Glioblastoma (GBM) is the most prevalent and lethal primary brain tumor, characterized by rapid progression, high recurrence rates, and a median survival of less than 15 months despite current therapeutic interventions. Standard treatments such as surgical resection, radiotherapy, and temozolomide (TMZ) chemotherapy offer limited benefit due to the infiltrative nature of the tumor and the blood-brain barrier. Moreover, GBM frequently develops resistance to TMZ through O6-methylguanine-DNA methyltransferase (MGMT)-mediated repair of chemotherapy-induced DNA damage, significantly reducing treatment effectiveness. During treatment, GBM cells and the surrounding tumor microenvironment (TME) undergo significant physiological stress, including hypoxia, inflammation, and DNA damage. These stressors induce the release of damage-associated molecular patterns (DAMPs), among which High Mobility Group Box 1 (HMGB1) plays a pivotal role. HMGB1 is a multifunctional nuclear protein that, depending on its redox state and subcellular localization, can regulate tumor proliferation, invasion, angiogenesis, and immune modulation. Accumulating evidence suggests that extracellular HMGB1 contributes to tumor progression and therapeutic resistance through complex interactions with immune and stromal components of the TME. In our present study, we aim to validate the protumorigenic functions of HMGB1 using integrated bioinformatic approaches and in vitro analyses to substantiate its relevance in GBM pathology and therapy resistance. Specifically, we explored the correlation between HMGB1 expression and TMZ resistance, examining its association with MGMT expression and the activation of downstream signaling pathways, such as MEK1/2-ERK1/2. By elucidating these molecular interactions, we aim to clarify the mechanisms through which HMGB1 promotes therapy resistance. Additionally, we performed in-silico screening to identify HMGB1-targeting inhibitory compounds with the potential to concurrently suppress MGMT expression and other crucial components involved in TMZ resistance. Collectively, our findings aim to reinforce the significance of HMGB1 as a prognostic biomarker and therapeutic target, offering new opportunities for more effective and personalized treatment strategies for GBM patients.

#3185 SCR-A019, a first-in-class biparatopic ADC targeting MSLN, with a novel topoisomerase I inhibitor demonstrates encouraging efficacy in preclinical models.

Qiong Wang, Yayuan Fu, Qi Deng, Chunlei Xia, Hui Zheng, Youfu Chu, Renhong Tang

Simcere Zaiming, State Key Laboratory of Neurology and Oncology Drug Development. Simcere Pharmaceutical Group, Shanghai, China

Background: Mesothelin (MSLN) is a GPI-anchored glycoprotein that is expressed on many cancers but limited in normal tissues, which makes it an attractive target for antibody-based cancer therapy. However, MSLN is shed from surface of cells at high levels via proteases that cleave at its membrane-proximal C-terminal region. Shed MSLN accumulates in patient fluids and tumors and can block anti-MSLN antibodies from killing cancer cells. To overcome the challenge of MSLN shedding, we developed a novel biparatopic ADC which prefers binding to membrane MSLN rather than soluble MSLN.
Method & Results: The biparatopic ADC SCR-A019 is conjugated with novel topoisomerase 1 inhibitor (CPT116) via a hydrophilic cleavable linker at DAR 6. SCR-A019 specifically recognizes human MSLN with high affinity and showed enhanced internalization and binding capacity compared to parental monoclonal antibody ADC and benchmark ADC in multiple tumor cell lines. In vitro cytotoxicity experiment demonstrated that SCR-A019 induced tumor cell lysis. Compared to benchmark ADC, SCR-A019 drived potent cytotoxicity in the presence of soluble MSLN. In vivo, SCR-A019 showed specific, dose-dependent anti-tumor efficacy toward MSLN positive tumor xenografts including lung and ovary cancer cells. Besides, SCR-A019 exhibited stronger anti-tumor activity than their parental monoclonal-ADC or benchmark ADC. SCR-A019 also have very good stability and favorable developability.
Conclusion: These preclinical data demonstrated SCR-A019 could be a potential first-in-class biparatopic BsADC to overcome the obstacles in antibody-based MSLN-targeting cancer therapy.

#3186 MDM2 Knockdown Enhances Phosphorylation of MCM2 during Cell Cycle Progression.

Nikita Meghani[1], Viola Ellison[2], Jill Bargonetti[1]

[1]Departments of Biology and Biochemistry, The Graduate Center, City University of New York, New York, NY,[2]The Department of Biological Sciences, Hunter College, City University of New York, New York, NY

MDM2 is an oncogenic E3 ubiquitin ligase that forms heterodimers with the homolog MDMX (also known as MDM4) and is classically known for targeting wild-type p53 for proteasomal degradation. However, in breast cancer harboring mutant p53, MDM2 and MDMX have oncogenic roles independent of p53. The MDM2-MDMX complex interacts with mutant p53 without actively degrading it. In breast cancer models that co-express high levels of mutant p53, MDM2, and MDMX, we identified a tripartite complex that regulates DNA repair protein recruitment of 53BP2 and MDC1. Additionally, mutant p53 colocalizes with replication-associated Mini Chromosome Maintenance2-7 (MCM2-7) helicase and Poly (ADP-ribose) polymerase 1(PARP1), forming what we refer to as the mutant p53-PARP-MCM axis. We are using isogenic estrogen receptor-positive T47D cells expressing missense mutant p53 L194F either with and without MDM2 or MDMX knockdown to dissect if the helicase component MCM2 is regulated by these protein scaffolds. We employed western blotting, immunofluorescence, and proximity ligation assays (PLA) to assess their influences on of MDM family member protein expression on MCM2 phenotype. Preliminary result showed that MDM2 knockdown correlated with increased phosphorylation of MCM2 at serine 108, a marker of replication stress, indicating that the presence of MDM2 mitigates replication stress. Using Proximity Ligation Assay, we observed that MDM2 and MCM2 were in close nuclear proximity. However, co-immunoprecipitation did not detect a direct MDM2-MCM2 protein-protein interaction. Future experiments will address whether the directional interaction between MDM2 and mutant p53 facilitates the role of MDM2 in mitigating replication stress signaling. These evaluations may allow for the mutant p53 and MDM2 overexpression biomarkers to serve as a targetable scaffolding hub for drug targeting.

#3187 A patient-derived organoid screening platform for evaluating KRAS inhibitor efficacy.

Merel Derksen, Yasmine Abouleila, Mariana Martins Costa Silva, Gerben ten Hag, Rene Overmeer, Farzin Pourfarzad, Fabian Stavenuiter, Robert G. J. Vries, Sylvia F. Boj

HUB Organoids B.V., Utrecht, Netherlands

The Kirsten rat sarcoma (KRAS) gene is a proto-oncogene frequently mutated in colorectal cancer (CRC), pancreatic ductal adenocarcinoma (PDAC), and non-small cell lung cancer (NSCLC), and is often associated with poor clinical outcomes. KRAS has long been considered an elusive and historically “undruggable” target in cancer therapy. However, recent breakthroughs, including the clinical approval of KRAS^G12C inhibitors such as Sotorasib and Adagrasib, have paved the way for novel compounds targeting KRAS^G12C and other KRAS mutations. The development of KRAS inhibitors can be accelerated and de-risked by using patient-relevant preclinical models that enable efficacy screening and safety assessment. Patient-derived organoids (PDOs), or HUB Organoids®, are advanced 3D models derived from adult stem cells of normal and malignant epithelial tissues, including colon, pancreas, and lung. They recapitulate the molecular heterogeneity, morphology, and functionality of the original tissue, accurately reflecting patient-specific responses HUB Organoids support high-throughput screening, providing a powerful, scalable platform for testing drug efficacy, safety, and resistance mechanisms. Their characterized genomic and transcriptomic profiles allow drug responses to be linked to molecular features, enabling patient stratification. In this study We demonstrate the suitability of our PDO-based platform for KRAS inhibitor screening within six weeks. Eight KRAS inhibitors at various clinical development stages were tested on a panel of over 20 PDOs (CRC, PDAC, and NSCLC) harbouring KRAS mutations (G12C, G12D, Q61R, G13C, G12V, and G12S) using an ATP-based viability assay. Responses varied across PDOs. Notably, G12C and G12D mutants showed selective sensitivity to KRAS^G12C and KRAS^G12D inhibitors, respectively. Resistance to these inhibitors was mitigated by combining them with an EGFR inhibitor, consistent with EGF-driven resistance mechanisms. Additionally, KRAS PDO screening enables assessment of drug synergy and safety in normal tissue-derived PDOs. In conclusion, HUB’s KRAS PDO screening platform offers a time-efficient, mutation-specific approach for evaluating compound specificity, potency, and combination strategies for KRAS-targeted therapies.

: Epigenetic Changes as Molecular Markers of Cancer
Poster Session

#3191 Loss of SMYD5 downregulates proliferative signaling pathways in B cell acute lymphoblasticleukemia.

Brunna Leticia Oliveira Santana[1], Mariana Braccialli de Loyola[1], Brenno Vinicius Martins Henrique[2], Ana Cristina Moura Gualberto[1], **Fabio Pittella-Silva**[1]

[1]Laboratory of Molecular Pathology of Cancer, Faculty of Health Sciences, University of Brasilia, Brasilia, Brazil,[2]Brasilia Children?s Hospital, Brasilia, Brazil

Acute lymphoblastic leukemia (ALL) is characterized by the uncontrolled proliferation of immature lymphoblasts, leading to impaired normal hematopoiesis and potential infiltration of extramedullary tissues. B-cell acute lymphoblastic leukemia (B-ALL) predominantly affects children aged 1 to 4 years, with a progressive decline in incidence in older age groups. Histone methyltransferases (HMTs) act as key epigenetic regulators, and their dysregulation has been associated with tumor initiation and progression. The *SMYD5* gene, a member of the HMT family, is found to be overexpressed in ALL patients and has been linked to hematopoietic, inflammatory processes, genomic stability and regulation of protein synthesis. However, its specific role in ALL remains poorly understood. Therefore, investigating the function of *SMYD5* in this context may provide insights that contribute to the development of more effective diagnostic and therapeutic strategies. We performed a combination of *in silico* and *in vitro* analyses. *In silico* analyses using public databases were conducted to evaluate *SMYD5* mRNA expression in B-cell acute lymphoblastic leukemia (B-ALL). Subsequently, *in vitro* experiments were performed using a CRISPR-Cas9-mediated knockout (KO) approach in the REH leukemic cell line. Following confirmation of SMYD5 loss at the protein level, transcriptomic profiling was carried out to identify differentially expressed genes and to investigate their involvement in relevant biological pathways. *In silico* analysis revealed that *SMYD5* mRNA expression was significantly higher in B-ALL samples compared with healthy bone marrow samples ($p = 0.0022$). In the in *vitro analysis*, *SMYD5* mRNA expression was compared across B-ALL cell lines, and the REH cell line was selected because it displayed the highest expression level. Subsequently, gene knockout (KO) was performed, resulting in the generation of two clones with reduced SMYD5 protein levels. RNA sequencing revealed substantial transcriptional changes in the KO clones compared with the wild-type cell line. GSEA analysis revealed positive enrichment in clones C52 and C78 for the E2F Targets (NES = 3.08, FDR < 0.001; NES = 2.93, FDR < 0.001), Myc Targets V1 (NES = 2.88, FDR < 0.001; NES = 2.86, FDR < 0.001), and Myc Targets V2 (NES = 2.31, FDR < 0.001; NES = 2.33, FDR < 0.001). The reduction of *SMYD5* in knockout clones was associated with downregulation of key proliferative pathways, suggesting its involvement in maintaining proliferative capacity and leukemogenesis. Literature evidence indicates that the E2F and Myc Targets (V1 and V2) pathways regulate pro-proliferative transcriptional programs in B-ALL. Accordingly, our findings suggest that SMYD5 loss dampens these transcriptional programs, potentially reducing the proliferative rate of leukemic cells and highlighting this gene as a potential therapeutic target.

#3192 Genome-wide DNA methylation profiling reveals distinct epigenetic landscapes and novel biomarkers in estrogen receptor-positive and -negative breast cancers.

Dalma Muller, **Balazs Gyorffy**

Semmelweis University, Budapest, Hungary

BACKGROUND: Breast cancer is a molecularly heterogeneous disease driven partly by subtype-specific DNA methylation patterns with diagnostic and prognostic potential. We aimed to construct a comprehensive methylation dataset to identify novel differentially methylated regions, define the global methylation patterns distinguishing breast carcinomas from normal tissue, and characterize differences between estrogen receptor (ER)-positive and ER-negative tumors.
METHODS: We curated a large-scale methylation dataset by processing raw data from HumanMethylation450 and EPIC array platforms (GEO accessions GPL13534, GPL21145) from GEO and GDC. The cohort included solid tissue samples from untreated breast cancer patients and healthy cases. Data preprocessing, BMIQ normalization, and quality control were performed using minfi and wateRmelon in R. Probes were annotated into functional gene regions (TSS1500, TSS200, 5'UTR, first exon, gene body and 3'UTR). Differential methylation analysis ($\Delta\beta > 0.2$) between normal, ER+, and ER- groups was conducted using Kruskal-Wallis and Mann-Whitney tests with Bonferroni correction. Biomarker potential was evaluated using receiver operating characteristic (ROC) analysis with 5-fold cross-validation (cvAUC). Gene Ontology (GO) enrichment was performed with clusterProfiler.
RESULTS: Based on HM450K and EPIC arrays, tumors exhibited significant, location-specific methylation shifts versus normal tissue, with distinct ER-positive and ER-negative patterns. ER-positive tumors showed pervasive promoter hypermethylation (455 hyper-, and 43 hypomethylated gene regions; $\Delta\beta>0.2$, $p<0.05$), enriched for pattern specification (HM450K: 4.7 fold enrichment (FE), $p<0.001$; EPIC: 9.3 FE, $p<0.05$) and appetite regulation (HM450K: 17.2, $p<0.001$; EPIC: 34.3 FE, $p<0.001$). ER-negative tumors (354 hyper-, and 23 hypomethylated gene regions shared by platforms with $\Delta\beta>0.2$, $p<0.05$), and were enriched for homophilic cell adhesion (EPIC: 16.2 FE, $p<0.001$) and olfactory receptor genes (EPIC: FE 12.2, $p>0.001$). Both platforms consistently identified high-confidence, differentially methylated regions, such as hypermethylation in the NEURL2 gene body in ER-positive (cvAUC: 0.99 HM450K, 0.99 EPIC; $\Delta\beta$ HM450K: 0.43, EPIC: 0.3) and the NKAPL 5'UTR in ER-negative tumors (cvAUC: 0.99 HM450K, 0.99 EPIC; $\Delta\beta$ HM450K: 0.47, EPIC: 0.44).
CONCLUSIONS: This study mapped the methylomes of ER+ and ER- breast cancers, identifying subtype-specific patterns of epigenetic dysregulation. The dataset and interactive visualization tools are available at epigenplot.com.

#3193 Secreted BRAF V600E drives ADAR1-dependent RNA editing and defines a therapeutic vulnerability in colorectal cancer.

Toshiaki Takahashi[1], Kunitoshi Shigeyasu[2], Kazuya Moriwake[2], Masashi Kayano[2], Hibiki Umeda[2], Kazuhiro Yoshida[2], Sho Takeda[2], Yuki Matsumi[2], Hiroyuki Kishimoto[2], Tomokazu Fuji[2], Kazuya Yasui[2], Hideki Yamamoto[3], Kosei Takagi[2], Hiroyuki Michiue[4], Yoshiko Mori[5], Fuminori Teraishi[2], Hiroshi Tazawa[2], Yuzo Umeda[6], Ajay Goel[1], Toshiyoshi Fujiwara[2]

[1]Beckman Research Institute of The City of Hope, Duarte, CA,[2]Department of Gastroenterological Surgery, Okayama University, Okayama, Japan,[3]Department of Clinical Genomic Medicine, Okayama University, Okayama, Japan,[4]Neutron Therapy Research Center, Okayama University, Okayama, Japan,[5]Department of Clinical Genetics, Saitama Medical University, Saitama, Japan,[6]Department of Hepatobiliary Pancreatic and Transplantation Surgery, Ehime University, Ehime, Japan

Background & Aims:The BRAF V600E mutation occurs in approximately 8-12% of colorectal cancers (CRC) and confers poor prognosis and therapeutic resistance. Despite the clinical success of combined BRAF and EGFR inhibition in the BEACON trial, resistance rapidly develops. Adenosine-to-inosine RNA editing, which is a post-transcriptional modification driven by adenosine deaminase acting on RNA (ADAR), promotes tumor malignancy and the acquisition of metastatic potential. We previously reported that ADAR1-high macrophages act as mediators of drug resistance and proposed ADAR1-targeted therapy as a potential new approach (Molecular Cancer, 2025). However, the specific patient population likely to benefit from ADAR1-targeted therapy remains unclear. This study investigated whether secreted BRAF V600E protein induces ADAR1-dependent RNA editing to promote tumor progression and therapeutic resistance, and whether JAK inhibition can enhance the efficacy of BRAF/EGFR-targeted therapy.
Methods:We combined analysis of clinical CRC tissues, spatial transcriptomics, and RNA sequencing with functional in vitro and in vivo models to characterize BRAF V600E secretion, intracellular distribution, and downstream molecular effects. Pharmacologic inhibition using JAK, EGFR, and BRAF inhibitors was used to evaluate their effects on the ADAR1-RNA editing pathway and associated tumor phenotypes.
Results:BRAF V600E-mutant CRC cells secreted the mutant BRAF protein through extracellular vesicles and soluble forms that were detectable in systemic circulation and distant tissues. ADAR1 expression was significantly higher in BRAF-mutant vs. BRAF-wild CRC ($p<0.001$). Stromal macrophages and fibroblasts internalizing extracellular BRAF V600E exhibited robust ADAR1 induction and hyper-RNA editing via type I interferon-JAK/STAT signaling, promoting immunosuppressive and tumor-supportive phenotypes. Wild-type tumor cells exposed to BRAF V600E protein upregulated ADAR1 and displayed enhanced proliferation and invasion, suggesting horizontal transfer of malignant traits. While combined BRAF/EGFR inhibition in HT29 and Colo205 cells suppressed direct oncogenic signaling, it paradoxically activated the JAK/STAT-ADAR1 axis, increasing RNA editing and resistance. Co-treatment with JAK inhibitors mitigated this effect, restored sensitivity, and suppressed tumor growth in preclinical models.
Conclusions:Our findings define a novel circulating ‘BRAF-ADAR1-RNA editing’ axis that contributes to immune evasion and resistance in BRAF-mutant CRC. Dual targeting of this pathway, through JAK or ADAR1 inhibition in combination with BRAF/EGFR blockade, represents a rational therapeutic strategy to overcome refractory, mutation-driven colorectal cancer.

#3194 *SETD4* regulates cell proliferation and methotrexate response in pediatric acute lymphoblastic leukemia.

Mariana B. de Loyola, Ana Cristina Moura Gualberto, Brunna Santana, Fabio Pittella-Silva

University of Brasilia, Brasilia, Brazil

Acute lymphoblastic leukemia (ALL) is the most common malignancy in the pediatric population and presents high remission rates. However, relapse persists as a major concern and the disease remains a leading cause of mortality among children and adolescents. Methotrexate (MTX) is widely used in ALL treatment, although resistance is frequently observed in relapsed patients. Leukemogenesis and treatment response are influenced by alterations in gene expression and epigenetic regulation. *SETD4* is a histone lysine methyltransferase that modulates chromatin structure and transcriptional programs linked to oncogenesis. In this study, we investigated its role in leukemogenesis. In our cohort of 83 Brazilian pediatric ALL patients, we observed *SETD4* overexpression, a finding supported by the BloodSpot Leukemia MILE Study cohort, in which *SETD4* upregulation was particularly evident among patients with the t(12;21) translocation. We further analyzed TCGA RNA-seq data from the TARGET-ALL Phase II study, stratifying patients by *SETD4* expression levels. High *SETD4* was associated with enrichment of proliferation-related pathways, including E2F, MYC, G2M checkpoint and DNA repair, which drive accelerated cell-cycle progression and increased leukemic cell survival. To validate these findings, we upregulated *SETD4* in the low-expressing Nalm-6 cell line and knocked down *SETD4* in the high-expressing REH line using siRNA. *SETD4* overexpression increased proliferation in Nalm-6 at 24h (FC= 1.7, $p < 0.01$), 48h (FC= 1.6, $p < 0.01$) and 72h (FC= 2.0, $p < 0.001$), whereas *SETD4* silencing reduced proliferation in REH at 24h (FC= 0.8, $p < 0.05$) and 48h (FC= 0.7, $p < 0.05$). Both systems demonstrated direct association between *SETD4* levels and leukemic cell proliferation. Since methotrexate targets proliferative processes, we investigated whether *SETD4* also influences treatment sensitivity. Higher *SETD4* levels increased sensitivity to MTX (FC= 1.4, $p < 0.0001$), whereas *SETD4* silencing reduced sensitivity (FC= 0.7, $p < 0.001$). Together, these results highlight *SETD4* as a promising biomarker candidate for leukemic burden and treatment response in pediatric ALL.

#3196 MPP8 inhibits PRKN signaling through interactions with SIRT1 and ZEB1 to promote bladder cancer proliferation and metastasis.

Stephany Gonzalez Tineo, Ryan M. Kemper, Surya K. Tripathi, Daniel J. Crona

Division of Pharmacotherapy and Experimental Therapeutics, UNC Eshelman School of Pharmacy, University of North Carolina, North Carolina, NC

Background: Metastatic bladder cancer (mBC) remains incurable, and epigenetic dysregulation is associated with disease progression. We hypothesize that the H3K9me3 reader protein MPP8 complexes with class III histone deacetylase SIRT1 and transcription factor ZEB1 to drive proliferation and metastasis. Here, we explore how MPP8 knockdown ($MPP8^{KD}$) disrupts MPP8-SIRT1-ZEB1 interactions, thereby altering differentially expressed genes (DEGs) and gene networks and abrogating proliferation and metastasis.
Methods: UM-UC-3 mBC cells were used to compare $MPP8^{KD}$ and untransfected ($MPP8^{WT}$) cells. RNA-seq quantified differential expression. DEGs were analyzed in R v4.1.1 using DESeq2.3. Gene enrichment was assessed with GSEA v4.2.3 (Hallmark sets) and IPA pathway analyses (Qiagen). Co-IP WBs evaluated MPP8-SIRT1-ZEB1 protein complexes. CellTiter-Glo™ evaluated differences in viability. Clonogenic assays assessed proliferation while migration/invasion assays evaluated metastatic potential. $MPP8^{KD}$ and $MPP8^{WT}$ cells were injected into NSG mouse flanks, and changes to both tumor volume and TBW were measured until tumors were ≥ 2 cm^3.
Results: Over-representation analysis of DEGs indicated $MPP8^{KD}$ reduced mBC cell growth and DNA replication, as well as increased inhibition of cell migration. GSEA identified downregulated E2F (NES=-1.9, q=0.02) and enrichment of TNFα signaling via NFKB gene sets (NES=1.71, q=0.01). IPA revealed activation of the Parkinson's signaling pathway (z-score=1.54, P=1.1E-03), and consistent with GSEA analyses, predicted reduced proliferation and cellular stress responses. A custom IPA gene network of top DEGs included Parkinson's signaling pathway genes (e.g., PRKN) and demonstrated that MPP8, SIRT1, ZEB1 all act upstream of pathway genes. Moreover, SIRT1 and PRKN were predicted to interact through protein-protein interactions, while $MPP8^{KD}$ directly increased PRKN expression (LFC=1.658, q=2.39E-03). Functionally, we demonstrated MPP8 forms a complex with SIRT1 and ZEB1 in $MPP8^{WT}$ cells, while the MPP8-SIRT1-ZEB1 interactions were lost in $MPP8^{KD}$ cells. $MPP8^{KD}$ reduced viability (44% vs. 84% after 48 h; P=0.0001), colony growth (13% vs. 36% plate covered with colonies at 10 d; P=0.0001), number of migrated cells (97 vs. 470 cells after 18 h; P<0.0001), and number of invading cells (44 vs. 130 cells after 18 h; P=0.02). By D+32 post-injection, all mice with $MPP8^{WT}$ cells were sacrificed (mean vol. 2,859 ± 761 mm^3; n=8). At D+32, tumor volume was significantly smaller in $MPP8^{KD1}$ (mean vol. 234 ± 447 mm^3, P<0.0001; n=8) and $MPP8^{KD2}$ mice (mean vol. 1,341 ± 785 mm^3, P=0.002; n=8). At D+32, changes in TBW were not observed.
Conclusions: Our data suggest the MPP8-SIRT1-ZEB1 axis is a key driver of mBC, and $MPP8^{KD}$ results in PRKN activation that could halt mBC proliferation and metastasis.

#3197 PROMISE, a clonal promoter methylation signature capturing early epigenetic evolution and prognostic programs across epithelial cancers.

Francisco Gimeno-Valiente[1], Constantino De La Vega[2], Yun-Hsin Liu[1], Carla Castignani[3], Ieva Usaite[1], Martin Arana Jorge[1], Elrick Hillary[1], Stephan Beck[4], Miljana Tanic[5], Jonas Demeulemeester[6], Peter Van Loo[7], Charles Swanton[3], Mariam Jamal-Hanjani[8], Nnennaya Kanu[1]

[1]University College London (UCL), London, United Kingdom,[2]University of Cambridge, Cambridge, United Kingdom,[3]The Francis Crick Institute, London, United Kingdom,[4]UCL Cancer Institute, London, United Kingdom,[5]Institute for Oncology and Radiology of Serbia, Belgrade, Serbia,[6]Integrative Cancer Genomics Laboratory, Department of Oncology, KU Leuven, Leuven, Belgium,[7]The University of Texas MD Anderson Cancer Center, Houston, TX,[8]University College London (UCL) Cancer Institute, London, United Kingdom

Epigenetic remodeling is a hallmark of tumor evolution, yet the timing and clonality of promoter methylation events remain poorly defined. We investigated the spatial architecture of promoter DNA methylation in multiregion lung adenocarcinoma (LUAD) to identify clonal epigenetic alterations and evaluate their prognostic and translational relevance across cancers. Reduced representation bisulfite sequencing (RRBS) was performed on 151 tumor regions from 32 TRACERx LUAD patients with matched normal tissue. Differentially methylated regions (DMRs) were quantified for intratumor (ITH) and intertumor (ITeH) heterogeneity. Clonality was evaluated through three complementary metrics of methylation ubiquity, followed by univariate and LASSO Cox modeling. The resulting 30DMR panel, termed PROMISE, was derived through clustering concordance with TCGA LUAD and independently validated in CPTAC 3. PROMISE was subsequently tested for pancancer specificity across 18 tumor types from several publicly available sources.We identified 21,358 promoter DMRs showing a continuum of ITH and ITeH patterns. Promoters with low ITH but high ITeH, ubiquitously hypermethylated within tumors yet variable across patients, represented early clonal events significantly associated with poor survival. LASSO Cox selection yielded a 30-DMR signature encompassing genes involved in immune regulation, epithelial polarity, and TGFβ signaling. PROMISE robustly stratified patients into high and low risk groups in both TCGA LUAD and CPTAC 3 cohorts (logrank $P < 0.01$) and remained independent of clinicopathologic variables. Cross-cancer analyses revealed strong prognostic associations in kidney, thyroid, liver, and colorectal cancers, but minimal signal in squamous, stromal rich, or hematologic malignancies.PROMISE captures a panepithelial program of early, clonal promoter hypermethylation recurrent across multiple carcinomas and predictive of outcome in selected epithelial tumors. These findings highlight clonal methylation remodeling as an early determinant of tumor evolution and nominate PROMISE as a clinically actionable biomarker for cancer risk stratification.

#3198 BAP1 loss rewires chromatin and lineage identity in uveal melanoma.

Daulet Aitymbayev[1], Emma Hammes[1], Lucinda Innes[2], Holy Mary Zaher[3], Juan Martinez Villalobos[4], Arnaud Augert[1], Mathieu Bakhoum[3]

[1]Pathology and Molecular Medicine, Yale University, New Haven, CT,[2]Cornell University, New York, NY,[3]Ophthalmology and Visual Sciences, Yale University, New Haven, CT,[4]University of Connecticut Health Center, Farmington, CT

Background: BAP1 is a chromatin-associated deubiquitinase that antagonizes Polycomb Repressive Complex 1 (PRC1)-mediated ubiquitination, thereby stabilizing chromatin accessibility and genomic integrity. Uveal melanoma is the most common intraocular cancer in adults and loss of BAP1 tracks with a high-risk, metastatic phenotype. However, how BAP1 loss reprograms the epigenetic landscape to drive these lineage and phenotypic changes remains unknown. Our objective is to define the chromatin and transcriptional consequences of BAP1 loss in uveal melanoma.

Description of experimental procedures: To identify regulatory mechanisms altered secondary to BAP1 loss, we profiled the epigenome upon BAP1 loss using ATAC-seq, RNA-seq, and CUT&RUN for repressive marks such as H2AK119Ub and H3K27me3. Differential chromatin accessibility was identified using DiffBind, and motif enrichment was performed with HOMER, to infer changes in lineage-defining transcriptional circuits. Multi-omic integration with RNA-seq and public UM datasets (including TCGA) was used to align BAP1-dependent epigenetic states with low and high-risk tumor classes and to connect epigenetic remodeling to lineage states (melanocytic vs neural crest-like).

Summary of new results: BAP1 loss induced widespread changes in chromatin accessibility and repressive histone marks, including a global reduction in H2AK119Ub and redistribution of H3K27me3. These alterations were not uniform across the genome: distal elements, particularly on chromosome 8, preferentially lost repressive marks and gained accessibility in BAP1-deficient cells, consistent with enhancer remodeling at loci associated with high-risk uveal melanoma. CUTnRUN and ATAC analyses separated genomic regions into two major subsets: 1) melanocytic-lineage regulatory elements that gained repressive marks and lost accessibility, and 2) regions associated with neural crest-like and invasive programs that became more accessible and enhancer-like. AP-2 motifs were strongly enriched within ATAC-seq peaks that gained accessibility in BAP1-deficient UM, and displayed lower H3K27me3 and H2AK119Ub peaks, reflecting a more permissive chromatin state at these regions relative to indolent UM. Together, these data link BAP1 loss to a coordinated epigenetic shift from a melanocytic toward a neural crest-like epigenetic state.

Conclusions: Loss of BAP1 in uveal melanoma is associated with epigenetic remodeling, characterized by redistribution of repressive histone marks, and enhancer reorganization. This epigenetic reprogramming aligns with loss of melanocytic identity and emergence of a neural crest-like invasive state, providing a mechanistic link between BAP1 loss and aggressive tumor behavior.

#3199 Investigating gene regulatory mechanisms associated with B-cell acute lymphoblastic leukemia incidence in Hispanic/Latino populations.

Clarissa Garcia, Julian Grandvallet Contreras, Tzu Phang, Matthew T. Witkowski

The University of Colorado-Anschutz Medical Campus, Aurora, CO

B-cell acute lymphoblastic leukemia (B-ALL) is the most common childhood cancer. In the United States, Hispanic/Latino children exhibit a higher incidence and lower overall survival than non-Hispanic White patients, independent of social determinants. Genome-wide association studies have identified several single-nucleotide polymorphisms (SNPs) associated with B-ALL risk, including a recurrent variant, rs7090445, located in intron 3 of the *ARID5B gene locus*. The rs7090445 risk allele (C) is ~36% more common in Latino/Admixed-American individuals than in non-Latino Whites and rises with Indigenous-American ancestry, highlighting its potential role in B-ALL incidence disparities. The rs7090445 SNP resides within a lymphoid-specific enhancer that physically interacts with the *ARID5B* promoter. However, the role of this non-coding variant in B-cell transformation remains unclear. In humans, *ARID5B* mRNA expression increases at the pro-B cell stage, subsequently peaking at the pre-B stage. In mice, *Arid5b* deletion causes a differentiation delay at the pre-B stage, highlighting the importance of *Arid5b* dosage in B cell progenitor maturation. We hypothesize the B-ALL-associated ARID5B SNP rs7090445 perturbs enhancer function and disrupts normal B-cell development by reshaping the epigenetic landscape governing ARID5B transcription. To investigate this, we analyzed primary B-ALL patient and healthy bone marrow donor ATAC-Seq and RNA-seq datasets to define how the SNP influences chromatin accessibility, transcription factor occupancy, and gene expression across specific lymphoid subpopulations. These analyses revealed the rs7090445 risk allele elicited pro-B cell-specific reductions in *ARID5B* intronic enhancer accessibility and *ARID5B* transcription, with ongoing analysis dissecting genome-wide chromatin accessibility footprints. To functionally dissect these observations, we generated isogenic B-ALL cell clones harboring the rs7090445 risk and non-risk allele. Analyses of these engineered lines recapitulate allele-specific differences observed in patient samples, supporting a direct role for rs7090445 in modulating enhancer function and *ARID5B* gene activation. Ongoing studies aim to map SNP-altered transcription factor footprints and validate candidate regulators in B-ALL cell lines and patient-derived xenograft models. These findings provide a rationale for investigating how rs7090445 may perturb gene-regulatory networks influencing B-cell development and B-ALL.

#3200 WREm6A Prism: Single-cell sequencing of m6A methylation expression signatures and its clinical translation in esophageal squamous cell carcinoma.

Yuan Li, Zhuya Xiao, Qian Mo, Qian Wang, Caiyutian Zhang, Tian Tang

RenMin Hospital of Wuhan University, Wuhan, Hubei, China

Single-cell sequencing and m6A methylation have emerged as focal points in the life sciences. Their convergence—single-cell m6A methylation sequencing—has opened a fresh vantage point, yet comprehensive characterization and translational exploitation remain limited. Leveraging existing platforms, we have devised an integrative strategy that translates the dynamic m6A circuitry into disease-oriented research. m6A methylation is catalyzed by Writers, interpreted by Readers and erased by Erasers. The steady-state abundance of the modification is therefore dictated by the balanced expression of these three determinants. We have translated this ternary logic into a visualization framework—the WREm6A Prism—by projecting Writer/Reader/Eraser transcriptomes onto a ternary phase diagram. Analogous to a prism that disperses white light into a spectrum, the Prism has decomposed single-cell m6A landscapes into interpretable, color-coded maps that integrate multi-omics dimensions. In the context of esophageal squamous-cell carcinoma (ESCC), we have generated and mapped >68 000 malignant and 21 000 micro-environmental cells onto the WREm6A Prism. Primarily, identified three conserved m6A-modulation archetypes: W-high (stem-like), R-high (differentiated), E-high (inflamed/stressed). These archetypes have been independently validated in two external cohorts using both bulk and single-cell data. Prism coordinates have proven more predictive of response to treatment than conventional expression signatures, showing promising application in the prospective selection of patients for targeted or immune combination therapy. Thus, the WREm6A Prism has been established as an intuitive, quantitative and clinically actionable model for interrogating ternary regulatory systems. It has provided a fresh perspective on ESCC biology and has offered immediate translational utilities that are now being extended to other tumour types.

#3201 Chromatin accessibility differentiates cancer associated fibroblast subtypes in pancreatic cancer.

Minh Duc Pham, Chang-Il Hwang, Kedi Huang

University of California, Davis, Davis, CA

Pancreatic ductal adenocarcinoma (PDAC) remains the deadliest cancer with only 13% of five-year survival rate in patients. However, effective drug delivery and administration of immunotherapy have been limited due to the dense fibrotic stroma in PDAC tumor microenvironment, majorly contributed by cancer-associated fibroblasts (CAFs). Unfortunately, targeting CAFs to enhance PDAC treatment has not yet been successful due to the lack of understanding in CAF activation, heterogeneity, and plasticity. Previous scRNA-seq studies revealed different CAF subtypes with diverse phenotypes and functions but the underlying mechanisms of CAF activation remain unclear. Of note, CAFs do not genetically differ from their origins, and they are interconvertible depending on external factors and signaling cues. This plasticity feature suggests that CAFs are characterized by their cellular states rather than an end-of-point differentiation. Therefore, we hypothesized that CAFs activation is regulated by epigenetic reprogramming. Using ATAC-seq and innovative PDAC organoid-CAF co-culture models, we revealed distinct chromatin accessibility profiles of two major CAF subtypes, myofibroblasts and inflammatory fibroblasts *in vitro*. Gained differentially accessible regions were identified across genomes, located not only at promoters but also at enhancers, and they were highly associated with transcriptional signatures of each subtype. In line with this, analysis on snATAC-seq of the fibroblast population within PDAC tumor tissues of both human patients and mouse models also confirmed the distinct chromatin accessibility profiles of different CAF subtypes. Interestingly, by overlaying with snRNA-seq, we discovered that chromatin structure of CAF was primed to be accessible towards late-stage myofibroblast subtype during tumorigenesis. Overall, our study demonstrates the epigenetic basis of CAF plasticity both *in vitro* and *in vivo*, suggesting a novel therapeutic strategy of epigenetically targeting CAF to remodel the stroma and improve treatment outcomes in PDAC patients.

#3202 RNA editing is the potential biomarker for carcinogenesis of Crohn's disease.

Kazuya Moriwake, Kunitoshi Shigeyasu, Masashi Kayano, Eiki Miyake, Yuhei Kondo, Yuya Sakurai, Shunsuke Nakamura, Masafumi Takahashi, Kaori Nitta, Nobuhiko Kanaya, Yoshitaka Kondo, Hiroshi Tazawa, Toshiyoushi Fujiwara

Okayama Univ. Graduate School of Med., Dentistry & Pharm. Sci., Okayama, Japan

Background: Crohn's disease is one of inflammatory bowel disease alongside ulcerative colitis. In Crohn's disease, the major clinical concerns include fibrotic strictures of the ileum and carcinogenesis in the lower rectum and anus. Crohn's disease is associated with higher risk of carcinogenesis than the general population. However, the mechanisms driving carcinogenesis in Crohn's disease remain poorly understood. We recently reported that ADAR1-mediated RNA editing can mark carcinogenesis in ulcerative colitis. In this study, we therefore examine the potential role of ADAR1 in Crohn's disease-associated cancer.
Methods: A single-center retrospective study was conducted on 51 Crohn's disease patients who underwent colorectal resection of at our hospital in 2008-2023. There were 46 non-cancer tissue and five rectal cancer tissue. The expression level of ADAR1 protein was analyzed by immunohistochemistry (IHC) in FFPE samples with immunoreactive score. In vivo, we established AOM/DSS carcinogenesis model mouse. ADAR1 expression and RNA editing level were analyzed by IHC and RT-qPCR.
Results: ADAR1 expression levels were significantly elevated in cancer tissues compared to non-cancer tissues ($p < 0.05$) in colorectal epithelial cells. In addition, ADAR1 expression was upregulated at both the transcriptomic levels ($p = 0.0308$) and protein levels ($p < 0.05$) in the colorectal epithelial tissues of model mouse. Furthermore, the AZIN1 RNA editing ratio was significantly increased in colorectal tissues of model mouse as determined by RESSq-PCR ($p = 0.043$).
Conclusion: In this study, elevated expression of RNA editing enzymes has been observed in cancer tissues of Crohn's disease. A similar result was also observed in colorectal epithelial cells of colitis and carcinogenesis model mouse. These findings suggest that continued research may help establish ADAR1 as a potential biomarker and treatment target in inflammatory bowel disease.

#3203 Deciphering gene regulatory network and spatial heterogeneity underlying cutaneous T cell lymphoma large cell transformation.

Xiaofei Song[1], Jennifer M. Garbarino[2], COLIN NG[2], Lucia Seminario-Vidal[3], Carly M. Harro[4], Jodi A. Balasi[1], Chaomei Zhang[1], Nan Sun[1], Douglas C. Marchion[1], Sean J. Yoder[1], Jose R. Conejo-Garcia[5], Pei-Ling Chen[1]

[1]Moffitt Cancer Center, Tampa, FL,[2]AtlasXomics Inc, New Haven, CT,[3]Eli Lilly, Indianapolis, IN,[4]University of Pennsylvania, Philadelphia, PA,[5]Duke University School of Medicine, Durham, NC

Cutaneous T cell lymphoma (CTCL) is a rare malignancy of skin-homing T cells, with Mycosis Fungoides (MF) representing 50-70% of all cases. Although MF typically follows an indolent clinical course, a subset of MF patients progresses to develop large cell transformation (LCT) that is associated with a worse outcome. Disease progression from patch/plaque (PP) lesions to transformed tumor (TT) is accompanied by profound genetic and transcriptional alterations across multiple signaling pathways, including oxidative phosphorylation and MYC, posing a significant challenge for single-agent therapeutic strategies. Epigenetic therapies such as HDAC inhibitors have shown limited efficacy, underscoring the need to identify key transcription factors (TFs) and novel gene regulatory networks (GRNs) that drive CTCL disease progression and may serve as targeted vulnerabilities. In this study, we first performed joint profiling of gene expression and chromatin accessibility using scMultiome on six MF samples (2 PP and 4 TT). By integrating TF expression, chromatin accessibility at targeting regions, and expression of nearby genes, we inferred cell-type specific GRNs across the tumor microenvironment cell types, including the malignant T cells in PP and TT lesions, and other benign immune and non-immune cells. Importantly, this analysis identified JUND-associated GRNs enriched in B cells and ATF6 networks in myeloid cells, demonstrating robust regulatory signal recovery. Applying the same framework, we identified RUNX2 and ATF2 as putative regulators of PP malignant T cells, and LEF1, IKZF2, and TCF7 as key drivers of transformed CTCL cells. We further validated the critical roles of these transcription factors in in-house and publicly available scRNAseq datasets. To investigate the spatially resolved chromatin accessibility landscape in CTCL, we generated the first spatial ATACseq dataset for this rare cancer and profiled paired PP and TT lesions from the same patient. Spatial clustering and inferred copy number analysis revealed distinct epigenetic clone structures, including PP-dominant clones, TT-dominant clones, and shared clones between PP and TT. Notably, GRNs enriched in PP or TT by scMultiome were recapitulated within PP-dominant and TT-dominant spatial ATAC clones, respectively, highlighting consistent regulatory programs across modalities. Together, these results uncover previously unrecognized GRNs associated with MF progression and provide the first spatially resolved epigenetic map of CTCL. Our findings demonstrated potential regulators and clonal heterogeneity that may inform the development of novel therapeutic strategies, including precision epigenetic or combination therapies.

#3204 DNA methylation profiling in ethnically diverse prostate tissues to identify novel biomarkers predicting prostate cancer progression.

Claire A. Stevens[1], Leonardo Gonzalez-Smith[1], Colton Stensrud[1], Divya Ranjith[1], Jenaye Mack[2], Sarah Buxbaum[3], Sara Falzarano[2], Suhn K. Rhie[1]

[1]Keck School of Medicine of USC, Los Angeles, CA,[2]University of Florida, Gainesville, FL,[3]Florida A&M University, Tallahassee, FL

Prostate cancer (PCa) is the most common non-dermatological malignancy and the second leading cause of cancer-related deaths among men in the United States. Disparate clinical outcomes are especially observed between patients of African American (AA) and European American (EA) ancestry. This difference may reflect the long-term biological consequences of systemic racism, including differential environmental exposures and unequal access to healthcare. Additionally, these factors, along with genetic variation across ancestries, can contribute to epigenetic changes in PCa, including DNA methylation. To date, whole-DNA-methylome data has overrepresented EA individuals, and was used to develop DNA methylation-based biomarkers for PCa. In this study, we comprehensively characterize the genome-wide DNA methylome of PCa in a cohort of ethnically diverse individuals to identify new PCa-specific epigenetic features and a novel set of DNA methylation biomarkers. We obtained formalin-fixed paraffin-embedded (FFPE) prostate tissues from AA and EA PCa patients and generated DNA methylation profiles across normal controls and tumors spanning multiple Gleason grades, molecular subtypes, and pathological features. FFPE tissue regions were macrodissected based on pathologic annotations, allowing for recovery of Gleason grade-specific DNA. DNA methylation assays included both the Illumina Infinium Methylation EPIC array and Whole-Genome Bisulfite Sequencing (WGBS). We identified thousands of hypomethylated and hypermethylated CpG sites between normal and tumor samples across prostate tissue samples first profiled by both the EPIC array that were also covered by WGBS. Based on the most variable differentially methylated regions (DMRs), we identified clusters of tumor samples exhibiting distinct DNA methylation patterns. When we developed a model to identify DMRs that are predictive of tumor grade and other clinicopathological features; interestingly, we found that some DMRs were located within intergenic regions, including enhancers of genes that are typically upregulated in PCa. Additionally, we identified PCa-specific partially methylated domains, which are progressively hypomethylated throughout tumor progression. The average methylation levels at these regions predicted tumor grade. Overall, this study identifies PCa-specific epigenetic features, revealing potential new biomarkers that predict PCa severity and progression, with the inclusion of an ethnically diverse cohort.

#3205 Single cell DNA methylation of early breast cancer reveals epigenomic response to driver mutations and unique signatures of progression and invasion.

Ryan Mulqueen[1], Xiang Li[2], Mariam Mosaad[3], Shanshan Bai[1], Jianzhuo Li[1], Emi Sei[1], Savitri Krishnamurthy[1], Alastair Thompson[4], Nicholas E. Navin[1]

[1]UT MD Anderson Cancer Center, Houston, TX,[2]Department of Bioengineering, Rice University, Houston, TX,[3]Department of Systems Biology, UT MD Anderson Cancer Center, Houston, TX,[4]Baylor College of Medicine, Dan L. Duncan Cancer Center, Houston, TX

The pre-cancerous stage of invasive breast ductal carcinoma (IDC), termed ductal carcinoma *in situ* (DCIS) is a noninvasive neoplasm of the breast duct and is treated by surgical resection and radiation as standard of care. Pathology grading and mutational profiling do not sufficiently predict DCIS progression or recurrence; this uncertainty leads to overtreatment of an estimated 60% of possibly indolent lesions, via invasive surgical interventions and aggressive neoadjuvant therapies. Recent multicancer screening through DNA methylation markers of cell-free DNA show success in identifying staging and type of multiple cancers but fall short on DCIS and early-stage IDC, and do not predict progression nor recurrence. Further, since the methyl- group is covalently linked to DNA it is stable in FFPE-stored clinical samples for decades, allowing retrospective studies on progression and recurrence in a disease which can take decades to progress.

We leverage this promising modality to expand upon our knowledge of DNA methylation in normal, DCIS and synchronous (DCIS+IDC) breast samples using our high-throughput single cell methylation (scMET) method. We profiled 23,692 cells across 13 normal, 10 DCIS, and 18 synchronous samples, equating to >650X coverage of the methylome in total. We paired single cell RNA (scRNA) profiles for all samples, resulting in 154,695 scRNA profiles. As a first-of-its-kind data set, we define methylation-based markers for all expected cell types, including cancer-associated fibroblasts and tumor endothelial cells, enriched in the tumor microenvironment and absent in the normal tissue samples. Through paired copy number calling on scRNA and scMET we match transcriptomes and methylomes to 74 subclonal populations across our DCIS and synchronous samples. In addition to patient and subclone specific mutational events, dozens of these subclones share stereotyped early breast cancer driver events such as 1q amplification and 16q loss. Through these shared events we characterize methylome response to gene dosage changes. Through lineage tracing of inherited methylation changes, known as “epimutations”, we track subclonal populations back to their diploid cell of origin: luminal hormone-responsive epithelial cells. Finally, through our whole methylome capture per cell, we match cell types and subclones to telomere lengths. This reveals signatures of aging with cell type specificity and marked decrease in telomere length through cancer progression. In sum, this study measures the the breast methylome as it progresses from a normal to neoplastic to invasive phenotypes through an epigenetic modality that shows great promise as a biomarker. This work will inform clinically viable approaches to patient stratification to better determine DCIS risk of progression and recurrence.

#3206 Unraveling novel epigenetic therapies for the treatment of TP53^{WT}glioblastoma.

Laurence Haddadin, Shuo Zhang, Mansi Solanki, Bin Lu, Xueqin (Sherine) Sun

Cancer Genome and Epigenetics Program, Sanford Burnham Prebys Medical Discovery Institute, San Diego, CA

Glioblastoma (GBM) remains the most aggressive and treatment-resistant primary brain tumor in adults, with median patient survival of only 12-15 months despite current standard-of-care therapies. To identify new therapeutic strategies, we investigated how chromatin remodeling regulates cell-state transitions in TP53 wild-type (TP53^{WT}) GBM, which represents the majority of cases. We found that the chromatin regulator BRD8, a component of the EP400 complex, acts as a key suppressor of p53 activity. BRD8 maintains H2A.Z occupancy at p53 target loci to repress its tumor-suppressive paradigm. Depletion of BRD8 disrupts this interaction, increases chromatin accessibility, and reactivates p53-dependent transcriptional programs, resulting in a stable cell cycle arrest and a senescent phenotype accompanied by widespread transcriptomic reprogramming. Through small-molecule screening, we identified compounds that selectively impair the survival of BRD8-deficient cells, revealing specific vulnerabilities associated with this arrested state. We further discovered that the histone variant, macroH2A (mH2A), enforces the changes in chromatin accessibility and transcriptional output following BRD8 perturbation, functioning as epigenetic switches that stabilize this altered cell state. Together, these findings reveal a chromatin-based mechanism governing proliferative control in GBM and highlight actionable vulnerabilities that could be exploited through targeted pharmacologic intervention.

#3207 SNP rs4381241 promotes renal cell carcinoma progression via the *FAF1-HDAC3-PDGFB* axis.

Haodong Liu, Xinru Yu, Zeyun Mi, **Kexin Chen**

Tianjin Medical Univ. Cancer Inst. & Hospital, Tianjin, China, Tianjin, China

BackgroundRenal cell carcinoma (RCC) is a highly lethal cancer with limited therapeutic options. Genetic heterogeneity, driven by genomic alterations, plays a key role in tumor progression and resistance to treatment. Genome-wide association studies (GWAS) have identified single nucleotide polymorphisms (SNPs) linked to cancer susceptibility and prognosis. However, the functional mechanisms of these SNPs in regulating RCC development remain unclear. Investigating these SNPs could reveal new therapeutic targets.
MethodsThe functional relevance of the SNP was assessed using EMSA, dual-luciferase reporter assays, and CRISPRa/i to confirm its impact on FAF1 expression. 3C/4C analyses confirmed physical interaction with the FAF1 enhancer region. FAF1 expression was measured in TCGA datasets and RCC tissues using qPCR and Western blot. Gene set enrichment analysis (GSEA) identified PDGFB as a downstream target. Gain- and loss-of-function assays were conducted in RCC cell lines, including CCK-8, wound healing, transwell migration, and colony formation assays, along with in vivo subcutaneous xenograft models. Co-IP, CUT&Tag, and ChIP-qPCR were used to study FAF1's interaction with HDAC3 and its role in PDGFB transcription.
ResultsThe SNP rs4381241, in the intronic region of FAF1, acts as an enhancer that regulates FAF1 transcription. The T>C substitution reduces FAF1 expression. In both TCGA data and RCC tissues, FAF1 mRNA and protein levels were lower in tumors compared to adjacent normal tissues, with higher FAF1 levels linked to better prognosis. Functional assays showed that FAF1 overexpression suppressed cell proliferation and migration in vitro, and tumor growth in vivo, confirming its tumor-suppressive role. Mechanistically, FAF1 interacts with HDAC3 to recruit it to the PDGFB promoter, leading to histone deacetylation at H3K9ac and H3K27ac, suppressing PDGFB transcription and inhibiting PDGFRB/PI3K-AKT signaling.
ConclusionThe intronic SNP rs4381241 is a functional enhancer variant regulating FAF1 expression in RCC. FAF1 suppresses RCC cell proliferation and migration and interacts with HDAC3 to repress PDGFB transcription, inhibiting the PDGFRB/PI3K-AKT pathway. These findings highlight rs4381241 as a key modulator of RCC progression through the FAF1-HDAC3-PDGFB axis.
Keywordsrenal cell carcinoma, rs4381241, FAF1, HDAC3, PDGFB

#3209 Enzymatic enrichment of unmethylated cell-free DNA improves the sensitivity of fragmentomic analysis for the diagnosis of patients with lung cancer.

Valentina Miano[1], Paulina Siejka-Zielińska[1], Calum Mould[1], Sean Knight[2], Seamus Grundy[3], **Robert K. Neely**[1]

[1]Tagomics Ltd, Cambridge, United Kingdom,[2]Lydia Becker Institute of Immunology and Inflammation, University of Manchester, Manchester, United Kingdom,[3]Northern Care Alliance NHS Foundation Trust, Salford, United Kingdom

Global loss of genomic DNA methylation is associated with the progression of cancer. This genome-wide hypomethylation is thought to result from increased rates of genome replication in rapidly dividing cancer cells. We leveraged this aspect of cancer biology to address the challenge of early disease detection in cell-free DNA from a cohort of lung cancer patients. We combined Tagomics' Activace platform, which enriches unmethylated CpG sites of the genome for sequencing, with genome-wide, fragmentomic analysis on this hypomethylated DNA fraction. Using a single sample input (>5 ng of cell free DNA) Activace enables a multiomic (epigenomic and fragmentomic) read-out with only 70 M sequencing reads. We tested the utility of this approach on a small cohort of 36 patients, who presented at the clinic with symptoms of lung cancer, had a blood sample taken and went on to receive a diagnosis using gold-standard testing (imaging, pathology). The cohort contained 14 cancer-free patients, 12 patients with an early-stage (Stage I & II) diagnosis of non-small cell lung cancer and 10 patients with a late-stage (Stage III & IV) diagnosis of non-small cell lung cancer. We sequenced the cfDNA obtained from the plasma of these patients; and enriched and sequenced the unmethylated DNA fraction from the same patients, using Tagomics' Activace platform. We compared the fragmentomics profiles of both the enriched, unmethylated DNA and the whole cfDNA and evaluated the impact of the enrichment on our ability to classify the cohort. Using a leave-one-out approach, a logistic regression classifier, trained on the end motif profiles of the Activace dataset (enriched for unmethylated CpG sites), we correctly classified all but two of the early-stage lung cancer cases (91% sensitivity, 100% specificity). By contrast, using an analogous approach in the WGS dataset (whole cfDNA) eight lung cancer cases (seven early-stage and one late-stage) were misclassified (64% sensitivity, 100% specificity). Multiomics tools, such as the Tagomics' Activace platform enable information-rich insight into disease biology and will likely outperform single analyte-based tests, in the future. The enrichment of DNA containing unmethylated CpG sites improves sensitivity of fragmentomic analysis, relative to analogous analysis of the whole genome, likely due to the enrichment of tumour-derived, hypomethylated DNA fragments in patients with cancer.

#3210 Epigenomic liquid biopsy molecular lung subtyping and real-world (RW) patient outcomes in advanced NSCLC (aNSCLC).

Jayati Saha, Nicole Zhang, Sheila R. Solomon, Shaun Forbes, Matthew Ellis

Guardant Health, Palo Alto, CA

Introduction: NSCLC subtypes include adenocarcinoma (LUAD), squamous cell (LUSC), and small cell (SCLC). Mixed histology, limited sampling, and discordant interpretations often delay treatment. To address this, a plasma-based Molecular Lung Subtype Predictor (MLSP) was developed to quantify LUAD, LUSC, and SCLC from circulating hypermethylated DNA (Guardant360 Liquid, Guardant Health). We report concordance between MLSP and histology from test requisition forms (TRF), real-world (RW) outcomes by therapy type, and subtype-specific genomic profiles.

Methods: The InfinityAI Data Library links de-identified genomic/epigenomic results with longitudinal claims data. Samples were considered “pure” when ≥90% signal was from one subtype. Cohorts were stratified by MLSP-TRF concordance and first-line therapy post-Guardant360 Liquid: chemotherapy (chemo), immunotherapy (IO), chemo-IO, or targeted therapy. RW time to treatment discontinuation (RW-TTD) and time to next treatment (RW-TTNT) were analyzed using Kaplan-Meier and log-rank tests.

Results: Among 8,559 MLSP results, 69.4% were LUAD, 12.4% LUSC, 3.7% SCLC, and 14.6% mixed. Concordance with TRF was 91.6% (LUAD), 75.1% (LUSC), and 56.1% (SCLC). In MLSP-LUAD, Tier 1 mutations included *KRAS G12C* (11.9%), *EGFR* ex19del (9.5%), and *BRAF V600E* (2.1%); *PIK3CA E545K* (6%) was common in MLSP-LUSC, and *RB1* (19%) in MLSP-SCLC. Targetable biomarkers occurred in 43.5% of MLSP-LUAD vs 3.4% LUSC and 2.6% SCLC. In discordant MLSP-TRF cases, genomic profiles favored MLSP predictions. KRAS G12C (7%), PIK3CA E545K (5%), and RB1 (39%) were the most frequent subtype-specific alterations. Targeted therapy improved RW outcomes in MLSP-LUAD; chemo-IO yielded best outcomes in MLSP-LUSC, and IO benefited MLSP-SCLC. Discordant cases treated with IO or targeted therapy showed extended RW-TTNT and RW-TTD, aligning with MLSP-predicted biology.

Conclusion: This study demonstrated high concordance between MLS and TRF, which is consistent with previous analyses. The genomics and RW outcomes of discordant cases were more consistent with MLSP-predicted subtype vs. TRF-reported histology. Discordant pts exhibited genomic patterns and RW outcomes more aligned closely with the MLSP-predictions, suggesting MLSP may more accurately represent underlying tumor biology than standard histology.

#3211 A novel workflow for ultra short cfDNA fragmentomics and multiomic profiling in liquid biopsies.

Xiaojing Yang[1], Madison Valle[1], Duang Ratanachan[1], Kaitlyn Lee[1], Neeti Swarup[2], Irene Choi[2], Hanjun Kim[1], David T. Wong[2]

[1]Zymo Research Corp., Irvine, CA,[2]University of California, Los Angeles, Los Angeles, CA

Background: Liquid biopsy matrices—including plasma, serum, saliva, and urine—are increasingly used for non-invasive cancer detection, companion diagnostics, and recurrence monitoring. However, conventional column-based purification and double-stranded DNA library preparation fail to capture the full cfDNA landscape, particularly ultra-short fragments and single-stranded DNA (ssDNA). We evaluated a novel nucleic acid purification method paired with an ssDNA-compatible library preparation workflow to enable more comprehensive cfDNA profiling, serum and saliva samples as model systems.

Results: We compared several commercially available bead-based cfDNA extraction methods. The MAGicBead cfDNA Isolation Kit, which incorporates a novel nucleic-acid-binding surface, yielded the highest cfDNA recovery. Recovered cfDNA was processed using a library preparation workflow derived from the original Splinted Ligation Adapter Tagging (SPLAT) chemistry, enabling capture of both dsDNA and ssDNA. A distinct population of ultra-short DNA fragments (35-75 bp) was observed in the mapped reads and was detected only with MAGicBead purification, while the dominant nucleosome-associated peak was retained.To determine whether these ultra-short fragments were single-stranded, isolated cfDNA was treated with a single-strand-specific nuclease prior to library preparation. Following digestion, the short-fragment signal was no longer detectable, confirming their ssDNA nature and underscoring the need for an ssDNA-compatible SPLAT-derived workflow.We next applied the optimized workflow to plasma from lung cancer patients and observed differences in the proportion of ultra-short cfDNA fragments relative to healthy controls, suggesting potential fragmentomic utility.Because saliva is an emerging but technically challenging liquid biopsy matrix due to mixed human-microbial content and heterogeneous fragmentation, we further evaluated the workflow in saliva. The ssDNA fragment population was again recovered, and sequencing simultaneously revealed microbial signatures, demonstrating that the workflow captures both host and microbial DNA in a single run and supports a multi-omic approach that may enhance diagnostic performance.

Conclusions: The MAGicBead cfDNA Isolation Kit, combined with SPLAT DNA library preparation, enables robust recovery of ultra-short cfDNA fragments that are routinely lost with conventional workflows. This approach supports comprehensive cfDNA profiling across and below the nucleosome-size range. Our pilot studies reveal previously unrecognized cfDNA features and point toward more sensitive strategies for cancer diagnostics and biomarker discovery.

#3212 Enhancing the detection of circulating tumor DNA by combining Interlace™ global methylation discovery with next-generation sequencing test Labcorp Plasma Complete™.

Kimberly A. Holden[1], Cynthia Maddox[2], Calum Mould[3], Nana Mensah[3], Luca Tosti[3], Iwo Pieniak[3], Paulina Siejka-Zielinska[3], Stephen Evans[3], Debora Lucarelli[3], Robert Neely[3], Anthony Smith[3], Kenneth C. Valkenburg[2], Marcia Eisenberg[4], Brian Caveney[4], Eric Severson[4], Taylor J. Jensen[4], Shakti Ramkissoon[4], Jonathan Williams[1]

[1]Labcorp, San Diego, CA,[2]Labcorp, Baltimore, MD,[3]Tagomics, Ltd., Cambridge, United Kingdom,[4]Labcorp, Durham, NC

Genome-wide methylation patterns are a powerful biomarker. The detection of aberrant methylation has many oncological applications, including using tumor DNA for cancer detection and therapy selection. In liquid biopsies, the ability to detect small amounts of circulating tumor DNA (ctDNA) is crucial to enable earlier diagnosis, monitor minimal residual disease, and assess treatment response. This study evaluated Interlace, an enzymatic technology that enriches unmethylated DNA molecules, to detect ctDNA. This methodology uses an engineered methyltransferase enzyme to target and tag unmethylated CpG sites across the genome. Libraries are then prepared from these tagged regions and sequenced while simultaneously allowing unenriched product to be utilized for downstream molecular applications such as hybrid capture. Interlace was run in parallel with Labcorp Plasma Complete (LPC), a 521-gene next-generation sequencing (NGS) hybrid capture assay that detects genetic alterations in cell free DNA (cfDNA) from the plasma of cancer patients. LPC reports single nucleotide variants (SNVs), insertions and deletions (indels), translocations, copy number amplifications, microsatellite instability (MSI), and blood tumor mutation burden (bTMB). To evaluate the analytical performance of the two tests in parallel, a sample cohort (n=45) including cfDNA reference samples, noncancerous wild-type controls, cancer cell lines, and cfDNA from cancer patients was processed. A head-to-head comparison of LPC results for samples processed with and without the Interlace assay demonstrated 96.7% positive percent agreement and 99.5% positive predictive value. Interlace was able to detect tumor DNA down to 0.1% tumor content in a dilution series created by mixing sheared tumor and wild-type cell line DNA, representative of ctDNA, at target concentrations from 0% to 10%. Using identified differentially methylated regions as input into unsupervised clustering or a proprietary machine learning model, Interlace was able to differentiate blinded cancer cfDNA from cancer cell lines from wild-type samples. Multiomics platforms that evaluate multiple analytes from a single sample, as described here, are powerful tools to provide a more comprehensive view of patient samples. The combination of LPC for somatic variant reporting with Interlace methylation-based ctDNA detection may allow for increased sensitivity in reporting circulating tumor DNA in plasma samples from cancer patients.

#3213 Utility of TAPS+: a positive-readout methylation sequencing approach for high-fidelity epigenetic profiling.

Kimberly A. Holden[1], Kerry D. Fitzgerald[1], Adib Shafi[1], Ashraf Shabaneh[1], Dennis D. Krutkin[1], Tong Liu[1], Eyad Almasri[1], Graham McLennan[1], Nathan Faulkner[1], Craig Marshall[2], Travis Sanders[2], Thomas Harrison[2], Eduard Casas[2], Kristina Giorda[2], Doug Wendel[2], Brian Kudlow[2], Shakti Ramkissoon[3], Marcia Eisenberg[3], Brian Caveney[3], Eric Severson[3], Taylor J. Jensen[3], Jonathan Williams[1]

[1]Labcorp, San Diego, CA,[2]Watchmaker Genomics, Boulder, CO,[3]Labcorp, Durham, NC

Accurate methylation sequencing from clinical samples is challenging due to DNA-damaging chemistries that reduce sequence diversity, limiting data quality and reproducibility—particularly for fragmented or low-input materials such as cfDNA. The objective of this study was to evaluate a new positive-readout methylation method (TAPS+) in a clinically relevant cohort and compare its performance to an enzymatic methylation conversion method employing a negative-readout approach. TAPS+ is a non-damaging chemistry that converts methylated cytosines to thymines while preserving unmethylated cytosines, maintaining full sequence complexity and enabling direct methylation detection. This method was applied to a 24-sample cohort comprising invasive breast carcinoma patients, healthy donors, and control samples spanning a range of methylation states. Libraries were sequenced in parallel with those from an enzymatic negative-readout method to assess conversion efficiency, background, and biological concordance of differentially methylated regions (DMRs). The R package methylKit was used for DMR analysis, and biomarker candidates were identified based on statistically significant methylation differences within annotated genomic regions. Compared to the negative-readout method, TAPS+ achieved a shorter turnaround time and higher library yields across all sample types. In cfDNA samples, TAPS+ produced significantly higher methylation ratios than the negative-readout method ($p = 8.6e-10$). A methylated control showed an 88.8% 5mC rate with TAPS+, versus 76.8% with the negative-readout method, suggesting greater accuracy. CpG island methylation was strongly correlated across methods, though the negative-readout method had greater noise at low coverage sites. Both breast cancer patients and healthy individuals exhibited a characteristic dip in average DNA methylation levels around transcription start sites, consistent with promoter hypomethylation, with no significant differences observed between cohorts. DMR analysis with TAPS+ identified significant biomarker candidates, including *SHH* hypermethylation ($q = 3.15e-5$), associated with cancer development and progression. Additional biomarkers were associated with developmental pathways, cancer signaling, transcriptional regulation, and immune response. The negative-readout dataset did not demonstrate strong biomarker candidates indicative of disease status. TAPS+ enables high-fidelity methylation sequencing from diverse and challenging clinical materials, supporting robust epigenetic analysis within a streamlined workflow. The positive-readout approach demonstrated superior data quality and biological relevance compared to an enzymatic negative-readout method, highlighting its potential utility for translational research, early detection, and clinical assay development.

#3214 Dysregulation of the RNA modification m6A promotes cancer progression and provides therapeutic opportunities.

Gudrun Stengel, Zachary Miles, Eric Davis, Byron Purse

Alida Biosciences Inc, San Diego, CA

The objective of this study is to determine how sensitive detection and quantitation of the RNA modification *N*6-methyladenosine (m6A) can enable cancer detection, mechanistic insights into tumor biology, and improved monitoring of treatment responses. RNA modifications, which are co- and post-transcriptional alterations to nucleobases or ribose, are key regulators of nearly all aspects of RNA metabolism, including transcription, splicing, localization, translation, stability, and interactions with RNA-binding proteins. Among these, m6A is the most abundant modification in human mRNA and long noncoding RNA and is frequently dysregulated in cancer. To enable comprehensive analysis of RNA modifications, we applied a multiplexed proximity-barcoding assay that enriches for modified RNA fragments, encodes modification sites during cDNA synthesis, and quantifies their abundance at each locus using synthetic spike-in controls for calibration. This approach allows concurrent detection of m6A, inosine, and pseudouridine, providing a multidimensional, high-sensitivity view of the cancer epitranscriptome. Application of this assay to neuroblastoma samples and cell line-derived xenograft tumor models revealed consistent increases in m6A abundance across all tumor types examined. Notably, m6A peak patterns also distinguished MYCN-amplified (MNA^+) from ALT-activated (ALT^+) and low-risk neuroblastomas, demonstrating that the method can resolve biologically and clinically distinct subgroups. Treatment of neuroblastoma cell lines and xenograft-derived samples with STC-15, a small-molecule inhibitor targeting the primary m6A writer enzyme METTL3, led to a dose-dependent reduction in m6A levels measurable by this assay. METTL3 inhibition was associated with decreased tumor cell viability and increased sensitivity to chemotherapeutics such as doxorubicin. Sensitive, quantitative measurement of m6A and related RNA modifications provides a powerful strategy to detect cancer-associated epitranscriptomic dysregulation, to dissect molecular heterogeneity in neuroblastoma, and to monitor therapeutic responses to METTL3-targeted interventions.

#3219 Arid1a directs lineage specification in mammary epithelial cells.

Erik Ladewig[1], Amaia Arruabarrena-Aristorena[2], Estelle Deby[3], Srushti Kittane[4], Fresia Pareja[5], Ryan Blawski[6], Yangzhenyu Gao[7], Laura Baldino[1], Vito Rebecca[4], Emiliano Cocco[8], Hongkai Ji[4], Pau Castel[9], Christina Leslie[1], Wouter Karthaus[10], Eneda Toska[11]

[1]Memorial Sloan Kettering Cancer Center, New York, NY,[2]Department of Genetics, Physical Anthropology and Animal Physiology, University of the Basque Country UPV/EHU, Bilbao, Spain,[3]School of Life Sciences, Swiss Institute for Experimental Cancer Research (ISREC), Lausanne, Switzerland,[4]Johns Hopkins University, Baltimore, MD,[5]Memorial Sloan Kettering Cancer Center, New York, NY,[6]Johns Hopkins Medicine, Baltimore, MD,[7]Biochemistry and Molecular Biology, Johns Hopkins University, Baltimore, MD,[8]University of Miami, Miami, FL,[9]NYU Grossman School of Medicine, San Francisco, CA,[10]The Ecole polytechnique federale de Lausanne, Lausanne, Switzerland,[11]Johns Hopkins University School of Medicine, Baltimore, MD

Epigenetic regulation is essential for mammary gland development, yet the specific chromatin remodelers that govern mammary epithelial cell fate remain poorly defined. Mutations in SWI/SNF chromatin remodeling complex subunits occur in more than 20% of human cancers, with ARID1A being the most frequently altered. In breast cancer, ARID1A loss of function mutations are enriched in metastatic estrogen receptor-positive (ER^+) disease and associated with endocrine therapy resistance. To define the developmental role of Arid1a in vivo, we generated mice with mammary epithelium specific Arid1a deletion. These animals displayed disrupted ductal branching and aberrant terminal end bud formation. Mammary organoids derived from Arid1a deficient tissue further revealed abnormal cystic morphology and impaired differentiation. To dissect the molecular consequences of Arid1a loss, we performed single cell multiomic profiling that combine single nucleus RNA and chromatin accessibility sequencing from the same cells, together with H3K27ac and BRG1 CUT&RUN-seq. Arid1a loss caused a collapse of normal mammary epithelial lineage architecture, with single cell analyses showing failure to maintain basal, luminal progenitor, and alveolar identities. Instead, Arid1a deficient cells were restricted to an undifferentiated luminal hormonal like state characterized by reduced estrogen receptor signaling competence. Chromatin profiling revealed profound remodeling, including decreased accessibility and impaired SWI/SNF targeting at lineage defining transcription factors (TF) such as Foxa1, Gata3, and Sox9. A CRISPR/Cas9 pooled loss of function screen identified Foxa1 and Meis1 as essential regulators whose deletion recapitulated the Arid1a null phenotype, positioning them as downstream effectors required for mammary cell fate specification. Notably, Meis1 emerged as a previously unrecognized regulator of luminal hormonal identity. Our work provides a framework for understanding how Arid1a rewires the chromatin landscape and transcriptional network in normal mammary development. By identifying lineage specific TF motifs and critical regulators like Meis1, we identify new opportunities for targeted therapeutic intervention.

#3220 Integrated epigenomic profiling reveals distinct transcription factor networks driving therapy resistance in estrogen receptor positive metastatic breast cancer.

Gizem Yayli-Vokshi[1], Sandra Cohen[2], Weiling Li[1], Hong Shao[3], Sydney Bowker[4], Elisa de Stanchina[4], Pedram Razavi[5], Sarat Chandarlapaty[5], Ekta Khurana[6]

[1]Systems and Computational Biomedicine, Weill Cornell Medicine, New York, NY,[2]Sandra and Edward Meyer Cancer Center, Weill Cornell Medicine, New York, NY,[3]Human Oncology and Pathogenesis Program, Memorial Sloan Kettering Cancer Center, New York, NY,[4]Anti-Tumor Assessment Core, Memorial Sloan Kettering Cancer Center, New York, NY,[5]Memorial Sloan Kettering Cancer Center, New York, NY,[6]Weill Cornell Medicine, New York, NY

Background: Endocrine therapy resistance in estrogen receptor positive metastatic breast cancer remains poorly understood, with many resistant tumors lacking actionable genomic alterations. Emerging evidence suggests epigenetic reprogramming drives resistance through transcription factor regulatory network rewiring, yet comprehensive epigenomic characterization of resistant tumors remains limited.
Methods: We performed integrated ATAC-seq and RNA-seq profiling in clinically relevant models of therapy-resistant and sensitive estrogen receptor positive metastatic breast cancer, including patient-derived xenografts harboring diverse genomic alterations, along with sensitive breast cancer cell lines. We applied unsupervised clustering to chromatin accessibility and gene expression data to identify non-genomic clusters. Master regulators were identified by integrating transcription factor binding motif enrichment in accessible chromatin regions with downstream target gene expression networks.
Results: We identified five distinct epigenomic clusters of therapy-resistant estrogen receptor positive metastatic breast cancer, each driven by unique master transcription factor regulatory programs. Cluster 1, comprising all sensitive models such as patient-derived xenografts and cell lines, retained luminal hormone-responsive identity. Therapy resistant tumors segregated into four distinct programs: Cluster 2 showed pioneer factor dominance with enhanced chromatin remodeling while maintaining partial luminal features. Cluster 5 represented an *ESR1*-mutant luminal HER2 hybrid state with *ERBB2* amplification, combining altered estrogen receptor signaling with receptor tyrosine kinase activation. Cluster 4 displayed mesenchymal resistance via epithelial-mesenchymal transition. Cluster 3 represented the most dedifferentiated phenotype, an inflammatory cancer stem cell state with FOXA1 loss.
Conclusion: Our integrated epigenomic approach reveals that therapy-resistance in estrogen receptor positive metastatic breast cancer is orchestrated by four distinct transcription factor-driven regulatory programs that emerge through non-genetic rewiring rather than genomic alterations alone. These clusters span a spectrum from pioneer factor-mediated chromatin remodeling and hybrid luminal-HER2 states to mesenchymal plasticity and inflammatory stem-like networks. Importantly, these epigenetic clusters may explain mutation-negative resistance and reveal subtype-specific therapeutic vulnerabilities. This molecular framework provides a roadmap for precision medicine approaches tailored to the epigenomic state of resistant metastatic breast cancer.

#3221 Profiling histone modifications in single cells to gain insight into the effects of epigenetic drug treatment on tumor cells.

Shuwen Chen[1], Lisa Welter[1], Gilma Sevilla[1], Ploy Setthasap[1], Yana Ryan[1], Shiyi Yin[1], Alan Du[1], Jackson Peterson[1], Mike Covington[1], Mohammad Fallahi[1], Kazuo Tori[1], Bryan Bell[1], Bria Graham[2], Matt J. Meiners[2], Andrea L. Johnstone[2], Keith E. Maier[2], Martis W. Cowles[2], Bryan J. Venters[2], Michael Keogh[2], Xuan Qu[3], Colin McCornack[3], Ting Wang[3], Yue Yun[1], Andrew Farmer[1]

[1]Takara Bio USA, Inc., San Jose, CA,[2]EpiCypher, Inc., Durham, NC,[3]Washington University School of Medicine in St. Louis, St. Louis, MO

Epigenomic remodeling, such as changes in chromatin state, plays a crucial role in cancer biology by regulating gene expression changes that drive tumor progression, immune evasion, and the evolution of therapeutic resistance. Popular methods to study the epigenome include assay for transposase-accessible chromatin with sequencing (ATAC-seq) and chromatin immunoprecipitation sequencing (ChIP-seq). ATAC-seq only profiles open chromatin, missing critical details about the nature of accessible regions or silenced chromatin. ChIP-seq and its newer relative, cleavage under targets and tagmentation (CUT&Tag), provide more detailed information on chromatin states by targeting histone modifications with specific antibodies. ChIP-seq requires 10^6 cells to generate meaningful data—too high for precious samples. CUT&Tag offers higher sensitivity with 10-100x lower input and a significantly simplified workflow. When studying epigenetic changes in cancer, it is widely accepted that single-cell resolution is essential, given the complexity and heterogeneity of tumors and their microenvironment. Hence, there is a high demand to convert current epigenetic assays from bulk to single-cell resolution. In CUT&Tag, DNA is tagmented with a protein A/G-Tn5 fusion enzyme, which inserts sequencing adapters in situ for cell-specific labeling—enabling single-cell resolution. Some labs have experimented with single-cell CUT&Tag (scCUT&Tag), but here we present a novel, ready-to-use, validated method for automated, high-throughput scCUT&Tag. To assess drug induced changes in acetylation, we profiled H3K27ac patterns in thousands of single cells from a lung cancer cell line (A549 WT and A549 p53 KO) before and after epigenetic treatment (decitabine + panabinistat vs DMSO control).We observed global cell-type-specific acetylation in response to epigenetic therapy in both A549 WT and A549 p53 KO cells. When comparing scCUT&Tag data with single-cell total RNA-seq data we found that increased acetylation at gene promoters and enhancers correlated with increased gene expression, corroborating the observed changes in histone modification. In summary, the validated scCUT&Tag method provides a high-throughput, automated approach to identify genes regulated in response to epigenetic drug treatment of tumor cells at the single-cell level. Integrating this single-cell expression data provides deeper insight into cellular regulation, particularly in the context of drug responses in tumor cells.

#3222 Identifying novel biomarkers for Saudi glioblastoma multiform using multi-omics approach.

Abdulmonem A. Alsaleh[1], Ahmed Aloraidi[2], Bahauddeen M. Alrfaei[1]

[1]Blood and Cancer Research, King Abdullah International Medical Research Center, Riyadh, Saudi Arabia,[2]Neurosurgery, , King Abdulaziz Medical City (KAMC), Riyadh, Saudi Arabia

Background: Glioblastoma Multiform (GBM) is a high grade aggressive glioma of the brain and it accounts for almost half of malignant tumours of the central nervous system. As per the latest Saudi Cancer Incidence Report, GBM is the most common central nervous system tumour nationally with about 15 months survival following diagnosis.
Aims: There is a need to identify new molecular biomarkers that can improve diagnostic accuracy and provide a more reliable prognostic prediction, especially for Saudi GBM patients.
Methods: The study recruited 30 consented GBM patients from King Abdulaziz Medical City, Ministry of National Guard Health Affairs (MNGHA) hospitals, Riyadh, under protocol No. RC13/258/R. Resected brain tumour tissues were collected on surgery day and immediately were snap-frozen. DNA and RNA extraction were conducted as per standard protocols. Libraries for Illumina Whole Genome Sequencing, Illumina RNA Sequencing and MGI Whole Genome Bisulfite Sequencing were prepared as per manufacturer's protocols. Analysis pipeline included: 1) quality check of sequence reads, 2) trimming, 3) mapping to reference genome (annotation), 4) generating hit counts, 5) pairwise comparison/enrichment analysis, and 6) pathway analysis.
Results: Preliminary RNA sequencing data of two trial GBM samples has generated 19k and 21k paired end 2 x 150 sequence reads. Majority of the sequence reads (87%) had good quality (Phred Score > 30) and majority had a unique genome mapping (70% of sequence reads). The analysis revealed 19,007 normalised counts and the two samples had high correlation (Spearman's correlation $r = 0.787$, $P < 0.001$). Additionally, the analysis identified 904 Differentially Expressed Genes (DEG), of which 434 and 470 upregulated and downregulated genes, respectively. Additional sequencing data are expected to be generated with full multi-omics integration analysis to be done.
Conclusion: This study marks the first to investigate the GBM multi-omics profile of the untapped Saudi GBM and to further identify and validate novel biomarkers that are population-specific to guide clinical diagnosis and prognosis for GBM.

#3223 Chromatin profiling from formalin-fixed paraffin-embedded samples for biomarker discovery.

Andrea Lynn Johnstone, Eva Brill, Vishnu U. Kumary, Morgan Oatley, Martis W. Cowles, Michael-Christopher Keogh, Bryan J. Venters

EpiCypher, Inc, Durham, NC

As the oncology field moves towards a precision medicine model of patient care, understanding and profiling the epigenetic landscape is increasingly important. Gene expression and cell function are regulated by epigenomic features, including histone post-translational modifications (PTMs), transcription factors, and other chromatin proteins. Mapping the location of these features provides a powerful approach to study chromatin mechanisms driving disease and can be leveraged for biomarker and drug development. Formalin-fixed paraffin-embedded (FFPE) tissues banked from cancer clinical trials could be a rich resource for retrospective biomarker studies, due to their association with drug response and disease progression data. However, using FFPE tissues for genomic mapping assays has been technically challenging for multiple reasons. For instance, the removal of paraffin, heavy cross-linking conditions, and degraded nucleic acids can make FFPE samples unsuitable for standard transcriptomic and epigenomic mapping assays (RNA-seq, ATAC-seq, ChIP-seq). To better leverage chromatin profiling for translational research, we developed a modified CUT&Tag workflow that is compatible with FFPE samples (CUT&Tag-FFPE). CUT&Tag (Cleavage Under Targets and Tagmentation) is an immunotethering-based strategy that uses pAG-Tn5 to selectively cleave and ligate sequencing adapters at antibody-bound chromatin. The entire assay takes place on-slide with intact cells or nuclei extracted from scrolls, enabling a highly streamlined workflow. In this study, we optimized every major step of the workflow, including paraffin removal, *in situ* tissue permeability or nuclei extraction, crosslink removal, antibody selection, and tagmentation. We have applied these modifications to successfully map transcription-linked open chromatin across a variety of FFPE sample tissue types from mouse and human. We find that CUT&Tag-FFPE correlates with RNA-seq and ATAC-seq from corresponding fresh, frozen material. Additionally, we observed open chromatin at tissue specific promoters and at distal elements, such as enhancers. By enabling insights into genomic regulatory mechanisms from FFPE biorepositories, CUT&Tag-FFPE has the potential to accelerate biomarker discovery and drug development research for precision oncology.

#3224 Loss of PIWIL4-piRNA interaction reveals uncertain somatic epigenomic evolution.

Yu-Wei Leu, Shu-Huei Hsiao

National Chung Cheng Univ., Chiayi County, Taiwan

Analyzing genomic and epigenomic changes that are either randomly or causally induced enhances precision medicine. Knockout (KO) of the Piwi-interacting RNAs (piRNA)-interacting genes *PIWIL4* or *L1TD1* in cancer and normal cells may unleash the oncogenic evolution to produce genomic alterations and subsequent alternations. Our findings show that whereas the binding motifs of important epigenetic markers (CTCF, acetylated histone H3 at lysine 27, and trimethylated histone H3 at lysine 9) were maintained in KOs, their global binding sites were markedly changed. Changes in transposable element abundance, chromatin conformation, transcript variations, and gene expression profiles were all found at the same time. Additionally, we discovered new oncogenic insertions and deletions (indels) in the coding sequences of the KOs, indicating separate gene evolution. Our findings also show an unanticipated epigenomic evolution through altered chromatin locations and evolutionary rates. Significantly, we discovered similar patterns of altered transcript variants, increased indels, and transposable element shifts in a number of models, including models of myeloproliferative neoplasm (MPN) expressed by JAK2V617, aged mesenchymal stem cells, *SARS-CoV-2* replicon-expressed cells, and a fetal alcohol syndrome rat model. Genetic reversion was unable to restore these modified transcript variants or transposable element abundances, according to a convincing finding from an MPN model. These results offer strong support for piRNAs' role in somatic genome protection and a potential uncertainty law in epigenomic evolution. (Supported by NSTC 114-2320-B-194 -001, Taiwan)

#3225 Resolving genome regulatory complexity with new multiomic long-read sequencing tools for chromatin state and genetic variation.

Lu Sun[1], James T. Anderson[1], Connor P. Frasier[1], Allison R. Hickman[1], Sabrina R. Hunt[1], Emily A. Madden[1], Keith E. Maier[1], Andrea L. Johnstone[1], Zu-Wen Sun[1], Martis W. Cowles[1], Andrew B. Stergachis[2], Bryan J. Venters[1], Michael-Christopher Keogh[1]

[1]Epicypher Inc, Durham, NC,[2]Devision of Medical Genetics, Department of Medicine, University of Washington, Seattle, WA

High-resolution epigenomic insights are vital to inform the discovery of biomarkers and mechanisms in cancer research. Modern short-read sequencing (SRS) methods such as ATAC-seq, WGBS, and CUT&RUN/ChIP-seq have served as workhorses for studying chromatin architecture, but they are fundamentally limited. These methods lack multiomic insights, requiring labor-intensitve, costly, and sample-consuming parallel assays. Moreover, these assays fragment DNA, losing critical information about coordinated regulatory effects, and are blind to repetitive and structurally complex regions of the genome. These limitations constrain progress in understanding gene regulation and translating genetic discoveries into clinical insights. To overcome these limitations, EpiCypher is developing multiomic long-read sequencing (LRS) technologies that enable single-molecule epigenomic profiling. These approaches directly record chromatin features onto native DNA, preserving the intrinsic relationships between chromatin states and genetic variation across individual DNA molecules. Fiber-seq employs an N6-adenine (6mA) methyltransferase (Hia5) to record chromatin accessibility directly onto DNA, while retaining endogenous DNA methylation (5mC). We have streamlined Hia5 manufacturing and labeling workflows, enabling robust single-molecule chromatin accessibility profiling with near base-pair resolution, readily adopted at the bench. Fiber-seq reveals precise transcription factor (TF) binding footprints and cis-regulatory haplotypes as demonstrated in a genetic disease diagnosis (PMID: 40166185), highlighting its potential for variant-to-function discovery in diseases. DAF-seq (Deaminase-Assisted single-molecule chromatin Fiber sequencing), complements this approach by using a dsDNA cytosine deaminase (SsDddA) to encode chromatin accessibility as a mutation maintained through PCR amplification. As a result, DAF-seq can deliver high-resolution chromatin profiles and TF footprints from low-inputs or even single-cells (bioRxiv DOI: 10.1101/2024.11.06.622310). Remarkably, DAF-seq delivers nearly a 7,000-fold improvement in genome coverage compared to leading single-cell ATAC-seq technologies, while operating at a fraction of the cost.Together, Fiber-seq and DAF-seq represent a versatile toolkit: Fiber-seq provides an unbiased multiomic discovery to simultaneously assess chromatin accessibility, DNA methylation, and inferred TF binding genome-wide; while DAF-seq enables targeted chromatin accessibility mapping from low-input samples, resolving heterogeneity at single-molecule resolution. These LRS technologies bridge genetic and chromatin regulatory information on single molecules to reveal disease mechanisms, define drug responses, and drive precision medicine.

#3226 FOXA1 alterations drive endocrine therapy resistance through unique transcriptional and epigenomic programs in breast cancer.

Srushti Kittane[1], Subhiksha Nandakumar[2], Enrico Moiso[2], Walid Khaled Chatila[2], Yangzhenyu Gao[3], Elza C. de Bruin[4], Claudette Falato[5], Ji Li[6], Hongkai Ji[7], Nikolaus Schultz[2], Maurizio Scaltriti[8], Pedram Razavi[2], Eneda Toska[9]

[1]Johns Hopkins University, Baltimore, MD,[2]Memorial Sloan Kettering Cancer Center, New York, NY,[3]University of North Carolina, Chapel Hill, MD,[4]AstraZeneca Oncology R&D, Cambridge, United Kingdom,[5]AstraZeneca Oncology R&D, Barcelona, Spain,[6]AstraZeneca Oncology R&D, Boston, MA,[7]Johns Hopkins Bloomberg School of Public Health, Baltimore, MD,[8]AstraZeneca Oncology R&D - MedImmune, LLC, Gaitherburg, MD,[9]Johns Hopkins University School of Medicine, Baltimore, MD

Breast cancer is histologically classified into invasive ductal carcinoma (IDC, ~70-80% of cases) and invasive lobular carcinoma (ILC, 10-15%). Both are predominantly estrogen receptor-positive (ER+) and treated with endocrine therapy, yet resistance inevitably develops, driving metastasis and poor outcomes. ILC exhibits hallmark E-cadherin loss, distinct metastatic patterns, and reduced endocrine therapy response compared with stage-matched IDC. However, treatment remains uniform across histologies, underscoring the need to define shared and subtype-specific drivers of resistance. Clinicogenomic analyses of >8,500 MSK-IMPACT tumors revealed recurrent FOXA1 mutations in ER+ disease, enriched in ILC (8% vs 4% in IDC). As a pioneer transcription factor that licenses ER chromatin binding, FOXA1 alterations may reshape ER signaling to promote therapy resistance. To investigate this, we functionally characterized recurrent FOXA1 Helix 1 (H1), Wing2 (W2), and betastrand3 (S3) mutations in IDC (MCF7, T47D), and H1, W2 variants in ILC (MDA-MB-134VI). We assessed treatment response under estrogen deprivation, fulvestrant or oral SERDs ± CDK4/6i and profiled transcriptional and chromatin changes using RNA-seq, ER CUT&RUN, ATAC-seq, and qPLEX-RIME. Across both histologies, FOXA1 mutations conferred a selective growth advantage under estrogen deprivation modeling AI therapy, while retaining sensitivity to SERDs and SERD+CDK4/6i. Mechanistically, H1 mutants were hypermorphic in IDC and ILC, increasing ER recruitment and chromatin accessibility to strengthen canonical estrogen-responsive programs. W2 variants exhibited histology-specific consequences: in IDC they increased ER chromatin binding without pioneering, consistent with enhanced EP300/NCOA3 co-activator engagement, whereas in ILC they also increased accessibility, displaying lineage-restricted pioneer function. Ductal-specific S3 mutants were neomorphic, redirecting FOXA1 to an alternative DNA motif, reprogramming accessibility, and activating proliferation, metabolic, and endocrine-resistant gene networks. Interactome profiling supported enrichment of stemness-linked chromatin remodeling networks.Together, these findings demonstrate that recurrent FOXA1 mutations establish mechanistically distinct oncogenic classes that promote endocrine resistance in ER+ breast cancer with their distribution differing by histology. ILC is enriched for hypermorphic H1 and W2 variants that enhance pioneering and chromatin opening, whereas IDC harbors W2 mutants lacking pioneer activity and neomorphic S3 variants that rewire chromatin. These insights support FOXA1 mutation status as a biomarker of aromatase inhibitor resistance and highlight the need for histology-tailored therapeutic strategies.

#3227 Defining neural molecular features and their functional significance in lung cancer.

Reshmee Bhattacharya, Daphni van Rinsum, Anna Dykhno, Hideo Watanabe

Division of Pulmonary, Critical Care and Sleep Medicine, Department of Medicine, Icahn School of Medicine at Mount Sinai, New York, NY

Background: Lung cancer remains the leading cause of cancer-related mortality, accounting for over 150,000 deaths annually in the US. Although genomic characterization and immunotherapy have significantly reshaped the treatment landscape, overall 5-year survival remains low at ~29.7%, partially due to the heterogeneity across and within histologic subtypes. Lung cancers with neuroendocrine (NE) features exhibit particularly aggressive clinical behavior, including high rates of brain metastasis and poor responsiveness to immunotherapy. Emerging evidence suggests that a subset of LUAD acquires neural traits independent of NE identity. Acquisition of intrinsic neuron-like electrical activity in NE-SCLC drives tumorigenic capability and metastatic potential has been also reported. These neural features may represent an unrecognized biological axis associated with lineage plasticity, metastasis, and immune escape.

Rationale and hypothesis: Our previous epigenomic studies identified neural-like lineage subclasses within LUSC (nLUSC) signified by SOX2/BRN2 circuitry in contrast to classical subset signified by SOX2/TP63 circuitry. Neural factors were unexpectedly co-opted in lung cancer to establish enhancer landscapes consistent with neural developmental pathways. We hypothesize that co-opted neural circuitries establish neural-like epigenomic programs in lung cancers, conferring enhanced neural affinity and intrinsic immune privilege that facilitate metastasis and resistance to immunotherapy.

Experimental procedures: First, we cultured nLUSC cell lines with or without ectopic dNp63 expression that suppresses neural program and quantified migration toward differentiated human glutamatergic neurons in transwell, along with profiling transcriptomic and epigenomic remodeling upon interaction with neurons. Second, we stimulated a panel of classical and neural LUSC cells with IFN-γ to measure the antigen presentation activity. We co-cultured T cells with LUSC lines and measured intracellular and released Granzyme B and perforin levels to quantify T cell-mediated cytotoxicity, along with profiling transcriptomes and enhancer landscapes to identify enrichment of neural signatures.

Results: nLUSC exhibits functionally distinct behaviors compared to their classical counterparts. nLUSC cells demonstrated enhanced migratory capacity towards neurons. Classical cells maintained stronger antigen-presenting potential by both MHC-I and MHC-II markers at baseline and predominantly upregulated APM and enhanced their immunogenicity, whereas nLUSC cells exhibited a more immunosuppressive response; e.g., upregulation of PD-L1**,** CD95 and HLA-E upon IFNγ stimulation.

Conclusions: The study reveals that neural and classical lung cancer subtypes are not only transcriptionally divergent but also functionally distinct in behaviors relevant to neural affinity and immune escape.

#3228 Spatial epigenomic landscape of NF-PanNETs defines tumor progression and microenvironmental niches.

Yang Liu, Dejiang Wang, Xiangjun Di, Jing Du

Yale University, New Haven, CT

Non-functional pancreatic neuroendocrine tumors (NF-PanNETs) display substantial clinical and biological heterogeneity, yet the epigenetic mechanisms and spatial contexts that shape this diversity remain poorly defined. To address this gap, we performed an integrated analysis combining single-nucleus ATAC-seq (snATAC-seq) with spatial ATAC-seq across tumors of varying grades. snATAC-seq resolves chromatin accessibility landscapes for distinct tumor subtypes, immune populations, and cancer-associated fibroblasts (CAFs), uncovering transcription factor (TF) programs that underpin tumor progression and modulate microenvironmental interactions. Spatial ATAC-seq adds a critical layer of context, revealing two major tumor-stroma ecological niches: a proliferative niche characterized by E2F, MYC, and mTORC1 signaling, and an invasive niche enriched for Snail family TFs and KRAS pathway activation. These spatially anchored regulatory circuits highlight how NF-PanNET cell states emerge from the interplay between intrinsic epigenetic programs and local tissue environments. Collectively, our study establishes a spatially resolved epigenomic framework for dissecting NF-PanNET heterogeneity and evolution, providing new biomarkers, regulatory axes, and mechanistic insights with implications for molecular stratification and precision therapy.

#3229 The chromatin remodeler SMARCA5 displays ancestry-specific functions in African American prostate cancer.

Shahid Hussain[1], Khalid Mir[2], Sajad A. Wani[3], Solomon Rotimi[4], Lara Sucheston-Campbell[2], Clayton C. Yates[5], **Moray J. Campbell**[1]

[1]Cedars-Sinai Medical Center, Los Angeles, CA,[2]Karmanos Cancer Institute, Detroit, MI,[3]University of Cincinnati, Cincinnati, OH,[4]Covenant University, Ota, Ogun State, Nigeria,[5]Sidney Kimmel Comprehensive Cancer Center, Baltimore, MD

Previously, we identified that BAZ1A and SMARCA5 were significantly downregulated in in African American (AA) prostate cancer (PCa), and that BAZ1A altered vitamin D receptor (VDR)-dependent transcriptional sensitivity. SMARCA5 is the ATPase core of different chromatin remodeling complexes, including WICH that promotes accessible chromatin at developmental enhancers, and NoRC, which mediated repression of rDNA transcription and contributes to nucleolar stress pathways. In the current study we tested how ancestry shaped the composition and impact of the SMARCA5 complex. Integrative ATAC-Seq, and H3K27ac and AR CUT&RUN in AA (RC43T and RC77T) and European American (EA, LNCaP) PCa cell models revealed AA-specific H3K27ac marked accessible chromatin. These regions were enriched for motifs including the basic leucine zipper/AP-1 motifs such as BATF and significantly intersected AA PCa enhancer landscapes. Likewise, the AR cistrome from AA PCa cell lines significantly intersected with the AR cistrome derived from AA primary tumors. To test whether SMARCA5 complex composition and function differed by ancestry, we performed CRISPR activation of SMARCA5 in AA and EA PCa models. RIME revealed selective assembly of SMARCA5 with WICH and NoRC subunits in AA, but not in EA cells. CUT&RUN demonstrated that AA-enriched SMARCA5 complexes targeted distinct enhancers and promoters compared to LNCaP cells and mirrored the basal H3K27ac cistromes. Reflecting lineage- and stress response-specific roles the AA SMARCA5 cistrome was enriched BATF, VDR, and p53/p73 motifs. Transcriptomic analysis demonstrated that SMARCA5 activation induced a strong luminal differentiation program unique to AA PCa, supported by GSEA. SMARCA5 controlled VDR target genes in AA cells included VDR governed miRNA (e.g. miR-200c) that also related to differentiation. Integrated ATAC- and RNA-Seq analyses demonstrated that luminal genes were the dominant contributors to active enhancer-transcriptome correlations in AA PCa, confirmed using random forest approaches. Finally, ancestry-stratified clinical cohorts from Africa, AA, and EA PCa showed significant clinical associations between vitamin D levels, SMARCA5-dependent gene signatures and tumor grade. Together, these findings suggest that reduced SMARCA5 expression impacts both the availability of lineage-defining active enhancers and the establishment of heterochromatin boundaries, potentially in response to stress (and mediated by p53/p73 pathways). In this manner, ancestry selectively disrupts the SMARCA5 complex, and shapes transcriptional outputs. SMARCA5 complex composition and its chromatin outputs represent ancestry-stratified features with potential biomarker and therapeutic relevance in AA PCa.

#3230 Epigenomic rewiring driven by BAP1 loss in uveal melanoma.

Gulum Yenisehirli[1], Aristeidis G. Telonis[1], Renata L. Volonterio[1], Monica Lopez[1], Jeffim N. Kuznetsoff[1], Ashley N. Zuniga[1], J. William Harbour[2], Zelia M. Correa[1], Stefan Kurtenbach[1]

[1]University of Miami Miller School of Medicine, Miami, FL,[2]Ophthalmology, UT Southwestern Medical Center, Dallas, TX

Loss-of-function mutations of the epigenetic regulator BAP1, the catalytic subunit of the PR-DUB complex, are among the strongest predictors of metastasis in uveal melanoma (UM). Although BAP1 loss is known to disrupt chromatin organization, the specific epigenetic mechanisms that reshape cell identity and promote tumor progression remain poorly defined. Here, we investigated the epigenomic rewiring driven by BAP1 loss using ATAC-seq, reduced-representation bisulfite sequencing, histone modification profiling, and RNA-seq across three BAP1-wildtype and three BAP1-mutant UM cell lines, as well as a normal human uveal melanocyte (UMC) cell line and its isogenic BAP1-knockout counterpart. This design enabled us to isolate the BAP1-dependent chromatin and transcriptional changes in both normal and transformed uveal cells. BAP1-mutant UM displayed coordinated activation of angiogenic and neuronal-mimicry gene programs, accompanied by suppression of immune and inflammatory signaling. Chromatin accessibility analyses revealed a broad reduction of SOX family activity in both UM and melanocyte models lacking BAP1, suggesting that BAP1 maintains lineage-defining SOX programs. In parallel, we identified a distinct set of transcription factors consistently enriched across all UM lines, independent of BAP1 status, highlighting conserved regulatory networks underlying UM biology. DNA methylation profiling uncovered an unexpected global hypomethylation phenotype in BAP1-mutant UM, further highlighting a broader role for BAP1 in maintaining epigenomic organization. Together, these data reveal the multilayered epigenomic consequences of BAP1 mutations and identify regulatory circuits driven by BAP1 loss that drive tumor progression and metastasis in uveal melanoma.

#3231 Chromatin profiling reveals the impact of fulvestrant on estrogen receptor-driven chromatin dynamics in breast cancer cells.

Celine Barlier[1], Mathias Simplicien[1], Ana Hermoso[1], Anais Pourrat[1], Elsa Moreau[1], Celia Fontana[2], Aurelia Delherme[2], Natalie Daluege[3], Gurpreet Bharaj[3], Cibele de Oliveira[3], Alexander Vogt[3], Vincent Piras[1], Coralie Hoareau-Aveilla[1], **Francisco Cruzalegui**[1], Gaylor Boulay[1], Isabel Paiva[1]

[1]Evotec SE, Toulouse, France,[2]Evotec ID, Lyon, France,[3]Evotec, Hamburg, Germany

Background: Epigenetic dysregulations are linked to various diseases, including cancer. Among them, breast cancer is the second leading cause of cancer-related deaths in women with 50% of mortalities attributable to estrogen receptor-positive (ER+) tumors. Endocrine therapies targeting the ER such as Tamoxifen, Fulvestrant (FULV) and Aromatase inhibitors, are widely used in the clinic. Among these therapeutic agents, FULV has been shown to fully antagonize ER activity, primarily through the rapid degradation and elimination of ER from target tissues. However, recent findings indicate that ER, when engaged with FULV, retains the ability to translocate to the nucleus and bind DNA whereas appearing transcriptionally inert.

Results: In this study, we aimed to further investigate the effects of FULV and Estradiol (E2), the natural ER ligand, on ER cistrome, chromatin accessibility, gene transcription, and H3K27ac genome-wide patterns in ER+ breast cancer cell lines. Using the innovative CUT&Tag technology, we first confirmed that both FULV and E2 promote ER binding to DNA. Our findings revealed that E2 not only enhances chromatin accessibility and gene expression but also increases H3K27ac levels at ER binding sites. In contrast, FULV does not significantly alter chromatin accessibility or transcription but is not completely inert, as it induces increases in H3K27ac at a subset of ER binding sites. These observations indicate a decoupling between histone acetylation and transcriptional output under FULV treatment.

Conclusions: This study provides new insights into the mechanistic impact of FULV on ER activity, highlighting its ability to modulate H3K27ac dynamics even in the absence of transcriptional changes. These findings underscore the complexity of ER signaling and suggest that FULV's therapeutic effects may extend beyond simple antagonism of ER activity.

#3232 NOP16 is a histone mimetic that regulates histone H3K27 methylation and gene repression.

Aamir Khan*[1], Ken Takashima*[2], Dian-Jang Lee[3], Maria Fernanda Trovero[4], Xing Wang[1], M. Hafiz Rothi[4], Ying Zhang[3], Zilan Li[5], Sarah Niesen[1], Julia Natale[5], Ernst Schmid[3], Joseph Al Haddad[5], Sabine Dietmann[6], Sumio Ohtsuki[7], Shannan Ho Sui[8], Hiroyuki Oshiumi[2], Judy Lieberman[9], Eric Lieberman Greer[1]

[1]Department of Pediatrics, Washington University School of Medicine in St. Louis, St. Louis, MO,[2]Department of Immunology, Kumamoto University, Kumamoto, Japan,[3]Department of Pediatrics, Boston Children's Hospital, Boston, MA,[4]Department of Pediatrics, Harvard Medical School, Boston, MA,[5]Division of Newborn Medicine, Boston Children's Hospital, Boston, MA,[6]Department of Developmental Biology and Center of Regenerative Medicine, Washington University School of Medicine in St. Louis, St. Louis, MO,[7]Department of Pharmaceutical Microbiology, Kumamoto University, Kumamoto, Japan,[8]Bioinformatics Core, Department of Biostatistics, Harvard T.H. Chan School of Public Health, Boston, MA,[9]Professor of Pediatrics, Dana-Farber Cancer Institute, Harvard Cancer Center, Boston, MA

Post-translational modifications of histone tails alter chromatin accessibility to regulate gene expression. Some viruses exploit the importance of histone modifications by expressing histone mimetic proteins that contain histone-like sequences to sequester complexes that recognize modified histones. Here we identify an evolutionarily conserved and ubiquitously expressed, endogenous mammalian protein Nucleolar protein 16 (NOP16) that functions as a H3K27 mimic. NOP16 binds to EED in the H3K27 trimethylation PRC2 complex and to the H3K27 demethylase JMJD3. NOP16 competitively inhibits the interaction between EED and H3K27me3 and causes EED to translocate from the nucleoplasm to the nucleolus, thereby negatively regulating H3K27me3 modification in the nucleoplasm. NOP16 is overexpressed and linked to poor prognosis in breast cancer. Depletion of NOP16 in breast cancer cell lines causes cell cycle arrest, decreases cell proliferation and selectively decreases expression of E2F target genes and of genes involved in cell cycle, growth and apoptosis. Conversely, ectopic NOP16 expression in triple negative breast cancer cell lines increases cell proliferation, cell migration and invasivity *in vitro* and tumor growth *in vivo*, while NOP16 knockout or knockdown has the opposite effect. Thus, NOP16 is a histone mimic that competes with Histone H3 for H3K27 methylation and demethylation. When it is overexpressed in cancer, it derepresses genes that promote cell cycle progression to augment breast cancer growth**.**

#3236 Genomic landscape of bladder cancer in a turkish cohort: Unveiling the unique mutational spectrum with clinical insights.

Burcu Yucel[1], Fatma Zehra Sarı[2], Dine Guner Mercan[2], Huseyin Ozgur Kazan[1], Ceren Sumer[2], Melike Akman[2], Demet Akdeniz Odemiş[2], Mehmet Baysan[3], Asıf Yıldırım[1], Mahmut Gumuş[1]

[1]Istanbul Medeniyet University, Istanbul, Turkey,[2]Health Institutes of Turkiye, Istanbul, Turkey,[3]Istanbul Technical University, Istanbul, Turkey

Introduction: Bladder cancer is predominantly urothelial carcinoma, and the majority of patients present with non-muscle-invasive bladder cancer (NMIBC), which has a high recurrence rate, or muscle-invasive bladder cancer (MIBC), which is less common but has a high risk of metastasis. Tumor heterogeneity is a characteristic feature of bladder cancer and is associated with a high mutational burden. While chemotherapy is an important treatment modality, tumor heterogeneity ultimately leads to drug resistance and post-treatment recurrence. Identifying the molecular mechanisms underlying both NMIBC and MIBC tumors and identifying biomarkers and therapeutic targets is crucial for disease treatment. Advances in next-generation sequencing technology have enabled advances in understanding the molecular mechanisms of bladder cancer, defining tumor heterogeneity at the genomic levels, and enabling more clinically relevant targeted therapies and effective immunotherapies. This first project, initiated within the National Cancer Genome Project in Turkiye, aimed to discover novel cancer-specific variants through whole genome and transcriptome analyses of bladder cancer tumors.
Methods: Sixty patients diagnosed with bladder cancer were included in the study. DNA was isolated from tumor tissue and blood samples taken from patients with a mass measuring 2 cm or larger on imaging and/or diagnostic cystoscopy who gave informed consent. Two patients were excluded from the study due to different diagnosis. Library preparation from the patients' genetic and somatic DNA samples was performed as recommended by the Illumina PCR-free tagmentation kit. Whole genome sequencing was performed on an Illumina Novaseq 6000 instrument. Somatic and germline variant calling analyses were performed using Illumina Dragen software.
Results: Tumor and blood samples from 48 male (82.75%) and 10 female (17.25%) patients were analyzed. Of the patients, 24.13% (14 patients) reported non-smoking, while 31.03% reported a history of cancer in a first-degree relative. Clinic evaluation revealed 19 (32.75%) of the patients had MIBC, and 39 (67.24%) had NMIBC. The mean age was 67.4±10.54. Of the pathogenic variants obtained through filtering, 45.40% were determined missense mutations, and 22.95% were stop-gained. Most frequently mutated genes detected in our study population were TERT (52.54%), PTPRG (40.67%), and FGFR2/FGFR3 (38.98%), respectively. In previous studies, frequently mutated TP53 and KRAS mutations were observed at a rate of 37.28%, while MYC mutations were observed at a rate of 33.89% in our analysis.
Conclusion: Despite the limited number of patients enrolled in the study, our results unveiled a unique mutational spectrum of bladder cancer in Turkiye. The resulting data will be a valuable resource for understanding drug resistance in bladder cancer and developing therapeutic approaches.

#3237 A multimodal sequencing framework to define viral and host genomic heterogeneity in HPV associated head and neck cancer.

Ella P. Jackert, Shu-Yun Cheng, Swar Vimawala, Liyang Tang, Daniel Kwon, Niels C. Kokot, Uttam Sinha, Albert Y. Han

Caruso Department of Otolaryngology Head and Neck Surgery, University of Southern California, Los Angeles, CA

Background: This study aims to integrate viral and host genomic analyses with social determinants of health (SDOH) to improve biologic risk stratification in patients with human papillomavirus-associated head and neck cancer (HPV+ HNC).
Methods: Patients with biopsy-proven, p16-positive HPV+ HNC were enrolled. Archived or fresh tumor tissue underwent DNA extraction followed by HPV consensus-primer genotyping targeted to the L1 locus (MY09/MY11 primer sequences) to determine viral type. Samples with confirmed HPV infection proceed to short-read sequencing for viral genotype characterization and host mutational profiling, and long-read sequencing to define HPV integration architecture, HPV-host fusion events, and larger structural variants. Demographic, clinical, and SDOH variables were collected to explore associations between patient context and genomic heterogeneity.
Results: To date, 10 patients have provided informed consent and have been enrolled in this study. Additionally, eights archived tumor specimens have been analyzed. The cohort consists of seven White male, two Hispanic or Latino male, and one White female patients. Archived specimens were derived from three White, two Asian, two Black, and one Hispanic patient. Preliminary HPV genotyping demonstrates a distribution of high-risk HPV types, including HPV16, HPV18, HPV33, HPV35, and HPV59. These early results suggest a potential variation across ancestry and SDOH-defined clusters, with White patients predominantly demonstrating the HPV16 genotype, while there is a higher prevalence of non-16 types amongst other racial and ethnic groups.
Conclusions: These early findings highlight the value of broadening HPV genotype characterization and capturing patient diversity to uncover the full spectrum of viral and host genomic variation in HPV+ HNC. Ongoing expansion of the cohort and completion of sequencing analyses will be critical next steps toward defining clinically meaningful genomic subgroups and developing future frameworks for precision risk stratification, surveillance, and treatment personalization in HPV-associated head and neck cancer.

#3238 Integrity of high-molecular-weight DNA is essential for accurate long-read sequencing and comprehensive cancer genomics.

Susan M. Magdaleno[1], Juili Kelvekar[1], Monica K. Campbell[2], Alexis Tapanes-Castillo[3], Hannah E. Saunders[1]

[1]Research and Development, Thermo Fisher Scientific, Austin, TX,[2]Research and Development, Galatea Biotech, Miami Lakes, FL,[3]St. Thomas University, Miami Gardens, FL

Accurate genomic characterization in oncology and cancer research depends on the quality and integrity of input DNA. Conventional genomic DNA (gDNA) extraction kits often produce short or degraded fragments due to excessive mechanical or chemical disruption during lysis, multiple manual transfer steps, and prolonged elution conditions, which limit the utility of extracted DNA for long-read sequencing and structural variant analysis. Short-read sequencing (50-600 bp) further compounds these limitations by providing incomplete assemblies and reduced ability to resolve large-scale rearrangements. Long-read technologies such as Oxford Nanopore and PacBio overcome these issues but require intact, high molecular weight (HMW) DNA fragments (>10 kb). To address these challenges, genomic DNA was extracted from whole blood, cultured cells, and tissue using the Applied Biosystems™ MagMAX™ High Molecular Weight (HMW) DNA Kit on the Thermo Scientific™ KingFisher™ Flex system. The fully automated workflow—comprising cell lysis, magnetic-bead-based DNA binding, sequential washing, and low-salt elution—reduces manual intervention and potential shearing events while improving consistency across users and sample types. An optional brief enzymatic digestion (<15 min) was included for tissue samples to optimize recovery of long fragments. DNA yield and integrity were quantified using Qubit™ fluorometry, Agilent TapeStation, and pulsed-field electrophoresis, and performance was compared against commonly used silica column- and precipitation-based kits. Long-read sequencing was used to assess read length distribution, coverage uniformity, and structural variant detection. Legacy manual and semi-automated gDNA kits exhibited substantial variability in yield (coefficient of variation (CV) >15%) and produced fragmented DNA with median fragment sizes typically below 20 kb, resulting in truncated reads and reduced sensitivity for detecting large deletions and rearrangements. In contrast, the MagMAX™ HMW automated workflow consistently produced DNA fragments >100 kb, with an average yield of 5 µg per sample and CV <1 across replicates; across sample types, 85% of fragments exceeded 40 kb and 75% exceeded 100 kb, enabling longer read lengths and higher variant concordance. The automated process supported batch processing of up to 96 samples in under two hours with less than 30 minutes of hands-on time, substantially reducing operator bias and inter-run variability. Overall, automating the MagMAX™ HMW DNA kit on the KingFisher™ instrument proved essential for preserving DNA integrity, improving reproducibility, and increasing throughput, enabling generation of high-quality HMW DNA that enhances read continuity, structural variant resolution, and data reliability—supporting more complete genomic profiling and accelerating translational oncology research.

#3239 Single assay, tumor-only, somatic SNVs, SVs, and CNVs profiling using nanopore adaptive sampling.

Sergey Aganezov[1], Philipp Rescheneder[2], Rory Sinnott[3], Sissel Juul[1]

[1]Oxford Nanopore Technologies, Inc, New York, NY,[2]Oxford Nanopore Technologies GmbH, Munich, Germany,[3]Oxford Nanopore Technologies plc, Oxford, United Kingdom

Background.
Tumor-only (T-only) testing often trades high sensitivity at low allele fraction (AF) - when using amplicon or hybrid-capture based enrichment - against comprehensive structural and copy-number profiling and overall ease of use, when using whole genome sequencing. Nanopore adaptive sampling (AS) enriches targets by rejecting reads during sequencing if they don't overlap with user-defined targets, yielding high-depth (100-200X) long read (8-15kb) data on target and shallow (5-15X and 500bp) sequencing off-target. As a result, AS simplifies experimental setup by not requiring PCR or pulldown-based enrichment, while at the same time enabling the detection of single nucleotide variants (SNVs), structural variants (SVs), and copy number variations (CNVs) in a single assay.
Methods.
Here, we evaluated variant calling accuracy for T-only AS on a highly aberrant genome (COLO829) and on a "synthetic," less-aberrant genome constructed in silico from COLO829 and its matched normal, retaining only a small number of large-scale CNV events. Performance was assessed across coverage/purity ladders that emulate common conditions. Sequencing targeted a generic multi-region, 700+ cancer-gene-aware panel augmented to cover a range of SV types present in COLO829. SNVs and SVs were inferred with long-read tumor-only pipelines. SVs included translocations, deletions, duplications, and insertions. Genome-wide CNV profiles were derived from the same AS datasets by leveraging off-target reads.
Results.
SNVs.
High (100-200X) on-target depth enabled confident recovery of somatic SNVs at relevant AFs, with high recall down to 0.05 AF and high precision down to 0.1-0.2 AF. These results were consistent across coverage/purity ladders.
SVs.
Long-read on-target data supported robust detection of inter- and intra-chromosomal rearrangements. Notably, events were recovered even when only partially overlapping with the target regions.
CNVs.
The high number of short off-target reads generated stable, genome-wide CNV segmentations from the same runs. Inferred CNV profiles demonstrated expected broad gains and losses on the highly aberrant genome as well as on the synthetic, less-aberrant construct across coverage/purity ladders.
Conclusions.
A single T-only nanopore AS run can (1) deliver sensitive SNV detection via high on-target coverage, (2) provide robust SV discovery, including one-breakend-on-target cases, and (3) yield genome-wide CNV profiles from off-target signal. By avoiding laborious panel-specific hybrid capture assays through simple software-defined targeting, AS offers a practical, streamlined, and highly flexible approach to single-assay tumor-only characterization that covers the full breadth of genomic variation found in cancer.

#3240 Altering is easy, engineering is hard: An automated platform for reproducible, high-fidelity genome engineering.

Travis J. Maures, Montse Morell

EditCo Bio, Redwood City, CA

CRISPR has enabled routine genome editing, but the lack of reproducibility across experiments, cell types, and laboratories remains a major barrier to translational applications. To address this, we developed an automated, industrial-scale gene-editing platform designed to minimize edit-to-edit variability and preserve genomic integrity across diverse cell types. The system performs thousands of concurrent genome-editing reactions under fully tracked and standardized conditions, minimizing batch effects, and ensuring consistent reagent handling and cell maintenance. This environment enables quantitative assessment of editing efficiency and quality across immortalized, primary, and induced pluripotent stem (iPS) cells, generating large-scale datasets that inform both product development and process improvement. Beyond the products and services created on this platform, EditCo Bio applies analytics generated from each project to learn from every edit. The resulting data guide the continuous evolution of our editing strategies and cell-maintenance processes. To demonstrate the analytical power of this approach, we applied the platform in a large-scale study of site-dependent homology-directed repair (HDR) efficiency across several hundred genomic safe-harbor sites in human iPSCs. By systematically varying donor design and chemical modifiers, we identified discrete genomic loci that reproducibly support high knock-in efficiency while maintaining cell viability. Expanded studies further revealed experimental conditions that promote recurrent structural genomic variations, including large deletions and rearrangements, which are undetectable by conventional short-read QC. The results of this work established methods, to (1) accurately measure these structural variations and (2), reduce their occurrence through optimized design and process control. Together, these findings describe an automated cell-engineering platform that transforms genome editing from an empirical procedure into a controlled engineering process.

#3241 High-fidelity whole genome sequencing from low-input FFPE samples: Enabling accurate tumor-informed MRD assay design through superior variant detection and uniform coverage.

Vanessa Process, Sushant Khanal, Madan Ambavaram, Sameer Vasantgadkar, Luca Beker, Alaina Villarreal, Jose Gil, Andrew Laneville, Martina Werner, Greg Endress, Ulrich Thomann, **Eugenio Daviso**

Covaris, LLC, Woburn, MA

Introduction: Tumor-informed Minimal Residual Disease (MRD) monitoring relies on the precise identification of patient-specific somatic variants from primary tumor tissue. However, these samples are frequently archived as Formalin-Fixed Paraffin-Embedded (FFPE) blocks, where DNA damage, fragmentation, and chemical modifications (e.g., cytosine deamination) compromise sequencing quality. Inaccurate baseline profiling can lead to the selection of artifacts as tracking targets or the omission of critical sub-clonal mutations, ultimately reducing MRD assay sensitivity. Here, we present a high-fidelity Whole Genome Sequencing (WGS) workflow optimized for low-input FFPE samples that minimizes amplification bias and artifacts, ensuring the generation of reliable genomic maps necessary for robust MRD target selection.

Methods: Genomic DNA was extracted from FFPE-processed NA12878 cells (FF12878) using the Covaris truXTRAC® FFPE SMART Kit with Adaptive Focused Acoustics (AFA®) technology to ensure active paraffin removal and rehydration. WGS libraries were constructed using the truCOVER® WGS Library Prep Kit with Amplification. The workflow was evaluated using DNA inputs ranging from 1 ng to 50 ng. Library performance was benchmarked against high-quality genomic DNA (NA12878) inputs (0.1 ng - 50 ng). Libraries were sequenced on an Illumina NovaSeq™ X Plus. Data was analyzed for coverage uniformity, duplication rates, and variant calling accuracy (F1 scores) for SNPs and INDELs using the GIAB truth set.

Results: The optimized workflow demonstrated exceptional sensitivity, generating high-complexity libraries from as little as 1 ng of FFPE DNA. Critical for MRD design, the method exhibited minimized GC bias, maintaining normalized coverage centered around 1.0 across 504 clinically relevant cancer genes (TSO500 panel), irrespective of input amount. This uniformity ensures that potential tracking mutations in difficult-to-sequence regions are not missed. Variant calling analysis revealed that the workflow effectively overcomes FFPE-induced damage; F1 scores for SNPs and INDELs in FFPE samples (5 ng) were comparable to those of high-quality gDNA (>0.91 for INDELs and >0.97 for SNPs). Furthermore, duplication rates were significantly controlled (~19% for 5 ng FFPE), maximizing the unique read depth required to validate low-frequency truncal mutations essential for longitudinal tracking.

Conclusions: We have validated a robust WGS workflow that unlocks archival FFPE tissues for high-fidelity genomic profiling, overcoming traditional barriers of low input and DNA damage. By delivering superior coverage uniformity and high variant calling accuracy, this solution provides the precise genomic baseline required for designing highly specific tumor-informed MRD assays

#3242 Integrated long-read target enrichment and comprehensive genomic profiling for hematologic malignancies using the SureSelect Cancer Pan Heme assay.

Brandyn Clark, Adam Janssen, Jeff Fox, Nedda Saremi, Kristi Stephenson, Kelle Hammock, Bahram Arezi

Agilent Technologies, Inc., Santa Clara, CA

Next-generation sequencing (NGS) has transformed cancer research, yet its effectiveness is often constrained by sample quality, tumor fraction, and limitations inherent to short-read sequencing—particularly in detecting structural variants, complex rearrangements, and alterations in repetitive or polymorphic regions. Long-read sequencing offers a solution, but cost and throughput challenges persist. To address these limitations, we developed a flexible, automation-compatible library preparation and target enrichment workflow that supports DNA inputs down to 200 ng, accommodates both enzymatic and mechanical shearing, and enables fast hybridization (90 minutes). Coupled with long-read sequencing and the SureSelect Cancer Pan Heme assay, this platform enables detection of main genomic alterations—including SNVs, indels, CNVs, and gene fusions—within a single assay. The SureSelect Cancer Pan Heme panel, codeveloped with Roswell Park Comprehensive Cancer Center, interrogates 359 DNA and 124 RNA genes, delivering integrated DNA/RNA analysis and overcoming the limitations of conventional single-analyte methods such as karyotyping, FISH, and PCR. Although in this study, we only focus on DNA as the substrate. We demonstrate high enrichment efficiency using a novel fast hybridization buffer, achieving on-target rates >80% for libraries with insert sizes up to 4-5 kb. Comparative analysis versus short-read approaches reveals superior coverage in challenging genomic regions using enriched long-read sequencing as well as allowing to phase variants. This solution offers a cost-effective, scalable, and rapid-turnaround workflow for molecular laboratories, advancing precision oncology in hematologic malignancies. For Research Use Only. Not for use in diagnostic procedures.

#3243 Investigating the value of testing for actionable alterations and circulating tumor DNA in breast and colorectal cancers.

Gargi D. Basu, Nick Johnson, Angela Deem, Judith Frederick, Terence Wong, Janine R. LoBello, Szabolcs Szelinger, Nishitha Therala, Mark Evans, Miriam Walker, Jean-Paul De La O

Exact Sciences Corporation, Madison, WI

Tumor molecular profiling may reveal distinct biological behaviors by identifying actionable alterations (AAs), informing precision oncology. However, the effect of molecular characteristics on ctDNA detection and monitoring is not well studied. Here, we evaluated patients with breast cancer (BC; all subtypes) or colorectal cancer (CRC) who received whole transcriptome and whole exome profiling with the OncoExTra® assay and assessment of circulating tumor DNA (ctDNA) status using the Oncodetect™ assay. The primary objective was to describe the frequency of AAs in BC and CRC overall and stratified by ctDNA status, tumor subtype, and clinical stage. In total, 88 patients were evaluated (42 BC and 46 CRC). All CRC patients and 41 BC patients (97.6%) had an AA identified, and 52.3% had an AA associated with FDA-approved therapy. All stage II-IV tumors (80 samples) and 6 of 7 stage I tumors (85.7%) had an AA. HR+/HER2- BC samples had AAs associated with approved matched therapy in 13 (54.2%) samples , which included *PIK3CA* mutations associated with alpelisib, capivasertib, and/or inavolisib (7 samples; 16.7%) and 1 *ESR1* alteration. *PIK3CA* mutations were present in 9 of 34 (26.5%) stage II/III CRCs, where aspirin therapy has been shown to improve survival. Within our limited cohort, AAs with approved matched therapies were found in 81.8% of stage I-II and 65.7% of stage III-IV CRC and were found in 31.3% and 36.0% of stage I-II vs III-IV BCs, respectively. Among ctDNA-positive BC samples, 27.6% had an AA associated with approved matched therapy vs. 46.2% in ctDNA-negative samples. For CRC, these frequencies were 62.1% and 82.4%, respectively. No association was found between any AA and ctDNA detection. Other AAs associated with FDA-approved therapies are listed in the table. Detection of AAs associated with FDA-approved matched therapy in approximately half of samples tested for ctDNA suggests it may influence therapy selection and disease management.

#3244 Rapid, one-tube sub 10-minute whole genome library prep for cfDNA.

Ben Krajacich, Seana Lymer, Kevin Green, Xiaodong Qi, Kyle Donohoe, June (Junhua) Zhao, Michael Previte

Element Biosciences, Inc., San Diego, CA

As next-generation sequencing (NGS) costs have decreased, it is increasingly more feasible to perform whole genome sequencing instead of a targeted approach to obtain more comprehensive genome information, better cover difficult regions, and provide insights for rare diseases. With increasing adoption of NGS, there is an emphasis on optimizing and streamlining the entire process, particularly library preparation and sequencing steps to reduce turnaround times and simplify workflows. Standard library prep has many complex and time-consuming steps such as end-repair, A-tailing, and PCR that increase barrier to entry for users, require specialized equipment, and can also induce unique errors to the final library. Additionally, each of these steps can also have impacts to the efficiency in which you convert input material into sequenceable library which may be critically limiting in material-limited applications. We have developed a new methodology for a rapid, one-tube, whole genome library prep prior to sequencing on the AVITI ™ platform. Through DNA fragmentation and single-adapter addition, this approach allows for highly efficient PCR-free library creation in under 10 minutes of total time, while maintaining the ability for paired-end sequencing chemistry through circularization on-instrument. We demonstrate the library prep workflow's efficiency on extracted gDNA (Coriell and *E.* coli, *H. influenzae*, and *R. palustris* bacteria to span content across GC ranges) and Horizon cfDNA material (Mimix Multiplex I cfDNA reference at 1-5% VAF). We found high conversion efficiency with <80ng of gDNA allowing for full AVITI24 ™ output of up to 1.5B reads, with high estimated library complexity. Additionally, when more depth per target is needed, we show compatibility of the fast, clean-up free workflow with our Trinity ™ technology which removes need for off-board washing and QC steps, allowing for library prep and enrichment within the timeframe of a standard NGS library prep (<2 hours). These techniques hold promise to streamline and integrate NGS preparation and sequencing while maintaining quality and reducing workflow burden.

#3245 Scaling liquid biopsy biomarker discovery: Multi-center, analytical validation of high resolution ctDNA profiling using TSO500 v2 on NovaSeq X Plus.

Gabriela Edwards Faret[1], Emmanuel Riviere[1], Silvie Franck[1], **Bart Tegenbos**[1], Lisa Van den Bossche[1], Joke Verbist[1], Lien Heyrman[1], Magdalena Lesnicki[2], Rachel Raz[2], Brian Chapman[2], Eric Harness[2], Jan Van de Velde[1], Dirk Goossens[1], Jurgen Del Favero[1]

[1]CellCarta, Antwerp, Belgium,[2]CellCarta, Naperville, IL

Illumina's TruSight™ Oncology 500 (TSO500) ctDNA v2 assay, enables comprehensive genomic profiling from plasma, allowing non-invasive, repeatable monitoring of tumor evolution during clinical studies. The assay covers a broad panel of 523 clinically relevant cancer genes and provides sensitive detection of key biomarkers such as SNVs, indels, CNVs, gene fusions, MSI, and TMB, all from a simple blood draw. Therefore, this RUO assay is well-suited for exploratory biomarker discovery, response monitoring, and mechanistic insights during immunotherapy and targeted therapy development without the need for fresh tissue biopsies.

A validation study was performed to characterize the analytical performance of TSO500 ctDNA v2 assay on the NovaSeq™ X Plus platform for comprehensive genomic profiling of 523 cancer-related genes in ctDNA. The assay was evaluated at two CellCarta laboratories (Antwerp, Belgium and Naperville, USA). Accuracy was assessed using reference materials with a variant allele frequency (VAF) threshold of 0.5% for SNVs and indels. Across both sites, the assay demonstrated >95% overall percent agreement for SNV, indel, CNV, MSI, and TMB results, with positive percent agreement >93.5% and negative percent agreement >95% for SNV, indel, and CNV (no negative reference materials were available for MSI and TMB). Precision assessments showed >97% concordance for intra-run, inter-run, and inter-operator comparisons across all variant classes.

Limit of detection verification confirmed 100% detection of SNVs down to 0.25% VAF, indels down to 0.5% VAF, and CNVs at >1.0 fold change. The optimal input for the assay was determined to be 20 ng ctDNA; however, evaluation of lower inputs (10 ng and 5 ng) demonstrated that while these samples did not consistently meet QC thresholds, SNV and indel detection remained robust, with >98% concordance for SNVs and >95% for indels. Lower input material may therefore be used for exploratory analyses, with the understanding that reduced coverage may limit detection sensitivity (potential false negatives) but does not introduce false-positive variant calls.

These results confirm that the TSO500 ctDNA v2 assay delivers reproducible, high-resolution genomic profiling across sites, supporting its applicability for exploratory biomarker analyses and longitudinal response monitoring in clinical studies.

#3246 SeqF™: evaluation of an affordable nanopore-based assay for decentralized tumor profiling.

Kimberly A. Holden[1], Roi Feingersch[2], Dvir Dahary[2], Margalit Feiger[2], Tal Havkin-Solomon[2], Benjamin M. Cohen[2], George Way[1], Shakti Ramkissoon[3], Marcia Eisenberg[3], Brian Caveney[3], Eric Severson[3], Taylor J. Jensen[3], Jonathan Williams[1]

[1]Labcorp, San Diego, CA,[2]Foresee Genomics, Bar Lev, Israel,[3]Labcorp, Durham, NC

Comprehensive genomic profiling (CGP) guides precision oncology, yet access remains limited in community and regional laboratories. SeqF is a Nanopore-based targeted sequencing workflow for low-throughput assays, utilizing the MinION™ device with standard molecular biology equipment and dedicated bioinformatic analysis software. SeqF was evaluated using 40 DNA samples, derived from clinical and reference specimens, with 20 samples analyzed in each of two targeted panels: EGFR-pathway (commercial off-the-shelf amplicon panel; 12 amplicons across 4 genes; ~1.5 kb total) and MPN (custom amplicon panel; 80 amplicons across 20 genes; ~35 kb total). Testing was performed in a clinical research and development laboratory. The wet-lab workflow comprises PCR-based target enrichment, sample indexing/barcoding, and incorporation of unique molecular identifiers (UMIs) for the EGFR panel only. Indexed libraries then undergo rolling-circle amplification followed by adapter ligation for Nanopore sequencing. Library preparation spans two days, followed by ~12-24 hours of sequencing (runs may be stopped early once coverage targets are met). The analysis pipeline is run via a user interface and involves base calling from raw sequencing reads (HAC in MinKNOW), followed by an automated pipeline that includes demultiplexing, consensus (error correction), alignment, variant calling, annotation, and QC. When compared to sequencing performed on Illumina instruments, and using paired tumor specimens, SeqF achieved >99.7% concordance for single-nucleotide variants at ≥5% variant allele frequency (VAF). Correlations between the measured VAFs (5-40%) in clinical samples and reference standards were ≥95% in both panels tested. The workflow demonstrated feasibility for small batch sizes and delivered robust analytical performance. The process was completed in under 72 hours, from extracted sample to VCF file and sequencing run QC report generation. SeqF enables decentralized tumor profiling with low infrastructure requirements and rapid results, potentially expanding access to precision oncology in community laboratory settings. The streamlined workflow and analysis pipeline may help democratize access to molecular diagnostics, ultimately improving patient outcomes through more timely and personalized treatment decisions. Future enhancements such as expanded panel content, broader UMI integration, and real-time variant interpretation will significantly increase the platform’s utility. This increased utility will enable scalable precision oncology across a wider range of cancer types and healthcare environments.

#3247 Origins of structural variant junctional insertions across >8,000 TCGA whole genomes.

