, prolonged survival, and elicited potent local and systemic antitumor responses.
CONCLUSION: TIL-NPs potently activate and reprogram TILs in vivo, enhancing cytotoxicity and systemic antitumor immunity, highlighting their translational potential for adoptive T-cell therapy in solid tumors.

#7778 GS24-B047, a potential best-in-class DLL3-targeting T-cell engager with integrated costimulatory signal, for the treatment of small cell lung cancer.

Zeng Qi[1], **Fu Li**[1], Zhiyu Cui[1], Hongmei Xie[1], Sijia Liu[1], Dechen Cao[1], Liang Xu[1], Yihui Lin[1], Lishan Kang[1], Siqin Wang[1], Lei Jin[2], John L. Xu[2]

[1]Changchun GeneScience Pharmaceutical Co., Ltd., Shanghai, China,[2]Changchun GeneScience Pharmaceutical Co., Ltd, Shanghai, China

Background: Small cell lung cancer (SCLC) remains an aggressive malignancy with limited therapeutic options and poor prognosis, particularly in the relapsed/refractory settings. DLL3, a tumor-associated antigen highly expressed on SCLC cells with minimal expression in normal tissues, represents a promising therapeutic target. While T-cell engagers (TCEs) targeting DLL3 and CD3, such as Tarlatamab, have demonstrated clinical activity, maintaining T-cell function in the tumor microenvironment remains challenging, and improvements in progression-free survival (PFS) have been limited. GS24-B047 is a novel DLL3-targeting TCE that incorporates a proprietary costimulatory signal designed to enhance T cell activation and persistence, with the potential to improve clinical efficacy in SCLC patients.

Methods: Binding activity and specificity of GS24-B047 to DLL3, CD3, and the costimulatory target were characterized by surface plasmon resonance (SPR), Octet biosensor, and flow cytometry. *In vitro* functional activity was assessed in co-culture assays with human PBMCs and DLL3-expressing SCLC cell lines, measuring T cell activation, cytokine release, and cytotoxicity. *In vivo* anti-tumor efficacy was evaluated in SCLC cell-derived xenograft (CDX) models with human immune system reconstitution.

Results: GS24-B047 bound to DLL3 with sub-nanomolar affinity, recognizing a distinct, more membrane-proximal epitope as compared to Tarlatamab, and effectively mediated simultaneous engagement of DLL3 on tumor cells and CD3 on T cells. *In vitro*, GS24-B047 induced T cell activation, proliferation, and cytokine secretion, and exhibited potent cytotoxicity against DLL3-expressing SCLC cell lines (with EC_{50} values in the picomolar range). GS24-B047 demonstrated a favorable therapeutic index with a high ratio of tumor cell killing to IL-6 release. The integrated costimulatory signal reduced markers of T-cell exhaustion as compared to a benchmark DLL3xCD3 TCE, supporting a more sustained T-cell response. *In vivo*, GS24-B047 treatment resulted in significant and durable tumor regression in multiple CDX models of SCLC, showing enhanced anti-tumor activity when compared to clinical benchmarks.

Conclusion: GS24-B047 is a novel DLL3-targeting TCE with integrated costimulation that promotes potent and sustained anti-tumor immunity in preclinical SCLC models. Collectively, our data support GS24-B047 as a potential therapeutic candidate for SCLC and warrant further evaluation in IND-enabling studies.

#7779 A tunable interleukin-18 (IL-18) platform engineered for complete escape from the decoy receptor IL-18 binding protein (IL-18BP).

Haiming Huang[1], Wencong Peng[1], Ruohan Zhu[1], Quanxiao Li[1], Liwen Ji[1], Yao Lu[1], Dong Wei[1], Yanling Wu[2], Tianlei Ying[2]

[1]Suzhou Forlong Biotechnology Co., Ltd, Suzhou, China,[2]Key Laboratory of Medical Molecular Virology (MOE/NHC/CAMS), Shanghai Institute of Infectious Disease and Biosecurity, School of Basic Medical Sciences, Fudan University, Shanghai, China

Background: IL-18 is a potent immune cytokine that promotes $CD8^+$ T-cell- and NK-cell-mediated antitumor responses. Its therapeutic potential is limited by rapid neutralization by IL-18BP, poor stability, short half-life, and systemic toxicity. Multiple efforts have attempted to generate IL-18 variants that escape IL-18BP neutralization, but current variants either retain residual IL-18BP binding or require extensive mutations. Our goal was to produce IL-18 variants fully resistant to IL-18BP with minimal mutations while maintaining controlled IL-18 activity via engaging the IL-18 receptor (IL-18R1).
Methods: Using structural modeling with our AI-driven Intelligent Biomolecular Discovery Platform, we identified amino acids critical for IL-18BP and IL-18R1 interactions. A combinatorial IL-18 library was constructed by site-directed mutagenesis and displayed on yeast. Variants that lost IL-18BP binding but retained IL-18R1 interaction were enriched by FACS. DNA coding sequences of positive clones were Sanger sequenced, subcloned into mammalian expression vector. And recombinant proteins were purified. IL-18R1-specific binding and IL-18BP escape were confirmed by ELISA, and binding KDs were determined by bio-layer interferometry. Functional activity was assessed by IFN-γ production from human PBMCs in the presence of 5 μg/mL IL-18BP.
Results: We initially identified a positive clone named E8 which showed reducing binding affinity to IL-18BP. We further obtained more than 200 clones which completely lost binding to IL-18BP from a secondary library based on the sequence of E8. Multiple sequence alignment revealed that clones with few amino acid mutations could fully abolish IL-18BP binding while retaining minimal IL-18R1 interaction. In addition, specific amino acid positions were identified whose single or combined mutation restored IL-18R1 affinity. Combinatorial mutations of specificity-related and affinity-related amino acids yielded a panel of over 100 IL-18 variants with IL-18R1 binding KDs ranging from 10^{-9} to 10^{-7} M and complete loss of IL-18BP binding. Representative variants activated human PBMCs with graded IFN-γ responses despite presence of high IL-18BP levels. One representative variant was fused to a anti-PD-1 IgG and demonstrated a tumor growth inhibition of 98% in mouse MC38 tumor model.
Conclusion: We developed a series of engineered IL-18 variants (IL-18v) that fully escape IL-18BP neutralization while providing tunable IL-18R1 affinity. This IL-18v platform enables customizable cytokine potency and supports diverse research and therapeutic applications, including incorporation into fusion proteins, targeted cytokine therapies, and next-generation immunotherapy strategies.

#7780 The first-in-class covalent peroxiredoxin 3 (PRX3) inhibitor RSO-021 modulates immune phenotypes in mesothelioma.

Victoria Gibson[1], Joanna Dzialo[2], Aida Habibovic[1], Christopher Landry[1], Dean Fennell[2], **Brian Cunniff**[1]

[1]University of Vermont Cancer Center, Burlington, VT,[2]Mesothelioma Research Programme, University of Leicester, Leicester, UK, Leicester, United Kingdom

RSO-021 is the clinical formulation of the first-in-class covalent peroxiredoxin 3 (PRX3) inhibitor thiostrepton (TS). TS covalently inactivates PRX3 active site cysteines leading to increased oxidative stress and apoptotic tumor cell death. RSO-021 was safe and showed early anti-tumor activity in a phase 1 trial in patients with malignant pleural effusion (MPE) arising from mesothelioma or metastatic disease to the lung (Fennell et al. *J Clin Oncol* 42, 3019-3019(2024)). The phase 2 trial is currently ongoing (NCT05278975). In this study we profiled immune signatures of human mesothelioma cell lines and patient derived explants treated with TS, and malignant pleural effusions from patients treated with RSO-021. Treatment of human mesothelioma cell lines showed TS down-regulated expression of PD-L1 and increased MHC class 1 expression. RNA-sequencing of human mesothelioma cells and patient-derived mesothelioma explants treated with TS showed modulation of transforming growth factor beta (TGFβ), tumor necrosis factor (TNFα), interferon alpha, and interferon gamma gene signatures. We performed multiplex ELISA analysis of cytokines in MPE from patients treated with RSO-021 via an intrapleural catheter to the pleural space. The levels of Resistin, a cytokine related to macrophage signaling in mesothelioma, was significantly increased 24 hours and 7-days post RSO-021 treatment. Levels of IL-6 and IL-8 were increased 24 hours after RSO-021 treatment and returned to baseline at 7 days. Lastly, in a syngeneic mouse model of mesothelioma end stage tumor burden was assessed in mice treated with TS, anti-PD1/anti-CTLA4 antibodies, or a combination of TS and anti-PD1/anti-CTLA4 antibodies. TS treated mice showed 30% tumor reduction. Anti-PD1/anti-CTLA4 antibody treated animals showed partial responses with 2 of 6 mice having complete tumor reduction. The combo of TS plus anti-PD1/anti-CTLA4 antibody showed complete tumor reduction in 6 of 6 mice. Together, these data highlight the immunomodulatory activity in cells, mouse models, and human tissue with RSO-021 and support further clinical development of RSO-021 in combination with immune-oncology therapies.

#7781 Patient derived tumor-immune organoids capture the functional and mechanistic interface in predicting response to standard therapeutics and immunotherapeutics in colorectal cancer patients.

Suman Dutta[1], Debarpan Mitra[2], Manoranjan Jha[1], Rimi Mukherjee[2], Juluri Srinivas[3], Kadambari Dixit[1], Krishanu Dey[1], Aswin Pandit[3], Sindu Pilli[1], Chandra C. Ghosh[2], Amjad Hussain[2], Gnaneswar Atturu[4], Ram Shankar Upadhayaya[1], Pradip K Majumder[5], Biswanath Majumder[1]

[1]Aryastha Life Sciences Private Limited, Hyderabad, India,[2]CanFinis Therapeutics, RISE, IISER, Kolkata, India,[3]Renova Century Hospitals, Hyderabad, India,[4]Care Hospital, Hyderabad, India,[5]Aryastha Life Sciences Inc, Cambridge, MA

Background: Colorectal cancer (CRC) is an emerging challenge, with rising early onset incidence and high mortality among younger individuals. Curative outcomes remain difficult due to its complexity. While chemotherapy and targeted drugs remain standard, immune checkpoint inhibitors (ICI) and engineered CAR-T are advancing as promising therapy options.
Objectives: Here we report the development of Aryastha BioSolution®, an integrated patient-derived tumor-immune organoid platform designed to predict therapeutic responses in CRC. The mechanistic interface of this platform enables parallel assessment of agents, ICI, and adoptive cell therapies, while capturing patient specific tumor-immune interaction dynamics that underlie treatment sensitivity and resistance.
Experimental procedure: Patient Derived Tumor Organoids (PDTOs) were established from surgically resected colorectal tumors and maintained in 3D milieu. PDTOs were treated with human equivalent doses of Oxaliplatin and Capecitabine and tumor killing was measured by live/dead staining. PDTOs were also co-cultured with human immune cells (PBMCs or engineered CAR-Ts) for 72 hours. Dynamics of tumor-immune engagement and therapy-induced organoid killing was tracked using time-lapse live imaging. Modulatory effects of ICI and CAR-T and their inflammatory responses were determined 72 hours post-culture by IFN-γ and chemokines levels.
Results: Early passage PDTOs retained the core genomic and phenotypic landscape of parent tumors, including point mutations, copy-number alterations, microsatellite (MSI) profile, as well as viability (Ki67) and histopathology signatures. Evaluation of SOC regimens showed that PDTO sensitivity markedly correlated with clinical treatment outcomes as measured by PET-CT. Co-culture assays showed distinct infiltration and killing trajectories of ICI treated PBMCs and CAR-T, characterized by robust cytolytic activity and close to 50% tumor volume reduction. We identified augmented IFN-γ and proinflammatory chemokines in responder PDTOs. Genomic profile (MSI-H/MMRd, tumor mutational burden, transcriptomic profile) and reactivity of tumor using these functional readouts underscore the mechanism of response and non-response which align with their known clinical trends.
Conclusions: The PDTO platform effectively bridges the translational gap that conventional models fail to overcome. Aryastha BioSolutions® provides a clinically aligned drug-response system that captures the phenotypic diversity of CRC and delineates the biology distinguishing responders from non-responders, enabling rational therapeutic combinations. The platform's high translatability positions it to strengthen clinical trial design and personalize both standard and emerging immunotherapy approaches.

#7782 Cbl-b-Notch1 axis blockers rewire immunosuppressive tumors to drive cytotoxic and anti-angiogenic immune responses.

Zhi Huang[1], Mairah Khan[2], Laura Naldi[3], Brionna King[1], Luis Del Valle[1], Silvana Leit[4], Beth Browning[4], Christine Loh[4], Lucio Miele[1], Giulia Monticone[1]

[1]LSU Health New Orleans, New Orleans, LA,[2]Department of Urology, Northwestern University, Chicago, IL,[3]University of Florence, Florence, Italy,[4]Nimbus Discovery LLC, Cambridge, MA

Background. Immunotherapies aimed at enhancing antitumor immune responses or delay immune cell exhaustion have shown encouraging results across multiple cancer types. However, immunotherapy still presents limited and variable response rates in immunosuppressive solid tumors, where cancer cells develop multiple strategies to evade and block antitumor immune responses. As a result, options to treat immunosuppressive tumors remain limited and this calls for the development of novel targeted immunotherapies to meet this critical need. Our group recently proved that an immunosuppressive pathway, named as the Cbl-b-Notch1 axis, exists in T cells and acts to constrain T cell function by means of increased Notch1 degradation by Casitas B-lineage lymphoma proto-oncogene B (Cbl-b), following T cell activation. We also found that inhibiting Cbl-b using small-molecule inhibitors effectively restores Notch1 level and enhances CD8 and CD4 T cell functions in *in vitro* and *ex vivo* conditions. In this study, we aimed to demonstrate the effectiveness and the underlying mechanisms though which blocking the Cbl-b-Notch1 axis rewires the immunosuppressive tumor microenvironment to mount protective antitumor immune responses.

Experimental procedures and results. This work leveraged a combination of genetic editing, targeted immune cell depletion, *in silico*, *in vivo*, *ex vivo* models and functional assays in primary cells. We found that blocking the Cbl-b-Notch1 axis, via Cbl-b inhibition, is effective in hindering tumor growth in immunosuppressive Triple-Negative Breast Cancer (TNBC) models (C0321 and 4T1) and pre-clinical tumor-derived organoids. We found that Cbl-b inhibition exerts its antitumor effects primarily by conferring a cytotoxic Th9 phenotype to CD4 T cells, via Notch1 stimulation which regulates cytotoxic and Th9 features, including Granzyme B (GZMB) and IL9 secretion. Cbl-b-inhibitor-primed CD4 T cells reshape the tumor microenvironment through multifaceted mechanisms: (i) exert direct cytotoxicity against tumor cells via GZMB, (ii) recruit and enable CD8 T cell cytotoxic responses, (iii) reprogram macrophages to produce Thrombospondin-1 (Thbs1), via Notch1-dependend release of IL9 in the tumor microenvironment and (iv) hence leads to strong anti-angiogenesis effects that cut off the nutrients supply within the tumor. These findings are consistent with TNBC patient data in which increased Notch1, IL9 and Thbs1 expression are predictive of a better prognosis and longer survival.

Conclusions. Overall, our work identifies Cbl-b-Notch1 axis blockers, like Cbl-b inhibitors, as a promising strategy to reprogram anticancer immune responses, remodel the tumor microenvironment, and suppress tumor growth, providing a promising avenue for next-generation targeted immunotherapies.

#7783 Collagen-binding IL-12 remodels immunosuppresive microenvironment and improves survival in recurrent glioblastoma.

Opeyemi Iwaloye[1], Jun Takei[1], Lewis Barr[1], Ken Furudate[2], Koichi Sasaki[3], Haruka Ichie[1], Shunsuke Tsuzuki[1], Jun Ishihara[3], Satoru Osuka[1]

Recurrent GBM (rGBM) is the most aggressive malignant brain tumors, with a median survival of 6 months. rGBM establishes a severe immunosuppressive tumor microenvironment (TME) with increased Tregs and impaired CD8 T cell recruitment, rendering immunotherapies effective in other cancers ineffective. While IL-12 is a potent immunostimulatory cytokine capable of remodeling this immunosuppressive TME, systemic delivery causes severe toxicity, hindering clinical application. Therefore, technology to selectively deliver IL-12 to rGBM tumors is critically needed. rGBM acquires treatment resistance through construction of a unique extracellular matrix (ECM); therefore, we conceived of utilizing this as a reservoir to accumulate IL-12. Through screening, we focused on COL I & III, minimally expressed in normal brain but highly upregulated after radiotherapy and in rGBM. We created CBD-IL-12 by fusing IL-12 with the collagen-binding domain (CBD) of von Willebrand factor (vWF), leveraging vWF's selective binding to COL I & III at sites of vascular disruption, inflammation, and tumors while sparing normal organs. Biodistribution assays in a mouse rGBM model demonstrated selective CBD-IL-12 accumulation in rGBM tumors without accumulation in other COL I & III-high organs. Toxicity studies in mice and dogs showed CBD-IL-12 significantly reduced peripheral IFN-γ levels compared to IL-12 without hepatic or pancreatic dysfunction. Spectral flow cytometry and single-cell RNA-seq revealed that CBD-IL-12 increased effector memory CD8 T cells, M1-like macrophages, and DCs while reducing Tregs, exhausted T cells, M2-like macrophages, and MDSCs, dramatically reversing immunosuppression. CBD-IL-12 (25μg i.v., twice) prolonged survival by 260% with a 13% CR rate in rGBM mice models. Combining CBD-IL-12 with radiotherapy achieved 63% CR. Notably, in our rGBM model where radiotherapy alone provided no survival benefit, combination with CBD-IL-12 achieved dramatic tumor suppression, likely through radiation-induced COL I & III upregulation and enhanced macrophage/microglia recruitment. Long-term survivors demonstrated durable immune memory by rechallenge testing. For clinical translation, we engineered humanized CBD-IL-12 and validated its efficacy in 3D human GBM slice cultures, demonstrating increased CD8 T cells and reduced Tregs. Collagen-binding IL-12 overcomed rGBM immunosuppression with potent antitumor effects, representing a promising novel immunotherapeutic approach.

#7784 Targeting PRMT7 elicits anti-AML immunity by promoting MHC-I expression.

Shuaishuai Ge[1], Kaixiu Luo[2], Lei Zhang[1], Meng Liu[1], Xin He[1], Guohua Wu[1], Yang Li[1], Yadav P. Umesh[1], Haojie Dong[1], Shengli Xue[3], Jian Jin[2], Ling Li[1]

[1]City of Hope National Medical Center, Duarte, CA,[2]Icahn School of Medicine at Mount Sinai, New York, NY,[3]The First Affiliated Hospital of Soochow University, Suzhou, China

Protein arginine methylation regulates several cellular functions, including RNA splicing, translation and DNA damage repair. Protein arginine N-methyltransferase (PRMT) dysregulation is often seen in malignant hematopoiesis. PRMT7, the only type III PRMT, catalyzes monomethyl arginine (MMA) modification, but its role in leukemogenesis is elusive. Re-analysis of a previous genome-wide CRISPR/Cas9 screen revealed PRMT7 to be a crucial negative-regulator of MHC-I, prompting us to ask whether PRMT7 inhibition might promote anti-AML immunity. To assess the potential PRMT7 function in MHC-I presenting, we knocked out PRMT7 in human AML lines including THP-1 and Molm13 and assessed MHC-I levels. Relative to controls, PRMT7 KO remarkably upregulated MHC-I expression in both lines. We also observed MHC-I upregulation was also observed in both cell lines after treatment with the targeted degrader (PRMT7 PROTAC) ex-vivo at relatively low concentrations, while the same dose of either compound spared normal hematopoietic stem/progenitor ($CD34^+$) cells. To confirm MHC-I dynamics in an MLL-AF9 mouse model, we generated a Prmt7 KO MLL-MA9 mouse model from hematopoietic-specific Prmt7 KO mice ($Prmt7^{fl/fl}$;Vav1-Cre) and observed 2-fold upregulation of H-2Kb expression relative to WT MLL-AF9 cells.Given the critical role of MHC-I in $CD8^+$ T cell activation, we next asked whether PRMT7 deletion would enhance $CD8^+$ T cell responses. We evaluated human T cell killing effects in PRMT7-KO/-WT THP-1 or Molm13 cells cocultured with activated $CD8^+$ T cells derived from healthy donors. Post-coculture, we found that PRMT7 KO AML cells were more susceptible to human T cell-mediated killing. In agreement, PRMT7 KO murine AML cells were more sensitive to mouse T cell-mediated killing using a coculture model of MA9 and syngeneic active $CD8^+$ T cells. Moreover, following PRMT7 PROTAC pretreatment, THP1 cells were more sensitive to human T cells mediated killing in a coculture system of THP1 cells and $CD8^+$ T cells.Next, to assess whether PRMT7 deletion impairs normal hematopoiesis, we analyzed total bone marrow cellularity and lineage frequency in Prmt7 KO (Vav1-Cre+) versus Prmt7-WT (Vav1-Cre-) mice via Cytek full-spectrum flow cytometry. While total BM cellularity was comparable, PRMT7 KO slightly increased the number of $CD4^+$ or $CD8^+$
T cells. These results suggest that although PRMT7 function is likely dispensable for normal hematopoiesis, PRMT7 loss may have a modest effect on T cell proliferation or activation. In future studies, we will confirm whether PRMT7 inhibition promotes anti-tumor T cell activity in-vivo, and whether the underlying mechanism is via MHC-I regulation. Overall, we have shown that PRMT7 depletion or pharmacological inhibition enhances T cell function in part by upregulating MHC-I. These findings suggest that combining PRMT7 inhibitors with immunotherapy could be a promising strategy to overcome AML's immune-cold properties.

#7785 Spatial profiling reveals epigenetic and immunotherapy-driven remodeling of the tumor and lymph node microenvironment in HPV-associated HNSCC.

Takeshi Ito[1], Alexander Ladenheim[1], Hans Zhao[1], Ernest Hidalgo Cedeno[1], Benjamin Judson[1], Saral Mehra[1], Ansley Roche[1], Zafar Sayed[1], Avanti Verma[1], Natalia Isaeva[2], Wendell Yarbrough[2], Aarti Bhatia[1], Barbara Burtness[1], **Michael Chiorazzi**[1]

[1]Yale Cancer Center, New Haven, CT,[2]UNC School of Medicine, Chapel Hill, NC

Human papillomavirus (HPV) leads to most oropharynx cancers in the United States, with increasing incidence, significant morbidity from therapy and mortality from metastatic recurrence. HPV+ tumors exhibit a higher cure rate with surgery or chemoradiation but display lower sensitivity to immune checkpoint inhibitors (ICI). Tumor-draining lymph nodes (LNs), crucial for antigen presentation and T-cell priming in the cancer-immunity cycle, remain less well studied with respect to the effects of epigenomic and ICI agents on the LN microenvironment (LNME).

HPV-positive tumors exhibit a distinct hypermethylation pattern compared with HPV-negative tumors, promoting immune evasion and providing rationale for an ongoing window-of-opportunity trial testing the epigenomic agent 5-azacytidine (5-AzaC) in combination with the ICI nivolumab. In this trial, patients with resectable HPV+ head and neck squamous cell carcinoma (HNSCC) are randomized 2:2:1 to nivolumab, nivolumab plus 5-AzaC, or 5-AzaC alone prior to standard-of-care resection and pathology-directed adjuvant therapy.

We assessed the impact of trial therapies on immune infiltration and cell states in the TME and LNME using quantitative multiplex immunofluorescence on tumor and draining LN tissue donated by a subset of trial participants (n=14 patients) as well as untreated controls. We constructed a tissue microarray (TMA) comprising tumor resection tissue and involved LN tissue sampled with four-fold redundancy. Using qIF panels to assay protein expression of CD3, CD4, CD8, CD20, Ki67, GZMB, we investigated immune cell characteristics and activation. Initial analyses reveal the impacts of 5-AzaC vs nivolumab vs 5-AzaC+Nivo on tumor architecture and cell states in HNSCC tumor tissues. Trial therapies display effects on T cell infiltration, as hypothesized, with combination therapy leading to significant increases in CD3+ T cells, including both CD4+ and CD8+ subsets ($p<0.05$).

We next performed spatial gene expression profiling to identify the impacts of trial therapies on architecture and cell states in tumor and LN. Included in our gene panel were HPV probes to mark cells bearing viral transformation. Initial analyses of 462,376 cells assayed in situ demonstrate the presence of varied immune populations, including macrophages, tumor infiltrating CD8 T cells, CD4 T cells, in tumor and LNs, confirming the utility of spatial approaches to correlate gene expression profiles with clinical drug response parameters.

In depth immunologic analyses of patient tissues reveal potent effects of trial therapies on the LNME in HPV-associated HNSCC and suggest that epigenomic alteration may prime the TME for more effective immune responses. Detailed evaluation of the LNME may nominate novel biomarkers of immunotherapy response and identify future druggable targets within this critical anatomic site.

#7786 Targeted, conditionally active interferons, interleukins and CD8 T cell engagers for novel cancer immunotherapies.

Lennart Zabeau[1], Anje Cauwels[1], Leander Huyghe[1], Silvie Taveirne[1], Joris Wauman[1], Alexander Van Parys[1], Jared E. Lopes[2], Erik Depla[1], **Niko Kley**[2]

[1]Orionis Biosciences BV, Ghent, Belgium,[2]Orionis Biosciences Inc., Waltham, MA

Cytokines, including interferons (IFNs) and various interleukins (ILs) such as IL-2 and IL-1, play major roles in the regulation of innate/adaptive immune responses and the emergence and progression of multiple cancer types. This involves both immune and cancer cell intrinsic signaling pathways. For example, IFNs and ILs are potent stimulators of tumor neoantigen processing and presentation by antigen presenting cells, activation of CD8 T and NK cells, and modulation of immune suppressive components of tumor microenvironments (e.g., MDSCs, TAMs). Repression of cancer cell intrinsic IFN signaling is implicated in mechanisms whereby oncogenic signals (e.g., KRAS mutations, MYC overexpression, p53 loss of function) contribute to establishment and maintenance of an immune-suppressive tumor microenvironment. We have established a multifaceted technology foundation for the engineering of vectorized, on-target, conditionally active cytokines to exploit their therapeutic potential and simultaneously avoid systemic toxicities associated with traditional cytokine-based therapies. We will describe applications of our technology innovations for the development of targeted cDC1 dendritic cell activators, immune checkpoint regulatory cell engagers, and potent CD8 T cell-selective engagers with broad spectrum cancer application potential. Examples of these we have recently advanced into clinical trials.

#7787 Phenotype-tailored prophylactic immunomodulation enables safe immune checkpoint inhibitor rechallenge after severe irAEs in high-risk patients.

Lucrezia Mencarelli, Pierre Van Mol, Douglas Daoudlarian, Sofiya Latifyan, Nuria Alfonso Mederos, Hasna Bouchaab, Matteo Torsello, Antonia Stamatiou, Nicolas Etienne, Karim Abdelhamid, Nabila Ferahta, Athina Stravodimou, Keyvan Shabafrouz, Solange Peters, **Michel Obeid**

CHUV, Lausanne, Switzerland

Background: Severe immune-related adverse events (irAEs) frequently lead to permanent discontinuation of immune checkpoint inhibitors (ICIs). Whether phenotype-tailored prophylactic immunomodulation (PTPI) can safely enable ICI rechallenge in such high-risk patients is unknown.
Methods: We retrospectively studied patients with ICI interruption after at least one grade ≥2 irAE who were subsequently rechallenged under prophylactic biologic immunomodulation in a tertiary immuno-oncology toxicity program. Prophylaxis was selected according to the dominant inflammatory phenotype of the index irAE, with or without low-dose steroids. Primary endpoints were ICI discontinuation due to irAEs at 3 and 6 months and incidence of grade ≥3 irAEs during rechallenge. Secondary endpoints included timing and phenotype of recurrent irAEs, an “immune tolerance enabling strategy” (ITES; on ICI at 6 months without grade ≥3 irAEs), disease control rates (DCR) and exploratory comparisons by prophylaxis class
Results: Thirty-eight patients were rechallenged under prophylaxis. irAEs were rheumatologic (39%), colitis (32%) and uveitis (8%); 66% were multi-organ. Twelve patients (32%) had received combination and 26 (68%) anti-PD-(L)1. The main tumour types were lung (39%), melanoma (32%), renal cell carcinoma (13%). Prophylaxis consisted of IL-6R blockade in 61% and TNF blockade in 26%. During rechallenge, 26% developed grade ≥3 irAEs. IrAE-related ICI discontinuation occurred in 16% and 24% at 3 and 6 months, respectively; among 15 patients who discontinued for irAEs, median time to discontinuation was 130 days. Median time to recurrent irAE was 108 days with 50% occurring >90 days. ITES was achieved in 55% of patients, with median ICI duration 201 days. In colitis, TNF-based prophylaxis was associated with rare colitis recurrences (11%) and fewer irAE-related discontinuations than non-TNF strategies. In rheumatologic phenotypes, IL-6R blockade showed lower recurrence (14%) and fewer irAE-related discontinuations than minimal/non-IL-6R prophylaxis. Only one patient (3%) discontinued ICI for an infectious complication, no grade 4 irAEs occurred. DCR at 3, 6, 9 and 12 months were 52%, 63%, 62% and 65%, respectively.
Conclusions: In high-risk patients, PTPI enabled prolonged ICI exposure with acceptable high-grade toxicity, low irAE-driven discontinuation, preserved disease control, supporting organ-tailored prophylaxis as a strategy to be tested in prospective trials.

#7788 Daiad-2/15: A conditionally active, targeted, hyperpotent IL-2/IL-15 immune agonist is safe and effective *in vivo*.

Anu Jayabalu, Mark E. Branum, **Jonathan G. Drachman**, Alexander Astrakhan

StradBio, Inc., Seattle, WA

Although high-dose interleukin-2 (IL-2) has been approved for the treatment of certain cancers since 1992, widespread use has been limited due to systemic toxicity, including cytokine release syndrome and vascular leak syndrome. Versions of IL-2 with reduced potency have been studied, but these variants have reduced efficacy as well as toxicity. In this report, we describe Daiad-2/15, a computationally designed, highly potent IL-2/IL-15 agonist that is delivered specifically to tumor-targeting T cells without systemic immune activation. Using our Daiad^{TM} platform technology, a logic gate was engineered by splitting Neo-2/15 into two separate pieces. The individual split Neo-2/15 domains are unable to bind or activate the IL-2 receptor complex. By fusing each portion of the cytokine mimetic to a targeting domain, two distinct modules are created, which together constitute Daiad-2/15. *In vitro*, Daiad-2/15 activates only T cells that express the targeted antigen, with a 10,000-fold lower threshold for signaling compared to antigen-negative T cells. By targeting two different antigens, the Daiad-2/15 acts as an effective 'AND' gate, only activating T cells that express both antigens. Furthermore, Daiad-2/15 does not trans-activate target-negative cells, even when present in an admixed culture. The Daiad architecture is compatible with both full length and single-domain antibodies and leads to antigen-specific T cell expansion *in vitro*. We designed Daiad-2/15 to activate exhausted T cells in the tumor microenvironment using nanobodies specific for PD1 and LAG3. We evaluated the tolerability and antitumor activity of Daiad-2/15 in a stringent syngeneic tumor model, CT26. Individual checkpoint-specific Daiad-2/15 modules had no impact on tumor growth or weight loss, while the wild-type IL-2 and the parental Neo2/15 cytokine mimetic were toxic *in vivo*. Treating mice with both Daiad-2/15 modules, specific for PD1and LAG3, resulted in significantly improved antitumor activity compared to the two nanobodies alone, with no signs of systemic toxicity. Together, our data suggest that Daiad-2/15 could potentiate the systemic delivery of a highly potent immune agonist to specific immune cells in the tumor microenvironment and draining lymph nodes with a wide therapeutic index. Additional preclinical studies are underway, and clinical testing of Daiad-2/15 is planned.

#7789 ACM-CpG, a polymersome-delivered TLR9 agonist, elicits rapid and broad immune activation in a phase I trial for advanced solid tumors.

Amit Jain[1], Aaron C. Tan[1], Andrea Budiman[1], Nan Jiang[1], Kim Peng Tan[2], Jackwee Lim[2], Loo Ser Yue[3], Jian Hang Lam[3], Yan Jun Lee[3], Teck Wan Chia[3], Katherine Schultheis[3], Madhavan Nallani[3], Daniel Sw Tan[1]

[1]National Cancer Centre Singapore, Singapore, Singapore,[2]A*STAR, Singapore, Singapore,[3]ACM BIolabs Pte Ltd, Singapore, Singapore, Singapore

Background: ACM-CpG is a novel innate immune activator comprising of TLR9 agonist CpG7909 encapsulated within polymer vesicles (“polymersomes”). This formulation enhances in vivo immune activation compared with free CpG. In preclinical animal models, ACM-CpG induced tumor regression, durable antitumor immune memory, and growth inhibition of distal, non-injected tumors. Intramuscular administration also achieved tumor control on abscopal subcutaneous tumors. Based on these findings, a Phase I clinical trial (NCT06587295) was initiated at the National Cancer Centre Singapore to evaluate the safety and early efficacy signals of intramuscular ACM-CpG monotherapy in patients with advanced solid malignancies.

Methods: This is a 3+3 dose-escalation study of ACM-CpG administered intramuscularly as monotherapy. Eligible patients had advanced cancers with prior clinical response to immune checkpoint inhibitors, either alone or in combination with chemotherapy. A total of 8 patients have been treated to date in the monotherapy arm. Subsequent study arms will assess ACM-CpG in combination with immune checkpoint inhibitors or cancer peptide vaccines. Immune responses were profiled using CyTOF, multiplex cytokine assays (Luminex/Olink), IFN-γ ELISPOT, and single-cell RNA/TCR sequencing.

Results: Pharmacodynamic data covering the first treatment cycle of all patients shows that ACM-CpG triggered rapid and coordinated activation across multiple innate and adaptive compartments within 24 hours post-injection. Immune profiling showed expansion of myeloid populations with upregulation of activation markers CD86, CD38, and CD40, accompanied by transient expansion of MDSCs and pDCs, indicating strong antigen-presenting activity. Adaptive immune activation was demonstrated by proliferation and activation of NK cells and $CD4^+$/$CD8^+$ T cells expressing CD69, along with PD-1 upregulation in some patients, consistent with T-cell priming. Cytokine profiling revealed 5-30-fold elevations of MCP-1, MCP-2, CXCL10, and CXCL11, reflecting potent TLR9-driven pro-inflammatory signaling. IFN-γ ELISPOT confirmed a 1.4-3.4-fold increase in antigen-specific IFN-γ-secreting T cells. Single-cell transcriptomics identified strong type I interferon signatures and upregulation of innate and adaptive immune effectors. CpG7909 was rapidly cleared within 24 hours, with no systemic accumulation observed. ACM-CpG was well tolerated with no dose-limiting toxicities observed.

Conclusions: ACM-CpG induces rapid, broad-spectrum immune activation, engaging both innate and adaptive compartments and enhancing cytokine and T-cell responses with a favorable safety profile. These early clinical findings support continued development of ACM-CpG as a potent monotherapy and a versatile immunologic amplifier for combination immunotherapy.

#7790 Peptide-delivered low dose IL-2 reprograms pancreatic cancer immunity to improve survival.

In Hwan Park, Shawn Abeynaike, Ashley Martinez, Jonathan Cho, Daisuke Nishizaki, Gregory P. Botta

UCSD Moores Cancer Center, La Jolla, CA

Metastatic pancreatic cancer (PC) has a dismal 5-year survival of only 2% due to limited chemotherapy efficacy, poor drug penetration, and an immunosuppressive TIME. Dense desmoplasia, inactive anti T-cells, and highly enriched immunosuppressive Tregs hinder immunotherapy responses.IL-2, a dual-function cytokine that promotes T-cell growth at high concentrations while also inducing immunosuppression at lower concentrations. High dose (HD) IL-2 is a highly an active immunotherapy that enhances cytotoxic T-cell activity while attenuating suppressive Tregs with cures in melanoma and renal cell carcinoma. Unfortunately, HD IL-2 has significant systemic toxicities that induce capillary leak syndrome (CLS), severe hypotension, and renal failure. The CendR-peptide (iRGD) binds to av/B3 integrins specifically at the tumor and induces a NRP-1 dependent transcytotic uptake of co-administered drug and is currently being evaluated in Phase 2 metastatic PC clinical trials. We hypothesized that iRGD could direct systemically low dose (LD) IL-2 into mouse PC and concentrate it locally within the tumor as HD IL-2. As such, we immunomodulate the TIME of PC to activate CD8 cytotoxic T-cells, reduce tumor growth and increases survival while reducing systemic toxicity associated with HD IL-2.Orthotopic KPC PC were developed in C57BL6 WT mice. Tumor-bearing mice were treated i.v. with iRGD and titrated concentrations of IL-2 (3/week). Tumors were analyzed for CD8+ T-cell proliferation, activation, and cytotoxicity. CD8 T cell depletion confirmed necessity of cytotoxic T cells. Lung tissue was evaluated for IL-2 induced CLS. Patient-derived PDAC slice cultures were treated ex vivo for translational relevance. iRGD + LD IL-2 significantly reduced tumor weight and increased survival compared with monotherapy or HD IL-2. The median survival in treated mice was significantly increased. iRGD combination treatment avoided cachexia, CLS, and systemic inflammation, with no elevation in IL-6 or TNF-a. iRGD combined with LD IL-2 did not reduce Treg numbers or increase CD8 T-cell infiltration/proliferation, but enhanced resident cytotoxic T-cell activity as demonstrated by increased p-STAT5, Granzyme B, and cl-Caspase 3. CD8+ T-cell depletion abrogated these effects, confirming CD8+ T cell dependence. In patient-derived PDAC slice cultures, iRGD+IL-2 increased Granzyme B, supporting translational relevance. Importantly, the peptide combination therapy avoids the severe side effects of CLS and cachexia commonly associated with HD IL-2. This combination significantly improves anti-tumor responses and prolongs survival in preclinical models of mouse and human PC, highlighting a robust, safe, and sustained anti-tumor immune response. iRGD combined with LD IL-2 has appropriate pre-clinical anti-cancer and safety signals to warrant early Phase 1 clinical trials in PC.

#7791 PAI-1 inhibition attenuates the inflammatory response in a murine model of sclerodermatous chronic graft-versus-host disease.

Sahra Gabure, Yogamaya Divakar Prabhu, Vasantharaja Raguraman, Shanid Mohiyuddin, Yan Ji, William Fay, Senthilnathan Palaniyandi, Gerhard Hildebrandt

University of Missouri, Columbia, MO

Hematopoietic stem cell transplantation (HSCT) is a critical tool for managing malignant and defective disorders of hematopoiesis but is limited by graft-versus-host disease (GVHD). Chronic GVHD (cGVHD) remains a leading cause of non-relapse morbidity and mortality following allogeneic HSCT. Due to its high immunoreactivity, the skin is most commonly affected in cGVHD, where it undergoes aberrant tissue repair and progressive fibrosis. Therapeutic options for sclerodermatous cGVHD are limited and disease progression drives long-term morbidity and functional impairment. Plasminogen Activator Inhibitor-1 (PAI-1) is a mediator of tissue remodeling and fibrosis, regulating extracellular matrix deposition and the migration of fibrogenic cell populations. In this study, we hypothesized that pharmacologic inhibition of PAI-1 may improve clinical and histopathological outcomes in a murine model of sclerodermatous cGVHD by reducing pro-fibrotic signaling. C57BL/6 mice were conditioned with total body irradiation followed by intravenous infusion of bone marrow cells and splenocytes of either syngeneic (C57BL/6) or allogeneic (LP/J) donors. Mice received oral PAI-1 inhibitor PAI-039 (10 mg/kg) or vehicle every other day from day +14 until day +56. Clinical signs of GVHD and survival were monitored throughout this duration. At day +56, tissues and serum were collected for downstream molecular analyses. PAI-039 treatment improved survival and clinical GVHD scores. Serum levels of pro-inflammatory cytokines IFN-γ ($P=0.006$) and TNF-α ($P=0.002$) were significantly reduced in PAI-039 treated mice compared to controls, alongside decreased expression of IFN-γ ($P=0.04$) in skin isolates. These findings indicate that PAI-1 inhibition may provide therapeutic benefit in the treatment of sclerodermatous cGVHD by disrupting pathogenic fibrotic signaling, warranting further investigation.

#7792 PIK3CA activating mutation reshapes the tumor microenvironment to promote immune evasion in squamous cell carcinoma.

Sydney Fisher, Benjamin Nicholson, Weijie Guo, Yuxuan Phoenix Miao

University of Chicago, Chicago, IL

Head and neck squamous cell carcinoma (HNSCC) is a leader in cancer incidence worldwide. Although the introduction of immunotherapy, such as immune checkpoint blockade (ICB), has improved the landscape of cancer treatment in many solid tumors, including HNSCCs, there remain challenges in achieving durable responses with such therapies. Indeed, HNSCC patients often relapse following ICB treatment. While relapse events are high, there is a lack of understanding of the mechanisms underlying cancer immune evasion. These disparities in patient outcomes strongly suggest the existence of genetic variations that underlie their distinct responses to ICB. Although the specific oncogenic mutations responsible for driving relapse in SCC patients remain unclear, it is critical to elucidate the mechanisms of cancer immune evasion in individuals with specific genetic profiles to enhance the precision of immunotherapy. We aim to understand the genetic basis shaping the immune suppressive TME and hypothesize that oncogenic driver mutations play a dominant role in preventing the immune clearance of transformed cells by reprogramming the immune landscape in the tumors. To determine the critical genetic signatures enriched in SCC patients that can impact anti-tumor immunity, we analyzed TCGA data which revealed a strong negative correlation between *PIK3CA* level and CD8+ T cell signatures. We have identified that activating mutations in the *PIK3CA* gene, found in 20% of HNSCCs, promote rapid tumor relapse after initial response to anti-PD-L1 and anti-CTLA-4 ICB treatments. Utilizing single-cell analysis, quantitative immune profiling, and multiplexed imaging, our lab showed that tumor-initiating cells (TICs) in SCCs can have an intricate dialogue with myeloid-derived suppressor cells (MDSCs) where TICs secrete factors to enhance MDSC recruitment and suppressive function on cytotoxic T cells. Our lab also identified that SOX2 amplification in *PIK3CA* mutant SCC could modulate neutrophils and block their interferon responses via activation of fatty acid desaturase 1 (FADS1) to aid neutrophils in maintaining their immune suppressive functions during immunotherapy treatments. As such, this study has led to key mechanistic understanding of how *PIK3CA* mutation allows cancer cells to shape the immune suppressive responses. Thus, our findings uncover a unique mechanism whereby *PIK3CA* mutant SCCs critically shape the tumor microenvironment to survive robust immunotherapy and give rise to tumor relapse.

#7793 Bioelectromagnetic reprogramming of tumor-immune metabolism to selectively destroy NSCLC.

[1]Geminii, Inc., Chicago, IL,[2]University of Iowa, Iowa City, IA,[3]Director, Free Radical & Radiation Bio., University of Iowa, Iowa City, IA

BACKGROUND: Dysregulated oxygen and redox-active metal metabolism create an oxidized tumor microenvironment in non-small cell lung cancer (NSCLC). Tumors accumulate reactive oxygen species (ROS) and labile iron, promoting progression yet creating a vulnerability to iron-catalyzed ROS and lipid peroxidation. This oxidized microenvironment also alters tumor-immune metabolic balance, impeding immune function in the TME. Existing electromagnetic-based therapies such as tumor treating fields and electroporation do not directly target redox-metabolic vulnerabilities and have usability constraints. Building on our recent work published in *Cell Metabolism* showing that orthogonally applied static electromagnetic fields (EMFs) safely reprogram redox and glucose metabolism to treat diabetes, we sought to determine whether a bioelectromagnetic modality applied during convenient treatment times could be engineered to reprogram tumor-immune metabolism for selective killing of NSCLC.
METHODS: We engineered a device to deliver orthogonally oriented static EMFs for ≥6 hours / day. Mice bearing human NSCLC xenografts (H1299 & A549) or syngeneic LLC tumors were randomized to EMF or sham. Tumor growth, survival & combination with chemoradiation therapies were evaluated. Mechanistic studies assessed lipid peroxidation, γH2AX, T-cell activation/exhaustion & antigen-specific $CD8^+$ trafficking, $CD4^+$/$CD8^+$ depletion, and effects of scavenging H_2O_2, labile iron, or lipid peroxides on ferroptotic pathways. Histopathology assessed toxicity.
RESULTS: EMF monotherapy inhibited tumor growth & prolonged survival versus sham and improved chemoradiation efficacy. EMF-treated tumors showed increased lipid peroxides and γH2AX, consistent with lipid peroxidation and DNA damage induced tumor death. In syngeneic tumors, EMF enhanced $CD8^+$ and $CD4^+$ T-cell activation and reduced exhaustion. OT-I and T-cell depletion studies showed EMF efficacy requires antigen-specific adaptive immunity. Genetic scavenging of H_2O_2, iron, or lipid peroxides within tumors attenuated EMF-induced tumor killing, demonstrating ferroptotic tumor death without normal-tissue toxicity.
CONCLUSIONS: Orthogonally applied static EMFs represent a novel bioelectronic strategy to selectively kill NSCLC by exploiting redox-metabolic vulnerabilities and activating antitumor immunity. This bioelectronic modality could be used to safely enhance tumor killing while overcoming adherence challenges of existing field-based modalities.

#7794 When stress spreads: Transmissible ER stress as a driver of immune remodeling in PDAC.

Naveen Chintala Ramulu[1], Shreya Pokharel[1], Nishanthini Pirashanna[2], Basel Abuaita[2], Joseph Francis[1]

[1]Comparative Biomedical Sciences, Louisiana State University, Baton Rouge, LA,[2]Pathobiological Sciences, Louisiana State University, Baton Rouge, LA

Pancreatic ductal adenocarcinoma (PDAC) remains one of the most lethal malignancies, with a 5-year survival rate of only 11%. Within the PDAC tumor microenvironment (TME), rapidly proliferating tumor cells outgrow the vascular supply, creating hostile microenvironmental conditions such as nutrient deprivation, hypoxia, and high metabolic demand. This, in turn, perturbs the protein folding capacity of the endoplasmic reticulum (ER), thereby provoking a cellular state of 'ER Stress'. Also, tumor cells can disseminate ER stress to the stromal cells within the TME in a process known as 'transmissible ER stress'. Although PDAC is considered an immunologically 'cold' tumor, ER stress appears to rewire the host immune system for tumor cell immune evasion. In this regard, we determined if the bone marrow-derived macrophages (BMDM) are susceptible to "transmissible" ER stress. Herein, murine pancreatic Panc02 and KPC cells (transmitter cells) were treated with thapsigargin (Tg), and the ER stress-conditioned medium was used to culture the murine BMDMs (receiver cells). Our preliminary data demonstrated that BMDMs cultured in ER-stress-conditioned medium demonstrated a significant transcriptional upregulation of proinflammatory modulators, including *iNOS*, IRE1α(*Xbp1*, nuclear factor-kappaB (*NF-κB*), and cyclooxygenase-2 (*COX-2*). Strikingly, this inflammatory state co-occurred with increased *Arg1*, consistent with an immunosuppressive, tumor-promoting macrophage phenotype. Altogether, this transcriptional profile reflects a hybrid inflammatory-immunoregulatory state characteristic of PDAC tumor-associated macrophages (TAMs). To delineate the mechanism by which transmissible ER stress modulates the immune profile of BMDMs, we propose genetic ablation and/or pharmacological inhibition of the classical stress pathways, including IRE1α, PERK, and ATF6, to determine their effect on BMDM polarization. In conclusion, our findings provide new insights into the dynamic crosstalk between PDAC cells and BMDMs, highlighting two key aspects: a) the complexity underlying the concurrent pro-inflammatory and immunosuppressive features within the TME following ER stress, and b) raises the possibility that this phenomenon may contribute to the attenuation of intrinsic antitumor T-cell responses..

Key Words: Pancreatic ductal adenocarcinoma, tumor microenvironment, ER stress, bone marrow-derived macrophages.

#7798 Embryonal and alveolar rhabdomyosarcoma immunotherapy treatment benefit prediction by CURE AI.

Amit Weiss[1], Ofir Landau[1], Tzvi Lederer[1], Gregory Koushnir[1], Radesh P. Nattamai Malli[1], Tal Shor[1], Daniel Khankin[1], Vitalay Fomin[1], **Neil Pfister**[2]

[1]Numenos, New York, NY,[2]University of Alabama at Birmingham; Numenos, Birmingham, AL

Clinical trials are not able to study individual treatment effects as methods to do so have not yet matured into practical use. For decades, we have studied groups of patients enrolled on a trial, comparing groups of patients as large cohorts and losing signal for important, complex features that define individuals. Foundation models take a different approach. Using the CURE AI foundation model generated from clinical and multi-omics data from hundreds of thousands of patients, complex and non-linear biological patterns can be found in new datasets that can provide insights into disease biology. We previously identified a complex signature predictive of immunotherapy treatment benefit compared to chemotherapy benefit by analysis of a set of non-small cell lung cancer clinical trials (Weiss et al., AI in Precision Oncology, 2025). In the current study, we theorized that we could apply predictors of immunotherapy response/nonresponse from adult clinical trials to pediatric cancer patients. If feasible, this approach could dramatically accelerate progress in pediatric cancer treatment development by leading to the development of better treatment strategies that could immediately be assessed on pediatric clinical trials.
We analyzed RNA sequencing from over 50 types of pediatric cancers to predict treatment benefit of immunotherapy relative to chemotherapy. Alveolar and embryonal rhabdomyosarcomas (RMS) stood out as notable case studies as the majority of patients in both rhabdomyosarcoma groups were, based on treatment response prediction from adult immunotherapy clinical trials, predicted to respond favorably to immunotherapy. However, about one-third of both RMS subtypes were predicted to be resistant to immunotherapy. Alveolar RMS had significantly more immunotherapy resistance-related genes upregulated in patients with predicted immunotherapy resistance compared to embryonal RMS, with largely different compositions of immune-related genes between the RMS subtypes. Interestingly, CURE AI identified 36 genes with > 4-fold upregulation that were in common between embryonal and alveolar RMS patients with predicted immunotherapy resistance including many genes not previously associated with RMS or immunotherapy resistance including TLL2 and F2RL2, suggesting that these pathways may be targeted to overcome immunotherapy resistance in RMS. Furthermore, alveolar RMS-specific and embryonal RMS-specific cytokine signatures were identified that could be implemented to guide patient selection for immunotherapy treatment.
These results demonstrate that biological foundation models can be used to analyze adult clinical trials to gain novel insights into different cancer types to generate patient-level pediatric data that could justify accelerated clinical trial concept development in pediatric cancers.

#7801 Preclinical efficacy of DLL3 targeted CAR T cells in neuroblastoma.

Salvatore M. Aspromonte, Tamar Feinberg, Ali Cihan, Samantha Brosius, Armaan H. Siddiquee, Dylan Domenico, Daoqi You, Shakeel Modak, Kevin J. Curran, Andrew L. Kung, Anthony Daniyan, Filemon Dela Cruz

Memorial Sloan Kettering Cancer Center, New York, NY

Background: Neuroblastoma (NBL), the most common extracranial solid tumor in children, accounts for 15% of pediatric cancer deaths, and survival after relapse remains <50%. To expand immunotherapeutic options, we evaluated Delta-like ligand 3 (DLL3), an inhibitory NOTCH ligand normally silenced in healthy tissues but aberrantly expressed in neuroendocrine tumors. NOTCH dysregulation in NBL and emerging datasets indicating DLL3 expression support investigation of DLL3 as a target and assessment of IL-18-armored DLL3-directed CAR T cells originally developed for small-cell lung cancer.
Methods: DLL3 expression was assessed in NBL patient samples and PDX models by RNA sequencing, immunohistochemistry (IHC), and flow cytometry. IL-18-armored DLL3 CAR T cells were tested in vitro against NBL cell lines across multiple effector-to-tumor (E:T) ratios. Cumulative killing was compared using Vardi's test for area-under-the-curve analysis, and Wilcoxon rank-sum tests evaluated differences at individual E:T ratios.
Results: RNA sequencing of pediatric solid tumors treated at MSK (n=540) showed that NBL (n=109) had the highest DLL3 transcript levels relative to other non-CNS tumors (0-19.7 TPM; median 0.38). In NBL patient samples, IHC (n=31) demonstrated DLL3 protein expression (H-score ≥10, range 10-300, median 100) in 52% (16/31) with strong transcript-protein concordance (Spearman $r=0.847$, $p=2\times10^{-9}$). In NBL PDX models, DLL3 protein expression was detected in 63% (19/30), with H-scores ranging 10-123 (median 73). Flow cytometry across five PDX models spanning H-scores 7-105 showed DLL3 surface expression on 25-88% of tumor cells, confirming antigen accessibility. IL-18-armored DLL3-CAR T cells exhibited significantly greater cumulative cytotoxicity than untransduced T cells against two DLL3+ NBL cell lines, SK-N-DZ (51% DLL3+, $p=0.03$) and SK-N-SH (29% DLL3+, $p=0.03$), with activity across multiple E:T ratios ($p<0.05$). To confirm antigen specificity, IL-18-armored DLL3-CAR T cells were compared with a clinical-grade IL-18-armored CD371-directed CAR (CLEAR AML) as a non-DLL3-targeting control. DLL3-CAR T cells exhibited significantly greater cytotoxicity against both cell lines (SK-N-DZ, $p=0.0006$; SK-N-SH, $p=0.0004$) and outperformed the control CAR across all E:T ratios ($p<0.001$).
Conclusions: DLL3 is expressed in a subset of NBL patient tumors and PDX models and is accessible for CAR targeting. IL-18-armored DLL3-directed CAR T cells show strong in vitro cytotoxicity against DLL3+ NBL models. In vivo testing in a DLL3+ NBL PDX is underway. These findings support DLL3 as a promising immunotherapeutic target and justify further development of DLL3-directed CAR T therapy for NBL.