Youyun Zheng[1], Gregory Raskind[1], Sophie Webster[1], Narmen Azazmeh[1], Haruna Tomono[1], Andrew Cherniack[1], David Lehotzky[1], Ron Solan[1], Antonia Kowalewski[1], Xavi Loinaz[1], Hansol Park[2], Vasuki N. Swamy[1], David Heiman[1], Samantha Van Seters[1], Saveliy Belkin[1], Sam Wiseman[1], Chunyang Bao[2], Luis A. Corchete Sanchez[1], Zachary Everton[1], Ryul Kim[2], Beomki Lee[2], Won-Chul Lee[2], Chip Stewart[1], Gengchao Wang[1], Brian P. Danysh[1], Young Seok Ju[2], Esther Rheinbay[1], Gad Getz[3], Rameen Beroukhim[1]

[1]Cancer Program, Broad Institute, Cambridge, MA,[2]Inocras, San Diego, CA,[3]Massachusetts General Hospital, Charlestown, MA

Double-strand break repair leaves recognizable footprints in the genome. Among the most specific are short sequences inserted at structural-variant (SV) junctions—templated insertions often attributed to polymerase-θ-mediated end joining (TMEJ). Yet common readouts based on exact string matches overlook sequence background, distance from the break, and the topological context of candidate templates, inflating false positives and blurring mechanistic interpretation. We present a scalable statistical framework that infers templated insertions with controlled specificity by modeling alignment-score distributions against a distance-adjusted, genome-wide empirical null. The approach explicitly accommodates imperfect copying and partitions candidate templates into four breakpoint-proximal configurations, capturing positional and strand relationships that are informative of mechanisms. Applied to large somatic and germline whole-genome cohorts, the method reveals that template usage spans all configurations but differs systematically across cellular contexts. A notable fraction of events reflect imperfect copying, consistent with error-prone synthesis, whereas one configuration shows comparatively higher apparent fidelity—suggesting distinct biochemical routes within a broader TMEJ-like landscape. Configuration calls also stratify SV architecture: some are enriched in simple rearrangements while others localize to clustered, complex regions, indicating that local topology and repair pathway choice are linked. Beyond structure, configuration-specific burdens align with DNA-repair states and selected genotypes: contexts consistent with homologous-recombination deficiency show enrichment in particular configurations, while others display the opposite directionality, underscoring that “templated insertion” is not a single phenomenon but a family of related processes with diverging determinants. To enable cohort-scale analysis, we optimized the core alignment to produce full score matrices in a single pass and packaged the workflow into a containerized pipeline, yielding order-of-magnitude speedups and portable reproducibility. Together, these results establish a configuration-aware, statistically principled readout of templated insertions that is robust to sequence confounders and informative about mechanisms. Practically, the framework provides (i) a sharper lens for studying double-strand break repair in human samples, (ii) leads for repair-state biomarkers, and (iii) hypotheses connecting SV topology to polymerase usage. In doing so, it aims to move the field from anecdotal sequence sketches toward reproducible, cohort-scale inferences about double-strand break repair involving junctional insertions.

#3248 Characterization of multiple myeloma genomes with LinkPrep assay enables detection of somatic variation and SV-driven interactions of the 3D genome.

Lisa Munding[1], Nathan Becker[2], Enze Liu[2], Alexander Fortuna[1], Jonathan Torchia[1], Aneta Mikulasova[3], J. Zachary Sanborn[1], Brian Walker[2]

[1]Dovetail Genomics, part of CantataBio, Scotts Valley, CA,[2]Myeloma Institute, Sylvester Comprehensive Cancer Center, University of Miami, Miami, FL,[3]University of Edenburgh, Edenburgh, United Kingdom

Multiple myeloma (MM) is characterized by its genomic complexity that includes recurrent driver single nucleotide variation (SNVs) alongside a high burden of structural variation (SV). Complete characterization of somatic variation in a MM genome is dependent on a technology that can accurately and sensitively detect both small and large variants. Here, we demonstrate performance of a novel linked-read approach, called LinkPrep™ technology, for high accuracy detection of both small and large somatic variants in four separate relapse MM genomes.Four MM patient-derived xenografts were profiled with Dovetail® LinkPrep™ kit and sequenced to ~30X on an Illumina platform. Data was analyzed through the Dovetail Analysis Portal to detect SNVs/Indels (DeepSomatic), CNVs (Purple), and SVs (HiC-breakfinder and proprietary tools). Call sets were compared against other genomics technologies including WGS (80X tumor/ 30X normal), PacBio (15X), and OGM (400X).LinkPrep + Dovetail Analysis Portal returned high quality variant results for the four MM samples. LinkPrep data recalled all pathogenic SNV/Indels detected by 80X WGS (notable pathogenic variants were detected in NRAS, KRAS, TP53). LinkPrep data further detected SVs involving the *IGH* locus (inversions and translocations) in all four samples. Deeper analysis of one sample (M24) highlights that LinkPrep data detects genetic alterations common in MM including SNV mutations in NRAS and TP53 (both occurring at 100% VAF), *IGH* rearrangements, chr 1q gain, chr 1p loss of heterozygosity, trisomy of chr 5,7, and 15, and complex rearrangements involving chromosomes 2, 3, 4, 16, and 19. With the exception of a confident subclonal (1% SV-VAF) unbalanced translocation detected by LinkPrep, the remaining LinkPrep large SV calls were validated by other genomics methods. Underscoring the capability of LinkPrep for SV detection, LinkPrep calls at 30X contain >10-100 times more read support for every SV call over other technologies. Using the linked-read feature of LinkPrep data along with CNV segment calls and SV calls provided through the Dovetail Analysis Portal a candidate solution is derived for the complex rearrangement involving chromosomes 2, 3, 4, 16, and 19. This LinkPrep solution, refined down to base pair resolution for every breakpoint, is verified by 400X OGM data. Uniquely, LinkPrep data further enables visualization of the SV-reconstructed 3D genome and reveals neo-loops connecting enhancers with promoters to suggest enhancer hijacking mechanisms associated with the complex rearrangement.Together, these data demonstrate that LinkPrep linked-reads enable improved characterization of somatic variation in highly rearranged genomes, while simultaneously detecting epigenetic states -- all enabled with the accuracy and cost-effectiveness of short read sequencing.

#3249 Extending a cfDNA-optimized library preparation workflow to mechanically sheared FFPE DNA for high-quality NGS data.

Sean Tighe, Owen Smith, Tiffany Truong, Tong Liu, **Elian Lee**, Esteban Toro, Siyuan Chen

Twist Bioscience, South San Francisco, CA

Formalin-fixed, paraffin-embedded (FFPE) tissues are a foundation of retrospective oncology studies but FFPE samples remain challenging for next-generation sequencing (NGS) due to DNA fragmentation, cross-linking, base damage, and highly variable yield. These factors impact library conversion and complexity and can introduce artifactual variants that confound low-frequency mutation detection. To address similar challenges in liquid biopsy, the Twist cfDNA Library Preparation Kit was engineered to deliver high conversion, high-complexity libraries from low-input cell-free DNA, leveraging an optimized end-repair/ligation chemistry with a Twist-engineered T4 DNA ligase. We demonstrate that this chemistry is well-suited for FFPE DNA that has been mechanically fragmented. Here, we evaluated the performance of the Twist cfDNA Library Preparation Kit on mechanically sheared FFPE control standards as well as FFPE DNA extracted from solid tumor blocks.

FFPE samples were processed and extracted, followed by acoustic mechanical shearing. Libraries were prepared with the Twist cfDNA Library Preparation Kit and Twist UMI adapter system followed by target enrichment with oncology-focused capture panels, before sequencing on Illumina instruments. Across FFPE samples of various DIN scores, the cfDNA-optimized workflow produced robust libraries at low input, with high adapter-ligation efficiency, improved library complexity, and uniform target coverage. Duplication rates and off-target reads remained low despite variation in FFPE quality. UMI-based consensus calling efficiently suppressed FFPE-associated artifacts, enabling confident detection of low variant allele frequency (VAF) somatic mutations that align with control expectations. Performance trends scaled favorably with decreasing input mass, supporting sequencing applications for limited, archival material.

These results demonstrate that a library preparation chemistry optimized for low-input, fragmented cfDNA can be effectively repurposed for mechanically sheared FFPE DNA. Combining standardized mechanical shearing with the Twist cfDNA Library Preparation Kit and target enrichment provides a unified workflow for liquid biopsy and tissue-based NGS, expanding the utility of Twist's library preparation and target enrichment solutions for sensitive variant detection in challenging oncology samples.

#3250 Comparative study of human and canine nerve sheath tumors in terms of morphology, prognosis, treatment, epigenetics, transcriptomics, and genomics.

Jace P. Landry[1], Angela D. Bhalla[1], Sharon M. Landers[1], Rossana Lazcano[1], Lindsay A. Parker[2], Tasha M. Miller[2], Noelle Niemi[2], Heather G. Lyu[1], Heather A. Lillemoe[1], **Emily Z. Keung**[1], Christopher P. Scally[1], Christina L. Roland[1], Kelly K. Hunt[1], John M. Slopis[1], Ian E. McCutcheon[1], Beth Boudreau[2], Heather Wilson-Robles[2], Alexander J. Lazar[1], Kunal Rai[1], Dominique J. Wiener[2], Brian W. Davis[2], Brandan Wustefeld-Janssens[2], Keila E. Torres[1]

[1]UT MD Anderson Cancer Center, Houston, TX,[2]Texas A&M University, College Station, TX

INTRODUCTION: Malignant peripheral nerve sheath tumors (MPNSTs) are aggressive sarcomas. An obstacle to treating MPNSTs is a lack of effective systemic therapies. Although over 70% of human MPNSTs have lost or inactivated the epigenome regulator polycomb repressive complex 2 (*PRC2*) (DeRaedt *et al*., *Nature*, 2014), its activity and contribution to canine PNST progression remain unclear.
METHODS: This study compared canine peripheral nerve sheath tumors (PNSTs) and human MPNSTs across biological and clinical features, including PRC2 activity. Immunohistochemical analysis was performed for a human tissue microarray of 54 neurofibromas and 139 MPNSTs, and 63 canine PNSTs for H3K27me3, a repressive histone mark deposited by intact PRC2, and H3K27ac, which increases globally upon H3K27me3 loss. To understand the genomic alterations present in canine PNSTs, we analyzed tumor mutation burden, copy number alteration, and transcriptomes of eight canine PNST/normal pairs.
RESULTS: The results suggested that H3K27me3 loss and associated gain of H3K27ac epigenetically drive human and canine tumors. This study provided evidence that human and canine PNSTs are clinicopathologically similar and may also be similarly driven by epigenetic mechanisms.
CONCLUSIONS: Further studies are warranted to evaluate whether these epigenetic deregulations alter similar gene signatures in humans and canine patients. The knowledge gained from this work advances our understanding of the molecular drivers of MPNST and informs potential therapeutics to evaluate in future clinical studies.

#3251 Insights from liquid biopsy testing in clinical settings: Analysis of an Indian dataset.

Urvashi Bahadur, Aarthi Ravichandran, Bhanumathy G, Sreelaksh Raju, Suhasini Narain, Kaushiki K, Kalainanghi Neelagandan, Anusha N J, Aishwarya Ramkumar, Saman Sajjad, Dhanashree A. More, Ramya Raviprakash, Tanvi Mathur, Srivathsan Adimoolam, Mahalakshmi Prakash, Divya Priya A, Anitha N R, Suruchi Aggarwal, Swetha Nayanala, Shanmukh Katragadda, Sameer Phalke, Vamsi Veeramachaneni

Strand Life Sciences, Bengaluru, India

While solid tumor profiling by tissue Next Generation Sequencing(NGS) is now undertaken routinely in the clinical setting, the availability and adoption of cell free (cf) DNA based NGS assays is limited in the Indian context. This retrospective study assesses the utility of liquid biopsy testing using a validated targeted panel in a clinical setting.A total of 495 plasma samples were analyzed for single-nucleotide variants, indels, copy-number variants, and gene fusions using a targeted unique molecular identifier (UMI) based 74-gene liquid biopsy panel. The panel covers all genes with a Tier 1 drug recommendation for therapy,and additional Tier 2 genes for prognosis or added clinical impact. Variants were assessed for clinical significance,and classified using AMP guidelines. Actionability was defined as the presence of Tier 1 or Tier 2 alterations with therapeutic, prognostic or diagnostic relevance.The most common tumor types tested were NSCLC (43.2%), colorectal cancer (12.1%), and breast cancer (10.1%), followed by hepatobiliary, prostate, pancreatic, and ovarian cancers. Overall, 61.4% of samples (304/495) harbored at least one actionable alteration, with Tier 1 variants detected in 26.5% of the cases. The mean number of alterations in actionable cases was 2.0. The overall actionability of 61.4% was comparable to the actionability obtained from a similar cohort of tissue samples analyzed on the solid biopsy version of this panel (68.3% of 621 cases), thus highlighting the sensitivity and high clinical yield of this panel. The actionability for each cancer type was high for certain cancers; NSCLC (62.1%; n=214), colon (56.7%; n=60), breast (70.0%; n=50) , hepatobiliary (57.6%, n=33, and carcinoma of unknown primary (46.4%, n=28). The most frequently mutated gene overall was TP53, detected in 36.36% of the cases.The distribution of the variant allele frequency (VAF) was also examined. Across 617 reportable events, VAFs ranged from 0.15% to 92.0%. The median VAF was 3.97%, and the 75th percentile was at 19.8%, consistent with the clinical settings in which liquid biopsy is used. 2% of cases had variants with VAF >75%, and these were all found to be in EGFR or TP53, suggestive of copy-number gains in these genes in late-stage disease. Additionally, ESR1 resistance mutations were detected in 11 of the 50 breast cases, underscoring the utility of liquid biopsy in detecting markers of acquired resistance.This analysis thus demonstrates that a compact, guideline-aligned ctDNA panel provides robust detection of clinically meaningful alterations across diverse solid tumors. High rates of actionability, together with the identification of resistance-associated events, support the value of liquid biopsy as a practical and informative tool for precision oncology.

#3252 Simplified genomic profiling using Aspyre Lung solves real-life challenges with limited and poor-quality tissue.

Elizabeth Gillon-Zhang[1], Eleanor Gray[2], Candace King[1], Ethan Clark[1], Cory Kiser[1], Mary Beth Rossi[1], Julia Brown[1], Ryan Evans[1], Katherine Knudsen[1], James Schaffernoth[1], Tatiana Yuen[1], **Magdalena Stolarek-Januszkiewicz**[2], Sophie Hackinger[2], Amanda Green[1], Kelly Pitts[1], Honey V. Reddi[1], Shari Brown[1], Barnaby Balmforth[2]

[1]Biofidelity Inc, Morrisville, NC,[2]Biofidelity Ltd, Cambridge, United Kingdom

Advanced NSCLC treatment guidelines recommend testing patients for genomic biomarkers to access over 30 FDA-approved targeted therapies. Challenges in NSCLC molecular testing include the need for assessment of multiple variants in both DNA and RNA, sample quality and quantity, cost, and clinical need for rapid turn-around time for timely treatment initiation (recommended <14 days). Aspyre Clinical Test for Lung (Tissue or Blood) is a targeted genomic profiling assay which informs on 114 actionable and prognostic biomarkers across 11 first-line genes (*ALK*, *BRAF*, *EGFR*, *ERBB2*, *KRAS*, *MET*, *RET*, *ROS1*, *NTRK1*/*2*/*3*) in patients with NSCLC. The novel assay uses standard PCR and real-time PCR equipment and interrogates nucleic acid directly without a capture step in a highly sensitive and cost-effective manner, enabling rapid and accurate clinical decision making. We present results from an initial cohort of clinical samples sent to Biofidelity Inc. Laboratory (a CAP/CLIA site). De-identified demographic and clinical data were analyzed including biopsy type, pathology diagnosis, tumor content, % necrosis, turnaround time, and variant identified. 177 clinical samples were analyzed, with retrospective, research and non-NSCLC samples excluded prior to analysis. 177 samples were eligible for inclusion. Diagnoses included adenocarcinoma (n=90), squamous cell carcinoma (n=34), unspecified NSCLC (n=49) and other (n=4). 20/177 samples were quantity not sufficient for one or more of tumor (n=11), DNA (n=6) or RNA (n=9); however, 177/177 samples passed internal assay performance checks for both DNA and RNA analysis (100%). Median tumor content was 40% (range 2-95%). Overall, 85 (47.8 %) of samples were positive for a variant, including SNV in *BRAF*, *EGFR*, and *KRAS*, *EGFR* exon 19 deletions and exon 20 insertions, insertions in *ERBB2*, *MET* exon 14 skipping and gene fusions involving *ALK*, *RET* and *ROS1*. QNS samples yielded nine variant calls of which seven were actionable. Of the samples with associated staging information, 32 were Stages I-IIIA (with 22 variant calls, 68.8%) and 30 were IIIB-IV (with 18 variant calls, 60.0%). 93.2% of samples were reported within the target two-day turnaround time (median 2, range 1-4). Aspyre Lung (Tissue) has a high assay success rate and proven rapid 2-day turnaround time, suitable as a cost-effective method for first-line or at relapse testing option, or for samples that are scant, of low quality, and can provide a large fraction of NSCLC patients with actionable biomarker information. Aspyre Lung Tissue simplified genomic profiling offers a new paradigm for informing cancer care management and enables more patients with NSCLC to benefit from effective and better tolerated targeted therapies.

#3253 A new workflow for FFPE tumor samples enables a streamlined solution for structural variant detection and phasing of somatic mutations through long read sequencing.

Camille Conner[1], Ian McLaughlin[1], Juniper Lake[1], Davy Lee[1], Heather Ferrao[1], Greg Endress[2], Ulrich Thomann[2], Martina Werner[2], Luca Beker[2]

[1]PacBio, Menlo Park, CA,[2]Covaris, Woburn, MA

INTRODUCTION: HiFi long-read sequencing provides highly accurate reads of fragments from 500 bp to 25,000 bp in length. These long reads offer an agnostic measure of sequence length and enable structural variant detection, phasing, and direct methylation analysis. However, FFPE tissue has been difficult for HiFi sequencing because extraction often yields short, damaged fragments and fixation crosslinks DNA which disrupts long-read sequencing.
METHODS: We applied the Covaris truXTRAC FFPE extraction by Adaptive Focused Acoustics (AFA) to recover long DNA fragments from FFPE blocks, including molecules up to 5000 bp. To maximize sequencing efficiency, we developed a Kinnex-based library preparation that concatenates multiple FFPE fragments into longer molecules. Kinnex involves PCR, which removes methylation information but preserves sequence quality and contiguity. The Kinnex for FFPE workflow requires 50 ng of input DNA per sample.
RESULTS: Brain, kidney, and uterine tumor FFPE samples were sequenced using this approach, generating more than 100 million HiFi reads per sample with mean read lengths of 750-1,500 bp. The resulting data showed high-quality reads and consistent variant detection across the genome. Variant calling detects >11,000 structural variants and >5.1M small variants per sample, with 60% of variants phased into haplotypes.
CONCLUSIONS: Combining Covaris long-fragment extraction with Kinnex library concatenation makes FFPE samples compatible with HiFi long-read sequencing. Using HiFi sequencing on samples prepared from Covaris-extracted DNA generated high yield sequencing libraries from FFPE samples across diverse tissue types demonstrating consistent performance across varying DNA quality and tissue cellularity. This workflow enables comprehensive analysis of archived tumor genomes, offering a more complete view of genomic variation and fragment characteristics from clinically relevant samples.

#3254 Gene profiling using whole genome analysis of bile tract cancer and its association with clinical factors.

Toshio Kokuryo, Masaki Sunagawa, Junpei Yamaguchi, Taisuke Baba, Takashi Mizuno, Shunsuke Onoe, Nobuyuki Watanabe, Mihoko Yamada, Shoji Kawakatsu, Tomoki Ebata

Division of Surgical Oncology, Nagoya University Graduate School of Medicine, Nagoya, Japan

Background: Bile tract cancer (BTC) is a malignant tumor with poor prognosis. The genetic background and molecular profiles of BTC remain poorly understood. Objective: To clarify the genetic diversity of BTC using whole-genome analysis and identify gene mutations as targets for novel diagnostic and therapeutic approaches.
Methods: Whole-genome sequencing was performed using paired tumor and normal tissue samples from 7 patients with BTC who underwent surgery at our institution. Somatic mutations were detected and annotated using snpEff. Oncoplot analysis visualized mutation accumulation patterns, and associations with clinical factors including lymph node metastasis, vascular invasion, neural invasion, portal vein invasion, and IPNB.
Results: On classification of detected somatic mutations, annotation revealed that intergenic region mutations (mean: 31,085, range: 26,588-39,135) were most frequent. Frameshift variants (mean: 16.7, range: 11-25), splice donor/acceptor variants (mean: 34.3, range: 17-45), and stop gained mutations (mean: 7.4, range: 2-10) were identified as important functional mutations. In addition, missense variants (mean: 529.4, range: 363-647) were also identified. Regarding nonsynonymous mutations, missense mutations were most common in variant classification, and SNPs (single nucleotide polymorphisms) were most frequent in variant type. Among SNV classes, T to G and C to T transitions were highly identified. Thirty genes, including MUC16 and MUC6, were identified with mutations in 3 or more of the 7 cases. Oncoplot analysis of these genes suggested that mutations accumulated more extensively and were associated with tumor mutation burden (TMB) in samples without vascular invasion. In contrast, no accumulation patterns of mutations were observed concerning lymph node metastasis, neural invasion, portal vein invasion, or IPNB. Among the genes (331 mutations, 321 genes) registered in The Cancer Genome Atlas (TCGA) bile duct cancer database, our study identified MUC16, OBSCN, and TP53. However, no overlap in their mutations was observed. It suggests extremely high genetic heterogeneity in BTC.
Conclusion: BTC is characterized by a high mutational burden and genetic diversity. An association between vascular invasion status and mutation accumulation was suggested. Gene profiling is considered important for personalized medicine, and the identified gene mutations may serve as potential targets for novel diagnostic and therapeutic approaches.

#3255 Long-read hybrid-capture based targeting of 95 known cancer genes detects large structural and complex variants with a simple bioinformatics workflow and an AI-based clinical interpretation solution..

Nathan H. Blewett, Megan Zais, Jingxiao Zhang, Jixin Deng, John DiCarlo, Jamie Hill, Christa Haldrup, Matthew Fosbrink, Jonathan Shaffer

Research & Development, QIAGEN Sciences, LLC, Frederick, MD

Short read sequencing has driven progress in identifying cancer-causing mutations ranging from SNPs to small indels. However, the ability to define complex mutations that span multiple kilobases is limited with traditional NGS approaches due to short read lengths. Targeted long-read sequencing, on the other hand, enables characterization of novel, complex mutations as long reads can span and be phased across large genomic regions. Long-read hybrid capture offers probe design flexibility for capturing targeted regions with unresolved structural variants. Here we describe the development of QIAseq xHYB Long Read Hereditary Cancer Panel and chemistry for detection of large structural variants in 95 known cancer driver genes.QIAseq xHYB Long Read Hereditary Cancer Panel and analysis pipelines were used to identify large structural variants in genes involved in cancer progression that human reference DNA were known to harbor. Libraries were prepared using enzymatic long-read fragmentation, after which targeted regions were captured with probes optimized for long DNA fragments. Captured DNA was amplified with chemistry developed for long, fast PCR and sequenced on both PacBio and Oxford Nanopore platforms. Real-time adaptive sampling was also used on the Oxford Nanopore platform to increase sequencing depth and improve uniformity. The resulting long-read sequencing data was mapped and large structural variants detected with CLC Genomics Workbench Lightspeed Module and Franklin by QIAGEN, a cloud-based, AI-powered platform that integrates the world's first open genomic community to power precision medicine at scale.The QIAseq xHYB Long Read probe design targets entire genes, including introns and UTR's, capturing extended regions of genes in an unbiased manner. Enzymatic fragmentation produced libraries with average read lengths of 4.5 kb. Sequencing eight QIAseq xHYB Hereditary Cancer Panel libraries from one capture pool on a Revio SMRTcell yields 30X average coverage, and uniformity greater than 95% of reads > 0.2X of the mean. Sequencing the same libraries on the Oxford Nanopore Minion platform resulted in 12X average coverage, and uniformity greater than 90% of reads > 0.2X of the mean. To increase Minion sequencing depth, we used real-time adaptive sampling to enrich for our target regions, which resulted in average of 30X coverage, and 93% of reads > 0.2X of the mean for 8 libraries on the Nanopore platform. Downstream analysis with CLC Genomics Workbench Lightspeed Module clearly identified the expected large structural variants in Coriell reference DNA, and subsequent clinical interpretation performed by AI-powered Franklin produced informative actionable conclusions from the structural variant reference DNA investigated.

#3256 Identification of germline variants associated with somatic mutational profiles in triple-negative breast cancer among African American women.

Guochong Jia[1], Jie Ping[1], Christine B. Ambrosone[2], John D. Carpten[3], Julie R. Palmer[4], Song Yao[5], Wei Zheng[1]

[1]Vanderbilt University Medical Center, Nashville, TN,[2]Roswell Park Cancer Institute, Buffalo, NY,[3]City of Hope, Duarte, CA,[4]Professor of Epidemiology, Boston University, Boston, MA,[5]Postdoctoral Res. Associate, Dept. of Cancer Prev. & Control, Roswell Park Cancer Institute, Buffalo, NY

African American (AA) women have a higher incidence of triple-negative breast cancer (TNBC) and are diagnosed at an earlier age than women of European ancestry, yet remain underrepresented in cancer genomic studies. We recently charted the mutational landscape of TNBC in 426 AA women. Here, we investigated the associations between germline variants and somatic mutational profiles in those patients.

Whole-exome sequencing was performed on germline and tumor DNA from 426 patients; 402 also had germline whole-genome sequencing or array data. We analyzed somatic mutation status of 49 TNBC or other cancer genes (>2% frequency) and mutational signatures present in>20% samples (SBS1, SBS2, SBS3, SBS5, SBS13, ID6, ID8, and a new indel signature characterized by longer indels ≥5 bp). Germline factors included 1) pathogenic variants at TNBC genes, 2) cis-variants within 500kb of somatic mutated genes, 3) polygenic risk scores (PRS) for TNBC and overall breast cancer in AA women, and 4) credible causal variants (CCVs) with posterior inclusion probability >0.8 at breast cancer risk loci. Pathogenic variants included 34 germline mutations identified in *BRCA1, BRCA2, PALB2,* and *CDH1*, which were classified as pathogenic or likely pathogenic by ClinVar (n=25) or nonsense/frameshift variants (n=9). Firth logistic regression and zero-inflated negative binomial regression were used, adjusting for age at diagnosis, mutation rate, tumor purity, stage, grade, carrier of pathogenic variant (in analyses for other germline factors), and top five germline genotype principal components.

There was no significant association of somatic mutations in the 49 genes with pathogenic variants, cis-variants, or CCVs at risk loci. Patients carrying pathogenic variants in *BRCA1, BRCA2, PALB2,* and *CDH1* were substantially more likely to exhibit SBS3 and ID6, two homologous recombination deficiency (HRD)-related signatures, with 15% (incidence relative ratio, IRR 1.15, 95% CI 1.03-1.28) and 48% (IRR 1.48, 95% CI 1.18-1.87) higher counts, respectively. PRS for TNBC showed no significant associations with mutational signatures. The PRS for overall breast cancer showed a nominally significant inverse association with SBS2 and SBS5 (P=0.01 and 0.02), which may be attributable to potential collider bias inherent to the case-only design. Although no CCVs reached significance after Bonferroni correction, the risk allele of rs6482189, a variant included in the PRS for overall breast cancer but not for TNBC, was associated with the new ID signature (IRR 1.33, 1.17-1.50, $P=7.93\times10^{-6}$).

In summary, this study this study examined germline-somatic relationships in TNBC among AA women, confirmed enrichment of HRD-related signatures in pathogenic variant carriers, and identified a breast cancer risk variant associated with a novel indel signature, offering insights into TNBC biology in AA women.

#3257 Improved Variantplex workflow reduces assay time and enhances sensitivity for acute myeloid leukemia targets.

David Knupp, Michael Washburn

Integrated DNA Technologies, Boulder, CO

Introduction: Acute myeloid leukemia (AML) is a hematologic malignancy with high mortality. Detecting AML minimal residual disease (MRD) throughout the patient's care continuum can be challenging. Anchored Multiplex PCR (AMP™) VARIANT*Plex* assay solutions have been previously used to assess mutations in AML samples; however, the need for faster and more sensitive assay solutions warrants the development of new chemistry workflows to deliver on the need to identify mutations at low variant allele frequencies (≤0.01% VAF) in AML MRD samples. To meet this need, we developed an optimized VARIANT*Plex* workflow to reduce assay turnaround time and increase sensitivity for AML-relevant targets.

Methods: Seraseq Myeloid Mutation Mix was spiked into Genome-in-a-Bottle DNA at frequencies of 1-0.01% and processed using the standard low allele frequency (AF) VARIANT*Plex* workflow and the new optimized workflow. The Archer panel utilized for prepping all samples was designed to target hotspots within 8 genes relevant to AML. Libraries were pooled and sequenced on multiple sequencing platforms. Data were analyzed with Archer Analysis v7.4 using targeted mutation files and customized filters to enhance variant identification in analytical sensitivity.

Results: The new VARIANT*Plex* chemistry workflow reduced total assay time from ~1.5 days to ~7 hours and decreased the number of required bead cleanups from five to three. Workflow improvements increased DNA-to-library conversion resulting in substantial increases to Unique On-Target reads that yielded >100% increase in unique base coverage across AML panel targets. Utilizing tailored PCR conditions for low variant identification also boosted assay performance. The newly developed VARIANT*Plex* assay solution identified the expected (7/7) AML-relevant SNVs/indels and FLT3-ITDs down to 0.01%, with full target space powered to at least 0.1% variant identification.

Conclusions: This improved VARIANT*Plex* workflow enables rapid, highly sensitive identification of AML mutations, supporting MRD identification applications.

#3258 Metatranscriptomic signatures in triple negative breast cancer.

Roshan Kumar[1], Golya Shahrokhi[1], Shafiq Shaikh[1], Sunday Negedu[1], Nicole He[1], Clayton C. Yates[2], Upender Manne[3], Akinyemi I. Ojesina[1]

[1]Medical College of Wisconsin, Milwaukee, WI,[2]Sidney Kimmel Comprehensive Cancer Center, Baltimore, MD,[3]University of Alabama at Birmingham, Birmingham, AL

Triple-negative breast cancer (TNBC) exhibits racial disparities, with women of African ancestry (AA) experiencing higher incidence rates compared to women of European ancestry (EA). To investigate these differences, we performed a comprehensive meta-transcriptomic analysis on TNBC tumor tissues from 17 AA and 19 EA women, using microbial transcript, gene expression and microRNA expression datasets. Hierarchical clustering revealed two distinct groups primarily separated by racial ancestry, with AA tumors exhibiting higher abundance of *Hafnia* and elevated MIR4707 expression, while EA tumors showed increased *Erwinia* levels and MIR1248 expression. Cellular composition analysis using xCell demonstrated that AA tumors had higher Th1 cell abundance, whereas EA tumors contained higher M2 macrophage abundance; particularly, AA women with high M2 macrophage levels experienced poorer disease-free survival (DFS) compared to EA women. Furthermore, we identified a significant association between elevated *SPDYE2B* gene expression, increased *Hafnia* abundance, and reduced DFS, highlighting complex host-microbe interactions. These findings reveal distinct microbial and immune profiles in TNBC tumors between AA and EA patients, with specific bacterial genera and immune cell populations showing ancestry-associated patterns that may contribute to observed disparities in disease outcomes.

#3259 Detection and functional assessment of extrachromosomal DNA amplifications in FFPE lung tumor specimens using Hi-C sequencing.

Kristin Sikkink, Blake Skrable, Alex Hastie, Anthony Schmitt

Arima Genomics, Carlsbad, CA

INTRO: Accurate detection of extrachromosomal DNA (ecDNA) has become increasingly important in oncology diagnostics, as ecDNA-mediated oncogene amplification drives aggressive tumor behavior, therapeutic resistance, and is associated with poor clinical outcomes. As the significance of ecDNA in tumor biology becomes clearer, sensitive methods for identifying and characterizing these structures are essential. Hi-C sequencing has emerged as a powerful approach for ecDNA detection, with our group first demonstrating accurate ecDNA identification from FFPE tumor specimens while others have developed Hi-C based tools for ecDNA detection, sequence reconstruction, and regulatory landscape analysis. Here, we leverage Hi-C to characterize the ecDNA landscape in advanced non-small cell lung cancer (NSCLC) tumors lacking other identifiable drivers by prior CGP analysis.
METHODS: FFPE samples from NSCLC tumors (n=97) were retrospectively selected from patients with Stage III/IV disease whose prior CGP showed no EGFR/RAS mutations or gene fusions (“driver-negative”). Hi-C sequencing was performed by Arima Genomics, and rearrangements, gene fusions, and CNVs (including ecDNAs and other amplifications) were identified with Arima-SV pipeline. Functional characterization of oncogenes on ecDNAs was assessed by IHC. FISH studies are ongoing to corroborate Hi-C based predictions of ecDNAs and other chromosomal amplifications (e.g. homogeneously staining regions (HSRs)).
RESULTS: 95/97 (98%) Hi-C libraries passed QC and were deeply sequenced and analyzed. 33/95 (35%) tumors had amplifications containing at least one oncogene. 13/95 (14%) tumors carried oncogene amplifications predicted to be extra-chromosomal, including those involving MYCL (1), NFIB (1), PDGFD (1), CCND1 (1), CCND3(1), CCNE1 (1), EGFR (2), ERBB2 (1), KRAS (1), FGFR1 (1), and MYC (2). The remaining 20/95 (21%) were predicted to be chromosomally integrated amplifications including CCND1 (1), FGFR1 (12), KIT (2), MDM2 (1), MET (1), MYC (1), NTRK1 (1), and NRG1 (1). Twenty-six tumors had sufficient tissue remaining for functional characterization and a corresponding commercially available IHC test for protein expression. Of these, 7/7 (100%) amplifications predicted to be extra-chromosomal were expressed at the protein level, whereas only 8/19 (42%) not predicted to be extra-chromosomal were expressed at the protein level.
CONCLUSIONS: These data demonstrate that Hi-C can detect ecDNA amplifications from routine FFPE lung tumor specimens and distinguish them from their chromosomally integrated amplification counterparts. This distinction is important because it correlates with amplified oncogene expression patterns and is necessary to inform clinical and translational research programs requiring precise understanding of underlying amplification mechanisms.

#3260 Development of multimodal comprehensive genomic profiling panel with on-flow cell hybrid capture.

Mariam Ashraf[1], Michelle Baird[1], Markus Storbeck[1], Xiaodong Qi[2], June (Junhua) Zhao[2], **Helene Bauby**[1], Zhong Wu[3], Jonathan M. Shaffer[1]

[1]QIAGEN, Inc., Germantown, MD,[2]Element Biosciences, Inc., San Diego, CA,[3]QIAGEN, Inc., Frederick, MD

Hybrid capture is a widely used technique for comprehensive genomic profiling (CGP) due to its ability to target large number of regions and allows for the simultaneous detection of multiple types of genomic alterations. Traditional hybrid capture workflows, however, are often time-intensive and technically demanding, requiring long hybridization time, multiple wash steps, and tightly controlled thermal conditions, all of which limit throughput and turnaround time.

The Element Biosciences AVITI^{TM} sequencer, featuring its Trinity^{TM} flow cell, introduces an integrated hybrid capture system that performs on-flow cell target capture, washing and eliminates post-capture amplification. This innovation reduces total workflow time and improves capture specificity, but also introduces new challenges for the relatively small CGP panel application due to the higher input requirements and lack of post-capture amplification.

To address this limitation, a hybrid capture-based, multimodal library preparation workflow with the QIAseq xHYB CGP panel was optimized for compatibility with the AVITI system and Trinity flow cell. This involved designing AVITI-specific adapters and index primers, as well as modification of hybrid capture and library preparation protocols to suit the Trinity platform.

Our study revealed that multimodal libraries prepared with AVITI-specific adapter and index are fully compatible with Trinity workflow. In addition, optimal CGP panel performance can be achieved by using a newly developed hybrid capture buffer at 71 °C for as low as 0.5 hour compared to traditional hybridization conditions of 60 °C for 16 hours. Furthermore, this workflow is compatible with both fresh DNA and FFPE DNA. Additionally, to achieve optimal Trinity output, we increased the yield of the standard multimodal workflow by implementing an enhanced amplification module. This involved increased amounts of primers and high-fidelity polymerase, along with optimized cycling conditions, resulting in a four-fold increase in library yield for both whole genome and whole transcriptome libraries. This optimized workflow enables robust CGP panel hybrid capture sequencing on the Trinity flow cell from low-input DNA, supporting small sample sets and expanding access to hybrid capture sequencing for low-throughput laboratories.

#3261 Evaluation of FFPE-extracted nucleic acid quality and performance from various commercial extraction kits using contrived multiplexed reference materials.

Dana J. Ruminski Lowe, Richard Howard, Serene Roque, Praveena Kamineni, Edward S. Davis, Andrew Anfora, Yves Konigshofer, Catherine Huang, Russell K. Garlick

LGC, Gaithersburg, MD

Next generation sequencing (NGS) assays and other advanced genomic techniques for tumor profiling require sufficient and high-quality nucleic acid input. Formalin fixed and paraffin embedded (FFPE) samples are a common, yet challenging type of patient sample often used in these tests. Often in clinical labs, the patient specimen is limited, so pre-analytical handling is critical; maximizing nucleic acid yield from the sample is important, but quality and performance in downstream assays cannot be sacrificed. Furthermore, labs must consider the workflow of the extraction system, ease of use, and processing time. Highly consistent, whole process reference materials can greatly facilitate method evaluation. Here we assess the yield, quality, and performance of nucleic acids obtained with industry leading FFPE extraction kits using various Seraseq FFPE standards. Normal human cells were engineered to carry DNA and/or RNA variants. Variant allele frequency (VAF) and concentration in the cells were verified using the Bio-Rad QX-200 Droplet Digital PCR (ddPCR) System. The cells were formalin fixed, embedded in paraffin blocks and sectioned at 10-micron thickness. Extraction was performed with various commercially available kits from QIAGEN, Promega, Beckman Coulter, and AutoGen. Yields were analyzed using Qubit kits and ddPCR. TapeStation assays were used to assess fragment size and quality. VAF and concentration were again measured by ddPCR as well as several NGS assays. Yields, quality, and fragment size were variable between extraction kits. Interestingly, yields determined using Qubit did not always correlate with those measured by ddPCR. Similarly, for some DNA variants, there was a discrepancy between VAFs measured by different extraction kits, which seemed to be related to the GC content of nearby sequences. Increasing the salt concentration of buffer used in the extraction process rescued coverage of variants with lower nearby GC% regions indicating some extraction conditions can be detrimental to accurate variant quantification. Assessing performance of all steps of a tumor profiling workflow, from extraction to variant calling, is imperative to ensure high sensitivity and specificity. Extraction of nucleic acids from FFPE is a critical step that can affect the ability of the assay to accurately detect all variants in a patient sample. As shown here, a consistent standard that is readily available and contains many variants of varying complexity can be an invaluable tool in extraction assessment and optimization.

#3262 Characterization of NGS reference standards for genetic and epigenetic content.

Jayanthi Ramprakash, Matthew G. Butler, Ojaswee Dahal, Colt W. Nash, Andrew T. Anfora, **Yves Konigshofer**

LGC, Gaithersburg, MD

Here, we provide a deeper genetic and epigenetic analysis of cell lines used in reference standards. Blends of tumor and donor-matched normal cell lines can be used to create reference standards for the development and analytical validation of diagnostics in oncology. The normal component is often used as the source of germline single nucleotide polymorphisms (SNPs) to assess copy number variation (CNV), allelic ratios, and loss of heterozygosity (LOH) in the tumor component, to identify additional somatic mutations, and to enumerate these somatic mutations to determine tumor mutational burden (TMB). By adjusting the ratio of tumor and normal components, it is possible to simulate different tumor fractions to establish limits of detection. In order to better characterize the cell lines that are used in TMB and homologous recombination deficiency (HRD) reference standards, we carried out shallow whole genome shotgun (WGS) sequencing to determine CNV and supplemented that with whole exome sequencing to assess allelic ratios and LOH. Epigenetic analyses were carried out to evaluate CpG methylation. Through this characterization, several of the cell lines used for TMB were found to harbor deletions in the region containing the genes MTAP, CDKN2A, and CDKN2B. In a HRD low-positive cell line, PTEN was found to be fully deleted and surrounded by a larger LOH region. In a HRD high-positive cell line, BRCA1 showed signs of CpG methylation in its promoter. In conclusion, these characterizations provide additional utility to existing reference standards.

#3263 Where sensitivity meets complexity: Electrophoretic assessment of genomic DNA integrity at low concentrations and for FFPE samples using DIN-based analysis.

Solange Borg[1], Isabell Priester[2], Annika Dorn[2], Tim Butler[3]

[1]Agilent Technologies, Inc., La Jolla, CA,[2]Agilent Technologies, Inc., Waldbronn, Germany,[3]Agilent Technologies, Inc., Santa Clara, CA

DNA quality is a critical metric of success in downstream applications such as next-generation sequencing (NGS). However, formalin-fixed paraffin-embedded (FFPE) tissues and low-input sources like dried blood spots and buccal swabs often yield fragmented or chemically modified DNA, complicating quality control and subsequent analysis. To evaluate the impact of various sample sources on sample quality and integrity, genomic DNA (gDNA) was extracted from whole blood, dried blood spots, buccal swabs, saliva, and two FFPE tissue types using various commercial kits. Samples were analyzed on an automated electrophoresis platform and a high-sensitivity assay providing a DNA Integrity Number (DIN) to quantify DNA quality. For all samples DIN values across a broad concentration range were successfully generated showing the varying levels of degradation patterns. DIN values were reproducible across replicates and concentrations, confirming assay robustness, however FFPE samples showed significant DIN variability depending on the extraction method. DIN-based electrophoretic analysis offers a reproducible and objective measure of gDNA integrity, making it suitable for low-concentration and degraded samples in genomics workflows requiring stringent quality control, such as NGS.

#3264 Epidemiology meets novel transcriptomics in poorly differentiated endometrial carcinomas.

Thulo Molefi[1], Motshedisi Sebitloane[2], **Zodwa Dlamini**[3]

[1]Medical Oncology, University of Pretoria, Pretoria, South Africa,[2]Discipline of Obstetrics and Gynecology, School of Clinical Medicine, University of Pretoria, Pretoria, South Africa,[3]Pan African Cancer Research Institute (PACRI), University of Pretoria, Pretoria, South Africa

Background: Endometrial cancer (EC) is the commonest gynecological malignancy in high-income settings and is traditionally divided into estrogen-related Type I and non-estrogenic Type II diseases. Type II histologies carry a poorer prognosis and have been under-characterized molecularly in African populations. South African EC data are sparse and largely extrapolated from international cohorts. This study addresses epidemiologic and transcriptomic gaps by profiling clinical outcomes and RNA-level alterations in South African women with epithelial EC, with emphasis on Black females and comparison to African American datasets.
Materials and Methods: Retrospective review of 290 electronic health records (2009-2019) from Inkosi Albert Luthuli Central Hospital to determine incidence, FIGO stage distribution, and survival for epithelial EC. Molecular profiling of 76 poorly differentiated FFPE tumor specimens: total RNA extraction, short-read RNA sequencing, alignment with STAR, quantification with featureCounts/StringTie. Analyses included differential gene expression ($|\log2FC| \geq 1.0$), alternative-splicing (ΔPSI), novel-isoform discovery, and Reactome pathway enrichment to define dysregulated pathways. Publicly available African American datasets were used for cross-population comparisons.
Results: Type II histologies comprised 47.9% of cases and aligned with advanced FIGO stage and median overall survival of 3.7 months. Transcriptome analysis revealed a dual signature: upregulation of MAPK/ERK and retinoic-acid pathways (e.g., MKNK2 +2.03 $\log_2$FC, RARA +2.14) alongside repression of RNA-Pol II transcription and cell-cycle regulators (e.g., ZNF793 −5.26, MYC −4.50). Exon-skipping in GJA1 and widespread intron retention marked splicing rewiring. StringTie uncovered novel lncRNA and zinc-finger isoforms (e.g., LINC01605), two layers absent from existing annotations. Cross-population analysis confirmed key shared drivers of the copy-number-high/p53-abnormal subtype, while novel splicing variants emerged as population-specific.
Conclusion: These findings validate the predominance and aggressiveness of Type II endometrial carcinoma in South African women. The study reveals unique transcriptomic and splicing landscapes in Black females that extend TCGA subtyping. Novel kinase and lncRNA targets (MKNK2, SRPK1, LINC01605) hold promise for tailored therapeutics. Integrating molecular classification into national guidelines, bolstering diagnostic infrastructure, and launching precision-medicine trials will be essential to narrow survival disparities and deliver equitable, biomarker-driven care.

#3265 An optimized WGS workflow for FFPE samples: Enabling high-confidence variant detection for MRD surveillance.

Bella Pfeiffer, Gabrie l Lipof, Alaina Villareal, Kristopher Amirault, Sameer Vasantgadkar, **Madan Ambavaram**, Vanessa Process, Sushant Khanal, Martina Werner, Greg Endress, Ulrich Thomann, Eugenio Daviso

Covaris, LLC, Woburn, MA

This study aimed to define a robust and synergistic workflow for FFPE-based whole genome sequencing (WGS) by evaluating how different extraction and library preparation methods impact coverage uniformity and the reliable detection of complex, actionable variants.Despite representing the vast majority of tumor specimens, formalin-fixed paraffin-embedded (FFPE) samples present significant DNA quality issues that challenge variant calling accuracy and limit their potential for whole genome sequencing (WGS) in precision oncology. Optimizing DNA extraction and library preparation is therefore essential to maximize WGS data quality from FFPE samples, particularly for sensitive applications like tissue-informed Minimal Residual Disease (MRD) monitoring. In this study, we evaluated the impact of different workflow combinations on WGS data quality. We compared libraries from four GIAB FFPE control samples (HG002/3/4/5) prepared using two extraction methods and two library preparation kits. This work expands on previous findings by including bioinformatic analysis of complex variants, coverage uniformity, and clinically relevant variant calling. Performance was assessed via: 1) precision and accuracy of large insertion-deletions (INDELs >16 bp), 2) genome-wide coverage uniformity, and 3) SNP/INDEL variant calling in clinically actionable Tier 1A gene variants. Our analysis of large INDELs (>16 bp) confirmed trends observed in small variant data. The combined Covaris extraction and library prep workflow demonstrated significantly higher precision and accuracy compared to other combinations. Analysis of genome-wide coverage distribution showed that the workflow produced superior coverage uniformity, with a lower coefficient of variation (CV) and a higher percentage of the genome covered. Regarding the calling of clinically actionable Tier 1A variants, the Covaris workflow again achieved the highest F1, precision, and recall. These analyses demonstrate that a workflow optimized for both extraction and library preparation provides a robust solution for FFPE-based WGS. This approach ensures higher data quality, more uniform genome coverage, and more reliable detection of complex and clinically actionable variants. This high-fidelity variant calling directly addresses a central challenge in FFPE-based precision oncology, providing the confident variant detection essential for applications including tumor profiling and MRD surveillance.

#3269 Rebalancing systemic and cellular energy dysmetabolism in Chronic Lymphocytic Leukemia through exercise training.

Uzma Zaheer[1], Ellie Miles[1], Angela Avramovska[1], Vithushan Srikumaran[1], Andrew Hulton[1], Long Li[1], Caitlin Jeary[1], Andrea Sitlinger[2], Renata Walewska[3], Barbara Fielding[1], David Bartlett[1]

[1]University of Surrey, Guildford, United Kingdom,[2]Duke University Medical Centre, Durham, NC,[3]University Hospitals Dorset NHS Foundation Trust, Dorset, United Kingdom

Introduction: Chronic lymphocytic leukaemia (CLL) cells abnormally express lipoprotein lipase (LPL), an enzyme typically restricted to adipocytes and myocytes for lipid-mediated energy utilisation. This enables CLL cells to store and utilise lipids, potentially competing with or diverting resources from healthy tissues. *In vitro* studies suggest that reducing fatty acid availability may limit CLL proliferation; however, little is known about how patients can modulate this process *in vivo*. Exercise training offers a systemic, non-pharmacological approach to counter metabolic dysregulation, with potential benefits for tumour control and overall health.
Methods: We conducted a 12-week exercise trial involving five treatment-naive (TN-CLL) and five previously treated (Td-CLL) patients. We assessed the metabolic fate of ingested lipids before (Baseline) and after (Post-Intervention) the program. Patients consumed a meal containing 200mg palmitic acid tracer (^{13}CPA), and blood samples were collected hourly for 3 hours (T_{0h}-T_{3h}). We assessed ^{13}CPA enrichment in plasma triacylglycerol (TAG) and non-esterified fatty acids (NEFA), and total fatty acids in immune cells (PBMC) using mass spectrometry, and data were analysed using RM-ANOVA.
Results: Post-meal ingestion, ^{13}CPA enrichment in plasma TAG and NEFA increased steadily from T_{1h}-T_{3h} ($p<0.001$). At Baseline T_{3h}, TN-CLL exhibited higher plasma ^{13}CPA-TAG and unlabelled PA-TAG incorporation than Td-CLL ($p<0.001$). Post-Intervention T_{3h}, TN-CLL ^{13}CPA-TAG levels decreased ($p<0.05$) and were no longer significantly different than Td-CLL. TN-CLL ^{13}CPA-NEFA enrichment increased post-Intervention compared to Td-CLL ($p<0.05$), suggesting enhanced ^{13}CPA-TAG hydrolysis. Similarly, ^{13}CPA uptake into PBMCs, which was higher in TN-CLL at Baseline T_{3h} ($p<0.05$), reduced Post-intervention.
Conclusion: This pilot study demonstrates the feasibility of stable isotope tracing to assess *in vivo* lipid uptake in CLL. Exercise training in TN-CLL patients reduced lipid uptake, suggesting a shift towards a more balanced and healthier metabolic profile. Further research is needed to determine whether exercise can disrupt the lipid dependence of CLL cells.

#3270 Leukemia induced cachexia is driven by dysregulated tryptophan metabolism resulting in inhibition of muscle regenerative capacity.

Alyssa Nicole Polski-Delve[1], Charlotte Hellmich[1], Paul Lonsdale[2], Trey Koev[3], Rebecca Maynard[1], Gwenaelle Le Gall[1], Timothy Pearson[2], Ulrike Mayer[2], Kristian Bowles[4], Stuart Rushworth[1]

[1]Metabolic Health, University of East Anglia, Norwich, United Kingdom,[2]Biological Sciences, University of East Anglia, Norwich, United Kingdom,[3]Chemistry, University of East Anglia, Norwich, United Kingdom,[4]Department of Haematology, Norfolk and Norwich University Hospitals NHS Foundation Trust, University of East Anglia, Norwich, United Kingdom

Cachectic muscle wasting occurs in many cancers but remains poorly defined in hematological malignancies. Leukaemia associated muscle loss is often exacerbated by chemotherapy, limiting treatment efficacy and presenting a poor prognosis, yet its mechanisms remain unclear. We aim to define drivers of leukaemia induced muscle atrophy, focusing on metabolic dysregulation. Using a syngeneic acute myeloid leukaemia mouse model in which C57/Bl6 mice received MN1-overexpressing cells intravenously, we observed significant weight loss independent of food intake. Gastrocnemius mass was significantly reduced in tumor-bearing mice compared to non-tumor bearing controls. H&E staining identified structural abnormalities and reduced fiber area. RNA seq followed by confirmation with RT-qPCR showed strong induction of atrophy genes TRIM63 and FBXO32, consolidating atrophy within our model. To assess muscle regeneration, we used a Pax7-CreERT2 reporter mouse model expressing tdTomato, allowing visualization of the satellite cells. Despite similar satellite-cell numbers in AML and controls, AML muscles displayed higher overall integrated density, indicating increased Pax7 expression and therefore satellite cell activation. However, centrally located nuclei were absent, revealing impaired regenerative activity. To define metabolic contributors, we performed NMR on serum. Tumor-bearing mice showed broad depletion of amino acids, however kynurenine pathway metabolites were strongly elevated. Metabolites of this pathway such as kynurenate and quinolinate have been linked to enhanced oxidative stress and aryl hydrocarbon receptor signaling that can impair muscle stem cell function and promote catabolism (Grishanova A. and Perepechaeva M. 2024). Due to altered amino acid levels and the RNA seq data, we examined transporter mRNA expression in the muscles and found significant upregulation of LAT1 during disease progression, which exchanges intracellular glutamine for branched-chain amino acids and tryptophan, the initial metabolite of the kynurenine pathway. Furthermore, cytokine profiling revealed multiple elevated atrophy-associated mediators, including GDF-15, IL-6, CXCL2, and CD14. IL17A was most elevated (7-fold), consistent with its reported role in lung cancer cachexia via JAK2/STAT3 signaling (Ying L. *et al* 2022). In summary, we have used a multi-omic approach to elucidate metabolic and cytokine changes that occur during leukaemia to drive cachexia. Future work will investigate the mechanism that drives these leukaemia-induced alterations to identify potential therapeutic interventions.

#3271 Integrated metabolic and cell-health profiling as a framework for defining cellular state.

Kayla Sylvester, Anthony C. Lauer, Gediminas Vidugiris, Donna Leippe, Jolanta Vidugiriene

Promega, Madison, WI

Defining cellular state requires understanding how multiple metabolic features change together, yet most assays capture only single parameters. We developed an integrated bioluminescent profiling strategy that measures coordinated metabolic and cell-health indicators from the same low-input sample, providing a practical way to resolve early pathway activity and cellular condition across immune and cancer systems. The approach uses a suite of luminescent assays to quantify ATP, NAD, total NADP(H), metabolic activity, and nutrient utilization including glucose consumption, lactate secretion, and malate accumulation. Together, these features report on glycolytic engagement, mitochondrial contribution, and redox balance, generating compact multiparametric profiles not achievable with isolated assays. In primary T cells, the integrated profiles distinguished early glycolytic, NAD-rich states linked to rapid expansion from more oxidative states associated with memory-biased phenotypes. These early metabolic patterns emerged within the first 72 hours of activation and aligned with later differences in proliferation and T cell-subset composition, demonstrating that early metabolic signatures capture functional trajectories beyond initial activation markers. In cancer-cell models, the same measurements resolved nutrient-dependent shifts in metabolic balance and stress adaptation, illustrating how environmental composition shapes pathway use and overall cellular fitness. The workflow uses standard luminescent instrumentation, minimal material, and is adaptable to additional metabolic markers as the platform evolves. By capturing coordinated metabolic and cell-health features within a scalable framework, this approach provides a practical way to define cellular state and relate early metabolic patterns to later functional behavior across diverse experimental contexts.

#3273 The mitochondrial protease YME1L regulates type 1 interferon signaling via the STING pathway in AML.

Yihe Zhang, Geethu Thomas, Rose Hurren, Yongran Yan, Marcela Gronda, Dakai Ling, Andrea Arruda, Mark David Minden, Aaron D. Schimmer

UHN Princess Margaret Cancer Centre, Toronto, ON, Canada

Yeast mitochondrial escape 1-like 1 (YME1L) is one of four mitochondrial ATP-dependent proteases responsible for maintaining mitochondrial proteostasis and is the sole ATP-dependent protease acting on substrates in the intermembrane space. Here, we investigated the expression and functional importance of YME1L in acute myeloid leukemia (AML).

YME1L protein was upregulated in 6 out of 7 AML cell lines and 17 of 23 primary AML patient samples compared to normal hematopoietic stem cells. Overexpression occurred equally across cytogenetic risk groups of AML. Moreover, high YME1L mRNA expression correlated with inferior 5-year overall survival in AML patients.

To evaluate the essentiality of YME1L in AML, we knocked down the protease in AML cell lines (OCI-AML2, NB4, TEX, and THP-1) with shRNA. YME1L knockdown decreased cell proliferation and clonogenic growth in all tested cell lines. Interestingly, YME1L knockdown did not induce cell death as measured by Annexin V/PI staining. Rather, YME1L knockdown induced AML differentiation as evidenced by increased expression of CD14, a marker of monocytic differentiation.

Depletion of YME1L with shRNA also reduced the engraftment of TEX cells and primary AML cells in the marrow of NSG immunodeficient mice.

To investigate the functional importance of YME1L depletion, we performed RNA sequencing of AML cells after YME1L depletion. Knockdown of YME1L upregulated genes associated with type I interferon (IFN) signaling, defense response to virus, and viral mimicry. We validated the results by real-time PCR and ELISA, confirming the upregulation of IFN-β, IFN-γ, ISG15, IFI44, and IFIT2 following YME1L knockdown. We demonstrated that activation of IFN signaling was secondary to activation of the cGAS-STING pathway as pharmacological inhibition of STING abolished the upregulation of IFN signaling after YME1L depletion. cGAS-STING signalling can be activated by the accumulation of double-stranded DNA (dsDNA) in the cytosol. We showed that YME1L knockdown promoted the leakage of dsDNA from the mitochondria into the cytosol. We also demonstrated that dsDNA leaked into the cytosol via the mitochondrial VDAC channel as treatment of AML cells with the VDAC channel inhibitor, VBIT-4, prevented the accumulation of cytosolic dsDNA and the upregulation of IFN signaling after YME1L knockdown in AML cells.

In summary, we demonstrated that YME1L is overexpressed in a subset of AML cell lines and primary patient samples and is required for AML proliferation and clonogenic growth. YME1L regulates the leakage of mtDNA into the cytoplasm, activation of the cGAS-STING-IFN axis, and controls AML differentiation. Thus, we have uncovered novel functions for the mitochondrial protease YME1L and suggest that targeting YME1L may be a novel strategy in the case of some AML patients.

#3274 Low-protein diet limits liver melanoma metastasis by enhancing natural killer cell function.

Anastasios Bampalis[1], Annalisa Altera[1], Katherine Hampton[1], Alyssa Polski-Delve[1], Charlotte Hellmich[1], Tabitha Barlett[1], Nilda Ilker[1], Matthew Markham[1], Catherine Chinnery[2], Gwenaelle Le Gall[1], Naiara Beraza[3], Stuart Rushworth[1]

[1]Norwich Medical School, University of East Anglia, Norwich, United Kingdom,[2]Haematology department, Norfolk and Norwich University Hospitals, Norwich, United Kingdom,[3]Quadram Institute, Norwich, United Kingdom

Liver metastasis represents a major clinical challenge across multiple cancer types, contributing significantly to patient morbidity and mortality due to the liver's unique immunometabolic environment that supports tumour growth. Low-protein diet (LPD) has been shown to reshape the immunological landscape of the liver and provide a protective phenotype against inflammation and infection. Here, we investigate the impact of LPD on the progression of metastatic melanoma. C57BL/6 female mice were fed *ad libitum* with an isocaloric control diet (22% protein) or with LPD (6% protein) for a duration of two or six weeks before experimental endpoints. Mice were injected with B16F10 melanoma cells intravenously two weeks before experimental endpoints. Nuclear magnetic resonance was used for the detection of metabolites in the liver, lungs and blood serum. Transcriptome analysis was performed on mRNA sequencing data obtained from lung and liver RNA. Flow cytometry was used to screen immune cell populations in the liver. LPD-fed mice showed an 87.5% reduction in melanoma metastatic modules in the liver ($p = 0.021$, Mann-Whitney U (MWU) test), while no reduction was observed in the lungs. Metabolite analysis in the liver identified 15 differentially abundant metabolites ($p.adj < 0.05$, MWU test) and pathway impact analysis (False Discovery Rate (FDR) < 0.05) with MetaboAnalyst identified 14 enriched pathways between the control diet and LPD. Tryptophan catabolism was down-regulated by LPD. Transcriptome analysis in the liver with DESeq2 identified 240 significantly upregulated and 244 downregulated genes in LPD ($|log2FC| > 1$ and $p.adj < 0.05$, Wald test). Gene-set enrichment analysis identified several pathways deregulated in LPD, including downregulation of Tryptophan metabolism, which confirmed our metabolite analysis. These results indicate a shift in immune cell function in the liver, with the Kynurenine pathway heavily impacted. We therefore examined liver immune cells by flow cytometry. Isolated immune cells from the liver showed a 25.2% ($p.adj = 0.012$, MWU test) increase in the Natural Killer (NK) cell ($CD45^+$, $CD3^-$, $NK1.1^+$) population between the control diet and LPD mice. These results suggest an immunological shift toward enhanced NK cell activity in the livers of LPD mice, potentially driven by reduced Tryptophan metabolism and consequently lower downstream Kynurenine levels. Because Kynurenine can result in downregulation of genes encoding NK-activating receptors, its reduction may help sustain NK cell activation. This heightened NK activity could contribute to the decreased number of metastatic melanoma nodules observed in LPD mice. Future work will focus on elucidating the mechanisms underlying this NK cell-mediated protective effect.

#3275 Dietary fiber intake modifies the bile acid metabolic profile in the DIET trial - A randomized double blinded dietary intervention study in melanoma patients receiving immunotherapy.

Yan Jiang, Yufan Qiu, Johannes Fahrmann, Ehsan Irajizad, Satabdi Saha, Nazli Dizman, Christine B. Peterson, Elizabeth M. Burton, Michael A. Davies, Nadim J. Ajami, Jennifer A. Wargo, Jennifer L. McQuade, Carrie R. Daniel-MacDougall

UT MD Anderson Cancer Center, Houston, TX

Background: Dietary fiber is associated with response to immune checkpoint blockade (ICB) in melanoma. We previously conducted the DIET trial (NCT04645680) which was a fully controlled feeding study comparing a high fiber versus a healthy control diet in melanoma patients receiving ICB. The trial revealed that high fiber diet is feasible and safe, and patients on high fiber diet demonstrated a numerically higher response rate. Herein, we report a secondary objective of the effects of dietary intervention on systemic metabolism.
Methods: Melanoma patients (n=45) initiating ICB were randomized (2:1), following a 1-week equilibration, to either a high fiber (30 g/d fiber ramped-up biweekly via whole foods to 50 g/d) or a healthy control diet (20 g/d fiber) for the study duration (up to 10 weeks). Longitudinal blood specimens were collected at baseline and at each infusion (when treated locally) for up to three cycles during the study. Sera from 43 patients were processed for untargeted metabolomics and bile acid (BA) profiling using LC-MS/MS methods. Current analysis focuses on comparison of paired samples from patients in the high fiber (n=6) and the control arm (n=8) collected during equilibration vs week 1-4, reflecting a dietary fiber 30-40 g/day in the high fiber arm.
Results: The untargeted metabolomics analyses revealed changes in BAs and glycine- and taurine- conjugated derivates to be reduced in the high fiber arm compared to control (Wilcoxon rank sum test $p<0.05$). Targeted BA profiling confirmed a decrease in unconjugated secondary BAs and secondary-to-primary BA ratios, which may influence anti-tumor immunity. Specifically, our findings suggest that dietary fiber reduced gut microbiota mediated biotransformation of secondary BAs (deoxycholic acid, lithocholic acid and ursodeoxycholic acid) from primary BAs (cholic acid and chenodeoxycholic acid). Conjugated to unconjugated BA ratios were also decreased in the high fiber arm, suggesting potentially reduced hepatic BA conjugation. Furthermore, in mouse avatar models of melanoma, fecal microbiota transplant was performed using paired fecal specimens (pre vs post high fiber diet) from participants in the DIET trial. Post-high fiber diet recipients showed improved ICB response and decreased secondary-to-primary BA ratios in the circulation (n=5) compared to pre-high fiber diet recipients.
Conclusion: Consistent with prior controlled feeding studies in other settings, our collective findings from circulating metabolites suggested that dietary fiber intervention modulates microbiome mediated secondary BA synthesis and conjugation linked to ICB response. These findings warrant further mechanistic studies in preclinical models and in larger cohort of patients.

#3276 Tracing and modeling lipid homeostasis to understand keratinocyte biology.

Zoya Y. Chih, Michael S. M. Mah, Matthew J. Kolar, Christian M. Metallo

Salk Institute for Biological Studies, La Jolla, CA

Dysregulation of metabolism contributes to the development and progression of many diseases, including cancer. Sphingolipids are bioactive lipids that mediate key cellular functions, such as signaling, apoptosis, and cell proliferation. Previously, we showed the role of serine metabolism in sensitizing tumors through altered sphingolipid biosynthesis to induce metabolic stress, thereby constraining tumor growth. Given the importance of serine, and other nonessential amino acids, in oncogenesis and lipid metabolism, our focus is to explore the tricarboxylic acid (TCA) cycle and sphingolipid metabolic flux in keratinocytes and how these may be dysregulated in cancer. To first evaluate sphingolipid biosynthesis in human keratinocytes, we performed flux measurements in media containing ^{13}C-serine and ^{13}C-glycine, which revealed decreased synthesis of ceramides and sphingomyelins in differentiated keratinocytes compared with undifferentiated keratinocytes. Stable isotope tracing with uniformly-labeled ^{13}C-glucose showed increased flux through the TCA cycle upon differentiation. These data highlight the distinct metabolic changes induced by differentiation and serve as a benchmark for future studies in defining TCA metabolic flux and acyl chain specific alterations to sphingolipid pools in non-melanoma skin cancer models.

#3277 Targeting cytosolic mutant IDH1 by hyperactivation to induce cancer cytotoxicity.

ZIQI Yu, Andrew Intlekofer

Weill Cornell Grad. School of Medical Sci., New York, NY

Somatic mutations in isocitrate dehydrogenase (IDH) enzymes are hallmarks of acute myeloid leukemia (AML), glioma, and several other cancers. Mutant IDH enzymes lose their normal function of catalyzing NADP(H)-dependent conversion of isocitrate to α-ketoglutarate (α-KG) and instead gain an abnormal new activity that reduces α-KG to 2-hydroxyglutarate (2HG), an oncometabolite that drives chromatin hypermethylation and blocks differentiation. Although FDA-approved inhibitors such as ivosidenib and enasidenib effectively suppress 2HG, fewer than half of patients respond, and resistance invariably develops. We discovered that genetic or pharmacologic hyperactivation, rather than inhibition, of mitochondrial mutant IDH2 triggers lethal metabolic toxicity that selectively eliminates IDH2-mutant cancer cells. Building on these findings, we hypothesized that hyperactivation of cytosolic mutant IDH1 could similarly cause toxic 2HG accumulation, redox imbalance, and selective death of IDH1-mutant cancer cells. To test this hypothesis, we engineered human cancer cell lines with inducible expression of hyperactive IDH1 mutants, which resulted in excessive 2HG production, metabolic dysfunction, and impaired cell fitness. In parallel, we found that activation of mitochondrial 2HG production in IDH1-mutant cancer cells triggers profound metabolic collapse, leading to impaired cell growth in vitro and in vivo. Together, these results suggest that direct or indirect hyperactivation of the mutant IDH1 pathway may represent a new therapeutic strategy --- targeting cytosolic IDH1 mutations by driving cancer cells beyond their metabolic limits.

#3278 Metabolic pathway signatures defining response to CD19 CAR T-Cell therapy in aggressive B-cell non-hodgkin lymphoma.

Melinda S.Y. Tan[1], Panwen Wang[2], Patrizia Mondello[1], Jacqueline Turner[1], Andre de Menezes Silva Corraes[1], Chen Wu[1], Zuoyi Shao[1], Kevin Regan[1], Ma Audrey[1], Arushi Khurana[1], Nora N. Benanni[1], Yucai Wang[1], Paul Hampel[1], Jonas Paludo[1], Saad J. Kenderian[1], Urshila Durani[1], Patrick B. Johnston[3], Jose Caetano Villasboas[1], Stephen M. Ansell[4], Ying Li[5], Haidong Dong[6], Hu Zeng[1], Yi Lin[7]

[1]Mayo Clinic, Rochester, MN,[2]Mayo Clinic, Scottsdale, AZ,[3]Hematology, Mayo Clinic, Rochester, MN,[4]Assistant Professor, Div. of Hematology, Mayo Clinic College of Medicine, Rochester, MN,[5]Mayo clinic, Jacksonville, FL,[6]Mayo Clinic College of Medicine and Science, Rochester, MN,[7]Asst. Professor, Div. of Hemat., Mayo Clinic, Rochester, MN

Chimeric antigen receptor (CAR) T-cell therapy achieves high response rates in relapsed/refractory aggressive B-cell non-Hodgkin lymphoma, yet only 40% of patients achieve durable remission. Identifying biological programs linked to long-term response remains critical. As metabolic fitness underlies T-cell persistence and effector function, we profiled metabolic pathways associated with clinical outcomes following commercial CD19 CAR T-cell therapy.

Single-cell RNA sequencing of peripheral blood mononuclear cells collected at baseline (BL), peak CAR-T expansion (PK), and one-month post-infusion (M1) was analyzed using CellRanger v7.0.1, immunopipe. Seurat v4.3.0 was applied for unsupervised clustering to delineate cell subsets based on top differentially expressed genes. Patients were categorized as durable complete remission (CR ≥6 months; n = 16), primary refractory (PD1; n = 4), or relapse after initial response (PD2; n = 12). Gene-set enrichment analysis defined metabolic pathway activity across T-cell, monocyte, dendritic cell (DC), and natural killer (NK) subsets.

Oxidative phosphorylation (OXPHOS) emerged as the dominant metabolic program distinguishing clinical outcomes. At BL and PK, OXPHOS was consistently enriched in PD1 relative to CR across T-cell, monocyte, and DC subsets, suggesting early oxidative activation in non-responders. By M1, this pattern inverted, with higher OXPHOS activity in CR. PD2 largely paralleled PD1, but several subsets including CD8 T central memory, classical monocytes TGFβ, intermediate monocytes CD38, monocytic myeloid-derived suppressor cell (mMDSC) HIF1A, and mMDSC SIRPA, showed OXPHOS enrichment in CR at BL and/or PK that persisted through M1. In contrast, DC and NK subsets exhibited the opposite pattern: OXPHOS was enriched in CR at PK (conventional DC 2 (cDC2), plasmacytoid DC (pDC), NK, proliferating NK), but shifted toward enrichment in PD2 at M1 (cDC2, NK, NK CD56bright).

Glycolysis (GLY) followed a similar trajectory in monocytes and NK cells, with enrichment in PD1/PD2 at BL and PK, followed by enrichment in CR at M1. In T-cells, PD1 maintained GLY enrichment from BL through PK, with no significant differences observed at M1.

The inositol-phosphate metabolism pathway showed a more static pattern and was consistently enriched in multiple PD2 effector and memory T-cell subsets without reversal at M1.

Taken together, these data reveal distinct, lineage-specific metabolic signatures that differentiate durable remission from early and late progression. Dynamic OXPHOS and GLY programming, characterized by lower activity early and enhanced activity at M1 in CR, may reflect adaptive metabolic programming that supports sustained antitumor immunity. Immune-metabolic profiling may therefore serve as a biomarker of response and highlight actionable metabolic pathways to enhance CAR T-cell durability.

#3279 Metabolomic profiling reveals plasma LPC as an indicator of systemic inflammation and immunotherapy response in squamous cell carcinoma.

Tomoyuki Iwasaki[1], Hidekazu Shirota[1], Eiji Hishinuma[2], Naomi Matsukawa[2], Yuki Kasahara[1], Hisato Kawakami[1]

[1]Department of Medical Oncology, Tohoku University Hospital, Sendai, Japan,[2]Tohoku Medical Megabank Organization, Tohoku University, Sendai, Japan

Cancer is increasingly recognized as a systemic disease characterized not only by local tumor growth but also by widespread metabolic and immunologic disturbances that shape disease progression and treatment response. To clarify systemic metabolic alterations associated with prognosis and immune checkpoint inhibitor (ICI) efficacy in squamous cell carcinoma (SCC), we conducted an integrated multi-omics analysis of plasma from 149 patients with advanced or recurrent esophageal or head and neck SCC. Targeted metabolomics quantified 635 metabolites, which were combined with detailed clinical, proteomic, and cytokine datasets. Weighted gene correlation network analysis revealed a single metabolite group—lysophosphatidylcholines (LPCs)—as most strongly associated with the Glasgow Prognostic Score, a marker of systemic inflammation and patient survival. Across nearly all measurable LPC species, plasma levels were markedly reduced in patients with elevated inflammatory burden and poor prognosis. LPC concentrations showed minimal correlation with tumor size, treatment line, or performance status, indicating that LPC reduction reflects host systemic conditions rather than tumor burden or treatment exposure. Survival analysis demonstrated that patients with low LPC levels had significantly shorter overall survival, with the strongest association observed in those receiving ICIs. Among ICI-treated patients, especially those treated in the first-line setting, low LPC levels identified individuals with minimal therapeutic benefit, whereas LPC levels were not prognostic in patients never exposed to ICIs. To explore the biological context of LPC loss, we analyzed plasma proteomic and cytokine profiles. Proteomic signatures in the low-LPC group revealed enrichment of pathways related to inflammation, innate immunity, and coagulation activation; levels of CRP, serum amyloid A, and other acute-phase reactants were substantially increased. Cytokine profiling demonstrated that low LPC levels were accompanied by elevated IL-6, IL-10, and TNF-α, further supporting the presence of systemic chronic inflammation. Conversely, chemokines such as CCL2 and CXCL8 were higher in patients with preserved LPC levels. Together, these multi-omics findings indicate that decreased LPC marks a systemic pro-inflammatory and immunosuppressive state that undermines antitumor immunity and reduces responsiveness to PD-1 blockade.

#3280 Rewiring glutamine metabolism restores osteoblast differentiation in multiple myeloma.

Mumtaz Shirin, Natalya N. Pavlova

Oncological Sciences, University of Utah, Huntsman Cancer Institute, Salt Lake City, UT

More than 80% of multiple myeloma (MM) patients are diagnosed with pathological bone fractures or osteolysis. Currently, no therapeutic strategies focus on restoring bone-building osteoblast cells in patients with MM osteolytic lesions. Metabolic rewiring in MM displays high glutamine dependence or “addiction”, leading to glutamine depletion from the local niche, the bone. Notably, glutamine is essential for driving commitment and differentiation into bone-building osteoblasts to meet the high anabolic demands. The mechanism by which the glutamine-dependent osteoblast progenitor cells sense and respond to glutamine depletion by MM is unexplored. In this study, we demonstrate that the polyglutamine tract of the key osteoblast-differentiation transcription factor, Runt-related transcription factor 2 (RUNX2), serves as the molecular sensor that is exquisitely sensitive to glutamine depletion and consequently inhibits osteoblast differentiation in a glutamine-deprived bone niche developed by MM. We assessed osteoblast differentiation using growth assay, gene expression analysis, and differentiation staining assays. Nascent mRNA translation was measured using a fluorescent reporter-based assay and an on-membrane assay. These systems were analyzed under glutamine depletion, rerouting, or with MM cells. Our findings demonstrate that the polyglutamine tract senses a glutamine deficit resulting from the uncharging of glutamine tRNAs, leading to the suppression of translation of nascent RUNX2 mRNA and, consequently, osteoblast differentiation. Deletion or shortening of the polyglutamine tract renders RUNX2 insensitive to glutamine depletion. Supraphysiological RUNX2 in glutamine-depleted osteoblast progenitors compromises cell fitness, suggesting an adaptive function for this sensing mechanism. Furthermore, in osteoblast progenitors, rerouting glutamine towards anabolic pathways restores nascent RUNX2 translation and osteoblast differentiation under glutamine depletion. We found that MM cells suppress osteoblast differentiation, which can be restored by rerouting glutamine in osteoblast progenitors. These findings demonstrate that the critical transcription factor RUNX2 possesses an in-built glutamine sensor, the polyglutamine tract, which enables it to adapt and make cell fate decisions in response to glutamine deficit. Rerouting glutamine in osteoblast progenitors to make glutamine available for differentiation represents a novel therapeutic strategy to restore bone formation in the MM bone niche.

#3281 Cardiolipin acyl chain remodeling is a therapeutic target in aggressive infantile embryonal brain tumors.

Evangelos Liapis[1], Allison Maas[1], Lea Maristela[1], Adele Ponzoni[1], Kelly O'Neill[1], Annupurna Pamreddy[1], Francesca M. Cozzi[1], Brent Harris[2], Tara Lozy[1], Derek Hanson[3], **Claire L. Carter**[4]

[1]Hackensack Meridian Center for Discovery and Innovation, Nutley, NJ,[2]Georgetown University, Washington, DC,[3]Hackensack Meridian School of Medicine, Hackensack, NJ,[4]Hackensack Meridian School of Medicine, Nutley, NJ

Background: Pediatric embryonal brain tumors that impact infants are highly aggressive CNS WHO grade 4 neoplasms with no standard-of-care. These encompass embryonal tumor with multilayered rosettes (ETMR), atypical teratoid rhabdoid tumor (AT/RT), group 3 medulloblastoma (MB-G3) and recurrent/metastatic sonic hedgehog medulloblastoma (MB-SHH). These tumors have low inter-tumoral genetic heterogeneity yet present with diverse histological features and developmental locations within the brain, which makes identifying therapeutic targets a challenge. The mechanisms driving therapeutic resistance for currently used treatment regimens are unknown. New and more effective treatments are urgently needed. Cardiolipins are mitochondrial-specific lipids, and their fatty acid composition has been shown to regulate mitochondrial structure and function. Despite the known functional significance of cardiolipins, their structure-specific accumulation in relation to mitochondrial phenotypes and cellular function in aggressive pediatric embryonal brain tumors remain ill-defined. Methods: Spatial lipidomic profiles in patient samples and 3D models were determined using mass spectrometry imaging. Cell proliferation and mitochondrial bioenergetics and dynamics were characterized using multiplex immunofluorescence (mIF), transmission electron microscopy, western blotting and metabolic assays. LCLAT1 KD was carried out using siRNA and inducible shRNA. Results: We detected a structure-specific accumulation of cardiolipins and increased expression of the cardiolipin acyl chain remodeling enzyme, LCLAT1 within proliferating tumor cells in patient samples and the 3D tumorspheres. The mitochondria in the proliferating tumor cells were fragmented and displayed a tubular cristae architecture. LCLAT1 KD in ETMR altered cardiolipin profiles, significantly reduced 3D tumorsphere growth, decreased Sox2 and N-Myc expression, increased p53 and p21 expression, and significantly increased LIN28A expression with a parallel increase in the early neuronal marker, doublecortin. Conclusions: Our findings provide novel insight into aggressive infantile embryonal brain tumor biology based on mitochondrial phenotypes and the fatty acid composition of the multifunctional mitochondrial-specific lipid, cardiolipin. We additionally showed evidence of a switch from a stem cell phenotype to upregulated neuronal differentiation pathways following CL fatty acyl chain remodeling in ETMR. Our findings underscore the intimate relationship between CL structure, mitochondrial phenotypes and embryonal brain tumor cell fate. On-going studies: Determine the *in vivo* and *in vitro* functional significance of cardiolipin acyl chain remodeling in ETMR and AT/RT, with a focus on LIN28A and differentiation pathways.

#3282 Metabolic reprogramming in Li-Fraumeni Syndrome underlies the pre-cancer niche and cancer predisposition.

Paula Rosanna Quaglietta, Ashby Kissoondoyal, Noel Wei Yang Ong, Nicholas Fischer, David Malkin

The Hospital for Sick Children, Toronto, ON, Canada

Li-Fraumeni Syndrome (LFS) is a hereditary cancer predisposition syndrome associated with germline mutations in *TP53* (mutp53). Mutp53 abrogates normal tumor-suppressive functions, including DNA repair, metabolism, and apoptosis. The accumulation of these effects, along with clonal expansion of metabolically reprogrammed cells, can enhance cell survival and adaptation to stress conditions, priming a pre-cancerous niche. We hypothesize that germline *TP53* mutations alter metabolism to promote a pre-cancerous primed state. Moreover, metabolic interventions can reverse this state to reduce cancer onset in LFS. LFS (*Trp53*$^{+/R172H}$) mice and wild-type (WT) littermates were followed across four age cohorts (60, 120, 210, 300 days) and treated with metformin-supplemented drinking water (1mg/mL) or left untreated. At endpoint, plasma, muscle, liver, kidney, spleen, thymus, and brain tissues were collected. Flow cytometry immune profiling was performed on spleen and thymus. All tissues were analyzed by LC-MS/MS untargeted proteomics and Seahorse metabolic assays. All statistics were performed in R. Splenic lymphocyte proportions did not differ between LFS and WT mice across development, however we did observe significantly different metabolic states ($p<0.05$). LFS mice expressed significantly higher metabolism-associated functional exhaustion markers KLRG1 and PD1 on NK cells and CD4+ T cells, respectively. Metformin treatment rescued this phenotype by significantly reduced PD1 expression on exhausted T cells (CD4+, CD8+, and CD4+CD8+ double-positive; $p<0.05$) in LFS mice. Tissue proteomics revealed key metabolic and developmental pathway differences in LFS mice, and the effect of longitudinal metformin on the pre-cancer niche. These pathways are being further validated through *in vitro* assays with patient-derived cells to help delineate the role of various cell types in LFS pre-cancer priming. We demonstrated that metabolic reprogramming occurs systemically in LFS to promote a cancer-primed state. Moreover, treatment with a metabolic modulator can aid in rescuing these changes, suggesting potential a potential cancer interception or treatment for LFS patients to revert the cancer priming phenotype.

#3283 Metabolic crosstalk between fatty acid oxidation and glycolysis underlies glioblastoma viability.

Lola Martinez Ibarguren[1], Fiorella Orsini Zanetti[1], Sofia Paz Osorio Rencoret[1], Maria Florencia Arbe[1], Marina Perona[2], Gabriela Salamone[3], Gerardo Martin Oresti[4], Pablo J Saez[5], Catalina Lodillinsky[6], **Marcela Solange Villaverde**[7]

[1]Universidad de Buenos Aires, Facultad de Medicina, Instituto de Oncologia Angel H. Roffo, Buenos Aires, Argentina,[2]Comision Nacional de Energia Atomica, Buenos Aires, Argentina,[3]Academia Nacional de Medicina, Instituto de Medicina Experimental, CONICET, Buenos Aires, Argentina,[4]Instituto de Investigaciones Bioquimicas de Bahia Blanca (INIBIBB, CONICET-UNS), Bahia Blanca, Argentina,[5]Universitatsklinikum Hamburg-Eppendorf (UKE), Hamburg, Germany,[6]Universidad de Buenos Aires, Facultad de Medicina, Instituto de Oncologia Angel H Roffo, Buenos Aires, Argentina,[7]Universidad de Buenos Aires, Facultad de Medicina, Instituto de Oncologia Angel H. Roffo, CONICET, Buenos Aires, Argentina

Metabolic rewiring supports glioblastoma (GB) progression, yet the contribution of fatty acid oxidation (FAO) to GB metabolic plasticity remains poorly defined. GB tumors display elevated expression of FAO-related genes, including carnitine palmitoyltransferase 1A (CPT1A), suggesting a potential reliance on this pathway. Here, we evaluated the functional relevance of FAO in U251 GB cells using etomoxir (ETO), a CPT1A inhibitor. ETO markedly reduced cell viability in monolayers (5-day exposure) and 3D spheroids (9-day exposure; IC50=118 µM) and rapidly disrupted spheroid architecture within 48 hours. Short-term treatment with 200 µM ETO did not alter cell size or granularity, but FAO inhibition induced a clear metabolic shift characterized by increased glucose consumption, elevated lactate release, and enhanced extracellular acidification, consistent with compensatory glycolytic upregulation. To test whether this adaptive response creates a metabolic vulnerability, we inhibited glycolysis with 2-deoxyglucose (2DG). Combined ETO+2DG treatment significantly potentiated cytotoxicity compared with either agent alone after 72 hours. These findings indicate that FAO serves as a relevant energy source in GB cells and that its inhibition triggers increased glycolytic flux as a compensatory mechanism. Together, our data reveal a targetable FAO-glycolysis crosstalk in GB and support the therapeutic potential of dual metabolic pathway inhibition to exploit GB metabolic flexibility.

#3284 CSF metabolomics reveals alterations in one-carbon metabolism and phosphatidylcholine abundance in a methotrexate-treated juvenile rat model.

Jeremy Willekens[1], Chadni Patel[1], Frank Diglio[2], Peter D. Cole[3]

[1]Pediatric Hematology/Oncology, Rutgers Cancer Institute of New Jersey, New Brunswick, NJ,[2]Rutgers Cancer Institute of New Jersey, New Brunswick, NJ,[3]Rutgers Cancer Institute of New Jersey, Montclair, NJ

Background:Although typically curative, treatment for pediatric acute lymphoblastic leukemia (ALL) is associated with neurotoxicity and leads to chemotherapy-related cognitive impairment (CRCI) in 40-70% of survivors, significantly impacting their quality of life. Methotrexate (MTX), a key component of ALL chemotherapy regimens, is a major contributor to CRCI. Using cerebrospinal fluid (CSF) metabolomics, our previous work showed that pediatric patients undergoing chemotherapy exhibited alterations in lipid metabolism, particularly phosphatidylcholines (PC). However, because ALL chemotherapy involves multiple agents, the specific contribution of MTX to these metabolic alterations remains unclear.
Experimental procedures:Using a juvenile rat model designed to isolate MTX-specific effects within a pediatric-relevant context, we administered six intraperitoneal (0.5 mg/kg per dose) and four intrathecal (1 mg/kg per dose) MTX injections between 3 and 8 weeks of age. To characterize MTX-induced metabolic changes, we performed CSF metabolomics at the time of the first intraperitoneal injection and at the fourth. Five weeks after the last injection, we assessed whether MTX exposure impaired spatial and visual memory using Object Placement (OP) and novel Object Recognition (OR) behavioral tests, respectively, in comparison to PBS-treated controls.
Results:MTX-treated rats exhibited spatial and visual memory impairments compared with controls. In accordance with our previous results and MTX's mechanism of action, determinants of one-carbon metabolism were downregulated in the CSF of MTX-treated animals over time. This includes S-adenosylmethionine (SAM, FC = 0.36, p-adj = 0.02) and methionine (FC = 3.24E-06, p-adj = 6.41E-06). In contrast, transsulfuration pathway metabolites such as cystathionine (FC = 3.98, p-adj = 0.001) and cysteine (FC = 2.81, p-adj = 0.02) were upregulated. Last, MTX treatment also induced alterations in lipid metabolism compared to controls, with a significant over-representation of 8 plasmalogens and 9 PC, consistent with our findings in the CSF of pediatric ALL patients undergoing chemotherapy.
Conclusion:Although in use for more than eight decades, neither the mechanism of action nor the side effects of MTX are fully understood. Preclinical models therefore remain instrumental for defining MTX's contribution to chemotherapy-related neurotoxicity. This work, together with our recent findings in humans, demonstrates that CSF metabolomics may enable the early identification of patients at risk for CRCI through predictive biomarkers and guide future neuroprotective interventions.

#3285 Itaconate acts as an oncometabolite to drive lethal pediatric ependymomas.

Siva Kumar Natarajan[1], Joanna Lum[2], James Haggerty-Skeans[3], Minal Nenwani[2], Sanjana Eyunni[2], Mateus Mota[3], Jill Bayliss[3], Akash Deogharkar[1], Erin Hamanishi[1], Simon Hoffman[1], Eleanor Young[2], Qiuyang Zhang[2], Rijul Mehta[1], Abhijit Parolia[1], Peter Sajjakulnukit[2], Robert Doherty[1], Carl Koschmann[4], Arul M. Chinnaiyan[2], Costas Andreas Lyssiotis[2], Deepak Nagrath[2], Sriram Venneti[3]

[1]Pathology, University of Michigan Medical School, Ann Arbor, MI,[2]University of Michigan, Ann Arbor, MI,[3]University of Michigan Medical School, Ann Arbor, MI,[4]Univ. of Michigan Health System, Ann Arbor, MI

ZFTA-RELA ependymomas are highly aggressive brain tumors with significant mortality. These tumors are characterized by the oncogenic fusion of a putative chromatin remodeler ZFTA and the NFκB effector RELA. Using a comprehensive metabolic screen, we discovered that ZFTA-RELA cells generate itaconate, a metabolite linked to the TCA cycle. Although itaconate is a well-known immunomodulatory metabolite produced by macrophages, its production and function within tumor cells have been unclear. We found that itaconate is synthesized by Aconitate Decarboxylase-1 (ACOD1), and that ZFTA-RELA induces ACOD1 expression in an NFκB-dependent manner. Itaconate production in turn supports a coupled metabolic-epigenetic feed-forward loop that sustains pathogenic ZFTA-RELA fusion expression through H3K4me3-dependent, epigenetic activation. To provide the metabolic input required for itaconate synthesis, ZFTA-RELA tumors suppress *PTEN* expression to activate PI3K/AKT signaling pathway. The increased glutaminolysis in these tumors supplied the carbon needed for itaconate generation. As a result, inhibiting glutamine metabolism reduces pathogenic ZFTA-RELA levels and shows strong therapeutic efficacy in multiple in vivo models. Moreover, combining glutamine antagonists with PI3K/mTOR inhibitors prevents spinal metastasis. Overall, our findings show that ZFTA-RELA ependymomas hijack the macrophage-associated itaconate metabolic pathway to epigenetically reinforce expression of the ZFTA-RELA fusion driver, identifying itaconate as an oncometabolite. These results highlight itaconate upregulation as an unrecognized driver of ZFTA-RELA ependymoma and point to new therapeutic avenues for children affected by this devastating disease, while broadening our understanding of oncometabolites as a distinct class of cancer dependencies.

#3286 The Warburg hijack of myeloid immunity via mitochondrial dysregulation in glioblastoma.

Chun Wai Aeon Kwok, Karrie Mei Yee Kiang, Gilberto Ka Kit Leung

Department of Surgery, The University of Hong Kong, Pokfulam, Hong Kong

This study aims to illustrate how the Warburg effect drives glioblastoma (GBM) growth and development by dysregulating myeloid mitochondrial dynamics and evading myeloid immunity in the lactate-rich environment. The myeloid immunity is often reprogrammed and suppressed by GBM. A major driver is the lactate-rich, glycolysis-preferred metabolic tumor microenvironment (TME) established by the Warburg effect. Recent studies suggest that the Warburg metabolism shifts tumor-associated myeloid cells (macrophages and microglia) towards an anti-inflammatory, pro-tumorigenic phenotype and promotes glioblastoma growth by immunosuppressing local myeloid defence. Here, we investigate the interplay between the high-lactate acidic TME and myeloid evasion, with a specific focus on lactate-induced disruption of mitochondrial dynamics. We re-analyzed publicly available bulk RNA-sequencing data (GSE216070) from four GBM samples with and without pharmacological lactate inhibition. Glycolytic activity and M2-like myeloid polarization scores were calculated as the mean $\log_2(CPM+1)$ expression of curated hallmark gene sets. The Warburg signatures were then correlated with gene sets reflecting reactive oxygen species regulation and inter- and intra-cellular mitochondrial dynamics. The analysis deciphers how lactate-driven metabolic rewiring of myeloid mitochondria contributes to GBM invasion and immune escape. To further understand how the Warburg effect orchestrates myeloid evasion in GBM, we propose to perform lactate pre-treated, vitamin C (lactate inhibitor) pre-treated and control myeloid cell cultures, then compare their pro-tumorigenic ability via conditioned medium in GBM proliferation and temozolomide chemoresistance assessment. In addition, the pre-treated myeloid cells will be seeded on the opposite side of μ-Dishes with GBM cells in between, to observe if there is any preferential growth or invasion towards either side under live-cell confocal imaging. The mitochondrial dynamics of the pre-treated cells will also be studied through Western blot and flow cytometry. Preliminary results showed high levels of M2-like immunosuppression, reactive oxygen species mechanism and mitochondrial dynamics and surveillance under the Warburg glycolysis environment. With the poor overall survival rate of high-LDHA patients from the Kaplan-Meier curve, the Warburg metabolism serves as a promising therapeutic target. Our study elucidates how Warburg metabolism promotes GBM immune evasion and invasion by inducing mitochondrial dysregulation in brain myeloid cells via the lactate-rich tumor microenvironment.

#3287 Mitochondrial biogenesis fuels the energetic demands of grade 2 meningiomas.

Stella G. Cavalcante[1], Benedito J. A. Pereira[1], Antonio M. Lerario[2], **Sueli M. Oba-Shinjo**[1], Suely Kazue Nagahashi Marie[3]

[1]Neurology, University of Sao Paulo, Faculty of Medicine, Sao Paulo, Brazil,[2]Internal Medicine, University of Michigan, Ann Arbor, MI,[3]University of Sao Paulo, Sao Paulo, Brazil

Meningioma is the most common primary intracranial tumor, accounting for 37.6% of all brain tumors, and is predominantly classified as grade 1 (G1) or 2 (G2). While G1 tumors typically follow a benign clinical course, G2 meningiomas are more aggressive and exhibit higher recurrence rates. Despite their clinical relevance, the metabolic features of G2 meningiomas - particularly the contribution of mitochondrial function - remain poorly defined. Mitochondria, the cellular powerhouses responsible for ATP production, are essential for meeting the elevated metabolic demands of tumor growth. Prior transcriptomic studies suggest that G2 meningiomas exhibit enhanced oxidative metabolism, cell division, and motility. The objective of this study was to identify mitochondrial components that support the bioenergetic requirements of G2 tumors. Transcriptomic analysis revealed elevated expression of TFAM, the master regulator and protector of mitochondrial DNA (mtDNA), in G2 compared to G1 meningiomas. Its transcriptional coactivator PGC1-α (encoded by *PPARGC1A*) was also upregulated, and both genes demonstrated a strong positive correlation, suggesting that the TFAM/PGC1-α axis may drive increased mtDNA copy number in G2 tumors. Immunostaining confirmed grade-specific TFAM localization, with G2 tumors displaying more diffuse cytosolic distribution. Furthermore, G2 meningiomas showed increased mitochondrial activity, evidenced by upregulated mitoribosomal gene expression and activation of oxidative phosphorylation and tricarboxylic acid cycle pathways. Collectively, these findings indicate that the TFAM/PGC1-α/mtDNA axis is activated in G2 meningiomas, potentially enabling the elevated energy production needed to sustain their increased proliferative and migratory capacity.

#3288 Spermine enhances oxidative phosphorylation independently of translation in glioblastoma.

Alexandra Carbone, Tim Horton, Ayush Rana, Scott Welford

Cancer Biology, University of Miami Miller School of Medicine, Miami, FL

Glioblastoma (GBM) is the most aggressive and lethal primary malignant brain tumor, with a mean survival of only 15 months, emphasizing the need for novel therapeutic strategies. Polyamines, small positively charged molecules necessary for cell proliferation, are frequently dysregulated in multiple cancer types, including GBM. Despite this, their distinct role in tumorigenesis has not been well characterized. There are three major polyamines: putrescine, spermidine, and spermine. Putrescine is converted into spermidine, which is further converted into spermine. The role of spermidine has been well defined, as it serves as a precursor for eIF5a-deoxyhypusine, which undergoes hypusination to promote translation of growth factors. Spermine Synthase (SMS), the enzyme that catalyzes the conversion of spermidine to spermine, is upregulated in high-grade gliomas. Preliminary data suggests that SMS is necessary for GBM tumor development and growth, supporting the idea that polyamine metabolism can be a targetable vulnerability in GBM. However, the specific role of spermine, the product of SMS, in GBM remains unknown. We hypothesize that spermine has distinct, non-redundant cellular functions in GBM and aim to elucidate its role using a CRISPR-mediated autochthonous mouse model of GBM. In this model, a plasmid encoding Cas9 and guide RNAs targeting the tumor suppressors PTEN, P53, and NF1 along with polyamine-related genes of interest are introduced into mouse embryos via intrauterine electroporation (IUE), leading to GBM tumor development. Utilizing this system, we have found that SMS knockout (KO) significantly inhibits GBM growth *in vitro* and *in vivo*. Interestingly, supplementing physiological concentrations of spermine failed to restore cell viability and oxidative phosphorylation (OCR) in SMS KO cells, while wild-type cells exhibited a robust increase in OCR upon spermine supplementation. Further investigation revealed spermine enhances OCR independently of translation, suggesting that it may function through a post-translational modification (PTM) mechanism. Ongoing studies aim to further characterize the role of SMS and spermine in GBM metabolism and tumor growth. These findings suggest that spermine is a critical regulator of GBM development and progression and may offer a novel metabolic target for therapeutic intervention.

#3289 Lipid metabolic rewiring in cancer: A proteomic insight into new axis of therapeutic vulnerability.

Sivasubramani Narayanan, Poorvi Subramanian, Afsana Parveen Jahir Hussain, Natarajan Aravindan

Oklahoma State University, Stillwater, OK

Lipid metabolism plays a pivotal role in cancer progression, influencing cellular energy balance, membrane synthesis, and signaling pathways that drive proliferation and survival. Our previous findings state that in neuroblastoma (NB), a lethal pediatric tumor, loss of retinal degeneration protein 3 (RD3) leads to increased lipid droplet accumulation. Importantly, our studies also found out that RD3 loss in NB results in increased tumor aggressiveness and metastasis, consequent poor clinical outcome of patients. However, the molecular mechanisms underlying the metabolic shift and tumor progression in NB remain unclear. Herein, we investigated the mechanism behind the RD3-dependent metabolic reprogramming in NB by assessing the directed proteomics shift. Proteomic profiling was performed using NB patient-derived clones during diagnosis (CHLA-15, CHLA-42) those harbor high RD3, and in their reverse-engineered (RD3 stably knockdown) counterparts. Global proteomics was performed using DIA on an Orbitrap Exploris 480 (Ideaproteomics) applying statistical (log_2 fold change, $-log_{10}$(Padj) FDR correction) considerations. Functional mapping was performed, and differential expression was realized using Omics Playground V4 (BigOmics analytics). Our findings demonstrate that RD3 knockdown induces a pronounced adipogenic signature in NB. Among the proteins altered, 71 were strongly linked to lipid metabolic pathways, including 47 that were upregulated and 24 that were downregulated. Notably, the upregulation of GPAT1 reflects RD3-dependent control of glycerophospholipid synthesis; increased levels of ACOX1, ECH1 and ACADM indicate RD3-mediated fatty acid β-oxidation; and elevated GPAT4 and DGAT1 expression supports a role for RD3 in modulating triglyceride biosynthesis. In addition, ESYT1 upregulation highlights RD3 involvement in lipid trafficking. PLIN2 downregulation underscores RD3-dependent regulation of lipid droplet dynamics, while reduced SCP2 and APOE expression points to RD3-associated control of cholesterol transport. Our study for the first time recognized that RD3 deficiency dysregulates lipid metabolic activity. This RD3-dependent metabolic disruption of lipid homeostasis leads to the aggressiveness of NB tumors, resulting in poor patient survival. Therefore, harnessing the mechanism of this unrecognized axis of metabolic reprogramming in NB could lead to promising avenues for novel targeted interventions and improve patient survival. #3290 Rewiring of pyruvate metabolism in neonatal CD8$^+$ T cells alters functionality and antitumor immunity.

Elinor DeCleene[1], Amy Reynolds[1], Daniela Vega-Mendoza[1], Rebeca Rodriguez[1], Mingkee Achom[1], Naomei Lidman[1], Jose Almeida-Santos[1], Grace Rish[1], Samuel Markson[2], Jared H. Rowe[1]

[1]Dana-Farber Cancer Institute, Boston, MA,[2]Harvard Medical School, Boston, MA

Neuroblastoma (NBL) is the most common extracranial solid tumor in children, accounting for ~15% of pediatric cancer-related deaths. Despite these relatively poor outcomes in high-risk disease, children under 18 months of age often demonstrate spontaneous tumor regression. The mechanisms leading to spontaneous NBL regression are incompletely described and likely consist of both cell intrinsic and extrinsic features. In contrast to the relatively poor immunogenicity of high-risk NBL, regressing tumors have a distinct immunological “signature” suggesting the immune system may play a critical role in this process. The function of individual immune cells is dynamic in early life as the immune system develops. We posited that functional differences in the infant immune system could provide inherent advantages for antitumor immunity against NBL. In particular, neonatal CD8$^+$ T cells have increased proliferative potential, enhanced cytokine production, and may resist exhaustion relative to their adult counterparts. We hypothesized the enhanced functionality of neonatal T cells is controlled by the utilization of distinct pathways of cellular metabolism. We identified that following *in vitro* activation, neonatal CD8$^+$ T cells have distinct RNA expression profiles of genes related to cell metabolism compared to adult T cells. The expression of pathways associated with central carbon metabolism were markedly different between neonatal and adult T cells. Pyruvate serves as the central metabolite hub for these processes, and isotopomer tracing revealed that neonatal T cells process pyruvate differently than adult cells. Extracellular pyruvate supplementation was essential for the proliferation and effector cytokine production in neonatal CD8$^+$ T cells. Neonatal T cells had a preferential conversion of pyruvate to alanine indicating an enhanced use of the glutamic pyruvate transaminase (GPT) reaction. Ongoing studies will identify the subcellular compartmentalization (i.e. cytoplasmic, mitochondrial) and impact of NBL-imposed metabolic constraints in the tumor microenvironment on this newly identified metabolic feature of neonatal T cells.

#3294 Cell-Autonomous EPHB2 signaling sustains neuroendocrine prostate cancer.

Xinyao Pang[1], Mingchen Shi[2], Dong Lin[2], Adam Classen[1], Hui Xue[3], Xin Dong[3], Rebecca Wu[3], Zoe Maylin[1], Ning Kang[3], Yen-Yi Lin[1], Yu Wang[1], Wei Dong[1], Martin E. Gleave[4], Colin Collins[1], Christopher J. Ong[5], Yuzhuo Wang[3]

[1]University of British Columbia, Vancouver, BC, Canada,[2]Vancouver Prostate Center, Vancouver, BC, Canada,[3]BC Cancer Research Centre, Vancouver, BC, Canada,[4]Distinguised Professor, Dept. of Urological Sciences, University of British Columbia, Vancouver, BC, Canada,[5]Surgery, University of British Columbia, Vancouver, BC, Canada

Neuroendocrine prostate cancer (NEPC) is a lethal subtype of prostate cancer that commonly develops from prostatic adenocarcinoma after long-term androgen deprivation therapy (ADT). Its incidence has risen markedly over the past decade with the widespread use of potent AR pathway inhibitors (ARPIs), yet no effective, approved therapies exist. Most studies focus on terminal NEPC, while the early drivers and transitional cellular states remain poorly defined. To address this gap, we used the LTL331/LTL331R patient-derived xenograft (PDX) model, the only available PDX system that faithfully recapitulate ADT-induced adenocarcinoma-to-NEPC transdifferentiation. Through longitudinal single cell transcriptomic sequencing across the entire process of adenocarcinoma-to-NEPC transdifferentiation of human prostate cancer, we identified a distinct intermediate, transitional cell state in the lineage shift. Within this state, EPHB2 emerged as a potential lineage-determining receptor activated at the onset of NE transdifferentiation. Mechanistically, we found that endothelial cells (ECs) in the tumor microenvironment (TME) initiate NE transdifferentiation by activating an EFNB2-EFNA5-EPHB2 axis in cancer cells. EC-derived EFNB2 upregulates EFNA5, which subsequently activates EPHB2 in a cell-autonomous manner. This signaling pair suppresses AR signaling and luminal lineage programs while promoting NE lineage initiation. In terminal NEPC, sustained EFNA5-driven EPHB2 activation maintains NE identity and enhances aggressiveness through a self-reinforcing loop. Functionally, EPHB2 inhibitor significantly reduced NEPC cell proliferation and NE marker expression. Importantly, combining an EPHB2 inhibitor with an EZH2 inhibitor partially reversed the NE phenotype, restored AR signaling, and resensitized NEPC cells to ARPIs.In conclusion, EPHB2 functions as a dual-phase regulator in NEPC, initially activated by TME-derived ephrin ligands to trigger NE transdifferentiation and later sustained through cell-autonomous signaling to maintain terminal NEPC. These findings position EPHB2 as a promising therapeutic target in intercepting NEPC development and progression.

#3295 Pi3k autoinhibition dictates rras2 dependency across HER2-amplified and PI3K-mutant cancers.

Miranda R. Cabanski-Dunning[1], Matthew J. Sale[2], Lucy C. Young[1], Maria Tarazona-Guzman[1], Dylan Aguinaldo[1], Madeleine Sitton[1], Rony Andre Francois[1], Frank McCormick[1]

[1]UCSF Helen Diller Family Comprehensive Cancer Ctr., San Francisco, CA,[2]UCSF - University of California San Francisco, San Francisco, CA

Aberrant PI3K signaling drives cancer growth, yet tumors activate p110α through distinct mechanisms. In normal cells, the regulatory subunit p85 restrains p110α until activated receptors recruit the complex to membranes. HER2-amplified tumors intensify this route through phosphorylated HER3, which provides multiple phospho-sites that both recruit PI3K and relieve autoinhibition. PIK3CA mutations found in various cancer types, including those with HER2 amplification, can weaken the restraint of p85 and bypass receptor control while preserving the requirement for membrane localization. Given that p110α still requires membrane localization even after autoinhibition is relieved, tumors often use oncogenic KRAS to provide this input. However, most HER2-amplified and many PIK3CA-mutant cancers lack KRAS mutations, suggesting alternative RAS-family proteins may fill this role.To define the contribution of RAS to PI3K signaling in a HER2-amplified context with wild-type p110α, we used KRAS G12C KYSE-410 cells. Through targeted siRNA knockdown, we identified RRAS2, not KRAS G12C, as the dominant PI3K driver, resulting in a ~60% reduction in pAKT. Replacing endogenous p110α with a RAS-binding-defective mutant produced the same effect, demonstrating that RRAS2 exclusively engages this site. Exogenous expression of oncogenic RRAS2 failed to restore pAKT in the presence of the HER2 kinase inhibitor tucatinib, even though RRAS2 remained GTP-loaded, membrane-localized, and bound to p110α. These results show that RRAS2 alone is insufficient to activate PI3K in the absence of phospho-HER3.To test whether p85 restraint prevents RRAS2 from activating PI3K, we expressed p110α mutants that destabilize the helical (E545K) or C2 (C420R) interface with p85. Both mutants restored RRAS2-driven signaling after tucatinib treatment, demonstrating that RRAS2 activates PI3K only when autoinhibition is relieved. To test the model in a physiological context, we used JIMT1 cells, which endogenously co-amplify HER2 and RRAS2 and carry the C420R mutation in p110α. Tucatininb treatment did not affect pAKT, indicating that RRAS2 can sustain PI3K activity when p110α autoinhibition is relieved. RRAS2 knockdown or re-expression of wild-type p110α restored tucatinib sensitivity, confirming that RRAS2 engagement and p110α–p85 regulation form key regulatory nodes.Further, DepMap analyses reveal increased RRAS2 dependency in cells with destabilizing p110α–p85 mutations in the absence of RTK amplification, supporting a model in which RRAS2-driven PI3K signaling requires both relief of autoinhibition and membrane localization.Together, our findings demonstrate that RRAS2 can drive PI3K signaling in contexts previously seen as RAS-independent and where recruitment mechanisms were unclear. Thus, highlighting an additional regulatory node of PI3K activation in HER2-amplified and PI3K-destabilized contexts.

#3296 The receptor-like protein tyrosine phosphatase PTPRH modulates dephosphorylation of the tyrosine kinases EPHA2 and EGFR, alters cell morphology and adhesion, and behaves as a tumor-suppressor in non-small cell lung cancer cell.

Mylena Ortiz[1], Deeya Patel[1], Jesus Garcia-Lerena[1], Andrew C. Nelson[2], Matthew Swiatnicki[1], Eran Andrechek[3]

[1]Michigan State University, East Lansing, MI,[2]University of Minnesota, Minneapolis, MN,[3]Asst. Professor, Dept. of Physiology, Michigan State University, East Lansing, MI

Introduction: The delicate balance of protein phosphorylation is often disrupted in cancers, with hyperactivity of kinases and inactivation of phosphatases driving cell proliferation and survival pathways. PTPRH, a protein tyrosine phosphatase, is found to be mutated in ~5% of non-small cell lung cancer (NSCLC) cases. However, the biological processes in which PTPRH is involved and how they may contribute to tumorigenesis are unknown.
Methods: We uncovered PTPRH's candidate interactors and associated pathways by applying a proximity-dependent biotinylation assay (BioID) and generating a signature transcriptomics in two NSCLC cell lines derived from the primary tumor (NCI-H23) or a metastatic site (NCI-H2023). Spatial subcellular localization, morphological analysis, and cell signaling alteration induced by PTPRH gain or loss were evaluated by confocal microscopy, image analysis, western blot, and cell adhesion assays under basal or stimulated conditions. Functional effects on migration and tumor suppression were assessed using *in vitro* assays and tail-vein or flank injections of PTPRH-overexpressing NSCLC cells in NOD-SCID mice.
Results: PTPRH candidate interactors include signaling molecules and structural proteins linked to integrins and focal adhesions, adherens junctions, migration, and the cytoskeleton, besides stable or transient interactions with the receptor tyrosine kinases (RTK) EGFR, EPHA2, and ROR2, and the phosphatases PTPN3 and PTPRJ. Considering the importance of EGFR in driving lung cancers and the role of EPHA2 in regulating cell adhesion, we delved deeper into understanding how PTPRH regulates RTKs signaling. Overexpression of PTPRH decreased phosphorylation levels of EGFR at the tyrosine residue 1173 (1197) and EPHA2 at tyrosine residue 588 in the primary site-derived cell line following EGF or ephrin-A1/collagen I stimulation. Imaging revealed that the phosphatase and EPHA2 colocalize subcellularly, with PTPRH gain inducing morphological alterations, such as increased eccentricity and smaller size, besides changes in the cytoskeleton organization. These changes are accompanied by increased FAK Y397 phosphorylation, but reduced cell adhesion to the ECM. Additionally, pathway enrichment analysis revealed downregulation of multiple oncogenic, metabolic, and cell adhesion signaling pathways, with increased levels of the phosphatase leading to reduced migration *in vitro*, suppressed tumor growth, reduced cell colonization to the lungs, prolonged tumor latency, and tumor differentiation *in vivo*.
Conclusion: PTPRH regulates key signaling and structural networks, modulating RTK activity, morphology, adhesion, and tumor behavior. Its loss may facilitate NSCLC progression.

#3297 HER2 overexpression confers osimertinib resistance in EGFR-mutant lung cancer.

Gaku Yamamoto, Yu Tanaka, Miku Tsukuda, Sato Sayaka, Saori Matsui, Tetsuya Sakai, Hiroki Izumi, Eri Sugiyama, Yoshitaka Zenke, Shigeki Umemura, Kiyotaka Yoh, Koichi Goto, Hibiki Udagawa

National Cancer Center Hospital East, Kashiwa, Japan

HER2 amplification has been identified in 2-5% of patients with EGFR-mutant lung cancer who have acquired resistance to osimertinib; however, its precise mechanisms in mediating resistance remain unclear. This study aims to elucidate how HER2 aberration contributes to acquired resistance to osimertinib through multiple preclinical approaches. EGFR-mutant cell lines stably overexpressing HER2 were generated by lentiviral transduction using PC9 (EGFR exon 19 deletion) and H1975 (EGFR L858R). Although HER2-overexpressing cells displayed comparable short-term (3-day) sensitivity to osimertinib *in vitro* relative to empty-vector controls, long-term assays (>7 days) revealed a remarkable increase in resistant colony formation across both HER2-overexpressing models. Next, xenograft models bearing HER2-overexpressing cells were established in nude mice to evaluate *in vivo* responses to osimertinib. Continuous oral administration of osimertinib induced initial tumor shrinkage in HER2-overexpressing xenografts; however, these tumors subsequently demonstrated pronounced regrowth, whereas parental tumors exhibited more durable responses. Finally, the combination of a HER2-targeted tyrosine kinase inhibitor and osimertinib synergistically suppressed tumor cell growth in HER2-overexpressing EGFR-mutant cells. In conclusion, HER2 overexpression induced acquired resistance to osimertinib, whereas dual HER2/EGFR blockade overcame this resistance, highlighting this approach as a promising therapeutic strategy for EGFR-mutant lung cancer.

#3298 Preclinical development of TJ106, a potent biparatopic dual payload ADC targeting HER2 for the treatment of Enhertu-resistant tumors.

Siyi Hu, Mao Huang, Xiaobo Cai, Shugaku Takeda, Li Qi, Yangxin Zhang, Haiyan Wu, Yan Zhang, Yanli Mao, Zhaoyuan Chen

Phrontline Biopharma Co., Ltd., Shanghai, China

Background: HER2 overexpression is associated with increased metastatic potential and poor clinical outcomes across multiple tumor types, including breast, gastric, gastroesophageal junction, and lung cancers. Enhertu (trastuzumab deruxtecan, DS-8201a) has transformed HER2-targeted therapy by demonstrating efficacy in HER2-expressing and previously refractory tumors through delivery of a potent topoisomerase I inhibitor payload (DXd) with bystander effect. However, clinical resistance to Enhertu has emerged, driven by mechanisms such as reduced payload sensitivity, HER2 downregulation or heterogeneity, and adaptations within the tumor microenvironment. To address this unmet need, we developed TJ106, a novel biparatopic, dual-payload HER2-targeting antibody-drug conjugate (ADC) designed to enhance tumor cell internalization, overcome resistance mechanisms, and improve the therapeutic window.

Methods: Antibody internalization was evaluated by flow cytometry (FACS). The CellCounting-Lite 2.0 luminescent viability assay was used to assess the in vitro cytotoxicity of TJ106. In vivo antitumor activity was investigated in cell-derived xenograft (CDX) and patient-derived xenograft (PDX) models with high, moderate, or low HER2 expression.

Results: TJ106 consists of a biparotopic antibody, generated from trastuzumab and pertuzumab using knob-into-hole technology, conjugated in a site-specific manner (DAR 4) to the dual-linker payload DLP1, which combines a topoisomerase I inhibitor and a microtubule inhibitor. TJ106 showed superior internalization compared with trastuzumab or pertuzumab in HER2-moderate JIMT-1 (IHC 2+) breast cancer cells and HER2-low Colo-205 (IHC 1+) colorectal cancer cells. TJ106 also exhibited enhanced in vitro cytotoxicity across HER2-expressing tumor cell lines, including NCI-N87 (HER2 3+) gastric cancer, JIMT-1, and Colo-205, compared with trastuzumab-DLP1, pertuzumab-DLP1, and DS-8201a. In the JIMT-1 CDX model, TJ106 demonstrated superior antitumor efficacy versus comparators: TJ106 at 3.0 mg/kg achieved 81.8% tumor growth inhibition (TGI), compared with 69.0%, 71.0%, and 53.0% TGI for trastuzumab-DLP1, pertuzumab-DLP1, and DS-8201a, respectively. TJ106 was well tolerated in mice with no observed treatment-related body weight loss. Furthermore, TJ106 effectively inhibited tumor growth in two Enhertu-resistant PDX models (LD1-0017 and LU9681-R1P12) and one Enhertu-resistant NCI-N87 CDX model.

Conclusion: TJ106, a novel biparatopic dual-payload HER2-targeting ADC, demonstrates robust in vitro and in vivo antitumor activity, including in Enhertu-resistant models, supporting its further clinical development for patients with advanced HER2-expressing tumors.

#3299 Autocrine lymphotoxin signalling promotes ovarian tumor growth through CD74.

Tat San Lau[1], Yi Shun Wong[1], Maciej Jakub Trybull[2], Kit Ying Loucia Chan[1], Ho Sze Jacqueline Lee[1], Chi Chiu Wang[1], Joseph Kwong[2]

[1]Department of Obstetrics and Gynaecology, The Chinese University of Hong Kong, Hong Kong, Hong Kong,[2]School of Medicine, Keele University, Keele, United Kingdom

Background: Ovarian cancer is the eighth most common cause of cancer and cancer death in women worldwide. The 5-year overall survival rate for advanced-stage ovarian cancer is 10-40%. A new therapy for advanced ovarian cancer is urgently needed. Identifying signalling pathways which promote tumor growth is crucial to developing targeted therapy. Lymphotoxin is overexpressed in ovarian cancer cells and mediates tumor-stromal interaction in ovarian tumor. However, the transcription regulation of lymphotoxin and the role of autocrine lymphotoxin signalling in ovarian cancer cells are still unclear.
Methods: To investigate transcriptional regulation of lymphotoxin, correlation analysis and pharmacologic inhibitions was performed in human ovarian cancer cell lines. To investigate autocrine lymphotoxin signalling, lymphotoxin-beta (LTB) was edited in human ovarian cancer cells by CRISPR-cas9 knockout. On the contrary, lymphotoxin genes (Lta and Ltb) were overexpressed in mouse ovarian cancer cells by stable transfection. Tumor growth was examined by cancer spheroid in vitro model and preclinical metastatic tumor in vivo model. Involvement of lymphotoxin-beta receptor (LTBR) and noncanonical NF-κB pathway (RelB and p52) were investigated by pharmacological inhibitions. To identify NF-κB target genes, differentially expressed genes were analysed by NanoString nCounter pan-cancer pathways panel. Relationships between lymphotoxin, NF-κB and CD74 in ovarian tumor samples (TCGA and CUHK) were performed by correlation analysis. Function of CD74 was investigated by CRISPR-cas9 knockout in human ovarian cancer cells.
Results: Positive correlations between IL33 and LTB expression, and between ST2 and LTA expression, are found in human ovarian cancer cell lines. Inhibition of IL33 and ST2 downregulates LTA transcription in human ovarian cancer cells. LTB knockout in human ovarian cancer cells induces cell cycle G2/M arrest and reduces tumor growth in vitro, whereas lymphotoxin overexpression in mouse ovarian cancer cells increases tumor growth in vitro and in vivo. Inhibition of LTBR and p52 reduces lymphotoxin-mediated ovarian tumor growth in vitro and in vivo. Cd74 is upregulated in mouse ovarian cancer cells after lymphotoxin overexpression and LTBR activation. In human ovarian cancer cells, CD74 transcription is regulated by lymphotoxin-LTBR-noncanonical-NF-κB pathway. Positive correlations between lymphotoxin, NFKB2, RELB and CD74 mRNA expressions are found in ovarian tumor samples. CD74 knockout in human ovarian cancer cells induces G2/M cell cycle arrest and reduces tumor growth in vitro.
Conclusion: Our results demonstrated that IL33-ST2 pathway positively regulates lymphotoxin expression in ovarian cancer, and autocrine lymphotoxin signalling promotes ovarian tumor growth through CD74. These results are a foundation for developing targeted therapy for advanced ovarian cancer.

#3300 Targeting OSMR signaling networks for precision oncology.

Pradeep Chaluvally-Raghavan

Medical College of Wisconsin, Milwaukee, WI

Oncostatin M (OSM) is a member of the IL-6 cytokine subfamily that binds to the Oncostatin M receptor (OSMR) and activates JAK/STAT-mediated oncogenic signaling**.** Our single-cell RNA sequencing (scRNA-seq) revealed that OSMR is highly expressed in tumor epithelial cells, whereas its ligand, OSM, is predominantly produced by tumor-associated macrophages. Our data established that OSM-induced STAT3 activation was markedly more robust than that induced by other IL-6 family ligands, leading to enhanced OSMR-driven cellular invasion, migration, and tumor growth**.** Overall, our findings highlight OSMR signaling as a promising therapeutic vulnerability in ovarian cancer. To address the lack of OSMR-targeted treatments, this study aims to develop a monoclonal antibody that blocks OSMR signaling in cancer cells without harming normal epithelial, stromal, or immune cells. We employed sc-RNA seq, clinical samples and signaling pathway analysis to characterize how OSMR serves as a signaling addiction mechanism in cancer cells. To elucidate the mechanism of actions, we performed live-cell image analysis, receptor dimerization assays, in-cell Western analyses and *in vivo* tumor growth assays.Our data shows that anti-OSMR antibody effectively blocked the binding of the ligand OSM to OSMR and subsequently inhibited OSMR dimerization with IL6ST. We also observed that OSMR antibody induced internalization and cytoplasmic degradation of OSMR, resulting in a marked reduction in STAT3 activation, tumor cell invasion, tumor growth, and metastasis. Transcriptome-based analyses, along with *in vitro* and functional assays, further revealed that cisplatin-resistant ovarian cancer cells express significantly higher levels of OSMR compared to cisplatin-sensitive cells, and that these resistant cells depend on OSMR signaling for aggressive tumor growth. Consistently, the treatment of anti-OSMR antibodies sensitized cancer cells to cisplatin therapy both *in vitro* and *in vivo*.In sum, our studies demonstrate that OSMR represents a therapeutically targetable driver of highly aggressive and chemo-resistant ovarian cancers. We also observed an elevated expression of OSMR in pancreatic cancer, glioblastoma, and stomach adenocarcinoma, suggesting a broader clinical applicability of OSMR therapy. Based on the promise of our anti-OSMR therapy *in vivo*, we are actively developing antibody-drug conjugates (ADCs) and bispecific T-cell engagers (BiTEs) of OSMR antibody to further enhance its antitumor efficacy.

#3301 TAK1 is a key regulator of oncogenic signaling and differentiation blockade in rhabdomyosarcoma.

Anh Tuan Vuong[1], Aniket S. Joshi[1], Anirban Roy[1], Kavya Mathukumalli[1], Phuong T. Ho[1], Raksha Bhat[1], Meiricris Tomaz da Silva[1], Tagari Samanta[2], Meghana Trivedi[3], Bin Guo[1], Benny A. Kaipparettu[4], Ashok Kumar[1]

[1]University of Houston, College of Pharmacy, Houston, TX,[2]Baylor College of Medicine, Houston, TX,[3]University of Houston, Houston, TX,[4]Lester and Sue Smith Breast Center, Baylor College of Medicine, Dan L. Duncan Cancer Center, Houston, TX

Rhabdomyosarcoma (RMS) is a malignant soft tissue sarcoma with a skeletal muscle phenotype, accounting for approximately 50% of all pediatric soft tissue sarcomas and 8% of all childhood cancers. Although RMS cells express myogenic regulatory factors, they fail to undergo terminal differentiation into mature muscle cells. Transforming growth factor β-activated kinase 1 (TAK1) is a major signaling protein that activates multiple intracellular pathways in response to growth factors, cytokines, and microbial products. Emerging evidence suggests that TAK1 is also an important regulator of self-renewal, proliferation, and differentiation of muscle progenitor cells. However, the role and mechanisms of action of TAK1 in RMS remain completely unknown. In this study, we demonstrate that TAK1 expression and activity are markedly elevated in a panel of RMS cell lines and in patient tumor specimens. Reverse phase protein array (RPPA) analyses revealed that TAK1 regulates the expression and activity of many molecules involved in cell cycle control, cell proliferation, and oncogenic signaling. Genetic knockdown or pharmacological inhibition of TAK1 suppresses RMS cell proliferation, migration, and invasiveness, while also promoting terminal myogenic differentiation. TAK1 inhibits differentiation in RMS, at least in part, through up-regulating YAP1 signaling. Our results also demonstrate that inducible knockdown of TAK1 in human RMS xenografts retards tumor growth and enhances myogenic differentiation *in vivo*. Collectively, these findings uncover a previously unrecognized role for TAK1 in RMS growth and differentiation, and suggest that TAK1 can be a potential therapeutic target for the treatment of RMS.

#3302 Phosphorylation of StarD10 regulates ErbB2-mediated alcohol-induced breast cancer progression.

Manisha Dagar, Youngyi Lim, Swati Chandla, Monica Justo, Nirmala Mavela, Komal Ramani, Maria Lauda Tomasi

Cedars-Sinai Medical Center, Los Angeles, CA

Introduction: Breast cancer remains the second most common cancer among women worldwide. Excessive alcohol consumption significantly increases breast cancer risk, with even moderate drinking (one drink per day) raising the risk by about 10% compared to non-drinkers. STAR-related lipid transfer domain-containing protein 10 (StarD10), a phosphoprotein overexpressed in 35-40% of primary human breast cancers, interacts with the ErbB2 signaling pathway to promote tumor growth. Our previous studies showed that ethanol exposure causes StarD10 dephosphorylation and enhances ErbB2 expression, leading to increased malignancy and aggressiveness. However, the mechanistic role of StarD10 as a subcellular lipid transporter in regulating ErbB2-driven signaling is still not well understood. This study investigates how ethanol affects StarD10 activity and the ErbB2 signaling pathway using three-dimensional breast cancer organoid models.
Materials and Methods: Lipid overlay assays and co-immunostaining were performed to assess StarD10's lipid-binding specificity in breast cancer cells (MCF-7, SKBR-3, and BT-474) and three-dimensional breast cancer organoid models (PDxO). Additionally, organoids were CRISPR gene-edited to validate the functional outcome of pre-identified StarD10 phospho-sites. Activation of the ErbB2-regulated AKT-mTOR pathway was analyzed by Western blot. Cell viability and migration were analyzed in CRISPR gene-edited breast cancer cells.
Results: A significant decrease in StarD10 phosphorylation was observed in breast cancer cells (MCF-7, SKBR-3, BT-474) and breast cancer organoids (PDxO) in the presence of ethanol. Lipid overlay assay showed that StarD10 interacts with multiple phosphoinositides, including PI(3)P, PI(4)P, PI(5)P, PI(3,4)P_2, PI(4,5)P_2, and PI(3,4,5)P_3. Co-immunostaining further demonstrated an ethanol-induced increase in the interaction between StarD10 and PIP2/PIP3. Inhibition of PP2A activity by CRISPR-mediated gene editing prevented ethanol-induced StarD10 dephosphorylation and the ErbB2-mediated AKT-mTOR pathway, indicating that these phosphatases act as positive regulators of StarD10 function in the organoid model. Moreover, PP2A gene editing significantly reduced cell viability and migration compared to ethanol-treated cells, suggesting a critical role for PP2A-mediated dephosphorylation of StarD10 in promoting ethanol-induced breast cancer cell aggressiveness.
Conclusions: Our findings show that ethanol promotes breast cancer progression by causing dephosphorylation of StarD10 at the T288 residue. Using organoid models, we demonstrate that PP2A phosphatase positively regulates StarD10 activity. Targeting the phosphorylation pathway of StarD10 may serve as a potential therapeutic strategy to reduce alcohol-related breast cancer progression.

#3303 Investigating the impact of HER4 mutations on HER2 signaling.

Denis M. Collins[1], Marta Valenti[2], Johanna Gaubatz[2], Debbie O'Reilly[2], Birgit Bossenmaier[3], Bryan Hennessy[4], John Paul Crown[5]

[1]Cancer Biotherapeutics Research Group, Dublin City University, Dublin, Ireland,[2]Dublin City University, Dublin, Ireland,[3]Bossenmaier Consulting, Munich, Germany,[4]Beaumont Hospital, Dublin, Ireland,[5]St. Vincent's University Hospital - Dublin, Dublin 4, Ireland

Background: HER2 is amplified in ~20% of breast cancers (BCs) and is a member of the HER/ErbB receptor tyrosine kinase family that also includes EGFR, HER2 and HER3. HER4 is mutated in 7% of HER2+ BCs but there are limited data on the impact of HER4 point mutations (MUTs) on HER2 signaling. Previous work has identified EGFR, p38 MAPK, Src and STAT3 as targets impacted by HER4 overexpression. HEK293 cells express wild type (WT) EGFR and negligible levels of HER2, HER3 and HER4. Using plasmid-based overexpression in HEK293 cells, this study examines the co-expression of WT HER2 with WT HER4 or HER4 point MUTs (2 extracellular domain (ECD) and 6 intracellular domain (ICD)).

Methods: Eight HER4 MUTs identified from the COSMIC database were investigated. Four were predicted to be deleterious/damaging and four neutral/tolerated (Provean/SIFT). MUT1 (p.E202D) and MUT2 (p.P224R) are in the ECD; MUT3-MUT8 (p.T1036I, p.Y1242C, p.H1245N, p.S1246R, p.L1247M, p.H1255N) are in the ICD. Mutant primers (Sigma Aldrich) were used for site-directed mutagenesis (QuikChange Lightning) with pRK5 HER4 WT used as a template to generate eight validated HER4 MUT plasmids (SequiServe). HEK293 cells were transfected (Fugene) with either empty vector, GFP control, WT HER2 plasmid, WT HER4, WT HER2/WT HER4, or WT HER2 combined with each HER4 MUT. Transfection was confirmed by Western blot. Protein lysates were analyzed in triplicate by reverse phase protein array (RPPA) to quantify 50 total and 34 phospho-proteins (84 targets). Significant changes ($p < 0.05$) were determined by Student's t-test.

Results: Total EGFR levels were unchanged in response to transfection with WT HER2 or WT HER4, however EGFR phosphorylation at Y992 and Y1068 increased significantly ($p<0.05$) for WT HER2 and WT HER4 individually or in combination. Unlike WT HER4, WT HER2 did not increase phosphorylated levels of p38 MAPK, Src or STAT3. When co-transfected with WT HER2, changes induced by WT HER4 were maintained for Src (Y416) ($p=0.02$) and STAT3 (Y705) ($p<0.01$) but not p38 MAPK (T180/Y182) ($p=0.11$). In the presence of WT HER2, HER4 MUT6 increased phosphorylated HER2 (Y1248) levels ($p=0.01$), and MUTs 2, 6, 7 and 8 significantly increased levels of phosphorylated EGFR (Y1173). In addition, HER4 MUT6 reduced Src (Y527) phosphorylation ($p=0.01$).

Conclusions: Our data reports HER4-activated intracellular signaling pathways distinct from HER2, and HER4 MUTs that can alter EGFR and HER2 activity. These results provide preliminary evidence for the phenotypic impact of the HER4 MUTs examined on HER2 signaling.

#3304 *β,β*-dimethylacrylalkannin inhibits colorectal cancer growth *in vitro* and *in vivo* by targeted FGFR1.

Ran Zhao[1], Fanxiang Yin[1], Kangdong Liu[1], MeeHyun Lee[2], Zigang Dong[1]

[1]Zhengzhou University Medical College, Zhengzhou, Henan, China,[2]Post-Doc, Cellular And Molecular Biology, China-US (Henan) Hormel Cancer Institute, Zhengzhou, China

Background: Colorectal cancer (CRC) continues to be a major global heaith challenge, ranking as a top cause of cancer-related death fatalities. Alarmingly, the five-year survival rate for CRC patients hovers around a mere 10-30%. The disruption of fibroblast growth factor receptor (FGFRs) signaling pathways is significantly implicated in the onset and advancement of colorectal cancer (CRC), presenting a promising target for therapeutic intervention in CRC management. Further investigation is essential to comprehensively elucidate the role of FGFR1 in CRC and to develop effective FGFR1-targeted therapies.

Purpose: This study aims to demonstrate the oncogenic role of FGFR1 in colorectal cancer and investigate the potential therapeutic benefits of inhibiting FGFR1 activity using *β, β*-dimethylacrylalkannin (*β,β*-DMAA) as an FGFR1 inhibitor.

Methods: In the present study, we performed tissue array, kinase profiling analysis assay, computational docking model, knockdown assay to predict and explore the inhibitor of FGFR1. Furthermore, we utilized kinase assay, pull-down, cell proliferation and Patient derived xenograft (PDX) mouse model assays to discover an FGFR1 inhibitor and assess its effects on colorectal cancer growth.

Results: In this study, we found that FGFR1 protein is significantly overexpressed in colorectal cancer and plays a pivotal role in regulated cell growth, particularly in colorectal cancer patients. Furthermore, we conducted a computational docking, kinase profiling analysis, simulation and identified that *β,β*-DMAA could directly bind with FGFR1 within ATP binding pocket domain. Cell-based assays confirmed that *β,β*-DMAA not only inhibited the growth of colon cancer cells but also induced cell cycle arrest, apoptosis, and the modulation of FGFR1-mediated signaling pathways. Moreover, *β,β*-DMAA effectively attenuated the growth of PDX tumors in mice that were FGFR1-positive, all without causing significant toxicity. In summary, our study highlights the pivotal role of FGFR1 in colorectal cancer, suggesting that inhibiting FGFR1 activity could be a promising strategy for therapeutic intervention. We present strong evidence that targeting FGFR1 with *β,β*-DMAA is a viable approach for the management of colorectal cancer. Given its low toxicity and high efficacy, *β,β*-DMAA, as an FGFR1 inhibitor, warrants further investigation in clinical settings for the treatment of FGFR1-positive tumors.

#3305 Biochemical and cellular evaluation of HUNK inhibition by an FDA approved drug as potential therapeutic strategy for HER2+ breast cancer.