#7802 cGAS-STING pathway agonist plus immune checkpoint inhibitor augments chemotherapy effectiveness in murine osteosarcoma models.

Mayra L. Mendiola, Michele Doucet, Erin E. Resch, Brian H. Ladle

Johns Hopkins University School of Medicine, Baltimore, MD

Osteosarcoma (OS) is the most prevalent pediatric bone cancer, and standard of care treatment includes neoadjuvant chemotherapy, surgery, and adjuvant chemotherapy. Several prognostic factors for overall survival have been identified, including >95% tumor necrosis at the time of primary surgery (surrogate of chemotherapy sensitivity) and the degree of inflammatory immune infiltrates in the tumor at diagnosis. We hypothesize that increasing the immune infiltrates in OS will improve tumor sensitivity to chemotherapy and overall survival. Our group has studied the impact of activating the cGAS-STING pathway in OS via intratumoral delivery of ADU-S100 — a potent STING agonist — in both murine and canine OS. ADU-S100 increases levels of pro-inflammatory cytokines and chemokines, including Tumor Necrosis Factor-α, Interferon-β, Interleukin-6, CCL5 and CXCL10 in the treated tumors. In addition, increased activated macrophage, T-, and B-cell infiltrates are observed. We hypothesized that combining the ADU-S100 STING agonist with chemotherapy could improve outcomes in our models of OS. As we have shown the effects of STING agonist to recruit T-cells into the tumor, we also incorporated immune checkpoint inhibitor (ICI) treatment (anti-PD1 and anti-CTLA4). We used the syngeneic murine OS cell line F420 to establish intratibial tumors in C57BL/6 mice. Once tumors were palpable, cohorts of mice were treated with ADU-S100 followed by carboplatin and ICI, comparing outcomes to the monotherapy and dual therapy control cohorts. ADU-S100 + carboplatin (standard OS chemotherapy in canines) or ADU-S100 + carboplatin + ICI significantly increases ($P<0.05$) median survival compared to any of the treatments given as monotherapy. The addition of ICI to ADU-S100 + carboplatin appears to further extend the survival in responder mice. At day 40 post-tumor challenge, 46% of the ADU-S100 + carboplatin + ICI treated mice continue with disease control compared to 9% in the ADU-S100 + carboplatin treated cohort ($P=0.035$). Ongoing studies include combining ADU-S100 + ICI with doxorubicin, cisplatin, and methotrexate (standard of care chemotherapy agents given for OS in humans) and investigations of the mechanisms determining responder versus non-responder mice.

#7805 Development of a GFRA2-targeting antibody drug conjugate for neuroblastoma (NB), and Ewing sarcoma (EWS).

Amber K. Hamilton[1], Seungmin Shin[2], Raphael D. Lopez[1], Nicholas Hartnett[1], Alexander B. Radaoui[1], Maggie Hines[2], Maria Evancho[1], Rebecca S. Kaufman[1], Khushbu Patel[1], Karina L. Conkrite[1], Dan Martinez[1], Brian Mooney[3], Michelle E. Keyel[4], Elissa Levine[5], Alberto D. Guerra[1], Jarrett Lindsay[1], Yael P. Mosse[1], Jennifer Pogoriler[1], Gregg Morin[6], Poul H. Sorensen[6], Patrick J. Grohar[5], Benjamin A. Garcia[7], C. Patrick Reynolds[4], Wei Li[2], Sharon J. Diskin[1], John M. Maris[1]

[1]Children's Hospital of Philadelphia, Philadelphia, PA,[2]University of Pittsburgh, Pittsburgh, PA,[3]BC Cancer Research Institute, Vancouver, BC, Canada,[4]Texas Tech University Health Sciences Center, Lubbock, TX,[5]University of Michigan Medical School, Ann Arbor, MI,[6]University of British Columbia, Vancouver, BC, Canada,[7]Washington University School of Medicine in St. Louis, St. Louis, MO

Background: We recently defined the NB/EWS surfaceomes using integrative proteogenomics to prioritize proteins as candidate immunotherapeutic targets. GFRA2 was a top ranked candidate for both NB and EWS (*Clin Cancer Res* 2023, *Cancer Cell* 2024).

Aims: (1) Validate and assess mechanism of GFRA2 overexpression; (2) Identify selective antibody binders to GFRA2; (3) Engineer antibody drug conjugates (ADCs) and test for internalization and potency.

Methods: ChIP- and RNA-sequencing of NB and RNA-sequencing following siRNA depletion of EWSR1::FLI1 were used to evaluate mechanisms of GFRA2 overexpression. GFRA2 abundance and cellular localization was evaluated by flow cytometry and immunofluorescence. Phage display was performed with recombinant GFRA2 extracellular domain protein as the bait and the highly conserved GFRA1 and GFRA3 recombinant proteins as counters. In parallel, we humanized the anti-GFRA2 murine HSAN antibody. While we plan on reporting on several linker-payload combinations, here we focus on the initial humanized HSAN antibody conjugated to pyrrolobenzodiazepine (PBD) via a cleavable linker, which was tested for internalization using live cell imaging and cytotoxicity across a panel of human NB and EWS preclinical models.

Results: We identified a proximal super enhancer (Percentile: 97.4%-99.7%) or enhancer (94.4%-97.7%) in all 10 NB cell lines profiled. Depletion of EWSR1::FLI1 resulted in significantly decreased GFRA2 mRNA expression across 6 EWS cell lines ($P<0.0001$), and this was validated via immunoblotting. GFRA2 protein was expressed uniformly and to variable degrees on the cell surface of 10 NB cell lines, 8 NB patient-derived xenografts, and 6 EWS cell lines by flow cytometry and/or immunofluorescence. Patient tumor RNA-Seq showed 92.8% of NB (N=126; median=47.65) and 74% of EWS (N=85, median=11.47) had high expression defined as a GFRA2 TPM > 5. Phage display panning of fully human antibody fragments yielded three Fabs and one VH single domain antibody specific to GFRA2 with moderate binding affinity (50-500 nM). Humanized HSAN (co-hu-HSAN) showed high binding affinity specific to GFRA2 (1-10 nM). We then showed robust internalization of co-hu-HSAN across 6 NB cell lines. A co-hu-HSAN-PBD ADC showed potent and specific cytotoxicity across GFRA2+ cell lines (NB=2; median IC_{50}=1.69;2.92pM, EWS=2; median IC_{50}=9.81;12.43pM) with no cytotoxicity in GFRA2 null cell lines (N=2; median IC_{50}=NA).

Conclusions: GFRA2 is a lineage restricted oncoprotein abundantly expressed in both NB/EWS, as well as other human solid cancers. We show initial proof-of-concept for potent and specific cytotoxicity in both NB/EWS with the co-hu-HSAN-PBD ADC. We will report on efficacy testing of the co-hu-HSAN-PBD ADC across NB/EWS xenograft models. Work to affinity enhance the fully human binders, and progress with additional linker/payload combinations are ongoing and will be reported.

#7806 CAR priming lowers TCR activation threshold to enhance recognition of low affinity tumor antigens.

Chu-Hsuan Chiu[1], Leo D. Wang[2]

[1]Beckman Research Institute of City of Hope, Duarte, CA,[2]Beckman Research Institute, City of Hope, Duarte, CA

Chimeric antigen receptor (CAR)-T cell therapy has shown remarkable efficacy in hematologic malignancies but has achieved limited success in solid tumors due to barriers such as immunosuppressive tumor microenvironments and poor antigen presentation1. Primary brain tumors, across pediatric and adult settings, represent a particularly difficult target: they display profound intratumoral heterogeneity, frequently downregulate MHC class I2, and often present low-avidity or subclonally expressed antigens that are poorly recognized by conventional T cell receptors (TCRs). Prior studies have reported crosstalk between CAR and TCR signaling, suggesting that TCR expression is important for optimal CAR function3, and others indicate that CAR function may be suppressed when encountering low-avidity TCR antigens4. Our preliminary data show that CAR priming enhances TCR responses against weak antigens and promotes a more memory-like, less effector-like phenotype, a state linked to improved persistence and durable tumor control. Together, these findings highlight a key gap: how CAR signaling influences TCR function in the setting of weak antigens. Addressing this question is particularly critical in brain tumors, where recognition of low-avidity and poorly presented antigens limits the efficacy of current CAR T-cell therapies.

#7808 Efficacy of AZD0754, a dominant-negative TGFβRII-armored STEAP2 CAR T-cell therapy, in Ewing sarcoma xenograft models.

Peter Zanvit[1], Brianna Janocha[1], Shannon Breen[1], Christine Fazenbaker[1], Jessica Pezold[1], Lihe Zhang[1], David Clark[1], Nicolas Giraldo[2], Ryan Golden[1], Jonathan Fitzgerald[3], Mark Cobbold[3], Gordon Moody[1], Emily Bosco[1]

[1]Early Oncology, AstraZeneca Pharmaceuticals LP, Gaithersburg, MD,[2]Scientific Affairs, Global Diagnostics, AstraZeneca, Barcelona, Spain,[3]Early Oncology, AstraZeneca Pharmaceuticals LP, Waltham, MA

Background:
Ewing sarcoma (EWS) is a rare, aggressive bone and soft tissue malignancy predominantly affecting children and young adults. Despite advances in multimodal therapy, treatment options remain limited for refractory or relapsed EWS (1). Chimeric antigen receptor (CAR) T-cell therapy has shown marked efficacy in hematologic malignancies and is being developed for solid tumors. AZD0754 is a STEAP2-targeted CAR T-cell therapy incorporating a dominant-negative TGFβRII (dnTGFβRII) armoring strategy and is in Phase 1 clinical development for prostate cancer. Recent published proteomic analyses identified STEAP2 expression in EWS patient samples and cell line-derived xenografts, supporting STEAP2 as a potential candidate immunotherapeutic target (2).
Methods:
STEAP2 surface expression was evaluated across different human EWS cell lines by flow cytometry. AZD0754-mediated cytotoxicity was assessed *in vitro* using the xCELLigence real-time cell analysis platform. Based on *in vitro* results, A673, RD-ES, and SK-NEP-1 xenograft models were selected for *in vivo* efficacy studies. Mice received varying doses of AZD0754, and tumor growth and overall survival were monitored. Blood was collected at different time points for serum cytokine analysis to assess pharmacodynamic activity.
Results:
EWS cell lines expressed detectable cell surface expression of STEAP2 at receptor densities much lower than workhorse prostate cancer cell lines. Despite this, AZD0754 was capable of inducing antigen-dependent cytotoxicity *in vitro* and suppressing tumor growth in EWS xenograft models. AZD0754 exhibited dose-dependent antitumor activity that correlated with serum IFNγ levels, indicating on-target immune engagement.
Conclusions:
AZD0754 demonstrates robust preclinical anti-tumor activity against EWS *in vitro* and *in vivo*, with dose-dependent efficacy and corresponding cytokine levels. These findings support STEAP2 as a potential therapeutic target in EWS. STEAP2 targeting has the potential to address a critical unmet need in EWS by expanding treatment options to biologic and immune-based therapies.

#7809 Epitope-encoded mRNA-LNP vaccine to enhance anti-tumor potency and persistence of PHOX2B peptide-centric CAR T cells.

Timothy T. Spear[1], Nicholas Hartnett[1], Elisabeth Posthill[1], David Groff[1], Dana Al-Halawani[1], Minu Samanta[1], Keelan O'Reilly[1], Richa Kapoor[1], Muzamil Want[1], Lingling Liu[2], Tingting Wang[2], Ruoning Wang[3], Richard Madnick[4], Irina Shkundina[4], Kristopher R. Bosse[1], Mohamad-Gabriel Alameh[1], Drew Weissman[4], John M. Maris[1]

[1]Children's Hospital of Philadelphia, Philadelphia, PA,[2]Nationwide Children's Hospital, Columbus, OH,[3]Postdoctoral Fellow, Dept. of Immunology, Nationwide Children's Hospital, Columbus, OH,[4]University of Pennsylvania, Philadelphia, PA

Background: A Phase 1/1b clinical trial testing peptide-centric chimeric antigen receptor (PC-CAR) T cells that recognize a peptide derived from the major neuroblastoma oncoprotein PHOX2B presented in the context of HLA-A*24:02 and 20 other HLA-A alleles is showing early signs of safety and efficacy (NCT07007117). Anticipated barriers to durable cures include poor persistence and a hostile tumor immune microenvironment (TIME). We hypothesize that persistence and potency can be enhanced, without compromising safety, through the deployment of a “CAR boosting” PHOX2B epitope-encoding mRNA-lipid nanoparticle (LNP) vaccine.
Methods: We established a screening platform to test various PHOX2B mRNAs and LNP designs, and here report on the prioritized formulation: a nucleoside-modified PHOX2B 9mer monomer encapsulated by FDA-approved LNP SM-102. In parallel, we established a genetically engineered mouse model (GEMM) of NB to deploy our PHOX2B epitope mRNA-LNP vaccination strategy *in vivo*.

Results: A24$^+$ healthy donor or NB patient monocyte-derived dendritic cells (moDCs) treated with vaccine exhibited log-fold higher PHOX2B 9mer presentation compared to tumor cells and upregulated T cell costimulatory ligands CD80/86 and CD40. PC-CAR T cells exposed to vaccine-treated moDCs had significantly increased proliferation, polyfunctionality, and migratory markers compared to co-cultures with HLA matched NB cell lines. Moreover, vaccine-treated moDCs enriched central, effector, and/or stem cell memory PC-CAR T cell immunophenotypes (donor/patient-dependent) compared to tumor-induced PD1^{hi}CD39^{hi} terminal effectors. PC-CAR T cells primed with vaccine-treated moDCs maintained significantly greater cytotoxicity in serial tumor rechallenges. A comprehensive characterization of the immunobiological effects of mRNA-LNP on DC and PC-CAR T cell function using O-link proteomics and transcriptional profiling are ongoing and will be reported.

GEMM-derived allografts faithfully recapitulate human disease and express a chimeric HLA-A*24:02/H-2K^b MHC that presents a conserved PHOX2B 9mer. Murine (m)PC-CAR T cells engineered with clinical scFv conjoined to murine 41BB- or CD28-CD3ζ were polyfunctional and cytotoxic against A24/H-2K^b allografts. Vaccine-treated A24/H-2K^b knock-in mice presented PHOX2B 9mer by DCs in spleen and lymph nodes, activating PC-CAR T cells. Comprehensive *in vivo* evaluation of mPC-CAR-T expansion, memory formation, and anti-tumor potency with TIME spatialomic profiling are ongoing and will be reported.
Conclusion: These IND-enabling studies will inform our clinical vaccine dosing strategy with the recommended Phase 2 PC-CAR T cell dose in an upcoming trial amendment. This CAR boosting vaccine may not only improve efficacy of PC-CAR T cells for NB but also guide mRNA-LNP enhancement strategies for other adoptive cellular therapies.

#7810 Engineering macrophages as a novel therapeutic approach for high-risk neuroblastoma.

Ke-En Tan[1], Kok Siong Yeo[2], Cheng Zhang[3], Caleb Baker[2], Shyang Hong Tan[3], Alexis M. Sosic[2], Yat-Yuen Lim[1], Choong-Yong Ung[3], Cristina Correia[3], Stephanie F. Polites[4], Yi Lin[5], William A. Weiss[6], Hu Li[3], Shizhen Zhu[2]

[1]University of Malaya, Kuala Lumpur, Malaysia,[2]Department of Biochemistry and Molecular Biology, Mayo Clinic College of Medicine, Rochester, MN,[3]Department of Molecular Pharmacology and Experimental Therapeutics, Mayo Clinic College of Medicine, Rochester, MN,[4]Department of Surgery, Mayo Clinic, Rochester, MN,[5]Division of Hematology, Mayo Clinic, Rochester, MN,[6]University of California, San Francisco, CA

Neuroblastoma (NB) accounts for 10% of pediatric cancer-related deaths. High-risk NB is frequently metastatic at diagnosis and has a poor 5-year survival rate (<50%) despite aggressive treatment. GD2, a disialoganglioside glycolipid that is expressed in nearly all NBs, has been validated as a promising immunotherapy target. Although GD2-CAR-T cells have been clinically evaluated, their efficacy has been limited by poor tumor infiltration and the immunosuppressive tumor microenvironment (TME), highlighting the need for alternative immune-based strategies. With inherent capacity of macrophages to infiltrate tumors, phagocytose cancer cells, and modulate TME, they represent a promising alternative strategy for immunotherapy in NB. In this study, we developed and evaluated GD2-CAR-macrophages (GD2-CAR-Ms) as a novel therapeutic approach for NB. GD2-specific CAR constructs were designed, validated, and introduced into multiple human and murine monocyte/macrophage cell lines via lentiviral transduction. Fluorescent microscopy and flow cytometry confirmed a significant enhancement in the phagocytosis of GD2-high NB cells by GD2-CAR-Ms containing *Hu3F8* single-chain variable fragment (*scFv*). A strong positive correlation was observed between GD2 expression levels on the target cells and phagocytosis efficiency of GD2-CAR-Ms, indicating that the phagocytic activity of GD2-CAR-Ms is antigen-specific. Anti-tumor efficacy was further evaluated *in vivo* using an immunocompetent *Mycn*-expressing NB non-genetically engineered mouse model (MYCN-NGEMM). Mice treated with GD2-CAR-Ms exhibited significantly reduced tumor burden and prolonged survival compared to control groups. Notably, treatment of mice bearing GD2-high tumors resulted in markedly improved survival, including one complete remission among ten treated animals, underscoring the therapeutic potential of GD2-targeted macrophage therapy. Histological analysis showed increased deposition of connective tissues and decreased tumor cells density, suggesting TME remodeling. Furthermore, immunohistochemistry reveals increased immune cell infiltration, particularly of macrophages, neutrophils and T cells, indicating a favorable shift in the immune TME from “cold” to “hot” following GD2-CAR-M treatment. Additionally, inhibition of tumor growth was also observed in our zebrafish NB model after GD2-CAR-Ms treatment, further supporting their therapeutic potential. Together, our findings demonstrate that GD2-CAR-Ms exhibit potent antitumor activity and reshape the tumor immune microenvironment, supporting their translational potential as a therapeutic strategy for high-risk NB.

#7811 Using γδ T cells as a potent adoptive cell therapy platform in models of pediatric sarcoma.

Jessica P. Sanchez[1], Anne-Katrin Urzynicok[1], Gabriella Albert[2], Eduardo Davila[2], Brian H. Ladle[1]

[1]Johns Hopkins University School of Medicine, Baltimore, MD,[2]University of Colorado, Anschutz Medical Campus, Aurora, CO

New treatment approaches for high-risk pediatric sarcomas are desperately needed. Immunotherapy advances with adoptive cell therapy in hematologic malignancies have not yet been translated to pediatric solid tumors including sarcomas. Hallmarks of the immune microenvironment in pediatric sarcomas include the presence of immunosuppressive immune cells and cytokines, and a lack of potent T cell activation. We are seeking ways to overcome these barriers to effective adoptive cell therapy in pediatric sarcomas. γδ T cells are known to have innate anti-tumor activity across many cancers but their activity against pediatric sarcomas remains poorly characterized. Here we detail the anti-tumor activity of γδ T cells against a panel of human and murine models of pediatric sarcomas including human and murine osteosarcoma (OS), human and murine rhabdomyosarcoma (RMS), and human Ewings sarcoma (EWS). Human and murine γδ T cells demonstrated varied anti-tumor activity across the different models of pediatric sarcomas. Co-cultures of varying effector to target ratios (E:T) of γδ T cells to tumor demonstrated strong anti-tumor effects against our models of OS and EWS. Interestingly, RMS, especially the human fusion-positive RMS cell line Rh30 showed significant resistance to γδ T cell killing. We further assessed the γδ T cell potency against pediatric sarcomas in vivo. In our syngeneic and human tumor xenograft models of sarcoma we observed temporary tumor growth control following adoptive transfer with ten million activated γδ T cells highlighting the need to improve in vivo function. We explored the addition of intratumoral STING (stimulator of interferon genes) agonist with the goal of increasing γδ T cell trafficking to the tumor. We show that STING agonist delivery prior to adoptive transfer results in increased numbers of γδ T cells in the tumor. In addition, we are exploring the introduction of a novel synthetic co-receptor, CD8a:MyD88, shown previously to augment αβ T cell effector function, to determine if γδ T cell function can be improved as well. We transduced γδ T cells ex vivo to express the CD8a:MyD88 synthetic co-receptor resulting in improved in vitro tumor lytic function and increased interferon gamma production when co-cultured with osteosarcoma cells compared to control vector-transduced T cells. Ongoing and future work is investigating the in vivo effectiveness of the CD8a:MyD88 expressing γδ T cells in our panel of sarcoma models. These studies further define the obstacles and potential solutions to successful adoptive T cell therapy for pediatric sarcomas.

#7812 Preclinical evaluation of a dnTGFβR-armored GPC3 CAR-T (AZD5851) in pediatric solid tumor PDX models - A report from the Pediatric Preclinical *In Vivo* Testing (PIVOT) Consortium.

Introduction

GPC3 is a heparan sulfate proteoglycan aberrantly expressed in pediatric tumors such as hepatoblastoma (HBL), Wilms tumor (WT), germ cell tumors (GCT), malignant rhabdoid tumor (MRT), and rhabdomyosarcoma (RMS). AZD5851 is an armored GPC3-targeted CAR-T incorporating a dominant-negative TGF-β receptor II (dnTGFβRII) to resist TGF-β-mediated inhibition and enhance functionality. AZD5851 was evaluated in pediatric patient-derived xenograft (PDX) models to assess antitumor activity and associations between GPC3 and TGF-β expression.

Methods

PDX models were characterized by IHC for GPC3 (H-score) and TGF-β (% cells ≥1+ staining in tumor and stroma). Stromal TGF-β was classified as low (≤30%), moderate (31-60%), or high (>60%). Nine PDX models (3 WT, 2 HBL, 2 GCT, 1 MRT, 1 RMS) were treated in NSG MHC DKO mice (Jackson Laboratory) with 5×10^6 AZD5851 or untransduced T cells intravenously. Tumor responses were categorized per established PIVOT metrics (Houghton et al., 2007) using an event definition of >4-fold increase in tumor volume. For EFS analyses, a complementary definition of tumor volume >1,000 mm^3 or moribund status was also applied to account for delayed tumor regression typical of CAR-T therapies. EFS distributions were estimated by Kaplan-Meier analysis and compared using the log-rank test.

Results

PDX models demonstrated variable GPC3 expression (median H-score = 90, range 0-254). TGF-β staining was low in tumor cells (<5-20%) but prominent in stroma (40-90%, median ~80%). Only models with GPC3 H-scores >200 (2 HBL, 1 RMS) showed partial responses (PR) or stable disease (SD). One HBL model exhibited initial progression followed by regression after day 21. Models with H-scores <200 showed only PD. EFS analysis showed that AZD5851 significantly prolonged EFS in models with high GPC3 expression (H-score >200; $p = 0.002$-0.01, log-rank) compared with controls, while models with lower expression (≤100) showed no significant differences ($p \geq 0.2$). Responses occurred in models with both moderate (40%) and high (90%) stromal TGF-β, suggesting dnTGFβRII armoring may protect CAR-T cells from TGF-β-mediated suppression.

Conclusions

AZD5851 demonstrated tumor-regressing activity in pediatric PDX models with high GPC3 expression (RMS, HBL). Activity across models was heterogeneous, with evidence of delayed responses following initial progression. As seen with other CAR T-cell therapies, delayed activity may reflect in vivo proliferation and expansion of infused cells, and standard event-based metrics may not fully capture this effect. These findings support clinical evaluation of GPC3 CAR T cells with dnTGFβR armoring for GPC3-expressing pediatric cancers such as RMS and HBL and suggest that GPC3 expression by IHC may serve as a predictive biomarker of response.

#7813 Antitumor activity of a B7-H3 antibody-drug conjugate in osteosarcoma patient-derived and metastatic models.

Wendong Zhang[1], **Adil Bahadir**[1], Zhongting Zhang[1], Yianhua Yi[1], Zhaohui Xu[1], Simon Olivares[1], Harjeet Singh[1], AMER NAJJAR[1], Caterina Longo[1], Xin Zhou[1], Jasbir Kaur[2], Hiroki Torikai[2], Chunhua Shi[2], Jonathan Gill[1], Michael Roth[1], Tim Heffernan[2], Richard Gorlick[1]

[1]UT MD Anderson Cancer Center, Houston, TX,[2]Oncology Research for Biologics and Immunotherapy Translation (ORBIT), MD Anderson Cancer Center, Houston, TX

Background: Osteosarcoma outcomes have not improved in over three decades, and prognosis remains poor for patients with pulmonary metastases. B7-H3 is highly expressed on osteosarcoma with limited normal-tissue expression, making it an attractive therapeutic target. This study evaluated the antitumor activity of a B7-H3-targeting antibody-drug conjugate (B7H3 ADC) in osteosarcoma PDX and metastatic models.
Methods: The B7-H3 antibody (developed by ORBIT, MD Anderson) was conjugated to the tesirine payload SG3249. In vitro, cell viability was assessed in six PDX-derived osteosarcoma cell lines treated with B7H3 ADC (10-point dilution, 1000 nM start) over 120 h using Incucyte imaging. IC_{50} values were calculated by nonlinear regression, and dose-response effects were analyzed by one-way ANOVA with η^2 and Cohen's f. In vivo, six PDX models were treated with a single 1 mg/kg IP dose of B7H3 ADC, isotype-ADC, or PBS. Tumor growth inhibition and EFS were evaluated. Metastatic efficacy was assessed in IV and tibial injection models using luciferase-labeled SJSA LM7 cells, with treatment initiated at ~3×10^6 photons/sec.
Results: B7H3 ADC produced strong, dose-dependent cytotoxicity across all six cell lines (IC_{50} = 0.0795-0.6703 nM), with large effect sizes (η^2 = 0.80-0.93; Cohen's f = 2.01-3.65; $p < 0.001$). In vivo, three of six PDX models achieved maintained complete response (MCR), two showed partial response (PR), and one exhibited progressive disease (PD). In the IV metastasis model, control mice required euthanasia beginning on day 20, whereas all treated mice remained metastasis-free through day 93. In the tibial model, control mice were euthanized by day 25 with lung metastases detected by day 22. Treated mice showed complete tibial tumor regression by day 17 and remained metastasis-free through day 64.
Conclusions: B7H3 ADC demonstrated potent and reproducible antitumor activity in osteosarcoma PDX and metastatic models, inducing durable tumor regression and preventing metastatic progression. These findings support B7-H3 as a promising therapeutic target and justify further development of B7H3 ADC for primary and metastatic osteosarcoma.

#7814 Ganglioside targeting: Exerting sweet revenge on neuroblastoma.

[1]Pediatric Oncology, Dana-Farber Cancer Institute, Boston, MA,[2]Boston Children's Hospital, Boston, MA,[3]Medicinal Chemistry and Molecular Pharmacology, Perdue University, West Lafayette, IN,[4]Stanford University, Stanford, CA,[5]Children's Hospital Los Angeles, Los Angeles, CA,[6]Dana-Farber Cancer Institute, Boston, MA,[7]Stanford University School of Medicine, Palo Alto, CA

Neuroblastoma (NBL) is the most common extracranial solid tumor diagnosed in children and is responsible for 11% of pediatric cancer deaths. Dinutuximab is an FDA approved monoclonal antibody (mAb) against GD2, used in the treatment of high-risk NBL. Despite integration of dinutuximab into upfront treatment protocols, 40-50% of patients still relapse and eventually die of their disease. Resistance to anti-GD2 therapy is poorly understood. Previously, we have shown GD2 loss in xenografts in response to anti-GD2 immunotherapy. This resistance mechanism is driven by downregulation of one enzyme, ST8SIA1 while other enzymes in the GD2 pathway remain unchanged. We hypothesized that loss of ST8SIA1 leads to reduced GD2 and a compensatory increase in GM2. In the present work, we validate our hypothesis, vetting GM2 as an immunotherapy target for which we engineered GM2-specific chimeric antigen receptors (CAR) and mAbs and tested their efficacy and safety in murine models.First, we tested anti-GM2 mAbs as a monotherapy in 3 metastatic NBL xenograft models. Regardless of initial efficacy, monotherapy fail to provide long-lasting responses and eventually all mice relapsed. However, because each antibody showed partial activity in the GD2-high model, we added a combination-therapy arm in the next experiment. The combination proved to be superior, as all mice receiving it saw tumor eradication and long-term survival.We then tested anti-GM2 CAR T cells, based on the same binder used for mAbs, and saw robust and durable responses. Dual targeting GD2 and GM2, with a tandem GM2-GD2 CAR, was able to eliminate the tumors completely and provided long-term survival.Ganglioside distribution in normal tissue is poorly understood. However, it is known that GD2 is present in peripheral nerves, where it causes neuropathic pain, the main dose-limiting toxicity. To anticipate potential toxicities the combination could present, we optimized ganglioside detection by IHC on frozen tissue and successfully screened healthy tissue microarrays (TMAs). GM2 showed limited tissue distribution, being restricted to the kidneys and thyroid. More importantly, no overlap between GD2 and GM2 was observed.We also screened murine tissues from in search of a safety model. The kidneys of C57Bl/6 mice showed GM2 levels comparable to human kidneys, so were used for toxicity studies. GM2 mAbs were well tolerated with no evidence of off-target toxicity, no weight loss or noticeable pathological features.Finally, courtesy of NANT, we procured viably frozen bone marrow samples from relapsed NBL patients, previously treated with anti-GD2. These samples showed heterogeneous GD2, yet high GM2.Together these data shows, GD2 loss driven by immunotherapy and a concomitant increase in GM2. More importantly, it validates GM2 as an alternative target for GD2 low NBL and because GM2 has limited normal-tissue expression, it can be safely targeted alongside GD2 to prevent antigen escape

#7815 Efficacy of ABBV-706, a SEZ6-targeted topoisomerase 1 inhibitor ADC: A report from the Pediatric Preclinical In Vivo Testing (PIVOT) Program.

[1]St. Jude Children's Research Hospital, Memphis, TN,[2]Children's Hospital of Philadelphia, Philadelphia, PA,[3]Ann & Robert H. Lurie Children's Hosp. of Chicago, Chicago, IL,[4]The Jackson Laboratory, Bar Harbor, ME,[5]The Jackson Laboratory, Sacramento, CA,[6]The Jackson Laboratory, Farmington, CT,[7]AbbVie Inc, North Chicago, IL,[8]National Cancer Institute, Bethesda, MD

Introduction: ABBV-706 is an antibody-drug conjugate (ADC) composed of a monoclonal antibody targeting the seizure-related homolog 6 (SEZ6) surface protein linked to topoisomerase 1 inhibitor payload. A Phase 1 trial of ABBV-706 is underway in adults with SEZ6 expressing relapsed solid tumors (NCT05599984). ABBV-706 became of interest as SEZ6 is highly expressed in many pediatric cancers. The goal was to evaluate ABBV-706 in models of childhood cancers with notable SEZ6 expression: neuroblastoma (NB), medulloblastoma (MB), retinoblastoma (RB), and alveolar rhabdomyosarcoma (ARMS) and compare the activity to vehicle and isotype non-target control ADC (IC-ADC).

Methods: Pediatric xenograft models were screened for SEZ6 expression. Single agent in vivo studies were completed in NB, MB, RB, and ARMS models with varying SEZ6 expression. After engraftment, 2 total doses of ABBV-706 or IC-ADC were given by IP injection 3 weeks apart at 2 dose levels (DL1, DL2). Efficacy was assessed by median event free survival (KM med, in days) and objective response measure (ORM, Ped Blood Cancer 2007;49:928-940). ORM defines an objective response as partial, complete, or maintained complete response (PR, CR, and MCR) compared to stable disease (SD) or progressive disease, with or without growth delay (PD2 and PD1, respectively).

Results: ABBV-706 showed efficacy in a broad range of SEZ6 expressing non-CNS (NB, RB, ARMS) models. At DL1, PR, CR, or MCR responses were seen in 8 of 11 models. At DL2, 9 of 11 models had PR, CR, or MCR responses. For most models, ABBV-706 was more active than IC-ADC. Survival advantage was observed in 1 of 2 MB models.

Conclusion: We showed high anti-tumor activity for ABBV-706 in multiple SEZ6 expressing models and enhanced efficacy versus IC-ADC. Due to high expression of SEZ6 in several pediatric histologies, ABBV-706 has potential for clinical activity in patients with these cancers.

#7816 Spatial profiling identifies tumor-associated stroma enrichment and MIF as potential immunotherapy targets in primary Ewing sarcomas.

Christopher Kuo[1], Krinio Giannikou[1], Nuoya Wang[2], Mikako Warren[1], Andrew E. Goodspeed[3], Nick Shillingford[1], Mas Hayashi[4], Micha S. Raredon[2], James Amatruda[1]

[1]Children's Hospital Los Angeles, Los Angeles, CA,[2]Yale School of Medicine, New Haven, CT,[3]University of Colorado Cancer Center,, Aurora, CO,[4]The University of Colorado School of Medicine, Aurora, CO

Objective: To date, the response rate of immunotherapy in Ewing sarcoma (EwS) has been poor. The vast majority of children with metastatic or relapsed EwS die despite current intensive, multimodal therapy. The tumor immune microenvironment (TME) has a vital role in cancer survival and progression with implications in drug resistance and immune escape. However, there is a lack of understanding of the TME of EwS. Although recent single-cell RNA sequencing of EwS and immune cells have revealed a heterogenous transcriptional landscape with distinct subsets of immune cell populations in EwS, little is known about the spatial organization and spatial microenvironmental niches of the TME of EwS.

Methods: We performed Spatial Transcriptomics (ST) on 16 primary treatment naïve EwS tumor biopsies from patients with localized EwS (L-EwS) or with metastatic EwS (M-EwS), complemented by high-plex spatial proteomic analysis.

Results: Integrated analysis revealed inter- and intra-tumoral heterogeneity. We inferred the stromal regions of tumors transcriptionally and noted that tumors from L-EwS had significantly more stromal signature than M-EwS (p-value <2.2e-16). Gene set enrichment analysis using Hallmark gene sets revealed that L-EwS tumors were enriched in epithelial mesenchymal transition (EMT) and inflammatory signatures (adjusted p-value <0.05) and M-EwS tumors were enriched in proliferative signatures (adjusted p-value <0.05). We identified a set of 46 unique genes enriched in L-EwS that overlapped with genes in EMT hallmark pathways and were predominantly extracellular matrix related (ECM-r) genes such as *COL3A1, COL1A2, ITGB1, MMP2, ACTA2, TNC, TGFB1*. These ECM-r genes spatially overlapped with the stromal regions of individual tumors. Through spatial ligand-receptor analysis, we showed that the stromal enriched regions harbor unique extracellular matrix related cytokines, immune recruitment and proinflammatory microenvironmental signals, implying EwS stroma may play an anti-tumor role by acting as an immune recruitment center. All EwS tumors expressed pro-tumorigenic MIF-CD74 immune signaling connectivity, suggesting a potential immune-evasive mechanism.

Conclusion: L-EwS tumors are enriched in ECM and ECM-related microenvironmental signals compared to M-EwS. Spatial cellular microenvironmental signals reveal the potential immune recruitment role of tumor-associated stroma, our findings provide spatial insight into the TME of EwS and provide a rationale for the preclinical investigation of MIF as a potential target for EwS immunotherapy.

#7820 CHIP detection in solid tumors differs between liquid biopsy testing approaches.

Florian Klemm[1], Fuad Mohammad[2], Alex Charles Tuck[1], Grecia Morales[2], Rochelle Awuku[3], Katya Mokretar[3], Alasdair Heasman[3], Gareth Gerrard[4], Persephone du Parcq[3], Zhenyu Xu[1]

[1]SOPHiA GENETICS, Rolle, Switzerland,[2]SOPHiA GENETICS, Boston, MA,[3]Synnovis, Cancer Genetics, Guy's Hospital, London, United Kingdom,[4]South East Genomic Laboratory Hub, London, United Kingdom

Objective: Clonal hematopoiesis of indeterminate potential (CHIP) arises from somatic variants in hematopoietic progenitor cells and is more frequent in older individuals. CHIP can appear as incidental findings in cell-free DNA (cfDNA) from patients with solid tumors, introducing biological background noise that may confound result interpretation. MSK-ACCESS® powered with SOPHiA DDM™ incorporates matched white blood cell (WBC) DNA sequencing to allow filtering of CHIP and germline variants. This study evaluated CHIP detection in patients with solid tumors across different cfDNA testing approaches.
Materials and Methods: We conducted a multicenter, retrospective observational study; results from one center are presented here. Samples from 102 individuals with colorectal, prostate, pancreatic, or breast cancer were analyzed. cfDNA and matched WBC gDNA were processed using MSK-ACCESS® powered with SOPHiA DDM™, which detects SNVs/INDELs, CNVs, and structural variants. Orthogonal results from a centralized, send-out cfDNA-only assay were also available, including annotations for putative germline and CHIP variants. Concordance (percent positive agreement, PPA) was assessed while also focusing on discordant CHIP calls attributable to the inclusion of WBC sequencing.
Results: MSK-ACCESS® powered with SOPHiA DDM™ achieved 95% PPA for all variants with variant allele frequencies (VAF) ≥ 0.5% independent of classification, consistent with its limit of detection. Detected VAF showed strong correlation with the orthogonal assay (R^2 = 0.86). Discordant CHIP and tumor-specific calls were observed between the cfDNA-only approach and MSK-ACCESS® powered with SOPHiA DDM™. These were influenced by factors such as cfDNA-to-WBC VAF ratio thresholds, gene set composition (e.g., *DNMT3A* vs. *TP53*), and statistical filtering criteria. Overall percent agreement (OPA) for CHIP calls is under evaluation.
Conclusion: Incorporating matched WBC sequencing, as implemented in MSK-ACCESS® powered with SOPHiA DDM™, yields a potential advantage in resolving CHIP-related ambiguity compared to tumor-only cfDNA approaches. Continued assessment across methodologies and further evaluation are warranted.

#7821 Plasma-based comprehensive epigenomic profiling enables multiplexed prediction of target gene expression and detection of resistance mechanisms.

Clark[1], Khoi Nguyen[1], Daniel Karl[1], Kristian Cibulskis[1], Karl Semaan[2], Marc Eid[2], Jacob E. Berchuck[3], Corrie A. Painter[1], Matthew L. Eaton[1], J. Carl Barrett[1]

[1]Precede Biosciences, Inc., Boston, MA,[2]Dana Farber Cancer Institute, Boston, MA,[3]Winship Cancer Institute, Emory University School of Medicine, Atlanta, GA

Background: As novel targeted therapies including drug, radio-, and immune-conjugates, advance toward broad clinical implementation, there is an urgent need for scalable, minimally invasive diagnostics capable of resolving gene expression programs to guide patient selection and therapeutic monitoring. We applied a comprehensive epigenomics liquid biopsy and machine learning platform to infer tumor gene expression, delineate lineage plasticity, and reveal therapeutically relevant molecular programs and resistance mechanisms from only 1 mL of plasma.
Methods: 1 mL of plasma from a pan-cancer cohort of patients (95 prostate adenocarcinoma (PRAD), 19 neuroendocrine prostate cancer (NEPC), 45 non-small cell lung cancer, 58 small cell lung cancer, 130 breast cancer, 21 gastroesophageal cancer, and 5 ovarian cancer) was profiled using Precede Biosciences liquid biopsy platform. All samples were assessed for the expression of therapeutically relevant targets. In prostate cancer, samples were further evaluated for the extent of neuroendocrine (NE) transformation, a key mechanism of lineage plasticity and therapeutic resistance.
Results: Plasma-derived NE scores distinguished prostate adenocarcinoma (PRAD, n = 97) from neuroendocrine prostate cancer (NEPC, n = 15) along a continuous axis. Intermediate scores suggested partial or heterogeneous NE differentiation, with concurrent expression of PRAD- and NE-associated markers. Within these prostate cancer samples, predicted gene expression profiles clearly differentiated PRAD (high AR, KLK2, KLK3, FOLH1/PSMA) from NEPC (high CHGA, DLL3, SEZ6). DLL3 expression was further assessed across a multi-cancer cohort, and plasma-based predictions demonstrated a dynamic range consistent with published observations in tissue using both IHC and RNA-seq. For a subset of patients with matched FFPE tissue, immunohistochemistry for key drug targets is being performed to assess concordance with plasma-based expression predictions.
Conclusion: Plasma-based epigenomic profiling resolved tumor gene expression programs of key therapeutic targets such as DLL3 and delineated a continuum of neuroendocrine differentiation, uncovering molecular states associated with therapeutic response and resistance. Collectively, these findings underscore the potential of a minimally invasive, comprehensive epigenomics platform to deliver real-time, gene expression-level insights into tumor evolution and target expression, thereby guiding therapeutic decision-making.

#7822 High-sensitivity cfDNA detection of KRAS amplification subtypes to inform targeted therapy response and resistance mechanisms.

Yong Huang, Lisha Zhu, Binggang Xiang, Pan Du

Predicine, Inc., Hayward, CA

Background: *KRAS* is a key oncogenic driver gene, and both mutations and amplifications serve as important therapeutic targets and resistance biomarkers. Point mutations, amplifications of the wildtype allele, or amplifications of the mutant allele (sometimes via mutant allele-specific imbalance (MASI)) in *KRAS* all may impact cancer therapy greatly. Detection of *KRAS* amplifications in cell-free DNA (cfDNA) samples is particularly challenging because *KRAS* spans a relatively small 45kb region within a highly variable segment on chromosome 12. Achieving sensitive and accurate detection of *KRAS* amplifications in cfDNA and distinguishing the amplification types remains a pressing need in tumor drug development.

Methods: We developed a proprietary algorithm to enhance tumor fraction estimation and CNV calling of large genomic regions. Using 200 plasma samples , we developed a new model for the relationship among tumor fraction, observed copy number and variant allele frequencies. This model enables more comprehensive investigation of *KRAS* amplification events, including differentiation between focal amplification and large genomic fragment level amplification of *KRAS*, and between wild type allele amplification and mutant allele amplification in samples with *KRAS* driver mutations. The refined model also improves sensitivity of *KRAS* amplification calling when the amplification types can be assigned.

Results: Application of the new model allowed accurate determination of *KRAS* amplification types in most of the evaluated samples. In an expanded cohort of 800 cfDNA samples representing diverse solid tumors, *KRAS* amplification positive cases increased by 10% with the use of the refined model. Amplification types (wild-type allele or mutant allele amplification; focal or large genomic level) could be resolved in more than 80% of the cases. KRAS ctDNA dynamics were observed in both baseline and on-treatment samples.

Conclusions: This study provides an in-depth analysis of *KRAS* amplification profiles in cfDNA samples and introduces an improved model for *KRAS* copy number calling. The enhanced method increases detection sensitivity and yields richer biological insights by distinguishing amplification subtypes. These advancements strengthen the clinical utility of cfDNA-based KRAS assessment for therapeutic decision-making and drug development.

#7823 Ultrasensitive abnormal DNA methylation detection in plasma samples from patients with three different childhood sarcomas.

Giancarlo Bonora[1], Ziqi Zhu[1], Binggang Xiang[1], Kemin Zhou[1], Pan Du[1], Soumya Turaga[2], Glenson Samuel[3], Andrew Godwin[2]

[1]Predicine, Inc., Hayward, CA,[2]University of Kansas Medical Center, Overland Park, KS,[3]Children's Mercy Hospital, Kansas City, MO

Introduction: Early and accurate detection of Ewing sarcoma (EWS), Osteosarcoma (OS), Rhabdomyosarcoma (RMS), is critical because these aggressive pediatric and adolescent malignancies progress rapidly, often metastasize at diagnosis, and require timely, targeted therapy to improve survival and reduce long-term morbidity. Aberrant cell-free DNA (cfDNA) methylation pattern profiling holds great promise for the non-invasive detection and monitoring of cancer. However, sarcomas generally shed less DNA into the bloodstream than other cancers, making them particularly challenging cases that require highly sensitive detection methods. Here, we used an ultrasensitive cfDNA methylation assay to detect abnormal methylation patterns in archival plasma samples from seven patients representing three sarcoma subtypes. We observed robust aberrant methylation patterns in all samples, highlighting the potential of epigenetic alterations as a non-invasive indicator of tumor burden.

Methods: Longitudinal plasma samples were obtained from seven sarcoma patients: 3 patients with EWS 2 with OS and 2 with RMS. Samples were variously collected post-surgery and radiation treatment, when there was no evidence of disease, or at the time of relapse. cfDNA methylation was profiled using PredicineALERT™, a panel-based DNA methylation assay designed to detect abnormally methylated genomic fragments relative to a background model constructed from healthy-donor plasma. Importantly, only 1 ml of archival plasma stored in Acid-Citrate-Dextrose was used.

Results: Differentially methylated fragments (DMFs) were detected across the genome in all sarcoma samples, with DMF counts markedly higher than those observed in healthy-donor controls. Sarcoma samples clustered distinctly away from the controls, with patient samples grouping together and showing evidence of subtype-specific DMF patterns. DMF dynamics also corresponded with disease progression in that signal decreased for patients in remission and increased in cases showing relapse.

Conclusion: This study demonstrates the utility of cfDNA methylation profiling for sensitive, non-invasive detection and tracking of disease in childhood sarcoma patients. Future work will include generating corresponding tumor-tissue methylation libraries to confirm that plasma-derived methylation signatures are subtype-specific and biologically representative and evaluation of an extend longitudinal biobank of pediatric sarcoma patients.

#7824 Plasma-only classification of CHIP, low-VAF germline, and somatic variants enables accurate tumor-fraction estimation without matched normal samples.

Tiantian Zheng, Yong Huang, Chao Dai, Junmei Wang, Xiaohong Wang, Pan Du

Predicine, Inc., Hayward, CA

Background: Clonal hematopoiesis (CHIP) and germline variants commonly appear in cell-free DNA (cfDNA) and confound tumor genotyping. We analyzed historical paired plasma and Peripheral Blood Mononuclear Cell (PBMC)/buffy coat samples to (i) quantify CHIP prevalence and variant allele frequency (VAF) distributions, (ii) characterize low-VAF germline signals attributable to copy number variation (CNV) or alignment artifacts, (iii) identify tumor-derived somatic variants by integrating fragmentomics, CNV context, and longitudinal VAF dynamics, and (iv) benchmark plasma-only tumor-fraction (TF) estimation. Data were generated with the PredicineCARE and PredicineATLAS assays.

Methods: We retrospectively profiled ~1,000 plasma samples spanning prostate, breast, colorectal, lung, pancreatic, and other solid tumors with matched PBMC/buffy coat specimens. UMI-aware pipelines called single nucleotide variants/insertions/deletions/CNVs. Variants were annotated for CHIP drivers (e.g., *DNMT3A, TET2, ASXL1, PPM1D, TP53, SF3B1/SRSF2/U2AF1, JAK2*), population AF, hotspots, and an in-house knowledge base. Low-VAF germline events were adjudicated using a genome-wide germline SNP skeleton to explain deviations from the ~50% heterozygous expectation under local CNV. We trained and locked a plasma-only classifier (CHIP/germline/somatic) and estimated mutation-derived TF from tumor-assigned variants, benchmarking both against matched-normal labels. Longitudinal analyses (baseline + follow-up, months apart) assessed VAF dynamics and further improved the tumor fraction detection sensitivity.

Results: CHIP was prevalent and dominated by *DNMT3A/TET2/ASXL1*, with a minority of high-VAF clones; VAF distributions were summarized with and without TF normalization. Low-VAF germline signals were frequent but often CNV-driven, resolved by the SNP-skeleton model. On single-timepoint plasma, >95% of CHIP variants with VAF > 2% were correctly classified. Incorporating longitudinal VAF dynamics further differentiated low-VAF CHIP when TF changed >2-fold between draws, while tumor-derived variants tracked response/progression. The plasma-only TF showed excellent concordance with matched-normal TF (concordance correlation coefficient > 0.95).

Conclusions: CHIP is common and often low-VAF; a non-trivial fraction of apparent low-VAF germline findings reflect copy-number-induced VAF shifts. A plasma-only strategy that integrates CNV-aware germline modeling, CHIP gene context, fragmentomics, and longitudinal VAF dynamics closely reproduces matched-normal truth, enabling accurate somatic calling and tumor-fraction estimation without matched PBMC/buffy coat.

#7825 Ultra-sensitive MRD detection through comprehensive structural variant profiling in solid and hematologic malignancies.

Kemin Zhou, Yong Huang, Abby He, Junmei Wang, Binggang Xiang, Xiaohong Wang, Pan Du

Predicine Inc, Hayward, CA

Background: Structural variants (SVs), including fusions, translocations, large insertions/deletions, inversions and duplications, are highly tumor-specific genomic events and powerful biomarkers for molecular residual disease (MRD) assessment. Detecting SVs with unknown partners using short-read sequencing remains challenging, especially at ultra-low variant fractions. We developed the Predicine DeepSEA SV detection algorithm to enable comprehensive discovery and sensitive tracking of multi-class SVs in tissue and plasma.
Methods: Predicine DeepSEA integrates de novo assembly, refined BWA-based re-alignment, fragment-level molecular quantification, and combined split-read and paired-read evidence to detect and classify five SV subtypes with high accuracy. The workflow was applied to tumor tissue and matched longitudinal plasma samples from 30 patients with solid tumors or hematologic malignancies. PredicineBEACON MRD assays incorporated somatic SV breakpoints identified by whole-genome sequencing of high-tumor-fraction (>20% TF) baseline samples. Personalized SV-based panels were then designed for targeted MRD tracking. Analytical sensitivity was evaluated using titration experiments in which patient-derived cfDNA was spiked into healthy donor cfDNA at defined dilutions down to 1 part per million (ppm).
Results: DeepSEA identified diverse somatic SVs across all tumors, enabling construction of individualized MRD marker sets. In longitudinal plasma analysis, patient-specific SVs were quantifiable at extremely low variant fractions, and integration of multiple SV markers improved detection robustness compared with single-event tracking. In dilution studies, the PredicineBEACON assay achieved reliable MRD detection down to 1 ppm with high specificity, supported by fragment-level consensus filtering and multi-evidence breakpoint calls. SV-derived signals were detectable in both solid and hematologic cancers, underscoring the platform's broad applicability.
Conclusion: The Predicine DeepSEA pipeline provides sensitive and specific detection of structural variants in tissue and plasma. Incorporation of SVs into the PredicineBEACON MRD assay enables highly sensitive, personalized ctDNA tracking with detection limits approaching 1 ppm. This SV-based framework delivers a technically robust and broadly applicable platform for molecular monitoring across diverse cancer types.

#7826 Monitoring molecular residual disease in colorectal cancer using tumor-informed ctDNA analysis.

William C. Cho[1], Qianqian Yao[2], Yingyu Wang[2], Tam Berntsen[2], George Yeung[2], Paul Tang[2], Tobias Wittkop[2], Li Weng[2], Lui Ng[3], Dominic C.C. Foo[3]

[1]Department of Clinical Oncology, Queen Elizabeth Hospital, Hong Kong SAR, China,[2]Department of Research and Development, AccuraGen Inc., San Jose, CA,[3]Department of Surgery, University of Hong Kong, Hong Kong SAR, China

Background: Circulating tumor DNA (ctDNA) has become a critical tool for detecting molecular residual disease (MRD) and predicting recurrence in colorectal cancer (CRC). Tumor-informed ctDNA assays depend on a reference mutation profile from tumor tissue, commonly sourced from formalin-fixed, paraffin-embedded (FFPE) or fresh-frozen (FF) samples. Although FFPE tissues are widely available, they are susceptible to formalin-induced artifacts that may affect mutation calling accuracy. This study evaluated the sensitivity and specificity of ctDNA MRD assays, compared the mutation profiles and ctDNA MRD performance between FFPE and FF tissues, and evaluated the prognostic value of ctDNA.

Methods: We analyzed 28 CRC patients after curative-intent surgery. Whole-genome sequencing of 18 FFPE and 16 FF tumor samples (including six matched pairs) was conducted to assess variant burden, allele frequency, and mutational signatures. Plasma ctDNA was measured pre- and post-operatively using the tandem error-correction sequencing platform (AccuScan). Performance metrics for recurrence were evaluated at a landmark period (2-6 weeks post-surgery) and during longitudinal follow-up. Disease-free survival (DFS) was analyzed with Kaplan-Meier methods.

Results: FFPE samples exhibited a higher median variant count than FF tissues (8,774 vs. 4,906, $p = 0.001$) and lower variant allele frequency (17.54% vs. 21.38%, $p = 0.033$), along with enriched A>T transversions ($p = 0.031$). Despite these differences, ctDNA MRD detection showed 100% specificity and positive predictive value for recurrence across tissue types. FFPE-informed testing showed higher sensitivity during longitudinal monitoring (88.9% vs. 71.4%). MRD positivity was strongly associated with reduced DFS ($p < 0.0001$). In two cases, recurrence detected by FFPE-informed testing was missed with FF-based analysis, suggesting potential false negatives with FF samples.

Discussion: These findings support that FFPE tissues, despite more artifacts, are a clinically practical and often more sensitive source for ctDNA MRD assays after bioinformatic processing. The high specificity of ctDNA underscores its utility in guiding treatment decisions. This study confirms the prognostic value of ctDNA and promotes the use of archival FFPE tissues to improve test accessibility without compromising accuracy, facilitating the integration of liquid biopsy into personalized CRC management.

#7827 Analytical evaluation of tumor-naive ctDNA molecular response detection through baseline informed comprehensive genomic profiling with matched white blood cell analyses.

Cynthia Maddox[1], Cesar Nalvarte[1], Amanda Harvey[1], Vito Caropreso[1], Andrew Georgiadis[1], Aanavi Karandikar[1], Kenneth C. Valkenburg[1], Eric Severson[2], Taylor J. Jenson[2], Shakti Ramkissoon[2], Mark Sausen[1]

[1]Labcorp, Baltimore, MD,[2]Labcorp, Durham, NC

Liquid biopsies can provide an improvement over existing diagnostic modalities to detect, characterize and monitor cancer across the care continuum. Circulating tumor DNA (ctDNA) dynamics have been shown to identify cancer progression earlier than can be achieved with imaging-based assessments, however, can be limited due to low tumor burden together with the biological background associated with germline and clonal hematopoietic (CH) alterations in cell-free DNA. PGDx elio® plasma complete™ (EPC) is a pan-solid tumor hybrid capture, next-generation sequencing (NGS) comprehensive genomic profiling test for the identification of single nucleotide variants (SNVs), insertions and deletions (indels), copy number amplifications, translocations, microsatellite instability (MSI), and blood tumor mutation burden (bTMB) across 521 genes. To optimize EPC for the sensitive and specific detection and quantification of limited ctDNA levels, patient-matched white blood cells (WBCs) were sequenced and a baseline informed bioinformatic approach was implemented, aggregating the tumor-specific mutational signature across the panel. To demonstrate the analytical performance of this strategy, noncancerous donor plasma samples (n=29, 25 ng each) and four contrived reference models were analyzed across seven tumor content levels, with five replicates of each model evaluated at each level (n=140, 25 ng each). These studies demonstrated 100% specificity (116/116) with a limit of detection (95%) of 0.05% tumor and limit of quantification of 0.15% tumor (<20% median CV). Taken together, these data demonstrate that through the integrated analysis of cfDNA and matched white blood cell DNA, with a tumor-naïve approach, EPC can achieve increased sensitivity for the accurate detection and quantification of ctDNA required for the assessment of molecular response in patients with metastatic solid tumors.

#7828 Development of a comprehensive tumor-informed ctDNA workflow for ultrasensitive molecular residual disease detection using diverse tumor profiling inputs.

Leisa Jackson, Helen Halpin, Emma Longshore, Gary A. Pestano

Biodesix, Inc., Louisville, CO

Background: Circulating tumor DNA (ctDNA) analysis represents a transformative approach to molecular residual disease (MRD) surveillance, enabling non-invasive disease monitoring and treatment response assessment. While tumor-agnostic methodologies offer broad applicability, tumor-informed strategies leveraging patient-specific genomic alterations can provide enhanced sensitivity for detecting low-burden disease. We developed an integrated wet lab and bioinformatics workflow capable of identifying and monitoring structural variants (SVs), single nucleotide variants (SNVs), and insertions/deletions (Indels) across multiple genomic profiling platforms.

Methods: Patient-specific variant discovery was performed using whole genome sequencing (WGS), comprehensive genomic profiling (CGP), or whole exome sequencing (WES) using formalin-fixed paraffin-embedded tissue (FFPET) specimens. Our proprietary informatics pipeline annotated, filtered, and prioritized variants based on stringent quality metrics and variant allele frequency. To evaluate WGS inputs, two clinical metastatic castration-resistant prostate cancer (mCRPC) specimens with matched FFPET and plasma were used to design multiplexed droplet digital PCR (ddPCR) assays for detection of up to 12 SVs per reaction well. For cases with CGP inputs, off-the-shelf duplex ddPCR assays were used to monitor 6 unique SNVs detected across clinical mCRPC patients. The informatics pipeline was also employed to identify SVs, SNVs, and small Indels from patients with WES data from tissue.

Results: WGS libraries were successfully generated and passed quality control using as little as 40 ng FFPET DNA. Sequencing identified multiple high-confidence SVs, from which bespoke assays were designed. Assays were pooled and evaluated for cross-reactivity with wild-type genomic DNA and no-template controls. All CGP-derived targets were successfully detected in matched baseline plasma specimens with variant allele frequencies as low as 0.12 percent. WES data analysis from 8 subjects identified multiple SVs, SNVs, and Indels using a proprietary informatics pipeline. However, no WES-identified SVs were suitable for ddPCR assay design, suggesting SNV and Indel targets may be more appropriate for this data input type.

Conclusions: This study demonstrates successful development of a comprehensive ctDNA workflow for MRD detection using mCRPC specimens. The workflow accommodates multiple sequencing input types (WGS, CGP, WES) and successfully detects low-frequency variants in plasma using multiplex ddPCR. These data suggest that WGS-derived SVs and CGP- or WES-derived SNVs/Indels represent complementary strategies for tumor-informed MRD monitoring. Further validation studies with larger cohorts from various cancer types are planned.

#7829 Fragmented plasma cfDNA as a prognostic and surveillance biomarker for locoregional recurrence in oral squamous cell carcinoma.

Jiyoung Lee[1], Mi Rim Lee[1], Sumin Kang[1], Jung-Ah Hwang[2], Hye Won Shon[1], Yu-Sun Lee[1], Sun Il Choi[1], Gyeongmin Kang[1], Jong-Ho Lee[1], Sun-Young Kong[1], Sung Weon Choi[1], Yun-Hee Kim[1]

[1]National Cancer Center, Goyang-si, Korea, Republic of,[2]Geninus Inc., Seoul, Korea, Republic of

Oral squamous cell carcinoma (OSCC) frequently exhibits early locoregional recurrence despite adjuvant therapy. Circulating cell-free DNA (cfDNA) has emerged as a minimally invasive approach for evaluating tumor burden and disease dynamics. While most studies have focused on ctDNA mutations, the prognostic value of cfDNA fragmentomics—particularly mononucleosomal and dinucleosomal DNA—remains unclear in OSCC. Here, we investigated baseline cfDNA characteristics, mutational profiles, and fragmentation patterns, and evaluated their utility for recurrence prediction and longitudinal surveillance. Sixty-eight HPV-negative OSCC patients were prospectively enrolled, and plasma was collected at diagnosis and during follow-up. Baseline cfDNA was detected in 98.5% of patients (mean 6.65 μg/mL). Higher cfDNA levels correlated with aggressive clinical features, including advanced T stage, lymph node metastasis, and TNM III-IV disease, supporting its association with tumor burden. Targeted sequencing identified somatic variants in 30 genes, most commonly NOTCH1 (41%), FBXW7 (25%), and MGA (22%). Pathogenic variants were less frequent and did not correlate with TNM stage, and patients who recurred harbored fewer detectable mutations, indicating limited prognostic value of mutation-based profiling. Fragmentation analysis revealed distinct clinical implications for mono- and dinucleosomal cfDNA. Elevated baseline mononucleosomal cfDNA predicted recurrence, and a 3 ng/mL cutoff identified patients with significantly shorter recurrence-free survival. Dinucleosomal cfDNA, however, demonstrated superior value for longitudinal surveillance. Among 16 patients with locoregional recurrence, 13 (81%) showed detectable dinucleosomal cfDNA at or before radiologic confirmation, often during imaging-negative intervals. Persistent dinucleosomal cfDNA reflected ongoing local tumor activity, whereas metastatic recurrences rarely showed positivity. These results demonstrate that cfDNA fragmentomics provides prognostic information beyond mutation profiling in OSCC. Baseline mononucleosomal cfDNA stratifies patients at increased risk of recurrence, while the presence of dinucleosomal cfDNA offers a sensitive and clinically practical indicator of emerging locoregional disease. Together, these fragment-based biomarkers support the incorporation of cfDNA fragmentation analysis into postoperative surveillance strategies for earlier and more accurate detection of relapse.

#7830 Transport under various conditions: Evaluating blood sample stability across seasons.

Daniel Grolz[1], Markus Wolf[1], Daniela Mancarella-Langer[1], Franziska Kaiser[1], Michelle Walther[2], Eric Provencer[2]

[1]QIAGEN GmbH, Hilden, Germany,[2]BD, Franklin Lakes, NJ

INTRODUCTION: For analysis of circulating cell-free DNA (ccfDNA) in cancer screening or monitoring, specialized blood collection tubes - such as the PAXgene® Blood ccfDNA Tube (PreAnalytiX) - offer a reliable solution for users who are unable to process samples within 4 hours of collection. These tubes stabilize ccfDNA profiles by preventing blood cells from releasing genomic DNA (gDNA) during transport, thereby preserving sample integrity for sensitive downstream ccfDNA analyses. According to international standards and regulations (ISO 20186-3:2019, (EU) 2017/746 on In Vitro Diagnostic Medical Devices) preanalytical conditions like sample collection, transport, and storage must be validated to ensure that the quality of ccfDNA is maintained. Here, we evaluated sample packaging, temperature fluctuations during transit, and the impact of shipment on downstream assay performance to assess whether blood samples in PAXgene tubes can be transported at ambient temperature.

METHODS: Blood was collected from 30 apparently healthy consented donors into PAXgene Blood ccfDNA Tubes. Filled tubes were processed within 4 hours after phlebotomy or stored refrigerated (2-8°C), at 15°C or at room temperature (15-25°C) for 10 days and at 30°C for 7 days. For international transport tubes were shipped from the collection site (QIAGEN, Hilden, Germany) to an external processing site (BD, Franklin Lakes, USA). Samples were placed in insulated boxes compliant with IATA standards and without active temperature control. This included a leakproof triple packaging concept with a primary receptacle, a secondary package, and a rigid outer package. Upon arrival, blood samples were processed directly or subjected to an additional transport simulation test according to requirements defined in the standard ASTM D4169. Plasma and cellular fraction were separated, frozen and shipped back to QIAGEN for ccfDNA and gDNA extraction and analysis.

RESULTS: Temperature fluctuations during transport were in the range of 18-35°C during summer and 7-25°C during winter. Additional drop, vibration and altitude tests to simulate transportation by truck, rail and air did not compromise yield or quality of DNA. The relative yield of ccfDNA from plasma, measured by qPCR, between samples processed immediately and after storage or transport and simulation was only slightly increased with mean values between 1.0- to 1.3-fold. gDNA yield and purity measured by spectrophotometry were high for all conditions in the range of 26 to 55 µg of gDNA per mL of cellular fraction and mean 260/280 ratios between 1.80 and 1.82.

CONCLUSION: Excellent sample stability could be demonstrated in whole blood samples collected into PAXgene Blood ccfDNA Tubes under both controlled storage and real-world transport conditions. The data confirm that sample integrity is maintained following air and ground transportation at ambient temperatures across both summer and winter seasons.

#7831 Diagnostic genomics in retinoblastoma: Aqueous humor outperforms blood for tumor-specific insights.

Elaine Huang[1], Atrey Khoche[1], Sabrina Abed[2], Venkata Yellapantula[3], Laura Kagami[3], Brianne Brown[2], Liya Xu[2], Jesse L. Berry[2]

[1]Keck School of Medicine of USC, Los Angeles, CA,[2]Childrens Hospital Los Angeles, Los Angeles, CA,[3]Center for Personalized Medicine, Childrens Hospital Los Angeles, Los Angeles, CA

Purpose: There remains controversy in ocular oncology over whether blood or AH is a superior liquid biopsy for retinoblastoma (RB). Herein, we compare their diagnostic utility.

Methods: Matched AH and plasma were collected at diagnosis from 13 patients (16 eyes) with RB. Cell-free DNA was sequenced to assess copy number alteration (CNA) amplitude; ichorCNA software was used to estimate tumor fraction (TFx). Paired results were compared using the Wilcoxon test.

Results: SCNAs were detectable in 93.8% of AH samples versus 53.8% of plasma samples. Plasma TFx was significantly lower (4.33-7.84%; average 7.65%) than AH TFx (4.69-99.37%; average 34.19%; p=0.004), with a median difference of 16.73%. Plasma CNAs were detected only in patients with Group D/E eyes, two-thirds of which were enucleated. By contrast, AH enabled CNA detection across all groups. In 75% of patients positive in both substrates, AH identified additional alterations absent in plasma. In bilateral cases (23%), AH revealed eye-specific alterations indistinguishable in plasma. No evidence of metastasis was observed at average follow-up of 4 months.

Conclusion: While blood CNA detection may correlate with advanced disease, AH demonstrates superior sensitivity for intraocular diagnosis.

Clinical Implication: Validated by a CLIA-certified assay (LBSeq4Kids), AH consistently outperforms plasma as a biopsy surrogate.

#7832 Plasma epigenomic profiling captures B-cell lymphoma biology.

Aleem Aamir[1], Steven De Michino[1], Michael Hong[2], Ting Liu[2], Victoria Shelton[2], Benjamin Haibe-Kains[1], Michael M. Hoffman[1], Mathieu Lupien[1], Robert Kridel[2], Benjamin Lok[1], Scott V. Bratman[1]

[1]Medical Biophysics, University of Toronto, Toronto, ON, Canada,[2]Princess Margaret Cancer Center, Toronto, ON, Canada

Background: B-cell lymphomas (BCLs), including diffuse large B-cell lymphoma (DLBCL) and follicular lymphoma (FL), display widespread epigenetic dysregulation. The histone methyltransferase EZH2 catalyzes the repressive mark H3K27me3 and is an important epigenetic regulator for B-cell development. Although previous work has examined H3K27me3 in BCL tumour samples, the landscape of H3K27me3-decorated cell-free chromatin in BCL remains largely unexplored.

Methods: We performed cfChIP-seq targeting H3K27me3 on n=55 DLBCL, n=19 FL, and n=21 non-cancer controls from the Princess Margaret LIBERATE study. For global analyses, reads were counted in 10kb genomic windows and background reads were subtracted using a truncated Poisson MLE and data were library size normalized. BCL scores were computed using leave-one-out NNLS against a healthy reference panel and a high-burden lymphoma archetype. For promoter analyses, reads ±2kb of the TSS were counted and library size normalized.

Results: Global plasma H3K27me3 profiles in advanced-stage BCL separate from limited-stage BCL and non-lymphoma samples. Mean BCL scores were higher in advanced-stage BCL($p<0.0001$) and limited-stage BCL ($p<0.05$) compared to non-lymphoma controls. Moreover, both DLBCL ($p<0.0001$) and FL ($p<0.001$) had higher mean BCL scores than non-lymphoma controls. BCL scores were highly correlated to PC1 ($\rho=0.902$, $p=2.97e-35$) and the orthogonal tumour fraction metrics including mean VAF from targeted sequencing ($\rho=0.850$, $p=4.79e-18$), ichorCNA tumour fraction from ~0.5X WGS ($\rho=0.779$, $p=3.86e-12$), and total lesion glycolysis from FDG-PET/CT ($\rho=0.669$, $p=1.37e-10$). Correlation analysis between H3K27me3 signal at promoters and mean VAF revealed a negative association at B-cell lineage loci such as PAX5 ($r=-0.705$, $p=1.29e-09$) and DTX1 ($r=-0.622$, $p=3.11e-07$), and a positive association at other hematopoietic lineage loci such as MCEMP1 ($r=0.746$, $p=4.1e-11$) and IL6R ($r=0.635$, $p=1.46e-07$), indicating an increased contribution of B-cell lineage contribution with increasing tumour fraction.

Conclusions: These data show that plasma H3K27me3 profiles capture disease burden and reflect underlying tumour biology in BCL. Furthermore, these profiles capture lineage-specific promoter repression patterns, manifesting in negative correlations between H3K27me3 signal B-cell lineage markers and tumour fraction, contrasting positive correlations observed at markers of other hematopoietic lineages. Overall, cfChIP-seq of H3K27me3 provides a non-invasive epigenomic readout of circulating cell-free chromatin in BCL.

#7833 A novel extraction method for enrichment of circulating cell-free DNA.

Seka Lazare, Megan Rivera, Zachary Costliow, Ashley Tellis, Zhuosheng Gu, Michael A. Harmon, Wendy Winckler

Droplet Biosciences, Inc., Cambridge, MA

Proximal biofluids have shown enriched sensitivity for liquid biopsy but present unique preanalytical challenges. Even in plasma, variations in collection or processing can affect cell-free DNA (cfDNA) isolation and size profiles. These differences may affect downstream sensitivity.

Our lab has pioneered the use of lymphatic exudate (“lymph”) from surgical drains as a novel proximal liquid biofluid for MRD detection. We have previously shown that lymph collected 24 hours after surgery identified molecular residual disease (MRD) in head and neck squamous cell carcinoma (HNSCC). This biofluid contains lymphatic fluid, blood, and interstitial fluid, and differs markedly from blood or plasma. cfDNA in lymph displays distinct nucleosomal distribution, including prominent mono- and dinucleosome peaks (“cfDNA fraction”), but most extracellular DNA is >700 bp (“HMW fraction”). Our analysis revealed that tumor-derived DNA is more abundant within the < 700 bp cfDNA fraction.

To negate the signal-diluting effects of the HMW fraction, we developed a novel extraction method that simultaneously maximizes cfDNA recovery and selectively depletes HMW DNA. The method utilizes Proteinase K treatment for protein removal, selective bead-based removal of the HMW fraction, and purification of the enriched cfDNA from the supernatant.

We benchmarked this method against three commercial cfDNA extraction kits. To characterize all size fractions, we also generated a non-depleted extract using a simplified version of our protocol lacking the selective bead-binding step. We refer to this non-depleted material as “raw cfDNA extract.” Lymph was collected in K2EDTA/Streck blood collection tubes, centrifuged to remove cells and debris, and the supernatant stored at -80 °C (n=36). All 36 samples were processed using our novel extraction method; matched subsets were used for commercial kit comparisons. cfDNA concentration and size distribution were analyzed using Qubit dsDNA and Tapestation cfDNA assays respectively, with cfDNA defined as fragments 50-700 bp.

Raw cfDNA extract was highly concentrated (mean 40 ng/µL of extracted lymph, n=9) but displayed variable purity (6-31%). Commercial kits yielded highly variable quantity and purity (cfDNA yield = 0.08-19.88 ng/µL of extracted lymph; purity = 1.3-31%; n = 3, 3 and 2 for kits 1-3). In stark contrast, our novel extraction method delivered high yield and purity consistently across all 36 extractions (mean yield = 1.8 ng/µL, cfDNA purity = 92% [80-98%]).

We present an optimized cfDNA extraction method which consistently yields high purity, concentrated cfDNA from biofluids with substantial HMW fractions, dramatically increasing the effective ctDNA yield compared to standard commercial protocols. This technical advancement resolves a critical preanalytical challenge for assays using lymphatic exudate, enabling sensitive clinical monitoring with this readily available proximal biofluid.

#7834 DNA methylation: A highly accurate biomarker for treatment monitoring - A retrospective case study using cfDNA methylation and machine learning in breast cancer patients.

Jean-Valery Turatsinze[1], Andrea Blum[1], Adrien Godfroid[1], **Ekaterina Gracheva**[2], Matteo Tosolini[1]

[1]Hologic Diagenode, Liege, Belgium,[2]Diagenode LLC, Denville, NJ

DNA methylation plays a critical role in gene regulation and maintaining genomic stability. Abnormal DNA methylation patterns are common in breast cancer and relate to tumor growth and resistance to therapy. Liquid biopsies, especially analyzing cell-free DNA (cfDNA) in plasma, offer a minimally invasive way to monitor tumor-specific molecular changes in real time. This study evaluates the power of DNA methylation analysis to identify biomarkers for monitoring breast cancer treatment. Plasma samples from healthy individuals were used to first determine the reproducibility and robustness of the technology, while plasma from patients with breast cancer at different stages of disease was used for a biological validation study. After cfDNA extraction, all samples have been subjected to EM-seq library preparation followed by capture and next-generation sequencing. Sequenced reads were aligned to the human reference genome (hg38), and the DNA methylation levels were measured and filtered. The most differentially methylated CpGs were used as features for supervised machine learning models to differentiate between four disease states: progressive disease, partial remission, and complete remission, while some patients still showed residual abnormalities. The results of the analytical study demonstrate that the Hologic Diagenode Human Methylome procedure is highly reproducible across operators, input amounts, and technical replicates during the analytical phase. The biological validation demonstrates that, in patients undergoing various treatment regimens, the identified DNA methylation signature can predict their clinical state — ranging from progressive disease to partial and complete remission — with extremely high accuracy (92%). CpGs included in the identified signature were also relevant to the clinical context, as their associated genes were previously associated with cancer. These results underscore the potential of DNA methylation as a powerful molecular biomarker, not only for cancer diagnosis but also for treatment monitoring and potentially for minimal residual disease (MRD) detection.

#7835 Integrated DNA/RNA recovery from 1-20 mL inputs enables sensitive KRAS G12V detection in a liquid biopsy model.

Mayer Saidian, Jason Saenz, Carlos Hernandez, Cameron Van Dieren, Daniel Cedeno, Nafiseh Jafari

nRichDX, Irvine, CA

Introduction: Liquid-biopsy applications increasingly need concurrent access to tumor-derived DNA and RNA, sensitivity at low variant abundance, and support for larger input volumes. Separate cfDNA/cfRNA workflows add hands-on time and can limit sensitivity. We evaluated a single-extraction total nucleic acid (TNA) workflow designed to co-recover circulating DNA and RNA across inputs ranging from 1 to 20 mL.
Methods: Conditioned media from KRAS-G12V-positive H441 cells were pooled, clarified, and filtered to form a uniform tumor-conditioned matrix. Replicate extractions (n = 5 per condition) were performed at 1, 5, 10, and 20 mL using the same silica-magnetic-bead TNA chemistry and a single fixed-volume eluate. Eluate was split post-extraction for DNA (Qubit HS DNA; KRAS-G12V qPCR) and RNA (Qubit HS RNA; RT-qPCR). Metrics included total yield, KRAS-G12V copies/mL, allele fraction, and coefficient of variation (CV). Rare-event performance was tested using a dilution series (100%, 20%, 5%, 1%, 0.2% KRAS-G12V) extracted at 20 mL (n = 5 per level). Fragment integrity for 1 mL vs 20 mL inputs was evaluated by high-sensitivity capillary electrophoresis.
Results: KRAS-G12V copies/mL scaled linearly with input volume for both DNA- and RNA-derived signal ($R^2 \geq 0.98$ across 1-20 mL; within-volume CV≤15%). Increasing input reduced allele-fraction variance, improving quantitative precision without changing chemistry or handling. Split-eluate analysis showed strong concordance between DNA and RNA KRAS-G12V copies/mL across volumes, demonstrating that one extraction supports both genomic (mutation) and transcriptional readouts. In dilution experiments at 20 mL, KRAS-G12V was consistently detected down to 0.2% variant fraction. Fragment analysis confirmed cf-like size profiles (~160-180 bp) with minimal high-molecular-weight carryover at all inputs.
Conclusions: A single-eluate TNA workflow co-recovers DNA and RNA from up to 20 mL input, yields linear signal scaling, preserves cf-like integrity, and maintains detection at low simulated tumor fractions. Larger inputs not only boost recovery but also tighten allele-fraction precision. These data support high-volume, integrated DNA/RNA liquid biopsy workflows for applications such as minimal residual disease monitoring and longitudinal response assessment.

#7836 Automated high-volume cfDNA extraction on a liquid-handling platform achieves analytical equivalence to a manual high-input magnetic-bead workflow with 96-sample throughput.

Nafiseh Jafari, Cameron Van Dieren, Jason Saenz, Carlos Hernandez, Daniel Cedeno, Mayer Saidian

nRichDX, Irvine, CA

Introduction: High-volume cfDNA extraction improves sensitivity for liquid biopsy studies but is limited by manual hands-on time and variability. We evaluated whether implementing a high-volume magnetic-bead cfDNA workflow on an automated liquid-handling platform maintains analytical performance while increasing throughput and reducing labor.
Methods: Human plasma collected in K2EDTA tubes was processed using double centrifugation (low- then high-speed). Urine was preserved in Tris-EDTA pH 8 and clarified by high-speed centrifugation. Plasma and urine inputs (1-20 mL) were extracted manually or on the automated platform using identical magnetic-bead chemistry; only wash/elution steps were automated. Replicates were run across multiple reagent lots and days. Endpoints included cfDNA yield (Qubit HS), fragment metrics (Agilent cfDNA ScreenTape), and locus-specific qPCR. Pre-specified non-inferiority margins were ±10% for yield and fragment attributes. Equivalence was assessed with paired statistics, TOST, Bland-Altman, and variance components. Operational metrics included batch size, hands-on time (HOT), turnaround time (TAT), and walk-away time. Cross-contamination was assessed using checkerboard layouts analyzed by Qubit and qPCR. End-to-end traceability used unique barcodes on capture tubes readable by the automation platform.
Results: Automation preserved analytical performance across matrices and input volumes. The automated/manual yield ratio was 0.93 (95% CI ±7.8%), meeting the ±10% non-inferiority criterion (TOST $p < 0.05$). Fragment metrics—including modal size (~170 bp), 50-700 bp distribution, and mono:di-nucleosome ratios—were equivalent, differing by ~1% with between-run CV ≈1%. qPCR copy numbers showed minimal bias (mean 3.35 copies/reaction) with acceptable limits of agreement; limits of detection were identical for all loci. All 96-sample runs met QC thresholds. Checkerboard assays showed no detectable cross-contamination. Automation increased batch capacity from ~24-48 to 96 samples/run, reduced HOT by ~70-85% (to ~2 hours per batch), and shortened TAT by ~40-60%, providing ~2.5 hours of walk-away time.
Conclusions: Automating a high-volume magnetic-bead cfDNA workflow delivers analytical equivalence to manual processing while enabling 96-sample throughput and major reductions in labor and turnaround time. These findings support automation as a scalable solution for high-volume cfDNA programs requiring consistent, high-sensitivity performance. Portions of this text were generated with AI and were reviewed, edited, and approved by the authors.

#7837 Enhanced sensitivity and scalability in liquid biopsy through integrated high-volume cfDNA extraction and droplet digital PCR mutation detection.

Nafiseh Jafari[1], Andrew Partner[2], Necip Mehmet[2], Nish Kumar[2], Prithwish Pal[2], Jason Saenz[1], Carlos Hernandez[1], Daniel Cedeno[1], Cameron Van Dieren[1], Mayer Saidian[1]

[1]nRichDX, Irvine, CA,[2]Bio-Rad Laboratories, Inc, Pleasanton, CA

Introduction: Detecting rare tumor-derived variants in plasma requires both efficient recovery of cell-free DNA (cfDNA) and highly quantitative mutation analysis. Conventional extraction methods are limited by low input capacity and potential bias toward longer fragments, which can compromise sensitivity for low-frequency alleles.
Methods: Plasma cfDNA was extracted using the nRichDX Revolution cfDNA Max20 Kit, a high-volume magnetic-bead-based system, and then compared with the Qiagen QIAamp Circulating Nucleic Acid Kit. Pooled human plasma (1-15 mL, n = 3) and contrived samples spiked with 1% EGFR E746_A750delELREA (COSM6223) and KRAS G12C (COSM516) mutant gBlocks were processed per manufacturer's protocols. cfDNA concentration was measured by Qubit fluorometry, and mutation fractional abundance was quantified using the Bio-Rad QX600™ Droplet Digital™ PCR System (ddPCR™). Linearity, recovery efficiency, and reproducibility were evaluated across input volumes.
Results: The nRichDX Revolution cfDNA Max20 Kit demonstrated linear cfDNA recovery across 1-15 mL plasma inputs ($R^2 = 0.98$) and maintains scalability up to 50 mL without reconcentration or parallel extractions. When coupled with the Bio-Rad ddPCR System, mutation analysis consistently detected 1% variant allele frequencies, yielding 15-30% higher measured fractional abundance compared to the Qiagen QIAamp Circulating Nucleic Acid Kit, which uses carrier RNA.The nRichDX workflow preserved short cfDNA fragments critical for mutation detection, improving signal-to-background ratios and enhancing analytical sensitivity. Replicate variability remained below 10%, confirming robust precision across input volumes.
Conclusions: Integration of the nRichDX Revolution cfDNA Max20 Kit with the Bio-Rad QX600 ddPCR System enhances analytical sensitivity, recovery accuracy, and scalability for cfDNA-based liquid biopsy applications. By maintaining cfDNA integrity and eliminating carrier RNA interference, this workflow enables the reliable quantification of low-frequency variants, supporting clinical research in early detection, therapy monitoring, and minimal residual disease assessment.

#7838 Innovative biomarker discovery: A non-invasive, comprehensive tumor characterization approach with plasma and urine from breast cancer patients.

Ivonne Nel, Ekaterina Firsova, Laura Weydandt, Bahriye Aktas

Dept. of Gynecology, Leipzig University, Medical Faculty, Leipzig, Germany

Background: Circulating cell-free DNA (cfDNA) profiling from blood plasma has demonstrated considerable potential for clinical applications in breast cancer, yet urinary cfDNA remains less explored. In a previous pilot study of plasma-derived and matching urinary cfDNA (n=30), we have found plasma and urines may be complementary liquid biopsy samples for molecular profiling.
Methods: In this study, we expand to a larger patient cohort. To enhance the sensitivity of the assay, we utilized direct preservation with Urinary Analyte Stabilizer, which led to improved yield and quality of cfDNA from urine samples. We conducted an extensive analysis of 150 matched plasma and urine samples from breast cancer patients utilizing QIAGEN's QIAseq Human Breast Cancer Panel, Element Biosciences' Aviti system, CLC secondary analysis and QCI Interpret bioinformatic solutions.Results: The cfDNA levels in urine were increased compared to plasma but with minimal correlation between the two body fluids. Compared to the pilot study the validation study achieved improved sequencing precision and enhanced variant detection and identification. Both cfDNA sources led to quantitatively and qualitatively comparable results with a median number of 137 vs. 131 somatic variants in plasma vs. urine. Further, 53% of the variants had a super low abundance with VAF< 3%. The variants were similarly distributed in matching plasma and urinary cfDNA samples (5 vs. 4% pathogenic, 15 vs. 17% likely pathogenic, 73 vs. 76% VUS). We found 571 shared variants among both body fluids with a median of 14 shared pathogenic variants per sample.
Conclusion: Unlocking the clinical utility of urinary cfDNA as a non-invasive approach could redefine liquid biopsy strategies, offering a more comprehensive and dynamic view of tumor evolution and therapeutic response.

#7839 EU Instand-NGS4P: Pre-analytical multimodal workflows for NGS research and future precision cancer care.

Franziska Kaiser[1], Daniela Mancarella-Langer[1], Daniel Groelz[1], Jorg Lindenmann[2], Iurii Mykoliuk[2], Paul Swatek[2], Peter Michael Abuja[3], Kurt Zatloukal[3], Kalle Guenther[1], Uwe Oelmueller[1]

[1]QIAGEN GmbH, Hilden, Germany,[2]Division of Thoracic and Hyperbaric Surgery, Medical University of Graz, Graz, Austria,[3]Diagnostic and Research Institute of Pathology, Medical University of Graz, Graz, Austria

INTRODUCTION: The EU-funded Pre-Commercial Research project Instand-NGS4P (GA no. 874719) aims to improve cancer research by developing complete workflows for NGS, from specimen collection through data analysis and reporting. Multimodal testing involves analyzing multiple specimen types from one individual and/or multiple analytes (e.g., RNA, circulating cell-free DNA [ccfDNA], gDNA) from a single specimen. This can improve diagnostics by combining complementary results and increase sensitivity for earlier cancer detection. We developed 23 novel integrated NGS workflows for research purposes. Here, we present six exemplary workflows that may inform future innovation in clinical applications.

METHODS: Different specimen types were obtained from lung cancer patients at the Medical University of Graz (Austria) under local ethics committee approval. Whole blood specimens were collected and stabilized in PAXgene® Blood ccfDNA Tubes. Urine specimens were collected and stabilized using the PAXgene Urine Liquid Biopsy Set. Tumor tissue was preserved by PAXgene Tissue or formalin fixation followed by paraffin embedding (PFPE and FFPE) as well as cryopreservation. Stabilized specimens were shipped to QIAGEN, Hilden, Germany. Blood ccfDNA and gDNA were extracted using the QIAamp® DSP Circulating Nucleic Acid Kit and QIAsymphony® DSP DNA Mini Kit. Urine cell-free DNA (cfDNA) was isolated upon arrival at QIAGEN and after additional storage using the QIAsymphony DSP Circulating DNA Kit. Tissue gDNA was extracted using the PAXgene Tissue DNA Kit for PFPE samples, QIAamp DNA FFPE Advanced UNG Kit for FFPE samples and QIAamp DNA Mini Kit for cryopreserved samples. Mutation analysis of cfDNA was performed with QIAseq® Targeted cfDNA Ultra Human Lung Cancer Panel, while gDNA was analyzed with QIAseq Targeted DNA Pro Human Lung Cancer Focus Panel. Sequencing runs were performed using the Illumina® NextSeq® 500/550 Mid Output Kit v2.5 (300 cycles).

RESULTS: The developed workflows encompass specimen collection, stabilization, storage, analyte isolation, quality control (QC), library preparation, and sequencing. A novel QC concept enables traceability and process standardization through systematic metadata documentation. Specimens yielded high-quality libraries and successful sequencing performance across all analyte runs. Comparative mutational profiling of blood ccfDNA, urine cfDNA, and tissue DNA revealed both overlapping as well as complementary variants in key tumor genes. This gain in molecular information may lead to further development of multimodal liquid biopsy-based approaches with urine as a valuable complementing specimen type.

CONCLUSIONS: Our NGS workflows support multi- and single-mode testing for cancer research. They are developed in alignment with recognized international regulatory principles to enable comprehensive validation from sample collection to assay output.

#7840 Evaluation of somatic mutations in cell-free DNA as noninvasive biomarkers of cancer in asymptomatic pregnant women.

Zhigang Kang[1], Amy E. Turriff[2], Yuelin Jack Zhu[1], Erica Pehrsson[1], Hsein-Chao Chou[1], Jun Wei[1], Kerstin Heselmeyer-Haddad[1], Paul S. Meltzer[1], Javed Khan[1], Liang Cao[1], Diana W. Bianchi[2]

[1]National Cancer Institute, Bethesda, MD,[2]National Human Genome Research Institute, Bethesda, MD

Prenatal cell-free (cf) DNA sequencing for fetal aneuploidy incidentally detects circulating tumor DNA in the plasma of asymptomatic pregnant women. Distinguishing the subset of women with malignant tumors detected by prenatal sequencing from those with benign conditions, such as uterine fibroids, is critical to maternal medical management. In this pilot study, prospectively collected blood samples from 65 pregnant or postpartum women with and without occult cancers were analyzed blindly for cfDNA somatic mutations in 275 cancer-associated genes. Somatic variants were common among all 65 women, however, when stringent mutation analysis criteria were applied, these data could independently differentiate women with cancer with a sensitivity of 80.6% and specificity of 100%. Mutation profiling complements radiographic imaging by clarifying tumor origin, evaluating malignancy in indeterminate cases, identifying actionable genomic alterations, and flagging high-risk patients for urgent intervention. These findings provide preliminary evidence that cfDNA somatic mutations could serve as an additional noninvasive biomarker of malignancy potentially aiding the management of women with prenatal cfDNA findings suspicious for cancer.

#7841 Evaluation of uProcess for detection of oncogene sequences in buffer and urine by qPCR following 3-minute capture and 5- minute purification procedure.

Floyd E. Taub[1], Sean Pearson[1], Suzin E. M. Wright[1], Charles (Preston) Neff[2]

[1]aiGENE, Inc, Aurora, CO,[2]CU Medical Center, Aurora, CO

Cell-free DNA (cfDNA) and circulating tumor DNA (ctDNA), found in blood and urine, have firmly established themselves as key analytes for the diagnosis of various cancers and defining therapy. Primary sequence and epigenetic markers within cfDNA are key in screening and monitoring for cancer. However, both screening and long-term monitoring have two major limitations - test sensitivity and individual participation. Even as NGS, ddPCR, and other methods continue to improve, they require large amounts of cfDNA to reliably detect rare ctDNA fragments. For example, a single BioRad ddPCR reaction can analyze 1 ug of short cfDNA, but a single tube of blood might yield on the order of 10ng, thus cutting potential sensitivity 100x. Additionally, participation is typically a severe impediment to screening and long-term monitoring. Historically, this has been a major obstacle, especially for screening. Travel to clinics, pain/difficulty of phlebotomy, and patient aversion to it limit participation. Urine offers a far more accessible alternative, but ctDNA concentrations are lower and current urine-based cfDNA/ctDNA collection methods have yet to achieve yields adequate for highly sensitive testing. A ug of cfDNA is required for detection at the 0.001% level. Herein, we test and optimize a system (uProcess) designed for at-home urine filtration; it was previously demonstrated to capture over 2 ug of cfDNA from 200 mL of urine on a mail-in filter cartridge. Compared to previous versions, we have reduced the elution volume 5-fold from 2.5 to 0.5 mls, allowing concentrated samples for downstream processing. We demonstrated that the improved device can efficiently concentrate oncogene sequences, in buffer or urine, into a small elution volume in under five minutes vs. typical procedures taking 90-120 minutes. We then detected KRAS and TP53 oncogenes by qPCR, underscoring that the method produces ctDNA suitable for downstream usage. Together, these findings support the potential of uProcess to significantly expand access to cfDNA/ctDNA testing, improve sensitivity, shorten cfDNA purification time, and overcome longstanding barriers to cancer screening or monitoring.

#7842 A new high fidelity PCR master mix with broad NGS workflow compatibility and superior performance in high sensitivity applications.

Margaret R. Heider, Kyle Vrtis, Jian Sun, Bradley W. Langhorst, Chen Song, Yan Wang, Nicole M. Nichols

New England Biolabs, Inc., Ipswich, MA

The widespread adoption of sensitive mutation profiling in precision oncology and the emergence of next-generation sequencing platforms with increasing data quality demand high accuracy library preparation tools. Additionally, PCR master mixes used in NGS library prep are often specialized for specific applications, sometimes necessitating inconveniently distinct library preparation workflows within the same lab depending on the use case. Here we introduce a new PCR master mix that can be used for a wide array of input amounts, sample types, and workflows including whole genome sequencing (WGS), library prep for hybrid capture, and post-hybrid capture amplification. Using whole genome sequencing of different DNA sample types and species, we demonstrate high library yield, uniform genome coverage, and consistent library insert size across a broad range of cycle numbers for both picogram and high nanogram levels of DNA input. Next, we applied this PCR master mix to hybrid capture workflows, achieving sufficient library yield for capture and robust amplification of post-capture libraries in the presence of streptavidin beads. Using tissue-extracted DNA and cell-free DNA (cfDNA) samples, we demonstrated the critical importance of fidelity to enable highly precise single nucleotide variant (SNV) and indel calling. As part of a library prep workflow that maximizes conversion and introduces minimal errors, this PCR master mix can enable more accurate and cost-effective somatic variant detection. This new PCR master mix is designed to be readily applied to most DNA library prep applications with broad input amount and cycle number compatibility. Our data emphasizes the benefits of a high-fidelity PCR master mix as part of a high conversion library prep workflow for sensitive variant detection and high accuracy sequencing platforms.

#7843 Integrated multiomics for deep molecular exploration of prostate cancer from urine.

Bhaven Mehta[1], Andrea O'Hara[1], Ethan Stancliffe[2], Tom Cohen[2], David Corney[1], Haythem Latif[1]

[1]GENEWIZ from Azenta Life Sciences, Burlington, MA,[2]Panome Bio, St. Louis, MO

Background: The omics era has greatly expanded the repertoire of approaches available to unravel the complexity underpinning human health, with the ability to rapidly characterize genomes, epigenomes, transcriptomes, proteomes and metabolomes from a wide range of sample types. Urogenital cancers, including prostate cancer, is the most prevalent cancer in men. Current early detection methods rely on blood screening of prostate-specific antigen (PSA), however, it has a high rate of false positives, resulting in the search for alternative biomarkers. Urine is an ultra-non-invasive analyte ideal for urogenital cancer detection, including prostate cancer. Cell free RNA/DNA (cfRNA/DNA), along with metabolomics directly from urine, is an ideal candidate for biomarker identification for use in diagnostics, treatment monitoring and tumor tissue of origin prediction.
Methods: Here we describe integrated metabolomics and RNA-Seq analysis from a series of prostate cancer affected and control urine samples. First, cfRNA from affected and control samples were isolated using a specialized method with efficient cfRNA recovery rate from urine. The cfRNA was then subjected to highly sensitive RNA-Seq to evaluate a series of prostate cancer biomarkers. The same urine samples were also subjected to metabolite profiling using multiple complementary LC-MS assays to deliver the highest quality untargeted metabolomics data. Both data types were used for integrated multiomics analysis.
Results: Urine proves to be an ideal ultra-non-invasive method for biomarker screening and detection. Integrated analysis across multiple data modalities, including transcriptomics and metabolomics, allows for holistic views of pathways and processes that are highly impacted, with increased statistical significance than any one modality alone.
Conclusion: Biomarker detection and multiomics analyses are critical to assess individuals in both pre- and post-treatment during therapeutic development and early-stage clinical trials. Urine offers a truly non-invasive approach that, when combined with omics tools, can provide comprehensive insight across urogenital patient cohorts.

#7844 Simultaneous identification of methylation and somatic variants can improve sensitivity for cancer detection and monitoring.

Tom Charlesworth, Cillian Nolan, Luke Sarre, Fabio Puddu, Angela Simeone, Aurelie Modat, Ermira Lleshi, Robert Crawford, Robert J. Osborne, **Thao Huynh**

biomodal Ltd, Cambridge, United Kingdom

There is increasing evidence that combining genetic and DNA methylation information in cancer research and diagnostics provides significant utility. For example, bi-allelic inactivation of tumour suppressor genes commonly occurs through a combination of somatic mutation at one allele and epigenetic silencing of the second allele and can be a key driver of cancer progression. In addition, gene fusions have an impact on DNA methylation patterns and DNA methylation changes can provide information on gene fusion status, even where the fusion event itself cannot be confidently identified in genetic sequencing data. Furthermore, combined genetic and epigenetic analysis of individual DNA fragments can increase sensitivity of somatic variant detection, which is particularly important in liquid biopsy applications. Here we analyse cell-free DNA (cfDNA) using 6-base sequencing with duet evoC, which calls genetic mutations and distinguishes between 5-methylcytosine (5mC) and 5-hydroxymethylcytosine (5hmC) with high accuracy. We leverage duet evoC to confidently identify circulating-tumor DNA (ctDNA) fragments in cfDNA, a method that can be generally applied to increase the sensitivity of MRD detection. We also demonstrate that bi-allelic inactivation of tumor suppressor genes in patient samples can be identified in a single assay. Further, we identify methylation patterns that are indicative of gene fusions or chromosomal rearrangements, opening the possibility of improving the sensitivity of gene fusion detection in clinical samples.

#7845 Dynamic plasma *KRAS* and *EGFR* ctDNA profiling identifies treatment response and nascent resistance in metastatic lung cancer.

Valentina Buzzi[1], Greta Berti[2], Michele Santillo[1], Arianna Belli[3], Giulia Favarato[4], Mauro Iannopollo[2], Elisabetta Rosi[3], Federico Lavorini[3], Sara Tomassetti[4], Annarosa Arcangeli[1], **Elena Lastraioli**[1]

[1]Universita degli Studi di Firenze - UniFI (University of Florence), Firenze, Italy,[2]Medical Oncology, S. Jacopo Hospital, Pistoia, Italy,[3]Pulmonology and Intensive Care Unit, Careggi University Hospital, Firenze, Italy,[4]Interventional Pulmonology Unit, Careggi University Hospital, Firenze, Italy

Background: Liquid biopsy enables minimally invasive tumor genomic assessment. We evaluated serial circulating tumor DNA (ctDNA) monitoring for KRAS and EGFR in metastatic lung cancer to characterize mutational dynamics, correlate changes with clinical events, and assess plasma testing for early resistance detection.
Aims: Describe longitudinal KRAS and EGFR plasma patterns during systemic therapy and relate ctDNA kinetics to treatment changes and outcomes.
Methods: Thirty-five metastatic lung cancer patients were prospectively enrolled (31.4% female; median age 70, IQR 41-84). Plasma was collected at baseline and, for 20 patients, at weeks 4, 8, 12 and 24 and thereafter until progression or death. KRAS and EGFR status was assessed with targeted ctDNA assays using the Idylla platform.
Results: Tissue-plasma concordance was fair to moderate for KRAS and EGFR (Cohen's kappa 0.35 and 0.43). Serial monitoring showed marked interpatient heterogeneity and dynamic shifts in mutant allele fractions. Two patients had early KRAS increases at week 4; one died and the other progressed to second-line therapy and developed a second KRAS codon 12 mutation (G12R alongside baseline G12C) at week 8, consistent with clonal diversification. Another patient showed oscillating KRAS detection—present at baseline and week 8 but absent at weeks 4 and 12—suggesting transient clonal suppression and re-expansion related to treatment scheduling. One patient's EGFR levels tracked therapy: high at baseline and week 4, cleared at week 8 after switching to Amivantamab, then reappeared at week 12 after treatment discontinuation for toxicity. EGFR mutations were observed in one patient only (8.3%); others remained EGFR wild type throughout follow-up.
Conclusions: Longitudinal plasma KRAS and EGFR testing captured evolving mutational landscapes that anticipated progression and reflected treatment effects, including emergence of secondary clones and transient suppression of mutant fractions. Serial ctDNA profiling is a pragmatic adjunct to tissue genotyping for early resistance detection and therapeutic guidance. Larger cohorts are needed to quantify predictive performance and integrate ctDNA kinetics into clinical decision algorithms.

: Real World Impact of Prognostic and Predictive Parameters
Poster Session

#7849 Real-world landscape analysis of circulating tumor DNA minimal residual disease as a clinical trial endpoint in breast cancer.

Momo Arai[1], Alaa Khalilaa[1], **Ahmed Elkhanany**[2]

[1]Alfaisal University, Riyadh, Saudi Arabia,[2]Baylor College of Medicine, Houston, TX

Background: Minimal Residual Disease (MRD) assessment via circulating tumor DNA (ctDNA) offers superior sensitivity over imaging for relapse detection and monitoring. In breast cancer, MRD identifies molecular relapse with a median 8.9-month lead time from prior studies, serving as an independent prognostic and potential predictive marker for outcome and therapy escalation.
Methods: A systematic ClinicalTrials.gov search (July 2025) yielded 133 trials; 124 met inclusion. Studies were stratified by endpoint hierarchy (primary vs. secondary), status, and methodology (tumor-informed, panel-based, methylation, or CTC/protein/tissue).
Results: Among 124 trials, MRD was primary endpoint in 56 (45%) and secondary in 66 (53%). Only 4 primary-endpoint trials have published results, while 52 are ongoing. Tumor-informed/patient-specific assays were the dominant modality (38%), followed by CTC/tissue (20%), fixed panels (17%), and methylation (7%); 18% were unreported. Published clinical utility (primary-endpoint trials). In metastatic guidance (NCT05079074), 85% of patients had baseline ctDNA positivity, and those receiving druggable mutation-guided therapy achieved improved progression-free survival (PFS) versus physician's choice (HR 0.45). In a prognostication cohort (NCT03792529), genomic profiling identified frequent TP53 (44%), PIK3CA (28.4%), and ERBB2 (24.8%) alterations; high ctDNA fraction and blood tumor mutational burden (bTMB) predicted shorter PFS in TNBC and HER2+ subtypes. In the relapse-prediction setting (NCT02797652), baseline ctDNA was detected in ~70% (21/30) of operable patients; post-operative ctDNA positivity was 100% predictive of distant metastasis, yielding 71.4% sensitivity for clinical relapses. In an early-detection setting (NCT05227261), among 9,024 individuals screened (0.48% positive), a multi-cancer test demonstrated 99.71% specificity, 70.83% sensitivity, 39.53% positive predictive value, and 99.92% negative predictive value. Monitoring and MRD-adaptive strategies. Serial ctDNA clearance in immunotherapy trials (e.g., NCT02644369) tracked survival, with 100% of patients achieving clearance remaining alive at a median 25-month follow-up. Active MRD-adaptive investigations now deploy randomization to escalation at molecular relapses (e.g., DARE/NCT04567420), single-arm escalation in MRD-positive HER2+ disease (e.g., NCT05388149), and clearance-based de-escalation (e.g., NCT06970912).
Conclusions: ctDNA-MRD integration in breast cancer trials is expanding rapidly, shifting to tumor-informed assays. Published data validate ctDNA as a potent prognostic tool (71.4% relapse sensitivity) and predictive biomarker (HR 0.45 intervention benefit). As evidence matures with ongoing randomized trials, assay standardization and actionability remains critical for clinical translation.

#7850 Real-world concordance analysis of functional drug sensitivity testing in solid cancers with prospective observational case series of pancreatic cancer.

Weng Tong Ho[1], **Masturah Rashid**[1], Jhin Jieh Lim[1], John Seng Hooi Low[2], Yugarajah Asokumaran[2], Shin Yee Wong[2], David Khie Siong Hii[2], Edward Kai-Hua Chow[1]

[1]KYAN Technologies, Singapore, Singapore,[2]OncoCare Cancer Centre, Selangor, Malaysia

Background:
Fluorouracil- and Gemcitabine-based combinations are the preferred early treatments of pancreatic ductal adenocarcinoma (PDAC). However, treatment choice is empirical due to the lack of reliable predictive biomarkers. We report an observational case series using Optim.AI™, a functional drug sensitivity testing (DST) platform, to identify the activity toward standard-of-care regimes and assess concordance with clinical response.
Methods:
Tumor samples from PDAC patients underwent ex vivo analysis using Optim.AI™ platform. Tumor cells were isolated and tested with a customized panel of chemotherapeutic and targeted agents, including standard-of-care treatment. Optim.AI™ assesses all possible combinations and ranks them by sensitivity for individual patients. Clinical responses were obtained from chart review, and concordance with ex vivo findings was assessed. To further evaluate performance across tumor types, 76 solid cancer cases were evaluated for Optim.AI™ functional testing were also analyzed. Retrospective concordance was determined by evaluating tumor cell viability responses generated by Optim.AI™ against the treatments previously administered to the corresponding patients.
Results:
Optim.AI™ reports were successfully generated for 95% of the samples with sufficient yield for testing. Pan-cancer retrospective analysis also demonstrated 91% concordance between Optim.AI™-reported sensitivities and prior clinical responses across the 76 solid tumor cases evaluated. Six PDAC patients underwent functional DST, with Optim.AI™ reports generated within a median turnaround of six days from sample collection. Substantial inter-patient variability in ex vivo drug sensitivity toward the standard-of-care was observed. Across six patients, there were seven assessable clinical outcomes corresponding to the combinations tested ex vivo. Optim.AI™ correctly predicted resistance to the prior or ongoing therapy in six out of seven instances (NCV > 0.5 defined as ex vivo resistance), resulting in a predictive accuracy of 85.7%. Furthermore, Optim.AI™ identified a combination regimen that was more sensitive than the treatments previously administered, underscoring its potential value in guiding more effective therapeutic options for refractory cases.
Conclusions:
This study highlights the feasibility and potential clinical relevance of Optim.AI™ in PDAC. Optim.AI™ revealed individualized drug response profiles, including cases in which standard treatments may be resistant, achieving a predictive accuracy of 85%. These findings are consistent with results from the pan-cancer retrospective concordance analysis.

#7851 Early-phase clinical trial referral and outcomes in breast cancer: A prospective screening cohort and a real-world Phase I program experience at Gustave Roussy..

Alessandra Spata[1], Matthieu Roulleaux-Dugage[2], Berenger Poirier[1], Christophe Massard[2], Sophie C. Postel-Vinay[2], Antoine Hollebecque[2], Madona Sakkal[2], Kaissa Ouali[2], Rastislav Bahleda[2], Yohann Loriot[2], Joana M. Ribeiro[2], Barbara Pistilli[1], Cyril Roussel-Simonin[2]

[1]Departement de Medecine Oncologique, Gustave Roussy Cancer Center, Villejuif, France,[2]Departement des Innovations Therapeutique et des Essais Precoces (DITEP), Gustave Roussy Cancer Center, Villejuif, France

Background: Early-phase clinical trials are increasingly relevant for metastatic breast cancer, but referral timing and benefit remain insufficiently documented.
Methods: We analyzed two complementary cohorts. The first comprised 231 consecutive metastatic breast cancer patients prospectively screened for early-phase trial consideration at Gustave Roussy. The second included all breast cancer patients who initiated treatment in a phase I trial (C1D1 cohort) since 2009. Baseline characteristics, treatment history, referral decisions, RECIST outcomes, progression-free survival (PFS), and overall survival (OS) were collected.
Results: In the prospective cohort (n=231), most patients had HR+/HER2- (54%) or TNBC (40%) disease. Only 18% underwent molecular profiling before referral review. Overall, 39% were referred to a phase-I trial, while the main reasons for non-referral were absence of available trial slots (37.3%), excessive prior treatment lines (36.4%), lack of measurable disease (7.4%) and brain metastases (6.2%). Patients entering phase I screening had received fewer prior therapies (median 3 vs 6) than those excluded, highlighting that late referral frequently precluded eligibility.In the C1D1 cohort (n=343), median age at treatment start was 52 years and patients had received a median of 3 prior lines of therapy. TNBC accounted for 48% of treated cases, followed by HR+/HER2- (45%) and HER2+ (7%). Most patients received targeted therapy (66%), immunotherapy (20%) or intratumoral therapy (8.1%). Median PFS and OS were 3.2 and 11.5 months. HER2-positive disease achieved the longest PFS (4.24 months), followed by HR+/HER2- (3.19 months) and TNBC (2.86 months). The overall response rate was 13.4% and the clinical benefit rate was 52.8%. The highest responses were observed in HER2-positive tumors (31.8%), whereas TNBC demonstrated the lowest (~7%). Targeted therapies achieved the best outcomes (median PFS 3.7 months), while intratumoral approaches showed limited benefit (2.1 months).
Conclusions: Most patients in the prospective cohort were referred late and became ineligible due to protocol-defined treatment history or disease burden. Early molecular profiling and proactive referral are essential to preserve eligibility. Patients who receive phase I treatment derive meaningful benefit, particularly with targeted approaches, supporting earlier integration of phase I programs in the breast cancer therapeutic sequence.