Safnas Farwin AbdulSalam[1], Mia M. Eason[2], Shuguang Liang[1], Alison Goupil[3], Anthony Acinapura[1], Maia Dominguez[4], Peter Gallagher[1], Yuan Wang[1], Jianghong Wu[5], Haiching Ma[1]

[1]Reaction Biology Corp., Malvern, PA,[2]Reaction Biology Corp., West Chester, PA,[3]Reaction Biology Corp., Pottstown, PA,[4]Reaction Biology Corp., Media, PA,[5]Reaction Biology Europe GmbH, Freiburg im Breisgau, Germany

Kinase inhibitors have been on spotlight for cancer drug discovery ever since the approval of Imatinib and recently the 100th small molecule kinase inhibitor was approved by the FDA showing the potential of kinase inhibitors for cancer therapeutics and beyond. HER2 kinase is an established drug target in breast cancer therapeutics with multiple inhibitors developed against this target over time. However, cancer developing drug resistance to these inhibitors over time remain as a prognostic challenge for aggressive breast cancer treatment. Recent studies investigating the HER2 resistance mechanism of breast cancers identify HUNK (hormonally upregulated neu-associated Kinase) playing a crucial role in promoting HER2+ breast cancer cell survival and inhibitors resistance via phosphorylation of Rubicon. Recently a first in class HUNK targeted inhibitor HSL119 has been identified and characterized to demonstrate potential of targeting HUNK as a treatment strategy for HER2 resistant breast cancers, but more potent inhibitors for this target are yet to be identified. To address this, we screened 145 FDA approved compounds in HUNK biochemical kinase assay in Reaction Biology's HotSpot assay platform and identified Momelotinib, an orally available JAK1/JAK2/ACVR1 inhibitor used to treat myelofibrosis, inhibiting HUNK with 7.9 nM IC_{50}. NanoBRET target engagement assay confirmed Momelotinib binds cellular HUNK in live HEK293 cells. Furthermore, CellTiter-Glo assays demonstrated Momelotinib inhibits proliferation of HER2+ JIMT1 cells and triple-negative 4T1 breast cancer cells, while caspase-3/7 activation assays indicated Momelotinib induces apoptotic cell death in both lines. These findings highlight Momelotinib as a potential therapeutic candidate for overcoming HER2 inhibitor resistance in breast cancer.

#3306 The role of DDR1 ectodomain shedding in glioblastoma radiation resistance.

Sophia Dunlap[1], Caitlin A. Harvey[1], Christopher D. Willey[2], Ahn Erin[2]

[1]University of Alabama at Birmingham, Birmingham, AL,[2]O'Neal Comprehensive Cancer Center at UAB, Birmingham, AL

Introduction: Glioblastoma (GBM) is the most common malignant brain tumor in adults, and resistance to radiation therapy remains a major therapeutic obstacle. Although genetic alterations contribute to GBM progression, they do not fully explain the emergence of radiation resistance, suggesting contributions from non-genetic mechanisms. Notably, radiation-resistant GBM exhibits elevated collagen deposition. Discoidin domain receptor tyrosine kinase 1 (DDR1), a collagen-binding receptor regulated by ectodomain shedding, is highly expressed in GBM. Here, we demonstrate that radiation-resistant GBM alters DDR1 activity and shedding in response to collagen to promote tumor cell proliferation.

Methods and Results: To investigate DDR1 regulation, we utilized a GBM patient-derived xenoline pair, JX39P (radiation-sensitive) and JX39P-RT (radiation-resistant). JX39P-RT displayed significantly higher DDR1 mRNA and protein expression. When cells were embedded in collagen I to mimic the extracellular environment, DDR1 phosphorylation at Y792 increased more rapidly and to a greater extent in JX39P-RT than in JX39P. Collagen embedment also led to the accumulation of a short DDR1 fragment in JX39P-RT, indicating enhanced ectodomain shedding. Western blotting of conditioned media confirmed increased release of the DDR1 N-terminal fragment and confirmed that ectodomain shedding occurred only in JX39P-RT in response to collagen. Treatment of JX39P-RT cells with marimastat, a broad-spectrum MMP inhibitor, diminished both the N-terminal fragment shed in the media and the short C-terminal fragment in cell lysates. Consistent with elevated DDR1 expression and activation, JX39P-RT exhibited increased phospho-ERK1/2 levels when embedded in collagen I, indicating enhanced downstream signaling pathways. Furthermore, cell proliferation assays and Ki67 staining showed that JX39P cells proliferate more rapidly than JX39P-RT in liquid culture; however, when embedded in collagen I, JX39P showed no significant change in Ki67 staining, whereas JX39P-RT demonstrated a time-dependent increase, indicating that radiation-resistant GBM cells proliferate in response to collagen- and DDR1-mediated signaling.

Conclusions: Together, our results identify DDR1 upregulation and ectodomain shedding as key adaptive mechanisms that promote proliferation and survival of radiation-resistant GBM cells. These regulatory processes enable resistant cells to sustain growth under therapeutic stress, providing a potential mechanism of therapeutic evasion. Future studies will investigate how DDR1 shedding and downstream signaling integrate to maintain radiation resistance and explore strategies to sensitize GBM to radiation therapy.

#3307 CD99 homophilic signaling between tumor-associated macrophages and glioblastoma cells regulates response to immunotherapy.

Tongchao Jiang[1], Zilu Huang[2], Nan Li[3], Haishuang Sun[4], **Tongcui Jiang**[5]

[1]Robert H. Lurie Comprehensive Cancer Ctr. of Northwestern Univ., Chicago, IL,[2]Sun Yat-sen University Cancer Center, Guangzhou, China,[3]Department of Neurosurgery, The First Affiliated Hospital of USTC, Division of Life Sciences and Medicine, University of Science and Technology of China, Hefei, China,[4]Department of Medical Oncology, Sun Yat-sen University Cancer Center, Guangzhou, China,[5]Department of Biochemistry & Molecular Biology, School of Basic Medical Sciences, Anhui Medical University, Hefei, China

Background: Glioblastoma (GBM) is characterized by inevitable recurrence and profound therapy resistance, particularly to immunotherapy, and effective options for recurrent disease remain extremely limited. An immunosuppressive tumor microenvironment dominated by tumor-associated macrophages (TAMs) plays a central role in attenuating antitumor immunity and sustaining therapy resistance. However, the contact-dependent signaling mechanisms linking GBM cells and TAMs to tumor recurrence and treatment failure remain poorly defined.
Methods: We integrated publicly available scRNA-seq datasets from primary and recurrent GBM, as well as from immunotherapy responders and non-responders to map tumor-immune cell communication. Bulk transcriptomic data from TCGA-GBM and two CGGA cohorts (CGGA-693 and CGGA-325) were analyzed to determine the association of CD99 expression with patient survival, activation of signaling pathways, and oncogenic hallmark gene signatures. Spatial transcriptomics were used to assess the spatial proximity of CD99-high tumor cells and macrophages and the local signaling activity. For experimental validation, we performed in vitro and in vivo studies to assess whether CD99 blockade enhances the efficacy of anti-tumor immunotherapy.
Results: Single-cell communication analysis revealed that macrophage populations were enriched and transcriptionally activated in recurrent GBM and immunotherapy non-responders, with CD99 homophilic-mediated interactions between macrophages and tumor cells specifically enriched in these settings. Across TCGA and CGGA cohorts, high CD99 expression was associated with worse overall survival (TCGA-GBM, $p = 0.017$; CGGA-693, $p = 0.047$; CGGA-325, $p = 0.0039$), enhanced JAK/STAT signaling, higher EMT pathway scores, and elevated expression of TGF-β, IL-10, and M2-related gene signatures. Spatial transcriptomics confirmed that CD99-high tumor cells were preferentially neighbored by macrophages, and these niches displayed elevated JAK2/STAT3 activity. Experimentally, under immunotherapy-mimicking conditions, CD99 blockade reduced JAK2/STAT3 signaling and EMT marker expression in GBM cells, lowered TGF-β/IL-10 secretion, and diminished M2 polarization of macrophages in co-culture. In mouse models, combining CD99 inhibition with anti-PD-L1 further suppressed tumor growth and attenuated the tumor-promoting effect of co-injected macrophages.
Conclusions: These findings suggest CD99 homophilic engagement between GBM cells and macrophages as a critical amplifier of a JAK2/STAT3-EMT-M2 polarization loop that drives therapy resistance. Targeting CD99-mediated tumor-macrophage crosstalk may represent a promising strategy to overcome resistance and improve outcomes in GBM.

#3308 NRG1/HER3 axis drives therapy resistance in head and neck squamous cell carcinoma: Evidence from patient-derived xenografts.

Anna Francia[1], Cinzia Girone[1], Boobash-Raj Selvadurai[2], Daria Maria Filippini[3], Giulia Querzoli[4], Matteo Fermi[5], Achille Tarsitano[6], Federica Pagano[1], Davide Zilio[1], Paola Cecchi[1], Andrea Ardizzoni[3], Yosef Yarden[7], Mattia Lauriola[1], **Donatella Romaniello**[1]

[1]Department of Medical and Surgical Sciences, Alma Mater Studiorum Universita di Bologna, Bologna, Italy,[2]Department of Immunology and Regenerative Biology, Systems immunology, Weizmann Institute of Science, Rehovot, Israel,[3]Medical Oncology Unit, IRCCS Azienda Ospedaliero-Universitaria di Bologna, Bologna, Italy,[4]Pathology Unit, IRCCS Azienda Ospedaliero-Universitaria di Bologna, Bologna, Italy,[5]Department of Otorhinolaryngology-Head and Neck Surgery, IRCCS Azienda Ospedaliero-Universitaria di Bologna, Bologna, Italy,[6]Oral and Maxillofacial Surgery Unit, IRCCS Azienda Ospedaliero-Universitaria Di Bologna, Bologna, Italy,[7]Weizmann Institute of Science, Rehovot, Israel

Epidermal Growth Factor Receptor (EGFR) is commonly overexpressed and associated with poor clinical outcomes in Head and Neck Squamous Cell Carcinoma (HNSCC). Indeed, the EGFR monoclonal antibody, Cetuximab (CTX) has been the first FDA-approved targeted drug but demonstrating limited (10-30%) and not durable response due to both intrinsic and acquired resistance mechanisms. Data from our *in vitro* experiments, and confirmed by the literature, showed an increased HER3 protein level after cetuximab treatment in HNSCC 2D cell lines, suggesting that this receptor may represent a bypass pathway to anti-EGFR therapy.However, given the complexity of HNSCC, characterized by different etiology, anatomical sites and high inter- and intratumoral heterogeneity, we focused our research study on a more representative model establishing a small set of characterized patient-derived xenografts (PDXs). Palpable tumors were cryopreserved and expanded for drug testing and ex vivo characterization. Immunohistochemistry analysis revealed that all the established PDX models recapitulate morphological and functional traits of the corresponding patient tumors. While, NGS, Western Blots and QF-PRO®, a FRET-FLIM based technic, identified distinct EGFR signature, protein expression and heterodimers distribution across samples. These results reflected a differential response to anti-EGFR blockade *in vivo*. Moreover, analysis conducted in one PDX model, derived from HPV negative sample, showed high expression of EGFR family members, HER2 and HER3, when tumors are no more responding to CTX treatment.In conclusion, characterized PDX models will help to identify HNSCC subgroups that may benefit to a combinatorial approach using anti-HER3 innovative drugs, like bispecific antibodies, antibody-drug conjugates or aptamers, to bypass compensatory signaling pathway and improve CTX sensitivity.

#3309 Daple-FLT3 gene fusion activates and localizes through a distinct mechanism from FLT3-ITD.

Darren Kao[1], Michael Acquazzino[1], Arnel Ibarra[1], Elena Valenzuela[1], Haley Mai[1], Kimberly Aguilar[1], Elliot Stieglitz[2], Jason Ear[1]

[1]California Polytechnic University, Pomona, Pomona, CA,[2]Pediatrics, UCSF, San Francisco, CA

Gene fusions are stable protein products often occurring from chromosomal rearrangements. These chimeric proteins typically contain distinct molecular entities from each parent gene, and thus, create a product with altered or aberrant function. Gene fusions are frequently found in cancers, including Leukemia. Here, we characterize the kinase activity and subcellular distribution of the Daple-FLT3 (CCDC88C-FLT3) fusion oncoprotein—a rare, but recurrent gene fusion found in patients with hematological malignancies. The protein contains the FLT3 kinase domain and is activated without ligand stimulation. This leads to activation in STAT5a, AKT, and MAPK signaling, which can be modulated by the tyrosine kinase inhibitor (TKIs) sorafenib and to the most specific FLT3 inhibitor quizartinib. The fusions localize to the pericentrosomal space, a unique subcellular localization pattern that is different compared to the well-known FLT3-ITD mutation. We further demonstrate that localization and maximal kinase activation is dependent on the Daple coiled-coil domain. These findings provide evidence that targeting Daple-FLT3 outside of its kinase domain (i.e. the coiled-coil region) may be a complementary approach with TKI therapy.

#3310 UCHL1 deubiquitinates CIP2A to promote tumor progression in gastric cancer.

Lee Ga-ye[1], In-ho Jeong[2], Peter CW Lee[2]

[1]Department of Biochemistry & Molecular Biology, Brain Korea 21 Project, University of Ulsan College of Medicine, Asan Medical Center, Seoul, Korea, Republic of,[2]Department of Biomedical Sciences, University of Ulsan College of Medicine, Seoul, Korea, Republic of

Gastric cancer is one of the most prevalent malignancies worldwide and the fourth leading cause of cancer-related mortality. The intracellular protein degradation mechanisms, both Ubiquitination and Deubiquitination are called proteostasis, which regulate protein stability and play essential roles in tumorigenesis. Among deubiquitinases, UCHL1 has been implicated in the progression of numerous types of cancers, but its functional role in gastric cancer remains to be fully understood. In this study, we found that UCHL1 expression is markedly upregulated in gastric cancer tissues compared to adjacent normal tissues. Also, elevated UCHL1 expression is associated with poor patient's prognosis, supporting its potential role as an oncogenic factor and knockdown of UCHL1 suppressed cell proliferation, migration and invasion in gastric cancer cells. We sought to identify novel binding partners of UCHL1 and revealed that CIP2A is a substrate of UCHL1. Furthermore, UCHL1 downregulation led to reduced expression of the c-Myc protein, a downstream target of CIP2A, followed by suppression of the cell cycle, particularly through the regulation of Cyclin D1. These findings demonstrate that UCHL1 promotes cell growth via the CIP2A-c-Myc-Cyclin D1 axis, underscoring its potential as a therapeutic target in gastric cancer.

#3311 Autologous colorectal cancer-mesothelial co-culture model identifies stromal FGFR3 dependency driving peritoneal dissemination.

Hiroaki Kasashima[1], Yasuhiro Fukui[1], Iguru Omori[1], Zizhou Wang[1], Nobuhiro Naito[1], Yukina Kusunoki[1], Kenji Kuroda[1], Yuichiro Miki[1], Mami Yoshii[1], Tatsuro Tamura[1], Masatsune Shibutani[1], Takahiro Toyokawa[1], Masakazu Yashiro[1], Yuki Nakanishi[2], Naoko Ohtani[1], Kiyoshi Maeda[1]

[1]Osaka Metropolitan University, Osaka, Japan,[2]Kyoto Univ. Graduate School of Medicine, Kyoto, Japan

Background: Peritoneal dissemination of colorectal cancer (CRC) remains a fatal disease with limited therapeutic options. Mesothelial cells, which line the peritoneal cavity, play critical roles in metastatic implantation and stromal remodeling, yet the mechanisms governing tumor-stroma interactions in this setting remain poorly understood. We aimed to establish a physiologically relevant model to elucidate these interactions and identify stromal vulnerabilities.
Methods: We simultaneously derived a novel CRC cell line (OMUCR-1) and cancer-associated mesothelial cells (CAmeso) from the malignant ascites of a single patient with metastatic CRC. As a control, normal mesothelial cells (Nmeso) were established from a patient without dissemination. Cell morphology, growth kinetics, STR profile, and mutational status were characterized. The effects of CAmeso on CRC migration and invasion were evaluated using wound-healing and Matrigel assays. In vivo, OMUCR-1 cells were implanted alone or co-transplanted with CAmeso into nude mice. RNA sequencing was performed to analyze host stromal gene expression, and FGFR inhibition (BGJ398) was tested therapeutically.
Results:OMUCR-1 cells exhibited robust tumorigenicity and harbored KRAS (G12D) and TP53 (R306) mutations. CAmeso significantly enhanced CRC cell migration and invasion in vitro. In xenografts, co-transplantation with CAmeso yielded markedly larger tumors enriched in αSMA-positive stroma compared with OMUCR-1 alone. Bulk RNA-seq revealed upregulation of murine Fgfr3 in tumors containing CAmeso. Pharmacologic FGFR blockade with BGJ398 reduced tumor size and depleted FGFR3-positive stromal components, indicating stromal FGFR3 dependency.
Conclusions: We report the first concurrent establishment of CRC and mesothelial cell lines from the same patient, providing an autologous system for dissecting tumor-stroma crosstalk during peritoneal metastasis. Our findings highlight stromal FGFR3 signaling as a potential mediator of CRC progression and a promising target for therapeutic intervention. This unique platform offers a valuable resource for mechanistic and translational studies on the peritoneal microenvironment in advanced colorectal cancer.

#3312 FLT4-mediated ferroptosis resistance in renal cell carcinoma.

Djazia Haferssas[1], Nathalie Henley[2], Jonatan Barrera Chimal[2], Casimiro Gerarduzzi[1]

[1]University of Montreal, Montreal, QC, Canada,[2]Centre de Recherche de l'Hopital Maisonneuve Rosemont, Montreal, QC, Canada

Background: Renal Cell Carcinoma (RCC) is one of the ten most frequently diagnosed cancers worldwide and constitutes 2-3% of all adult cancers. Tyrosine Kinase Inhibitors (TKIs) are commonly used to treat RCC and have been shown to induce tumor cell ferroptosis, a non-apoptotic form of cell death triggered by lipid peroxidation. However, many patients develop resistance, leading to poor outcomes. FLT4, a receptor tyrosine kinase frequently deregulated in RCC, has been associated with poor survival, yet its contribution to ferroptosis resistance remains unclear.
Hypothesis: We hypothesized that FLT4-driven signaling contributes to a cellular state that reduces ferroptosis sensitivity and promotes RCC progression.
Methods: 1) FLT4 expression and clinical correlations were assessed using The Cancer Genome Atlas (TCGA) RCC RNAseq datasets. 2) ACHN and Caki-2 RCC cell lines were used to examine how FLT4 signaling influences proliferation, survival, stress-response pathways, lipid-associated gene expression, and ferroptosis sensitivity. 3) Luciferase- and FLT4 ovrexpressing RCC cells were implanted into NOD/SCID immunodeficient mice to evaluate tumor growth and ferroptosis-related markers in vivo.
Results: FLT4 was significantly upregulated in RCC and associated with reduced patient survival. In vitro, enhanced FLT4 signaling promoted RCC cell proliferation and survival, was accompanied by reduced activity of stress-response pathways, and led to lower lipid peroxidation and decreased ferroptosis sensitivity. In vivo, FLT4 overexpression accelerated tumor growth and was associated with reduced expression of ferroptosis-related markers.
Conclusion: FLT4 expression is associated with increased RCC cell growth and reduced ferroptosis sensitivity in our models. These findings describe the phenotypic consequences of altered FLT4 signaling in RCC and highlight FLT4 as a potential target for improving RCC outcomes.

#3313 BAP1 stabilizes BIRC5 to promote chemoresistance in gastric cancer.

Park Yu-Jin[1], In-ho Jeong[2], Peter CW Lee[2]

[1]Department of Biochemistry & Molecular Biology, Brain Korea 21 Project, University of Ulsan College of Medicine, Asan Medical Center, Seoul, Korea, Republic of,[2]Department of Biomedical Sciences, University of Ulsan College of Medicine, Seoul, Korea, Republic of

Gastric cancer is a highly aggressive malignancy associated with poor prognosis. 5-Fluorouracil (5FU) is an anticancer drug widely used to treat gastric cancer, however, the development of drug resistance during treatment remains a major clinical challenge. Therefore, understanding the molecular mechanisms underlying 5-FU resistance is essential for improving chemotherapeutic efficacy. The ubiquitin-proteasome system (UPS) is a key regulatory mechanism that controls the stability and function of intracellular proteins, with deubiquitinases (DUBs) serving as important modulators within this pathway. BRCA1-associated protein-1 (BAP1) is a representative DUB that has been implicated in tumorigenesis across various cancers; however, its role in gastric cancer and drug resistance remains poorly understood. In this study, we found that not only BAP1 but also anti-apoptotic protein BIRC5 is expressed at higher levels in 5FU-resistant gastric cancer cells compared to normal gastric cancer cells. We confirmed that BAP1 stabilizes BIRC5, a known anti-apoptotic protein, through deubiquitination. And we identified that knockdown of BAP1 reduced viability, migration, and invasion of gastric cancer cells. Furthermore, reduced BAP1 expression decreased BIRC5 protein expression, and induced apoptosis through the cleavage of PARP and Caspase-3. Notably, treatment with the selective BAP1 inhibitor iBAP-II increased the sensitivity of gastric cancer cells to 5-FU. Our findings revealed that BAP1 enhances 5-FU resistance and promotes gastric cancer progression by stabilizing BIRC5 and highlight BAP1 as a potential therapeutic target to enhance the efficacy of chemotherapy in gastric cancer.

#3314 RIPK2 promotes metastatic behavior in inflammatory breast cancer and is an attractive therapeutic target.

Innocent Ojobile[1], Alaa Zare[2], John M. Githaka[2], Einav Renert[1], Lynne-Marie Postovit[1]

[1]Queen's University, Kingston, ON, Canada,[2]University of Alberta, Edmonton, AB, Canada

Inflammatory breast cancer (IBC) is a rare but aggressive type of breast cancer characterized by early and rapid metastasis leading to poor clinical outcomes. The tumor microenvironment (TME), including immune cells, fibroblasts and endothelial cells, has emerged as a major regulator of IBC aggressiveness, however little is known about how IBC cells may orchestrate this pro-tumorigenic milieu. Inflammatory pathways such as NF-kB, concomitant with cytokine-induced signalling, are upregulated in IBC; however, the mechanisms underpinning these pathways are poorly understood. Receptor Interacting Protein Kinase 2 (RIPK2) mediates nucleotide-binding oligomerization domain (NOD) cell signaling that has been shown to activate NF-kB and to mediate chronic inflammation in a variety of diseases. Herein, we demonstrate that RIPK2 mediates the metastatic behavior in IBC by regulating NF-kB signaling and cytokine production. Specifically, using gain and loss of function strategies, including shRNAs, CRISPR gene editing and a small molecule inhibitor, we show that RIPK2 promotes an inflammatory transcriptome in IBC cells leading to the secretion of factors such as IL-8, IL-6 and Activin-A. As a corollary, RIPK2 enhances key IBC phenotypes, including angiogenic potential, emboli (sphere) formation, 3D invasion, a hybrid-EMT phenotype and metastatic growth in the lung. Collectively, we provide pioneering evidence that RIPK2 regulates the pro-inflammatory phenotype of IBC cells, making it an attractive target for the treatment of this disease.

#3315 CYLD regulates thrombin-induced p38-p65 signaling to inhibit breast cancer progression.

Julio Macias Pimentel, Naa-Oye Bosompra, JoAnn Trejo

Pharmacology, University of California San Diego - UCSD, San Diego, CA

G-protein coupled receptors (GPCRs) are a large and diverse family of cell surface receptors that regulate various physiological responses. Dysregulation of GPCR signaling is associated with multiple diseases, making this receptor family the largest target class of FDA-approved drugs. However, the mechanisms that regulate GPCR signaling are not well defined, and thus important to understand for improving the development of GPCR-targeted drugs. While phosphorylation is recognized as a key mechanism in GPCR regulation, GPCRs are also subject to ubiquitination, which is best known to promote lysosomal degradation. However, we showed that protease-activated receptor 1 (PAR1), which, upon thrombin stimulation undergoes ubiquitination and promotes non-canonical TAB1/TAB2 dependent activation of the p38 MAPK pathway on endosomes. This paradigm underscores a critical limitation of current therapeutic strategies, which predominantly target plasma membrane-initiated signaling while overlooking the contributions of endosomal signaling pathways. Although several E3 ligases have been identified to ubiquitinate GPCRs, the deubiquitinases that reverse this modification remain poorly defined, leaving a major gap in our ability to modulate GPCR signaling with precision in inflammatory diseases. Thrombin-activated PAR1 coupling to endosomal p38 signaling axis provides a powerful model to study how ubiquitination and deubiquitination regulate GPCR signaling. We identified the deubiquitinase CYLD as a key regulator of thrombin-induced PAR1-p38 signaling in endothelial and HeLa cells. Extending these findings to cancer, I demonstrated that thrombin activates p38 in multiple triple-negative breast cancer (TNBC) cell lines where PAR1 is highly expressed. In TNBC cells, CYLD knockdown increased both basal/thrombin-induced phosphorylation of p38 MAPK and p65. Using siRNA and pharmacological inhibitors, I further demonstrated that thrombin-induced p38 signaling functions upstream of NF-κB/p65, with co-immunoprecipitation confirming that p38 directly co-associates and phosphorylates p65 rather than other NF-κB pathway components. Downstream, this pathway drives nuclear translocation of phosphorylated p65, revealed by immunofluorescence and shown to be p38-dependent, as nuclear localization was abrogated by the p38 inhibitor BIRB 796. Functionally, thrombin-p38-p65 signaling upregulated pro-inflammatory cytokines including IL-6, IL-8, IL-1α, and IL-1β, as detected by human cytokine arrays and validated by RT-PCR. Finally, CYLD knockdown enhanced TNBC cell proliferation and migration, demonstrating that CYLD suppresses TNBC growth by inhibiting thrombin-p38-p65-signaling. Collectively, these findings reveal a novel mechanism by which CYLD inhibits TNBC progression through regulation of thrombin-p38-p65 signaling.

#3316 The mystery behind mSin1 phosphorylation.

Samira Mahmoudi, Bing Cheng, Yan Luo, Lei Liu, Shile Huang

Department of Biochemistry and Molecular Biology, LSU Health Shreveport, Shreveport, LA

Mammalian stress-activated protein kinase-interacting protein 1 (mSin1), a core component of the mechanistic target of rapamycin complex 2 (mTORC2), is less well characterized than other mTOR subunits. In particular, the mechanisms regulating its phosphorylation and its functional contribution to mTOR signaling remain poorly defined. Conflicting reports suggest that phosphorylation of mSin1 at T86 is mediated either by Akt or by ribosomal protein S6 kinase 1 (S6K1), highlighting uncertainty regarding its upstream regulation. These discrepancies underscore the need for deeper investigation into the kinases and pathways governing mSin1 phosphorylation. We found that rapamycin treatment decreases overall phosphorylation while paradoxically increasing T86 phosphorylation of mSin1 across multiple normal and cancer cell lines. These effects are independent of mTORC1/mTORC2 and downstream effectors (S6K1 and Akt) yet requires mTOR kinase activity and the subunit mLST8 (mammalian lethal with SEC13 protein 8). Since mTOR acts as a nutrient sensor, we also examined the effect of nutrient availability on mSin1 phosphorylation. Prolonged glucose deprivation, but not amino acid deprivation, markedly decreased mSin1 phosphorylation in HeLa cells, which was restored upon glucose repletion. These effects were not observed in Rh30, VSMC, and MEF cells. Collectively, our findings suggest that that rapamycin inhibits mSin1 phosphorylation by targeting a novel mTOR complex and might be associated with glucose metabolism in some contexts. Further research is needed to define the exact phosphorylation sites and their significance as well as the new mTOR complex regulating these phosphorylation sites.

#3317 ICA-1S and Selinexor decreases atypical teratoid rhabdoid tumor (ATRT) survival and proliferation.

Nuzhat Nowshin Oishee[1], Abigail Oluwafisayo Olatunji[2], Abiral Hasib Shourav[3], Grazielly Teodoro[3], Anna Kharitonova[3], Mildred Acevedo-Duncan[3]

[1]Chemistry, University of South Florida - Upward Bound, Tampa, FL,[2]University of South Florida - Upward Bound, Tampa, FL,[3]University of South Florida, Tampa, FL

Atypical teratoid rhabdoid tumor (ATRT) is a rare, aggressive and rapidly growing cancerous brain and spinal cord tumor mainly affecting young children, less than 3 years of age. ATRT consists of less than 5% of all pediatric CNS tumors. Abnormalities in chromosome 22q11, which includes the putative tumor suppressor gene SMARCB1 are frequently seen in ATRT. SMARCB1is a component of an SWI/SNF ATP-dependent chromatin-remodeling complex that controls the expression of certain target genes involved in cell cycle regulation. Approximately, 75% of ATRTs contains the homozygous deletions of SMARCB1, or loss of one allele and mutation of the other copy for the gene. Due to the rare and complex nature of the disease, ATRT is under researched. It is crucial to understand the signaling pathways that operate in the cell proliferation and survival of the ATRT tumors, and to establish a targeted therapy for this disease. One promising area that can be explored is the atypical Protein Kinase Cs (aPKCs). Protein Kinase C-iota (PKC-ι), an aPKCs isozyme, is over-expressed in many types of cancers. PKC-ι plays a major role in tumorigenesis because it is over-expressed and impacted by PI3K, PTEN and other signaling pathways. However, the role of aPKCs is yet to be discovered in the cell proliferation and survival of the ATRT cells. Therefore, in this study we aim to use, a novel PKC-ι inhibitor ICA-1S, alone or in-combination with Selinexor, and observe the subsequent effects on the ATRT cell proliferation and survival. The central hypothesis is that a PKC-ι inhibitor (ICA-1S) alone or in combination with Selinexor can restrain pediatric ATRT cell proliferation and cell survival by intercepting the PKC-ι/Cdk7/Cdk2 and PKC-ι/Bad pathways cascade in-vivo. To validate the hypothesis, we examined the effects of ICA-1S alone or in combination with Selinexor on the proliferation of ATRT cells. The results of a proliferation assay after a four-day treatment period with ICA-1S, Selinexor and combination helped us achieve the inhibitory concentration of the drugs that reduced the cancer cell proliferation to approximately 50%, which was at 20μM with ICA-1S alone for both the ATRT cells. We also tested various concentrations of Selinexor ranging from 400nM to 1.5μM, which showed more than 50% reduction in ATRT cell proliferation at 400nM, which was the lowest concentration used for both the cell lines. For the CHLA-05 cells, ICA-1S and Selinexor combination treatments caused significant reductions at 20μM ICA-1S+800nM Selinexor. For the CHLA06 cells, ICA-1S and Selinexor combination treatments caused significant reductions at 20μM ICA-1S+400nM Selinexor. These cell proliferation data suggest that ICA-1S and Selinexor have a synergistic effect on the ATRT cells. Furthermore, we plan on observing the effect the combination treatment on PKC-ι/Cdk7/Cdk2 and PKC-ι/Bad pathways both *in-vitro* and *in-vivo.*

#3318 The regulation of IL-6/gp130 signaling by PTPRF in colon cancer.

Haley Stanczyk[1], Carolina Galeano-Naranjo[1], Tianyan Gao[2]

[1]Molecular and Cellular Biochemistry, University of Kentucky, Lexington, KY,[2]Markey Cancer Center, University of Kentucky, Lexington, KY

Elevated Interleukin 6 (IL-6) levels and the activation of IL6/JAK/STAT3 signaling play an important role in promoting tumor growth and progression in colorectal cancer, making the IL-6 pathway a potential therapeutic target. Binding of IL-6 stimulates the formation of a receptor complex consisting of the IL-6 receptor and its co-receptor, gp130, which triggers the activation of JAK family kinases to phosphorylate tyrosine residues on the intracellular domain of gp130. The phosphorylated tyrosine residues act as docking sites for key signaling components, including transcription factor STAT3. Docking of STAT3 to gp130 allows for the phosphorylation of Tyr705 on STAT3 by JAK, the residue necessary for dimerization and nuclear translocation of STAT3 to promote gene transcription. While the phosphorylation-dependent activation of the IL-6 pathway has been intensively investigated, the regulation of signaling inactivation by protein phosphatases remains largely unexplored. Here we determined the role of protein tyrosine phosphatase receptor type F (PTPRF) in negatively regulating the tyrosine phosphorylation steps that control IL-6/gp130 signaling. The expression of PTPRF was depleted by CRISPR-mediated knockout or doxycycline inducible RNAi in 293T and colon cancer cells. We found that PTPRF downregulation resulted in an increase in total protein expression as well as tyrosine phosphorylation of gp130 basally. Additionally, IL-6 stimulation-induced activation of Jak family kinases, as indicated by Tyr1007/1008 phosphorylation, was largely increased and more sustained in PTPRF knockout cells compared to control. Furthermore, results from co-immunoprecipitation experiments showed that the association of STAT3 with gp130 was increased in PTPRF knockout cells, consistent with increased JAK activation. Functionally, the expression of SOCS3, a STAT3 target gene, was significantly elevated upon IL-6 stimulation as determined by RT-qPCR in PTPRF knockdown colon cancer cells. Taken together, this study identifies PTPRF as a novel regulator of the IL-6/gp130 signaling pathway in colon cancer.

#3319 IL-1 beta/ IL-6 co-stimulation synergistically mediates DUOX2/DUOXA2 complex up-regulation via JAK/STAT and p38 signaling events.

Jennifer L. Meitzler[1], Becky A. Diebold[1], David J. Mallick[2], Yongzhong Wu[1], Smitha Antony[2], Mariam M. Konate[2], Krishnendu Roy[2], James H. Doroshow[2]

[1]Developmental Therapeutic Branch, NCI, Bethesda, MD,[2]NCI Division of Cancer Treatment and Diagnosis, Bethesda, MD

Chronic inflammation increases the susceptibility of the colon to neoplasia and cancer through establishment of an inflammatory microenvironment and persistent release of reactive oxygen species (ROS), inducing genome damage. Interleukin -1beta (IL-1beta), a pro-inflammatory cytokine, plays a pivotal role in the pathogenesis of acute and chronic intestinal inflammation, regulating both innate and adaptive immune responses. IL-1beta has been shown to promote accumulation of IL-17A through lymphoid and Th17 infiltration in the colon tumor microenvironment, supporting increased inflammation and correlating directly with poor patient prognosis. New insights into the signaling pathways supported by IL-1beta in the pathogenesis of colon cancer, including angiogenesis and metastasis, may provide downstream targets for treatments that minimally perturb intestinal immunity. Prior studies from our group have demonstrated significant up-regulation of IL-1, dual oxidase 2 (DUOX2) and its partner maturation factor, DUOXA2, in surgically resected colon cancer specimens compared with adjacent normal colonic epithelium. To elucidate a direct link between IL-1 family cytokines, DUOX2/DUOXA2 derived ROS, and colorectal cancer, we examined human colon cancer cells (HT29, Ls513, T84 and Colo205) stimulated with IL-1beta, in cooperation with IL-6. Co-stimulation resulted in a dramatic, synergistic up-regulation of a hydrogen peroxide producing (Amplex Red oxidizing) DUOX2 enzyme complex and was directly associated with enhanced histone H2AX phosphorylation (γH2AX), a marker of DNA double strand breaks. Interestingly, this concentration- and time-dependent induction of expression and oxidative response was not mediated by other IL-1 family members (IL-18, IL-33 or IL-37). Investigations with the interleukin-1 receptor antagonist anakinra established that signaling for IL-1beta/IL-6 co-treatments proceeded through the IL-1 receptor for all cell lines, though minimal receptor expression is present in T84 and Ls513 cells. Similarly, exposure to tocilizumab, an IL-6R antagonist, demonstrated that the IL-1beta/IL-6 synergistic increase in DUOX2/DUOXA2 complex expression is IL-6 receptor dependent. Perturbation of the IL-1 and IL-6 signaling pathway elements MYD88, IRAK1, STAT1, and STAT3 by siRNA knockdown demonstrated their significant contribution to DUOX2/DUOXA2 up-regulation, while dependence on RELA was absent. Knockdown facilitated by MAPK14 siRNA and SB203580 p38 alpha/beta inhibition also demonstrated a role for p38alpha in the regulation of DUOX2/DUOXA2 expression by the IL-1beta/IL-6 signaling axis. Current studies are focused on elucidating the DUOX2 promoter transcription factor binding site(s) responsible for DUOX2 up-regulation through chromatin immunoprecipitation.

#3321 Validating upstream kinase predictions by linking activity to drug target proximity.

Dora Schuller, **Gitanjali Dharmadhikari**, Monique Mommersteeg, Liesbeth Houkes, Simar Pal Singh, Rik de Wijn

PamGene International B.V., 's-Hertogenbosch, Netherlands

Introduction: Sustained cell signaling is one of the hallmarks of tumor growth. Deregulation of kinase signaling can be studied by methods such as peptide microarrays or phospho-proteomics. For this, the prediction of kinases from phosphorylation signatures is a critical and complex. The aim of our study is to validate the biological relevance of kinase predictions, which we evaluate by the integration of kinase activity profiles with sensitivity data from the Genomics of Drug Sensitivity in Cancer (GDSC). A fundamental sensitivity mechanism involves repressing the activity of the drug's target kinase and its downstream survival pathways. We can test this mechanism through network analysis, hypothesizing that the signaling networks of active kinases and drug targets show high connectivity in sensitive cells, that should reflect the biological relevance of the kinase predictions.

Methods: Serine/Threonine Kinase (STK) activity profiling of 11 B-cell lymphoma cell lines was performed via the KinomePro platform (PamGene International B.V.). Kinases were predicted for 10 cell lines generally sensitive to multiple drugs (IC_{50} < 1 µm) compared to one relatively resistant control line (showing sensitivity to a smaller number of drugs). Cell line specific networks were generated from the top kinases and the target kinases of drugs the cells were most sensitive to, using the STRING protein-protein interaction database and Prize-Collecting Steiner Forest algorithm.

Results: To quantify signaling proximity of kinases and drug targets, we developed the network connectivity score. For each cell line, we calculated network connectivity using the median of the shortest paths between each kinase and drug target. This was then tested for statistical significance against a reference set of 50 random networks, generated using the original drug targets and randomized kinase data. Kinase predictions for 5 out of 10 B-cell lymphoma cell lines resulted in significant network connectivity score ($p < 0.07$), depending on the parameters used in the prediction algorithm. These results demonstrate the method’s utility to identify optimal parameter settings for the prediction algorithm.

Conclusion: We developed a validation method for the biological relevance of kinase predictions from phosphorylation signatures obtained in a cellular context. Future work will focus on applying this method to improve studies of the role of kinases in signal transduction by evaluating and optimizing the performance of kinase prediction methods and their potential biases.

#3322 Next-Generation FemtoQuest™ system enables dual-analyte ultrasensitive quantitation of active and total HGF in melanoma plasma samples.

Joseph B. Hwang[1], Raad Gitan[2], Matthew Lippold[2], Brooke Gilliam[2], Rick Wiese[2]

[1]R&D, MilliporeSigma, St. Louis, MO,[2]MilliporeSigma, St. Louis, MO

Hepatic growth factor (HGF) binds to the HGF receptor tyrosine kinase, also known as c-Met. Autophosphorylation of the HGF receptor leads to recruitment and activation of multiple downstream signaling molecules involved in MAPK, Akt/PI3K, STAT and NF-kB pathways. Activation of HGF receptor by HGF can lead to cell growth, cell motility, angiogenesis and cell survival. Upregulation of this pathway can lead to tumorigenesis of different types of cancer. Various approaches to inhibiting this HGF/c-Met axis have been explored, including c-Met neutralizing antibodies and small molecule inhibitors without much success. It is critical to understand the mechanisms of the HGF/c-Met axis to facilitate novel therapies. It is important to differentiate between the active versus total HGF concentration in the blood. Pro-HGF peptide is secreted by liver cells into extracellular matrix, where it can be cleaved by proteases into alpha and beta subunits, which form the active tetramer of 2 alpha and 2 beta subunits. It is the active form of HGF that binds and activate c-Met. We developed an ultrasensitive immunoassay platform utilizing SMC® technology to address the challenge of quantifying low-abundance proteins in blood. Our next-generation FemtoQuest™ system enables detection of two analytes in a single assay well, maximizing sample efficiency. For this study, we developed a novel 2-plex immunoassay that can detect active HGF and total HGF (active HGF plus pro-HGF) simultaneously in a single well. This kit was able to achieve the sensitivity needed to quantitate both apparently healthy and melanoma plasma samples. Statistical difference for both Active HGF and Total HGF were observed in healthy versus melanoma samples. This high sensitivity immunoassay kit can differentiate between active HGF versus total HGF and allow measurement of low abundance proteins, demonstrating the platform's capability to detect differential HGF expression patterns in cancer samples.

#3326 C-myc driven by differentiation factors in early-onset colorectal cancer (EOCRC).

Kazuaki Okamoto[1], Yalda Naeini[2], Anton Bilchik[3], Dave Hoon[1]

[1]Department of Translational Molecular Medicine, St. John's Cancer Institute (SJCI), Providence St. John's Health Center (PSJHC), Santa Monica, CA,[2]Department of Surgical Pathology, PSJHC, Santa Monica, CA,[3]Department of Gastrointestinal and Hepatobiliary Surgery, PSJHC, Santa Monica, CA

Background: Early-onset colorectal cancer (EOCRC), patients diagnosed with CRC <50 yrs has become a rapidly increasing global threat in recent years. Generally, EOCRC is known for its high malignancy, characterized by advanced stages at diagnosis and often undifferentiated histological types. Despite numerous previous studies, its molecular pathological characteristics remain largely unexplored. The purpose of this study is to elucidate the progression mechanisms of EOCRC versus Late-onset CRC (LOCRC).

Methods: To identify genes characteristic of EOCRC, an *in silico* analysis was conducted by comparing RNA-seq data from CRC patients aged aged ≤45 with those aged ≥ 60 and using TCGA COAD/READ and GSE39582 CRC database. At the PSJHC, among patients who underwent primary tumor resection for CRC between 2018 and 2021, we then divided 30 patients into two groups using the cutoffs of 45 and 60 yrs of age, respectively. We then performed single-cell level spatial transcriptome analysis using Xenium(10X). Pathways were validated through these analyses using multiplex immunofluorescence (Akoya) staining and *in vitro* analysis with colon cancer cell lines.

Results: In the *in silico* analysis, regulatory gene of cell differentiation exhibited significantly higher RNA expression in EOCRC patients compared to those with LOCRC. The expression levels of these genes are associated with poor overall survival. Furthermore, *in vitro* analysis demonstrated a significant increase in c-myc expression through the NF-κB pathway and the promotion of tumor growth induced by the upregulation of the downstream differentiation factors. Additionally, it was demonstrated that the expression of differentiation factors and respective receptors are higher at the protein level in the EOCRC patients than the LOCRC patients ($p<0.001$). In multiplex immunofluorescence, significant correlation between the expression of differentiation factors and c-myc was observed.

Conclusions: In EOCRC, differentiation factors were expressed at higher levels compared to LOCRC, suggesting that they upregulate c-Myc through the NF-κB pathway. These differentiation factors may contribute to the poor prognosis observed in EOCRC versus LOCRC.

#3327 Structure and function of the L-MYC N-terminus impacts strategies to inhibit the MYC family of oncoproteins.

Tristan M. Kenney[1], Scott Houliston[1], Peter Chien-feng Lin[2], Nikan Movahedi[1], Cheryl Arrowsmith[1], **Linda Z. Penn**[1]

[1]UHN Princess Margaret Cancer Centre, Toronto, ON, Canada,[2]University of Toronto, Toronto, ON, Canada

The *MYC* family of transforming oncogenes function as regulators of gene transcription and is composed of three members, *MYC*, *MYCN* and *MYCL*. As the c-MYC (MYC) protein is deregulated in >50% of human cancers, the role, regulation and structural features of MYC have been well-studied. By contrast, the L-MYC protein has been relatively understudied as historically, oncogenic deregulation was evident only in a subset of small cell lung carcinomas (SCLCs). However, with recent deep genomic analyses of primary patient samples, L-MYC has been shown to be deregulated in numerous human cancers. With this revelation it is important to understand how the L-MYC protein compares to MYC at the structural level, particularly for the development of broad-spectrum inhibitors of the MYC family.

Here we first show that L-MYC expression is anti-correlated with MYC expression and is elevated in several primary patient tumor samples compared to normal, providing further evidence for L-MYC as a driver oncoprotein in primary human cancers. Next, we provide new insights into the biophysical features of an N-terminal region within the transactivation domain of L-MYC, which harbors two regions conserved amongst the MYC family: MYC box 0 (MB0) and MYC box I (MBI). NMR spectroscopy of residues 1-80 of L-MYC confirms that, similar to MYC, it is largely intrinsically disordered and interacts with the known MYC MB0-interacting protein, PNUTS (Phosphatase 1 NUclear Targeting Subunit). On the other hand, L-MYC does not interact with the MYC MB1-interacting protein Bin1 (Bridging integrator 1), suggesting a potential mechanism by which L-MYC evades this tumor suppressor. Together, these results further substantiate the oncogenic role of L-MYC in human cancer and deeply enhance our understanding of the biophysical nature of L-MYC to better inform strategies for the development of anti-cancer therapeutics targeting the MYC family of oncoproteins.

#3328 Investigating resistance to beta-catenin degradation in a colorectal cancer cell line.

Reiss Clifford[1], Christopher I. Milton[1], Jasjot Singh[2], Marc Krenkel[2], Pradeep Ramagiri[1], Konstantinos Mitsopoulos[1], Frank Fischer[2], Marissa V. Powers[1], Dirk Wienke[2], Paul A. Clarke[1]

[1]The Institute of Cancer Research, London, London, United Kingdom,[2]The Healthcare Business of Merck KGaA, Darmstadt, Germany

Oncogenic mutations to the Wnt pathway are present in approximately 80% of colorectal cancer (CRC) patients. In mouse CRC models, Beta-Catenin (BC) loss inhibits tumour growth reinforcing BC as a promising anticancer target. Small molecules or peptides targeting BC have been reported but these generally lack features of high-quality chemical probes. To date there are no reports of these tool compounds progressing to chemical series with more drug-like physiochemical and pharmaceutical characteristics, yet interest in developing BC inhibitors or degraders remains. To explore potential fragment-binding pockets on BC we established a BC-degron model for genetic rescue experiments using the dTAG system to degrade FKBP12^{F36V}-tagged BC. Based on literature and in-house date we selected the APC-mutant, BC-dependent SW480 human CRC cell line as our model of choice. During the characterisation of multiple dTAG single cell clones we identified two resistant SW480 cell clones which proliferated despite BC degradation. One line (Res1) contained no detectable BC protein following treatment with the dTAG^{V}-1 heterobifunctional degrader molecule. Whereas the other, Res2, retained expression of an internally truncated species of BC,that was sufficient to rescue WT-BC function. Genetic and proteomic profiling were used to define the response of resistant populations to BC degradation. Res2 exhibited a similar molecular profile to cells expressing full length BC. Res1 exhibited a proteomic profile distinct from sensitive cells after BC degradation. BC-driven oncogenic gene expression profile was degraded in resistant cells, similarly to sensitive cells. But metabolic pathways, including autophagy, were markedly altered in resistant cells. Additionally, we found a region of chromosome 19 lost only in Res1. Res1 exhibited distinct morphological features to sensitive cells and an increased migratory capacity. Multiple patient-like cancer stem cell subtypes have been classified within the SW480 CRC cell line population, with different invasive and Wnt signalling capacities. But their responses to BC inhibition or loss are unknown. Molecular and cellular characterisation of Res-1 is on-going to identify key SW480 subtype features and mechanism of resistance to BC loss as potential biomarkers to predict patients with resistance to BC inhibition and suggest novel pathway dependencies which can be exploited for combination therapies alongside BC inhibition or degradation.

#3330 Spatial and molecular profiling of tumor initiation in ccRCC.

Omar Bouricha[1], Daqi Deng[1], Anne-Laure Cattin[1], Matous Elphick[1], Scott Shepherd[1], Cathy D. Vocke[2], W. Marston Linehan[3], Samra Turajlic[4]

[1]Cancer Dynamics Laboratory, The Francis Crick Institute, London, United Kingdom,[2]National Cancer Institute, Bethesda, MD,[3]Chief, Urologic Onc. Branch, National Cancer Institute, Bethesda, MD,[4]CRUK Manchester Institute, Manchester, United Kingdom

Clear Cell Renal Cell Carcinoma (ccRCC) is the most common and aggressive type of kidney cancer. ccRCC originates from proximal tubule (PT) epithelial cells in the nephron. Its initiation is characterised by a linear evolution from the loss of one copy of chromosome 3p to the inactivation of the second VHL allele on the remaining copy of 3p. Computational studies established that 3p loss occurs several decades before diagnosis. This offers an unprecedented window of opportunity for early detection, cancer prevention and for broader pan-cancer learning. However, the biological mechanisms driving the pre-cancerous expansion of PT cells harboring these events remain elusive. One of the major unmet needs in ccRCC initiation is the identification of molecular biomarkers for the initially quiescent tumor-initiating cell. Previous studies established that the putative ccRCC cell of origin (COO) is a subtype of PT cells characterized by VCAM1 expression, a marker of tubular injury in human kidneys. Therefore, we hypothesized that VCAM1 can be used as a marker to enrich for cells that have lost a copy of chromosome 3p. Preliminary single-cell whole genome sequencing (WGS) of VCAM1+ PT cells revealed a high incidence of aneuploidies, including chromosome 3-related aneuploidies, indicating that these cells represent a chromosomally unstable epithelial subpopulation within morphologically normal kidney tissue. Therefore, this data supports VCAM1 as a candidate marker for the study of ccRCC initiation in human kidneys.Despite its quasi-ubiquitous role in ccRCC initiation, several studies show that VHL inactivation is insufficient for tumorigenesis in mammalian kidneys. To study this, we used histological analysis of VHL patient-derived normal kidney tissues, where 3p loss occurs on the background of a germline VHL mutation. We demonstrated that VHL inactivation (marked by CAIX expression) occurs in all major cortical epithelial cell types. Surprisingly, only the proportion of CAIX+ distal tubule (DT) cells showed a significant correlation with the age of the patient at the time of tissue collection. In addition, there is a significantly higher proportion of multicellular DT CAIX+ foci compared to CAIX+ PT foci, suggesting clonal expansion after VHL inactivation is favored in DT cells. Only a minority of CAIX+ PT foci were multicellular, indicating that unknown cell-intrinsic or extrinsic factors are necessary for clonal expansion. Results from our cohort show a positive association between the density of VCAM1+ PT cells and CAIX+ PT in VHL patient-derived normal kidney tissues, indicating that tissue stress levels may potentiate the selection and expansion of VHL inactivation in the human kidney. Our data offers novel insight in the putative COO of ccRCC and the mechanisms driving the earliest stages of ccRCC. Moving forward, we plan to expand our cohort and molecularly profile VCAM1+ and CAIX+ cells using multi-omic approaches.

#3331 NanoGlio recapitulates *IDH*-mutant glioma biology and therapeutic response to vorasidenib.

Uijin Kim[1], Satoru Kawakita[1], Emily Miller[1], Wei Huang[1], Francisco Bustamante[1], Lauren Vanderpool[1], Chongming Jiang[1], Albert Lai[2], Zhaohui Wang[1]

[1]Terasaki Institute for Biomedical Innovation, Woodland Hills, CA,[2]Department of Neurology, UCLA Health, Los Angeles, CA

IDH-mutant gliomas are a biologically and clinically distinct subset of diffuse gliomas that remain challenging to model *in vitro*. Vorasidenib, a brain-penetrant dual IDH1/2 inhibitor, is the first FDA-approved targeted therapy for grade 2 non-enhancing gliomas in 2024. Here, we present NanoGlio, a nanoliter-scale organoid platform that enables rapid, passage-zero functional drug testing using minimal patient-derived material. NanoGlio supports the formation of uniform, viable tumor organoids that preserve the cytoarchitecture and cellular heterogeneity of the parental tumors. We established NanoGlio models from 13 cases of grade 2, 5 cases of grade 3, and 9 cases of grade 4 *IDH*-mutant gliomas, including spatially distinct enhancing and non-enhancing regions from 4 patients. Single-cell RNA sequencing confirmed that NanoGlio retains tumor-intrinsic heterogeneity and myeloid lineages present in the original tissue. High-content phenotypic screening revealed heterogeneous responses to Vorasidenib, with NanoGlio sensitivity correlating with tumor grade and molecular subtype. Notably, Vorasidenib induced differentiation-like morphologic changes in grade 2 models but paradoxically enhanced proliferation in a subset of high-grade models. Bulk RNA sequencing showed that NanoGlio captures *in vivo*-like drug response programs, particularly in immune-related and glial differentiation pathways that overlap with molecular changes reported in clinical trials. Furthermore, NanoGlio-derived conditioned media, when applied to co-cultures of HER2-specific chimeric antigen receptor (CAR) T cells and HER2-positive SKOV3 tumor cells, enabled functional assessment of soluble factor-mediated immune suppression. Together, these data establish NanoGlio as a scalable, patient-relevant organoid platform for modeling IDH-mutant glioma biology and therapeutic response, with direct applications to drug-response prediction and rational combination strategies in precision oncology.

#3332 Functional role of PHLDA1 down regulation leads to morphological changes and increased proliferation in MCF-7 breast cancer cells.

Ana Carolina Pavanelli[1], Flavia Rotea Mangone[1], Fernando M. Simabuco[2], Maria Aparecida Nagai[3]

[1]Center for Translational Research in Oncology, Instituto do Cancer do Estado de Sao Paulo and Comprehensive Center for Precision Oncology, Sao Paulo, Brazil,[2]Departamento de Bioquimica, Universidade Federal de Sao Paulo, Sao Paulo, Brazil,[3]Center for Translational Research in Oncology, Instituto do Cancer do Estado de Sao Paulo and Comprehensive Center for Precision Oncology/Disciplina de Oncologia do Departamento de Radiologia e Oncologia, Sao Paulo, Brazil

The PHLDA1 (pleckstrin homology-like domain Family A, member 1) belongs to a family of genes that encode phosphatidylinositol (PIP) binding proteins and function as inhibitors of Akt activation. Previously, we have shown that PHLDA1 down-regulation is a strong predictor of poor prognosis for breast cancer (BC) patients. We have also demonstrated that decreased PHLDA1 expression is associated with more aggressive behavior in non-malignant mammary cells and is linked to a more aggressive BC phenotype and a worse prognosis. Additionally, we demonstrated that PHLDA1 expression is regulated by estrogen via ER. Here, we sought to investigate the effects of PHLDA1 knockdown on cell proliferation, migration, and colony formation, and further assess its involvement in the response to endocrine therapies. The MCF-7 cells were transfected using a CRISPR/Cas9 vector (p5pCas(BB)-2A-Puro (PX459) V2.0) that included guide RNAs (gRNAs) designed to silence the PHLDA1 gene, as well as a control vector with scrambled gRNAs. PHLDA1 knockdown clones (MCF-7koPHLDA1) were confirmed by western blot and qRT-PCR. MCF-7koPHLDA1 clones displayed morphological changes, including loss of regular angular and spindle shapes and a more dispersed cell arrangement. We performed the colorimetric MTT reduction assay to evaluate the effect of PHLDA1 knockdown on the proliferation. MCF-7koPHLDA1 has significantly higher proliferation rates than MCF-7 transfected with the vector containing a scramble (MCF-7-SC). In addition, a clonogenic assay followed by crystal violet staining showed that MCF-7koPHLDA1 also exhibited higher colony-forming ability, with a dispersed organization and limited cell-cell contact, compared with MCF-7-SC. Our data suggest that decreased PHLDA1 expression enhances the proliferation and colony-forming ability of MCF7 cells. Additionally, the obtained clones will be assessed for how PHLDA1 expression influences their response to tamoxifen and fulvestrant treatments. Supported by FAPESP.

#3333 CHAF1A phosphorylation by PLK1 promotes AR-driven enzalutamide resistance in prostate cancer.

Sai Wu[1], Chaohao Li[1], Jia Peng[2], Xiaoqi Liu[1]

[1]University of Kentucky, Lexington, KY,[2]Department of Toxicology and Cancer Biology, University of Kentucky, Lexington, KY

Prostate cancer (PCa) remains a major global health challenge, ranking as the second most frequently diagnosed malignancy and the fifth leading cause of cancer-related mortality among men. Although androgen deprivation therapy and next-generation androgen receptor (AR) pathway inhibitors, such as enzalutamide, have improved clinical outcomes, the inevitable emergence of castration-resistant prostate cancer (CRPC) and treatment resistance underscores the need to elucidate the underlying molecular mechanisms. Polo-like kinase 1 (PLK1), a conserved serine/threonine kinase essential for mitosis, has been implicated in promoting enzalutamide resistance; however, the mechanistic basis of this phenomenon remains insufficiently understood. In this study, we identify Chromatin Assembly Factor 1 subunit A (CHAF1A) as a previously unrecognized modulator of AR signaling and a critical contributor to enzalutamide resistance. Analysis of the clinical database revealed that CHAF1A is significantly overexpressed in PCa compared with benign prostate tissues, and elevated CHAF1A levels correlate with poor patient prognosis. Functional assays demonstrated that CHAF1A knockdown in C4-2 and 22Rv1 cells suppresses cell proliferation, decreases PSA expression, and restores sensitivity to enzalutamide. Conversely, CHAF1A overexpression in C4-2 and LNCaP cells enhances proliferation and upregulates AR downstream effectors. Mechanistic studies revealed that CHAF1A is a potential substrate of PLK1 and undergoes phosphorylation at threonine 591 (T591). Introduction of a phosphorylation-deficient mutant, CHAF1A-T591A, into C4-2 cells attenuated AR signaling and significantly increased their responsiveness to enzalutamide. RNA sequencing further demonstrated pronounced downregulation of AR signaling in CHAF1A-T591A-expressing cells compared with wild-type controls. Using ChIP-qPCR, we show that CHAF1A enhances AR binding to promoter regions of key downstream targets, thereby elevating AR transcriptional activity. Importantly, the T591A mutation markedly diminished AR chromatin occupancy, indicating that PLK1-mediated phosphorylation at T591 is required for CHAF1A-dependent AR activation. Collectively, these findings identify CHAF1A as a novel enhancer of AR chromatin binding and transcriptional output, acting through a PLK1-dependent phosphorylation mechanism. We propose that elevated CHAF1A expression drives enzalutamide resistance by sustaining AR pathway activation, and that disruption of PLK1-mediated CHAF1A phosphorylation represents a promising therapeutic strategy to overcome resistance in CRPC.

#3334 The human Flower isoform hFWE4 facilitates cornification in cutaneous squamous cell carcinoma.

Justin C. Rudd, Patrick T. Kuwong, Rachel E. Johnson, Louise N. Monga-Wells, Meghan Vo, Julia Russolillo, Shreya Reddy, Mallory Jacob, Hunter Litz, Changzhao Li, Andrew Siref, James A. Grunkemeyer, Laura A. Hansen

Creighton University, Omaha, NE

Background: Cutaneous squamous cell carcinoma (cSCC) arises from transformed keratinocytes that often retain partial differentiation potential. Because differentiation status correlates with prognosis, molecular markers that distinguish well- from poorly-differentiated (WD vs PD) tumors are of clinical value. Flower (FWE), a four-transmembrane protein that regulates lamellar body (LB) trafficking during epidermal barrier formation, was examined here as a candidate marker and regulator of terminal differentiation in cSCC.

Methods: FWE expression was analyzed in human cSCC cell lines, xenografts, and clinical tumors. CRISPR/Cas9 was used to generate hFWE knockout (KO) SCC-13 cells for xenografting in NCG mice (n=12). RNA-seq, immunoblotting, and immunofluorescence quantified differentiation-associated changes in KO tumors. Lentiviral EGFP-2A-hFWE4 constructs were used to assess impact of hFWE4 overexpression on proliferation and differentiation outcomes.

Results: FWE was induced during Ca^{2+}-driven differentiation of cultured SCC cells and localized to suprabasal keratinocytes in SCC-13 xenografts. *hFWE* KO tumors exhibited a slight reduction in average mass (0.33 to 0.19g, $p<0.05$) and showed altered keratinization characterized by reduced keratohyalin granule-containing cells and solid parakeratosis. Immunofluorescence of KO tumors revealed 63% and 82% reductions in filaggrin- and loricrin-positive areas, respectively ($p<0.01$-0.0001), while RNA-seq identified 73 downregulated genes (FDR<0.05, $|\log_2 FC|>1$)—enriched for LB and cornification pathways—including *KLK5*, *KLK7*, *SLURP1*, and *LORICRIN*. Ectopic hFWE4 expression induced G1 arrest (↑G1 by 5-17%, ↓S-phase by 6-10%; $p < 0.0001$) in SCC-13, COLO 16 and SCC-12b.2 cells, and reduced the fraction of cells that were $Ki67^+$ (0.57% to 0.13%, $p<0.05$) and $ITGB1^+$ (11.3% to 2.4%, $p<0.05$) while increasing the fraction that were filaggrin$<^+$ (34.6% to 57.2%; $p<0.01$) in SCC-13 xenografts. In human tumors (WD n=9, PD n=5), FWE-positive area was significantly higher in WD than PD regions (6.2-fold increase; $p<0.0001$).

Conclusions: In cSCC, loss of FWE disrupts LB-dependent cornification, while ectopic expression elicits G1-arrest and differentiation. As high FWE-positive area correlates with increased differentiation grade in human cSCC, we propose that FWE represents both a mechanistic regulator of cornification and a promising molecular marker for objective grading of cSCC differentiation.

#3335 Trop-1/EpCAM Thr115 is a novel inducer of cancer cell proliferation and drives hyperproliferative lung damage in COVID-19.

Saverio Alberti[1], Milena Baldassarri[2], Marco Trerotola[3], Giulia Brunelli[2], Laura Bergantini[2], Benedetta tella[2], Giulia Rollo[2], Emanuela Guerra[3], martina ceci[3], Ludovica Pantalone[3], Elena Bargagli[2], Rossano Lattanzio[3], Antonino Moschella[1], Federica M. Previtera[1], Cristiana Bellan[2], Nicola La Francesca[2], Cristoforo Pomara[4], Network for Italian Genomes, GEN-COVID Multicenter Study, Alessandra Renieri[2], Chiara Fallerini[2]

[1]University of Messina, MESSINA, Italy,[2]University of Siena, Siena, Italy,[3]University of Chieti, Chieti, Italy,[4]University of Catania, Catania, Italy

SARS-CoV-2 infection triggers an acute reaction that can severely impair lung function. However, the underlying molecular processes are poorly understood. Our findings showed that the pM115T polymorphism of TROP1/EPCAM associates with COVID-19 severity. The p.M115T polymorphism of TROP1/EPCAM gene had been associated with higher frequency of early-onset breast cancer. However, the functional role of Thr115 Trop-1/EpCAM remained essentially unknown. We explored whether the Thr115 Trop-1/EpCAM acts as a driver of cell proliferation and whether this can play a role in lung pathology / lesion repair in COVID-19 patients. TROP1/EPCAM knockout embryonic stem cells showed altered proliferation. The Trop-1/EpCAM Thr115 allele was found to drive hyperproliferative capacity in murine fibrosarcoma cells, whereas the Met115 allele did not. A corresponding role was assessed in human colon cancer cells, through CRISPR-Cas9 ablation of the endogenous TROP1/EPCAM and comparative transfection of Trop-1/EpCAM Thr115 or Met115 alleles. The Trop-1/EpCAM Thr115 was shown to induce colon cancer cell hyperproliferation, whereas the Met115 allele was devoid of cell growth-driving capacity. Trop-1/EpCAM Thr115 was correspondingly shown to drive the main pathological mechanisms that lead to oxygen-exchange impairment in COVID-19. Morphometric analysis of autoptic lung samples, immunohistochemistry analysis for Trop-1/EpCAM expression, Ki67 proliferation index and comparative computational image analysis were utilized to analyze SARS-CoV-2-infected lungs at autopsy. This showed hyperproliferation of Thr115 Trop-1/EpCAM+ epithelial cells over the alveolar epithelium damaged by the infection. This correlated with Thr115 Trop-1/EpCAM+ inflammatory cells hyperproliferation and alveolar hyaline membrane formation. These multi-layered barriers were computed to reduce oxygen diffusion by up to 100-fold versus normal alveolar structures, with a critical pathological impact. Our findings identify a novel mechanism of induction of cancer cell proliferation by a polymorphic, wild-type Trop-1/EpCAM. A corresponding process was shown to operate in COVID-19 patients, causing an aberrant lung repair, via Trop-1/EpCAM Thr115-induced cell overproliferation. These findings indicate unexpected parallels between inflammation-driven wound-repair in the lungs and cancer cell hyperproliferation as driven by via Trop-1/EpCAM Thr115. Novel diagnostic/ prognostic/ therapeutic opportunities are suggested in Thr115 Trop-1/EpCAM+ COVID-19 patients, and in Thr115 Trop-1/EpCAM+ cancer patients. Acknowledgments: Grant PNRR - Tuscany Health Ecosystem (THE), Next Generation EU, Missione 4, Componente 2, Inv. 1.5, CUP B63C22000680007.

#3336 cGAS/STING-activated macrophages form lipophagosomes to regulate TME and promote progression in obesity-associated pancreatic cancer.

Yi-ting Chen[1], **Zu-Wei Wang**[2], Jin-peng Lu[3], Hao-xiang Zhang[2], Shun-cang Zhu[3], Hong-yi Lin[2], Shi Chen[2]

[1]Fuzhou University, Fuzhou, China,[2]Fuzhou University Affiliated Provincial Hospital, Fuzhou, China,[3]Fujian Medical University, Fuzhou, China

Background: Obesity significantly accelerates pancreatic cancer progression and worsens patient prognosis. However, the specific mechanisms by which macrophages regulate the tumor microenvironment (TME) in obese pancreatic cancer patients remain unclear. Understanding how macrophage-mediated TME remodeling contributes to accelerated disease progression in obesity-associated pancreatic cancer is crucial for developing targeted therapeutic strategies.
Methods: We investigated macrophage phenotypic changes and TME regulation in obesity-associated pancreatic cancer progression. We analyzed cGAS/STING pathway activation in tumor-associated macrophages, characterized mediating lipophagosome formation through lipid engulfment, and examined the resulting immunosuppressive TME. The study evaluated T cell dysfunction, regulatory T cell expansion, and the mechanistic role of tumor-derived mitochondrial DNA in macrophage activation.
Results: We identified a comprehensive mechanism whereby macrophages promote obese pancreatic cancer patient progression through cGAS/STING-mediated lipophagosome formation and TME regulation. Obesity-associated pancreatic cancer develops within a characteristic immunosuppressive environment where macrophages undergo cGAS/STING pathway activation, leading to their differentiation into foam macrophages. These STING-activated macrophages simultaneously cause CD8+ T cell exhaustion and promote regulatory T cell proliferation while competitively uptaking lipids, thereby depleting metabolic resources essential for CD8+ T cell function. Through this lipid engulfment process, STING-activated macrophages form specialized organelles called lipophagosomes, which further enhance Treg proliferation and amplify immunosuppression within the TME. Mechanistically, tumor cells in the obesity environment release mitochondrial DNA that serves as the primary trigger for macrophage cGAS/STING activation, establishing a feed-forward loop that maintains and intensifies the obesity-induced immunosuppressive environment, ultimately driving accelerated tumor progression.
Conclusions: Our findings demonstrate that macrophages promote obese pancreatic cancer patient progression through cGAS/STING-activated lipophagosome formation, which remodels the TME into an immunosuppressive state. This macrophage-centric mechanism provides novel therapeutic targets for treating obesity-associated pancreatic cancer progression.

#3340 Toward large-scale clinical implementation of extracellular vesicle profiling for precision oncology.
Antonia Schubert[1], Nadine Winkler[1], Robert Ihnatko[2], Joscha Kraske[3], Sunanjay Bajaj[3], Michelle Ne?ling[4], Karsten Richter[4], Dirk Jager[3], Guy Ungerechts[3], Oliver Sedlaczek[5], Jeroen Krijgsveld[2], Thomas Walle[3], Michael Boutros[1]

[1]Signaling and Functional Genomics, German Cancer Research Center (DKFZ), Heidelberg, Germany,[2]Proteomics of Stem Cells and Cancer, German Cancer Research Center (DKFZ), Heidelberg, Germany,[3]Medical Oncology, University Hospital and Medical Faculty Heidelberg, Heidelberg, Germany,[4]Central Unit Electron Microscopy, German Cancer Research Center (DKFZ), Heidelberg, Germany,[5]Department of Radiology, German Cancer Research Center (DKFZ), Heidelberg, Germany

Extracellular vesicles (EVs) are nanosized, membrane-bound particles released by all cell types. They carry proteins, nucleic acids, and lipids reflective of their cellular origin and have emerged as promising non-invasive biomarkers for cancer diagnosis and monitoring of therapy response. However, the clinical translation of EV-based assays remains limited by heterogeneous isolation methods, a lack of standardization of the clinical workflows, and insufficient validation in large patient cohorts.
To address these challenges, our group at the National Center for Tumor Diseases in Heidelberg, Germany, has developed an EV profiling framework compliant with MISEV2023 recommendations. We systematically benchmark isolation and pre-processing procedures to ensure reproducibility and compatibility with high-throughput liquid biopsy workflows within the prospective *EValuate* study (S-773/2021). Blood samples are collected *via* the NCT Cell and Liquid Biobank, processed within 30 minutes, and stored as serum and plasma aliquots at -80 °C for longitudinal analyses. To enable large-cohort EV analyses, we also characterized a miniaturized size-exclusion chromatography protocol using low-volume serum or plasma, which requires no specialized equipment and complements conventional differential centrifugation workflows.
To demonstrate the feasibility of the pipeline, we collected and analyzed a total of 125 serum samples - 109 from 24 patients with hepatocellular carcinoma (HCC) undergoing immune checkpoint inhibitor therapy and 16 quality-control samples from four healthy donors. EVs were isolated and characterized by transmission electron microscopy, nanoparticle tracking analysis, Western blotting, quantitative protein assays, and subsequently profiled proteomically to identify EV-derived protein signatures associated with disease course, radiological treatment response (RECIST), and survival.
This standardized, high-throughput EV workflow bridges biobanking, analytical validation, and clinical correlation, providing a robust and scalable framework for integrating EV-based liquid biopsy assays into precision oncology.

#3341 Focused ultrasound BBB opening yields distinct, tissue-specific extracellular vesicle profiles for glioblastoma liquid biopsy.

Andrew Thede[1], Zehra Demir[1], Khondamir Imomnazarov[2], Stefanyda Maslova[1], Rachel Short-Miller[3], Sean Lodmell[3], Kelley VanVaerenberghe[3], Claire Seibold[3], Adam LaBonte[3], Katie Havranek[3], **Natasha D. Sheybani**[1]

[1]Department of Biomedical Engineering, University of Virginia, Charlottesville, VA,[2]Department of Neuroscience, University of Virginia, Charlottesville, VA,[3]FYR, Missoula, MT

Introduction: Extracellular vesicles (EVs) are highly information-dense liquid biopsy reservoirs carrying proteins, RNAs, lipids, and metabolites that reflect the real-time state of their parent cells. In glioblastoma (GBM), EVs offer a uniquely accessible window into an otherwise sequestered compartment, yet the blood brain barrier (BBB) restricts their enrichment and profile within the circulation. Focused ultrasound (FUS) with microbubbles is now a clinically burgeoning method for transient and precise local opening of the BBB, creating an opportunity to interrogate EV flux from tumor and surrounding brain. While FUS-mediated BBB opening (BBBO) has been shown to augment circulating nucleic acids via “sonobiopsy,” its effects on EV release and cargo remain poorly defined. Here, we evaluate how FUS-BBBO alters the abundance and composition of tumor- versus brain-derived EVs enriched from blood plasma in a high-fidelity GBM model.

Methods: Orthotopic GBMs were established via intracranial SB28 implantation (n=24). Tumors were screened by contrast-enhanced MRI and randomized into volume-matched sham or FUS treatment groups. BBBO was performed using a neuronavigation-guided preclinical FUS system. Plasma was collected 30 min or 24 h post-treatment. EVs were isolated by ion-exchange chromatography and characterized by NTA and Western blot. Tumor- and brain-derived EVs were enriched using Tumor SPARCs™ and Neuro SPARCs™, respectively, and subjected to DIA-MS proteomic analysis.

Results: FUS-BBBO did not significantly alter total plasma EV concentrations associated with either compartment; rather, it induced substantial remodeling of EV cargo. Across samples, >5,000 proteins were identified. Approximately 80% of differentially abundant proteins were unique to either the tumor- or brain-derived EV panel, indicating compartment-specific responses to FUS. Strikingly, FUS exposure yielded 222 and 290 unique proteins within brain-derived and tumor-derived circulating EV populations, respectively. Pathway analysis revealed enrichment in vesicle trafficking, neurovascular stress signaling, cytoskeletal remodeling, and immune regulatory pathways - potentially reflecting FUS-induced alterations in tumor microenvironmental stress, BBB dynamics, and neuro-immune cross-talk.

Conclusions: FUS-BBBO drives robust, compartment-specific reprogramming of EV proteomes in GBM, revealing biomarker candidates absent under sham conditions. These findings position EV profiling as a sensitive approach for capturing FUS-induced tissue remodeling and may expand the biomarker repertoire available for spatially selective GBM liquid biopsy. Ongoing studies are assessing temporal dynamics and correspondence with parental tissue proteomes.

#3342 Mito-EV-driven mitochondrial transfer: A trigger for ferroptosis in glioblastoma.

Junbo Liao, Shuhan Cao, Ka Kit Gilberto Leung, Karrie. M Kiang

Department of Surgery, The University of Hong Kong, Pokfulam, Hong Kong

Background: Glioblastoma (GBM) is the most aggressive primary brain tumor, with limited therapeutic options due to metabolic adaptability and resistance to cell death. Ferroptosis, an iron-dependent pathway involving lipid peroxidation, offers a promising GBM target. Extracellular vesicle (EV)-based mitochondrial transfer enables intercellular shuttling of damaged mitochondria, modulating recipient cell metabolism in cancer microenvironments. During adipocyte thermogenesis, damaged mitochondria are released as Mito-EVs under stress conditions like obesity. This study explores how Mito-EV-mediated transfer from stressed adipocytes activates ferroptosis in GBM cells.
Methods: Mito-EVs containing stressed mitochondria were isolated from adipocytes via centrifugation and characterized by microscopy and protein analysis. GBM cells were exposed to Mito-EVs for mitochondrial transfer, compared to free mitochondria, and confirmed by imaging. Ferroptosis was induced with activators and evaluated through cell death and stress markers. In vivo, circulating Mito-EVs from an obese mouse model were injected into GBM tumor models, alone or with ferroptosis agents, with tumor response assessed by imaging and tissue analysis.
Results: Mito-EV transfer enhanced mitochondrial uptake in GBM cells over free mitochondria, integrating into networks and inducing oxidative stress. This increased ferroptosis sensitivity, with reduced activator requirements and altered cell death regulators. In vivo, Mito-EV treatment promoted ferroptosis and, when combined with activators, reduced tumor growth with ferroptosis evidence and low toxicity.
Conclusions: Mito-EV-mediated mitochondrial transfer from stressed adipocytes boosts ferroptosis in GBM via oxidative stress, proposing a new strategy using circulating Mito-EVs for anticancer effects in obesity-linked contexts.

#3343 ATP6V1C1 in cancer-associated fibroblast-derived extracellular vesicles affects the metastasis and therapeutic sensitivity of lung adenocarcinoma.

Xuanming Chen, Jue Li, **Kai Xiao**

Laboratory of Precision Therapeutics, Department of Pulmonary and Critical Care Medicine, West China hospital, Sichuan University, Chengdu, China

Cancer-associated fibroblast (CAF)-derived extracellular vesicles (EVs) are known to promote lung adenocarcinoma (LUAD) progression, yet the specific protein cargos responsible for this effect remain poorly defined. In this study, we generated a library of patient-derived fibroblasts (PDFs) from paired LUAD tumor and adjacent noncancerous tissues. Through integrated transcriptomic analysis and surface marker identification, we characterized CAFs and normal fibroblasts (NFs), subsequently isolating a distinct CAF subset with high pro-migratory activity using transwell assays. Quantitative proteomic profiling of EVs from 30 matched CAF-NF pairs revealed a high-quality dataset of 2,492 proteins and identified ATP6V1C1, a subunit of the V-ATPase complex, as a highly enriched protein in pro-migratory CAF-EVs. We further demonstrated that CAF-EV-mediated transfer of ATP6V1C1 drove LUAD cell migration and metastasis, a finding robustly validated in cell lines, patient-derived cells (PDCs), and an orthotopic patient-derived xenograft (PDX) model. At the molecular level, EV-delivered ATP6V1C1 suppressed insulin-like growth factor binding protein 3 (IGFBP3) by downregulating the transcription factor ID1. This suppression of IGFBP3 not only triggered epithelial-mesenchymal transition (EMT) but also amplified the IGF1/IGF1R/Akt/ERK oncogenic pathway driven by CAF-secreted IGF1. This dual action creates a self-reinforcing feed-forward loop that exacerbates metastasis. A high-throughput screen using PDCs and patient-derived organoids (PDOs) identified dronedarone as a promising drug repurposing candidate; its therapeutic efficacy was inversely correlated with ATP6V1C1 expression. Targeting ATP6V1C1 disrupted cholesterol homeostasis and synergized with dronedarone to overcome resistance to EGFR tyrosine kinase inhibitors (EGFR-TKIs) in preclinical models. In conclusion, our findings unveil ATP6V1C1 as a dual regulator of LUAD metastasis and propose a novel stroma-targeted combination therapy to suppress tumor progression and combat drug resistance.

#3344 Pyk2 controls rab proteins by vesicle trafficking in glioblastoma cells.

Neisha Marie Ramirez Serrano, Lilia Kucheryavykh

Biochemistry, Universidad Central del Caribe, Bayamon, PR

Glioblastoma (GBM) is the most aggressive primary brain tumor, with a median survival of less than one year. GBM progression depends on constant communication between tumor cells and their microenvironment, primarily mediated through extracellular vesicles (EVs). These vesicles often contain chemokines such as CCL2, CCL12, and CCL5, which attract immune cells. Once recruited, these immune cells can be reprogrammed by tumor-derived signals to support tumor growth. Pyk2 regulates the trafficking and release of EVs by interacting with Rab GTPases, regulators of intracellular vesicle transport. Through activation of RhoA and reorganization of actin, Pyk2 facilitates vesicle movement toward the plasma membrane and their subsequent secretion. We hypothesized that Pyk2 regulates EV trafficking and secretion in GBM cells by coordinating Rab GTPase activity and actin cytoskeletal remodelling.Primary human GBM cell lines with and without CRISPR/Cas9-mediated Pyk2 knockout (Pyk2KO) were analysed. EVs were isolated and characterized by flow cytometry, MEK/ERK signaling was inhibited using Avutometinib(1μM). Confocal immunofluorescent revealed that Pyk2 promotes Rab27a association with $CD63^{+}$ vesicles, consistent with its role in regulating multivesicular body docking and exosome release. Pyk2 regulates actin dependent trafficking of Rab27a thereby controlling vesicle transport and secretion. Quantitative analysis showed that Pyk2KO shifted the EV population toward larger vesicles. Pyk2KO reduced EV cargo levels of CCL2, CCL5, TNF, and VEGF, mediators of TAM activation and angiogenesis. These data indicate that Pyk2 regulates Rab27a-dependent endosomal vesicle docking and release, whereas MEK/ERK signaling enhances plasma membrane-derived EV shedding. Together, these pathways shape the size and immune regulatory cargo of EVs.

Pyk2 controls Rab proteins by vesicle trafficking in glioblastoma cells

#3345 Horizontal transfer of functional extrachromosomal DNA via extracellular vesicles in FGFR2-amplified cancer.

Irene Salamon[1], Giulia Gallerani[2], Jens Luebeck[3], Gianluca Storci[1], Simone Spandau[3], Beatrice Fontana[2], Alessia Soru[2], Mattia Riefolo[1], Marco Pagano Mariano[4], Ilaria Pace[2], Andrea Cavazzoni[4], Vineet Bafna[3], Massimiliano Bonafe'[2], **Manuela Ferracin**[2]

[1]IRCCS Azienda Ospedaliero-Universitaria di Bologna, Bologna, Italy,[2]Alma Mater Studiorum Universita di Bologna, Bologna, Italy,[3]UC San Diego, Tacoma, WA,[4]Department of Medicine and Surgery, University of Parma, Parma, Italy

Cancer cells actively release extracellular vesicles (EVs) into the tumor microenvironment, where they interact with both malignant and non-malignant cells, activating signaling pathways and reshaping the microenvironment. In this study, we investigated EVs secreted by *FGFR2*-amplified cancers of unknown primary (CUPs), which generate extrachromosomal circular DNA (ecDNA) as a mechanism of oncogene amplification. We found that *FGFR2*-containing ecDNA is packaged into both small and large EVs, horizontally transferred to recipient cells, and remains functionally active. Upon exposure to CUP-derived EVs—either by direct administration or co-culture—cancer (NCI-N87, THP1) and non-cancer (HUVEC, fibroblasts) cells internalized *FGFR2* ecDNA, which was subsequently transcribed and translated to some extent. Functionally, CUP-derived EVs polarized THP1 cells toward an M2-like phenotype and promoted HUVEC proliferation. *In vivo*, xenografts generated from CUP cell lines released circulating FGFR2$^+$ EVs, which mediated the systemic transfer of *FGFR2* ecDNA to distant organs. Collectively, these findings demonstrate that tumor-derived EVs can propagate and horizontally transfer oncogenic ecDNA both *in vitro* and *in vivo*, providing a possible mechanistic basis for the high metastatic potential of this tumor type.

#3346 Modeling breast cancer extracellular vesicle-mediated degradation of the lymphatic glycocalyx using a 3D organ-on-chip platform.

Justin Lau[1], Issahy Cano[2], Esak Lee[1]

[1]Biomedical Engineering, Cornell University, Ithaca, NY,[2]Cornell University, Ithaca, NY

Triple-negative breast cancer (TNBC) relies primarily on lymphatic vessels for early metastatic spread, and tumor-secreted factors—including extracellular vesicles (EVs)—can condition the lymphatic microenvironment to facilitate dissemination. The lymphatic endothelial glycocalyx (eGCX) is a sugar-rich barrier that regulates permeability and cell adhesion, yet its susceptibility to tumor-driven remodeling remains poorly understood.

Using a transwell coculture model of LECs and TNBCs, we found that TNBC-conditioned environments markedly disrupt the lymphatic eGCX. MDA-MB-231 conditioned media reduced wheat germ agglutinin (WGA, total glycocalyx) staining by 45.41 ± 9.37 percent, heparan sulfate (HS), one of the most abundant glycocalyx components, by 38.87 ± 8.84 percent, and overall eGCX thickness by 49.37 ± 3.93 percent. SUM-149 conditioned media similarly reduced glycocalyx thickness by 36.80 ± 5.11 percent. TNBC exposure also induced morphological changes in lymphatic endothelial cells (LECs) consistent with impaired barrier function and active glycocalyx remodeling.

To identify specific drivers of this disruption, EVs from TNBC and non-tumorigenic control cells were isolated using a membrane-affinity method and characterized by nanoparticle tracking analysis. LECs exposed to TNBC EVs exhibited reduced WGA and HS staining, and altered VE-cadherin junctions. Protease profiling revealed enrichment of ADAM9, Cathepsin X/Z/P, and MMP-8 in TNBC EVs, suggesting that EV-associated proteases mediate eGCX degradation.

To establish a physiologically relevant baseline, human LECs were cultured in collagen-filled PDMS microfluidic chips under luminal shear (~4 dynes/cm^2). This 3D system produced a significantly thicker eGCX than 2D monolayers (WGA staining intensity in 3D relative to 2D: 1.311 ± 0.096; $p \leq 0.01$), validating its use for assessing tumor- and EV-induced glycocalyx remodeling. This 3D lymphatic organ-on-chip model provides a physiologically relevant platform to study eGCX dynamics and EV-mediated vascular remodeling.

Together, these findings demonstrate that TNBC-derived EVs carry proteolytic cargo capable of degrading the lymphatic eGCX, linking tumor secretome signaling to early lymphatic metastasis. We are now using this organ-on-chip system to investigate the effects of individual EV-associated proteases on glycocalyx remodeling, as well as the potential of targeted therapeutics to preserve eGCX integrity under TNBC conditioning, with the goal of preventing the creation of a metastatic-permissive lymphatic microenvironment.

#3347 Proteomic and functional divergence of small and large extracellular vesicles reveal subtype-specific drivers of ovarian cancer progression.

Kalpana Deepa Priya Dorayappan[1], Fries Brian[2], Wei Fu[3], Ganesh Yadaigiri[1], Lakshmi Narasimhan Chakrapani[1], Sydney Wiggins[4], Shyam Sundaram[5], Thangavel Muthusamy[6], Sudhiksha Anbu Chelian[7], Gabriela S. Vendrell[2], Qi-En Wang[8], David E. Cohn[1], Lianbo Yu[9], David O'Malley[1], Colin Hisey[4], Selvendiran Karuppaiyah[1]

[1]OB/GYN, The Ohio State University, Columbus, OH,[2]The Ohio State University, Columbus, OH,[3]Biomedical Engineering, The Ohio State University, Columbus, OH,[4]Biomedical Engineering, Northwestern University, Evanston, IL,[5]University of Southern California, Los Angeles, CA,[6]Sree Balaji Medical College and Hospital, Chennai, India,[7]Health & Rehabilitation Sciences, The Ohio State University, Columbus, OH,[8]Radiation Oncology, The Ohio State University, Columbus, OH,[9]Medical Bioinformatics, The Ohio State University, Columbus, OH

Objective: High-grade serous ovarian cancer (HGSOC) progression and therapeutic resistance are increasingly attributed to extracellular vesicle (EV) mediated communication. While small EVs (SEVs) are widely studied, the proteome and biological contributions of large EVs (LEVs) remain poorly defined. This study aimed to (i) establish long-term bioreactor-based production of extracellular vesicles (SEVs and LEVs) from ovarian cancer cell lines, (ii) define subtype-specific proteomic cargo, and (iii) compare the functional roles of SEVs and LEVs in tumor growth, metastasis, and immune modulation.
Methods: OVCAR4, CaOV3, and SKOV3 ovarian cancer cell lines were expanded in T-175 flasks and gradually transitioned to serum-free CDM-HD media in Bioreactors. Cell lines were maintained for eight weeks in bioreactors to measure EV secretion. SEVs and LEVs were isolated by ultracentrifugation followed by size-exclusion chromatography (SEC). Particle number and size were quantified by nanoparticle tracking analysis (NTA), and protein concentration was measured by Nano Drop. EV identity and purity were confirmed by Western blotting (CD9, CD63, CD81, LAMP1), Imaging Flow Cytometry (ISF), and transmission electron microscopy (TEM). Proteomic profiling of SEVs and LEVs was performed for each cell line, with downstream pathway analysis using Ingenuity Pathway Analysis. Functional assays included: (i) EdU proliferation assays, (ii) migration and invasion assays, (iii) splenocyte co-culture to evaluate immune modulation, and (iv) mouse xenograft models to assess EV-dependent tumor growth and metastatic dissemination.
Results: Bioreactors supported stable EV production in OVCAR4 and CaOV3 cells, while SKOV3 adapted poorly. NTA and ISF confirmed consistent EV output across eight weeks. SEVs were enriched for CD9, CD63, and CD81, whereas LEVs showed strong LAMP1 expression. Proteomics revealed distinct cargo profiles: SEVs contained proteins linked to cytoskeletal remodeling, migration, and metastatic signaling, while LEVs carried proteins involved in proliferation, metabolism, and stress responses. Functionally, SEVs enhanced migration, invasion, metastatic burden, and immune suppression, whereas LEVs promoted cell proliferation and larger primary tumors in-vivo.
Conclusion: SEVs and LEVs derived from ovarian cancer cells exhibit distinct proteomic signature and exert divergent effects on tumor progression. SEVs predominantly drive metastatic potential, whereas LEVs enhance proliferative tumor growth. EV subtype specific characterization provides new opportunities for biomarker discovery and targeted therapeutic strategies in HGSOC.

#3348 Liposarcoma-derived extracellular vesicles suppress STING signaling and impair innate immune activation in macrophages.

Qi Zhang, Patricia Sarchet, Fernanda C. C. de Faria, Priya Dhawale, Sydney Rentsch, Roma Karna, Valerie Grignol, Jing Wang, Raphael Pollock, Federica Calore

The Ohio State University Comprehensive Cancer Center, Columbus, OH

Purpose: Macrophages are the most abundant immune population in the liposarcoma tumor microenvironment (TME). We previously showed that extracellular vesicles (EVs) released by de-differentiated liposarcoma (DDLPS) promote tumor progression by inducing IL6 secretion from macrophages. Here, we investigated whether DDLPS-derived EVs also disrupt macrophages innate immune signaling.
Methods: U937 cells were differentiated into macrophages with PMA. CD14+ monocytes isolated from PBMCs were differentiated into monocyte-derived macrophages (MDMs) using M-CSF, and macrophage identity was confirmed by flow cytometry. EVs were isolated from Lipo141 and Lipo246 conditioned medium via ultracentrifugation, and from patient serum using ExoQuick. Differentiated macrophages were treated with EVs for 24h, followed by cGAMP stimulation. Gene expression of ifnb1 and innate immunity-related chemokines were assessed by qRT-PCR, while IFNβ secretion was determined by ELISA assay. STING pathway activation was investigated by western blot analysis.
Results: DDLPS-derived EVs markedly suppressed macrophage responses to cGAMP. In U937-derived macrophages, EVs exposure significantly reduced ifnb1 induction ($p=0.044$) and IFNβ secretion in response to cGAMP. EVs isolated from the serum of healthy donors or DDLPS patients ($n=12$) confirmed these findings, with patient-derived EVs leading to a stronger inhibition of ifnb1 ($p=0.0012$) and reduced IFNβ protein levels compared to healthy donor group. Western blot analysis showed decreased phosphorylation of IRF3 and STING, with total protein levels unchanged, indicating selective impairment of STING pathway activation. Consistent with these data, MDMs exhibited similar functional suppression: EV-treated cells displayed reduced induction of ccl5, cxcl9, cxcl10, ifnb1 and ISG15 in response to cGAMP stimulation.
Conclusion: DDLPS-derived EVs impair macrophage responsiveness to cGAMP by suppressing STING pathway activation. These findings reveal an EV-mediated mechanism of immune evasion in liposarcoma and highlight the STING axis as a potential therapeutic target to restore antitumor immune function.

#3350 Isolation and characterization of prostate-specific extracellular vesicles from prostate cancer patients.

Shashi Anand[1], Emily Ridden[2], Ty W. Turner[2], Kunwar Somesh Vikramdeo[1], Ramya Krishna Velagapudi[3], Denise C. Cornelius[2], Ajay Pratap Singh[1], Xinchun Zhou[3]

[1]Department of Cell and Molecular Biology, Cancer Center and Research Institute, University of Mississippi Medical Center, Jackson, MS,[2]Department of Pharmacology and Toxicology, University of Mississippi Medical Center, Jackson, MS,[3]Department of Pathology, Cancer Center and Research Institute, University of Mississippi Medical Center, Jackson, MS

Background: Plasma-derived extracellular vesicles (EV) represent a complex mixture of vesicles originating from diverse tissues. The selective isolation of prostate-specific extracellular vesicles (PSEV) can offer improved specificity for diagnostic and prognostic biomarker development as well as monitoring therapeutic response of prostate cancer (PCa). This study aimed to compare the yield and quality of PSEV enriched from total EV preparations with those isolated directly from plasma.
Materials and methods: Twelve (12) plasma samples (6 from patients with PCa, and 6 from non-cancer subjects) were used in this study. The total EV were isolated with SmartSEC^{TM} columns following the manufacturer's instructions. The PSEV were enriched with anti-PSMA-conjugated magnetic beads from isolated total EV and also directly from plasma samples. Nanoparticle tracking analysis (NTA) was performed to examine the concentration (particles/mL), average diameter (nm), and volume (nm^3) for total EV and PSEV. The ultrastructure of isolated PSEV was imaged under a JOEL JEM1400 transmission electron microscope. The mean values were subjected to an unpaired t-test analysis, and a p-value of less than 0.05 was considered statistically significant.
Results: NTA analysis showed that 1) Total extracellular vesicles isolated with the column resulted in a significant yield from each plasma sample (1.4E+11 to 7.52E+11 particles/ml, 149.8 to 182 nm in diameter, and 752 to 1,360 nm^3 in volume); 2) PSEV concentration was higher in plasma from African American (AA) population ($178.9x10^9$/ml) than in plasma from Caucasian American (CA) population ($166.6x10^9$/ml); 3) the PSEV concentration was higher in method using anti-PSMA-conjugated magnetic beads from plasma directly ($13.4x10^9$/ml) as compared to that enriched from total extracellular vesicles obtained via column ($10.98x10^9$/ml); 4) the average PSEV diameter was greater in method using anti-PSMA-conjugated magnetic beads directly from plasma (198.7nm) as compared to that from total extracellular vesicles obtained via column (149.3nm, p=0.002); and 5) PSEV was about 3.1% of total EV in non-cancer subjects, and 4.7% of total extracellular vesicles in PCa. The TEM analysis demonstrated the existence of electron-dense oval or round particles in diameters ranging from 30-258 nm. However, PSEV showed some spikes on the particle surface.
Conclusion: PSEV enrichment using anti-PSMA-conjugated magnetic beads is a feasible approach that could enhance the specificity of potential EV-associated biomarkers, aiding in improved diagnosis, prognosis, risk prediction, and monitoring therapeutic responses in prostate cancer.

#3351 Exploring the effects of extracellular vesicles secreted by cofilin-1 overexpressing cells on the migration and invasion ability of human lung cancer cells.

Huang Bo-Han, Yi-Jang Lee

Biomedical Imaging and Radiological Sciences, National Yang Ming Chiao Tung University, Taipei, Taiwan

Object: Type I actin-severing protein cofilin-1 (CFL-1) is a widely expressed regulator of the microfilament cytoskeleton in non-muscle cells. It plays a crucial role in actin cytoskeleton construction and influences cell motility. Overexpression of CFL-1 has been observed in various cancers and is related to tumor migration, invasion, and metastasis. In addition, studies have shown that the cytoskeleton plays a key role in exocytosis, implicating that CFL-1 may be a potential regulator of this process. Cancer cells secrete abundant extracellular vesicles (EVs) to mediate intercellular communication, and exosomes are one of the subtypes. Tumor-derived exosomes can promote tumor invasion and metastasis. Recent studies showed that CFL-1 is highly expressed in exosomes from advanced cancer, but its potential mechanisms in tumor-related exosomes remain unclear. Therefore, this study aims to explore the effects of CFL-1 on exosome secretion and whether CFL-1 influences lung cancer cells via exosome-mediated mechanisms.
Methods: This study used H1299/tet-on-cofilin-1 (HCOXP) cells, a tetracycline-inducible cell line, which can induce cofilin-1 overexpression. First, conditioned medium was collected from HCOXP cells overexpressing cofilin-1, and exosomes were isolated by ultracentrifugation. Second, the purity of the isolated exosomes was verified by nanoparticle tracking analysis, transmission electron microscopy, and western blotting. To evaluate the impact on cell migration and invasion, exosomes derived from HCOXP cells were added to H1299, CL1-0, and BEAS2-B cells. Furthermore, the expression levels of matrix metalloproteinases (MMPs) in exosomes from HCOXP cells with and without cofilin-1 overexpression were compared.
Results: The results showed that overexpression of CFL-1 stimulated cells to secrete more exosomes. It is also found that these exosomes may contain more contents. When these exosomes were applied to lung cancer and normal cells, exosomes derived from CFL-1 overexpressing HCOXP cells significantly accelerated the migration and invasion of H1299 cells. However, no increase in migration and invasion ability was observed in CL1-0 or BEAS-2B cells following treatment with these exosomes. In addition, elevated levels of matrix metalloproteinases (MMPs) were detected in exosomes from CFL-1-overexpressing HCOXP cells.
Conclusion: Overexpression of CFL-1 in HCOXP cells was found to promote exosome secretion. These exosomes appear to exhibit homing specificity, potentially influencing their effects on target cells. Overall, this study found the critical role of CFL-1 in regulating the release and the potential impact of exosomes in the tumor microenvironment.

#3353 Pyroptosis-derived extracellular vesicles as key immunoactivators in near-infrared photoimmunotherapy.

Fan Chen[1], Yuxuan Li[1], Ye Lu[1], Peng Guo[1], Weifeng Qian[2], Wei-Hong Tan[1]

[1]Hangzhou Institute of Medicine, Chinese Academy of Sciences, Hangzhou, China,[2]The Affiliated Suzhou Hospital of Nanjing Medical University, Gusu School, Nanjing Medical University, Suzhou, China

Background: Pyroptosis, a lytic and highly inflammatory form of programmed cell death, has emerged as a powerful mechanism for augmenting anti-tumor immunity. Although antibody drug conjugate (ADC)-mediated near-infrared photoimmunotherapy (NIR-PIT) can induce tumor-specific pyroptosis and enhance immune responses, the downstream mediators that bridge pyroptotic cell death to immune activation remain undefined. Here, we investigated whether pyroptosis-derived extracellular vesicles (Pyro-EVs) constitute a key immunostimulatory output of tumor pyroptosis and sought to define their molecular composition and immune-activating functions.
Methods: Pyroptosis was induced in SCC7 murine carcinoma cells using Cetuximab-IR700, a clinically-approved NIR-PIT ADC. EVs released during pyroptosis were isolated by ultracentrifugation and characterized by NTA and nano-flow cytometry. Deep proteomic profiling with organelle-origin mapping, GO enrichment, and nuclear-cytoplasmic signature scoring was performed to define Pyro-EV identity. DNA cargo was examined by nano-flow cytometry, DNase-protection assays, and confocal microscopy. Immunological activity was evaluated by exposing macrophages to Pyro-EVs, followed by RNA-seq, ELISA, and Western blot assessment of nucleic-acid sensing pathways.
Results: NIR-triggered pyroptosis induced rapid release of a distinct EV population, generating Pyro-EVs at 2-3x the abundance of basal EVs. Proteomics identified a pyroptosis-specific signature with 726 emergent proteins enriched for ribosomal subunits, chromatin components, and DNA-binding regulators, absent in apoptotic or necrotic EVs. These molecular hallmarks indicate nuclear rupture and cytoplasmic mixing, establishing Pyro-EVs as a unique class of lytic cell-death-derived vesicles. Pyro-EVs carried elevated levels of double-stranded nuclear DNA, confirmed by DNase resistance and colocalization with chromatin-binding proteins. Functionally, Pyro-EVs were strong activators of innate immunity, inducing broad M1-polarizing programs in macrophages. RNA-seq showed induction of TLR7/9, MyD88, IRAK1/4, and NF-κB-related genes; Western blot validated activation of the TLR7/9-MyD88-IRAK-p65 axis, and ELISA demonstrated increased secretion of TNF-α, IL-6, and other cytokines, confirming DNA-sensing-dependent innate immune activation.
Conclusions: This study identifies Pyro-EVs as a previously unrecognized, immunogenic vesicle class that emerges during NIR-PIT. Pyro-EVs are rich in nuclear DNA and chromatin-associated factors and serve as high-potency activators of macrophage TLR7/9 signaling, establishing them as a central mediator connecting pyroptotic tumor death to innate immune amplification. These findings redefine the immunobiology of pyroptosis and uncover Pyro-EVs as a mechanistic driver of pyroptosis-induced anti-tumor immunity.

#3354 Chemoradiation treatment increases extracellular vesicle release causing treatment resistance in rectal cancer cell lines.

Vivek Somasundaram, Jeremie M. P. Lever, Regina Irwin, Teresa C. Beamon, Karin M. Hardiman

Surgery, University of Alabama at Birmingham, Birmingham, AL

Introduction: Colorectal cancer (CRC) is the 3rd most prevalent form of cancer in the U.S., with younger Americans comprising an increasing fraction of case numbers. Current treatment includes chemoradiation treatment (CRT) followed by surgical resection in incomplete responders. Only about 25% of patients have a complete response to CRT due to the presence of treatment resistance in most patients. ST6GAL1 is a sialyltransferase, that has been shown to be upregulated in various cancer types, including CRC. Our group has previously shown that it confers treatment resistance to CRT *in vitro* and *in vivo*. We have also shown that ST6GAL1 is packaged into extracellular vesicles (ECVs) by human CRC cel lines, and that these ECVs can transfer treatment resistance between cells. We hypothesized that CRT would increase ECV release, thereby, spreading treatment resistance and that these ECVs could be measured in the plasma of a patient derived xenograft model of rectal cancer.

Methods: We cultured SW620 CRC cells, treated with or without 5-Flourouracil and 5 Gy of radiation (CRT), and isolated ECVs from the cells' conditioned medium using differential centrifugation. ECV size and concentration were determined using a Nanosight with NTA software. Our previously validated SW620 ST6GAL1 Control vector (CV) and knockdown (KD) cell line was used to assess transfer of resistance to apoptosis after CRT. We added ECVs isolated from untreated or CRT treated SW620 cells to ST6GAL1 KD cells, treated with 5 Gy of CRT, and performed immunofluorescence for cleaved caspase-3 (CC3). We also co-cultured KD cells with CV cells (+/- CRT) and assessed CC33 staining after CRT. We assessed tumor and plasma ECV levels of ST6GAL1 before, during, and after CRT in a PDX model of rectal cancer.

Results: SW620 cells undergoing CRT had a greater than twofold higher release of ECVs/cell compared to untreated cells (*2.57* ± 0.84 *p=0.033, n=4)*. No significant differences were detected in mean ECV size between CRT(+) and CRT(-) emitting cells. ST6GAL KD cells directly treated with SW620 ECVs cells from either CRT treated or untreated donor cells showed a significantly reduced CC3 production after CRT compared to untreated KD cells. Co-culture of KD cells with radiated CV cells reduced CC3 levels after CRT (1.59± 0.32, n=2). ST6GAL1 could be measured in ECVs isolated from the plasma of the PDX model and the number of ECVs and amount of ST6GAL1 both increased during CRT.

Conclusion: We have shown that exogenously added ECVs containing ST6GAL1 confer treatment resistance *in vitro.* Our co-culture data additionally validates this finding by showing that ST6GAL1 containing cells can transfer ECVs to neighboring cells and confer treatment resistance. Our data reveals that ECV release is increased in response to CRT *in vitro* and *in vivo*. If seen in patients, this increase could be spreading resistance, potentially worsening treatment outcomes.

#3355 Exosomal genetic cargo shift dictated by RD3 deficiency steers progressive neuroblastoma evolution.

Afsana Parveen Jahir Hussain[1], Sreenidhi Mohanvelu[1], Loganayaki Periyasamy[1], Poorvi Subramanian[1], Sheeja Aravindan[2], Natarajan Aravindan[1]

[1]Oklahoma State University, Stillwater, OK,[2]OU Health Stephenson Cancer Center, Oklahoma City, OK

Exosomes are central mediators of systemic cellular communication, directing tumor evolution through the dynamic exchange of genetic and molecular cargo. Neuroblastoma (NB), a lethal pediatric tumor of embryonal origin, where selection and enrichment of treatment-resistant cancer stem cell clones have decisive impact. Recently, we identified acquired RD3 deficiency prompts tumor cell plasticity and regulates tumor progression. Herein, we investigated whether RD3 controls delivery of exosomal genetic cargo. For this we utilized our custom archived Neural crest cell specific Cre conditional LoxP-directed RD3-Knockout (KO, *Tg* mice) driven human syntenic spontaneous NB. Serum exosomes were isolated, from RD3-KO mice and compared with their wild-type counterparts. Exosomal RNA was isolated using the Total Exosome RNA and Protein Isolation kit, characterized by nanoparticle tracking analysis, flow cytometry, transmission electron microscopy, and was then analyzed by paired-end Illumina RNA sequencing. Differential gene expression (DEG) was computed using $\log_2$ fold change with $\log_2$ FDR. DEG analysis identified an animal-independent signature of 53 upregulated and another 1,396 downregulated genes. Functional annotation in Ingenuity Pathway Analysis revealed enrichment in therapy-resistance pathways, including angiogenesis signaling by VEGF (*VEGFA, KDR, FLT1*), NAD^+ salvage pathway II mediated DNA damage response (*NMRK1, NT5C2, NT5C1A*), cell cycle control (*CDK6, CDC7, SIN3A*), pro-survival CXCR4 signaling (*HSP90AA1, RAB11FIP3*), extracellular matrix remodeling (*COL1A1, ADAM12, HSPG2, CD31*), and immune/inflammatory signaling (CD27, IL-1) pathways. Furthermore, oncogenic cell signaling pathways, including RhoGDI signaling (*CDC42, PAK1, ARHGEF2),* regulating migration, invasion, and WNT/β-catenin signaling (*SOX17, MAP3K7, WNT9A*), regulating stemness maintenance, were decisively reprogrammed. These results, for the first time, distinctly demonstrate that RD3 deficiency drives molecular rearrangements that promote therapy resistance, underscoring its central function in exosome-mediated cancer cell signaling that survives intensive multimodal clinical therapy. Crucially, our findings position RD3-regulated exosomal genetic cargo as a promising biomarker and therapeutic target for better clinical management of progressive NB. **FUNDING:** DOD-CA-210339; OCAST-HR19-04; NIH-P20GM103639

#3356 Tumor-derived exosomes promote renal cancer progression via reprogramming of tumor-associated macrophages.

Jinlu Dai[1], Suguru Kadomoto[1], Tyler Robinson[1], Evan T. Keller[2]

[1]University of Michigan, Ann Arbor, MI,[2]Professor, University of Michigan, Ann Arbor, MI

Renal cell carcinoma (RCC), the most common type of kidney cancer, relies heavily on the complex ecosystem of the Tumor Microenvironment (TME) for its progression. A critical cellular component within the TME is the Tumor-Associated Macrophage (TAM), which often adopts a pro-tumor, M2-like phenotype that supports angiogenesis, invasion, and immune suppression. This study investigates the role of tumor-derived exosomes (TDEs) in mediating this critical reprogramming event. In vitro experiments utilized human (786-O renal cancer cell line and THP-1 monocytes) and mouse (Renca RCC and RAW 264.7 monocytes/macrophage) cell lines. The macrophages were treated with RCC-derived exosomes, and the conditioned medium (CM) was used to treat parental RCC cells. Functional assays demonstrated that exosome-educated macrophage CM significantly increased the proliferation, migration, and invasion of both human and mouse RCC cells. Furthermore, Western blot and ELISA analysis confirmed that TDE treatment successfully reprogrammed macrophages, leading to altered cytokine profiles indicative of polarization toward a pro-tumor phenotype. In vivo, the impact of the TDE-educated macrophage CM was assessed in SCID and BALB/c mouse models using intracardial and intrarenal RCC injections. Bioluminescence imaging (BLI) confirmed that CM from exosome-treated macrophages significantly enhanced tumor progression and distant metastasis compared to controls. In conclusion, this research identifies tumor-derived exosomes as critical signaling vectors that effectively reprogram TAMs into pro-tumorigenic cells. This exosome-mediated communication promotes a highly permissive TME, leading to accelerated renal cancer progression and metastasis. These findings highlight the TDE-TAM axis as a potent therapeutic target for mitigating RCC malignancy.

#3358 The consequences of progenitor neutrophil evacuation into the periphery during breast cancer.

Mariah Branson[1], Carolyn Schroeder[2], Melissa Meyer[1]

[1]Microbiology, Immunology, and Pathology, Des Moines University Medicine and Health Sciences, West Des Moines, IA,[2]Office of Research, Des Moines University Medicine and Health Sciences, West Des Moines, IA

Recent results suggest neutrophil progenitors and immature neutrophils are appearing in the periphery in response to cancer and pathogens. The tumor microenvironment (TME) may take advantage of neutrophil progenitor susceptibility by signaling for the neutrophil to support tumor growth. This project tests the hypothesis that neutrophil progenitors experiencing the periphery during cancer will take on unique phenotypic and functional states depending on which tissue they are transferred into, and to which tissues they transit to post-transfer. In mice bearing PyMT B6 orthotopic tumors, congenically marked $CD45.2^+$ neutrophil progenitors were transferred into $CD45.1^+$ recipient mice. Two neutrophil progenitor populations were transferred: total bone marrow neutrophils ($Ly6G^+$), and pre-neus ($CD117^+Ly6G^+$). Cells were transferred into the blood of tumor and non-tumor bearing mice, and into the tumor of tumor bearing mice. After 1 day, tissues were isolated to quantitate adoptively transferred cells in the following tissues: bone marrow, blood, spleen, tumor and lymph nodes. Adoptively transferred cells were also measured for changes in phenotype using spectral flow cytometry and changes in function, including their ability to produce Reactive Oxygen Species (ROS), an anti-microbial function of neutrophils. Preliminary results show that the site of adoptive transfer affects the accumulation of adoptively transferred cells in tissues. Together, these data will help us further understand how tissue environments directly shape neutrophil phenotype and function. If we identify tissue environments influencing neutrophil functionality and expression, especially if promoting pro-tumoral functions, we can further identify pathways and signals to block therapeutically. This method may depress tumor progression, increasing patient survival rates.

#3359 Distinct profile of peritoneal lavage fluid extracellular vesicles in gastrointestinal carcinomatosis.

Fatemeh Tajik, Vinodh Kumar Radhakrishnan, Alex N. Dang, Aaqil M. Khan, Melanie Roman, Shaun Daly, Areg Grigorian, Cristobal Barrios, Sigrid Burruss, Maheswari Senthil

Department of Surgery, University of California, Irvine Medical Center, Orange, CA

Introduction: Gastrointestinal peritoneal carcinomatosis (GI PC) poses significant diagnostic and therapeutic challenges. The commonly used diagnostic tools such as circulating tumor DNA have poor sensitivity in PC. Recent evidence suggests that peritoneal cavity small extracellular vesicles (EV) play a critical role in peritoneal metastasis development and progression. We sought to compare the peritoneal lavage fluid (PL) EV profile (quantity and gene expression) to non-cancer PL to identify the potential of PL EV testing as a liquid biopsy in PC.

Methods: PL samples were collected from GI PC patients and non-cancer patients. The inclusion criteria for the non-cancer cohort were BMI 18-30, no cancer/autoimmune history, and had a non-inflammatory indication for surgery (ex. hernia repair). EVs were isolated by precipitation and characterized via nanoparticle tracking analysis (NTA), cryo-electron microscopy (cryo-EM), and western blot. Size distribution (0.5-199.5nm, 200.5-500.5nm) and concentration were quantified by NTA. EV RNA was profiled using NanoString PanCancer Panel (770 genes). Differential expression used $\log_2$ fold change ≥1.5 or ≤-1.5 and p≤0.05.

Results: A total of 66 PL samples were collected (35 cancer and 31 non-cancer). Of the 31 non-cancer PL, only 19 samples had EV pellets, indicating that in the rest of the samples there were too few EVs to result in an EV pellet. However, all cancer PL had an EV pellet. NTA of the samples that had adequate EV showed that the total quantity of EV (as $\times 10^5$ particles/mL) was approximately two-fold higher in cancer samples compared to the non-cancer cohort (10.9×10^5 vs. 4.5×10^5; p=0.0005). The difference between the cancer and non-cancer PL EV quantity was retained even after systemic therapy (9.7×10^5 vs. 4.5×10^5; p=0.0002). Cryo-EM demonstrated distinct structural differences of EV between the groups, with cancer-derived EVs exhibiting multilayered, multicompartment, and cargo-dense structures, whereas non-cancer samples predominantly contained simple monolayer vesicles. Gene expression profiling demonstrated significant overexpression of genes involved in epithelial-mesenchymal transition, metastasis, cell-cycle regulation, angiogenesis, and extracellular matrix organization (STAB1, PRF1, CCDC80, SPARCL1, VHL, RHOA) in the cancer cohort compared to the non-cancer cohort.

Conclusion: Our study represents one of the largest studies of PL comparison of GI PC to non-cancer. In GI PC the amount of EV and the biophysical and molecular signatures are distinctly different from the non-cancer group. PL EV can be developed into a liquid biopsy in GI PC to fill a critical clinical need.

#3360 Environmental impact on the secretion of tumor-derived exosomes.

Haylie Pullan

Brigham Young University, Provo, UT

Cancer continues to be one of the most prominent and devastating health issues in the world. In the year 2024, an estimated 2,001,140 new cases of cancer were be diagnosed in the United States alone. Of those over 2 million cases, 611,720 people will die from the disease (National Cancer Institute). Our goal is to utilize the basic progression and anatomy of a cancer tumor to help address this horrible disease that takes the lives of so many. Exosomal research is a new field that utilizes proteins, DNA, and RNA from secreted extracellular vesicles to determine tumor characteristics and optimize treatment strategies. While this innovative technique holds promise, the relationship between exosomes and their associated parent cells remains inadequately understood. This research intends to bridge the gap in knowledge by investigating the relationship between the environmental conditions of the parent cell and the secreted exosome characteristics. These characteristics include protein content, types, and the exosome-to-cell ratio. It has been stated in previous literature that cells under more stressful environmental conditions, such as serum starvation and hypoxia, will secrete more exosomes. However, we believe the secretion of exosomes is dependent on cell line and environment. A variety of cell lines that make up a gastrointestinal tumor, including Jurkat, THP-1, MRC5, HUVEC, and AGS cells, were grown and put under these conditions to have their associated exosomes analyzed. This approach enabled us to investigate the impact of serum starvation and hypoxia, showing that low nutrition from media led to a decrease in the number of exosomes, while increased hypoxic conditions led to an increase in secretion. This knowledge can have broad implications for cancer diagnosis and innovative treatment strategies. Our research holds the potential to unveil insights into the intricate interplay between exosomes and cancer, contributing to more effective therapeutic approaches.

#3361 Precise isolation of tumor-relevant EV sub-populations using the Kairos cLDEP particle sorter.

Boyang Su[1], Shujun Xu[2], Reese Wunsche[1], Dennis Lee[1], Hon Leong[1]

[1]Biological Sciences Platform, Sunnybrook Research Institute, Toronto, ON, Canada,[2]Molecular Genetics, University of Toronto, Toronto, ON, Canada

Extracellular vesicles (EVs) are cell-derived fragments released by all cell types and are promising platforms for cancer detection and nanomedicine. Isolating and enriching ultra-pure EV sub-populations from patient biofluids based on cell- or cancer-specific biomarkers can reveal tumor-derived molecular signatures with diagnostic and therapeutic implications. However, most existing EV isolation methods rely on size and density, lacking specificity for defined EV subtypes. Existing nano flow cytometry (nFC) platforms (e.g., Astrios EQ) for EV sub-population sorting are also unsatisfactory due to lengthy preparation, limited specificity, and unknown recovery of target sub-populations. To overcome these limitations, we utilized the Apogee Kairos particle sorter, which applies centripetal liquid dielectrophoretic (cLDEP) force to redirect fluids around optically identified EVs, enabling high-speed, high-precision EV sub-population sorting. Operational protocols were optimized using polystyrene beads of defined sizes, achieving 97% purity and 40% recovery. EVs were isolated from cell culture conditioned media (CM) and prostate cancer patient plasma based on size (200-300 nm, 300-400 nm, 600-900 nm, >900 nm), and further sorted post nucleic acid staining, immunolabeling for EV membrane biomarkers (CD9, CD63, etc.) and cancer-associated biomarkers (PSMA, EpCAM, etc.), achieving 83.5-89.4% purity of target EV sub-populations. Transmission electron microscopy confirmed preserved EV vesicular integrity post-sorting. Protein and RNA analyses revealed the presence of molecular cargo in sorted sub-populations consistent with EV identity and disease relevance. We established a robust standard operating protocol (SOP) for the Kairos cLDEP sorter, providing a powerful approach for isolating cancer-derived EV sub-populations with high precision. This platform advances the utility of EV-based liquid biopsies by enabling tumor-selective EV capture for downstream molecular profiling.

#3362 Lipid nanoprobe magnetic beads enable high-purity plasma EV isolation for broad-spectrum cancer biomarker detection.

Qiuyan Ma, Dehe Kong, Sidhant Narula, Jin-Qiu (Jessie) Chen

OriGene Technologies, Inc., Rockville, MD

Introduction: Extracellular Vesicles (EVs) carry tumor-derived biomolecules and represent a promising source for liquid biopsy-based cancer detection. Many recent studies have revealed critical biomarkers from plasma EV, establish potential diagnostic targets for pancreatic cancers, ovarian cancers and other hard-to-diagnose cancers[1]. Unlike circulating free DNA (cfDNA) or soluble proteins, EVs are actively secreted by viable tumor cells and encapsulate proteins, nucleic acids, and lipids within a protective bilayer that preserves molecular integrity. This stability and cell specificity make EVs ideal for minimally invasive disease monitoring. However, plasma EV isolation remains challenged by abundant protein contaminants that compromise downstream molecular analysis. A simple, high-purity, automation-compatible isolation method is essential to improve EV-based biomarker profiling, particularly from heterogeneous blood derived samples.

Methods: A lipid nanoprobe (LNP)-based magnetic bead system (Captis Diagnostics Inc) was optimized for rapid, high-specificity enrichment of plasma EVs [2]. EVs post enrichment were assessed by cargo DNA, RNA and core tetraspanin abundance compared with pre-enrichment samples. Depletion of albumin and lipoprotein contaminants were confirmed by immunoassays. Comparative recovery efficiency and purity metrics were benchmarked against leading commercial EV isolation reagents. To assess broad biomarker compatibility, EVs from multiple cancer cell lines were spiked into healthy plasma and isolated using LNP beads. Enriched EVs were analyzed using OriGene multiplexed immunoassay panels covering cancer-relevant protein classes, including adhesion molecules, oncogenic receptors, and immune-modulatory factors. These markers represent key tumor hallmarks such as invasion, migration, immune evasion, and therapeutic resistance—commonly represented in EVs from solid tumors.

Results: LNP-based EV enrichment achieved very high EV recovery (>85%) with substantially reduced albumin and lipoprotein carryover compared with benchmark reagents. The immunoassay panels demonstrated robust detection of key cancer-associated biomarkers across diverse cell-line-derived EVs. The results demonstrating strong EV-specific signals and substantial reduction of nonspecific background These findings indicate that LNP isolation provides superior purity and robust compatibility with downstream quantitative analyses.

Conclusion: LNP-mediated EV enrichment provides a rapid, high-purity, and sample-efficient platform for capturing cancer-derived biomarkers directly from plasma. When integrated with omic-assays, this approach enables broad phenotypic characterization of tumor-derived EVs and supports development of minimally invasive diagnostic and treatment-monitoring strategies.

#3363 Fibroblast exosomes induce stromal matrix assembly and breast tumor growth and metastasis.

Bong Hwan Sung[1], Merlyn Emmanuel[2], Metti Gari[3], Jorge Guerrero[4], Maria Virumbrales-Munoz[5], David Inman[3], Evan Krystofiak[1], Alan Rapraeger[6], Suzanne M. Ponik[7], Alissa M. Weaver[1]

[1]Cell & Developmental Biology, Vanderbilt University School of Medicine, Nashville, TN,[2]University of British Columbia, Vancouver, BC, Canada,[3]Cell and Regenerative Biology, University of Wisconsin-Madison School of Medicine and Public Health, Madison, WI,[4]McArdle Laboratory for Cancer Research, University of Wisconsin-Madison School of Medicine and Public Health, Madison, WI,[5]Department of Obstetrics and Gynecology, University of Wisconsin-Madison School of Medicine and Public Health, Madison, WI,[6]Human Oncology, University of Wisconsin-Madison School of Medicine and Public Health, Madison, WI,[7]University of Wisconsin-Madison, Madison, WI

Stromal matrix assembly is a key feature of aggressive tumors and is associated with poor prognosis of breast cancer patients. Fibronectin is a key stromal matrix molecule whose assembly into fibrils is thought to require cells and which serves as a template for stromal matrix assembly. Fibroblasts are the major cell type that secretes and assembles fibronectin and stromal matrix. Here, we identify that small exosome-type small EVs secreted by fibroblasts are critical initiators of fibronectin assembly, revealing a previously unrecognized mechanism of stromal matrix formation. Fibroblasts engineered to be deficient in exosome secretion showed greatly reduced assembly of fibronectin and other stromal matrix molecules in 2D, 3D, and *in vivo* environments, and led to reduced tumor growth and lung metastasis by triple-negative breast cancer cells. Furthermore, transgenic mice with defects in exosome secretion had greatly reduced lung fibrosis after treatment with bleomycin. In a direct test of exosome function on fibronectin assembly, we find that the addition of purified small EVs to purified soluble fibronectin in a cell-free system is sufficient to induce fibronectin assembly. The EV-induced fibronectin assembly requires the presence of fibronectin-binding integrins and syndecan-1 in the EVs. We propose a new model in which secreted exosomes directly drive stromal matrix assembly and tissue fibrosis.

#3364 Exosomes derived from tumor cells in acidic extracellular environment inhibit liver metastasis.

Bei Jin, Weijia Peng, Jingxuan Pan

Sun Yat-sen University, Guangzhou, China

Distant metastasis is the leading cause of cancer-related mortality in patients with solid tumor. Tumor cells tend to colonize specific target organs, exhibiting organ tropism. For instance, ~85% of patients with metastatic uveal melanoma (UM) metastasize to sole organ liver; up to 50% of patients with colorectal carcinoma (CRC) develop liver metastasis. Liver-organotropic metastasis is the consequence of reciprocal cross talk between tumor cells and host microenvironment within the liver. Tumor microenvironment (TME), characterized by acidity and hypoxia, represents a hostile milieu that favors tumor cells over non-tumor cells which cannot adapt. Exosomes, small membranous vesicles encompassing biologically active components (namely proteins, miRNAs, and lipids, etc.), are pivotal in mediating intercellular communication. We aimed at exploring the mechanism by which exosomes mediating the intercellular communication in liver colonization. We found that hepatic metastasis in CRC was significantly facilitated by exosomes derived from tumor cells in normal extracellular environment (normal exosomes), which was, however, remarkably diminished by those derived from tumor cells in normal extracellular environment (acidic exosomes). Further study revealed that exosomes derived from tumor cells in acidic extracellular environment were enriched with the metastasis-suppressor NME1. Acidic exosomal NME1 were uptaken by adjacent tumor cells, resulting in degradation of DDR1 and CD155 via chaperone-mediated autophagy. The decreased DDR1 abolished cancer stem-like cells in UM and CRC. Decline of CD155 in tumor cells enhanced the infiltration of $CD8^+$ T cells in metastatic colonization in liver. These results indicated a novel mechanism whereby tumor cell-derived exosomes mediating intercellular communication to regulate hepatic metastasis.

#3365 Novel mechanism of tumor fibrosis mediated by interorgan crosstalk.

Akiho Nishimura, Takatsugu Ishimoto, Takashi Semba, Atsuko Yonemura

Japanese Foundation for Cancer Research, Tokyo, Japan

Diffuse-type gastric cancer (DGC) shows strong interactions between cancer-associated fibroblasts (CAFs) and cancer cells through PDGF/PDGFR signaling. While PDGFR is expressed in CAFs, PDGF ligands were believed to be mainly secreted by cancer cells. However, DGC cohort analysis revealed a correlation between stromal fibrosis and platelet aggregation, suggesting that platelets may serve as an alternative PDGF source. This study aims to elucidate the mechanisms of interorgan crosstalk through GC fibrosis-bone marrow (BM) hematopoiesis-platelet axis. IL6 was particularly upregulated in DGC and correlated with fibrosis. We established an orthotopic model using IL6-overexpressing murine GC cells, which developed fibrotic tumors. Notably, platelets in peripheral blood of these mice showed increased count, size, and PDGFD concentration. Cell population analysis in BM revealed increased megakaryocyte progenitors and decreased erythroid progenitors, indicating IL6-induced hematopoietic imbalance. These findings suggest that IL6 promotes PDGFD-rich platelet production, contributing to tumor fibrosis. This study highlights a key role of BM-derived platelets to enhance tumor fibrosis in DGC.

#3366 Muscle iron overload contributes to cancer cachexia-induced muscle wasting.

Subin Pyo[1], Yichi Zhang[1], Anna Barbeau[1], ChiHin Feng[1], Amit Roopan[1], Ning Liu[2], Eric N. Olson[2], Matthew G. Vander Heiden[1]

[1]Biology, Koch Inst. for Integrative Cancer Research at MIT, Cambridge, MA,[2]Molecular Biology, University of Texas Southwestern Medical Center, Dallas, TX

Cancer cachexia is a prevalent and often fatal systemic metabolic condition that is characterized by muscle wasting with or without fat wasting. Muscle wasting is therefore the central component of cancer cachexia but the mechanisms whereby cancer leads to skeletal muscle wasting are not well understood. We used several different mouse models of pancreatic ductal adenocarcinoma (PDAC) as well as C26 allograft, one of the most commonly studied models of cancer cachexia, to study the mechanisms underlying cancer cachexia-induced muscle wasting. Transcriptome analyses on cachexic muscle revealed the upregulation of genes related to iron metabolism. To interrogate whether perturbations to muscle iron metabolism can contribute to muscle wasting, we identified that muscle iron levels are elevated in cachexic muscle. Secondly, mice fed low, medium, and high iron diets and showed a positive correlation between dietary iron intake and the severity of muscle wasting. We further demonstrated that increased muscle iron contributes to muscle wasting by generating muscle-specific transgenic mice overexpressing the transferrin receptor (TFRC), which is the primary method of iron intake into the cell. TFRC transgenic mice exhibited decreased muscle mass and myofiber areas compared to mice not overexpressing TFRC. TFRC transgenic mice injected with C26 cancer cells also showed increased muscle wasting compared to control mice with C26 cells. Furthermore, muscle-specific deletion of TFRC in muscle using a muscle-specific tamoxifen-inducible Cre mouse line bred to a conditional TFRC floxed mouse line rescued C26-induced muscle wasting. Our work rigorously demonstrates that elevated muscle iron leads to muscle wasting, and this elevated muscle iron in cancer cachexic muscle contributes to cancer cachexia-induced muscle wasting. Current work is being done to test whether elevated muscle iron is seen in human samples and to decipher the mechanisms by which muscle iron overload leads to muscle wasting.

#3367 Mitochondrial calcium uniporter drives cancer cachexia in pancreatic ductal adenocarcinoma through NETosis-mediated skeletal muscle atrophy.

Xiuchao Wang, Jihui Hao

Tianjin Medical Univ. Cancer Inst. & Hospital, Tianjin, China

Purpose: Cancer cachexia, characterized by persistent weight loss, skeletal muscle atrophy, and adipose tissue reduction—with progressive skeletal muscle wasting being the predominant manifestation—represents a major cause of mortality in pancreatic ductal adenocarcinoma (PDAC) patients. Cachexia is a common and severe complication in PDAC, significantly impacting patients' quality of life and prognosis. This study investigates the role of the mitochondrial calcium uniporter (MCU) in PDAC-associated cachexia, potentially offering novel interventional strategies for its prevention.
Experimental Design: MCU expression was analyzed in PDAC patient tissues and correlated with cachexia incidence. Spontaneous tumor models and orthotopic PDAC models using MCU-overexpressing and control stable cell lines were established to evaluate tumor progression and muscle atrophy. Neutrophil extracellular traps (NETs) formation was detected by H3cit/MPO/DAPI multiplex immunofluorescence. NETs function was examined through anti-Ly6G-mediated neutrophil depletion, DNase I treatment, and $Pad4^{-/-}$ mice. Secretome analysis identified MCU-regulated mechanisms in NETs formation, validated through recombinant protein treatment and receptor inhibition. The role of CCDC25 was investigated using genetic knockout models and AAV9-mediated skeletal muscle-specific silencing.
Results: MCU overexpression significantly correlated with cachexia incidence and reduced skeletal muscle mass in PDAC patients. Compared to the MCU-overexpression group, control mice demonstrated attenuated tumor growth and preserved muscle mass independent of tumor burden. MCU-overexpressing PDAC models showed significantly elevated NETs infiltration in skeletal muscle, while NETs clearance prevented muscle atrophy. MCU overexpression induced cellular senescence and senescence-associated secretory phenotype (SASP) secretion (particularly C3 and CXCL1), promoting NETosis through C3aR and CXCR2 signaling. CCDC25 was identified as a critical NET DNA receptor in skeletal muscle, mediating muscle atrophy through RAC1-dependent ROS production.
Conclusion: Our study reveals a novel signaling pathway wherein tumor MCU overexpression promotes cellular senescence and SASP secretion, driving NETs formation through C3/CXCL1 signaling. NETs engage CCDC25 receptors on muscle cells, activating the RAC1-ROS signaling pathway that ultimately leads to muscle atrophy.
Impact: These findings establish the MCU-NETs-CCDC25 axis as a key mechanism in PDAC-associated cachexia and suggest multiple therapeutic strategies—including MCU inhibition, NETs degradation, and CCDC25 blockade—providing new directions for alleviating cachexia and preserving muscle mass in cancer patients.

#3368 Metabolite-driven post-translational modifications regulate mitochondrial homeostasis in the glioblastoma microenvironment.

Zhongsheng You, Karrie Kiang, Gilberto Leung

The University of Hong Kong, Hong Kong, Hong Kong

Glioblastoma (GBM) is a highly aggressive brain tumor with a dismal prognosis, demanding new therapeutic strategies. A key challenge in treating GBM is the complex communication between tumor cells and the surrounding tumor microenvironment (TME), which enhances tumor resilience. This study investigated how metabolites, abundant in the TME due to altered cancer metabolism, influence intercellular communication and mitochondrial dynamics in GBM. We hypothesized that specific post-translational modifications (PTMs), driven by these metabolites, regulate mitochondrial homeostasis and function, thereby promoting tumor progression. To test this hypothesis, we employed a range of experimental procedures. Co-culture systems were established to model the interaction between GBM cells and stromal cells within the TME. We utilized flow cytometry to analyze cellular characteristics and interactions, while Western blotting and immunofluorescence were used to examine protein expression, localization, and PTMs. Functional assays, including various commercial kits, were performed to assess mitochondrial biology. Bioinformatics analyses were conducted to identify potential molecular pathways involved, and these findings were validated in vivo using animal models. Our unpublished data reveal that an abnormal increase in a specific tumor metabolite leads to the PTM of key proteins. This modification alters the function and expression of these proteins, resulting in heightened interaction between GBM cells and stromal cells. Consequently, we observed an enhancement of mitochondrial-related biological functions within the GBM cells, which ultimately fuels tumor progression. In conclusion, our findings demonstrate that metabolic byproducts in the GBM microenvironment act as signaling molecules, effectively "hijacking" normal stromal cells to support the mitochondrial homeostasis and growth of the tumor. This novel mechanism of intercellular communication presents a potential new axis in GBM pathophysiology, offering promising therapeutic targets to disrupt tumor progression and improve patient outcomes.

#7149 The paradoxical role of SIRT1 in glioblastoma mediated by the tumor microenvironment.