#7852 Tobacco, nicotine, cannabis, and alcohol use among LGBTQ+ patients with cancer: Real-world analysis at an NCI-Designated Comprehensive Cancer Center.

Min-Jeong Yang[1], Shahrzad A. Zamani[2], Matthew B. Schabath[2]

[1]Rutgers University - New Brunswick, New Brunswick, NJ,[2]H. Lee Moffitt Cancer Center and Research Institute, Tampa, FL

Background: Prior studies have described patterns of substance use, such as tobacco and alcohol use, that are elevated among sexual and gender minority (SGM) individuals with cancer. However, the findings have been limited to specific cancers and study designs (e.g., population-based survey). Real-world data can reveal important insights into the substance use behaviors among SGM cancer patients to meet the patients' needs and provide tailored cancer care. In this study, we conducted a real-world analysis on the association between substance use (tobacco, nicotine, cannabis, and alcohol) by SGM status.

Methods: This study included 110,072 cancer patients who completed a standard-of-care electronic patient questionnaire (EPQ) during their initial visit at the Moffitt Cancer Center (Tampa, FL). The EPQ captures patient-reported information on demographics (including sexual orientation and gender identity [SOGI]), medical history, family cancer history, lifestyle factors, use of complementary and alternative medicine, and quality of life. SGM and non-SGM patients were identified using the SOGI items. The outcome variables included (1) past and current tobacco and nicotine product use, (2) recent alcohol use, and (3) recent substance and non-medically indicated prescription medication use. Pearson's Chi-Square test was utilized; significance was determined by $p<0.05$.

Results: Approximately 3.1% of the population self-identified as an SGM. Compared to non-SGM patients, SGMs reported higher rates of current cigarette smoking (14.8% vs 10.7%; $p<.001$), smoking their first cigarette after waking up (within 5 minutes: 5.6% vs 4.7%; 6-30 minutes: 13.1 vs. 10.8%, $p<.001$), current pipe smoking (0.2% vs 0.1%, $p<.001$), current and former electronic cigarette use (4.0% vs 1.7% and 9.6% vs 4.3%, respectively, $p<.001$), alcohol use in the past year ($p<.001$), more number of drinks on the days of alcohol use ($p<.001$), and past 3-months cannabis use (4.7% vs 2.1%) along with sedatives and stimulants use ($p<.001$). However, SGM reported lower use of ever pipe (2.0% and 2.8%, $p<.001$), ever and current cigar ($p<.01$), ever and current smokeless tobacco ($p<.001$), and alcohol more than 9 days per month ($p<.01$).

Discussion: These data suggest that SGM cancer patients, compared to non-SGM cancer patients, present with higher use of tobacco, nicotine, cannabis, and alcohol. These results add to the existing literature by elucidating patterns of substance use among SGM cancer patients with heterogeneous cancer types. Further research is warranted on the patterns of substance use among subgroups of SGM patients and the potential need for systematic assessment and early intervention.

#7853 A seven-gene mutation signature predicts immunotherapy benefit in bladder cancer.

I-Cheng Huang, Chun-Nan Kuo

School of Pharmacy, College of Pharmacy, Taipei Medical University, Taipei, Taiwan

Introduction: Immunotherapy plays an important role in advanced bladder cancer. However, no mutation-based biomarker has been established to reliably predict immunotherapy benefit in bladder cancer. This study aimed to identify the gene mutation signature predicting immunotherapy efficacy.
Method: We retrieved genetic and clinical data of patients with bladder cancer and immunotherapy treatment from MSK-TMB cohort. We selected targeted mutation genes if they occurred in more than three patients, with a higher incidence rate in survival patients, and belonged to non-synonymous mutation. Based on the selected genes, we categorized patients into three groups: compound mutation, single mutation and wild-type group. We compared the efficacy on overall survival (OS) among the three groups. Tumor mutation burden (TMB) was then integrated with the selected gene mutation information for further survival analysis.
Result: A total of 215 patients from MSK-TMB cohort were included. The mean age was 67.1-year-old. The cohort consisted 116 (80.6%) males and the mean TMB was 11.7/megabase. Among 468 identified genes, seven genes were found following the selection criteria.The median OS was not reached, 19, and 11 months in compound mutation group, single group and wild-type group ($p < 0.001$ for compound mutation vs. wild-type group, 0.0063 for single mutation vs. wild-type group, respectively). After integrating TMB status, a survival advantage was observed among patients in the compound mutation with low TMB (compound-L) group. The median OS was NR, 13.5, and 9.0 months in the compound-L, single mutation with low TMB (single-L), and wild-type with low TMB (WT-L) groups ($p = 0.055$ for compound-L vs. single-L; $p < 0.001$ for compound-L vs. WT-L, respectively).
Discussion: These findings provide evidence that the seven-gene mutation signature has potential as a predictive biomarker for the efficacy of immunotherapy in metastatic bladder cancer. Furter validation and functional studies are warranted.

#7854 Prognostic impact of gain-of-function TP53 mutations on outcomes in HER2-negative advanced gastric cancer.

Jong-Ho Kim[1], Jwa Hoon Kim[2], Ji Won Lee[2]

[1]Korea University Research Institute for Medical Bigdata Science, Korea University College of Medicine, Seoul, Korea, Republic of,[2]Korea University College of Medicine, Seoul, Korea, Republic of

Background:
TP53 alterations are among the most prevalent genomic events across solid tumors, yet the biological and clinical heterogeneity of TP53 mutation types—particularly gain-of-function (GOF) variants—remains poorly defined in advanced gastric cancer (AGC). GOF mutations involving the DNA-binding domain can confer oncogenic properties beyond simple loss of tumor suppressor activity. We aimed to characterize the landscape of GOF and non-GOF TP53 mutations and evaluate their prognostic relevance in patients with HER2-negative AGC treated with first-line oxaliplatin-based chemotherapy.
Methods:
From 2017-2021, tumor tissues from 675 patients with AGC were sequenced. Among these, 409 patients with HER2-negative AGC receiving first-line FOLFOX (n=188) or XELOX (n=221) were included. Targeted sequencing was performed using CancerSCAN or K-MASTER v1.0/v1.1 NGS panels. GOF TP53 variants were prespecified (R175H, R248W, R248Q, R249S, R273H, R273L, R282W), with all remaining alterations classified as non-GOF. PFS and OS were assessed using Kaplan-Meier methods.
Results:
Among 675 patients, 409 patients with HER2-negative AGC were treated with first-line FOLFOX (n=188) or XELOX (n=221). TP53 mutation was identified in 115 (28.1%) of 409 patients; GOF (n=21, 5.1%) and non-GOF (n=94, 23.0%). The most common hotspot of GOF TP53 mutations was R175H (n=8), followed by R248W (n=7), R248Q (n=4), and R273H (n=2). With a median follow-up duration of 22.7 months, the median progression-free survival (PFS) with FOLFOX/XELOX and overall survival (OS) of 409 patients were 5.1 and 21.8 months, respectively. Patients with TP53 mutated AGC showed significantly shorter PFS than those with wild-type TP53 mutation (median 4.8 vs. 5.3 months, *P*=0.049). There were no significant differences in PFS between GOF TP53 and non-GOF TP53 mutated AGC (median 4.9 vs. 4.8 months, *P*=0.680). There were no significant differences in OS between TP53 mutated and wild-type AGC (18.4 vs. 22.0 months, *P*=0.261). Median OS seemed to be numerically shorter in patients with GOF TP53 mutated AGC compared to those with non-GOF TP53 mutated and wild-type AGC (15.7 vs. 19.3 vs. 22.0 months, *P*=0.442).
Conclusions:
TP53 mutations—including biologically aggressive GOF variants—were identified in nearly one-third of HER2-negative AGC patients. Although statistical significance was not achieved, GOF TP53 mutations demonstrated a consistent pattern toward inferior survival, suggesting their potential role as poor-prognostic genomic biomarkers in chemotherapy-treated AGC. Larger prospective analyses integrating molecular subtypes and immunologic signatures are warranted to clarify the therapeutic and biological relevance of TP53 functional subclasses.

#7855 Transcriptomic profiling of Ki67 expression in melanoma patient specimens reveals distinct immune signatures.

Eleanor A. Fallon[1], Kei Kawashima[2], Kazuaki Takabe[2]

[1]Surgical Oncology, Roswell Park Comprehensive Cancer Center, Buffalo, NY,[2]Roswell Park Comprehensive Cancer Center, Buffalo, NY

Background: The Ki67 gene (MKI67) is clinically relevant as a marker of high cellular activity in melanoma among other cancer subtypes. We hypothesized that transcriptomic profiling of human melanoma tissue as stratified by MIK67-high and MKI67-low expression may correlate with immune signatures of biologic activity and with clinical outcomes.
Methods: Analyzed tumor tissue included subcutaneous melanoma metastatic sites and lymph nodes (GSE22153 n=57), tumor biopsies (GSE65904 n=214), The Cancer Genome Atlas (TCGA n=443), pre-ICB biopsies (GSE78220 n=28), and pre-treatment plus on-treatment mixed Immune Checkpoint Blockade (ICB) cohorts (GSE91061 n=65). Median MKI67 expression was utilized to stratify the groups. The xCell platform was utilized to analyze cellular subsets. Hallmark gene sets within the Molecular Signatures Database (MSigDB) were utilized for the Gene Set Enrichment Analysis (GSEA). The immune subtype classification as described by Thorsson *et al.* was utilized.
Results: The MKI67 transcriptomic expression correlated with highly proliferative genesets including E2F targets, G2M checkpoint, mitotic spindle, and MYC targets v1/v2 (|NES|>1.5 and FDR < 0.25 for all pathways). Within the TCGA cohort, the proliferative and wound healing pathways were enriched ($p<0.05$), further supporting the concept that Ki67-high is indeed indicative of greater cell turnover and activity. Interestingly, silent and non-silent mutation rates were higher in the MKI67-high group ($p=0.00187$ and 0.00262, respectively) but this was not the case for neoantigens ($p=0.163$). On Chi-squared analysis, the TCGA dataset (n=441) demonstrated an association between MKI67-high expression (n=220) and KIT mutations (n=13, $p=0.043$), as well as CDKN2A mutations (n=20, $p=0.004$). On xCell analysis, Th1 cells demonstrated MKI67-high expression was associated with Th1 cell infiltration in the TCGA and GSE65904 cohorts ($p<0.05$), but this associated was weaker for Th2 cells. There were no statistically significant differences across the groups in terms of clinical features such as race, gender, anatomic site or melanoma stage (e.g. T, N) as relating to Ki-67 expression. Overall Survival (OS) and Disease-Free Survival (DFS) were both associated with lower MKI67 expression at the 100-month time point ($p=0.0004$ and $p=0.0177$, respectively), but this difference was lost on later clinical follow-up.
Conclusions: We have herein utilized analysis of the MKI67 transcriptome as a means to interrogate the underlying molecular biology of melanoma tumors as they relate to the tumor immune microenvironment and clinical outcomes. MKI67 expression correlates with a unique constellation of gene enrichment and immune infiltration as well as tissue mutations and warrants further investigation as a potential tool for clinical decision-making.

#7856 Prevalence and association of clonal hematopoiesis with cardiovascular health in patients of the Avera sequencing and analytics protocol (ASAP) Study.

Mikayla Bendix[1], McKenna Perrin[2], Ryan Vaca[2], Padmapriya Swaminathan[2], Crystal Hattum[2], Shakeel Mir[3], Lucia Speroni[3], Emily Teslow[3], David Starks[2], Benjamin Solomon[2], William Spanos[2], Rachel Elsey[2], Tobias Meissner[2]

[1]Sanford School of Medecine, University of South Dakota, Vermillion, SD,[2]Avera Cancer Institute, Sioux Falls, SD,[3]Tempus AI, Chicago, IL

Introduction: Clonal Hematopoiesis (CH) refers to age-associated somatic mutations in hematopoietic stem cells. CH may be incidentally discovered in oncology patients via next-generation sequencing. Cancer therapies such as cytotoxic chemotherapy and radiation can accelerate the development or expansion of CH, particularly in genes associated with therapy-related myeloid neoplasms. Certain CH variants are also linked to increased cardiovascular (CV) risk. Understanding which patients are at higher risk of poor CV outcomes is an underrecognized threat to long-term cancer survivorship.

Methods: This retrospective cohort study of Avera Sequencing and Analytics Protocol (ASAP; NCT05142033) patients used Tempus xF+, a cell-free DNA liquid biopsy panel (~1.8 Mb) that detects single-nucleotide variants and insertions/deletions across 523 genes, including all tests completed prior to March 2025. CH classification was based on mutations in 17 commonly associated genes. Data on demographics, CV outcomes, (e.g., stroke, hypertension, angina, myocardial infarction, heart failure, arrhythmias, valvular heart disease, and venous thrombosis), cancer characteristics, and labs were extracted from the EMR using ICD-10-based SQL queries. Statistical analyses evaluated differences by presence of CH.

Results: A total of 456 patients were included in the final analysis. 197 (43%) patients were identified as CH-positive. The most frequently mutated genes were DNMT3A, TP53, and PPM1D. Results supported that CH is an age-associated condition, with prevalence rising from 11% in patients under 50 years old, to 30% among those aged 50-59, 42% in the 60-69 age group and reaching 56% in patients over 70. CV events were observed in 72.6% of CH patients, compared to 57.5% of non-CH patients. Among CH-positive individuals, the average VAF was 8.4% (0.3% - 77.0%) for those with CV events, versus 7.6% (0.3% - 51.6%) for those without. Consistent with existing literature, TET2 and ASXL1 mutations conferred the highest probabilities of developing CV outcomes. Pancreatic (OR 5.9, $p = 0.2$), lung (OR 4.1, $p = 0.02$), and esophageal (OR 3.5, $p = 0.6$) cancers exhibited strong but variably significant associations with CV risk, potentially limited by sample size.

Conclusion: Our findings are consistent with previously reported data showing higher rates of CV outcomes in patients with CH in this oncology patient cohort. Some limitations of this study include the retrospective, single cohort design, the use of correlational data, and potential selection bias for study inclusion. This data supports the need for development of cardiology referral guidelines to reduce morbidity and mortality of CV outcomes in oncology patients where CH mutations are identified by liquid biopsy testing.

#7857 Multi-modal real-world data uncovers predictors of clinical response to TOP1i and optimizes ADC strategies in colorectal cancer.

Alireza Tafazzol[1], Sebastian Cruz-Gonzalez[1], Xu Shi[1], Zoltan Dezso[1], Douglas E. Kline[2], Jack Chen[3], Peter J. Ansell[4], Relja Popovic[5], Rong Chen[5], Josue Samayoa[5], Xi Zhao[1], Weilong Zhao[1]

[1]Quantitative Medicine and Genomics, AbbVie, South San Francisco, CA,[2]Oncology Discovery Research, AbbVie, North Chicago, IL,[3]Precision Medicine, AbbVie, South San Francisco, CA,[4]Precision Medicine, AbbVie, North Chicago, IL,[5]Quantitative Medicine and Genomics, AbbVie, North Chicago, IL

Real-world data (RWD) encompassing diverse treatment regimens offers a valuable opportunity to identify predictive biomarkers of response and resistance across broad patient populations. Although data from clinical trials with antibody-drug conjugate (ADC) therapies remains limited, analysis of large standard-of-care cohorts offers valuable insight into chemotherapy resistance. For example, irinotecan—a widely used topoisomerase I inhibitor (TOP1i) in metastatic colorectal cancer (CRC) regimens—serves as a model to infer potential resistance to ADCs that utilize TOP1i payloads and the feasibility of combination strategies.

We analyzed ConcertAI PT360® electronic health records linked to Caris Life Sciences genomic data for 810 CRC patients with available clinical responses and pre-treatment samples to investigate irinotecan response and resistance mechanisms. Patients were classified into responder (R; n = 241), non-responder (NR; n = 308), acquired resistance (AR; n = 181, transition from R to NR), and stable disease (SD; n = 80). Response to irinotecan was associated with significantly better overall survival ($p < 0.0001$), with median OS of 106, 87, 73, and 47 months for R, SD, AR, and NR, respectively. Response classifications and transcriptomic data were independent of covariates such as ECOG score, diagnostic stage, ethnicity, sex, or age. Most patients were microsatellite stable with low tumor mutational burden.

Gene expression and mutation profiling revealed upregulation of mucins (*MUC5AC*, *MUC2*) and enrichment of *KRAS* mutations in NR, indicating a mucinous CRC subtype resistant to irinotecan. Conversely, *TOP1* gene amplification and increased expression were more frequent in R. Pathway analysis indicated higher inflammation and pre-existing immune activity in R/AR versus NR, especially B cell immunity. Gene signatures of tertiary lymphoid structures were also elevated in R/AR, further linking to B-cell immunity. Longitudinal samples revealed enhanced anti-tumor immune signatures post treatment, including dendritic cell activation, upregulated antigen presentation, and elevated interferon-gamma signaling. Additionally, we utilized an innovative *in silico* CRISPR knockout machine learning model on curated RWD to identify potential novel targets to overcome irinotecan resistance.

This study leveraged a rigorously curated multi-modal RWD cohort of CRC patients treated with irinotecan to elucidate mechanisms of clinical response and resistance. Enrichment of immune activation pathways in irinotecan responders suggests that baseline tumor microenvironment may predict outcome, while increased immune signatures post-treatment indicate that combining immunotherapy could enhance responses. These findings provide insights into the biomarkers associated with systemic TOP1i and may inform further clinical development of TOP1i-ADCs.

#7858 Machine learning predicts retinoblastoma (Rb) function in real-world small cell lung cancer patients.

Sana Parveen[1], Neshatul Haque[2], Emma T. Corcoran[3], Sebastia Franch-Exposito[3], Prerna Jain[3], Jacob Mercer[3], Anthony J. Trimboli[4], Gustavo W. Leone[4], Navonil de Sarkar[4], Abdul R. Naqash[5], Christine M. Lovly[6], Paul Fields[3], Hui-Zi Chen[1]

[1]Division of Hematology & Oncology, Department of Medicine, Medical College of Wisconsin, Wauwatosa, WI,[2]Linda T. and John A. Mellowes Center for Genomic Sciences and Precision Medicine, Medical College of Wisconsin, Wauwatosa, WI,[3]Tempus AI, Chicago, IL,[4]Department of Pathology, Medical College of Wisconsin, Wauwatosa, WI,[5]Department of Medicine, The University of Oklahoma, Oklahoma City, OK,[6]Department of Medical Oncology & Therapeutics Research, City of Hope Comprehensive Cancer Ctr., Duarte, CA

Inactivation of the retinoblastoma (Rb) tumor suppressor has long been considered a molecular hallmark of small cell lung carcinoma (SCLC), an aggressive form of bronchogenic, smoking-induced lung cancer with an extremely poor prognosis. Currently, SCLC can be classified into the following molecular subtypes: ASCL1, NEUROD1, POU2F3, and Inflamed. We analyzed a real-world cohort of ~1,400 SCLC tumors sequenced with both Tempus xT (DNA sequencing) and xR (RNA sequencing) and assigned them to molecular subtypes based on non-matrix factorization. Interestingly, we determined that *RB1* alterations (e.g. single nucleotide variants, insertions/deletions) were not detected in approximately 30% of the Tempus SCLC cohort, regardless of tumor molecular subtype. However, absence of *RB1* genomic alterations does not guarantee Rb protein function in SCLC, as alternate mechanisms such as *RB1* promoter hypermethylation may result in gene silencing and loss-of-function (LOF), along with intronic splicing mutations that may not be well captured in probe-based methods. Therefore, we developed a machine learning model (Nested Random Forest) to predict Rb LOF in the Tempus SCLC cohort. We trained our model using 21,656 features including genomic, transcriptomic and clinical variables from 409 Tempus SCLC patients (cross-validation AUC 0.924 ± 0.020), whose tumors were either (1) *RB1*-altered and had low *RB1* expression (defined as less than 25th percentile of expression of *RB1*-altered samples) or (2) *RB1* wild-type and had high *RB1* expression (defined as greater than 75th percentile of expression of *RB1* wild-type samples). We then applied the model to remaining N=1,224 SCLC tumors in the Tempus dataset. Surprisingly, our model predicted that ~30% (N=241) of *RB1*-altered tumors (N=837) had an Rb wild-type or functional phenotype. This finding contradicts the notion that all *RB1* genomic aberrations lead to loss of Rb pathway activity. Conversely, our model predicted that a proportion of *RB1* wild-type tumors had Rb LOF, due to mechanisms such as *CDKN2A* (*p16^{INK4a}*) deletion. Furthermore, we evaluated the frequency of predicted Rb function in the four SCLC subtypes. Our results showed that approximately one half of POU2F3 and Inflamed tumors had predicted Rb function, while approximately only 20% of ASCL1 and NEUROD1 tumors had predicted Rb function. In conclusion, our machine learning model predicted that a considerable number of real-world SCLC patients may contain a functional Rb pathway despite having genomic alterations in *RB1*. The impact of our finding on clinical outcomes including response to first-line chemotherapy and immunotherapy in real-world SCLC patients is currently being evaluated.

#7859 Exploring multilevel risk factors for metabolic dysfunction-associated steatotic liver disease (MASLD) in an electronic health record (EHR)-based cohort.

Janet N. Chu[1], Mindy Hebert-Derouen[2], Alison Canchola[3], Alyssa Cortella[3], Pushkar Inamdar[3], Hashem B. El-Serag[4], Scarlett L. Gomez[5], Salma Shariff-Marco[6]

[1]Medicine, UCSF- University of California, San Francisco, San Francisco, CA,[2]Department of Public Health Sciences, New Mexico State University, Las Cruces, NM,[3]Epidemiology & Biostatistics, UCSF- University of California, San Francisco, San Francisco, CA,[4]Baylor College of Medicine, Houston, TX,[5]Epidemiology & Biostatistics, UCSF - University of California San Francisco, San Francisco, CA,[6]Epidemiology and Biostatistics, UCSF - University of California San Francisco, San Francisco, CA

Background: MASLD is a growing risk factor for liver cancer. Few studies have examined multilevel risk factors contributing to MASLD disparities, particularly the impact of neighborhood attributes. Elucidating multilevel risk factors can help identify groups relevant for targeted interventions to mitigate liver disease, including liver cancer.
Methods: Our EHR-based cohort included adults with at least one in-person visit between 2000-2017 to Kaiser Permanente Hawai'i. From the EHR, we extracted data on patient sociodemographic characteristics; diagnostic codes; medication prescriptions; and lab results. Patient observations were appended to census tract-level neighborhood SES (nSES). The outcome was incident MASLD, defined using ICD-codes with follow-up until 12/31/2017. We used multivariable Cox proportional hazards regression to explore factors associated with incident MASLD; models were adjusted for baseline year and decile of number of encounters. Model 1 included sociodemographic variables (i.e., sex, race/ethnicity, English proficiency); in Model 2 we retained sociodemographic variables which were multivariably statistically significant and added clinical characteristics (i.e., body mass index [BMI], smoking history, hypertension, diabetes, and hyperlipidemia); and in Model 3 we retained clinical characteristics which were multivariably statistically significant and added nSES.
Results: Of 439,709 patients, 8,339 had incident MASLD during 18,350 person-years of follow up. In Model 1, males had higher risk of developing MASLD than females. Compared to non-Hispanic White individuals, those who identified as Chinese, Japanese, Korean, multiracial, or Hispanic had higher risk (HR range 1.08-1.83), and as Native Hawaiian, Pacific Islander, or Black had lower risk of MASLD (HR range 0.54-0.78). Limited English proficiency was associated with increased MASLD risk (HR= 1.52, 95% CI 1.30-1.78). In model 2, overweight and obese BMI, ever smoking, elevated triglycerides, low HDL, and diabetes were associated with higher MASLD risk (HR range 1.02-1.99). In Model 3, nSES was not statistically significantly associated with MASLD risk when added to sociodemographic and clinical factors. Significant factors in prior models remained independently associated with MASLD risk, except for smoking.
Discussion: Our study provided critical disaggregated data on MASLD risk for ethnic groups that are typically understudied. We found that among this diverse cohort, disparities in MASLD incidence persist, despite adjusting for other sociodemographic, clinical, and neighborhood SES. Future efforts to reduce MASLD burden may consider focusing on these ethnic groups at higher risk. Furthermore, future studies should explore the role of other neighborhood social and built attributes such as food environment and access to parks.

#7860 Fusion gene machine learning models improve clinical outcome prediction of hepatocellular carcinoma.

Jian-Hua Luo[1], Silvia Liu[1], Yanping Yu[2]

[1]University of Pittsburgh, Pittsburgh, PA,[2]Assistant Professor, Dept. of Pathology, University of Pittsburgh, Pittsburgh, PA

Hepatocellular carcinoma is one of the most lethal malignancies for humans. Assessing the clinical outcomes of HCC remains challenging. In this study, we analyzed a panel of 20 fusion genes in 200 hepatocellular carcinoma (HCC) samples to predict the recurrence and survival rates of HCC patients undergoing surgical interventions using machine learning models. The results showed that fusion genes, Milan criteria, serum α-fetal protein (AFP), and pathology grade had moderate predictive accuracy for HCC recurrence. However, the combination of selected fusion genes with these clinical parameters significantly enhanced the prediction accuracy of each parameter. When models of fusion genes were applied to predict the 3-year survival rate of HCC patients, they outperformed the Milan criteria, pathology grade, and serum AFP. The combination of a fusion gene panel with Milan criteria, pathology grade, or serum AFP yielded significantly improved results compared to those produced by these clinical parameters alone. As a result, examining the fusion gene status of HCC samples may hold promise as a new and improved approach to assessing the clinical outcomes of this disease.

#7861 Translating temporal multi-disease pathways in multiple cancer types using real-world clinical data.

Md Ashad Alam

Ochsner Health System, New Orleans, LA

Although several pre-cancer comorbidities have been described, the role of medically interpretable preceding diagnoses as multi-disease pathways (MDPs) remains underexplored in the U.S. population. We analyzed electronic health record data from Ochsner Health (Louisiana) spanning 2013-2022, encompassing more than 4.1 million patients. Disease trajectories were identified by analyzing pairs of diagnoses that exhibited significant temporal correlations. To construct three-diagnosis trajectories, we merged overlapping pairs (e.g.,D1→D2 and D2→C (cancer) were combined to form D1→D2→C). For each patient, all three-step diagnostic sequences were extracted, and the pairs within each triplet were tested for directiona lsignificance. We applied this analysis to ten high-burden cancers, breast, melanoma, lung, prostate, pancreatic, liver, bladder, leukemia, ovarian, and colorectal, which yielded 501 (11 significant), 507 (10),194 (2), 349 (8), 49, 132 (3), 111, 84, 39, and 155 directional associations, respectively. Significant directional trajectories to cancer included breast lump → abnormal breast imaging, joint disorder → overuse/soft-tissue disorder, joint disorder → shoulder lesion, acute sinusitis → acute upperrespiratory infection, osteoporosis → other bone disorder, knee osteoarthritis → joint disorder, majordepression → anxiety disorder, acute pharyngitis → acute upper respiratory infection, cough → breathingab normality, joint disorder → other soft-tissue disorder, and finger/toe deformity → bonedensity/structure disorder preceding breast cancer; acute viral hepatitis → liver fibrosis/cirrhosis, chronicviral hepatitis → liver cirrhosis (unspecified), and liver fibrosis/cirrhosis → other liver disease precedingliver cancer; urinary frequency → sexual dysfunction, joint disorder → shoulder lesion, benign prostatichyperplasia → abnormal tumor markers, knee osteoarthritis → joint disorder, erectile dysfunction →abnormal tumor markers, joint disorder → other soft-tissue disorder, obstructive/reflux uropathy →benign prostatic hyperplasia, and osteoarthritis → joint disorder preceding prostate cancer; osteoarthritis of knee → joint disorder → soft-tissue disorder preceding lung cancer; and actinic keratosis → seborrheickeratosis, osteoarthritis → joint disorder, allergic/vasomotor rhinitis → chronic sinusitis, and joint disorder→ soft-tissue disorder preceding melanoma cancer. An important consideration in this approach is that while these MDPs are statistically significant, they may not represent causative associations. For example, conditions such as erectile dysfunction may lead to age-appropriate screening in a high cancer risk population. Likewise, a diagnosis of breast lump may directly imply cancer prior to formal diagnosis. Biologically plausibility of all significant MDPs should be investigated individually.

#7862 Population analysis and immunologic landscape of melanoma in people living with HIV.

Lindsay Barger[1], Derek Wang[2], Ashley Saravia[1], Valeria Mezzano-Robinson[3], Gyles Ward[3], Cynthia Loomis[3], Carly Feldman[4], Madalina Tuluc[4], Rino S. Seedor[4], Peter J. Gaskill[1], Anna E. Coghill[5], Gita Suneja[6], Iman Dehzangi[2], Jenna Hope[1], George Jour[3], **Gabriele Romano**[1]

[1]Drexel University College of Medicine, Philadelphia, PA,[2]Rutgers University, Camden, NJ,[3]NYU Langone Health, New York, NY,[4]Thomas Jefferson University, Philadelphia, PA,[5]Moffitt Cancer Center, Tampa, FL,[6]Huntsman Cancer Institute, Salt Lake City, UT

Purpose: To dissect the clinical and immunological features of people living with HIV (PLWH) diagnosed with melanoma, who have consistently shown worse outcomes than HIV-negative individuals (PLw/oH) with the same cancer.
Experimental Design: We analyzed electronic health records from 1,087 PLWH and 394,437 PLw/oH with melanoma. Demographic and clinical characteristics were compared. Spatial immune transcriptomics (72 immune-related genes) was performed on melanoma tumor samples (n=11), with downstream validation using multiplex immunofluorescence (n=15 PLWH, n=14 PLw/oH).
Results: PLWH were diagnosed at a younger age, had greater representation of Hispanic and Black individuals, and showed reduced survival. They also had a markedly increased risk of brain metastases. PLWH experienced significant delays in initiating immune checkpoint inhibitor (ICI) therapy and had worse post-ICI survival, even after balancing covariates. Spatial transcriptomics revealed a more immunosuppressive tumor microenvironment in PLWH, with increased transcription of immune checkpoints (PD1, LAG3) and reduced antigen-presentation markers (HLA-DRB, B2M), with distinct spatial distributions in tumors and surrounding microenvironments. Multiplex immunofluorescence demonstrated features of an exhausted $CD8^+$ T cell compartment, including enrichment of $PD1^{int}LAG3^-$ and $PD1^{int}LAG3^+$ subpopulations, and a significant accumulation of myeloid-derived suppressor cells ($CD11b^+$ $HLA\text{-}DR^-$ $CD33^+$).
Conclusions: Melanoma in PLWH is associated with distinct clinical and immunological features, including delayed ICI treatment, reduced survival, and an immunosuppressive microenvironment with exhausted $CD8^+$ T cells and expanded myeloid-derived suppressor cells. These findings suggest that chronic HIV infection may impair antitumor immunity in melanoma. Targeting the pathways identified here may improve therapeutic responses and outcomes in this population.

#7863 Aspirin and celecoxib use and overall survival in ER+/HER2- metastatic breast cancer: A large real-world cohort analysis.

Mostafa Eysha[1], Mohanad Elchouemi[1], Harshitha Popuri[1], Gaurav Periapattanam[1], Arsalaan Asad[2], Yasmin Youssef[3], Ahmed Elkhanany[4], Sumit Gaur[5]

[1]Texas Tech Univ. Foster School of Medicine, El Paso, TX,[2]University of Texas Medical Branch John Sealy School of Medicine, Galveston, TX,[3]Mansoura university, faculty of medicine, Mansoura, Egypt,[4]Baylor College of Medicine, Houston, TX,[5]Texas Tech Univ. Foster School of Medicine,, El Paso, TX

Background: Endocrine resistance in ER+/HER2- breast cancer (BC) is frequently linked to PI3K-AKT-mTOR pathway dysregulation. While aspirin benefits *PIK3CA*-mutant colorectal cancer, randomized trials of adjuvant endocrine therapy ± COX inhibition in BC failed to demonstrate survival benefits, potentially due to lack of biomarker selection. Given that ER+/HER2- metastatic disease is clinically enriched for PI3K pathway activation, we hypothesized that real-world aspirin and celecoxib (COXI) use might be associated with improved survival in this population. This study evaluated the association between COXI use and survival in ER+/HER2- metastatic BC, utilizing this subtype as a clinical proxy for *PIK3CA* pathway activation.

Methods: Using the TriNetX US Collaborative Network, we identified patients with ER+/HER2- metastatic BC via ICD-10 codes and biomarker fields. Patients were grouped into three prevalent-user cohorts based on post-diagnosis medication use: (1) control (no use); (2) single-agent COXI; and (3) combination COXI (aspirin and celecoxib). Propensity score matching (1:1) was utilized to balance cohorts for demographics, comorbidities, cardiovascular risk factors, and concomitant systemic therapies (endocrine agents, chemotherapy, and CDK4/6 inhibitors). We estimated Hazard Ratios (HRs) for overall mortality and Major Adverse Cardiovascular Events (MACE: myocardial infarction, stroke, and cardiovascular death).

Results: After matching, 14,955 patient pairs (Single-agent vs. Control) and 1,913 patient pairs (Combination vs. Control) were analyzed. The Combination cohort demonstrated the lowest mortality hazard (HR, 0.429; 95% CI, 0.379-0.486; $p < 0.0001$). The Single-agent cohort also showed a significantly lower mortality hazard compared to controls (HR, 0.629; 95% CI, 0.604-0.656; $p < 0.0001$). Conversely, the hazard of MACE was significantly higher in both treated groups compared to controls (Combination: HR, 1.492; Single-agent: HR, 1.641; both $p < 0.0001$).

Conclusion: In this large real-world cohort of ER+/HER2- metastatic breast cancer, aspirin and/or celecoxib use was associated with a graded improvement in overall survival. This association persisted despite the treated groups showing a significantly higher risk of MACE. This difference, even after PSM, reflects residual confounding due to bias by indication. This suggests the survival improvement is driven by a genuine oncologic effect, mitigating concerns about "healthy user" bias. However, findings must be interpreted cautiously given the observational design and potential for biases such as immortal time bias and residual confounding. *PIK3CA* genomic data was sparse in this dataset, precluding genotype-stratified analyses. These results support further investigation via prospective, biomarker-driven trials specifically targeting *PIK3CA*-associated ER+/HER2- disease.

#7864 Real-world overall survival and healthcare utilization with CDK4/6 inhibitor based regimens versus chemotherapy in previously treated HR+/HER2+ metastatic breast cancer: A TriNetX Global Collaborative Network analysis.

Mostafa Eysha[1], Usman Hussain[1], Mohanad Elchouemi[1], Mariah Black[1], Sharon Siby[1], Wanyu Zhang[2], Arsalaan Asad[3], Ahmed Elkhanany[4]

[1]Texas Tech Univ. Foster School of Medicine, El Paso, TX,[2]Duke Universoty, Durham, NC,[3]UTMB John Sealy School of Medicine, Galveston, TX,[4]Baylor College of Medicine, Houston, TX

Background: In the phase II monarcHER trial, abemaciclib plus trastuzumab with or without endocrine therapy improved overall survival (OS) versus chemotherapy plus trastuzumab in heavily pretreated hormone receptor-positive (HR+)/HER2+ metastatic breast cancer. Robust real-world evidence (RWE) comparing CDK4/6 inhibitor-based regimens with chemotherapy in this setting remains limited.
Methods: We conducted a retrospective cohort study using de-identified electronic health records from the TriNetX Global Collaborative Network to compare two regimens in adults with highly pretreated HR+/HER2+ metastatic breast cancer: (1) CDK4/6 inhibitor plus endocrine and anti-HER2 therapy, and (2) chemotherapy plus anti-HER2 therapy. Prior exposure to anti-HER2 regimens was present, but explicit progression events and line counts were unavailable. The primary endpoint was overall survival (OS) up to 1200 days; secondary endpoints included neutropenia, heart failure (as a proxy for cardiotoxicity), and emergency department (ED) visits. Propensity score matching (1:1) was used to balance cohorts on demographics and comorbidities. Survival probabilities and hazard ratios (HRs) were estimated using Kaplan-Meier methods, log-rank tests, and Cox proportional hazards models.
Results: PSM resulted in 140 patients per cohort with balanced baselines. Median follow-up was 573 days for chemotherapy and 479 days for CDK4/6 inhibitor therapy. Over 1200 days, death occurred in 36.4% (51/140) of the chemotherapy cohort and 17.1% (24/140) of the CDK4/6 inhibitor cohort, a 19.3% absolute risk reduction (95% CI, 9.2-29.4) favoring CDK4/6 inhibitors. Over the 1200-day, CDK4/6 inhibitor-based regimens significantly lowered the hazard of death compared to chemotherapy (HR, 0.52; 95% CI, 0.32-0.84; p=0.007). Neutropenia and heart failure were similar, but ED visits were more frequent with chemotherapy (HR 1.59; p=0.012).
Conclusions: In this real-world, propensity-matched analysis of previously treated HR+/HER2+ metastatic breast cancer, CDK4/6 inhibitor-based endocrine and anti-HER2 therapy was associated with substantially lower mortality risk (HR 0.52; 19.3% absolute risk reduction) and reduced ED utilization compared with chemotherapy plus anti-HER2 therapy over a 1200-day window. These findings support the OS benefit seen in monarcHER and reinforce targeted endocrine strategies as clinically relevant alternatives to chemotherapy in heavily pretreated HR+/HER2+ metastatic breast cancer, despite the limitations of retrospective, non-randomized real-world evidence.

#7865 Survival profile of patients presented at technology-enhanced multidisciplinary cancer conferences.

Opuruiche Ibekwe[1], Carmelo Gaudioso[1], Quratulain Sabih[2], Han Yu[3], Peter Frederick[4], Ellis G. Levine[5], Chukwumere E. Nwogu[1]

[1]Thoracic Surgery, Roswell Park Comprehensive Cancer Center, Buffalo, NY,[2]Breast Surgery, University of Pittsburgh Medical Center, Pittsburgh, PA,[3]Biostatistics & Bioinformatics, Roswell Park Comprehensive Cancer Center, Buffalo, NY,[4]Gynecologic Oncology, Roswell Park Comprehensive Cancer Center, Buffalo, NY,[5]Breast Medical Oncology, Roswell Park Comprehensive Cancer Center, Buffalo, NY

Background: Emerging research suggests that multidisciplinary cancer conferences (MCCs) positively impact survival in cancer patients. This study aimed to assess the survival outcomes in technology-enhanced thoracic, gynecology and breast tumor boards.
Methods: We conducted a prospective study, pre vs post implementation of a tumor board technology platform, September 2020 to February 2022 in a comprehensive cancer center. Using data sourced from the cancer registry, we compared the survival rates of patients presented at the thoracic, gynecology, and breast MCCs with matched cases not presented at the MCCs. Comparisons were made using the Mann-Whitney U and Fisher's Exact test. Survival outcomes were summarized using Kaplan-Meier methods.
Results: A total of 214, 75, and 52 cancer patients presented at the thoracic, breast and gynecology MCCs, respectively, were matched with corresponding numbers of non-MCC cohorts. Patients in the thoracic MCC cohort had an increased overall survival compared with that of the non-MCC cohort (median time = 47.8 vs 37.2 months, p=0.013) and cancer-specific survival (median time = 77.9 vs 51.5 months, p=0.019). We found no significant survival benefit in the breast and gynecology MCCs or after implementation of the technology platform.
Conclusion: MCCs lead to improved survival outcomes in thoracic cancer patients. A larger sample size would be required to fully assess any potential survival impact in breast and gynecologic oncology patients. Our study did not show that the digital tumor board platform had an impact on the survival outcome for patients presented at any of the MCCs.

#7866 BMI- and subtype-specific molecular clusters reveal distinct obesity mechanisms in breast cancer across Nigerian and U.S. cohorts.

Oyomoare Osazuwa-Peters[1], Jovita Kokwesiga Byemerwa[1], Omolola Salako[2], Adetola Daramola[2], Olusegun Isaac Alatise[3], Gabriel Ogun[4], Tomi Akinyemiju[5]

[1]Population Health Sciences, Duke University School of Medicine, Durham, NC,[2]College of Medicine, University of Lagos, Lagos, Nigeria,[3]Obafemi Awolowo University, Ile-Ife, Nigeria,[4]University College Hospital, University of Ibadan, Ibadan, Nigeria,[5]Duke University School of Medicine, Durham, NC

Background: Obesity is a major breast cancer risk factor, yet its biological mechanisms remain poorly characterized in African populations. We hypothesized that distinct obesity-associated molecular signatures would differentiate obese from normal-weight Nigerian women and reveal subtype-specific patterns in U.S. women.
Methods: Targeted gene expression profiling (NanoString, 785 genes) was performed on tumors from 46 Nigerian women (MEND), and publicly available gene expression data from Women's Circle of Health Study (WCHS; n=367; African and European ancestry) were analyzed. Enrichment scores for obesity-related pathways (glycolysis, inflammation, Extracellular matrix (ECM) remodeling, adipokine signaling, insulin/IGF1 signaling, hypoxia, cholesterol biosynthesis) were computed using Gene Set Variation Analysis in R (v4.5.0) with KEGG and Reactome gene sets. Bipartite network clustering identified co-occurring mechanism clusters. Associations were tested for cluster membership with BMI using Firth logistic regression for MEND, and with subtype and ancestry using standard logistic regression for WCHS, adjusting for covariates (MEND: age, subtype, menopausal status; WCHS: age).
Results: MEND participants averaged 48.7 (10.6) years; WCHS averaged 54.07 (11.99) years. In MEND, three clusters emerged (Q=0.14, p<0.05): Cluster 1 (hypoxia, cholesterol biosynthesis), Cluster 2 (ECM remodeling, adipokine, insulin/IGF1 signaling), and Cluster 3 (glycolysis, inflammation). Overweight/obese women had higher odds of Cluster 2 (aOR=5.4, 95% CI: 1.3-31.3), while normal-weight women were enriched for Cluster 1 (0.12, 0.02-0.54). In WCHS, six enrichment scores yielded three clusters (Q=0.10, p<0.05): Cluster 1 (inflammation, hypoxia), Cluster 2 (ECM remodeling, insulin/IGF1 signaling), and Cluster 3 (adipokine signaling, glycolysis). Cluster membership did not differ by ancestry, but subtype associations (Luminal A reference) were striking: Cluster 1 strongly associated with Luminal A (Luminal B: 0.33, 0.18-0.61; HER2: 0.15, 0.06-0.34; Triple Neg: 0.19, 0.11-0.34), Cluster 2 with Luminal B (3.47, 1.8-6.9) and HER2 (4.09, 1.9-8.99), and Cluster 3 with Triple Negative (3.15, 1.78-5.73).
Conclusions: Obesity-linked mechanisms differ by BMI and subtype. ECM remodeling and growth factor signaling dominate obesity-related tumors, while hypoxia and lipid metabolism characterize normal-weight tumors. Subtype-specific clustering suggests heterogeneity beyond BMI. Findings highlight opportunities for precision prevention and treatment, including metabolic pathway targeting and potential use of GLP-1 receptor agonists in high-risk subtypes.

#7867 Independent effects of genetic risk, socioeconomic status, and lifestyle factors in melanoma: A large-scale gene-environment analysis.

Elle Kim[1], Nilanjan Chatterjee[2]

[1]Johns Hopkins Medicine, Baltimore, MD,[2]Johns Hopkins Kimmel Comp. Cancer Ctr., Baltimore, MD

Background: Melanoma is the 5th most common cancer with an increasing incidence in the younger population. Prior literatures have shown that melanoma incidence paradoxically increases with socioeconomic affluence. Yet, the mechanisms underlying this pattern remains unclear. Prior gene-environment studies have focused primarily on sun exposure and phenotypic traits, with socioeconomic context largely unexplored. Our study integrates genetic, socioeconomic, and lifestyle data from the United Kingdom Biobank (UKBB) to disentangle the independent and joint effects of genetic risk and socioeconomic factors on melanoma incidence.

Methods: We analyzed 303,880 UKBB participants using Cox proportional hazards models to estimate hazard ratios (HRs) and 95% confidence intervals (CIs) for incident melanoma in an unrelated White British ancestry. We adjusted for sex, body mass index, smoking, skin color, alcohol intake frequency, vitamin D levels, sun-protection behavior, and assessment center (proxy for home location). We modelled the effects of the Index of Multiple Deprivation (IMD) by quartiles and polygenic risk score (PRS) on incident melanoma: IMD and PRS independently, additive model (IMD + PRS), and an interaction model (IMD × PRS).

Results: In the IMD-only model, compared to the least deprived (Q1), participants in Q3 and Q4 had significantly lower risk of melanoma incidence (Q3: HR = 0.84 [95% CI = 0.72 - 0.98]; Q4: HR = 0.84, [95% CI = 0.71 - 1.00]). In the PRS-only model, each unit increase in PRS was associated with a 2.16-fold increased melanoma risk (HR = 2.16 [95% CI = 1.99 - 2.34]). In the additive model, PRS and IMD effect remained largely unchanged. The interaction model showed no evidence of IMD-PRS interaction (HR 1.0; $p > 0.6$).

Conclusions: Greater genetic susceptibility and higher socioeconomic status was associated with increased melanoma risk through independent and non-interacting pathways. Even after accounting for lifestyle factors, socioeconomic differences remained, suggesting that melanoma risk is shaped by factors extending beyond individual lifestyle and behavior. Our findings highlight that there is no evidence that socioeconomic disparities reflect differences in genetic susceptibility, reinforcing the need for prevention and early detection strategies that address both inherited risk and social and structural contexts.

#7868 Skin and systemic interplay in immune checkpoint inhibitor therapy: Evidence of global immune activation.

Elle Kim[1], Joel Chaim Sunshine[2]

[1]Johns Hopkins Medicine, Baltimore, MD,[2]Johns Hopkins University School of Medicine, Baltimore, MD

Background: Immune-related adverse events (irAEs) from immune checkpoint inhibitor therapies (ICI; PD-1/L1, CTLA-4, and/or LAG3) are non-trivial. Cutaneous irAEs (cirAEs) are some of the earliest to occur, but their implication as markers of broader systemic immune activation remains unclear.
Objective: To evaluate the association between cirAEs and systemic irAEs in melanoma patients receiving ICI.
Methods: We performed a retrospective cohort study of 18,886 (aged 18 or older) primary melanoma patients (C43) using the TrinetX network. We performed 1:1 propensity score matching (PSM) between patients who developed cirAEs within 6 months of ICI initiation (cirAE group) and those that did not (non-cirAE group). Time-to-event analyses for 13 organ-systems (cardiac, endocrine, renal, pulmonary, neurologic, hepatic, hematologic, musculoskeletal, ocular, gastrointestinal (GI), rheumatologic, and electrolyte abnormalities) involving 54 distinct irAE categories were performed using Kaplan-Meier curves and Cox models. To approximate temporal ordering, we applied a dual index-date framework: a primary analysis anchoring both cohorts at ICI initiation, and a secondary analysis re-anchoring the cirAE cohort at the onset of cirAE. For each outcome, equality of hazard ratios (HRs) across anchors was tested using a Wald chi-square test with a false discovery rate correction to evaluate for coherence between the frameworks.
Results: In the matched cohort, the cox model showed significantly higher hazards in patients who developed cirAEs in the first year post-ICI. 32 distinct conditions were significantly associated with cirAEs. HRs ranged from 1.4 to nearly 5-fold higher vs. the matched non-cirAE cohort. The strongest signals were in GI (mucosal and secretory disorders; HR=5.06[3.54-7.23]), joint disorders (musculoskeletal conditions including pain, stiffness, and bursopathy, HR=2.67[2.08-3.42]), and esophagitis (HR=2.64[1.41-4.97]). Nine out of the 32 conditions including hypo-osmolality and hyponatremia and acute kidney injury showed non-coherence, marked by attenuated HRs and loss of significance in the cirAE-anchored analysis compared to the primary. As expected, the cirAE group showed improved survival (HR=0.61[0.54-0.70]) in the cirAE cohort (86%) compared to 79% in the non-cirAE group at the end of the 1-year time window, corresponding to approximately 171 additional survivors in the cirAE cohort.
Conclusions: cirAEs are associated with increased 1-year risk of numerous systemic irAEs across multiple organ systems, whereas others show reduced effect sizes in the secondary analysis, suggesting that their risk is concentrated pre-cirAE. The robustness of associations across temporal anchors suggests that cirAEs may serve as early markers of broader immune activation, warranting enhanced monitoring and multidisciplinary management.

: Targeted Therapies, Predispositions, and Survivorship in Pediatric Cancers
Poster Session

#7870 Targeting the MYC-SUMO axis with TAK-981 reverses immune suppression and restores antigen presentation in osteosarcoma.

Bikesh Kumar Nirala[1], Jeffrey Ritzenthaler[2], Tajhal Patel[3], Taku Yamamichi[1], Ryo Tsukada[1], Lyazat Kurenbekova[3], Juan Dou[2], Heath Bradley[2], Atreyi Dasgupta[4], Jason T. Yustein[2]

[1]Pediatrics, Emory University, Atlanta, GA,[2]Emory University, Atlanta, GA,[3]Baylor College of Medicine, Houston, TX,[4]Texas Children's Hospital Cancer & Hematology Ctr., Houston, TX

Background: Osteosarcoma (OS), the most common primary bone cancer in adolescents, remains difficult to treat due to aggressive growth, early metastasis, and poor response to immunotherapy. About 20-30% of OS harbor 8q24 amplification, causing MYC overexpression and an immune-cold tumor microenvironment (TME). To investigate MYC-driven immune evasion, we generated an osteoblast-specific Myc-knockin GEMM and performed complementary mechanistic studies.
Methods: The Myc-knockin model was characterized through histopathology, growth kinetics, immune profiling (flow cytometry, IHC), Western blotting, and RNA-seq. Antigen-presentation machinery (APM) gene expression was assessed in GEMM tumors, OS PDXs, and public datasets. MYC dependence was tested using dTAG degradation and siRNA knockdown. Because MYC is linked to SUMO-dependent repression, we examined the SUMO pathway using the SAE inhibitor TAK-981 and SAE1 knockdown. SUMO-interactome profiling (SUMO-IP/MS) identified MYC-associated SUMO substrates.
Results: The MYC-knockin GEMM developed rapidly progressive and highly metastatic OS that transcriptionally resembled MYC-high human OS. MYC activation produced a strongly immunosuppressive TME with reduced CD45⁺ cells and broad APM repression. MYC loss restored APM expression, establishing MYC as a key inhibitor of antigen presentation. SUMOylation machinery (SUMO1/2, SAE1/2, UBC9) was elevated in MYC-high models and inversely correlated with APM. TAK-981 showed potent MYC-selective cytotoxicity in vitro, with MYC-high cells far more sensitive than MYC-low counterparts across mouse and PDX lines. TAK-981 also reduced proliferation, migration, and sphere formation. In vivo, TAK-981 significantly suppressed tumor growth across syngeneic and PDX models. Transcriptomics revealed reduced MYC targets, EMT, glycolysis, and G2/M signaling, alongside induction of IFN-α/γ pathways, inflammatory responses, and APM genes. SUMO-IP/MS identified MYC-regulated SUMO-interacting proteins, including G3BP1/2, TARDBP, EIF3D, and PSMD4, implicating SUMO-dependent immune-evasion mechanisms. Combining TAK-981 with a STING agonist produced synergistic tumor control, achieving near-complete responses.
Conclusions: MYC drives immune suppression in OS through SUMO-dependent repression of antigen-presentation and innate immune pathways. Targeting the MYC-SUMO axis with TAK-981 converts the TME from immune-cold to immune-inflamed and enhances immunotherapy responses, supporting TAK-981-based combinations as a promising strategy for MYC-driven OS.

#7871 Onvansertib-mediated PLK1 inhibition reduces cell viability in neuroblastoma cells.

Aileen A. Yasukochi[1], Susanna Kim[2], CARLA SAMPAIO[3], Peter E. Zage[3]

[1]San Diego State University, San Diego, CA,[2]University of California San Diego, San Diego, CA,[3]UCSD Moores Cancer Center, San Diego, CA

Background: Neuroblastoma is the most common extracranial solid tumor of childhood and accounts for a significant proportion of pediatric cancer-related mortality. Despite advances in multimodal therapy including intensive chemotherapy, radiotherapy, stem cell transplantation, patients with high-risk disease continue to experience poor long-term survival. Consequently, there is an urgent need for rationally designed targeted therapies that selectively impair oncogenic proliferation while minimizing systemic damage. Polo-like kinase 1 (PLK1), a serine/threonine kinase essential for mitotic entry, spindle assembly, chromosome alignment, and cytokinesis, is aberrantly overexpressed in neuroblastoma and contributes to unchecked cell-cycle progression and evasion of apoptotic cues. Onvansertib, a highly selective PLK1 inhibitor, has emerged as a promising therapeutic candidate due to its ability to disrupt mitotic fidelity and induce programmed cell death.
Method: In this study, we evaluated the therapeutic potential of Onvansertib across multiple neuroblastoma cell lines using cell viability assays and molecular analyses. CCK-8 assays demonstrated a clear dose-dependent decrease in cell viability following 24-72 hours of treatment, indicating significant suppression of proliferation. To uncover the mechanisms underlying reduced viability, we conducted Western blot analyses assessing markers of DNA damage, apoptosis and cell-cycle disruption.
Results: Onvansertib treatment resulted in substantial downregulation of PLK1 protein levels, consistent with effective pathway inhibition. Concurrently, we observed increased phosphorylation of H2AX, a hallmark of double-strand DNA breaks, indicating activation of DNA damage responses. Apoptotic signaling was strongly induced, as evidenced by elevated levels of cleaved PARP and cleaved caspase-3 across cell lines. Additionally, decreased phosphorylation of Cdc25c, a downstream regulator of mitotic entry, further supported disruption of normal mitotic progression.
Conclusion: Together, these findings demonstrate that Onvansertib effectively compromises neuroblastoma cell survival through a multifaceted mechanism involving mitotic disruption, DNA damage accumulation and apoptotic activation. By targeting a fundamental regulator of the cell cycle, PLK1 inhibition represents a compelling therapeutic strategy for high-risk neuroblastoma. These data support further exploration of Onvansertib in preclinical models and provide a strong rationale for its advancement toward clinical evaluation in this very prevalent malignancy.