Anza Mnahal, Wanjun Tang, Bo Chen, Karrie Mei Yee Kiang, Gilberto Ka Kit Leung

Department of Surgery, The University of Hong Kong, Hong Kong, Hong Kong

SIRT1, a NAD+-dependent deacetylase, plays a complex role in glioblastoma (GBM), with debates surrounding its function as either a promoter or suppressor of tumorigenesis. This study aims to understand the double roles of SIRT1 in GBM incorporating in vivo and in vitro models. We conducted a series of experimentation to understand the role of SIRT1 starting with comprehensive analysis of SIRT1 expression in patient datasets, followed by SIRT1 knockdown studies in various GBM cell lines (U87, U251, and patient-derived cells) and in orthotopic, subcutaneous and intracranial tumor induction in animal models. Pharmacological interventions using SIRT1 inhibitors were also employed. Our studies uncovered that higher the SIRT 1 expression level, better is the survival in low grade glioblastomas. On the other hand, knockdown of SIRT1 did not affect the in vitro cell proliferation or migration. However, there was significant effect of SIRT1 knockdown on tumor growth. The tumor growth decreased in both intracranial and subcutaneous models. Furthermore, we observed an altered interaction dynamics between tumor cells and the surrounding neurons, caused by SIRT1 knockdown. This indicates that the influence of tumor microenvironment on SIRT1's functional role. This study reveals the dual role of SIRT1 in GBM, highlighting it as a potential therapeutic target. The paradoxical role of SIRT1 inhibition in various models proves the importance of the tumor microenvironment in shaping GBM biology also providing a future target to study.

genOway, Lyon, France

Therapies targeting regulatory T cells (Tregs) have emerged as a promising strategy to overcome immune suppression and enhance anti-tumor immunity. Tregs maintain immune tolerance under physiological conditions, but within the tumor microenvironment they promote immune evasion and resistance to immunotherapy. Selective depletion or functional modulation of Tregs can restore effector T-cell activity and improve responses to checkpoint inhibitors and other immunotherapies. However, the development of Treg-targeting approaches requires preclinical models that accurately recapitulate human Treg biology, including phenotype, activation status, and distribution in peripheral tissues and tumors. Conventional mouse models often fail to reflect these human-specific features, limiting their predictive value for safety and efficacy. Humanized models that support the development and long-term engraftment of functional Tregs and mimic human immune-tumor interactions are therefore essential to bridge the translational gap and guide clinical development of next-generation immunotherapies. genO-BRGSF-HIS mice, engrafted with human hematopoietic stem cells, enable long-term reconstitution of diverse human T-cell subsets, including $CD4^+$, $CD8^+$, γδ T cells, and Tregs. Among emerging targets expressed by Treg, CCR8, a chemokine receptor expressed on Tregs, has gained attention for its potential in selective Treg depletion to enhance anti-tumor immunity. Importantly, CCR8 expression differs between species—restricted to tumor-infiltrating Tregs in mice but present on both infiltrating and peripheral Tregs in humans. We assessed CCR8 expression in genO-BRGSF-HIS mice and found a pattern consistent with human biology. Treatment of naïve genO-BRGSF-HIS mice with a CCR8-depleting antibody resulted in Treg depletion in spleen and blood. While efficacy of CCR8-targeting compounds remains to be investigated in genO-BRGSF-HIS mice, it is key to first investigate whether Treg cells are recruited into the tumor microenvironment (TME). Thus, we evaluated human immune cell infiltration in the TME of cell derived xenografts. Tumor infiltration by human immune cells varied by tumor type and burden, with Tregs ($CD4^+FoxP3^+CD127^-$) displaying dynamic activation profiles, including PD-1, GARP, and TIM-3 expression in the TME of A549 lung carcinoma xenografts. Notably, subsets resembling induced Tregs (iTregs) were identified, suggesting adaptive regulatory mechanisms within the TME. These findings support the use of genO-BRGSF-HIS mice as a translational platform for investigating Treg biology and evaluating therapeutic strategies in oncology.

#3372 Predictive in vitro assays and PBMC donor banking: reducing variability in humanized mouse studies.

Matthias Bleisch, Philipp Meyer, Ina Rohleff, Eva Oswald, Anna Edinger, **Julia B. Schueler**

Charles River Laboratories, Freiburg, Germany

Humanized mouse models are an essential tool for evaluating immunotherapies in vivo. The use of peripheral blood mononuclear cells (PBMCs) from healthy donors is common as they provide a functional human immune compartment capable of mediating responses such as T-cell activation and tumor clearance. However, donor variability introduces a significant challenge: PBMCs from different individuals differ in their immune cell composition, and alloreactivity. To address this, we established a PBMC donor bank. Each of the currently six donors are characterized for major phenotypic markers by flow cytometry, as well as HLA-type. In addition to the PBMCs itself we created a bank of expanded T cells as source for in vitro and in vivo assays. The phenotypic characterization of the PBMC revealed differences in all major cell types (T, B, NK, NK T cells and monocytes). However, all data were in physiological range. To deeper analyze the immune cells from different donors, we executed in vitro co-culture assays with a representative tumor cell line MDA-MB-231 to screen for killing potential. Solitumab, a CD3/EPCAM bispecific antibody was tested in the presence of expanded T cells from all donors in five independent runs against MDAMB-231. Efficacy was determined by CTG, oneGlo and flow cytometry in parallel to identify the optimal assay read-out. All three assay read-outs displayed acceptable run to run variability. However, flow cytometry was best suited to discriminate between cell viability of immune and tumor cells. The killing activity of the expanded T cells in vitro was predictive for the onset of GvHD in PBMC engrafted immune compromised NSG mice in vivo. Not only induced donors with higher killing efficiency in vitro an earlier onset of GvHD (day 18 post engraftment for donor 6 vs day 40 for donor 2) it also impacted overall survival (29 days vs 36 days, n.s. Kruskall-Wallis). The engraftment of human PBMC in vivo was characterized by analyzing human immune cells in peripheral blood of engrafted mice over the course of the experiment, GvHD scoring and body weight. Each donor displayed a specific pharmacokinetic of engraftment and different immune cell subtyping. These data are donor immanent, as they could be reproduced using the same donor in multiple independent experiments. The ability to induce antitumoral activity for immune modulating compounds was proven in different experimental set-ups for all six donors. A side-by-side comparison testing Solitumab against MDAMB-231 in vivo is currently under way. This approach enables the reduction of variability in tumor growth and treatment response for PBMC based in vivo studies. By banking PBMCs from multiple donors, researchers can pre-screen immune functionality using in vitro T cell killing assays before committing to in vivo studies. This ensures that only PBMC donors with the desired immune characteristics are selected for humanization in vivo thereby supporting the 3Rs.

#3373 Metabolism and carcinogenic potential of inorganic arsenic in humanized-liver mice.

Arpamas Vachiraarunwong[1], Shugo Suzuki[2], Masaki Fujioka[2], Runjie Guo[1], Guiyu Qiu[1], Yurina Kawamura[1], Ikue Noura[2], Anna Kakehashi[2], Hideki Wanibuchi[1], Min Gi[1]

[1]Environmental Risk Assessment, Osaka Metropolitan University, Graduate School of Medicine, Osaka, Japan,[2]Molecular Pathology, Osaka Metropolitan University, Graduate School of Medicine, Osaka, Japan

Inorganic arsenic is a known human carcinogen associated with liver and bladder cancer. Among its species, sodium arsenite (iAs^{III}) undergoes complex hepatic biotransformation, producing methylated metabolites such as monomethylated (MMA) and dimethylated (DMA) forms. However, its human-relevant mechanisms of metabolism and carcinogenicity remain unclear due to species differences in arsenic biotransformation. To clarify these differences, we employed a humanized-liver (HL) mouse model, in which mouse hepatocytes are replaced with human hepatocytes, to investigate the metabolism and carcinogenic potential of iAs^{III}. HL and wild type (WT) mice were administrated 50 ppm of iAs^{III} in drinking water for 4 weeks. Urine, liver, and bladder samples were collected for analysis. Urinary arsenic speciation was determined using high-performance liquid chromatography coupled with inductively coupled plasma mass spectrometry (HPLC-ICP-MS). Histopathology and immunohistochemistry were performed on both liver and bladder tissue, and gene expression profiles were analyzed using RNA sequencing and microarray, respectively. Urinary arsenic speciation revealed distinct species-dependent differences. Dimethylarsinic acid (DMA^{V}) was the predominant urinary arsenic metabolite in both HL and WT mice. Total urinary arsenic in HL mice was lower than in WT mice, but the distribution of metabolites differed markedly. The proportion of MMA^{V} in HL mice (26.4%) was substantially higher than in WT mice (4.7%), whereas DMA^{V} accounted for 58.5% in HL and 80.7% in WT mice. This urinary metabolite pattern more closely resembled that observed in humans exposed to inorganic arsenic. Hepatic arsenic methyltransferase (As3MT) expression was significantly elevated in WT mice treated with iAs^{III} but tended to decrease in HL mice. Gene expression profiles of liver and bladder tissues of HL mice also differed from those of WT mice. Immunohistochemical analysis of proliferation markers is currently underway to evaluate whether iAs^{III} promotes hepatocellular and urothelial proliferative response. Arsenic content in the liver is also currently under investigation, and pathway analysis of the transcriptomic data using Ingenuity Pathway Analysis (IPA) is ongoing to identify key molecular alterations for further validation. In conclusion, these findings indicate that human hepatocytes exhibit lower methylation capacity, resulting in higher proportions of toxic MMA species, suggesting that humans may be more susceptible to arsenic than mice. Furthermore, the HL mouse model effectively reflects human arsenic metabolism and provides a valuable *in vivo* platform for elucidating human-relevant metabolic, toxicological, and molecular mechanisms underlying arsenic-induced hepatotoxicity and carcinogenicity.

#3374 *In vivo* evaluation of immune checkpoint inhibitors using PBMC-humanized NOG-ΔMHC mice engrafted with PDX tumors.

Asami Hanazawa[1], Seinosuke Sakai[1], Masayuki Komatsu[1], Chiyoko Nishime[1], Naohisa Ogo[2], Masami Suzuki[1], Jun-ichi Hata[1], Akira Asai[2], Taichi Yamamoto[1]

[1]Central Institute for Experimental Medicine and Life Science (CIEM), Kawasaki, Japan,[2]Graduate School of Pharmaceutical Societies, University of Shizuoka, Shizuoka, Japan

Immunotherapy has emerged as the “fourth pillar” of cancer treatment, complementing surgery as well as chemo- and radiotherapies. Among these modalities, immune checkpoint inhibitors (ICIs), particularly anti-PD-1 antibodies, are key tools. Ongoing efforts are focused on identifying novel therapeutic targets and optimizing combination regimens using existing agents. Animal models are indispensable for evaluating the therapeutic efficacy and safety of preclinical drug development. However, conventional syngeneic mouse models often fail to recapitulate human pharmacodynamics and toxicity profiles, especially in molecularly targeted therapeutic contexts, where interspecies differences are pronounced, which underscores the urgent need for translationally relevant platforms.To address this gap, we established mouse models by engrafting human peripheral blood mononuclear cells (PBMCs) into NOG-ΔMHC mice, followed by the transplantation of patient-derived xenografts (PDXs) or PDX-derived cell lines (PDXCs). These models partially reconstitute human immune components, while PDX/PDXC tumors preserve critical features (e.g., histological architecture, cellular heterogeneity, and tumor microenvironment), thereby allowing for a more faithful modeling of human cancer, including immune-tumor cell interactions. We developed two distinct lung adenocarcinoma-derived PDX/PDXC models and optimized testing schedules tailored to each strain. Using these models, we assessed the antitumor efficacy of an anti-PD-1 antibody (KEYTRUDA®) and a novel IDO1/TDO2 dual inhibitor (KYPS-80), both applied as monotherapies and in combination. Both models exhibited tumor growth suppression across the treatment groups, accompanied by enhanced $CD8^+$ T cell activation. Histopathological analyses revealed tumor nest regression, single-cell necrosis, and fibrosis, indicating a therapeutic response. In conclusion, we developed a robust and translationally relevant platform for evaluating ICIs and combination immunotherapies, which recapitulates key aspects of human immune tumor dynamics and holds promise for advancing preclinical immuno-oncology research.

#3375 Novelapproaches fororthotopic tumor engraftment in humanized immune system mice.

Audrey Wetzel, Emilie Bayon, Anais Meynet-Cordonnier, Cecilia Mendez, Charline Boulout, Sebastien Tarbuyn, **Dan Georgess**

TransCure bioServices, Archamps, France

Humanized immune system (HIS) mice support engraftment with human tumors, thereby allowing the assessment of drug candidates in preclinical oncology without needing to develop mouse-specific analogs. The site most often used for tumor engraftment in mice is the subcutaneous flank, which leads to imperfect vascularization, prevents metastasis, and does not capture organ-specific biology. We therefore set to develop and validate five protocols for orthotopic engraftment of cancer cell lines that can be reproducibly utilized in HIS mice. The five orthotopic engraftment sites include the femoral bone marrow (via knee-cap surgery), mammary fat pad, liver (via injection in the spleen), pancreas, and lung. All protocols led to an engraftment rate of 100% and were amenable to tumor monitoring via caliper measurements or bioluminescence imaging. Focusing on the orthotopic lung model, we found that 85% of engrafted mice developed liver metastases. The peripheries of both primary (lung) and metastatic (liver) tumors we marked by strong fibrogenesis depicted by picrosirius red staining) and were infiltrated by human T and myeloid cells. In the lungs of engrafted mice, CD4+ T and NK cells upregulated CD25 and CD16 expression, respectively, indicating significant activation compared to non-engrafted mice. Altogether, our results demonstrate that HIS mice can be orthotopically engrafted as robustly and reproducibly as syngeneic models. We also showed that lung orthotopic engraftment leads to an organ specific immune response and distant metastasis, thereby representing a valuable platform for the assessment of novel oncology therapies.

#3376 Developing the next generation of customized human immune system mice for preclinical oncology.

Audrey Wetzel, Emilie Bayon, Sebastien Tabruyn, **Dan Georgess**

TransCure bioServices, Archamps, France

Humanized immune system (HIS) mice, which can be engrafted with human cell line-derived or patient-derived tumors, have become essential tools for preclinical and IND-enabling development of cell therapies and biologics in oncology. However, selecting the appropriate HIS model remains challenging given the diversity of humanizable mouse strains and immune-engraftment protocols. We first compared immune profiles, clinical symptoms, body weight, and survival in severely immunodeficient mice engrafted with either cord blood-derived $CD34^+$ hematopoietic stem cells (HSCs) or peripheral blood mononuclear cells (PBMCs). PBMC-engrafted mice demonstrated poor survival associated with early graft-versus-host disease (GvHD) and exhibited amplification of human T cells with a partially exhausted phenotype ($Lag\text{-}3^+$, $TIM\text{-}3^+$). In contrast, CD34-engrafted mice showed no health deterioration over 30 weeks and developed a complete human immune system comprising T, B, NK, and myeloid cells.These results place the CD34+ HSC engrafted HIS mice as overall superior model for drug assessment as it allows a longer, GvHD-free treatment window and a more complete immune system. We next implemented a universal, irradiation-free, chemoablation-based $CD34^+$ HSC-engraftment protocol to compare the extent of immune humanization across several severely immunodeficient strains, including foundational models (NOG, NCG, BNDG, BRG, and next-generation strains (NOG-EXL, which overexpresses human GM-CSF and IL-3; and FcResolv NOG, which lacks murine Fcγ receptors). For each strain, we measured survival, overall humanization rate (percentage of human among total immune cells), and human immune-subset frequencies in blood. Finally, we demonstrate how hydrodynamic gene delivery of one or more human cytokines into HIS mice can boost certain immune populations when a transgenic strain overexpressing these cytokines is unavailable. Altogether, our findings provide a knowledge base for the selection of the humanized immune system mouse model with the most suitable immune reconstitution profile for assessing any drug candidate based on its mechanisms of action.

#3378 Short telomeres limit braf^{V600E} driven melanomagenesis in humanized telomere (HuT) mice.

Md Hazzaz Bin Kabir[1], Jiawei Liu[1], Fan Zhang[1], Kenneth I Porter[1], Gavin P. Robertson[2], Jiyue Zhu[1]

[1]Pharmaceutical Sciences, Washington State Univ. College of Pharmacy, Spokane, WA,[2]Professor, Dept. of Pharmacology, Penn State University College of Medicine, Hershey, PA

Telomere length influences genomic stability, immune function, and cancer susceptibility. Although mice are widely used to model tumorigenesis, their telomeres are much longer than humans and generally do not impose telomere-dependent proliferative limits. To determine how human-like telomeres affects melanoma development, we used humanized telomere (HuT) mice (*Tert$^{h/h}$* and *Tert$^{h/-}$*) with short, human-range telomeres (7-9 kb) and compared them to wildtype C57BL/6 (*Tert$^{+/+}$*) mice (~50 kb). Oncogenic Braf^{V600E} was activated in *Braf$^{+/LSL\text{-}V600E}$*;*Tyr::CreERT$^{+/o}$* transgenic mice at 2 months of age via tamoxifen, followed by weekly UV exposure to model chronic sunlight-driven melanoma. Tumor initiation, growth, and burden were monitored for 40-60 weeks. Histology, immunohistochemistry, qRT-PCR, Tissues and tumors were analyzed by H&E, IHC, qRT-PCR, γH2AX, TRF2, and telomere analysis assessed tumor biology and genomic integrity. Immune cell populations in peripheral blood, bone marrow, spleen, and tumors were analyzed by flow cytometry. Primary melanoma cell cultures were established and evaluated for Tert mRNA expression, telomerase activity, and somatic mutation analysis. Kaplan-Meier analysis showed significantly delayed melanoma onset in HuT mice compared to wild-type controls (*Tert$^{h/h}$*, $p = 0.0053$; *Tert$^{h/-}$*, $p = 0.0001$; Log-rank test). *Tert$^{h/-}$* mice developed fewer tumors per animal than both *Tert$^{h/h}$* and wildtype mice. Interestingly, male *Tert$^{h/h}$* mice, but not wildtype or *Tert$^{h/-}$* mice, exhibited more rapid melanoma development than female littermates ($p = 0.0005$), mirroring the higher melanoma incidence observed in men. Histological analysis confirmed nevi and pigmented cells. These findings demonstrate that short, humanized telomeres suppress Braf^{V600E}-driven melanomagenesis in a genotype-, age-, and sex-dependent manner. The HuT mouse model provides a physiologically relevant platform to investigate telomere-regulated melanoma biology, immune-tumor interactions, and genomic instability, offering valuable insights for preclinical cancer research.

#3379 Small cell lung cancer humanized mouse models identifies unique T cell infiltration immune phenotypes in response to combination immune-radiation therapies..

Bell Wu[1], Xiaozhuo Ran[2], Olivia Huang[1], Lifang Song[2], Vivek Phillip[2], Adrian Sacher[3], Ming Sound Tsao[3], Benjamin Lok[1]

[1]Medical Biophysics, University of Toronto, Toronto, ON, Canada,[2]Princess Margaret Cancer Centre, Toronto, ON, Canada,[3]UHN Princess Margaret Cancer Centre, Toronto, ON, Canada

Background: Molecular classification of SCLC into subtypes (SCLC-*ASCL1*, SCLC-*NEUROD1*, SCLC-*POU2F3*, and SCLC-Inflamed) has revealed distinct immune contextures; however, preclinical research of the tumor-immune microenvironment is constrained by limited models that poorly capture POU2F3 and inflamed subtypes. To address this, we investigated peripheral blood mononuclear cell (PBMC) humanized mice (hu-mice) as a complement to conventional murine systems to broaden available tumor-immune models. We further characterized SCLC hu-mice for their ability to model therapeutic sensitivity, focusing on a novel triplet regimen, AZD1390 (ATM inhibitor) with radiotherapy (RT) and durvalumab (aPDL1), to investigate how DNA damage repair inhibition plus RT can reshape the immune microenvironment and sensitize SCLC subtypes to aPDL1.

Methods: Immunodeficient mice were intravenously injected with human PBMCs and subcutaneously engrafted with a panel of human SCLC cell-lines corresponding to all subtypes. Peripheral and infiltrating immunity were profiled with multiparameter flow cytometry to assess cytokine, exhaustion, and activation of subtype-specific tumour-immune interactions. Tumor infiltration kinetics and antitumor effects were evaluated following durvalumab monotherapy and combination therapy.

Results: T cell tumor infiltration varied by subtype with SCLC-Inflamed subtypes exhibiting the highest level of infiltration in an HLA-independent fashion. Infiltrating $CD8^+$ T cells rapidly acquired an exhaustion phenotype upregulating PD1, CD39, TOX and downregulating Ki67, IFNG, and TCF1, consistent with impaired effector function. aPDL1 monotherapy revealed subtype-specific sensitivity of engrafted cell-lines, with tumour control across multiple donors seen only in the SCLC-Inflamed cell-line, SBC5. AZD1390 and RT was selected as a candidate combination with aPDL1 as it stimulated increased chemokine (CCL5, CXCL10) expression via a cGAS-STING-mediated mechanism and increased surface PDL1 expression across multiple cell-lines *in vitro*. AZD1390 and RT sensitized otherwise non-responsive xenografts to aPDL1 *in vivo*. Treatment response was associated with higher proportions of $CD39^+CD103^+$ tumor-reactive T cells and reduced terminal exhaustion ($TCF1^-TOX^+$) suggesting a shift towards a more functional T cell repertoire.

Conclusions: Our preclinical observations demonstrate PBMC hu-mice as a viable platform to model intrinsic immune-tumor characteristics of engrafted human SCLC cell-lines. Combinatory radiation therapy enhanced anti-PDL1 efficacy in select models. Future studies will aim to identify response-defining features of treated models to improve patient selection in clinical trials.

#3380 Enhancing preclinical insights in immuno-oncology with humanized mice.

Caroline Mignard, Zoe Perin, Estelle Verronese, Damien France, Vincent Faugeroux, **Marc Hillairet de Boisferon**

Oncodesign Services, Dijon, France

Immune cells within the tumor microenvironment are increasingly recognized as critical targets for cancer therapy. However, findings from conventional animal models often fail to translate effectively to humans due to fundamental interspecies differences. This limitation has driven the development of humanized mouse models capable of more accurately recapitulating human immune biology and supporting the preclinical evaluation of emerging immunotherapeutic strategies.

To recreate a functional human immune system in immunodeficient mice, researchers commonly engraft either human peripheral blood mononuclear cells (PBMCs) or hematopoietic stem cells (HSCs). These humanized mouse models enable the study of human immune cell development, activation, and tumor–immune interactions in vivo, addressing key gaps that traditional syngeneic models cannot. When coupled with the implantation of human tumor cell lines or patient-derived xenografts, humanized mice provide a uniquely relevant platform for assessing a broad spectrum of oncological therapeutic strategies, including adoptive immune cell therapies, immune checkpoint inhibitors, and oncolytic viruses.

In this work, we present tumor growth dynamics and immune profiling outcomes across both subcutaneous and disseminated intravenous humanized tumor models. Randomization strategies incorporating tumor burden and immune cell engraftment are outlined to enhance experimental robustness. Key readouts capturing immune modulation and antitumor efficacy are detailed.

Illustrative datasets and case studies demonstrate the versatility and translational value of these platforms for preclinical assessment of immune-oncology drug candidates. Overall, the findings highlight humanized mice as a powerful bridge between discovery research and clinical development.

#3381 ImmunoPET reveals tumor-associated macrophages in humanized MDA-MB-231 models.

Pin Yi Lee[1], Ayla Vaughn Embs[1], Catesby Mallard[1], Chloe La Prairie[1], Jonathan Mallard[1], Masakazu Kamata[1], Harriet M. Kluger[2], Ping Zhang[1], Bernadette V. Marquez-Nostra[1]

[1]University of Alabama at Birmingham, Birmingham, AL,[2]Yale University, New Haven, CT

Background: Tumor-associated macrophages (TAMs) represent a major component of the tumor immune microenvironment and are associated with tumor progression and therapeutic resistance. Noninvasive detection of TAMs can provide valuable insight into immune infiltration and guide immunotherapy development. However, current macrophage imaging agents lack specificity for human pan-macrophages. In this study, we aim to image human macrophages in a humanized mouse model using our specific macrophage-targeted probe.

Methods: We developed a human-specific CD68-Fab fragment (Fab14) and radiolabeled it with zirconium-89 to obtain [^{89}Zr]Zr-DFO-Fab14. Humanized NSG-SGM3 and control NSG-SGM3 mice were implanted with MDA-MB-231 triple-negative breast cancer cells into the mammary fat pad. When tumors were palpable, mice were injected intravenously with 6.25 µg of human-specific, macrophage-selective [^{89}Zr]Zr-DFO-Fab14 (~30 µCi per mouse). PET imaging was performed at 2-, 24- and 48-hours post-injection (p.i.), and radiotracer uptake was quantified using SUVmean. Ex vivo biodistribution at 48 hours was assessed by gamma counting to evaluate radiotracer specificity and retention. Tumors were harvested for immunofluorescence (IF) analysis of human CD68 expression.

Results: At 2 hours p.i., quantitative analysis of [^{89}Zr]Zr-DFO-Fab14 uptake was similar in both humanized and control tumors, indicating comparable early distribution. By 24 hours, uptake of the immunoPET tracer was significantly higher and more sustained in humanized NSG-SGM3 mice (SUVmean = 0.29 ± 0.04) compared to control mice (SUVmean = 0.20 ± 0.03; ***p =0.0002). Biodistribution studies at 48 hours further validated the imaging specificity, showing markedly higher tumor retention in humanized NSG-SGM3 (4.66± 1.61 %ID/g) than in control NSG-SGM3 mice (1.71 ± 0.63 %ID/g). IF analysis confirmed abundant human CD68^{+} macrophage infiltration in humanized NSG-SGM3 tumors but not in NSG-SGM3 tumors, confirming the specificity of [^{89}Zr]Zr-DFO-Fab14 for human macrophages.

Conclusions: The human-specific [^{89}Zr]Zr-DFO-Fab14 demonstrates macrophage-specific retention in humanized tumors, enabling noninvasive visualization of human TAMs in vivo. This radiotracer represents a promising tool for studying macrophage dynamics in human immune-reconstituted systems and evaluating efficacy of macrophage-targeted therapies in cancer.

#3382 Characterization and preclinical efficacy of a CD3×CD20 bispecific T cell engager in a humanized PBMC mouse model.

Qikuan Chen, Longyun Zhang, Haixia Chen, Xiaowen Gong, Yanjie Chen, Mingqi Shao, Qi Zhu, Bobo Wang, Jingjing Zhu, Yinfei Yin

Shanghai ChemPartner Co., Ltd., Shanghai, China

Immuno-oncology (IO) therapies aim to harness and amplify the body's immune system to recognize, control, and destroy cancer cells. One key therapeutic goal in IO is to enhance T cell-mediated tumor killing. Currently established strategies include immune checkpoint inhibitors (ICIs), which release inhibitory brakes on T cells; T cell receptor-engineered T cell (TCR-T) therapies, which improve surface and intracellular antigen recognition; and chimeric antigen receptor (CAR) T cell therapies, which provide synthetic tumor antigen specificity. While these approaches have achieved success, they also face challenges such as T cell exhaustion, antigen escape, and safety and toxicity concerns, including cytokine release syndrome. Another emerging class of T cell-redirecting therapies are T cell engagers (TCEs); bi- or tri-specific antibodies that physically link T cells to tumor-associated antigens (TAAs). This interaction triggers robust T cell activation and a cascade of cytotoxic events culminating in tumor cell apoptosis. FDA-approved TCEs, such as Epcoritamab (CD3xCD20) for relapsed or refractory diffuse large B-cell lymphoma (DLBCL), Blinatumomab (CD3×CD19) for acute lymphoblastic leukemia (ALL) and Teclistamab (CD3×BCMA) for multiple myeloma, have demonstrated significant clinical efficacy in these respective diseases. While TCEs have shown success in treating hematologic malignancies, their role in Burkitt's lymphoma, an aggressive B-cell non-Hodgkin lymphoma linked to Epstein-Barr virus and MYC dysregulation, remains unexplored. Burkitt's lymphoma is generally considered highly curable using CD20 antibody-based immunotherapy, however resistance to anti-CD20 therapy is emerging, potentially linked to immune effector depletion and exhaustion from continuous intensive treatment. To investigate the efficacy of TCEs in Burkitt's lymphoma, we characterized a CD3×CD20 TCE using *in vitro* binding and cytotoxicity assays, and evaluated its therapeutic activity using an *in vivo* Raji xenograft model (cell line of Burkitt's lymphoma origin, expressing CD19/CD20) in humanized PBMC NOG mice. The CD3×CD20 TCE showed the most potent binding to Raji cells *in vitro*. Furthermore, in the humanized Raji model, the CD3×CD20 TCE achieved significant tumor regression in the high-dose group, and a partial response was observed in the low-dose group. Furthermore, both low and high doses of TCE resulted in a greater reduction in tumor volume compared to the ICI Toripalimab, a humanized PD-1 monoclonal antibody. Evidence of body weight loss (BWL) was observed in the groups that had PBMCs administered (tumour bearing animals), suggesting that the BWL is linked to the model and PBMC rather that the treatment. These findings highlight the potential of CD3×CD20 TCEs as an alternative strategy for treatment of Burkitt's lymphoma.

#3383 Robust multiplex cytokine profiling in second-generation humanized NOG mice using a 41-plex humanized mouse immune panel: Cross-donor validation and implications for translational oncology studies.

Philip Dube[1], Brooke Gilliam[2], Adam Bell[1], Nicholas Smith[1], Janell Richardson[1], Tina Raeber[2], Shane Curran[2], Monika Buczek[1]

[1]Taconic Biosciences, Inc., Rensselaer, NY,[2]MilliporeSigma, St Louis, MO

Background: Second-generation humanized NOG mice (HIS mice) enable evaluation of immune-oncology mechanisms within a physiologically relevant human immune microenvironment. However, translational interpretation of preclinical efficacy studies requires highly specific and reproducible quantification of human cytokines. To support robust immune monitoring, we co-evaluated a 41-plex humanized mouse cytokine/chemokine Luminex panel for performance across diverse human CD34+ donor sources and multiple HIS NOG model variants.

Study Aims/Hypothesis: We hypothesized that the human-specific analytes in the MILLIPLEX® 41-plex humanized mouse multiplex assay would show (i) high specificity for human cytokines with minimal cross-reactivity to host murine analytes, (ii) reproducible quantification across donor-to-donor variation, and (iii) consistent detection sensitivity across advanced HIS NOG models supporting translational oncology applications.

Results: Plasma samples were collected from HIS NOG cohorts reconstituted with ≥3 unrelated CD34+ donor pools and representing multiple second-generation humanized platforms. Across all donors and models, human-restricted analytes yielded quantifiable signals above background. Murine-only control samples confirmed negligible cross-reactivity. Inter-assay and intra-assay CVs demonstrated technical reproducibility. Donor-specific cytokine patterns (e.g., Th1/Th2 balance, myeloid-associated chemokines) were preserved across models, indicating biological fidelity rather than assay drift. Baseline cytokine architecture correlated with reconstitution kinetics and human immune cell subset frequencies, supporting biological coherence.

Conclusions: These validation data demonstrate that the MILLIPLEX® 41-plex Luminex assay provides reproducible, donor-consistent, and human-specific cytokine quantification in second-generation HIS NOG mice. These data support the assay's suitability for mechanistic and pharmacodynamic readouts in oncology studies requiring high-resolution human cytokine/chemokine profiling. Reliable multiplex cytokine measurement strengthens the translational bridge between HIS mouse studies and human immuno-oncology responses, enabling improved interpretation of therapeutic mechanisms, biomarkers, and treatment-induced immune modulation.

#3384 Innovative preclinical mouse models support development of CD3/EPCAM-targeting T-cell engagers.

Jay Zhang, Linlin Wang, Xiaojing Quan, Xiaofei Zhou, Jing Guo

Biocytogen, Waltham, MA

CD3, an essential subunit of the T-cell receptor (TCR) complex, delivers potent activation signals that induce T-cell cytotoxic activity upon engagement. EPCAM (epithelial cell adhesion molecule) is broadly expressed on normal epithelial cells and frequently overexpressed in epithelial-derived malignancies—such as colorectal, gastric, pancreatic, hepatic, breast, and ovarian cancers—making it a compelling target for immunotherapy. CD3 × EPCAM bispecific T-cell engagers (TCEs) function as molecular bridges that connect T cells with tumor cells, resulting in potent and specific tumor cell lysis. Despite their therapeutic promise, CD3 × EPCAM TCEs, particularly in solid tumors, encounter challenges including on-target/off-tumor toxicity, antigen heterogeneity, immunosuppressive tumor microenvironments, and cytokine release syndrome (CRS).

To support preclinical evaluation of CD3 × EPCAM bispecific antibodies, Biocytogen developed double humanized mice expressing humanized CD3E/D/G and EPCAM genes (B-hCD3EDG/hEPCAM mice) on a C57BL/6 background. Humanized *CD3E, CD3D,* and *CD3G* mRNA expression was confirmed by RT-PCR, and human CD3E protein expression on splenic T cells was validated by flow cytometry. Immunohistochemistry confirmed human EPCAM expression in the kidney, lung, skin, small intestine, and large intestine, but not in the heart, liver, or spleen. Flow cytometric analysis of leukocyte subpopulations in spleen, blood, and lymph nodes indicated that humanization did not alter immune cell frequency or distribution.

In a syngeneic tumor model, B-hCD3EDG/hEPCAM mice bearing EPCAM-humanized MC38 tumors exhibited significant tumor growth inhibition following solitomab treatment. This was accompanied by increased proportions of cytotoxic $CD8^+$ T cells and effector $CD4^+$ T cells at the tumor site, elevated cytotoxic $CD8^+$ T cells in the spleen, and enhanced T-cell proliferation in the blood. However, drug-related toxicity was observed in the ileum, characterized by focal epithelial cell necrosis in crypts, goblet cell hyperplasia, and eosinophilic infiltration.

A single-dose toxicity study further demonstrated transient cytokine release, with elevated serum levels of TNFα, IL-6, IL-10, and IFNγ within 24 hours post-dose, returning to baseline within 72 hours.

Collectively, these results validate the B-hCD3EDG/hEPCAM mouse model as a robust and physiologically relevant platform for pharmacological efficacy and safety assessment of CD3 × EPCAM bispecific antibodies in oncology research.

#3385 Humanized mouse models 2.0 - Improved preclinical evaluation of novel immune cell therapies, check point inhibitors, and immune cell engagers by excluding false positive or negative results.

Maria Stecklum[1], Philip Dube[2], Ditte Olsen[3], Jens Hoffmann[4]

[1]EPO GmbH, Berlin, Germany,[2]Taconic Biosciences, Inc., Rensselaer, NY,[3]Taconic, Tornbjergvej, Denmark,[4]Experimental Pharmacology and Oncology Berlin-Buch GmbH, Berlin, Germany

Background
The preclinical evaluation of novel immune therapies require mouse models with a humanized immune system. We previously demonstrated that either peripheral blood mononuclear cells (PBMC), subsets of PBMCs like T and NK cells or CD34+ hematopoietic stem cells (HSC) can be used to establish such models. With the development of next-generation NOG mice, lineage-specific differentiation of immune cell sub-populations of interest can be supported and Fc gamma receptor knock-out mice can exclude false positive or false negative results in studies with antibody-based therapies.
Methods
HSC-humanized mice were generated by i.v. transplantation of CD34+ stem cells using single donors or mixed HSC donor pools. HSC were transplanted to immunodeficient NOG mice and next-generation NOG strains as: NOG-EXL, hIL-2 NOG, hIL-6 NOG, and FcResolv™ NOG. Engraftment and lineage-specific differentiation were compared between the strains. Long-term survival was monitored and human immune cells counts in blood were analyzed by FACS every four weeks.
Breast cancer PDX were established on humanized FcResolv™ NOG mice and treated with different targeted antibodies, like Herceptin or check point inhibitors. Response to treatment was compared with PDX growing on NOG mice to evaluate whether murine FcγRs are confounding the study, leading to false positive or negative results.
Results
Humanized hIL-2 NOG mice showed significantly decreased survival after HSC transplantation in comparison to the other mouse strains. Mice had to be sacrificed within 6-8 weeks after HSC transplantation. In the other mouse strains, transplanted HSCs engrafted and differentiated mainly into B and T cells. NOG-EXL mice displayed the highest engraftment, with up to 80% of human cells in the blood, including a higher portion of myeloid cells after 8 to 12 weeks. Humanized NOG, hIL-6 NOG and FcResolv™ NOG mice showed the longest survival rate with over 400 days.
We have shown that breast cancer PDX models engraft on humanized FcResolv™ NOG and FcResolv™ NOG-EXL and removing murine FcγRs can improve accuracy for efficacy assessment of antibody-based therapies which include an Fc domain.
Conclusions
Next-generation NOG mouse strains, transgenic for human cytokines, can further improve the humanization of mouse models by inducing a lineage-specific differentiation of transplanted hematopoietic stem cells. Engraftment of human tumor cells or PDX seems not to be impaired on mice transgenic for human cytokines.
These improved human tumor-immune cell models allow more predictive preclinical translational studies on tumor immune biology as well as evaluation of new therapies.

#3386 MESHCAP (exogenous microbiota and humanized mice for lung cancer): Towards an innovative preclinical model for testing immunotherapies.

Pierre Montagne[1], Ulrich Jarry[1], Mathilde Harel[1], Laetitia Martinetti[2], Anna Le Mee[2], Charles Ricordel[3], Ahmad FAILI[2], Samer Kayal[4], Remy Pedeux[5], Marwan Touati[6], Valentin Quiniou[6], Hang-Phuong Pham[6]

[1]Biotrial, Rennes, France,[2]OSS - UMR 1242, Univ Rennes, INSERM, OSS, Rennes, France,[3]Pneumologie, Service de Pneumologie CHU Pontchaillou, Rennes, France,[4]Bacteriologie, Service de Bacteriologie CHU Pontchaillou, Rennes, France,[5]Oncotrial, Univ Rennes CNRS INSERM BIOSIT UAR 3480, Rennes, France,[6]PAREAN biotechnologies, St Malo, France

Small cell lung cancer (SCLC) is the most aggressive subtype of lung cancer. The recent combination of chemotherapy with immune checkpoint inhibitors shows a response in only 10 to 15% of patients. At the same time, numerous studies highlight the impact of gut microbiota composition on the response to immunotherapy. To address these current challenges, we are developing a xenograft model called "MESHCAP." This model involves grafting circulating tumor cells (CTCs) from SCLC patients onto mice that have been humanized for both their immune system and their gut microbiota. With its unique dual humanization, this model will allow us to take into account the influence of the microbiota when testing new therapeutic strategies. Based on the literature, we have identified a bacterial consortium hypothesized to be beneficial for the response to immunotherapy. This consortium is cultured in the laboratory and then inoculated into immunodeficient mice whose endogenous microbiota has been previously depleted by antibiotic treatment. We are able to detect the presence of these bacteria in the feces by 16S sequencing more than a month after inoculation. In parallel, we have humanized the immune system of immunodeficient mice by injecting human CD34+ hematopoietic stem cells. This engraftment results in chimerism of the mouse immune system. Currently, we are developing the generation of doubly humanized mice for both the microbiota and the immune system. Preliminary data suggest a cross-talk between the humanized microbiota and the human immune system. In our laboratory, we routinely isolate CTCs from patients diagnosed with CTC. We then inject them subcutaneously to generate CDXs (CTC-derived xenografts). It is these CDXs that we will implant into our doubly humanized mouse model to investigate the impact of the microbiota and immune system on therapies (e.g. immunotherapy).

#3387 Enhancing the predictability of human pharmacokinetics for antibody-drug conjugates (ADCs) using human FcRn transgenic mice.

Xinhe Feng[1], Kefeng Gong[1], Weifang Wang[1], Xinhua Ding[1], Ludovic Bourre[2], Xiaolong Tu[1], Luke Yu[2]

[1]Crown Bioscience, Taicang, China,[2]Crown Bioscience, Inc., San Diego, CA

Introduction Accurate human pharmacokinetic (PK) prediction for antibody-drug conjugates (ADCs) remains a pivotal challenge in early discovery and preclinical stages. Wild-type (WT) mouse models poorly predict human PK due to species-specific FcRn interactions. While hFcRn transgenic models improve mAb PK prediction, their value for complex ADCs requires further validation. This study evaluates hFcRn and HSA/hFcRn transgenic mice using marketed ADCs to establish their role in translational DMPK assessment.

Methods Four ADCs (T-DXd, T-DM1, SG, EV) were administered intravenously (10 mg/kg) to C57BL/6 WT, hFcRn, and HSA/hFcRn mice. Serial blood samples were collected over 28 days. Total antibody and ADC concentrations were measured by ELISA, free payloads by LC-MS/MS. PK parameters were derived via non-compartmental analysis.

Results WT mice consistently overestimated ADC half-lives, while hFcRn transgenic models showed human-relevant values. HSA/hFcRn mouse half-lives correlated strongly with human (r^2=0.95, $p<0.05$) and NHP (r^2=0.98, $p<0.01$). Please find the comparison of PK parameters in the table 1.

Furthermore, the platform successfully differentiated the stability characteristics between ADCs with stable (T-DXd) and more labile (EV) linkers, providing insights into ADC structure complexity and PK relationships.

Conclusion This study demonstrates that hFcRn transgenic mouse model accurately recapitulates human-relevant PK profiles that directly address a major limitation of conventional WT mouse models. The implementation of this platform enables more reliable human PK predictions and informs FIH trial design, and also provides a strategic approach to de-risking ADC development through data-driven candidate selection, reducing early discovery and late-stage dependency on NHP studies, and accelerating the translation of promising ADC therapeutics into clinical evaluation.

#3388 One-stop solution for preclinical evaluation of bispecific T-cell engagers targeting STEAP1.

Hongyan Sun, Yuqing Han, Fang Zhu, Yujing Zhang, Huixin Yang, Xiang Gao

GemPharmatech Co., Ltd., Nanjing, China

STEAP1 (Six-Transmembrane Epithelial Antigen of the Prostate 1) is a membrane protein highly expressed in prostate and other epithelial cancers, making it an attractive target for immune-based therapeutics. To support the development of STEAP1-directed agents, GemPharmatech established a comprehensive in vitro-in vivo evaluation platform designed to characterize STEAP1 expression, functional relevance, and T-cell engager (TCE)-mediated pharmacology. AMG509 (Xaluritamig), a Phase III STEAP1×CD3 TCE currently in clinical development, was used as a benchmark molecule to validate platform performance. Methods: In vitro assays were developed to quantify endogenous STEAP1 expression across prostate cancer cell lines (e.g., LNCaP, 22Rv1) using flow cytometry, followed by evaluation of T-cell dependent cytotoxicity (TDCC) with both luciferase-based and flow-based readouts. T-cell activation markers (CD69, CD25) and cell conjugation frequency were analyzed to characterize the efficiency of T-cell recruitment to STEAP1-positive tumor cells. Cytokine profiling (IL-2, IFN-γ, TNF-α, IL-6) was performed via Cytometric Bead Array (CBA) to monitor T-cell activation and cytokine release potential. Additionally, GemPharmatech engineered 22Rv1-hSTEAP1 and RM-1-hSTEAP1 cell lines to expand the translational scope of the STEAP1 platform across human and murine tumor contexts. In vivo, a panel of humanized immune mouse models (PBMC-NCG, NCG-MHC-dKO, and HSC-NCG) were employed to evaluate STEAP1-targeted TCE pharmacology under distinct immune settings. AMG509 treatment led to potent, antigen-dependent tumor suppression in STEAP1-positive xenografts, achieving >90% tumor growth inhibition and, in several cases, complete regression. Tumor analyses revealed robust infiltration of human CD3+ T-cells and increased local IFN-γ expression, consistent with effective STEAP1-directed immune engagement. Treated mice maintained stable body weight and displayed no signs of cytokine release syndrome (CRS) or graft-versus-host disease (GVHD), confirming the models' suitability for translational safety assessment. Collectively, these results demonstrate the establishment of a robust and modular evaluation workflow for STEAP1-targeted immunotherapies. By integrating antigen quantification, immune functional assays, and humanized in vivo systems, GemPharmatech's platform enables comprehensive and reproducible assessment of emerging TCE modalities. This work provides valuable preclinical insight into STEAP1 biology and establishes an experimental foundation for future therapeutic programs targeting this clinically relevant antigen.

#3389 Preclinical models for evaluating bispecific antibodies targeting PD-1 and VEGF.

Hongyan Sun, Chenyang Liu, Yunlong Jiang, Yujing Zhang, Huixin Yang, Xiang Gao

GemPharmatech Co., Ltd., Nanjing, China

Immune checkpoint inhibitors have transformed oncology treatment, yet primary and acquired resistance remain a significant clinical challenge. Bispecific antibodies targeting both PD-1 and VEGF have achieved remarkable success in clinical trials and have attracted widespread attention by concurrently modulating T-cell immunity while remodeling vasculature within the tumor microenvironment. Physiologically relevant preclinical models that accurately recapitulate human immune and target interactions are essential for evaluating novel therapeutics targeting PD-1 and VEGF. We established an integrated preclinical platform utilizing complementary humanized models. First, we developed BALB/c-hPD1/hPDL1 dual-humanized mice using CRISPR/Cas9 technology and engineered a CT26-hPDL1-hVEGFA dual-humanized colon carcinoma cell line. Implantation of these cells into BALB/c-hPD1/hPDL1 mice created an in vivo system simultaneously modeling the human PD-1/PD-L1 checkpoint and VEGFA signaling pathways. In this target-humanized model, the PD-1/VEGF bispecific antibody Ivonescimab demonstrated significant tumor growth inhibition, and showed superior efficacy compared to combination therapy with anti-PD-1 and anti-VEGFA antibodies, thereby validating the model's capability for assessing the synergistic effects of bispecific antibodies. To assess human T-cell-mediated responses to PD-1/VEGF bispecific antibody treatment, we established a dual-humanized model by engrafting the human tumor cell line LS174T into human peripheral blood mononuclear cell (PBMC) immune system humanized NCG mice. This model demonstrated robust human T-cell reconstitution suitable for evaluating mono- and combination therapies. In efficacy experiments using this model, Ivonescimab similarly exhibited potent antitumor activity with no observed treatment-related hemorrhagic complications, providing preliminary evidence for the safety profile of this combination strategy. These two models used together provide an integrated and translationally relevant preclinical platform for assessing efficacy and potential safety liabilities of PD-1/VEGF-targeted therapies. Using this comprehensive platform will effectively support the discovery and development of novel immunotherapies for complex indications, enabling preclinical risk assessment and accelerating candidate drug translation.

#3390 Enhanced human immune system engraftment in a novel triple-engineered NCG-hIL6-mTSLP-mFlt3-KOmouse model.

Hongyan Sun, Jun Xing, Shiying Guo, Yujing Zhang, Huixin Yang, Xiang Gao

GemPharmatech Co., Ltd., Nanjing, China

Robust humanized mouse models are critical for evaluating human hematopoietic stem cell (HSC) biology, immune system development, and therapeutic efficacy. The NCG strain provides a superior platform for human HSC engraftment due to severe immunodeficiency. To further enhance human immune system reconstitution, we engineered a next generation strain NCG-mTSLP-hIL6-mFlt3 KO by: 1. knocking in human IL6 (hIL6) to support human myeloid cell survival and inflammation, 2. transgenic (Tg) expression of mouse TSLP (mTSLP) to enhance human T and B cell development and lymphoid organogenesis, and 3. knocked-out (KO) mouse Flt3 (mFlt3) to eliminate cytokine competition for FLT3 ligand (FLT3L) and promote the expansion of FLT3-expressing human dendritic cells (DCs) and natural killer (NK) cells. Human CD34+ HSCs were transplanted into NCG and NCG-mTSLP-hIL6-mFlt3 KO mice. Human immune cell reconstitution was longitudinally monitored in the peripheral blood of mice by flow cytometry (up to 18 weeks post-transplantation). Human immunoglobulin (IgG and IgM) levels were quantified by ELISA. Selected cohorts of HSC-NCG-mTSLP-hIL6-mFlt3 KO mice received repeated intraperitoneal injections of recombinant human FLT3L protein at 18 weeks post-transplantation. Lymphoid tissue development was assessed anatomically. HSC-NCG-mTSLP-hIL6-mFlt3 KO mice exhibited improved engraftment and reconstitution of human immune cells compared to HSC-NCG controls. Flow cytometry revealed significantly higher levels of human T cells, NK cells, plasmacytoid DCs (pDCs), and conventional DCs (cDCs) in peripheral blood at multiple time points. Furthermore, functional human B cell maturation was confirmed by elevated serum levels of human IgG and IgM. Anatomical analysis revealed advanced development of various lymph nodes, which are key sites for antigen presentation and the initiation of adaptive immunity. Administration of exogenous human FLT3L further amplified reconstitution levels of human NK cells, pDCs, and cDCs, validating the responsiveness to human cytokine signaling. The NCG-mTSLP-hIL6-mFlt3 KO mouse model offers a powerful platform for human HSC engraftment and development of a functional, multi-lineage human immune system, including lymphoid (T, B), myeloid (DC subsets), and NK cells. Together with enhanced lymphoid organ development, this model is positioned to be a valuable tool for translational immunology and preclinical evaluation of immunotherapies.

#3391 The humanized FcRn mouse model: A superior platform for predicting human PK of therapeutic antibodies.

Hongyan Sun, Yujing Zhang, Yuansheng Yi, Huixin Yang, Xiang Gao

GemPharmatech Co., Ltd., Nanjing, China

Monoclonal antibodies (mAbs) are a rapidly expanding class of biotherapeutics with broad applications spanning oncology, autoimmune disorders, and infectious diseases. A key factor driving their clinical efficacy and dosing strategy is their pharmacokinetic (PK) profile, particularly serum half-life. While mice remain the preferred in vivo model for preclinical PK studies assessing absorption, distribution, metabolism, and excretion, conventional inbred and outbred strains fall short when it comes to accurately modeling the PK behavior of human mAbs and other human-derived biologics. The neonatal Fc receptor (FcRn) plays a pivotal role in regulating the extended half-life and homeostasis of immunoglobulin G (IgG) in vivo. By binding to IgG in a pH-dependent manner within acidic endosomes, FcRn rescues it from lysosomal degradation and recycles it back to the systemic circulation. This salvage pathway is a critical determinant of the PK profile of therapeutic mAbs. However, significant differences in the FcRn-IgG interaction exist between species, often leading to poor translatability of PK data from conventional mouse models, such as C57BL/6, to humans. To bridge this translational gap, we have developed a novel humanized FcRn mouse model, which expresses the human FcRn transgene while being deficient in the murine counterpart, providing a more reliable platform for evaluating the PK properties of human mAbs. In vivo PK studies comparing IgG1 and Keytruda in the humanized FcRn model versus wild-type C57BL/6 mice demonstrated a significantly improved correlation with known human PK profiles. The humanized FcRn model accurately recapitulated the expected serum half-life observed in patients, whereas wild-type mice exhibited artificially prolonged clearance due to murine FcRn-mediated recycling. To date, this FcRn humanized mouse model is the only validated rodent system capable of predicting the serum half-life of human IgG-based therapeutics. It serves as an essential tool for the non-clinical screening of mAb candidates to optimize half-life, reliably forecast human pharmacokinetics, and strategically guide clinical development plans.

#3392 Development of novel NCG-hIL15 and hIL-2 mouse models for preclinical assessment of human NK cell function.

Hongyan Sun, Yinlian Zhang, Yunlong Jiang, Yujing Zhang, Huixin Yang, Xiang Gao

GemPharmatech Co., Ltd., Nanjing, China

Natural Killer (NK) cells are critical mediators of antitumor immunity, exerting direct cytotoxicity and secreting immunoregulatory cytokines. They play a particularly important role in antibody-dependent cellular cytotoxicity (ADCC), a key mechanism harnessed by many therapeutic antibodies. To study these mechanisms, humanized mouse models have been employed, however; conventional human immune cell transplanted immunodeficient mouse models poorly support NK cell engraftment, limiting their translational utility. To address this gap, we developed two human cytokine-expressing mouse models on the NCG triple-immunodeficient mouse model that lacks functional T cells, B cells, and NK cells. TheNCG-hIL2 and NCG-hIL15, were engineered to constitutively express human IL-2 and human IL-15, respectively. These models were assessed for their ability to sustain human NK cell development and function after reconstitution with human hematopoietic stem cells (HSCs). The NCG-hIL2 model showed enhanced human NK cell reconstitution, underscoring the essential role of IL-2 in NK cell maturation and survival. In contrast, the NCG-hIL15 model supported robust co-engraftment of human T and NK cells, making it particularly suitable for evaluating combination T and NK cell-directed immunotherapies. Both models were evaluated in preclinical immunotherapy studies. The NCG-hIL2 model proved highly effective for assessing ADCC-mediated antibodies such as Trastuzumab, Margetuximab, Rituximab, and Blinatumomab. Together, the NCG-hIL2 and NCG-hIL15 models provide powerful and complementary platforms for studying human NK cell biology, cytokine-driven immunity, and anticancer immunotherapy.

#3396 Triple negative breast cancer organoids derived from circulating tumor cells to advance metastatic cancer research and drug resistance studies.

Shian-Jiun (SJ) Shih[1], David HSIEH[1], Felix Hsieh[1], Hsiang-Yun Lin[1], Hui Ren[2]

[1]Cellentia Inc., San Carlos, CA,[2]Precision AI, Foster City, CA

Triple-negative breast cancer (TNBC) remains challenging to treat due to a lack of effective targeted therapies, and a higher rate of metastasis compared to other breast cancer subtypes. Circulating tumor cells (CTCs) are a subset of cancer cells that shed from the primary tumor, survive in the circulatory system, and then form new metastatic tumors in new environments (s). We believe that a clinically relevant model of metastatic TNBC could be built from cultivation of functional CTCs in vitro, as we have done so for several solid tumors. To better represent the physiology of metastatic tumors, we aimed to culture these cells into 3D tumor organoids to mimic the establishment of early metastasis from CTCs. These CTC-derived tumor organoids would be a valuable platform for identifying novel drugs or drug combinations capable of effectively treating metastatic TNBC. We successfully established a TNBC CTC organoid line from the blood of a treatment-naïve stage 4 TNBC patient. From whole blood, we isolated CTC-containing PBMC, lysing residual red blood cells and seeding them into a proprietary media and plate system. To evaluate whether PBMC depletion would improve the cultivation of CTC organoids, we tested the use of anti-CD45 magnetic beads to deplete immune cells from the PBMC fraction. The cultures were closely monitored and replenished with fresh media every 2-3 days, and passaged to fresh plates every 2-3 weeks, enabling the steady removal of dead cells. This CTC organoid line of TNBC has been continuously passaged for four months now, consistently forms organoids of various sizes and as large as 200 microns, and slightly increases its growth rate over time. Morphology shows loose and irregular aggregates, similar to other breast cancer organoids, but unlike the spherical and densely packed organoids observed from CTC organoids from colon, renal, and other solid tumors. Due to the looser structure of these organoids, we found that cell health was best maintained during passaging by dissociating mechanically using a P1000 pipette, as opposed to enzymatic dissociation. This organoid line expresses EpCAM and cytokeratin, but not CD45, confirming an epithelial origin. Following our previous success in generating drug-resistant colonies from treating CTC organoid lines from colon and renal cancers with standard of care chemotherapy drugs, we are performing in vitro drug resistance colony selection on this TNBC CTC organoid line and applying RNA-Seq on these drug-resistant clones. Gene expression data are analyzed against public domain data from real patients and their treatment outcomes using an in-house AI algorithm to identify mechanisms of drug resistance. We intend to culture TNBC CTCs from new patient samples to increase our bank size, to improve our representation of the diversity of TNBC and validate the identified drug resistance mechanisms

#3397 Modeling cervical cancer heterogeneity using patient-derived organoids for precision treatment development.

Oda Floetre[1], Hege Fredriksen Berg[1], Dominika Aleksandra Hawryluk[1], Marta Espevold Hjelmeland[1], Stefania Bellone[2], Alessandro D. Santin[3], Camilla Krakstad[1], Mari Kylleso Halle[1]

[1]University of Bergen, Bergen, Norway,[2]Yale UNIV. School Of Med, New Haven, CT,[3]Yale University, New Haven, CT

Background: Cervical cancer encompasses diverse histologic and molecular subtypes, yet robust preclinical models that capture this heterogeneity remain limited. This gap continues to hinder the development of precision treatment strategies. **Objectives**: To establish and characterize a cervical cancer organoid library that reflects intertumoral heterogeneity and supports drug screening and functional genomic approaches.

Methods: Organoids were derived from resected cervical cancer tissue from 15 patients and embedded in Cultrex® to support 3D growth. Early- and late-passage organoids, alongside matched patient tumor tissue, underwent morphological evaluation, immunohistochemical profiling, and whole-exome sequencing. Matched 2D cultures were established to compare genomic features and treatment responses between 2D and 3D systems. Drug sensitivity assays including cisplatin, carboplatin, and antibody-drug conjugates (ADCs) are ongoing. Essential genes and therapeutic vulnerabilities will be identified by CRISPR/Cas screens in selected models.

Results: Organoids were successfully established from 40% of tumor samples, representing multiple histologic subtypes. These organoids preserved key morphological features of their corresponding tumors. Early drug response assays revealed heterogeneous sensitivity to platinum-based chemotherapy. Consistency in mutational and copy-number profiles between tumors and organoids at both early and late time points is being evaluated to determine genomic stability.

Conclusions: This organoid library provides a patient-relevant platform for studying tumor heterogeneity and therapeutic response. Ongoing genomic profiling combined with functional assays across this organoid library may reveal targetable vulnerabilities and ultimately advance precision medicine for cervical cancer patients.

#3398 Macrophage phagocytosis and efferocytosis: Implications for therapeutic modulation in the tumor microenvironment.

Veronica Bergo[1], Carla N. Castro[1], Arianna Bandini[2], Tamara Sahner[1], Sarah Huber[1], Sandra Moor[1], Philipp Metzger[1], Cynthia Obodozie[1], **Holger Weber**[1]

[1]Reaction Biology Europe GmbH, Freiburg, Germany,[2]Department of Translational Research and New Technologies in Medicine and Surgery, University of Pisa, Pisa, Italy

Macrophages play a central role in the tumor microenvironment. Depending on their activation state and local signals, they can exert both pro- and anti-tumorigenic effects. Tumor-associated macrophages (TAMs) often exhibit an immunosuppressive, pro-tumoral phenotype that promotes tumor growth, angiogenesis, metastasis, and therapy resistance. Due to their plasticity and abundance in solid tumors, TAMs are attractive therapeutic targets: either by reprogramming them toward an anti-tumoral state or depleting their tumor-supportive functions. Understanding macrophage behavior in cancer is critical for developing effective immunotherapies, given their dual roles. This requires reliable, physiologically relevant in vitro assays modeling key functions, such as phagocytosis, efferocytosis, cytokine secretion, and tumor cell interaction.

Macrophage phagocytosis and efferocytosis assays assess the impact of test compounds on the uptake activity of human M0, M1, and M2 macrophages. CD14+ monocytes are isolated from cryopreserved PBMCs and differentiated into M0 macrophages using M-CSF for six days, then polarized into M1 (IFN-γ + LPS), M2 (IL-4 + IL-13) or TAM-like (IL-4 + IL-10 + TGF-β) phenotypes. After polarization, cells are treated with test compounds at defined concentrations and time points, followed by incubation with either pHrodo™ bioparticles or apoptotic pHrodo™ labelled tumor cells (camptothecin-treated Raji cells) to assess phagocytosis or efferocytosis, respectively. Quantification is performed by measuring red fluorescence over 12 - 24 hours using a Cytation 5 reader.

Our experiments indicate that M0, M2 and TAM-like macrophages have a strong capacity for phagocytosis and efferocytosis, while M1 macrophages have minimal particle or apoptotic tumor cell uptake. Time-resolved analysis reveals distinct uptake kinetics. M0 and M2 macrophages rapidly internalize targets within 2-4 hours. However, M0 cells subsequently decline in activity, while M2 macrophages maintain a sustained plateau for up to 12 hours with an overall higher uptake. Repolarizing M2 macrophages to an M1 phenotype using LPS and IFN-γ markedly reduces their phagocytic capacity. Blocking the "don't eat me" signal with an anti-CD47 antibody significantly enhances the efferocytosis of Raji cells. We anticipate that cytokine profiling will reveal mechanistic differences between phagocytosis mediated by pattern recognition receptors and efferocytosis, which is critical for tissue homeostasis.

These findings suggest that the phenotype of macrophages strongly influences their phagocytic and efferocytic behavior, with M2 cells exhibiting the highest capacity. Strategies that modulate macrophage polarization or relieve inhibitory signals could enhance these functions and support further investigation into their therapeutic potential.

#3399 Highly multiplexed imaging allows for spatial characterization of tumor organoid models.

Anton Luis Villamejor, Joseph Lownik, Daria Mandel, Sinthia Kabir Mumu, Haley Norwood, Madhura Subba Rao, Joshua J. Breunig, Akil A. Merchant

Cedars-Sinai Medical Center, Los Angeles, CA

The emergence of 3D organoid models bridged the gap between 2D cell culture models and complex animal models. Its ability to accurately recapitulate the structure and function of organs and tumors made it a suitable system to perform mechanistic and perturbation studies with more complexities than a 2D cell culture but without the inconsistencies of animal models mimicking human diseases. One of the advantages of organoid models is it accurately represents a tissues structural environment. However, methods to image and spatially characterize organoid models have typically been limited to H&E staining which only gives a qualitative aspect of the structure. While single-plex immunohistochemical analysis is also possible, these tissues are limited and can be exhausted before full evaluation on multiple slides. Having the ability to image and characterize these structures in an efficient way not only validates the organoid's effectiveness to recapitulates the environment of the original tissue but also highlights spatial changes in these models throughout an experiment using only a single tissue slide. For this study, we produced patient-derived lymphoma and glioblastoma (GBM) cell line derived organoids. Organoids were fixed in hydroxyethyl agarose gel and embedded in paraffin. To spatially characterize the organoids produced, we utilized an automated sequential immunofluorescence imaging platform for its ability to detect up to 80 different proteins in a single protocol run. We selected 50 markers to develop the multiplex panel for organoid profiling. The panel consists of markers targeting extracellular matrix, cell phenotypes (GBM and lymphoma), and metabolic state. We believe that these set of markers can characterize and confirm the recapitulation of the two different organoids. In the patient derived lymphoma organoid, we observed cell type frequencies of T-cell subsets and B-cells which recapitulated flow cytometric analysis of the same organoid, confirming its ability to find relevant cell populations. This was additionally true for the GBM organoid, which contained a mixture of different neural cell states, similar to low-complexity single-plex assays performed on the same organoid. In addition, proliferative T-cells in the lymphoma organoid system also had higher levels of glycolytic and mitochondrial enzyme expression compared to non-proliferative subsets. This preliminary proof of principle demonstrates the utility of highly multiplexed imaging for the evaluation of organoid models with broad implications for pre-clinical and translational studies.

#3400 A 3D bioprinted hydrogel-based tumor model of non-small cell lung cancer for preclinical drug testing.

Jan A. Schlegel[1], Julia Thiel[1], Kanstantsin Lashuk[2], Schueler Julia[2], Thomas E. Murdter[1], Matthias Schwab[1], Meng Dong[1]

[1]Dr. Margarete Fischer-Bosch Institute of Clinical Pharmacology, Stuttgart, Germany,[2]Charles River Germany GmbH, Freiburg, Germany

Lung cancer is the most frequently diagnosed malignancy and remains the leading cause of cancer-related deaths worldwide. Non-small cell lung cancer (NSCLC) is the most prevalent subtype, accounting for the majority of these fatalities. Despite numerous approved therapies, the five-year survival rate for NSCLC patients remains poor, largely due to drug resistance and early relapse. Three-dimensional (3D) tumor models that better recapitulate the in vivo conditions of primary NSCLC hold significant potential for advancing both drug discovery and development. In this study, we developed a hydrogel-based, 3D-bioprinted NSCLC model in a tumor-slice format, in which tumor spheroids or organoids of NSCLC and primary CAFs were directly assembled to create a model that mimics the structure and biochemical properties of the tumor microenvironment (TME). Within this bioprinted approach the spatial distribution and compartment ratios can be defined, enhancing reproducibility and enabling a customizable TME reconstruction. A composite bioink consisting of alginate, collagen, and Matrigel was developed to generate a bio-functionalized hydrogel matrix that supports the structural stability and enables the co-culture of different cell types. Several drugs used for first-line treatment of NSCLC were applied to the system to evaluate the treatment efficiency. The printed 3D tumor slices can be cultured for up to 14 days while maintaining their architecture and proliferative capacity. The process is highly reproducible and supports consistent generation of tumor-like constructs suitable for downstream analyses and drug testing. Functional assays including cytotoxicity assays, live imaging, multiplex immunofluorescence staining and 3D imaging were established to assess cell viability, tumor-stromal cell interaction, and treatment response within the printed 3D tumor slices. The culture can also be expanded to include PBMCs to investigate immune cell behavior within the TME, making the model suitable for evaluating immunotherapies. In conclusion, we established a standardized 3D hydrogel-printed model incorporating NSCLC tumor spheroids or organoids and primary CAFs. By reconstructing the TME, this system provides a reproducible and physiologically relevant platform for preclinical drug screening and cancer research. Together with the established analytical methods, this platform serves as a valuable tool for drug discovery and development.

#3401 Modeling the multicellular blood-brain barrier with a PDX-derived glioblastoma microenvironment: comparing human and mouse biochip systems for tumor heterogeneity and drug response.

Michelle Zimmer[1], **Amelie Paillereau**[2], Thomas Sommermann[2], Lars Winkler[1], Joshua Alcaniz[1], Jens Hoffmann[1], Knut Rennert[2]

[1]Experimental Pharmacology and Oncology Berlin-Buch GmbH, Berlin, Germany,[2]Dynamic42 GmbH, Jena, Germany

Glioblastoma (GBM) is a highly malignant primary brain tumor whose therapeutic management is hindered by its invasive behavior and the restrictive properties of the blood-brain barrier (BBB). The BBB tightly regulates molecular transport between the circulatory system and the brain, limiting penetration of therapeutic agents. Widely used 2D *in vitro* systems offer little predictive value, as they lack key physiological features such as barrier integrity, multicellular complexity, and flow-dependent influences. As treatment efficacy depends on both, BBB permeability and direct tumor response, there is a critical need for advanced *in vitro* platforms that more accurately reproduce BBB function to support more reliable preclinical evaluation. To build a physiologically relevant BBB model, we assembled mouse or human brain capillary endothelial cells together with primary astrocytes and pericytes and tested their barrier formation both in static transwell systems and in a microfluidic chip platform. Different combinations and sources of BBB building cells were compared for junctional organization and barrier tightness. The addition of flow further reinforced barrier structure through shear-dependent junctional remodeling. These human and mouse BBB-on-chip models were then combined with patient-derived xenograft (PDX) GBM cell lines, generating a set of mouse PDX/GBM-on-chip and human GBM-on-chip models, that allow evaluation of tumor-heterogeneity under a human or mouse barrier. Initially, we compared treatment responses across conventional 2D cultures, static BBB constructs, the flow-based microfluidic model, and *in vivo* assays. Although 2D and *in vivo* studies demonstrated sensitivity towards cobimetinib, the compound was ineffective at inhibiting growth in the flow-integrated BBB chip. This is consistent with its inability to penetrate an intact barrier. In contrast, the BBB-permeable agent afatinib effectively reduced GBM growth *in vivo* and within the biochip, indicating that the chip reliably reflects whether therapeutic activity depends on BBB penetration. In summary, GBM-on-chip systems unite critical vascular barrier characteristics with GBM co-culture, offering a translational framework to examine tumor-barrier dynamics and determine compound passage across the BBB, thus more effectively connecting *in vitro* assays with PDX and human outcomes.

#3402 *THSD7B* loss is associated with oxaliplatin resistance in colorectal cancer patient-derived tumor organoids.

Graziana Spoto, Luca Falzone, Marco Fichera, Massimo Libra

Department of Biomedical and Biotechnological Sciences, University of Catania, Catania, Italy

Despite significant advances in systemic therapies for colorectal cancer (CRC), this tumor remains the second leading cause of cancer-related mortality worldwide. Among the chemotherapeutic agents most widely used in CRC, oxaliplatin (OX) represents a cornerstone of both single-agent and combination regimens. However, the acquisition of drug resistance mechanisms leads to the failure of these treatments, underscoring the need to elucidate the molecular determinants underlying chemoresistance. Therefore, this study aimed to identify the molecular determinants associated with resistance to OX-based therapies through integrated genomic and transcriptomic approaches performed on drug-sensitive and OX-resistant CRC patient-derived tumor organoids (PDTOs). OX- and FOLFOX-resistant CRC PDTOs (5.24-fold increment of drug resistance) were generated through the administration of increasing and sublethal doses of the drug for at least 90 days and integrated transcriptomic and exomic profiling were performed to characterize the molecular mechanisms sustaining chemoresistance. RNA-sequencing analyses revealed profound dysregulation of pathways involved in cytoskeletal regulation, extracellular space and cell death in both OX and FOLFOX-resistant models, while whole-exome sequencing identified newly acquired variants affecting genes related primarily to cell adhesion and extracellular matrix organization, with notable alterations affecting *LARGE1* and Thrombospondin Type-1 Domain-Containing Protein 7B (*THSD7B*), both genes potentially implicated in OX resistance. Particularly, the presence of the *THSD7B* NM_001080427.1:c.465dup, p.(Pro156ThrfsTer6) frameshift variant was first confirmed in OX-resistant PDTOs by droplet digital PCR (VAF=20.9%). RT-qPCR analyses performed in drug-sensitive and OX and FOLFOX-resistant PDTOs revealed markedly reduced *THSD7B* transcript levels in resistant models. Functional silencing of *THSD7B* using small interfering RNAs performed on Caco2, HT29, and HCT116 CRC cell lines led to a significant downregulation of *THSD7B* expression (from 27% to 90% reduction) and resulted in increased OX resistance, particularly in the more differentiated lines (Caco2 and HT29), whereas no substantial effect was observed in the undifferentiated HCT116 line. Overall, our data show for the first time that *THSD7B* loss mediates OX resistance in CRC. Intriguingly, this evidence has been recently associated with platinum resistance also in lung cancer; therefore, the evaluation of *THSD7B* status may represent a valuable strategy for the early identification of platinum-resistant patients to avoid the administration of ineffective and potentially harmful treatments.

#3403 High content imaging of patient cells to identify CLL and AML patient cohorts that predict drug responses.

David W. Andrews[1], Mark X. Li[1], Alla Buzina[1], Glauber C. Brito[2], Sila Usta[1], Brian Leber[3], Hubert Tsui[1], David Spaner[1]

[1]Sunnybrook Research Institute, Toronto, ON, Canada,[2]Federal University of Sergipe, Sao Cristovao, Brazil,[3]McMaster University, Hamilton, ON, Canada

Biomarkers that predict therapy response greatly facilitate applying precision medicine to patient treatment decisions. However, within populations of Chronic Lymphocytic Leukemia (CLL) and Acute Myelogenous Leukemia (AML) patients there is heterogeneity that is inherent to the disease and also between patients. This heterogeneity, obscures conventional potential biomarkers. As an alternative, we are applying confocal microscopy of live primary patient samples in 2D and 3D microenvironment models that mimic the bone marrow niche to identify cellular phenotypes that can be used as alternative biomarkers. For CLL, live cell painting using non-toxic dyes of cells from 133 patient samples that were grown in 2D niche mimetic cultures enabled machine learning from images. Feature reduction followed by unbiased image clustering revealed five cohorts of patients each with unique drug responses. The results of these studies suggest that high content imaging combined with machine learning and automated image analysis can be used to predict drug responses in a patient specific manner. For AML live cell painting revealed that a novel 3D microenvironmental model was required to inhibit differentiation and enable monitoring the growth of cells from bone marrow aspirates. We are currently applying machine learning to micrographs of AML patient samples stained for CD34 and CD45 to identify putative cancer stem cells within the 3D cultures and for image analysis of staining with a nuclear dye and Annexin V to assess cell-type specific responses to drugs targeting apoptosis proteins. Our results suggest that cellular phenotyping by high content imaging of patient cells grown in microenvironmental models may provide the biomarkers needed to enable precision patient treatment.

#3404 TR-107, a novel mitochondrial ClpP activator, exhibits potent antitumor activity in adrenocortical carcinoma models.

George Karadimov[1], Suresh Kumar[2], Yoo Sun Kim[1], Haiqing Fu[1], Edwin Iwanowicz[3], Lee M. Graves[4], Mirit Aladjem[1], Myriem Boufraqech[2], Jaydira Del Rivero[1]

[1]National Cancer Institute, Bethesda, MD,[2]National Cancer Institute, National Institiutes of Health, Bethesda, MD,[3]Madera Therapeutics, Cary, NC,[4]University of North Carolina School of Medicine, Chapel Hill, NC

Adrenocortical carcinoma (ACC) is a rare, aggressive malignancy arising from the adrenal cortex with limited effective treatment options. The pathophysiology of ACC is characterized by aberrant steroidogenesis and mitochondrial enrichment, reflecting the central role of mitochondria in adrenal steroid hormone synthesis and tumor metabolism. We hypothesized that therapeutically targeting mitochondrial function could yield enhanced antitumor activity in ACC. To test this, we evaluated TR-107, a novel small-molecule agonist of the mitochondrial protease ClpP, which disrupts mitochondrial proteostasis and bioenergetics. TR-107 exhibited potent cytotoxicity at low nanomolar concentrations in NCI-H295R cells (IC_{50} ≈ 24 nM) and in ACC patient-derived organoids (PDOs) (IC_{50} ≈ 15 nM), significantly reducing cell viability and confluency *in vitro*. EdU-based flow cytometry demonstrated reduced S-phase populations and cell size following 48-hour TR-107 treatment, consistent with G1 and G2 arrest. Annexin V/PI assays revealed increased early and late apoptotic fractions in treated ACC cells, confirming apoptotic cell death. Similarly, ACC PDOs and patient-derived xenograft organoids (PDXOs) exhibited substantial decreases in viability upon ClpP activation. Given the high expression of IGF-2 and IGF-1R signaling in ACC, we next examined the combinatorial potential of TR-107 with IGF-1R inhibition. Co-treatment produced synergistic reductions in viability across NCI-H295R cells and PDOs. Collectively, these findings identify mitochondrial ClpP activation as a promising therapeutic strategy for ACC and demonstrate that TR-107 exerts potent antitumor activity as a monotherapy or in combination with IGF-1R blockade. These results provide strong preclinical support for advancing ClpP agonists toward clinical development for the treatment of ACC.

#3405 ATCC's patient-derived 2-D & 3-D cancer models make translational oncology a reality for the scientific community.

Abhay Andar, Ajeet Singh, Changsuk Moon, Stephen Friend, Matthew Graziano, Ruby E. Thamert, Fernanda Ventura, Utsav Sharma, Jonathan Jacobs, **Carolina Lucchesi**

Microphysiological Systems, American Type Culture Collection (ATCC), Manassas, VA

Background: The Human Cancer Models Initiative (HCMI) is a global effort led by the National Cancer Institute (NCI) to advance translational oncology through patient-derived cancer models. Traditional cell lines often fail to capture the complexity of human tumors, limiting their relevance in drug discovery. HCMI addresses this by generating biologically relevant 2-D and 3-D models from patient samples, emphasizing genomic fidelity and clinical relevance. ATCC contributes to the initiative by developing, manufacturing, and distributing these models worldwide. Over 300 models have been released across 28 tissue types, including colorectal, pancreas, brain, and esophagus as well as rare cancers such as Wilms tumor and Ewing's sarcoma. These models span diverse diagnoses, age groups, and racial backgrounds, supporting research into tumor heterogeneity and health disparities. Comparative analyses show strong alignment with The Cancer Genome Atlas (TCGA), retaining over 80% of oncogenic drivers and preserving key transcriptional and epigenetic features. HCMI models offer a robust platform for precision oncology, enabling drug screening, biomarker discovery, and personalized medicine.

Results and discussion: To date, the portfolio includes 329 models spanning common and rare cancers, comprising 91 colon, 54 pancreas, 50 brain, and 37 esophagus. Diversity includes clinical stage, age, and racial representation, enhancing translational relevance. Genomic profiling confirms strong fidelity to patient tumors. TCGA comparisons show >80% retention of oncogenic drivers and high concordance for mutations like BRAF (SKCM), KRAS (PAAD), APC (COAD/READ), and TP53 (ESCA). Concordance exceeds 90% for several cancer types. Additionally, 95% of tumor-model pairs show significant similarity in DNA methylation, and >80% align transcriptionally, preserving epigenetic and transcriptomic features. Models include primary (61%), metastatic (31%), and recurrent (7%) tumors, with samples from varied racial and age groups. This heterogeneity supports research into tumor evolution, drug response variability, and disparities in cancer care.

Conclusion: HCMI offers a next-generation resource for oncology research. By providing clinically relevant, patient-derived models with rich molecular annotation, it enables drug discovery, biomarker validation, and personalized therapy development, bridging the gap between preclinical studies and clinical outcomes.

#3406 Establishing an osteosarcoma organoid model reflecting the bone microenvironment.

Xin Li, Zhi Yang, Ba xuan Hoang, Bo Han

Keck School of Medicine of USC, Los Angeles, CA

Osteosarcoma is the most common primary malignant bone tumor in children and young adults and usually arises in the metaphyses of long bones during periods of rapid skeletal growth. Survival for metastatic or relapsed disease remains poor, and most in vitro studies still rely on two-dimensional plastic cultures that do not reproduce the mineralized matrix, stromal cells, and matrix-bound growth factors that shape osteosarcoma behavior in bone.To address this gap, we established a stepwise bone-mimetic system using Saos-2 osteoblastic osteosarcoma cells. Demineralized bone matrix (DBM) serves as a defined source of bone-matrix-derived growth factors (DBM-DGF), including growth factors such as TGF-β, BMPs, and IGF-1, which act together in a combined effect. Fresh human bone chips provide a more complete bone surrogate with native mineralized matrix, matrix-derived factors, and resident bone cells. In tier 1, Saos-2 cells were treated with matrix-derived growth factor preparations that had been prescreened and grouped by osteoinductive activity. Proliferation was measured by MTT assay. Saos-2 cells showed a graded increase in proliferation across DBM-DGF groups, with the highest-activity preparations producing the strongest proliferative response. These findings indicate that DBM potency directly influences the growth-promoting strength of bone-matrix-derived signals and can be used to approximate “young,” more proliferative, growth-factor-rich bone versus more “aged,” growth-factor-poor bone.In tier 2, conditioned medium from bone-matrix-derived stromal cells is applied to Saos-2 cultures to model paracrine co-culture and test how stromal secreted factors regulate proliferation, differentiation, and migration. In tier 3, fresh human bone chips are combined with Saos-2 cells in three dimensions so that tumor cells experience intact mineralized matrix, matrix-bound growth factors, and resident bone cells at the same time, creating a bone-like microenvironment. This tiered platform directly compares isolated matrix-derived signals with a structurally and cellularly complex bone surrogate and provides a practical, more physiologically relevant model for studying tumor-bone interactions, age-related changes in the bone environment, and for preclinical testing of candidate therapies in osteosarcoma.

#3407 Ensuring diverse *in vitro* lung cancer models: Development of alveolar epithelial cell lines, patient-derived xenografts, and lung adenocarcinoma cell lines from individuals of African ancestry.

Karla E. Gonzalez[1], Bianca Dal Bo[1], Chunli Yan[1], Donna Loza[2], Matthew A. Gladstone[1], Anthony W. Kim[3], Scott M. Atay[3], Takashi Harano[3], W. Dean Wallace[4], Ben Y. Tew[5], Bodour Salhia[5], Beiyun Zhou[6], Kweku Ofosu-Asante[7], Kyle R. Philips[8], Benjamin J. Ryder[8], Desmond Kwakye[7], Chase A. Lilly[7], Yong Huang[8], Nazarius S. Lamango[7], Ite A. Offringa[1]

[1]Surgery, Cancer Biology, USC Norris Comprehensive Cancer Center, Los Angeles, CA,[2]Surgery, USC Norris Comprehensive Cancer Center, Los Angeles, CA,[3]Surgery, USC Keck School of Medicine, Los Angeles, CA,[4]Pathology, USC Norris Comprehensive Cancer Center, Los Angeles, CA,[5]Cancer Biology, USC Norris Comprehensive Cancer Center, Los Angeles, CA,[6]Medicine, USC Keck School of Medicine, Los Angeles, CA,[7]Florida Agricultural and Mechanical University, Tallahassee, FL,[8]University of Florida, Gainesville, FL

Lung cancer disproportionately affects individuals of African ancestry (AA), particularly men, who experience 12% higher incidence and 15% higher death rates than European ancestry men. The causes of this disparity remain unclear; while smoking is the most substantial risk factor for lung cancer, AA men do not smoke more than other groups. Despite the lack of understanding of the increased lung cancer risk and death rates of the AA population, the tools to study lung cancer in this group lag far behind; there are very limited *in vitro* models to study lung cancer in AA individuals. Lung adenocarcinoma (LUAD), which originates in the alveolar epithelium, is the most common histological subtype of lung cancer in all population groups. Immortalized human alveolar epithelial cells (ihAEC) are therefore key tools for studying the etiology and development of LUAD, as well as effects of environmental exposures. In addition to ihAECs, patient-derived xenografts (PDXs), in which human tumors are implanted and grown in immunodeficient mice, and *in vitro* cultured LUAD cell lines, are valuable tools to study lung adenocarcinoma. To address the shortage of these models developed from AA patients, we are taking a 3-pronged approach. We are collecting non-tumor and LUAD tissues from AA lung cancer patients with full consent. When sufficient non-tumor tissue is available, we isolate alveolar epithelial cells and use a CRISPR/Cas9-based gene-delivery approach to generate ihAEC lines. We direct genomic integration of simian virus 40 large-tumor antigen (SV40 LgT) and human telomerase reverse transcriptase (*TERT*) genes into the adeno-associated virus integration site 1 (AAVS1), a safe harbor region that prevents inserted genes from being silenced. When sufficient LUAD tumor tissue is available, we implant tumor sections subcutaneously in immunodeficient mice. Tumors that grow are explanted for a new round of propagation in mice as well as *in vitro* culture. To date one PDX has been established, and cells are in culture from non-tumor and tumor tissue; further characterization is in progress. The development of new ihAEC lines, PDXs, and LUAD cell lines will provide valuable tools for studying responses to environmental exposures, carcinogen detoxification processes, oncogenic transformation, and for testing novel therapies in ancestry-appropriate models. This work is an important step towards minimizing lung cancer health disparities caused by the absence of diverse model systems.

Supported by grants U54CA233396, U54CA233444, and U54CA233465 from the National Institutes of Health (NIH)/National Cancer Institute (NCI), and the Norris Comprehensive Cancer Center core grant, award number P30CA014089 from the NIH/NCI.

#3408 Patient-derived tumor models of tyrosine kinase inhibitor-induced neuroendocrine-transformed lung carcinoma.

Matthew Djan[1], Sebastiao N. Martins-Filho[2], Nhu-An Pham[3], Nikolina Radulovich[3], Quan Li[3], Ming Li[3], Geoffrey Liu[3], Ming Sound Tsao[3]

[1]Medical Biophysics, University of Toronto, Toronto, ON, Canada,[2]Laboratory Medicine and Pathology, University of Alberta, Edmonton, AB, Canada,[3]UHN Princess Margaret Cancer Centre, Toronto, ON, Canada

Background: Lung cancer is the leading cause of cancer-related deaths worldwide, with non-small cell lung cancer (NSCLC) comprising 85% of cases and small cell lung cancer (SCLC) 15%. Tyrosine kinase inhibitors (TKIs) are the frontline therapy for *EGFR*-mutant and *ALK*-fusion adenocarcinomas, yet most patients develop resistance. In 5-10% of TKI-resistant cases, adenocarcinomas (ADC) undergo lineage switching to aggressive neuroendocrine (NE) carcinomas, including LCNEC and SCLC; these patients lack effective therapies and have poor clinical outcomes. To better study NE-transformed tumors, we established clinically relevant patient-derived xenograft (PDX) and xenograft-derived organoid (XDO) models to identify novel therapeutic vulnerabilities and elucidate mechanisms underlying NE transformation.

Methods: Patient biopsy tissues were subcutaneously engrafted into NOD-SCID mice to generate nine NE-transformed PDX models, and six matched long-term XDOs (>10 passages) were established using organoid culture protocol. PDXs/XDOs were characterized by H&E and immunohistochemistry, whole-exome sequencing, and bulk RNA-sequencing. For *in vivo* therapeutic profiling, donor PDX tumors were expanded and randomized into four arms: vehicle, Osimertinib (25 mg/kg, QDx5), chemotherapy [Cisplatin (3 mg/kg, QW) + Etoposide (8 mg/kg, TIW)], or combination. For *in vitro* drug testing, XDOs were dissociated into single cells, seeded into 384-well plates, and treated with Osimertinib, Cisplatin, or Etoposide across a 21-point dilution series (1 nM-10 μM), with viability measured on Day 7 using CellTiter-Glo 3D.

Results: Paired PDXs/XDOs retained key genetic drivers, including *EGFR, TP53,* and *RB1* mutations, along with recurrent alterations in the NOTCH signaling pathway. Histologically, the models recapitulated patient tumor phenotypes, including three SCLC-transformed, two LCNEC-transformed (one ADC-like, one NE-like), and one mixed ADC/SCLC case. Notably, the mixed-histology model maintained both ADC and SCLC components in long-term XDO culture, preserving intratumoral heterogeneity. *In vivo* therapeutic testing revealed minimal response to Osimertinib, chemotherapy, or combination therapy in NE-high tumors, whereas an ADC-like LCNEC PDX exhibited sensitivity to these treatment arms, consistent with clinical observations. XDO drug responses were highly concordant with their matched PDXs, demonstrating resistance to Osimertinib and chemotherapy (IC_{50} > 1 μM). Preliminary high-throughput screening of XDOs with a 58-compound epigenetic probe library identified a candidate therapeutic target to be presented.

Conclusion: Our NE-transformed models preserve patient tumor molecular features, histopathology, and therapeutic response, providing robust platforms to identify novel therapeutic strategies and dissect mechanisms driving lung NE transformation.

#3409 A vascularized 3D microfluidic breast tumor platform for characterizing lymphovascular space invasion among inflammatory breast cancer cell lines.

Melika Mehrabi Dehdezi[1], **Ali Moghaddaszadeh**[1], Zoe Apsel[1], Surbhi Shivhare[2], Xiaoding Hu[2], Bisrat G. Debeb[2], Wendy A. Woodward[3], Marissa Nichole Rylander[1]

[1]University of Texas at Austin, Austin, TX,[2]UT MD Anderson Cancer Center, Houston, TX,[3]Associate Professor, Radiation Oncology, UT MD Anderson Cancer Center, Houston, TX

Highly aggressive cancers such as inflammatory breast cancer (IBC) are characterized by the presence of tumor cell emboli within lymphatic and blood vessels, a phenomenon known as lymphovascular space invasion (LVSI). In this study, we developed a vascularized 3D in vitro tumor microfluidic platform to evaluate LVSI mechanisms including tumor invasion, cancer cells intravasation, vascular and Extracellular Matrix (ECM) remodeling, and emboli formation in IBC cell lines (MDA-IBC3, A3250, and SUM149).Initially, various collagen concentrations (2,3,4,5and 6 mg/mL) were evaluated using optical fiber-based interferometry nanoindentation to measure collagen hydrogel stiffness and identify a concentration representative of normal breast tissue (0.5-1 kPa). A 4 mg/mL collagen concentration was selected, yielding an average stiffness of approximately 0.7 kPa, and was used to assess how the incorporation of cancer cells alters ECM stiffness. Platforms were fabricated by polymerizing a 4 mg/mL collagen type I solution containing cancer cells (2 million cells/mL) around two 22G needles to form vascular channels. These channels were seeded with mKate-tagged telomerase-immortalized endothelial (TIME) cells at 10 million cells/mL, and a shear stress of 4 dyn/cm² was applied to establish aligned, functional endothelium. Confocal microscopy was used to monitor vessel sprouting, permeability, emboli formation, and tumor cell intravasation for one week. Effluent media was collected on Days 3 and 7 for cytokine analysis. By day 7, vessel coverage was significantly reduced in TIME+A3250 and TIME+SUM149 platforms compared to TIME-only and TIME+IBC3 platforms ($p < 0.001$). Although the number of endothelial sprouts was significantly higher in TIME+A3250 platforms compared to TIME+IBC3, the average sprout length did not differ significantly. A3250 cells also exhibited a higher frequency of invadopodia-positive tumor cells compared to MDA-IBC3, indicating a greater invasive phenotype. Consistent with this, the number of intravasated A3250 cells was approximately 15-fold higher than that of MDA-IBC3 cells. Spatial analyses of the platforms' midplanes images further revealed that A3250 cells accumulated around the vessel to a much greater extent than the area farther from the vessel over time. Notably, platforms containing A3250 cells showed an extreme hydrogel deformation, including central separation, suggesting profound collagen remodeling driven by this cell line. This trend was not observed with the other IBC lines (MDA-IBC3 and SUM149).In conclusion, our results indicate that the A3250 IBC cell line shows a more aggressive phenotype compared to the other IBC cell lines. We observed significantly higher intravasation relative to MDA-IBC3, greater disruption of endothelial vessel coverage, and a higher frequency of invadopodia-positive cells.

#3410 Engineering prostate tumor microenvironments via the granular environment for lattice self-assembly (GELS) system.

Alia Starman, Cris Angeles, Ally Freidholm, Ethan Lin, Gabriel Leonard Galahad Declercq, Hunain Khawaja, Cynthia Miranti, Alexander McGhee

University of Arizona Cancer Center, Tucson, AZ

Developing physiologically relevant in vitro tumor microenvironment models demands faithful reproduction of tissue architecture, mechanical properties, and vascularization. To meet these requirements, I have developed a technique called Granular Environment for Lattice Self-assembly (GELS), which leverages granular hydrogel as modular building blocks that both support and constrain cell adhesion, migration, and collective remodeling. GELS is particularly well suited to prostate cancer engineering due to its emergent architecture resembling branching glands and ducts. In GELS, cells remodel their surroundings in proportion to the energy landscape required to displace neighboring granules. When nearby energy barriers are low, cells drive extensive reorganization, whereas high barriers restrict them to localized adjustments. By tuning the spatial distribution and magnitude of these barriers through granule size, surface chemistry, and connectivity, we can implement broad patterns, while allowing cells to contribute fine structural detail by adaptively responding to native chemical cues that guide tissue formation. Preliminary results demonstrate that altering granule size and composition induces a transition from disconnected, organoid-like aggregates to continuous, tissue-like arrangements with interconnected microchannels. We aim to use these insights to derive predictive design rules for tissue self-assembly, enabling the creation of in vitro models for specific tumor microenvironments, including the prostate. By seeding fibroblasts in well-defined patterns within GELS, first we established a healthy stromal environment into which prostate cancer spheroids can be introduced. The subsequent transition of fibroblasts into cancer-associated fibroblasts (CAFs) will be monitored through traction force microscopy for changes in alignment and ELISA readouts of TGF-β levels and localization. These measurements will link mechanical remodeling to biochemical signaling in a dynamically evolving TME. This method holds the potential to significantly advance the field of cancer engineering by enabling the creation of more complex and viable TME models with live readouts of key signals.

#3411 Mechanochemical effects of growth factor gradients in colorectal cancer organoids.

Gabriel L. G. Declercq, Alex Borowiec, Alejandro Moncada, Alia Starman, Surajinder Bharaj, Kevin Pond, Alexander McGhee

University of Arizona Cancer Center, Tucson, AZ

Understanding how colorectal cancer (CRC) cells respond to growth factor (GF) cues in addition to mechanical forces is essential for defining the mechanisms that regulate tissue organization and tumor progression. Here, we used a platform that co-registers mechanical outputs with biochemical readouts to investigate CRC organoid responses to well-defined spatiotemporal GF gradients produced by GF-loaded beads. Embedding the beads within a liquid-like solid microenvironment creates a diffusion-limited system, enabling stable and quantifiable gradient formation. GF-loaded beads were positioned at defined locations within the *in vitro* model to establish local concentration fields, measured through spatially distributed ELISA beads operating under non-depleting Langmuir adsorption conditions. Concurrently, 2D CRC organoids expressing Erk and Akt kinase translocation reporters were cultured on ECM-functionalized hydrogels embedded with fiduciary traction beads, enabling reconstruction of traction stress maps via particle-tracking-based traction force microscopy. Preliminary data shows that organoids exposed to steep GF gradients will exhibit elevated Erk activity along gradient-facing edges, while regions experiencing lower concentrations will display reduced Akt activation. This spatiotemporal response further demonstrates that traction forces will increase in regions with high local GF concentration, indicating a gradient-dependent mechanochemical response. These projected spatial correlations will reveal discrete concentration thresholds above which CRC cells transition from apical to focal contractility, a shift that reflects loss of epithelial organization, increased ECM engagement, and acquisition of a more motile, invasion-prone phenotype relevant to tumor progression. Collectively, these outcomes demonstrate that localized GF release from GF-loaded beads can be quantitatively mapped and directly linked to force generation and kinase dynamics within CRC organoids. This integrated approach will establish a unified framework for probing how GF gradients and mechanical cues interact to shape CRC cell behavior, providing a platform for subtype-specific studies and enabling engineering-driven strategies for targeted therapeutic intervention.

#3412 Next-generation cancer organoids 2.0 in precision cancer medicine: Patient-derived pancreatic ductal adenocarcinoma organoids model tells not only drug sensitivity but also complexity of tumor biology.

Hyemin Kim, Younghoon Choi, Eun Mi Lee, Jungmyoung Han, Se-Hoon Lee, Kwang Hyuck Lee, Jong Kyun Lee, Kyu Taek Lee, So Jeong Yoon, Hongbeom Kim, Sang Hyun Shin, Jin Seok Heo, In Woong Han, Joo Kyung Park

Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, Korea, Republic of

Introduction : Organotypic models of patient-specific tumors are revolutionizing our understanding of cancer heterogeneity and its implications for personalized medicine. The study's aims were as follows: 1) to establish a PDAC patient-derived organoid (PDO) model obtained from various PDAC specimens. 2) to find out clinicogenomic factors affecting patients' outcomes.
Methods : The SMC PDAC Cohort Patients were prospectively enrolled and underwent EUS-guided FNB, metastatic sites (such as liver, ascites, lung, and bone), and surgical resection. PDAC PDOs were comprehensively analyzed for histology, next generation sequencing (NGS), and high-throughput screening (HTS) drug sensitivity tests.
Results : The 735 PDAC patients were prospectively enrolled in this study. PDAC PDO platform has been trying to establish from the following cancer specimens: ascites, biopsies from bone, liver, lung, and pancreas, or surgical resection. The success rate was as follows according to the source of obtaining site; ascites due to peritoneal seeding (3/3: 100%), bone mets (1/1: 100%), EUS-FNB (195/183: 87.8%), liver mets (7/8: 87.5%), lung mets (1/1: 100%), surgical specimens (394/500: 78.8%) and PDO was successfully established within 8.2±2.6 days. It took approximately 3 weeks to acquire each specimen and generate sufficient PDAC PDOs for the simultaneous HTS drug sensitivity test and NGS. Whole exome or genome sequencing (WES/WGS, n=302) showed an almost identical concordance between original PDAC tissues and matched PDOs and the increased frequency of genetic alterations in PDOs. The HTS drug sensitivity test (n=151) revealed the clinical correlation between the PDO response and the actual chemotherapeutic response of the study patients in both palliative and adjuvant in real-world settings (ranging from 84.0~ to 91.2%). In addition, whole transcriptome sequencing (n=308) identified nab-paclitaxel resistance-associated genes such as ITGB7, ANPEP, and ST3GAL1, and also found early recurrence-related genes including COL2A1, CALB1, and CYP24A1 in the extracellular matrix, calcium signaling, and vitamin D metabolism.
Conclusions : The PDAC PDO platform may become a valuable tool for personalized medicine and may give us insights into tumor biology.

#3413 Generation of a distal lung cancer organoid model using oncogenic ret-expressing induced pluripotent stem cells.

Jinwook Hwang[1], Christophe Desterke[2], Paul Marcoux[1], Mohamed Amin Bani[3], Frank Griscelli[1], Annelise Bennaceur Griscelli[1], **Ali G. Turhan**[1]

[1]INSERM U1310, Villejuif, France,[2]Universite Paris Saclay, INSERM U1310, Villejuif, France,[3]Gustave Roussy Cancer Center, Villejuif, France

3D-lung organoids generated from normal iPSCs represent a powerful tool to study human lung development and disease. The tyrosine kinase receptor RET is altered by genetic fusions in a subset non-small cell lung cancers (NSCLC). To determine if we can generate lung cancer organoids in this context, we used two iPSC lines harboring RET with oncogenic M918T and C634Y mutations and evaluated their ability to give rose to distal lung organoid structures. NKX2-1+ lung progenitor cells (LPC) were generated after 14 days of culture followed by air-liquid interface cultures giving rise to alveolar structures by day +38. These cells expressed alveolar differentiation markers (such as SFTPC) as well as PD-L1, TTF-1, MUC1, and CK5/6. Transplantation of day+14 LPCs into NOD/SCID mice generated tumors in RET-expressing organoids only whose immunostaining also revealed presence of bronchial structures, ciliated cells, goblet cells and the well-established squamous cell carcinoma marker p40. Single-cell RNA sequencing analyses revealed the presence of fetal neuroendocrine cells, goblet cells as well as alveolar type 2 cells. This single cell RNAseq signature allowed to determine the major genes involved with response or resistance to Selpercatinib, the major inhibitor targeting RET-altered lung cancers.

Significance : These findings show for the first time to our knowledge that iPSC-derived distal lung organoids with oncogenic RET overexpression can recapitulate the characteristics of RET-Driven non-small cell lung cancer (NSCLC). This experimental tool has significant potential as a preclinical model for identifying new therapeutic targets in RET-inhibitor-refractory lung cancers.

#3414 PDO as Translational Model for Biomarker Discovery in NSCLC.

Maria C. Speranza[1], Anna Pasto[2], Halh Al-Serori[2], Elisavet Chatzopoulou[2], Veronika Yankova[2], Henrik Hammaren[3], Patricia Sauer[3], Kathrin Uhrig[3], Helena Rannikmae[2], Lena Eismann[3], Edward Curry[2], Tony NG[2], Kenneth W. Hance[4]

[1]GlaxoSmithKline plc, Boston, MA,[2]GlaxoSmithKline plc, Stevenage, United Kingdom,[3]GlaxoSmithKline plc, Heidelberg, Germany,[4]GlaxoSmithKline plc, Malvern, PA

This study leverages treatment-naïve patient-derived organoids (PDOs) as a powerful translational model to drive biomarker discovery in non-small cell lung cancer (NSCLC). Current biomarker discovery efforts rely predominantly on publicly available datasets that predict cell surface localization at the RNA level. By focusing on the proteomic characterization of the cell surface, specifically targeting N-glycosylated proteins, we aim to capture the dynamic landscape of membrane proteins that play key roles in tumor biology.We performed a surfaceome screening on a cohort of 15 NSCLC organoids and 5 matched normal lung organoids after in vitro treatment with saline, cisplatin and B7H3 ADC. Live-cell biotin labeling followed by enrichment enabled isolation of glycosylated cell surface proteins. Downstream LC-MS/MS-based proteomics allowed quantitative profiling of both enriched and total protein fractions. Concurrently, transcriptomic profiling via RNA-seq and WGS will enable cross-comparative analysis. This proteogenomic approach will be critical given that transcript-level data do not always reflect actual protein expression, particularly for membrane proteins that may be subject to complex post-translational modifications and regulation. Comprehensive multiomic in silico analyses are currently ongoing to integrate our experimental data with external databases, including CPTAC, TCGA, TEMPUS, and GTEx. These computational analyses are designed to refine our list of candidate biomarkers based on high protein expression and differential expression pre- and post-treatment.Our approach underscores the potential of utilizing advanced proteomic and transcriptomic methodologies in tandem with cutting-edge in silico analyses to better understand tumor biology. Further analysis and validation studies will be needed to ensure that the biomarkers we identify have the highest translational potential and can be used as effective diagnostic tools.

#3415 Establishment and characterization of novel patient-derived esophageal tumoroids with long term cultivability.

Takashi Urano[1], Etsuko Yokota[1], Miki Iwai[1], Takuro Yukawa[1], Nagio Takigawa[2], Hideyo Fujiwara[1], Takashi Akiyama[1], Minoru Haisa[1], Takuya Fukazawa[1], Yoshio Naomoto[3], Tomoki Yamatsuji[3]

[1]Kawasaki Medical School, Kurashiki, Japan,[2]General Internal Medicine 4, Kawasaki Medical School, Kurashiki, Japan,[3]General Surgery, Kawasaki Medical School, Kurashiki, Japan

Esophageal cancer, which includes esophageal squamous cell carcinoma (ESCC) and esophageal adenocarcinoma (EAC), is a highly aggressive malignancy and ranks as the eleventh most prevalent cancer worldwide. Despite therapeutic progress, the 5-year survival rate remains poor. To enable the development of new treatment strategies, robust preclinical models of esophageal carcinoma are essential. Recent progress has enabled three-dimensional (3D) organoid systems generated from adult or pluripotent stem cells. Such organoids faithfully reproduce the architecture and functions of the tissue of origin and have been established from multiple human sources, including patient-derived tumors of the colon, prostate, breast, pancreas, esophagus, bladder, and liver. In this study, we generated three human esophageal cancer organoids from surgical specimens and maintained long-term cultures exceeding 12 months. All lines also met a practical durability benchmark—continuous growth for ≥3 months or ≥10 serial passages—thereby enabling consistent pharmacologic testing and cross-batch reproducibility. Two organoids originated from ESCC, and one from EAC that arose in Barrett's esophagus. Whole-exome sequencing showed that these organoids preserved the genetic alterations present in the corresponding primary tumors. In parallel, patient-derived xenografts recapitulated the histopathology of the original esophageal cancers. Comprehensive assessments, including copy-number profiling and immunohistochemistry, demonstrated HER2 expression with amplification and HER3 expression with mutation in the EAC-derived organoid. Notably, HER2-directed antibody-drug conjugates (ADCs), including trastuzumab deruxtecan (T-DXd) and pertuzumab deruxtecan (P-DXd), effectively reduced tumor cell viability in these organoids. The successful creation of esophageal organoids with durable cultivability enables reproducible foundational studies, including drug-sensitivity testing, which are critical for advancing personalized therapy and rational treatment design. This work provides actionable resources for clinicians and researchers seeking to improve therapeutic approaches for esophageal cancer.

#3416 Functional heterogeneity of the human blood-tumor barrier phenotype induced by patient-derived glioblastoma spheroids.

Srishti Kala[1], Luke M. Markowski[2], Moriah E. Katt[2]

[1]Cancer Cell Biology, West Virginia Univ. School of Medicine, Morgantown, WV,[2]Department of Chemical and Biomedical Engineering, West Virginia University, Morgantown, WV

The fundamental limitation to effective chemotherapy in Glioblastoma Multiforme (GBM) is the highly restrictive nature of the Blood-Tumor Barrier (BTB). The BTB functions as a robust regulatory interface, tightly controlling the efflux and influx of compounds and greatly restricting therapeutic access to the tumor microenvironment. We hypothesize that the BTB's functional phenotype is not static but is dynamically modulated by tumor characteristics. This observed heterogeneity is clinically actionable: tailoring drug delivery strategies to match individual tumor profiles is essential for improving prognosis. Thus, compiling a comprehensive database correlating BTB transport characteristics with molecular profiles is necessary to inform rational drug delivery design and optimize clinical outcomes. This study was designed to systematically outline the functional heterogeneity inherent in BTB transport mechanisms, comparing phenotypes induced by two separate Patient-Derived GBM Spheroid (PDS) *in vitro* transwell system. Our human model utilized iPSC-derived Brain Microvascular Endothelial-like Cells (hiPSC-BMECs) co-cultured with the two PDS samples to accurately model the complex neurovascular unit. We utilized a multi-modal functional assessment evaluating barrier integrity, paracellular transport, transcellular permeability, and efflux profile, to comprehensively characterize both the passive "leakiness" and active "tightness" of the BTB. These findings confirm that patient-specific GBM spheroids induce demonstrably heterogeneous BTB functional phenotypes. Junctional integrity is modulated by PDS co-culture, with heterogenous responses corresponding with GBM molecular profile. With limited paracellular “leakiness” and dysregulated active transport seen in both pinocytotic and efflux mechanisms. Current clinical assessment of BTB disruption relies primarily on Gadolinium enhancement on MRI, which only detects gross barrier breakdown. It fails to characterize the subtle, active, and heterogeneous transport mechanisms that significantly impede drug concentration in the tumor mass. Our *in vitro* approach provides a necessary, precise translational tool capable of characterizing the BTB's function from a patient's tumor sample, facilitating the development of truly personalized and effective drug delivery strategies in GBM therapy.

#3417 Development of a patient-derived pancreatic cancer organoid-CAF coculture model to study tumor microenvironment influence on radiotherapy response.

Diego Munoz-Salazar[1], Carolina Bizama[1], Paola Caprile[2], Fernanda Cabrera[1], Angel Castillo[1], Victor Manriquez[1], Macarena Medina[1], Pablo Munoz-Schuffenegger[3], Juan Carlos Roa[1], **Patricia Garcia**[1]

[1]Department of Pathology, Faculty of Medicine, Pontificia Universidad Catolica de Chile, Santiago, Chile,[2]Institute of Physics, Faculty of Physics, Pontificia Universidad Catolica de Chile, Santiago, Chile,[3]Radiation Oncology Unit, Department of Hematology - Oncology, Faculty of Medicine, Pontificia Universidad Catolica de Chile, Santiago, Chile

Introduction: Radiotherapy (RT) is a fundamental treatment modality for pancreatic ductal adenocarcinoma (PDAC) at all disease stages. However, local relapse, driven by treatment resistance, remains a critical issue for improving patient outcomes. While tumor cell-intrinsic factors contribute to resistance, evidence indicates that the tumor microenvironment (TME), particularly cancer-associated fibroblasts (CAFs), plays a crucial role through different mechanisms. Current patient-derived organoid (PDO) models fail to authentically recapitulate CAF-tumor interactions and their influence on RT response, limiting their translational relevance. We developed a coculture system to better mimic these interactions and enable physiologically relevant radiobiological studies.
Methods: PDOs of PDAC and primary CAFs were cocultured in 3D suspension in ultra-low attachment plates with 300ug/mL of Matrigel. The structural integrity and composition of the resulting aggregates were characterized using H&E, Masson's trichrome, PAS-Alcian blue staining, and immunofluorescence (IF) for vimentin, pan-cytokeratin, phalloidin, and DAPI. To test the utility of this model for RT studies, cocultures were exposed to a single radiation dose of 8 Gy. Radiobiological effects were evaluated 12 days post-treatment using H&E, immunohistochemistry for Ki-67 and p16, IF (γ-H2AX), and calcein-AM/propidium iodide viability assay.
Results: The established protocol generated aggregates with organized epithelial-stromal compartmentalization, confirmed by IF and histological analysis. Following a single 8 Gy radiation dose, cocultures exhibited reduced aggregate size and decreased cellular density within the first 12 days post-treatment, with significantly impaired growth kinetics compared to untreated controls. Histological analysis of irradiated samples showed disrupted matrix integrity and increased cellular fragmentation. Elevated γ-H2AX foci indicated DNA double-strand breaks, while reduced Ki-67 and increased p16 staining reflected decreased proliferation and increased senescence.
Conclusion: This work establishes a direct coculture model of patient-derived PDAC organoids with CAFs, providing a platform to characterize RT response in a compartmentalized tumor-stroma context. Our findings reveal compartment-specific responses and differential growth dynamics, highlighting the utility of integrated tumor-stromal models for investigating the effects of RT and advancing toward more physiologically relevant preclinical approaches.
Funding: ANID/FONDECYT Grants #1241269 and 1221253, ANID/FONDAP Grant #152220002.

#3418 Pre-treatment patient-derived esophageal squamous cell carcinoma organoids as a predictive platform for docetaxel, cisplatin and fluorouracil neoadjuvant chemotherapy.

Hajime Kashima[1], Kazuhiro Noma[1], Akito Shimizu[1], Yasushige Takeda[1], Yohei Mizusawa[1], Tasuku Matsumoto[1], Hijiri Matsumoto[1], Tomoyoshi Kunitomo[1], Masashi Hashimoto[1], Naoaki Maeda[1], Satoru Kikuchi[1], Shunsuke Tanabe[1], Hotaka Kawai[2], Toshiaki Ohara[3], Hiroshi Tazawa[1], Hiroshi Nakagawa[4], Toshiyoshi Fujiwara[1]

[1]Gastroenterological Surgery, Okayama University Hospital, Okayama, Japan,[2]Oral Pathology and Medicine, Okayama University Graduate School of Medicine, Dentistry and Pharmaceutical Sciences, Okayama, Japan,[3]Pathology, Okayama University Graduate School of Medicine, Dentistry and Pharmaceutical Sciences, Okayama, Japan,[4]Columbia University, New York, NY

Background: Patient-derived organoids (PDOs) are a promising platform for functional precision oncology. In esophageal squamous cell carcinoma (ESCC), docetaxel/cisplatin/fluorouracil (DCF) is a standard neoadjuvant regimen, yet some patients show poor pathological response, underscoring the need for treatment-naïve biopsy-derived PDO models to predict individual benefit.

Methods: Treatment-naïve endoscopic biopsies from ESCC patients were used to generate three-dimensional PDOs in Matrigel-based, growth factor-supplemented culture. We analyzed 48 consecutive cases collected after technical standardization. Successful establishment was defined as organoid formation after the first cell seeding, and long-term maintenance as ≥5 passages. Long-term PDOs from patients who received DCF followed by esophagectomy were subjected to 72-hour dose-response assays; IC_{50} values were compared with pathological response and clinical course.

Results: PDOs were successfully established in 45/48 cases, and long-term maintenance was achieved in 10/48. Three long-term PDO cases received preoperative DCF alone and underwent esophagectomy (Cases A-C). Case A (pT2N2M0, Ryan grade 1, Ly0, V0) showed low IC_{50} values for all three drugs, indicating broad in vitro sensitivity concordant with good pathological response without lymphovascular invasion. Case B (pT3N0M0, Ryan grade 2, Ly0, V0, positive margin) exhibited markedly elevated IC_{50} values for all drugs, consistent with global drug resistance and suboptimal local control. Case C (pT3N1M0, Ryan grade 2, Ly1b, V1b) showed selective resistance to docetaxel but low IC_{50} values for cisplatin and 5-fluorouracil, paralleling an intermediate pathological response with persistent lymphovascular invasion. PDO drug sensitivity patterns qualitatively paralleled the degree of pathological response, with triple-sensitive PDOs associated with more favorable regression.

Conclusions: Although the current long-term maintenance rate of ESCC PDOs remains modest, PDOs derived from pre-treatment biopsies showed concordance between in vitro DCF sensitivity and clinical response, supporting their potential as a platform to predict neoadjuvant efficacy. Further case accrual and refinement of culture conditions may enable individualized perioperative treatment strategies guided by PDO-derived drug sensitivity.

#3419 Structural heterogeneity of tumor spheroids using quantitative assessment of autofluorescence.

Prabhat Suman, Sooraj Kakkat, Joel F. Andrews, Chandrani Sarkar, Dhananjay T. Tambe, **Debanjan Chakroborty**

University of South Alabama, Mobile, AL

Introduction: Intratumor heterogeneity is a well-recognized contributor to tumor progression and the development of treatment resistance. Procedures like traditional sampling and bulk sequencing often fall short of capturing the vascular intratumoral landscape. Here, we introduce a novel analytical workflow that uses quantitative 3D autofluorescence imaging to examine the structure and cellular organization of breast cancer cells (BCC) spheroids generated from BCCs and fibroblasts (MEFs and CAFs). This innovative approach enables characterization of structure in multicellular tumor spheroids via fluorescence-based volumetric imaging and computational tools.

Methods: Tumor spheroids were created by co-culturing 4T1 (mouse BCC) with MEFs or CAFs in a 2:1 ratio. The spheroids were generated using 24-well AggreWell plates (STEMCELL Technologies), and Z-stack images were taken using a confocal microscope. Custom software was developed using the Google Colab cloud platform and various Python libraries, including OpenCV and scikit-image. Z-stack images were acquired with the EGFP green and red fluorescence channels, and combined at each z-level using the maximum intensity of the two channels. To focus on large-scale objects, the image was filtered using a Gaussian filter and converted to a binary image using the Otsu algorithm. The fluorescent-intensity-weighted centroid of the spheroid was then estimated. With respect to this centroid, three radial functions were computed: mean intensity, standard deviation, and coefficient of variation. Using a log-log regression fit, the power-law relationship between the mean and standard deviation was computed, and Taylor's exponent for each type of spheroid was determined.

Results and Conclusion: Our results identify a significant difference in intra-spheroidal heterogeneity between spheroids grown with MEFs, CAFs, or BCCs. The Taylor's exponent, b, for group A (4T1 and MEFs) spheroids was about 1, indicating a Poisson-like distribution. However, for Group B spheroids (4T1 and CAFs), the exponent was larger, suggesting a super-Poisson aggregation. The fitted exponents (mean ± SD) were $b = 1.12 \pm 0.05$ for the A group and $b = 1.38 \pm 0.04$ for the B group. These higher-exponent spheroids indicate greater radial heterogeneity and uneven distribution of the fluorescent signal. A Taylor's exponent $b > 1$ signifies that the standard deviation grows faster than the mean. i.e., the greater the mean intensity, the more extreme were the denser and rarer regions of the spheroid, potentially creating drug-resistance niches within the spheroid. Our findings are significant and indicate that this label-free, noninvasive method can be used to detect intertumoral heterogeneity in the near future. These insights can inspire future studies to explore changes within the tumor microenvironment and design new strategies targeting treatment-resistant niches in solid tumors.

#3420 DoE-based optimization of transposon-based gene insertion using the Harbor-IN system.

Kanstantsin Lashuk[1], Corey Brizzee[2], Ina Rohleff[1], **Julia B. Schueler**[1]

[1]Charles River Laboratories, Freiburg, Germany,[2]Demeetra, Lexington, KY

Efficient and safe genetic labeling of mammalian cells is essential for applications in cell tracking, functional assays, and high-throughput screening. In this study, we developed and optimized a biosafety level 1 (BSL-1) protocol for stable integration of fluorescent and luminescent reporter genes using a transposon-based system. A Design of Experiments (DoE) approach was employed to systematically optimize co-transfection conditions of plasmid DNA encoding the reporter gene and in vitro-transcribed RNA encoding the transposase. Four commonly used transfection reagents—Lipofectamine 3000, PEI, ViaFect, and jetPRIME—were evaluated for their efficiency and compatibility with the system. Key factors such as nucleic acid ratios, total cargo amount, and reagent concentration were varied to maximize integration efficiency while maintaining cell viability. The optimized protocol achieved robust and reproducible reporter expression across multiple cell types without requiring viral vectors or higher biosafety containment. This work provides a scalable, non-viral strategy for generating stably labeled cell populations, enabling downstream applications in imaging, functional genomics, and assay development under standard laboratory conditions.

#3421 Bioprinted colorectal cancer organoids as a platform for large-scale therapeutic screening.

Taehee Kim, Jonathan Levi, Catherine Chen, Lindsay Ng, Alice Soragni

UCLA - University of California Los Angeles, Los Angeles, CA

Colorectal cancer is the fourth leading cause of cancer-related deaths in the United States. Among patients with metastatic colorectal cancer, approximately 70-75% survive more than 1 year after diagnosis, 30-35% survive more than 3 years, and fewer than 20% survive beyond 5 years. The main treatment options for unresectable metastatic colorectal cancer include cytotoxic chemotherapy, biologics, immunotherapy, and combinations thereof. Therapeutic options for unresectable metastatic disease remain limited, and more predictive preclinical platforms are urgently needed. To address this need, we developed a high-throughput mini-ring screening platform using patient-derived colorectal cancer organoids generated through 3D bioprinting. We generated and screened more than 28,000 bioprinted organoid mini-rings to ensure uniform size, architecture, and reproducibility across models.Screens incorporated standard colorectal cancer agents, including 5-fluorouracil, capecitabine, irinotecan, leucovorin, and oxaliplatin, along with a targeted 100-compound targeted panel spanning diverse pathways. Dose-response profiling enabled robust IC50 determination and revealed distinct sensitivity and resistance patterns across organoid models representing multiple disease stages. Transcriptomic analyses for each model were integrated to contextualize these functional profiles and identify pathway-level features associated with therapeutic vulnerability.This work shows how bioprinted colorectal cancer organoids provide a scalable and biologically relevant platform for high-throughput drug screening to support the development of more precise and effective therapeutic strategies for colorectal cancer.

#3422 Live, label free 3D virtual HE imaging of small intestinal organoids using holotomography and generative cross-modality artificial intelligence.

Jimin Cho[1], **Juyeon Park**[1], Hyun-Seok Min[2], YongKeun Park[1]

[1]KAIST, Daejeon-si, Korea, Republic of,[2]Tomocube, Daejeon, Korea, Republic of

Organoids provide physiologically relevant 3D models of tumor biology, but current imaging depends on fluorescence labeling, clearing, or destructive sectioning, limiting longitudinal analysis and perturbing native states. Holotomography (HT) enables long-term, high-resolution, label-free 3D imaging of live intestinal organoids, capturing crypt budding, mitosis, apoptosis, and drug-induced cytotoxicity. Generative frameworks that translate refractive index (RI) tomography into multiplexed fluorescence or H&E-like contrast, including RI2FL and 3D virtual H&E, have shown accurate cross-modality prediction. Here, we integrate these technologies to achieve live, label-free 3D virtual H&E visualization of growing intestinal organoids.Mouse small intestinal organoids were imaged continuously for 120 hours using low-coherence HT. 3D RI tomograms covering whole organoids were reconstructed and stitched. A 3D generative translation model—trained on paired RI–H&E data from human colon cancer tissues and extended using RI2FL's generalizable strategy—was adapted to predict 3D virtual H&E volumes directly from RI stacks, without staining, fixation, or sectioning. Resulting images were evaluated for epithelial architecture, crypt–villus organization, nuclear morphology, luminal topology, and drug-induced injury. Cisplatin-treated organoids were monitored over days.Label-free HT revealed morphogenesis including symmetry breaking, crypt budding, epithelial migration, extrusion, and luminal remodeling. Applying the model to live RI volumes produced artifact-free 3D virtual H&E with hallmark features: basophilic nuclei, eosinophilic cytoplasm, apical organization, Paneth-like granularity, and mucin-rich domains. Depth-resolved virtual H&E preserved axial continuity of crypt–villus structures. In drug-response assays, cisplatin induced early nuclear condensation, crypt collapse, and epithelial fragmentation; virtual H&E highlighted these patterns more clearly than raw RI, while HT-derived metrics showed decreases in protein density and dry mass. The model maintained stable inference across dynamic, unlabeled, live samples, extending RI2FL's cross-system generalizability to complex multicellular organoids.This work establishes the first long-term, fully label-free 3D virtual H&E imaging of live organoids, enabling multi-day, non-destructive histology with subcellular contrast. The approach quantitatively captures pharmacodynamic injury and viability and offers a scalable platform for preclinical oncology, drug screening, and organoid pathology, introducing a new paradigm of live virtual histopathology.

#3423 Integrating PDX and PDX-derived organoid platforms to enhance translational drug discovery in breast cancer.

Erin E. Trachet[1], Liqiang Zhang[2], Kari Kotlarczyk[3], Gregg Hirschfeld[4], Damaris Diaz[5], Paul Gonzales[5]

[1]Scientific Engagement, TD2 Oncology, Scottsdale, AZ,[2]Preclinical Bioanalysis, TD2 Oncology, Scottsdale, AZ,[3]Preclinical In Vitro, TD2 Oncology, Scottsdale, AZ,[4]Preclinical In Vivo, TD2 Oncology, Scottsdale, AZ,[5]Preclinical, TD2 Oncology, Scottsdale, AZ

Breast cancer remains a leading cause of mortality among women, underscoring the need for translational models that more accurately predict clinical response. Traditional immortalized cancer cell lines lack the genetic diversity, three-dimensional architecture, and stromal microenvironmental context of patient tumors, thereby limiting their translational relevance. Patient-derived xenograft (PDX) models preserve the histologic and molecular features of primary breast tumors across passages and have become powerful systems for evaluating therapeutic response, mechanisms of resistance, and biomarker discovery across subtypes including triple-negative, HER2-positive, and hormone receptor-positive cancers. Despite their translational relevance, PDX studies are resource intensive and low throughput. To address these constraints, patient-derived organoids (PDxO) generated from PDX tumors provide an efficient ex vivo platform for early screening and mechanistic assessment. PDxO models preserve genomic fidelity and phenotypic heterogeneity, enabling direct comparison of drug responses between in vitro and in vivo systems. This integrated workflow supports rapid, iterative evaluation in which compounds are first screened in PDxO cultures to assess efficacy, cytotoxicity, and mechanism of action, followed by validation in matched PDX models to confirm pharmacodynamic performance and in vivo antitumor activity. We have established an advanced organoid-based drug discovery platform by leveraging our breast cancer PDX collection to generate robust PDxO models. We developed and validated high-quality organoid drug-screening assays using CellTiter-Glo 3D and real-time live-cell imaging with the Incucyte system, enabling quantitative assessment of viability, growth kinetics, and treatment responses. Using models such as HCI-015 and HCI-032, we demonstrated consistent organoid formation, reproducible drug sensitivity profiling, and applicability across diverse therapeutic modalities, including agents under evaluation for immunotherapy combinations. Collectively, the integrated use of PDX and PDxO platforms enable a more comprehensive understanding of breast cancer biology and therapeutic vulnerabilities. Correlating drug response data across systems reveals model-specific and subtype-dependent differences, facilitating rational treatment selection and biomarker identification. This complementary approach advances precision oncology by linking high-throughput ex vivo screening with biologically relevant in vivo validation, thereby accelerating the translation of preclinical discoveries into actionable clinical strategies.

#3424 Comparative analysis of 2D and 3D cell culture methods on DNA methylation patterns in medulloblastoma.

Karen Sperle[1], Laurel Stell[2], Micheal Avoseh[3], Aderonke Ajongbolo[1], Haozhe Zheng[4], Darrin Pochan[4], **Sigrid Langhans**[1]

[1]Neurology, Nemours Children's Hospital, Wilmington, DE,[2]Stanford University, Palo Alto, CA,[3]Nemours Children's Hospital, Wilmington, DE,[4]Materials Science and Engineering, University of Delaware, Newark, DE

Epigenetic processes including histone modifications, DNA methylation, chromatin remodeling, and regulatory non-coding RNAs such as microRNAs regulate gene expression without direct alterations to the genome. Among these, DNA methylation which involves the addition of a methyl group to the fifth carbon of cytosine (C), forming 5-methylcytosine (5mC) most frequently in CpG dinucleotides (CpGs), is one of the most studied epigenetic modifications. DNA methylation has been shown to influence tumor development, tumor progression and therapy response in various cancers, including medulloblastoma, the most common malignant brain tumor in children. Due to the extensive genome-wide profiling done by several international consortia and independent groups, extensive genomic databases, including DNA methylation profiles, are publicly available for medulloblastoma making it suitable as a model system to study whether different cell culture techniques influence DNA methylation patterns. Here we sought to investigate whether 3D cell culture systems, commonly referred to as more closely recapitulating in vivo tumor microenvironments, promote DNA methylation patterns in tumor cell lines that are more closely aligned with those of patient tumors. Most commonly used human medulloblastoma cell lines, traditionally cultured as 2D monolayers, were subjected to both anchorage-independent (spheroids) and scaffold-based (collagen, Matrigel, synthetic peptide hydrogel) 3D cell culture methods. Genome-wide methylation profiles were generated using the Infinium MethylationEPIC BeadChip Arrays and compared to the Molecular Neuropathology group/Deutsches Krebsforschungszentrum (DKFZ) brain classifier database. Surprisingly, none of the human medulloblastoma cell lines was considered a match (score equal to or higher than 0.9) and three out of the five cell lines initially tested had values of less than 0.3 and did not meet the study criterion. Moreover, there was considerable differences in scores between cell lines but not between culture condition (2D versus 3D) for a given cell line even when applying different normalization methods to reduce non-biological artifacts. Thus, spheroid- or scaffold-based 3D cell culture methods did not translate into better alignment with patient-derived methylation profiles and suggests limited potential for these models to replicate patient tumor profiles. Furthermore, our data reveal that even in conjunction with advanced cell culture technology, the choice of biological model is a crucial component in engineering accurate disease models.

#3425 Leveraging bioconvergence to enhance organ-on-a-chip technology and revolutionize drug discovery and development.

Shashi K. Tiwari[1], Stephan Krieg[2], Fong Cheng Pan[1], David Austin[1], Kevin Su[3], Luisa Marie Pfeifer[2], Mathab Asadian[4], Xiaoping Song[4], Laura Chacon Orellana[4], Rashmi Ramesh[4], Alessandra Venz[4], Bastien Duckert[4], Mara Lucchetti[4], Joseph Lento[1], Sophie Roth[4], Olivier Henry[4], Dries Braeken[4], Laura Braeuninger-Weimer[5], Philip Hewitt[2], Steven Johnston[6], Vi Chu[1]

[1]MilliporeSigma, Temecula, CA,[2]Merck Healthcare, Darmstadt, Germany,[3]R&D, MilliporeSigma, Temecula, CA,[4]iMEC, Leuven, Belgium,[5]Merck Ventures, Frankfurt, Germany,[6]EMD Group, Darmstadt, Germany

Background: Bioconvergence combines materials science, microelectronics with organoid biology to revolutionize organ-on-a-chip (OOC) technology, facilitating effective translational drug discovery. Our initiative aims to develop new generation of in vitro platforms by integrating human 3D cell cultures with a semiconductor-based, sensor-integrated microfluidic silicon chip, enabling the simulation of interconnected multi-organ physiology.
Methods: We developed human gut and liver organoids from induced pluripotent stem cells (iPSCs) and patient-derived organoid (PDO). The organoids were validated for lineage identity and functionality through immunofluorescence for key markers, RT-qPCR for gene panels, and functional assays such as transepithelial electrical resistance (TEER) and enzyme activity. This validated biology was integrated by connecting it to fluidic and electrical interfaces in sterile conditions.
Results: Duodenal PDO-derived gut organoids exhibited well-defined epithelial architecture and barrier integrity, along with the expression of essential transporters (BCRP) and metabolic enzymes (CYP3A4, UGT1A1). They also displayed lineage markers, including brush border (Villin), goblet (MUC2), Paneth (LYZ), and enteroendocrine (CHGA) cells. iPSC-derived mature liver organoids expressed markers for hepatocytes and cholangiocytes, including albumin, Sox9, CK7, and CK19, demonstrating Phase I/II metabolic competence and relevant drug transporters (CYP3A4, GST, MDR1/P-gp, MRP2). These organoid systems establish a solid foundation for exploring the viability and functionality of the platform.
Conclusions: Integrating validated human organoid biology with scalable semiconductor microfluidics creates a microphysiological platform that significantly enhances translational relevance for toxicology, drug metabolism and pharmacokinetics (DMPK), and disease modeling. It supports the development of safer, more effective therapies while minimizing reliance on animal studies.

#3429 Macrophages promote immunotherapy resistance of hepatocellular carcinoma through increasing tumor cell lipid availability.

Zhixian Liang, Xiaohang LONG, ZHEWEN XIONG, PATRICK WONG, Siyuan HUANG, Siyun Chen, Yiling Zhang, Lingyun ZHANG, Chunning Leung, Saiming Ngai, Stephen Lam CHAN, Alfred S. L. Cheng

The Chinese University of HONG KONG, HONG KONG, China

Hepatocellular carcinoma (HCC) is the most common type of liver cancer. Although increasing immune checkpoint blockade (ICB) inhibitors have been applied in HCC clinical trials, the immunosuppressive tumor microenvironment (TME) restricts therapeutic responses to a small subset of patients. The triggering receptor expressed on myeloid cells-2 (TREM2) plays a critical role in counteracting inflammation and maintaining metabolic fitness in myeloid cells. Recently, we performed single-cell RNA sequencing (scRNA-seq) on tumor biopsies from a phase II clinical trial of pembrolizumab on advanced hepatitis B virus (HBV)-related HCC patients (NCT03419481) and identified a subset of tumor-associated macrophages (TAMs) over-expressing TREM2, which were enriched in non-responders following therapy. Consistently, our syngeneic ICB-sensitive and resistant HCC mouse models verified that $Trem2^+$ TAMs were adaptively increased after anti-PD-1 treatment in resistant tumors. We observed that $TREM2^+$ TAMs enriched in lipid-laden TME and transferred fatty acids to tumor cells. *Trem2* deficiency in myeloid cells reduced the lipid level of tumor cells and re-sensitized them to anti-PD-1 therapy.

#3430 NR4A3 functions as an immuno-metabolic checkpoint in tumor-associated macrophages to mediate radiotherapy sensitivity in rectal cancer.

Xiaowan Guo[1], Gan Tao[2], Xiuli Guo[1], Kehua Hu[1], Rurui Xue[1], Yunli Mo[1], Hui Qiu[1], **Qiuji Wu**[1]

[1]Zhongnan Hospital of Wuhan University, Wuhan, China,[2]The First Affiliated Hospital of Anhui Medical University, Hefei, China

Background: Radiotherapy resistance remains a major therapeutic challenge in rectal cancer. Tumor-associated macrophages (TAMs) are pivotal components of the tumor immune microenvironment. The nuclear receptor NR4A3 is a key regulator of TAM activation. This study aimed to investigate the role of macrophage-expressing NR4A3 in radiotherapy sensitivity in rectal cancer.
Methods: Transcriptomic RNA sequencing analyses were used to identify key differential genes and pathways. Interfering RNAs were applied to modulate NR4A3 expression in macrophages. Signaling pathways and metabolic alterations were assessed by Western blot, qPCR, ELISA. Functional effects were evaluated in macrophage-colorectal cancer cell co-culture models.
Results: High NR4A3 expression in TAMs correlated with improved pathological response and prolonged survival in rectal cancer patients receiving neoadjuvant radiotherapy. Transcriptomic analysis revealed marked alterations in NR4A3 expression and lipid metabolism pathways in post-radiation cells. NR4A3 expression was induced in macrophages following radiotherapy, which was consistently validated in vitro (THP-1, RAW264.7), in murine MC-38 xenograft models, and human rectal cancer samples. NR4A3 knockdown promoted an M2-like polarization state (evidenced by elevated CD163, IL-10) and enhanced expression of immune checkpoint molecules (PD-L1, siglec-15), while suppressing M1 markers (CD86, IL-1β, TNFα). Functional assays revealed that NR4A3-deficient macrophages lost tumor-suppressive capacity in co-culture systems. On the other hand, NR4A3 promoted cholesterol synthesis and efflux in macrophages, with ABCG1 identified as a critical downstream cholesterol exporter. Macrophage-derived cholesterol contributed to tumor cell proliferation. Inhibiting ABCG1 rescued tumor suppressive effect of radiation-activated macrophages.
Conclusion: NR4A3 acts as a radiation-induced "immuno-metabolic checkpoint" in TAMs, enhancing M1 polarization and antitumor immunity, while concurrently driving ABCG1-dependent cholesterol efflux and a pro-tumor metabolic milieu. These results illuminate the dual role of NR4A3 in mediating the paradoxical effects of radiotherapy on the immune microenvironment and underscore its potential as a therapeutic target for overcoming radiotherapy resistance in rectal cancer.

#3431 Neutrophil-like monocytes (NeuMos) with high levels of CXCL2 expression orchestrate systemic granulopoiesis and drive immunotherapy resistance in TNBC.

Fulya Alkan[1], Hilmi K. Alkan[1], Ahmet Caglayan[2], Aysun Caglayan[2], Aminah Lawal[3], Neva Celiker[3], Huidong Shi[4], Thomas Vogl[5], Nouri Neamati[6], Wicha Max[7], Hasan Korkaya[3]

[1]Oncology, Wayne State University, Detroit, MI,[2]University of Michigan, Ann Arbor, MI,[3]Wayne State University, Detroit, MI,[4]Medical College of Georgia, Augusta, GA,[5]Institute of Immunology, Muenster, Germany,[6]Univ. of Michigan College of Pharmacy, Ann Arbor, MI,[7]Department of Internal Medicine, University of Michigan, Ann Arbor, MI

Triple-negative breast cancer (TNBC) is characterized by early metastatic spread and poor response to immunotherapy, yet the systemic immune mechanisms underlying this aggressive behavior remain poorly defined. Using a comprehensive multi-omics approach that integrates single-cell RNA sequencing (scRNA-seq), high-dimensional mass cytometry (CyTOF), flow cytometry analyses, in vivo genetic perturbations, and multiple syngeneic TNBC models, our preliminary data suggested that recently introduced neutrophil-like monocyte population (NeuMo) emerges selectively within highly metastatic tumors. NeuMos exhibit a dynamic monocyte–granulocyte transcriptional profile and initiate a pro-inflammatory cascade driven by CXCL2, and G-CSF signaling. This axis induces robust emergency granulopoiesis in the spleen, markedly expanding immature $CD11b^{+}Ly6G^{+}CXCR2^{+}$ granulocytic cells that infiltrate tumors and peripheral tissues establishing systemic immunosuppression. In contrast, non-metastatic EMT6 tumors maintain balanced adaptive and innate immune compartments with minimal granulocytic activation, highlighting the specificity of NeuMo-driven inflammation to aggressive TNBC states. Functional experiments demonstrate that deletion of S100A9, an upstream amplifier of this inflammatory circuit, disrupts granulocytic expansion, reduces splenic hypertrophy, diminishes lung metastasis, and significantly enhances the therapeutic efficacy of PD-L1 blockade in both AT3 and E0771 TNBC models. These findings put S100A9 as a critical mediator of immunotherapy resistance. Analysis of human TNBC datasets, including TCGA, reveals early induction of S100A8/A9, G-CSF, and CXCL1/2 gene programs associated with high-grade tumors and poor survival, underscoring the clinical relevance of this pathway. Collectively, our work identifies NeuMo-driven inflammatory mediator as a central mechanism linking TNBC tumor-intrinsic programs to systemic immune remodeling, metastasis, and checkpoint resistance. These results not only define a novel myeloid-based biomarker signature for aggressive TNBC but also nominate the S100A9/CXCL2/G-CSF axis as an actionable therapeutic target to improve immunotherapy outcomes.

#3432 Role of M2 macrophages in chemoresistance about the tumor microenvironment of epithelial ovarian cancer.

Jaesung Ryu[1], Baek MooJun[2], HyoWook Gil[3], Eunjung Yang[3], Kwangseock Kim[2], Taewan Kim[4], Kong Hyejeong[5], Beamjun Park[5], **Seob Jeon**[2]

[1]Korea Research Institute of Bioscience and Biotechnology, Daejeon, Korea, Republic of,[2]Soonchunhyang University Cheonan Hospital, Cheonan, Korea, Republic of,[3]Soonchunhyang Cheonan Hospital Medical Center, Cheonan, Korea, Republic of,[4]Soonchunhyang University, Cheonan, Korea, Republic of,[5]Soonchunhyang University, Asan, Korea, Republic of

OBJECTIVE One of the hallmark characteristics of ovarian cancer is the development of resistance to chemotherapeutics. The mutual interactions with tumor cells and stromal microenvironment contribute to phenotypically polarization of tumor associated macrophages. Macrophages consist of at least two subgroups, M1 and M2. M2 macrophages are endowed with a repertoire of tumor-promoting capabilities involving immuno-suppression, angiogenesis and neovascularization, as well as stromal activation and remodeling. Therefore, there is a need for more practical targets to inhibit chemotherapeutic drug resistance and cancer progression due to ovarian cancer-macrophage interactions. To better understand the mechanism of chemoresistance in ovarian cancer cells, we aimed to investigate the influence of macrophages on the tumor cell response to carboplatin and identify the genes associated with chemoresistance.

METHODS Macrophages were differentiated into M1 and M2 macrophages by cytokine treatment of monocytes. The tumor microenvironment (TME) was modified by transwell co-culture assay. We treated the carboplatin and tested chemoresistance. We also examined expression of key genes associated with EMT (Epithelial-Mesenchymal Transition), PD-L1 and chemoresistance. Nanostring analysis identified gene expression changes in tumor signaling pathways in ovarian cancer cells co-cultured with M2 macrophages compared to single-cultures. Functional study (proliferation, migration, invasion, wound healing) were performed to determine the role of the M2 macrophage in ovarian cancer.

RESULTS Compared to single-cultured ovarian cancer cells, iNOS was downregulated in co-cultured with M2 macrophages, while PD-L1,CD206,TGF-b,MDR1,CSF-1 and Arg1 were upregulated. PD-L1 was also upregulated in M2 macrophages. Ovarian cancer cells co-cultured with M2 macrophages showed higher carboplatin resistance compared to single-cultured ovarian cancer cells. EMT-promoting related genes CD2,VIM, ZEB1 and SNAIL1 were upregulated in ovarian cancer cells co-cultured with M2 macrophages. Nanostring analysis revealed changes in the expression levels of genes associated with tumor signaling pathway activation and EMT. Ovarian cancer cells co-cultured with M2 macrophages performed functional study, we found that the functional abilities of the cancer cells were all significantly increased.

CONCLUSION We identified changes in the expression of various genes in ovarian cancer cells which were co-cultured with M2 macrophages, and identified upregulation of PD-L1 as a key factor in chemoresistance. We have also conducted additional nanostrings to refine the impact of M2 macrophage and ovarian cancer cell interactions on tumour signalling pathways as well as chemoresistance in the tumour microenvironment, and will be analysing these data and conducting further experiments.

#3433 A new classification of tumor-associated macrophages and their roles in resistance to immune checkpoint therapy.

Bryan T. Weselman, Satish Kumar Reddy Noonepalle, Manasa Suresh, Alexandra Singh, Isabella Duchovny, Xintang Li, Mackenna Ward, Alejandro Villagra

Georgetown Lombardi Comprehensive Cancer Ctr., Washington, DC

Tumor-associated macrophages (TAMs) perform a wide range of functions in the tumor microenvironment (TME), several of which contribute to resistance to immune checkpoint therapy. Given their high abundance and diverse functions, altering TAM activity is a promising supplement to immune checkpoint therapy. We demonstrate the potential of a new classification of TAMs, characterized by functional distinctions in gene expression, cell-cell interactions, and spatial localization. We validate the functions suggested by gene expression using *ex vivo* functional assays with primary TAMs. We compare markers of the eight functional TAM subpopulations in murine melanoma data with those in human data to develop a translatable gene signature for each functional subtype. We demonstrate that treating bone marrow-derived macrophages with different cytokine combinations can replicate TAM subtypes *in vitro*, advancing the field beyond the conventional M1-M2 model and enabling a more comprehensive approach. To demonstrate the importance of TAM subpopulations in response to immune checkpoint therapy, we show differences in the abundance of each subtype in untreated murine tumor models that are responsive or non-responsive to anti-PD-1 therapy. At the single-cell RNA-seq level, we find changes in the TAM landscape of murine SM1 melanoma tumors after systemic treatment with epigenetic-modifying agents, with or without anti-PD-1 therapy, and compare these changes with those observed in publicly available human melanoma data. Anti-PD-1 therapy in murine tumors results in a clear enrichment of APC-TAMs (an antigen-presenting, phagocytic, and complement-driven subpopulation), which is further enhanced by systemic HDAC inhibitors. The IFN-TAMs, which reflect a more conventional “M1” macrophage, are less strongly associated with response to immune checkpoint therapy. We see a reduction in angiogenic, hypoxia-driven “AFH-TAMs” in response to multiple anti-cancer therapies. In future studies, we will harness the APC-TAM population to overcome resistance to immune checkpoint therapy in multiple murine tumor types. Compared with melanoma tumors, murine breast cancers have a significantly higher proportion of ECM-TAMs, macrophages involved in extracellular matrix remodeling and homeostasis. We will aim to pharmacologically alter the abundance of other tumor-supporting macrophage populations, depending on the characteristics of different tumor types.

#3434 Spatially resolved multi-omic profiling reveals BRCA-dependent immune remodeling during PARP inhibition and PD-L1 blockade.

Kenichi Shimada[1], Filipa Lynce[2], Claudine Isaacs[3], Xue Geng[3], Edward T. Richardson[4], Candace Mainor[3], Mei Wei[5], Julie M. Collins[3], Paula R. Pohlmann[6], Arielle L. Heeke[7], Kelly F. [1]Harvard Medical School, Boston, MA,[2]Dana-Farber Cancer Institute, Boston, MA,[3]Georgetown University, Washington, DC,[4]Brigham and Women's Hospital, Boston, MA,[5]University of Utah, Salt Lake City, UT,[6]The University of Texas MD Anderson Cancer Center, Houston, TX,[7]Atrium Health, Charlotte, NC

Background

PARP inhibitors (PARPi) induce synthetic lethality in BRCA1/2-mutant (BRCA-MUT) tumors and can activate DNA-damage-linked immune pathways. The TALAVE study (NCT03964532) examined the combination of the PARPi (talazoparib) with PD-L1 blockade (avelumab). Here we evaluated spatially resolved immune signaling and remodeling in response to talazoparib alone and with avelumab.

Methods

24 patients with advanced HER2-negative breast cancer (12 BRCA-MUT, 12 BRCA-WT) received talazoparib then talazoparib + avelumab. Serial biopsies (baseline, post-PARPi [BX2], post-combination [BX3]) underwent transcriptomic, spatial protein, and multiplex IF. BRCA-dependent TME remodeling and cellular neighborhood (CN) shifts were assessed.

Results

BRCA-MUT tumors showed 83% objective response and 100% clinical benefit, whereas BRCA-WT tumors exhibited minimal activity. BRCA-MUT tumors became fragmented with increased immune activity, while BRCA-WT tumors remained compact and immunosuppressed. γH2AX and pTBK1 were spatially co-expressed and sustained in BRCA-MUT tumors during treatment but declined in BRCA-WT tumors. BRCA-MUT tumors displayed enrichment of $CD8^+$ T cells and $CD163^+$ macrophages after PARPi, whereas $CD4^+$ T cells and $CD68^+CD163^+$ macrophages were depleted in BRCA-WT tumors. PD-1^+ $CD8^+$ T cells were strongly linked to local $CD4^+$ T cell density, and PD-1^+ frequency in $CD8^+$ T cells correlated with longer PFS at baseline and BX3 in BRCA-MUT but not BRCA-WT tumors.

CN analysis revealed $CD4^+$ and $CD8^+$ enriched neighborhoods with intermediate PD-1 expression that expanded after therapy in BRCA-MUT but not BRCA-WT tumors, and these CNs lacked PD-$L1^+$ cells. Between BX2 and BX3, BRCA-MUT tumors sustained immune activity but showed no further T cell activation or infiltration. Spatial mapping identified three PD-$L1^+$ CN types: (1) T cell-dense niches with high PD-1/PD-L1 and γH2AX-pTBK1 activity enriched only at baseline, largely lost after PARPi; (2) macrophage-T cell mixtures that were depleted during therapy; and (3) PD-$L1^+$ dying tumor cells lacking pTBK1 activity and T cell engagement. Across contexts, PD-L1 was either lost before PD-L1 blockade or confined to regions isolated from T cells, leaving little opportunity to reinvigorate T cells.

Conclusions

PARP inhibition reshaped the TME of BRCA-MUT tumors by inducing tumor fragmentation, sustaining γH2AX-pTBK1 signaling, and restoring $CD4^+$ and $CD163^+$ immune cells, whereas BRCA-WT tumors remained structurally intact and immunosuppressed. PD-1^+ T cells localized to PD-L1-negative neighborhoods, and PD-$L1^+$ tumor/myeloid cells were rapidly lost or confined to dying, immune-excluded regions, limiting the impact of PD-L1 blockade. Although PARPi re-engaged T cell programs in BRCA-MUT tumors, strategies beyond PD-L1 inhibition will be required to further enhance T cell infiltration and activation.

#3435 Spatial transcriptomic profiling reveals distinct tumor microenvironment remodeling patterns associated with immune checkpoint blockade response in lung adenocarcinoma.

Heesoo Yoon[1], Jin-Wook Choi[2], Sejoon Lee[2], Jin-Haeng Chung[1], Hyojin Kim[1]

[1]Department of Pathology, Seoul National University Bundang Hospital, Seongnam-si, Korea, Republic of,[2]Precision Medicine Center, Seoul National University Bundang Hospital, Seongnam-si, Korea, Republic of

Although immune checkpoint blockade (ICB) has improved clinical outcomes in non-small cell lung cancer (NSCLC), many patients remain resistant, underscoring the need to understand how the tumor microenvironment (TME) evolves during therapy. Therefore, this study aims to characterize spatial TME remodeling associated with ICB. We performed 10x Genomics Visium spatial transcriptomic profiling on paired pre- and post-treatment tumor samples from seven patients with lung adenocarcinoma. Three patients were classified as responders based on immune Response Evaluation Criteria In Solid Tumors criteria (all stable disease) and were compared with four non-responders. The responder group received a mean of 13 ICB cycles, whereas non-responders received 2 cycles. Pre-treatment samples were obtained from lung (n = 4) and lymph node (n = 3), while post-treatment samples were collected from lung (n = 2), lymph node (n = 2), bone (n = 2), and brain (n = 1). After quality control, the mean number of spots was 2212, with a minimum of 266 spots, a maximum of 4715 spots, for a total of 30,968 spots. Spatial profiling demonstrated that responders exhibited consistently higher infiltration of plasma cells and B cells in both pre- and post-treatment samples. In contrast, non-responders showed increased proportions of cancer-associated fibroblasts (CAFs) at both time points. In the pre-treatment samples, responders showed upregulation of HLA-DMA and HLA-C, suggesting preservation of antigen presentation pathways. Additionally, IGKC, IGHG2, and IGHG1 were upregulated, indicating B-cell activation. Non-responders showed upregulation of extracellular matrix (ECM)-remodeling genes (TMSB4X, ACTB) and ferritin metabolism genes (FTL). In the post-treatment samples, non-responders also showed upregulation of ECM-remodeling genes (COL5A1, COL5A2, COL6A2, COL6A1, FN1, TIMP2, MMP2, MMP14), indicating enhanced tumor cell adaptation to a hostile microenvironment and a potential link to M2-like macrophage polarization. In summary, our findings demonstrate that ICB responders exhibit plasma/B-cell-enriched TMEs, whereas non-responders are characterized by increased CAF infiltration along with ECM remodeling and ferritin metabolism gene upregulation, suggesting a potential mechanism of immune resistance. We are currently validating the impact of this ferritin-associated ECM remodeling signature on ICB therapy outcomes in an independent cohort.

#3436 Emerging evidence of cellular dormancy programs in non-small cell lung cancer (NSCLC).

Grace Ha, Melissa Tracy, Anthony Griffen, Daniel Bravo, Dior Dedushi, Terence Li, David Schecter, Neel Chudgar, Chaoyuan Kuang, Julio Aguirre-Ghiso, Brendon Stiles, Lindsay M. LaFave

Montefiore Medical Center / Albert Einstein College of Medicine, Bronx, NY

Despite the practice-changing incorporation of neoadjuvant chemoimmunotherapy (nCI) into the management of clinical stage II-III NSCLC, lung cancer recurrence remains a clinical challenge. At our institution, long-term follow-up has revealed individuals with evidence of recurrence after curative-intent therapy despite demonstrating initial response to nICI and surgery. One potential explanation is cellular dormancy, a state of reversible growth arrest characterized by reduced metabolism and therapeutic resistance, a process well described in breast and head and neck cancers. To investigate lung cancer dormancy, our group has begun collecting lung tumor bed tissue from resected NSCLC patients following nCI. Using these tissues and downstream patient derived organoid (PDO) generation as our primary model, we aimed to characterize dormancy associated gene expression in NSCLC and determine whether chemotherapy and/or immunotherapy induce these programs. We used complementary approaches to address this question. First, to investigate the impact of nCI on tumor heterogeneity and dormancy programs, single-cell Assay for Transposase-Accessible Chromatin (scATAC) sequencing was performed on surgically resected clinical stage II-III NSCLC specimens representing a range of responses to nCI (untreated, 50%, 85%, and 100% regression). We examined gene activity scores across these samples using chromatin accessibility. Our analyses indicated that untreated patient samples exhibited known intratumoral heterogeneity, including cell states with chromatin features similar to alveolar differentiation intermediates, which have been observed as important precursors to lung cancer evolution. Additionally, scATAC-seq from four resected tumors revealed a distinct EPCAM-positive cell population with high gene scores for numerous known cellular dormancy markers, including NR2F1, BHLHE41, SOX9, SOX2, p21, p27, and RARβ. These cells were enriched in untreated samples, suggesting a pre-existing dormant-like subpopulation, but were also present in tumors across all nICI response categories, suggesting the persistence or induction of dormancy following treatment. In parallel, we examined the expression of canonical dormancy markers using quantitative polymerase chain reaction (qPCR), which demonstrated that Cisplatin exposure to PDOs increased the expression of NR2F1, SOX9, p21, and p27 and decreased Ki67, consistent with treatment-induced dormancy. These studies serve as the foundation for dormancy modeling in NSCLC PDOs. Ongoing efforts include cytokine profiling of patient blood samples with the goal of identifying inflammatory signatures that distinguish complete responders from partial responders to nICI.

#3437 Dynamic waves of anti-and pro-tumoral myeloid and Treg cells are generated in response to cyclophosphamide.

Andrea Franceschini[1], Giovanna Talarico[1], Davide Lombardi[1], Stefania Orecchioni[1], Giulia Bravetti[1], Iros Barozzi[2], Paolo Falvo[1], **Francesco Bertolini**[1]

[1]IEO - European Institute of Oncology, Milan, Italy,[2]Center for Cancer Research, Medical University of Vienna, Vienna, Austria

In addition to its direct cytotoxic effects on cancer cells, chemotherapy exerts profound influences on immune cells. These immunological effects must be carefully considered when designing clinically effective combination regimens that include both chemotherapeutic and immunotherapeutic agents. Cyclophosphamide (Cy), a widely used alkylating chemotherapeutic agent, is known to affect various components of the adaptive immune system and natural killer (NK) cells. Based on the observation that a single dose of Cy can lead to increased tumor growth in EMT6 triple-negative breast cancer-bearing mice with predominant myeloid infiltration (but not in 4T1- bearing mice with predominant lymphoid infiltrate), we investigated the immune transcriptional programs triggered by Cy. Using flow cytometry and single-cell transcriptome analysis in tumor-free, tumor-bearing, and Cy-treated mice, we identify novel effects of Cy on neutrophils—innate immune cells increasingly recognized for their roles in both cancer immune tolerance and rejection. One day after Cy administration, a subset of neutrophils expressing an interferon (IFN) signature and associated with anti-tumor activity is expanded, while neutrophils displaying a potentially pro-tumoral Il1b/TNF inflammatory signature and immunosuppressive regulatory T (Treg) cells are reduced. However, in the absence of additional Cy treatment, these effects are reversed by day 10, with the re-emergence of the pro-tumoral neutrophil population. To functionally validate these single-cell findings and directly test the role of myeloid cells in mediating tumor rebound, we performed in vivo immune cell depletion experiments in the EMT6 model. Mice were injected intraperitoneally with neutralizing antibodies against CD11b or Ly6G, targeting myeloid cells and (more selectively) neutrophils, respectively. Depletion efficiency was confirmed by flow cytometry analysis of peripheral blood. Following depletion, mice were orthotopically transplanted with EMT6 cells and treated with a single dose of Cy. Tumor growth in mice receiving either Cy alone or neutralizing antibodies alone was comparable to that of untreated controls, indicating that neither intervention alone was sufficient to control tumor progression. In contrast, the combination of Cy with broad myeloid-cell and selective neutrophil depletion produced a marked anti-tumor effect, resulting in a significant reduction in tumor size compared with all other groups. This experiment represents the functional validation of our single-cell transcriptomic data, suggesting that neutrophils actively drive tumor rebound following transient Cy exposure. These findings highlight the dynamic and time-dependent nature of Cy's immunomodulatory effects and have implications for the design of effective combinatorial anti-cancer therapies.

#3438 DNA damaging therapies induce a pro-tumorigenic fibroblast phenotype.

Emily Lay[1], Mikal Negasi[2], Ben Flynn[3], Tressan Grant[1], Ioanna Kontou[1], Gernot Walko[3], **Ute Jungwirth**[2]

[1]University of Bath, Bath, United Kingdom,[2]Newcastle University, Newcastle upon Tyne, United Kingdom,[3]Queen Mary University of London, London, United Kingdom

There is growing evidence that anticancer therapies not only target tumour cells but also reshape the tumour microenvironment, paradoxically enabling fibroblasts to acquire a pro-tumorigenic phenotype. These fibroblasts are characterised by an altered secretome and extensive extracellular matrix (ECM) remodelling, which promote therapy resistance and tumour progression.
In this study, we demonstrate that DNA damage-inducing anticancer drugs drive normal fibroblasts towards a fibrosis- and cancer-associated fibroblast (CAF)-like phenotype. Using 3D cell-derived ECM deposition assays, we show that treatment of both normal fibroblasts and CAFs stimulates the formation of a more anisotropic ECM with enlarged pores. This remodelled ECM enhances cancer cell adhesion and proliferation, while unexpectedly reducing migration across the matrix. In contrast, the soluble secretome does not affect cancer cell proliferation but significantly increases chemotactic migration towards the therapy-exposed fibroblasts.
Gene expression profiling by RNA sequencing combined with 2D and 3D *in vitro* analyses, reveals that prolonged drug exposure induces fibroblast senescence, marked by upregulation of β-galactosidase, IL6, CDKN1A, and CDKN2A expression. The therapy-induced senescent fibroblasts also display features of a myofibroblast-like CAF (myCAF) phenotype, including enhanced contractility and increased expression of ACTA2, PDGFRA, MMPs, TIMPs, and extracellular matrix components such as collagens, vitronectin, and VCAM. We have previously shown that myCAFs can promote *in vivo* growth and metastasis, underscoring their critical role in tumour progression.
Our findings suggest that therapy-induced senescence in fibroblasts may create a permissive microenvironment for tumour progression.

#3439 Albumin-bound paclitaxel induced stromal reprogramming drives PDAC resistance to AG neoadjuvant chemotherapy.

Haorui Li, Tiansuo Zhao, Xi Ma, Xiang He, Hongji Dai, Bin Wang

Tianjin Medical University Cancer Institute & Hospital, Tianjin, China

Pancreatic ductal adenocarcinoma (PDAC) is a highly lethal malignancy for which neoadjuvant chemotherapy with albumin-bound paclitaxel plus gemcitabine (AG) is a standard first-line approach. However, secondary resistance to AG therapy is common and its underlying mechanisms remain poorly defined. In this study, we investigated how neoadjuvant AG therapy shapes the tumor stroma in PDAC. Single-cell transcriptomics of patient tumors revealed that AG treatment induces a phenotypic switch of cancer-associated fibroblasts (CAFs) from myCAFs to iCAFs states and identified a previously unrecognized TMEM100^{+}CAFs subset enriched in non-responders. Mechanistic studies showed that albumin-bound paclitaxel activates IL-2-STAT5 signaling to drive TMEM100 expression, and that TMEM100^{+}CAFs promote chemoresistance through paracrine secretion of amphiregulin (AREG) and activation of tumor EGFR signaling. Genetic ablation or antibody blockade of TMEM100^{+}CAFs in mouse models reversed CAFs switching and significantly enhanced the antitumor efficacy of AG therapy. These findings map chemotherapy-induced CAFs plasticity, reveal a TMEM100-AREG axis of resistance, and highlight TMEM100^{+}CAFs as a promising target to sensitize PDAC to neoadjuvant treatment.

#3441 Androgen-driven sexual dimorphism reshapes immune crosstalk and limits immunotherapy response in PDAC.

Sonia Mecorapaj[1], Tenzin Passang[2], Fanyuan Zeng[2], Zihan Chen[1], Shuhua Wang[2], Tuisha Gupta[1], Shayna Jankowski[2], Jian-Ming Li[1], Cynthia R. Giver[3], Swapnaa Balaji[4], Kiranj Chaudagar[2], Edmund K. Waller[5]

[1]Hematology & Oncology, Emory Winship Cancer Institute, Atlanta, GA,[2]Emory Winship Cancer Institute, Atlanta, GA,[3]Hematology and Medical Oncology, Emory Winship Cancer Institute, Atlanta, GA,[4]Cambium Oncology, Atlanta, GA,[5]Emory University School of Medicine, Atlanta, GA

Pancreatic ductal adenocarcinoma (PDAC) remains a lethal cancer, with only 13% of patients surviving 5 years. The limited efficacy of anti-PD-1/PD-L1 therapies indicates that additional immunoregulatory pathways sustain the immunosuppressive tumor microenvironment (TME) that restricts T-cell infiltration. Our recent studies (Ravindranathan Nat Com 2022) demonstrated that combined blockade of vasoactive intestinal peptide (VIP) receptor (VPAC) and PD-1 signaling eradicated PDAC in ~50% of mice, although the underlying mechanism of VPAC inhibition remains undefined. Therefore, we hypothesized that VPAC blockade reshapes the immune microenvironment to enhance antigen presentation and T cell responses to anti-PD1 immunotherapy in PDAC.To address this, we characterized the expression of VIP and VPAC on cancer cells, immune cells, and stromal cells in the PDAC TME. We studied the impact of VPAC signaling on the immune functions of myeloid/lymphoid cells and on the architecture of the TME using PDAC patient specimens, murine models, and relevant *in vitro/ex vivo* systems. Tumor growth kinetics were performed to assess the anti-tumor potential of VPAC blockade.*In vitro* secretome analysis showed that murine MT5 PDAC cells secrete more VIP than KPC-luc, consistent with their faster tumor-growth kinetics. To assess host-intrinsic VIP effects in TME we compared tumor progression in WT and *vip*-knockout (*vip-ko*) mice and found markedly slower growth in *vip-ko* mice, especially in females vs. males. To explore the cellular basis of the anti-tumor response, we depleted immune cell subsets and compared tumor growth kinetics in both female and male *vip-ko* mice. Depletion of CD8+ or CD4+ T cells and of CSF1R+ myeloid cells accelerated tumor growth in *vip-ko* mice, whereas clodronate depletion of phagocytic macrophages attenuated anti-tumor responses only in females. Androgen blockade (ARB) with degarelix restored male responsiveness to VPAC inhibition, highlighting androgen-driven resistance in male against VPAC blockade. Mechanistically, VIP from $CD29^{+}PD\text{-}L1^{+}$ fibroblasts suppressed macrophage phagocytosis of PDAC cells, while VIP loss restored this activity. Strikingly, AR activation further suppressed macrophage phagocytosis selectively in males. Mechanistically, TNF-α and MIF secreted from γδ-T cells and $GZMK^{+}CD8^{+}$ T cells, respectively, enhanced anti-tumor phagocytosis in female *vip-ko* mice. Combined AR blockade, anti-PD-1, VPAC antagonism, and taxotere markedly extended survival in WT male mice bearing orthotopic MT5 PDAC (MST 54 vs. 18 days for untreated control).These findings show that VPAC signaling restrains TNF-α– and MIF-dependent immune crosstalk and limits phagocytic PDAC clearance. These data also reveal androgen-suppressed phagocytosis as a driver of sexual dimorphism in response to VPAC antagonism and suggest translatable approaches for PDAC treatment.

#3442 TiME evolution in the context of diffuse astrocytoma post-therapy relapse and progression.

Aliisa Tiihonen[1], Iida Salonen[1], Ella Raulamo[1], Eelis Mikkonen[1], Emilia Maki[1], Maria Annala[1], Tomi Hoikka[1], Ismail Hermelo[1], Anna Denes[2], Thomas Olsson Bontell[3], Helena Caren[4], Asgeir Jakola[2], Hannu Haapasalo[5], Kirsi Rautajoki[1]

[1]Tampere University and TAYS Cancer Center, Tampere, Finland,[2]Institute of Neuroscience and Physiology, Department of Clinical Neuroscience, Sahlgrenska Academy, University of Gothenburg, Gothenburg, Sweden,[3]Department of Clinical Pathology, Sahlgrenska University Hospital, Gothenburg, Sweden,[4]Sahlgrenska Center for Cancer Research, Department of Medical Biochemistry and Cell biology, University of Gothenburg, Gothenburg, Sweden,[5]Department of Pathology, Fimlab Laboratories PLC., Tampere University Hospital, Tampere, Finland

Tumor recurrence and progression are common in IDH-mutant diffuse astrocytomas, which are typically diagnosed as low-grade central nervous system tumors, but frequently progress to grade 4 after conventional therapy, leading to worsened patient prognosis. The biological mechanisms underlying this pattern of recurrence, particularly the contribution of the tumor immune microenvironment (TiME) to treatment resistance and post-therapy progression, remain poorly understood.

To investigate the evolution of the TiME in these tumors, we analyzed a cohort of more than 80 patients with IDH-mutant astrocytoma. For most patients, longitudinal tumor samples were available from both pre-treatment and post-therapy relapse or progression. Using advanced spatial profiling approaches, including highly multiplex immunohistochemistry (mIHC), we characterized immune and cancer cell subtype populations and assessed how their abundance and spatial organization change as tumors recur and progress to higher grade. All findings are being evaluated in the context of patient treatment history and overall survival.

Our preliminary analyses, based on a subset of the full cohort, reveal differences in overall tumor composition both across patients and within matched primary and relapse tumor pairs, highlighting inter- and intra-patient heterogeneity in the TiME. When examining progression-related changes in recurrent tumors, we observe a marked accumulation of $CD163^+$ macrophages and microglia, accompanied by a decrease in $CD163^-$ myeloid phenotypes after chemotherapy. Relapse tumors also show increased infiltration of both $CD4^+$ and $CD8^+$ T cells, suggesting enhanced lymphocytic response during recurrence.

Treatment-specific differences were similarly apparent. Tumors from patients who received combined radiation and chemotherapy showed a higher overall accumulation of immune cells compared to those treated with radiation therapy alone, indicating a potential additive impact on immune cell recruitment. Furthermore, tumor grade appeared to influence overall myeloid composition, with low-grade tumors (WHO grade 2 to 3) exhibiting a higher proportion of microglia compared to high-grade (grade 4) tumors.

Together, this longitudinal dataset provides insights into both recurrent and patient-specific alterations in the TiME that accompany tumor relapse and progression. As these observations are derived from preliminary analyses of a partial cohort, they will be validated in the complete dataset. Ultimately, this work aims to improve our understanding of treatment failure mechanisms and arising opportunities in diffuse astrocytomas.

#3443 Tumor and microenvironmental co-evolution in metastatic triple-negative breast cancer during immunotherapy.

Seongyeol Park[1], Manon de Graaf[2], Artem Lomakin[1], Zhicheng Ma[1], Noah F. Greenwald[1], Lise Mangiante[1], Clemens L. Weiss[1], Brennan Geti Simon[1], Michael Angelo[3], Marleen Kok[2], Christina Curtis[1]

[1]Stanford University School of Medicine, Stanford, CA,[2]The Netherlands Cancer Institute, Amsterdam, Netherlands,[3]Stanford University, Palo Alto, CA

Cancer cells are constantly shaped by the immune system and the dynamic microenvironment surrounding them. Decoding this co-evolution is essential for uncovering the forces that drive tumor progression and determine therapeutic response. Metastatic triple-negative breast cancer (mTNBC) is the most aggressive subtype of breast cancer with a clear need for better treatment options. While recent immunotherapy trials for mTNBC have shown promise in some PD-L1-positive tumors, the reasons for limited and inconsistent responses remain unclear. To investigate these dynamics, we established a multimodal, longitudinal dataset that combines spatial proteomics (MIBI, 40-plex protein) and spatial transcriptomics (CosMx, 6k-plex) from patients with mTNBC enrolled in the phase II TONIC trial in which nivolumab was given to patients regardless of PD-L1 status (NCT02499367). We collected 400 tissue samples from 110 patients, including both pre- and on-treatment biopsies, enabling detailed analysis of tumor-microenvironment interactions and evolution during immunotherapy. Patients with a complete or partial response, or with stable disease lasting longer than 24 weeks, were classified as responders. Using the SpaTopic algorithm, we extracted ten spatial niches (cellular neighborhoods) in our dataset, six of which were dominated by cancer cells. Comparing these with gene expression-based cell clusters revealed a significant link between tumor cell states and their spatial niches. For instance, tumor inflammatory response gene sets are associated with the immune infiltration niche, while hypoxia and epithelial-mesenchymal transition (EMT) gene sets are related to the tumor core. We also defined genomic clusters based on copy-number alterations inferred from spatial transcriptomics data. Within the same genomic cluster, diverse cellular states and spatial niches were observed, indicating that cancer can adapt non-genetically to different niches. Notably, responders exhibited more organized and consistent changes in cellular states and spatial niches before and after immunotherapy, in contrast to non-responders. For example, cancer cells from responders showed increased expression in inflammatory response genes, while non-responders exhibited patient-specific cellular states. This multi-dimensional approach advances our understanding of tumor-immune interactions in mTNBC and offers potential strategies to enhance immunotherapy response.

#3444 Spatial profiling of recurrent glioblastoma in a Phase I clinical trial reveals favorable immune remodeling induced by intracerebroventricular CAR T therapy.

Wesley V. Wilson[1], MacLean P. Nasrallah[2], Nakial Cross[3], Yael A. Day[2], Vanessa Gonzalez[2], Rachel M. Leskowitz[2], Amy Marshall[2], Julie K. Jadlowsky[4], Gabriela Plesa[2], Donald L. Siegel[2], Elizabeth O. Hexner[2], Joseph A. Fraietta[5], Carl H. June[6], Stephen J. Bagley[2], Donald O'Rourke[2], Zev Binder[5], Andrew J. Rech[5]

[1]Princess Margaret Cancer Centre, University Health Network, Toronto, ON, Canada,[2]Penn Medicine, Philadelphia, PA,[3]Perelman School of Medicine Univ. of Pennsylvania, Philadelphia, PA,[4]CCI, Penn Medicine, Philadelphia, PA,[5]University of Pennsylvania, Philadelphia, PA,[6]Program Director of Translational Research, Abramson Family Cancer Research Inst, University of Pennsylvania, Philadelphia, PA

Recurrent glioblastoma (rGBM) is an aggressive brain tumor with median survival under one year after standard chemoradiation. Antigen heterogeneity, immune exclusion, and a suppressive tumor microenvironment (TME) limit responses to immunotherapy. A first-in-human phase 1 trial of intracerebroventricular EGFR/IL13Rα2 CAR T cells (CART-EGFR-IL13Rα2) in EGFR-amplified rGBM was feasible, produced manageable neurotoxicity, and induced radiographic tumor regressions in a subset of patients (NCT05168423).
To understand how this therapy reshapes the local TME, we analyzed paired tumor resections from 6 patients enrolled in the phase 1 trial, with specimens obtained from the primary intracranial disease site at trial enrollment (pre-treatment) and at radiographic progression after CART-EGFR-IL13Rα2 infusion. Multimodal spatial profiling included regional transcriptomic and protein mapping (GeoMx), single-cell whole-transcriptome imaging (CosMx), and high-resolution spatial transcriptomics (Visium HD). We annotated tumor, myeloid, lymphoid, and stromal compartments and derived composite scores for stemness, invasion, cell death, and immune regulation. Neighborhood- and interaction-based analyses were used to compare cellular states and cell-cell communication.
Across patients, post-treatment samples showed reduced expression of CAR target antigen and a shift in tumor-intrinsic programs toward less stem-like, less migratory, and more apoptotic states, despite radiographic progression. The post-treatment TME was remodeled, with fewer suppressive myeloid- and B-cell-rich niches and increases in interferon-responsive and T cell-associated activation programs. Spatial interaction analyses indicated that pre-treatment rGBM contained dense networks of myeloid-tumor and myeloid-T-cell contacts consistent with impaired antigen presentation and effector function. Post-treatment specimens, in contrast, showed partial disruption of these suppressive circuits and the emergence of microenvironments more permissive to T-cell infiltration and activity.
In the parent phase 1 trial, CART-EGFR-IL13Rα2 was feasible & induced radiographic tumor regressions in a subset of patients. This correlative spatial analysis suggests that prior EGFR/IL13Rα2 CAR T exposure can leave a less suppressive, more immunologically engaged TME at the primary site, even in resections obtained at radiographic progression. Together, these data support the idea that intracerebroventricular CAR T therapy may condition rGBM for subsequent immunotherapy. Myeloid and B-cell interactions are highlighted as candidate targets for armoring next-generation CAR T cells and for designing rational combination and sequencing strategies.

#3445 Astrocytes reprogram radiation-resistant glioblastoma to reveal new therapeutic vulnerabilities.

Rana Abdelgawad[1], Andrew Dhawan[2]

[1]Pharmacology, Cwru, Cleveland, OH,[2]Department of Cancer Sciences, Cleveland Clinic Research, Cleveland, OH

Glioblastoma (GBM) is a highly aggressive and therapy-resistant brain tumor, with limited treatment options and poor patient prognosis. One major barrier to effective treatment is the tumor's interaction with the surrounding brain microenvironment, particularly astrocytes, which can modulate therapeutic responses and contribute to resistance. To investigate how astrocytes influence resistance and uncover exploitable vulnerabilities, we developed direct and transwell co-cultures using patient-derived (HW1) GBM cells and primary human astrocytes plated across multiple ratios (10:90, 50:50, and 90:10). This novel co-culture system enabled us to model both contact-dependent and paracrine astrocyte signaling. We tested whether astrocytes at different densities were able to modulate tumor response to a panel of clinical and pre-clinical drugs, in the post-radiation setting. GBM-astrocyte cocultures were exposed to a clinically relevant radiation protocol (three cycles of 2 Gy daily x 5 days) and screened against 12 drugs, encompassing DNA-damaging agents, multi-kinase inhibitors, and nuclear transport inhibitors. Notably in direct co-cultures, even low concentrations of astrocytes (as few as 10%) significantly altered GBM sensitivity to multiple compounds. Additionally, radiation induced a therapeutic vulnerability in GBM cells when co-cultured with astrocytes, not present in GBM monocultures, to selinexor, afatinib, altiratinib, and crenolanib, with strongest effects at intermediate astrocyte:GBM ratios (10:90, 50:50). Transwell experiments demonstrated similar shifts in sensitivity, supporting the hypothesis that astrocyte-secreted paracrine factors alone are sufficient to reprogram GBM drug response. These observations imply that astrocytes reprogram resistance-associated pathways in GBM cell lines post-radiation treatment, potentially hijacking saturated DNA repair mechanisms, cell cycle checkpoints, stress signaling, and transporter activity, all of which invites further mechanistic investigation. Building upon these findings, ongoing studies include genetic validation of candidate pathways, expanded transwell assays to further separate contact-dependent and paracrine mechanisms, and live-cell imaging to define the temporal resistance dynamics. In conclusion, our study demonstrates that the presence of astrocytes alone significantly influences GBM response to therapy, and radiation therapy can further expose collateral sensitivities driven by astrocyte signaling. Modeling and mechanistically dissecting these microenvironmental interactions is essential for identifying new avenues for combination therapies that may improve outcomes in a cancer type where innovation is urgently needed.

#3446 Loxl2 drives neutrophil-mediated immune evasion and resistance to anti PD-1 therapy in murine melanoma.

Jiah Yang[1], Emre Arslan[2], Veena Kochat[3], Suresh Satpati[3], Kunal Rai[3]

[1]Graduate School of Biomedical Science, UT MD Anderson Cancer Center, Houston, TX,[2]UT MD Anderson Cancer Center, College Station, TX,[3]UT MD Anderson Cancer Center, Houston, TX

Immune checkpoint blockade (ICB) therapy with anti-PD-1 (αPD-1) has revolutionized melanoma treatment; however, response rates remain suboptimal due to innate or adaptive resistance mechanisms. Although substantial efforts have focused on enlightening resistance mechanism and improving the efficacy, the role of epigenetic regulation within tumor remains insufficiently explored.scRNA-seq and scATAC-seq analysis of pre- and post-treatment samples from non-responding melanoma patients revealed upregulation of H3K4 oxidase LOXL2 following nivolumab treatment. LOXL2 expression was enriched in an uncharacterized tumor subcluster, distinct from hypoxic tumor and fibroblast clusters. These findings led us to hypothesize that LOXL2 contributes to immune evasion and promotes αPD-1 resistant tumor microenvironment.To test this, we evaluated the impact of LOXL2 knockdown (KD) in a murine subcutaneous (SQ) melanoma model treated with αPD-1. Tumors were profiled using scRNA-seq to assess cell-type-specific transcriptional changes and immune composition. LOXL2 KD significantly improved a-PD-1 efficacy in B6 SQ tumors, reducing N2 pro-tumorigenic neutrophils and increasing cytotoxic CD8+ T cell infiltration.To investigate how LOXL2 influences tumor-associated neutrophils (TANs) polarization, we examined epigenomic alterations and downstream gene regulation upon LOXL2 KD. We identified SOCS1-mediated NF- κB transcriptional attenuation, along with reduced secretion of pro-inflammatory cytokines (i.e. IL-1β, TGFβ) which favors N1 rather than N2 polarization.Collectively, our findings suggest that LOXL2-driven tumors secrete cytokines that promote N2 neutrophil polarization, leading to CD8+ T cell exclusion and resistance to αPD-1 therapy. Targeting LOXL2 may reprogram the tumor immune microenvironment toward an immune-responsive state, offering a potential strategy to enhance ICB response in melanoma.

#3447 Type III collagen regulated by stress signaling drives chemoresistance in pancreatic cancer by inducing tumor dormancy and remodeling the immunosuppressive niche.

Haiyan Xu, Yicheng Zhou, Shengbai Xue, Siming Wu, Liwei Wang

State Key Laboratory of Systems Medicine for Cancer, Shanghai Cancer Institute, Department of Oncology, Renji Hospital, School of Medicine, Shanghai Jiao Tong University, Shanghai, China

Chemotherapy resistance remains the primary cause of treatment failure in pancreatic ductal adenocarcinoma (PDAC). Therapy induced tumor dormancy enables tumor cells escape from chemotherapy cytotoxicity. Our study reveals that gemcitabine treatment triggers extracellular matrix (ECM) fibrosis and collagen rearrangement, with significant accumulation of type III Collagen (COL3). Crucially, exogenous COL3 supplementation in subcutaneous and orthotopic PDAC models could induce tumor cell dormancy accompanied by p21/p27 upregulation and promote chemoresistance. Meanwhile, COL3 enrich tumor-associated macrophages (TAMs) within chemoresistant niches. Mechanistically, COL3 induction was driven by CREB3L1-activated unfolded protein response (UPR) during chemotherapy stress. CREB3L1 regulated dormancy associated molecules like COL3, p21 and p27 and remodeled the stromal microenvironment. These findings establish COL3 as a central mediator of PDAC chemoresistance by orchestrating dormancy and immunosuppressive niche formation. Targeting the CREB3L1-COL3 axis represents a promising strategy to overcome acquired resistance in pancreatic cancer.

#3448 Sequential senescence-escape cycles drive genomic heterogeneity and osimertinib resistance in EGFR-mutant NSCLC.

Nazia Jamil[1], Hayley McDaid[2], Howard D. Hosgood[3], Qualia Hooker[4], Nadjet Cornejal[2]

[1]Institute for Clinical and Translational Research at Einstein and Montefiore, Albert Einstein College of Medicine, Bronx, NY,[2]Molecular Pharmacology, Albert Einstein College of Medicine, Bronx, NY,[3]Epidemiology, Albert Einstein College of Medicine, Bronx, NY,[4]Van Andel Institute (VAI), Grand Rapids, MI

Acquired resistance to osimertinib remains a critical challenge in the management of EGFR-mutant (EGFR$^+$) NSCLC. Although most patients initially respond, relapse is universal, even after prolonged remissions, suggesting that this interval reflects a durable drug-induced proliferative arrest consistent with cellular senescence. We demonstrate Osimertinib-Induced Senescence (OsIS) in EGFR$^+$ NSCLC cells and show that, several weeks after drug withdrawal, senescent cells resume proliferation. To determine how repeated senescence and escape influence therapeutic response and genomic evolution, we generated isogenic cell lines expanded through four sequential rounds of OsIS over approximately six months. Four distinct evolutionary trajectories were selected, each exhibiting varying degrees of resistance to EGFR inhibitors. Although OsIS-derived lines retained sensitivity to cisplatin, they displayed heterogeneous responses to pemetrexed, while sensitivity to tubulin-interacting drugs and navitoclax was preserved. Genomic analyses confirmed that resistance did not arise from *de novo* single nucleotide mutations or copy number amplification in EGFR or MET. Instead, all OsIS-derived lines had increased tumor mutational burden and acquired mutational signatures associated with base-excision repair defects, replication stress, and, in the most resistant line, oxidative stress. Despite these signatures, therapies directed at DNA repair or replication stress were uniformly ineffective, indicating that resistance was not driven by discrete genomic lesions but rather by age-associated mutational drift. These findings support a model in which OsIS functions as an evolutionary bottleneck whose escape promotes genomic heterogeneity and promotes resistance to EGFR inhibition.

#3449 Heterogeneity in outcomes of cytokine blockade identifies plausible role for SPP1+macrophages in colorectal liver metastasis immune suppression.

Kristin Goodsell[1], Jason Carter[1], Sheela Damle[2], Xiuyun Jiang[1], Heidi Kenerson[1], Ian N. Crispe[1], Venu G. Pillarisetty[1]

[1]Surgery, University of Washington, Seattle, WA,[2]Hematology/Oncology, University of Washington, Seattle, WA

The failure of immunotherapy to demonstrate a benefit in patients with colorectal cancer liver metastases (CRLM) is likely due to both liver-specific immune tolerance and cancer-specific immune evasion mediated by tumor associated macrophages (TAMs), suppressive cytokines (e.g., interleukin-10/IL-10), and immune checkpoints, such as PD-1-PD-L1. We previously demonstrated that IL-10 blockade can activate antitumor immunity in tumor slice cultures (TSC) of CRLM, while PD-1 blockade failed to do so. We hypothesized that immunosuppressive TAMs in the tumor immune microenvironment (TIME) contributed to treatement failure.

Cases were classified as responders or non-responders to IL-10 blockade. Clinical characteristics were analyzed. Bulk and single cell RNA sequencing (RNAseq) and multiplexed immunofluorescence (mIF) were performed on subsets of treated samples. RNAseq data were analyzed in R (Seurat) and Python (Scanpy). AIVIA software was used to quantify SPP1 staining on mIF.

IL-10 blockade increased apoptosis (29% to 45%, $p<0.05$) across all TSC (n=59). Using two tailed t-test, cases were classified by percent apoptosis in anti-IL-10 treatment versus control as responders (53% vs 23%, $p<0.05$) and non-responders (25% vs 24%, $p=0.67$).

Clinical characteristics including primary site, metachronous/synchronous metastasis, mutation status, and prior therapy were not significantly different between groups. BulkRNAseq demonstrated no difference in baseline IL-10 or IL-10 receptor gene expression between groups. scRNAseq identified TAMs as the major source and both T cells and TAMs as recipients of IL-10 signaling.

While non-responders had higher baseline expression of genes related to CD8+ T cell activation ($p=0.03$) and cytotoxicity ($p=0.03$), they also had a higher abundance of M2-macrophage related genes ($p=0.02$) and CD8+ T cell exhaustion ($p=0.04$). Further interrogation of immunosuppressive signaling pathways showed that *SPP1* (encoding osteopontin/OPN) is largely expressed by TAMs within CRLM, while T cells and TAMs express OPN receptors (CD44, ITGB1). mIF demonstrates colocalization of macrophage markers (CD68/CD163) and OPN/SPP1. Preliminary analysis showed that non-responders had significantly more OPN/SPP1+ cells on baseline mIF (4.3 vs 0.1%, $P=0.01$).

Importantly, we determined that OPN secretion is significantly reduced in responders but unchanged in non-responders. The results suggest a role for TAM-related OPN-mediated immunosuppression in the failure of immunomodulatory treatment.

We identify *SPP1+* TAMs as a potentially critical immunosuppressive population in the TIME of liver metastases. Future work will leverage both orthotopic CRLM models and spatial transcriptomics of human tumors to explore the role of osteopontin signaling in CRLM.

#3450 Tumor mass dormancy - a potential driver of long-term persistent melanoma after immunotherapy?.

Yingxiao Shi[1], Zoltan Maliga[2], Tuulia Vallius[3], Shishir Pant[3], Roxanne Pelletier[3], Brigette Kobs[2], Priyanka Solanky[3], Yiwen He[1], Eliezer M. Van Allen[4], Sandro Santagata[5], Patrick Ott[4], Christine G. Lian[6], Elizabeth I. Buchbinder[4], David Liu[4], Peter Karl Sorger[7]

[1]DFCI/Harvard Medical School, Boston, MA,[2]Laboratory of Systems Pharmacology, Harvard Medical School, Boston, MA,[3]Harvard Medical School, Boston, MA,[4]Dana-Farber Cancer Institute, Boston, MA,[5]Brigham and Women's Hospital, Boston, MA,[6]Brigham and Women's Hospital, Harvard Medical School, Boston, MA,[7]DFCI/Harvard Medical School

Introduction - Persistent residual lesions represent a common yet ambiguous outcome in melanoma patients treated with immune checkpoint inhibitors (ICIs). These lesions can reflect either (i) disease eradication with fibrosis and necrosis, or multiple modes of tumor dormancy, including (ii) residual disease characterized by cellular dormancy or quiescence, and (iii) macroscopic tumor mass dormancy, in which overall stability emerges from a dynamic balance between tumor proliferation and loss. Because these lesions are infrequently biopsied, the biological mechanisms that sustain these forms of dormancy remain poorly defined. This study aimed to characterize the cellular and microenvironmental states underlying persistent residual disease following ICI therapy.
Methods - We performed multi-omics spatial profiling on persistent residual lesions resected from six ICI-treated melanoma patients. For comparison, we included lymph node metastases from patients who progressed after ICIs.
Results - In 4 of 6 patients, persistent residual lesions consisted largely of immune cells and scar tissue, suggesting that the PET signal may arise primarily from non-tumor components rather than residual viable tumor. In contrast, one patient with a large residual lymph node lesion harbored viable, proliferating tumor cells at levels comparable to — or exceeding — those in lymph node lesions from patients with active clinical progression after ICI therapy. Extensive cytotoxic T-cell infiltration and high levels of programmed cell death were observed within this lesion. Although some tumor cells expressed cellular dormancy-associated markers (e.g., p27), this was not the dominant tumor state. Strikingly, in another patient, a persistent residual lesion that was pathologically negative for tumor cells by H&E contained discrete nests of tumor cells identified by multiplex IF, with approximately half of them proliferating in close proximity to immune cells.
Conclusion - Together, these findings demonstrate that post-ICI residual disease can arise from persistent, viable tumor cells and that the phenotype is more consistent with tumor mass dormancy rather than the classical cellular dormancy concept. Furthermore, the persistent residual lesion can harbor viable and proliferative tumor cells despite appearing clinically stable, underscoring that such lesions may act as reservoirs with potential for late progression. This dormancy-like state has important implications for patient monitoring, clinical interpretation of stability, and long-term management following ICI therapy.

#3451 Single-cell transcriptomic insights into tumor and immune dynamics driving resistance to ixazomib combined with gemcitabine and doxorubicin in SMARCB1-deficient renal medullary carcinoma.

Kai Yu, Rebecca Tidwell, Tharakeswara Bathala, Rahul Sheth, Menuka Karki, Jianfeng Chen, Jing Qian, Fei Duan, Luigi Perelli, Melinda Soeung, Priya Rao, Arlene Siefker-Radtke, Najat Daw, Davis Ingram, Diana Shamsutdinova, Khalida Wani, Wei-Lien Wang, Alexander Lazar, Zilong Zhao, Sabitha Prabhakaran, Neus Bota, Andrew Futreal, Rare Tumor Initiative Team, Patient Mosaic Team, Liuqing Yang, Chunru Lin, Giannicola Genovese, Jianjun Gao, Linghua Wang, Nizar Tannir, Pavlos Msaouel

UT MD Anderson Cancer Center, Houston, TX

SMARCB1-deficient renal medullary carcinoma (RMC) is a highly aggressive kidney cancer characterized by replication stress and proteotoxic vulnerabilities, yet the molecular determinants of therapy response remain poorly understood. To delineate the mechanisms of response and resistance, we performed integrative single-cell and bulk multi-omic profiling of tumor samples from patients with RMC treated with a combination of the proteasome inhibitor ixazomib, gemcitabine, and doxorubicin. Analysis of 33,410 single cells from 11 patients revealed pronounced intratumoral and microenvironmental heterogeneity. Responding tumors displayed immune-inflamed microenvironments enriched for $CD8^+$ cytotoxic T cells, effector-like and Tfh $CD4^+$ T cells, NK cells, plasmacytoid (pDC) and conventional dendritic cells (cDC1/cDC2), and *S100A8*$^+$ monocytes, consistent with enhanced antigen presentation and effector activation. In contrast, non-responders exhibited abundant macrophages, regulatory T cells, plasma cells, and inflammatory and myofibroblastic cancer-associated fibroblasts (iCAFs/mCAFs), forming immunosuppressive stromal-myeloid circuits that impeded cytotoxic infiltration and response. Malignant cells segregated into six transcriptional states, including proliferative, hypoxia-responsive, epithelial-mesenchymal, and neuroendocrine-squamous hybrid lineages. A proliferative state marked by replication stress, unfolded-protein-response activation, and proteasome component upregulation was enriched in non-responders and persisted at progression, suggesting adaptive proteostasis-driven resistance. Copy-number analyses identified focal gains in *BAG4*, *UBE4B*, and *UBE2W* that may enhance apoptosis evasion and p53 degradation, reinforcing proteotoxic resilience. In contrast, well-differentiated and immune-mimicry tumor states correlated with improved survival. Integrative cell-cell communication analysis highlighted stromal-immune signaling through *BMP4/5* and *WNT4/6* as a hallmark of resistant tumors, whereas *BMP6* expression associated with dendritic-cell activation and favorable immune remodeling. Together, these findings define molecular and cellular programs underlying therapeutic response in RMC and nominate actionable stress-adaptation and stromal-immune circuits as potential targets for future biomarker-guided combination strategies.

#3452 Exploiting stromal vulnerabilities: NFATC2-expressing CAFs enhance chemotherapy sensitivity and reveal a targetable ERBB axis in pancreatic cancer.

Jiahao Guo[1], Samuele Cancellieri[1], **Biswajyoti Sahu**[2]

[1]NCMBM, University of Oslo, Dept. of Medical Genetics, Institute for Cancer Research, Oslo, Norway,[2]Applied Tumor Genomics Research Program, University of Helsinki, Finland, NCMBM, University of Oslo, Dept. of Medical Genetics, Institute for Cancer Research, Oslo, Norway

Pancreatic ductal adenocarcinoma (PDAC) persists as one of the most therapeutically recalcitrant solid tumors, driven in part by an extensive desmoplastic stroma dominated by cancer-associated fibroblasts (CAFs). CAF heterogeneity and transcriptional plasticity are increasingly recognized as key determinants of tumor evolution and treatment response, yet how neoadjuvant therapy reshapes CAF states in human PDAC remains poorly defined. We applied gene regulatory network analysis to single-cell RNA sequencing data from 43 PDAC tumors collected following neoadjuvant therapy. This analysis uncovered a previously undescribed CAF subpopulation defined by expression of the transcription factor NFATC2, classically associated with T-cell signaling. NFATC2-expressing CAFs were significantly enriched in patients exhibiting robust treatment response and extended progression-free survival. Tumors containing this CAF state displayed reduced lymph-node metastasis and a distinct stromal transcriptional program characterized by enhanced pro-apoptotic signaling and suppression of ERBB pathway activity. Functional co-culture assays revealed that NFATC2-expressing CAFs potentiate FOLFIRINOX-induced apoptosis in PDAC cells. Moreover, ERBB inhibition produced strong synergistic cytotoxicity when combined with either FOLFIRINOX or gemcitabine/nab-paclitaxel, suggesting a mechanistically grounded combination strategy for overcoming stromal-mediated resistance. These findings identify NFATC2-expressing CAFs as a predictive stromal biomarker of therapeutic responsiveness and define a tumor-restraining CAF state with actionable molecular features. This work reveals a previously unrecognized vulnerability within the PDAC microenvironment and supports rational integration of ERBB-targeted agents with current neoadjuvant regimens to enhance treatment efficacy in PDAC.

#3453 Macrophage polarization in ALK+ non-small cell lung cancer: Implications for treatment targeting.

Marisa E. Aikins[1], Abdullah Saeed[2], Derek Nancarrow[1], Peter J. Ulintz[3], Peggy Hsu[3], Yusoo Lee[4], Sofia Merajver[5], Kiran H. Lagisetty[5]

[1]Internal Medicine, University of Michigan, Ann Arbor, MI,[2]Thoracic Surgery, University of Michigan, Ann Arbor, MI,[3]University of Michigan, Ann Arbor, MI,[4]University of Michigan Medical School, Ann Arbor, MI,[5]University of Michigan Health System, Ann Arbor, MI

Background: Anaplastic lymphoma kinase-positive non-small cell lung cancer (ALK+ NSCLC) comprises 5-6% of all lung cancers with a median survival rate of 6.8 years. The primary treatment is tyrosine kinase inhibitors (TKI) which have a 30-80% response rate but acquired resistance is inevitable. One area of potential intervention is within the tumor-immune microenvironment (TIME) but the standard immunotherapies, such as immune checkpoint inhibitors, have resulted in low overall response rate (10-15%), toxicity, or inconclusive therapeutic effects in ALK+ NSCLC as a single agent or combined with TKIs in clinical trials. Therefore, it is imperative to gain a more in-depth understanding of the TIME evolution. In particular, there has been increasing evidence showing that macrophage polarization is involved in NSCLC tumorigenesis and drug resistance. The timing, phenotype, and functional state of macrophages within ALK+ NSCLC may offer opportunities for therapeutic targeting.
Methods:Three investigations were carried out to investigate ALK+ NSCLC macrophage evolution: (1) a de novo and treatment-naïve study setting where intratracheal instillation of a CRISPR/Cas9 adenoviral system was administered in C57BL/6 mice for chromosomal rearrangement of *alk* and *eml4* leading to spontaneous formation of tumors in the lungs, (2) a heterotopic TKI treatment study setting where ALK+ NSCLC cells syngeneic to C57BL/6 mice were injected subcutaneously, and (3) analysis of ALK+ NSCLC patient legacy and local cohorts. Tumors from the animal studies were harvested at early, intermediate, and late time points for analysis of macrophage phenotypes. Legacy and local patient cohorts were analyzed to investigate and validate macrophage results in a broad and heterogenous population of ALK+ NSCLC patients.
Results:Macrophage frequency in ALK+ NSCLC increased during tumor progression with localization occurring primarily at the periphery of the tumor. The addition of Lorlatinib further increased macrophage frequency. Macrophage polarization was also altered by specific TKI treatments. Alectinib increased pro-inflammatory:anti-inflammatory macrophage ratios over time, reaching 0.55 at the late time point, which was significantly higher than Lorlatinib at 0.13. Compared with other oncogene-driven NSCLC, ALK+ patients in legacy and local RNAseq datasets demonstrated a lower frequency of pro-inflammatory macrophages.
Conclusions:Differential macrophage polarization was demonstrated using de novo untreated and subcutaneous TKI treated ALK+ NSCLC animal models. Macrophage polarization appears to be TKI-specific with Alectinib treatment increasing pro-inflammatory macrophage subsets and decreasing anti-inflammatory subsets while Lorlatinib shows the opposite despite a smaller tumor size. Macrophage polarization has potential to be a promising avenue for therapeutic intervention.

#3454 Dynamic alteration of ANXA2 expression as a predictor of response to neoadjuvant bevacizumab in newly diagnosed glioblastoma.

Taketo Ezaki[1], Ryota Tamura[1], Yohei Yamamoto[2], Jun Takei[2], Akihiko Teshigawara[2], Kyoichi Tomoto[2], Yasuharu Akasaki[2], Masahiro Toda[1], Yuichi Murayama[2], Hikaru Sasaki[3], Keisuke Miyake[4], Toshihide Tanaka[2]

[1]Department of Neurosurgery, Keio University School of Medcine, Shinjuku-ku, Japan,[2]Department of Neurosurgery, The Jikei University School of Medicine, Minato-ku, Japan,[3]Department of Neurosurgery, Tokyo Dental College Ichikawa General Hospital, Ichikawa-shi, Japan,[4]Department of Neurosurgery, Kagawa University School of Medcine, Miki-cho, Japan

Background: Bevacizumab (Bev) provides only modest and transient benefit in glioblastoma (GBM), and the molecular mechanisms underlying Bev resistance remain insufficiently characterized. Annexin A2 (ANXA2) plays a key role in angiogenesis, extracellular matrix remodeling, and invasive tumor phenotypes, and has emerged as a potential mediator of Bev resistance biology. This study aimed to elucidate the clinical significance of ANXA2 expression dynamics in newly diagnosed GBM by analyzing paired tumor samples obtained pre- and post-Bev therapy, with a focus on their association with treatment response and survival outcomes.
Method: We analyzed 65 samples obtained from 33 patients with GBM, including newly diagnosed GBM without Bev treatment (Naïve Bev; n=15), neoadjuvant Bev treated (NeoBev; n=18), and recurrent GBM after Bev therapy (Refractory Bev) comprising paired pre- and post-Bev samples in same patients. ANXA2 expression was evaluated by qPCR and immunohistochemistry. Progression-free survival (PFS) and overall survival (OS) were also evaluated according to *ANXA2* expression levels, and recurrence patterns on MRI were compared.
Results: Paired analyses showed *ANXA2* expression tended to be higher in Refractory Bev compared with initial surgery specimens, regardless of prior Bev exposure. Immunohistochemistry demonstrated comparable ANXA2 expression across Naïve Bev, NeoBev, and Refractory Bev cohorts. *ANXA2* expression was not associated with prognosis in Naïlve Bev; however, lower expression correlated with favorable PFS in NeoBev (p=0.1062) and significantly longer OS (p=0.0025). Patients receiving ≥ 10 Bev cycles showed significantly lower ANXA2 expression than those with < 10 cycles (p=0.0168), and lower expression in NeoBev resulted in prolonged OS. T1Gd responders showed a trend toward longer PFS (p=0.1037), with a similar trend in T2/FLAIR poor responders (p=0.0688). No significant association was found between *ANXA2* expression and recurrence patterns on MRI.
Conclusion: ANXA2 may represent a key molecular determinant of angiogenesis and invasion and could serve as both a prognostic and predictive biomarker for neoadjuvant Bev response.

#3455 POSTN-driven mechanotransduction sustains β-catenin activity in CAFs to promote melanoma progression and drug resistance.

Jie Wang[1], Bruna DA SILVA SOLEY[2], Linli Zhou[1], Yuhang Zhang[2]

[1]University of Cincinnati College of Pharmacy, Cincinnati, OH,[2]University of Cincinnati, Cincinnati, OH

Cancer-associated fibroblasts (CAFs) are pivotal modulators of the tumor microenvironment, orchestrating extracellular matrix (ECM) remodeling, inflammation, and therapeutic resistance. However, the mechanisms governing their dynamic response to targeted therapies, particularly in melanoma, remain incompletely understood. Our previous work identified β-catenin as a central driver of CAF activation in melanoma. Building on this, we recently discovered that periostin (POSTN), a matricellular protein primarily secreted by CAFs, acts as a major downstream effector of β-catenin-mediated transcriptional reprogramming.In this study, we uncover a novel β-catenin-TCF-POSTN regulatory axis that underlies CAF-mediated resistance to BRAF inhibition in melanoma. Specifically, we show that nuclear β-catenin interacts with TCF4 to drive POSTN expression and secretion in CAFs. Disrupting this interaction, using a dominant-negative TCF4 mutant or the pharmacological inhibitor PNU74654, significantly reduced POSTN expression, mimicking the effects of β-catenin inhibition. Phenotypically, POSTN depletion impaired CAF proliferation, cytoskeletal dynamics, and their ability to promote melanoma cell proliferation and resistance to BRAF inhibition *in vitro*.Mechanistically, we identified a POSTN-driven outside-in mechanotransduction loop in which POSTN activates integrin-focal adhesion signaling to promote actin stress fiber assembly. The resulting cytoskeletal tension induced nuclear deformation, facilitating β-catenin nuclear translocation, thereby sustaining POSTN expression and reinforcing a self-amplifying feedback loop. Interruption of this loop via POSTN knockdown or using actin polymerization inhibitor Cytochalasin D reduced nuclear β-catenin levels, confirming the existence of a POSTN-driven outside-in signaling cascade.Using BRAF-mutant melanoma xenograft models, in which either POSTN expression was ablated or β-catenin-TCF4 interaction was blocked in CAFs, suppressed tumor progression and sensitized melanoma cells to BRAF inhibition. Conversely, POSTN overexpression in CAFs enhanced tumor progression, ECM deposition, including collagen and fibronectin, and resistance to BRAF inhibitors. Importantly, both preclinical models and melanoma patient samples revealed a strong correlation between POSTN expression and nuclear β-catenin accumulation in CAFs.Together, our findings define an important POSTN-mediated feedback loop that sustains nuclear β-catenin signaling and reinforces CAF activation. This axis promotes ECM remodeling and contributes to melanoma progression and targeted therapy resistance. Targeting the β-catenin-TCF4-POSTN circuit represents a promising stroma-targeting strategy to advance targeted therapies against melanoma and improve clinical outcomes.

#3456 Spatial evolution of the tumor immune microenvironment between primary and recurrent serous ovarian cancer using a sixty plex multiplex immuno oncology panel.

Hayeon Shin, Jue young Kim, Yoon Joo Kim, Yookyung Lee, Jae-Hoon Kim

Gangnam Severance Hospital, Seoul, Korea, Republic of

Background: Despite advances in treatment, recurrent ovarian cancer continues to exhibit high recurrence rates, and immune checkpoint inhibitors (ICIs) demonstrate limited response (10-15%) due to a strongly immunosuppressive tumor immune microenvironment (TIME). The mechanisms of immune escape during recurrence remain insufficiently understood, highlighting the need for spatial characterization of TIME remodeling to optimize biomarker-guided combination immunotherapy.
Methods: Formalin-fixed paraffin-embedded (FFPE) primary and recurrent tumor tissues from patients with recurrent serous ovarian cancer were used to construct matched tissue microarrays (TMAs). Multiplex immunofluorescence staining was performed using the Akoya IO60 immuno-oncology panel. Quantitative spatial image analysis was conducted using the Qupath workflow to assess immune cell composition, phenotypes, and tumor-immune architecture changes associated with recurrence.
Results: A total of 58 patients were included, of whom 35 had matched primary and recurrent tumor specimens available. Based on chemotherapy response classification, 41 patients were categorized as platinum-sensitive and 8 as platinum-resistant. Spatial profiling analysis is ongoing. Preliminary observations suggest heterogeneous shifts in T-cell subsets (CD3, CD4, CD8), regulatory T cells (FOXP3+), and immunosuppressive myeloid populations (CD163+, CD206+), along with altered immune checkpoint pathways (PD-1, PD-L1, LAG-3, VISTA) and tumor phenotypes (PanCK, EpCAM) between primary and recurrent tumors.
Conclusion: This study aims to characterize spatial evolution of TIME during recurrence and identify immune escape mechanisms contributing to treatment resistance. The findings are expected to guide the development of precision immunotherapy strategies and improve clinical outcomes for patients with recurrent ovarian cancer.

#3457 Myeloid-derived suppressor cells mediate ferroptosis resistance in HR+/HER2- breast cancer via the ARID1A/AKR1C2 axis.

Guidong Chen, Jinpu Yu

Tianjin Medical Univ. Cancer Inst. & Hospital, Tianjin, China

Breast cancer is the most common malignancy in women, with approximately 70% of cases classified as the HR+/HER2- subtype. Recurrence and metastasis remain the leading causes of mortality in breast cancer patients. Resistance to ferroptosis has been recognized as a key factor in breast cancer progression, yet its relationship with myeloid-derived suppressor cells (MDSCs)-a critical component of the tumor microenvironment-has remained largely unexplored. In this study, we demonstrated that co-incubation of HR+/HER2- breast cancer cells with MDSCs significantly reduced their sensitivity to ferroptosis inducers and this process was closely associated with the downregulation of ARID1A expression. Further bioinformatic analysis and functional cellular experiments indicated that ARID1A loss drived the marked upregulation of the ferroptosis-suppressive gene AKR1C2 through epigenetic regulation. Overall, our findings reveal that MDSCs modulate AKR1C2 transcription by regulating ARID1A expression in HR+/HER2- breast cancer cells, thereby providing a promising strategy for the development of novel therapeutic targets against breast cancer.

#3458 Targeting the CD44-SPP1 axis to overcome therapy resistance in bladder cancer.

Hiba Siddiqui[1], Yuzhen Zhou[1], Jihyun Lee[2], Kevin Bi[3], Jacqueline T. Ochoa[3], Martin Egger[1], Eliezer M. Van Allen[1], Filipe L. De Carvalho[2], Kent W. Mouw[1]

[1]Dana-Farber Cancer Institute, Boston, MA,[2]Brigham and Women's Hospital, Boston, MA,[3]Broad Institute, Cambridge, MA

Introduction: Cisplatin-based chemotherapy remains a mainstay of treatment for muscle-invasive bladder cancer (MIBC), and the recent approval of antibody-drug conjugates (ADCs) enfortumab vedotin (EV) combined with pembrolizumab (P) as the first-line treatment has expanded therapeutic options. However, primary non-response and acquired resistance to these treatments result in poor clinical outcomes. Tumor cells interact with the tumor microenvironment (TME), where tumor-associated macrophages (TAMs) comprise 50-80% of non-tumors cells and can promote an immunosuppresive TME that drives therapeutic resistance. However, the mechanisms underlying tumor-macrophage crosstalk in cisplatin- and EV-based therapeutic settings remain poorly defined.
Methods: We employed snRNA-seq to analyze human samples and performed combined analyses with publicly available datasets. Spatial transcriptomics were used to characterize the distribution of TAM subtypes. CRISPR-Cas9 was used to generate CD44-deficient bladder cancer cell lines and SPP1-deficient macrophages. A series of *in vitro* functional assays including flow cytometry-based macrophage phenotype profiling, phagocytosis assays, immunoblots, and viability assays were performed across cisplatin and MMAE treatment conditions. Direct and indirect co-culturing systems were used to model tumor cell-macrophage interactions. Immunocompetent murine bladder cancer models were used to evaluate therapeutic responses when combining CD44-SPP1 blockade with cisplatin or EV. RNA sequencing was performed to profile gene expression changes in tumor cells and macrophages following CD44-SPP1 axis modulation.
Results: Tumor cell CD44 expression and macrophage SPP1 expression are positively correlated with cisplatin resistance and poor clinical outcomes in bladder cancer patients. SPP1-expressing macrophages were spatially localized near CD44-positive tumor cells in resistant tumors. Cisplatin and EV treatment increased CD44 and SPP1 expression in tumor cells and macrophages, respectively, and recombinant SPP1 was sufficient to induce tumor cell CD44 expression. CD44 deletion enhanced tumor cell response to cisplatin and EV, and flow cytometry and immunoblots showed that SPP1-deficient macrophages exhibit altered polarization states and enhanced phagocytic potential. Co-implantation of CD44-expressing tumor cells with SPP1-deficient macrophages reduced tumor growth. Comprehensive immune profiling of TME changes under various genetic and treatment conditions is underway.
Conclusion: Disrupting the CD44-SPP1 interaction sensitizes bladder tumors to cisplatin and EV. By defining macrophage phenotypes and polarization states within the CD44-SPP1 axis, this work supports therapeutic approaches such as engineered macrophage-based immunotherapies to overcome therapeutic resistance in MIBC.

: Migration and Invasion
Poster Session

#3462 The scaffold protein CNK3 mediates pro-invasive signalling in glioblastoma.

Guillaume Serwe, David Kachaner, Thomas Perreault, Marc K. Saba-El-Leil, Driss Lajoie, Genevieve Arseneault, Vincent Quoc-Huy Trinh, Marc Therrien

Institute for Research in Immunology and Cancer (IRIC), Montreal, QC, Canada

Glioblastoma (GBM) is the deadliest brain cancer with a five-year survival rate of 7% and a lack of targeted therapies for its treatment. One of the main factors limiting better treatment outcomes is the invasiveness of GBM cells, a property which reduces the efficacy of surgical resection and makes recurrence almost inevitable. The development of therapeutics for restraining cell invasion is therefore a crucial goal in the biomedical community. The invasive capacity of GBM cells is largely driven by a rewiring of signal transduction networks which results in abnormal activity of the motility-regulating RHO family GTPases, and activation of pro-invasive gene expression programs. However, the molecular mechanisms controlling this signalling switch are not fully understood, and their elucidation represents a significant challenge in biomedical research.
Our goal is to improve the understanding of rewired signalling in GBM cells by studying the functions of the CNK scaffold protein family. Through genetic knockdown/knockout and in vitro cell migration and invasion assays with GBM cell lines we identified the CNK3 member as a new pro-invasive factor. Crucially, this is also the case in vivo, as loss of CNK3 expression greatly reduced tumour volume in an orthotopic mouse xenograft model. Using GTPase pulldown assays, we then determined that CNK3 supports cell motility by promoting the activation of the RHO GTPases RAC1 and CDC42, while inhibiting the activity of RHOA. Consistent with these findings, CNK3 is required for normal actin-based protrusion formation at the leading-edge of migrating cells, and limits cell contractility and cell-substrate adhesion. To determine the molecular mechanism of action by which CNK3 functions as a scaffold protein, we then identified its proximal interactome by TurboID and validated its functional binding partners through co-immunoprecipitation and functional rescue experiments. These include the RAC1/CDC42 GTPase-activating protein ARHGAP39, and the MAP4K kinases MAP4K4, TNIK, and MINK1. Finally, we identified upstream growth factors and receptor tyrosine kinases (RTKs) that regulate CNK3-dependent motility and RHO GTPase activity. Thus, CNK3 functions by linking signalling by upstream RTKs to downstream regulation of RHO GTPases. Current efforts focus on the identification of pro-motility transcription programs regulated by this signalling axis.
Our research identifies the CNK3 scaffold protein as a new driver of motility in GBM cells and advances our understanding of the molecular mechanisms underlying their invasive behaviour. Ultimately, CNK3 and its binding partners could be new therapeutic targets for limiting the spread of GBM and improving patient survival.

#3463 Exploiting mechanisms of glioblastoma invasion to induce vulnerabilities that promote synergistic lethality.

Rifat S. Sajid[1], Lennart J. van Winden[2], Okty Abbasi Borhani[1], Evelyn R. Kamski-Hennekam[1], Ameesha Paliwal[1], Nakita E. K. Gopal[1], Lauren Omoto[1], Olaf van Tellingen[2], Phedias Diamandis[1]

[1]Princess Margaret Cancer Centre, University Health Network, Toronto, ON, Canada,[2]Department of Pharmacology, Netherlands Cancer Institute, Amsterdam, Netherlands

Glioblastoma (GBM) is the most common and aggressive form of adult brain cancer. Diffuse infiltration of tumor cells into surrounding vital brain tissue prevents complete surgical removal and poses a significant challenge to treatment. Therefore, a better understanding of the molecular programs that drive GBM invasion is crucial to designing more effective therapies. We hypothesized that GBM invasion is mediated by generalizable molecular mechanisms and that disrupting these programs induced vulnerabilities that could be exploited by combination therapies. In this study, we used a clinically diverse cohort of 17 patient-derived GBM cell lines and advanced experimental conditions to develop more controlled models of GBM invasion. Since hypoxia is a known driver of tumor invasion, we cultured GBM cells under 20%, 1%, and 0.2% oxygen concentrations and performed mass spectrometry-based profiling to investigate the invasive signaling pathways promoted by hypoxia. Additionally, we also performed mass spectrometry-based profiling of GBM cells cultured in the glioma cerebral organoid (GLICO) model of brain infiltration to investigate hypoxia-independent invasion mechanisms. These analyses identified the enrichment of several integrin-related signaling signatures as a general mediator of GBM invasion across cell lines, in both hypoxia-induced invasion conditions and in brain infiltration. To identify downstream targets of the integrin signaling pathway that could impair tumor cell migration, we performed a chemical screen using a MAPK compound library (*n*=802 compounds), which identified MAP4K4 as a top invasion-specific kinase. Pharmacological inhibition of MAP4K4 significantly impaired migration across multiple cell lines in live imaging experiments and reduced tumor infiltration in GLICOs, supporting its broad generalizability as a target to disrupt GBM invasion. By performing phospho-proteomic profiling, we then mechanistically determined that MAP4K4 inhibition led to the dysregulation of focal adhesion dynamics and cytoskeletal remodeling, which was validated through live fluorescent imaging experiments. Lastly, to explore if MAP4K4 inhibition induced vulnerabilities that could be exploited by sequential treatment with a second compound, we performed a combination screen using an FDA approved drug library (*n*=3196 compounds). We identified three compounds with a synergistic effect dependent on MAP4K4 inhibition that reduced tumor cell viability by 35-40% compared to single agent treatment. As the therapeutic strategies to treat GBM have remained unchanged for decades, the administration of synergistic drug combinations that exploit the characteristic infiltrative nature of GBM may therefore represent a promising treatment avenue for this devastating disease.

#3464 Defining the role of CRK and CRKL in glioblastoma invasiveness: from cell culture to mouse models.

Piyanka Hettiarachchi, Neka Large, Taeju Peter Park

Children's Mercy Kansas City, Kansas City, MO

Glioblastoma is the most aggressive primary malignant brain tumor affecting both adults and children, with a median survival of only about 15 months despite the standard treatments of surgery, radiation, and chemotherapy. Complete surgical resection is hindered by the highly infiltrative nature of glioblastoma cells, making tumor invasion the most significant cause of recurrence. Dysregulation of CT10 regulator of kinase (CRK) and CRK-like (CRKL) proteins has been implicated in multiple cancers, including glioblastoma, in which their overexpression correlates with poor prognosis. We hypothesized that CRK and CRKL are essential in glioblastoma cell invasion and that their inhibition suppresses tumor infiltration and enhances treatment efficacy. To test this hypothesis, we performed transient and stable knockdown of CRK, CRKL, or both in glioblastoma cell lines (U118-MG and LN-229) using siRNA transfection and shRNA lentiviral transduction. Western blot analyses confirmed significant reductions in target protein levels. Using the xCELLigence real-time cell analysis system, we assessed the impact of CRK and CRKL knockdown on glioblastoma cell adhesion, migration, and invasion. CRKL knockdown substantially reduced all three processes, whereas combined CRK/CRKL knockdown completely abolished adhesion, migration, and invasion. These consistent results across three glioblastoma lines highlight essential, overlapping roles of CRK and CRKL in regulating glioblastoma cell motility. To examine the dependence of in vivo glioblastoma growth and invasion on CRK and CRKL, we transplanted LN-229 glioblastoma cells expressing luciferase and GFP into immunodeficient (NSG) mouse brains using stereotactic surgery. Luciferase and GFP enabled us to monitor in vivo tumor growth through IVIS imaging and identify infiltrating tumor cells by GFP immunohistochemistry. Histological analysis of the xenografted brains revealed diffuse invasion of glioblastoma cells into surrounding brain regions. Currently, we transplant glioblastoma cells with CRK/CRKL knockdown to determine the requirement of CRK/CRKL in glioblastoma invasion in vivo. Then, we plan to test the effects of CRK/CRKL-antagonist peptides we developed on glioblastoma invasion in the mouse brain. Our study highlights the promise of targeting CRK and CRKL as a therapeutic strategy to mitigate glioblastoma invasion and improve the efficacy of standard care for glioblastoma.

#3465 An investigation into the role of AVIL, an actin-binding protein, in glioblastoma metabolism.

Summer Johnson, Robbie Cornelison, Adelaide Fierti, Martyna Glowczyk, Hui Li

University of Virginia School of Medicine, Charlottesville, VA

Glioblastoma (GBM) is one of the deadliest cancers characterized, is highly aggressive, invasive, and incurable, with an average survival of 15 months. The Li Lab identified *AVIL* as a novel proto-oncogene, which is aberrantly expressed in the tissue of cancers like glioblastoma. AVIL is a calcium dependent actin binding protein, implicated in cytoskeletal dynamics. Under physiological conditions, the expression of *AVIL* is limited to a handful of cell types: tuft cells, kidney podocytes, and sensory neurons, suggesting a tightly regulated role. In addition, our lab generated an *AVIL* KO mouse model that has no side effects and are fertile with viable offspring. Previous work has led to the development of a first-in-class small molecule inhibitor against AVIL (C1). While the upregulation of *AVIL* is observed in GBM, the molecular mechanisms involved are still unknown. This project aims to define the interactions and pathways involving AVIL with the goal of determining a molecular mechanism regarding alterations in metabolic phenotype. To elucidate the molecular mechanism of AVIL, we used a comprehensive bioinformatic analysis to pinpoint pathways and downstream targets. We conducted an unbiased screen of the protein using mass spectrometry on glioblastoma (U87) cells treated with C1 over a period of 72 hours. We also utilized RNA sequencing of GBM cells treated with C1 and astrocytes transduced with AVIL. Furthermore, we utilized Seahorse Mitochondrial Stress Tests as a screen for metabolism and mitochondrial function to validate our bioinformatic observations. One candidate mechanism we observed in the MS data suggested that treatment with the inhibitor induced a proteomic change from a glycolytic to an oxidative-phosphorylation profile, indicating a potential metabolic modulatory role of AVIL. This is particularly interesting because actin-glycolytic enzyme interactions are linked to the cytoskeletal regulation of metabolism. In addition, RNA sequencing data presented glycolysis as a top gene set that is differentially expressed after treatment with C1. After exogenous expression of AVIL in human astrocytes, there is an increase in basal metabolic rate and maximal respiration. Defining the metabolic interactions of AVIL will help determine the signaling pathways that are perturbed by *AVIL* expression and reveal downstream effectors. I hypothesize that *AVIL* expression regulates glycolysis via interactions with glycolytic enzymes offering a potential therapeutic strategy for GBM.

#3466 CTNNA1 promotes invasion and migration in clear cell renal cell carcinoma via N-cadherin-dependent adhesion and RhoA modulation.

Shinta Suenaga, Sei Naito, Hiromi Ito, Yuki Takai, Takafumi Narisawa, Mayu Yagi, Atsushi Yamagishi, Hayato Nishida, Norihiko Tsuchiya

Yamagata University Hospital, Yamagata city, Japan

Background and Objectives Clear cell renal cell carcinoma (ccRCC) frequently exhibits amplification of chromosome 5q31.2; however, the biological impact of this alteration remains unclear. CTNNA1, which is located in this region, regulates cell-cell adhesion, but its function in ccRCC has not been fully characterized. This study aimed to clarify the role CTNNA1 in ccRCC progression and its association with cadherin-mediated adhesion and invasive potential.
Methods Whole-transcriptome data from 57 metastatic ccRCC cases treated at Yamagata University were analyzed to assess CTNNA1 expression and its correlation with 5q copy number variation. TCGA data were used to compare cadherin expression profiles. Human ccRCC cell lines (A-498, 786-O, 769-P) underwent CTNNA knockdown using small interfering RNA (siRNA). Expression levels were verified by quantitative real-time PCR (qRT-PCR) and western blotting. Cell invasion and migration were measured by trans well assays, and protein localization was examined by immunofluorescence microscopy.
Results CTNNA1 expression was elevated in ccRCC cases with 5q amplification and correlated with increased invasive potential. Despite low E-cadherin expression, CTNNA1 formed a complex and co-localized with N-cadherin, contributing to intercellular adhesion. CTNNA1 silencing significantly reduced invasion, while overexpression enhanced it. Immunofluorescence revealed αE-catenin localization at cell-cell junctions in adherent cells and a perinuclear redistribution in isolated cells. RhoA localization mirrored CTNNA1 and was disrupted following CTNNA1 knockdown, suggesting its involvement in regulating polarity and migration through RhoA signaling.
Conclusions CTNNA1 promotes ccRCC cell invasion and migration through N-cadherin-mediated adhesion and modulation of RhoA signaling regulation. CTNNA1 may represent a potential therapeutic target for metastasis prevention in ccRCC.

#3467 SUMOylation regulates GATA2 stability to control uterine serous carcinoma invasion.

Anuoluwapo A. Mattix[1], Peng Liu[2], Molly A. Accola[3], William M. Rehrauer[3], Daniel R. Matson[1]

[1]Department of Pathology and Laboratory Medicine, University of Wisconsin-Madison, Madison, WI,[2]Department of Biostatistics and Medical Informatics, University of Wisconsin-Madison, Madison, WI,[3]University of Wisconsin Hospitals and Clinics, Madison, WI

Background: Uterine serous carcinoma (USC) is an aggressive uterine cancer subtype that is responsible for 40% of uterine cancer deaths. We recently demonstrated that USCs lose expression of the zinc-finger transcription factor GATA2 which drives USC invasion, predicts USC recurrence, and is closely correlated with poor cancer-related and overall survival. However, the mechanistic basis of GATA2 downregulation in USC remains unknown.

Methods: *GATA2* RNA transcripts were correlated to patient outcomes derived from The Cancer Genome Atlas (TCGA). *GATA2* gene methylation was assessed in isolated genomic DNA from patient USC tumors by bisulfite sequencing. Ark1 and Ark2 USC cell lines were utilized for *in vitro* studies. GATA2 half-life was measured using cycloheximide chase experiments paired with inhibitors of phosphorylation (staurosporine), acetylation (C646), SUMOylation (ML792), cysteine peptidase activity (N-Ethylmaleimide/NEM), and proteasome-dependent degradation (MG132). Anti-GATA2 immunoprecipitations were performed with custom anti-GATA2 antibodies (Im et al, 2005). Depletion of PIAS2, SENP1, and SUMO2/3 was performed using commercially available siRNAs. Levels of GAPDH, GATA2, PIAS2, SENP1, and SUMO2/3 were measured by western blotting. USC invasion was assessed using Matrigel-coated membrane transwell inserts.

Results: GATA2 IHC protein levels showed no correlation with *GATA2* gene body or proximal promoter DNA methylation, and *GATA2* transcript levels did not predict patient outcome across TCGA USC cases. Post-translationally, USC GATA2 protein half-life was approximately 60 minutes after cycloheximide treatment. Co-treatment with the SUMOylation inhibitor ML792 or the proteasome inhibitor MG132 prolonged GATA2 half-life compared with vehicle, whereas NEM treatment, which inhibits de-SUMOylation and de-ubiquitination, shortened GATA2 half-life. Direct GATA2 SUMOylation was confirmed by anti-GATA2 immunoprecipitation and SUMO2/3 western blot. A candidate siRNA-based approach found that depletion of the E3 SUMO ligase PIAS2 elevated GATA2 levels, while depletion of the SUMO peptidase SENP1 reduced GATA2 levels. siRNA-mediated SUMO2/3 depletion significantly increased GATA2 levels in USC cells and suppressed USC invasion *in vitro* compared to siScramble controls.

Conclusion: USC GATA2 levels are determined by post-translational mechanisms. GATA2 protein has a rapid 60-minute half-life determined by SUMOylation and proteasome-mediated degradation. Depletion experiments support PIAS2 as the GATA2-targeting E3 SUMO ligase and SENP1 as the GATA2-targeting SUMO peptidase. SUMO inhibition increased USC GATA2 levels and suppressed USC invasion, suggesting that SUMO-targeting agents may suppress USC spread through upregulation of GATA2 levels.

#3468 Adrenergic signaling in adipocytes drives ovarian cancer cell invasion.

Monica A. Haughan[1], Carlismari Grundmann[2], Hannah J. Lusk[2], Laura M. Sanchez[2], Joanna E. Burdette[1]

[1]Department of Pharmaceutical Sciences, University of Illinois at Chicago, Chicago, IL,[2]Department of Chemistry and Biochemistry, University of California Santa Cruz, Santa Cruz, CA

High grade serous cancer (HGSC) is the most common and lethal ovarian cancer subtype. HGSC can arise from the fallopian tube and habitually metastasizes to the omentum; consequently, we seek to further elucidate the metabolic crosstalk involved in HGSC colonization of omentum. By applying imaging mass spectrometry (IMS) to co-cultures of HGSC cells and omental explants we are able spatially resolve the chemistry produced and identify molecules unique to the HGSC + omentum cultures as compared to non-tumorigenic co-cultures or monocultures. One such molecule is epinephrine which IMS reveals to be produced by the omentum. From this we hypothesize autocrine epinephrine signaling in omental adipocytes liberates fatty acids driving tumor progression. To aid in more mechanistic investigation a human, pre-adipocyte line which forms spheroids and differentiates to mature adipocytes in culture is employed. Analyzed by IMS adipocyte spheroids and co-cultures with HGSC produced epinephrine confirming an omental cell type responsible to be adipocytes. Omental explants and adipocyte spheroids were subjected to treatment with epinephrine (10μM) or propranolol (1μM) and the resulting conditioned media collected. Three HGSC models -MOE PTEN^{shRNA}, OVCAR4, and OVCAR8- were treated with conditioned media and their invasive potential measured by Matrigel coated Boyden chamber. Propranolol treated conditioned media from either adipocyte source resulted in significantly decreased invasion compared to control while epinephrine treated omental conditioned media significantly increased MOE PTEN^{shRNA} invasion. Untargeted lipidomics performed on treated adipocyte spheroid conditioned media has uncovered lipid species differentially regulated between the epinephrine and propranolol treated conditioned medias including fatty acyls, sterols, and N-acylethanolamides. Current work seeks to explore the impact of epinephrine on sterol biosynthesis, determine if any identified lipid species is sufficient to drive HGSC cell invasion, and identify an upstream HGSC signal inducing epinephrine production in the adipocytes. Overall, we seek to expand our understanding of signaling critical in colonization of the omental metastatic niche and the role of the epinephrine therein.

#3469 A novel mTORC2 signaling pathway defines the pro-metastatic invadopodia network in urothelial carcinoma.

Donna Elizabeth Hansel, Jianya Huan, Francis Anthony San Lucas

UT MD Anderson Cancer Center, Houston, TX

BackgroundUrothelial carcinoma (UC), the most common form of bladder cancer, remains a leading cause of cancer-related mortality worldwide. UC outcomes are driven primarily by stage and grade of the tumor, with highlyinvasive and metastatic tumors showing significantly reduced treatment outcomes. Despite ongoing research,mechanisms that define this behavior in UC remain poorly understood. Our laboratory has identifiedmammalian target of rapamycin complex 2 (mTORC2) as a key regulator of invasive behavior in UC and anassociation between increased mTORC2 activity and higher UC stage.
MethodsGene and protein analyses were performed using Gene Set Enrichment Analysis (GSEA) andphosphoproteomic profiling. Immunohistochemistry and multi-Immunol fluorescence (mIF) assays were used todetermine expression and co-localization of proteins within invadopodia. Targeting of pathway componentswas performed using RNA silencing and inhibitor application, with functional outputs assayed using gelatindegradation assay, transwell invasion, and cell migration assessments.
ResultsOur study identified that mTORC2 can interact with TKS5α, an invadopodial scaffold protein, through putativemTOR phosphorylation. Furthermore, mTORC2 and TKS5α appear co-localize within cells and to the invasiveedge of tumors. Silencing of either mTORC2 or TKS5α results in similar phenotypes in cell invasion and matrixdegradation. Analysis of the Cancer Genome Atlas UC cohort showed high TKS5α expression was associatedwith reduced survival, and GSEA analysis showed PI3K/AKT/mTOR signaling was significantly enriched intumors with high TKS5α expression. These findings suggest that mTORC2 may promote pro-invasive andpro-metastatic activities through invadopodia formation and via a novel, and actionable, signaling cascade thatincludes TKS5α.
SummaryOur studies support a critical role for mTORC2 in driving invasion and metastasis in UC, as demonstrated byboth in vitro and human bladder cancer sample analysis. The study introduces a previously unrecognizedsignaling axis involving mTORC2 and TKS5α in invadopodia formation and metastasis in UC. The results fromthese studies have the potential to define a novel signaling axis in UC invadopodia that broadens ourmechanistic understanding of bladder

#3470 The role of LAP1 isoform balance in regulating nuclear plasticity during confined cancer cell migration.

Alicja Katarzyna Skwara[1], Victoria Sanz-Moreno[2], Jeremy G. Carlton[3]

[1]Cancer Research UK London Research Inst., London, United Kingdom,[2]ICR, London, United Kingdom,[3]King's College London, London, United Kingdom

Metastasis, which accounts for the majority of cancer-related deaths, requires cells to squeeze through narrow extracellular spaces, where the stiffness of the nucleus becomes a major physical barrier. This nuclear deformability is largely governed by nuclear envelope (NE) proteins, including lamina-associated polypeptide 1 (LAP1). LAP1, encoded by *TOR1AIP1*, exists as two isoforms generated from alternative translation start sites: the longer LAP1B, which binds tightly to the nuclear lamina and stabilizes the nucleus, and the shorter LAP1C, which interacts more loosely and promotes nuclear flexibility. Transcriptomic profiling of patient-derived melanoma cell line pairs revealed elevated LAP1 expression in more metastatic cells, with a higher LAP1C:LAP1B ratio associated with increased migratory potential.To dissect the functional consequences of this ratio, we generated stable melanoma cell lines overexpressing mRuby-tagged LAP1B, LAP1C, or wild-type LAP1 via retroviral transduction. Expression and localization were confirmed by immunofluorescence and Western blotting. We then assessed cell motility using transwell migration assays to mimic the mechanical constraints of tissue invasion. We demonstrated that LAP1C overexpression significantly enhanced migration, while LAP1B reduced it, without affecting nuclear morphology or actomyosin contractility. These findings suggest that LAP1 directly regulates nuclear plasticity to enable movement through confined environments.Preliminary data indicate that cellular stress can alter the LAP1C:LAP1B ratio, suggesting that isoform switching may be a regulated adaptive mechanism. This suggests that changes in the tumour microenvironment such as metabolic stress could influence nuclear mechanics through differential LAP1 expression.Strikingly, we found that primary immune and leukemia cells exclusively express the shorter LAP1C isoform, implying that the absence of LAP1B may facilitate their rapid amoeboid migration through dense tissues. Future work will explore how LAP1 isoform regulation supports leukemia cell motility in confined migration, providing broader insight into how nuclear envelope composition shapes cancer cell invasiveness.

#3471 Double-pillar co-culture (DPC) platform for evaluating cancer invasion and immunotherapy efficacy.

Seung Joon Kim[1], Sung Jae Chang[2], Sang-Yun Lee[3], Sang Hyo Kim[2], Bosung Ku[4], Dong Woo Lee[2]

[1]The Catholic University of Korea, Seoul, Korea, Republic of,[2]Gachon University, Seongnam-si, Korea, Republic of,[3]Chungnam National University, Daejeon, Korea, Republic of,[4]Medical & Bio Decision (MBD) Co., Ltd, Suwon-si, Korea, Republic of

Background: Co-culture is an essential in vitro technique for evaluating cancer invasion and immunotherapy efficacy, as tumor-stroma and tumor-immune interactions critically influence cancer progression and therapeutic response. Conventional assays, such as Transwell-based migration or invasion systems, are limited because they cannot simultaneously quantify cell invasion and viability, reducing physiological relevance. To address this, we developed a double-pillar co-culture (DPC) platform enabling high-throughput screening while culturing two distinct cell types in a spatially defined 3D architecture. Cancer cells embedded in Matrigel are seeded onto a central pillar to form a 3D tumor-like spot, while stromal cells, including fibroblasts or immune cells, are embedded in Matrigel on an outer, slightly lower pillar surrounding the core. This configuration allows direct visualization of invasion from the central mass and concurrent monitoring of cell viability.
Methods: A549 lung cancer cells and stromal cells (fibroblasts or lymphocytes) were co-cultured using the DPC platform. For drug screening, compounds including immune checkpoint-targeting drugs were applied to assess their effects on invasion and viability. To evaluate immune cytotoxicity, A549 cells were stabilized in the central pillar for three days, followed by addition of Jurkat cells to the outer pillar at a 1:5 ratio and co-cultured for an extended period. Invasion and viability were quantified using live-cell imaging and fluorescence-based assays and compared to monoculture or vehicle-treated controls.
Results: Co-culture of A549 cells with fibroblasts increased invasion over time. High-throughput screening using multiple compounds showed inhibitory effects on cancer cell invasion. Among them, the EGFR inhibitor Dacomitinib reduced invasion by <40% while maintaining >95% viability, demonstrating anti-invasive activity independent of cytotoxicity. Co-culture with Jurkat cells decreased cancer cell viability by ~55% compared to monoculture, confirming significant immune-mediated cytotoxicity.
Conclusions: The DPC platform provides a physiologically relevant, high-throughput system for simultaneous assessment of cancer invasion and immune cytotoxicity. It enables identification of compounds with selective anti-invasive effects and evaluation of immunotherapy efficacy, offering a versatile tool for preclinical cancer research.

#3472 Targeting a novel secreted protein to modulate MMP activity and restrain lung adenocarcinoma metastasis.

Chi-Ya Shen[1], Wen-Hsin Chang[2], Fan-Ni Hsing[1], Yi-Jing Hsiao[3], Yu-Wen Liao[1], Kang-Yi Su[1], Yu-Ju Chen[3], Ching-Ying Kuo[1], Sung-Liang Yu[1]

[1]Department of Clinical Laboratory Sciences and Medical Biotechnology, College of Medicine, National Taiwan University, Taipei, Taiwan,[2]Graduate Institute of Medical Science, College of Medicine, Taipei Medical University, Taipei, Taiwan,[3]Institute of Chemistry, Academia Sinica, Taipei, Taiwan

Metastasis remains one of the major causes of mortality in lung adenocarcinoma, whereas effective therapies to prevent tumor dissemination remain limited. In our study, we identified complement 1q and tumor necrosis factor-related protein 7 (C1QTNF7), a poorly characterized and dysregulated protein in lung adenocarcinoma, as a potential regulator of metastatic progression. Across six independent proteomic cohorts, we observed a consistent downregulation of C1QTNF7 in tumor tissues compared with paired normal tissues adjacent to the tumor (NAT). Lung adenocarcinoma patients with higher C1QTNF7 expression exhibited earlier-stage disease, better pathological differentiation, and prolonged survival, suggesting that C1QTNF7 may exert a biological function beyond serving as a prognostic marker. Transcriptomic profiling revealed that C1QTNF7-low tumors were enriched for metastasis-related signatures. In contrast, overexpression of C1QTNF7 in cell models significantly suppressed these pathways. Functional assays validated that C1QTNF7 suppressed cell migration and invasion *in vitro*, and further restrained metastatic growth in mouse orthotopic models. Subsequent analysis revealed that matrix metalloproteinases (MMPs), including MMP1, MMP9, and MMP15, were negatively regulated by C1QTNF7 at both the expression and activity levels. Notably, this suppression was consistent across clinical samples and cell models, suggesting that these MMPs may act as key downstream effectors modulating the anti-invasive function of C1QTNF7. Treatment with conditioned medium or recombinant C1QTNF7 protein recapitulated the anti-invasive effects, indicating an extracellular, receptor-mediated mechanism. Furthermore, experiments using the truncated mutant protein demonstrated that the C1q globular domain primarily mediates this activity. Together, our findings unveil C1QTNF7 as a novel secreted protein with potent anti-metastatic activity in lung adenocarcinoma. By suppressing MMP-driven invasion, C1QTNF7 contributes to a favorable clinical outcome. Given its secretory nature and functional domain specificity, C1QTNF7 represents a promising therapeutic candidate for targeting tumor metastasis in lung adenocarcinoma.

#3473 Hypoxia reveals a polyaneuploid cancer cell phenotype with features implicated in tumor escape and early metastasis.

Noreen Hosny[1], Shengkai Li[2], Sarah R. Amend[3], Arwa Abdelshafy[1], Robert A. Gatenby[4], Kenneth J. Pienta[3], Joel Brown[4], Junle Qu[5], Robert H. Austin[2]

[1]Department of Molecular Biology, Princeton University, Princeton, NJ,[2]Department of Physics, Princeton University, Princeton, NJ,[3]Johns Hopkins School of Medicine, Baltimore, MD,[4]Moffitt Cancer Center, Tampa, FL,[5]Shenzhen University, Shenzhen, China

Ten million people die every year globally due to metastasis, as metastatic disease remains largely incurable with existing therapies. Polyaneuploid cancer cells (PACCs), which are large, endoreplicated cells that arise in response to environmental stressors, have recently been shown to possess an increased capacity for metastatic behavior. Prior studies have enriched for PACCs using high doses of chemotherapy and have demonstrated their altered nutrient-sensing capabilities, yet the dynamics of PACCs within a native, tumor-like hypoxic microenvironment remain poorly defined.

In this study, we use our previously established *in vitro* membrane-based culture system that allows cancer cells to self-generate physiologically relevant oxygen gradients. Prostate cancer cells rest beneath an acrylic plug and consume the limited oxygen available directly beneath it, while oxygen diffuses inward from the plug periphery to generate a stable radial gradient. This is coupled with a phosphorescent oxygen-sensing film, whose signal increases in the absence of oxygen, enabling real-time spatial visualization and quantification of hypoxia.

Prostate cancer-derived PACCs emerged in response to the hypoxic stress and were identified in real time using morphology-based criteria (≥1500 μm^2 area and ≥3-fold growth over 16 hours). Similar to previous reports in normoxia, long-term single-cell tracking under hypoxia revealed that PACCs exhibited significantly greater net displacement than non-PACCs, suggesting a heightened capacity to invade surrounding tissue during metastatic progression. PACCs also demonstrated a stronger directional bias toward higher oxygen regions within the gradient. This aerotactic behavior suggests two possible roles in PACC dynamics: (1) escape from severely hypoxic tumor regions for survival, and (2) migration toward oxygen-rich vasculature for intravasation during metastasis. Preliminary work in ovarian cancer cells demonstrates similarly enhanced motility of PACCs, suggesting that this phenotype may extend beyond prostate cancer.

Altogether, these findings suggest that hypoxia shapes a PACC phenotype with enhanced motility and oxygen-directed migration, which may confer increased metastatic potential. Future work will incorporate hanging-drop tumor spheroids in this system to enable 3D modeling of hypoxic PACC behavior and determine whether aerotaxis facilitates outward migration toward oxygen-rich regions.

#3474 Effect of Piezo1 activation and CYRI-B loss in melanoma cell membrane dynamics.

Advait Raja, Sayantika Ghosh, Laura Machesky

Department of Biochemistry, Sanger Building, 80 Tennis Court Road, University of Cambridge, Cambridge, United Kingdom

Background

Cancer cell migration is a critical step in metastasis, driven by cytoskeletal remodelling in response to extracellular mechanical cues. Piezo1, a mechanosensitive ion channel, has been known to promote cell motility through calcium-dependent activation of actin-regulatory pathways. In parallel, CYRI-B acts as a local inhibitor of lamellipodial protrusion by binding Rac1 to prevent activation of the Scar/WAVE complex. However, whether these two pathways interact to regulate cancer cell motility remains unexplored.

Methods

Using B16F1 mouse melanoma cells, we investigated how Piezo1 activation (via the small molecule agonist Yoda1) and CYRI-B knockout influence collective cell migration and membrane fluctuations during cell spreading. Scratch-wound healing assays quantified collective migration, and phase-contract live-cell imaging with kymograph analysis assessed spreading and protrusion behaviour in both wild-type and CYRI-B knockout cells with and without treatment with Yoda1.

Results

Piezo1 activation significantly increased collective cell migration by approximately 35%, cell area by approximately 30%, and membrane fluctuations by approximately two-fold in wild-type cells. However, none of these changes were observed after Piezo1 activation in CYRI-B knockout cells. Kymograph analysis showed that protrusion length increased along with protrusion angle after Piezo1 activation in the presence of CYRI-B. However, these increases were also not observed in CYRI-B knockout cells.

Conclusion

Our findings show that CYRI-B may influence the Piezo1-mediated increase in cancer cell migration and membrane dynamics. This raises the possibility of a previously unrecognized connection between mechanosensitive Piezo1 activation and CYRI-B-mediated membrane fluctuations, adding a new dimension to membrane dynamics in cancer cell motility and spreading.

#3475 Pseudopodia coordinate environmental sensing with nuclear signaling through localized gene regulatory machinery.

Kourosh Kouhmareh[1], Thi Hoa Le[1], Richard L. Klemke[2]

[1]UC San Diego School of Medicine, La Jolla, CA,[2]UCSD Moores Cancer Center, La Jolla, CA

Cells dynamically extend membrane protrusions known as pseudopodia to explore their local microenvironment, facilitating interactions with neighboring cells and extracellular matrix (ECM) components. These structures are implicated in regulating fundamental cellular processes, including migration, differentiation, proliferation, and mechanotransduction. While pseudopodia have long been proposed to function as sensory organelles that relay external cues to the nucleus, the molecular mechanisms underlying this spatial signaling remain incompletely understood. Here, we utilized a microporous membrane-based purification strategy that enables the selective isolation of pseudopodia in response to chemotactic gradients. Using paired transcriptomic and proteomic profiling, we compared isolated pseudopodia and their corresponding cell bodies from highly migratory cells. We identify a distinct enrichment of nuclear transport proteins, RNA splicing enzymes, chromatin remodelers, and components of the translational machinery within pseudopodia, supporting a model in which these structures act as early relay sites for gene regulatory signaling. Extending these findings to human cancer, we applied a pseudopodia-specific gene signature to single-cell RNA sequencing datasets from primary breast, bladder, and pancreatic tumors. Malignant epithelial cells highly enriched for our pseudopodium-associated gene set exhibited coordinated upregulation of chromatin remodeling, intracellular signaling and transport, ECM adhesion, and RNA regulatory pathways, mirroring the protrusion-associated programs identified *in vitro*. Collectively, our findings establish pseudopodia as spatially compartmentalized signaling hubs that couple environmental sensing to chromatin regulation and transcriptional reprogramming. This work uncovers a previously unappreciated mechanism by which cellular architecture directs gene expression changes relevant to both normal physiology and disease.

#3476 Bioenergetic pathways regulate distinct patterns of invasion and matrix remodeling in breast cancer cells upon YAP/TAZ activation.

Adil Khan, Haider Abbas Ali, Bishant Karki, **Jacopo Ferruzzi**

University of Texas at Dallas, Richardson, TX

Breast cancer invasion relies on complex interactions between intracellular signals and microenvironmental factors. Central to this process are the transcription factors YAP and TAZ, two key regulators of the Hippo signaling pathway. YAP/TAZ respond to mechanical and metabolic cues by translocating to the nucleus, where they regulate genetic programs that promote tumor progression. Within the tumor milieu, extracellular matrix (ECM) densification, alignment, and altered cell metabolism modulate the invasive phenotype of breast tumors. However, the role of YAP/TAZ activation in regulating ECM mechanics and cancer cell metabolism during invasion remains poorly understood. To address this gap, we utilized breast cancer spheroids to investigate how inhibition of either glycolysis or oxidative phosphorylation (OxPhos) influences invasion dynamics and ECM remodeling under inducible YAP/TAZ activation. MCF-10A breast cancer epithelial cells and doxycycline inducible nuclear mutants MCF-10A YAP(5SA) and TAZ(4SA) were used to generate spheroids and to conduct invasion assays in 3D collagen I. Control MCF-10A spheroids exhibited limited ECM remodeling and invaded collectively. In contrast, YAP/TAZ-activated spheroids displayed increased proliferation and invaded aggressively through a combination of collective protrusions and single cell migration. Structural and mechanical changes in collagen were monitored using 3D Magnetic Twisting Rheometry, a novel technique to assess heterogeneous stiffening of the tumor microenvironment. We found that YAP/TAZ activated spheroids aligned peritumoral collagen radially and stiffened the matrix. A Seahorse assay revealed that TAZ activation upregulates both glycolysis and OxPhos, while YAP activation primarily increases glycolysis. To explore metabolic heterogeneities during invasion, we used Fluorescence Lifetime Imaging Microscopy (FLIM) of the metabolic cofactor NAD(P)H. FLIM showed that, upon YAP/TAZ activation, the spheroid core exhibited an optical signature consistent with glycolysis, while the periphery adopted a mix of glycolysis and OxPhos. Pharmacological inhibition of metabolic pathways further elucidated the role of metabolism in spheroid invasion. In control spheroids, inhibiting either glycolysis or OxPhos hindered invasion. In contrast, in YAP/TAZ activated spheroids, inhibition of OxPhos shifted invasion from collective to single cell modality. Conversely, inhibition of glycolysis reduced single cell migration, shifting invasion towards collective migration. Taken together, our findings suggest that YAP/TAZ activation confers metabolic adaptability to invading spheroids, highlighting the crucial role of YAP/TAZ-mediated metabolic reprogramming in regulating breast cancer cell invasion modalities, as well as the associated changes in contractility and ECM remodeling.

#3477 Multi-scale modeling to predict cancer cell mechanics and migration based on transcriptional state and microenvironment.

Esra Tiftik Karabay[1], Stephanie I. Fraley[2], Parag Katira[1]

[1]Mechanical Engineering, San Diego State University, San Diego, CA,[2]Bioengineering, University of California, San Diego, San Diego, CA

Cancer is a disease characterized by increasing heterogeneity as it progresses. Single-cell RNA sequencing has shed light on the variety of states that cancer cells can adopt, but connecting transcriptional signatures to functional outcomes remains a major challenge. Here, we have taken a multi-scale modeling approach to connect heterogeneous cytoskeletal gene expression programs exhibited by breast cancer cells to biochemical signaling networks and extracellular matrix conditions that regulate the cellular mechanical state. Our model, G-BoHyM-3D, comprises three key components: transcriptomic data, Boolean-Hybrid-Modular Model (BoHyM), and 3D stochastic cell simulations. We identified multiple signaling nodes that connect various extracellular and gene expression signals to key cytoskeletal proteins. The signaling network is solved using a Boolean Hybrid Modular (BoHyM) approach specifically developed to deal with the distinct timescales and complexities of biochemical signaling processes. This integrated framework predicted differences in cell migration behavior of MDA-MB-231 breast cancer cells based on single-cell transcriptional differences. Further development will offer a versatile and user-modifiable tool for investigating how both extracellular and intracellular signaling mechanisms regulate cellular cytoskeleton components, which in turn influence cell-substrate interactions, force generation, invasion, migration, and emergent phenomena such as collective rotational and invasive cell migration.

#3478 The role of *Shroom3* downstream of Wnt/planar cell polarity signaling in breast cancer cell migration.

Julie A. Learn[1], Kacey VanderVorst[1], Kwabena A. Badu-Nkansah[2], Kermit L. Carraway[1], Sean R. Collins[2]

[1]Biochemistry and Molecular Medicine, University of California, Davis, Davis, CA,[2]Microbiology and Molecular Genetics, University of California, Davis, Davis, CA

The 5-year survival rate for patients diagnosed with metastatic breast cancer (BC) remains below 30%, highlighting the need to better understand the molecular mechanisms driving BC metastasis in order to reveal novel opportunities for therapeutic intervention. Wnt/planar cell polarity (Wnt/PCP) is a non-canonical Wnt signaling pathway that regulates epithelial tissue organization and cell migration during embryonic development. Core Wnt/PCP components are upregulated in more aggressive BCs, and their expression is associated with poor patient outcomes. Our group has demonstrated a role for Wnt/PCP in promoting BC cell dissemination; however, the mechanistic details linking core Wnt/PCP components to downstream actin cytoskeletal rearrangements that drive migration and invasion are not well understood. We therefore performed a phosphoproteomics screen using MDA-MB-231 triple negative BC cells to identify proteins differentially phosphorylated in response to pathway activation by the non-canonical Wnt ligand Wnt5a. Among the proteins identified was Shroom3 (Shrm3), in which two serine residues were significantly phosphorylated in response to Wnt5a treatment. Shrm3 is an F-actin-binding scaffolding protein known to recruit Rho kinase (ROCK), actin, and myosin to the apex of apically constricting cells to drive tissue morphogenesis during development and has previously been shown to function downstream of the Wnt/PCP pathway and to bind the effector Dvl2. Given its described functions, Shrm3 is a promising candidate to serve as a direct link between core Wnt/PCP components and the actin cytoskeleton. Knockdown (KD) of Shrm3 reduces both basal and Wnt/PCP-mediated BC cell migration, as well as the formation of actin-rich protrusions at the leading edge of migrating cells. Live-cell imaging confirms reduced lamellipodia formation and reveals that Shrm3 KD cell protrusions are shorter-lived, retract more quickly, and are less polarized to the leading edge. Additionally, loss of Shrm3 reduces activation of myosin light chain and myosin recruitment to the leading edge of BC cells. Co-localization of Shrm3, ROCK, and core Wnt/PCP component Vangl1 is observed at migratory protrusions, and we also observe Shrm3 localizing to focal adhesions (FAs). Loss of Shrm3 reduces FA number and size and may reduce cell–substrate adhesion. Whether phosphorylation of Shrm3 downstream of Wnt/PCP activation regulates these functions is currently under investigation. Based on these findings, we suggest a model in which core Wnt/PCP components recruit Shrm3 to the leading edge of migrating BC cells, where Shrm3 recruits ROCK, actin, and myosin to promote properly localized contractility that supports lamellipodia stabilization and focal adhesion maturation.

#3479 Estrogen promotes structural memory in breast cancer.

Makena Manes, Samantha Hill, Robert Shaw, Yanqing Zhu, Marco Padilla-Rodriguez, Ghassan Mouneimne

Univ. of Arizona, Tucson, AZ

Mechanobiology investigates how cells sense and respond to physical cues such as stiffness, tension, and shear that shape cytoskeletal architecture, transcriptional programs, and cell behavior. In breast tumors, matrix stiffening and altered tensile forces strongly influence invasion and metastatic potential, and recent data show that invasive estrogen receptor (ER) positive tumors are unexpectedly stiffer and exhibit sharper stiffness gradients than ER-negative disease. Mechanical inputs remodel cytoskeletal and adhesion networks and activate signaling pathways that stabilize long-term behaviors, giving rise to mechanical memory. Although mechanical memory has been linked to durotaxis and poor outcomes, how estrogen intersects with stiffness to establish these structural states remains unclear. Here, we show that estrogen signaling directly enhances structural mechanical memory in breast cancer cells. Estrogen reorganizes focal adhesions and cortical actin architecture in a stiffness-dependent manner, increasing mechanosensing, traction generation, and durotactic migration on stiff substrates while stabilizing suppressive cortical actin bundles on soft substrates. These mechanically encoded states persist even after cells leave their original environment, and their magnitude correlates with estrogen receptor activity, aligning with emerging evidence that ER-positive tumors with strong stiffness-response signatures have worse clinical outcomes and show selective benefit from antifibrotic therapy. Together, these findings reveal that estrogen does not simply modulate gene expression but actively shapes the mechanical states that sustain invasion, identifying hormone-mechanics interactions as tractable targets for limiting progression in ER-positive breast cancer.

#3480 The HER2Δ16 splice variant fuels breast cancer metastasis through integrin-driven signaling.

Guillaume de Lhoneux, Jonathan Boucher, Genevieve Lavoie, Laure Voisin, Marc K. Saba-El-Leil, Sylvain Meloche, Philippe P. Roux

Institute for Research in Immunology and Cancer (IRIC), Montreal, QC, Canada

The HER2Δ16 splice variant, generated by exclusion of exon 16 from *ERBB2*, is frequently detected in aggressive HER2-positive breast tumors and has been linked to enhanced tumorigenicity and therapy resistance. Unlike full-length HER2, HER2Δ16 forms constitutively active homodimers, yet the mechanisms driving its aggressive behavior remain poorly defined.

Using isogenic models expressing full-length HER2 or HER2Δ16, we integrated cell surface proteomics with transcriptomic profiling to identify pathways uniquely altered by the splice variant. HER2Δ16 expression induced a wide range of cell-surface changes, including a striking enrichment of RGD-binding integrins. This remodeling was validated in HER2-positive patient tumors stratified for high *versus* low HER2Δ16 expression. HER2Δ16 cells displayed robust activation of the focal adhesion kinase (FAK) pathway and exhibited enhanced migration, invasion, and anchorage-independent growth. Functional perturbation studies demonstrated that HER2Δ16-driven aggressiveness requires integrin signaling. Integrin depletion or pharmacological inhibition of FAK significantly impaired motility, invasion, and growth in soft agar. *In vivo*, systemic FAK inhibition markedly reduced HER2Δ16 tumor growth and metastatic dissemination in immunodeficient mice, establishing integrin-FAK signaling as a therapeutic vulnerability associated with HER2Δ16 expression.

These findings identify integrin-FAK signaling as a central effector of HER2Δ16-induced metastasis and reveal a previously unrecognized mechanism by which this splice variant rewires the adhesion landscape to promote invasive progression. Targeting integrin-driven signaling may provide a promising strategy to counteract metastatic dissemination in HER2Δ16-positive breast cancer.

#3481 Investigating Frizzled7-driven regulation of Vangl1 in Wnt/PCP signaling in breast cancer.

Savannah R. Free, Kermit L. Carraway, Courtney Dreyer

Biochemistry and Molecular Medicine, UC Davis Medical Center, Sacramento, CA

Wnt/Planar Cell Polarity (Wnt/PCP) signaling is a non-canonical developmental pathway reactivated during tumorigenesis in many cancers, where it promotes tumor aggressiveness and correlates with poor prognosis (Hatakeyama et al., 2014). Vangl1, a transmembrane scaffolding protein specific to Wnt/PCP signaling, is an important site for assembly of protein complexes which drive cytoskeletal rearrangement at the leading edge of migratory cells, thereby supporting metastasis (Dreyer et al., 2023). Vangl1 interacts with the Wnt/PCP transmembrane receptor Frizzled7 both intercellularly—to promote polarity and establish epithelial organization—and intracellularly—to drive localized signaling events that promote migration. However, the regulatory relationship between Vangl1 and Frizzled7 is not fully understood.We recently found that Vangl1 undergoes a Frizzled7-dependent post-translational modification, evident from a mobility shift on SDS-PAGE upon Frizzled7 overexpression. Biochemical assays revealed this is a phosphorylation event that: (1) requires Vangl1's C-terminal PDZ-binding motif, (2) occurs independently of Wnt5a (the presumed Wnt/PCP ligand), and (3) persists despite mutation of two candidate phosphorylation sites—leaving the true sites undetermined.To identify key players and investigate functional consequences of this phosphorylation event, we performed Vangl1 immunoprecipitation-mass spectrometry (IP-MS) with and without Frizzled7 expression. The results identified several Vangl1 interactors, both known and novel, whose binding is altered by Frizzled7. These findings suggest that Frizzled7 may regulate Vangl1 function through phosphorylation-dependent modulation of its protein interactions and provide a foundation for future studies on how these interactions influence cancer cell migration and metastatic behavior.

#3482 NOVA1 regulates alternative splicing of CD44 to suppress breast cancer invasion and metastasis.

Jiefeng Huang, Hong Hu

Department of Breast Surgery, Shenzhen People's Hospital, Shenzhen, China

Background: Aberrant alternative splicing (AS) promotes breast cancer progression by enhancing cellular plasticity, invasion, and metastasis. NOVA1, a neuron-specific RNA-binding protein and splicing regulator, has been implicated in multiple diseases, but its role in breast cancer remains unclear.
Methods:NOVA1 expression and clinicopathologic relevance were analyzed using TCGA and GSEA datasets and validated in patient samples by RT-qPCR, Western blotting, and immunohistochemistry. Functional assays (wound healing, transwell invasion, and mouse metastasis models) were performed following NOVA1 overexpression or knockdown. Transcriptomic sequencing and AS analyses identified NOVA1-regulated splicing events, followed by validation and rescue experiments focusing on CD44 isoforms.
Results: Analysis of 89 paired primary breast carcinomas and matched adjacent normal tissues from the TCGA dataset revealed that NOVA1 is among the most differentially expressed splicing factors. NOVA1 expression was reduced in breast cancer and associated with favorable prognosis. NOVA1 overexpression inhibited migration, invasion, and metastasis and suppressed epithelial-mesenchymal transition (EMT). Transcriptome profiling indicated that NOVA1 regulates extracellular matrix organization and alternative splicing of *CD44*, leading to reduced expression of the pro-metastatic isoform CD44v6. Conversely, NOVA1 silencing increased CD44v6 expression and enhanced metastatic potential. Rosiglitazone treatment restored NOVA1 expression and reduced cancer cell invasiveness.
Conclusions:NOVA1 functions as a metastasis suppressor by repressing CD44v6-mediated EMT, establishing a novel NOVA1-CD44v6 splicing axis in breast cancer. Pharmacologic induction of NOVA1 may represent a promising strategy to limit metastatic progression.

#3483 LRRC15-Integrin β1 connection in osteosarcoma cells: Linking adhesion to invasion.

Sanjit Mukherjee[1], Wei-Dong Chen[1], Lisa M. Jenkins[2], Yuelin Zhu[1], Marbin Pineda[1], Robert Walker[1], Paul S. Meltzer[1]

[1]Molecular Genetics Section, Genetics Branch, Center for Cancer Research, National Cancer Institute, National Institutes of Health, Bethesda, MD,[2]Mass Spectrometry Section, Laboratory of Cell Biology, Center for Cancer Research, National Cancer, National Institutes of Health, Bethesda, MD

Osteosarcoma (OSA) is the most common primary bone cancer in children and adolescents, typically arising during rapid skeletal growth. A frequent feature of OSA is an osteoblastic phenotype with abnormal bone formation. Leucine-rich repeat containing 15 (LRRC15) is a cell-surface protein highly expressed in several solid tumors, particularly OSA. Our previous work identified LRRC15 as a key adhesion molecule regulating migration, invasion, and cell–extracellular matrix (ECM) interactions in OSA cells. Time-course single-cell transcriptomics of LRRC15 knockdown revealed dysregulation of several integrins. Integrins are αβ heterodimeric transmembrane receptors essential for cell–ECM adhesion and bidirectional signaling. The β1 subunit (ITGB1) is especially important in cancer, pairing with several α subunits to bind collagen, fibronectin, and laminin. LRRC15 depletion modestly reduced ITGB1 at both gene and protein levels. Collagen-binding integrins (ITGA1, ITGA10) and RGD-binding integrins (ITGAV, ITGB5) were similarly downregulated. Given the overlap between pathways affected by LRRC15 loss and integrin biology, we hypothesized that LRRC15 and ITGB1 may functionally interact to regulate OSA cell adhesion and migration.

We generated CRISPR-Cas9 knockouts (KO) of LRRC15 and ITGB1 in OSA cell lines. Both LRRC15 and ITGB1 KO cells exhibited comparable defects in proliferation, migration, and spheroid invasion, suggesting a strong functional connection between these molecules. Quantitative mass spectrometry and western blots demonstrated decreased LRRC15 expression in ITGB1 KO cells, and reduced ITGB1 expression in LRRC15 KO cells. Notably, rescue of LRRC15 in KO cells resulted in elevated ITGB1 expression. Furthermore, to detect physical interaction, we performed immunoprecipitation with LRRC15 using extracts from parental and LRRC15 KO cells, followed by immunoblotting with an ITGB1 antibody. A significantly lower ITGB1 signal was detected in LRRC15 KO cells. Similarly, when immunoprecipitation was performed with an ITGB1 antibody and detected by immunoblotting with an LRRC15 antibody, we observed reduced LRRC15 expression in ITGB1 KO cells. These findings indicate that ITGB1 and LRRC15 may physically interact with each other. Taken together, our findings indicate that LRRC15 may modulate integrin-mediated adhesion and signaling in OSA. Specifically, the interaction between LRRC15 and integrin β1 appears critical for maintaining integrin-dependent pathways that drive cell proliferation, migration, and invasion. Further mechanistic studies will be required to delineate the molecular basis of this interaction and its contribution to tumor progression and metastasis

#3486 Elucidating the role of ecDNA in treatment resistance and immune evasion within pediatric medulloblastoma.

Meenakshi Singhal[1], Joy Ku[1], Kun Wang[2], Rohit Bhargava[3]

[1]Carle Illinois College of Medicine, Urbana, IL,[2]Department of Comparative Biosciences, University of Illinois, Urbana-Champaign, Urbana, IL,[3]Department of Bioengineering, University of Illinois at Urbana-Champaign, Urbana, IL

PurposeExtrachromosomal DNA (ecDNA) has been identified as a key driver of cancer evolution and poor clinical prognosis, with emerging research describing its utility for risk stratification. Coupled with current investigations in immunotherapy-based strategies for pediatric medulloblastoma (MBL), we conducted a data-driven pathway analysis to elicit the mechanisms by which ecDNA oncogenes might be implicated in disease pathogenesis. These insights could inform robust molecular subtyping for improved understanding and outcomes in MBL.
IntroductionThere are four major molecular subtypes of MBL: WNT, G4, SHH, and G3, in order of best to worst prognosis. While greater ecDNA counts have been reported to be associated with worse outcomes, we qualitatively evaluated the pathways involved, with a focus on immune evasion and drug resistance. Within the Childhood Cancer Data Initiative (CCDI) database, oncogenes amplified on ecDNA are denoted as either canonical or non-canonical, with the former referring to established drivers of malignant transformation through dysregulated pathways in apoptosis, cell proliferation, etc. Compared to these well-established direct drivers of oncogenesis, we hypothesized that “non-canonical” oncogenes may serve as an undertapped source of pharmacological insights.
MethodsPatient cohorts were generated using the CCDI database by filtering MBL subclasses for cases with both available survival data and ecDNA presence: SHH (n=33 patients; 787 unique genes on ecDNA); G3 (n=19; 161); G4 (n=25; 291); WNT (n=0; 0). Genes identified in more than three patients per subtype were selected for our pathway analysis.
ResultsWhile ecDNA genes were often related to cell cycle dynamics and adhesion proteins, a primarily non-canonical subset is involved in immune dysregulation through various mechanisms. For SHH patients, GLI2 (n=6 patients) upregulates Wnt signaling, reducing natural killer (NK) and CD8+ T cell activity. In G3 patients, both RAD21 and UTP23 (n=3) are implicated in immune evasion, the former by inhibiting interferon signaling and CD8+ T cell function and the latter through reduced dendritic cell activity. In the G4 subclass, NBAS (n=5) is associated with reduced NK cell function and immunodeficiency disorders, while high CDK6 (n=4) is correlated with T cell suppression. Meanwhile, FZD1 (n=4) promotes Wnt signaling-based chemoresistance, and FAM49A (n=3) is a negative regulator of T cell activation. Although these genes have been previously shown to confer worse prognosis across other cancer types, their role in mediating MBL outcomes has not been established.
ConclusionThere are no approved immunotherapeutic strategies for pediatric MBL, despite evidence of immunomodulatory mechanisms. Our preliminary computational results provide guidance to developing ecDNA screenings that could inform personalized therapies and redefine the standard of care.

#3487 XPO1 as a therapeutic vulnerability in atypical teratoid rhabdoid tumors.

Tessa O. House[1], Irina Alimova[2], Shawna Larsen[1], Gillian Murdock[2], Angela Pierce[2], Breauna Brunt[2], Stefania Tocci[1], Sofia Krykunenko[1], Marissa Coppola[1], Anat Erdreich-Epstein[1], Ron Firestein[3], Natalie Serkova[4], Rajeev Vibhakar[2], **Jessica W. Tsai**[1]

[1]Children's Hospital Los Angeles, Los Angeles, CA,[2]The Morgan Adams Foundation Pediatric Brain Tumor Research Program, Children's Hospital Colorado, Aurora, CO,[3]Hudson Institute of Medical Research, Clayton, Australia,[4]Radiology, University of Colorado Anschutz Medical Campus, Aurora, CO

Background: Atypical teratoid rhabdoid tumor (ATRT) is an aggressive central nervous system tumor that mostly affects infants and children under the age of 3. While there have been some improvements in clinical outcomes with multimodal therapy, there remains significant morbidity and toxicities associated with intensive therapy. Therefore, there is a dire need for less toxic and improved therapies for children with ATRT. The identification of cancer dependencies can be utilized to determine novel therapeutic approaches. We identified exportin-1 (XPO1), a nuclear export protein that transports cargo proteins from the nucleus to the cytoplasm, as a novel dependency in ATRT. In other cancers, elevated XPO1 expression has been associated with poor prognosis.

Methods: We utilized an integrative approach harnessing *in vitro* ATRT models, functional genomics, drug assays, flow cytometry, transcriptomics, and *in vivo* intracranial xenograft models to systematically test the hypothesis that XPO1 is a therapeutic vulnerability in ATRT.

Results: RNA-sequencing data across pediatric brain tumor cell lines reveals that XPO1 is highly expressed in ATRT cells. We utilized CRIPSR-Cas9 to knockout XPO1 expression in a panel of patient-derived ATRT cells and found significant defects in cell viability and proliferation. Pharmacologic inhibition of XPO1 using six different selective inhibitors of nuclear export (SINEs) in multiple ATRT cell lines showed sub-10 nM IC50 values. We found that XPO1 inhibition led to on target degradation of XPO1 protein levels. In ATRT cells treated with an XPO1 inhibitor selinexor, Annexin V flow cytometry showed increased apoptosis relative to DMSO. In addition, ATRT cells treated with selinexor demonstrated G1 cell cycle arrest. Western blotting revealed a significant increase in cleaved caspase-3 levels and activation of TP53 with pharmacologic XPO1 inhibition. Transcriptomic analysis of ATRT cells with genetic and pharmacologic inhibition of XPO1 showed significant upregulation of apoptosis and TP53 signaling pathways, with concurrent depletion of cell cycle gene sets. Lastly, using *in vivo* intracranial xenograft models, the combination of selinexor with radiation and cyclophosphamide led to a reduction of tumor size and significant increase in animal survival.

Conclusion: We demonstrate that XPO1 is a dependency in ATRT, and targeting XPO1 in combination with cytotoxic chemotherapy shows high translational potential.

#3488 Advancing pediatric tumor subtype classification on the pediatric cancer (PeCan) knowledge base by integrating molecular and morphology data.

Stephanie Sandor[1], Delaram Rahbarinia[1], Yuan Feng[1], Ramzi Alsallaq[1], Van L. Nguyen[1], Daniel K. Putnam[1], David Finkelstein[1], Jinman Park[1], Bo Wang[1], Jobin Sunny[1], Jian Wang[1], Sue Qiu[1], Michael Edmonson[1], Robert Greenhalgh[1], Meghann Kirk[1], Ira Baranova[1], Stephen V. Rice[1], Abbas Shirinifard[2], Hoaran Chen[2], Ali F. Pour[2], Clay McLeod[1], Lu Wang[3], Jeffery Klco[3], Brent Orr[3], Michael Dyer[2], Xiang Chen[1], Xiaotu Ma[1], Michael Rusch[1], Jinghui Zhang[1]

[1]Computational Biology, St. Jude Children's Research Hospital, Memphis, TN,[2]Developmental Neurobiology, St. Jude Children's Research Hospital, Memphis, TN,[3]Pathology, St. Jude Children's Research Hospital, Memphis, TN

Recent advances in multi-omics profiling have accelerated the discovery of molecular targets in pediatric cancers. However, clinical interpretation remains constrained by evolving diagnostic standards and limited representation of rare subtypes. To address this, we developed the Cancer Classifications for Kids (CC4K) - a harmonized, molecular classification-driven framework aligned with WHO tumor classification and recent publication standards for pediatric tumors. Using pathogenic variant data hosted on St. Jude Cloud PeCan Knowledge Base (https://pecan.stjude.cloud), we classified 230 subtypes for hematological malignancies (n=70), solid tumors (n=97), and brain tumors (n=63). Most recently, the pathogenic point mutations, CNVs, and gene fusions from ~1,511 paired tumor-normal samples, profiled by the ongoing NCI's Childhood Cancer Data Initiative (CCDI), were integrated into PeCan, extending the subtype repertoire by ~53% (80 new subtypes). Importantly, classification of additional subtypes required aligning molecular data with clinical features, which revealed 16 evidence categories, including "biomarker-confirmed" (n=440) and "rescued" (n=353). Furthermore, the integration of additional multi-modal approaches provided clarity on existing classifications with ambiguous or conflicting data. For example, integrating the data from the Molecular Characterization Initiative (MCI) improved our definition of several previously ambiguous cases including a small round blue cell tumor redefined as Ewing sarcoma following identification of a novel *EWSR1::FUS* reciprocal fusion event, reclassification of an ependymoma as intracranial mesenchymal tumor, *FET::CREB*-fusion positive, and validation of an atypical *NRAS*-positive alveolar rhabdomyosarcoma. Additionally, the integration of CCDI data fine-tuned our knowledgebase on the therapy-relevant molecular drivers such as activation of the Hedgehog signaling pathway in embryonal rhabdomyosarcoma and activation of the PI-3K pathway by recurrent *AKT* hotspot mutations in multiple cancer types. Distribution of tumor mutation burdens from each cancer subtype revealed hypermutators with distinct etiologies as identified through subsequent mutational signature analyses. Collectively, these results demonstrate the importance of a harmonized framework for systematic cross-cohort integration that advances diagnostic precision through molecular-pathologic consensus, helps unravel the complex landscape of rare pediatric tumor subtypes, and lays the groundwork for future therapeutic and classification refinements across the pediatric oncology ecosystem.