#7872 CDK7 inhibition mitigates AZD1775 resistance via chromatin reprogramming in MYC-MB.

Kiara Smart, Bethany Veo, Rajeev Vibhakar

The University of Colorado School of Medicine, Aurora, CO

Medulloblastoma (MB) is the most common malignant brain tumor in children, comprising ~20% of pediatric brain tumors. MB is a heterogeneous disease, with clinical outcomes heavily influenced by molecular subgroups. Among these, Group 3 MB, characterized by MYC amplification, exhibits the poorest prognosis, with a high propensity for metastasis and recurrence. Our previous research identified WEE1 as a critical regulator of MB cell survival and found that Myc-driven MB is particularly sensitive to the WEE1 inhibitor AZD1775. Although AZD1775 has demonstrated efficacy, especially when combined with genotoxic agents, resistance to small molecule inhibitors often emerges, limiting its therapeutic potential.CDK7, a kinase essential for transcriptional initiation via phosphorylation of RNA Pol II's C-terminal domain, plays a critical role in Myc-driven malignancies and is frequently enriched at super-enhancers. AZD1775-resistant cells undergo chromatin reorganization to establish alternate cis-acting elements that promote transcription of DNA repair and proliferation genes, circumventing treatment. We hypothesized that targeting CDK7-mediated transcriptional reprogramming could overcome AZD1775 resistance.Using the CDK7 inhibitor THZ1, we performed western blot analysis of DNA repair proteins and observed inhibition of ATM pathway activation, a key component of the DNA damage response. Proliferation assays in both parental and AZD1775-resistant cell lines demonstrated that combining AZD1775 with THZ1 significantly suppressed cell growth. These findings suggest that THZ1 may reverse adaptive chromatin reorganization, sensitizing resistant MB cells to AZD1775 and enhancing the overall therapeutic response.Future studies will investigate the potential of combining CDK7 inhibitors with other epigenetic modulators to further disrupt resistance mechanisms and improve treatment outcomes in aggressive MB subtypes, particularly Group 3 MB. This approach offers a promising avenue for overcoming therapeutic resistance and advancing precision medicine in medulloblastoma.

#7873 *In vivo* preclinical efficacy of a novel "payload-bearing" peptide LX-101 targeting IGF-1R in Ewing sarcoma.

Roberto Cardenas-Zuniga, Jiaqian Fan, Asmaa G. Ahmed, Marcus Thurm, Kien Ryan Cao, Clement Agyemang, Danh Truong, Joseph A. Ludwig

UT MD Anderson Cancer Center, Houston, TX

Ewing sarcoma (ES) is an extremely aggressive and highly metastatic bone cancer in children and young adults, ranked as the second most frequent bone tumor in pediatric patients. With a survival of ~80% for localized and regional tumors, which can drop down to ~40% for metastatic cases, standard treatment for ES usually includes radiotherapy, surgery, and chemotherapy based on the VDC/IE regimen. Alternative therapeutic approaches targeting critical pathways with recognized roles in tumorigenesis, such as IGF-1, PI3K, and mTOR, have also demonstrated remarkable clinical activity as single agents or in combinations for several cancer types. For this reason, it is imperative to confirm and generate preclinical evidence of anticancer activity in ES. Here, we tested the *in vitro* and *in vivo* efficacy of LX-101, a next-generation therapy targeting IGF-1R, which couples a proprietary IGF-1 variant to a cytotoxic MTX payload, as a single agent or in combination with alpelisib (a PI3K inhibitor) and temsirolimus (an mTOR inhibitor) in various ES models. We tested the *in vitro* activity of LX-101 on the proliferation and viability of A-673, ES-8, and TC-71 cell lines. Once anti-proliferative activity was confirmed, we evaluated the sensitivity of all three ES cell lines to the combination of LX-101 with alpelisib and temsirolimus, estimating synergistic effects on the viability of the ES cultures. To consolidate that the cytotoxic effect on ES is mediated by on-target impact, we examined the changes in the expression and activation of IGF-1 downstream effectors by western blot, which were clearly reduced after LX-101 exposure in all three cell lines when compared with non-exposed cells, confirming that LX-101 inhibits the activation of IGF-1R, and indicating the suppression of the IGF-1 pathway. Finally, we tested the in vivo activity using three different PDX Ewing sarcoma models, with and without alpelisib or temsirolimus to assess synergistic preclinical efficacy. The pharmacodynamic effects were evaluated using a custom tissue microarray (TMA) analysis, using sequential multiplex immunofluorescence of 40 proteins related to the IGF/PI3K/mTOR signaling pathway.Our results indicate that LX-101 exhibits potent single-agent activity in the preclinical setting as an anti-cancer agent for ES, and even stronger activity when combined with agents that inhibit PI3K or mTOR. Collectively, the preclinical efficacy demonstrated provides a strong rationale for advancing LX-101 into clinical trials for ES.

#7874 Dose-response efficacy of cell adhesion molecule 1 (CADM1)-GGFG-Exatecan vs CADM1-PEG3-VC-Exatecan in preclinical osteosarcoma models.

Zhongting Zhang[1], Caterina Longo[1], Wendong Zhang[1], Yifei Wang[2], Yanhua Yi[1], Zhaohui Xu[1], Xin Zhou[1], Adil Bahadir[1], Michael Roth[1], Jonathan Gill[1], Richard Gorlick[1]

[1]UT MD Anderson Cancer Center, Houston, TX,[2]Orthopaedic Oncology, UT MD Anderson Cancer Center, Houston, TX

Background: Osteosarcoma is the most common primary bone malignancy in children and young adults. Despite multimodal therapy, survival rates have remained unchanged since the 1980s. Antibody-drug conjugates (ADCs) targeting CADM1 show promise as targeted treatments. This study compares the dose-response effectiveness of two CADM1-targeted ADC formulations, CADM1-GGFG-Exatecan and CADM1-PEG3-VC-Exatecan, in preclinical osteosarcoma models. Both ADCs are conjugated with Exatecan, a potent topoisomerase I inhibitor, but differ in their linker structures (GGFG vs PEG3), which may affect payload release and tumor penetration.

Methods: We assessed the cytotoxicity of both ADCs in osteosarcoma cell lines (HOS, OS17, OS31) to determine IC_{50} values. Internalization studies compared uptake kinetics in the same lines. In vivo testing evaluated both ADCs in six patient-derived xenograft (PDX) osteosarcoma models (OS1, OS2, OS9, OS17, OS31, OS33) at doses of 3 mg/kg and 6 mg/kg. Human-IgG1-GGFG-Exatecan, Human-IgG1-PEG3-VC-Exatecan, and PBS served as isotype and vehicle controls. Tumor growth inhibition and event-free survival (EFS) were measured.

Results: CADM1-GGFG-Exatecan showed significantly greater anti-tumor activity than CADM1-PEG3-VC-Exatecan, with lower IC_{50} values and higher internalization in CADM1-expressing cells. Internalization of CADM1-GGFG-Exatecan reached a steady plateau by day 4, whereas CADM1-PEG3-VC-Exatecan showed minimal uptake. In vivo, both ADCs were well tolerated (≤10% body weight loss). CADM1-GGFG-Exatecan significantly prolonged EFS across all six PDX models ($P < 0.05$), inducing maintained complete responses (MCR) in OS1, OS31, and OS33, a partial response (PR) in OS2, and progressive disease (PD) in OS9 and OS17. In contrast, PEG3-VC-Exatecan and all controls resulted in PD in all models.

Conclusion: CADM1-GGFG-Exatecan demonstrates superior dose-response efficacy versus CADM1-PEG3-VC-Exatecan in both in vitro and in vivo osteosarcoma models. Its enhanced anti-tumor activity, likely driven by improved internalization and potency, supports further development in CADM1-expressing osteosarcoma, including optimization of pharmacokinetics and combination strategies.

#7875 Eflornithine and venetoclax combination therapy: Targeting senescence to induce apoptosis in neuroblastoma.

Tarlan Arjmandi, Jeremy Hengst, Muhammad Younis, Meenakshi Shukla, Mohammad Haque, Katherine McClain, Jonathan Lerch, Thussenthan Walter-Angelo, Giselle Saulnier Sholler

Penn State College of Medicine, Hershey, PA

High-risk neuroblastoma (HRNB) is difficult to cure due to relapses and limited therapeutic durability. Eflornithine, an inhibitor of ornithine decarboxylase, inhibits polyamine synthesis and is clinically effective in preventing HRNB recurrence. Eflornithine induces a stable senescent phenotype that suppresses proliferation. Eliminating these senescent HRNB cells is of therapeutic interest. Venetoclax, a selective Bcl-2 inhibitor approved for hematologic malignancies, has been identified as a potent senolytic that triggers apoptosis in senescent cells. We therefore hypothesized that venetoclax may induce apoptosis in eflornithine-induced senescent HRNB cells, thereby overcoming tumor persistence. HRNB cells (BE2c cell line) were sequentially treated with eflornithine for 4 days to induce senescence followed by the addition of venetoclax for 18 hours to induce apoptosis. Senescence was assessed by β-galactosidase staining and p21, p16, and p27 protein expression. Apoptosis and survival markers were analyzed by Western blotting to detect Mcl-1, BAG3, GLS1, cleaved Caspase-3, and cleaved PARP. Cytokine levels were measured by qPCR. Treatment of NB cells with eflornithine induced a robust senescence response, increasing β-galactosidase activity and expression of p21, p16, and p27 in a time-dependent manner. Venetoclax alone failed to induce apoptosis and instead upregulated the pro-survival protein Mcl-1 (5.5-fold), whereas pre-treatment with eflornithine both reduced basal Mcl-1 (0.5-fold) and prevented venetoclax-induced Mcl-1 elevation (0.03-fold in the combination). Consistent with eflornithine's effect on polyamine-dependent translation, BAG3, a chaperone that stabilizes Mcl-1, was downregulated, providing a mechanistic basis for Mcl-1 destabilization and enhanced venetoclax sensitivity. Eflornithine also decreased expression of GLS1, an enzyme linked to mitochondrial fitness and anti-apoptotic signaling. Sequential treatment of eflornithine followed by venetoclax triggered strong activation of apoptotic markers, increasing cleaved Caspase-3 (1.4-fold) and cleaved PARP (9-fold) compared to vehicle, confirming a synergistic shift from senescence to apoptosis. Cytokine analysis revealed selective remodeling of the SASP, with an increase in IL-1β (33-fold) and IL-6 (6-fold), and IFN-γ (>50-fold). Together, these findings establish a novel mechanistically informed combinatorial strategy in which polyamine depletion converts senescent tumor cells into apoptotically vulnerable targets, offering a promising therapeutic avenue for HRNB. Ongoing in vivo studies will determine the translational potential of eflornithine + venetoclax as a rational senescence-targeting regimen.

#7876 Melatonin protects against long-term doxorubicin-induced cardiotoxicity in a preclinical model of childhood cancer survivors.

Marisol Fernandez Ortiz, Logan Davis, Joseph Schell, Erik Marchant, Blake Rasmussen, David Gius, Gregory Aune

The University of Texas at San Antonio, San Antonio, TX

Cardiovascular disease is the leading cause of early mortality among childhood cancer survivors. Most of these patients receive anthracyclines, particularly doxorubicin (DOX), due to its high efficacy against solid tumors and hematological malignancies. However, DOX is associated with long-term cardiac toxicity, including delayed cardiac dysfunction and irreversible heart failure, making survivorship care a growing concern. A proposed mechanism of long-term doxorubicin-induced cardiotoxicity (DOXIC) is the accumulation of DOX in cardiomyocyte mitochondria, which increases free radical production, promotes oxidative stress, and progressively impairs cardiac function. We hypothesized that melatonin (aMT), a mitochondria-targeted antioxidant, could prevent DOXIC. Melatonin has demonstrated safety at high doses and can enhance chemotherapy efficacy. This study evaluated the cardioprotective effects of aMT in a mouse model mimicking childhood cancer survivorship. Wild-type mice received DOX from 3 to 5 weeks of age and were assessed at 12 months. aMT was administered during DOX treatment and continued for one month afterward. Experimental groups included: (1) Vehicle, (2) DOX, and (3) DOX + aMT. Cardiac function, mitochondrial structure and function, and gene expression were evaluated using echocardiography, TEM, high-resolution respirometry and mRNA sequencing. Gene Set Enrichment Analysis (GSEA) and Ingenuity Pathway Analysis (IPA) were used for transcriptomic analysis. Melatonin preserved cardiac function both during and long after DOX exposure and protected mitochondrial ultrastructure and function. GSEA showed that aMT upregulated genes related to cardiac development, contractility, action potential, sarcomere structure, and energy metabolism. IPA further revealed that aMT suppressed pathways involved in heart disease, among them cardiomyopathy, myocardial dysfunction and hypertrophy of left ventricle, apoptosis and organismal death, while enhancing those linked to cardiac contractility, cell viability and survival, microtubule organization, and DNA repair. These findings provide the first evidence that melatonin can prevent long-term DOXIC, supporting its potential as a cardioprotective agent for childhood cancer survivors.

#7877 Combination of AVA-NP-695 and DDRi demonstrates strong synergy resulting in potent anti-tumor activity in rare pediatric cancers.

Aditya Kulkarni[1], Borja Ruiz-Fernandez de Cordoba[2], Avijit Goswami[3], Sandeep Goyal[3], Kawaljit Singh[3], Princy Khurana[3], Alejandro Sweet-Cordero[4]

[1]Avammune Therapeutics, Levitown, PA,[2]University of California San Francisco, San Francisco, CA,[3]Avammune Lifesciences, Bangalore, India,[4]UCSF - University of California San Francisco, San Francisco, CA

Background: Ectonucleotide pyrophosphatase/phosphodiesterase 1 (ENPP1) overexpression is linked to poor prognosis in various cancers, including astrocyte tumors, triple-negative breast cancer (TNBC), Ewing sarcoma (EWS), and osteosarcoma (OS). Transcriptomics and proteomic analyses highlight the highest ENPP1 expression in EWS, OS, and breast cancer. Importantly, ENPP1 is increasingly implicated in driving lung and bone metastasis, a major clinical challenge for cancers like TNBC, Ewing sarcoma, and osteosarcoma. Overall, ENPP1 is a clinically relevant and druggable target for several hard-to-treat ICB-refractory cancers. Therefore, the therapeutic of ENPP1 inhibition was explored as monotherapy as well as in combination with DDR inhibitors like Ceralasertib and Olaparib.
Methods: The potency of AVA-NP-695, a small-molecule ENPP1 inhibitor, was validated through enzymatic assays using different substrates. Pharmacokinetic profiles were evaluated in mice, rats, and beagle dogs. ENPP1 expression and cGAMP export were evaluated after dsDNA stimulation, and ENPP1 activity was measured using a biochemical assay in OS cell lines, including OSPDX-cell lines. Mono and combination therapy effects of AVA-NP-695 and Olaparib/Ceralasertib were evaluated in OS and EWS models.
Results: AVA-NP-695 demonstrated potent and selective ENPP1 inhibition with no adverse effects in repeat-dose and dose-escalation toxicity studies. In OS models, AVA-NP-695 induced tumor regression in both paratibial (orthotopic) and metastatic (lung) contexts. Interestingly, targeted pharmacological screen revealed synthetic lethality between AVA-NP-695 and both Olaparib/Ceralasertib in osteosarcoma cell lines. In two patient-derived xenograft (PDX) OS models (OS384 and OS526), as well as in a EWS (A673) CDX model, AVA-NP-695 administered as a monotherapy showed similar efficacy as olaparib alone, and the combination of the two agents combination resulted in significant tumour regression. In GS383 intrapulmonary model, it achieved strong tumor shrinkage in lung nodules on post-treatment scans and prolonged progression-free survival. Similar effects were observed in combination with Ceralasertib in case of Osteosarcoma syngeneic model.
Conclusions: These findings underscore the therapeutic potential of AVA-NP-695 across hard-to-treat ICB-refractory pediatric cancers such as OS and EWS. AVA-NP-695 exploits ENPP1 inhibition to exert a strong anti-tumor response and obliviates metastasis. Additionally, AVA-NP-695 also demonstrates strong synergy with DDR inhibitors like Olaparib and Ceralasertib in both these cancers. Overall, these findings demonstrate that AVA-NP-695 has strong potential as a therapeutic modality in OS and EWS as a monotherapy and combination with DDR inhibitors.

#7878 Disrupting the lipid-ETV6 axis: A therapeutic vulnerability in Ewing sarcoma.

Yuan Gao, Hang Zhao

Pharmacology, Case Western Reserve University School of Medicine, Cleveland, OH

Ewing sarcoma is a transcriptionally driven pediatric cancer with few targetable dependencies. Through a gain-of-function metabolic screen, we discovered that Ewing sarcoma cells exhibit lineage-specific hypersensitivity to activation of glycerophospholipid metabolism. Mechanistic studies revealed that phosphatidic acid (PA), a central lipid signaling molecule, directly binds to the transcriptional repressor ETV6, an essential and selective dependency in Ewing sarcoma. PA binding disrupts ETV6 oligomerization and chromatin occupancy, leading to de-repression of its target genes. We further mapped this interaction to a unique five-amino acid motif in the ETV6 ETS domain and generated lipid-insensitive mutants that retain DNA binding but resist PA-induced inactivation. CRISPR activation of endogenous PA-producing enzymes phenocopied the effects of exogenous PA, supporting a direct role for lipid signaling in modulating ETV6 function and tumor cell viability. These findings define a previously unrecognized lipid-sensitive transcriptional state in Ewing sarcoma and reveal the ETV6-PA axis as a novel therapeutic target.

#7879 Opaganib in combination with oxaliplatin and doxorubicin as a novel salvage therapy for relapsed/refractory high-risk neuroblastoma.

Jeremy Hengst[1], Mohammad Haque[1], Muhammad Younis[1], Thussenthan Walter Angelo[1], Anna Bourne[1], Katherine McClain[1], Meenakshi Shukla[1], Jonathan Lerch[1], Tarlan Arjmandi[1], Eric Cochran[1], Lynn Maines[2], Charles D. Smith[2], Vladimir S. Spiegelman[1], Jacqueline M. Kraveka[3], Giselle L. Saulnier Sholler[1]

[1]Penn State College of Medicine, Hershey, PA,[2]Apogee Biotechnology, Hershey, PA,[3]Medical University of South Carolina, Charleston, SC

The combination of oxaliplatin and doxorubicin (OXDOX) has shown efficacy in heavily pre-treated neuroblastoma (NB) patients. Nevertheless, addition of agents that enhance response to OXDOX may improve outcomes. DOX has been shown to up-regulate the expression of the Sphingosine kinases (SphK1 and SphK2) and enhance the production of pro-survival sphingosine-1-phosphate (S1P) at the expense of pro-apoptotic ceramide (Cer) which, in turn, mediates resistance to DOX. Elsewhere, studies have shown that the SphKs regulate the sensitivity of cells to OX. Inhibition of SphK activity decreases S1P production and may reverse OXDOX resistance. The purpose of this study was to determine whether the addition of the SphK2 inhibitor, opaganib, could improve the efficacy of OXDOX salvage therapy for high risk relapsed/refractory neuroblastoma (HRNB) patients. An immunocompetent mouse model of HRNB was utilized with 9464-D M2 cells grown subcutaneously in syngeneic C57BL/6 mice, to evaluate the efficacy of the combined treatment relative to OXDOX and opaganib alone cohorts. Opaganib has been shown to reduce c-Myc and n-Myc expression. Western blot analysis evaluated the expression of n-Myc, Mcl-1, and markers of apoptosis including cleaved Caspase 3 and cleaved PARP in response to single agent and combination treatments. The reduction of MYCN in MYCN amplified NB patients was further explored to examine the ability of opaganib to directly target engage n-Myc using the Cellular Thermal Shift (CETSA) assay and Isothermal Dose-Response Fingerprint (ITDRF) assays. In the immunocompetent 9464-D mouse model, the combination of agents significantly reduced tumor size relative to opaganib alone and OXDOX alone cohorts ($p<0.001$). IHC staining demonstrated that the combination reduced proliferation (Ki-67), enhanced apoptosis (Caspase 3) and, enhanced macrophage infiltration (CD68) into the tumor microenvironment. Western blot analysis revealed that opaganib reduced n-Myc and Mcl-1 expression (> 5-fold). CETSA experiments confirmed direct target engagement of n-Myc by opaganib in live, whole cell assays. ITDRF assays determined that opaganib binds to n-Myc with micromolar affinity, consistent with its IC50 for cell viability. Time course assays demonstrated that opaganib rapidly bound n-Myc within 30 minutes of exposure. Together, these studies indicate that opaganib enhances the therapeutic efficacy of the OXDOX combination by both altering sphingolipid metabolic profiles to enhance the production of pro-apoptotic ceramide and by directly binding to and destabilizing n-Myc, a key oncogenic driver of high-risk NB. Opaganib has been extensively tested in adult COVID patient populations with a favorable toxicity profile. Clinical testing of this novel three-drug combination in NB patients is under evaluation by the Beat Childhood Cancer Research Consortium.

#7881 Hijacking the BRD4-NUT fusion oncoprotein to activate programmed cell death.

Kelly Wang[1], Yanlan Wang[1], Tian Qiu[2], Brendan G. Dwyer[2], Daryl Griffin[3], Geoffrey I. Shapiro[3], Chris A. French[4], Nathanael S. Gray[2], Gerald R. Crabtree[1]

[1]Dept. of Pathology and Developmental Biology, Stanford University, Stanford, CA,[2]Dept. of Chemical and Systems Biology, Stanford University, Stanford, CA,[3]Dept. of Medical Oncology and Medicine, Dana-Farber Cancer Institute, Brigham and Women's Hospital and Harvard Medical School, Boston, MA,[4]Professor, Dept. of Pathology, Brigham and Women's Hospital and Harvard Medical School, Boston, MA

Fusion oncogenes account for about 10-20% of all cancer drivers and generally result from in-frame recombination with specific partners. Cancers driven by fusion oncogenes often occur in young people whose genomes are relatively free of other mutations, providing a singular reliance on the fusion and its underlying mechanisms. Despite this focus, fusion oncogenes — particularly those that arise from transcription factors — have been difficult to target therapeutically. We demonstrate in this study that the fusion oncoprotein BRD4-NUT can be used to specifically activate programmed cell death in an aggressive form of squamous cancer, NUT carcinoma (NC). NC is caused by a translocation of the *NUTM1* gene downstream of the *BRD4* gene. Transcription of the fusion gene is therefore controlled by the *BRD4* regulatory region, leading to high-level expression of the fusion oncoprotein. The NUT protein is normally restricted to the testes, where it is essential for histone hyperacetylation, histone removal and replacement by protamines. NC currently has a mean survival of 6-9 months and no approved treatments. We reasoned that the oncogenic program of BRD4-NUT could be reprogrammed to activate a synthetic death circuit. To selectively inhibit NC, we developed bifunctional molecules that target the BRD4-NUT fusion, BRD4 and PARP. We call the new class of molecules DD-CIPs for DNA Damage-Chemical Inducers of Proximity. The most potent member of this new class (TWQ-184) kills NC cell lines (10-15, SW and 14169) at concentrations between 0.74 nM and 6 nM. TWQ-184 forms a ternary complex with BRD4-NUT and PARP, resulting in cell death. P300 inhibitors partially rescue NC cells from TWQ-184-induced apoptosis, suggesting that transcription at PARP-bound DNA breaks driven by BRD4-NUT is required to initiate cell death. TWQ-184 induces γH2AX deposition and ATM activation within 24 hours, suggesting that PARP-bound single-strand breaks are converted to lethal double-strand breaks in the cancer cells. Exposure to TWQ-184 for one hour gives near-complete NC death at 72 hours, suggesting that intermittent dosing might be effective. TWQ-184 additionally exhibits high specificity for the malignant cells, evidenced by the substantial therapeutic windows between NC cell lines and healthy human lymphocytes and fibroblasts. Based on our current findings, the compound's high efficacy in the cancer cells and low toxicity in healthy cells offer a promising approach to treat NC. This strategy for hijacking a fusion oncoprotein to activate transcriptionally coupled DNA damage-mediated cell death could be applicable to other transcriptional fusion oncogenes.

#7883 Surface CADM1 (Cell Adhesion Molecule 1) abundance predicts payload delivery and in-vitro efficacy of CADM1-GGFG-Exatecan ADC in osteosarcoma, aiding optimal candidate selection.

Caterina Longo[1], Zhongting Zhang[2], Wendong Zhang[2], Yifei Wang[2], Adil Bahadir[2], Yi Yanhua[2], Zhaohui Xu[2], Xin Zhou[1], Michael Roth[3], Jonathan Gill[2], Richard Gorlick[2]

[1]The University of Texas MD Anderson Cancer Center, Houston, TX,[2]UT MD Anderson Cancer Center, Houston, TX,[3]The University of Texas MD Anderson Cancer Center

Background: ADC development in osteosarcoma has been hindered by the absence of effective, targetable surface antigens. We previously identified CADM1, a cell-surface adhesion molecule, as a promising therapeutic target and generated three CADM1-directed ADCs (CADM1-Tesirine, CADM1-PEG-Exatecan, and CADM1-GGFG-Exatecan) with distinct linker-payload combinations. To select the optimal candidate for clinical translation, we evaluated target engagement and target-dependent cytotoxicity across multiple in vitro models.
Methods: Confocal microscopy was used to visualize ADC trafficking through cellular compartments and its lysosomal localization over time. CADM1 knockout (KO) osteosarcoma cell lines (SaOS2 and OS31) were generated using CRISPR/Cas9 and validated by flow cytometry, Western blotting, and mass spectrometry (MS). Cell-surface CADM1 levels were quantified by MS and correlated with ADC cytotoxicity (IC_{50} values) measured by real-time live-cell imaging on the IncuCyte platform. Spearman correlation analyses across nine osteosarcoma cell lines assessed the relationship between CADM1 expression and ADC potency for all three constructs.
Results: Confocal time-course imaging showed ADC trafficking from the plasma membrane (30 min) to lysosomes (6 h) and cytoplasmic dispersion (24 h), absent in CADM1-KO cells, confirming target-mediated internalization and lysosomal processing. CRISPR/Cas9-mediated knockout of CADM1 was achieved in SaOS2 and OS31 osteosarcoma cell lines. Loss of CADM1 expression was confirmed by flow cytometry, Western blotting, and mass spectrometry, showing complete depletion of surface protein. CADM1 loss markedly reduced ADC cytotoxicity (IC_{50} = 77.41 nM in SaOS2 CADM1-KO vs 0.014 nM in SaOS2), confirming on-target activity. Across nine osteosarcoma models, CADM1 surface abundance strongly correlated with drug potency, most notably for CADM1-GGFG-Exatecan (Spearman ρ = -0.98, p = 0.001). These data identify CADM1 as a determinant of ADC efficacy and highlight the contribution of other ADC components.
Conclusions: These data demonstrate potent, target-dependent activity of the generated CADM1-targeted ADCs, validating CADM1 as a rational therapeutic target. Among them, CADM1-GGFG-Exatecan showed the strongest correlation between IC_{50} and target expression, supporting selective cytotoxic delivery. In vivo efficacy and toxicology studies are ongoing to finalize candidate selection.

#7884 Germline genetic testing trends in pediatric cancer patients: A SEER registry analysis.

Claire Johns[1], Minxuan Huang[1], Rebecca Hodan[2], Molly McGuinness[2], Allison W. Kurian[2], Raya Saab[1]

[1]Stanford Children's Health, Palo Alto, CA,[2]Stanford University, Stanford, CA

Germline pathogenic variants (PVs) are reported to occur in 8-16% of pediatric cancer patients, and have important implications for potential treatment modifications, cancer surveillance, and family cascade testing. Data are lacking on the utilization and results of germline testing in pediatric oncology patients. We utilized statewide SEER registry data from California and Georgia to identify patients aged ≤ 19 years diagnosed with cancer between January 1, 2013, and December 31, 2019. Linked germline genetic tests pooled from four laboratories (Ambry Genetics, Bioreference/GeneDx, Labcorp/Invitae, and Myriad Genetics) were reviewed. Results were evaluated by cancer type, demographic information, and year of diagnosis using descriptive and multivariable logistic regression analyses. PV prevalence was assessed by affected gene. Among 16,613 analyzed patients, 344 (2%) underwent germline testing. Testing rate was highest in patients with carcinomas (4.6%) and lowest in those with hematologic malignancies (0.3%). Testing rates increased from 0.7% in 2013 to 4.0% in 2019. Patients in the fifth quintile (highest) socioeconomic level had the highest testing rate (2.9%) (OR 1.58, 95% confidence interval 1.07-2.31, p=0.020 vs. the first quintile (lowest)). Testing was higher in non-Hispanic white and Asian patients compared to other races, however, this was not statistically significant in multivariable analysis. Of the patients who underwent testing, 75/344 (22%) had a germline PV. *TP53* was the most frequently tested gene. *RB1* and *TP53* had the highest yield of PVs amongst patients tested (12/151 and 12/241 respectively). To our knowledge, this is the first population level report of germline genetic testing in pediatric cancer patients. While the rate of germline testing increased significantly from 2013-2019, the rate in 2019 rate remained low at 4%. Higher rates of testing were seen in solid malignancies, which coincides with previous reports of higher germline PV prevalence in solid tumor patients. Germline testing utilization varied by socioeconomic quintile but not by race or ethnicity. These results establish a population-level baseline for germline testing rate and results in pediatric cancer patients; identify testing gaps and disparities; and demonstrate an urgent need for education about germline testing for patients and their families.

#7885 Defining genome-wide cfDNA methylation landscapes in pediatric and adolescent and young adult (AYA) bone and soft-tissue sarcomas.

Lilli J. Greiner, Roman O. Kowalchuk, Jeff Szymanski, Pradeep S. Chauhan, Adam Amundson, Peter J. Schoettler, Wendy Allen-Rhoades, Stephanie F. Polites, Peter S. Rose, Kelly Bailey, Linda McAllister-Lucas, Anita Mahajan, Nadia Laack, Aadel Chaudhuri

Mayo Clinic Hospital-Rochester, Rochester, MN

Background: Pediatric and AYA sarcomas are rare, biologically heterogeneous tumors with limited noninvasive biomarkers to guide diagnosis, personalized treatment, and disease monitoring. Standard-of-care evaluation relies on invasive biopsies that carry procedural risks and imaging modalities with limited sensitivity for detecting minimal residual disease and distinguishing tumor types. Cell-free DNA (cfDNA) methylation profiling offers a minimally invasive alternative capable of capturing tumor-derived epigenomic alterations and has consistently shown strong clinical utility in adult malignancies. However, genome-wide cfDNA methylation patterns across diverse pediatric and AYA sarcoma subtypes remain poorly defined.
Methods: Plasma was collected from 93 pediatric and AYA patients (pediatric <18 years; AYA 15-39 years) representing 27 Ewing sarcoma, 17 rhabdomyosarcoma, 11 liposarcoma, 10 chordoma, 8 synovial sarcoma, 7 chondrosarcoma, 6 osteosarcoma, and 6 fibrosarcoma cases, plus 19 matched healthy donors. cfDNA was isolated from 1 mL plasma, quantified by Qubit, and assessed by Bioanalyzer. Libraries were prepared using the NEBNext EM-seq v2 workflow with PCR cycles scaled to cfDNA input amount. Genome-wide sequencing (15× target depth) was followed by alignment, deduplication, and methylation calling. MultiQC was used to assess depth, duplication rate, conversion efficiency, and CpG coverage. Global methylation summaries were computed, and methylKit was used to generate per-CpG and 1-kb tiling matrices and initiate differential methylation analyses.
Results: Ewing sarcoma patients had significantly higher plasma cfDNA concentrations than age- and sex-matched healthy donors (24.4 vs 4.6 ng/mL, $p < 0.0001$), whereas cfDNA levels for other sarcoma subtypes overlapped with the healthy cohort. Low or undetectable cfDNA concentrations by Qubit were far more common among non-Ewing sarcoma samples (23 of 66) than Ewing sarcoma (1 of 27). All samples achieved sufficient CpG coverage for genome-wide methylation modeling. Global methylation summaries revealed no significant differences in mean β-values across sarcoma subtypes or versus healthy donors. An independent analysis of the Ewing subset identified 299 significant differentially methylated regions (DMRs), supporting the detectability of disease-specific methylation changes.
Conclusions: These results demonstrate the feasibility of high-quality cfDNA methylome profiling across a large and diverse pediatric and AYA sarcoma cohort, including in plasma samples with cfDNA concentrations below the limit of detection. While global methylation levels appear broadly similar across subtypes, proof-of-concept DMR analysis in Ewing sarcoma suggests that subtype-specific epigenomic signatures could enable future noninvasive diagnostic tools for pediatric and AYA sarcomas.

#7886 Therapy-related clonal hematopoiesis in pediatric cancer survivors.

Michael R. Kessler[1], Yash Pershad[2], Robert W. Corty[3], Eric T. Shinohara[1], Debra Friedman[4], Alexander G. Bick[2], Ben H. Park[5], Leo Y. Luo[1]

[1]Department of Radiation Oncology, Vanderbilt University Medical Center, Nashville, TN,[2]Division of Genetic Medicine, Department of Medicine, Vanderbilt University Medical Center, Nashville, TN,[3]Division of Rheumatology and Immunology, Department of Medicine, Vanderbilt University Medical Center, Nashville, TN,[4]Division of Pediatric Hematology and Oncology, Department of Pediatrics, Vanderbilt University Medical Center, Nashville, TN,[5]Division of Hematology and Oncology, Department of Medicine, Vanderbilt University Medical Center, Nashville, TN

Background: Clonal hematopoiesis of indeterminate potential (CHIP) refers to clonal expansion of hematopoietic stem cells due to somatic mutations and is associated with heightened risk of myeloid neoplasms and cardiovascular diseases. Genotoxic therapies such as chemotherapy and radiation therapy are well-recognized contributors to CHIP in adult cancer population. However, CHIP prevalence, mutational patterns, and treatment associations in pediatric populations remain poorly characterized.

Methods: We conducted a retrospective analysis of pediatric patients (age ≤ 18) diagnosed with cancer with blood samples collected after cancer therapy. CHIP was defined as the presence of a pathogenic somatic mutation in an accepted driver gene with variant allele frequency (VAF) ≥2%. CHIP prevalence was estimated overall and stratified by histology and therapeutic exposure. Logistic regression with Firth correction and exposure adjustment was used for multivariable analyses. *TP53* variants with known Li-Fraumeni syndrome association and VAF >40% were considered germline mutations and excluded from analyses.

Results: CHIP mutations were identified in 23 of 1,052 (2.2%) patients in this cohort. Mutations occurred most frequently in the *TET2* (26%), *DNMT3A* (22%), and *KRAS* (13%) genes. CHIP prevalence was numerically higher among patients who received chemotherapy (3.3% vs. 1.4%, p=0.055). Multivariable analysis showed a modest female predominance (OR 0.45, p=0.04) and a trend toward higher CHIP risk with chemotherapy (OR 1.9, p=0.16). Among drug classes, antimetabolite therapy showed the highest CHIP prevalence (OR 3.46, p = 0.048), driven by methotrexate exposure (OR 21.5, p = 0.001). No correlations were found with age, histology, or radiation.

Conclusion: We identified a low overall prevalence of CHIP in pediatric cancer patients and an association with antimetabolite therapy. Further studies are needed to define the long-term clinical implications of clonal hematopoiesis in pediatric cancer survivors.

Baseline characteristics by CHIP status

Characteristic			Overall (n = 1052)	No CHIP mutation (n = 1029)	CHIP mutation (n = 23)	p-value
Age (mean ± SD)			11.5 ± 7.4	11.6 ± 7.4	9.3 ± 5.7	**0.083**

#7887 Associations between polygenic risk scores for immune dysregulation and Hodgkin lymphoma in childhood cancer survivors.

Ji Yun Tark[1], Sharon M. Castellino[2], Philip J. Lupo[2], Austin L. Brown[3]

[1]Department of Medicine, Baylor College of Medicine, Houston, TX,[2]Department of Pediatrics, Emory University School of Medicine, Atlanta, GA,[3]Department of Pediatrics, Baylor College of Medicine, Houston, TX

Background: Hodgkin lymphoma (HL) is the most common malignancy diagnosed in adolescents aged 15-19 years. Epidemiologic evidence suggests a link between HL incidence and immune dysregulation, suggesting that genetic variability in immune function may contribute to disease susceptibility. However, the extent of shared genetic overlap between immunologic and oncologic phenotypes has not been fully elucidated. To address this gap, we evaluated associations between HL and polygenic risk scores (PRS) for various immune-related conditions previously implicated in HL risk, to determine whether specific immune predispositions are enriched among cases of HL compared with other non-hematologic malignancies.

Methods: We used the St. Jude Survivorship Portal, which aggregates data on ~8000 childhood cancer survivors from the St. Jude Lifetime (SJLIFE) and the Childhood Cancer Survivor Study (CCSS) cohorts. The portal integrates 1,600 phenotypic variables with ~400 million genetic variants and includes PRS available derived from the PGS Catalog. We summarized demographic characteristics using the Portal's summary tools, then applied logistic regression to estimate odds ratios (OR) and 95% confidence intervals (CIs) for HL versus other non-hematologic malignancies per one-unit increase in PRS for five immune-related traits (dermatitis, asthma, Crohn's disease, rheumatoid arthritis, and systemic lupus erythematosus), adjusting for age at cancer diagnosis and sex. For each trait, we selected one PRS from the Portal's precomputed set, prioritizing those with larger discovery samples, broader variant coverage, and ancestry diversity. Analyses were conducted in the combined cohort (3,322 HL and 14,167 other survivors).

Results: Among 17,489 survivors of HL and other non-hematologic malignancies, the median age at cancer diagnosis was 7.7 years (IQR 2.8-13.9); 52% were male, and 86% were White, 9% Black, and 5% other. In adjusted logistic regression models, a higher dermatitis PRS was significantly associated with higher odds of HL compared with other non-hematologic malignancies (OR 5.3, 95% CI 1.8-15.4, p=0.002). No significant associations were observed for PRS associated with asthma (OR 1.1, 95% CI 0.7-1.9, p=0.656), Crohn's disease (OR 0.9, 95% CI 0.6-1.3, p=0.604), rheumatoid arthritis (OR 1.0, 95% CI 0.9-1.0, p=0.223), or systemic lupus erythematosus (OR 0.9, 95% CI 0.8-1.1, p=0.455) and HL relative to non-hematologic malignancies.

Conclusion: Using the St. Jude Survivorship Portal, we observed that survivors of HL tend to harbor a higher dermatitis PRS compared with survivors of non-hematologic malignancies. Although these findings are exploratory and should be interpreted with caution, they highlight a potential role for immune-related genetic variation in HL etiology and demonstrate a need for further investigation and independent validation.

#7888 Financial hardships and chronic medical conditions in adolescent and young adult cancer survivors.

Diego Del Toro Rivera[1], Qian Li[1], Anne Kirchhoff[2], Salene M. Jones[3], Candice A. M. Sauder[1], Ann M. Brunson[1], Charles P. Quensenberry[4], Lisa M. Moy[4], Renata Abrahao[1], Ted Wun[1], Hazel B. Nichols[5], Lawrence H. Kushi[4], Jessica Chubak[6], Erin E. Hahn[7], **Theresa H. M. Keegan**[1]

[1]UC Davis Comprehensive Cancer Center, Sacramento, CA,[2]University of Utah, Salt Lake City, UT,[3]Fred Hutch Cancer Center, Seattle, WA,[4]Kaiser Permanente Northern California, Oakland, CA,[5]University of North Carolina at Chapel Hill, Chapel Hill, NC,[6]Kaiser Permanente Washington Health Research Institute, Seattle, WA,[7]Kaiser Permanente Southern California, Pasadena, CA

Adolescents and young adult (AYA) cancer survivors face a higher risk of chronic medical conditions and are more likely to delay or forgo health care due to costs compared to same-age individuals without cancer. They also experience greater financial hardship than older adult survivors. However, gaps remain in our understanding of the financial hardships associated with cancer or the lasting health effects of treatment in AYA cancer survivors. In the Valuing Opinions and Insights from Cancer Experiences (VOICE) Study, participants diagnosed during 2016-2022 with 10 common AYA cancers between ages 15-39 years in California completed a survey in 2023-2024. Financial hardship was measured by financial debt due to cancer and 8 questions on the impact of medical expenses in the past year, categorized into trouble meeting needs (e.g., put off major purchases, unable to pay for basic necessities), asset depletion (e.g., took money from savings/retirement, credit card debt) and major financial changes (e.g., needed mortgage against home, thought about bankruptcy). In addition, we assessed whether AYAs were diagnosed after cancer diagnosis with 10 chronic medical conditions (asthma/lung problems, blood clots, bladder dysfunction, diabetes, heart conditions, hypertension, kidney dysfunction, liver problems, osteoporosis, thyroid problems). We examined the association of each financial hardship with 1 or ≥2 (vs 0) medical conditions using multinomial logistic regression, adjusting for age, sex, race/ethnicity, current health insurance and cancer type. Among 3,685 AYAs, most were age 30-39 years at diagnosis (70.6%), of non-Hispanic (NH) White (34.6%) or Hispanic (32.4%) race or ethnicity and had employer-sponsored insurance (66.6%). Breast (25.3%), thyroid (22.4%) melanoma (10.0%), and testicular (10.3%) were the most common cancers. Overall, 18.9% and 7.8% of AYAs developed 1 or ≥2 of the 10 chronic medical conditions, respectively. Nearly one-fifth (18.8%) of AYAs experienced financial debt since their cancer diagnosis. In the past year, approximately one-third of AYAs experienced trouble meeting needs (27.5%) and asset depletion (31.7%), while 6.1% experienced major financial changes. In multivariable models, AYAs with ≥2 conditions were more likely to have financial debt (odds ratio (OR)=1.99, 95% confidence interval (CI) 1.50-2.64 vs. no medical conditions), trouble meeting needs (OR=2.05, CI 1.58-2.67), asset depletion (OR=1.83, CI 1.42-2.37) and major financial changes (OR=2.24, CI 1.49-3.36). Financial hardship impacts one-third of AYA cancer survivors, and those with chronic medical conditions have a substantially greater likelihood of experiencing financial hardship. Our findings highlight the long-term economic impact of cancer in this population and the need to evaluate the effectiveness of targeted interventions, such as financial navigation, to address financial burden.

#7889 Integrating genetic predictors into breast cancer risk stratification among female survivors of childhood cancer.

Aparna Srinivasan[1], Jian Wang[2], Gavriel Matt[2], Lauren J. Mills[1], Yadav Sapkota[2], Zhaoming Wang[3], Tianzhong Yang[1], Joseph P. Neglia[1], Lucie M. Turcotte[1], Melissa M. Hudson[2], Kirsten K. Ness[2], Gregory T. Armstrong[2], Jinghui Zhang[2], Leslie L. Robison[2], Xin Zhou[2], Yutaka Yasui[2], Cindy Im[1]

[1]Pediatrics, University of Minnesota, Minneapolis, MN,[2]St. Jude Children's Research Hospital, Memphis, TN,[3]University of South Florida, Tempa, FL

Background: Childhood cancer survivors are at high risk for developing breast cancer (BC). Existing BC risk stratification tools primarily consider childhood cancer treatment risk factors, but do not assess genetic predictors. The St. Jude Survivorship Portal (https://survivorship.stjude.cloud) is a new open-access online data resource that supports deeper investigations of late effects genetic susceptibility. In this study, we evaluated data available in this portal, specifically common and rare genetic variation, for their relative contributions to subsequent BC risk stratification.
Methods: Five-year female survivors from 2 cohort studies (Childhood Cancer Survivor Study; St. Jude Lifetime Cohort) were analyzed. Common variants were assessed using 99 published general population sporadic BC polygenic risk scores (PRSs), computed using whole-genome sequencing (WGS) or imputed array-based genotype data. Hazard ratios (HRs) were estimated with Cox regression using age as the time scale and adjusted for genetic ancestry, batch, and chest radiotherapy (RT) and anthracycline doses. PRS-RT interactions assessed whether PRSs modified risks conferred by chest RT dose. Rare pathogenic/likely pathogenic (P/LP) variants in BC susceptibility genes examined in general population sequencing studies (BRCA1, BRCA2, CHEK2, PALB2, RAD51C, RAD51D, TP53, ATM) were evaluated.
Results: In this multi-ancestry cohort (N=5388; 88% European, 8% African, 4% Asian ancestry), the median attained age was 38y (IQR 30-46) and 63% were treated with chest RT. 319 survivors developed BC. Overall, 90.1% of sporadic BC PRSs were nominally replicated (P<0.05). No PRS modified chest RT-related BC risk. Notably, the most studied BC PRS (313 variants; evaluated in >70 studies) did not show the strongest risk association in survivors (HR per SD=1.17, 95% CI=1.04-1.31). Instead, PRSs with more variants genome-wide demonstrated effect sizes similar to some treatment predictors (e.g., “best” PRS: ~6.4 million variants, HR per SD=1.71, 95% CI=1.43-2.05; P=4.2x10-9). BC PRSs with the strongest associations (top 25%) were 4.7-times more likely to include variants mapped to multiple (2) DNA repair pathways (P=0.018). Among the 3292 survivors with WGS, 61 (1.8%) carried rare P/LP variants in BC risk genes. Carrying BC P/LP variants was suggestively associated with BC risk (HR=2.40, P=0.055). While the best BC PRS had greater risk stratification potential (top vs bottom 20%: HR=5.94, 95% CI=2.70-13.07, P=8.6x10-6), most (4 out of 6) BC-affected survivors with BC P/LP variants were not captured by this PRS cutoff.
Conclusions: Overall, our results suggest specific published sporadic BC PRSs could be considered in future updates to childhood cancer survivorship care guidelines and in subsequent BC risk prediction models. Further study of targeted BC pathogenic risk variant screening is needed in this population.

#7890 Insights into chemotherapy-related cognitive impairment in childhood acute myeloid leukemia survivors.

Joel Costoya[1], Carolyn Cabrera[2], Joaquin J. Jimenez[3]

[1]Department of Biochemistry and Molecular Biology, University of Miami Miller School of Medicine, Miami, FL,[2]University of Miami Miller School of Medicine, Miami, FL,[3]Phillip Frost Department of Dermatology and Cutaneous Surgery, University of Miami Miller School of Medicine, Miami, FL

Chemotherapy-related cognitive impairment (CRCI) has mainly been explored within the context of childhood ALL survivors, whereas data analyzing for pediatric AML neurocognitive outcomes following chemotherapy remains sparse. Standard induction therapy for pediatric AML involves the use of high dose Ara-C intrathecal chemotherapy for CNS prophylaxis, sometimes combined with Methotrexate, both well-documented causal agents regarding neurotoxicity and their link to CRCI. In order to better understand how standard induction therapy affects neurocognitive outcomes for childhood survivors of AML, we searched PubMed, EMBASE, and PsycINFO (2015-2025) using terms such as “childhood acute myeloid leukemia”, “neurocognitive outcomes”, “ ‘chemo brain’ ”, and “cognitive”. Inclusion criteria were limited to pediatric AML-specific cohorts who had undergone validated neuropsychological testing and/or self-reported outcomes. Exclusion criteria were HSCT/cranial RT unless chemotherapy-only results were separable. Three peer-reviewed studies, and one meeting abstract were found which met the criteria. Across AML-specific cohorts, treatment with conventional therapy was associated with impairment in at least one neurocognitive domain, with the relative risk for impairment in two domains being demonstrably higher in the CCSS AML cohort. These studies revealed broad impairment across all domains, with working memory emerging as being notably affected, and exhibiting lasting negative effects on QoL persisting well into adulthood amongst these cohorts. Other similarly impaired neurocognitive domains corresponded to issues with emotional regulation and efficiency accomplishing tasks. One study found no difference in FSIQ when comparing AML survivors to population means, yet their study had an n=12, and showed time since diagnosis, and age at assessment were significant predictors of FSIQ. Additionally, these studies also support the risk for CRCI independent of HSCT, as large survivorship analysis differentiating intense chemotherapy with or without HSCT still found measurable neurocognitive impairment regardless of treatment modality. Given the current evidence, childhood survivors of AML exposed to standard induction therapies are at risk of developing CRCI, with working memory and executive functioning being likely impaired. A significant fraction of pediatric AML survivors experience CRCI may be suffering from unrecognized health conditions, and as such may largely benefit from increased neurocognitive monitoring and resources. As for future pediatric AML patients, careful consideration of these neurocognitive consequences could inform risk-stratified intensity adjustments and introduce targeted neuroprotective strategies during therapy, minimizing cognitive morbidity and allowing patients to not only live longer, but live better.

#7891 Real world treatment with molecularly matched targeted therapies in the era of pediatric precision cancer medicine: Gaining ground or inching forward?.

Jennifer A. Oberg[1], Jack Boublik-Whiteley[2]

[1]Pediatrics, Division of Pediatric Oncology, Columbia University Medical Center, New York, NY,[2]Los Altos High School, Los Altos, CA

Introduction: Children and adolescents diagnosed with relapsed/refractory or high-risk cancer have a poor prognosis and <20% survival rates for those with recurrent disease. Several pediatric precision cancer medicine programs have been established to inform clinical decision making and provide molecularly matched therapeutic options for patients in need. However, the clinical benefit of these therapies in real-world settings is unknown. A review of the literature and patients sequenced through the Precision in Pediatric Sequencing (PIPseq) program at Columbia University Medical Center (CUMC) was conducted to describe outcomes of patients with solid or CNS tumors treated with a molecularly matched targeted therapy (MTT).

Methods: PubMed and the CUMC medical record were reviewed between 2013-2025. Patient-level molecular and treatment data were extracted for those diagnosed with high-risk or relapsed/refractory disease. Clinical benefit rate (CBR) (percent complete response (CR), partial response (PR), and stable disease (SD) for >/= 6 months) was evaluated. Progression free (PFS) and overall survival (OS) differences were assessed using the log-rank test.

Results: 20 studies and 29 PIPseq patients were identified. 233 CNS and 394 solid tumor (ST) patients were included. 40% (CNS), 23% (ST) and 30% overall derived clinical benefit. Patients with low grade glioma had the highest CBR (69%, n = 36) and medulloblastoma had the lowest CBR (20%, n = 20). CBR for the largest CNS cohort, high grade glioma, was (25%, n = 122). CBR for select ST subtypes were 16% (adrenal, n = 81), 11% (osteosarcoma, n = 65), 16% (rhabdomyosarcoma, n = 55) and 12% (Ewing sarcoma, n = 33). Kaplan-Meier survival analysis was conducted to compare survival distributions across treatment categories, MTT monotherapy, multi agent MTT, and MTT+chemotherapy. By treatment category, median PFS/OS for CNS patients (n = 166/138) were 5.5/32.1, 14/32.2, and 4.8/24 months, respectively. Log-rank tests indicated a significant PFS/non-significant OS difference, $X^2(2) = 7.45/1.12$, $p = .025/.571$ with an estimated median follow-up of 28/32.1 months. Median PFS/OS times for ST patients (n = 263/179) by treatment category were 4.2/11.6, 1.7/32.3, and 4.1/13.7 months, respectively with non-significant differences in survival, $X^2(2) = 4.1/1.72$, $p = .129/.423$. The estimated median follow-up was 22.8/28.2 months.

Conclusions: Overall, 30% of patients treated with MTT derived clinical benefit. There was a significant difference in PFS but not OS for CNS patients with multiagent MTT yielding the longest PFS and OS compared to MTT monotherapy or MTT+chemotherapy. Treatment modality did not reveal a significant difference in survival for ST patients. Longer follow up beyond 2 years is needed to assess survival in pediatric patients treated with MTT.

#7892 Multi-ancestry genome-wide association study (GWAS) of pediatric acute myeloid leukemia (AML) risk identifies four risk loci.

Cindy Im[1], **Lauren J. Mills**[1], Peggy Meng[2], Marijana Vujkovic[3], Jenny N. Poynter[1], Melissa Maria Hudson[2], Kirsten K. Ness[2], Joseph L. Wiemels[4], Logan G. Spector[1], Saonli Basu[5], Zhaoming Wang[6], Richard Aplenc[7]

[1]University of Minnesota, Minneapolis, MN,[2]St. Jude Children's Research Hospital, Memphis, TN,[3]University of Pennsylvania, Philadelphia, PA,[4]University of Southern California, Los Angeles, CA,[5]Masonic Cancer Center, Minneapolis, MN,[6]University of South Florida, Tampa, FL,[7]Children's Hospital of Philadelphia, Philadelphia, PA

Introduction: AML is a relatively rare pediatric hematological malignancy, but its treatment outcomes trail other acute leukemias with a 5-year survival rate at ~70%. While genome-scale susceptibility studies of adult AML risk have been conducted, similar pediatric AML studies have not been published.

Methods: 1854 pediatric AML cases (diagnosis age <25y) were assembled from the Children's Oncology Group (clinical trials AAML-03P1/0531/1031), Hospital for Sick Children (CA), International Berlin-Frankfurt-Münster Study Group (DE), and Royal Alexandra Hospital for Children (AUS). Cases were genotyped with the Illumina HumanOmni 2.5 BeadChip. Using ADMIXTURE-inferred global genetic ancestry, 1355 cases were grouped in African (AFR, N=95), Admixed American (AMR, N=118), East Asian (EAS, N=74) and European (EUR, N=1068) ancestry groups. Sex-/ancestry-matched publicly available adult controls from 3 external cohorts (Age-Related Eye Disease Study, Health and Retirement Study, Long Life Family Study) genotyped with the same platform were identified at a ~4:1 ratio. TOPMed-based imputation (version r3) supported ancestry-specific GWAS with 5.5-10.7 million common variants (minor allele frequency, MAF≥1%). Logistic regression models adjusted for population substructure tested variant risk associations. Multi-ancestry meta-analysis was performed using an inverse variance-weighted fixed effects model.