#3489 EWSR1::WT1 fusion oncoprotein and the androgen receptor shape the biology of desmoplastic small round cell tumors.

Danh Truong[1], Emre Arslan[1], Veena Kochat[1], Jiaqian Fan[1], Diana Shamsutdinova[1], Davis Ingram[1], Kevin Murgas[1], Clement Agyemang[1], Roberto Cardenas-Zuniga[1], Asmaa G. Ahmed[1], Justin Magrath[2], Alexander Lazar[1], Najat Daw Bitar[1], Sean B. Lee[2], Andrea Hayes-Dixon[3], Kunal Rai[1], Joseph A. Ludwig[1]

[1]UT MD Anderson Cancer Center, Houston, TX,[2]Tulane University School of Medicine, New Orleans, LA,[3]Howard University, Washington, DC

Desmoplastic small round cell tumors (DSRCTs) are rare, aggressive sarcomas driven by the EWSR1::WT1 fusion oncoprotein (FP) and marked by poor long-term survival. Despite a relatively quiet genome with a single known oncogenic driver, DSRCTs display striking transcriptional heterogeneity and express markers from multiple lineages, epithelial, mesenchymal, myogenic, and neural. DSRCTs show a strong male predominance, suggesting a potential role for sex-specific regulatory mechanisms, including androgen receptor (AR) signaling. To investigate the molecular basis of this complexity, we generated a comprehensive, multi-modal atlas of DSRCT, integrating transcriptomic, epigenomic, and spatial omics data (10x Genomics). We focused on dissecting the regulatory architecture shaped by the EWSR1::WT1 fusion and transcription factors such as AR, aiming to uncover mechanisms of lineage specification and therapeutic vulnerabilities. We hypothesized that epigenetic regulation of the EWSR1::WT1 FP contributes to this lineage divergence. To explore FP activity, we found that neogenes (non-coding RNA FP targets) and known FP-regulated genes were more highly expressed in NE-lineage tumors, suggesting that FP affects lineage type. Spatial transcriptomic analysis revealed intratumoral heterogeneity, with distinct clusters of epithelial (AR+, cytokeratin+) and non-epithelial tumor cells. Despite phenotypic differences, all tumor cells expressed neogenes, as confirmed by RNA in situ hybridization (RNAScope). Epigenetic profiling showed enrichment of Forkhead TFs (FOXA1/2). FOXA2 was associated with NE, and AR/GRHL2 were associated with epithelial lineages. CUT&RUN analysis of AR after DHT stimulation revealed co-occupancy of FOXA1/2 and WT1 at AR-bound regions, suggesting interaction between AR signaling, FP, and FOXA1/2. FP knockdown in DSRCT cell lines induced a shift toward an epithelial-like state, increased FOXA1, and decreased FOXA2 expression. Tumor cells exhibit both inter- and intra-tumoral heterogeneity, adopting epithelial and NE phenotypes. We find that the high FP levels favor a NE-lineage state mediated by chromatin accessibility and transcriptional regulation. Spatial analyses revealed co-existing epithelial and non-epithelial tumor cells within the same nests, underscoring the intratumoral heterogeneity. The interaction between FP, AR, and Forkhead transcription factors (FOXA1/2) suggests a potential mechanism by which oncogenic FPs and lineage-defining transcription factors converge to regulate tumor phenotype.

#3490 Preservation and clonal behavior of extrachromosomal DNA in patient-derived xenograft models of childhood cancers.

Rishaan Kenkre[1], Jon D. Larson[1], Owen Chapman[2], Jens Luebeck[3], Yan Yeun Lo[1], Paul Megan[4], Wenshu Zhang[5], Vineet Bafna[3], Robert Wechsler-Reya[6], Lukas Chavez[1]

[1]Sanford Burnham Prebys Medical Discovery Institute, La Jolla, CA,[2]Department of Neuro-oncology, Nagoya City University Graduate School of Medical Sciences, Nagoya, Japan,[3]Department of Computer Science and Engineering, University of California San Diego, San Diego, CA,[4]Rady Children's Hospital, San Diego, CA,[5]University of California San Diego, San Diego, CA,[6]Department of Neurology, Columbia University Irving Medical Center, New York, NY

Background: Extrachromosomal DNA (ecDNA) is a class of structural variants linked to poor prognosis in pediatric cancers. Patient-derived xenograft (PDX) models are crucial tools for basic and translational cancer research, as they are believed to recapitulate the molecular features and intratumoral heterogeneity present in patient tumors. However, ecDNA demonstrates unique evolutionary dynamics under selective pressure, and the behavior of ecDNA during PDX model development and propagation remains largely uncharacterized. This study investigates the fidelity of PDX models in representing ecDNA from primary tumors. By analyzing ecDNA sequence composition and copy number conservation across a variety of pediatric solid cancers, we evaluate the extent to which PDX models recapitulate the ecDNA landscape observed in human tumors.

Methods: Amplicon Architect, a tool that reconstructs focally amplified DNA regions to understand cancer genome architecture, was used to analyze the whole-genome sequencing (WGS) of 338 PDX models and 127 corresponding primary tumors. ecDNA status, sequence, copy number, and associated genes were compared between PDX models and their matched human tumors. Additionally, multiome RNA and ATAC single-cell sequencing of a PDX tumor enabled comparison of ecDNA intratumoral heterogeneity relative to similar data previously obtained from the primary tumor.

Results: ecDNA in PDX models largely recapitulated the spectrum of oncogene amplifications observed in human tumors, with MYCN being the most frequently amplified. ecDNA status remained unchanged for a majority of the PDX models (106/127, 83%) compared to the primary tumors, with 20% of previously ecDNA-negative cases acquiring ecDNA during PDX development. Consequently, ecDNA was more prevalent in the PDX models than in their corresponding human tumors (McNemar's test, $p = 0.0014$). Detailed examination of ecDNA sequences in tumor-PDX pairs showed substantial conservation (67% with >90% sequence overlap) but variable breakpoint concordance. Single-cell analysis demonstrated that rare ecDNA-positive cells from the primary tumor preferentially drive PDX tumor development.

Conclusion: This study highlights the prevalence, oncogenic content, and conservation of ecDNA in PDX models relative to pediatric patient tumors. We observed that ecDNA frequently recapitulates oncogene amplifications found in human cancers, is generally preserved during PDX establishment, and reflects subtype-specific patterns across tumor types. These findings support the utility of PDX models in studying ecDNA biology and their implications for the study of pediatric cancer progression and treatment. Longitudinal sampling during PDX tumor growth and under therapeutic pressure could provide valuable insights into the dynamics of molecular evolution, clonal selection, and ecDNA-driven therapy resistance.

#3491 Epigenetic regulation of the RAB5B GTPase expression in B-cell acute lymphoblastic leukemia.

Katarina Dovat, Yali Ding, Daniel Bogush, Rabab Husain, Ryan Chingakham, Dhimant Desai, Sinisa Dovat

Penn State College of Medicine, Hershey, PA

Ras analog in brain (Rab) proteins are important parts of small GTPase signaling pathways in human malignancies. RAB5B is the GTPase, which promotes cellular proliferation and is overexpressed in a large number of human cancers, including leukemia. Regulation of RAB5B transcription in human hematological malignancies is mostly unknown. Here, we analyze regulation of RAB5B transcription in human B-cell acute lymphoblastic leukemia (B-ALL). The use of global chromatin immunoprecipitation coupled with next generation sequencing (ChIP-seq), showed increased occupancy of IKAROS tumor suppressor protein at the promoter of RAB5B gene in several B-ALL cell lines and primary B-ALL cells. IKAROS direct binding to promoter of RAB5B was confirmed by quantitative chromatin immunoprecipitation (qChIP). The role of IKAROS in transcriptional regulation of RAB5BB in B-ALL was assessed by gain-of-function and loss-of-function experiments. Luciferase reporter assay showed that IKAROS directly represses transcription of RAB5B. Overexpression of IKAROS in B-ALL cells via retroviral transduction resulted in increased IKAROS binding to the RAB5B promoter and decreased RAB5B transcription. This was associated with enrichment in constitutive heterochromatin marker, H3K9me3 and the loss of active chromatin markers, H3K4me3 and H3K27ac. In contrast, shRNA-mediated knockdown of IKAROS inhibited IKAROS binding to the RAB5B promoter and resulted in increased RAB5B expression, along with increased enrichment of H3K4me3 and H3K27ac active chromatin markers, and the loss of H3K9me3 marker at RAB5B promoter. Primary B-ALL cells that carry deletion of one IKAROS allele have increased expression of RAB5B, associated with strong enrichment of H3K4me3 and H3K27ac, as well as the absence of H3K9me3 at RAB5B promoter. In conclusion, presented data suggest that IKAROS functions as a direct transcriptional repressor of RAB5B in B-ALL and that the mechanism of RAB5B repression by IKAROS involves formation of heterochromatin at the RAB5B promoter. Results uncovered a novel mechanism through which IKAROS exerts its tumor suppressor effect and regulate transcription and cellular proliferation in leukemia. Supported by NIH/NCI R01 CA278226 grant.

#3492 Targeting ALKBH5 mediated ChREBP signaling impairs cancer stem cell metabolism and tumor growth in medulloblastoma.

Panneerdoss Subbarayalu[1], Daisy Medina[1], Prabhakar Pitta Venkata[1], Shahad Abdulsahib[1], Saif Nirzhor[1], Santosh Timilsina[1], Deepika Singh[1], Phat Do[1], Desiree Denman[1], Krishna Priya Evani[2], Dhiya Billa[3], Meera Nair[1], Esha Reddy[4], Yogesh Gupta[1], Peter Houghton[1], Yidong Chen[1], Suryavathi Viswanadhapalli[1], Gangadhara R. Sareddy[1], Andrew Brenner[1], Ratna K. Vadlamudi[1], Manjeet Rao[1]

[1]UT Health San Antonio, San Antonio, TX,[2]UT San Antonio, San Antonio, TX,[3]Trinity University, San Antonio, TX,[4]Southern Methodist University, Dallas, TX

Background: Medulloblastoma (MB) is the most common malignant pediatric brain tumor and a major cause of childhood cancer mortality. It comprises four molecular subgroups: WNT, SHH, Group 3, and Group 4. Group 3 MB, often marked by c-MYC amplification, has the worst prognosis. Despite surgery, radiation, and chemotherapy, high-risk patients face low 5-year survival and frequent relapse. Current treatments cause severe side effects. Cancer stem cells (CSCs) drive MB aggressiveness, therapy resistance, and recurrence. This project aims to uncover mechanisms sustaining CSCs and MB progression.
Methods: MB cell lines (HD-MB03, D556, D425, DAOY) with ALKBH5 overexpression, knockdown (siRNA), or knockout (CRISPR), along with controls, were analyzed using viability, migration, invasion, colony formation, cell cycle, and apoptosis assays. RNA sequencing identified ALKBH5-regulated genes, validated by RT-qPCR, western blot, and RNA immunoprecipitation. An orthotopic intracranial xenograft model assessed ALKBH5's tumor-promoting role in vivo.
Results: To explore the role of m6A RNA methylation in medulloblastoma (MB), we silenced key regulators (writers: METTL3, METTL14; erasers: ALKBH5, FTO) in MB cell lines. ALKBH5 depletion caused the greatest reduction in proliferation, suggesting its therapeutic potential. Analysis of pediatric cancer datasets and tissue microarrays confirmed ALKBH5 overexpression and amplification in MB. Knockdown of ALKBH5 increased global m6A levels and reduced MB cell viability, migration, invasion, and stemness (medullosphere formation and NANOG, OCT4, SOX9 expression). Apoptosis assays showed elevated Annexin V-positive cells, and in vivo studies demonstrated suppressed tumor growth in orthotopic xenografts. ALKBH5 loss also increased DNA damage markers (γH2AX, 53BP1). RNA-seq and IPA revealed downregulation of genes involved in glycolysis, lipogenesis, and c-MYC targets, including ChREBP. Western blot confirmed decreased protein levels in these pathways.
Conclusion: ALKBH5 is a critical regulator of MB tumorigenesis and CSC maintenance via m6A RNA demethylation. Targeting ALKBH5 may offer a promising therapeutic strategy to inhibit MB progression, overcome therapy resistance, and improve outcomes for high-risk MB patients.

#3493 UltraFast whole genome sequencing enables personalized treatments in childhood cancers.

Aditi Vedi[1], Jamie Trotman[2], Joao Dias[1], Martina Mijuskovic[3], Sera Choi[3], Laura Kingham[2], Rachel Moore[4], Sarah M. Leiter[1], Rowena Guermech[2], Amanda Semerene[2], Aviva Grisby[2], Sophie Wool[2], Victoria Joslin[2], Zoya Kingsbury[3], Mark Ross[3], David Bentley[5], Sam Behjati[1], Sean Humphray[3], Patrick Tarpey[4], David Rowitch[1]

[1]University of Cambridge, Cambridge, United Kingdom,[2]Cambridge University Hospitals NHS Foundation Trust, Cambridge, United Kingdom,[3]Illumina Inc, Cambridge, United Kingdom,[4]National Health Services (England), Leeds, United Kingdom,[5]Solexa, Inc. (Illumina Cambridge), Essex, United Kingdom

Background: Whole genome sequencing (WGS) improves childhood cancer management by detecting clinically actionable variants beyond the scope of standard assays. However, current turnaround times (TAT) are well beyond clinical decision-making windows. We developed a novel 'Ultra-Fast Whole Genome Sequencing' (UF-WGS) technology to deliver comprehensive genomic results within days, and evaluated its feasibility, accuracy, and clinical impact in real-world pediatric hematology/oncology.**Methods:** Children with suspected or confirmed malignancy in Cambridge were recruited between 2023–2025. Tumor, bone marrow, and/or blood samples were analysed with UF-WGS and standard genomic medicine service (GMS-WGS) concurrently. UF-WGS deploys Constellation mapped read technology, eliminating library preparation by applying crude lysate or DNA directly onto the flowcell surface providing enhanced genome coverage, variant calling and phasing. Variant calls and TAT were benchmarked against GMS-WGS. Only clinically actionable variants as per the UK national genomics test directory were reported. Clinical utility was assessed by multidisciplinary review.**Results:** Fifty-four patients representing the expected range of childhood malignancies were recruited. UF-WGS reduced mean TAT of clinically actionable WGS reports from 37 to 3 days. It recalled 95% of somatic and germline variants and detected 19 additional variants, leading to alterations in clinical management. Discrepancies were due to tissue heterogeneity or low variant allele frequency. Median sequencing depth of UF-WGS (137× tumor; 84× germline) was superior to GMS-WGS (97x tumor; 42x germline).UF-WGS enabled demonstrable clinical benefit including risk stratification, target identification and pharmacogenomic guidance in 18/35 (51%) of prospectively recruited patients. UF-WGS supported de-escalation of therapy, earlier initiation of targeted treatments and optimization of surgical timing. For one patient, rapid identification of a germline *ACVR1* mutation allowed a diagnosis of fibrodysplasia ossificans progressiva, avoiding harmful interventions. In 9/19 (47%) retrospective cases, independent reviewers judged that real-time UF-WGS would have improved management.UF-WGS was particularly advantageous in leukemia, where tumor-only analysis avoided delays associated with obtaining germline DNA. The clinical value of delivering comprehensive cytogenetic, minimal residual disease, and pharmacogenomic data within 72 hours is particularly great in this disease setting. **Conclusions:** UF-WGS is feasible, accurate and clinically impactful in pediatric cancer, delivering real-time WGS to inform management decisions. It offers a scalable framework to consolidate multiple molecular assays into a single, rapid test, supporting ambitions for faster genomic diagnosis and equitable precision medicine delivery internationally.

#3494 Epigenetic landscape and gene regulation in embryonal brain tumors with multilayered rosettes.

Shanzheng Wang[1], Sander Lambo[1], Monika Mauermann[1], Phylicia Stathi[2], Robert Autry[1], Natalie Jager[1], Stefan M. Pfister[1], Marcel Kool[1]

[1]Hopp Children's Cancer Center Heidelberg (KiTZ), Heidelberg, Germany,[2]Princess Maxima Center for Pediatric Oncology, Utrecht, Netherlands

Embryonal tumors with multilayered rosettes (ETMRs) are relatively rare but highly aggressive pediatric brain tumors that mainly affect children under four years of age and are generally associated with poor clinical outcomes. Around 90% of ETMRs harbor amplification of the chromosome 19 miRNA cluster (*C19MC*), in most cases fused to the *TTHY1* gene. The second most recurrent aberration, present in about half of the *C19MC*-negative cases, are bi-allelic mutations in *DICER1*. *C19MC* amplification and positive LIN28A immunostaining are key diagnostic markers for ETMRs. ETMRs also exhibited a distinct DNA methylation profile compared with other embryonal brain tumors such as medulloblastomas (MBs) and atypical teratoid/rhabdoid tumors (ATRTs). However, the detailed epigenetic landscape defined by DNA methylation and histone modifications, its effects on transcriptional regulation in ETMRs, and how these associations differ from MBs, ATRTs, and normal brain tissues remain largely unexplored.

To decode the ETMR epigenome, we generated, collected, and integrated whole genome bisulfite sequencing (WGBS), chromatin immunoprecipitation sequencing (ChIP-seq) of various histone marks and epigenetic regulators, RNA sequencing (RNA-seq), and ribosome profiling (Ribo-seq) data from a series of ETMRs, similar data from a series of MBs and ATRTs covering all molecular subtypes, and normal brain tissues for comparison reasons.

Through integrative multi-omics analyses, we delineated chromatin states and DNA methylation-defined genomic segments of ETMRs for the first time. ETMR genomes are globally hypomethylated, with wider distributions of unmethylated regions (UMRs) and DNA methylation valleys (DMVs) on its genome compared with MBs, ATRTs, and normal brain tissues. These regions are associated with genes involved in embryonal brain development, essential cellular processes, and oncogenic pathways. Low methylated regions (LMRs) are enriched for transcription factor binding motifs such as CTCF and SOX2, and also act as potential enhancers that modulate several transcriptional and epigenetic regulators. Partially methylated domains are correlated with transcriptional repression in ETMRs, consistent with observations in other biological systems. Moreover, TET enzymes are highly expressed in ETMRs, potentially regulated by BET family proteins such as BRD4. Pharmacological inhibition of TETs and BRDs reduced ETMR cell viability.

In summary, our study provides a comprehensive epigenetic landscape of ETMR and its relationship to transcriptional regulation, revealing distinct regulatory mechanisms that enhance understanding of ETMR biology, and identifying potential therapeutic targets for experimental and preclinical validations in this lethal tumor type.

#3495 Characterizing the MYC-induced immunopeptidome.

Jack Faulkner, Anwesha Dasgupta, John R. Prensner

University of Michigan, Ann Arbor, MI

Medulloblastoma, the most common malignant brain tumor typically found in children ages 0-9, comprises four subgroups, each with distinct molecular characteristics. Children with MYC or MYCN amplifications, which occur in Group 3 and Sonic Hedgehog subgroups, respectively, face poor survival rates and high metastasis. MYC and MYCN, both DNA-binding transcription factors, drive oncogenesis by promoting rapid cell division. This study investigates how MYC(N) upregulation stimulates the production of immunogenic neoantigens from non-canonical peptides, which may serve as novel targets for immunotherapy. Prior work shows post-transcriptional control is a critical component of MYC biology, with Group 3 tumors exhibiting significant protein-RNA dyssynchrony. Intriguingly, MYC preferentially drives the translation of upstream open reading frames (uORFs), which are non-canonical peptides that are largely unstable but exhibit robust presentation on the MHC-I antigen system.To test this, we engineered UW228 and ONS76 medulloblastoma cell lines to express MYC or MYCN cDNAs using GFP as a control and verified overexpression via western blotting and qPCR. We assessed HLA-I protein uniformity via flow cytometry. Ribosome and RNA sequencing were used to identify actively translated genomic regions and mRNA transcript levels. HLA-I immunopeptidomics was completed to identify non-canonical peptides with increased surface presence due to MYC(N) expression.We successfully verified MYC(N) overexpression and demonstrated the required HLA-I expression for immunopeptidomic analysis. The sequencing data confirmed that MYC(N) drives the translation of specific non-canonical peptides uORFs, showing increased immunopeptidome complexity in high-risk medulloblastoma models. These results are broadly supportive of MYC(N)'s role in driving the flux of non-productive peptides.Completion of this research will identify novel antigens linked to MYC(N), offering critical information for the development of medulloblastoma-specific immunotherapies to improve outcomes for affected patients. Future research will investigate MYC(N)’s impact on proteasome function and the BAG6 complex, which is responsible for regulating proteasomal degradation of non-canonical translation products. Pathway analyses will also be conducted to compare gene family expression and identify upregulated and downregulated biological functions.

#3496 Epigenetic repurposing by CBFA2T3-GLIS2 reveals a druggable DNA methylation axis in high-risk pediatric AML vulnerability in pediatric AML.

Samrat Roy Choudhury[1], Arundhati Chavan[1], Rhonda E. Ries[2], Giselle Almeida Gonzalez[1], Soheil Meshinchi[2], Jason E. Farrar[1]

[1]Arkansas Children's Research Institute, University of Arkansas for Medical Sciences, Little Rock, AR,[2]Translational Science and Therapeutics Division, Fred Hutchinson Cancer Center, Seattle, WA

The CBFA2T3-GLIS2 (C/G) fusion defines an infant-restricted, clinically devastating subtype of pediatric AML with relapse rates exceeding 90%. While C/G is known to remodel the enhancer landscape, the epigenetic mechanisms that sustain leukemic identity and enforce apoptotic resistance remain undefined.To resolve this, we performed integrative multi-omic epigenetic profiling across primary patient samples, C/G$^+$ AML lines, and a developmentally faithful cord blood CD34$^+$ HSPC model. Genome-wide DNAm mapping (meEM-seq), chromatin profiling (CUT&RUN, ATAC-seq), and transcriptomics uncovered a promoter-biased hypermethylation program unique to C/G$^+$ AML, with ~50% of altered CpGs localized to promoters ($\Delta\beta \geq 0.2$ vs NBM). Despite unaltered global 5mC levels, C/G bound and transcriptionally activated DNMT3B, which imposed focal promoter hypermethylation specifically at transcriptionally active, enhancer-connected loci. Strikingly, these hypermethylated promoters did not silence gene expression; instead, they stabilized expression of CRE-linked genes enriched for apoptotic regulation, EMT, KRAS signaling, and heme metabolism—revealing that C/G converts DNA methylation into a stabilizing rather than repressive epigenetic signal.CRISPR-mediated DNMT3B knockout validated this mechanism: DNMT3B loss reduced locus-specific 5mC and downregulated C/G-dependent targets but induced compensatory DNMT1 and UHRF1 upregulation, forming a maintenance shunt that preserved DNAm at apoptotic effector loci and sustained an elevated apoptotic threshold. Targeted dCas9-TET1 demethylation of the pro-apoptotic gene PMAIP1 (NOXA) restored transcriptional inducibility and apoptotic signaling, directly confirming that DNAm constrains activation of death pathways. In vivo, DNMT3B-deficient xenografts regained Venetoclax sensitivity and extended survival, phenocopying DNMT inhibition and validating the therapeutic relevance of this epigenetic axis. Collectively, these findings establish C/G as a developmental epigenetic architect that repurposes DNA methylation to stabilize oncogenic transcriptional circuits and maintain apoptosis resistance. By defining the C/G-DNMT3B-DNMT1/UHRF1 axis and its enhancer-linked promoter hypermethylation signature, this work identifies aberrant DNAm as a structural and druggable vulnerability, providing the mechanistic rationale for integrating DNMT inhibition with BCL-2 blockade in high-risk pediatric AML.

#3497 Comprehensive analysis of genomic landscape of ultra-rare pediatric malignant rhabdoid tumors.

Elizabeth Rasmussen[1], Elena Mironova[1], Dias Kurmashev[1], Kendra Maa?[2], Stefanie Volz[3], Zhao Lai[1], Stefan M. Pfister[2], Yidong Chen[1], Raushan Kurmasheva[1]

[1]UT San Antonio Greehey Children's Cancer Res. Inst., San Antonio, TX,[2]Hopp Children's Cancer Center Heidelberg (KiTZ), Heidelberg, Germany,[3]Division of Pediatric Neurooncology, German Cancer Consortium (DKTK) and German Cancer Research Center (DKFZ), Heidelberg, Germany

Malignant rhabdoid tumors (MRTs) are ultra-rare, highly aggressive pediatric tumors that occur predominantly in infants, with the highest incidence in children under one year of age. MRTs exhibit high metastatic potential and poor prognosis, with 5-year event-free survival rates below 20%. There are currently no effective therapies for these patients. To better elucidate the molecular mechanisms driving MRT and identify potential therapeutic vulnerabilities, we constructed a comprehensive genomic landscape of 16 MRT xenograft models using whole-genome sequencing (WGS), transcriptome profiling (RNAseq), and DNA methylation analysis (EM-seq), representing intracranial (AT/RT; n=6), extracranial (RTK; n=5), and soft tissue subtypes (n=5). This work builds on our previous studies investigating the *in-vivo* activity of the combination of the PARP1 inhibitor, PEGylated talazoparib (PEG~TLZ), and the DNA alkalyating agent, temozolomide (TMZ), in MRTs, as well as the associated transcriptional changes underlying therapeutic response. WGS analysis revealed recurrent mutations in *TP53*, *BRCA1*, and *BRCA2* genes across tumors, regardless of tumor demographics. All 16 MRT tumors harbored *SMARCB1* alterations, including single-nucleotide variants, whole or partial gene deletion, and/or loss of heterozygosity (LOH). Consistently, LOH was confirmed in 15 of 16 tumors. Differential expression analyses identified elevated activity of Receptor Tyrosine Kinase (RTK), Ephrin, and Epidermal Growth Factor Receptor (EGFR) signaling pathways in good responders (maintained/complete response) compared with poor responders (partial response or progressive disease) across treatment groups (PEG~TLZ, TMZ, and the combination), as reported previously. RNAseq further detected several gene fusions, one of which was experimentally validated. Supervised clustering of EM-seq data revealed a characteristic binary methylation pattern independent of tissue origin. Differential methylation analysis of promoter CpG islands identified 5 genes exhibiting a strong inverse correlation between DNA methylation and mRNA expression, highlighting potential therapeutic targets whose activity may be modulated *via* epigenetic mechanisms. Overall, our comprehensive multi-omics characterization of these ultra-rare MRTs establishes a foundational and enduring resource for the pediatric cancer research community. By providing deeply annotated genomic, transcriptomic, and epigenomic profiles across diverse MRT subtypes, this dataset will support long-term mechanistic studies, enable identification of therapeutic vulnerabilities, and help guide the development of future clinical strategies for this highly aggressive pediatric cancer.

#3498 Improving the utility of the single-cell pediatric cancer atlas through updated cell type annotations, CNV inference, and visualization tools.

Allegra G. Hawkins[1], Joshua A. Shapiro[1], Stephanie J. Spielman[1], David S. Mejia[1], Deepashree Venkatesh Prasad[1], Nozomi Ichihara[1], Arkadii Yakovets[1], Avrohom M. Gottlieb[1], Kurt G. Wheeler[2], Chante J. Bethell[3], Steven M. Foltz[4], Jennifer O'Malley[1], Casey S. Greene[5], Jaclyn N. Taroni[1]

[1]Alex's Lemonade Stand Foundation, Bala Cynwyd, PA,[2]Reify Health, Boston, MA,[3]The University of Texas MD Anderson Cancer Center, Houston, TX,[4]Multiple Myeloma Research Foundation, Boston, MA,[5]University of Colorado Anschutz Medical Campus, Aurora, CO

The Single-cell Pediatric Cancer Atlas (ScPCA) Portal (https://scpca.alexslemonade.org/), developed and maintained by the Childhood Cancer Data Lab, is a data resource for uniformly processed single-cell and single-nuclei RNA sequencing data, as well as de-identified metadata from pediatric tumor samples. Originally comprised of data from 10 projects funded by Alex's Lemonade Stand Foundation (ALSF), the Portal currently contains summarized gene expression data for over 700 samples across more than 50 cancer types drawn from ALSF-funded and community-contributed datasets. Downloads include gene expression data as SingleCellExperiment or AnnData objects containing raw and normalized counts, PCA and UMAP coordinates, and summary reports. Some samples have additional data from bulk RNA-seq, spatial transcriptomics, and/or feature barcoding (e.g., CITE-seq and cell hashing) included in the download. All data on the Portal were uniformly processed using scpca-nf, an efficient and open-source Nextflow workflow written and maintained by the Data Lab, which utilizes alevin-fry to quantify gene expression.

Since presenting the ScPCA Portal at the 2024 AACR Annual Meeting, several new features have been added to the available data. Automated cell type annotation is now performed using three unique methods: SingleR, CellAssign, and SCimilarity. If two of the three methods agree, an ontology-aware consensus cell type label is assigned. The individual annotations and the consensus cell types are included in the cell metadata of the downloaded objects. Some projects also include manually-curated cell type annotations generated as part of the OpenScPCA project (https://openscpca.readthedocs.io).

In addition, copy-number variation (CNV) inference is now performed on each sample using the InferCNV package, specifying the i6 HMM to quantify specific CNV events. Since InferCNV quantifies CNV events using a designated set of normal, or non-malignant, reference cells, consensus cell types are used to identify a diagnosis-appropriate normal cell reference for each sample. The total CNVs observed and the full HMM metadata table are stored in the processed SingleCellExperiment and AnnData objects. The updated cell type annotation and implementation of InferCNV are included as part of the open-source workflow, scpca-nf. The workflow and associated documentation are freely available at https://github.com/AlexsLemonade/scpca-nf.

Finally, the ScPCA Portal hosts an instance of the UCSC Cell Browser, enabling users to visualize and interact with the gene expression data for all samples without needing to download the data. Comprehensive documentation about data processing and the contents of files on the portal, including a guide to getting started working with an ScPCA dataset, can be found at https://scpca.readthedocs.io.

#3499 BRD9 functions as a negative regulator of GBAF in synovial sarcoma.

Jinxiu Li[1], Mary Nelson[1], Li Li[1], Xiaobo Xia[2], Christine Stephan[2], Katarzyna Modzelewska[1], Gary Yu[2], Iain Mulford[2], Honnappa Srinivas[2], Xinyi Ge[1], Sarah McCollum[1], Ewin R Jones[1], Yixuan Guo[1], Xi Chen[2], Thomas Zoller[2], Gregory Hollingworth[2], Ensar Halilovic[3], Tinya J. Abrams[4], Edmund Harrington[2], Sofia Gkountela[5], Giorgio Galli[5], Hans Voshol[6], Nathalie Carte[2], Jason Thomas[2], Xiaoyang Zhang[7], David Lum[7], Martin Hirst[8], Jeffery Yap[7], William Forrester[2], Bradley R. Cairns[7], Kevin Bruce Jones[7]

[1]University of Utah, Salt Lake City, UT,[2]Novartis Biomedical Research, Cambridge, MA,[3]Oncology Translational Medicine, Novartis Insts. for BioMedical Research, Cambridge, MA,[4]Novartis (Cambridge, MA), Acton, MA,[5]Novartis Institutes for Biomedical Research, Basel, Switzerland,[6]Novartis Biomedical Research, Basel, Switzerland,[7]University of Utah Huntsman Cancer Institute, Salt Lake City, UT,[8]Canada's Michael Smith Genome Sciences Centre, Vancouver, BC, Canada

Synovial sarcoma (SyS) incorporates the SS18::SSX fusion oncoprotein into GLTSCR1-containing BRG1/BRM and associated factors (GBAF) complexes, and demonstrated a dependency on GBAF subunit, BRD9. However, SyS clinical trials with multiple BRD9 degraders failed to achieve clinically impactful remissions. Here, we provide a mechanistic framework to explain these results. BRD9 depletion serves to blunt proliferation in SySs harboring minimal genomic alterations, rare in trial participants. In cultured cells, xenografts, and recombinant purified complexes, BRD9 loss does not impact GBAF assembly. Although BRD9 degradation in SyS reduces GBAF enrichment at target loci, BRD9-less complexes maintain or increase chromatin accessibility and associated gene transcription. Biochemical assays with purified recombinant GBAF demonstrate markedly increased nucleosome sliding in the absence of BRD9. Thus, BRD9 restrains GBAF activity, with BRD9 degradation increasing enzymatic remodeling and target gene expression by fusion oncoprotein-distributed GBAFs in SyS. This subtle epigenetic disturbance creates a low hurdle for SyS to surpass.

#3500 Synergistic targeting of EP300/CBP and EYA co-activators collapses the rhabdomyosarcoma core regulatory circuit.

Annika Gustafson[1], Stephanie Nance[2], Berkley Gryder[3], Noha A. Shendy[2], Lars Wick[1], Grace McKay-Corkum[2], K. Elaine Ritter[2], Stephen Connor Purdy[1], Arthur R. Wolin[1], Sheera R. [1]University of Colorado Anschutz, Anschutz, CO,[2]St. Jude Children's Research Hospital, Memphis, TN,[3]Case Western Reserve University School of Medicine, Cleveland, OH,[4]Massachusetts General Hospital, Boston, MA,[5]Dana-Farber Cancer Institute, Boston, MA,[6]University of Colorado Boulder, Boulder, CO,[7]Broad Institute of MIT and Harvard, Cambridge, MA,[8]Emory University, Atlanta, GA,[9]Koch Inst. for Integrative Cancer Research at MIT, Cambridge, MA,[10]National Cancer Institute, Bethesda, MD,[11]University of Minnesota, Minneapolis, MN,[12]MGH/Harvard Medical School, Stoneham, MA

Rhabdomyosarcoma (RMS) is a high-risk and lethal pediatric sarcoma that resembles developing skeletal muscle. RMS tumors have low mutation burdens, but these scant mutations often alter genes involved in transcriptional control. Transcriptional dysregulation is critical to RMS pathogenesis, supported by studies in both RMS tumors carrying mutationally derived chimeric transcription factors (“fusion positive (FP)”), or those without (“fusion negative” (FN)). However, mechanisms to selectively target dysregulated transcription in RMS remain outstanding. Here, we develop a novel approach targeting RMS transcription comprising simultaneous targeting of two distinctly acting transcriptional co-activators. We discover a common cell identity-controlling pan-RMS core regulatory circuit (CRC) composed of oncogenic and lineage-specific myogenic master transcription factors (mTFs). These mTFs are regulated by super-enhancers, and they co-bind genome-wide to control the malignant transcriptome of both FP- and FN-RMS. Using a super-enhancer-based reporter screen, we identify the EP300/CBP inhibitor A485 as a potent inhibitor of the pan-RMS CRC, though efficacy of this compound was limited by toxicity. To enhance on-target specificity, we identify the protein EYA2 as a co-factor that binds directly to SIX1, a member of the pan-RMS CRC and exploit a recently developed second-generation EYA1/2 tyrosine phosphatase inhibitor, LG1-34, to inactivate its function. While A485 and LG1-34 independently reduce mTF transcription and drive RMS cell death, in combination, these agents function synergistically to reduce RMS growth in vitro and in vivo. These results demonstrate that combined targeting of enhancer maintenance and CRC cofactors is a powerful strategy to suppress the RMS transcriptome and enforce RMS cell death.

#3501 A critical dependency in Ewing sarcoma: PAX7 attenuates EWS::FLI1 activity at de novo microsatellite enhancers to maintain oncogenesis.

Caroline Fraser, Alex Belt, Andrew McFadden, Ian Davis

UNC Lineberger Comprehensive Cancer Center, Chapel Hill, NC

The pediatric cancer Ewing sarcoma is driven by the fusion oncoprotein EWS::FLI1, which retains the DNA-binding domain of FLI1. Rather than canonical ETS sites, EWS::FLI1 is retargeted to GGAA-microsatellite loci, where it remodels chromatin to establish de novo enhancer elements that drive oncogenic transcription. Because EWS::FLI1 lacks intrinsic chromatin-remodeling activity, it depends on recruited proteins to regulate chromatin. Furthermore, precise regulation of EWS::FLI1 activity is critical: both over and under expression of EWS::FLI1 result in cell cycle arrest. However, mechanisms of EWS::FLI1 regulation at non-canonical GGAA-mSats remain unknown. We used a proximity-labelling proteomic approach to identify EWS::FLI1-associated proteins in a native chromatin context. We discovered that the myogenic transcription factor PAX7 selectively interacts with EWS::FLI1 but not wild-type FLI1. PAX7 silencing impaired cell proliferation, indicating an essential role. We found that *PAX7* is itself a direct target gene of EWS::FLI1, associated with high, ubiquitous PAX7 expression in EwS tumors. Mechanistically, EWS::FLI1 drives the relocalization of PAX7 to GGAA-mSats and ETS-sites, where PAX7 modulates chromatin accessibility and attenuates EWS::FLI1-driven transcription. At GGAA-mSats, PAX7 depletion results in chromatin opening, whereas at ETS sites, chromatin accessibility is deregulated. PAX7 depletion results in and an exaggerated EWS::FLI1 transcriptional response. Mutational analysis of PAX7 revealed that its Paired DNA binding domain and OAR-domain are required for interaction with EWS::FLI1 and that interaction between the two transcription factors is required for cell proliferation. These findings define PAX7 as a context-specific regulator of EWS::FLI1 activity at non-canonical GGAA-microsatellite enhancers and identify a previously unrecognized vulnerability in Ewing sarcoma that could be exploited for future therapeutic intervention.

#3502 Loss of histone 3 lysine 9 trimethylation drives recurrence in high-risk pediatric medulloblastoma.

John DeSisto, Andrew M. Donson, Bethany Veo, Rajeev Vibhakar

The University of Colorado School of Medicine, Aurora, CO

Background: Pediatric Group 3 medulloblastoma (G3 MB) recurs in more than 40% of cases. Initial treatment typically includes surgical resection followed by craniospinal irradiation (RT) and chemotherapy with cisplatin and cyclophosphamide. Recurrent G3 MB is usually metastatic, has poor long-term survival, and no survival-altering treatment. Treatment of recurrent G3 MB impacts only a portion of tumor cells, or worse, may facilitate the emergence of treatment resistant cell clones. G3 MB's cells of origin correspond to neural stem or progenitor cells that originate early in normal development. This suggests that pluripotency genes whose expression is normally epigenetically silenced are reactivated in G3 MB oncogenesis and recurrence. Histone 3 post-translational modifications, particularly trimethylation of histone 3 lysine 9 (H3K9me3), silence expression of pluripotency genes when no longer needed during development. We hypothesize that loss of H3K9me3 at key pluripotency genes facilitates G3 MB recurrence. **Methods:** To model recurrence, we developed treatment-resistant cell lines, tumoroids and orthotopic patient-derived xenograft (PDX) mouse models of G3 MB. Using single cell RNA-Seq and multiomics we analyzed gene accessibility and expression changes between primary-recurrent patient sample pairs. To define cell and tumor micro-environment changes during recurrence, we conducted spatial transcriptomics of primary-recurrent patient sample pairs using a customized gene list. **Results:** Analysis of primary-recurrent patient sample pairs revealed that most cell types are conserved during recurrence, mesenchymal cells begin to outnumber angiogenic populations, hypoxic populations increase, and neural stemlike cells replace progenitor-like populations. Treatment of G3 MB cells with near-IC_{50} levels of cisplatin or RT + cisplatin produces a treatment resistant / recurrent phenotype with enriched DNA repair capability, enriched MAPK and autophagy pathways, and depleted p53 activity. Cisplatin + cyclophosphamide treatment of mice with PDX tumors extends survival but ultimately results in aggressive treatment resistant tumors with divergent stemlike populations as compared to the primary tumors. Expression of *SETDB1,* a demethylase (DM) that removes H3K9me3, decreased upon G3 MB recurrence, while expression of *EHMT2*, a methyltransferase (MT) that places H3K9me2, increased. Similar trends were not observed in non-G3 MB samples. **Conclusions and ongoing work:** H3K9 MT and DM alterations suggest the loss of H3K9me3 leads to emergence of pluripotent gene expression during G3 MB recurrence. We are analyzing CUT & RUN data to verify whether H3K9me3 occupancy is altered through changes in expression of H3K9 MTs and DMs. Longer term, we plan to evaluate whether inhibiting the loss of H3K9me3 diminishes the frequency or severity of recurrence in G3 MB models.

#3503 Somatic changes in Y chromosome copy number are associated with clinical and molecular features in neuroblastoma.

Teodoro Rivera-Wills, Preshita Dave, Esther Rheinbay

Mass General Cancer Center, Boston, MA

Introduction: Neuroblastoma survival is decreased in males, and loss of the Y chromosome (LOY) has been recently shown to affect cancer incidence, survival, and response to therapy in certain tumor types; therefore, we set out to test whether LOY is linked to clinical and molecular features in neuroblastoma.
Methods: Using publicly available allele-specific copy number from next-generation sequencing of neuroblastoma (Korber et al. 2023), we identified areas of duplication or deletion in regions of the Y chromosome. Y chromosome copy number was compared to molecular and clinical variables.
Results: There were 64 tumors from male patients in the cohort, of whom 15 (23.4%) had loss of the Y chromosome and 12 (18.8%) had duplication of the Y chromosome. There was a significant survival advantage in patients with duplications of the Y chromosome, while there was no difference in survival in patients with LOY compared to wild type. We also tested whether LOY is associated with specific molecular features in neuroblastoma. We found that 17q gain ($p=0.01$) and 11q loss ($p<0.001$) were strongly associated with LOY, while MYCN amplification ($p=0.003$) was inversely associated. We also found a significant association with Alternative Lengthening of Telomeres ($p<0.001$).
Conclusions: Our analysis shows that there are significant associations between LOY and specific molecular mechanisms in pediatric neuroblastoma. While we did not observe an association between LOY and survival, we did detect improved survival in patients with a gain of Y. This observation may be linked to other features, such as genome doubling, and merits further analysis.

#3504 Mithramycin analogues trap the EWS-FLI1 transcriptional complex, evict ETV6, and disable oncogenic condensate function in Ewing sarcoma.

Srijan Acharya[1], Rajesh Yetirajam[1], Yasuda Kazuto[1], Suhas Bhosale[2], Jurgen Rohr[2], Markos Leggas[1]

[1]Pharmaceutical Sciences, St. Jude Children's Research Hospital, Memphis, TN,[2]Pharmaceutical Sciences, University of Kentucky, Lexington, KY

Background: Ewing sarcoma is an aggressive pediatric cancer driven by the EWS-FLI1 fusion oncoprotein, which assembles into nuclear transcriptional condensates essential for oncogenic gene regulation. MTMSA-Trp is a synthetic mithramycin (MTM) analogue with improved pharmacokinetics and in vivo efficacy in Ewing sarcoma. MTMSA-Trp binds to the minor groove of DNA and interacts with the major groove-bound EWS-FLI1, but the mechanistic details of these interactions are not well understood.
Methods and Results: Using luciferase reporter assays, we show that MTMSA-Trp selectively inhibits EWS-FLI1-dependent transcription at nanomolar potency, with weaker effects on Sp1-driven transcription. MTMSA-Trp activity is attenuated in EWS-FLI1 knockdown cells, indicating functional dependence. Western blotting confirmed MTMSA-Trp-mediated suppression of EWS-FLI1-regulated targets in multiple Ewing sarcoma cell lines, while non-Ewing lines exhibited minimal response. qRT-PCR analyses revealed that MTMSA-Trp downregulates EWS-FLI1 mRNA, while paradoxically stabilizing its protein and shifting downstream transcriptional programs consistent with EWS-FLI1 antagonism. Biophysical assays demonstrated increased thermal and proteolytic stability of EWS-FLI1 upon MTMSA-Trp treatment, suggesting drug-induced stabilization of the EWS-FLI1 complex. Protein stability assays further showed that MTMSA-Trp prolongs the half-life of EWS-FLI1 in an EWS-FLI1-dependent manner, whereas ETV6, though functionally linked, was not stabilized but essentially evicted from the nucleus. Subcellular fractionation revealed that MTMSA-Trp increases nuclear retention of EWS-FLI1 while dynamically redistributing ETV6 in an EWS-FLI1-dependent manner. These effects extended to chromatin-associated partners of EWS-FLI1 condensates, including BAF155, BAF60a, and ARID1a. Immunofluorescence confirmed that MTMSA-Trp preserved ARID1a-containing nuclear condensates, protecting them from degradation by cycloheximide, and did so only in the presence of EWS-FLI1. At the transcriptional level, MTMSA-Trp downregulated CDK7 and hyperphosphorylated RNA Pol II CTD accompanied by accelerated RPB1 degradation. These effects were abolished when EWS-FLI1 was silenced.
Conclusions: Our results show that MTMSA-Trp binds to and stabilizes the EWS-FLI1 transcriptional complex, maintains its associated condensates, and alters gene expression by disrupting RNA Pol II activity. These findings reveal a previously overlooked mechanism of action for MTM analogues in their interaction with the transcriptional complex, ETV6, and phase-separated oncogenic complexes. They further support the potential of these compounds as a therapeutic approach for Ewing sarcoma.

#3505 DNA methylation signatures of diet quality and treatment-related cardiotoxicity in childhood cancer survivors.

Yoonji Kim[1], Xiaoxi Meng[1], Kwangyeon Oh[1], Tuo Lan[2], Tiffany Eulalio[1], Heather L. Mulder[3], John B. Easton[3], Jinghui Zhang[3], Emily Walker[4], Geoffrey A. Neale[4], Deo Kumar Srivastava[5], Min Ni[6], I-Chan Huang[1], Stephanie B. Dixon[6], Gregory T. Armstrong[1], Melissa M. Hudson[1], Kirsten K. Ness[1], Yikyung Park[2], Zhaoming Wang[1]

[1]St. Jude Children's Research Hospital, Memphis, TN,[2]Washington University in St. Louis, St. Louis, MO,[3]Computational Biology, St. Jude Children's Research Hospital, Memphis, TN,[4]Hartwell Center, St. Jude Children's Research Hospital, Memphis, TN,[5]Biostatistics, St. Jude Children's Research Hospital, Memphis, TN,[6]Oncology, St. Jude Children's Research Hospital, Memphis, TN

Background: Childhood cancer survivors are at increased risk of cardiometabolic risk factors (CMRF) and cardiovascular disease (CVD) due to cancer treatment exposures. Whether DNA methylation (DNAm) signature of diet quality can remediate these risks remains unclear.
Methods: We examined blood DNAm signatures of diet quality and their associations with CMRF/CVD among 2,191 adult survivors of childhood cancer and 283 community controls from the St. Jude Lifetime Cohort. Diet quality was assessed using the Healthy Eating Index (HEI)-2015 and alternate Mediterranean Diet Score (aMED), respectively. Genome-wide DNAm was profiled using the Illumina EPIC BeadChip V1. We identified differentially methylated positions (DMPs), genes (DMGs) and regions (DMRs) for diet quality-associated DNAm signatures in blood, from which DNAm-based scores for a healthy diet (DNAmDiet) were further derived. Multivariable logistic regression examined associations between DNAmDiet and seven outcomes: abnormal glucose metabolism, hypertension, hypertriglyceridemia, hypercholesterolemia, obesity, cardiomyopathy, and myocardial infarction. We also compared diet- and treatment-related methylation effects, focusing on CpGs where healthy diet-associated methylation changes occurred in the opposite direction of treatment-induced alterations, suggesting potential remediation of treatment-related DNAm alterations.
Results: We identified 29 DMPs, 113 DMRs, and 53 DMGs significantly associated with HEI-2015, and 9 DMPs, 16 DMRs, and 16 DMGs associated with aMED ($P<9\times10^{-8}$ for DMPs; FDR<0.05 for DMRs or DMGs). Diet-associated DNAm signatures mapped to key genes including AHRR, CPOX, CLDND1, GPR15, LY9, and MAP4K4, many of which are involved in immune regulation, cellular signaling, nutrient-sensing, suggesting that healthy diet may influence epigenetic regulation of immune and metabolic pathways. A DNAmDiet score based on aMED signatures was associated with lower risk of cardiomyopathy (Odds Ratio [OR]=0.76; 95% CI, 0.65-0.92), hypercholesterolemia (OR=0.65; 95% CI, 0.50-0.84), and hypertriglyceridemia (OR=0.78; 95% CI, 0.63-0.97). Effect sizes for diet-associated DMPs were, on average, twice as large in survivors as in community controls ($|\beta survivor|/|\beta control|=2.02$; P<0.001), despite strong correlations between populations (r=0.85; P<0.001). We found that up to 87.5% of treatment-associated DMPs showed opposite associations with HEI-2015 or aMED scores, with up to 8.9% reaching statistical significance.
Conclusions: DNAm signatures of healthy diet were associated with lower risks of specific cardiometabolic and cardiovascular outcomes. Importantly, healthy diet-related DNAm changes were in the opposite direction of treatment-induced DNAm alterations, suggesting potential for epigenetic recovery through dietary interventions.

: Therapeutic Modulation of the Tumor Microenvironment: New Targets and Approaches 1
Poster Session

#3508 Glioblastoma treatment with multifunctional nanodrug inhibiting laminin-411 activates local immune response, increases survival of mice and reveals AI-selected immune molecular pathways.

Alexander V. Ljubimov[1], Rameshwar Patil[2], Vladimir A. Ljubimov[3], Hui Ding[3], Yizhou Wang[4], Sarah Song[4], Andrei A. Kramerov[1], Oksana Chepurna[1], Vanessa Borges[1], Jessica Dos Santos[1], Eggehard Holler[5], Julia Y. Ljubimova[5], Keith L. Black[3]

[1]Biomedical Sciences, Cedars-Sinai Health Sciences University, Los Angeles, CA,[2]Neurosurgery, Loma Linda University, Loma Linda, CA,[3]Neurosurgery, Cedars-Sinai Health Sciences University, Los Angeles, CA,[4]Computational Biomedicine, Cedars-Sinai Health Sciences University, Los Angeles, CA,[5]Terasaki Institute for Biomedical Innovation, Los Angeles, CA

Introduction: Cancer microenvironment influences tumor growth, invasion, and escape from immune surveillance. Glioblastoma (GBM) extracellular matrix (ECM) especially laminins play an important role in tumor progression. We previously observed a correlation in GBM samples from 130 patients between increased expression of ECM laminin-411 (α4β1γ1) and faster tumor recurrence with decreased patient survival. Laminin-411 is a basement membrane component that can also modulate immune response through Notch signaling. We developed novel nanoconjugate (NC) blocking laminin-411 that can activate GBM local immune system after brain delivery.
Methods: NC was based on non-toxic poly (β-L-malic acid, P) with covalently attached antisense oligonucleotides (AON) against laminin-411 α4 and β1 chains, as well as trileucine (LLL) peptide for endosomal escape, AP-2 peptide for blood-brain barrier (BBB) crossing and GBM cell targeting. The NC was thoroughly characterized and was intravenously administered to mice (5 injections) with intracranial syngeneic GL261 GBM. The NC selected for treatment had the structure [P/mPEG5000(2%)/LLL(40%)/AON(α4β1)(2.0%)/AP-2(2%)]. Tumor RNA sequencing (RNA-seq) was analyzed by bioinformatics with artificial intelligence and validated for select genes by immunohistochemistry. Immune cell populations were analyzed by flow cytometry.
Results: NC treatment in vivo suppressed GBM growth and significantly prolonged animal survival. RNA-sec analysis after treatment with NC suppressing tumor laminin-411 suggested anti-tumor effect with upregulation of apoptotic Casp3, Ifng, Tnf, Il1a, and Il1b genes and reduction of glioma proliferation markers and oncogenes EGFR, c-Myc, Klf4, Irf4, and Ki-67, as well as Notch ligand Dll3. Ingenuity pathway analysis artificial intelligence module AI interpret predicted activation of inflammatory pathways involved in cell signaling during immune responses, pathways related to adhesion and migration of immune cells, and general immune response. In agreement with these data, protein validation showed decreased Ki-67 and Dll3, and increased T cell marker CD4, inflammatory markers IFNγ and TNFα, and anti-tumor M1 macrophage marker NOS2/iNOS. Interestingly, the immunostaining for markers of GBM stem cells, CD133 and nestin, was markedly decreased upon treatment. Flow cytometry also suggested activation of immune response after NC administration.
Conclusion: We describe a novel GBM treatment strategy via NC crossing BBB and targeting critical ECM and immune components of tumor microenvironment that are largely independent of heterogeneous genetic mutations in glioblastoma. Support: NIH grants R01 CA284247, R01 CA188743, R01 CA206220, R01 CA209921, R01 EY013431

#3509 Targeting Spns2 induces immunogenic cell death and systemic anti-tumor immunity to suppress metastasis.

Han Gyul Lee[1], Wyatt Wofford[1], Alhaji H. Janneh[2], Paramita Chakarborty[1], Natalia Oleinik[1], Mohamed Faisal Kassir[1], Odai Darawshi[1], Neil Parikh[3], Stefano Berto[1], Kevin R. Lynch[3], Webster L. Santos[4], Ozgur Şahin[1], Shikhar Mehrotra[1], Besim Ogretmen[1]

[1]The Medical University of South Carolina (MUSC), Charleston, SC,[2]Memorial Sloan Kettering Cancer Center, New York, NY,[3]The University of Virginia, Charlottesville, VA,[4]The Virginia Polytechnic Institute and State University, Blacksburg, VA

Background: Spinster homolog 2 (SPNS2) exports sphingosine-1-phosphate (S1P) to promote oncogenic signaling. Although SPNS2 is associated with metastatic progression, its tumor-intrinsic role in regulating immunogenic cell death (ICD) and anti-tumor immunity remains unclear. We examined how genetic or pharmacologic inhibition of SPNS2 influences metastasis, ICD induction, and systemic immune activation.
Methods: Patient datasets were analyzed in conjunction with breast (4T1, EMT6) and melanoma (B16) models. SPNS2 was ablated using CRISPR or inhibited using a first-in-class small-molecule SPNS2 inhibitor. S1P export, migration, and S1PR1-AKT signaling were assessed in vitro. Orthotopic, tail-vein, co-injection, and vaccination models were used to evaluate tumor growth, metastatic spread, ICD signatures, and systemic immunity. Individual DAMP pathways were disrupted to test mechanistic requirements.
Results: High SPNS2 expression correlated with poor survival across multiple cancer types. SPNS2 promoted S1P export, S1PR1-AKT activation, epithelial-mesenchymal transition, stemness, and lung colonization, whereas SPNS2 loss impaired migration and markedly reduced spontaneous and experimental metastases. SPNS2 inhibition elicited hallmark ICD features—including eIF2α phosphorylation, calreticulin exposure, and ATP/HMGB1 release—enhancing antigen presentation, expanding $CD4^+$ and $CD8^+$ T cells, and limiting primary tumor growth, metastasis, and postsurgical relapse. Vaccination with SPNS2-deficient or inhibitor-treated tumor cells protected against rechallenge with 4T1 or antigenically distinct EMT6 tumors. Disruption of individual DAMP pathways attenuated these responses, demonstrating ICD dependence. **Conclusions:** SPNS2-mediated S1P transport drives metastasis and immune evasion, whereas SPNS2 inhibition induces ICD and potent systemic T-cell immunity. Targeting SPNS2 represents a therapeutic strategy to suppress metastatic progression and generate durable anti-tumor immunity.

#3510 High-dose FcRH5xCD3 T-cell-engaging bispecific antibody (TCB) overcomes Treg-mediated suppression in-vitro in multiple myeloma.

Kai Lu[1], Darya Khantakova[2], Rin Nakamura[1], Kerstin Trunzer[3], Hyun Yong Jin[1], Elizabeth Punnoose[1], Elizabeth Germino[1], Katerina Hatzi[1]

[1]Genentech, South San Francisco, CA,[2]Washington University School of Medicine, St. Louis, MO,[3]Roche, Basel, Switzerland

T-cell-engaging bispecific antibody (TCB) redirect cytotoxic T-cells to recognize and eliminate multiple myeloma (MM) cells, yet their activity may be influenced by the immunosuppressive tumor microenvironment, including regulatory T-cells (Tregs). Previous studies have suggested that Tregs may influence TCB-mediated cytotoxicity. To test this directly, we developed a human in-vitro co-culture model consisting of healthy donor-derived primary PBMCs, MM cell lines, and ex-vivo activated autologous Tregs, treated with a FcRH5×CD3 T-cell-engaging bispecific antibody analogous to cevostamab which is currently in clinical development. Myeloma cell killing was quantified by multiparametric flow cytometry across a dose range of TCB concentrations. At low FcRH5×CD3 doses, addition of Tregs significantly reduced MM cell killing, T-cell proliferation (Ki-67), and cytokine production (Granzyme B), consistent with Treg-mediated suppression. However, at higher TCB concentrations, cytotoxicity, cytokine production, and T-cell activation were restored, consistent with the idea that higher FcRH5×CD3 levels can overcome Treg-induced inhibition. Importantly, depletion of the added Tregs using an anti-CD25 depleting monoclonal antibody (analogous to CD25-targeting Treg depleters under clinical investigation) reversed the reduction in MM cell killing observed at low TCB concentrations, confirming that the inhibitory effect was Treg-dependent. This dose-dependent pattern was consistent across multiple donors, demonstrating that potent TCB activity effectively overrides Treg suppression. These findings suggest that achieving sufficient T-cell activation through optimal FcRH5 TCB dosing could counteract Treg-mediated immunosuppression in patients, supporting dose selection strategies that maximize efficacy within the immunoregulatory landscape of multiple myeloma.

#3511 Reprogramming the tumor microenviroment to halt metastasis: Akos targets metastatic cancer-associated fibroblast in solid tumors.

Valentina Cerda I[1], Benjamin Prieto[2], Muriel Nunez[2], Daniela Barrera[2], Alexis Salas[3], Patricia Garcia[4], Enrique Brandan[1], Javier Cerda-Infante[2]

[1]Universidad San Sebastian, Santiago, Chile,[2]Environ SpA, Santiago, Chile,[3]Universidad de Concepcion, Concepcion, Chile,[4]Pontificia Universidad Catolica de Chile, Santiago, Chile

Background: Metastasis accounts for ~90% of cancer-related deaths and remains poorly controlled by therapies that primarily target cancer cells. Metastatic cancer–associated fibroblasts (mCAF) are key orchestrators of the tumor microenvironment, driving extracellular matrix remodeling, epithelial–mesenchymal transition, immune evasion, and metastatic dissemination. We identified in mCAF a proteoglycan-modified receptor that integrates these programs and developed Akos, a first-in-class small-molecule inhibitor that selectively blocks its formation and signaling. Here we extend those findings by defining the mechanism of action of Akos on tumor–stroma crosstalk and its molecular specificity toward a proteoglycan-modified stromal receptor in mCAF.
Methods: Primary stromal cultures were established from core biopsies of patients with metastatic cancer (mCAF), non-metastatic cancer (CAF), and non-malignant tissue (BAF). Target expression and Akos modulation were evaluated by gene profiling, IHC, and western blot. Co-cultures measured mCAF-driven invasion, proliferation, and EMT with/without Akos. Prostate, breast, colorectal, and pancreatic xenografts assessed tumor growth and metastasis after Akos treatment. Systemic toxicity, PK, and stromal proteoglycan selectivity were determined. Mechanistic studies examined how Akos-modulated changes in the proteoglycan-modified receptor in mCAF translated into alterations in pro-migratory and invasive signaling in tumor cells.
Results: Akos potently inhibited mCAF-induced tumor cell invasion and proliferation and reduced epithelial–mesenchymal transition markers in tumor cells. Mechanistic analyses showed that Akos selectively blocked formation of the proteoglycan-modified stromal receptor in mCAF, without affecting the expression of other stromal proteoglycans, and downregulated downstream mediators of migration, invasion, and extracellular matrix remodeling. These changes were associated with decreased activation of pro-metastatic signaling in tumor cells in co-culture. In xenograft models, Akos reduced tumor volume by up to 50-fold and tumor weight by up to 30-fold compared with vehicle and completely abrogated spontaneous metastatic foci in all evaluated models, while maintaining stable systemic exposure and no meaningful off-target toxicity.
Discussion: Akos is a highly specific stromal-directed therapy that reprograms metastatic CAF by inhibiting a defined proteoglycan-dependent receptor, disrupts tumor–stroma signaling to tumor cells, and completely blocks spontaneous metastasis across multiple solid tumor models. The combination of mechanistic specificity, robust antimetastatic activity, and favorable safety profile supports the clinical development of Akos as a first-in-class antimetastatic therapy targeting the tumor microenvironment.

#3512 High-precision carbon ion radiotherapy elicits effective in-situ tumor vaccination and durable antitumor immunity.

Sarah Meister[1], Matilde Recusani[1], Maximilian Knoll[1], Ralph Sinn[2], Aoife Gahlawat[1], Jennifer Furkel[1], Michael Breckwoldt[2], Dirk Jager[3], Jurgen Debus[4], Amir Abdollahi[1]

[1]Clinical Cooperation Unit Translational Radiation Oncology, National Center for Tumor Diseases (NCT), German Cancer Research Center (DKFZ), Heidelberg University Hospital (UKHD), Heidelberg Ion-Beam Therapy Center (HIT), Heidelberg, Germany,[2]Clinical Cooperation Unit Translational Radiation Oncology, Neuroradiology Department, National Center for Tumor Diseases (NCT), German Cancer Research Center (DKFZ), Heidelberg University Hospital (UKHD), Heidelberg, Germany,[3]Medical Oncology, National Center for Tumor Diseases (NCT), Heidelberg University Hospital (UKHD), Heidelberg, Germany,[4]Heidelberg University Hospital (UKHD), Heidelberg Ion-Beam Therapy Center (HIT), Heidelberg, Germany

With advent of carbon ion radiotherapy (CIRT) the spatio-temporal precision of external-beam radiotherapy has nearly reached the physical limits. We sought to investigate the potential of CIRT in reprograming the tumor immune microenvironment (TIME). To this end, three syngeneic tumor models were systematically investigated for their response to fractionated (5 x 3 Gy) CIRT vs. standard photon irradiation (XIRT). The models included the paradigmatic C57BL/6 tumor models of colorectal carcinoma (MC-38) and prostate cancer (RM1) as well as genetically engineered non-small cell lung cancer model (Pik3ca+, p53+/–, Y856). We observed substantially augmented antitumoral activity and relative biological effectiveness (RBE) of CIRT vs. XIRT in all three models. Intriguingly, CIRT achieved 100% cure rates in MC-38 and 67% in the Y856 model and increased the median overall survival (OS) three-fold vs. XIRT in the RM1 model. Immunohistological, single-cell transcriptome, and CyTOF analyses revealed enhanced immune cell infiltration in CIRT-treated tumors compared to controls. Moreover, enhanced infiltration of intravenously transferred Superparamagnetic Iron Oxide Nanoparticle (SPION) labelled T cells after CIRT was traced by MRI. The antitumoral responses elicited by CIRT could be significantly reduced in all three tumor models by abrogating the adaptive immune response via depletion of cytotoxic T cells using anti-CD8a antibodies. Additional experiments in immunocompromised athymic nude mice (Foxn1nu/nu) confirmed the significant impact of adaptive immunity in CIRT-elicited antitumoral effects with marked reduction of OS and zero cure rates across all three models. To examine the durability of CIRT-induced in-situ tumor vaccination, cured mice were rechallenged on abscopal sites at day 77 post-CIRT. In the MC-38 model, 100% of the abscopal tumors were rejected within 14 days after implantation indicating that CIRT induces a robust and durable systemic antitumor immunity. Together, our findings highlight the pivotal contribution of adaptive immunity to effective CIRT-induced TIME reprogramming for curative treatments. CIRT may provide novel and effective means of high-precision spatio-temporally controlled in-situ tumor vaccination.

#3513 The novel lncRNA *SEAL1* - key regulator of the pan-cancer myCAF cell state dictating prognosis ans immunotherapy response - is a promising new therapeutic target for solid cancers.

Emely Moller[1], Baroj Abdulkarim[1], Venkatesh Kancherla[1], Soumitra Ghosh[2], Sanne Schrevens[1], Rene Dreos[1], Kristen Gentry[3], Claire Roberts[3], Marco Mina[1], Rudi Micheletti[3], G. Paolo Dotto[4], Daniel Blessing[5], Samir Ounzain[5]

[1]HAYA Therapeutics SA, Epalinges, Lausanne, Switzerland,[2]Department of Immunobiology, University of Lausanne (UNIL), Lausanne, Switzerland,[3]HAYA Therapeutics INC, San Diego, CA,[4]University of Lausanne (UNIL), Epalinges, Switzerland,[5]HAYA Therapeutics SA, HAYA Therapeutics INC, Epalinges, Lausanne, Switzerland

A desmoplastic reaction in the solid tumor microenvironment (TME), typically characterized by extracellular matrix (ECM) dysregulation and an immune suppressive milieu, is a key factor contributing to tumor aggression, therapeutic resistance, metastasis and inevitably poor patient prognosis. Cancer-associated fibroblasts (CAFs), in particular myofibroblast-like CAFs (myCAFs), are central players in the development of TME desmoplasia in the most common and aggressive solid cancers such as breast, lung, head & neck and pancreatic. The contribution of myCAFs to standard-of-care treatment resistance and immunotherapy failure has raised their attraction as therapeutic targets. However, myCAF-targeting therapies have not yet proven to be effective for clinical use and is still a largely unexplored area of solid cancer therapeutics. Long non-coding RNAs (lncRNAs) are increasingly recognized as key regulators of epigenomic and transcriptomic cellular processes and characterized by highly cell-state and disease-specific expression. Targeting myCAF-specific regulatory lncRNAs constitutes a novel therapeutic approach to reduce myCAF-driven detrimental changes in the TME, coupled to an increased susceptibility to combination treatments. Here we identified a novel lncRNA *SEAL1* which is restrictively expressed in the pan-cancer myCAF cell state associated with poor patient prognosis and treatment response. Independent analyses of breast, head & neck and pancreatic cancer patient datasets demonstrated *SEAL1* as a key component of disease-driving myCAF co-regulatory networks. By antisense oligonucleotide (ASO)-mediated targeting of *SEAL1,* and of the murine functional analog *Seal1*, we demonstrated that the myCAF identity was potently reduced in *in vitro* cellular models. In contrast, ASO- or CRISPRi-mediated targeting of *LRRC15/Lrrc15*, a *SEAL1* downstream marker associated with the myCAF cell identity, had no effect on the disease-driving myCAF cell state. *LRRC15* has previously been associated with poor prognosis and an unfavorable response to immunotherapy, being actively pursued as a potential CAF therapeutic target. Moreover, by utilizing a xenograft co-injection *in vivo* model, *SEAL1* targeting in patient-derived myCAFs reduced tumor volume whereas *LRRC15* targeting had no effect. Taken together, this study emphasizes that the Regulatory Genome is still largely under explored and that novel discoveries such as *SEAL1* may uncover previously unknown biological mechanisms. By leveraging regulatory lncRNAs as potent modifiers of specific disease-states, we conclude that the *SEAL1* lncRNA is a major determinant of myCAF pro-tumorigenic transcriptional programs of therapeutic value.

#3514 Histone deacetylase 9 (HDAC9) mediates therapy resistance by regulating tumor-neutrophil interaction in advanced hepatocellular carcinoma.

Yunong Xie[1], Minghe Zhang[1], Linglin Liu[1], Yimiao He[1], Jiahuan Cai[1], Clive Yik-Sham Chung[2], Leung Hoi Wing[1], Terence Kin-Wah Lee[3], Stephanie Ma[2], Ka-Fai To[1], Jingying Zhou[1], Carol Man Carol Tong[1]

[1]The Chinese University of Hong Kong, Hong Kong, Hong Kong,[2]The University of Hong Kong, Hong Kong, Hong Kong,[3]Hong Kong Polytechnic University, Hong Kong

Tyrosine kinase inhibitors (TKIs) and immune checkpoint blockade (ICB) therapies are standard treatments for advanced hepatocellular carcinoma (HCC), but their efficacy is limited by therapy resistance. This study investigates the mechanisms underlying resistance, focusing on the role of tumor-immune interaction. Using single-cell RNA sequencing (scRNA-seq) in a TKI-treated immunocompetent mouse model, we identified an expansion of poorly differentiated tumor cells with significant upregulation of histone deacetylase 9 (HDAC9). Elevated HDAC9 enhanced cancer stemness and reduced the efficacy of TKI therapy. Beyond TKIs, HDAC9 also contributed to ICB resistance by suppressing $CD8^+$ T cell infiltration and cytotoxicity, partly through interactions with immunosuppressive neutrophils exhibiting a neutrophil extracellular trap (NET) phenotype. Neutrophil depletion reversed ICB resistance, restoring $CD8^+$ T cell infiltration and function. Mechanistically, HDAC9 deacetylates translation initiation factor 4 gamma 2 (eIF4G2), enhancing its interaction with YTHDF3 to promote m6A-dependent protein translation, including signaling molecules that mediate tumor-neutrophil crosstalk. Clinicopathological analysis confirmed that HDAC9 correlates with increased neutrophil infiltration and reduced cytotoxic immune activity in HCC patients. These findings identify HDAC9 as a key immunoregulator driving therapy resistance and suggest that targeting the HDAC9/eIF4G2/YTHDF3 axis may improve the efficacy of TKI and ICB therapies in advanced HCC.

#3515 Modulating pancreatic juice ENPP1-STING crosstalk to reprogram the tumor immune landscape in pancreatic cancer.

Sadaaki Nishimura, Jun Tauchi, Ryota Tanaka, Shigeaki Kurihara, Masahiko Kinoshita, Kohei Nishio, HIroji Shinkawa, Takeaki Ishizawa

Hepatobiliary-pancreatic surgery, Osaka Metropolitan Univ. Graduate School of Med., Osaka, Japan

Background:
Pancreatic cancer is among the deadliest solid tumors, primarily due to its profoundly immunosuppressive tumor microenvironment (TME) characterized by poor T-cell infiltration and resistance to immunotherapy. We previously demonstrated that modulation of the STING (Stimulator of Interferon Genes) pathway in hepatic stellate cells, controlled by the autophagy adaptors NBR1 and p62, can convert hepatocellular carcinoma from a “cold” to a “hot” immune phenotype (Molecular Cell, Nishimura S., 2024). These findings highlight the therapeutic potential of precise STING pathway regulation within the stromal compartment.
Objective:
This study aims to elucidate how ENPP1 (ecto-nucleotide pyrophosphatase/phosphodiesterase 1), an enzyme highly enriched in pancreatic juice, shapes the pancreatic TME by modulating extracellular cGAMP availability and STING activation. Because ENPP1 degrades cGAMP—the essential second messenger driving STING signaling—we hypothesize that elevated ENPP1 activity suppresses innate immune sensing and promotes a cold TME in pancreatic cancer.
Methods:
We will analyze pancreatic juice and matched tumor tissues from patients undergoing pancreatic surgery. ENPP1 enzymatic activity, cGAMP degradation capacity, and STING pathway activation (TBK1/IRF3 phosphorylation, type I interferon signatures) will be quantified. Immune profiling will be performed to assess correlations with T-cell infiltration, myeloid composition, and markers of immune exclusion. We will further evaluate whether ENPP1 levels are associated with treatment resistance or clinical outcomes.
Results and Significance:
We anticipate that high ENPP1 activity will correlate with suppressed STING signaling and reduced immune infiltration, defining a mechanism by which pancreatic tumors maintain an immunologically cold TME. This work has the potential to establish ENPP1 as a biomarker for therapeutic resistance and to support the development of ENPP1-STING-targeted strategies—such as ENPP1 inhibition or cGAMP stabilization—to convert pancreatic tumors into a more immune-responsive state. Pancreatic juice-based immune monitoring may provide a minimally invasive tool for real-time assessment of TME immune status.

#3518 Role of sialic acid-siglec axis in pancreatic cancer immune evasion.

Barnita Haldar[1], Karin Hardiman[2], Susan Bellis[1]

[1]Cell Developmental and Integrative Biology, University of Alabama at Birmingham, Birmingham, AL,[2]Department of Surgery, University of Alabama at Birmingham, Birmingham, AL

Pancreatic ductal adenocarcinoma (PDAC) is an aggressive malignancy. A key factor contributing to the lethality of PDAC is immune evasion. Tumor cells suppress anti-tumor immunity by activating immune checkpoint proteins on immune cells including macrophages. Siglec receptors are one of the main checkpoint molecules on macrophages. The ligand for Siglecs is sialic acid. To effectuate immune suppression via Siglecs, PDAC cells increase their surface sialylation by upregulating the expression of sialyltransferases such as ST6GAL1. ST6GAL1 adds an α2,6-linked sialic acid to N-glycans. Both α2,6 sialylation and ST6GAL1 expression are markedly increased in PDAC cells. Our prior studies revealed potent tumor-autonomous functions for ST6GAL1. Our new unpublished results suggest that the tumorigenic effects of ST6GAL1 are also driven by its role in creating sialoglycan ligands for macrophage Siglecs. Macrophages that are polarized to an immunosuppressive M2 phenotype are key contributors to PDAC progression. The goal of our study is to determine whether macrophage Siglecs are promising therapeutic targets for preventing M2 polarization, thus restoring anti-tumor immunity and preventing PDAC progression. We investigated macrophage polarization in our genetically engineered mouse models of PDAC, utilizing either pancreas-specific knock-in of oncogenic K-ras (KC mouse) or K-ras in combination with ST6GAL1 knock-in (KSC mouse). Single-cell RNA sequencing, flow cytometry, and immunohistochemistry showed an increased number of M2 macrophages in KSC vs. KC pancreata. Macrophages co-cultured with ST6GAL1-overexpressed PDAC cells showed increased expression of M2 markers. But adding Siglec-blocking antibodies reversed the ST6GAL1-mediated M2 polarization, indicating that the ST6GAL-mediated M2 polarization of macrophages is mediated through Siglec signaling. Additionally, we determined the phagocytotic capacity of macrophages, which is an established functional readout for anti-tumor behavior of macrophages. Immunofluorescence microscopy and flow cytometry showed that the phagocytotic capability of macrophages was suppressed by ST6GAL1-overexpressed PDAC cells but recovered by Siglec blocking antibody. Overall, our data demonstrate that α2,6 sialic acids on PDAC cells engage with Siglecs on macrophages to induce polarization of macrophages into an immunosuppressive M2 phenotype. Collectively, these results reveal a potential mechanism for targeting Siglecs as a promising immune checkpoint therapy for PDAC patients with high levels of ST6GAL1. Traditional T cell-based checkpoint therapies have limited effectiveness in PDAC. Targeting Siglec checkpoints presents an opportunity to enhance the anti-tumor activity of macrophages, the primary immune cell type within the PDAC tumor microenvironment.

#3519 PD-L2-RGMb interaction modulates anti-cancer immunity through swinging the shift of Th1/Th2 cell balance.

Siyi He[1], Xiaoyi Chong[1], Fangli Jiang[2], Xinru Hua[1], Chenlin Cao[1], Cheng Zhang[3], Xiaotian Zhang[4], Lin Shen[1]

[1]Peking University Cancer Hospital & Institute, Beijing, China,[2]Jiangsu Province Hospital, Nanjing, China,[3]Department of Gastrointestinal Oncology, Peking University Cancer Hospital & Institute, Beijing, China,[4]Affiliated Cancer Hospital of Inner Mongolia Medical University,Peking University Cancer Hospital Inner Mongolia Hospital, Hohhot, China

Immune checkpoint blockade has revolutionized gastric cancer (GC) treatment, yet primary and acquired resistance remain major clinical challenges. Here, we identified extracellular vesicles (EVs) expressing programmed death-ligand 2 (PD-L2-EVs) as a key determinant of anti-PD1 response in GC. Through profiling the extracellular vesicle protein expression profiles in plasma samples from a retrospective cohort of 76 patients, we demonstrated that high baseline PD-L2-EV levels correlate with improved immunotherapy response and survival. Using multiple immunocompetent murine models, we showed that PD-L2-EVs synergize with anti-PD1 to suppress tumor growth by remodeling the tumor immune microenvironment, enhancing $CD8^+$ T cell and NK cell infiltration while reducing immunosuppressive cell populations. Mechanistically, PD-L2 possesses differential binding dynamics between PD1 and repulsive guidance molecule b (RGMb), its binding to the latter mediates Th1 differentiation through promoting STAT4-signaling and augments $CD8^+$ T cell's anti-tumor immunity. On the other hand, AFP reduces cancer cell's expression of PD-L2 and impaired Th1 differentiation, which explained the resistance to immunotherapy for the subtype of AFP-GC. Importantly, through shifting T helper 1/2 cells' balance towards Th1 under PD1 blockade, PD-L2-EV enhances the efficacy of anti-PD1 but not for anti-PD-L1 therapy. Our work nominated PD-L2-EVs as a predictive biomarker in guiding the selection of different types of immunotherapy and potentiates engineered PD-L2-EV as a candidate for therapeutic combination, particularly in AFP-positive patients.

#3520 New role for CDK6 activation in tumor-induced monocyte and platelet reprogramming in breast cancer.

Karen Norek[1], Jacob Kennard[1], Kenneth Fu[1], Robert Shepherd[1], Kristina Rinker[2], **Olesya Kharenko**[1]

[1]Syantra Inc, Calgary, AB, Canada,[2]Schulich School of Engineering, Department of Biomedical Engineering, Syantra Inc; University of Calgary, Calgary, AB, Canada

Background: Tumor-derived signals can reprogram immune cells and platelets to support cancer progression. However, the regulatory mechanisms underlying this systemic education are not well understood.
Methods: RNA sequencing was performed on isolated platelet and white blood cell fractions from breast cancer patients and on THP-1 monocytes exposed to triple-negative breast cancer (TNBC) MDA-MB-231 cells. Transcriptomic data was analyzed using Ingenuity Pathway Analysis (IPA) and Gene Set Enrichment Analysis (GSEA) to identify upstream regulators and enriched pathways.
Results: In both clinical and in-vitro datasets, CDK6 emerged as a key upstream regulator. In patient-derived platelets, CDK6 was identified as a major activated regulator in cancer versus non-cancer samples suggesting a role in tumor-driven systemic remodeling. The CDK6 regulatory network included upregulated and downregulated genes that were significantly modulated. In THP-1 monocytes following contact with TNBC cells, CDK6 activation was confirmed by IPA and accompanied by GSEA enrichment of cell cycle-related pathways such as “regulation of cell cycle process.” Functionally, THP-1 cells exposed to TNBC cells or conditioned media displayed increased proliferation, indicating tumor-induced monocyte reprogramming. This effect was reversed by CDK4/6 inhibitors, highlighting a new immunomodulatory mechanism of these standard-of-care drugs.
Conclusions and Translational Relevance: CDK4/6 activation represents a shared hallmark of tumor education across immune and platelet compartments. These findings reveal a novel mechanism of systemic immune modulation and suggest that CDK4/6 inhibitors can reverse oncogenic activation in monocytes and platelets. This study extends the relevance of these agents beyond tumor cell-intrinsic effects. Targeting CDK6-dependent immune reprogramming may offer a novel strategy to disrupt systemic tumor-immune crosstalk and improve therapeutic responses in breast cancer.

#3521 Studying the mechanism of action and bystander effect of the GSK5764227 antibody-drug conjugate in patient-derived cancer organoids.

Maria Fankhaenel[1], Priya Narayanan[1], Halh Al-Serori[1], Veronika Yankova[1], Mint Htun[1], Elias Sulaiman[1], Barbara Seller[2], Irina Piven[2], Lena Wedeken[2], **Anna Pasto**[1], Tony NG[1]

[1]GlaxoSmithKline plc, Stevenage, United Kingdom,[2]GlaxoSmithKline plc, Berlin, Germany

B7-H3, a member of the B7 family of proteins, is expressed in a variety of tumour types and has emerged as a novel target for cancer therapies due to its specific expression in tumour cells and minimal expression in normal tissues. One potential therapy route comprises of an antibody-drug conjugate (ADC) that specifically binds to B7-H3 and delivers a topoisomerase inhibitor (TOPOi) as its cytotoxic payload. The GSK clinical-stage B7-H3 ADC (GSK5764227) has shown promising results in cancer patients where other treatment options have been exhausted. However, the precise mechanism underlying its therapeutic efficacy remains unclear. We utilised patient-derived organoids (PDOs) generated from different tumour types to investigate the mechanism of action of GSK5764227, from target binding and internalisation to trafficking through endosomal and autophagy pathways to treatment response. By leveraging a partially knockout PDO model, containing a mixture of B7-H3 positive and negative cells, we explored the potential bystander effect of the compound using spatial multiplex and real time imaging at multiple timepoints. In parallel, we analysed the cargo of extracellular vesicles to assess their role in delivering the payload to neighbouring B7-H3 negative cells and enhancing the overall treatment response. Our findings shows that GSK5764227 after binding to B7-H3 within minutes of treatment initiation, is internalised, and trafficked from early endosomes to lysosomes within 24 hours, where the cytotoxic payload is likely cleaved and released. The cleaved payload induces DNA damage, cell cycle arrest and apoptosis through Topoisomerase I inhibition. Furthermore, we observed that payload is trafficking into neighbouring cells through extracellular vesicles derived from treated PDOs, inducing treatment effects, including DNA damage in B7-H3 negative cells, further supporting the drug's bystander effect. Altogether, this work characterises how GSK5764227 induces cell cycle arrest and tumour apoptosis directly in B7-H3 positive cells and indirectly in neighbouring B7-H3 negative cells via bystander effect. Combining clinical, molecular and imaging data, this study enhances our understanding of the drug's mechanism of action and provides a foundation for optimising its use in difficult-to-treat-cancers, ultimately guiding personalised therapeutic strategies for patients.

#3522 Vitamin D (calcitriol) potentiates CB2-mediated anti-tumor responses in prostate cancer cell lines: Molecular mechanisms and therapeutic potential.

William B. Speed[1], Cimona Vaughn Hinton[2], Nakea Pennant[2]

[1]Microbiology, Biochemistry and Immunology, Morehouse School of Medicine, Atlanta, GA,[2]Morehouse School of Medicine, Atlanta, GA

Prostate cancer (PCa) is the most frequently diagnosed non-skin cancer among U.S. men and remains the second leading cause of cancer-related mortality. Vitamin D receptor (VDR) signaling exerts antiproliferative and pro-differentiation effects in prostate tumors, while Cannabinoid Receptor 2 (CB2) has been implicated in immune modulation and antitumor activity. Emerging evidence suggests potential crosstalk between CB2 activation and VDR pathways. We hypothesize that CB2 activation induces VDR expression in prostate cancer cells. DU145 and PC3 cells were plated in complete RPMI for 24 hours, serum-starved for 24 hours, and treated with 10 nM calcitriol, 1 nM AM1241 (CB2 agonist), or starvation media alone. In PC3 cells, AM1241 induced VDR expression at levels comparable to calcitriol, whereas DU145 cells showed minimal induction relative to controls. These preliminary findings suggest a cell line–dependent effect whereby CB2 agonism may enhance VDR expression. Ongoing studies are evaluating whether CB2 activation further augments VDR signaling and modulates its tumor-suppressive functions in prostate cancer.

#3523 Immunological roles of antigen-presenting cancer-associated fibroblasts and mesothelial cells in colorectal cancer.

Yasuhiro Fukui[1], Hiroaki Kasashima[1], Yukina Kusunoki[2], Nobuhiro Naito[1], Zizhou Wang[1], Iguru Omori[1], Yuki Seki[1], Kenji Kuroda[1], Yuichirou Miki[1], Mami Yoshii[1], Tatsurou Tamura[1], Masatsune Shibutani[1], Takahiro Toyokawa[1], Masakazu Yashiro[3], Yuki Nakanishi[4], Naoko Ohtani[2], Kiyoshi Maeda[1]

[1]Department of Gastroenterological Surgery, Graduate School of Medicine, Osaka Metropolitan University, Osaka, Japan,[2]Pathophysiology, Osaka Metropolitan University, Osaka, Japan,[3]Molecular Oncology and Therapeutics, Osaka Metropolitan University, Osaka, Japan,[4]Gastroenterology and Hepatology, Kyoto University, Kyoto, Japan

Cancer-associated fibroblasts (CAFs) play crucial roles in tumor progression and metastasis through their interactions with cancer and immune cells in the tumor microenvironment. Among CAF subsets, antigen-presenting CAFs (apCAFs), characterized by their expression of MHC class II molecules and antigen-presenting ability, have been shown to exert immunosuppressive effects and are thought to originate from mesothelial cells. In this study, we investigated the immune-related functions of apCAFs and mesothelial cells in colorectal cancer (CRC). Using an orthotopic transplantation mouse model, human CRC surgical specimens, and established CAF and mesothelial cell lines, we analyzed their interactions with colorectal cancer cells. Immunohistochemical analysis of CRC tissues revealed that patients with HLA-DR-positive stromal cells had significantly poorer recurrence-free survival compared to HLA-DR-negative patients. The proportion of apCAF marker-positive stromal cells increased with tumor stage. In orthotopically transplanted CRC tumors, flow cytometric analysis demonstrated that the proportion of apCAFs peaked six weeks after transplantation, followed by an increase in myofibroblastic CAFs (myCAFs). Gene expression analysis of mesothelial cells, which are proposed to give rise to apCAFs, showed elevated expression of apCAF-related genes in cancer-associated mesothelial cells (CAmeso) compared with normal mesothelial cells. In an allogeneic mixed lymphocyte reaction using human mesothelial cells, the proliferation of $CD4^+$ T cells was significantly reduced when co-cultured with CAmeso compared to dendritic cells alone, indicating that CAmeso exert immunosuppressive effects despite their antigen-presenting potential. In addition, single-cell RNA sequencing identified CAF subsets with high SLPI expression, suggesting the existence of immunomodulatory CAF populations within the tumor stroma. Furthermore, immunofluorescence staining confirmed the presence of stromal cells co-expressing αSMA and SLPI, and patients with αSMA^+SLPI^+ stromal cells had significantly worse prognosis. Notably, αSMA^+SLPI^+ stromal cells were more abundant in liver metastases and peritoneal dissemination lesions than in primary colorectal cancer tissues, suggesting that these cells may be involved in metastatic progression. Taken together, these findings demonstrate that apCAFs are associated with poor clinical outcomes in CRC, and that cancer-associated mesothelial cells acquire antigen-presenting but immunosuppressive properties under the influence of cancer cells, thereby contributing to tumor progression and unfavorable prognosis.

#3524 Exploring both targeted and untargeted (bystander) effects of GSK5764227 antibody-drug conjugate in patient-derived tumor explants (PDEs).

Debayan Mukherjee[1], Jenny Wade[1], Morgan Heycock[1], Mint Htun[1], Benjamin Miller[2], Zeinab Mokhtari[3], Diana Munera[1], Anna Pasto[1], Paul Barber[1], Tony NG[1], Sue Griffin[1]

[1]Oncology Translational Research, GSK, Stevenage, United Kingdom,[2]Development Biostatistics, GSK, Stevenage, United Kingdom,[3]Oncology Translational Research, GSK, Heidelberg, Germany

Background: B7-H3, a member of the B7 family of immune checkpoint molecules, is emerging as a promising therapeutic target due to its overexpression in several cancers and association with poor clinical outcome. GSK5764227 is a fully humanized IgG-1 monoclonal antibody against B7-H3 conjugated to a topoisomerase 1 (TOP1) inhibitor. GSK5764227 is predicted to selectively target the tumor cells by delivering potent payload, however the role of direct killing vs effects on bystander tumor cells is unknown.
Methods: In this study by using spatial imaging endpoints, we evaluate the expression of B7-H3 and associated genes/ proteins in surgically resected NSCLC tumors samples (Stage IB-IIIB). We then establish a NSCLC patient derived tumor explants (PDE) model, which re-capitulates the pathological tumor microenvironment (TME), and treat the PDE fragments with anti-B7-H3 ADC (GSK5764227), naked anti-B7-H3mAb (GSK5764224), and human-IgG1 control mAb in culture for 72hrs. Using multiplex imaging endpoints, we assess the spatial distribution and binding of GSK5764227 and payload (TOP1 inhibitor) in key cellular subsets and evaluate cell killing (Cleaved Caspase-3) within the TME.
Results: In NSCLC tumor tissues, the B7-H3 protein is abundantly expressed in proliferative tumor epithelial and cancer associated fibroblast (CAFs) cells, but at low-levels in adjacent normal tissue. TOP1 and TOP1 inhibitor sensitivity genes are abundantly expressed in proliferative tumor epithelial and fibroblasts, suggesting that these cells maybe be sensitive to ADC. In PDE models, GSK5764227 and payload showed preferential binding to B7-H3 positive epithelial (EpCam+), fibroblast (aSMA+) and macrophage (CD68+) subsets. In a subset of B7-H3 negative cells, the payload was also detected, suggestive of either downregulation/degradation via internalization of B7-H3 receptor after binding to the ADC, or payload diffusion in B7-H3 negative cells (bystander-effect). This correlated with significant increase in cleaved caspase-3+ staining in payload+ tumor epithelial, macrophages and fibroblast, suggestive that the cell killing could be driven by direct payload deposition in the target population and that all 3-cell types are sensitive to killing by the TOP1 inhibitor payload.
Conclusions: Our results potentially aid in mechanistic understanding of the inter-play between ADC binding and payload deposition, bystander effect and heterogeneity of tumor response, which will support the future design of clinical trials with GSK5764227.

#3525 Structural variation shapes clonal evolution in pediatric cancer.

Robert Greenhalgh[1], Bensheng Ju[1], Samuel W. Brady[2], John Easton[1], Sivaraman Natarajan[1], Jinghui Zhang[1]

[1]Computational Biology, St. Jude Children's Research Hospital, Memphis, TN,[2]Pharmacy and Pharmaceutical Sciences, St. Jude Children's Research Hospital, Memphis, TN

Tumor clonal evolution is driven by the selection or acquisition of mutations that confer an advantage under the pressures of therapeutic intervention. Much of the knowledge of clonal evolutionary trajectories is based upon single nucleotide variants (SNVs), a mutation type well-suited for detecting subclones and estimating their cancer cell fraction by deep sequencing. To explore the role of structural variants (SVs) in the evolutionary process, we analyzed 13 pediatric cancer patients with multiple spatiotemporally distinct tumor samples and patient-derived xenografts (PDXs) profiled by whole-genome sequencing (WGS). In addition to *de novo* SV calling, the SV presence across all tumor samples from the same patient was analyzed by Fuzzion2, which uses pattern matching to find SVs at a sensitivity as low as a single read pair. We found that clonal architectures defined by SVs largely mirrored those of SNVs, although the branch lengths could differ if SV formation was not affected by therapy-related mutagenesis (e.g. cisplatin). SV-based mutational processes, such as RAG-mediated recombination in leukemia, can be active from diagnosis to relapse, and complex SVs caused by chromothripsis may not be selected for despite their predominant presence at diagnosis. A trio of diagnosis-relapsed rhabdomyosarcoma samples exhibited an intriguing pattern of sharing an ancestral extrachromosomal amplicon of *MDM2*, which co-existed with a second amplicon distinct at diagnosis and relapse. RNA sequencing confirmed each amplicon led to overexpression of different subsets of genes, and SVs derived from WGS indicated that the amplicon private to relapse may have merged with the ancestral *MDM2* amplicon. Validation of this finding is currently underway, leveraging long-read sequencing and cells derived from PDX models of these tumors. Our study emphasizes the importance of examining SVs to gain perspective on the dynamic changes that impact driver genes and amplicon architecture during therapy and may offer new insights on strategies to overcome therapeutic resistance.

#3526 Dynamic evolution of oncogene amplification across 80,000 cancer cell genomes.

Yu[1], Charles M. Rudin[1], Andrea Ventura[3], Andrew William McPherson[1], Marc Williams[1], Sohrab Shah[1]

[1]Memorial Sloan Kettering Cancer Center, New York, NY,[2]BC Cancer Research, Vancouver, BC, Canada,[3]Memorial Sloan Kettering Cancer Center, Mamaroneck, NY

Copy-number (CN) amplification is a major mechanism of oncogene activation and a therapeutic target, yet its evolution in human cancers is incompletely understood. We analyzed single-cell whole-genome sequencing (scWGS) data from >80,000 cancer cells in 100 tumors from major cancer types (ovary, breast, lung, and brain) and experimental models to resolve mechanisms and evolution of oncogene amplification. CN distributions across cells revealed two patterns: narrow, uniform peaks from symmetric segregation, consistent with intrachromosomal amplifications (ICamps), and broad, heavy-tailed variation with extreme outliers (>100 copies/cell) indicative of extrachromosomal circular DNA (ecDNA). A probabilistic mixture model of these distributions classified 74 (15%) of 503 amplified regions as ecDNA. These ecDNAs most frequently involved *MYC*, *EGFR*, and *MDM2*, and were enriched in glioblastoma and lung cancers, whereas ovarian and triple-negative breast cancers predominantly showed ICamps. Notably, ICamp events showed significant subclonal specificity, with 227 (53%) of 429 events displaying multiple modes in the CN distribution. These modes were congruent with other genomic features from phylogenetic analysis, suggesting lineage inheritance patterns of symmetric division and clonal expansion. Diversification arose via numeric mechanisms (aneuploidy or genome doubling) and subclone-specific structural variants (e.g., breakage-fusion-bridge cycles or chromothripsis). CN modulation was bidirectional, including loss of amplified derivative chromosome via subclone-specific aneuploidy. Joint analysis of copy-number and structural variants at single-cell resolution uncovered several mechanisms of ecDNA-driven cancer evolution. First, remodeling of ecDNAs through internal rearrangements and recombination between distinct species was often observed, leading to oncogene co-selection. Second, convergent evolution via acquisition of distinct *EGFR*-containing ecDNAs was observed in a glioblastoma, suggesting the potential role of ecDNA loss in shaping subsequent evolution. Third, scWGS of isogenic cell lines distinguished present ecDNAs from historical ecDNAs that underwent genomic rearrangements resulting in chromosomal re-integration. Finally, we show that comparison between circular genome graph-based prediction versus the CN distribution-based prediction of ecDNAs revealed substantial discrepancy with notable tissue-type specificity. In conclusion, this study reveals interpretable distributions of oncogene amplifications consistent with distinct ICamp and ecDNA generative processes. This approach, refining ecDNA identification beyond standard genome graphs, further elucidates how distinct mechanisms of oncogene amplification diversify cancer cell populations. We suggest these new insights will inform patient selection for emerging ecDNA-directed therapies.

#3527 Clonal evolutionary trajectory of HER2-positive breast cancer with ERBB2 or PIK3CA mutations under neoadjuvant treatment.

Kang Wang, Ioannis Zerdes, Emmanouil G. Sifakis, Dimitrios Salgkamis, Jonas Bergh, Thomas Hatschek, Alexios Matikas, Theodoros Foukakis

Karolinska Institutet, Stockholm, Sweden

Background: ERBB2 and PIK3CA are among the most commonly mutated genes in HER2-positive breast cancer and are known mediators of resistance to HER2-targeted therapies. However, the molecular evolution of these mutant tumors under treatment remains poorly understood. In this study, we profiled the multi-omics landscape of ERBB2- and PIK3CA-mutant tumors from the randomized PREDIX HER2 trial, which compared neoadjuvant trastuzumab emtansine (T-DM1) with dual HER2 blockade plus chemotherapy in early-stage HER2-positive disease.
Methods: Fresh-frozen tumor biopsies were used for RNA sequencing and whole-exome sequencing (WES), while FFPE biopsies were used for Xenium 5K spatial transcriptomics. Longitudinal differential gene expressions were analyzed using Gaussian mixed-effects models. Tumor subtypes were assigned with a five-subtype single-sample predictor (SSP.Subtype). Somatic mutations and copy number alterations were profiled using GATK4 Mutect2 and GISTIC2. Somatic mutations were filtered and curated using a 5% variant allele frequency (VAF) cut-off.
Results: Of the 190 patients with available WES data, 7 (3.7%) and 49 (25.8%) patients carried non-synonymous ERBB2 mutations (median VAF = 0.28) and PIK3CA mutations (median VAF = 0.21), respectively. In those patients who did not achieve pathological complete response (pCR) (63%), we identified two ERBB2 mutations (S310Y and R143*) that were consistently detected prior to, during, and after treatment, all located in the extracellular domain. Notably, both tumors maintained the HER2-enriched subtype and ERBB2 amplification during treatment, suggesting mutations may influence trastuzumab binding and blocking HER2 signals. Similarly, we identified 10 patients with persistent PIK3CA mutations during treatment, all of which were known gain-of-function alterations. Only one out of four tumors retained the HER2-enriched subtype, suggesting a potential shift in molecular phenotype under therapeutic selective pressure. Phylogenetic analysis further revealed recurrent clonal expansion involving PIK3CA and acquired KLB mutations, the latter implicated in the regulation of cholesterol metabolism. Further *in vitro* validation of KLB-FGF21 signaling is ongoing.
Conclusion: This longitudinal evolutionary analysis of ERBB2- or PIK3CA-mutant, HER2+ breast cancer suggests that tumors evolve heterogeneously under HER2-targeted therapies, revealing the positive selection of pathogenic ERBB2 and PIK3CA mutations.

#3528 EED drives the small cell lung cancer neuroendocrine phenotype in lung cancer histological transformation.

Yixiang Li[1], Yasmin N. Laimon[2], Hyeonseo Cho[1], Marina Vivero[2], Gabriel R. De Oliveira[2], Andrew Delcea[2], Varunika Savla[2], Yuting Chen[3], Yavuz Durmaz[1], Xintao Qiu[1], Shweta Kukreja[1], Rong Li[1], Talal El Zarif[4], Wesley S. Lu[1], McKayla Van Orden[1], Jacob E Berchuck[5], Roderick Bronson[6], Shuqiang Li[7], Hongbin Ji[3], Katerina A. Politi[8], Matthew L. Freedman[1], Henry Long[1], Sabina Signoretti[2], Matthew Gilbert Oser[1]

[1]DFCI/Harvard Medical School, Boston, MA,[2]Department of Pathology, Brigham and Women's Hospital, Boston, MA,[3]Shanghai Institute of Biochemistry and Cell Biology, Shanghai, China,[4]Dana-Farber Cancer Institute, Boston, MA,[5]Winship Cancer Institute/Emory University School of Medicine, Atlanta, GA,[6]Harvard Medical School, Boston, MA,[7]Broad Institute of MIT and Harvard, Cambridge, MA,[8]Yale Cancer Center, New Haven, CT

Lung cancer histological transformation from lung adenocarcinoma (LUAD) to small cell lung cancer (SCLC) can occur as a resistance mechanism to targeted therapies, particularly in *EGFR*-mutant LUADs with concurrent *RB1* and *TP53* mutations. SCLC transformation has a poor prognosis and there are no targeted therapies to block SCLC transformation. Increased PRC2 complex expression is correlated with SCLC transformation, but it is unknown whether PRC2 complex is functionally necessary for SCLC transformation. In this study, we investigated the functional role of EED, a scaffolding component of the PRC2 complex, in SCLC tumorigenesis and in LUAD to SCLC transformation utilizing two state-of-the-art CRISPR-based, autochthonous immunocompetent genetically engineered mouse models (GEMMs) with comprehensive genomic, transcriptomic, and epigenomic analyses. In a *de novo* SCLC GEMM, we show that loss of EED hinders SCLC development and selects for the formation of LUAD through a NEUROD1-positive intermediate cell state. Mechanistically, EED loss de-represses bivalent genes co-marked by H3K27me3 and H3K4me3, including LUAD oncogenic RAS, PI3K, and MAPK pathway genes, to promote transformation to LUAD. Consistently, these same signaling pathway genes are bivalently marked and silenced in human SCLC patient-derived xenografts, indicating a conserved PRC2-mediated mechanism to repress LUAD oncogenic signaling to maintain the SCLC neuroendocrine identity. In a novel CRISPR-based *EGFR*-mutant LUAD GEMM with *RB1/TP53* loss, we found EED is necessary for LUAD to SCLC transformation and metastatic progression following EGFR withdrawal. Altogether, these findings identify the PRC2 complex as an epigenetic regulator that maintains the SCLC neuroendocrine identity and highlights EED inhibition as a potential therapeutic approach to prevent SCLC transformation in high-risk LUAD.

#3529 Identification of the clonal origin of endometriosis-associated ovarian cancer in normal endometrium.

Koichi Watanabe, Nobuyuki Kakiuchi, Kosuke Ieiri, Hirona Maeda, Tomonori Hirano, Mana Taki, Koji Yamanoi, Ryusuke Murakami, Masaki Mandai, Seishi Ogawa

Kyoto University, Kyoto, Japan

[Introduction]Recent studies have revealed pervasive mutations in cancer-related genes within many normal tissues, including the endometrium. Endometriosis-associated ovarian cancer (EAOC) is hypothesized to arise from endometriotic lesions seeded from the endometrium to the ovary, although direct evidence supporting this origin has been lacking. This study aimed to identify the clonal origin of EAOC in the endometrium by detecting shared somatic mutations between EAOC tumors and endometrial clones.
[Methods]We performed high-density sampling of histologically normal endometrial tissues from 6 patients diagnosed with EAOC (5-32 sample/patient, 84 samples in total) and conducted whole-exome sequencing. The resulting somatic mutation profiles were compared with those of the matched EAOC tumors from the same patients.
[Results]Endometrial samples harbored a median of 28.5 (range 6-74) somatic mutations. In 78 of 84 histologically normal endometrial samples (93%), one or more of known driver gene mutations involving *PIK3CA, PIK3R1, KRAS, PPP2R1A, ARHGAP35* and *FBXW7* were identified, with an average of 2.4 mutations/sample (range 0-7). *PIK3CA* mutations were the most common, detected in 44 of 84 samples (52%), followed by *ARHGAP35* mutations (25/84, 30%). Notably, in two cases, we identified an endometrial sample sharing multiple somatic mutations with the EAOC tumors. In Case 1 (74 y/o, ovarian clear cell carcinoma), one of 32 endometrial samples shared 16 mutations with the tumor, including alterations in *PTEN*, *PIK3CA*, and *KRAS*. In Case 2 (31 y/o, bilateral ovarian endometrioid carcinoma), one of 6 endometrial samples shared 11 mutations with the tumor, including in *PIK3CA, AKT1, PPP2R1A* and *CTNNB1*. Phylogenetic analysis using whole-genome sequencing estimated that the most recent common ancestor of the cancer diverged from the normal endometrial clone in their early 20s in both cases. In Case 1, the tumor acquired additional copy number alterations not present in the endometrial ancestor, suggesting their potential role in carcinogenesis. By contrast, in Case 2 no clear genetic differences were detected between the ancestral endometrial clone and the ovarian tumor, suggesting that the transition from normal tissue to cancer may be driven by non-genetic events.
[Conclusion]We demonstrated that at least some EAOC tumors originate from an ancestral clone in the histologically normal endometrium. This ancestral clone had already acquired multiple driver
events contributing to carcinogenesis. Our findings provide new insights into the early events underlying EAOC development.

#3530 Drug pressure driven evolution upregulates CIDEA to reprogram lipid metabolism and promote chemoresistance in colorectal cancer.

Haigui Wan[1], Yao Shang[2], Dongwen Chen[2], Chuling Hu[2], Yiran Bie[2], Zhengran Zhou[1], Zhengyu Wei[2], Chong Chen[1], Yifan Zheng[2], Peishan Hu[2], Xiaojian Wu[2]

ABSTRACT

BACKGROUND: Chemoresistance remains a major challenge to long-term survival in colorectal cancer (CRC). Although lipid metabolic reprogramming is a key adaptation under sustained drug pressure, its dynamic changes and core regulators remain unclear. Defining the clonal evolution and metabolic drivers of acquired resistance is essential for identifying therapeutic targets.

METHODS: Forty-six CRC PDOs were established and subjected to long-term, dose-escalating FOLFOX induction to generate resistance models. Whole-exome sequencing (WES) and RNA-seq were performed before and after induction to assess genomic stability, clonal evolution, and transcriptional remodeling. Multi-cohort validation used TCGA, ICGC-ARGO, and recurrent tumor samples from our institution. Functional assays—including lipid metabolic activity, stemness phenotype, and chemosensitivity analyses—were performed for candidate genes, followed by overexpression and knockdown PDO models to evaluate in vivo effects using xenografts.

RESULTS: Resistant PDOs exhibited denser and more irregular structures with reduced gland-like morphology. Early-stage PDOs retained ~80% of the mutational landscape of primary tumors; with prolonged induction, drug pressure drove clonal selection and genomic drift, with ~60% of mutations retained in late stages, indicating PDOs maintain tumor representativeness during long-term culture. Copy-number alterations of dominant clones correlated with gene expression, suggesting a gene-dosage effect. Multi-omics analyses revealed marked upregulation of CIDEA in resistant PDOs, accompanied by lipid metabolic remodeling and increased expression of FASN, ACACB, FABP1, CD36, along with activation of MAPK and PI3K-Akt pathways. Across TCGA, ICGC-ARGO, and recurrent cohorts, high CIDEA expression was associated with advanced stage and higher recurrence. Functionally, CIDEA overexpression promoted lipid droplet accumulation and enhanced fatty acid oxidation (FAO), driving chemoresistance, whereas CIDEA knockdown reduced FAO, downregulated lipid metabolic genes, and restored chemosensitivity. FAO inhibition reversed resistance in CIDEA-overexpressing cells. In vivo xenografts confirmed that CIDEA knockdown improved chemosensitivity, while CIDEA-driven resistance was reversed by FAO inhibition.

CONCLUSIONS: This study delineates the clonal evolution and lipid metabolic remodeling underlying acquired chemoresistance in CRC and identifies CIDEA as a key driver that promotes resistance through lipid droplet accumulation and enhanced FAO, highlighting its therapeutic potential.

Key words: Colorectal cancer; Chemoresistance; Patient-derived organoids; Clonal evolution; Lipid metabolic reprogramming

#3531 Temporal ordering of genomic events reveals distinct evolutionary trajectories in early-onset breast cancer.

Sejung Lee[1], Jeonghyeok Lim[2], Hyeji Kim[3], Min-Chae Kang[4], Eun-Gyeong Lee[3], Sun-Young Kong[5], Jinhyuk Bhin[1]

[1]Biomedical Systems Informatics, Yonsei University College of Medicine SBSI, Seoul, Korea, Republic of,[2]Graduate School of Medical Science, Brain Korea 21 Project, Yonsei University College of Medicine SBSI, Seoul, Korea, Republic of,[3]Cancer Biomedical Science, Graduate School of Cancer Science and Policy, National Cancer Center, Goyang, Korea, Republic of,[4]Targeted Therapy Branch, Research Institute, National Cancer Center, Goyang, Korea, Republic of,[5]Department of Laboratory Medicine, Hospital, National Cancer Center, Goyang, Korea, Republic of

Introduction:
Early-onset breast cancer (EOBC), diagnosed in women under 40, exhibits more aggressive behavior than later onset breast cancer (LOBC), with a higher recurrence rate and poorer prognosis. Despite these clinical differences, the genomic basis of EOBC remains poorly understood, making it crucial to explore these distinctions in order to elucidate age-associated genetic and tumor evolutionary features of EOBC.

Methods:
We performed whole-genome sequencing on 169 Korean breast cancer patients (97 EOBC, 72 LOBC) to comprehensively characterize their genomic landscapes, including single-nucleotide variants (SNVs), copy-number variants (CNVs), and structural variants (SVs). We analyzed germline & somatic driver mutations and mutational signatures to compare the etiological mechanisms between EOBC and LOBC, and reconstructed clonal architectures to determine the molecular timing and temporal ordering of key driver events in both age groups.

Results:
In EOBC, we observed a higher frequency of GATA3, PPM1D, and MYC alterations. The structural rearrangement landscape was characterized by enrichment of intra-chromosomal rearrangements on chromosomes 1q and 8, as well as inter-chromosomal rearrangements involving chromosomes 17 and 8. Copy-number and mutational signature analyses further showed increased prevalence of chromosomal LOH (CN13), chromothripsis-associated amplifications (CN8), and DNA damage-repair-related signatures, including D8 (replication stress) and M2 (base excision repair errors), indicating that EOBC is driven by oncogene activation and replication stress-associated genomic instability. In terms of tumor evolution, EOBC follows a rapid, oncogene-driven trajectory initiated by early TP53-inactivating mutations and PIK3CA-activating mutations, which promote tumor cell survival and proliferation. Whole-genome duplication (WGD) arises subsequently and occurs relatively early in the evolutionary course of EOBC compared with LOBC, further buffering and amplifying pre-existing genomic instability and accelerating tumor progression. In contrast, LOBC exhibited a higher frequency of PTEN mutations and WGD, which underpinned large-scale genomic alterations, including extensive tumor suppressor losses and copy-number signatures related to chromothripsis and WGD (CN25, CN6, CN7), collectively contributing to sustained genomic instability. Evolutionarily, LOBC appears to progress more gradually, beginning with 1q gains (MDM4, MCL1) and early loss of tumor suppressors that support tumor survival and invasion, with WGD typically occurring at a later stage and adding further genomic instability after prolonged tumor development.

Conclusion:
EOBC follows a rapid, oncogene-driven evolutionary trajectory with early genomic instability and WGD, whereas LOBC progresses more gradually with later tumor suppressor loss and WGD.

#3532 Genetic insights into clonal evolution from normal prostate epithelium to cancer via HighGradePIN.

Graduate School of Medicine, Kyoto, Japan,[2]Kyoto University Graduate School of Medicine, Kyoto, Japan,[3]Kyoto University Hospital, Kyoto, Japan,[4]Kyoto University, Kyoto, Japan,[5]Kyushu Univ. Graduate School of Medical Sci., Fukuoka, Japan,[6]Kyoto Universtiy Hospital, Kyoto, Japan,[7]Institute for Virus Research, Kyoto Univ., Kyoto, Japan,[8]Postdoctral Research Fellow, Dept. of Urology, Kyoto University Graduate School of Medicine, Kyoto, Japan

Background Prostate cancer (PC) is one of the most prevalent cancers in the developed world, where its incidence is still increasing. Most PCs are thought to arise from high-grade prostatic intraepithelial neoplasia (HGPIN), a well-recognized precursor lesion. However, the genetic landscape of HGPIN and its relationship with normal prostate epithelium (NPE) and PC remains to be fully explored. To clarify the early genetic events and clonal dynamics underlying PC development, we performed comprehensive genomic profiling of NPE, HGPIN, and PC.

Methods We performed laser-capture microdissection (LMD) to obtain samples from PC (n = 49), HGPIN (n = 77), and NEP (n =393), which were subjected to whole-exome sequencing (WES). We measured genome-wide mutation burdens in normal prostate epithelium from 5 patients using a highly accurate sequencing platform, Nanoseq.

Results In NanoSeq, a total of 10,047 SNVs & indels were detected across 393 NPE samples, based on which the mutation accumulation rate in NPE was estimated to be 0.205 mutations/year/exon. Several mutations were shared between NPE and HGPIN as well as between HGPIN and PC, suggesting a common clonal origin. Pathogenic FOXA1 mutations were frequently detected in both HGPIN and PC. Although pathogenic FOXA1 mutations were also found in NPE, they did not overlapped with those in HGPIN or PC and therefore, likely represent independent mutational events. In one case, spatially distinct multifocal cancers exhibited multiple FOXA1 mutations, each of which was shared with corresponding adjacent HGPIN. In additional cases, 12 mutations were shared across PCa, HGPIN, and NPE samples, although no known driver mutations were detected therein. These findings suggest that PCa may arise from clones with apparently normal histology, which progress through HGPIN to PC. Phylogenetic analysis of these samples revealed that PC and HGPIN diverged from a common normal ancestor approximately 45 years earlier.

Conclusions We successfully characterized somatic mutations and CNVs in apparently normal prostate epithelium, which were shared between HGPIN and adjacent PC in some cases. The presence of shared somatic mutations supports a clonal continuum from normal epithelium to precursor lesions and invasive carcinoma. These insights enhance our understanding of early prostate carcinogenesis and highlight potential avenues for early detection and intervention.

#3533 Integrative spatial profiling of protein and chromosomal alterations across normal, precancer, and cancer revealed the presence of aneuploidy in the normal fallopian tube.

Tanjina Kader[1], Yu-An Chen[1], Clemens Hug[1], Jia-Ren Lin[1], Jeremy Muhlich[1], Euihye Jung[2], Charles Drescher[3], Ronny I. Drapkin[4], Peter Karl Sorger[5], Sandro Santagata[6]

[1]Harvard Medical School, Boston, MA,[2]Perelman School of Med. Univ. of Pennsylvania, Philadelphia,[3]Fred Hutchinson Cancer Center, Seattle, WA,[4]University of Pennsylvania, Merion Station, PA,[5]DFCI/Harvard Medical School,[6]Brigham and Women's Hospital, Boston, MA

Introduction: Simultaneous measurement of protein expression and chromosomal alterations within the same FFPE section enables direct analysis of clonal selection and disease progression from normal epithelium through precancerous to cancerous states. We developed a unified workflow based on the one-shot Orion multiplexed imaging platform (Lin et al., Nature Cancer 2023) that integrates high-dimensional protein imaging with a conventional DNA-FISH assay for in situ detection of chromosomal copy number alterations (CNAs). Traditional DNA-FISH, although widely used in diagnostic practice, requires protease digestion and permeabilization steps that destroy antigen epitopes and distort nuclear morphology, preventing reliable protein detection and limiting integration with immunofluorescence. The challenge spans both normal precursor and malignant tissues, where densely packed or overlapping nuclei complicate single-cell CNA scoring - an issue that is now particularly relevant, given the growing recognition that aneuploidy can arise even in morphologically normal epithelia.
Method: Recent advances in multiplexed imaging now enable phenotypic characterization of individual cells harboring CNAs, a capability previously unattainable with conventional immunofluorescence. To realize this potential, we optimized fixation, hybridization, and imaging parameters to preserve both antigenicity and nuclear architecture while maintaining robust CNA detection. The resulting ORION-FISH workflow enables simultaneous visualization and quantification of protein states and chromosomal alterations within the same section.
Results: We have found that normal fallopian tube epithelium harbors MYC and/or CCNE1, both of which are common CNAs in High Grade Serous Ovarian Cancer (HGSOC) and its precursor lesion, Serous Tubal Intraepithelial Carcinoma (STIC). We have also found that these aneuploid cells may have been under strong negative selection pressure, partially due to strong immune surveillance. Currently, we are analyzing in depth precursor samples and HGSOC specimens that will be presented at the meeting. Conclusion: We applied ORION-FISH approach to HGSOC and its precursors to generate spatial maps of aneuploidy and cell states across the normal-precancer-cancer continuum, establishing a foundation for our studies in the HGSOC Pre-Cancer Atlas 2.0.

#3534 Forecasting oncogene amplification and tumor suppressor deletion.

[1]Spanish National Cancer Research Ctr. (CNIO), Madrid, Spain,[2]Memorial Sloan Kettering Cancer Center, New York, NY,[3]University of Bergen, Bergen, Norway,[4]Universidad de Navarra, Pamplona, Spain,[5]University of Vigo, Vigo, Spain,[6]Universite Libre de Bruxelles, Brussels, Belgium,[7]Institut Universitaire du Cancer de Toulouse-Oncopole, Toulouse, France,[8]CNIO-H12o Lung Cancer Unit, Hospital Universitario 12 de Octubre, Madrid, Spain,[9]Hospital Universitario 12 de Octubre, Madrid, Spain

Oncogene amplification and tumor suppressor deletion can drive tumor initiation, progression and treatment resistance. Detection at diagnosis often signals poor prognosis, but it can also enable opportunities for treatment with highly effective targeted therapies. Predicting the likelihood that a patient will acquire these driver alterations in the future using a genomic test represents an opportunity to realize the benefits of interventions earlier, potentially with preventative intent. Here, we present a forecasting framework that takes as input a DNA copy number profile and predicts whether the tumor will acquire an oncogene amplification or tumor suppressor deletion in the future. This framework leverages mutation rate estimates from the input tumor, alongside gene-specific selection coefficients derived from a large cohort of 7,880 tumors. We demonstrate feasibility using 7,042 single-time-point samples and longitudinally collected tumor pairs from 44 prostate and 100 lung cancers, identifying tumors that went on to acquire amplifications at a later time point with an average AUC of 0.87. We show potential clinical utility by forecasting poor prognosis in low-grade gliomas via CDK4/PDGFRA amplification or CDKN2A deletion, and osimertinib resistance in lung cancers via MET amplification. This study serves as a proof-of-concept for a new class of biomarker, wherein selective pressures and mutation-generating processes can be harnessed to anticipate future genomic alterations.

#3535 Multi-omics analysis of longitudinal melanoma samples reveals evolutionary transitions and therapy-associated cell-state switching.

Background: In-transit metastasis (ITM) in melanoma is associated with poor prognosis, yet patients show widely variable clinical outcomes from rapid progression to durable responses. To investigate the mechanisms underlying these variations, we performed multi-omics profiling of sequential tumor biopsies from an ITM melanoma patient who progressed to stage IV over 4 years.
Methods: Whole-exome sequencing (WES) from 14 tumors was analyzed using ABSOLUTE for purity-adjusted variant and CNA calling. Pyclone and PhylogicNDT defined mutational clusters based on cancer cell fraction (CCF) and inferred tumor lineages. The phylogenetic map was then integrated with clinical metadata. Gene set enrichment analysis (GSEA) on bulk RNA-seq assessed lineage- and time-associated melanoma signatures and transcriptional programs.
Results: Phylogenetic reconstruction captured 3 major lineages (L1: ITM; L2: ITM + distant subcutaneous metastases; L3: distant skin metastases) from a common ancestral clone. Combination of anti-PD1 and intralesional T-VEC therapy reshaped the genomic landscape of tumor clones, selectively favoring L3, which expanded into clonality while L1 became undetectable, consistent with therapy-associated selection. L2, branched off L1, also exhibited persistent survival and immune resistance. RNA-seq showed evidence for a coordinated shift from a highly differentiated state towards an AXL-high state following clinical immune intervention. Transcriptional tumor state heterogeneity increased over time, independent of lineages. Both ITM (L2) and distant (L3) lineages initially displayed more invasive, mesenchymal-like cell state profiles immediately following the clone formation, but transitioned towards more differentiated tumor states, benefiting cell proliferation and clonal expansion. By the end of the clinical course, all distant lesions across anatomical sites converged on an MITF-driven, melanocytic-like proliferative state.
Conclusion: This study reconstructed a phylogenetic map for tumor evolution through multi-omics, longitudinal data from an ITM patient to reveal key pathways and tumor state changes associated with metastatic events and heterogeneity in clinical responses. In the next step, the individual phylogenetic trees will be compared with other patients in the cohort to explore intra-tumoral, inter-tumoral, and inter-patient heterogeneity in tumor progression, metastasis sites, and resistance to therapy.

#3536 Quantifying evolutionary dynamics and tumor heterogeneity in oncogene-addicted advanced non-small cell lung cancer.

[1]Chemical Biology, Harvard University, Cambridge, MA,[2]Cancer Program, Broad Institute of MIT and Harvard, Cambridge, MA,[3]Cancer Center, Massachussetts General Hospital, Boston, MA,[4]Massachusetts General Hospital, Charlestown, MA

Non-small cell lung cancer (NSCLC) is characterized by oncogene addiction, where unique genetic, epigenetic, and transcriptomic alterations drive tumor initiation, growth, and survival. Tyrosine kinase inhibitors (TKIs) against actionable oncogenes showed initial promise, but acquired resistance remain significant clinical challenges. To define the evolutionary dynamics underlying resistance and tumor heterogeneity, we integrated WES/WGS and RNA sequencing data from 1,253 longitudinal biopsies and multi-site rapid autopsies from 104 patients, including an ALK-rearranged cohort. We developed a unified framework combining cutting-edge computational tools and novel statistical methods to characterize and quantify tumor heterogeneity under TKI selective pressure. In 2 ALK-rearranged cases with acquired resistance to TKIs, we identified subclones with multiple compound ALK mutations. In pt062, 2 ALK double-mutant subclones shared an ancestral resistance mutation C1156Y, and independently developed secondary hits L1198F and I1171S, where I1171S retains partial sensitivity to Lorlatinib, potentially revealing a transient therapeutic window before full resistance. In pt992, 3 ALK double-mutant subclones shared an original mutation F1193Y, and independently acquired secondary hits G1269A, E1210K, and G1210R, driving differential resistance to Crizotinib and Lorlatinib. In pt992, F1193Y may be a rare activating mutation that is insufficient to confer resistance to ALK TKIs alone, but promoted resistance in combination with secondary hits. Phylogenetic analysis revealed predominantly monoclonal seeding early in disease in pt062 vs polyclonal reseeding after the emergence of resistance in pt992. Metastatic route inference in pt992 suggests that a mix of distinct subclones result in lesions with triple ALK mutations. Intra-tumor heterogeneity (ITH) calculated from the clonal diversity index revealed that TKI exposure increased ITH, resulting in lesion-specific subclones. In pt992, divergent clonal dynamics in G1202R+ clones showed lower ITH than E1210K+ clones. The founding clones persisted at ~50% (pt992) and 85% (pt062) tumor fraction post-TKI, indicating inadequate selective pressure. Copy number alteration- and transcriptomic-based ITH suggest possible structural differences in clonal populations between primary and metastatic tumors. Bray-Curtis dissimilarity scores of inter-tumor heterogeneity revealed 3 clusters in both cases, suggesting that metastatic lesions evolved from specific subclones. RNA-seq immune deconvolution via CIBERSORT showed variable immune cell infiltration patterns without correlation to clinical outcome. These results demonstrate that TKIs drive clonal diversification and evolution of resistance in oncogene-addicted NSCLC, and offer a quantitative framework for lineage-informed therapeutic strategies.

#3537 *Rb1* loss defines distinct migration histories in metastatic prostate cancer subtypes.

Dawid G. Nowak[1], **Ryan N. Serio**[1], Lise M. Brault[1], Domenic V. Gargiulo[1], Rebecca Hassett[2], Ryan J. Chaffee[1], Stephen J. Staklinski[2], Billy Lu[1], Adam C. Siepel[2]

[1]Meyer Cancer Center, Weill Cornell Medicine, New York, NY,[2]Cold Spring Harbor Laboratory, New York, NY

Rb1 loss is a hallmark of lethal castration-resistant prostate cancer (CRPC), yet its role in shaping metastatic dissemination patterns remains poorly understood. Using our EvoCaP somatically engineered mouse model (SEMM), we generated *Pten*/*Trp53*/*Rb1*-deficient (*2PR*) mice and compared them to *Pten*/*Trp53*-deficient (*2P*) controls. Loss of *Rb1* dramatically increased metastatic burden, particularly to visceral organs, and promoted neuroendocrine (NE) differentiation. Lineage tracing revealed that *2PR* tumors establish metastatic hub organs that seed cascade dissemination to multiple secondary sites. Histologically, *2PR* tumors displayed distinct NE and mesenchymal-like (ML) compartments, with NE regions showing elevated β-catenin and EZH2 expression, markers of aggressive castration-resistant prostate cancers including: CRPC-WNT (Wnt signaling driven) and CRPC-NE (EZH2-high) subtypes. Organoids derived from *2PR* tumors confirmed these transcriptional changes and showed enhanced sensitivity to EZH2 and WNT inhibitors. These findings reveal how *Rb1* loss drives lineage plasticity and metastatic evolution in prostate cancer, identifying therapeutic vulnerabilities in this lethal disease subtype.

#3538 Clonal landscape of human nephrons.

Kosuke Ieiri[1], Nobuyuki Kakiuchi[2], Koichi Watananbe[1], Tomonori Hirano[1], Shun Kawaguchi[1], Hirona Maeda[1], Yoshikage Inoue[1], Tatsuki R. Kataoka[3], Hiroko Tanaka[4], Satoru Miyano[4], Masaki Shiota[5], Eto Masatoshi[5], Seishi Ogawa[1]

[1]Department of Pathology and Tumor Biology, Kyoto University, Kyoto, Japan,[2]The Hakubi Center for Advanced Research, Kyoto University, Kyoto, Japan,[3]Department of Pathology, Iwate Medical University, 1-1-1 Idaidori, Yahaba, Shiwa District, Iwate, Japan,[4]Department of Integrated Analytics, M&D Data Science Center, Tokyo Medical and Dental University, Tokyo, Japan,[5]Department of Urology, Graduate School of Medical Science, Kyushu University, Fukuoka, Japan

Background: Renal cell carcinoma (RCC) subtypes are believed to arise from distinct nephron segments, suggesting that the accumulation and patterns of genetic alterations in normal nephron may also vary by segment. However, due to the intricate architecture and the technical challenges in isolating each nephron segment separately, the mutational landscape within the nephrons remains poorly understood.
Methods: We used laser-capture microdissection (LCM) to isolate five distinct nephron segments, including proximal convoluted and straight tubules (PCT and PST), distal convoluted and straight tubules (DCT and DST), and collecting ducts (CD), which were then analyzed using a highly accurate sequencing platform (NanoSeq) and whole exome sequencing (WES).
Results: NanoSeq analysis of the 175 LCM samples from 12 patients revealed that single nucleotide variants (SNVs) linearly increased with aging. However, the accumulation rate markedly varied across segments: PCT and PST showed notably higher rates (123 and 132 SNVs per genome/year, respectively), compared with DST (28), DCT (27), and the lowest in CDs (18). Seven SBS signatures (SBS1,5,8,12,40a-c) were detected. The age-related SBS5 was similar across all segments and accounted for most of the mutations in the distal compartments. In contrast, SBS12, SBS40b and SBS40c were largely confined to the proximal segments, mostly explaining their higher mutational burdens. Furthermore, the SBS12 signature was significantly enriched in PCT, showing a strong transcriptional strand bias. WES analyses on the 683 LCM samples from 6 patients showed frequent monoclonal expansion in the proximal tubules and CDs of aged donors, which were rarely seen in distal tubules. Notably, an extensively expanded clone in the PCT harboring a 3p loss and a mutation affecting PBRM1, a common driver gene in clear cell RCC, was observed in morphologically normal PCTs. In total, 11.7% of all LCM samples harbored ≥1 non-synonymous mutations affecting known RCC driver genes. Most of these mutations were detected in proximal tubules, while rarely found in distal tubules and CDs. Copy number alterations were quite common, found in 35.1% of the samples and strongly correlated with donor age. The most frequent alterations included gains of Chromosomes 10 and 7 and losses of Chromosomes 18 and 22. Of note, chromosome 10 gain was mostly confined to proximal nephrons, while Chromosome 18 loss was almost exclusively found in CD.
Conclusion: Aging kidney nephrons undergo pronounced remodeling characterized by segment-specific accumulation of mutations and clonal expansions. Proximal tubules exhibit the highest mutation rates and accumulate RCC driver alterations. The strong enrichment of the SBS12 signature in the PCT confirmed the previous view that PCT is the origin of this RCC subtype. The strong strand bias for SBS12 suggests the influence of exogenous mutagens absorbed from PCTs, and identifying the causative agent could be important for RCC prevention.

#3539 Spatial profiling of prostate cancer clonal evolution linked to nodal metastases.

Alastair David Lamb[1], Joakim Lundeberg[2], Sandy Figiel[3], Max Beesley[1], Mengxiao He[2]

[1]Queen Mary University of London, London, United Kingdom,[2]Science for Life Laboratory, KTH Royal Institute of Technology, Stockholm, Sweden,[3]University of Oxford, Oxford, United Kingdom

The progression of prostate cancer (PCa) to metastatic disease remains a critical clinical challenge, making it essential to gain a detailed understanding of the factors that enable certain subclones to invade and spread. Building on our previous study, which examined genomic variations in benign and malignant prostate tissues by inferring copy number alterations (CNA) from spatial transcriptomics data[1], this study aims to trace the spatial evolutionary trajectories of PCa subclones within the prostate and to draining lymph nodes and to identify alterations in associated microenvironments features of the metastatic transition.

To achieve this, we performed spatial transcriptomics on entire prostate axial disks and patient-matched lymph node metastases from 10 individuals. Standard spatial transcriptomics (55 µm) was used for tissue profiling; from the spatial transcriptomics data, copy number alterations (CNAs) were inferred to identify distinct tumor subclones, and phylogenetic trees constructed to describe their evolutionary relationships. Additionally, high-resolution spatial transcriptomics (2 µm) technology was employed to gain a cellular-level view of the immediate tumor-microenvironment (TME) surrounding specific subclones in two selected patients.

Analysis of over 1,000,000 barcoded regions identified many distinct tumor subclones, enabling us to trace their evolutionary trajectories spatially. We observed notable subclonal events within the lymph nodes, including polyclonal colonization, indicating multiple origin events during the evolution of the primary disease. Exploration of the immediate TME revealed significant cellular heterogeneity and upregulation of genes related to antigen presentation and inflammatory pathways concentrated near ancestral tumor clones, specifically at the tumor border. By focusing on the inferred CNA profiles of the metastasizing clone across patients, we identified several common features defining the metastatic transition. Additionally, we were able to identify these metastasizing clones in matched diagnostic biopsies taken several months before prostatectomy was performed, raising the possibility of identifying potentially lethal disease at presentation.

In summary, our study provides a detailed spatial map of PCa clonal evolution and dissemination, linking primary tumors to nodal metastases and revealing altered cell composition and gene expression around tumor clone borders. Importantly, it demonstrates subclonal events within lymph nodes, polyclonal colonization, and the potential to identify metastasizing clones at diagnosis, with implications for risk-stratification and treatment decisions in PCa.

#3540 *KRAS*allelic imbalance reshapes tumor evolution through selective clonal outgrowth and chromosomal instability in NSCLC.

Li Zhang, Angeliki Bania, Enrico Gurreri, Alessia Savarese, Roberta Rinaldi, Calogero Carlino, Luigi Perelli, Giannicola Genovese

UT MD Anderson Cancer Center, Houston, TX

KRAS-mutant non-small cell lung cancer (NSCLC), which accounts ~25% of all NSCLC cases, remains one of the most refractory solid tumors due to its pronounced evolutionary adaptability and propensity to develop resistance. *KRAS* allelic imbalance, including loss of heterozygosity (LOH), is recurrently observed in patient tumors, its functional role in shaping clonal selection and tumor evolution remains unclear.We hypothesize that distinct subpopulations harbors LOH of *KRAS* driven by competitive fitness and acquire unique genomic events. To investigate how KRAS allelic imbalance influences tumor evolutionary trajectories, we developed a somatic mosaic genetically engineered mouse model (smGEMM) that integrates a 200-gene CRISPR-Cas9-GFP perturbation library with an allele-resolving fluorescent reporter (Tdtomato) embedded on murine chromosome 6, ~30 Mb from *Kras*^WT and in trans with *Kras*^LSL-G12D. Each perturbation is encoded by an sgRNA coupled to a unique capture sequence, allowing the combined sgRNA-capture element to serve as a recoverable molecular barcode for clonal tracing. This platform allows simultaneous readout of allelic configuration and competitive fitness, facilitating in vivo tracking of both *Kras*-heterozygous (TdT^+/GFP^+) and *Kras*-LOH (TdT^-/GFP^+) subclones.Preliminary lineage-resolved analyses revealed a consistent and reproducible selective expansion of *Kras*-LOH subclones across biological replicates. LOH subclones consistently formed larger tumors and overtook heterozygous populations, demonstrating that allelic imbalance confers a potential competitive advantage rather than representing neutral drift. We performed whole-genome profiling of reporter-mapped subclones showed that *Kras*-LOH tumors undergo extensive genomic rearrangements, including broad copy-number alterations, structural variations, and chromothripsis events. Our findings indicate that genome-scale instability emerges as a positively selected trait during the competitive expansion of LOH subclones.Our study identifies *Kras* allelic imbalance as an active driver of clonal evolution, linking selective advantage, clonal expansion, and increasing genomic complexity. By coupling allele-specific fluorescent tracing with a focused, CRISPR perturbation library, we uncover mechanistic insights into *Kras*-mutant NSCLC evolution and reveal evolutionary vulnerabilities that may be leveraged to prevent or overcome resistance in *KRAS*-driven lung cancer.

#3541 Dynamics of clonal hematopoiesis in ovarian cancer survivors: Correlation with carboplatin and PARP inhibitor exposure.