Results: Four novel genome-wide significant ($P<5x10^{-8}$) pediatric AML risk loci (*PRIM2*, *HERC2*, *AGRN*, *DEFB131A*) were identified in the EUR GWAS (N=5340), with moderate per-allele odd ratios (OR range: 1.9-2.9). *In silico* analyses indicated lead variants at *HERC2*, *AGRN*, and *DEFB131A* loci are in active chromatin regions in blood or bone marrow tissues and overlap transcription factor binding sites, including in leukemia cell lines. The *HERC2* index variant (OR=1.9, 95% CI: 1.5-2.3) is associated with *HERC2* expression in venous blood (GTEx). Multiple variants at known EUR adult AML risk locus *KMT5B* were also nominally replicated ($P=8.7x10^{-3}$). Additional suggestive associations ($P<1x10^{-6}$) in the AFR (N=475) and AMR (N=518) GWAS were seen; among these, putative pediatric AML risk locus *KANK1*, which was characterized by low frequency (MAF=1-5%) AFR-specific effect alleles, i.e., nearly absent in other ancestries, is notable for its large risk effects (OR=5.6, 95% CI: 3.0-10.7). The multi-ancestry meta-analysis did not reveal additional genetic signals shared across ancestry groups.

Conclusion: We report results from the first pediatric AML GWAS (N=6507, 1355 cases) using international data. We identified 4 novel EUR-specific risk loci, a plausible novel AFR-specific risk locus, and replicated *KMT5B*, a risk locus reported in a EUR adult AML meta-analysis. Future work includes replication and functional validation studies.

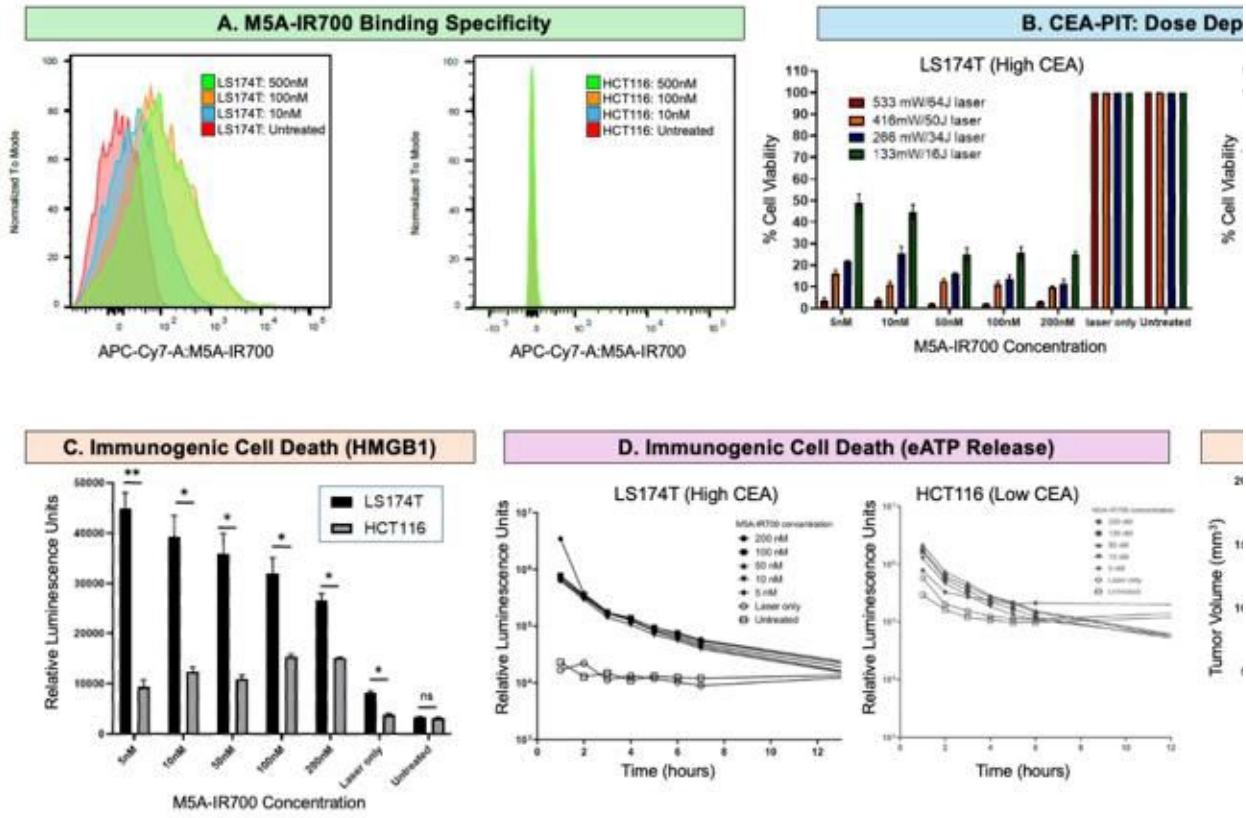
#7896 Induction of targeted-cytoxicity and immunogenic cell death using an anti-CEA antibody linked to IRDye700Dx.

Simran Mehta[1], Jitender Jitender[1], Teresa Hong[1], Michael Bouvet[2], John E. Shively[1], Paul J. Yazaki[1], **Thinzar Min Lwin**[3]

[1]City of Hope Comprehensive Cancer Ctr., Duarte, CA,[2]UCSD Medical Ctr., La Jolla, CA,[3]Department of Surgery, City of Hope Comprehensive Cancer Ctr., Duarte, CA

Introduction: Near-infrared photoimmunotherapy (NIR-PIT) uses antibody-photosensitizer conjugates to induce spatially controlled and targeted cytotoxicity. The IRDye700DX phthalocyanine photosensitizer undergoes photochemical alterations upon activation with 690 nm light which results in targeted cell death via membrane disruption on cancer cells. This study evaluated the therapeutic efficacy and antigen specificity of a carcinoembryonic (CEA) antigen-targeted NIR-PIT using the humanized anti-CEA antibody (M5A) conjugated to IRDye700Dx (M5A-IR700) in a colon cancer model.
Methods: M5A was conjugated to NHS-IRDye700DX and validated for binding to human colon cancer cell lines with high-CEA (LS174T), low-CEA (HCT116) by flow cytometry. In vitro, cells were exposed to graded NIR irradiation (690 nm), assessed for cell death (MTS) and evaluated for immunogenic cell death markers (ICD, extracellular ATP, HMGB1). In vivo efficacy was evaluated in athymic mice bearing subcutaneous LS174T xenografts. Mice received intravenous M5A-IR700 (75 µg) followed 24 hours later by a 690 nm laser treatment (150 mW/cm², 30 minutes).
Results: Flow cytometry confirmed robust, antigen-dependent binding in high-CEA LS174T cells relative to the weak binding observed in low-CEA HCT116 cells (Figure 1A). NIR-PIT with M5A-IR700 resulted in light fluence-dependent and concentration-dependent cytotoxicity (Figure 1B). Maximal phototoxicity was observed in LS174T at 64 J/cm². In contrast, there was minimal response in low CEA expressing HCT116 cells, confirming antigen-density dependent cytotoxicity. Extracellular ATP and HMGB1 were significantly elevated in LS174T but not HCT116 cells (Figure 1C). Rapid release of extracellular ATP occurred immediately following NIR-PIT in LS174T cells and this response was attenuated in HCT116 cells. These findings indicate an antigen-restricted induction of ICD. Mice treated with M5A-IR700 and laser activation (M5A-IR700 PIT) demonstrate significant suppression of tumor volume over 30 days compared with untreated controls and mice receiving antibody alone ($p<0.01$) (Figure 1E).
Conclusion: CEA-targeted NIR-PIT using M5A-IR700 effectively induced antigen-specific immunogenic cell death in vitro and robust tumor control in vivo. Differential responses between LS174T and HCT116 validate antigen density dependence which is essential for clinical translation. These findings provide strong rationale for clinical development of M5A-IR700-mediated NIR-PIT as targeted therapy for CEA-positive colorectal cancers.



#7897 Novel Rho-GTPase regulatory protein gene family variants are frequent and associate with poor survival in patients (pts) with acute myeloid leukemia (AML).

Ethan Hamp[1], Lorenz Oelschlager[2], Bailee N. Kain[3], Deedra Nicolet[4], Krzysztof Mrozek[1], Katherine E. Miller[5], Audrey Bollas[5], Michael C. Walker[4], Christopher J. Bloomfield Center for Leukemia Outcomes Research, Columbus, OH,[5]Institute for Genomic Medicine, Nationwide Children's Hospital, Columbus, OH,[6]University of Alabama, Birmingham, AL,[7]Emory University, Atlanta, GA,[8]Wake Forest University, Winston-Salem, NC,[9]Division of Oncology, Washington University School of Medicine, Saint Louis, MO,[10]College of Medicine, University of Chicago, Chicago, IL,[11]Department of Oncology, Albert Einstein College of Medicine, New York City, NY,[12]Department of Medical Oncology, Dana-Farber Cancer Institute, Boston, MA,[13]Department of Internal Medicine, University of Cincinnati, Cincinnati, OH,[14]University of Pennsylvania, Philadelphia, PA,[15]OHSU Knight Cancer Institute, Portland, OR,[16]St. Jude Children's Research Hospital, Memphis, TN

Introduction: AML is a molecularly heterogeneous disease that is classified by recurrent cytogenetic abnormalities and gene mutations. Recent studies have shown divergent frequencies of several genetic aberrations depending on genetic ancestry and self-reported race/ethnicity, highlighting the need to broaden sequencing efforts to include more diverse pts.
Methods: We performed paired tumor/normal whole exome sequencing (WES) and transcriptome sequencing on 271 ancestry and/or ethnically diverse pts [including 100 African American (AA) and 71 self-identified Hispanic pts; CALGB/Alliance], and a validation cohort of 45 AA pts (University of Pennsylvania).
Results: We identified >20 genes to be mutated in 3-8% of pts that were not seen in previous sequencing efforts of predominantly non-Hispanic White/European ancestry (EA) pts. Notably, variants in genes encoding Rho-GTPase regulatory proteins (*ARHG* family, belonging to the *RAS* gene superfamily) were identified in 12% of pts, placing these genes in the top 5 of recurrently mutated genes in this pt cohort. This frequency was confirmed in the second cohort of AA pts (n=7/45, 15%). In contrast, analysis of 805 EA adults with WES data (BeatAML 2022) and 877 pediatric AML pts (TARGET) found *ARHG* gene family variants in 26/805 (3%) and 17/877 (1.9%) of EA AML pts, respectively. With a median age of 41y, *ARHG*-mutated(m) pts tended to be younger (P=.16) and more often diagnosed with core-binding factor AML (39% vs 19%, P=.02). *ARHG* mutations frequently co-occurred with *NRAS* and *FLT3* mut (each found in 35% of *ARHG*m pts). Notably, survival of *ARHG*m pts was poor, with a median overall survival (OS) of <12 months, thereby mirroring OS of the 2022 European LeukemiaNet (ELN) Adverse risk group. Within the 2022 ELN Favorable risk group in the ancestry diverse cohort, *ARHG*m pts had shorter OS than *ARHG*wt pts (P=.02). The clinical outcome was especially poor in young adolescents and adults (AYA, 18-39y) (mut vs wt; 3y disease-free survival, 10% vs 50%, P<.001; 3y OS, 20% vs 55%, P=.008). RNAseq of 17 *ARHG*m pts showed transcriptomic RAS pathway activation, with 52% displaying a RAS-associated signature, also in the absence of other *RAS* mutations. Furthermore, bulk transcriptomic analyses of 1250 AML pts identified 120 predicted *RAS* signature genes, with the upregulated genes being enriched in metallopeptidases, MAP kinase phosphatases, and *ARHG* genes.
Conclusion: We identified mutations in *ARHG* family genes as frequent yet thus far unrecognized RAS pathway activators in AML associated with poor survival that are not yet included in clinical testing panels. Their lack of recognition is likely due to the heterogeneity of mutationally affected *ARHG* family genes, enrichment in AYA pts and the high frequency in pts of non-European ancestry, both of which are pt populations that were underrepresented in previous sequencing efforts.

#7898 Clinical benefit of the HIF-2α inhibitor casdatifan (Cas) across molecular subtypes in clear cell renal cell carcinoma (ccRCC) patients from the ARC-20 Clinical Study.

Benjamin Weeder[1], Yinghui Guan[1], Jaskirat Singh[1], Brian Rini[2], Toni K. Choueiri[3], Angelo Kaplan[1], Omar Kabbarah[1], Soonweng Cho[1]

[1]Arcus Biosciences, Inc., Hayward, CA,[2]Vanderbilt, Nashville, TN,[3]Dana-Farber Cancer Institute, Boston, MA

Introduction: Recently, casdatifan (Cas), an orally bioavailable small molecule inhibitor of hypoxia-inducible factor-2 alpha (HIF-2α), demonstrated promising efficacy in metastatic ccRCC in the ARC-20 clinical trial (NCT05536141). Despite progress towards the identification of ccRCC molecular subtypes, the relationship between established molecular classifications (Motzer et al., Cancer Cell 2020), HIF-2α transcriptional signatures (Courtney et al., CCR 2020), and clinical benefit from HIF-2α inhibitors has not been investigated. Herein we explore whether patients characterized by these RNA-based molecular subtypes show evidence of HIF-2α activity and whether they derive clinical benefit from Cas monotherapy.
Methods: Archival tumor biopsies were taken from 67 ccRCC patients enrolled in ARC-20 who received daily doses ≥50mg of Cas monotherapy. Molecular subtypes were defined based on the quantile normalized RNA expression of literature-defined molecular signatures. Gene signature assessment across subtypes was performed using ssGSEA on voom-normalized RNA expression levels.
Results: Using literature-based classification of ARC-20 samples, patients were assigned to one of six molecular subtypes (angiogenesis/stromal, angiogenesis, immune/proliferative, proliferative, stromal/proliferative, or unclassified), falling into one of three broader molecular categories (angiogenesis, immune, or other). Cas monotherapy resulted in similar disease control rate (DCR) and progression free survival (PFS) across the previously derived molecular subtypes (χ^2=0.26, p=0.878; Log-rank p>0.9). We further explored the relationship between HIF-2α activity and previously defined ccRCC subtypes using HIF-2α-related gene expression signatures; there was no enrichment of HIF-2α related gene expression signatures in these predefined molecular categories. However, we observed a strong relationship between the expression of HIF-2α transcriptional signatures and clinical benefit in patients treated with Cas monotherapy. In contrast, higher HIF-2α gene signature expression was associated with shorter PFS in patients treated with either sunitinib (Log-rank, p<0.001) or atezolizumab plus bevacizumab (Log-rank p=0.012) in available data from the IMmotion 151 study.
Conclusions: The HIF-2α inhibitor Cas produces similar clinical benefit in all previously described molecular subtypes of ccRCC. While most ARC-20 patients derived benefit from Cas monotherapy, there was a strong relationship between clinical benefit (PFS) and expression levels of HIF-2α transcriptional signatures in tumor samples.

#7899 BGB-21447, a next generation Bcl-2 inhibitor, shows high potential in Bcl-2 overexpressing B cell non-Hodgkin lymphomas (NHL) cancers in preclinical studies.

Haitao Wang[1], Lin Li[1], Yiwen Wang[1], Weiwei Song[1], Shuang Peng[1], Sijia Zhai[1], Ziyu Jia[1], Peng Chi[1], Teiko Sumiyoshi[2], Ting Deng[3], Yang Liu[3], Wei Jin[1], Zhirong Shen[3]

[1]BeOne Medicine (Beijing) Co., Ltd., Beijing, China,[2]BeOne Medicines USA, Inc., San Carlos, CA,[3]BeOne Medicines (Shanghai) Co., Ltd., Shanghai, China

Background: Venetoclax's success in CLL/SLL and AML validates Bcl-2 as a therapeutic target in hematologic malignancies. However, suboptimal efficacy has limited its development in DLBCL and multiple myeloma (MM) , raising uncertainty about whether Bcl-2 is an effective target in these diseases or if a more potent Bcl-2 inhibitor is needed. Biologically, DLBCL has ≥20% BCL2 genetic alterations or ≥50% overexpression in patients, while Bcl-2 overexpression is also commonly observed in MM patients. These findings underscore the relevance of targeting Bcl-2 in both indications. In this study, we evaluate the potential of BGB-21447, a next-generation Bcl-2 inhibitor structurally distinct from sonrotoclax (BGB-11417), mainly in DLBCL/B-NHL via preclinical studies.

Methods: Cell viability was assessed by CTG assay *in vitro*. Xenografts were established by subcutaneously inoculating cancer cells into NCG mice for in vivo efficacy evaluation. Bcl-2 protein levels were quantified using western blot and ELISA.

Results: A panel of 21 DLBCL cell lines (15 GCB-DLBCL and 6 ABC-DLBCL) was tested for sensitivity to BGB-21447. In vitro CTG assays showed that 8/21 DLBCL cell lines responded to BGB-21447 with single-digit nanomolar (nM) potency, while the others were resistant. Sensitivity did not correlate with cell-of-origin subtype, but was enriched in cell lines with BCL2 genetic alterations, such as BCL2 amplification or t(14;18) translocation. Bcl-2 protein expression analysis revealed that these genetic alterations were associated with high Bcl-2 protein levels, as determined by western blot and ELISA. Notably, only cell lines with high Bcl-2 protein level were sensitive to BGB-21447, suggesting Bcl-2 protein expression as a potential predictive biomarker. In vitro studies in Bcl-2-dependent DLBCL and MCL cell lines demonstrated that BGB-21447 is over 50-fold more potent than venetoclax, indicating strong potential in indications where venetoclax efficacy is limited. This was further supported by in vivo studies: BGB-21447, at 4 or 8 mpk QD (clinically achievable doses), showed significant anti-tumor activity in Toledo xenografts, while venetoclax at 50mpk QD (doses relevant to 1200 mg QD in humans) showed only partial efficacy. In SU-DHL-6 xenografts, venetoclax at 50 mpk QD had minimal effect, whereas BGB-21447 at 8 mpk significantly inhibited tumor growth. Similar trends were observed in Minami-1 (FL model) xenografts, where BGB-21447 induced complete tumor regression, while venetoclax at 50 mpk QD showed partial activity.

Conclusions: These findings indicate that BGB-21447 is a Bcl-2 inhibitor with substantially greater potency than venetoclax and strong potential in indications such as DLBCL where venetoclax has suboptimal efficacy. Clinical trials are needed to validate these results.

#7900 Clinical significance of elevated *UBQLN4* expression with resistance to cisplatin in intrahepatic cholangiocarcinoma.

Kodai Abe[1], Kelly K. Chong[1], Yuta Abe[2], Minoru Kitago[2], Motonori Edanami[2], Yosuke Uematsu[2], Yohei Masugi[3], Akihisa Ueno[3], Anton Bilchik[4], Yosef Shiloh[5], Yuko Kitagawa[2], Dave Hoon[1]

[1]Translational Molecular Medicine, Providence Saint John's Cancer Institute, Santa Monica, CA,[2]Surgery, Keio University School of Medicine, Tokyo, Shinjuku-ku, Japan,[3]Diagnostic pathology, Keio University School of Medicine, Tokyo, Shinjuku-ku, Japan,[4]Gastrointestinal and Hepatobiliary Surgery, Providence Saint John's Health Center, Santa Monica, CA,[5]Human Molecular Genetics and Biochemistry, The David and Inez Myers Laboratory for Cancer Research, Tel Aviv, Israel

Backgrounds & Aims: Intrahepatic cholangiocarcinoma (iCCA) is a devastating biliary tract cancer increasing in incidence worldwide with limited treatment options. We previously identified ubiquilin-4 (*UBQLN4*) was associated with prognosis and chemotherapy response in breast and esophageal cancer. *UBQLN4* is a ubiquitinated-binding protein which inhibits homologous recombination repair while promoting non-homologous end-joining repair in DNA damage repair. The objective of this study is to determine the clinical utility of *UBQLN4*, as a potential prognostic biomarker associated with iCCA clinical outcomes.

Methods: The public datasets from TCGA-CHOL (n=32), DepMap, and Fu-iCCA cohort (n=238), GSE107943 (n=30), and GSE32225 (n=148) were assessed for copy number variation (CNV) and/or mRNA expression analysis of *UBQLN4* located on 1q22 chromosome. As validation, an independent cohort of iCCA patients (n=66) were analyzed for clinical significance of *UBQLN4*. We finally investigated *in-vitro* analysis to evaluate the molecular features and cisplatin-resistance (CR) mechanism of UBQLN4.

Results: GISTIC analysis of TCGA-CHOL dataset showed that 1q22 including *UBQLN4* is one of the highest amplifications in all chromosomes. There is high correlation between CNV and mRNA expression of *UBQLN4* gene in iCCA tissues from TCGA-CHOL, DepMap, and FuiCCA cohort. *UBQLN4* was also found to be upregulated in iCCA tissues compared to normal liver tissues or biliary epithelium from TCGA-CHOL, GSE107943 and GSE32225 datasets. In an independent iCCA validation cohort, *UBQLN4* mRNA upregulation was significantly associated with poor recurrence-free survival ($p = 0.025$). *UBQLN4* mRNA high expression was an independent recurrence risk factor in a multivariate cox regression analysis (Hazard risk = 2.26, 95% confidence interval 1.00 - 5.11, $p = 0.048$). In *in-vitro* using iCCA cell lines (RBE and HCCC9810), knockdown of *UBQLN4* lead to high sensitivity for cisplatin compared to controls; however, CR-iCCA cell lines showed high UBQLN4 expression concomitant with increased phosphorylated ATM (pATM). Moreover, 3D spheroid assay revealed UBQLN4 and pATM are expressed significantly higher in CR-iCCA cell lines than respective parental cell lines. In clinically annotated iCCA specimens, non-responders to neoadjuvant chemotherapy including cisplatin had increased UBQLN4 and pATM protein levels in iCCA tissues as assessed by multiplex immunofluorescence, supporting that FuiCCA cohorts showed high UBQLN4 and pATM protein levels lead to worse prognosis (p=0.049).

Conclusions: Upregulated *UBQLN4* expression correlates with postoperative recurrence as well as resistance to cisplatin in iCCA patients, indicating that *UBQLN4* is a strong prognostic biomarker related to cisplatin treatment of iCCA patients.

#7901 Renal cancer early diagnosis using a novel B7-H3 targeted ultrasound contrast imaging.

Arutselvan Natarajan, Jihye Baek, Ramasamy Paulmurugan, Jeremy Dahl

Stanford University, Stanford, CA

Aim: Cost-effective or accessible methods to detect kidney cancers, especially those with renal insufficiency, remain elusive. We propose ultrasound molecular imaging (UMI) using microbubbles (MBs) targeted to cancer-associated vascular endothelial (VE) markers as a diagnostic imaging tool for kidney cancer with high specificity. CD276 (B7-H3), an immune checkpoint (IC) marker and a member of the immunoglobulin superfamily, is overexpressed on the VE cells of different cancers including renal cancer.

Methods: We have developed an engineered affibody (Aby) specifically targeting both mouse and human B7-H3 for imaging renal cancer in vivo using US. In this study, we biotinylated the Aby and linked to MBs that were functionalized with avidin to create B7-H3 targetable MBs (TMBs) or with a scrambled Aby not binding to B7-H3 as a control MBs (non-targeted MBs or NTMBs), yielding (10×10^8 MBs/mL). Balb/C mice (n=4) were implanted with renca kidney cancer cells at the lower flank for in vivo imaging of VE-B7-H3 expression in the tumor. We also performed immunofluorescence (IF) analysis of the tumor tissue for the presence of B7-H3 and CD31 on VE cells at the vessels in the tumor microenvironment (TME).

Results: Mice were imaged after tumor growth reached to 0.8-1.1 mm diameter with UMI, after administration of $1\text{-}2 \times 10^7$ TMBs or NTMBs in 200 µL of saline. Compared to control NTMBs, the UMI signal using B7-H3-targeted TMBs was significantly higher (P= 0.002). IF analysis confirmed a high correspondence between B7-H3 and the universal vascular CD31 marker.

Conclusions: The developed TMBs were able to detect and image the in vivo expression of tumor-associated B7-H3 in the VE cells. The results support the feasibility of these B7-H3-TMBs in translating into human kidney cancer diagnosis using UMI.

#7902 Analytical accuracy and clinical performance of the OncoMate MSI Dx Analysis System in a subset of KEYNOTE-775 endometrial carcinoma classified as MSS (not MSI-H) by the companion diagnostic.

Sam Sibley[1], Matthew Marton[2], Amy Wehn[2], Yiwei Zhang[2], Kathryn Oostdik[1], Ryan Mordini[1], Gary Tarpley[1]

[1]Promega, Madison, WI,[2]Merck & Co., Rahway, NJ

Background: Advanced endometrial carcinoma (EC) presents a major clinical challenge, with poor prognosis and few treatment options. Pembrolizumab (KEYTRUDA®) in combination with lenvatinib (LENVIMA®) has been approved by the FDA for the treatment of adult patients with advanced EC that is mismatch repair proficient (pMMR) or not microsatellite instability high (MSI-H). The OncoMate® MSI Dx Analysis System is a PCR-based assay for MSI determination in FFPE tumor tissue with custom software for automated analysis. Here, we present analytical accuracy and clinical performance data that supported FDA approval of the OncoMate® MSI Dx assay as a companion diagnostic (CDx) to identify patients with advanced EC who may benefit from treatment with pembrolizumab plus lenvatinib.

Design: Analytical accuracy was assessed retrospectively in 255 EC samples from the KEYNOTE-775 clinical trial by comparing OncoMate® MSI Dx assay results with a commercially available immunohistochemistry (IHC) panel. Clinical performance was evaluated in a bridging study (n=489) linking MSI status with outcomes from KEYNOTE-775. The efficacy of pembrolizumab plus lenvatinib versus treatment of physician's choice (TPC) was estimated for progression-free survival (PFS), overall survival (OS), objective response rates (ORR), and duration of response (DOR) for the CDx-defined microsatellite stable (MSS; equivalent to not MSI-H) subpopulation.

Results: Analytical accuracy was high: agreement between MSS vs pMMR results was 99.0% (95% CI, 96.5-99.7%), agreement between MSI-H vs dMMR results was 91.7% (95% CI, 80.4-96.7%), and overall agreement was 97.6% (95% CI, 95.0-98.9%). In the clinical cohort, patients with MSS tumors identified by the OncoMate® MSI Dx assay demonstrated significant benefit from pembrolizumab plus lenvatinib versus TPC, with improvements in PFS, OS, ORR, and DOR consistent with published trial results.

Conclusion: The OncoMate® MSI Dx assay was accurate compared with an established IHC orthogonal method and provided complementary information to IHC about tumor MMR status for some patients. The assay, which directly assesses DNA MMR function via microsatellites, retrospectively identified EC patients who would benefit from combination treatment with pembrolizumab plus lenvatinib compared with TPC. Specifically, pembrolizumab plus lenvatinib efficacy in a subset of KEYNOTE-775 participants with CDx-defined MSS (not MSI-H) tumors was comparable to the efficacy observed in all IHC-defined pMMR participants randomized in the original trial. These results support use of the OncoMate® MSI Dx assay for this indication and validate that PCR- and IHC-based methods identify comparable patient populations who benefit from pembrolizumab plus lenvatinib.

#7903 MiR-362-3p enhances platinum response in breast cancer.

Zhaoji Liu[1], Shizhong Ke[1], Xiaohui Li[1], Catherine Wu[1], Madison M. Uyemura[1], Brian R. Sardella[1], Erica S. Massicott[1], Lin Wang[1], Emily K. Aronson[1], Dimitra Karagkouni[1], Nikolas Kalavros[1], Ioannis S. Vlachos[1], Felipe Batalini[2], Cristina S. Bogsan[1], Jit Kong Cheong[3], Lihan Zhou[3], He Cheng[3], Phillip Munson[3], Erica L. Mayer[4], Judy E. Garber[4], Stuart J. Schnitt[1], Nadine M. Tung[1], Andrea L. Kasinski[5], Frank J. Slack[1], **Gerburg M. Wulf**[1], Yujing J. Heng[1]

[1]Beth Israel Deaconess Medical Center, Boston, MA,[2]Mayo Clinic, Phoenix, AZ,[3]Mirxes, Singapore, Singapore,[4]Dana Farber Cancer Institute, Boston, MA,[5]Purdue University, West Lafayette, IN

The INFORM trial (NCT01670500) was a randomized, two-arm Phase II neoadjuvant study comparing the efficacy of a platinum-based regimen (cisplatin) versus an anthracycline (AC)-based regimen in participants with germline *BRCA1/2* mutations and early-stage, HER2-negative breast cancer. MicroRNAs (miRNAs) are emerging as promising non-invasive biomarkers for disease detection and treatment monitoring. The initial aim of this study was to evaluate whether pretreatment plasma miRNA profiles were associated with treatment outcomes in the INFORM trial cohort. Pretreatment plasma samples from 97 INFORM participants (n=53 cisplatin and n=44 AC) were screened for 352 miRNAs commonly implicated in cancer using the qPCR-based ID3EAL^{TM} Cancer Panel. Twenty out of 53 participants achieved residual cancer burden (RCB) score of 0 or 1 with cisplatin and 20/44 with AC. Higher plasma miR-362-3p expression was associated with a favorable response to cisplatin (1.7-fold; p<0.01), but not to AC. MiR-362-3p expression in paired pretreatment tumor biopsies (n=79) did not significantly correlate with plasma expression and was not associated with RCB 0/1 (p>0.05). In TCGA, miR-362-3p expression was higher in breast tumors than in adjacent normal tissue, and higher in triple negative breast cancers (TNBCs) compared with hormone receptor-positive tumors (both FDR<0.001), independent of *BRCA* mutation or Single Base Substitution Signature 3 (SBS3) status. The miR-362-3p findings in INFORM did not replicate in a sister trial, TBCRC 030 (NCT01982448; 11 out of 46 cisplatin-treated patients achieved RCB 0/1, p=0.46). These results suggest that while miR-362-3p is unsuitable as a circulating biomarker for cisplatin response, it may play an important biological role in mediating cisplatin sensitivity in TNBCs, independent of *BRCA1/2* mutations. Functional studies demonstrated that miR-362-3p is expressed and secreted by TNBC cell lines, operates as a tumor suppressor, and generally correlates with cisplatin sensitivity. Overexpression of miR-362-3p rendered MDA-MB-231 and CAL-51 cells cisplatin sensitive, while knockdown induced resistance in MDA-MB-436 cells. Ongoing studies are testing whether these effects translate in xenograft models. *In* silico and functional assays identified *BCLAF1*, a DNA damage response (DDR) regulator, as a direct target of miR-362-3p. Overexpression of miR-362-3p suppresses *BCLAF1* mRNA and protein levels. Our findings demonstrate that miR-362-3p enhances cisplatin responsiveness by targeting *BCLAF1*. A miR-362-3p-based therapeutic may be useful as a co-agent to enhance tumor responses to platinum-based chemotherapy.

#7904 Galectin-9 as a glycan-modulating adjuvant to enhance Elotuzumab-mediated immunotherapy in multiple myeloma.

Rajib Kumar Shil[1], Guenther Koehne[2], Charles J. Dimitroff[1]

[1]Cellular and Molecular Medicine, Florida International University, Miami, FL,[2]Hematologic Oncology and Benign Hematology, Baptist Health South Florida/Miami Cancer Institute, Miami, FL

Multiple myeloma (MM) is a hematologic malignancy characterized by the clonal expansion of malignant antibody-producing plasma cells within the bone marrow. Despite advances in therapeutic strategies, MM remains incurable, emphasizing the need for innovative approaches to augment current immunotherapies. The surface glycan repertoire or glycome profile of myeloma cells plays a pivotal role in modulating host-tumor immune interactions, influencing both immune recognition and therapeutic responsiveness. Galectin-9 (Gal-9), a β-galactoside-binding lectin, has emerged as a key regulator of immune and tumor cell signaling through its interaction with specific glycan structures. Recent findings from our laboratory revealed a strong binding affinity of Gal-9 for B cell surface glycans, resulting in the upregulation of signaling lymphocytic activation molecule F7 (SLAMF7), a critical immunoregulatory receptor expressed on malignant plasma cells and a validated therapeutic target of the monoclonal antibody Elotuzumab. In this study, we investigated whether Gal-9 treatment enhances Elotuzumab efficacy by modulating SLAMF7 expression and immune responsiveness in MM cells. Using flow cytometry, we quantified Gal-9 binding and SLAMF7 surface expression across B-lymphoblast models and primary MM bone marrow samples. Gal-9 exposure significantly increased SLAMF7 expression (~3-fold) compared to untreated controls. Furthermore, Gal-9-primed MM cells exhibited augmented antibody-dependent cellular cytotoxicity (ADCC) when co-cultured with natural killer (NK) cells in the presence of anti-SLAMF7 antibody Elotuzumab, suggesting (~2.5-fold) functional enhancement of immune-mediated cytotoxicity. All methods were conducted at least 3 times and analyzed for statistical significance using Student's t-test (*$p \leq 0.05$, **$p \leq 0.01$, *** $p \leq 0.001$). Collectively, these findings highlight Gal-9 as a promising combinatorial agent capable of enhancing SLAMF7 expression and amplifying Elotuzumab-induced cytotoxicity in MM. This study underscores the therapeutic potential of integrating glycan-targeting strategies with existing monoclonal antibody-based regimens to improve treatment efficacy and patient outcomes in multiple myeloma.

#7905 Dihydroorotate dehydrogenase (DHODH) inhibition as a promising therapeutic strategy with synergistic targeting of ROR1 in small cell lung cancer.

Bahareh Nourmohammadi[1], Ola A. Elgamal[2], Sandip Vibhute[1], Christopher C. Coss[1], Thomas E. Goodwin[3], Erin Hertlein[2], Joseph M. Amann[1], Ju Hwan Cho[1], Chad E. Bennett[1], John C. Byrd[2], David P. Carbone[1]

[1]The Ohio State University, Columbus, OH,[2]University of Cincinnati, Cincinnati, OH,[3]Hendrix College, Conway, AR

Small-cell lung cancer is an aggressive subtype of lung cancer with poor prognosis and comprises approximately 15% of all lung cancers. The frontline therapy for SCLC is platinum-etoposide chemotherapy. However, patients almost relapse shortly after the start of therapy, and second line therapies typically provide only a few months of benefit. Clearly, better therapeutics are necessary for the treatment of SCLC. Cancer cells often have dysregulated metabolic pathways. These changes are often necessary to enable the continued proliferation of cancer cells. Dihydroorotate dehydrogenase (DHODH), which catalyzes the conversion of dihydroorotate to orotate in the pyrimidine *de novo* synthesis pathway, has a particular role in the survival of multiple cancers including SCLC. Recent studies have shown that SCLC cells are thought to respond to therapy but recur due to a chemotherapy-resistant “stem cell” or “persister” population of tumor cells induced by therapy. Receptor tyrosine kinase-like orphan receptor 1 (ROR1) is a receptor tyrosine kinase that is re-expressed in multiple cancers, including SCLC, where its expression is associated with shorter survival and rapid relapse. Therefore, targeting ROR1 may reduce stem-like tumor cells and improve therapeutic response in SCLC. We evaluated the effect of HOSU-53, a DHODH inhibitor, on SCLC tumor growth *in vitro*. We measured IC50s of 18 SCLC cell lines and most SCLC cells showed promising sensitivity to HOSU-53 treatment. However, some SCLC cells demonstrated resistance to DHODH inhibition. Therefore, we evaluated the synergy between HOSU-53 and KAN0441571C, a ROR1 inhibitor *in vitro*. SCLC cells were treated with the compounds as single agents as well as the combination. Synergy was observed between KAN0441571C and HOSU-53 in SCLC cells. To evaluate the effect of DHODH inhibition on SCLC tumor growth *in vivo*, we treated xenograft models with HOSU-53 alone or in combination with etoposide plus cisplatin. We observed a significant decrease in tumor volume when HOSU-53 was used alone and in combination, without significant animal weight loss. Additionally, to evaluate the effect of HOSU-53 and ROR1 inhibition on tumor burden *in vivo*, a treatment-resistant xenograft SCLC model was treated with HOSU-53 and KAN0441571C as single agents and the combination. We observed a significant reduction in tumor volume in the combination arm compared with the single-agent treatment arms, without significant loss of body weight. Together, these data demonstrated the promising efficacy of HOSU-53 as single agent as well as in combination with KAN0441571C in treatment-resistant SCLC models. These findings support the initiation of a phase I clinical trial to evaluate the preliminary efficacy and tolerability of HOSU-53 and support the strategy of targeting DHODH and ROR1 as a potential therapeutic approach for the treatment of SCLC.

#7906 Integrated multi-omics profiling identifies an immunotherapy vulnerable and prognostic associated subtype in cholangiocarcinoma.

Lu Chen, Xiangdong Tian

Tianjin Medical Univ. Cancer Inst. & Hospital, Tianjin, China

Cholangiocarcinoma (CCA) is an aggressive malignancy with poor prognosis and limited treatment options. This study performed integrated multi-omics profiling as well as immunohistochemical validation on 424 CCA patients, identifying four molecular subtypes with distinct clinical and immunological features: C1 (Proliferative): Driven by *TP53/KRAS* mutations and CpG island methylator phenotype (CIMP+) hypermethylation, showing Th17 cells infiltration and poor outcomes; C2 (Immune-Suppressed Macro_LYVE1, (ISM_LYVE1)): Stroma-rich with LYVE1$^+$ macrophages and epithelial-mesenchymal transition (EMT) activation; C3 (Immune-Activated Macro_C1QC (ISM_C1QC)): Enriched in C1QC$^+$ macrophages, CD8$^+$ T-cells, and metabolic pathways, highly responsive to immune checkpoint blockade (75% Overall Response Rate (ORR)); C4 (Immune-Excluded, (IE)): FGFR2-altered and IDH1-mutant, with an immunologically-cold phenotype. We validated ATP2B1 as a novel prognostic biomarker and developed a 160-gene classifier for subtype prediction. The C3 subtype's exceptional immune checkpoint blockade (ICB) response, independent of conventional biomarkers (PD-L1/microsatellite instability (MSI)/tumor mutational burden (TMB)), highlights the clinical utility of this classification system in guiding precision immunotherapy for CCA.

#7907 Genomic, immune, and clinical characterization of estrogen receptor-positive, HER2-low breast cancer: The NextGIM trial latest updates.

Barbara Cardinali[1], Alice Stella[1], Chiara Molinelli[1], Marco Bruzzone[1], Yanina Lizet Castillo[1], Francesca Pitto[1], Barbara Massa[1], Simona Pigozzi[2], Andrea Sciutto[1], Giorgia Anselmi[1], Maria Dono[1], Virna Maltoni[2], Benedetta Conte[3], Giulia Buzzatti[1], Davide Soldato[1], Gaia Griguolo[4], Valentina Guarneri[4], Mario Giuliano[5], Caterina Marchio[6], Fabio Puglisi[7], Lorenzo Gerratana[7], Francesca Poggio[1], Lucia Del Mastro[1]

[1]IRCCS Ospedale Policlinico San Martino, Genova, Italy,[2]University of Genova, Genova, Italy,[3]University of Piemonte Orientale, Novara, Italy,[4]Institute of Oncology IOV-IRCCS, Padova, Italy,[5]University of Naples "Federico II", Naples, Italy,[6]FPO Istituto Candiolo (IRCCS), Candiolo, Italy,[7]Centro di Riferimento Oncologico IRCCS, Aviano, Italy

Background: Approximately 47-65% of estrogen receptor-positive (ER+)/HER2-negative breast cancers (BC), although classified as HER2-negative due to the absence of HER2 gene amplification, exhibit low levels of HER2 expression (referred to as HER2-low BC) with immunohistochemistry (IHC) 1+ or 2+ without amplification scores. More recently, an additional subclass—HER2-ultralow—has been proposed for tumors with HER2 IHC-0 and <10% tumor cell staining. Emerging evidence indicates that HER2-low and HER2-ultralow BC may represent biologically distinct entities compared with HER2-null BC. Here, the latest updates of the NextGIM trail, a retrospective, multicenter translational study designed to comprehensively characterize ER+/HER2-low BC, are presented.
Methods: Primary tumor samples from patients enrolled in three randomized clinical trials (GIM2, GIM4, and GIM10) of the GIM (Gruppo Italiano Mammella) Investigator Group, underwent re-assessment of HER2 expression and tumor-infiltrating lymphocytes (TILs) in accordance with ASCO/CAP and TILs Working Group guidelines. In parallel, gene expression profiling was performed using the nCounter Breast Cancer 360 Panel on the NanoString platform. Clinical and survival data will be updated and integrated to evaluate potential prognostic markers and to investigate mechanisms of treatment resistance.
Results: To date, from a total of 283 patients selected at participating centres, 208 samples were deemed suitable for molecular analyses after pathological and RNA quality/quantity assessment. HER2 expression has been re-evaluated in 179 samples. At diagnosis, HER2 classification was: 45.8% HER2-negative (IHC not specified), 26.8% HER2-0, 19.6% HER2-1+, and 7.8% HER2-2+. After pathological reassessment, the distribution shifted to 58.7% HER2-null, 20.7% HER2-ultralow, 15.1% HER2 1+, 5.0% HER2 2+, and 0.6% HER2 3+. Notably, HER2-null BC resulted more prevalent in older archival samples (before 2011). TILs levels ≤1% were more frequently observed in HER2-null and HER2-ultralow tumors compared with HER2-1+ and HER2-2+ (59.1% & 67.6% vs. 25.9% & 55.6%).. Genomic profiling has been completed for 208 cases and data analyses are ongoing. An integrated analysis of molecular, pathological and clinical data will be conducted upon completion of the dataset.
Conclusion: The results obtained so far from HER2 re-evaluation has indicated that the interval between sample collection and reassessment can affect tissue antigenicity and immunohistochemistry results, and should be considered when re-evaluating HER2 status for therapeutic purposes. Overall, the study is expected, integrating genomic, immunological, and clinical information, to validate HER2-low and -ultralow expression as prognostic/predictive biomarkers to support personalized treatment.

#7908 Distinct molecular and clinical aggressiveness in very early-onset colorectal cancer: Survival and genomic divergence between patients aged 30-39 vs 40-49 years.

Andrea Pretta[1], Gaia Rebecchi[2], Giulia Maddalena[3], Federica Marmorino[4], Pina Ziranu[5], Federica Manoni[6], Maria Caterina De Grandis[3], Martina Carullo[4], Clelia Donisi[5], Giovanni Randon[6], Eleonora Perissinotto[3], Ada Taravella[4], Vincenzo Nasca[6], Federica Buggin[3], Paolo Ciraci[4], Francesca Bergamo[3], Chiara Cremolini[7], Sara Lonardi[3], Mario Scartozzi[5], Filippo Pietrantonio[6]

[1]Medical Oncology Unit, University and University Hospital of Cagliari, Cagliari, Italy,[2]IRCCS Istituto Nazionale dei Tumori, Milan, Italy,[3]Oncology Unit 1, Veneto Institute of Oncology IOV-IRCCS, Padua, Italy,[4]Unit of Oncology, University Hospital of Pisa, Pisa, Italy,[5]Medical Oncology Unit, University Hospital and University of Cagliari, Cagliari, Italy,[6]Fondazione IRCCS Istituto Nazionale dei Tumori, Milan, Italy,[7]Polo Oncologico - AOUP, Pisa, Italy

Background: Early-onset colorectal cancer (EO-CRC) is rising worldwide and exhibits clinical heterogeneity. Patients under 40 may constitute a biologically distinct subgroup within EO-CRC. We investigated whether “very early-onset” colorectal cancer (VEO-CRC, ages 30-39) exhibits specific clinical and genomic features compared with patients aged 40-49, and whether these differences lead to variations in survival at the point of metastatic diagnosis.

Methods: We analysed metastatic EO-CRC patients from a multi-institutional database, divided into two predefined age groups: 30-39 years (n=65) and 40-49 years (n=199). Overall survival (OS) from metastatic diagnosis was estimated using Kaplan-Meier methods, and hazard ratios (HRS) were calculated with Cox regression. Comprehensive genomic profiling was carried out using the Foundation Medicine next-generation sequencing platform (FoundationOne® CDx / Heme; over 300 cancer-related genes). Key molecular alterations (KRAS, NRAS, BRAF, APC, PTEN, POLE) were compared using odds ratios (ORs), with prespecified one-sided tests for directionality. Baseline clinicopathologic characteristics were assessed with χ^2 or Fisher’s exact tests.

Results: Median OS was notably shorter in patients aged 30-39 years than in those aged 40-49 years (30.0 vs 38.0 months; log-rank p = 0.0269; HR = 0.67, 95% CI 0.48-0.96). A distinct genomic profile appeared in VEO-CRC, characterised by higher KRAS mutation rates (55.4% vs 42.0%; OR=1.71; 95% CI 0.98-3.01; one-sided p=0.041) and lower APC alterations (69.2% vs 82.0%; OR=0.49; 95% CI 0.26-0.94; one-sided p=0.024). NRAS, BRAF, PTEN, and POLE alterations were directionally consistent with a more aggressive biology, although event counts were limited. Clinically, overall ECOG distribution was similar (χ^2 p=0.099), but ECOG 0 was more common in VEO-CRC (89.1% vs 76.8%; p=0.0468). Peritoneal metastases occurred significantly more frequently in patients aged 30-39 (32.3% vs 19.6%; p=0.041). No differences were observed regarding liver, lung, or nodal involvement.

Conclusions: Patients aged 30-39 years constitute a biologically distinct subgroup within EO-CRC, with shorter survival, greater KRAS enrichment, fewer APC alterations, and increased peritoneal involvement, despite similar performance status. These findings support the emerging idea of an “ultra-young,” genomically driven CRC subtype, with implications for disease biology, risk assessment, and treatment development.

#7909 Exploring a LINC00092-associated multiomics signature as a clinically tractable biomarker in colorectal cancer.

Pankaj Kumar Ahluwalia, Alicia Walker, Sade Logan, Denton Lord, Shamia Jordan, Kimya Jones, Ashis Mondal, Ravindra Kolhe

Pathology, Augusta University, Augusta, GA

Colorectal cancer (CRC) exhibits significant inter-patient heterogeneity, limiting the efficacy of modern targeted and immunotherapies. Advances in genomics continue to improve our understanding of CRC. Long non-coding RNAs (lncRNAs) are emerging as key regulators of cancer metabolism and immunity. We evaluated the systems-level role and translational potential of a LINC00092-centered multiomics signature as a clinically tractable biomarker. Under an IRB approved protocol at Augusta University, we profiled 50 paired FFPE CRC tumor and normal-adjacent tissues using a NanoString assay and 8-plex multiplex immunofluorescence spatial imaging. For orthogonal validation, we analyzed 304 TCGA-COAD tumors to identify a LINC00092-centered gene signature, infer pathway flux via PROGENy, characterize metabolic enrichment, and score MHC-I/II, antigen-processing, checkpoint, and immunoproteasome programs. In our paired cohort and TCGA, LINC00092 expression was significantly higher in NAT (normal-adjacent tissue) than in matched tumors, consistent with a NAT-enriched state. LINC00092-high tumors retained elements of this state, whereas LINC00092-low tumors showed a distinct, alternate state. Immune cell profiling and deconvolution revealed distinct immune composition with altered inflammatory signatures in LINC00092-low tumors. LINC00092-high tumors displayed suppression of EGFR/PI3K/MAPK and hypoxia/JAK-STAT signaling with preserved pro-apoptotic (e.g., TRAIL/p53) activity. Concurrently, they exhibited higher MHC-II and checkpoint scores but reduced immunoproteasome activity, defining an antigen-presenting, T cell-modulated, checkpoint-rich state. In contrast, LINC00092-low tumors clustered into a hyperproliferative, hypoxia-adapted, immune-cold/immunoproteasome-high phenotype. Metabolic enrichment supported a lipid- and nucleotide-centric reprogramming in LINC00092-high tumors, with increased fatty acid oxidation, sphingolipid and eicosanoid pathways, and pyrimidine synthesis, indicating a distinct immunometabolic mode rather than purely hyperproliferative growth. In summary, a LINC00092-based multiomics signature, measurable in routine FFPE tissue, separates CRC tumors into groups with distinct signaling, metabolic, and immune profiles. This signature can help stratify patients for pro-apoptotic therapies, immunotherapy, and rational drug combinations.

#7910 Advanced preclinical cancer models and imaging protocols for translational treatment studies in orthotopic prostate, bladder, liver, pancreatic and brain cancer.

Celine Christine Jensen[1], Emilie Garly[1], Rikke Stagaard[1], Michala Nordfalk[1], Sigrid Cold[1], Mette Munk Wessel[1], Tea Kirkegaard Nielsen[1], Margarete Karg[1], Natalia Łopuszyńska[1], Marina Simon Martin[1], Sara Vangsgaard[1], Sebastian Gnosa[1], Ingrid Hunter[1], Emma Papin[1], Camilla Malec[1], Anne Hessellund Langhave[1], Trine Nielsen[1], Andreas Kjaer[2], Esben Christensen[1], Trine Bjoernbo Engel[1], **Lotte Kellemann**[1], Carsten Haagen Nielsen[1]

[1]Minerva Imaging, Oelstykke, Denmark,[2]Cluster for Molecular Imaging, Rigshospitalet & Department of Biomedical Sciences, University of Copenhagen, Copenhagen, Denmark

Introduction: Translatable animal models mimicking and predicting clinical disease outcomes are in high demand to increase the success rate of novel anti-cancer therapies. Orthotopic or metastatic cancer models, where tumors are established in their tissue of origin, have gained significant interest in drug development as they more accurately replicate the tumor microenvironment, metastatic behavior, and treatment response seen in patients. In these studies, we generated advanced orthotopic models of cancer including prostate, bladder and pancreas, as well as disseminated models of cancer spread to liver and brain. Furthermore, we developed imaging protocols to accurately monitor treatment responses and drug targeting engagement in preclinical studies.

Methods: Murine and human prostate cancer cell lines engineered to express human PSMA (RM-1.hPSMA and PC-3.hPSMA, respectively) were injected into the prostate gland of immunodeficient and immunocompetent mice. Human UM-UC-3 bladder cancer cells were intramurally injected into the bladder wall under laparotomy. Human BxPC-3 pancreatic cancer cells were surgically inoculated into the head of pancreas. Seeding in the liver was established by intrasplenic injection of murine 4T1 breast cancer cells. Metastatic seeding in the brain was established by injection of MDA-MB-231 TNBC cells into the intracarotid artery (ICt). Tumor growth was monitored using bioluminescence imaging (BLI), magnetic resonance imaging (MRI), and ultrasound (US), while SPECT/CT imaging was applied for target engagement of [^{177}Lu]Lu-PSMA-617. IHC and light sheet microscopy (LSM) were used to validate *in vivo* findings.

Results: Orthotopic tumors were successfully established in pancreas, bladder and prostate with a take-rate >90%, >60% and >75%, respectively. Intrasplenic inoculation led to numerous liver metastases with a take rate of 100%, while ICt inoculation resulted exclusively in the formation of brain metastases with a take rate >70%. MRI imaging revealed 1-7 metastases per animal with intra- and intersubject variation in BBB permeability. MRI and US provided accurate tumor volumetry, while BLI monitored viable tumor burden with correlation to different modalities across the studies, verified by IHC and LSM.

Conclusion: We successfully developed complex surgical procedures for establishing orthotopic models and models of metastatic spread for cancers with an unmet clinical need. All models presented with key characteristics of human disease. Combined with multimodal, reliable and state-of-the-art imaging readouts, this is an attractive platform to increase the translational value of preclinical studies with novel anti-cancer therapies and combinations.

#7911 Multi-cohort transcriptomic profiling identifies pathways driving high-risk biochemical recurrence in prostate cancer.

Sabrina Yepes-Rodriguez[1], Rafael Parra-Medina[2]

[1]Laboratorio de Patologia Molecular, Instituto Nacional de Cancerologia, Bogota, Colombia,[2]Instituto Nacional de Cancerologia, Bogota, Colombia

Background: Biochemical recurrence (BCR) after radical prostatectomy for localized or locally advanced prostate adenocarcinoma is clinically heterogeneous, and current risk categories only partially capture the underlying biology. Multi-cohort transcriptomic integration may clarify molecular distinctions between European Association of Urology (EAU) low- versus high-risk BCR. Objective: To identify reproducible gene-expression profile associated with high-risk BCR across independent datasets and to determine whether low-risk BCR tumors differ biologically from non-recurrent disease. Methods: Transcriptomic data were analyzed from TCGA-PRAD (n=479), GSE220095 (BCR-No=101, BCR-EAU-Low=45, BCR-EAU-High=30), GSE70768 (No=93, Low=7, High=12), GSE54460 (No=48, Low=29, High=21), and GSE70769 (No=49, Low=21, High=24). Cohorts were reclassified into and adapted EAU-like BCR groups. RNA-seq data were log-transformed. All matrices were then harmonized, filtered, and aligned to curated metadata. Differential expression was performed with limma on R software using contrasts High-vs-No, High-vs-Low, and Low-vs-No. Pathway enrichment was evaluated using preranked GSEA (GO/Reactome). Results: Across cohorts, high-risk BCR tumors consistently upregulated cell-cycle and DNA-replication programs, including G2/M checkpoint activation, sister chromatid segregation, replication-stress signaling, and mitotic spindle assembly. TCGA-PRAD high-risk tumors showed strong activation of ATR-dependent replication-stress pathways. GSE220095 high-risk cases exhibited enrichment of mitotic checkpoint and pre-replicative complex assembly mechanisms. In GSE70768, key differentially expressed genes included *PAGE4, PGM5, SERPINA3,* and *TOP2A*, indicating loss of androgen-regulated stress-response programs and increased proliferative drive. GSE70769 and GSE54460 similarly converged on cell-cycle deregulation, chromatin remodeling, and ECM/EMT-related signaling. The absence of DEGs between low- and high-risk BCR groups—despite marked differences between high-risk and No-BCR—suggests that low-risk tumors form a heterogeneous intermediate state, sharing baseline expression with No-BCR cases while lacking the proliferative and replication-stress programs. Computational workflow and writing support was provided by an AI-based language (ChatGPT, OpenAI). Conclusions: High-risk BCR tumors show a strong, reproducible transcriptional signature driven by replication stress and proliferative pathways, whereas low-risk BCR tumors are molecularly similar to non-recurrent diseases. These results provide biological validation of the EAU risk stratification system and highlight the potential of transcriptomic profiling to refine surveillance and treatment decisions after prostatectomy.

#7912 Performance analysis of a novel PD-L1 CAL10 assay in esophageal cancer.

Ibrahim Abukhiran[1], Matthew G. Hanna[1], Dimitrios Korentzelos[1], Rajiv Dhir[1], Aatur D. Singhi[1], Shubham Dayal[2], Joseph Chiweshe[2], Xiaozhi Zhou[2], Robert Monroe[3], Michelle Wood-Trageser[1]

[1]University of Pittsburgh Medical Center, Pittsburgh, PA,[2]Leica Biosystems, Vista, CA,[3]Danaher Diagnostics, Vista, CA

Background: Esophageal cancer (ESCC) remains a highly lethal disease due to late diagnosis and limited responsiveness to conventional therapies. Recent studies have highlighted the role of immune checkpoint pathways in its pathogenesis, particularly the PD-1/PD-L1 interaction, which enables tumor cells to escape immune surveillance. We have developed a PD-L1 CAL10 assay for immunohistochemical (IHC) detection of PD-L1 in ESCC specimens.
Here, we have compared this novel PD-L1 CAL10 assay for IHC detection of PD-L1 in ESCC specimens with two common research-utilized PD-L1 IHC assays.
Design: The primary objective was to compare the PD-L1 CAL10 assay with other commercially available assays, SP263 and 22C3, at ≥1% tumor proportion score (TPS) and ≥50% TPS cutoffs. Also, we measured interobserver/interpathologist agreement (secondary objective) for each assay type at ≥1% TPS and ≥50% TPS cutoffs. Seventy (70) whole tissue formalin fixed paraffin embedded (FFPE) unique ESCC cases were included in the study. Each case was serially sectioned at 4 µm. Each of these sections was stained with H&E and anti-PD-L1 antibodies: CAL10 on Leica Biosystems BOND RX, SP263 on Ventana BenchMark ULTRA, and Agilent/Dako's 22C3 optimized for use on a Ventana Discovery Ultra. These tissue-mounted glass slides were scored manually by 3 pathologists, with a washout period of two weeks between reads for each clone. In comparison to other assays, the PD-L1 CAL10 stained slides had no significant background or artifacts. Each pathologist scored independently, and the majority score for the PD-L1 status (positive or negative) was recorded.
Results: The PD-L1 CAL10 assay showed comparable interassay and interreader variability (Table 1). Additionally, its scoring pattern was similar to the other two PD-L1 clones.

Table 1. TPS agreement rates

Interassay	**CAL10 vs. SP263**	**CAL10 vs. 22C3**	**SP263 vs. 22C3**
≥1% TPS cutoff	Almost perfect (k= 0.82)	Moderate (k=0.59)	Substantial (k=0.67)
	OPA-91.2%	OPA-79.7%	OPA - 84.1%
≥50% TPS cutoff	Moderate (k= 0.42)	Slight (k=0.19)	Substantial (k=0.65)
	OPA-92.6%	OPA-89.9%	OPA - 97.1%
Interpathologist	**CAL10**	**SP263**	**22C3**
≥1% TPS cutoff	Moderate (k=0.54)	Substantial (k=0.71)	Moderate (k=0.53)
≥50% TPS cutoff	Moderate (k=0.48)	Fair (k=0.37)	Moderate (k=0.42)
k, Cohen's kappa statistic; OPA, Overall percent agreement			

Conclusion: The initial results suggest that the PD-L1 CAL10 assay is comparable to the other tested PD-L1 assays for ESCC specimens and can be a suitable option for further translational research evaluations.

#7913 OXC-101 (karonudib) in canine lymphoma and hemangiosarcoma: Safety, early efficacy, and translational potential.

Kumar Sanjiv[1], Sara Saelstrom[2], Martin Scobie[3], Ulrika warpman Berglung[3], Thomas Helleday[1], Henrik Ronnberg[2]

[1]Oncology and Pathology, Karolinska Institute, Science for Life Laboratory, Solna, Sweden,[2]University Animal hospital (UDS) and HBIO, Swedish University of Agricultural Sciences, SLU, Uppsala, Sweden,[3]Oxcia AB, Solna, Sweden

Background: Canine lymphoma (CL) and hemangiosarcoma (HSA) are aggressive malignancies. Current treatments have limited efficacy, profound toxicity which causes poor quality of life (QoL) in patients. There is strong biological and clinical similarity to human non-Hodgkin lymphoma and human angiosarcoma, which makes dogs an attractive model for translation research. OXC-101 (Karonudib), a dual-function MTH1 inhibitor, induces incorporation of oxidized nucleotides into DNA and inhibits microtubule polymerization and includes the toxicity in cancer cells. OXC-101 is currently being evaluated in two human clinical trials (Phase 1 solid tumors; Phase 1/2 hematologic malignancies) and has received Orphan Drug Designation for acute myeloid leukemia, underscoring its translational relevance.
Methods: We conducted an open-label pilot study to assess safety and preliminary efficacy of oral OXC-101 in nine pet dogs with CL (n=6) or HSA (n=3). Dogs received 8-10 mg/kg orally twice daily every other day for up to eight months. Clinical exams, laboratory analyses, and owner feedback were used to monitor safety, response, and quality of life.
Results: Eight dogs (five CL, three HSA) completed the evaluable portion; two withdrew for reasons unrelated to treatment. Most CL cases enrolled to trial had relapsed disease after Adriamycin-based chemotherapy. Relapsed CL dogs showed stable disease to partial responses lasting up to five months, with improved quality of life and no evident toxicity. One treatment-naïve stage V CL dog showed rapid lymph node reduction and normalization of liver enzymes within 21 days before voluntary withdrawal. In HSA, two out of three splenectomised dogs remain recurrence-free beyond 150 days with good QoL. In all the enrolled patients, OXC-101 was found to be well tolerated, with no gastrointestinal side effects, no neutropenia/ Thrombocytopenia or any significant biochemical abnormalities.
Conclusions: This pilot study shows that OXC-101 is safe and demonstrates early antitumor activity in relapsed CL and post-operative HSA. Given the close parallels between these canine cancers and their human counterparts—and ongoing human trials— these results strongly support further clinical development. OXC-101 may represent a promising new targeted therapy for both veterinary and human oncology.

#7914 Preclinical modeling of plasmacytoid urothelial carcinoma to study cancer mechanisms and therapeutic response.

Kanisha Kar[1], Caroline Dickey[1], William Kim[1], Kathryn Gessner[2]

[1]UNC Lineberger Comprehensive Cancer Center, Chapel Hill, NC,[2]University of North Carolina at Chapel Hill, Chapel Hill, NC

Plasmacytoid urothelial carcinoma (PUC) is an aggressive histologic subtype of bladder cancer with poor patient outcomes and worse response to standard chemotherapies than conventional histology urothelial carcinoma (CUC). The hallmark molecular alteration in PUC is loss of E-cadherin, which can occur through mutations or promoter hypermethylation of *CDH1*, the gene encoding E-cadherin. Aside from E-cadherin loss, the mutational spectrum of PUC is similar to that of CUC, although with higher rates of mutations in RB1 and p53 in PUC. E-cadherin, a transmembrane glycoprotein essential for epithelial adhesion and integrity, is a central regulator of EMT. Decreased expression of E-cadherin promotes EMT through transcriptional repressors (Snail, Slug, Twist, ZEB1/2), a cadherin switch, and epigenetic remodeling, driving enhanced invasiveness and metastatic potential. Despite our knowledge regarding the function of E-cadherin, the precise mechanism by which E-cadherin loss promotes disease progression and therapeutic resistance within urothelial carcinoma is not understood. Additionally, due to the lack of a preclinical PUC model and the limited ability to perform randomized controlled trials in this rare tumor type, clinicians face uncertainty regarding which therapeutic agents are most effective, reinforcing the need for innovative preclinical studies. Therefore, we aim to interrogate the impact of CDH1 loss in PUC on cancer phenotypes, elucidate mechanistic insights, and identify novel therapeutic strategies for PUC through preclinical modeling. To model PUC biology, we utilized CRISPR/Cas9 mediated knockout to generate CDH1 loss in two luminal (UPPL1541, UPPL1595) and one basal (BBN963) previously established murine bladder cancer cell lines using three independent gRNAs. Resulting CDH1 mutations at the CRISPR-Cas9 target site were confirmed by Sanger sequencing and E-cadherin protein loss confirmed by western blot. Compared to non-targeted, CDH1-intact control cells, CDH1-knockout cells demonstrate increased N-cadherin protein expression and increased expression of the mesenchymal markers Snail, Slug, ZEB1, and Vimentin by western blot. CDH1 knockout cells did not demonstrate a difference in cell proliferation compared to non-targeting controls, as determined by cell-titer glo assay. On transwell invasion assay, CDH1 knockout cells demonstrate significantly increased cell invasion compared to nontargeted, CDH1-intact control cells. These findings demonstrate that CDH1 loss is associated with upregulation of the epithelial-to-mesenchymal transition and enhanced *in vitro* cell invasion in urothelial carcinoma. We will continue to advance this work by dissecting tumor-microenvironment interactions and therapeutic responses in syngeneic models, positioning this platform as a novel preclinical resource for the clinically-challenging PUC variant.

#7915 Molecular landscape of colorectal cancer (CRC) with KRAS 13D mutations.

Masango Samuel[1], Yuliang Chen[2], Sarah Castillo[3], Chenbo Sun[2], Natalia Ignatenko[2], Daruka Mahadevan[4], **Ritu Pandey**[5]

[1]University of Arizona Health Sciences, Tucson, AZ,[2]University of Arizona Cancer Center, Tucson, AZ,[3]University of Arizona, Tucson, AZ,[4]UT Health Science Center at San Antonio, San Antonio, TX,[5]University of Arizona Cancer Center, Department of Cellular and Molecular Medicine, Tucson, AZ

Background: Colorectal cancer (CRC) is one of the leading causes of cancer related mortality across the world. Approximately 50% of the CRC patients exhibit mutation in the KRAS gene, most frequently found in codons 12 and 13. KRAS 13D mutation tumors are unique in that they are more aggressive and have different treatment response and outcome than tumors with other KRAS gene mutations. This is attributed to the underlying combination of distinct biology. We report a detailed comparative study of stratified KRAS 13D mutant patients with disease, poor outcome, exceptional response and mutant cell lines for distinct co-occurring mutations and gene expression.

Methods: RNA-Seq, whole exome sequencing and clinical data of CRC patients with known KRAS mutation type were obtained from Genomic Data Commons (GDC) while CRC cell lines data were obtained from NCBI GEO. The patient dataset included 170 KRAS mutated samples in Cancer Genome Atlas with 31 tumors with KRAS 13 mutations and NCI Exceptional responder's initiative with KRAS mutated samples. Normalized log transformed expression profiles and gene variants were statistically analyzed for differential expression, likelihood ratios, enrichment, correlation, odd ratios, deconvolution and log rank test for outcome using R (v4.5.1) and computing platform provided by GDC.

Observations: The KRAS 13 tumors proportionally had higher mutation burden (TMB) and prevalent in ascending colon compared to other location. The KRAS13D tumors were also of mixed CMS (consensus molecular) subtypes. Among the top mutated genes in KRAS mutated tumors there were common co-occurring mutations in both KRAS 12 and KRAS 13 but frequency of mutations in genes RYR2, FAT3, CMSD1 and MUC4 amongst others were enriched more in KRAS 13 mutated tumors. Cell lines expression data identifies specific genes uniquely overexpressed in KRAS 13 mutants and some of them were found to be common with genes over expressed in exceptional responders. The poor outcome patients compared with exceptional responders found differential genes with significance in cellular processes. Log rank test shows few of these genes associated with better or worse outcomes after treatment.

Conclusions and ongoing research: We found that a right combination of mutations could give KRAS 13D mutated tumors advantage to become more aggressive, but a background of unique network of gene expression could make the tumors respond well to treatment or resist therapy. We are currently testing the significance of these unique molecular correlates in KRAS 13D patient derived organoids with specific drugs and RAS inhibitor screens to provide insights into resistance and response of some of the KRAS 13D mutated CRC patients.

#7916 Galectin-2 expression in the tumor microenvironment: A silent pathway of pancreatic ductal adenocarcinoma progression.

Moacyr Jesus B. Melo Rego[1], Richard Tomasini[2], Sophie Vasseur[3], Maira Pitta[4], Maria Clara P. D. Sampaio[1], Amanda P. B. Albuquerque[1], Pascal Finetti[2], Claudio Montenegro[1], Michelly Cristiny Pereira[5], Michelle Rosa[1]

[1]Federal University of Pernambuco (UFPE), Recife, Brazil,[2]CRCM, Marseille, France,[3]INSERM 4624, Marseille, France,[4]UFPE, Recife, Brazil,[5]Federal University of Pernambuco (UFPE), Olinda, Brazil

Background: Pancreatic ductal adenocarcinoma (PDAC) is an aggressive cancer with a complex microenvironment in which galectins play key roles. This study evaluated galectins expression to investigate its potential as a prognostic biomarker.

Methods: Transcriptomic analyses were performed *in silico* on a cohort of 938 individuals with primary PDAC. Laser microdissection, immunohistochemistry, and RT-qPCR were used to assess the expression profile in the tumor and stromal regions of PDAC biopsies. Serum GAL-2 levels were measured by ELISA. GAL2 expression was also evaluated during distinct stages of tumor progression using the KIC murine model.

Results: To analyze the galectin transcriptomic expression profile in human PDAC, transcripts of *LGALS* genes were evaluated in a cohort of 938 individuals diagnosed with primary PDAC tumors. *LGALS2* emerged as a key transcript, exhibiting expression levels two-fold below the median in PDAC samples. Correlation analysis of *LGALS* transcripts revealed a positive cluster among *LGALS2*, *LGALS3*, *LGALS4*, and *LGALS9*, and a negative association between *LGALS1* and *LGALS2*. *LGALS2* expression was downregulated in primary tumors (p = 8.76E-22) and metastatic sites (p = 2.75E-30) compared to both the control group and normal pancreatic tissue. In the KIC mouse model, a progressive reduction in *LGALS2* expression was observed throughout tumor progression, from early lesions to established primary and metastatic tumors. High *LGALS2* expression was associated with classical and well-differentiated epithelial PDAC subtypes, whereas low expression characterized basal-like, squamous, and mesenchymal tumors. Importantly, increased *LGALS2* expression correlated with better disease-free and overall survival. Furthermore, higher *LGALS2* expression was significantly associated with improved overall survival in patients treated with the FOLFIRINOX regimen (p = 4.08E-02). Additionally, low GAL-2 protein expression was observed in biopsies from patients diagnosed with PDAC. Serum GAL-2 levels were significantly lower in PDAC patients, especially those with metastasis when compared to health donors. Promoter hypomethylation (CpG island cpg25247183) was identified as a potential regulatory mechanism underlying its downregulation.

Conclusions: The downregulation of *LGALS2* expression across different stages of PDAC progression underscores its importance in tumor pathogenesis and suggests its potential as a prognostic and therapeutic biomarker.

#7917 RUVBL1 and SPARC as prognostic biomarkers in breast cancer.

Flavia Rotea Mangone[1], Fernando A. Soares[2], Maria Aparecida Nagai[3]

[1]Center for Translational Research in Oncology, Instituto do Cancer do Estado de Sao Paulo and Comprehensive Center for Precision Oncology, Sao Paulo, Brazil,[2]Department of Anatomic Pathology, Instituto D'Or de Pesquisa e Ensino (IDOR), Sao Paulo, Brazil,[3]Center for Translational Research in Oncology, Instituto do Cancer do Estado de Sao Paulo and Comprehensive Center for Precision Oncology/Disciplina de Oncologia do Departamento de Radiologia e Oncologia, Sao Paulo, Brazil

Despite significant progress in elucidating the biology of breast cancer, there remains a need for biomarkers for accurate prognostic stratification and prediction of therapeutic response. In the present study, we sought to determine the protein expression pattern and prognostic value of RUVBL1 alone or in combination with SPARC in breast cancer. We performed IHC analysis using antibodies against RUVBL1 and SPARC on a tissue microarray comprising 319 primary breast tumor samples. RUVBL1, a member of the highly conserved ATPases of the AAA+ superfamily, is involved in key cellular processes related to tumorigenesis. Our previous work has shown that the downregulation of SPARC protein expression, a matricellular protein with pleiotropic functions, is an independent prognostic factor for breast cancer. RUVBL1 expression was positively associated with HER2 positivity (p=0.006), post-menopausal status (p=0.007), and reduced ER/PR expression (p=0.046). Although we did not observe any significant prognostic value of RUVBL1 expression in our population, we observed a strong association between RUVBL1 and SPARC expression (p<0.0001). Moreover, the combined profile of high RUVBL1 and low SPARC expression stratified a subgroup of patients with markedly poorer survival outcomes (HR=2.49, 95% CI: 1.36–4.56, p=0.003), exhibiting a survival rate of 17%. Our results provide novel insights supporting the prognostic significance of RUVBL1 and SPARC in breast cancer. These findings underscore the need for further experimental and clinical investigations to fully understand the clinical implications of RUVBL1 and SPARC expression in breast cancer.

#7918 Suppression of MAGED1 increases sensitivity to PARP inhibitor in BRCA-mutated breast cancer cells.

In Hee Lee, Soo Jung Lee, Byeongju Kang, Jeeyeon Lee, Ho Yong Park, Joon Suk Moon, Ji-Young Park, Yee Soo Chae, Eun Ae Kim, Seol-Hwa Jeong, Jieun Kang

Kyungpook National Chilgok University Hospital, Daegu, Korea, Republic of

Background: MAGED1 (Melanoma Antigen Gene Family, Member D1) is a member of the MAGE gene family and is known to be involved in various cellular processes such as cell death, cell cycle regulation, and differentiation. Furthermore, previous studies indicate that MAGED1 is essential for double-strand break (DSB) repair via homologous recombination repair (HRR), and reduced MAGED1 expression sensitizes cancer cells to DNA-damaging agents. This study aimed to investigate the role of MAGED1 in HRR in triple-negative breast cancer (TNBC) and BRCA1/2 mutant breast cancer.
Methods: In this study, we validated the function of MAGED1 in HRD using siRNA in triple-negative breast cancer (TNBC) and BRCA-mutated breast cancer cell lines. Cell viability was assessed using CytoFLEX after treating Hs578T, HCC-1937 (BRCA1 5382insC), and BT-474 (BRCA2 c.0391C>A) breast cancer cell lines with cisplatin 200 μM, olaparib 200 μM, and niraparib 50 μM, respectively. Cells were transfected with control siRNA (si-Cont) or two independent siRNAs targeting MAGED1 (si-MAGED1 #1, si-MAGED1 #2).
Result: Using cytoFLEX flow cytometry, we investigated siRNA-mediated MAGED1 suppression in BRCA1/2 mutant breast cancer cell lines HCC-1937 (BRCA1 5382insC) and BT-474 (BRCA2 c.0391C>A) exhibited increased sensitivity compared to normal breast cells MCF10A and breast cancer cell lines MCF7 (luminal A) and Hs578T (TNBC). Furthermore, the platinum-based anticancer drug cisplatin was found not to affect MAGED1 inhibition, and the synergistic effect of PARP inhibitors on MAGED1 inhibition was more pronounced in BRCA-mutant cell lines. Additional studies involving RNF8, BARD1, RAD51, and ATM are underway to further elucidate the roles of HRD and MAGED1.
Conclusions: Our study demonstrates that silencing of MAGED1 enhances sensitivity to PARP inhibitors in BRCA1/2-mutant breast cancer cell lines. These results suggest that MAGED1 is involved in HRD and could be a therapeutic target to enhance PARP inhibitor response in breast cancer.

#7919 Clinical, genomic, and therapeutic outcomes of lung squamous cell carcinoma with high *LGR5* expression : A study from the LC-SCRUM-Asia database.

Yu Tanaka[1], Shuji Murakami[2], Kazumi Nishino[3], Motoko Tachihara[4], Ichiro Nakachi[5], Mayu Kawakami[6], Satoshi Hara[7], hitomi Aono[8], Shoichi Kuyama[9], Gaku Yamamoto[1], Eri Sugiyama[1], Tetsuya Sakai[1], Hiroki Izumi[1], Shigeki Umemura[1], HIBIKI UDAGAWA[1], Yoshitaka Zenke[1], Shingo Matsumoto[1], Kiyotaka Yoh[1], Koichi Goto[1]

[1]National Cancer Center Hospital East, Chiba, Japan,[2]Kanagawa Cancer Center, Kanagawa, Japan,[3]Osaka International Cancer Institute, Osaka, Japan,[4]Kobe University Hospital, Hyogo, Japan,[5]Research Scholar, Dept. of Medicine, University of Colorado Denver, Aurora, CO,[6]Saiseikai Imabari Hospital, Ehime, Japan,[7]Itami City Hospital, Osaka, Japan,[8]Tokyo Metropolitan Police Hospital, Tokyo, Japan,[9]National Hospital Organization Iwakuni Clinical Center, Yamaguchi, Japan

Introduction: Petosemtamab, a bispecific antibody targeting LGR5 (Leucine-rich repeat-containing G-protein coupled receptor 5) and EGFR, is under clinical development. Wnt-driven LGR5, a stem cell-associated marker, stabilizes EGFR by preventing lysosomal degradation, thereby promoting cancer cell survival. However, its role in lung squamous cell carcinoma (LUSC) remains unclear. This study evaluates the impact of *LGR5* expression on clinical characteristics, genomic alterations, and therapeutic outcomes in LUSC.

Methods: Using the LC-SCRUM-Asia clinico-genomic database, mRNA levels of *LGR5*, *EGFR*, and other genes were assessed via the AMOY Master Panel. High *LGR5* was defined as above the median. Clinical, genomic characteristics, and treatment outcomes were compared between high and low *LGR5* groups.

Results: *LGR5* expression was evaluated in 233 LUSC patients between June 2021 and February 2022. The median *LGR5* expression was 0.02 FPKM (range: 0.00-5.44), and the median *EGFR* expression was 12.09 FPKM (range: 0.07-572.49). No correlation was observed between *LGR5* and *EGFR* expression (Pearson r = -0.0387, $P = 0.687$). Clinical characteristics, including age, sex, smoking history, ECOG-PS, and clinical stage, did not differ significantly between high and low *LGR5* groups. The prevalence of driver gene alterations (*KRAS* mutation: 6 vs. 3, *EGFR* mutation: 2 vs. 4, *MET* ex14 skipping: 2 vs. 4, *ALK* fusion: 3 vs. 1) also showed no significant differences ($P = 0.816$). Among 103 patients receiving first-line ICI with or without chemotherapy, the median PFS was 8.0 months in the high *LGR5* group and 5.6 months in the low *LGR5* group (HR = 0.91, 95% CI: 0.58-1.44, $P = 0.570$). In 90 patients treated with first-line platinum-based chemotherapy, the median PFS was 5.5 months in the high *LGR5* group and 4.3 months in the low *LGR5* group (HR = 0.99, 95% CI: 0.52-1.91, $P = 0.985$). Wnt (*P*-weighted Log2FC = 0.753), Hedgehog (*P*-weighted Log2FC = 0.877), and Notch (*P*-weighted Log2FC = 0.564) pathways, key regulators of stem cell function, were significantly upregulated in the high *LGR5* group (all $P < 0.05$).

Conclusion: High LGR5 expression does not define a clinically or genomically distinct subgroup of LUSC; however, it is associated with a transcriptionally stemness-activated phenotype characterized by upregulation of Wnt, Hedgehog, and Notch pathways. These findings suggest that LGR5-high LUSC represents a biologically distinct subtype that may inform future development of LGR5×EGFR-targeted therapies.

#7920 Integrated proteogenomics reveals molecular predictors of recurrence beyond HER2 IHC in HER2-positive breast cancer.

Eunjoo Lee[1], Seung Min Park[2], Kyung-Hee Kim[3], So-Youn Jung[4], Gi Yeon Lee[5], Eun-Gyeong Lee[6], Min-Chae Kang[7], Jong Bae Park[8], Kong Sun-Young[1]

[1]National Cancer Center, Goyangsi, Korea, Republic of,[2]Targeted Therapy Branch, National Cancer Center, Goyangsi, Korea, Republic of,[3]Proteomics Analysis Team, Research Core Center, Research Institute, National Cancer Center, Goyangsi, Korea, Republic of,[4]National Cancer Center - Korea, Goyang-si, Korea, Republic of,[5]Targeted Therapy Branch,, National Cancer Center, Goyang, Korea, Republic of,[6]Center for Breast Cancer, National Cancer Center, Goyangsi, Korea, Republic of,[7]Hanyang Univ. College of Medicine, Seoul,[8]Cancer Biomedical Science, National Cancer Center, Goyangsi, Korea, Republic of

Purpose: Breast cancer remains the most common malignancy among women, with about 20% driven by HER2 overexpression. Although HER2-targeted therapies have improved outcomes, acquired resistance and recurrence persist. Clinical HER2 Immunohistochemistry(IHC) often fails to reflect actual HER2 abundance, as seen in both IHC-negative/high-protein and IHC 3+/low-protein cases. Thus we conducted an integrated proteogenomic analysis to define HER2 heterogeneity and identify recurrence-associated signatures.
Methods: Total of 62 patients with a median age of 41.5 years (range, 25-60) were included from National Cancer Center in Korea, and breast tumor tissues analyzed using an integrated proteogenomic workflow combining whole-exome sequencing, whole-transcriptome, global proteomics, phosphoproteomics, and PRM-based HER2 quantification. Differential genomic and proteomic features between the 46 non-recurrence and 15 recurrence patients were compared and validated in TCGA and CPTAC cohorts.
Results: Description between clinical IHC and quantitative HER2 measurement were observed in 10% of low HER2 and in 25% of high HER2 cases. Recurrent patients revealed frequent TP53 mutations, MYC amplification, and ERBB2 hotspot variants (E192* and D844*) in genomic profiling. DEGs analyses integrating RNA and proteomic expression identified a shared set of recurrence-associated genes, including ATXN7L3BM GPRC5A and GPRC5A and WNT5A, which collectively reflected pathways related to extracellular matrix remodeling, metastatic, signaling, metabloic reprogramming, and transcriptional regulation. METABRIC comparison showed similar patterns of ERBB2/MYC amplification, TP53 loss, and genomic instability observed in recurrent tumors. Mutational signature analysis indicated dominant contributions from aging-related, APOBEC-driven, and homologous recombination-defective processes. Copy-number signature profiling further identified five recurrent genomic subtypes (CNV48 A-E), including chromothripsis-like and loss of heterozygosity patterns shared with TCGA and METABRIC HER2-positive tumors.
Conclusions: These findings indicate that recurrence risk in HER2-positive breast cancer is determined more by initial tumor stage than by HER2 IHC status. This underscores the clinical value of quantitative proteogenomic assessment as a complementary tool to improve risk stratification beyond conventional HER2 testing. This work was supported by grant from the National Cancer Center. (Grant No. 2510692-1)

#7921 The development of a novel *PDGFRA* resistance mutation in a recurrent *KIT*-mutant gastrointestinal stromal tumor (GIST).

Rachael S. Lowney[1], Shruthi R. Perati[2], Aaron Dinerman[3], Abraham Hakim[1], Molly A. Sullivan[1], Stephanie N. Canady[1], Diane S. Ahn[1], Michael C. Heinrich[4], Homma Khosroyani[4], Andrew M. Blakely[5]

[1]National Institute for Cancer Research, Bethesda, MD,[2]Rutgers Robert Wood Johnson Medical School, New Brunswick, NJ,[3]University of South Alabama College of Medicine, Mobile, AL,[4]OHSU Knight Cancer Institute, Portland, OR,[5]National Cancer Institute, Bethesda, MD

Background: GISTs are sarcomas of the gastrointestinal tract that classically arise through mutations in *KIT* or *PDGFRA* tyrosine kinases. GISTs can exhibit both temporal and spatial mutational tumor heterogeneity, however, *KIT* and *PDGFRA* mutations are traditionally considered mutually exclusive. To date, only one other case of concurrent mutations exists in the literature. The purpose of this study was to investigate the relationship between primary, metastatic, and recurrent GIST tumors on the genomic level.

Methods: This patient with histologically confirmed GIST was enrolled on NCT04557969 and underwent complete cytoreductive surgery for metastatic GIST. A tissue section of the primary tumor was sent for next-generation sequencing (NGS) via the National Cancer Institute Comprehensive Oncologic Molecular Pathology and Sequencing Service (NCI-COMPASS) that utilized the TruSight Oncology 500 Gene Panel for detection of somatic mutations. NGS was repeated upon tumor recurrence and a peri-sigmoid mesocolic metastasis from the index surgery that was retrospectively noted to have no treatment effect. A detailed chart review, including medical history, operative reports, pathology reports, and NGS was performed.

Results: This patient is a 51-year-old male who presented with 3 large intra-abdominal masses and was discovered to have a *KIT* exon 11 GIST on biopsy. He was initiated on imatinib with significant response over one year of therapy. He then underwent exploratory laparotomy with resection of jejunal primary and multiple peritoneal metastases in November, 2023. NGS of the jejunal primary confirmed previously identified *KIT* exon 11 (p.Val560Asp) mutation. After 1 year of surveillance imaging on adjuvant imatinib, he was found to have an isolated lesion posterior to the left lower rectus. A review of the pathology report from the index surgery identified a peri-sigmoid metastases that demonstrated no treatment effect. A sample of this metastasis was sent for NGS which showed the previously known *KIT* exon 11 (p.Val560Asp) mutation and a new pathologic structural copy number variation (CNV) loss of *CDKN2A* on chr9:21968226. He underwent resection of the recurrent mass in March, 2025. NGS of the recurrence demonstrated the *KIT* exon 11 (p.Val560Asp) mutation, the CNV loss of *CDKN2A,* and a novel *PDGFRA* D842Y (p. Asp842Tyr) mutation that is considered imatinib-resistant.

Conclusion: This case demonstrates a rare example of a *PDGFRA* mutation present in a tumor recurrence that arose as a resistance mutation to a baseline *KIT* mutation. The presence of this CNV loss in both an imatinib -resistant metastasis and the peritoneal recurrence suggests a clonal relationship. This case highlights the geographic and temporal heterogeneity of GIST and underscores the importance of repeat NGS to evaluate GIST recurrences to inform subsequent medical therapy.

#7922 Effect of plasma activated media, with and without chemotherapeutics, on viability of normal and malignant human breast cells.

Jakob Doster[1], Lavanya Sankaran[2], Chuanling Xu[3], Nathalie Gonce[3], Valentyne Thomas[3], Sofia Melendrez[1], Komal Vig[4], Vijay Rangarari[5], Satyanarayana Pondugula[3], Amit Morey[1]

[1]Poultry Science, Auburn University, Auburn, AL,[2]College of Osteopathic Medicine, California Health Sciences University, Clovis, CA,[3]College of Veterinary Medicine, Auburn University, Auburn, AL,[4]Biological Sciences, Alabama State University, Montgomery, AL,[5]Materials Science and Engineering, Tuskegee University, Tuskegee, AL

Chemotherapy used for cancer treatment results in debilitating side effects for patients. Despite decades of research, enhancing drug sensitivity and minimizing toxicity remains a major challenge. Cold atmospheric plasma (CAP) offers a novel, non-thermal strategy to address this gap. CAP can alter biological processes at the cellular levelto amplify the effects of existing chemotherapeutics. However, the comparative impact of plasma-treated media on normal tissues remains poorly understood and represents a critical barrier to clinical translation. Therefore, the goal wasto determine the effect of the plasma-treated media, alone or in combination with chemotherapeutics, on viability of normal and malignant human breast cells. We conducted a series of experiments using malignant breast MCF-7 and MDA-MB-231 cell lines, and the corresponding normal breast MCF-10A cell line to assess the effects of plasma-treated media combined with different chemotherapeutic agents; paclitaxel, docetaxel, doxorubicin, cisplatin, carboplatin, 5-fluorouracil, and gemcitabine. Media were exposed to dielectric barrier discharge (DBD) air plasma for 5, 10, or 20 minutes before drug administration. Our results demonstrated that breast cancer cell lines showed limited responsiveness to plasma-treated media, whereas normal cells were markedly susceptible. Neither MCF-7 nor MDA-MB-231 cells displayed significant changes in viability following 5-minute plasma exposure, and only modest reductions were observed at 10- and 20-minute exposures across most drug conditions. Among the chemotherapeutics tested, docetaxel at 1 μM exhibited the most pronounced plasma-enhanced reduction in cancer cell viability. In contrast, MCF-10A cells demonstrated heightened sensitivity to plasma-treated media, consistently exhibiting approximately twice the loss of viability observed in cancer cells across nearly all treatment groups. These findings suggest that, within the current DBD air-plasma setup, the oxidative burden generated is disproportionately harmful to normal epithelial breast cell lines and does not produce a correspondingly advantageous cytotoxic effect in the malignant breast cell lines tested. Future studies will evaluate the effect of different types of plasma, alone or combined with chemotherapeutics, on both normal and breast cancer cells, and will investigate the underlying mechanisms.

#7926 Efficacy, *in vivo* safety, and PK/PD studies for novel, oral, highly selective PTPN2/1 inhibitor (ZE00-0388).

Alexei Pushechnikov[1], Ruben Karapetian[2], Stepan Mochalov[2], Sanja Baumann Tomovska[3], Nikolay Savchuk[3], Iain Dukes[3], Ruben Abagyan[4]

[1]Expert Systems, Inc., San Diego, CA,[2]Navegador Biosciences, Cantanhede, Portugal,[3]Mondego Bio, Cantanhede, Portugal,[4]MolSoft LLC, San Diego, CA

PTPN2 inhibition is a novel immuno-oncology approach: by releasing an intracellular “brake” it increases cytokine responsiveness (e.g., IFN-γ/JAK-STAT), boosts antigen presentation, and enhances T-cell cytotoxicity, helping to overcome immune evasion in tumors resistant to PD-1 blockade.
Our development candidate ZE00-0388 demonstrates potential best-in-class profile: Nanomolar potency with high selectivity for PTPN2/1 over other phosphatases, predictable PK/PD with sustained exposure above EC50, and proven target engagement. ZE00-0388 shows favorable bioavailability in all species, with best translation expected from dog to human.
The combination of anti-mPD-1 and ZE00-0388 exhibited remarkable dose-dependent anti-tumor efficacy against the subcutaneous MC38 colon model. Solo treatments with ZE00-0388 demonstrated tumor growth inhibition of 81% and in combination with anti-mPD-1 complete regression of tumor in 50% of animals. ZE00-0388 has a very favorable safety profile with tolerated doses significantly above pre-clinical proof-of-concept efficacious doses, which indicates that ZE00-0388 should have a very broad therapeutic window.

#7927 Exosomes, regulated by SPRED2, reshape tumor microenvironment via activating IL6/ STAT3 signaling.

Tong Gao[1], Akihiro Matsukawa[2]

[1]Department of Pathology and Experimental Medicine, Graduate School of Medicine, Dentistry and Pharmaceutical Sciences, Okayama University, Okayama, Japan,[2]Graduate School of Medicine, Dentistry and Pharmaceutical Sciences, Okayama University, Okayama, Japan

SPRED2 (Sprouty-related, EVH1 domain-containing protein 2) is a negative regulator of Ras-dependent ERK1/2 signaling. Our previous studies revealed that SPRED2 suppresses hepatocellular carcinoma (HCC) progression by limiting cancer stemness through a SPRED2/p53/miR-506-3p/KLF4 signaling axis. Loss of SPRED2 enhanced proliferation, invasion, and chemoresistance in HCC cells, highlighting its tumor-suppressive role.To further elucidate the broader role of SPRED2 in tumor biology, we shifted our focus from intracellular signaling in HCC to intercellular communication within the tumor microenvironment. Using esophageal squamous cell carcinoma (ESCC) as a model, we demonstrated that SPRED2 suppresses exosome secretion by modulating multivesicular body (MVB)-associated proteins VAMP2 and Syntaxin 4 (STX4). Exosomes, nanosized vesicles released upon MVB-plasma membrane fusion, are critical mediators of intercellular signaling in cancer. Loss of SPRED2 markedly increased exosome release, suggesting that SPRED2 negatively regulates exosome biogenesis and secretion. Functionally, ESCC-derived exosomes were found to carry biologically active interleukin-6 (IL-6), which promotes tumor proliferation and metastasis through two major mechanisms: activation of STAT3 signaling in ESCC cells and induction of tumor-associated macrophage (TAM) polarization within the tumor microenvironment. Notably, exosomes derived from SPRED2-deficient ESCC cells enhanced both tumor cell aggressiveness and TAM polarization, whereas exosomes from SPRED2-overexpressing cells exhibited inhibitory effects on M1 and M2 macrophage polarization. The polarized macrophages, in turn, promoted ESCC proliferation and invasion via STAT3 activation, establishing a reciprocal feed-forward loop between tumor cells and immune cells. Furthermore, exosomes from polarized THP-1 cells significantly accelerated tumor progression in vivo, an effect that was effectively attenuated by Tocilizumab, an IL-6 receptor inhibitor.Collectively, our findings identify SPRED2 as a key regulator of exosome biogenesis and secretion through its interaction with VAMP2 and STX4. By controlling IL-6-enriched exosome release, SPRED2 modulates tumor-immune cell communication and suppresses the formation of a pro-tumorigenic microenvironment, extending its role from an intracellular suppressor of cancer stemness to a central coordinator of tumor-immune interactions.

#7928 Immune microenvironmental patterns in rapidly progressive young-onset tongue cancer: A case series analysis.

Alisa Kimura[1], Takahiro Tsujikawa[1], Shota Sugaya[2], Yuna van der Aar[2], Koichi Yoshizawa[2], Sumiyo Saburi[2], Shigeyuki Mukudai[2], Hikaru Nagao[2], Aki Tamura[2], Nana Sakurai[2], Aya Miyagawa-Hayashino[3], Hiroshi Ogi[4], Saya Shibata[4], Eiichi Konishi[2], Kyoko Itoh[3], Shigeru Hirano[1]

[1]Department of Otolaryngology-Head and Neck Surgery, Kyoto Prefectural University of Medicine, Kyoto, Japan,[2]Kyoto Prefectural University of Medicine, Kyoto, Japan,[3]Department of Pathology and Applied Biology, Kyoto Prefectural University of Medicine, Kyoto, Japan,[4]SCREEN Holdings Co., Ltd., Kyoto, Japan

Young-onset tongue cancer is increasingly recognized as a distinct clinical entity, differing from conventional tongue cancer associated with alcohol and tobacco use in terms of risk factors, clinical behavior, and molecular alterations. In rapidly progressive cases, delayed diagnosis and therapeutic challenges have been highlighted. Prior studies have implicated a myeloid-inflamed tumor microenvironment in this subset, suggesting that unique immune landscapes may influence diseases trajectories and treatment response. We analyzed five cases of rapidly progressive young-onset tongue cancer, focusing on clinical characteristics, genetic alterations, and immune tumor microenvironmental features assessed by 14-marker multiplex immunohistochemistry. Patients ranged from 22 to 48 years (median, 40 years), with a median time to recurrence of three months following initial treatment. Three of 5 patients had no history of alcohol or tobacco use. TERT promoter mutation were identified in two cases. All tumors exhibited abundant tumor-associated macrophages. $CD8^+$ T cell infiltration showed inter-case variability, ranging from sparse to dense. However, in contrast to non-young-onset tongue cancer tissues, $CD8^+$ T cells in young-onset cases were frequently excluded from tumor cell nests, even in specimens with high overall infiltration. These findings suggest the presence of immune exclusion mechanisms underlying the rapid progression of young-onset tongue cancer. Immune exclusion may represent a key barrier to effective immunotherapy in this population and warrants further investigation as a therapeutic target.

#7929 DDR2-CAR macrophages reprogram the tumor microenvironment and normalize vasculature to potentiate antitumor immunity.

Dandan WANG

Guangzhou Medical University, Guangzhou, China

The immunosuppressive extracellular matrix (ECM) of solid tumors is a major barrier to effective antitumor immunity, primarily by fostering immune exclusion. Targeting cancer-associated fibroblasts (CAFs), particularly via discoidin domain receptor 2 (DDR2), has emerged as a strategic avenue to overcome this barrier. Here, we engineered DDR2-targeted chimeric antigen receptor macrophages (DDR2-CAR-M) to leverage macrophage infiltration capacity and disrupt ECM-mediated immunosuppression. In vitro studies demonstrated robust DDR2-CAR adenoviral transduction efficiency (>95%) in primary mouse bone marrow-derived macrophages, with flow cytometry confirming M1 polarization within 48 hours post-transduction. In murine models, immunofluorescence and in vivo imaging revealed elevated DDR2 expression in the ECM of LLC subcutaneous tumor, MC-38 subcutaneous tumor, and U87MG orthotopic glioblastoma model. Tumor growth curves demonstrated significant suppression of lung and colorectal cancers following DDR2-CAR-M combination therapy. Mechanistic investigations using single-cell RNA sequencing, pathological analysis, and flow cytometry indicated a marked activation of immune-related signaling pathways in the CAR-M treatment group, characterized by a significant increase in CD8+ T cells and dendritic cells, suggesting that CAR-M-mediated targeting of CAFs can effectively convert immunologically "cold" tumors into "hot" ones. Furthermore, DDR2-CAR-M remodeled the tumor microenvironment by inhibiting aberrant angiogenesis and promoting vascular normalization, enhancing antigen presentation by macrophages, and promoting T-cell infiltration. These findings establish DDR2-CAR-M as a novel immunotherapeutic approach for solid tumors through stromal reprogramming and immune microenvironment optimization.

#7930 Interaction of visceral adiposity and age in shaping the human breast tumor microenvironment.

Anlan Cao[1], Sophia Fuller[1], Jorge Gomez Tejeda Zanudo[2], Wendy Y. Chen[3], Deborah A. Dillon[4], Sandra S. McAllister[5], Rinath M. Jeselsohn[6], Bette J. Caan[1], Adrienne L. Castillo[1], **Elizabeth M. C. Feliciano**[1]

[1]Division of Research, Kaiser Permanente - Northern California, Pleasanton, CA,[2]Department of Medical Oncology, Dana-Farber Cancer Institute, Boston, MA,[3]Breast Oncology Program, Dana-Farber Brigham Cancer Center, Boston, MA,[4]Assistant Professor, Pathology, Dana-Farber Cancer Institute, Boston, MA,[5]Harvard Medical School, Boston, MA,[6]Dana-Farber Cancer Institute, Boston, MA

Background: Preclinical studies suggest that aging and adiposity synergistically impair anti-tumor immunity, but most evidence comes from triple negative breast cancer (TNBC) models. In humans, visceral adipose tissue (VAT), a metabolically active, pro-inflammatory depot not captured by body mass index, has been linked to alterations in the breast tumor microenvironment (TME), with patterns varying by molecular intrinsic subtype. However, the joint impact of aging and adiposity on the human breast TME remains poorly understood.

Methods: We included 1,377 women diagnosed with primary, stage II-III breast cancer who received treatment at Kaiser Permanente Northern California between 2005 and 2015 and had an abdominal computed tomography (CT) scan within 6 months of diagnosis and before systemic therapy. We selected a stratified random sample enriching for HER2+ and ER- tumors and isolated RNA from treatment-naïve specimens collected at biopsy or excision, verified RNA quality, and performed NanoString BC360™ profiling to determine PAM50 subtype and quantify TME-related gene expression levels. VAT area (cm^2) was quantified from CT scans at the third lumbar vertebra. We examined the differential gene expressions associated with high vs. low VAT index (VAT area scaled to height; ≥42.5 vs <42.5 cm^2/m^2) stratified by age as a proxy for menopausal status (≤55 vs >55) and PAM50 subtype.

Results: Patients were on average 56±13 years old at diagnosis. Most had overweight (30%, BMI 25-<30) or obesity (38%, BMI 30+) and stage II (58%) cancer. The PAM50 subtype distribution was: Basal-like (31%), HER2-enriched (25%), Luminal B (22%), and Luminal A (22%). VAT was associated with differential TME gene expression only among patients aged >55: In Basal-like tumors, high VAT was associated with upregulation of CDKN2A, a cell cycle inhibitor that can drive senescence, which in turn, promotes immune modulation, treatment resistance, and poor prognosis in TNBC. In Luminal A tumors, low VAT showed increased expression of genes associated with metabolic adaptation (PCK1) and differentiation regulators (ACVR1C, WIF1, SOCS2), whereas high VAT was linked to SPP1, a pro-inflammatory glycoprotein also related to senescence.

Conclusion: Excess VAT modifies breast TME gene expression in post-menopausal patients with Basal-like and Luminal A breast cancers. The differential expression patterns were suggestive of metabolic shifts and inflammatory reprogramming that could lead to an aggressive, pro-inflammatory and/or immunosuppressive breast TME in menopausal patients, negatively impacting treatment response. These findings highlight the interplay of aging and visceral adiposity in breast cancer biology and prognosis.

#7931 Distinct microbiota composition in anorectal mucosal melanoma is associated with resistance to immune checkpoint inhibition.

Pritika Parmar[1], Morgan MacBeth[2], Mallory Karr[2], Nichole Nusbacher[2], Stacey M. Bagby[2], Phaedra Whitty[2], Kylie Michel[2], Richard P. Tobin[3], Martin McCarter[3], Theresa Medina[2], Catherine Lozupone[2], William A. Robinson[2], Kasey Couts[2]

[1]Dermatology, University of Colorado Anschutz Medical Campus, Aurora, CO,[2]University of Colorado Anschutz Medical Campus, Aurora, CO,[3]Surgery, University of Colorado Anschutz Medical Campus, Aurora, CO

Anorectal mucosal melanoma (AMM) is a rare and aggressive melanoma subtype characterized by poor responses to immune checkpoint inhibitor (ICI) therapy. While cutaneous melanoma metastases to gastrointestinal (GI) sites often retain strong ICI responses, the mechanisms underlying poor responses in AMM remain unclear. Given that AMM arises in microbial rich mucosal environments, we hypothesized that tumor-associated microbiota may contribute to local immune suppression. To investigate this, we performed 16S rRNA gene sequencing on primary AMM tumors and compared their microbial composition with cutaneous melanoma GI metastases (CM-GI-met) and normal mucosal reference samples, including nasal, rectal, and vaginal swabs. AMM tumors were enriched with Firmicutes Clostridia taxa, including Lactospiraceae and Ruminococcaceae, known butyrate producers associated with immunomodulation. In contrast, CM-GI-met tumors exhibited distinct microbial signatures, with a relatively higher abundance of Fusobacteriaceae and Bacteriodaceae. These patients notably had improved ICI responses compared to AMM primaries. Functional profiling suggested that AMM microbiomes had increased butyrate synthesis, known to create an immunosuppressive tumor microenvironment, which may contribute to poor ICI response. These findings are also seen in our orthotopic rectal mouse melanoma model, which showed reduced tumor growth rates, tumor burden, and overall survival in mice treated with combination vancomycin (Gram-positive selective antibiotic which targets Firmicutes Clostridia) and anti-PD-1 therapy compared to controls and monotherapy. Our findings demonstrate that AMM tumors contain a distinct butyrate-rich microbiome that may contribute to local tumor evasion whereas CM tumors contain a more ICI-permissive microbiome.

#7932 FL115, a novel IL-15 superagonist rationally designed to minimize safety risks for cancer immunotherapy.

Quanxiao Li[1], Yaping Cheng[2], Dong Wei[1], Qiang Gao[3], Yanling Wu[2], Tianlei Ying[2]

[1]Forlong Biotechnology, Suzhou, China,[2]Key Laboratory of Medical Molecular Virology (MOE/NHC/CAMS), Shanghai Institute of Infectious Disease and Biosecurity, School of Basic Medical Sciences, Fudan University, Shanghai, China,[3]Department of Hepatobiliary Surgery and Transplantation, Liver Cancer Institute and Key Laboratory of Carcinogenesis and Cancer Invasion (MOE), Zhongshan Hospital, Fudan University, Shanghai, China

Background: Interleukin(IL)-15 is a potent cytokine that activates NK and T cells but has been hampered by a short half-life, systemic toxicity, and dependence on IL-15Rα Sushi domain (IL-15RαSu) trans-presentation. ALT803, an IgG1 Fc-fused IL-15RαSu and IL-15, has been FDA-approved for bladder cancer via intravesical instillation. Nonetheless, no IL-15 agonist has yet been approved for systemic use due to safety concerns and challenging therapeutic index. We developed a novel superagonist, FL115, by fusing IL-15RαSu and IL-15 with a single-chain Fc (sFc). This sFc is half size of human IgG1 Fc and lacks FcγRs binding while retaining FcRn binding, conferring FL115 a distinct and potentially improved profile compared with ALT803 *in vivo*.
Methods: Different mouse models were used to compare the efficacy and safety of FL115 and ALT803. The immunomodulatory mechanism of FL115 was analyzed via single-cell RNA sequencing (scRNA-seq), immune cell depletion, qPCR and flow cytometry. The structure of FL115/FcRn/β2M were elucidated through cryo-electron microscopy (Cryo-EM).
Results: FL115 was rationally designed to eliminate FcγR binding while retaining FcRn interaction. Cryo-EM analysis of FL115/FcRn/β2M complex revealed that sFc aligns with only one chain of Fc but deviated from the other, disrupting the key interface required for FcγR engagement and preventing FcγR-mediated immune activation. Consistent with structural insight, FL115 exhibited markedly improved *in vivo* safety compared with ALT803. At 20 mg/kg, ALT803 caused 100% mortality accompanied by severe liver injury and pro-inflammatory cytokines such as IL-6. In contrast, all FL115-treated mice survived without detectable toxicity. The maximum tolerated dose of FL115 was over 10 times than ALT803. scRNA-seq of liver tissue revealed that ALT803 promotes the activation of neutrophils and macrophages through FcγR signaling, leading to cytokine release and systemic toxicity. FL115, lacking FcγR-binding capacity, did not trigger these inflammatory pathways. Importantly, FL115 showed comparable efficacy to ALT803 in CT26 and B16-F10 tumor models. Single-cell transcriptomics revealed FL115 reshapes the tumor microenvironment by enhancing NK and T cells infiltration, pro-inflammatory macrophage polarization, and dendritic cell expansion.. Immune cell depletion confirmed that FL115's antitumor effect is exclusively NK cell-dependent. Deep analysis further showed FL115 promotes NK cell maturation, cytotoxicity, and intratumoral recruitment.
Conclusion: Our study revealed the mechanism underlying the superior safety of FL115 over ALT803 while exhibiting comparable anti-tumor activities. These findings highlight the rational design strategy of FL115 as next-generation IL-15-based superagonist, supporting its favorable safety and preliminary clinical responses observed in multiple Phase 1 clinical studies.

#7933 Extracellular vesicle-mediated transfer of cortisol-induced miR-143-3p from macrophages promotes angiogenesis.

Amod Sharma, Sarabjeet Kour Sudan, Ajay P. Singh, Seema Singh

Cell and Molecular Biology, Cancer Center and Research Institute, University of Mississippi Medical Center, Jackson, MS

Chronic stress can lead to hormonal imbalance and contribute to cancer risk and progression. We previously reported higher levels of serum cortisol in breast cancer (BC) patients compared to those without a cancer diagnosis. Furthermore, we observed relatively higher levels of serum cortisol in Black patients than their White counterparts. Additionally, we found that cortisol treatment promoted M2 polarization of macrophages by inducing the expression of miR-143-3p, which was also released in extracellular vesicles (EV). Here, we investigated the role of EV-encapsulated miR-143-3p in angiogenesis, considering the fact that Black patients exhibit a higher microvessel density in their breast tumors. Treatment of endothelial cells with EV from cortisol-treated macrophages (Corti-Mφ-EV) increased their proliferation, migration, invasion, and tube formation. Efficient uptake of EV by endothelial cells was confirmed by fluorescence-based imaging, which correlated with an increase in the intracellular levels of miR-143-3p in Corti-Mφ-EV treated endothelial cells. Pre-treatment of endothelial cells with a miR-143-3p inhibitor abrogated Corti-Mφ-EV-induced proliferation and tube formation, whereas transfection with a miR-143-3p mimic promoted these effects. Computational analysis using the web-based platforms (Targetscan and miRDB) identified IGFBP5 as a potential miR-143-3p target. A reduction in IGFBP5 expression was reported in Corti-Mφ-EV or miR-143-3p mimic-treated endothelial cells. siRNA-mediated knockdown of IGFBP5 also increased endothelial cell growth and tube formation. Interestingly, surveying of the TCGA dataset showed a significant positive correlation between the M2 macrophage marker (CD163) and endothelial cell markers (PECAM1 and CDH5). Altogether, these findings reveal a novel mechanism by which cortisol may promote angiogenesis, establishing an additional pathobiological connection of chronic stress with increased cancer risk.

#7934 IL-24 engineered mesenchymal stem cells as a novel therapeutic strategy to remodel the tumor microenvironment in non-small cell lung cancer.