Elizabeth M. Swisher[1], Marc R. Radke[1], Nithisha Khasnavis[1], Jennifer Lopez Ochoa[1], Mayumi Rubin-Saika[1], Enna Manhardt[1], Emiko Oshima[1], Alexandra Bachmann[1], Roseanne Gamboa[1], David Wu[1], Sioban Keel[1], Sergei Doulatov[2]

[1]University of Washington, Seattle, WA,[2]Columbia University, NYC, NY

Ovarian cancer (OC) survivors may develop therapy-related myeloid neoplasia (TMN), and risk is increased by PARP inhibitor (PARPi) exposure. We characterized clonal hematopoiesis (CH), which may pre-date TMN, in blood from OC survivors, and its relationship to therapeutic exposures in the CHANCES (Clonal Hematopoiesis in cANCEr Survivors) study. We sequenced blood cell DNA using BROCA-MY, our custom next-generation sequencing (NGS) panel with 72 genes associated with OC, bone marrow failure, and leukemia and CH and identified pathogenic variants (CHVs) at ≥1% variant allele frequency (VAF).We sequenced blood from 170 OC patients treated with carboplatin-based chemotherapy (OC chemo), 24 OC patients on a PARPi trial collected prior to subsequent diagnosis of TMN (pre-TMN), and 180 control subjects including OC patients without chemotherapy exposure (N=57) and age-matched cancer-free females (N=123). CHVs were common across all sample groups but were significantly more frequent in OC chemo (88/170, 52%) than controls (68/180, 38%, p=0.01). Within OC chemo cases, PARPi exposure was significantly associated with CHV detection: 39 (34.2%) had 0 CHV, 20 (17.5%) had 1 CHV and 55 (48.2%) had ≥2 CHVs, versus no PARPi exposure: 51 (51%) had 0 CHV, 29 (29%) had 1 CHV, and 20 (20%) had ≥2 CHVs (P<0.0001, chi-squared test for trend). CHVs were significantly more common in OC chemo cases than controls for *TP53* (7.6% vs 1.7%, p=0.009), *CHEK2* (11.2% vs 0.6%, p<0.0001) and *PPM1D* (21.8% vs 0.6%, p<0.0001) while CHVs in *DNMT3A* (21.8% vs 20.6%) and *TET2* (10% vs 7.2%) were identified at similar frequency. OC chemo and pre-TMN cases receiving more >1 platinum regimen had greater frequency of *TP53*-mutated CH (19/96, 19.8%), compared to ≤1 platinum regimens (4/81, 4.9%, p=0.003) We calculated the CH risk score (CHRS) for samples with available complete blood count results; the CHRS stratifies the risk of progression from CH to overt malignancy. OC chemo cases with CH were more likely to be categorized as high risk (7/23, 30.4%, CHRS≥1.0 predicting a >50% 10-year risk of progression to myeloid neoplasia) versus controls with CH (2/43, 4.7%, p=0.007). In serial samples collected from 41 participants in the CHANCES study, 83/88 (94.4%) CHVs were detectable in all samples. CH is frequent in both OC chemo cases and controls, but the number of mutations and involved genes vary by exposures, with chemotherapy selecting CHV in *CHEK2, PPM1D,* and *TP53*. *DNMT3A* and *TET2* CHVs, known to be associated with aging, were not impacted by chemotherapy exposure, while *TP53*-mutated CH was directly associated with platinum exposure, consistent with an increased risk for TMN development. We continue to collect serial samples via the CHANCES study to characterize CH dynamics and TMN risks in cancer survivors with the goal to generate a risk calculator specific for TMN and establish recommendations for surveillance of CH in cancer survivors.

#3542 Evolving toward precision oncology: Leveraging collateral drug responses for personalized second-line osteosarcoma treatment.

Elizabeth Nowak[1], **Jarrell Imamura**[2], Arda Durmaz[1], Masahiro Hitomi[3], Zachary Burke[1], Jacob G. Scott[4]

[1]The Cleveland Clinic, Cleveland, OH,[2]Cleveland Clinic Lerner College of Medicine, Cleveland, OH,[3]Project Staff, Dept. of Stem Cell Biology and Regenerative Medicine, The Cleveland Clinic, Cleveland, OH,[4]Case Comprehensive Cancer Center, Cleveland, OH

Objective: We aimed to model the evolution of chemoresistance to methotrexate, doxorubicin, and cisplatin (MAP) in vitro and to characterize collateral drug sensitivity and resistance patterns over time, potentially informing second-line treatment strategies in chemo resistant primary or recurrent disease.
Methods: Five evolutionary replicates of MG63.3 osteosarcoma cells were treated with six complete cycles of pulsed, clinically relevant doses of cisplatin and doxorubicin, alternating with methotrexate. Dose-response curves were performed after each chemotherapy cycle to assess resistance to MAP and collateral responses to 16 drugs and combinations. RNA sequencing and transcription factor activity inference were performed across treatment timepoints to temporally explore transcriptional correlates of drug response.
Results: Cells developed resistance to doxorubicin (1.49-2.59 fold) and methotrexate (0.92-2.87 fold) but remained sensitive to cisplatin. Collateral resistance emerged to etoposide, vincristine, and topotecan, while sensitivity increased to gemcitabine, cabozantinib, and palifosfamide. Collateral responses varied temporally, with some increasing linearly with evolution of MAP resistance, and some appearing transient or stochastic. Transcriptional profiling revealed increased activity of E2F and ERG and context-dependent roles for interferon signaling. Resistance phenotypes persisted after drug withdrawal and cryopreservation.
Conclusion: Our model reveals temporally dynamic, heterogeneous collateral responses during the development of chemoresistance to MAP in osteosarcoma. While cross-resistance to several agents emerged, collateral sensitivity to gemcitabine and cabozantinib supports a second line use for these agents. These data may inform rational sequencing of therapies to preempt or exploit resistance evolution.

#3544 Single-cell multi-omics uncovers coordinated epigenetic and transcriptomic evolution in IDH-mutant glioma.

Masashi Nomura[1], Ramya Raviram[2], Joshua S. Schiffman[2], Lillian Bussema[1], Vivian Lu[2], Noelle Wheeler[2], John Lee[1], Yilin Fan[1], Mian Hua Zheng[2], Florian Ruiz[1], Husain Danish[2], Sorcha Kellett[3], Labeeba Nusrat[3], Ronan Chaligne[4], Jason T. Huse[5], W. K. Alfred Yung[5], Shota Tanaka[6], Nobuhito Saito[7], Sunit Das[3], Catherine Potenski[2], Dan Landau[2], Mario L. Suva[1]

[1]Massachusetts General Hospital, Boston, MA,[2]Weill Cornell Medical College, New York, NY,[3]University of Toronto, Toronto, ON, Canada,[4]New York Genome Center, New York, NY,[5]MD Anderson Cancer Center, Houston, TX,[6]Okayama University, Okayama, Japan,[7]University of Tokyo, Tokyo, Japan

IDH-mutant gliomas (IDH-G) typically present as low-grade slow-growing tumors at diagnosis, but invariably progress to high-grade and incurable tumors despite maximal treatment. While previous bulk sequencing studies have shown that IDH-mutant gliomas undergo unique changes in DNA methylation and transcriptional programs during the tumor progression, how these jointly facilitate IDH-G evolution at cellular level has been poorly understood. To address this question, we profiled a longitudinal cohort of IDH-G (36 samples from 19 patients) by multi-omics single-nucleus sequencing, co-capturing full-length transcriptional (by Smart-Seq2) and DNA methylation (by extended-representation bisulfite sequencing (XRBS)) from the same single-nuclei. Compared to reduced-representation bisulfite sequencing (RRBS) used for single-cell DNA methylation profiling in our prior multi-omic single-cell study (Chaligne, et al, Nature Genetics, 2021), the XRBS adopted in this study provided higher coverage of CpG islands (mean of 378,888 vs 198,345, $P = 2.2 \times 10^{-16}$), especially in non-promoter regions. Single-nucleus RNA-sequencing analysis showed a longitudinal increase in the fraction of stem-like state and a reciprocal decrease in that of differentiated state after recurrence. Single-nucleus DNA methylation analysis revealed that in both IDH-G subsets (astrocytoma and oligodendroglioma), IDH-G progression was associated with methylation loss, which marks tumors with worse clinical outcome. This methylation loss was uniformly observed across malignant cells within the same individual tumors and was correlated with the increase in the fraction of stem-like population. This suggests that lower DNA methylation is not due to a change in cell state composition, but rather that it may underlie. Differentially methylated and expressed gene analyses of malignant cells with versus without methylation loss identified hypomethylation of PRC2 targets and increased expression of glioma stem-cell genes as potential mechanisms underlying the expansion of stem-like states. Leveraging our quantitative framework that directly measure cell state heritability and transition dynamics based on high-resolution lineage trees build by DNA methylation information suggested that decreased methylation reshapes cellular transitions to increased heritability of stem-like states and decreased differentiation. This study integrating single-cell methylation and transcription within an evolutionary framework shows how DNA methylation loss drives stem-like transcriptional states and altered cell-state dynamics in IDH-G, offering a blueprint for dissecting evolution in human cancers.

#3545 Integrated genomic and transcriptomic profiling uncovers spatial and evolutionary dynamics in astrocytoma.

Serafiina Jaatinen[1], Sonja Mantyla[1], Reetta Natkin[1], Ismail Hermelo[1], Anssi Nurminen[1], Aliisa Tiihonen[1], Iida Salonen[1], Elisa M. Vuorinen[1], Kristiina Nordfors[2], Hannu Haapasalo[3], Kirsi Rautajoki[1], Joonas Haapasalo[4], Matti Nykter[1]

[1]Tampere University, Faculty of Medicine and Health Technology, Tampere, Finland,[2]Tampere University Hospital, Unit of Pediatric Haematology and Oncology, Tampere, Finland,[3]Fimlab Laboratories ltd. and Tampere University, Tampere, Finland,[4]Tampere University Hospital and Tampere University, Department of Neurosurgery, Tampere, Finland

Intratumoral genomic heterogeneity in glioblastoma arises through clonal evolution and may contribute to treatment resistance and poor outcomes, yet the interplay between subclonal diversity and transcriptional states remains incompletely understood. We utilized multi-sampled whole-genome sequencing (WGS), bulk RNA sequencing, and single-cell RNA sequencing (scRNA-seq) to comprehensively map the layers of intratumoral transcriptomic and genomic heterogeneity and trace the evolutionary lineages across twelve spatially distinct tumor regions in two glioblastoma and one IDH mutant high-grade astrocytoma patients. In the IDH mutant astrocytoma, tumor evolution was characterized by early whole-genome duplication followed by a rare chromothripsis between chromosomes 2 and X, as well as region-specific hypermutation enriched for short insertions and deletions. In contrast, both glioblastomas exhibited linear evolution facilitated by early clonal copy number alterations and single-nucleotide variants, and in one patient, extensive loss of heterozygosity, extrachromosomal DNA structures, and high ploidy. Single-cell copy number analysis validated WGS-defined clones in this patient and uncovered additional subclones with distinct copy number alterations undetectable in bulk sequencing, refining the tumor's phylogenetic tree. Transcriptomic profiling revealed region- and clone-specific differences in glioblastoma cell states, while IDH mutant tumor regions generally exhibited neural progenitor-like activity in addition to astrocytoma-like programs. Glioblastoma samples were dominated by astrocytoma-like states but frequently displayed mesenchymal and endothelial-like transcriptional activity, with rarer and more heterogeneous niches of neural progenitor-like or oligodendrocyte precursor-like cells along with elevated proliferation and distinct maturation signatures. Moreover, scRNA-seq-derived subclones showed differences in mesenchymal-like expression and similar transcriptional branching with state differences observed in bulk RNA-seq, reflecting WGS-based clones. Together, these results demonstrate that intratumoral heterogeneity in adult diffuse astrocytomas arises from both genomic divergence and substantial transcriptional plasticity, while inter-patient diversity remains high across these aggressive tumors. By linking single-cell and bulk transcriptional profiles to evolutionary lineages, our multi-omic framework provides detailed insight into diffuse astrocytoma evolution and malignant cell-state organization.

#3546 Quantifying metabolic and clonal dynamics of evolving cancer cells.

Yi Zhong, Malak Aziz, Gabriel Hemighaus, Richa Mandrekar, **Alvin Makohon-Moore**

Center for Discovery and Innovation (Hackensack Meridian Health), Nutley, NJ

Scientists and clinicians have known for decades that cancer evolves within each patient as new clones emerge and the tumor progresses and spreads. Nonetheless, the molecular adaptations of clones evolving in dynamic environments remain difficult to define. Further, clones evolve for years prior to diagnosis and treatment, yet we know relatively little about cancer evolution before therapy. To directly quantify subclonal dynamics, we combined several novel methodologies to rigorously and comprehensively quantify human cancer cell dynamics by 1) evolving cancer cell populations that are comparable in size to clinically detectable human tumors (billions of cells) in highly controlled experimental conditions over extended periods, 2) analyzing cellular phenotypes and environmental parameters in real-time, 3) imposing precisely defined selective pressures such as treatment or metabolite depletion, 4) and enabling longitudinal sampling and characterization of cancer cells and their respective microenvironments. In combination with bioreactor culturing, we used genetic barcoding to quantify clonal dynamics occurring within each population and track the evolutionary fate of subclonal lineages. The size and duration of these cultures allowed us to consistently generate many samples from the same population over time, which is critical for modeling subclonal evolution occurring in patients and to identify adaptive mechanisms that are convergent or heterogeneous across clones. Thus far, we have successfully barcoded 14 human cell lines across solid and hematologic tumor types - including pancreatic, colorectal, leukemia, and others - and cultured these lines to evolve and expand unique clones from each population. We hypothesized that the survival of cancer cells under environmental constraints, including treatment-induced stress or nutrient-depleted microenvironments, is driven by intrinsic adaptive mechanisms that enable treatment resistance and continued evolution. Our results showed that cancer cells established highly dense and proliferative populations, with clones distinctly evolving across evolutionary pressures, including glucose limiting conditions and chemotherapy, while exhibiting ongoing reprogramming of gene and protein expression. Despite maintaining the media flow, oxygen level, and pH of each culture, cancer cells nonetheless depleted select metabolites, thereby fostering an imbalanced nutrient environment that is analogous to human tumors. In addition, we isolated clones from various timepoints across experiments to validate barcodes, quantify phenotypes, and enable experiments with defined subclone proportions. The impact of this work is to directly quantify the evolution of subclones under defined selective pressures, which is significant because the adaptive mechanisms we discover are expected to reveal novel therapeutic targets for enhancing treatments.

: Cancer Surveillance: Emerging Cancer Trends and Population Differences
Poster Session

#3551 Longitudinal changes in marital status, residence, and income among over 450,000 cancer patients: A SEER-based analysis.

Larry Mingda Zhao

BASIS Independent Silicon Valley Upper School, San Jose, CA

Background: The impact of cancer extends beyond clinical outcomes, often disrupting interpersonal relationships, residential stability, and financial security. However, longitudinal evidence on such changes and associated disparities remains limited.
Methods: A total of 457,058 adults diagnosed with multiple primary cancers in SEER-17 (2000-2021) were analyzed and changes in marital status, urbanicity, and household income between the first and last recorded diagnoses were assessed. Analyses were stratified by follow-up interval (short: 2-5 and long: >5 years). Logistic regression models adjusted for multiple demographic and clinical factors were used to estimate odds ratios (ORs) and 95% confidence intervals (CIs) for these changes.
Results: Among patients who were married at first diagnosis (n=255,939), 5% became not married (divorced/separated/single) and 11% were widowed; percentages were higher in women (6% not married; 16% widowed) than men (4%; 7%). Non-Hispanic Black (NHB) women and Hispanic women had the highest proportions becoming not married in both short- (8-11%) and long- (11-13%) intervals. Among patients who remained married from first to last diagnosis (n=214,956), 5% changed urbanicity (1.5% more rural; 3.4% more urban) and 26% changed income (15% increase; 10% decrease). In multivariate models, NHB patients had >2-fold higher odds of being unmarried (not married or widowed, adjusted OR=2.47, 95% CI 2.24-2.74 for short- and 2.19, 2.05-2.34 for long- intervals) and higher odds of income decrease (OR=1.22, 1.10-1.36 for short- and 1.44, 1.36-1.53 for long- interval) compared to non-Hispanic White patients. Hispanic patients also had elevated odds of becoming unmarried (OR=1.73,1.56-1.92 for short- and 1.56, 1.46-1.67 for long- interval), while Non-Hispanic Asian/Pacific Islander patients had lower odds of income decrease (OR=0.68, 0.59-0.78 for short- and 0.52, 0.48-0.57 for long- interval).
Conclusions: Cancer diagnoses are associated with considerable social-economic disturbances for patients, especially impacting women and vulnerable racial/ethnic populations. These findings emphasize the importance of implementing equity-focused interventions in susceptible demographics to address relationship strain, housing stability, and financial hardship.

#3552 Geographic and sociocultural disparities in breast cancer incidence and mortality in Latin America: Joinpoint trend analysis with a focus on regional variations within Colombia.

Oscar Marino Vidal

Medicine, Universidad del Norte, Barranquilla, Colombia

Background: Breast cancer (BC) remains the leading cause of cancer-related mortality among females worldwide. BC is the most common malignancy and cancer-related death among women in Latin America and the Caribbean (LAC), with substantial heterogeneity across the region. While overall BC burden continues to rise, geographic, demographic, and sociocultural disparities shape outcomes. Subnational analysis within countries such as Colombia is essential to identify context-specific challenges and opportunities for targeted interventions.

Methodology: We analyzed data from some of the most burdened countries in Latin America and compared them to the United States to quantify temporal trends in breast cancer (BC) incidence and mortality. Particular attention was given to subnational regions within Colombia. Using national and regional cancer registry sources and Joinpoint regression analysis to estimate annual (APC) and average annual percent change (AAPC) in incidence and mortality, Age-block analyses were performed to compare incidence by country and age group (Early adult, Adult, Later adult). Descriptive and ecological multivariable analyses explored associations with geographic, demographic, and sociocultural variables. We sought to relate these epidemiological trends to geographic, demographic (population structure), cultural, and lifestyle determinants, aiming to identify key correlations that may explain the variability in BC burden observed both between and within countries.

Results: Incidence and mortality rates increased with age across all countries. USA and Argentina exhibited the highest incidence among older adults, while Colombia had the lowest rates. Statistically significant differences in BC incidence were observed among countries in the adult and later adult age blocks (Kruskal-Wallis $p < 0.001$), but not among early adults. Joinpoint regression identified variation in the timing and magnitude of trend changes (joinpoints) between countries and within Colombian cities, with divergent patterns often corresponding to urbanization, socioeconomic status, and access to screening. Multivariable analyses revealed that regional disparities in incidence and mortality correlated more strongly with geographic, demographic, and lifestyle factors than with genetic ancestry.

Conclusions: Marked international and subnational disparities in BC incidence and mortality underscore the influence of geography, population structure, and sociocultural context in Latin America. Findings support the need for tailored public health strategies, emphasizing targeted screening and equitable access to care.

#3553 Geospatial clustering of socioeconomic deprivation and its impact on major cancers in Puerto Rico: 2014-2022..

Liliana Marie Castro-Jimenez[1], Yoel Velazquez Oliver[1], **Hilmaris Centeno-Girona**[1], Carlos R. Torres-Cintron[2], Elba V. Caraballo[1]

[1]Division of Shared Resources and Scientific Operations, University of Puerto Rico Comprehensive Cancer Center, San Juan, Puerto Rico,[2]Puerto Rico Central Cancer Registry, University of Puerto Rico Comprehensive Cancer Center, San Juan, Puerto Rico

Cancer incidence and mortality rates, as well as socioeconomic characteristics, can vary widely across the geographical landscape, challenging the common assumption of uniform risk throughout the population. A Deprivation Index for Puerto Rico was recently published by the Puerto Rico Institute of Statistics measuring economic mobility and demography to identify multidimensional poverty at the municipality level. Leveraging on this new index, this study aims to analyze the top five major cancers in Puerto Rico by sex and to examine their spatial correlation with the index during the period 2014-2022. Deprivation Index data at municipality level (n=78) was obtained using available data for 2014-2018 and 2019-2023 periods. Age-adjusted incidence (AAIRs) and mortality rates (AAMRs) for each top five female and male cancers were obtained from the Puerto Rico Central Cancer Registry. Global spatial autocorrelation for each period was assessed using Moran's index. Getis-Ord Gi* analysis identified high-deprivation (hot spots) and low-deprivation areas (cold spots) for each period. Municipalities identified as hot (n=15) and cold spots (n=19) in both periods were used to compare incidence and mortality using the Wilcoxon rank sum test. Analyses were conducted using R, version 4.4.1. The Deprivation Index of 2014-2018 demonstrated significant positive spatial autocorrelation for both periods: 2014-2018 (Moran index 0.59, $p<0.001$) and 2019-2023 (Moran index 0.44, $p<0.001$). A total of 34 municipalities were consistently classified as hot or cold spots in both periods. There is a notable difference in geographic deprivations areas. High-deprivation areas are concentrated in the southwestern part of the island, whereas cold spots are concentrated in the San Juan Metropolitan area of Puerto Rico. Differences were found across some cancer types with the Deprivation Index. Uterine cancer exhibited significantly higher AAIR in high-deprivation areas ($p<0.05$). Similarly, colorectal cancer in males showed a trend toward higher AAIR in high-deprivation areas ($p=0.107$). Lung and thyroid cancer for both sexes and prostate cancer had significantly lower AAIRs in high-deprivation areas ($p<0.05$). Lastly, ovarian cancer exhibited significantly higher AAMR in high-deprivation areas, while prostate cancer had higher AAMR in low-deprivation areas ($p<0.05$). Deprivation Index showed significant spatial autocorrelation over time, creating a distinct sociodemographic environment between areas. High-deprivation areas exhibited higher incidence for cancers like uterine, but lower incidence for lung, thyroid, and prostate cancer, which requires further analysis. Mortality is higher in high-deprivation areas for ovarian cancer, highlighting that socioeconomic barriers can worsen overall survival. These results emphasize the need for geographically targeted public health planning.

#3554 An entire-population analysis of nationwide trends in cancer incidence and mortality in hungary.

Zsolt Nagy, Balint Laszlo Balint, **Balazs Gyorffy**

Semmelweis University, Budapest, Hungary

BACKGROUND: Hungary faces a persistently high cancer burden, yet detailed, longitudinal assessments of population-level trends across major tumor types remain limited. Understanding shifts in incidence, mortality, and prevalence is essential for refining screening strategies and healthcare-system planning.
METHODS: Nationwide oncology records from the Hungarian National Health Insurance Fund (NEAK), completely covering the entire population of appr. 10 million, were analyzed for the five most common cancer types: breast (C50), colorectal (C18), lung (C34), prostate (C61), and stomach (C16). Annual incidence and mortality were calculated separately, while prevalence values represent two-year aggregated national counts. All metrics were summarized across both sexes and all age groups. Data were validated against established statistics from the Hungarian National Cancer Registry. Temporal changes represent differences between national baseline figures from 2018 and recent data through 2024.
RESULTS: The five tumor types exhibited consistent directional shifts nationwide. Breast cancer incidence increased 4.98%, mortality rose 42.69%, and crude prevalence increased from 37,887 to 39,773. Lung cancer incidence declined 10.61%, mortality decreased 3.02%, and crude prevalence fell from 31,829 to 28,452. Colorectal cancer incidence decreased 2.29%, mortality increased 21.24%, and crude prevalence declined from 27,589 to 26,956. Prostate cancer incidence rose 9.51%, mortality increased 32.55%, and crude prevalence increased from 19,046 to 20,858. Stomach cancer incidence increased 16.45%, mortality decreased 16.57%, and crude prevalence fell from 5,770 to 4,814. These patterns were observed across both sexes and all age groups, indicating broad population-level shifts rather than age- or sex-specific effects. A web tool was established to visualize these trends and is available at www.epidemplot.com.
CONCLUSIONS: Hungarian nationwide data reveal substantial mortality increases for breast, prostate, and colorectal cancers despite divergent incidence trends, indicating critical gaps in early detection and treatment pathways. Lung cancer demonstrated coordinated declines in both incidence and mortality. These findings highlight the need for targeted improvements in screening programs and care coordination for specific tumor types. This standardized framework enables ongoing national surveillance and expansion to additional malignancies.

#3555 Epidemiological characteristics of cancer patients at Ayder Comprehensive Specialized Hospital in Northern Ethiopia.

Meley Atakilti[1], Desta Mulu[2], Amanuel Asefa[2], Dawit Zenebe[3], Gebretsadik Lema[4], Engda Hagos[5]

[1]Medicine, Patriots Healing Medical Center, Mekelle, Ethiopia,[2]Oncology, College of Health Science, Mekelle University, Mekelle, Ethiopia,[3]Epidemiology, College of Health Science, Mekelle University, Mekelle, Ethiopia,[4]Public Health, College of Health Science, Mekelle University, Mekelle, Ethiopia,[5]Biology, Colgate University, Hamilton, NY

Cancer is a critical global public health issue, contributing to high rates of hospitalization and mortality worldwide yet limited research address population-based cancer data in East Africa particularly Northern Ethiopia. This study describes the epidemiology characteristics of cancer by demography, cancer type, and asses the risk factors and evaluates treatment and prevention modalities in Ayder Comprehensive Specialized Hospital, Tigray, Ethiopia filling a crucial information gap in the region. A retrospective descriptive cross-sectional study was employed, and data were extracted from hospital cancer registry and confirmed cancer patient's medical records spanning from September 2017 to September 2025. Key variables include age, sex, location, cancer type, treatment received and survival status. Statistical descriptive analysis was done across the data. The analysis includes 4229 cancer patients. Median age at diagnosis was 46 years and 63.2% of the patients were females. Nearly 44 % were aged 35 to 54. We found that the most common cancer was Breast (12.7%), Cervical (12.3%), Chronic Myeloid Leukemia (8.7%), colorectal cancer (7.5%), ovarian cancer (7%) and Non-Hodgkin Lymphoma (6.9%). While Cervical, Breast and Ovarian Cancer were the leading cancer types in females Chronic Myeloid Leukemia, Non-Hodgkin Lymphoma and Small/Chronic lymphocytic leukemia were among males. In a comprehensive analysis of female Breast cancer patients 25 % were under 40 years, the youngest being 19 and nearly half (45.3 %) of colonic cancer cases were diagnosed under 50 years of age, as young as 8 years old. In addition, a significant proportion of cancer cases (two third) were found in areas with ongoing conflict suggesting exposure to potential environmental risk factors. Significant variation in age and sex was noticed in this study**.** This study calls for expansion of cancer registry sites in the region. These unusual findings among these age groups suggest the need to screen the risk factors among young individuals for genetic predisposition and early environmental and lifestyle exposure in this population (Tigray is a conflict affected region with exposure to environmental contaminants for decades). The absence of molecular testing (BRCA 1 and 2, TP53, MLH1, and MSH2) and genetic risk assessment in those high-risk individuals in the region may be one contributing factor. In collaboration with laboratory research teams' genetic risk assessment is planned to further evaluate risk factors. Targeted earlier screening and management strategies are urgently needed to minimize cancer burden in this region.

#3556 Pediatric cancer in Puerto Rico: Epidemiologic trends and environmental risk context.

Celines Rodriguez Acevedo, Gabriela Pardo, Lenulisy Rosado, MiaSara Perez, Carolyn Ruiz, Karen Ortiz-Ortiz, Carlos R. Torres-Cintron, Ana Patricia Ortiz, Nancy Raquel Cardona, Rocio K. Rivera

University of Puerto Rico Comprehensive Cancer Center, San Juan, Puerto Rico

Background: Pediatric cancer in Puerto Rico shows distinct patterns compared to the U.S., with Hispanic children experiencing disproportionate burdens. Previous observations indicate high rates of malignant epithelial neoplasms, most of which are thyroid cancers. Puerto Rico also contains numerous EPA Superfund and Toxic Release Inventory (TRI) sites that release IARC-classified carcinogens. This study integrates pediatric cancer epidemiology with regional environmental contamination to contextualize risk patterns.

Methods: Pediatric cancer cases ages 0 to 18 diagnosed from 2009 to 2020 and pediatric thyroid cancer cases ages 0 to 20 diagnosed from 2000 to 2022, were obtained from the Puerto Rico Central Cancer Registry. Incidence, staging, and mortality patterns were described. Thyroid cancer case distribution was compared with the geographic placement of EPA Superfund and TRI facilities, and contaminant profiles were classified using IARC rankings.

Results: Among 1,666 pediatric cancer cases diagnosed from 2009 to 2020, the most common cancers were leukemias (24.25%), malignant epithelial neoplasms (predominantly thyroid cancers) & melanomas (18.19%), and lymphomas (15.85%). CNS tumors (5.2 %) and leukemias (4.5%) had the highest mortality. Neuroblastoma and malignant bone tumors showed high rates of local and distant metastatic disease at diagnosis. Several cancer groups demonstrated positive annual percentage changes. From 2000 to 2022, 380 pediatric thyroid cancer cases were identified, with the highest proportions in the Northeast, North, and Central regions, which also contain clusters of Superfund and TRI facilities that release IARC Group 1 carcinogens such as PCBs and cadmium.

Conclusion: Puerto Rico presents a distinct pediatric cancer profile, with thyroid cancer driving the high burden of malignant epithelial neoplasms and showing regional clustering near contaminated areas. These findings underscore the need to evaluate environmental exposures, diagnostic pathways, and structural determinants of pediatric cancer risk to support targeted interventions and enhanced surveillance.

#3557 Pediatric central nervous system tumors: An analysis of patients treated at Children's Nebraska over a 10-year period.

Amelia Nichols[1], Shinobu Watanabe-Galloway[1], Grace Lai[2]

[1]Department of Epidemiology, University of Nebraska Medical Center, Omaha, NE,[2]Department of Neurosurgery, University of Nebraska Medical Center, Omaha, NE

Nebraska has consistently had rates of pediatric Central Nervous System Neoplasms (CNS) above the national average. The study was an exploratory analysis using clinical data to characterize pediatric CNS tumors treated at Children's Nebraska or Nebraska Medicine over a 10-year period. Electronic health records were reviewed to identify patients diagnosed with a CNS tumor, aged 0 to 18 years, and treated at Children's Nebraska or Nebraska Medicine from 2013 to 2023. Data collected included demographics, clinical characteristics, and genetic testing information. ICD-0-3 codes were used to identify patients with a CNS tumor diagnosis. Diagnoses were classified according to the 2016 World Health Organization (WHO) Classification of Tumors. Zip codes were used to identify the Rural Urban Continuum Code (RUCC) of the patient's county of residence to determine urbanicity. The study population characteristics were summarized and descriptively compared by urbanicity, with chi-squared testing to determine significance. A total of 172 patients aged 0 to 18 years were identified as being diagnosed with a primary central nervous system tumor between 2013 to 2023. A greater proportion of patients were diagnosed at a younger age, with a median age at diagnosis of 7 years. The study population was predominantly female (55.81%; n=96), alive (77.33%; n=133), non-Hispanic White (72.09%; n=124), and from a metropolitan area (70.93%; n=122). Considering tumor characteristics, most diagnoses were malignant (87.21%; n=150) and made at the local stage (96.49%; n=165). Gliomas were the most diagnosed (65.12%; n=112) followed by embryonal tumors (16.86%; n=29). Tumor locations were predominantly reported as the brain stem (22.67%; n=39) or cerebellum (21.51%; n=37). Genetic testing data was available for 40 patients. The most affected gene was KIAA1549-BRAF (14.29%; n=6) and the most common gene effect was fusion (28.13%; n=9). Stratification by RUCC revealed minimal variations in the demographic and clinical characteristics between metropolitan and non-metropolitan areas. The proportion of malignant diagnoses, however, was higher non-metropolitan areas than metropolitan areas ($p = 0.0271$). Given the relative rarity of pediatric CNS tumors, data over an extended time period are required to accurately describe the disease and the population in which it occurs. In this analysis, we described the population of pediatric CNS tumor patients treated at Children's Nebraska and Nebraska Medicine. These methods can be expanded to include additional diagnostic years, clinical characteristics, or predictors, such as environmental exposures to gain a better understanding of the trends in pediatric CNS tumors.

#3558 Oral cancer incidence in British Columbia, Canada since the start of the COVID-19 pandemic.

Ilena S. Yim[1], Lewei Zhang[1], Rachel Murphy[2], Miriam P. Rosin[3], Denise M. Laronde[1]

[1]Oral Biological & Medical Sciences, University of British Columbia, Vancouver, BC, Canada,[2]School of Population and Public Health, University of British Columbia, Vancouver, BC, Canada,[3]BC Cancer Research Institute, Vancouver, BC, Canada

Objectives: Since the beginning of the COVID-19 pandemic, there have been notable disruptions to cancer services worldwide. With interruptions to the opportunistic screening of oral lesions at routine dental visits, an initial decrease in the diagnosis and thus incidence of concerning oral diseases, including oral cancer, is expected at the pandemic's onset. Following this, an increase in the diagnosis and incidence of oral cancer in the early years after the start of the pandemic is anticipated due to the recovery of diagnostic delays. However, it is possible that changes observed in the incidence are also related to contributing factors. While there is literature on the impacts of the COVID-19 pandemic on head and neck cancer incidence, minimal research considers temporal trends, which if not considered, it can bias results. Currently, there is no research on the pandemic's impact on oral cancer incidence beyond 2021, while taking into account temporal trends. This project will determine if the incidence of oral cancer in British Columbia, Canada has changed after the start of the COVID-19 pandemic when considering trends.

Methods: Data on the diagnosis of new oral cancers, from January 2010 to December 2022, in British Columbia, were retrieved from the BC Cancer Registry. Cancers of the lip and oral cavity, excluding skin and bone lesions, were included. Salivary gland and pharyngeal cancers were excluded. An interrupted time series design was used to determine differences in oral cancer incidence post-pandemic (2020 and after) by comparing the post-COVID-19 observed incidence to the expected (counterfactual) post-COVID-19 incidence. The expected post-COVID-19 incidence was based on the pre-COVID-19 trend (2010 to 2019). The pre-COVID-19 trend was calculated as the annual percentage change of age-standardized incidence rates using joinpoint regression. Ratios and 95% confidence intervals of observed versus counterfactual post-pandemic age-standardized incidence rates for 2020, 2021, and 2022 were used to determine differences in pre-and post-pandemic incidence.

Results: From 2010 to 2022, there were 3039 new cases of oral cancers in the oral epithelium of the lip and oral cavity diagnosed in British Columbia. There were no significant differences between the expected and observed post-COVID-19 oral cancer incidence overall and by sex-specific analysis. Although not significant, there were much fewer observed compared to expected cases of tongue cancers overall and for females. Age category- and site-specific analysis is to be completed.

Conclusion: Preliminary results suggest no differences in oral cancer incidence since the onset of the COVID-19 pandemic. Data beyond 2022 should be assessed to continue to determine for differences in oral cancer incidence post-pandemic.

#3559 Genetic and clinical profiles of early-onset prostate cancer in Puerto Rican men: A preliminary characterization.

Gustavo Alayon[1], Sebastian Bernaschina-Rivera[2], Natalia Yordan-Fernandez[3], Juliana Melendez-Ojeda[3], Gabriela Castro[4], Lenin Godoy[1], Fabiola Benitez-Rios[5], Laura F. Rodriguez-Fernandez[3], Carmen M. Ortiz-Sanchez[1], Gilberto Ruiz-Deya[1]

[1]Ponce Health Sciences University, Ponce, Puerto Rico,[2]Maimonides Medical Center, Brooklyn, NY,[3]Universidad de Puerto Rico Recinto de Ciencias Medicas, San Juan, Puerto Rico,[4]Pontificia Universidad Catolica de Puerto Rico, Ponce, Puerto Rico,[5]Boston Children's Hospital, Harvard Medical School, Boston, MA

Background: Prostate cancer (PCA) is the second leading cause of cancer-related death among men in the US. Early-onset prostate cancer (EOPCa) accounts for ~10% of all PCA diagnoses, with an ~58,694 new cases reported worldwide in 2021. Although EOPCa accounts for a growing proportion of cases, it remains underexplored. Younger patients often present with distinct clinical features, hereditary predispositions, and long-term survivorship challenges. Hispanic/Latino men, particularly those from Puerto Rico, experience disparities in incidence and outcomes, yet remain underrepresented in PCA research. A better understanding of the epidemiological, clinical, and germline genetic profile of Puerto Rican men with EOPCa is essential to guide risk stratification and inform precision medicine strategies.
Methods: This study retrospectively identified 80 cases of EOPCa of 9,393 patients treated for PCA between 2020-2025 in a tertiary hospital in southern PR. Demographic, clinicopathological variables were collected, including age, PSA, BMI, Gleason score (GS), tumor stage, family history, lifestyle factors, and treatments. Germline genetic testing results were analyzed and variants classified as pathogenic, variants of uncertain significance (VUS), or benign. Frequencies of recurrent alterations were calculated.
Results: Eighty patients were identified; 39 met the inclusion criteria. Age ranged 37-49 years (mean 45.7). PSA at diagnosis ranged 1.7-25.4 ng/mL (mean 6.2). Nearly half (48.7%) were obese (BMI ≥30). At biopsy, GS 6 was most frequent (56.4%); following prostatectomy (87.2% of cases), GS 6 remained most common (50.0%), followed by GS 8 (23.5%). Stage T2 (55.9%) and T3 (23.5%) predominated. Family history of PCA was reported by 38.0%. Most patients consumed alcohol (76.9%) but denied smoking (71.8%). Germline testing identified 10.3% pathogenic variants, 35.9% VUS, and 5.1% carriers, with the remainder negative. In total, 21 alterations were detected: 15 VUS, 5 pathogenic, and 1 benign. Alterations were distributed across 15 genes, with recurrent findings in RECQL4 (n=3), POLD1 (n=3), ATM (n=2), and TMEM127 (n=2).
Conclusions: This study provides the first characterization of the epidemiological, clinical, and germline genetic profile of EOPCa in Puerto Rico. Findings highlight a notable burden of germline alterations and underscore the importance of incorporating genetic testing into clinical management. Expanding research among underrepresented populations is critical to guide early detection, refine prognostication, and reduce PCA disparities.

#3560 Adult T-cell leukemia/lymphoma in America: Unmasking a preventable cancer in Caribbean-born communities.

Paulo S. Pinheiro[1], Amber N. Balda[2], Tabassum Z. Insaf[3], Baozhen Qiao[3], Sophia Hl George[1], Juan C. Ramos[1]

[1]University of Miami Sylvester Comprehensive Cancer Center, Miami, FL,[2]University of Miami Miller School of Medicine, Miami, FL,[3]Bureau of Cancer Epidemiology, New York State Department of Health, Albany, NY

BackgroundAdult T-cell leukemia/lymphoma (ATLL), caused by human T-lymphotropic virus type 1 (HTLV-1), is rare in the United States but endemic in the Caribbean, Japan, and West Africa. The burden of ATLL among Caribbean-born U.S. residents has not been quantified at the population level.

MethodsWe analyzed 2005-2022 data from the Cancer in North America (CiNA) registry to estimate ATLL incidence by race/ethnicity and nativity. Country-specific analyses were restricted to 13 states with <20% missing birthplace data. Sensitivity analyses addressed possible misclassification with peripheral T-cell lymphoma, not otherwise specified (PTCL-NOS). Cause-specific survival was assessed for Florida and New York using multivariable Cox regression and Kaplan-Meier methods.

ResultsATLL incidence was several dozen-fold higher among non-Hispanic Caribbean-born adults compared with U.S./Canada-born populations, with rates in some Caribbean-origin groups approaching those reported in southwestern Japan. Nearly half of all U.S. ATLL cases occurred in New York and Florida, which had the highest national incidence. Within the Caribbean diaspora, risk varied widely by country of birth, with the highest rates in the eastern Caribbean, while Hispanic Caribbean-born populations exhibited lower incidence overall.

Among more than one thousand patients from New York and Florida, five-year survival remained poor. Cutaneous and marrow-dominant forms showed better outcomes than nodal disease. After adjustment for age and sex, non-Hispanic Caribbean-born Black patients had roughly 2½-fold higher mortality than non-Hispanic White patients.

ConclusionsATLL among Caribbean-born U.S. populations represents one of the most concentrated yet preventable cancer disparities in the country. Because vertical HTLV-1 transmission drives lifetime risk, targeted surveillance, maternal screening, and culturally informed prevention programs are urgently warranted. These findings underscore the need for public-health recognition of ATLL as a preventable infection-associated malignancy in Caribbean-origin communities.

#3561 Breast cancer characteristics in relation to age at diagnosis, in a leading oncology institution in Cartagena, Colombia.

Elias Ferreira, Laura Suarez, Maria P. Valera, Jose Aldana, Juan S. Diaz, **Ines Benedetti**

School of Medicine, Histopathology Research group, Universidad de Cartagena, Cartagena, Colombia

Background: Breast cancer is a major public health problem, it is the most commonly diagnosed malignant neoplasia, and the leading cause of cancer deaths in women, worlwide and also in Colombia. .Women living in transitioned countries have considerably higher incidence rates compared with those in transitioning countries, this reflects a higher prevalence of some reproductive risk factors, including early age at menarche. There is scarce knowledge about the clinical characteristics of breast cancer patients living in developing countries. This study, evaluated and compared the characteristics of breast cancer cases in older, middle aged, and young women, treated at an oncology center in Colombia.Objective: To describe the characteristics of breast cancer cases treated in a leading oncology institution in Cartagena, Colombia, and their association with the age at the time of diagnosis.
Methods: A database of women treated for breast cancer at a leading oncology institution in Cartagena, Colombia, between January 2010 and December 2024, was retrospectively analyzed. Were compared clinical and histopathological characteristics between women aged 20 to <40, 40 to <65, and ≥65 years. Clinical information was collected: age at menarche, parity, stage at diagnosis and histological type.
Results: Were included 698 patients with a mean age at diagnosis of 56.06 years (SD=±13.16, 95%CI= 55.08-57.04). Most of cases were middle-aged women (40 to 65 years= 63.33%) with a high proportion of cases in older women (>65 years= 24.21%), and a smaller number of young women (20 to 39 years=10.45%). Were observed significant associations between age at diagnosis and age of menarche (mean=12.09 years, SD=±1.69, 95%CI= 12.74-13.03), (p=0.0001, t test); and, between age at diagnosis and number of pregnancies (mean=3.25, SD=±2.13, 95%CI= 3.08-3.42), (p=0.0001, t test). Most of the tumors (84.45%) were ductal carcinomas, followed by lobular carcinomas (6.3%), and other histological types in small proportion, a statistically significant difference was found between histological type and age (p=0.041, Fisher´s test). Of the patients, 57.11% presented with locally advanced disease (stage II), only 5% presented with metastatic disease, and there was a significant association between age and clinical stage at diagnosis (p=0.0099, X2).
Conclusion: These findings highlight significant associations between age at diagnosis, reproductive factors, and stage at presentation, suggesting different risk patterns across age groups. Most of the cases in this study cohort presented locally advanced disease at the moment of diagnosis, supporting the need for screening and care strategies adapted to age and individual risk in this setting. Future studies incorporating molecular profiling and survival outcomes will be essential to refine risk stratification and inform breast cancer control policies.

#3562 Sex-specific survival patterns in korean breast cancer: Explainable AI insights from K-CURE Cohort.

Seohyun Ahn[1], Juyeon Hwang[1], Sun-Young Kong[1], Jin Ho Park[2], So-Youn Jung[1], Hyun-Jin Kim[1]

[1]National Cancer Center - Korea, Goyang-si, Korea, Republic of,[2]Seoul National University Hospital, Seoul, Korea, Republic of

Background: Male breast cancer (MBC) is rare, but its incidence is increasing worldwide. Evidence regarding survival differences compared with female breast cancer (FBC) is limited. This study aimed to characterize sex-specific survival patterns in Korean breast cancer and to identify key contributing factors using explainable artificial intelligence (XAI) methods.

Methods: This study utilized data from the Korean Clinical Data Utilization for Research Excellence (K-CURE), a nationwide registry of all breast cancer cases in Korea. Patients diagnosed between 2012 and 2021 were analyzed by sex. Overall survival (OS) and breast cancer-specific survival (BCSS) were assessed using multivariable Cox proportional hazards models. XAI techniques, including SHAP and LIME, were applied to identify sex-specific contributors to survival.

Results: Among 200,222 patients (846 males, 199,376 females), males showed significantly poorer OS and BCSS than females (p<.001). This disparity persisted after adjustment (male OS HR ≈1.30-1.40; BCSS HR ≈1.40-1.50). Distant stage was associated with the highest mortality risk in both sexes (male HR ≈9-12; female HR ≈10-24). Distinct sex-specific patterns were observed. In males, metabolic indicators showed opposite associations with survival: higher hemoglobin was linked to lower mortality (HR ≈0.88), whereas higher fasting blood sugar was associated with increased mortality risk (HR ≈1.04). In females, hormone and targeted therapies were associated with reduced mortality (HR ≈0.30-0.55). XGBoost models achieved moderate predictive performance for both outcomes (OS AUC ≈0.85; BCSS AUC ≈0.87). SHAP and LIME analyses consistently supported these patterns, suggesting that metabolic profiles contributed more to risk estimation in males, whereas tumor stage and treatment factors were relatively more influential in females.

Conclusion: These findings indicate that sex differences in breast cancer survival arise not only from differences in overall risk profiles but also from distinct prognostic factors specific to each sex. In males, metabolic indicators were more closely associated with survival, whereas in females, tumor stage and treatment factors had greater relevance. Overall, these results reflect differing underlying mechanisms by sex and highlight the need for tailored, sex-specific management strategies in breast cancer care.

#3563 Survival differences after diagnosis of breast cancer as second primary cancer vs as first primary cancer.

Chun R. Chao[1], Hui Zhou[1], Cody Ramin[2], Lanfang Xu[1], Kimberly Cannavale[1], Hyuna Sung[3]

[1]Department of Research and Evaluation, Kaiser Permanente - Southern California, Pasadena, CA,[2]Department of Computational Biomedicine, Cedar-Sinai Medical Center, Los Angeles, CA,[3]American Cancer Society, Atlanta, GA

Introduction: The incidence of second primary cancer (SPC) is on the rise. In the United States, about 20% of all new cancers diagnosed annually are estimated to be SPC. Prior studies of the SEER registries suggested that survival was inferior in SPC compared with that in the first primary cancer (FPC) of the same type. However, these studies did not account for prognostic factors such as comorbidity, obesity, smoking, and insurance status. We examined survival after breast cancer diagnosis as a SPC vs. as a FPC in a large integrated health care delivery system.

Methods: We identified female members of Kaiser Permanente Southern California (KPSC) aged 18-84 years diagnosed with an invasive breast cancer as a FPC (for the FPC cohort) or SPC (for the SPC cohort) between 2000-2022 using KPSC's cancer registry. Women were followed until the earliest occurrence of death, diagnosis of a subsequent primary cancer, KPSC disenrollment, or 12/31/2023. All-cause and breast cancer-specific mortality were ascertained. Fine and Gray subdistribution hazard regression was used to estimate survival differences in the SPC and the FPC cohort accounting for competing risks. Multivariable models adjusted for age at diagnosis, stage, breast cancer subtype (luminal A, luminal B, HER2-enriched, and triple negative), race/ethnicity, year of diagnosis, Charlson's comorbidity index, body mass index, and smoking. Stratified analyses were performed by age at diagnosis (<50 yrs and ≥50 yrs), stage, and subtype.

Results: A total of 42,972 and 6,363 women were included in the breast FPC and SPC cohort (the mean age at diagnosis: 59.8 yr vs. 66.0 yr), respectively. About half of participants in both cohorts were racial/ethnic minorities. Sixty-five percent of the FPC cohort and 71% of the SPC cohort were diagnosed at localized stage. During a mean follow-up of 7 years, a total of 7,148 (17%) and 1,647 (26%) deaths were observed, including 4,035 (9%) and 838 (13%) breast cancer-specific deaths in the FPC and SPC cohort, respectively. In multivariable-adjusted models, there was an elevated overall mortality in the SPC cohort compared with the FPC [adjusted hazard ratio (aHR) = 1.35 (1.27-1.43)]. Elevated breast cancer-specific mortality was also noted in the SPC cohort: aHR=1.27 (1.17-1.38). Similar findings were observed when stratified by age, stage, or subtype (aHRs range between 1.33-1.40), with the exception that breast cancer-specific mortality was not elevated in SPC for triple-negative breast cancer [aHR=1.04 (0.85-1.27)].

Conclusion: Overall and breast cancer-specific mortality were higher after a breast SPC diagnosis compared to that after a breast FPC diagnosis among an insured population adjusting for prognostic factors. Further research is needed to shed light on the reasons underly the survival difference to inform management for the breast SPC.

#3564 Gastric cancer disparities across generations of Latino populations in the United States: Insights from the Multiethnic Cohort study.

Katherine De la Torre-Cisneros[1], Haejin In[1], Alexandra Adams[1], Chunxia Chen[1], Brijesh Rana[1], Lynne R. Wilkens[2], Meira Epplein[3]

[1]Rutgers Cancer Institute of New Jersey, New Brunswick, NJ,[2]University of Hawaii, Manoa, HI,[3]Duke University Medical Center, Durham, NC

Background: Individuals of Latin American origin in the United States (US) have higher incidence of gastric cancer (GC) than the general population. The contribution of immigration history to this disparity remains inadequately characterized. This study assessed the association between generational immigration status and GC risk among Latino populations.
Methods: We analyzed data from the population-based Multiethnic Cohort Study (MEC), which enrolled residents of Hawaii and California between 1993-1996. Participants who self-identified as Latino of Mexican, Central or South American descent were included, with non-Hispanic Whites (NHWs) as reference group. Cox proportional hazards models were used to estimate hazard ratios (HRs) and 95% confidence intervals (CIs) for GC overall and by anatomical subtype.
Results: Among 79,963 participants (median age 59 yr; 48% male), 377 incident GC cases were identified. Latino participants had around twice the risk of GC compared with NHWs. The risk remained stable across generations: first-generation (born in Mexico, Central/South America) had an HR of 2.17 (95%CI, 1.61-2.92); second-generation (US-born with one or both parents born in Mexico, Central/South America), HR 2.09 (95%CI, 1.56-2.80); and third-generation, HR 2.67 (95%CI, 1.87-3.82). No notable differences were observed across Mexican and Central/South American subgroups. Associations were stronger for non-cardia GC (HRs, 2.78, 2.62, and 3.42 for first-, second-, and third-generation, respectively) but were not significant for cardia GC.
Conclusions: Latino descendants showed more than twofold higher GC risk compared to NHWs, with elevated risk persisting across generations. No attenuation among US-born individuals suggests lasting ancestral or biological susceptibilities beyond immigration-related exposures. These findings underscore the need to identify at-risk populations and guide targeted prevention strategies.

Table 1. HRs of gastric cancer by generation status among Latino descendants

Descendants	NHW	First Generation	Second Generation	Third Generation
Latino				
Participants	39779	18720	14614	6850
Cases	103	123	104	47
HR (95%CI)	1.00	2.17(1.61-2.92)	2.09(1.56-2.80)	2.67(1.87-3.82)
Mexico				
Participants	39779	13703	14156	6850
Cases	103	78	102	47
HR (95%CI)	1.00	1.77(1.27-2.48)	2.03(1.51-2.73)	2.63(1.84-3.77
Central/South America				
Participants	39779	5005	139	6850
Cases	103	45	1	47
HR (95%CI)	1.00	2.78(1.90-4.06)	1.92(0.27-13.76)	2.52(1.75-3.63)

#3565 Epithelial ovarian cancer histotype distributions by race/ethnicity in Kaiser Permanente Northern California, 2000-2022.

Jennifer Anne Doherty[1], Martin Koebel[2], Jia Li[3], Laurie Grieshober[1], Valerie S. Lee[4], Lisa Moy[3], Juraj Kavecansky[5], Lindsay Jane Collin[6], Scarlett L. Gomez[7], Elisa V. Bandera[8], Lawrence H. Kushi[9]

[1]University of Utah Huntsman Cancer Institute, Salt Lake City, UT,[2]Alberta Precision Laboratories, Edmonton, AB, Canada,[3]Kaiser Permanente Northern California, Pleasanton, CA,[4]Kaiser Permanente Northern California Division of Research, Oakland, CA,[5]Kaiser Permanente, Antioch, CA,[6]Emory University, Rollins School of Public Health, Salt Lake City, UT,[7]University of Califonia San Francisco, San Francisco, CA,[8]Rutgers Cancer Institute of New Jersey, New Brunswick, NJ,[9]Director of Scientific Policy, Division of Research, Kaiser Permanente, Oakland, CA

Background: The 2014 and 2020 World Health Organization (WHO) diagnostic classification guidelines for epithelial ovarian cancer (EOC) standardized histotype classification, improved reproducibility across pathologists, and revealed distinct survival differences by histotype. EOC histotype distributions have not been characterized by racial/ethnic groups on a population level using these updated guidelines. We performed centralized pathology review using the WHO 2020 guidelines to characterize distributions of EOC histotypes across Black, Hispanic, non-Hispanic (NH) Asian and Pacific Islander (API), and NH white groups.
Methods: The Kaiser Permanente Research on Ovarian Cancer Survival study includes 6,067 EOC cases ages 18 years and older diagnosed in 2000-2022 who received care for their EOC at Kaiser Permanente Northern California. Original diagnostic slides were centrally reviewed using 2020 WHO guidelines for a subset of 2,470 cases (median 8 slides/patient, range 1-80). Slides for 20 cases did not contain tumor, and 109 were determined not to be EOC, leaving 2,341 cases for analysis. We assessed concordance of the distribution of EOC histotypes before (original diagnosis) and after re-review by calculating unweighted Cohen's Kappa for the cohort overall, and separately for racial/ethnic groups.
Results: Overall there was substantial agreement of histotype assignment between the original diagnosis and the pathologist's review (Kappa = 0.67). Agreement varied across racial/ethnic groups, with substantial agreement for NH API (n=640), Hispanic (n=522), and NH white groups (n=928; Kappas 0.73, 0.67, and 0.61, respectively), but moderate agreement for Black individuals (n=242; Kappa 0.59). Overall, proportions of the histotypes before and after study review increased for high grade serous (HGSC) from 58% to 62%; 14% to 17% for endometrioid; 2% to 3% for low grade serous; decreased for carcinoma, NOS from 5% to 0.6% and for grouped rare EOC histotypes including mixed from 4% to 2%; and were unchanged for clear cell, mucinous, and carcinosarcoma (9%, 4%, and 3%, respectively). The highest proportion of HGSC was among Black individuals (73%), and the lowest among NH API individuals (50%), with similar prevalences for Hispanic and NH white individuals (64% and 66%, respectively). Endometrioid, clear cell, and mucinous histotypes were more common among NH API individuals (23%, 14%, and 6%, respectively) compared with the other groups (ranges of 12-16%, 6-8%, and 2-3%, respectively).
Conclusions: Improved histotype assignment using WHO 2020 refined distinct differences in histotype distributions by race/ethnicity. Specifically, Black individuals are more likely to be diagnosed with the aggressive HGSC histotype, whereas among NH API individuals non-HGSC histotypes were more common, specifically clear cell, endometrioid, and mucinous histotypes.

#3566 Ovarian cancer survival in the era of targeted treatment: A nationwide study in Germany.

Silvia Mignozzi, Victoria Cooley, Lieke Lanjouw, **Renee Turzanski Fortner**

DKFZ German Cancer Research Center, Heidelberg, Germany

Ovarian cancer treatment has changed substantially over time, through the introduction of bevacizumab and PARP (poly[ADP]-ribose polymerase) (PARP) inhibitors for subsets of cases, added to platinum-based chemotherapies, together with improvements in outcomes of cytoreductive surgery. Population-based studies evaluating survival trends in the context of modern treatment are sparse. Nationwide data from the Center for Cancer Registry Data at the Robert Koch Institute and the Federal Statistical Office of Germany were used. Cases were diagnosed between 2010-2021. Results are presented for cases diagnosed through 2019 to allow for mortality follow-up.Flexible parametric models were used to evaluate three- and five-year relative survival in categories of calendar year from 2010-2012 (largely pre-targeted treatment period), 2013-2016, and 2017-2019 (targeted treatment period). Expected mortality rates were derived from German life tables, stratified by age, calendar year and federal state. A core flexible parametric model was adjusted by age at diagnosis and federal state. We further adjusted for histology and stage. Relative survival was predicted from models for females with a median age at diagnosis (63.5 years), diagnosed in the most common federal state (North Rhine-Westphalia) and for each calendar period, each histological subtype and stage group (I–II, III–IV).A total of 51,985 ovarian cancer cases were included. A total of 75% of cases were of high-grade serous histology. Overall, relative survival improved from the earliest evaluated period to the most recently evaluated period (three-year, 2010-2012=65%, 2017-2019=68%; five-year, 2010-2012=51%, 2017-2019=55%). This difference was evident in particular for stage III and IV disease (three-year, 2010-2012=54%, 2017-2019=58%; five-year, 2010-2012=36%, 2017-2019=40%), with improvements observed across histotype. Three-year relative survival for the predominant stage III and IV high-grade serous histotype increased from 54% to 57% across the study period, with a corresponding increase in five-year net survival of 36% to 40%.Ovarian cancer survival improved across the evaluated periods. These improvements are likely related to advancements in achieving minimal residual disease during cytoreductive surgery, given the improvements observed across histotype, together with the introduction of targeted therapies for select disease subgroups.

#3567 Projecting the future cancer burden in Singapore: National incidence and direct medical cost estimates to 2050.

Ian JY Wee[1], Hui Miao[2], Dawn Q. Chong[3], Evelyn YT Wong[3], Grace Yang[3], Kelvin Bryan Tan[4], Cheng Ean Chee[5], Iain B. Tan[3]

[1]Singapore General Hospital, Singapore, Singapore,[2]Saw Swee Hock School of Public Health, National University of Singapore, Singapore, Singapore,[3]National Cancer Centre Singapore, Singapore, Singapore,[4]Ministry of Health, Singapore, Singapore,[5]National University Cancer Institute, Singapore, Singapore

Introduction: Singapore's rapidly ageing population and lifestyle transitions have contributed to a rising cancer burden, placing increasing pressure on healthcare resources. Robust estimates of future cancer incidence and costs are essential to inform national capacity planning, financing strategies, and cancer care policy. Singapore Translational Cancer Consortium (STCC) sanctioned this study to use population estimates and cancer incidence to provide projections of cancer incidence and direct medical costs to the health system through 2050 for the top 15 cancers.

Methods: This population-based study used the National Trusted Research and Real-World Data Utilisation and Sharing Tech (TRUST) platform and included 268,189 incident cancer cases diagnosed from 2000-2021 in the Singapore Cancer Registry. Historical incidence trends were estimated using joinpoint regression. Future cancer incidence to 2050 was projected using generalized additive models stratified by age and sex. National medical claims from 2005-2016 were analyzed to estimate first-year and five-year post-diagnosis costs with a minimum follow-up of five years. Generalized linear models (gamma distribution, log link) were used to project per-patient costs, which were multiplied by projected incidence to obtain national-level expenditure till 2050.

Results: From 2000 to 2021, cancer cases in Singapore nearly doubled. The age-standardized incidence rate surged from 200.8 to 246.4 per 100,000 in women, while remaining stable in men (232.5 to 235.6 per 100,000). Annual percent increases were 0.88% (95% CI: 0.62-1.21) for women and 0.19% (95% CI: 0.06-0.35) for men. The overall annual cancer incidence is projected to soar 3.3-fold from 2.35 to 7.59 per 1,000 population by 2050. The incidence of cancer in females will increase by 3.5-fold (2.39→8.39 per 1,000), and in males nearly 3-fold (2.30→6.79 per 1,000). Adults aged ≥80 years will account for 37.1% of all cases in 2050, which is three times higher than 13.30% in 2000. Financial impact is large: first-year direct medical costs escalated by approximately three fold from US 104.4 million in 2005 to US 308.5 million in 2016. Five-year cumulative costs rose 3.5 fold from US 150.7 million to US 517.0 million during the same period. By 2050, national expenditure is expected to reach US 1.3 billion for cases in the first year post-diagnosis and US 23.6 billion over five years to the health system.

Conclusion: Our study showed that Singapore may face a dramatic escalation in cancer incidence and healthcare costs by 2050. These findings underscore an urgent imperative for early detection, robust prevention strategies, and sustainable financing models to address the mounting clinical and economic burden of cancer.

#3568 Differences in male breast cancer outcomes by race/ethnicity in Florida and the United States: A population-based comparison of FCDS and SEER.

Maurice Chery[1], Alex Sanchez[1], Jovanka Ravix[1], Olusanya Joshua Oluwole[1], Priscila Barreto Coelho[1], Kristy Samaroo[1], Fatima Rasheed[1], Ayodele Omotoso[1], Osmaray Morales Casanova[1], Matthew Schlumbrecht[2], Sophia Hl George[3]

[1]University of Miami, Miller School of Medicine, Miami, FL,[2]Division of Gynecology Oncology, Department of Obstetrics, Gynecology and Reproductive Sciences, University of Miami, Miller School of Medicine, Miami, FL,[3]Univ. of Miami Sylvester Comprehensive Cancer Ctr., Miami, FL

Introduction Male breast cancer (MBC) is rare (<1% of U.S. cases) yet clinically important. Evidence on racial/ethnic differences is limited and often comes from single registries. We characterize sociodemographic, clinical, and treatment features of MBC and evaluate factors associated with overall survival (OS) in Florida and the broader United States in relation to race/ethnicity and nativity.
Methods We performed a retrospective cohort study of the Florida Cancer Data System (FCDS, 1981-2020; N=1,878) and SEER 8 registries (1975-2022; N=4,754), including primary MBC (ICD-O-C56XX). We described sociodemographic variables (age, race/ethnicity; plus insurance/smoking in FCDS; marital status/area-level income in SEER), clinical features (grade, stage, ER/PR/HER2), and treatment types (surgery, chemotherapy, radiation). Registry-specific Cox models shared the same adjustment set (age, grade, stage, ER/PR/HER2, surgery, chemotherapy, radiation). Race/ethnicity was categorized as non-Hispanic White (NHW), non-Hispanic Black (NHB), and Hispanic. In FCDS, we also tested the moderating effect of nativity (U.S.-born vs non-U.S.-born) and the joint effect of race and nativity.
Results In FCDS (n=1,878; 80% NHW, 12% NHB, 8% Hispanic; mean age 67.5 years), NHB men vs NHW and Hispanic were younger at diagnosis (61 vs 69 vs 67 years), had shorter OS (38 vs 59 vs 49 months), more high-grade tumors (56% vs 37% vs 38%), more distant stage (15% vs 7% vs 11%), and lower surgery rates (77% vs 90% vs 86%; all $p<0.01$); ER/PR/HER2 status did not differ by race/ethnicity. In SEER (n=4,754; 84% NHW, 11% NHB, 5% Hispanic; mean age 67.0 years), NHB men were younger (62 vs 68 vs 64 years), had shorter OS (54 vs 70 vs 63 months), more distant stage (14% vs 7% vs 11%), and lower surgery rates (84% vs 91% vs 89%; all $p<0.01$). NHB men had fewer ER-positive (92% vs 96% vs 94%) and PR-positive tumors (80% vs 89% vs 85%; $p<0.01$), while HER2 status did not vary by race/ethnicity. In multivariable models, race/ethnicity was not associated with OS in FCDS; however, among NHB men, non-U.S.-born had lower mortality than U.S.-born (HR 0.54; 95% CI 0.34-0.86; interaction $p=0.01$). In SEER, NHB men had higher mortality than NHW (HR 1.22; 95% CI 1.07-1.38). In both registries, older age, high grade, distant stage, and omission of surgery were independently associated with higher mortality (all $p<0.01$).
Conclusion Across Florida and the United States, MBC OS is chiefly determined by age, grade, stage, and surgery. In SEER, NHB have higher adjusted mortality than NHW, an effect not seen in FCDS. In FCDS, nativity modifies risk among Black men: non-USB have lower mortality than USB. These findings support nativity-stratified surveillance and equity efforts to promote earlier diagnosis and consistent access to definitive surgery.

#3569 Incidence of early-onset solid cancers in Hungary in the first two decades of the 21st century based on a population-based registry.

Istvan Kenessey, Andras Weber, Maria Dobozi, Istvan Szatmari, Petra Parrag, Peter Nagy, Magdolna Dank

National Cancer Registry, National Institute of Oncology Hungary, Budapest, Hungary

Background: Newly discovered malignancies at a relatively younger age (<50) are of great scientific interest. Previous studies found that the incidence of these early-onset cancers showed a global increase, although the pattern varied by cancer type. However, analysis of the Hungarian data has not yet been published.
Methods: The Hungarian National Cancer Registry (HNCR) is responsible for data collection of the Hungarian cancer patients. Its operation is population-based in accordance with international standards and covers the entire country. Based on the 10th Revision of International Statistical Classification of Diseases and Related Health Problems, newly discovered cancer cases were extracted from the HNCR's database. The query focused on patients between the ages of 20 and 49 and period from 2001 to 2019. Next to absolute case numbers, age-standardized values were also analyzed (reference: European Standard Population 2013). Spearman's correlation test was performed to identify gender- and disease-specific trends.
Results: During the studied period, the incidence of early-onset cancers showed decrease among males, while it did not change among females. It should be noted that compared to the total number of newly discovered cancer cases, the proportion of early-onset cancers showed decreasing trend in both genders. Categorization by cancer type revealed that among younger age the incidence of female breast and uterine corpus cancer elevated, while cervical cancer showed a decrease - the latter trend exceeded that of the general population. The incidence of colorectal cancer did not change among females, but decreased among males. The incidence of tobacco-related lung cancer and head and neck region decreased.
Conclusion: Compared to analyses enrolled global trends, the Hungarian situation of early-onset cancers seemed to be more complex. On one hand, activities in the past few years such as introduction of HPV vaccination and restrictions on smoking resulted a decrease in the number of related cancers. On the other hand, new mechanisms underlying the increasing types of cancers (e.g. breast cancer) need to be identified.

#3570 Long-term mortality trends in hairy cell leukemia: A comprehensive U.S. population analysis (1999-2023).

Aqsa Z. Sorathia[1], Basel Aldroubi[1], **Disha Patel**[1], Safa S. Afridi[2], Michael Patrick[1]

[1]St. Joseph University Medical Center, Paterson, NJ,[2]SUNY Upstate University Hospital, Syracuse, NY

Hairy cell leukemia (HCL) is a rare indolent B-cell neoplasm with excellent survival outcomes following purine analog therapy. However, long-term national mortality trends remain underreported. This study aims to evaluate long-term patterns of HCL-related mortality and temporal changes in the United States. Methods:We analyzed CDC WONDER mortality records from 1999 to 2023 for individuals with HCL (ICD-10: C91.4). Age-adjusted mortality rates (AAMR) per 100,000 were calculated and stratified by age, sex, race, Hispanic origin, and place of death. Joinpoint regression (NCI Joinpoint v5.4.0, weighted BIC) identified annual percent changes (APC) and inflection points with 95% confidence intervals (CI). Results:A total of 4,496 HCL-related deaths occurred from 1999 to 2023. The overall AAMR declined from 0.056 in 1999 to 0.040 in 2018 (APC: -2.21; 95% CI: -6.37 to -1.29), followed by a nonsignificant increase to 0.043 in 2023 (APC: 5.07; 95% CI: -0.69 to 21.32). Among males, the AAMR decreased from 0.10 in 1999 to 0.07 in 2015 (APC: -2.22; 95% CI: -2.99 to -1.44), then significantly increased to 0.096 in 2023 (APC: 2.23; 95% CI: 0.69 to 3.80). Females demonstrated a continuous decline from 0.02 to 0.012 (APC: -2.35; 95% CI: -3.51 to -1.18). Mortality was concentrated in adults ≥65 years, with the highest rates in those ≥75 years (0.41-1.24 per 100,000). White individuals had the highest AAMR (0.061), followed by Black (0.020) and Asian or Pacific Islander (0.008). Non-Hispanic individuals accounted for 96% of deaths. Most deaths occurred in inpatient facilities (44%) or at home (26%). Conclusion: HCL-related mortality declined for nearly two decades but has begun to plateau, with a recent increase observed among males. Persistent declines among females contrast with increasing mortality in males, suggesting a widening difference in outcomes between the two groups. Mortality continues to be concentrated in older adults, reflecting the influence of age, comorbid illness, and treatment-related immunosuppression. Continued surveillance is needed to understand the factors driving these changes, including relapse patterns, treatment selection, and the challenges faced by an aging survivor population, to sustain progress and reduce emerging disparities.

#3571 Rising mortality from malignant pleural Effusion in the United States, 1999-2020: Population-level trends and disparities.

Aqsa Z. Sorathia, **Disha Patel**, Basel Aldroubi, Michael Patrick

St Joseph's University Medical Center, Paterson, NJ

Malignant pleural effusion (MPE) indicates extensive tumor involvement of the pleural space and often reflects aggressive disease characteristics and advanced cancer progression. Despite its clinical and prognostic importance across multiple solid tumors, national mortality patterns attributable to MPE remain poorly characterized. We performed a population-based analysis to define demographic and temporal trends in MPE-related deaths in the United States.Methods: Using CDC WONDER Multiple Cause-of-Death data (1999-2020), we identified U.S. deaths listing MPE (ICD-10 C78.2) as a contributing cause. Age-adjusted mortality rates (AAMR; per 100,000; 2000 U.S. standard population) were calculated overall and by sex, race, ethnicity, age, region, and urbanization level. Temporal trends were assessed with Joinpoint regression using log-linear modeling and Weighted BIC for model selection. Annual percent change (APC) estimates and 95% confidence intervals were reported for each segment.Results: A total of 68,700 MPE-related deaths occurred from 1999-2020. The national AAMR increased from 0.68 to 1.40 per 100,000. The optimal model identified two joinpoints (2001, 2007). A modest early increase (APC 1999-2001: +6.7%, 95% CI -2.9 to 15.4) was followed by a transient decline (2001-2007: -4.1%, -9.8 to 8.9). From 2007-2020, mortality rose significantly with an APC of +6.4% (95% CI 5.2-7.8; p<0.01). Females accounted for 58% of deaths; female AAMR rose from 0.68 to 1.44 per 100,000 with three trend segments (APC 1999-2001: +9.6%; 2001-2007: -4.2%; 2007-2020: +6.3%, p<0.01). Male AAMR increased from 0.66 to 1.33 per 100,000, with a single joinpoint at 2007 (APC 1999-2007: –3.1%; 2007-2020: +6.3%, both p<0.01). Most decedents were ≥65 years (70%). Across the study period, racial distribution included White (83%), Black (12%), and Asian/Pacific Islander (4%); 6% were Hispanic. Mortality rates were highest in medium and small metropolitan regions. 50% of all deaths occurred in hospitals, 28% at home, and 8% in hospice facilities. Conclusions: MPE-associated mortality in the U.S. has increased markedly over two decades, with a sustained rise after 2007. Persistent disparities by age, race, and urbanization highlight vulnerable populations and ongoing inequities in early cancer detection, access to systemic therapy, and palliative resources. These findings illustrate a growing burden of advanced malignant disease and support the need for earlier oncologic intervention, improved metastatic surveillance, and therapies that address both tumor control and pleural fluid accumulation. The escalation of MPE mortality further supports the development of disease-modifying interventions beyond conventional drainage-centered management.

#3572 Narrowing of sex and racial/ethnic ratios for hepatocellular carcinoma incidence in the United States, 1992 - 2022.

Samantha Sarlin, Aaron P. Thrift, Hyeyeun Lim

Baylor College of Medicine, Houston, TX

Background: Temporal trends in hepatocellular carcinoma (HCC) incidence in the U.S. have not been uniform across all adult populations. Most national analyses have focused on absolute rates within demographic groups rather than changes in incidence rate ratios (IRRs) over time. Because IRRs directly quantify relative disparities, evaluating their temporal trends can clarify how sex- and race/ethnicity-specific differences are evolving. We examined long-term trends in HCC incidence and IRRs using three decades of SEER data.

Methods: We analyzed HCC cases diagnosed from 1992 to 2022 in the SEER 12 registry. Age-adjusted incidence rates (per 100,000; 2000 U.S. standard) were calculated overall and by sex, race/ethnicity, and age group (<50 vs ≥50 years). Sex ratios were estimated with women as the reference group, while race/ethnicity ratios were estimated with non-Hispanic White (NHW) individuals as the reference group. Temporal trends were evaluated using Joinpoint regression to estimate annual percent change (APC) and average APC (AAPC) with 95% confidence intervals (CIs).

Results: 68,023 total HCC cases were identified. Annual cases increased from 840 in 1992 to 2,846 in 2022. Age-adjusted incidence rose from 4.27 to 7.84 per 100,000 (AAPC, 2.03%). Incidence increased during 1992-2009 (APC, 4.72%), was stable from 2009-2015, and declined during 2015-2022 (APC, 3.41%). Incidence remained higher in men, increasing from 6.97 to 12.24 per 100,000 (AAPC, 2.38%), compared with 2.13 to 3.95 per 100,000 in women (AAPC, 2.45%). However, the male-to-female IRR declined from 3.29 to 3.11, with an inflection in 2012; the IRR increased before 2012 (APC, 0.51%) and decreased thereafter (APC, -1.64%). Across racial/ethnic groups, incidence was highest among NH Asian or Pacific Islander (NHAPI) (14.27 per 100,000), followed by Hispanic (12.12), NH Black (NHB) (9.30), and NHW (4.37). AAPCs were highest for NHW (3.12%) and Hispanic (2.54%), intermediate for NHB (2.37%), and negative for NHAPI (-0.93%). Segment-specific APCs differed by group: NHW rates increased during 1992-2013 and declined thereafter; NHB and Hispanic rates increased during early periods and declined or stabilized in later years; NHAPI incidence increased modestly until 2007 and decreased thereafter. Similarly, the NHAPI:NHW IRR declined from 5.8 to 1.9 (AAPC, -3.93%); the NHB:NHW IRR declined from 2.0 to 1.4 (AAPC, -0.73%); and the Hispanic:NHW IRR decreased slightly from 2.7 to 2.4 (AAPC, -0.57%).

Conclusion: HCC incidence increased through the early 2010s but has declined since 2015. Sex- and race/ethnicity-specific IRRs narrowed across the study period, driven by declining rates among NHAPI and NHB populations and slower increases among Hispanic individuals relative to NHW. These 30-year trends demonstrate substantial shifts in the demographic distribution of HCC incidence in the U.S. and may reflect changes in etiology.

#3574 Epidemiology, survival, and prognostic factors of malignant eyelid tumors: A 17-year population-based study .

said yaseen[1], Bashar I. Almaraziq[2], Shaimaa A. Abdelmoneim[3], Ahmad S. Al Sakini[4], Hamza Khoursheed[1], Joud K. Alhousani[1], Alhareth Alhusban[5], Leen Abu Rabi[1], Ahmad Farouk Alzein[6], Issam Khourshid[7], Mohammad Almajali[1], Hashem Abu Serhan[8]

[1]Jordan University of Science and Technology, Irbid, Jordan,[2]School of Medicine,, Hashemite University, Zarqa, Jordan,[3]Egyptian Ministry of Health and Population, Alexandria, Egypt,[4]University of Baghdad, Baghdad, Iraq,[5]University of Jordan, Amman, Jordan,[6]University of Illinois Chicago, Chicago, IL,[7]Victoria Hospital, Scotland, Kirkcaldy, United Kingdom,[8]Hamad Medical Corporation, Doha, Qatar

Purpose: This study aimed to characterize the epidemiology, survival outcomes, and prognostic factors of primary malignant eyelid tumors, specifically sebaceous adenocarcinoma, malignant melanoma, and Merkel cell carcinoma (MCC).
Methods: We conducted a retrospective analysis of 3,082 cases of primary eyelid malignancies diagnosed between 2004-2021 from the Surveillance, Epidemiology, and End Results (SEER) database. Patients were categorized by histological subtype, age, race, tumor stage, and treatment modality. Kaplan-Meier survival analysis, log-rank tests, and Cox proportional hazards regression were employed to evaluate survival and identify prognostic factors.
Results: Sebaceous adenocarcinoma was the most prevalent subtype (26.57%), followed by malignant melanoma and MCC. Most patients (77.28%) were over 60 years old. While White individuals constituted the majority (86.9%), sebaceous adenocarcinoma showed a higher prevalence in Asian or Pacific Islander populations (11.8%). MCC exhibited the highest rate of distant metastases at diagnosis (19.4%). Surgery was the primary treatment (81.6%). Survival outcomes varied significantly by histology: MCC had the worst prognosis (5-year survival: 43.1%; median: 48 months), whereas melanoma had the best (5-year survival: 71.7%; median: 164 months). Cox regression identified age >60 years (HR: 4.25) and radiation therapy (HR: 2.01) as significant predictors of poor survival.
Conclusion: Malignant eyelid tumors exhibit significant heterogeneity in survival. MCC is associated with the highest mortality, and advanced age and radiation therapy are key prognostic factors, underscoring the need for histology-specific management strategies.

#3575 Early-onset colorectal and pancreatic cancer in the United States: Incidence and mortality projections through 2040.

Woo Joo Lee[1], Sumbal Aziz[1], Seon Hye Won[2], Muhammad Sohaib Asghar[1], Robin Park[3], Thomas Shimshak[1]

[1]Internal Medicine, AdventHealth Sebring, Sebring, FL,[2]Department of Family Medicine, Dongguk University Ilsan Hospital, Goyang-si, Korea, Republic of,[3]Department of Head and Neck-Endocrine Oncology, Moffitt Cancer Center, Tampa, FL

Background Incidence of early-onset colorectal cancer (CRC) and pancreatic cancer (PC) has been rising in many high-income countries, including the United States, but medium-term projections for young adults remain limited. Health-care systems need age-specific forecasts to plan screening, prevention, and survivorship services for adults younger than 50 years.
Methods We used population-based U.S. incidence data for CRC and PC from 1999-2022 and mortality data from 1999-2023, aggregated into 13 five-year age groups (20-24 to 80-84 years). Age-period-cohort (APC) models were fitted with Poisson likelihoods using natural cubic splines for descriptive analyses and a Bayesian APC (BAPC) framework with integrated nested Laplace approximation (INLA) and second-order random-walk priors for projections to 2040. For each cancer and endpoint (incidence or mortality), age-specific posterior means and 95% credible intervals (CrIs) were obtained and then summed over ages 20-49 years to derive projected case counts and rates per 100,000 persons using U.S. population projections.
Results In 2020, the modeled incidence of CRC among adults aged 20-49 years was 12.9 cases per 100,000 persons (95% CrI, 12.3-13.5), corresponding to 16,854 cases (16,092-17,616), and is projected to increase to 21.6 (10.9-32.3) per 100,000 in 2030 and 52.2 (0-162) per 100,000 in 2040, or approximately fourfold higher than the 2020 mean estimate with very wide uncertainty. PC incidence in this age group was 2.08 (1.89-2.27) per 100,000 in 2020, corresponding to 2,707 cases (2,460-2,953), and is projected to rise to 2.83 (2.23-3.43) in 2030 and 4.98 (2.02-7.94) in 2040, roughly a 2.4-fold increase. In contrast, CRC mortality among adults aged 20-49 years is projected to increase more modestly, from 2.81 (2.64-2.97) deaths per 100,000 in 2020 to 3.25 (2.45-4.06) in 2030 and 3.41 (0.51-6.31) in 2040. PC mortality projections are highly uncertain: the mean rate decreases from 2.29 (2.11-2.47) per 100,000 in 2020 to 0.76 (0.33-1.19) in 2030 and 0.38 (0-1.08) in 2040, but CrIs include near-zero and values close to the 2020 baseline.
Conclusions Our APC modeling suggests that, if recent trends persist, early-onset CRC incidence in U.S. adults aged 20-49 years might increase substantially through 2040, with more moderate but still meaningful increases in PC incidence. Projected mortality trends are less pronounced for CRC and highly uncertain for PC, underscoring that these estimates should be interpreted as scenario-based projections rather than precise forecasts. These findings support intensified prevention and early-detection strategies in younger adults while highlighting the need to update projections as additional data accrue.

#3576 Cross-cancer mortality trends in the era of immune checkpoint inhibition: A synthetic control analysis of U.S. cancer statistics.

Woo Joo Lee[1], Sumbal Aziz[1], Seon Hye Won[2], Muhammad Sohaib Asghar[1], Robin Park[3], Thomas Shimshak[1]

[1]Internal Medicine, AdventHealth Sebring, Sebring, FL,[2]Family Medicine, Dongguk University Ilsan Hospital, Goyang-si, Korea, Republic of,[3]Department of Head and Neck/Endocrine Oncology, Moffitt Cancer Center, Tampa, FL

Background: Immune checkpoint inhibitors (ICIs) improve survival in several advanced cancers, especially melanoma and non-small-cell lung cancer. Their overall impact on population-level cancer mortality is unclear.
Methods: We used U.S. Cancer Statistics mortality data from CDC WONDER, 1999-2019. Deaths by cancer site and year were age-standardized to the 2000 U.S. population. We defined an “early-ICI” cancer cluster (cutaneous melanoma; lung and bronchus; kidney and renal pelvis; urinary bladder; Hodgkin lymphoma) and constructed a synthetic control from all other sites with complete data. Synthetic-control models treated 1999-2013 as the pre-intervention period and 2014-2019 as the ICI era. We compared age-adjusted mortality and translated differences into “deaths averted” by multiplying the mortality gap by population size. Robustness was assessed with placebo-in-space and placebo-in-time analyses and site-specific controls. As a cross-check, we applied staggered-adoption difference-in-differences using year of first ICI approval by site.
Results: The early-ICI cluster had a modestly greater decline in age-adjusted mortality than its synthetic control after 2014. From 2014-2019, mortality averaged 0.41 deaths per 100,000 lower than the synthetic control, corresponding to an estimated 27,394 deaths averted versus the counterfactual trend. Pre-intervention fit was close (root-mean-square prediction error [RMSPE] 0.18), with higher post-intervention RMSPE (0.47; post/pre ratio 2.58). In placebo-in-space analyses, several non-ICI cancers had larger RMSPE ratios, indicating that the divergence was not unique. Placebo-in-time analyses using earlier hypothetical intervention years (2006-2010) produced smaller RMSPE ratios (1.39-1.81) than the 2014 specification. Site-level synthetic controls suggested deaths averted for melanoma, lung cancer, and Hodgkin lymphoma but excess deaths for kidney and bladder cancers, indicating heterogeneity. Staggered-adoption difference-in-differences estimated an average treatment effect of −0.96 deaths per 100,000 (95% CI −3.22 to 1.31), consistent with modest benefit or no effect.
Conclusions: In this national synthetic-control analysis, cancers with early ICI approvals had slightly greater mortality declines than other cancers, translating to tens of thousands of potentially averted deaths. However, placebo analyses and difference-in-differences indicate that these gains are modest, heterogeneous, and compatible with residual confounding or concurrent advances in care. ICIs thus appear to be an important contributor, but not the sole driver, of recent improvements in cancer mortality.

#3577 The persistence of racial disparities in prostate cancer survival: A time-varying conditional survival and mortality analysis.

Brendon Wang[1], Andrew Chen[2], Irene Wang[3], Candice Johnstone[1]

[1]Medical College of Wisconsin, Milwaukee, WI,[2]Northwestern Univ. Feinberg School of Medicine, Chicago, IL,[3]Einstein College of Medicine, Bronx, NY

Background: Racial disparities in prostate cancer survival are well-documented, but it is less clear how these mortality risks evolve as patients survive longer. Conditional survival (CS) provides a more dynamic and accurate prognosis for survivors by updating survival estimates over time.
Objective: To investigate racial differences in cancer-specific survival (CSS) and 5-year conditional survival (CS) among men with prostate cancer. We also assessed how the multivariable-adjusted hazard of cancer-specific mortality (CSM) by race changes conditional on time already survived.
Methods: We conducted a retrospective cohort study of 235,972 men diagnosed with prostate cancer (2004-2015) from the SEER database, limited to patients with known PSA and Gleason scores. We used Kaplan-Meier methods to estimate 5-year CSS at diagnosis and 5-year CS for men who had already survived 1-5 years. A series of time-varying multivariable Cox proportional hazards models were fit to calculate Hazard Ratios (HRs) for CSM, adjusting for age, sociodemographics, tumor characteristics (stage, grade, PSA, Gleason), and treatment.
Results: At diagnosis (0 years survived), 5-year CSS was 95.9% for White men, 96.2% for Asian/Pacific Islander (API) men, 94.6% for Black men, and 92.8% for American Indian/Alaska Native (AI/AN) men. While 5-year CS improved for all groups who survived 5 years, the gap between Black (95.5%) and White (96.1%) men narrowed but persisted. In multivariable Cox models at diagnosis, Black men had a significantly higher hazard of CSM compared to White men (HR: 1.07; 95% CI: 1.03-1.11, $P < 0.001$). This elevated mortality risk did not attenuate over time. Conversely, API men had a persistent survival advantage (HR at Year 0: 0.72; 95% CI: 0.68-0.77, $P < 0.001$). The mortality hazard for AI/AN men was not statistically different from White men (HR at Year 0: 1.06; 95% CI: 0.87-1.29, $P=0.54$).
Conclusion: Racial disparities in prostate cancer survival are established at diagnosis and, for Black and API men, persist for at least 5 years, even after adjusting for a comprehensive set of clinical and sociodemographic factors. The persistently higher mortality hazard for Black men highlights that survival gaps are not limited to factors at diagnosis. The lack of a significant difference for AI/AN men, despite lower initial CSS, warrants further investigation. These findings are critical for providing a more accurate, dynamic prognosis in long-term patient counseling.

#3578 Conditional overall survival analysis of HPV-positive oropharyngeal squamous cell carcinoma.

Andrew Chen[1], Irene Wang[2], Brendon Wang[3], Adin-Christian Andrei[1], Latifa Bazzi[1], Coyin Oh[1]

[1]Northwestern Univ. Feinberg School of Medicine, Chicago, IL,[2]Albert Einstein College of Medicine, Bronx, NY,[3]Medical College of Wisconsin, Milwaukee, WI

Background: The incidence of HPV-positive (HPV+) oropharyngeal squamous cell carcinoma (OPSCC) has risen drastically in recent years. Conditional overall survival (cOS) provides useful prognostic information for patients who have survived a certain time period following initial treatment, and can inform surveillance guidelines for HPV+ OPSCC. However, cOS for HPV+ OPSCC has not been evaluated in recent years. We sought to characterize residual survivorship among patients who remained alive at 1, 2, or 3 years after diagnosis by evaluating cOS, stratified by tumor staging and associated risk factors, in HPV+ OPSCC based on a large national cancer database.

Methods: We identified patients diagnosed with HPV+ OPSCC confirmed by p16 immunohistochemistry from 2018 to 2022 using the Surveillance, Epidemiology, and End Results (SEER) database. Demographics (race, gender, age), treatment modality (radiation, chemotherapy, surgery), and clinicopathological variables (overall staging, tumor size, number of positive regional nodes) were collected. Conditional Kaplan-Meier curves were used to summarize cOS stratified by overall stage and Cox regression models were generated to evaluate if tumor size, age, and performed surgery are associated with cOS.

Results: Of the 5298 patients included in the study cohort, 86% were male, 91% were white, 44% had undergone surgery, 84% received radiotherapy, and 64% received chemotherapy. The median age at diagnosis was 61 years old. Increased age (per-year hazard ratio, HR=1.052, 95% CI: 1.042-1.061, $p<0.0001$) and increased tumor size (for every 10mm increase, HR=1.053, 95% CI: 1.045-1.061, $p<0.0001$) were associated with increased mortality. Surgery was associated with lower mortality (HR=0.3023, 95% CI: 0.2478-0.3688, $p<0.0001$). The 4-year overall survival at diagnosis for the study cohort was 83.6% but the cOS increased to 93.5% among patients who had already survived the first two years. Higher disease stage was associated with larger gains in conditional survival. For Stage I patients, 4-year overall survival increased from 90.9% at diagnosis to a cOS of 98.2% among survivors at three years post-diagnosis. Similarly, these increases were from 77.9% to 95.7% for Stage II, 62.7% to 95.2% for Stage III, and 31.7% to 90% for Stage IV patients. Following three years of survival, conditional survival estimates across all stages converged to a high range of 90%-98.2%.

Conclusions: For each tumor stage, survival beyond each subsequent year is associated with a higher survival probability to Year 4. Patients with more advanced stage disease saw the largest gains in conditional survival probability over time. These results suggest that the clinical stage of HPV+ OPSCC may have less impact on continued survival after 3 years, which may have implications for prognostication and long-term surveillance. Further work is needed to evaluate these trends over a longer period of time.

#3579 Racial disparities in conditional survival among patients with oral cavity squamous cell carcinoma: A surveillance, epidemiology, and end results-based analysis.

Irene Wang[1], Brendon Wang[2], Andrew Chen[3], Noah Kornblum[1]

[1]Albert Einstein College of Medicine, Bronx, NY,[2]Medical College of Wisconsin, Milwaukee, WI,[3]Northwestern Univ. Feinberg School of Medicine, Chicago, IL

Background: Oral cavity squamous cell carcinoma (OCSCC) accounts for a substantial proportion of head and neck cancer–related morbidity and mortality in the United States. Persistent racial disparities in incidence, stage at diagnosis, access to surgical care, and overall survival have been well documented. Traditional survival estimates, however, do not reflect how prognosis evolves after patients survive the initial years following diagnosis. Conditional survival (CS) offers a dynamic estimate of prognosis over time and may better characterize the attenuation of racial survival gaps.

Methods: Using the SEER database, we conducted a population-based retrospective analysis of 24632 individuals diagnosed with OCSCC between 2004-2015. 5-year cancer-specific CS was calculated using the Kaplan-Meier method. Information including race, age, various socioeconomic demographics, tumor grade and stage, subsite, and treatment modality was used to perform multivariable Cox regression analysis and obtain hazard ratios (HRs) of 5-year mortality for race. All analyses were conducted using R (version 4.5.1).

Results: Of the OCSCC patients analyzed, 80.6% were White, 8.7% Black, and 10.7% Asian/Pacific Islander (API). Initial 5-year CS revealed marked disparities: Black patients (43.2%) had substantially lower survival than White (62.4%) and API patients (63.1%). However, conditional survival demonstrated a dynamic convergence pattern. By year 5 post-treatment, survivors showed narrowed differences: Black patients reached 84.7%, White patients 87.8%, and API patients 88.9% 5-year conditional survival. Time-varying multivariable Cox regression revealed evolving mortality patterns. Black patients faced increased death risk early (Year 0 HR: 1.15, 95% CI: 1.06-1.24; Year 1 HR: 1.22, 95% CI: 1.09-1.36), but this excess risk disappeared among long-term survivors (Year 4 HR: 1.05, $P = 0.651$; Year 5 HR: 1.08, $P = 0.589$). API patients consistently showed comparable outcomes to White patients across all timepoints (HRs: 0.87-1.02, all $P > 0.05$).

Conclusion: OCSCC racial survival disparities follow a convergence trajectory. While Black patients experience significantly worse outcomes initially, this gap contracts to just 3 percentage points among 5-year survivors, accompanied by complete resolution of excess mortality risk in adjusted models. This temporal concentration of disparities within the first three post-treatment years may implicate early-phase factors in treatment (e.g., diagnostic delays, treatment barriers) as drivers in early mortality. There was no statistically significant difference in API compared to White patients.

#3583 Distinct breast cancer gene signatures by estrogen receptor status associated with psychological distress.

Shipra Gandhi[1], Sayeeda Yasmeen[2], Spencer Rosario[2], Wiam Bshara[2], Thaer Khoury[2], Hans Minderman[2], Orla Maguire[2], Zhihong Gong[2], Ayana T. Ruffin[1], Megan Meek Wyatt[1], Mahmoud Abdelbary[1], Chrystal Mary Paulos[1], Elizabeth Repasky[2], Pawel Kalinski[3], Christine Ambrosone[2], Song Yao[2], Chi-Chen Hong[2]

[1]Winship Cancer Institute of Emory University, Atlanta, GA,[2]Roswell Park Comphrehensive Cancer center, Buffalo, NY,[3]University of Pittsburgh, Pittsburgh, PA

Background: Chronic psychosocial distress may accelerate breast cancer progression by altering immune, and inflammatory pathways, yet its genome-wide transcriptional effects in breast tumors remain unclear. This study uses RNA sequencing (RNA-seq) to characterize how distress influences transcriptional programs within the breast tumor microenvironment (TME).
Methods: Tumor samples from the Women's Health after Breast Cancer Study were analyzed for genome-wide transcriptional effects of distress. Participants completed the Perceived Stress Scale (PSS) and the Center for Epidemiologic Studies Depression Scale (CES-D) at diagnosis, including total scores and subscales (somatic symptoms, depressive affect, interpersonal problems, and positive affect). RNA-seq was performed on FFPE tumors from 195 women (152 ER+, 43 ER–). Principal component analysis (PCA) identified distress domains contributing to transcriptional variability. Participants were classified using PSS (>14 vs 0-14) and CES-D somatic symptoms (>3 vs ≤3). Differential gene-expression and gene-set enrichment analyses evaluated high-stress/low-somatic symptoms and low-stress/high-somatic symptoms groups vs a common low-stress/low-somatic symptoms reference, adjusting for age and education. Statistical significance was defined as FDR<0.05.
Results: PCA indicated subtype-specific distress signatures, with CES-D somatic symptoms explaining the most transcriptional variance in ER+ tumors and PSS explaining more variance in ER– tumors. In ER+ tumors, high stress with low somatic symptoms upregulated immune-activation pathways, including B-cell signaling, interferon responses, complement, and antigen presentation (top NES ~2.1-2.7, FDR<0.05). Key genes (*FLG, IGLV3-16, IGKV3D-15, RPS7P3*) mapped to immune-activation and interferon pathways. In ER– tumors, high stress showed enrichment of PD-1 co-inhibition and MHC-I antigen-presentation (NES=2.36 and 2.15, respectively, FDR<0.03), with suppression of neuronal, metabolic, mitochondrial, and protein-synthesis signaling (NES –1.4 to –2.1, FDR<0.05). High somatic symptoms in ER+ tumors enriched translational and ribosomal pathways (NES=3.0, FDR<0.01). In ER– tumors, high somatic symptoms were associated with increased keratinization, leptin, WNT, and IGF signaling (NES~1.8-2.7, FDR<0.02), and reduced chromatin-regulation, DNA replication, RNA-processing, translation pathways, and MHC-I antigen presentation (NES ~1.8 to -1.9, FDR<0.006).
Conclusions: Psychological distress shapes breast-tumor transcriptional programs in a subtype-specific manner. Stress and depressive domains map to distinct immune, metabolic, and biosynthetic pathways in ER+ vs ER– disease, suggesting that different forms of distress engage different processes in the TME. This information could be leveraged to design new treatments for patients.

#3584 Characterizing polygenic risk scores for cancer in prospective cohorts: Considering PRS method construction, age of diagnosis, genetic ancestry, and sample overlap.

Julie-Alexia Dias[1], Gillian King[2], David Bogumil[2], Brian Huang[2], Fei Chen[2], David V. Conti[2]

[1]Department of Biostatistics, Harvard University, Boston, MA,[2]University of Southern California, Los Angeles, CA

Well-established prospective cancer cohorts provide a unique opportunity to investigate the combined use of polygenic risk scores (PRSs) and non-genetic factors for personalized disease risk prediction. However, their application can vary depending on cohort-specific characteristics. We compared four PRS weighting strategies: PRS-CSx, Lassosum, a multi-ethnic joint analysis of marginal summary statistics (mJAM) forward selection procedure, and standard genome-wide association study (GWAS) derived weights, across eight large, prospective cohorts, totaling over a million subjects from the Multiethnic Cohort (MEC, n=73,139), the Genetic Epidemiology Research on Aging (GERA, n=103,358), the Women's Health Initiative (WHI, n=46,794), the Nurses' Health Studies I (NHS, n=20,195) and II (NHS2, n=16,082), the Health Professionals Follow-up Study (HPFS, n=12,649), the UK Biobank (UKB, n=474,775) and All of Us (AoU, n=317,956).

Together, these cohorts represent a uniquely diverse study population spanning multiple racial and ethnic groups, broad age distributions, and both overlapping and non-overlapping samples with discovery GWAS populations. We evaluated PRS performance for four major cancers (breast, prostate, colorectal, and lung) across all weighting methods and contexts. Our findings show that both the choice of PRS construction method and the characteristics of the target cohort substantially influence the characterization of disease risk.

By integrating four distinct PRS approaches across eight large and diverse prospective cohorts, this study provides one of the most comprehensive evaluations to date of context-dependent variation and provides guidance for ongoing development of risk prediction models that combine genetic and non-genetic factors.

#3585 A body mass index polygenic risk score (PRS_{BMI}) and obesity-related cancer risk among women in the Hispanic Community Health Study/Study of Latinos.

Humberto Parada[1], Tamar Sofer[2], Margaret Pichardo[3], Krista M. Perreira[4], Laura Zhou[5], Frank J. Penedo[6], Amber Pirzada[7], Martha Daviglus[8], Gregory A. Talavera[9], Linda C. Gallo[9]

[1]School of Public Health, San Diego State University, San Diego, CA,[2]Department of Biostatistics, Harvard Medical School, Boston, MA,[3]Department of Surgery, Hospital of the University of Pennsylvania, Philadelphia, PA,[4]Department of Social Medicine, University of North Carolina at Chapel Hill, Chapel Hill, NC,[5]Department of Biostatistics, University of North Carolina at Chapel Hill, Chapel Hill, NC,[6]Department of Psychology, University of Miami, Coral Gables, FL,[7]College of Medicine, University of Illinois, Chicago, IL,[8]Department of Medicine, University of Illinois Chicago, Chicago, IL,[9]Department of Psychology, San Diego State University, San Diego, CA

Background. Obesity is associated with an increased risk of cancer including cancers of the colon and rectum, endometrium, and breast among women. Polygenic risk scores (PRS), which sum the effects of risk variants, estimate an individual's genetic predisposition to complex phenotypic traits, such as obesity. We constructed a PRS for body mass index (PRS_{BMI}) and examined whether the PRS_{BMI} was associated with the risk of obesity-related cancers (ORCs) among Hispanic/Latina women. We also examined whether BMI moderated or mediated the association between PRS_{BMI} and ORC risk.

Methods. This prospective cohort study included 8,380 Hispanic/Latina women (mean age at baseline=41.8±0.3 years) from the Hispanic Community Health Study/Study of Latinos (HCHS/SOL). At baseline in 2008-2011, height and weight were measured and used to compute BMI, and participants provided blood samples for genotyping. The PRS_{BMI} was constructed using previously published weights downloaded from the polygenic score (PGS) catalog. The incidence of 13 obesity-related cancers diagnosed from baseline through 2021 was ascertained through linkages with four state cancer registries (n=223 incident ORCs were diagnosed over a mean follow-up of 10.8 years). Survey multivariable Cox regression models estimated the associations (hazard ratios, HRs, and 95% confidence intervals, CIs) between the PRS_{BMI} (per standard deviation, SD) and ORC risk overall and by BMI (<25 vs. ≥25 kg/m^2). Survey multivariable Cox regression and linear regression models tested the mediating effect of BMI (continuous, kg/m^2) on the association between PRS_{BMI} (per SD) and ORC risk.

Results. In stratified analyses, a 1-SD increase in the PRS_{BMI} was associated with an ORC HR of 0.74 (95%CI=0.56-0.97) among women with BMI<30 kg/m^2, but not among women with a BMI≥30 kg/m^2 (HR=0.95; 95%CI=0.68-1.33; $P_{Interaction}$=0.15). In mediation analyses, PRS_{BMI} was significantly associated with BMI (β_a=1.86; 95%CI=1.66-2.06); BMI was significantly associated with ORC risk, adjusting for PRS_{BMI} (β_b=0.07; SE=0.01; HR=1.07; 95%CI=1.05-0.19); and BMI significantly mediated the association between PRS_{BMI} and ORC risk (indirect effect, β_a*β_b=0.13; 95%CI=0.07-0.19).

Conclusion. Genes predisposing women to a higher BMI may primarily impact ORC risk through BMI. These results highlight the importance of weight management for cancer prevention among Hispanic/Latina women.

#3586 Validation and population projection of multi-cancer risk incorporating polygenic risk scores and non-genetic factors.

Emily L. Norton[1], Thomas Ahearn[2], Srijon Mukhopadhyay[3], Jeya Balasubramanian[2], Elle Kim[4], Sara Li[5], Parichoy Pal Choudhury[6], Montserrat Garcia-Closas[7], Nilanjan Chatterjee[1]

[1]Biostatistics, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD,[2]National Cancer Inst. Div. of Cancer Epidemiology & Genetics, Bethesda, MD,[3]University of North Carolina, Chapel Hill, NC,[4]Johns Hopkins School of Medicine, Baltimore, MD,[5]Johns Hopkins University, Baltimore, MD,[6]American Cancer Society, Atlanta, GA,[7]The Institute of Cancer Research, United Kingdom

Background: Multiple risk factors are shared across different cancers, yet risk assessment and prevention strategies remain largely site-specific. Meanwhile, multi-cancer detection tests are emerging as complementary approaches to site-specific screening strategies such as mammography, colonoscopy, and low-dose CT lung scans. Multi-cancer risk prediction could provide a more holistic understanding of an individual's cancer risk, with the potential to improve risk-stratified prevention and screening strategies across multiple cancer types.

Methods: We developed absolute risk models for 14 cancer sites using published non-genetic risk models incorporating 26 risk factors, together with established polygenic risk score (PRS) for each cancer site, using the Individualized Coherent Absolute Risk Estimator (iCARE) tool to integrate relative risk parameters, risk-factor distributions, population incidence rates, and mortality rates. We extended iCARE to estimate risk across multiple cancer sites over specified time intervals. Calibration (expected/observed (E/O) risk) and discrimination (area under the curve (AUC)) of site-specific and combined multi-cancer risk predictions were prospectively evaluated in the non-Hispanic White population in the Prostate, Lung, Colorectal, and Ovarian (PLCO) Cancer Screening Trial. Multi-cancer risk stratification for the US non-Hispanic White population was projected by applying our model with age specific incidence and mortality rates to a reference population derived from the National Health and Nutrition Examination Survey, the National Health Interview Survey, and the Breast Cancer Surveillance Consortium.

Results: Validation in PLCO showed comparable risk stratification between the sexes but better calibration for females (multi-cancer 10-yr risk E/O = 1.05 (95% CI: 1.03-1.07), AUC = 0.60) than males (E/O = 0.76 (95% CI: 0.75-0.77), AUC = 0.61). Between the first and last decile of predicted 10-year risk, the corresponding observed risk ranges 3-20% in females and 7-30% in males. Multi-cancer risk projections for the non-Hispanic White US reference population showed that 24% of males and 23% of females aged 18-74 are at moderate to high risk (10-year absolute risk ≥10%).

Conclusion: Multi-cancer risk prediction models combining non-genetic risk factors and PRS demonstrate meaningful risk stratification. Future studies will include calibration, validation, and projection of these models in US non-White populations. Such models may support counseling on lifestyle interventions that influence multiple cancer risks and help identify high-risk individuals for emerging multi-cancer screening approaches such as liquid biopsy tests. However, further model development and evaluation is needed to ensure optimal performance across population groups.

#3587 Independent validation of polygenic risk scores for overall and triple-negative breast cancer among high-risk African American women.

Yijia Sun[1], Timothy Simmons[2], James L. Li[3], Armaan Jamal[1], Achille V.C. Manirakiza[4], Dmitry Pruss[2], Sarah Ratzel[2], Olufunmilayo I. Olopade[4], Alexander Gutin[2], Elisha Hughes[2], Dezheng Huo[1]

[1]Public Health Sciences, University of Chicago, Chicago, IL,[2]Myriad Genetics, Inc., Salt Lake City, UT,[3]Interdisciplinary Scientist Training Program, University of Chicago, Chicago, IL,[4]Center for Innovation in Global Health, University of Chicago, Chicago, IL

Background: Polygenic risk scores (PRSs) are emerging tools for stratifying breast cancer (BC) risk. We developed PRSs of overall BC and triple-negative BC (TNBC) risk in women of African ancestry, using case-control data from studies unselected for family history. PRS could be part of comprehensive breast cancer risk assessment for women at higher risk due to cancer family history. Here we aimed to evaluate the performance of these PRSs in women with elevated cancer risk.
Methods: We included samples from African American women who underwent multigene hereditary genetic testing between 2016 and 2024 and who tested negative for pathogenic or likely pathogenic variants in known BC genes. Genotyping was performed using custom Axiom PMRA arrays (ThermoFisher) and imputation based on TOPMed reference data. We evaluated two PRS models for overall BC with 2,324,063 variants ("Overall BC Model 1") and 175,173 variants ("Overall BC Model 2"), and three PRS models for TNBC with 554,959 variants ("TNBC Model 1"), 37,226 variants ("TNBC Model 2"), and 162 variants ("PRS-162"). The 313-variant PRS developed in women of European ancestry (PRS-313) served as a benchmark. Only variants with imputation $R^2 \geq 0.7$ were included. Associations between PRSs and BC status were examined using multivariable logistic regression, adjusting for age at diagnosis or testing, the top ten principal components, and weighted family history of BC. Adjusted odds ratio (OR) per standard deviation and area under the curve (AUC) were calculated.
Results: The study included 19,455 unaffected and 12,067 women with BC (2,311 TNBC). Mean age at BC diagnosis was 55.2 years in BC cases vs. 42.1 years at testing in unaffected women. More unaffected women had a family history of BC in first-degree (32.8% vs. 28.0%) and second-degree relatives (55.7% vs. 35.0%) than affected women. Over 95% of African PRS variants and 82% of the PRS-313 variants had an imputation $R^2 \geq 0.7$. For overall BC, PRS-313 showed an AUC of 0.567 (95% confidence interval [CI]: 0.560, 0.574) and an OR of 1.28 (95% CI: 1.25, 1.31). In comparison, the African overall BC Models 1 and 2 performed better, with AUCs of 0.588 (95% CI: 0.580, 0.595) and 0.584 (95% CI: 0.576, 0.591) and ORs of 1.39 (95% CI: 1.35, 1.43) and 1.37 (95% CI: 1.34, 1.41), respectively. For TNBC, Models 1 and 2 yielded similar performance, with AUCs of 0.579 and 0.574, respectively. Notably, the TNBC PRS-162 showed very good performance with an AUC of 0.609 (95% CI: 0.596, 0.622) and an OR of 1.47 (95% CI: 1.40, 1.55).
Conclusion: The PRSs demonstrated good performance among women with a strong family history of BC, reflecting real-world populations where early PRS testing is most relevant for those at elevated risk. The high predictive accuracy of the 162-variant TNBC PRS supports its potential as a cost-effective risk assessment tool to promote equitable care.

#3589 Ancestry-driven transcriptional regulation of breast cancer genes through cis- and trans-eQTLs in colombian populations.

Laura Rey-Vargas, Lina Maria Bejarano, Patricia Lopez, Diego Felipe Ballen-Lozano, Silvia Juliana Serrano-Gomez

Instituto Nacional de Cancerologia, Bogota, D.C, Colombia

Introduction: Significant disparities in breast cancer phenotypes have been observed across population groups. Latina women show a higher prevalence of aggressive tumor subtypes and increased mortality compared to non-Hispanic White women. Genetic ancestry differences have been proposed as a potential mechanism influencing baseline tissue biology and tumor behavior. Specifically, ancestry-specific expression quantitative trait loci (eQTLs) may mediate these effects. This study aimed to identify ancestry-specific eQTLs associated with clinically relevant breast cancer genes.
Methods: RNA-seq data from tumor and adjacent non-tumoral breast tissue of 183 patients from the NCI of Colombia were analyzed to obtain genotypes using a GATK4 variant-calling pipeline and the TOPMed imputation server. Normalized gene expression matrices were generated with STAR and DESeq2, and eQTLs were identified using MatrixEQTL in R. Local ancestry was inferred with RFMix to filter eQTLs within regions enriched for specific ancestries.
Results: In non-tumor breast tissue, 234 Indigenous ancestry-specific cis-eQTLs associated with 18 eGenes were identified, with MACC1 being the only COSMIC-listed gene. Additionally, 1,371 Indigenous ancestry-specific trans-eQTLs were linked to 1,001 eGenes. After prioritization, 164 significant associations were identified, involving 31 COSMIC eGenes regulated by 76 trans-eQTLs. These included oncogenes such as ERBB2, CDK6, FGFR4, LASP1, and MDM2, and tumor suppressor genes like BRCA2, RB1, CDH1, and ATM. Conversely, 26 European ancestry-specific cis-eQTLs associated with four proximal eGenes (ST7L, SLC35E2A, PRPF38A, and ODR4) were identified. Moreover, 160 European ancestry-specific trans-eQTLs were linked to 194 eGenes showing enrichment in membrane-related processes, including oncogenes such as PRKCB and JAK3, and tumor suppressors like ATM and RB1. Due to low African ancestry representation among Colombian patients, this component was not analyzed. For Indigenous ancestry-specific eQTLs, trans associations between 12 variants located in 5q13.3 and tumor-relevant genes in 19q13.1, 11p15.5, and 1p34.2 were validated in cancer tissue, including MUC6, MED29, and PDCD5.
Conclusion: These findings suggest that in non-tumoral breast tissue, transcriptional regulation can be mediated by Indigenous and European ancestry-specific variants influencing the expression of genes with key roles in tumor-related pathways. Validation analyses in tumor tissue indicated that only a subset of Indigenous ancestry-specific eQTLs may retain trans-regulatory effects and contribute to breast cancer biology.

#3590 Genetic and immune signaling divergence underlies the inverse associationbetween asthma and cancer.

Kinsey Garofalo[1], Yinqiao Wang[2], Peyton Cook[1], Yujuan Guo[1], Yong Zhu[1]

[1]University of Arkansas for Medical Sciences, Little Rock, AR,[2]University of Southern California, Los Angeles, CA

An inverse association between asthma and several cancer types has been consistently observed across epidemiologic studies, yet the molecular mechanisms underlying this relationship remain unclear. To address this gap, we conducted a comprehensive genetic and functional analysis to identify variants, genes, and immune signaling pathways that may contribute to this protective association. From literature-validated genome-wide association studies, we compiled 246 asthma-associated SNPs and identified 14 variants that were also significantly associated with cancer risk. Notably, 11 of these SNPs demonstrated reversal directionality, where the asthma risk allele was associated with reduced cancer risk, particularly in glioma and colorectal cancer. Haplotype analysis further revealed 19 genes exhibiting diametric effects on asthma and cancer susceptibility. Among these, IL-9, TLR1, SMAD7, LPP, IL-7R, and HLA-DQB1 also showed inverse gene expression patterns between asthma tissues and multiple cancer types, indicating functional opposition at the transcriptional level. Pathway enrichment using Ingenuity Pathway Analysis identified Th1/Th2 immune axis regulation and glucocorticoid receptor signaling as central networks driving this biological divergence. Specifically, genes upregulated in asthma that elevate Th2-dominant IgE-mediated immune responses were linked to enhanced immunosurveillance and T-cell cytotoxic activation in cancer contexts, suggesting a mechanistic basis for reduced tumor initiation and progression. Meanwhile, glucocorticoid receptor isoform regulation emerged as a potential modulator linking asthma treatment to cancer vulnerability. Together, these results provide the first integrated genetic, transcriptomic, and pathway-level evidence supporting a causal immunologic framework for the inverse asthma-cancer association. This work highlights new molecular targets at the interface of allergic inflammation and tumor immunity and suggests opportunities for therapeutic repurposing of immune-modulating strategies used in asthma to inform cancer prevention and treatment.

#3591 Incorporation of polygenic risk scores with PSA testing for prostate cancer risk stratification in men undergoing prostate biopsy.

Daniel Sabater Minarim[1], Roshan Karunamuni[1], Kylie M. Morgan[1], Tyler Nelson[1], Craig Teerlink[2], Julie Lynch[2], Isla P. Garraway[3], Anna M. Dornisch[1], Tyler M. Seibert[1], Jason L. Vassy[4], Brent S. Rose[1]

[1]Radiation Medicine and Applied Sciences, UCSD Health, San Diego, CA,[2]VA Informatics and Computing Infrastructure, Salt Lake, UT,[3]Urology, UCLA Health, Los Angeles, CA,[4]Harvard Medical Scool, Boston, MA

Purpose: While prostate-specific antigen (PSA) screening reduces prostate cancer (PC) mortality, limited discriminatory ability leads to overdiagnosis of indolent disease and missed clinically significant PC. Genetically informed screening strategies utilizing polygenic scores may improve early PC detection. We hypothesized that incorporating polygenic scores for PC risk (PHS601) and benign elevated PSA (PRS447) with traditional risk factors would improve prediction of clinically significant PC on prostate biopsy in a diverse population.

Methods: We identified veterans who underwent their first prostate biopsy from October 1999 to September 2021 using the VA Corporate Data Warehouse, with genetic data from the Million Veteran Program. We excluded patients with prior PC diagnosis, those without pre-biopsy PSA within 90 days, and PSA levels >50 ng/mL. The cohort included 25,222 men: 19,376 (76.8%) White, 4,891 (19.4%) Black or African American, and 955 (3.8%) other race/ethnicities. The primary outcome was clinically significant PC (Gleason score ≥7). We evaluated two genetic scores (PHS601 and PSA447, both standardized to z-scores) along with pre-biopsy PSA, age at first biopsy, race/ethnicity, and smoking status. We performed multivariable logistic regression using three progressive models: clinical features alone, clinical features plus PHS601, and clinical features plus both genetic scores.

Results: Among 25,222 patients, 8,319 (32.9%) were diagnosed with clinically significant PC. Both genetic scores showed strong independent associations: elevated PHS601 increased risk (OR=1.73, 95% CI: 1.68-1.79, P<0.001), while higher PSA447 decreased risk (OR=0.69, 95% CI: 0.67-0.72, P<0.001). At PSA of 4 ng/mL, predicted probabilities of clinically significant cancer ranged from 9.1% to 56.9% across PHS601 percentile groups (≤2nd to ≥98th). Model discrimination improved from 0.635 (clinical features alone) to 0.714 (plus PHS601) to 0.737 (both genetic scores, p<0.001).

Conclusion: Polygenic scores for PC risk and benign PSA elevation significantly improve prediction of clinically significant PC on biopsy compared to traditional risk factors alone. These findings support genetically informed PC screening strategies. Men with low genetic PC risk could defer biopsy until higher PSA values, reducing overdiagnosis, while those with high genetic risk could undergo biopsy at lower PSA thresholds, reducing missed clinically significant PC.

#3592 Mitochondrial DNA breaks and copy number and the risk of lung cancer in never-smoking women.

Batel Blechter[1], Xiao-Ou Shu[2], Wei Hu[3], Elizabeth Francies[1], Wei Zheng[2], Yu-Tang Gao[4], Qiuyin Cai[2], Hui Cai[5], Gong Yang[6], H. Dean Hosgood[7], Richard Cawthon[8], Qing Lan[3]

[1]National Cancer Institute, Rockville, MD,[2]Vanderbilt University, Nashville, TN,[3]NCI Div. of Cancer Epidemiology & Genetics, Rockville, MD,[4]Chief, Dept. of Epidemiology, Shanghai Cancer Institute, Shanghai, China,[5]Vanderbilt University Medical Center, Nashville, TN,[6]Vanderbilt University School of Medicine, Nashville, TN,[7]Einstein University, New York City, NY,[8]University of Utah, Salt Lake City, UT

Introduction Lung cancer is the leading cause of cancer-related mortality worldwide, with approximately 25% of cases occurring in never-smokers, particularly East Asian women. Mitochondria are critical regulators of cellular energy production and oxidative stress responses, and mitochondrial DNA (mtDNA) is especially susceptible to damage from environmental exposures. While findings from previous studies on mtDNA copy number (mtDNAcn) and lung cancer risk have been mixed, mtDNA fraction with breaks (mtDNAfb) has recently emerged as a potential marker of oxidative stress and mitochondrial integrity. We investigated associations between prediagnostic mtDNAfb, mtDNAcn, and lung cancer risk in never-smoking women in the prospective Shanghai Women's Health Study (SWHS). **Methods** This nested case-control study included 789 incident lung cancer cases and 789 controls individually matched on birth year and blood collection date from the SWHS, a prospective cohort of 74,942 women enrolled between 1996 and 2000. DNA was extracted from white blood cells or buccal cells, and mtDNAfb was quantified using a high-throughput qPCR assay comparing amplification signals from TaqI-treated (digested) and untreated samples. Relative mtDNAcn was derived from qPCR measurements normalized to a reference gene. Conditional logistic regression was used to estimate odds ratios (ORs) and 95% confidence intervals (CIs) for the associations of mtDNAfb and mtDNAcn with lung cancer risk, adjusting for age, body mass index, and assay plate. Sensitivity analyses further controlled for education, environmental tobacco smoke exposure, family history of lung cancer, and mutual adjustment for mtDNAfb and mtDNAcn. Interaction between mtDNAfb and mtDNAcn was tested on a multiplicative scale. **Results** We observed higher mtDNAfb was associated with lower risk of lung cancer with participants in the highest mtDNAfb tertile having 34% lower odds compared with those in the lowest tertile (p trend = 0.026). No independent association was observed for mtDNAcn; however, a multiplicative interaction between mtDNAfb and mtDNAcn was identified (p interaction = 8.3×10^{-6}) where the association between mtDNAfb and lung cancer was more pronounced among participants with low mtDNAcn (OR = 0.47, 95% CI: 0.29-0.78) than those with high mtDNAcn (OR = 1.02, 95% CI: 0.58-1.79). **Conclusions** Lower mtDNAfb was associated with increased lung cancer risk among never-smoking women, particularly among women with low mtDNAcn, suggesting possible pathologic reductions in mitochondrial biogenesis and functioning, and consequently, reduced innate immune activation. These findings provide novel insights into mitochondrial dysfunction as a potential mechanism underlying lung cancer in never-smokers and warrant replication and mechanistic investigation in future studies.

#3593 Associations of BRCA1/2 mutations and polygenic risk score with prostate cancer risk and mortality in a founder population.

Ilir Agalliu[1], Mykhaylo Usyk[2], Michael D`Angelo[2], Victor Kamensky[1], Robert Burk[2]

[1]Epidemiology and Population Health, Albert Einstein College of Medicine, Bronx, NY,[2]Microbiology and Immunology, Pediatrics, Albert Einstein College of Medicine, Bronx, NY

Introduction: Prostate cancer (PrCa) is the most common solid tumor and the second-leading cause of cancer deaths among U.S. men. Although the multi-factorial etiology of this cancer indicates the involvement of several biological pathways, to date the role of rare vs common genetic variants (SNPs) in risk prediction of more aggressive or fatal PrCa remains unclear. The goal of this project is to examine the associations of rare germline *BRCA1/2* mutations and a polygenic risk score (PRS) with risks of total and aggressive PrCa as well as with overall and cancer-specific mortality in a founder population.

Methods: Epidemiological and germline genotype data collected from 943 PrCa cases and 1,199 controls of Ashkenazim Jewish descent were used in this analysis. We evaluated associations of *BRCA1* (185delAG) and *BRCA2* (6174delT) founder mutations and a PRS generated from 77 SNPs with risks of total PrCa and high-grade cancer (defined as Gleason score 7-10) using logistic and multinomial regression models, respectively, and adjusted for age and family history of PrCa. All men were followed for mortality via linkage with the U.S. National Death Index from recruitment into the study (between 1999 and 2003) through 12/31/2022. Cox regression models and competing risk analyses were used to examine associations of *BRCA1/2* mutations and PRS with overall and PrCa-specific mortality after adjustment for age, Charlson comorbidity index as well as clinical factors and PrCa treatment.

Results: The prevalence of *BRCA1 (185delAG:* 1.2% vs 0.7%*)* and *BRCA2 (6174delT:* 1.3% vs 0.9%*)* were higher in cases vs controls. Mutation carriers of either *BRCA1* or *BRCA2* mutations had ORs of 1.92 (95%CI 1.00-3.67) for total PrCa and 3.38 (95%CI 1.63-7.04) for high-grade PrCa compared to non-mutation carriers. The PRS score was also independently associated with a statistically significant 2.2 to 2.3-fold higher risk for total PrCa and aggressive cancer. During a median follow-up of 19.7 years a total of 712 out of 943 (76%) men diagnosed with PrCa had died, of whom 124 (17.4%) were PrCa-specific deaths. *BRCA2* mutation carriers had hazard ratios (HR) of 1.92 (p=0.008) and 2.88 (p=0.01) for overall and PrCa-specific mortality compared to non-mutation carriers. However, there was no association of the PRS score with PrCa-specific mortality (HR=0.98, p=0.89) and a borderline significant 9% lower risk (HR=0.91, p=0.05) with overall mortality.

Conclusion: Carriers of *BRCA1* and particularly *BRCA2* mutations have increased risks of more aggressive and fatal PrCa. Although the PRS score was associated with overall risk, it did not confer any elevated risk for higher Gleason score tumors or fatal PrCa. Evaluation for *BRCA2* mutations might be helpful for risk-stratification of men for PrCa screening and potentially targeted therapy.

#3594 Adrenal-permissive *HSD3B1* genotype and prostate cancer-specific mortality among patients: Insights from the multiethnic cohort Study.

Wei Xiong[1], Xin Sheng[1], Peggy Wan[1], Lynne R. Wilkens[2], Loic Le Marchand[2], David V. Conti[1], Christopher A. Haiman[1], Fei Chen[1]

[1]University of Southern California, Los Angeles, CA,[2]University of Hawaii Cancer Center, Honolulu, HI

Background: The *HSD3B1* gene encodes an androgen synthesis enzyme critical for prostate cancer (PCa) progression. The CC genotype of a common missense variant in *HSD3B1* (rs1047303) is considered adrenal-permissive, resulting in increased androgen synthesis, resistance to androgen deprivation therapy (ADT), and accelerated PCa progression. However, epidemiologic evidence linking this variant to prostate cancer-specific mortality (PCSM), particularly in diverse patient populations, remains limited.
Methods: We investigated the recessive effect of the C allele (CC vs. AA or AC) on PCSM among incident PCa cases in the Multiethnic Cohort (MEC). Cause-specific Cox proportional hazards regression models were used to estimate the hazard ratios (HRs) and 95% CI confidence intervals (CIs), with age since PCa diagnosis as the time scale. Covariates included tumor stage (localized, regional, or distant), Gleason grade (high: ≥8 or low: <8), first-degree family history of PCa, the first ten principal components, and initial course of treatment (chemotherapy, radiation therapy, hormone therapy, or surgery). Analyses were conducted overall and in cases stratified by tumor stage, grade, and metastatic status. A sensitivity analysis was conducted, restricted to men who underwent hormone therapy as part of the initial treatment. Statistical significance was defined as a two-sided p-value <0.05.
Results: Among the 3,216 incident PCa cases (34.7% Japanese Americans, 20.4% Latinos, 19.5% African Americans, 19.1% Whites, and 6.4% Native Hawaiians), 295 (9.2%) died due to PCa over a median follow-up of 5.9 years, and 115 (3.6%) carried the CC genotype. Compared to the AA/AC genotype, the CC genotype was associated with a suggestive 57% increased risk of PCSM (95% CI: 0.80-3.09, P=0.19). The association was stronger among patients with metastatic (HR=5.24, 95% CI: 1.01-8.48, P=0.01), advanced (HR=2.33, 95% CI: 0.67-8.08, P=0.18), or high-grade (HR=2.15, 95% CI: 0.80-5.79, P=0.13) PCa. In the hormone therapy subgroup, the CC genotype was significantly associated with increased PCSM among patients with metastatic (HR=6.79, 95% CI: 2.03-17.2, P<0.001) and advanced (HR=3.29, 95% CI: 1.10-11.7, P=0.03) disease.
Conclusion: In this multiethnic population of PCa cases, the adrenal-permissive CC genotype of *HSD3B1* rs1047303 variant was associated with a markedly increased risk of PCSM, particularly among patients with aggressive disease and those treated with hormone therapy. These findings suggest that *HSD3B1* genotyping may have clinical utility in identifying patients at higher risk of poor outcomes and guiding personalized treatment strategies. Further studies with larger sample sizes are needed to confirm these associations and explore their implications for clinical decision-making.

#3596 Characterizing BRCA1 and BRCA2 mutations in Cameroonian breast cancer patients: Efforts towards bridging the genomic gap in Africa.

Kenn Chi Ndi[1], Berthe Sabine Esson Mapoko[2], Vanessa Mouaye[3], Carmen Vanvolkenburgh[4], Bonaventure Dzekem[4], Paul Ndom[2], Dezheng Huo[4], Olufunmilayo I. Olopade[4]

[1]Medical Oncology, Centre Hospitalier Regional d'Ebolowa, Ebolowa, Cameroon,[2]Medical Oncology, Faculty of Medicine and Biomedical Sciences, University of Yaounde 1, Yaounde, Cameroon,[3]Cancer Control Committee, Yaounde, Cameroon,[4]University of Chicago Medical Center, Chicago, IL

Background: There are profound global inequities cancer genomics research, with publications focusing on cancer genetics from Africa representing only 0.016% of the global total. This genomic underrepresentation creates significant barriers to equitable cancer care and precision medicine for African populations. BRCA1/2 mutations remain critically understudied in these communities, limiting our understanding of hereditary breast cancer patterns. This pioneering study characterizes BRCA1/2 mutations among Cameroonian patients to lay the foundation for future genomic research and address critical knowledge gaps.
Methods: This hospital-based study recruited 82 breast cancer patients from 2 major treatment centers in Cameroon, an underserved population with limited access to genetic services. Following pre-test genetic counseling, saliva samples were collected and analyzed using next-generation sequencing for 29 cancer-associated genes. AI was used to improve the clarity of the language of this abstract.
Results: Pathogenic mutations were identified in 23 patients (28%), with BRCA1 (15) and BRCA2 (2) accounting for 73.9% of all mutations (18.3% and 2.4% of the total population, respectively). The most frequent BRCA1 mutation was *c.4484G>T(p.Arg1495Met)*, present in 7 patients (46.7% of BRCA1 mutations, 8.5% of total population), followed by *c.5155dup(p.Val1719Glyfs6)* in 3 (including 1 with bilateral breast cancer) patients (20% of BRCA1 mutations). *BRCA2* mutations included *c.1813dup(p.Ile605Asnfs*11) and *c.5572del(p.Thr1858Glnfs*5)*. Family history of cancer was reported in 73.9% of mutation carriers compared to 62.2% overall. Variants of uncertain significance were detected in 25.6% of patients. Two of those with the *c.4484G>T* BRCA1 mutation had an associated VUS in the PALB2 gene *(c.365A>G(p.Asp122Gly))*. They were both under 30 and had at least 4 first- and second-degree relatives with breast and ovarian cancer. Two other patients had the same VUS in APC *(c.3760A>G(p.Ile1254Val)*), all with at least 2 relatives with cancer and 1 had the BRCA1 c.4484G>T mutation and the other had no pathologic mutation identified.
Conclusions: This pioneering study reveals striking cancer health disparities, with BRCA1/BRCA2 mutation frequencies exceeding rates in well-studied populations. The predominance of specific mutations and VUSs suggests population-specific genetic architecture requiring tailored approaches. Our work provides a foundation for developing culturally-appropriate cancer prevention strategies, reducing genetic testing disparities, and advancing precision medicine accessibility in vulnerable populations, ultimately contributing to the global effort to eliminate cancer health disparities.

#3597 Defining cancer risk germline variants in shelterin complex genes - a genome-first analysis.

Hasset Nurelegne, Akanksha Nagarkar, Jung Kim, Douglas Stewart, Sharon Savage, Kelvin C. De Andrade

National Cancer Institute, Bethesda, MD

Background: The shelterin complex (encoded by ACD, POT1, TERF1, TERF2, TERF2IP, andTINF2) is essential for telomere maintenance and chromosome stability. Pathogenic or likelypathogenic (P/LP) germline variants in some shelterin genes cause telomere biology disorders aswell as cancer predisposition with long telomeres. To date, studies have focused on clinicallyascertained families. Genome-first approaches identify individuals with rare P/LP variants frompopulation-scale sequencing databases linked to electronic health records, enabling better estimates of variant prevalence and cancer risk.
Methods: We assessed rare (minor allele frequency<1%) P/LP germline variants in ACD,TERF1, TERF2, TERF2IP, and TINF2. Exome and phenotype data were analyzed from UKBiobank (UKB) (N=469,578) and Geisinger DiscovEHR cohort (N=216,361). Variants wereclassified using AutoGVP and literature review. Cancer prevalence and risk in carriers versusnoncarriers were evaluated using logistic regression models, respectively, adjusted for year ofbirth, sex, smoking status, alcohol intake, body mass index, and genetically determined ancestry.
Results: We identified 1,200 individuals (784 in UKB and 416 in Geisinger) with P/LP germlinevariants in shelterin complex genes. The prevalence of shelterin variants ranged from 1:1,886 to1:39,132 in UKB and 1:1,157 to 1:24,040 in Geisinger, ACD and TINF2 had the highestestimates and TERF2 the lowest. In ACD, a variant previously associated with cancer(c.488A>G, p.Asn163Ser) accounted for 49.3% of all ACD carriers. In UKB, TINF2 carriers hadsignificantly increased risk for melanoma (OR 5.33 (1.93-14.70); p=0.015), endocrine cancers(OR 25.30 (9.16-69.87); p<0.001), and mesothelioma (OR 18.38 (2.47-137.02); p=0.036) anddemonstrated overall earlier ages at cancer onset than noncarriers (p=0.0036). In Geisinger,TINF2 was associated with increased risk of cancers of soft tissue including heart (OR 6.76 (1.65-27.60); p=0.01), liver/ bile duct (OR 3.28 (1.03-10.50); p=0.05), and brain/nervous system(OR 5.19 (1.89-14.20); p<0.001). In Geisinger, ACD carriers with c.488A>G had an increasedrisk of eye and orbit cancers (OR 15.27 (2.10-111.00); p=0.007), although there was only onecarrier. The number of cancer events among individuals with TERF1, TERF2, and TERF2IPvariants was insufficient for statistical analyses.
Conclusion: In Geisinger, prevalence of rare P/LP shelterin gene variants was generally higherthan in UKB, reflecting the clinically enriched nature of that cohort. TINF2 had variants with thestrongest cancer associations. Longitudinal studies of younger cohorts are warranted to refineprevalence estimates and cancer risk associated with shelterin complex genes.

#3598 Investigating divergent ER$^+$and ER$^-$breast cancer subtype risks by using oppositely associated genetic variants.

Phillip Schofield[1], Meghana Pagadala[2], Timothy Sears[2], Hannah K. Carter[2]

[1]UC San Diego School of Medicine, La Jolla, CA,[2]UC San Diego, La Jolla, CA

Breast cancer is the second most common cause of cancer-related deaths among women in the United States, with its incidence increasing each year. Estrogen receptor-negative (ER$^-$) breast cancers are particularly aggressive and less responsive to conventional treatments compared to estrogen receptor-positive (ER$^+$) types, though they exhibit higher immunogenicity and better responses to immunotherapies. This study focuses on identifying single nucleotide polymorphisms (SNPs) that are oppositely associated between ER$^+$ and ER$^-$ breast cancers, meaning that the presence of a SNP increases the risk of one subtype while decreasing the risk of the other subtype. We identified 481 SNPs from the Breast Cancer Association Consortium (BCAC) that were oppositely associated between subtypes ($p < 0.1$) and cross-validated these associations using data from breast cancer patients in The Cancer Genome Atlas (TCGA), imputed using the TOPMED imputation server. Our findings revealed 45 SNPs associated with increased ER$^+$ risk but decreased ER$^-$ risk and 2 SNPs associated with increased ER$^-$ risk but decreased ER$^+$ risk that were concordant between the BCAC and TCGA datasets. Of the concordant SNPs that increased ER$^+$ risk, the majority mapped to a region of chromosome 11 near the known tumor suppressor gene *ATM;* however, one SNP on chromosome 10 (10:21471086:C/T) has been previously shown to increase circulating IGF-1 and decrease colorectal cancer risk to a greater extent in women than men. Further analysis using the CIBERSORTx tool showed that this SNP was associated with increased infiltration of perivascular-like immature cells in the tumor microenvironment. Of the SNPs that increased ER$^-$ risk, one localized to a poorly described antisense non-coding transcript of the *DLX2* gene which has been implicated in breast cancer, while the other localized to an intron of the *PTPRN2* gene that is implicated in type 1 diabetes mellitus and many cancers. While this study is limited by its focus on European women and the small sample size of ER$^-$ cases, the results offer preliminary insight into inherited variants that may differentially influence ER$^+$ and ER$^-$ disease, supporting future work aimed at clarifying the pathways that contribute to subtype-specific risk, immune infiltration, and treatment response.