Yuting Zhang[1], Yuxuan Zhang[1], Sai Fung Yeung[1], Chi-Hang Wong[1], Tsz Tung Kwong[1], Connie Wun Chun Hui[1], Stephen Kwok-Wing Tsui[2], Tony S. Mok[1], Desheng Liang[3], Molly Siu Ching Li[1]

[1]The Chinese University of Hong Kong, Hong Kong, Hong Kong,[2]School of Biomedical Sciences, Chinese University of Hong Kong (CUHK), Shatin, Hong Kong,[3]Central South University, Changsha, China

Immune checkpoint inhibitor (ICI) resistance in non-small cell lung cancer (NSCLC) is frequently driven by an immunosuppressive tumor microenvironment (TME). To address this issue, we developed IL-24-iMSC, a novel mesenchymal stem cell-based therapy designed to remodel the immunosuppressive tumor microenvironment through sustained secretion of interleukin 24 (IL-24), an immunomodulatory cytokine with anti-cancer properties. Induced mesenchymal stem cells (iMSCs) were derived from induced pluripotent stem cells (iPSCs) and the IL-24 gene was integrated into iMSC at the B2M locus under the control of the EF1α promoter using CRISPR/Cas. IL-24-iMSCs were confirmed to constitutively secrete IL-24. Metastatic lung cancer models were established by tail vein injection of Lewis Lung Carcinoma cells expressing luciferase (LLC-luc) into immunocompetent C57BL/6 mice. Tumor progression was monitored using an In Vivo Imaging System (IVIS). Treatment was administered 20 days after tumor inoculation, and mice were randomized into three groups: iMSC, IL-24-iMSC, or vehicle control. All mice were sacrificed three days after treatment. Tumor growth was confirmed by bioluminescence imaging using IVIS, and tumor samples were collected for immune profiling. While there was no significant difference in tumor growth among the three groups, tumors exposed to IL-24-iMSC demonstrated a pro-inflammatory phenotype. Multiplex immunohistochemistry confirmed infiltration of MSCs into the TME, with significantly increased IL-24 expression in the IL-24-iMSC arm. Compared with the control group (untreated), tumors treated with IL-24-iMSC showed increased CD8+ T cells, dendritic cells, and memory CD4+ T cells. IFN-γ and TNF-α expressions were also elevated in the IL-24-iMSC treatment arm. On the contrary, regulatory T cells and exhausted T cells (PD1+ TIM3+) were significantly reduced in the IL-24-iMSC group. In conclusion, IL-24-iMSCs demonstrated the ability to modulate immune cell composition within the tumor microenvironment, suggesting their potential to synergize with ICI in NSCLC.

#7935 Multimodal immunotherapy remodels the tumor microenvironment in hepatocellular carcinoma: Integrative spatial and transcriptomic profiling from a Phase II trial.

[1]Medical Oncology, Mayo Clinic Cancer Center, Rochester, MN,[2]Radiation Oncology, Mayo Clinic Cancer Center, Rochester, MN,[3]BostonGene Corporation, Waltham, MA,[4]Biomedical Informatics, Mayo Clinic, Scottsdale, AZ,[5]Quantitative Health Sciences, Mayo Clinic, Jacksonville, FL,[6]Mayo Clinic Cancer Center Minnesota, Rochester, MN,[7]Medical Oncology, Mayo Clinic, Rochester, MN,[8]Mayo Clinic College of Medicine and Science, Rochester, MN,[9]Research, Mayo Clinic, Rochester, MN,[10]Mayo Clinic, Rochester, MN,[11]Asst. Professor, Div. of Hemat., Mayo Clinic, Rochester, MN

Background: Hepatocellular carcinoma (HCC) is largely refractory to immune checkpoint blockade due to immune exclusion, stromal barriers, and aberrant vasculature. We evaluated whether multimodal therapy - external beam radiotherapy (EBRT) for antigen release, intratumoral dendritic cell (DC) vaccination for antigen presentation, PD-L1 blockade for immune activation, and VEGF inhibition for vascular normalization - could convert “cold” HCC tumors into sustained immune-inflamed states.

Methods: Serial biopsies (baseline, post-EBRT, end-of-treatment [EOT], and progression [PD] when available) from three patients enrolled in an ongoing phase II trial (NCT03942328) underwent multiplex immunofluorescence, spatial neighborhood analysis, and transcriptomic profiling. Longitudinal changes in cellular composition, immune-stromal architecture, spatial contact networks, and pathway activity were compared.

Results: Baseline tumor microenvironments (TMEs) were strongly immune-excluded, dominated by tumor (PanCK⁺60-70%) and stroma (SMA⁺/Vimentin⁺25-30%) with sparse immune infiltration (<10-15%). Post-therapy, immune complexity and spatial connectivity increased 2-3-fold in all patients. Patient 1 showed robust cold-to-hot conversion with CD8⁺(3x), CD4⁺(2.2x), and DC (2.3x) expansion, increased CD8-DC interactions (2.5x), and reduced tumor fraction (-40%). Transcriptomics showed marked upregulation of IFN-γ (↑3.4x), HLA-DRA (↑2.7x), and reductions in VEGFR2 (↓50%) and HIF1A (↓40%), consistent with vascular normalization. Patient 2 exhibited stromal/vascular remodeling and improved T-cell infiltration but restricted immune diversity, with CD4⁺/CD8⁺ dyads (↑2.2x) and B/NK cells(↓ 60%). Neighborhood diversity rose (3→7 communities) and immune-tumor proximity improved (distance ↓ 35%). Patient 3 showed transient inflaming with CD8⁺(↑3x), DC(↑2x), and new CD4-CD20/CD4-CD56 interactions, followed by relapse marked by stromal/myeloid re-expansion (SMA⁺↑1.8x, CD14⁺↑2.5x), angiogenic resurgence (VEGFR2/CD34⁺↑2.2x), contraction of immune networks, and genomic shift from activating CTNNB1 mutation loss to ATM gain. DCs accumulated but localized mainly to DC-DC or DC-myeloid niches, indicating non-productive antigen presentation.

Conclusions: Multimodal EBRT+DC+PD-L1/VEGF blockade induces four-sided synergistic TME reprogramming - antigen release, immune priming, checkpoint release, and vascular normalization - promoting cold-to-hot conversion in HCC. Durable inflaming correlates with sustained T-cell/DC expansion and vascular remodeling, whereas relapse reflects stromal/myeloid reinforcement and genomic adaptation. These findings define mechanistic trajectories of TME remodeling and highlight actionable barriers to sustained immunotherapy response in HCC.

#7936 Epigenetic reprogramming of stromal-epithelial crosstalk to improve immunotherapy response in pancreatic ductal adenocarcinoma.

Celia Martin-Otal[1], Daire Hanna[1], Kairbaan Hodivala-Dilke[1], Angus J. M. Cameron[2], Oliver Pearce[1], David Propper[1]

[1]Centre for Tumour Microenvironment, Barts Cancer Institute, London, United Kingdom,[2]Centre for Tumour Biology, Barts Cancer Institute, London, United Kingdom

Pancreatic ductal adenocarcinoma (PDAC) is highly aggressive and profoundly resistant to immunotherapy, driven by a dense, desmoplastic, and immunosuppressive stroma dominated by cancer-associated fibroblasts (CAFs). CAFs are genetically stable and abundant, making them attractive targets for epigenetic reprogramming to overcome immune exclusion.We hypothesized that epigenetic modulators could reshape CAF-cancer cell interactions, reduce immunosuppression, and enhance responsiveness to immunotherapies, including immune checkpoint blockade and CAR-T cells. Using a 3D PDAC co-culture spheroid model, we screened a panel of clinically relevant epigenetic agents. Transcriptomic profiling revealed drug-induced changes in both tumor and stromal compartments, focusing on CAF subtype reprogramming, stroma-epithelial crosstalk, tumor growth and invasion, immunosuppression, and matrisome remodeling.The CDK7 inhibitor CT7001 emerged as a promising candidate, profoundly altering CAF phenotype, reprogramming CAF subtypes, and modulating stromal gene expression, while reducing epithelial-mesenchymal transition and cell cycle pathways in cancer cells. In an orthotopic PDAC mouse model, CT7001 combined with Gemcitabine significantly extended survival. Notably, treated tumors exhibited increased T-cell infiltration into the otherwise immunologically “cold” PDAC microenvironment, highlighting its potential to sensitize tumors to immunotherapy. Ongoing spatial multiplex imaging and RNA-seq analyses aim to correlate *in vivo* immune and stromal changes with *in vitro* findings, supporting rational combination strategies. This epigenetic screening platform provides a predictive framework to evaluate compounds that overcome CAF-mediated immune exclusion and modulate the tumor microenvironment, offering new avenues to enhance PDAC responsiveness to diverse immunotherapies.

#7937 Advancing the best-in-class cross-specific LILRB1/LILRB2 antibody IOMX-0675 into clinical development for solid tumors.

[1]iOmx Therapeutics AG, Martinsried, Germany,[2]Proteinea, Cambridge, MA

IOMX-0675 is a fully human, cross-specific immunoglobulin G1 (IgG1) antibody targeting LILRB1 (ILT2) and LILRB2 (ILT4), two key immunosuppressive receptors that drive tumor immune evasion and resistance to T cell checkpoint blockade. LILRB1 and LILRB2 recognize both classical and non-classical MHC-I molecules and are highly expressed on tumor-infiltrating myeloid cells, with LILRB1 also being expressed on lymphoid cells. Molecular profiling revealed concurrent expression of highly homologous immune-activating LILRA1/LILRA3 with inhibitory LILRB1/LILRB2, underscoring the critical need for selective receptor targeting. IOMX-0675 exhibits a unique, superior binding profile defining its best-in-class potential: selective, high-affinity binding to inhibitory LILRB1/LILRB2 with minimal affinity to immune-activating LILRA1/LILRA3. This differentiated selectivity maximizes anti-tumor efficacy by preserving immune activation, while blocking immunosuppression. Comparative functional studies demonstrate IOMX-0675's superior potency in tumor cell phagocytosis as well as a repolarization activity of M2-macrophages compared to competitor compounds. Notably, only simultaneous blocking of LILRB1 and LILRB2 with dual-targeting IOMX-0675 leads to significant T cell activation in co-culture assays. In support of a potential clinical patient selection approach, a donor screening was performed *in vitro* which revealed a distinct IOMX-0675 efficacy profile with clear differences between responsive and non-responsive donors. An integrated multi-omics-based biomarker analysis offers strong potential for a future biomarker-driven patient selection process. Functional assays using stimulated PBMCs demonstrate that IOMX-0675 synergizes with anti-PD-1 treatment, potentiating pro-inflammatory cytokine secretion and driving cytotoxic T cell activation *in vitro*. Co-culture assays modeling patient-relevant tumor or lymph node microenvironments demonstrate that IOMX-0675 repolarizes immunosuppressive milieus and restores T cell function, in a situation where anti-PD-1 monotherapy is ineffective. In summary, IOMX-0675 represents a best-in-class therapeutic antibody that combines selective LILRB1/LILRB2 antagonism with minimal immune-activating receptor binding and demonstrates superior myeloid reprogramming and T cell restoration both *in vitro* and *in vivo*. IOMX-0675 will enter a Phase I/II clinical trial in early 2026 as monotherapy as well as combination therapy with anti-PD1 in patients with previously treated advanced/metastatic solid tumors.

#7938 Identification of a novel lncRNA in pancreatic cancer: Contribution to malignancy through Wnt pathway regulation.

Isshin Narumoto, Keiko Shinjo, Yutaka Kondo, Shu Hirako

Nagoya University, Nagoya, Japan

Long non-coding RNAs (lncRNAs) are non-coding RNAs longer than 200 nucleotides that play essential roles in transcriptional regulation and protein localization through interactions with various proteins. These functions have attracted considerable attention in cancer research.

We identified lnc243, which is highly expressed in mesenchymal-type cells of pancreatic ductal adenocarcinoma (PDAC) and is associated with poor patient survival. Previous studies reported that lnc243 regulates mRNA expression by acting as a competing endogenous RNA through binding to miRNAs. However, the subcellular localization of lnc243 and its function through protein interactions in PDAC remain poorly understood.RNA fluorescence in situ hybridization (RNA-FISH) revealed that lnc243 localization varies depending on the cellular state: it is localized to the cell membrane in adherent cells but translocates into the cytoplasm during invasion. Because lnc243 and β-catenin were found to co-localize on the cell membrane, we next examined their potential interaction using AlphaFold3. This analysis suggested a possible interaction between lnc243 and β-catenin, which was further supported by RNA immunoprecipitation showing that β-catenin binds to lnc243. Moreover, knockdown of lnc243 led to a decrease in the post-translational levels of β-catenin.

Mutations in Wnt pathway genes are rare in PDAC; however, increased lnc243 expression may represent an alternative mechanism for dysregulating β-catenin and promoting malignancy in PDAC.

#7939 Stress-induced anoikis-resistance triggers malignant-like phenotypes in uterine leiomyoma cells.

Roseli da Silva Soares[1], Edmund C. Baracat[2], **Katia C. Carvalho**[3]

[1]University of Sao Paulo, Faculty of Medicine, Sao Paulo, Brazil,[2]Sao Paulo University, Sao Paulo, Brazil,[3]Obstetrics and Gynecology, HCFMUSP, Sao Paulo, Brazil

Background: Uterine leiomyomas (LM) are the most common tumors in women of reproductive age and represent a major clinical burden. Although LM are classically considered benign, a long-standing scientific question concerns whether a subset of these tumors may undergo malignant transformation into leiomyosarcomas (LMS), a rare but highly aggressive uterine sarcoma. To date, this progression has not been conclusively demonstrated, yet it also cannot be fully excluded, and the biological mechanisms that might enable such a transition remain poorly understood. Anoikis resistance - the capacity of cells to survive loss of extracellular matrix attachment - is a hallmark of malignant transformation and early metastatic behavior in several solid tumors. Therefore, experimental models that induce anoikis resistance may offer insight into whether LM cells can acquire malignant-like traits under sustained cellular stress.
Methods: Established cell lines of myometrium (MM; PCS-460-011) and leiomyoma (LM; THESCs; CRL-4003) were cultured (1×10^5 cells/mL) on plates coated with 1% sterile agarose to prevent cell-matrix adhesion and maintained for 96 hours at 37°C and 5% CO_2. Surviving non-adherent spheroids (anoikis-resistant cells) were collected and replated under adherent conditions. This spheroid-formation cycle was repeated four times, generating the derived cell populations LM1C, LM2C, LM3C, and LM4C. Subsequently, spheroids were subjected to limiting dilution to obtain clonal populations. Five clones were randomly selected for expansion and functional/molecular analyses.
Results: Preliminary findings indicate that LM cells progressively lose adhesion capacity and acquire anoikis resistance, accompanied by notable phenotypic alterations. MM cells did not survive repeated adhesion-blocking cycles and were eliminated before cycle 5 (C5), whereas LM cells successfully persisted through all cycles. After clonal expansion, genetic identity was confirmed through sequencing, validating their LM origin. Clonogenic assays demonstrated significant behavioral changes: anoikis-resistant LM derivatives exhibited an increased ability to survive and proliferate independently of cell-cell contact compared with parental LM cells. Ongoing assays of proliferation, migration, and invasion further indicate important phenotypic and behavioral alterations in vitro.
Conclusion: The anoikis-resistance model appears to be a valuable tool for studying uterine leiomyoma biology. Our findings suggest that LM cells may acquire malignant-like traits when subjected to repeated adhesion stress, supporting the hypothesis that anoikis resistance may contribute to malignant transformation in uterine smooth muscle tumors.

#7940 Pharmacokinetics of TNX-1700 in non-human primates and human FcRn/serum albumin transgenic mice.

Mayanka Awasthi[1], Jennifer Cho[1], Nelson Martinez[1], Bernd Meibohm[2], Seth Lederman[3], Christopher Cooper[1], Sina Bavari[1], **Bruce L. Daugherty**[3]

[1]Tonix Pharmaceuticals, Inc., Frederick, MD,[2]University of Tennessee Health Science Center, Memphis, TN,[3]Tonix Pharmaceuticals, Inc., Chatham, NJ

Introduction: TNX-1700 is a novel recombinant fusion molecule of human Trefoil Factor-2 (TFF2) protein and human serum albumin (HSA) that is being investigated as a potential therapeutic for gastric cancer. In syngeneic mouse models of gastric and colorectal cancer, TNX-1700 functions as a CXCR4 partial agonist that activates antitumor immunity in the tumor microenvironment by modulating myeloid cell trafficking to reduce tumor-induced granulopoiesis and accumulation of immunosuppressive neutrophils. TNX-1700 is engineered to extend plasma half-life, enhance systemic exposure, and improve cancer immunotherapy. The HSA domain in TNX-1700 provides a long circulatory half-life (>14 days) and multiple ligand-binding sites. Approved albumin-linked drugs include detemir (Levemir®), liraglutide (Victoza®), and albiglutide (Eperzan®/Tanzeum®) for diabetes, and nanoparticle albumin-bound paclitaxel (nab-paclitaxel) for cancer therapy. TNX-1700 represents a next-generation application of the albumin platform in immuno-oncology.
Methods: The pharmacokinetics (PK) of TNX-1700 were evaluated in non-human primates (NHP; cynomolgus macaques) and double-transgenic mice expressing human neonatal Fc receptor (FcRn) and human serum albumin (HSA). Animals received a single dose of 1 mg/kg or 3 mg/kg TNX-1700, administered intravenously (IV) to NHPs or intraperitoneally (IP) to FcRn/HSA mice. For comparison, untagged human TFF2 (molar equivalent to TNX-1700) was also administered into FcRn/HSA mice. Serial blood samples were collected over 0-35 days and analyzed using the Boster PicoKine™ Human TFF2 ELISA kit. Pharmacokinetic parameters were determined by non-compartmental analysis.
Results: All animals survived without clinical signs or >10% body-weight loss. Comparable PK profiles were observed across species and doses. In cynomolgus macaques, mean terminal half-life (t½) was 7.1 days (%CV = 9.65), clearance (CL) 13.3 mL/day (%CV = 14.3), and volume of distribution (Vz) 135.2 mL (%CV = 18.3). Allometric scaling predicted in humans a t½ of 14.2 days (%CV = 12.9), CL = 105.2 mL/day (%CV = 26.4), and Vz = 2,158 mL (%CV = 34.0). Results from the humanized murine studies provided evidence that untagged human TFF2 is rapidly cleared and that fusion with HSA significantly increased the PK profile similar to that observed in NHPs and to levels supportive for clinical candidates.
Conclusion: TNX-1700 exhibited dose-independent, linear pharmacokinetics with low inter-animal variability, and exposure was consistent across doses and species. Although its half-life is shorter and clearance higher than IgG-based biologics, TNX-1700 substantially extends the half-life of TFF2 and achieves durable systemic exposure, supporting its potential as a therapeutic candidate for gastric cancer.

#7941 The Sphk1-B cell axis as a targetable immunoregulatory pathway in cancer.

Mona Singh[1], Prachi Gupta[2], Arezou Rahimi[1], Sunila Pradeep[1]

[1]Medical College of Wisconsin, Wauwatosa, WI,[2]Earle A. Chiles Research Institute, Portland, OR

Background: The sphingosine kinase 1 (SPHK1)/sphingosine-1-phosphate (S1P) signaling axis regulates tumor progression and immune suppression within the tumor microenvironment (TME). While SPHK1-mediated S1P generation is known to promote ovarian cancer growth, its role in shaping B cell-driven anti-tumor immunity remains unclear.

Methods and Results: Genetic ablation of SPHK1 (SPHK1$^{-/-}$) in murine ovarian cancer (ID8 Trp53$^{-/-}$; Brca2$^{-/-}$), melanoma (B16F10), and colorectal cancer (MC38) models resulted in markedly reduced tumor burden accompanied by ~50% reduction in S1P levels. Tumors from SPHK1$^{-/-}$ mice demonstrated increased immune infiltration, primarily B and T lymphocytes, and enrichment of immunoglobulin-related and antigen presentation gene signatures. Flow cytometry and IHC confirmed enhanced tumor-infiltrating CD19^{+} B cells, plasma cells, and upregulation of activation and antigen-presentation markers (CD69, CD80, CD86, CD40, MHC-II).Mechanistically, SPHK1 deficiency promoted metabolic reprogramming that supported plasma cell differentiation, characterized by elevated unfolded protein response (XBP1, BiP, GRP94), increased oxidative phosphorylation, ATP generation, mitochondrial biogenesis, and FOXO1 activation. Pharmacologic SPHK1 inhibition using PF543 phenocopied genetic knockout, increasing plasma cell frequency, immunoglobulin secretion, and activation-associated transcriptional programs. Taken together, our data suggest that SPHK1 inhibition activates B cells for enhanced anti- tumor immune response.

Conclusion: SPHK1/S1P axis inhibition reprograms B cells toward robust metabolic fitness, plasma cell differentiation, and antibody-mediated anti-tumor immunity. Targeting SPHK1 represents a promising strategy to boost humoral immunity and overcome immune-excluded ovarian cancer phenotypes.

Impact: This study uncovers a previously unrecognized immunometabolism by which SPHK1 controls B cell function, highlighting its therapeutic potential for enhancing anti-tumor immunity and improving immunotherapy responsiveness.

#7942 TAE226 reprograms immune-cold head and neck tumors to immune-hot, augmenting immunotherapy efficacy.

Atish Ranjan Mohanty[1], Dana Do[2], Sharad S. Singhal[3], Haiqing Li[4], Sravani Ramisetty[4], Raju Pillai[4], Sultatna Shoukath[5], Prakash Kulkarni[4], Ellie G. Maghami[6], Ravi Salgia[4], Erminia Massarelli[5]

[1]City of Hope Comprehensive Cancer Ctr., Duarte, CA,[2]City of Hope National Medical Center, Monrovia, CA,[3]Beckman Research Institute of The City of Hope, Duarte, CA,[4]City of Hope National Medical Center, Duarte, CA,[5]University of Texas, Tyler, TX,[6]Faculty, Div. of Surgery, City of Hope, Duarte, CA

Introduction: Current treatment strategies in advanced/recurrent LSCC include chemotherapy, radiation therapy, and immune checkpoint inhibitors (ICI). ICI treatment is associated with durable benefit in about 20% of patients with advanced/incurable platinum-resistant LSCC. There is a clear need to develop strategies to reprogram the tumor microenvironment (TME) from immune-cold to immune-hot to enhance T-cell infiltration and activation that correlate with ICI treatment response. We investigated the therapeutic potential of Focal Adhesion Kinase (FAK) inhibition using a tyrosine kinase inhibitor, TAE226, alone and in combination with anti-PD-1 immune checkpoint blockade, to reprogram the TME and enhance immunotherapeutic responsiveness in a model of platinum-resistant LSCC.
Methods: LSCC cell lines (SQ20B, SCC17A) were used to assess the inhibitory response to FAK inhibitors using the CCK-8 assay. RNA-seq was performed to evaluate global transcriptional changes and pathway enrichment. Syngeneic MOC2 mouse models were used to assess the therapeutic efficacy of TAE226 in combination with anti-PD-1 therapy. Post euthanization, the xenografts were processed for isolating single cells and performing single-cell RNA sequencing.
Results: TAE226 significantly reduced LSCC cell proliferation, viability, and wound-healing capacity, indicating potent anti-tumor activity. Bulk RNA-seq and pathway enrichment analyses revealed robust upregulation of interferon and cytokine signaling pathways, consistent with an immune-stimulatory phenotype, while downregulating proliferative and metabolic programs. This dual modulation suggests that TAE226 exerts both tumor-intrinsic anti-proliferative and tumor-extrinsic immune-activating effects. In the MOC2 syngeneic model, the combination of TAE226 and anti-PD-1 produced a synergistic response, resulting in markedly enhanced antitumor signaling and significantly greater tumor regression compared to either monotherapy. Single-cell RNA-seq further demonstrated that TAE226 treatment induced profound TME remodeling, characterized by expansion of cytotoxic $CD8^+$ T cells, dendritic cells, and activated macrophages, and depletion of proliferative epithelial and fibroblast-rich stromal clusters. Hallmark pathway analyses highlighted activation of interferon-α/γ, IL2-STAT5, TNFA-NFκB, and complement signaling-consistent with broad activation of innate and adaptive immune programs.
Conclusion: These findings indicate that TAE226 disrupts FAK-mediated adhesion and cytoskeletal signaling, converting the TME from immune-cold to immune-hot and enhancing responsiveness to immune checkpoint blockade and offering a promising therapeutic strategy for platinum-resistant laryngeal cancer.

#7943 TP53 mutation reshapes the immune microenvironment in endometrial cancer.

Konrad Snioch, Mahima Rasquinha, Dmitriy Zamarin

The Tisch Cancer Institute, Icahn School of Medicine at Mount Sinai, New York, NY

Gynecologic cancers account for almost 40% of all cancer cases and more than 30% of cancer-related deaths in women globally, with endometrial cancer (EC) being the most prevalent gynecological cancer in the US. Four principal molecular subtypes of EC include POLE-ultramutated, mismatch repair-deficient (dMMR), MMR-proficient (pMMR) copy-number (CN)-low cancers (TP53-wild type), and pMMR CN-high cancers (TP53 mutant). Despite the emergence of immune checkpoint blockade (ICB)as a promising treatment for many cancers, in EC only the first two subtypes (POLE and dMMR) are susceptible to immunotherapy, whereas pMMR CN-low and CN-high cancers are largely resistant. One key problem in understanding the reduced effectiveness and mechanism of action of ICB in EC is the lack of immunocompetent preclinical models that accurately recapitulate the genetics and biology of human ECs. To address this problem, we developed organoids from mice bearing conditional (LoxP-controlled) expression of the mutant genes most frequently mutated in human ECs, representative of CN-Low ($PTEN^{-/-}PIK3CA^{H1047R}$) and CN-high ($PTEN^{-/-}PIK3CAH^{1047R}p53^{R172H}$ and $PTEN^{-/-}PIK3CA^{H1047R}p53^{-/-}$) endometrial cancer subtypes. Using cyclic immunofluorescence (CyCIF), we performed spatially resolved, multiplex profiling of immune populations in TP53-mutant and TP53-wild-type EC samples.TP53-mutant tumors exhibited a myeloid-enriched microenvironment, with abundant macrophages and neutrophils, while lymphoid populations were comparatively sparse. PD-L1 expression was high in these tumors, whereas PD-1 expression was minimal or absent, suggesting an immunosuppressive environment. In contrast, TP53-wild-type tumors showed a more balanced immune composition, with higher lymphoid infiltration. These results indicate that TP53 mutation is associated with a myeloid-dominant, lymphoid-poor, and PD-L1-high immune landscape in EC, highlighting potential mechanisms of immune evasion and possible targets for combination immunotherapy.

#7944 Tumor immune micro-environment (TME) dynamics in longitudinal diffuse large B-cell lymphoma (DLBCL) cases from diagnosis to RCHOP relapse.

Raoul Santiago[1], Raquel Aloyz[2], Stephanie Bianco[1], Svetlana Dmitrienko[2], Nathalie Johnson[2], Andreas I. Papadakis[3], Naciba Benlimame[4], Cynthia Guilbert[2], Alan Spatz[5], Francois E. Mercier[2], Madelyne Abraham[2], Laura Hilton[6], David W. Scott[6], Koren K. Mann[7], Sarit Assouline[2]

[1]Research Center, CHU of Quebec, Laval University, Quebec, QC, Canada,[2]Segal Cancer Centre and Lady Davis Institute for Medical Research, Montreal, QC, Canada,[3]Molecular pathology, Lady Davis Institute for Medical Research, Montreal, QC, Canada,[4]The George and Olga Minarik Research Pathology Facility, Lady Davis Institute for Medical Research, Montreal, QC, Canada,[5]Molecular pathology, Lady Davis Institute for Medical Research, Montreal, QC, Canada, Montreal, QC, Canada,[6]Centre for Lymphoid Cancer, BC Cancer, Vancouver, BC, Canada,[7]Department of Pharmacology and Therapeutics, McGill University, Montreal, QC, Canada

DLBCL gene expression signatures from single-nucleus analyses have recently identified new tumor microenvironment (TME) archetypes (LymphoMAPs) linked to RCHOP and CAR-T cell sensitivity. While some archetypes are enriched at diagnosis or relapse, their stability during disease progression remains unclear. We analyzed longitudinal DLBCL cases using LymphoMAP signatures and histologic annotation to assess archetype switching after RCHOP.

Methods: We utilized two independent well-annotated DLBCL cohorts with paired diagnosis/relapse biopsies:23 in-house (46 samples) and 44 published cases (88 samples). Gene expression in our cohort was profiled using the NanoString Cancer Immune Panel on fixed (FFPE) specimens. The external dataset comprised whole-transcriptome from FFPE or fresh-frozen samples pre- and post-RCHOP. LymphoMapR predicted the archetypes from normalized counts: enriched in fibroblast and tumor-associated macrophages (FMAC), naïve and memory T cell (LN), activated macrophages and exhausted T cell (TEX). Samples with classification probability <0.7 were excluded. Additionally, we correlated the archetypes with histologic annotation from our cohort. Immunohistochemistry (IHC) supported T cell markers (CD3, CD4, CD8) and PDL1 expression. Multiplex OPAL imaging quantified macrophage markers (CD68, CD163) with immune checkpoint (CD47), and chemokines (CXCL9 and CXCL10) with receptor (CXCR3).

Results: In the in-house cohort, 8 patients relapsed following only RCHOP, others received ≥1 relapse regimen. One patient per cohort was excluded for low LymphoMAP confidence. Notably, archetype switching occurred in 13 of 22 patients (59%, 95% CI: 36-79%) in-house and 18 of 43 patients (42%, 95% CI: 28-57%) externally. To gain statistical power, the cohorts were combined, yielding an overall switch rate of 48% (95% CI: 36-60%). Switching was less frequent for patients with LN at diagnosis (38%, 95% CI: 23-57%) than FMAC (59%, 95% CI: 36-78%) or TEX (57%, 95% CI: 33-79%), but no consistent direction of switch or correlation with relapse timing was observed. Germinal center B-cell-like (GCB) DLBCLs were predominantly LN archetype (58%), whereas non-GCB encompassed all LymphoMAP archetypes, suggesting an association with cell-of-origin. Histology was consistent with LymphoMAP prediction: T cell abundance (CD3, CD4, CD8) and CXCR3 expression were highest in TEX, followed by LN and FMAC (p<0.05). IHC also demonstrated a significant decrease in CD3 and CD8 T cells at relapse compared with diagnosis.

Conclusions: Based on our observations, the immune environment of DLBCL is dynamic. Although relapse samples exhibited more T cell-depleted environments, changes in TME archetypes frequently occurred, without a dominant pattern. In the context of patient selection for CAR-T cell therapy, relapsed TME should not be inferred from TME at diagnosis.

#7945 Whole-genome doubling induces chromosomal instability to shape the tumor-immune microenvironment and impair the response to immune checkpoint inhibitors in non-small cell lung cancer.
Cheolyong Joe, Jinyong Kim, Hyemin Kim, Junsu Choe, Miran Jang, Eunjoo Oh, Naeun Lee, Subin Kim, Sehhoon Park, Hyun Ae Jung, Jong-Mu Sun, Jin Seok Ahn, Myung-Ju Ahn, Joo Kyung Park, Se-Hoon Lee

Department of Medicine, Sungkyunkwan University School of Medicine, Samsung Medical Center, Seoul, Korea, Republic of

Introduction: Whole genome doubling (WGD), observed in 30-40% of cancers, drives chromosomal instability (CIN), but its role in modulating the immune landscape in NSCLC remains unclear. We investigated how WGD shapes tumor-intrinsic and -extrinsic features to influence immune checkpoint inhibitors (ICI) response.
Methods: We analyzed 520 baseline NSCLC tumor tissues (WES, n=520; WTS, n=500). WGD was defined from WES-derived copy number profiles as >50% of the autosomal genome having a major copy number ≥2. Tumor-infiltrating lymphocytes (TILs) were quantified in a subset (n=304) via AI-powered spatial analysis of whole slide images (WSIs). Statistical comparisons utilized Fisher's exact and Wilcoxon rank-sum tests.
Results: Among 520 tumors, 202 (38.8%) were WGD+ and 318 (61.2%) were WGD-. TP53 mutations were significantly enriched in WGD+ tumors (57.4% vs WGD-: 40.3%, $p=1.51\times10^{-4}$). While the 17p13.1 (TP53) locus was significantly higher in WGD+ cohort (76.7% vs WGD-:39.9%, $p=8.82\times10^{-17}$). Furthermore, this coupling of TP53 mutation and LOH coupling was particularly prominent in WGD+: 90.3% (93/103 pre-WGD mutants) acquired LOH, vs 64.8% (83/128) in WGD- tumors. WGD+ tumors also exhibited a significantly higher burden of HLA Class I LOH burden (≥2 loci in 16.1% vs 6.3%, $p=8.42\times10^{-4}$). WGD+ tumors also showed significantly lower T cell infiltration. Using ploidy-corrected T cell fractions (n=520), the median T cell fraction was significantly lower in the WGD+ group than in the WGD- group (0.138 vs 0.184, $p=4.28\times10^{-4}$). Gene set enrichment analysis (GSEA) showed WGD+ tumors enriched metabolic/proliferative programs. In contrast, WGD- tumors upregulated immune-activation pathways. This "immune-cold" profile in WGD+ tumors was confirmed by significantly lower immune scores; median cytolytic activity score was 2.53 vs. 3.08 ($p=5.34\times10^{-5}$) and median TLS score was 5.40 vs. 6.51 ($p=1.05\times10^{-12}$). Spatially, AI-powered WSI analysis corroborated this, linking WGD+ tumors to fewer inflamed and more immune-desert phenotypes ($p=2.74\times10^{-3}$). Clinically, WGD status was significantly associated with inferior outcomes. Compared to non-WGD patients, WGD patients demonstrated worse overall survival (HR 1.284, 95% CI 1.050-1.569, $p=1.47\times10^{-2}$) and progression-free survival (HR 1.286, 95% CI 1.057-1.563, $p=1.18\times10^{-2}$).
Conclusion: In NSCLC, WGD promotes high genomic instability through TP53 mutation and critical HLA Class I LOH, enabling immune escape. This genomic landscape shapes an immunosuppressive ecosystem characterized by metabolic reprogramming, lower T cell infiltration, and immune-desert phenotypes. As a result, WGD defines an immune-refractory microenvironment and serves as a robust predictive biomarker for unfavorable ICI response.

#7946 Identification of a highly selective ITK inhibitor which promotes Th1 differentiation and alleviates T cell exhaustion *in vitro* and *in vivo*.

Lei Jiang, Zhiyong Yu, Xin Cheng, Baoying Cheng, Yuyao Zhang, Wenwen Zhao, Youxi Chen, **Feng Zhou**

Atheron Therapeutics, Ltd., Shanghai, China

ITK is a member of the TEC family of kinases, expressed in T, NK, and mast cells. ITK plays important roles in TCR signaling and T cell differentiation. Following TCR stimulation, ITK is recruited to the cell membrane and then leads to phosphorylation and activation of PLCγ1. ITK knockout mice show defects in Th2 differentiation, while retaining the ability to differentiate into Th1 cells, a phenomenon known as Th1 skewing. It is generally accepted that Th1 cells are the primary Th cell subtype associated with tumor elimination. ITK and RLK double knockout in T cells has a more substantial signaling defect, resulting in a profound loss of normal T cell function. Thus, it holds great therapeutic promise to treat cancer with selective ITK inhibitors while sparing RLK.Here, we report that ATH-409 is a highly selective, covalent ITK inhibitor with an IC50 of < 5 nM and more than 300-fold selectivity against RLK and at least 100-fold selectivity against the remaining 10 cysteine-containing kinases. In the kinase panel assay involving 430 kinases, ATH-409 exhibits inhibitory activity against less than 5 of these kinases, with an IC_{50} selectivity of at least 60-fold for all of the non-target kinases. ATH-409 potently suppresses ITK-mediated phosphorylation of PLCγ1 and TCR activation-induced IL2 release in PBMCs. At high concentrations, ATH-409 exerts an anti-proliferation effect on human primary T cells, while showing no impact on T cell viability. Under both polarizing and non-polarizing conditions, ATH-409 does not affect the production of Th1 cytokines, but decreases the release of Th2 cytokines. Additionally, ATH-409 attenuates the occurrence of T cell exhaustion. ATH-409 alone does not suppress the proliferation of CT26 cells *in vitro*, but does inhibit CT26 tumor growth *in vivo*, indicating that the anti-tumor effect of ATH-409 is achieved through regulating the immune system. In *in vivo* model, the ITK occupancy increases with the elevation of ATH-409. Furthermore, when ATH-409 is combined with PD-1 antibody and CTLA-4 antibody, the inhibitory effect on CT26 tumors is further enhanced. Analysis of tumor-infiltrating lymphocytes (TILs) reveals that under the combination treatment, the proportion of Th1 cells in tumors increases and T cell exhaustion is alleviated, which is consistent with the phenomena observed in *in vitro* experiments.

#7947 miR-150 orchestrates immune activation and lymphocyte trafficking in breast cancer.

Masanori Oshi[1], Rongrong Wu[2], Colin J. Rog[3], Li Yan[3], Takashi Ishikawa[4], Itaru Endo[5], Kazuaki Takabe[1]

[1]Roswell Park Comprehensive Cancer Center, Buffalo, NY,[2]Tokyo medical hospital, Tokyo, Japan,[3]Roswell Park Comprehensives Cancer Center, Buffalo, NY,[4]Breast Surgery, Tokyo Medical University, Tokyo, Japan,[5]Yokohama City University Hospital, Yokohama, Japan

Background: Tumor-infiltrating lymphocytes (TILs) are known to relate with response to treatments followed by better survival; however, majority of breast cancer (BC) hardly have any TILs. Thus, discovery of targetable novel mechanism of TIL infiltration is expected to have a major clinical implication. MiR-150 has been reported to promote cell proliferation and migration, but its role in TIL infiltration is not known. The aim of this study is to investigate the role and clinical relevance of tumor miR-150 expression and attraction of TILs in BC patients.
Methods: In silico analyses was conducted on total of 1,961 breast cancer patients from large independent cohorts, The Cancer Genome Atlas (TCGA) and the Molecular Taxonomy of Breast Cancer International Consortium (METABRIC). In Vitro experiments using MDA-MB231 and BT-549 BC cell lines and Jurkart lymphocyte cell line, were repeated three times to ensure rigor and reproducibility.
Results: As expected, miR-150 expression correlated with Nottingham grade and was higher in triple negative subtype in both cohorts (all $p<0.001$). On the other hand, miR-150 expression not only enriched MTORC1 and KRAS signaling, but also multiple immune-related Hallmark gene sets including IFN-Y, TNF-α, IL-2, IL-6, IFN-α, allograft rejection, and inflammatory response by gene set variant analysis (all Spearman's coefficient $r>0.50$ and $p<0.01$). High miR-150 expression significantly correlated with lymphocyte infiltration and TCR-Shannon in TCGA cohort. High miR-150 expression was associated with high infiltration of CD8+, CD4+ memory T cells and dendritic cells, and was strongly correlated with cytolytic activity consistently in both cohorts ($r=0.824$ and 0.786, both $p<0.01$), all suggesting strong relationship with immune cell infiltration and immune response. In agreement, high MiR-150 expression was associated with improved overall survival ($p<0.001$, $p=0.030$), particularly in ER-positive/HER2-negative patients. Surprisingly, mimic overexpression of miR-150 did not promote cell proliferation, migration nor invasion neither in MDA-MB231 or BT-549 BC cell lines. However, mimic overexpression of miR-150 in either MB231 or BT-549 cells significantly increased the migration intensity of Jurkart cells demonstrated by Transwell invasion assay. Further, mimic overexpression of miR-150 in MDA-MB231 cells enriched cell proliferation-related gene sets; E2F Targets, G2M checkpoint, as well as multiple immune-related gene sets including IFN-Y, TNF-α, IL-2, IL-6, allograft rejection and inflammatory response.
Conclusions: MiR-150 expression in patients' breast cancer evoke immune response, attracts lymphocytes to tumor microenvironment and is associated with overall survival.

#7948 Targeting the UFMylation pathway to promote immunotherapy response of breast cancers.

Ciara J. Miller[1], Jackson P. Riffee[1], Danielle R. Cook[2], **Timothy D. Martin**[1]

[1]Pharmacology, University of Virginia, Charlottesville, VA,[2]Hematology & Oncology, University of Virginia, Charlottesville, VA

The immune system puts immense selective pressure on tumors to evolve mechanisms to avoid immune mediated cell death during tumorigenesis. Ultimately, these evolved tumor cells fuel the aberrant growth that leads to metastasis and patient mortality. Immunotherapies have been breakthrough treatments for certain tumor types highlighting just how life-changing reinvigorating the immune system can be in the battle against cancer. Unfortunately, current immunotherapies do not work for all patients and tumor types so we must identify new strategies that can turn non-responding patients into potent responders. To identify candidate drug targets whose inhibition can increase anti-tumor immunity (ATI), we utilized in vivo CRISPR screens in syngeneic mouse breast (BC) cancer models. The results from these screens revealed that inhibition of protein UFMylation, a ubiquitin-like post-translational modification pathway that is most known for its role in promoting protein translational fidelity, results in tumor cell death only in the presence of a fully functioning immune system. We have identified that loss of UFMylation can alter inflammatory gene expression to remodel the tumor microenvironment, promote antigen processing and presentation through the regulation of MHC class I protein levels, and render tumor cells more sensitive to killing by T cells. Using orthotopic in vivo tumor models that fail to respond to immunotherapies, we demonstrate that combining UFMylation inhibition with immune checkpoint blockade leads to potent ATI and a reduction in tumor growth. These data identify protein UFMylation as a drug target whose inhibition generates an anti-tumor immune response in tumors that fail to respond to immunotherapies.

#7949 Pharmacologic wtIDH1 inhibition remodels the PDAC immune landscape and improves checkpoint blockade efficacy.

Priyashree Sunita[1], Shakti Pattanayak[1], Mehdad Zarei[1], Omid Hajihassani, Goutam dey, Hallie Graor, Sami Abul-Khoudoud, Faith Nakazzi, Jordan M Winter[2]

Introduction: Pancreatic ductal adenocarcinoma (PDAC) remains one of the most lethal human malignancies, with a five-year survival rate under 3%. Its aggressive biology, early metastasis, and profound resistance to therapy are driven in part by a dense, immunosuppressive tumor microenvironment (TME). Although metabolic inhibitors have shown promise in selecting molecular subtypes, the therapeutic potential of targeting metabolic vulnerabilities in wild-type tumors is less explored. Our earlier work identified that AG-120 (Ivosidenib), an FDA-approved inhibitor of mutant IDH1, also inhibits wild-type IDH1 (wtIDH1) under nutrient-restricted conditions typical of PDAC. Here, we investigate how wtIDH1 inhibition simultaneously disrupts tumor metabolism and reshapes the immune microenvironment.
Methods: Miapaca-2, Panc-1, and KPC cells were cultured in low-glucose (2.5 mM) and low-magnesium (0.08 mM) media to simulate PDAC metabolic stress. Cell viability was measured using Titer-Glo, PicoGreen, and colony-formation assays. Cytoplasmic reactive oxygen species and mitochondrial ROS were quantified via DCFDA and MitoSOX using fluorescence and flow cytometry. Proliferation and cell-cycle regulation were evaluated by CellTrace and BrdU incorporation. Orthotopic and syngeneic mouse models were used to assess therapeutic efficacy, immune-cell infiltration, and synergy with anti-PD-1 therapy.
Results: wtIDH1 inhibition significantly reduced cell proliferation, impaired DNA synthesis, and elevated mitochondrial and cytosolic ROS, leading to apoptosis. In vivo, Ivosidenib increased infiltration of $CD45^+$ immune cells, including $CD4^+$ and CD8+ central-memory T cells, and enhanced M1-like macrophage populations with reduced PD-L1 expression. Treatment group decreased M2-like monocytes and shifting the TME toward an inflammatory, anti-tumor state. Combination therapy with anti-PD-1 improved survival and conferred protection upon tumor rechallenge through robust central- and effector-memory T-cell expansion.
Conclusion: wtIDH1 inhibition offers a dual benefit in PDAC by impairing tumor metabolism and promoting immune activation. This metabolic-immune reprogramming provides a strong rationale for combining wtIDH1 inhibitors with existing immunotherapies.

#7950 Targeting the OSM-OSMR signaling axis to reprogram the tumor microenvironment and overcome immune suppression in pancreatic cancer.

Yuan Sui, Tony Hunter

Salk Institute, La Jolla, CA

Pancreatic ductal adenocarcinoma (PDA) is one of the deadliest malignancies, characterized by a dense, fibrotic, and immune-excluded tumor microenvironment (TME) that resists current therapies. Emerging evidence implicates the Oncostatin M (OSM)-Oncostatin M receptor (OSMR) signaling axis, a member of the IL-6 cytokine family, as a key driver of PDA progression through regulation of tumor-stroma-immune interactions. My research aims to define how OSM-OSMR signaling orchestrates the immune-suppressive microenvironment in PDA and to evaluate whether its inhibition can reprogram tumors toward immune responsiveness.Spatial transcriptomics analysis of treatment-naïve human PDA revealed high OSMR expression associated with cancer-associated fibroblast (CAF) activation, stromal stiffness, and enrichment of macrophage and monocyte gene signatures, alongside reduced $CD8^+$ T-cell infiltration. Integrated transcriptomic analyses identified OSMR-associated genes enriched for NF-κB, JAK-STAT, and IFN-γ pathways. Functional studies showed that OSM-OSMR signaling promotes PDA cell proliferation, migration, and invasion, while driving CAF activation and polarization of monocytes toward immunosuppressive $CD163^+/CD206^+$ macrophages. In *ex vivo* human PDA slice cultures, recombinant OSM enhanced proliferation and STAT3 phosphorylation, effects reversed by OSM or OSMR neutralizing antibodies.To dissect the underlying mechanisms, I employed CRISPR-engineered OSMR knockout and rescue PDA cell lines, OSMR-overexpressing CAFs, and 3D co-cultures with monocyte-derived macrophages, integrated with single-cell RNA-seq, phospho-proteomics, and spatial transcriptomics. Parallel translational studies will test OSM/OSMR-neutralizing antibodies in patient-derived organoids, tumor slice cultures, and genetically engineered mouse models (GEMMs), alone or in combination with FDA-approved chemotherapies. These studies will assess the effects of OSM-OSMR signaling on tumor growth, stromal remodeling, immune infiltration, and metastasis.By defining how OSM-OSMR signaling sustains PDA's fibrotic and immune-suppressive TME and establishing its therapeutic vulnerability, this work aims to develop rational strategies that reprogram the TME, enhance immunotherapy responsiveness, and improve outcomes for patients with pancreatic cancer.

#7951 Ovarian tumor FAK inhibition releases omega-3 fatty acids stimulating GATA6 peritoneal macrophage CXCL13 production augmenting TIGIT immunotherapy.

High grade serous ovarian cancer (HGSOC) is a lethal gynecologic malignancy due to accumulated therapy resistance. Focal adhesion kinase (FAK) expression is elevated in HGSOC, and inhibition of FAK activity (FAKi) in syngeneic ovarian tumors reduced tumor burden with elevated CXCL13 chemokine expression by peritoneal macrophages. Combining FAKi with pegylated doxorubicin chemotherapy and anti-TIGIT immune checkpoint antibody repressed tumors and extended survival with tertiary lymphoid structure formation. Peritoneal macrophage GATA6 inactivation reduced CXCL13 expression *in vivo*, enhanced FAK knockout (KO) tumor growth, and limited ascites B cell infiltration. FAKi-treated or FAK-KO conditioned media contained exosomes enriched with omega-3 fatty acids that stimulated macrophage CXCL13 production. As isolated by paracentesis, FAKi-treated HGSOC tumor cells or purified macrophages treated with eicosapentaenoic acid triggered anti-tumor macrophage reprogramming and CXCL13 expression. Together, our studies define a tumor lipid to macrophage signaling linkage upon FAK inhibition supporting B cell recruitment, survival, and anti-TIGIT immunotherapy enhancement.

#7952 Integrated tissue and secretome profiling identifies an IL-6/IL-8-dominant immune phenotype in peritoneal carcinomatosis.

Background: Peritoneal carcinomatosis (PC) is a late manifestation of abdominopelvic malignancies, often resistant to current treatments due to an incomplete understanding of its biological drivers within the peritoneal immune microenvironment. This study aimed to identify actionable therapeutic targets for PC by analyzing peritoneal soluble mediators and cellular composition in patients. Building on existing evidence implicating IL-8 as a critical mediator of tumor-associated inflammation and immunosuppression in other cancers and preliminary data in PC, the study also evaluated IL-8 pathway inhibition in a preclinical model.
Methods: Peritoneal tissue and fluid were collected from three patient groups: patients without benign conditions (n=15), cancer without PC (n=30), and confirmed PC (n=41). Immunohistochemistry was used to quantify immune cells in tissue and Luminex panels to analyze immune, inflammatory, and growth factors in peritoneal fluid. Statistical analyses identified group differences, correlations with disease burden (Peritoneal Cancer Index - PCI), and overall survival (OS). To assess therapeutic tractability of IL-8 axis blockade, a bioluminescent CT26-luc murine PC model was treated daily with the CXCR2 antagonist AZD5069 (100 mg/kg) or saline from day 0-9, with serial IVIS imaging, body-weight monitoring, and survival tracking through day 11.
Results: PC tissue exhibited increased immune cell infiltration compared to non-PC groups, including elevated mast cells, neutrophils, $CD4^+$ T cells, $CD14^+$ monocytes, $CD20^+$ B cells, and $CD138^+$ plasma cells. Secretomic analysis of peritoneal fluid in PC revealed a dominant IL-6/IL-8-centered inflammatory signature, with increased GRO, IL-6, IL-8, CXCL10, IL-10, and TGF-β. This pattern supports pro-angiogenic, immunosuppressive, and stromal-activation signaling. Densities of $CD4^+$, $CD14^+$, $CD20^+$, and $CD138^+$ cells positively correlated with PCI, indicating progressive immune-stromal co-evolution with tumor burden. In human samples, neutrophil infiltration correlated with worse OS, while $CD1a^+$ dendritic cell enrichment correlated with improved OS, underscoring the clinical relevance of the immunologic findings. In the murine model, AZD5069 demonstrated a therapeutic effect in 4 of 10 treated mice, suggesting potential efficacy of IL-8-axis targeting in specific patient subsets.
Conclusion: PC is characterized by distinct immune cell infiltration and a significant IL-6/IL-8 cytokine network. Both neutrophil infiltration and the IL-6/IL-8 axis are associated with disease burden and patient survival, highlighting the IL-6/IL-8 axis as a relevant therapeutic target. Preclinical evidence supports its potential in specific patient groups. Further research is needed to identify predictive biomarkers for treatment response and translate these findings into clinical strategies.

#7953 Engineered IL7/IL15 secreting iPSC-derived mesenchymal stromal cells convert the immunosuppressive into immune-activated tumor microenvironments (TME) and potentiate antitumor immunity.

Michael Andreeff[1], Sandeep Singh[1], Andrea Bedoy[1], Muharrem Muftuoglu[1], Li Li[1], Vivek Anand[1], Dipmoy Nath[2], Lauren Ostermann[1], Ivo Vletic[1], Christopher D. Pacheco[1], Mahesh Basyal[1], Taeyun Kim[3], Kyle M. Garland[3], Matthew Angel[2], Sanjeev Luther[2], Robert Pierce[2], Christopher B. Rohde[3]

Mesenchymal stromal cells (MSCs) derived from bone marrow (BM-MSCs) exhibit inherent tumor-tropic behavior (Andreeff M., Cancer Res. 2002, JNCI 2004). However, their finite proliferative lifespan, donor-to-donor variability, and senescence-associated transcriptional drift present barriers to clinical scalability. To address these limitations, we reprogrammed adult dermal fibroblasts into induced pluripotent stem cells (iPSCs) using a synthetic, non-integrating mRNA transfection system. These iPSCs were stably modified to express interleukin-7 and interleukin-15, prior to mesodermal lineage specification into MSCs (hereafter referred to as IL7-IL15-iMSCs). Flow cytometry and transcriptomic profiling confirmed expression of canonical MSC markers (CD73⁺CD90⁺CD105⁺), absence of hematopoietic or endothelial lineage antigens and trilineage differentiation potential. IL7-IL15-iMSCs secreted supraphysiologic levels of cytokines, converting immune-suppressive MSCs into immune-activating MSCs. In vitro, IL7-IL15-iMSCs induced potent T cell proliferation sustaining the long-term expansion of T cells, macrophages and CAR T cells in vitro, and induced tumor cell death in a triple co-culture system comprising IL7-IL15-iMSCs, the ovarian cancer cell line ID8, and human PBMCs. In a syngeneic mouse model of ovarian cancer (ID8 and platinum-resistant ID8 cells in C57BL/6 mice), intraperitoneal administration of IL7-IL15-MSCs resulted in reduced tumor burden and extended survival. Immunohistochemical and CyTOF analyses revealed massive infiltration of activated T cells, macrophages, and other immune cells into the tumor microenvironment (TME) as well as enrichment in tumoricidal M1-type macrophages, with no detection of exhausted or regulatory T cells, in contrast to controls. To mitigate pulmonary first-pass entrapment associated with systemic, intra-venous (IV) MSC delivery, we optimized a fractionated low-dose IV administration regimen in the orthotopic 4T1 triple-negative breast cancer model. Six weeks post IL7-IL15-iMSC IV administration, tissue IHC staining showed robust iMSC localization to the TME, infiltration of immune cells and tumor reduction as observed in ovarian cancer.

Conclusion: These data establish IL7-IL15-iMSCs as a novel, immunologically active stromal cell platform capable of remodeling the TME and amplifying both innate and adaptive anti-tumor responses. IL7-IL15 iMSC convert an immune-suppressed into an immune-activated TME in diverse tumor types. The scalability of iPSC-derived MSCs, combined with synthetic mRNA reprogramming and stable cytokine expression, supports the suitability of this platform for clinical translation. A first clinical trial in ovarian cancer is under development.