#3599 MYC exon 3 DNA methylation in peripheral blood and the risk of aggressive prostate cancer in the prostate, lung, colorectal, and ovarian cancer screening trial.

Patricia A. Erickson[1], Lauren M. Hurwitz[2], Soren M. Bentzen[3], Stella Koutros[2], Liying Yan[4], Matthew L. Poulin[4], Ann Meyer[4], Allen Burke[3], Arif Hussain[3], Sonja I. Berndt[2], **Kathryn Hughes Barry**[3]

[1]Huntsman Cancer Institute, Salt Lake City, UT,[2]National Cancer Institute, Rockville, MD,[3]University of Maryland School of Medicine, Baltimore, MD,[4]EpigenDx, Inc., Hopkinton, MA

Introduction*:* Our group previously reported that higher DNA methylation at two CpG sites in *MYC* exon 3 in peripheral blood was associated with a higher risk of aggressive prostate cancer (Barry et al, *Br J Cancer* 2017). Here we aimed to assess if our findings for these CpG sites would replicate in an independent group of men.

Methods*:* Using pre-diagnostic blood samples, we conducted a nested prostate cancer case-control study among non-Hispanic White men in the Prostate, Lung, Colorectal, and Ovarian (PLCO) Cancer Screening Trial who were not included in our previous study in PLCO. Cases comprised 251 men who were diagnosed with incident aggressive prostate cancer (stage III or IV or a total Gleason score>=8), and controls comprised 497 men without a previous history of prostate cancer. The controls were individually matched to the cases on several factors, including age at blood draw (+/- 3 yrs), calendar year of blood draw (+/- 3 years), study year of blood draw, sample type (i.e., whole blood or buffy coat), and the source of the DNA (i.e., available DNA from previous genotyping efforts in PLCO or new extractions). Percent DNA methylation at the CpG sites of interest in the exon 3 region of *MYC*, denoted as CpG 214 (GRCh37/hg19 coordinate: Chr8:128753154) and CpG 215 (Chr8:128753187), was quantified using pyrosequencing on bisulfite-treated DNA. We used conditional logistic regression to estimate odds ratios (OR) and 95% confidence intervals (95% CI) for DNA methylation levels, modeled as a continuous variable, in relation to aggressive prostate cancer. We also conducted a meta-analysis to combine the results from our two studies (total of 423 aggressive prostate cancer cases).

Results*:* For both CpG 214 and 215, we observed an elevated risk of aggressive prostate cancer with each unit increase of DNA methylation (for CpG 214, OR=1.05, 95% CI: 0.99-1.12, and for CpG 215, OR=1.03, 95% CI: 0.97-1.09). We observed similar patterns that were statistically significant for both CpG sites when meta-analyzing these results with our previous study (for CpG 214, OR=1.06, 95% CI: 1.02-1.10, and for CpG 215, OR=1.05, 95% CI: 1.01-1.10).

Conclusions: Adding to the literature on the role of *MYC* in prostate carcinogenesis, findings support that higher pre-diagnostic DNA methylation levels in *MYC* exon 3 in peripheral blood are associated with a higher risk of aggressive prostate cancer among non-Hispanic White men. Further study is needed in more diverse populations.

#3600 Pan-cancer genome-wide study reveals shared genetic architecture and novel pleiotropic variants across seven solid cancers.

Xunxuan Chen[1], Gamaliel T. Taengwa[2], Brandon J. Coombes[2], Stacey J. Winham[2]

[1]Cancer Biology, Keck School of Medicine, University of Southern California, Los Angeles, CA,[2]Quantitative Health Sciences, Mayo Clinic, Rochester, MN

Genome-wide association studies (GWAS) have identified thousands of genetic variants associated with individual cancer risk, and polygenic risk scores (PRS) are typically derived from these cancer-specific variants. Although previous pan-cancer studies revealed shared genetic architectures across cancer types, latent factors contributing to cancer risk have not been explored. This may allow for improved prediction of cancer risk based on a latent cancer factor which leverages shared variants across cancers. Here, we conducted an integrative pan-cancer GWAS across seven solid tumors (breast, ovarian, endometrial, pancreatic, lung, colorectal, melanoma) to identify shared latent genetic factors and novel pleiotropic variants. We curated the most recent and large-scale GWAS summary statistics to maximize statistical power, comprising 398,917 cases and 1,501,715 controls of European ancestry. Shared genetic structures among 6,346,960 common variants were evaluated using Genomic Structural Equation Modeling (GenomicSEM). Three latent factors (Common Cancer Factor, Female-Specific Cancer Factor and Non-Sex Specific Cancer Factor) were constructed, and associations of individual variants with each latent factor were estimated. Genome-wide significant loci ($p < 5x10^{-8}$) were functionally annotated and subjected to pathway enrichment analysis. Models capturing shared genetic risk across cancers fit the data well. A single “Common Cancer Factor” explained much of the shared risk (SRMR = 0.064 [lower is better], CFI = 0.938 [closer to 1 is better]), and a correlated two-factor model—distinguishing female-specific from other cancers—showed even stronger fit and biological relevance (SRMR = 0.055, CFI = 0.988). The one-factor (Common Cancer Factor; SRMR: 0.064, CFI: 0.938, AIC: 54.7, p_chisq: 0.021) and the two-factor (Female-Specific Cancer Factor and Non-Sex Specific Cancer Factor; SRMR: 0.055, CFI: 0.988, AIC: 45.4, p_chisq: 0.281) models demonstrated robust model fit and biological relevance. Factor-specific GWAS identified 233 genome-wide significant loci ($p < 5x10^{-8}$) with 24 distinct loci showing shared susceptibility across cancers. More importantly, we identified eight novel variants that were not previously reported or related with any cancer risk, potentially regulating cancer-related genes such as *PRC1*, *CEBPB*, *SMC2*, *KLF5* and *ATXN2*. Further analyses are needed to elucidate their roles in tumorigenesis. Our findings reveal a shared genetic architecture across major solid tumors and uncover novel pleiotropic variants with potential regulatory roles in oncogenesis. This study provides novel insights into the genetic basis of cancer susceptibility and supports the development of multi-cancer PRS to improve prediction in cancer prevention and prognosis.

#3601 Multi-population GWAS meta-analysis identifies novel bladder cancer susceptibility loci and highlights the genetic regulation of smoking-related risk.

Ludmila Prokunina-Olsson[1], Oscar Florez-Vargas[1], Michael G. Levin[2], Diptavo Dutta[1], Charles Breeze[1], Lauren M. Hurwitz[1], Wusheng Yan[1], Philippe Lamy[3], Brenen Papenberg[1], Kevin Wang[1], Chia-Han Lee[1], Roger L. Milne[4], Jian Gu[5], Caroline Y. Chanock[1], Nuria Malats[11], Debra T. Silverman[1], Lars Dyrskjot[3], Nathaniel Rothman[1], Scott M. Damrauer[2], Stella Koutros[1], Jeffrey S. Damrauer[13]

[1]National Cancer Institute, Rockville, MD,[2]University of Pennsylvania, Philadelphia, PA,[3]Aarhus University, Aarhus, Denmark,[4]Cancer Council Victoria, Melbourne, Australia,[5]University of Texas MD Anderson Cancer Center, Houston, TX,[6]American Cancer Society, Atlanta, GA,[7]Memorial Sloan Kettering Cancer Center, New York, NY,[8]International Agency for Research on Cancer, Lyon, France,[9]Riken, Yokohama, Japan,[10]University of Tokyo, Tokyo, Japan,[11]Spanish National Cancer Research Center (CNIO), Madrid, Spain,[12]Professor, Dept. of Epidemiology, Radboud University Nijmegen Medical Center, Nijmegen, Netherlands,[13]UNC Lineberger Comprehensive Cancer Center, Chapel Hill, NC

Urinary bladder cancer (BC) is the ninth most common malignancy worldwide. We conducted a meta-analysis of genome-wide association studies for BC risk in 32,470 cases and 1,753,462 controls, identifying 70 independent genome-wide significant loci, including 43 novel signals. A 70-marker polygenic risk score was strongly associated with BC risk (hazard ratio=1.61 (1.50-1.73) per standard deviation), substantially improving the area under the curve (AUC) when added to a model with age, sex, and smoking status (AUC=0.75 vs. 0.70, p=4.49E-20). BC risk variants (n=4,196 at p<5.0E-8) were enriched in regions of open chromatin in bladder tissue. Integrated germline, transcriptomic, and proteomic analyses nominated additional susceptibility genes and pathways, particularly related to xenobiotic metabolism. We detected a novel BC signal within a known smoking-related locus at 15q25.1 (rs7173514-C, OR=1.07, p=9.64E-10 for BC risk overall, $OR_{Never\text{-}Smoker}$=1.00 and $OR_{Ever\text{-}Smoker}$=1.14). This signal was primarily driven by an insertion/deletion variant within *CHRNA3*-3'UTR rs71581744/rs10637216 (A/ACCCC, r^2=0.78 with rs7173514 in Europeans) linked with smoking cessation, with an additional contribution from a known lead variant for smoking intensity (rs16969968-G/A, D398N within *CHRNA5*). Further analyses revealed significant heterogeneity for rs71581744 by BC subtype (muscle-invasiveness), particularly among current smokers ($OR_{Muscle\ Invasive}$=1.42 vs. $OR_{Non\text{-}muscle\ Invasive}$=1.11, $p_{heterogeneity}$=1.84E-02), consistent with epidemiologic observations that current smokers have a higher risk of muscle-invasive bladder cancer. Our *in-vitro* reporter assays for rs71581744-A/ACCCC demonstrated allele-specific effects on mRNA stability in several cell lines. Since neuronally expressed *CHRNA5* and *CHRNA3* encode subunits of the nicotinic acetylcholine receptors (nAChR) that regulate smoking behavior, we investigated their expression in normal brain tissues in GTEx. The BC risk signal colocalized with a top CHRNA3 eQTL in one brain area, with variable allelic expression imbalance for *CHRNA3* in several brain areas from the same donors. Our results implicate rs71581744-A/ACCCC as a functional variant contributing to BC risk via regulation of *CHRNA3* mRNA stability in specific brain areas, affecting nicotine reward/aversion circuits and possibly bladder function. Overall, our study provides new insights into BC genetics and etiology with relevant clinical implications.

#3602 Genome-wide association study of mantle cell lymphoma identifies novel loci suggesting a critical role for B-cell chromatin readers and DNA repair mechanisms.

Charles E. Breeze[1], Alyssa Clay-Gilmour[2], Hanla A. Park[3], Olafur B. Davi?sson[4], Angelica Macauda[5], Brenda M. Birmann[6], Elizabeth E. Brown[7], Murat Guler[8], Michelle A. T. Cerhan[5], Jonathan N. Hofmann[1], Qing Lan[1], Nathaniel Rothman[1], Ingrid Glimelius[17], Henrik Hjalgrim[12], James Mckay[3], Sonja I. Berndt[1]

[1]National Cancer Inst. Div. of Cancer Epidemiology & Genetics, Bethesda, MD,[2]University of South Carolina Arnold School of Public Health, Columbia, SC,[3]International Agency for Research on Cancer, Lyon, France,[4]Danish Cancer Society, Copenhagen, Denmark,[5]Mayo Clinic, Rochester, MN,[6]Dept of Medicine, Brigham and Women's Hospital, Boston, MA,[7]University of Alabama at Birmingham, O'Neal Comprehensive Cancer Center, Birmingham, AL,[8]German Cancer Research Center DKFZ, Heidelberg, Germany,[9]UT MD Anderson Cancer Center, Houston, TX,[10]Universitatsklinikum Freiburg, Freiburg, Germany,[11]University of Alabama at Birmingham, Birmingham, AL,[12]Danish Cancer Institute, Copenhagen, Denmark,[13]Karolinska Institutet, Stockholm, Sweden,[14]University of Oxford Nuffield Department of Population Health, Oxford, United Kingdom,[15]MD Anderson Cancer Center, Houston, TX,[16]City of Hope National Medical Center, Duarte, CA,[17]Uppsala University, Uppsala, Sweden

Background: Mantle cell lymphoma (MCL) is an aggressive and rare B-cell non-Hodgkin lymphoma with poor prognosis, even with treatment. Despite its clinical importance, the etiology of MCL remains largely unknown. Some studies have reported a positive association with family history, suggesting that genetic factors could contribute to risk. **Methods:** To identify germline genetic variants associated with risk, we conducted the first genome-wide association studies (GWAS) and GWAS meta-analysis for MCL, comprising 1,163 cases and 61,271 controls. The most significant loci were taken forward for replication in three independent studies, including 576 cases and 771,773 controls. To identify potential target genes and pathways of discovered loci, we conducted F-MAGMA, colocalization, and transcriptome-wide association study (TWAS) analyses. To gain insight into underlying regulatory mechanisms, we performed integrative epigenomic analyses using DNase I hotspots and histone mark ChIP-seq data across diverse cell types applying the FORGE2 framework. **Results:** In the joint analyses, we identified eight genome-wide significant loci ($P<5x10^{-8}$) associated with MCL risk, several of which were located near genes with known DNA repair (ATM), telomere (TERT), or RNA-binding functions (RBM20). Further analyses using F-MAGMA, which uses DNase-seq data to prioritize genes from GWAS, identified genes that were significantly associated with risk, including SP140, a chromatin reader and immune regulator of pathogen response. This gene also displayed strong colocalization with our lead variant in whole blood (COLOC posterior probability PP4=0.97). TWAS demonstrated significant associations with SP140 and ACTA2, which has been linked to cell proliferation ($P<3x10^{-6}$). Enrichment for DNase I hotspots was observed in B and T lymphocytes (q-value<0.05), providing evidence for a role in immune cell-specific regulatory regions. Enrichment for enhancer-associated histone mark H3K4me1 was observed in B cells (q-value<0.01), highlighting a role for immune cell-specific enhancers. Transcription factor (TF) motif enrichment analysis pointed to TFs critical for B-cell development and differentiation, notably TCF3 and EP300 (q<0.01 for both), suggesting an association between B-cell lineage regulation and MCL risk. Finally, genome-wide SNP-based heritability was estimated to be 17%, underscoring the importance of common variants in MCL risk. **Conclusion:** Our study provides novel insight into the inherited susceptibility of MCL by identifying eight significant loci and estimating substantial common variant heritability. These findings highlight a role for several distinct biological pathways -specifically DNA repair, telomerase function, and B-cell differentiation- in the etiology of MCL, offering new targets for mechanistic investigation.

#3603 Implications of multiple myeloma polygenic risk scores (PRS) for MGUS.

Alyssa Ione Clay-Gilmour[1], Angelica Macauda[2], Cristine Allmer[2], Danelle Moonen[2], Aaron D. Norman[2], Nicholas Boddicker[2], Janet E. Olson[2], Elizabeth E. Brown[3], Vincent S. Rajkumar[2], Esteban Braggio[4], David Murray[2], Susan Slager[2], Shaji Kunnathu Kumar[5], Celine Vachon[6]

[1]University of South Carolina, Columbia, SC,[2]Mayo Clinic, Rochester, MN,[3]University Alabama Birmingham, Birmingham, AL,[4]Mayo Clinic Arizona, Scottsdale, AZ,[5]Professor of Medicine, Dept. of Hematology, Mayo Clinic, Rochester, MN,[6]Mayo Clinic College of Medicine and Science, Rochester, MN

Background. Genome-wide association studies (GWAS) have identified 35 genetic susceptibility single-nucleotide polymorphisms (SNPs) for multiple myeloma (MM) in individuals of European ancestry (EA) and shown strong genetic correlation between MM and its precursor, monoclonal gammopathy of undetermined significance (MGUS). We evaluate the contribution of the 35 MM variants to MGUS susceptibility overall and by prognostic subgroups.

Methods. The study included 20,756 participants (14,486 controls, 1,883 with MGUS, and 2,163 with MM) from the Mayo Clinic. Logistic regression assuming an additive model estimated odds ratios (ORs) and 95% confidence intervals (CIs) for individual SNPs and for the MM-PRS, adjusted for age, sex, study, and principal components. The PRS was a weighted sum of 35 SNPs with effect estimates from the largest MM GWAS and was modeled continuously (per SD) and by quintiles (Q1-Q5). SNPnexus annotated variants that replicated in MGUS ($P < 0.05$ and $OR > 1.01$) versus those that did not ($P > 0.05$ and $OR < 1.01$).

Results. The 35-SNP MM-PRS was strongly associated with MM risk and modestly with MGUS. Compared with the middle quintile (Q3), MM odds rose from OR=0.55 (CI=0.46-0.65, $P=2.2e^{-11}$) in Q1 to OR = 1.82 (CI=1.59-2.09, $P=6.2e^{-18}$) in Q5. MGUS showed a similar, attenuated pattern (Q1 OR = 0.74, CI=0.64-0.84, $P=6.4e^{-6}$ / Q5 OR=1.36, CI=1.21-1.53, $P=3.4e^{-7}$). Each SD increase in PRS corresponded to OR=1.52 (CI=1.45-1.59, $P=1.3e^{-66}$) for MM and OR = 1.22 (CI=1.18-1.27, $P=1.0e^{-23}$) for MGUS. Higher PRS values were linked to larger M-protein ((0.1-1.5 g/dL: OR=1.40, CI=1.18-1.65, $P=5.8e^{-12}$) vs <0.1 g/dL: OR = 1.19, CI=1.13-1.24, $P=5.8e^{-12}$)) and abnormal free light chain (FLC) ratio ((OR = 1.33, CI=1.21-1.46, $P=1.0e^{-9}$) vs normal ratio (OR=1.19, CI=1.14-1.25, $P=1.4e^{-13}$)). Ten risk loci replicated in MGUS, mapping to genes involved in plasma-cell function, immune regulation, and DNA repair and enriched for Rho GTPase signaling, NF-κB-mediated apoptosis, and RNA polymerase II transcription, implicating early plasma-cell activation and transcriptional control. The 12 non-replicating loci, including *PHC3*, *ATG5*, and *NFIC*, mapped to genes involved in chromatin remodeling, autophagy, and SUMOylation, suggesting roles in stress response and genomic maintenance.

Conclusions. The MM-PRS captures shared heritability between MM and MGUS and correlates with MGUS subtype and severity. Replicating variants highlight immune and cell-cycle pathways relevant to MGUS onset, whereas non-replicating loci cluster in DNA-repair and stress-response processes, underscoring their potential role in progression.

#3604 Prostate cancer risk variants regulate oncogenes by activating enhancers and forming multi-connected enhancer-promoter hubs at different stages of prostate cancer.

Zexun Wu[1], Andrew Vu[2], Matthew Salcedo[1], Suhn K. Rhie[2]

[1]Keck School of Medicine, USC, Los Angeles, CA,[2]USC, Los Angeles, CA

Prostate cancer (PCa) is a complex disease and the second leading cause of cancer death in the US men. Clinical outcomes vary among PCa stages. PCa becomes increasingly aggressive, progressing from localized disease to metastatic PCa, then to metastatic castration-resistant PCa and ultimately to neuroendocrine PCa. Multi-ethnic genome-wide association studies have identified over a thousand of genetic variants associated with PCa risk, including variants linked to aggressive forms of the disease. Considering population-specific linkage disequilibrium patterns, we identified over 40,000 highly linked variants to PCa risk variants. However, most of these variants reside in non-coding regions, making it challenging to elucidate their roles in disease development and progression. Non-coding regions often include functional elements called regulatory elements such as promoters, enhancers, and insulators. Among regulatory elements, enhancer activities, which can be assessed by the histone modification mark H3K27ac, are tightly associated with cell fate. We therefore hypothesized that PCa risk variants affect enhancer activities at distinct disease stages, contributing to disease development and progression, and ultimately influencing clinical outcomes. In this study, we integrated over 200 H3K27ac ChIP-seq and over 550 RNA-seq datasets from prostate tissues and cell lines across PCa progression stages and found stage-specific enhancers and transcription factors (TFs) that are distinctly activated at different stages. Moreover, we found over 5,500 PCa risk variants located in enhancers containing motifs of the identified TFs. To evaluate the PCa risk variants associated with enhancer activities, we integrated patient tissue-derived H3K27ac ChIP-seq data and performed chromatin quantitative trait loci and allelic imbalance analyses. We identified over 700 variants associated with enhancer activities, including those affected by TF binding. Moreover, to identify target genes of these enhancer variants, we analyzed over 100 genome-wide chromatin interaction datasets. By integrating chromatin interaction data with epigenomic and transcriptomic data, we identified enhancer variants involved in chromatin looping to regulate transcription. Furthermore, we found over 1,700 enhancer variants located in multi-connected enhancer-promoter (E-P) hubs, including those potentially regulated by stage-specific TFs. Overall, these findings support a model in which genetic and epigenetic reprogramming converge on E-P hubs to drive transcription of oncogenes and promote disease initiation and progression in PCa.

#3605 Genetic insights into metabolic traits and prostate cancer susceptibility: A two sample Mendelian Randomization study.

HWA SUN KIM, Chung-woo Lee

VHS Medical Center, Seoul, Korea, Republic of

Background: Metabolic syndrome (MetS) and its components have been implicated in prostate cancer, but observational associations remain inconsistent and vulnerable to confounding. We conducted a two-sample Mendelian randomization (MR) study to clarify whether major MetS traits causally influence prostate cancer risk.

Methods: Genetic instruments for body mass index (BMI), waist circumference, systolic/diastolic blood pressure, fasting glucose, and lipid components such as triglycerides (TG), LDL-cholesterol, HDL-cholesterol, and total cholesterol were obtained from male-only large genome-wide association studies (UK Biobank) and MetS from multiple cohorts as exposure sets. Prostate cancer data set was derived from the FinnGen GWAS. Genome-wide significant variants ($p<5\times10^{-8}$) were clumped at $r^2<0.001$. Causal estimates were calculated using inverse-variance weighted (IVW), weighted median, and MR-Egger methods. Heterogeneity (Cochran's Q), horizontal pleiotropy (MR-Egger intercept, MR-PRESSO), and sensitivity analyses were performed.

Results: Higher genetically predicted fasting glucose was associated with reduced prostate cancer risk (OR 0.82, P=0.02). HDL-cholesterol (OR 1.52, P=0.052) and LDL-cholesterol (OR 0.87, P=0.07) showed suggestive effects. BMI, waist circumference, blood pressure, total cholesterol, and triglycerides showed no evidence of causal association.

Conclusions: Our findings implicate glucose and lipid metabolism pathways in prostate cancer susceptibility. Given the exploratory nature and the predominantly European ancestry of the datasets, large scale studies including diverse multiple-ethnic populations are required to confirm these associations and clarify the role of metabolic traits across different ancestries in prostate cancer epidemiology.

#3606 Identification of survival-associated germline variants in hepatocellular carcinoma.

Younghun Han[1], Jinyoung Byun[1], Lewis R. Roberts[2], Katherine A. McGlynn[3], Manal M. Hassan[4], Christopher I. Amos[1]

[1]University of New Mexico Comprehensive Cancer Center, Albuquerque, NM,[2]Mayo Clinic College of Medicine and Science, Rochester, MN,[3]National Cancer Institute - Cancer Genomics Research Laboratory (CGR), Rockville, MD,[4]Assistant Professor, Dept. of Gastrointestinal Medical Oncology, UT MD Anderson Cancer Center, Houston, TX

Background: Hepatocellular carcinoma (HCC) remains a leading cause of cancer-related mortality worldwide. Prognostic models for HCC primarily rely on tumor burden and liver function, with limited consideration of inherited genetic contributions to survival variability. Identifying germline variants associated with survival could refine prognosis and reveal biological mechanisms underlying disease progression.

Methods: We conducted a genome-wide association study (GWAS) of overall survival among 864 patients with HCC from the M.D. Anderson Cancer Center cohort. Genotyping, quality control, and imputation procedures followed previously described protocols (PMID: 38381705). Associations between genetic variants and overall survival were assessed using Cox proportional hazards models adjusted for age, sex, and the first five principal components. Genome-wide significance was defined as $P < 5\times10^{-8}$. Functional annotation and pathway enrichment analyses (MAGMA) were employed to investigate the biological relevance of the identified loci.

Results: After quality control, 8,525,017 single-nucleotide polymorphisms (SNPs) were analyzed. We identified seven new loci associated with HCC survival at the genome-wide significance level. Five out of seven loci are associated with anthropometric traits and hematological measurement traits, reflecting metabolism, hematopoiesis, immune function, and inflammation. A variant in the 3′ untranslated region (UTR3) of *STX7* showed a genome-wide significant association with overall survival (HR = 3.23; $P = 2.56 \times10^{-8}$). Carriers of the risk allele had significantly shorter survival times compared with noncarriers. Pathway analysis revealed enrichment in biologically relevant processes, including liver growth and regeneration (growth hormone and Interleukin-6 (IL-6) signaling pathway), implicating hepatocyte proliferation and IL-6/STAT3-mediated inflammatory signaling. Immune-related pathways, such as regulation of T cell activation and myeloid leukocyte migration, highlight the role of germline variation in immune surveillance. Moreover, pathways governing vascular remodeling and metabolic stress response (e.g., JAK activation, mitochondrial dynamics) suggest that inherited determinants of microenvironmental structure and hepatocyte resilience influence patient outcomes.

Conclusion: This germline GWAS of HCC survival identifies seven new genome-wide significant loci and implicates pathways involved in liver regeneration, inflammation, and tissue remodeling. These findings support a role for inherited genetic variation in shaping HCC prognosis and underscore the potential of integrating germline genetics into prognostic modelling and therapeutic target discovery.

#3607 Tissue-based proteome-wide association study identifies novel risk proteins and candidate drug targets for colorectal cancer.

Qing Li[1], Timothy Su[1], Chao Li[2], Quanhu Sheng[3], Shuai Xu[2], Wanqing Wen[4], Qi Dai[4], Martha J. Shrubsole[4], Jirong Long[4], Qiuyin Cai[1], Bing Zhang[5], Xioa-Ou Shu[1], Bhuminder Singh[1], Ken S. Lau[1], You Chen[6], Yuankai Huo[7], Zhijun Yin[1], Stephen B. Gruber[8], Riki (Ulrike) Peters[9], Victor R. Moreno[10], Wei Zheng[1], Xingyi Guo[1]

[1]Vanderbilt University Medical Center, Nashville, TN,[2]Vanderbilt University, Nashville, TN,[3]Department of Biostatistics, Vanderbilt University Medical Center,, Nashville, TN,[4]Department of Medicine, Vanderbilt University Medical Center, Nashville, TN,[5]Baylor College of Medicine, Houston, TX,[6]Department of Biomedical Informatics, Vanderbilt University Medical Center, Nashville, TN,[7]Department of Computer Science, Vanderbilt University, Nashville, TN,[8]City of Hope National Medical Center, Los Angeles, CA,[9]Fred Hutchinson Cancer Center, Seattle, WA,[10]Cancer Prevention Program, Catalan Institute of Oncology, Hopitalet de Llobregat, Spain

Background Colorectal cancer (CRC) is the second leading cause of cancer-related death worldwide. To date, ~250 genetic risk loci have been identified through genome-wide association studies (GWAS), and transcriptome-wide association studies (TWAS) has implicated ~500 putative CRC risk genes. However, proteins, the primary effectors of cellular function and drug response, remain underexplored. Thus, proteome-wide association studies (PWAS) linking genetic variation to protein abundance in colorectal tissue are essential for identifying causal proteins, clarifying disease mechanisms, and discovering therapeutic targets.

Methods We performed unbiased data-independent acquisition mass spectrometry on 323 normal colon tissues from the Tennessee Colorectal Polyp Study and BarcUVa-seq studies, quantifying >9,000 proteins, and generated matched blood genotypes. Protein preprocessing included low-abundance filtering, $\log_2$ transformation, and PEER adjustment. We conducted PWAS using our previously developed approach which integrates susceptible TF occupied cis-regulatory elements (PMID: 36402776) to build genetically predicted protein expression models and applied to two CRC GWAS datasets separately: (1) European ancestry (80,774 cases, 105,298 controls) and (2) a trans-ancestry meta-analysis (104,346 cases, 153,998 controls). Risk proteins were identified by combining results from both datasets. We performed pQTL analyses of known CRC lead variants (PMID: 38670944), followed by Bayesian colocalization, and evaluated therapeutic relevance by mapping CRC-associated proteins to drug-target interactions using DrugBank, ChEMBL, TTD, and Open Targets.

Results At a Bonferroni-corrected threshold of $P < 0.05$, our PWAS identified 41 proteins significantly associated with CRC risk, including 12 not previously linked to CRC. pQTL analyses identified 14 risk proteins, five with strong colocalization (PP.H4 > 0.8). We also found support for 76 previously reported CRC risk genes based on PWAS or pQTL signals at nominal $P < 0.05$. Among all risk proteins, 13 were potentially druggable, linked to 235 candidate therapeutic compounds. We provided the genetic evidence supporting multiple potential therapeutic drug targets for CRC prevention, with drug-protein interactions mapped to key CRC-relevant pathways such as PGE_2-EP4 signaling (e.g., PTGER4 protein inhibitor E7046, Phase I/II), redox homeostasis (TXN protein inhibitor PX-12, Phase II; ALDH2 approved inhibitor Disulfiram), and BET signaling (BD2-selective inhibitor ABBV-744, Phase I).

Conclusion This study provides the first large-scale tissue-based PWAS in CRC, identifying novel risk proteins and multiple potential druggable targets. These findings advance our understanding of CRC etiology and highlight new opportunities for therapeutic development and CRC prevention.

#3608 Multi-ancestry methylation-wide association analyses identifies putative risk methylation markers for breast cancer.

Shuai Xu[1], Jiajun Shi[2], Y-Thanh Lu[1], Guochong Damon Jia[2], Fei Ye[3], Qiuyin Cai[2], Jirong Long[4]

[1]Vanderbilt University, Nashville, TN,[2]Vanderbilt University Medical Center, Nashville, TN,[3]Vanderbilt University School of Medicine, Nashville, TN,[4]Asst. Professor, Dept. of Epidemiology, Vanderbilt University, Nashville, TN

Introduction: Aberrant DNA methylation is a hallmark of cancer. Identifying methylation sites (CpGs) associated with breast cancer risk may help to elucidate disease mechanisms and inform precision prevention. We conducted a multi-ancestry breast tissue-based methylome-wide association study (MeWAS) to discover breast cancer susceptibility CpGs.
Methods: We profiled DNA methylation in normal breast tissue from 152 African ancestry and 267 European ancestry women using the Illumina MethylationEPIC array, with matched genotype data. We trained ancestry-specific genetic prediction models for each methylation marker, and then tested associations with breast cancer risk by applying S-PrediXcan to ancestry-matched breast cancer GWAS summary statistics (European:133,384 cases and 113,789 controls; African :18,044 cases and 22,187 controls)). We also performed stratified analyses by estrogen receptor status (ER+, ER–) and triple-negative breast cancer (TNBC). Then fixed effect inverse variance weighted meta-analysis was conducted using METAL. Methylation set enrichment analysis was evaluated using R missMethyl.
Results: We successfully built 160,204 African ancestry and 166,069 European ancestry methylation imputation models ($R > 0.1$ and $P < 0.05$). Meta-analysis across ancestries identified 625 CpGs whose genetically predicted methylation levels were significantly associated with overall breast cancer risk (Bonferroni-adjusted $P < 0.05$), 458 (73.3%) of which have not been reported in prior breast tissue MeWAS. Notably, the significant association between genetically proxied methylation levels of cg23766285 and overall breast cancer risk were only observed among African Ancestry. Among 308 CpGs with valid prediction models in both ancestries, 265 (86.0%) showed concordant directions of association. We additionally identified 32, 11, and 11 CpGs that were exclusively associated with risk of ER+ and ER- breast cancer and TNBC at Bonferroni corrected $P <0.05$, respectively. CpGs associated with overall risk (odds ratio [OR], 1.19; 95% confidence interval [CI], 1.02-1.39), ER- breast cancer (OR, 1.97; 95% CI, 1.29-3.05), and TNBC (OR, 2.12; 95% CI, 1.27-3.61) were enriched in promoter regions, whereas ER+-associated CpGs were not. The identified CpGs are involved in various biological processes, including hormone, p53, and KRAS signaling pathways.
Discussion: This is the first multi-ancestry, large-scale, tissue-based MeWAS in breast cancer. Our findings offer novel insight into breast carcinogenesis and breast cancer disparities.

#3609 Identification of miRNA-related SNPs associated with kidney cancer in the Korean population.

Jung-Hee Lee[1], Minsun Jung[1], Sun Ha Jee[2]

[1]Yonsei University College of Medicine, Seoul, Korea, Republic of,[2]Department of Epidemiology and Health Promotion, Institute for Health Promotion, Graduate School of Public Health, Yonsei University, Seoul, Korea, Republic of

Background: MicroRNAs (miRNAs) are small non-coding RNAs that regulate gene expression post-transcriptionally and play critical roles in tumor development. Genetic variants located within miRNA precursor, mature, or seed regions may influence miRNA maturation or target binding, thereby affecting cancer susceptibility. This study aimed to identify miRNA-related single nucleotide polymorphisms (SNPs) associated with kidney cancer in a Korean population.

Methods: We performed genome-wide association analyses of kidney cancer in the Korean population using datasets from the Korean Cancer Prevention Study-II (KCPS-II) and the Korean Genome and Epidemiology Study (KOGES). A subsequent meta-analysis identified three miRNA-related single nucleotide polymorphisms (SNPs) significantly associated with kidney cancer. miRNA-related variants were annotated based on their location within pre-miRNA, mature miRNA sequences, or seed regions using the miRNASNP-v4 database. Functional relevance was interpreted according to predicted effects on miRNA biogenesis and target-binding specificity.

Results: miRNA-related SNPs showed genome-wide significant associations with kidney cancer. The pre-miRNA variant **rs1414273**, located in the hairpin of hsa-mir-548ac, demonstrated a strong association (effect = -1.1112, SE = 0.0498, P = 3.46×10^{-110}). This variant may alter Drosha processing efficiency, thereby affecting the production of miR-548ac. Because miR-548ac regulates genes involved in inflammatory signaling and protein quality-control pathways, disruption of its maturation may influence cellular stress responses relevant to renal tumorigenesis. The mature miRNA variant **rs73239138**, positioned within hsa-miR-1269a, showed a similarly robust association (effect = 1.076, SE = 0.0491, P = 1.71×10^{-106}). miR-1269a is an oncogenic miRNA overexpressed in at least nine cancers and regulates key targets (CXCL9, SOX6, FOXO1, ATRX, RASSF9, SMAD7, HOXD10, VASH1) through pathways such as TGF-β, PI3K/AKT, p53, and caspase-9 signaling; thus, a sequence alteration within its mature strand may affect RISC loading, target recognition, and amplify oncogenic post-transcriptional regulation in kidney cancer. The seed-region variant **rs2925980** in hsa-miR-7854-3p also reached genome-wide significance (effect = -1.0276, SE = 0.0494, P = 5.1×10^{-96}). Seed mutations can reprogram target specificity by creating or disrupting binding sites, suggesting that altered miR-7854-3p targeting contributes to renal cancer susceptibility.

Conclusions: These findings indicate that pre-miRNA, mature miRNA, and seed-region variants contribute to kidney cancer susceptibility in the Korean population. The identified SNPs provide a basis for functional validation and the development of miRNA-based biomarkers in kidney cancer.

#3610 Estrogen receptor-mediated pharmacogenomic eQTLs as predictors of endocrine therapy response in breast cancer.

Martin Meng, Huanyao Gao, August John, Arnab Ghosh, Shreya Indulkar, Liewei Wang

Mayo Clinic College of Medicine, Rochester, MN

Background: Approximately 70% of breast cancers are estrogen receptor-positive (ER+), and endocrine therapies, including selective estrogen receptor modulators (SERMs) and aromatase inhibitors (AIs), are standard-of-care. However, interpatient variability in treatment response and relapse remains substantial, suggesting underlying germline pharmacogenomic factors that modify ER signaling. Here, we mapped ER pharmacogenomic eQTLs to identify germline variants that modulate transcriptional responses to estradiol (E2) and tamoxifen (Tam).
Methods: We treated 30 genotyped lymphoblastoid cell lines (LCLs) with vehicle, E2, Tam, or E2+Tam and performed RNA-seq to quantify ligand-induced expression fold changes. Using MatrixEQTL, we identified SNP-gene PGx-eQTLs (cis, ±200 kb), requiring evidence of ER transcriptional specificity via (i) reversal by dual treatment, and (ii) overlap with ER ChIP-seq binding annotations. Clinical relevance was assessed by linkage to breast cancer GWAS datasets, including NSABP, MA.27, and M3. Chromatin regulatory states were annotated (ChromHMM), and transcription factor motif enrichment was performed from SNP-centered ±200 bp regions.
Results: Distinct PGx-eQTL architectures were identified for E2 and Tam, with partial overlap in ligand-responsive loci. ER PGx-eQTL variants were predominantly enriched in enhancer chromatin and co-localized with canonical ER-binding motifs. Integrative analysis with GWAS of breast cancer outcomes highlighted multiple drug-response-associated loci, including rs311392-MRPL15 and rs7953325-SYCP3. High MRPL15 expression was linked to shorter relapse-free survival, whereas high SYCP3 expression correlated with improved outcomes. Additional loci derived from a GWAS catalog for cancer and hormone phenotypes included rs2850247-SIK2 and rs11673604-LSM4, where higher SIK2 expression was associated with improved relapse-free survival and higher LSM4 expression with poorer outcomes.
Conclusions: We identified ligand-dependent ER PGx-eQTLs that mechanistically connect germline regulatory variants to transcriptional response heterogeneity and clinical endocrine therapy outcomes. These SNP-gene relationships represent potential biomarkers for precision endocrine therapy selection and may reveal endocrine-dependent therapeutic vulnerabilities.

#3611 Cell-type aware transcriptome-wide association study of mammographic density phenotypes.

Joseph H. Rothstein[1], Adriana Sistig[2], Sinan Zhu[3], Tejomay Gadgil[4], Li Shen[2], Stacey E. Alexeeff[4], Ninah Achacoso[4], Lori C. Sakoda[4], Vignesh A. Arasu[4], Laurie R. Margolies[2], Robert J. Klein[2], Laurel A. Habel[4], Xiaoyu Song[3], Pei Wang[2], Weiva Sieh[1]

[1]UT MD Anderson Cancer Center, Houston, TX,[2]Icahn School of Medicine at Mount Sinai, New York, NY,[3]Duke-NUS Medical School, Singapore, Singapore,[4]Kaiser Permanente, Oakland, CA

Background: Mammographic density (MD) phenotypes are highly heritable and strongly associated with breast cancer risk. Genetic variants identified by genome-wide association studies (GWAS) explain only a small fraction of the heritability, and the responsible genes remain largely unknown. Transcriptome-wide association studies (TWAS) can improve power and identify genes associated with MD through their genetically regulated gene expression (GReX) levels. However, cell type heterogeneity in bulk tissue samples can obscure disease associations. Here, we conduct TWAS of MD phenotypes using standard approaches and a new cell-type-aware framework.

Methods: The study population included 24,158 women of European ancestry who underwent screening with Hologic (n=20,282) or GE (n=3,876) digital mammography and participated in Kaiser's Research Program on Genes Environment and Health. Dense area (DA), nondense area (NDA), and percent density (PD) were measured centrally using Cumulus6. Tissue-level gene expression was estimated using standard elastic-net models. Cell-type-specific expression in mammary epithelial, fibroblast, and adipocyte cells was estimated using MiXcan. Linear regression was used to assess associations of GReX levels with MD phenotypes, adjusted for age, BMI, and other covariates. Significance was determined by controlling the false-discovery rate at 0.05.

Results: A total of 20 unique genes at 16 loci were significantly associated with MD phenotypes, including 10 genes at 7 loci for DA and 8 different genes at 7 loci for NDA. Of the 7 genes for PD, 2 also were associated with DA and 3 with NDA. Standard TWAS methods identified 8 genes whose tissue-level expression was significantly associated with MD phenotypes. In contrast, cell-type-aware analyses using MiXcan identified 10, 12, and 7 genes, respectively, using epithelial, fibroblast, or adipocyte models. Among the 12 genes identified by MiXcan but not standard methods, 2 showed opposite directions of association between different cell types.

Conclusion: This TWAS identified novel genes for MD phenotypes, and prioritized genes at known GWAS loci that are likely to be causally associated through their expression levels in mammary epithelial, fibroblast, or adipocyte cells. Disentangling the distinct effects of gene expression in different mammary cell types through cell-type-aware analysis can yield new gene discoveries and insights into the biological basis of dense vs. nondense breast tissue.

#3616 BXQ-350 reduces incidence, severity, and time to on-set of chemotherapy induced peripheral neuropathy via modulation of sphingolipid metabolism.

Gilles H. Tapolsky, Tariq Arshad, Michael Gazda, Nikhil Wilkins, Jackson Bond, James Beach

Bexion Pharmaceuticals, Covington, KY

Background: Chemotherapy Induced Peripheral Neuropathy (CIPN) is a debilitating side effect associated with many chemotherapeutic agents including cytotoxic and targeted agents. Damages to nerve cells are believed to be directly resulting from the antineoplastic agents' cytotoxicity, however, inflammation and the immune system are also involved and contribute to chronic CIPN. Increasing evidence also suggests that specific species of sphingolipids, including gangliosides (GM), lactosyl ceramides (LacCer), glucosyl ceramides (GluCer) and sphingosine-1-phosphate (S1P), may be involved as altered neuronal sphingolipid metabolism has been linked to neuropathic pain and development of CIPN. BXQ-350 is a nanovesicle of Saposin C, an allosteric activator of multiple enzymes controlling sphingolipid metabolism, that lowers systemic GM, LacCer, GlucCer and S1P. Method: BXQ-350 has been investigated preclinically in CIPN models. Clinically, BXQ-350 was investigated in an adult Phase 1 dose-escalation safety study in heavily pretreated all-comer cancer patients with advanced solid malignancies (NCT02859857), in a Phase 1 Proof of Concept (PoC) study in patients with established chronic CIPN from prior cancer treatments (NCT05291286) and is being investigated in a Phase 1b/2a study in combination with FOLFOX7+ Bevacizumab in newly diagnosed first line mCRC patients (NCT05322590). Results: Preclinical results revealed that BXQ-350 is neuroprotective against chemotherapeutic agents known to induce CIPN. Clinically, in the Phase 1 single agent study, several patients spontaneously reported a significant improvement of their neuropathic symptoms shortly after receiving BXQ-350. In the PoC phase 1 study, BXQ-350 treatment arm showed clinically meaningful and statistically significant improvement over placebo. In the combination study in 1L mCRC patients, BXQ-350 seems to delay the onset, severity and frequency of CIPN while enabling the administration of a higher cumulative dose of oxaliplatin. Longitudinal analyses of biomarkers (plasma cytokines, Neurofilament Light (NfL) chains, sphingolipids), and results from CIPN 20 questionnaires, and physician assessments, revealed there were positive correlations between physician assessments, CIPN 20 questionnaire results, NfL and sphingolipid profile changes. A strong correlation was noted between LacCer, a sphingolipid known to induce neurodegeneration and inflammation, in patients developing CIPN and with established chronic CIPN. Conclusions: Preclinical and clinical results suggest that BXQ-350 protects cancer patients from antineoplastic agents known to induce CIPN enabling the administration of higher cumulative doses of oxaliplatin in mCRC patients. A strong correlation was noted between CIPN and LacCer plasma levels and other CIPN biomarkers.

#3617 Immunogenomic alterations driving premalignant lesions to invasive lesions of the head and neck.

Foram Ujjvalkumar Vaidya[1], Alvaro Gutierrez[2], Abberly Lott Limbach[3], Bhavna Kumar[4], Martin P. Alphonse[5], James W. Rocco[4], Mariana Brait[1], Amanda Ewart Toland[6], David Sidransky[1]

[1]The Sidney Kimmel Comprehensive Cancer Center, Johns Hopkins University School of Medicine, Baltimore, MD,[2]Centro de Excelencia en Medicina Traslacional, Universidad de La Frontera, Temuco, Chile,[3]Department of Pathology, College of Medicine, The Ohio State University Wexner Medical Center, Columbus, OH,[4]Department of Otolaryngology-Head and Neck Surgery, OSU Comprehensive Cancer Center, The Ohio State University, Columbus, OH,[5]Department of Dermatology, Johns Hopkins University School of Medicine, Baltimore, MD,[6]Department of Cancer Biology and Genetics, OSU Comprehensive Cancer Center, The Ohio State University, Columbus, OH

Head and neck squamous cell carcinoma (HNSCC) is the seventh most prevalent type of cancer globally with 940,000 new cases and 480,000 fatalities yearly. Oral squamous cell carcinoma (OSCC) is characterized by molecular alterations that drive progression of some preneoplastic lesions to invasive cancer. Not all dysplastic premalignant lesions evolve into carcinoma *in situ* or full-blown carcinoma. Moreover, this transition may occur as these lesions evolve over years. Identifying precancerous lesions likely to progress to invasive cancer remains challenging. Comprehensive immunogenomic profiling may reveal whether immune tolerance is a hallmark of early dysplasia and/or an acquired prerequisite for malignant transformation. We thus conducted a longitudinal study with matched dysplastic and invasive lesions to uncover early molecular drivers, reveal clonal relationships, and to identify genomic and immune mechanisms underlying SCC progression. Samples were obtained from The Ohio State University (OSU) and The Johns Hopkins University (JH). RNA was extracted from a total of 111 FFPE samples from 34 patients with precursor lesions and/or HNSCC across different stages (OSU) and submitted for RNA sequencing. Differential gene expression analysis was performed in invasive versus dysplastic lesions. Immune-related transcripts were annotated by curated immune gene sets to characterize microenvironmental remodelling. To investigate the interactions between tumor and immune cells at the subcellular resolution, spatial transcriptomics of matched dysplasia and invasive SCC was performed in a subset of patients using 10X Genomics Visium HD platform followed by Seurat based downstream analysis. For tumor-immune interaction analysis, we integrated spatial data with a single-cell reference atlas containing annotated immune cell subtypes and tumor cell states. Bulk RNA-seq revealed 164 differentially expressed genes in invasive versus dysplastic lesion, with enrichment in extracellular matrix remodelling, epithelial-mesenchymal transition and cytokine signalling pathways. Moreover, 80% of immune genes (e.g. CXCL9/10, CCL5, STAT1) are upregulated in invasive SCC. Preliminary spatial transcriptomics data revealed distinct immune microenvironments between invasive and dysplastic regions, with enrichment of immune cells at the tumor-stroma interface. The current comparative analysis revealed distinct immune infiltration patterns between dysplastic and invasive lesions, suggesting the spatial evolution of immune evasion mechanisms during cancer progression. Our cohort of samples is unique with paired patient samples that progressed from a biopsy proven premalignant state to invasive cancer over time. Our preliminary data suggest that we can identify premalignant lesions likely to progress and targetable immunogenomic drivers to intercept cancer progression at an earliest stage.

#3618 Obesity-mediated extracellular vesicle secretion as a targetable driver of endometrial cancer initiation and progression.

Lakshmi Narasimhan Chakrapani[1], Kalapana Deepa Priya Dorayappan[1], Ganesh Yadagiri[1], Shyam Sundaram[1], Gabriela S. Vendrell[1], Takahiko Sakaue[2], Jessica Velasquez[1], Xavier Ryon Washington Ramesh[3], Thangavel Muthusamy[4], Casey M. Cosgrove[1], David E. Cohn[1], David M. O'Malley[1], Selvendiran Karuppaiyah[1]

[1]Obstetrics and Gynecology, The Ohio State University, Columbus, OH,[2]Obstetrics and Gynecology, Kurume University, Kurume, Japan,[3]Pathology, Sree Balaji Medical College and Hospital (SBMCH) - Bharath Institute of Higher Education and Research (BIHER), Chennai, India,[4]Cellular and Molecular Biochemistry, Sree Balaji Medical College and Hospital (SBMCH) - Bharath Institute of Higher Education and Research (BIHER), Chennai, India

Introduction: Endometrial cancer (EC) is the most common gynecologic malignancy in the United States, with obesity accounting for approximately 57% of cases. The molecular mechanisms linking obesity to EC initiation remain poorly defined. Emerging evidence suggests that obesity enhances extracellular vesicle (EV) secretion and alters EV-associated oncogenic signaling. This study investigates obesity-mediated EV dysregulation in adipose, uterine, and EC tissues and explores its role in early EC pathogenesis, biomarker development, and therapeutic intervention.

Methods: Endometrial hyperplasia and EC were induced in immunocompetent mice using high-fat diets (HFD; 45% or 60% kcal fat) for 25 weeks. Molecular profiling was conducted using LC-MS/MS. EV concentration and size were quantified by nanoparticle tracking analysis (NTA) and visualized by transmission electron microscopy (TEM). Expression of TMEM205, STAT5, FAS, and the tumor suppressor PIAS3 was assessed by immunohistochemistry, ELISA, and RT-PCR in tissues from HFD-treated mice and obese EC patients. Additional studies evaluated EV-mediated tumor progression and treatment response in xenograft models receiving chemotherapy or immunotherapy.

Results: Obese EC patient samples exhibited significantly increased EV secretion and upregulation of oncogenic proteins in adipose and uterine tissues compared to non-obese controls. In HFD-treated mice, elevated body weight, abdominal adiposity, uterine horn enlargement, and chronic inflammation correlated with endometrial hyperplasia and EC initiation. These phenotypes were associated with increased EV secretion, upregulation of TMEM205, FAS, and STAT5, and marked downregulation of PIAS3. HFD-induced EVs carried oncogenic proteins linked to elevated serum glucose and lipid levels and altered immune profiles. EVs from obese conditions also promoted aggressive EC progression and resistance to chemotherapy and immunotherapy. Treatment with the small-molecule EV secretion inhibitor DAP-5 significantly reduced body weight, adipose accumulation, and EV output in HFD-fed mice and restored normal uterine morphology while suppressing EV-associated oncogenic signaling.

Conclusion: Obesity-mediated EV secretion is a major driver of EC initiation and progression. Targeting EV biogenesis represents a promising preventive and therapeutic strategy for obesity-associated EC. These preclinical findings provide a strong rationale for advancing EV-targeted interventions, including first-in-human trials aimed at preventing obesity-driven EC development.

#3619 Red cabbage juice reprograms the gut microbiome and enhances butyrate production to prevent colorectal cancer.

Bineet Narayan[1], Yariswamy Manjunath[2], Nagabhhishek Sirpu Natesh[2], Chayanee Chanpanich[3], Parsa Ghadermazi[4], BLAKE ARCIGA[5], Samarth Kansara[6], Ajay Tosh[7], John Ulbrich[6], Mary Kate Grossmann[6], Hwang Jiwon[6], Van Nguyen[8], Vikas Satyananda[9], Jussuf T. Kaifi[9], Joshua Chan[4], **Satyanarayana Rachagani**[6]

[1]University of Missouri, Columbia, MO,[2]University of Missouri - Columbia, Columbia, MO,[3]Biomedical engineering, Colorado State University, Fort collins, CO,[4]Biomedical Engineering, Colorado State University, Fort Collins, CO,[5]Nextgen PHI, University of Missouri, Columbia, Columbia, MO,[6]Dept. Veterinary Medicine and Surgery, University of Missouri - Columbia, Columbia, MO,[7]Nextgen PHI, University of Missouri, Columbia, MO,[8]Pathology, University of Missouri, Columbia, MO,[9]Surgery, University of Missouri, Columbia, MO

Background Colorectal cancer (CRC) remains the second leading cause of cancer-related mortality in the United States, with Western diet-induced gut dysbiosis implicated in its pathogenesis. Early interventions targeting the gut microbiome offer a promising prevention strategy. Dietary approaches that enhance short-chain fatty acid (SCFA) production like butyrate, have emerged as potential chemopreventive measures. This study investigated the preventive efficacy of red cabbage juice (RCJ) in a genetically engineered mouse model of CRC by examining its effects on microbial composition, butyrate production and its translational relevance using CRC patient-derived organoids (PDOs).

Methods Tamoxifen inducible $APC^{fl/fl}$;$Cdx\text{-}Cre^{ER}$ (AC) mice for CRC were randomized to receive either phosphate-buffered saline (PBS) or RCJ as oral gavage for 10 weeks. Then, mice were injected with tamoxifen to induce CRC and monitored for weight loss and diarrhea. At the endpoint, colon tissues and cecal contents were collected for immunohistochemistry (IHC), metagenomic profiling, and fecal SCFA quantification by GC-MS/MS. In parallel, PDOs from CRC patients were developed and treated with RCJ alone or in combination with chemotherapeutic agents oxaliplatin or 5-fluorouracil (5-FU) and monitored in real-time on an IncuCyte platform and therapy responses (proliferation and apoptosis) were evaluated by IHC.

Results RCJ significantly reduced polyps and tumor progression in AC mice and improved survival compared to PBS group. Enhanced expression of mucosal protective mucins Muc2 and Muc4 in the colonic epithelium of RCJ-treated mice. Shotgun sequencing revealed enrichment of succinate-to-butyrate metabolic pathways, elevated fecal succinate, butyrate and abundance of butyrate-producing *Clostridia* etc. Treatment of PDOs with 6% RCJ inhibited PDO growth, number, size as analyzed by IncuCyte provided us with its translational relevance for CRC prevention. Further, RCJ and oxaliplatin combination therapy significantly reduced organoid number, size, area vs. RCJ alone, RCJ + 5-FU, or media control, suggesting that RCJ may enhance the therapeutic response of chemotherapy to combat CRC organoids growth. IHC images confirmed these effects, showing decreased proliferation, and increased apoptosis upon the treatment.

Conclusions RCJ modulates the gut microbiome and enhances butyrate production, correlating with reduced tumor burden in a preclinical CRC model. It also exerts inhibitory effect on CRC PDO growth, number, size. Notably, RCJ enhances the efficacy of oxaliplatin in PDOs, suggesting its potential to overcome chemoresistance. These findings underscore the translational potential of RCJ as a dietary intervention targeting gut microbiome-SCFA interactions and an adjunctive chemopreventive agent in CRC prevention, particularly in at-risk surgical populations.

#3620 The human virome and its association with clinical benefit of immune checkpoint inhibitor therapy among patients with advanced non-small cell lung cancer.

Anna E. Coghill[1], Jin Xu[1], Aleksandr Lazaryan[1], Doratha Armenthus Byrd[1], YOUNGCHUL KIM[2], Richard Pollenz[3], Lary A. Robinson[1]

[1]Moffitt Cancer Center, Tampa, FL,[2]Moffitt Cancer Center, TAMPA, FL,[3]University of South Florida, Tampa, FL

Background. The goal of this study was to examine the human gut virome in advanced lung cancer patients being treated with immune checkpoint inhibitor (ICI) therapy to determine whether patterns of viral detection could predict clinical benefit.

Methods. This cohort of 66 patients with stage III-IV lung cancer patients was recruited between June and February 2019. Eligibility was limited to treatment-naïve individuals who were scheduled to receive ICI therapy at Moffitt Cancer Center. DNA was extracted from stool collected within 24-72 hours prior to each patient's first ICI cycle. To generate the mammalian virus and bacterial virus (phage) taxonomic profiles, reads were aligned to publicly available databases using program Bowtie2 version 2.3.5.1. Multivariable logistic regression was used to estimate the association between the relative abundance of viral taxonomic units (OTUs) and ICI clinical benefit. Random forest machine learning analysis was used to select a set of viral OTUs whose relative abundance most accurately classified patients as yes/no for clinical benefit of ICI therapy.

Results. We observed clinical benefit in 34 lung cancer patients treated with ICI therapy. We observed differences in the relative abundance of multiple components of the human gut virome between lung cancer patients according to ICI clinical benefit. Most marked were the differences observed in the relative abundance of phages (bacterial viruses). We observed that 239 phages were abundant at different frequencies in lung cancer patients with versus without clinical benefit of ICI therapy at the $q<0.05$ level (multiple testing corrected p-value). In addition, an area under the curve (AUC) for discrimination of ICI clinical benefit of 91% could be achieved using a 15-phage combination. This included 10 OTUs from the family *Siphoviridae*, 2 from the family *Myoviridae*, 2 from *Podoviridae*, and 1 from family *Caudoviridales.* For all but one of these 15 phages, we were able to identify a consensus bacterial genus as the phage target with high confidence. Two of these bacteria - *Ruminococcus* and *Bacteroides* - have consistently been identified in microbiome studies as being associated with ICI response.

Conclusion. Implications of our research include not just the elucidation of a further component of the human gut environment - phages - that impacts human health and disease, but also the identification of its specific role in potentially altering response to cancer-directed immune checkpoint inhibitor therapy.

#3621 Fecal microbiome signatures for early detection of colorectal cancer and precursor lesions.

Mariana Bisarro Dos Reis[1], Monise Tadin Reis[1], Ana Flavia Peres[1], Claudio Lyoiti Hashimoto[1], Denise Peixoto Guimaraes[1], Jeremy Wang[2], Rui Manuel Reis[1]

[1]Barretos Cancer Hospital, Barretos, Brazil,[2]UNC School of Medicine, NC

Background: Colorectal cancer (CRC) remains a major global health burden, and the development of non-invasive biomarkers for early detection is a critical unmet need. Growing evidence indicates that intestinal microbiome dysbiosis contributes to the adenoma-carcinoma sequence and may support CRC risk stratification.
Aim: To investigate whether intestinal microbiome profiling from residual material of Fecal Immunochemical Test (FIT) samples can serve as a biomarker for CRC screening.
Methods: Residual stool samples from Brazilian FIT-positive individuals (n=133) were classified according to colonoscopy as no lesions (N=30), non-advanced adenoma (NAA=46), advanced adenoma (AA=13), or colorectal cancer (CA=44). In three individuals, the microbiome profile was compared on three collection tubes (two FIT tubes and Omnigut). Bacterial DNA from FIT samples underwent 16S rRNA sequencing on Oxford Nanopore MinION (R10.4.1 flow cells, for 48 hours). Reads were processed using Dorado, aligned with Emu to a curated full-length 16S database, and analyzed in QIIME2 using Python. Alpha diversity (25 different metrics), beta diversity (Jaccard, Bray-Curtis), and differential abundance (ANCOMBC) were assessed.
Results: Alpha diversity was significantly higher in CA samples compared with N and NAA patients (Chao 1, $p < 0.001$ and $p=0.006$; Observed features, $p < 0.001$ and $p=0.007$), with no difference compared to AA. Beta diversity (PERMANOVA, $p = 0.001$ for both metrics) showed significant compositional separation among CA and AA (Jaccard, $p=0.001$, Bray Curtis, $p=0.001$), NAA (Jaccard, $p=0.001$, Bray Curtis, $p=0.001$), and N (Jaccard, $p=0.001$, Bray Curtis, $p=0.003$). Differential abundance indicated increasing dysbiosis as lesions progressed. Compared with N samples, NAA exhibited 42 differentially abundant species (9 decreased, 33 increased), AA showed 65 species (15 decreased, 50 increased), and CRC showed pronounced dysbiosis with 179 species (28 decreased, 151 increased). Preliminary inspection highlights enrichment of *Fusobacterium nucleatum* in CA samples. Analysis of the taxonomic profiles revealed no differences in species composition among the three collection tubes analyzed.
Conclusion: Microbiome profiling using routine residual FIT samples is feasible and reveals a marked diversity shift along the adenoma-carcinoma spectrum. These findings
support the potential of FIT-derived microbiome signatures as non-invasive biomarkers for CRC early detection in Brazilian screening populations.

#3622 Precision therapy against CRC associated *Fusobacterium nucleatum* using bioengineered probiotics expressing guided antimicrobial peptides (gAMPs).

Ankan Choudhury, Colin Scano, Allison Barton, Leigh Greathouse

Baylor University, Waco, TX

Colorectal cancer (CRC) is a leading cause of cancer-related mortality, with Fusobacterium nucleatum (F. nucleatum) identified as a key contributor to its progression. This study explores a novel therapy that targets this pathogen by using a bioengineered probiotic that expresses guided antimicrobial peptides (gAMPs) to selectively inhibit F. nucleatum. in this study, Lactococcus lactis MG1363 was engineered to express gAMPs derived from Ovispirin and Cathelin-related peptide SCF, linked to a Statherin-derived guide peptide that binds specifically to the F. nucleatum membrane porin FomA. The bacteria expressed the AMP/gAMP under the induction of the PNisA promoter by nisin and secreted it via the extracellular secretion signal usp45. The resultant synthetic peptides and probiotics were assayed for antimicrobial activity against the targeted F. nucleatum and other non-target bacteria. Biofilm inhibition and growth kinetic assays were performed with synthetic peptides in vitro or the probiotic in co-culture with a polymicrobial community. We saw that statherin-derived guide peptide enhanced the binding affinity to F. nucleatum, significantly increasing attachment compared to control peptides. In vitro assays revealed that both unguided and guided AMPs effectively inhibited biofilm formation in F. nucleatum, with gAMPs showing reduced toxicity against non-target bacteria. The gAMPs were more effective in modulating growth kinetics, exhibiting selective toxicity towards F. nucleatum at lower concentrations. Co-culture experiments in a simulated human gut microbiome showed the gAMP probiotic maintained microbial diversity while effectively reducing F. nucleatum abundance. Quantitative PCR and 16S rRNA sequencing confirmed that gAMP treatment preserved the richness of the microbiota, contrasting with significant dysbiosis observed in control samples. These findings support the potential of engineered probiotics as a therapeutic approach that targets CRC-associated F. nucleatum.

#3623 Effects of the anti-obesity medication tirzepatide on the tumor microenvironment in a mouse model of obesity-associated, hormone-dependent breast cancer..

Charlotte E. Gibson[1], Amanda L. Kucinskas[2], Emma G. Bailey[1], Flora Tao[3], Katherine E. Sanchez[1], Katherine L. Cook[4], Erin D. Giles[1]

[1]Kinesiology, University of Michigan, Ann Arbor, MI,[2]University of Michigan Medical School, Ann Arbor, MI,[3]Johns Hopkins University, Baltimore, MD,[4]Wake Forest University School of Medicine, Winston Salem, NC

Numerous anti-obesity agents have been approved for obesity/diabetes treatment, but their impact on obesity-related breast cancer is not clear. Our pilot data supported a trend for reduced growth of estrogen-receptor positive (ER+) tumors with tirzepatide (TZP), an FDA-approved incretin mimetic targeting both GLP-1 and GIP receptors. Here, our goal was to determine if TZP-induced changes in the mammary tumor microenvironment contributed to the anti-cancer effects of TZP. Female C57/BL6 mice were fed a 46% high-fat diet to induce obesity. They were then randomized to receive tirzepatide (15-week dose escalation to 75nM) or vehicle for the duration of the study. Three weeks after starting TZP, tumors were initiated by injection of estrogen-receptor positive Py230 cells, and tumor volumes were measured twice weekly. Mice were terminated when tumor volumes reached humane endpoints, or after 16 weeks of treatment. Mammary adipose tissue was collected at the end of the study and processed for histological examination. Adipocyte size was assessed in H&E stained tissues using the Adiposoft plugin for ImageJ, and number of macrophages in the tumor microenvironment was assessed using Mac2 immunofluorescence staining. As expected, TZP induced ~20% weight loss, which was reflected in both an increase in the proportion of small adipocytes and a reduction in the number of large adipocytes in the tumor microenvironment (mammary gland). This suggests that changes in macrophage infiltration are not likely to contribute to the potential anti-cancer effects of TZP in our pilot studies. Ongoing studies will address additional mechanisms by which TZP affects tumors and/or the obese tumor microenvironment.

#3624 Long-term running and risk of colorectal adenoma and cancer.

Yiwen Zhang[1], Edward L. Giovannucci[2]

[1]Harvard School of Public Health, Boston, MA,[2]Professor of Nutrition & Epidem., Harvard TH Chan School of Public Health, Boston, MA

Introduction: Although physical activity is associated with lower risk of colorectal cancer, it was hypothesized that high levels of long-distance running may induce gastrointestinal ischemia and injury, raising concern about potential increased risk of colorectal carcinogenesis. Currently only a small cross-sectional study of 100 participants suggested intensive long-distance running is a risk factor for advanced colon adenomas. No large prospective study has comprehensively evaluated long-term running in relation to risk of colorectal adenoma and cancer.

Methods: We used data from three prospective cohorts: Health Professionals Follow-up Study, Nurses' Health Study (NHS), and NHSII. Running was assessed with biennial validated questionnaires and calculated as cumulative average over the past 8-year period to reflect long-term patterns. Colorectal adenoma risk was evaluated among 160,367 participants with at least one lower gastrointestinal endoscopy during follow-up with logistic regression models accounting for repeated observations. Colorectal cancer risk was analyzed with Cox proportional hazard models among 238,491 participants followed up to 32 years. Multivariable models were adjusted for potential confounders and total physical activity other than running. We also examined associations between running with resting heart rate and cardiometabolic biomarkers.

Results: We documented 12,426 conventional adenomas, 11,251 serrated polyps, and 3583 colorectal cancers during the follow-up period. Running was inversely associated with risk of conventional adenoma and serrated polyps. For high-risk adenoma, compared to participants who reported no running, the ORs (95% CIs) across >0-<1, 1-<2, 2-<3, 3-<4, and ≥4 h/week of running were 0.86 (0.76-0.98), 0.75 (0.55-1.00), 0.83 (0.56-1.23), 0.94 (0.52-1.66), and 0.51 (0.29-0.91), respectively. For colorectal cancer, compared to no running, the HRs (95% CIs) were 0.86 (0.76-0.97) for >0-<1 h/week, 0.60 (0.41-0.87) for 1-<2 h/week, and 0.81 (0.58-1.12) for ≥2 h/week. Results remained similar when further adjusted for body mass index. Biomarker analysis showed higher levels of running were associated with significant lower resting heart rate, lower inflammation status (lower CRP and IL-6), better insulinemic (lower C-peptide) and lipid profile (higher HDL-cholesterol and lower triglycerides), providing biologic support of our assessment of running.

Conclusion: In three large cohorts, long-term running was not associated with an increased risk of colorectal adenoma, serrated polyps, or colorectal cancer. Moderate running levels (approximately up to 2 h/week) were associated with lower risk of colorectal cancer and levels ≥4 h/week were associated with a lower risk of high-risk adenoma. These findings provide reassurance that habitual running, at levels up to at least 4 h/week, is safe and potentially beneficial with respect to colorectal neoplasia risk.

#3625 Central and peripheral adiposity and breast cancer risk in postmenopausal women: A pooled analysis of 11 cohort studies.

Isaias Leon-Cepeda[1], Craigg Pickett[2], Stephanie A. Smith-Warner[3], Robert J. MacInnis[4], Jeanine M. Genkinger[1]

[1]Epidemiology, Columbia University Mailman School of Public Health, New York, NY,[2]Department of Epidemiology and Preventive Medicine, School of Public Health & Preventive Medicine Monash University, Melbourne, Australia,[3]Departments of Nutrition and Epidemiology, Harvard T. H. Chan School of Public Health, Boston, MA,[4]Centre for Epidemiology and Biostatistics, Melbourne School of Population and Global Health, The University of Melbourne, Melbourne, Australia

Background: Central and peripheral adiposity, measured by waist circumference (WC), hip circumference (HC), and waist-to-hip ratio (WHR), has been positively associated with postmenopausal breast cancer (BC) risk, but results are inconsistent after adjustment for body mass index (BMI). Using pooled individual-level data from 11 prospective cohorts, we evaluated associations between WC, HC, WHR, and a body shape index (ABSI; based on waist, height, and weight) and risk of postmenopausal BC overall and BC subtypes defined by receptor status.
Methods: These preliminary analyses evaluated associations between WC, HC, WHR, and ABSI using consortium-wide quintiles and overall BC and tumor negative breast cancer (TNBC) in 402,682 postmenopausal women. Cox proportional hazards regression models were used to calculate hazard ratios (HRs) and 95% confidence intervals (95% CI), adjusting for age, year of questionnaire, study, family history of BC, and reproductive and lifestyle factors. Analyses were performed with and without adjustment for BMI.
Results: During a median follow-up of 2.9-27.5 years across studies, 20,752 incident invasive BC were documented (N=998 TNBC). The pooled multivariable BMI-adjusted HRs (95% CIs) for postmenopausal BC comparing quintile 5 to 2 were 1.14 (1.08-1.21) for WC; 1.06 (0.99-1.14) for HC; 1.10 (1.05-1.15) for WHR, and 1.03 (0.98-1.08) for ABSI. Similar associations were observed among never-users of menopausal hormone therapy. The pooled multivariable BMI-adjusted HRs (95% CIs) for postmenopausal TNBC comparing quintile 5 to 2 were 1.13 (0.87-1.46) for WC; 0.74 (0.45-1.21) for HC; 1.45 (1.15-1.84) for WHR, and 1.18 (0.95-1.47) for ABSI.
Conclusion: Higher compared to lower WC and WHR were associated with increased risk of postmenopausal BC, independent of BMI. Our findings suggest that individual and population-level strategies to prevent central adiposity could help reduce the risk of postmenopausal BC.

#3626 Early life exposures and cancer in adulthood: World Cancer Research Fund International's lifecourse research in cancer.

Vanessa Lani Zarya Gordon-Dseagu[1], Helen Croker[1], **Panagiota Mitrou**[1], Christelle Clary[1], John Krebs[2], Matty P. Weijenberg[3], Monica Baskin[4], Ellen Kampman[5], Laure Dossus[6], Franzel J. Van Duijnhoven[7], Dieuwertje E. Kok[8], Moniek van Zutphen[8]

[1]World Cancer Research Fund International, London, United Kingdom,[2]University of Oxford, Oxford, United Kingdom,[3]Associate Professor, Dept. of Epidem., Maastricht University, Maastricht, Netherlands,[4]VCU Massey Comprehensive Cancer Center, Richmond, VA,[5]Div. of Human Nutrition, Wageningen Univ., Wageningen, Netherlands,[6]IARC-WHO, Lyon, France,[7]Postdoctoral Researcher, Wageningen University, Wageningen, Netherlands,[8]Wageningen University & Research, Wageningen, Netherlands

Background There is increasing recognition that exposure to certain risk factors in early life (defined as birth, childhood, adolescence, and young adulthood) impacts disease risk (including cancer) in adulthood. The identification of age-specific "windows of opportunity" also enables the development of refined cancer prevention recommendations tailored to different life stages. Despite this, there is a paucity of evidence related to how body size and weight, diet, nutrition, and physical activity in early life influences adult cancer risk. The strength of the available evidence-base has also not been assessed in a systematic way.

Methods WCRF International's Global Cancer Update Programme (CUP Global) undertook a collaboration with Wageningen University and Research (WUR) to conduct systematic literature reviews and meta-analyses focused on early-life exposures (birth size, body weight, and alcohol consumption) and risk of colorectal and breast cancer in adulthood. A 2nd collaboration with the International Agency for Research on Cancer (IARC) reviewed relevant biological mechanisms. The Global CUP Global Panel of Experts then interpreted and graded the evidence using pre-defined criteria to determine likely causal associations.

Results Key exposures during early life related to birthweight, body size and alcohol, as well as the biological mechanisms that underpin them, that impact future cancer risk were identified. For colorectal cancer, birthweight was associated with a 9% (95% confidence interval: 1.01-1.16) increased risk, increased BMI during childhood, adolescence and young adulthood were also associated with increased risk. For breast cancer, greater birth weight, length and taller height in childhood inferred an increased risk. Higher BMI in childhood, adolescence and young adulthood were associated with lower risk. Our Panel of Experts concluded that the evidence for several of the associations was strong enough to suggest a likely causal association. In the future, WCRF International will use these results and further discussions with experts in the field of lifecourse research, public health, and policy to develop guidance and recommendations for researchers, policy makers and the public.

Conclusion The current reviews of the epidemiological and mechanistic evidence demonstrate how exposures related to diet, nutrition, and bodyweight can impact cancer risk in adulthood. Understanding the associations between our early years and cancer risk in adulthood enables a better understanding of the aetiology of cancer, how risk factors impact cancer risk as we age, whether there are critical timepoints/windows for cancer risk, and how our environment impacts cancer risk. These findings, alongside a growing evidence-base, enable the development of cancer prevention policy and public health recommendations.

#3627 Metabolomic signatures of physical activity in treatment-naive patients with early-onset vs. late-onset colorectal cancer: Results from the ColoCare Study.

Onc., University of Tennessee Health Science Center - Memphis, Memphis, TN,[11]Fred Hutchinson Cancer Center, Seattle, WA,[12]Samuel Oschin Comprehensive Cancer Institute, Los Angeles, CA,[13]Duke University, Durham, NC

Introduction: Emerging studies link physical inactivity to early-onset colorectal cancer (EOCRC), but most rely on subjective measures of physical activity (PA). Metabolite signatures may offer an objective measure of PA that also captures the systemic metabolic response to activity. We assessed a previously validated PA metabolomic signature in patients with recently diagnosed colorectal cancer (CRC) and compared profile scores between patients with EOCRC (<50 yrs) vs. non-EOCRC (≥50 yrs).

Methods: We examined baseline (pre-surgery) data from 122 stage I-III patients with CRC in the ColoCare Study at Huntsman Cancer Institute (Utah) and Heidelberg University Hospital (Germany). PA for the previous year was measured with the International Physical Activity Questionnaire-Short Form. Untargeted serum metabolites and complex lipids were profiled at the West Coast Metabolomics Center. We calculated a 24-metabolite PA signature developed in >6,000 cancer-free individuals (Papadimitriou et al., CEBP, 2025) consisting of acylcarnitines, glycerophospholipids, monosaccharides, amino acids, and sphingolipids. Following metabolite pre-processing, normalization, and scaling, we performed multivariable linear regression on 20 metabolites available in our dataset, adjusting for age, sex, tumor stage, and body mass index (BMI). Metabolite scores were calculated for each participant by multiplying normalized metabolite concentrations by the previously developed PA metabolite signature coefficients and were then compared between EOCRC vs. non-EOCRC survivors.

Results: Compared to patients with non-EOCRC (67±9 years, N=102), those with EOCRC (39±10 years, N=20) were diagnosed with higher stages (55% vs. 43% stage III), had lower prevalence of obese BMI (25% vs. 37%), and were more physically active (16±17 metabolic equivalent (MET) hrs/week vs. 11±17 MET hrs/week), p>0.05. Patients with EOCRC were more likely to meet PA guidelines (≥150 min/week of moderate to vigorous PA; 60% vs. 38%) compared to those with non-EOCRC, p>0.05. Among the 20 metabolites investigated in our data, 15 showed a consistent direction of association with the previously developed PA signature. Patients with EOCRC had higher scores of the PA metabolite signature (0.04±0.09) than older patients (-0.01±0.10), t=2.3, p=0.03. This modest association remained significant after adjustment for stage, sex, and BMI (β=0.05, p=0.048).

Conclusions: A PA metabolite signature showed comparable associations to questionnaire-derived PA measures in our CRC survivor cohort, consistent with findings in healthy individuals. Patients with EOCRC reported a higher level of PA compared to those with non-EOCRC and had a significantly higher PA metabolite signature score. The metabolite response to PA may clarify how physical inactivity influences EOCRC risk and outcomes.

#3628 Obesity, metabolic dysfunction, and cancer risk: Uncovering the metabolic landscape.

Liza Makowski[1], Mary Playdon[2], Bing Li[3], Sonia L. Sugg[3], Scott A. Summers[2], Cornelia M. Ulrich[2], Deirdre Tobias[4], Edward L. Giovannucci[5], Xuehong Zhang[6], James R. Hebert[7], E. Angela Murphy[8], Joeseph F. Pierre[9], Loretta DiPietro[10], Lorne J. Hofseth[11], **Marinella Temprosa**[12]

[1]University of Tennessee Health Science Center - Memphis, Memphis, TN,[2]University of Utah Huntsman Cancer Institute, Salt Lake City, UT,[3]University of Iowa, Iowa City, IA,[4]Brigham and Women's Hospital and Harvard Medical School, Boston, MA,[5]Professor of Nutrition & Epidem., Harvard TH Chan School of Public Health, Boston, MA,[6]Yale University, New Haven, CT,[7]Professor, Dept. of Epidemiology & Biostatistics, University of South Carolina School of Medicine, Columbia, SC,[8]Asst. Prof., Dept. of Path., Microbiology, & Immunology, University of South Carolina School of Medicine, Columbia, SC,[9]University of Wisconsin-Madison, Madison, WI,[10]George Washington University, Washington, DC,[11]Assistant Professor, Univ. of South Carolina College of Pharmacy, Columbia, SC,[12]Biostatistics and Bioinformatics, George Washington University, Washington, DC

As smoking rates decline, obesity has emerged as the leading modifiable risk factor for cancer in the United States. With obesity rates rising, especially in younger populations, its association with increased cancer risk is becoming more evident. There is an urgent need to understand the mechanisms underlying the relationship between obesity related metabolic dysregulation and cancer risk. This session highlights transdisciplinary research from the NCI-sponsored *Metabolic Dysregulation and Obesity Cancer Risk (MeDOC)* Consortium, which applies integrative methods across basic science, translational models, and clinical research. The MeDOC Consortium aims to discover mechanisms linking obesity and cancer to define markers that will enhance cancer risk prediction and identify targets for intervention. Metabolic alterations include immune dysfunction, metabolite signaling, hormonal imbalance, gut microbiome and adipocyte metabolism which can disrupt several downstream signaling pathways related to cancer initiation and progression. In our novel triangulation approach, we synthesize evidence from randomized controlled trials, mechanistic animal studies, and large-scale secondary data analyses establishing population-level patterns with clinical relevance to build a comprehensive metabolic atlas of cancer risk factors. Our research topics include the gut microbiome, lipid signaling, circulating metabolites, and local and systemic immune landscape, with a focus on how these processes influence the development of colorectal, breast, and liver cancers. We will highlight complementary research projects that bridge animal studies, human cohorts, and data science across diet, inflammation, microbiome, immunity, and obesity and weight loss. We will review current evidence and describe novel applications of systems biology with big data analytics featured as tools to integrate mechanistic insights and population-level patterns to establish robust causal frameworks. Early-career investigators will participate in an open discussion on emerging challenges and opportunities in obesity and cancer research. Specifically, we will report on the role of fatty acid binding protein, ceramides, bile acids, hormones, inflammation, and gut microbiome metabolites in cancers of the colon, breast, and liver, Through a translational lens, the session will emphasize how combining data science, bench studies, and interventional trials can accelerate the discovery of biomarkers, risk stratification tools, and actionable targets for cancer prevention or interception.

#3629 The association between obesity, diabetes and prostate cancer aggressiveness in Louisiana Cohort..

Hari K. Koul, Denise danos, Yong yi, Augusto Ochoa, Lucio Miele, Xio-Cheng Wu

LSU-LCMC Cancer Center, LSUHSC-School of Medicine, New Orleans, LA

Introduction Prostate cancer is the most common cancer in men the United States and Louisiana ranks third for prostate cancer mortality rates in the US. With over 40 % adult obesity rates, Louisiana ranks fourth among states for obesity rates. There is conflicting literature on the association between obesity, diabetes and PCa development. We aim to assess if there is an association between obesity, diabetes and PCa aggressiveness at the time of diagnosis, and if this association is modified by race or obesity status.
Methods Cases of primary invasive locoregional prostate cancer diagnosed in 2011-2020 were obtained from Louisiana Tumor Registry. PCa aggressiveness was defined in accordance with the TNM stage and Gleason score. Obesity was defined as BMI of 30 or higher, and type 2 diabetes was identified using ICD-10 codes. Linear trends were assessed with Cochran-Armitage Trend tests and highly aggressive disease at diagnosis was modeled using logistic regression. Analyses were performed overall and stratified by race.
Results The study included 22,554 cases. Most cases were white (62%), while 35% were Black, and 2% were Hispanic. The overall distribution of PCa aggressiveness was low (23%), intermediate (47%), and high (30%). PCa aggressiveness was significantly associated with older age, Black race, obesity, and diabetes ($p<.001$). Stratified by race, the relationship between diabetes and aggressiveness was significant among whites ($p<.001$) and Hispanics ($p=0.037$) but not Blacks ($p=0.398$). In multivariable models controlling for age and obesity, diabetes was significantly associated with high PCa aggressiveness among lean white (OR=1.40 (1.18,1.66)) and Hispanic (OR = 2.68 (1.13,6.36)) men, but not among lean (OR=1.08 (0.90,1.29)) or obese (OR= 0.94 (0.78,1.12)) Black men.
Conclusion We found that obesity is associated with increased risk of aggressive PCa in both Caucasian and Black men, and Obesity and Diabetes are risk factors that interact in PCa patients. Our ongoing research studies are aimed at assessing the contribution of social, environmental, behavioral, dietary and metabolic risk factors with a special emphasis on epigenetic and metabolic reprogramming for aggressive PCa within the Louisiana Cohort.

#3630 Physical activity, smoking and breast cancer risk: A prospective cohort study in the UK biobank.

Hannach Harsanyi[1], Andrew Harper[1], Heinz Freisling[2], Sasha Lupichuk[3], Adetunji T. Toriola[4], **Lin Yang**[3]

[1]Cancer Care Alberta, Calgary, AB, Canada,[2]International Agency for Research on Cancer,[3]University of Calgary, Calgary, AB, Canada,[4]Washington University School of Medicine in St. Louis, St. Louis, MO

Background: Physical activity and smoking are modifiable breast cancer risk factors that operate through partially shared biological pathways, such as hormone regulation and inflammation. However, their potential interactions, especially across menopausal groups, remain largely unexplored. This study aimed to assess whether smoking status modifies the association between physical activity and breast cancer risk.

Methods: Females ≥40 years without prior cancer in the UK Biobank (2007-2010) provided self-reported lifestyle factors. Physical activity was categorized using metabolic equivalent hours per week (MET-hrs/week): high (≥50), moderate (10-50), and low (<10). Incident cancers were ascertained through May 2022. Interaction between physical activity and smoking status (never, past, current) was evaluated using Cox proportional hazards models with product terms. Multivariable models were adjusted for anthropometrics, reproductive, lifestyle, socioeconomic and screening factors.

Results: Among 242 721 participants followed for a mean of 12.53 years (SD: 2.55), 773 premenopausal and 7989 postmenopausal breast cancer cases occurred. High physical activity was associated with lower risk of both premenopausal (HR=0.78, 95%CI: 0.62-0.97) and postmenopausal (HR=0.88, 95%CI: 0.83-0.94) breast cancer. Smoking status was not associated with premenopausal breast cancer risk (past smoker: HR=0.95, 95%CI:0.79-1.13; current: HR=0.89, 95%CI: 0.70-1.15) but was associated with a higher postmenopausal breast cancer risk (past smoker: HR=1.05, 95%CI:1.00-1.11; current: HR=1.13, 95%CI: 1.03-1.23). When evaluating the joint association between physical activity and smoking, current smoking appeard to attenuate the protective association of physical activity with both premenopausal (HR=1.61, 95%CI: 0.74-3.51) and postmenopausal (HR=1.29, 95%CI:1.02 to 1.62) breast cancer risk, although multiplicative interaction terms were not statistically significant.

Conclusions: Smoking status was not independently associated with premenopausal but associated with higher postmenopausal breast cancer risk. Nevertheless, current smokers appeared to derive less protective benefits from physical activity than never smokers. These findings highlight the importance of evaluating joint lifestyle effects rather than single exposure alone in breast cancer prevention.

#3631 Early BMI increase as a predictive biomarker for immune checkpoint inhibitor ±chemotherapy efficacyin advanced NSCLC: Integrating clinical, genomic, and circulating proteomic data.

Xinan Wang[1], Federica Pecci[2], Valentina Santo[2], Eleonora Gariazzo[2], Edoardo Garbo[2], Alessandro Di Federico[2], Joao Alessi[2], Yi Li[3], Biagio Ricciuti[2], David C. Christiani[4]

[1]Harvard School of Public Health, Boston, MA,[2]Dana-Farber Cancer Institute, Boston, MA,[3]Biostatistics, University of Michigan, Boston, MI,[4]Harvard Medical School, Boston, MA

Background: Baseline body mass index (BMI) has emerged as a prognostic factor for immune checkpoint inhibitor (ICI) in advanced NSCLC. However, with chemo-immunotherapy becoming standard of care, whether early BMI changes predict efficacy and differ by treatment regimen remains unclear. Identifying early predictive changes could inform timely interventions to improve treatment efficacy.
Methods: This retrospective study included patients with advanced NSCLC treated with ICI +/- chemotherapy. Baseline and longitudinal BMI were collected. Baseline covariates included age, sex, histology, smoking status, ECOG PS, TMB, PD-L1 TPS, and therapy line. Multivariable logistic and Cox models assessed early BMI changes at 3, 6, and 9 weeks and objective response rate (ORR), progression-free survival (PFS), and overall survival (OS), adjusting for baseline BMI and covariates. Time-dependent analyses verified temporal associations. To understand molecular profiles associated with baseline BMI (≥25 vs. <25 kg/m²), we assessed circulating proteins (Olink, 2700 proteins) in 141 patients and genomic alterations (OncoPanel) in 728 patients, adjusting for age, sex, and smoking.
Results: Among 1,110 patients (303 chemo-immunotherapy, 797 ICI monotherapy), early BMI increase independently predicted improved outcomes in both regimens, with stronger effects in chemo-immunotherapy. In chemo-immunotherapy, 1% BMI increase at 3 weeks predicted higher ORR (OR 1.48, 95% CI 1.15-2.03), PFS (HR 0.78, 95% CI 0.71-0.86), and OS (HR 0.77, 95% CI 0.69-0.86). Predictive value decreased over time (3, 6, 9 weeks), particularly in chemo-immunotherapy. Older patients with smoking history, lower TMB receiving chemo-immunotherapy were more likely to lose weight within 3 weeks. Genomically, KRAS, KMT2A, RASA1, FANCA, CTNNB1, and ATM mutations were enriched in higher BMI patients, while EGFR, PMS1, FH, TP53, and BAP1 mutations were more common in lower BMI patients. Circulating proteins (SSC4D, LEP, CDHR2 in higher BMI; FSHB, GHRL in lower BMI) showed sex-specific patterns and metabolic regulatory roles.
Conclusions: Early BMI increase predicts improved ICI outcomes in advanced NSCLC, with weight monitoring offering opportunities to optimize efficacy. Baseline BMI-associated genomic and proteomic profiles provide complementary insights: circulating proteins establish chronic metabolic selective environments, while tumor mutations represent evolutionary outcomes.

#3632 Adiposity and cancer: Updated meta-analysis incorporating the largest evidence base to date.

Eleanor Watts[1], Amparo Gonzalez-Feliciano[1], Marc Gunter[2], Nilanjan Chatterjee[3], Steven Moore[1]

[1]National Cancer Inst. Div. of Cancer Epidemiology & Genetics, Bethesda, MD,[2]Imperial College London, London, United Kingdom,[3]Johns Hopkins Kimmel Comp. Cancer Ctr., Baltimore, MD

Background: Global increases in body mass index (BMI) have made obesity a major public health challenge worldwide. Between 2016 and 2018, landmark reviews by the WCRF and IARC established elevated BMI as a risk factor for at least 12 cancers, yet uncertainties remain regarding generalizability beyond Europe and North America, associations with less common or smoking-related cancers, and the relevance of other adiposity measures such as waist circumference. Since these reviews, new large-scale cohorts, particularly in East Asia, and Mendelian randomization studies have greatly expanded available evidence, enabling reassessment of obesity-cancer associations.

Methods: We conducted a systematic review and meta-analysis of prospective cohorts examining BMI and risk of 25 common cancers, searching PubMed, EMBASE, and Scopus through April 23, 2025. Summary risk estimates were calculated using random-effects meta-analysis. We also meta-analysed Mendelian randomization studies, compared associations for BMI and waist circumference, and reviewed emerging imaging-based evidence.

Results: Across 226 articles comprising 1.5 million cancer data points, most cases originated from Europe (59.0%), followed by East Asia (30.1%) and North America (10.6%). BMI was positively associated with 19 cancer types and inversely associated with three. Positive associations for leukaemia (RR per 5 kg/m^2 = 1.09, 95% CI 1.05-1.13), non-Hodgkin lymphoma (1.05, 1.01-1.08), bladder cancer among never-smokers (1.04, 1.01-1.07), and glioma (1.03, 1.01-1.05) represent novel findings not reported in previous WCRF or IARC reviews, suggesting obesity may be linked to a broader range of cancers than previously recognised. For cancers where smoking is a dominant risk factor, we observed increased risks for head and neck cancer (1.07, 1.02-1.13) and bladder cancer, and decreased risks for oesophageal squamous cell carcinoma (0.72, 0.60-0.86) and lung cancer (0.92, 0.86-0.99) among never-smokers. Regional variation was evident, including stronger associations for postmenopausal breast and ovarian cancers in East Asia and weaker associations for gallbladder cancer, although many populations remain unrepresented. Mendelian randomization analyses were broadly consistent with a causal effect. Associations for BMI and waist circumference were highly similar, and available imaging data were limited.

Conclusions: This updated meta-analysis, representing the largest synthesis of evidence to date, highlights the substantial and expanding impact of obesity on cancer risk and underscores the urgent need to address this modifiable risk factor worldwide.

#3633 Synergistic effects of HIV and HPV coinfection in dysregulation of the oral mycobiome in Puerto Rican people with HIV.

Juliana M. Serrano-Rodriguez[1], Jurelis Torres-Reyes[2], Yakshi N. Ortiz-Maldonado[2], Gabriel Borges-Velez[2], Jeannette L. Salgado Montilla[2], Maria M. Sanchez-Vazquez[2], Magaly Martinez-Ferrer[3], Ramon F. Gonzalez-Garcia[4], Josue Perez-Santiago[2]

[1]University of Puerto Rico - Rio Piedras, San Juan, PR,[2]University of Puerto Rico Comprehensive Cancer Center, San Juan, PR,[3]University of Puerto Rico School of Medicine, San Juan, PR,[4]University of Puerto Rico School of Dental Medicine, San Juan, PR

Background: Despite advances in suppressive antiretroviral therapy, people with HIV (PWH) have a higher prevalence of HPV infection than people without HIV (PWOH), suggesting that other factors independent of HIV may be contributing to increased susceptibility of HPV infections in PWH. The human mycobiome (fungal communities of the microbiome) can play an important role in immune modulation, promoting activation of inflammatory pathways and the production of carcinogenic organic compounds. Non-medical factors such as oral HPV infections, can induce oral mycobiome community-level shifts which may facilitate oncogenesis, but it has not been evaluated in the context of HIV in PR. In this study, we evaluated the prevalence of oral HPV infection and chracterized the oral mycobiome in Puerto Rican PWH and PWOH with and without coinfection with oral HPV (HPV+ vs HPV-).
Methods: Saliva and oral rinse samples were collected from 132 sexually active individuals (PWH vs PWOH). Oral rinse samples were analyzed for HPV infection and genotype using the DNA ELISA kit HPV SPF10 and RHA kit HPV SPF10-LiPA25. Extracted DNA from saliva was used to sequence the ITS and characterize the oral mycobiome. Oral mycobiome was analyzed using Shannon index for diversity and Pielou index for evenness using QIIME2 and R-statistical software.
Results: The overall prevalence of oral HPV infection among participants of the study was 33%. The prevalence of oral HPV infection was 3x higher in PWH (44%) compared to PWOH (14%). Considering all HPV+ genotypes 47% were high-risk for cancer development (PWH= 95% vs PWOH= 5%). On the other hand, fungal diversity was significantly lower in PWH compared to PWOH (p= 0.038), while fungal diversity (p= 0.020) and evenness (p= 0.088) was lower in HPV+ individuals compared to HPV- individuals. Furthermore, HPV+ PWH showed significantly lower fungal diversity (p= 0.048) and evenness (p= 0.087) compared to HPV- PWOH. Moreover, PWH had significantly higher abundance of genus *Candida* than PWOH (p= 0.048). HPV+ PWH had significantly higher relative abundance of *Candida* in saliva (p= 0.007).
Conclusion: Higher prevalence of oral HPV infection was observed in PWH in comparison to PWOH in PR. Dysbiosis of the oral mycobiome was observed in both HIV and oral HPV infection, however independent of HIV status, HPV+ individuals had lower oral fungal species evenness. Moreover, *Candida* abundance levels were significantly higher in coinfection of HIV and HPV, indicating that the oral mycobiome may be potentially influenced by a synergistic effect caused by the coinfection. Overall, these findings suggest that HPV status greatly impacts oral mycobiome homeostasis that can potentially contribute to the natural history of HPV and increased cancer risk. Understanding the interplay between viral infections and the oral mycobiome may explain clinical disparities regarding the natural history of HPV in PR.

#3634 Effects of olive oil byproducts polyphenol reach extract on muscle function, sarcopenia-related parameters and skin health.

Adriana Albini[1], Sara Nofri[2], Danilo Morelli[3], Paola Corradino[1], Gianni Lo Franco[4], Calogero Caruso[5], Anna Aiello[5]

[1]IEO - European Institute of Oncology, Milan, Italy,[2]University of Florence, Firenze, Italy,[3]Fondazione IRCCS Istituto Tumori di Milano, Milan, Italy,[4]Fattoria la Vialla, Castiglion Fibocchi (AR), Italy,[5]Biomedicine, Neuroscience and Advanced Diagnostics, University of Palermo, Palermo, Italy

Sarcopenia, the age-related loss of skeletal muscle mass, strength, and function, represents a major determinant of frailty and disability in older adults. Nutraceutical strategies targeting inflammation and oxidative stress have been proposed as adjunctive countermeasures. Olive mill wastewater (OMWW), a byproduct of olive oil production, is rich in hydroxytyrosol and other polyphenols with potent antioxidant and anti-inflammatory effects. Results from a 30-day, single-arm pilot trial to evaluate several biometric and anthropometric parameters, after assumption of the OMWW extract, OMWW-OL (Oliphenolia®), revealed a positive trends to ameliorate sarcopenia-related values in adults with metabolic syndrome, a population at elevated risk for muscle decline. Twenty-nine participants were enrolled, and 23 (15 men, 8 women) completed the study. Assessments included bioimpedance-derived indices of muscle mass, anthropometry, handgrip strength, calf circumference, hydration, and inflammatory/metabolic markers at baseline (T0), after supplementation (T1), and 30 days post-intervention (T2). OMWW-OL was well tolerated. Participants showed modest but consistent trends toward improved fat-free mass index (FFMI), appendicular skeletal muscle mass (ASMM), and handgrip strength at T1, with partial persistence at T2. Calf circumference increased steadily across the observation period. Among biochemical markers, oxidized LDL (oxLDL), a lipid peroxidation indicator linked to muscle catabolism, showed a small but progressive reduction from T0 to T2, consistent with the antioxidant profile of OMWW polyphenols, whereas CRP exhibited a transient rise at T1 before returning near baseline at T2.Although statistical significance was limited by small sample size and study design, the observed trends align with preclinical evidence that OMWW polyphenols mitigate oxidative stress, suppress pro-inflammatory cytokines, and promote muscle protein homeostasis. These exploratory findings justify larger randomized trials to evaluate OMWW as a nutraceutical strategy for sarcopenia prevention and management. Sarcopenia has been also associated with cancer, is higher in oncology patients with metabolic syndrome and worsens response to therapy. Cosmeceutical preparations using OMWW-OL also reveal protective properties for the skin. One of the major polyphenols in OMWW-Ol is hydroxytyrosol, and investigations are ongoing oh the role of the purified substance.

#3635 Interim results of the BEFIT exercise intervention pilot study to assess the microbiome and immune function in a high-risk cohort for lung cancer.

Marisa Bittoni, Zachary Chaplow, Daniel Spakowicz

The Ohio State University, Columbus, OH

Background/Objective: Modifiable lifestyle risk factors, such as diet and exercise, have shown to be associated with reduced lung cancer risk. We recently launched a randomized controlled pilot trial, the BEFIT exercise intervention study, whose overall objectives are to: a) confirm the feasibility of an exercise intervention in high-risk smokers, and b) assess the intervention impact on the microbiome and inflammatory biomarkers**.** This report will describe interim study results, including participant characteristics, recruitment challenges and adherence in this ongoing study.
Methods: Participants from The Ohio State University Lung Cancer Screening Clinic (OSULCSC) and social media were randomized into one of two arms: (a) Exercise/Behavioral Support Intervention - an ACSM-approved 12-week virtual resistance training plus aerobic program, or (b) Standard of Care - an information-only, control condition (e.g. light walking). Eligibility criteria included: ages 40-80 years, exercise<150 minutes/week, 20 pack-year smoking history and computer/internet access. Blood draws, stool samples, physical activity measures and behavior change predictors will be evaluated at baseline and intervention completion, with 1-year follow-up to assess adherence.
Results: Individuals were primarily recruited through the OSULCSC and social media ads. Our goal was to recruit 40 participants (20 per arm), but due to dropout we had 20 in the intervention group and 16 in the control group. Common reasons for withdrawal include too busy, changed mind and no longer interested. Participant characteristics include mean age 63 years, 64% female, 89% white, 52% current smokers and mean BMI of 35 (obese) and 39% body fat. The intervention group showed significantly greater weight loss and increased lean muscle mass after the intervention. Adherence to the intervention was high with almost 90% of sessions attended with no adverse events reported. Biospecimen analyses and social cognitive intermediates are currently underway.
Discussion: We successfully launched the BEFIT exercise intervention study for long-time smokers at high risk for lung cancer with high adherence and no adverse events reported. Despite recruiting challenges and dropout, we successfully recruited and conducted the intervention, with significant improvements in weight loss and lean muscle mass after the intervention. We continue to analyze biospecimen data for changes in the gut microbiome and inflammation, and look forward to reporting these when completed.

#3636 Evaluation of a clinically integrated mHealth intervention to reduce sedentary time in adolescents and young adults with ALL during maintenance therapy.

Brittany J. Ivory[1], Yueh-Yun Chi[1], Jeannie M. Shin[1], Britni R. Belcher[2], David R. Freyer[1]

[1]Cancer and Blood Disease Institute, Children's Hospital Los Angeles, Los Angeles, CA,[2]Department of Population and Public Health Sciences, University of Southern California Keck School of Medicine, Los Angeles, CA

Background: Sedentary behavior (SB) is prevalent in early adolescents and young adults (eAYAs, 12-21 years) during acute lymphoblastic leukemia (ALL) treatment and contributes to cardiometabolic complications. Intervention during therapy can be challenging, but the maintenance phase may be opportune for SB intervention as toxicity from intensive therapy subsides and monthly visits allow for regular study contact.
Purpose: To evaluate the feasibility and acceptability of a clinically integrated, multi-component mobile health (mHealth) SB intervention in eAYAs during ALL maintenance phase; and assess effects on SB and health-related quality of life (HRQoL).
Methods: This ongoing 12-week, single-arm pilot trial includes a Fitbit with inactivity-triggered prompts, three in-clinic or virtual coaching sessions, and an app-based peer chat group. The intervention is aligned with one 12-week cycle of maintenance therapy, and in-person procedures coincide with monthly clinic visits. Feasibility is defined as ≥70% retention, N=20 enrolled, and Fitbit wear time ≥10 h/day on ≥70% days for ≥50% of sample. Acceptability is evaluated via exit surveys. At baseline and week 12, SB is assessed using the activPAL micro4 device and IPAQ questionnaire, and HRQoL is assessed via validated surveys. Outcome differences were compared by number of maintenance cycles completed at enrollment (≤ 2 [early] vs > 2 [late]).
Results: To date, N=20 are enrolled and N=16 have completed the study (median age=16.2 yrs; 69% male; 69% Hispanic; median BMI=23.3kg/m^2; 56% in early maintenance). Retention among completers is 94% (N=15) and 38% (N=6) met Fitbit wear time criteria, the majority of whom were in early maintenance (83% [N = 5] vs 14% [N = 1] in late maintenance). Acceptability is high: 93% (N=14) reported the intervention helped reduce SB and 100% would recommend it to peers. A greater proportion of participants in early vs late maintenance strongly agreed the intervention reduced SB (helpful: 88% vs 29%, p = 0.05; recommend: 88% vs 0%; p = 0.001). Overall, device-measured sedentary and sitting time decreased (−10.4 min/day and −26.3 min/day, respectively) and steps increased (+1,993/day) (all p>0.05); self-reported sitting time also decreased (−154 min/day, p=0.002). Participants in early maintenance showed similar trends to those in later cycles. There were no significant changes in HRQoL.
Conclusions: Preliminary findings indicate this mHealth SB intervention is feasible, acceptable, and can be clinically integrated during active maintenance therapy for eAYAs with ALL. Participants in early maintenance showed high adherence and engagement, suggesting the feasibility and benefit of SB intervention during active treatment for ALL and potential scalability to other types of cancer.

#3637 Improving therapeutic efficacy by targeting adenosine signaling in obese breast cancers.

Yueming Zhu, Amad Uddin, Xin Cui, Yong Wan

Emory Winship Cancer Institute, Atlanta, GA

Accumulated adipocytes in obese cancer patients significantly compromise therapeutic efficacy,yet the underlying mechanisms remain largely undefined. Here, we identify an OTUD4-driven proteolyticaxis as a critical regulator of immune suppression in obesity-associated triple-negative breast cancer(TNBC). Hyperactivation of OTUD4 enhances CD73-mediated adenosinergic signaling in cooperationwith TGF-β, establishing an immunosuppressive tumor microenvironment (TME) enriched with $TREM2^{+}APOE^{+}$ lipid-laden tumor-associated macrophages (LL-TAMs). This adenosine-rich niche promotes LL-TAM polarization toward a $CCL2^{+}$ $IL6^{+}$ efferocytic phenotype, collectively dampening cytotoxic T-cellactivity. Spatial and histologic analyses reveal regional co-expression of TGF-β, OTUD4, and CD73 withinimmune-suppressed tumor zones that spatially align with LL-TAM clusters. To therapeutically target thispathway, we developed W-DB53, a selective small-molecule inhibitor that disrupts the OTUD4-CD73interaction, depletes LL-TAMs, restores T-cell infiltration, and synergizes with immune checkpointinhibitors (ICIs) in obese TNBC models. These findings establish W-DB53 as a macrophage-remodelingprotein-protein interaction (PPI) inhibitor that reprograms efferocytosis and overcomes obesity-drivenimmune resistance in TNBC.

#3642 Capsaicin-nanoparticles sensitize human squamous cell lung cancer towards the growth-inhibitory activity of paclitaxel.

Amanda M. Sugrue, Kushal J. Modi, Reagan S. Light, Kaitlyn B. Conley, Sarah L. Miles, Piyali Dasgupta

Marshall University, Huntington, WV

Purpose of the Study: Squamous cell carcinoma of the lung (LUSC) develops in the central part of the lung, from cells lining the airways. It is characterized by rapid doubling time, aggressive clinical progression, and a dismal five-year survival rate. The first line treatment for LUSC includes a taxane with carboplatin and immunotherapy. The acquisition of resistance to paclitaxel is a major therapeutic challenge in human LUSCs. Several convergent studies show that nutritional phytochemicals can often improve the therapeutic response of chemotherapeutic drugs. The long-term objective of our laboratory is to identify dietary chemicals that may improve the anti-cancer activity of chemotherapeutic drugs. Our published data show that capsaicin (the spicy component of chili peppers) enhanced the pro-apoptotic activity of the chemotherapy drug camptothecin in human small-cell lung cancers. However, the feasibility of capsaicin as a potential anti-cancer drug is limited by its side effect profile. The administration of capsaicin produces heat sensation, GI irritation, stomach cramps, and nausea. A way to overcome these hurdles is to encapsulate capsaicin into sustained release polymeric systems. The objective of the present research project was to explore the combinatorial activity of Capsaicin [poly(lactic-co-glycolic acid)] nanoparticles (hereby called CAP-PLGA-NPs] and paclitaxel in human LUSCs.
Experimental Procedures: The pro-apoptotic activity of the combination of paclitaxel and CAP-PLGA-NPs was evaluated by Caspase-3 Activity Assays and Cell Death ELISA assays. We also determined the ability of the combination of paclitaxel and CAP-PLGA-NPs to inhibit anchorage-dependent growth using soft agar assay. Chou-Talalay isobologram analysis was used to determine whether the interaction between the two drugs was additive or synergistic.
Results: CAP-PLGA-NPs sensitized human LUSC cells towards the growth-inhibitory activity of paclitaxel
Conclusions: The administration of CAP-PLGA-NPs may enhance the growth-suppressive activity of paclitaxel in human LUSCs.

#3643 The combination of actinomycin D and resveratrol induces synergistic anticancer activities against aerodigestive tract cancers.

Raji M. Lukmon[1], Jihan F. Amin[2], **A.R.M. Ruhul Amin**[1]

[1]Pharmaceutical Sciences, Marshall University, Huntington, WV,[2]The Ohio State University, Columbus, OH

The practice of combining multiple drugs to increase pharmacological efficacy or reduce toxicity is widely adopted in cancer chemotherapeutics. Actinomycin D (Act D) is the first FDA-approved anticancer antibiotic. However, it's widespread application was hindered by severe dose-related toxicities. In the current study, we investigated the *in vitro* and *in vivo* anticancer efficacy of the combination of Act D with resveratrol, a natural dietary compound abundant in red grapes and wines. We found that the combination of Act D and resveratrol synergistically inhibited cancer cell growth *in vitro*. We also explored the underlying mechanism of this synergistic efficacy by investigating the activation of p53 pathway including the expression of p53 target genes *p21*, *PUMA* and *GDF15*. Consistent with the cell growth inhibition, Act D, resveratrol and their combination activated p53 and induced the expression of p21, PUMA and GDF15 mRNA and proteins. The combination had better effects than any of the single agent. Ablation of p53 expression by shRNA almost completely abolished the expression of p21, PUMA and GDF15 suggesting p53-dependent expression of these genes. Finally, we investigated the *in vivo* efficacy of these agents and their combination using MDA686TU (686TU) xenografts in nude mice. Although both Act D, resveratrol and their combination significantly inhibited the growth of xenografts, the combination did not have better effects when compared to single agent. The *in vivo* efficacy of these compounds was further supported by Ki-67 expression in tumor tissues. Taken together, our findings demonstrated that although the combination of Act D and resveratrol showed synergistic effects *in vitro*, the *in vivo* efficacy was not. Supported by P20GM103434 and R15DE032063.

#3644 Chromomycin A2 disrupts leukemia cell viability via integrated autophagic and apoptotic programs.

Keli Lima[1], Emilly O. Vieira[2], Rita C. Cavaglieri[1], Frederico L. Nogueira[1], Glaucia M. Machado-Santelli[2], Leticia V. Costa-Lotufo[2], Eduardo M. Rego[1], Joao A. Machado-Neto[2]

[1]Department of Internal Medicine, University of Sao Paulo, Sao Paulo, Brazil,[2]Department of Pharmacology, University of Sao Paulo, Sao Paulo, Brazil

Acute leukemias urgently require new therapeutic approaches due to high relapse rates and frequent resistance to standard treatments. Advances in molecular profiling have enabled more selective and less toxic strategies, especially for patients with poor prognosis. Chromomycins have emerged as potential agents because they bind GC-rich DNA regions, alter chromatin architecture, inhibit RNA polymerase, and suppress transcriptional programs essential for leukemic cell survival. Among them, chromomycin A2 remains largely unexplored in hematologic cancers despite reported activity in some solid tumors. We investigated chromomycin A2 in a broad panel of leukemia models. Twenty-two human blood cancer cell lines were analyzed (14 myeloid, 17 lymphoid), including resistant variants to venetoclax (n=2), quizartinib (n=1), and ATRA (n=1). Viability (MTT), apoptosis (annexin V/PI), and autonomous clonal growth in cytokine-free methylcellulose were evaluated. Ex vivo assays used primary AML (n=3) and ALL (n=3) samples. Molecular analyses included PCR arrays covering genes related to autophagy, apoptosis, DNA damage, and cell-cycle control, together with Western blotting. Statistical significance was defined as $p<0.05$. Chromomycin A2 reduced viability in all models in a dose-dependent manner (IC50: 0.40 - 4.42 nM). Resistant derivatives showed slightly higher IC_{50} values but remained sensitive. The compound induced time- and dose-dependent apoptosis and fully suppressed autonomous clonal growth at ≥5 nM. Early responses involved autophagy markers (LC3B-II accumulation, SQSTM1/p62 reduction), compatible with decreased transcriptional output and weakened survival signaling. With longer exposure, apoptotic markers (cleaved PARP1) and DNA damage (γH2AX) predominated. Gene expression data indicated a temporal sequence: activation of autophagy and cell-cycle arrest at 6 h, followed by apoptosis-related genes at 12 h. Enrichment analyses highlighted macroautophagy, mitochondrial apoptosis, and G1 DNA damage checkpoint pathways. In ex vivo assays, IC_{50} values ranged from 1.6 to 31.8 nM, with 81-92% efficacy in primary AML and ALL cells. Chromomycin A2 displayed strong antileukemic activity across in vitro and ex vivo models, including resistant subtypes. Its sequential induction of autophagy, apoptosis, and DNA damage suggests a multitarget mechanism. The inhibition of clonal growth indicates potential activity against leukemic stem/progenitor cells. These results support further preclinical development. Supported by FAPESP, CAPES, and CNPq.

#3646 Differential mechanisms of MCF-7 cytotoxicity by oleuropein and punicic acid and the role of oxidative stress and peroxiredoxin antioxidants.

Samantha Diiorio[1], Braden Quitmeyer[2], Shelley A. Phelan[1]

[1]Fairfield University, Fairfield, CT,[2]Histogenetics LLC, Ossining, NY

Many natural compounds have been shown to possess anticancer properties against breast cancer cells in vitro and/or in vivo, and there is increased interest in understanding the effects and mechanisms of action of such products as an alternative to traditional chemotherapy. Oleuropein is a polyphenolic compound derived from olive leaves that has demonstrated antioxidant and anticancer properties in breast cancer and other cancers. Punicic acid is a poly-5-unsaturated fatty acid found in pomegranate seeds that has also shown antioxidant and anticancer effects in various cancers. The MCF-7 cell line is an important model for estrogen receptor-positive (ER+) breast cancer which is useful for studying the effects and mechanisms of these natural products. We sought to compare oleuropein and punicic acid in this model and hypothesized that both would induce cytotoxicity in MCF-7 cells by increasing the oxidative stress and disrupting mitochondrial function. Cells were treated with 50 or 200 ug/ml oleuropein, 10 or 50 ug/ml punicic acid, or 70% ethanol as a control for 72 hours. Cytotoxicity was measured using an lactate dehydrogenase (LDH) release assay, and oxidative stress was assessed using the MitoSOX assay for mitochondrial ROS and malondialdehyde (MDA) quantification for lipid peroxidation. We found that oleuropein induced a significant increase in LDH release, and morphological changes consistent with apoptosis, but no significant increase in ROS. Punicic acid induced a dose-dependent increase in LDH release, and additionally led to an increase in mitochondrial ROS and lipid peroxidation. Since we previously reported significant induction of expression of the Peroxiredoxin antioxidant genes by both oleuropein and punicic acid in these cells, we also set out to examine the effects of Prdx suppression on susceptibility to these compounds. Using transient siRNA transfections targeting each of the six Prdx genes, we found that suppression of Prdx2, Prdx3, Prdx4 and Prdx5 significantly increased MCF-7 susceptibility to punicic acid, but not to oleuropein. Together, our data suggest that these compounds induce cytotoxicity through different mechanisms, with oxidative stress playing a major role in punicic acid-induced toxicity. Targeting peroxiredoxins may be an effective strategy for increasing breast cancer cell susceptibility to these compounds in future therapeutic applications.

#3647 Combining optimally synthesized quercetin analogs with BRAF inhibitors as a novel synergistic approach to treat melanoma.

Ahlam Armaly[1], Paige Toran[1], **Victoria Del Gaizo Moore**[2]

[1]Chemistry, Elon University, Elon, NC,[2]Pharmaceutical Sciences, High Point University, Fred Wilson School of Pharmacy, High Point, NC

The purpose of this research is to generate novel quercetin analogs to use in combination with vemurafenib as a more effective treatment for BRAF-mutated melanoma. Mutations that activate BRAF signaling are found in approximately half of melanoma patients and current clinical use of BRAF inhibitors are not considered curative as recurrence rates are still high. Furthermore, resistance to BRAF inhibitors can occur making the drug no longer effective. Quercetin is a common flavonoid small molecule found in many foods with known antitumorigenic activity. While quercetin has been heavily studied in various cancers, its clinical use is limited by its low bioavailability, most likely due to the presence of numerous phenol groups. We hypothesize that quercetin analogs with higher bioavailability would enhance its antitumorigenic properties, thereby increasing its synergistic potential with BRAF inhibitors.
There are two major stages of this research: 1. Making quercetin analogs, generation of BRAF-resistant melanoma cells, and analysis of base-line drug sensitivity and 2. Evaluation of synergistic drug combinations. First, we are using bio isosteric replacement to alter quercetin while maintaining desired biological functions. Numerous studies have focused on altering the phenol groups on quercetin to improve functionality, including methods to convert the phenol to less polar groups that can improve bioavailability and anticancer properties of the analogs. The novelty of these proposed analogs is introducing fluorinated phenol bio isosteres. Initial small-scale synthesis reactions have been run using a diethyl (bromodifluoromethyl)phosphonate reaction with commercially bought quercetin followed by column chromatography, which generated 2-3 products with several phenols functionalized with fluorine. Currently, those fractions are being further purified via additional chromatography, and then specific compounds will be identified using IR-spectroscopy, mass spectrometry, and H1-NMR. Drug sensitivity methods have also been established using CellTitre Glo 2.0 (Promega). Consistent with previously published results, the IC_{50} for Doxorubicin-HCl on SK-Mel28 cells is ~1uM. Resistance cells are currently being generated through short-term exposure of SK-Mel28 cells to 20uM vemurafenib. Next, cells will be chronically grown in a low concentration drug.
During stage 2, the synthesized quercetin analogs +/- vemurafenib will be tested on both untreated and vemurafenib-resistant melanoma cells. These experiments will examine the potential synergetic effects of these novel combinations while maximizing the clinical relevance to patients with BRAF-mutated melanoma by potentially mitigating the risk of high doses and prolonged use of vemurafenib.

#3648 Luteolin inhibits DNA methyltransferase 1 and alpha 6-integrin gene expression to suppress proliferation and stemness in breast cancer cells from patients of West African ancestry.

Michael H. Hall[1], Mya St. Louis[2], Ozichi Amobi[1], John Olanrewaju[3], Shawneee Angeloni[1], Ubaldo Soto[1], Eileen Brantley[1]

[1]Loma Linda University, Loma Linda, CA,[2]Oakwood University, Huntsville, AL,[3]Babcock University, Ilishan-Remo, Nigeria

Breast cancer mortality remains disproportionately high among women of West African (WA) ancestry, a disparity influenced in part by biological differences that shape how tumors behave and respond to treatment. We evaluated the ability of luteolin (a naturally occurring flavonoid) to confer anticancer actions in breast cancer cell lines from patients of WA and European ancestries. In estrogen receptor-positive (ER+) breast cancer cells, including those resistant to the anti-estrogen fulvestrant and triple-negative breast cancer (TNBC) models, luteolin reduced proliferation and impaired mammosphere formation. Our data suggest that luteolin can provide an alternative or complementary approach to treat breast cancer, irrespective of subtype. Notably, breast cancer cells from patients of WA ancestry demonstrated heightened sensitivity to luteolin's antiproliferative and anti-stemness effects, suggesting potential ancestry-related therapeutic vulnerabilities. Because the elevated stemness-associated molecules DNA methyltransferase 1 (DNMT1) and alpha-6 integrin (ITGA6) are both linked to poor outcomes and disease aggressiveness, we examined their regulation following luteolin treatment. Luteolin decreased the expression levels of DNMT1 and ITGA6. These findings suggest that luteolin and other natural products have the potential to help thwart drivers of aggressive breast cancer and improve breast cancer survival among patients of West African ancestry.

#3649 High-throughput screening of natural products discovers inhibitors of ribosome biogenesis.

Garrett Kimble[1], Michael Buszczak[2], Mark J. Henderson[3], Vincent Tagliabracci[2], Monagna Jarajapu[1], Bruce Posner[2], Barry R. O'Keefe[4], Sara Sanders[3]

[1]UTSW, Dallas, TX,[2]UT Southwestern Medical Center, Dallas, TX,[3]National Center for Advancing Translational Sciences(NCATS), Rockville, MD,[4]National Cancer Institute, Bethesda, MD

Cells must double their ribosome abundance every cell cycle. Thus, cancer cells have a high demand for ribosomes to match their high proliferation rate. For this reason, ribosome biogenesis has become an alluring target for cancer interventions. As the result of an evolutionary arms race, nature has produced a rich source of bioactive molecules and thus screening natural product fractions presents an opportunity to discover novel compounds that target ribosome biogenesis. In collaboration with the NIH's National Center for Advancing Translational Science (NCATS) we have screened the NCI's natural products library for inhibitors of ribosome biogenesis using a ribosome biogenesis reporter system called RiboSNAP. The RiboSNAP reporter incorporates a SNAP tag on an endogenous ribosomal protein that can be covalently labeled with fluorescent substrates in live cells. Substrates can then be washed out leaving newly synthesized SNAP tagged protein free for subsequent labeling with different substrates to distinguish between old and new ribosomes. This allows for the tracking of newly produced ribosomes from the nucleolus to the cytoplasm as a readout for ribosome biogenesis. Inhibitor discovery is predicated on the finding that inhibition of ribosome biogenesis throughout the pathway results in retention of newly translated SNAP tagged RPL28 protein in the nucleolus and/or nucleus. Previous work by our group and others has determined that nucleolar morphology serves as an indicator of ribosome biogenesis inhibitor mechanism of action and therefore different puncta morphologies indicate the inhibition of different targets. This image-based analysis suggests our screening efforts have identified not only inhibitors of rRNA transcription, but also rRNA processing and ribosome maturation. Once screening is complete, our efforts will shift towards purification of the active compounds and target identification to further our understanding of how ribosome biogenesis responds to perturbations and to develop cancer interventions. (This work was supported by 5UG3CA290312-01)

#3650 Evaluating the immunomodulatory role of celastrol in murine acute graft versus host disease after allogeneic hematopoietic stem cell transplantation.

Tara Chand Yadav[1], Yogamaya Divakar Prabhu[1], Vasantharaja Raguraman[1], Shanid Mohiyuddin[1], Venkatesh Rajamanickam[2], Ibrahim Mohammed[3], Deepthi Rao[3], Gerhard C. Hildebrandt[1], **Senthilnathan Palaniyandi**[1]

[1]Department of Medicine, Hematology and Medical Oncology, University of Missouri - Columbia, Columbia, MO,[2]Earle A. Chiles Research Institute, Providence Cancer Institute, Portland, OR,[3]Department of Pathology and Anatomical Sciences, University of Missouri - Columbia, Columbia, MO

Introduction: Allogenic hematopoietic stem cell transplantation (HSCT) is used to treat various hematological malignancies. Graft versus host disease (GVHD) is a serious complication arising after HSCT and acts as a major limiting factor of bone-marrow transplantation. Acute GVHD (aGVHD) primarily targets the gastrointestinal tract, skin, and liver, driven by alloreactive T-cells. We hypothesize that Celastrol, a bioactive triperpenoid possessing anti-inflammatory and anticancer properties, can mitigate aGVHD symptoms.

Methods: A well-defined murine aGVHD MHC-mismatched model was used, recipient (C57BL/6) mice received total body irradiation of 850 cGy and received bone marrow and splenocytes from either C57BL/6 (syngeneic) or BALB/c (allogeneic). They were then treated with Celastrol (2mg/kg) or vehicle control from day 1. On day 7, the animals were scored for clinical GVHD, euthanized, and their organs were collected for further analysis. The gut and colon pathology score was evaluated to assess inflammation, apoptosis, and disease severity.

Results: The clinical GVHD score showed a significant reduction in disease burden ($p < 0.0001$) in celastrol-treated mice compared to the allogenic control. The colon pathology scores also showed a significant decrease in gut injury in celastrol-treated ($p < 0.01$) mice compared to allogenic control. To assess the anti-inflammatory effect of Celastrol, we performed CD3+ staining of colon tissue, which showed significantly reduced ($p < 0.05$) T-cell infiltration in Celastrol-treated mice compared to allogenic control. A significant reduction in TUNEL-positive apoptotic cells ($p < 0.01$) was observed in the Celastrol-treated mice compared to allogenic recipients. To further validate and identify the pathways involved in pathophysiology, we performed RNASeq analysis. RNA-seq analysis of the colon identified differentially expressed genes (972 upregulated; 536 downregulated) between the Celastrol-treated and allogenic control group. Furthermore, gene set enrichment analysis revealed significant downregulation of genes Mpeg1, Lyz2, CX3CR1, Laptm5, and Pld4, which are relevant to the involvement of GM-CSF in the Celastrol-treated group. This suggests that GM-CSF-driven alloantigen presentation in the gut is reduced, thereby alleviating GVHD symptoms.

Conclusion: Celastrol acts as an anti-inflammatory immunomodulator, attenuating alloreactive immune cell-mediated injuries and protecting gut barrier integrity in aGVHD after hematopoietic stem cell transplantation.

#3651 Carnosic acid induces ROS and activates ASK1 signalling in NSCLC cells.

Eric J. O'Neill, Evangelia Tsiani

Health Sciences, Brock University, St. Catharines, ON, Canada

Carnosic acid (CA), a phenolic diterpene found in rosemary (*Rosmarinus officinalis*), has demonstrated anticancer activity in multiple tumor models; however, its mechanisms in non-small cell lung cancer (NSCLC) remain poorly defined. Many polyphenols exert biological effects through reactive oxygen species (ROS) generation and activation of apoptosis signal-regulating kinase 1 (ASK1)-mediated signalling, prompting this investigation into the role of ROS and ASK1 in the actions of CA. Cell viability was measured in NSCLC cells (H1299, A549, H460), and normal lung fibroblasts (MRC-5) following 48-hour CA treatment using the MTT assay. Migration of H1299 cells was assessed by scratch assay. ROS generation was quantified using dichlorodihydrofluorescin diacetate (DCFDA) fluorescence, and protein expression and activation were evaluated by western blotting and immunocytochemistry. CA decreased cell viability in a dose-dependent manner across NSCLC cell lines with IC_{50} in the micromolar range; H1299 showed the greatest sensitivity. In MRC-5 fibroblasts, maximal inhibition reached only ~50% of control compared with complete inhibition of growth observed in the NSCLC cell lines. In H1299 cells, CA significantly impaired wound closure after 24 hours, comparable to inhibition by paclitaxel. CA increased intracellular ROS levels and activated the antioxidant response pathway, evidenced by nuclear accumulation of nuclear factor erythroid 2-related factor 2 (Nrf2) and upregulation of heme oxygenase-1 (HO-1). Western blotting demonstrated activation of ASK1 and downstream mitogen-activated protein kinases (MAPK), including extracellular signal-regulated kinase (ERK), c-Jun N-terminal kinase (JNK), and p38. Pretreatment with N-acetylcysteine (NAC) attenuated CA-induced cytotoxicity, supporting a role for ROS in mediating these effects. In summary, carnosic acid inhibits viability and migration of NSCLC cells while partially sparing normal lung fibroblasts. Its effects involve ROS generation and activation of ASK1-dependent MAPK signaling. These findings provide mechanistic insight into the anticancer potential of CA in lung cancer. Future work will evaluate CA using an *in vivo* tumor xenograft model.

#3652 Thymoquinone blocks pancreatic ductal adenocarcinoma growth by altering novel circRNAs and miRNAs.

Bin Bao[1], Irfana Muqbil[2], Md Hafiz Uddin[1], Yang Shi[1], Yin Wan[1], Adeeb Aboukameel[1], Ramzi M. Mohammad[1]

[1]Oncology, Barbara Ann Karmanos Cancer Institute, Detroit, MI,[2]Lawrence Tech University, Southfield, MI

Pancreatic ductal adenocarcinoma (PDAC) is projected to become the second leading cause of cancer-related deaths worldwide underscoring the urgent need for the identification of novel therapeutical strategies. Circular RNAs (circRNAs) are a sub-group of small non-coding RNAs with a closed loop structure generated by back splicing of RNAs which play a significant role in the regulation of transcriptional and post-transcriptional processes of many genes. Altered regulations of circRNAs result in tumorigenesis and progression of a wide variety of tumors. To date there are no studies that have evaluated whether circRNAs could be modulated using natural agent derivatives for therapeutic benefit. The objective of this study is to identify tumor associated circRNAs and miRNAs modulated by black seed derivative *Nigella sativa* thymoquinone (TQ) in PDAC models. Methods: circRNA-seq, RNA pull-down, cell viability, RT-qPCR, CSC sphere formation, colony formation assays and miRNA transfection technique. TQ treatment resulted in the downregulation of PDAC-oncogenic circRNAs, along with the inhibition of cell growth, CSC self-renewal capacity, and clonogenic capacity. RT-qPCR showed that TQ suppressed the expression of 5 of the sequencing identified circRNAs (hsa_circ_0054853, hsa_circ_0012152, hsa_circ_0001495, hsa_circ_0006877, and hsa_circ_0000567) that were inherently elevated in PDAC and not in normal cells. CircR-0054853 was found to bind to specific tumor suppressor miRNAs, miR-1248 and miR-1287. The forced-expressions of these miRNAs result not only in the inhibition of cell growth but increased the sensitivity to TQ in PDAC cells as TQ treatment increased expressions of these miRNAs. These findings suggest that circR-0054853 may act as an oncogenic circRNA by sponging tumor-suppressive miRNAs, thereby promoting PDAC growth, a process that can be reversed by TQ. Notably, circR-0054853 contains 22 binding sites for AGO2, and RNA immunoprecipitation assays confirmed that its binding to AGO2 was downregulated by TQ. We also found that TQ significantly increased the efficacy of gemcitabine/nap-paclitaxel or pan Kras inhibitor RMC6236 in Kras mutant PDAC in vitro and animal models. The co-treatment of TQ with RMC6236 showed a remarkable combination effect on EZH2 and REK/MEK pathway in Kras mutant cells. In conclusion, for the first time we report that TQ has anti-tumor activity and exerts its inhibitory effects on tumor-associated cell signaling through the regulations of circRNAs, miRNAs and RBP interactions that warrants further pre-clinical and clinical investigations.

#3653 Screening of natural products library against 5-lipoxygenase (5-LOX) and mPGES1 proinflammatory targets for CRC interception.

Krishnendu Goswami[1], Nataliya Smith[2], Ravi Manjhi[2], Gopal Pathuri[1], Brandon Somerville[3], Yurong Song[3], Venkateshwar Madka[1], Kajal Biswas[4], Altaf Mohammed[4], Robert H. Shoemaker[4], Matthew J. Hart[2], **Chinthalapally V. Rao**[1]

[1]Center for Cancer Prevention and Drug Development, Stephenson Cancer Center, Department of Medicine, University of Oklahoma HSC, Oklahoma City, OK,[2]Center for Therapeutic Science, Department of Biochemistry and Physiology, University of Oklahoma HSC, Oklahoma City, OK,[3]Frederick National Laboratory for Cancer Research, Frederick, MD,[4]Division of Cancer Prevention, Chemopreventive Agent Development Research Group, National Cancer Institute, Rockville, MD

Colorectal Cancer (CRC) remains the leading cause of cancer-related mortality worldwide. Inflammation is a key hallmark of many cancers, including CRC. Pro-inflammatory lipid mediators play a key role, while COX-2 inhibiting NSAIDs are promising, their chronic use is linked with unwanted side-effects. In this context, mechanistic studies suggest that targeting microsomal prostaglandin synthase-1 (mPGES-1) and 5-lipoxygenase (5-LOX) with natural products (NP) presents a valuable opportunity to intercept CRC and mitigate those side effects. Here we aimed to perform high-throughput screening (HTS) of NCI NPs library (~500,000 semi-purified fractions) to identify potential inhibitors of 5-LOX and mPGES1; and further validate the purified compounds using secondary assays. To establish the enzyme activity inhibitory assays, first we developed a stable Human Embryonic Kidney (HEK) 293 cell lines with mPGES-1 and 5-LOX overexpression as well as 5-LOX overexpressing insect cells. Proteins expression was confirmed using western blotting. Lysates from human 5-LOX expressed in Sf9 insect cells and HEK-293 cells, were used to generate an assay format in 384-well microplates suitable for HTS. In this assay format, lysates are preincubated with inhibitors for 20 minutes, stimulated with arachidonic acid (AA) for 5 minutes. The production of free radicals, as a result of the conversion of AA to 5HPETE and LTA4 by 5-LOX activity, is detected upon the addition of 2',7'-dichlorodihydrofluorescein diacetate (H2DCFDA). The non-fluorescent H2DCFDA when oxidized by the free radicals, generates a highly fluorescent compound, which can be measured to quantify enzyme activity. The reaction was stopped after 15 minutes upon the addition of acetonitrile. Finally, enzyme activity was calculated by measuring "total relative fluorescence units (RFU) at 485-nm excitation and 530-nm emission spectra. The assay has been optimized using a final volume of 15ul and has a Z' Factor score of 0.65 and a S/B of 3.5 in 384-well microplates. The 5-LOX activity was completely inhibited by 20uM NDGA, a known inhibitor of 5-LOX. Additionally, a pre-plated NCI library of semi-purified NP fractions (5mg/ml stock in DMSO) has been assessed to validate the assay and identify potential fractions that demonstrate 5-LOX inhibitory activity. The fractions with the most promising activity based on this evaluation will be presented at the meeting. We have also optimized the mPGES1 activity assay using HEK293 cell line overexpressing COX2 and mPGES-1. In this assay format, treatment with AA results in elevated levels of PGE2, as detected in a PGE2 HTRF assay. In summary, these optimized assays will be employed for large scale robotic HTS of NCI NP library to discover and develop safer inhibitors of proinflammatory targets mPGES1 and 5-LOX for intercepting inflammation associated cancers. (Funded by NCI-UG3CA290310-01).

#3654 Plant-derived exosomes from black soybeans for combatting pancreatic and colon cancer cells.

Zhangzhu Ruixian[1], Makiko Nakahana[1], Yasuyuki Shimizu[1], Mohammed Salah[2], Hiroaki Akasaka[1], Hiroki Kawaguchi[1], Tomoya Ishida[1], Qin Qin[3], Qu Zhang[4], Takeaki Ishihara[1], Daisuke Miyawaki[1], Ryohei Sasaki[1]

[1]Radiation Oncology, Kobe University Graduate School of Medicine, Kobe, Japan,[2]Biochemistry, Faculty of Veterinary Medicine, Qena University, Qena, Egypt,[3]Radiation Oncology, Nanjing Medical University First Affiliated Hospital, Jiangsu Province Hospital, Nanjing, China,[4]Radiotherapy Center, Tongji Medical College, Hubei Cancer Hospital, Huazhong University of Science and Technology, Wuhan, China

Background: Plant-derived dietary exosomes are biocompatible granular vesicles that are considered safe and have been increasingly reported to exert beneficial effects on the human body. We independently developed a novel method for isolating food-derived exosomes from black soybeans and demonstrated their therapeutic efficacy against pancreatic and colon cancer cells.
Materials and methods: We developed a technique to efficiently isolate exosomes from freshly harvested black soybean pods. The size and morphology of the exosomes were evaluated using nanoparticle tracking analysis and transmission electron microscopy (TEM). The antitumor effects were evaluated by assessing the cell proliferation inhibitory effects using WST/MTT assays with human pancreatic cancer MIAPaca-2 and human colon cancer HCT116 cells. The efficacies of different exosome conditioning methods, such as freezing, boiling, boiling in salt, or immediate extraction, were compared in terms of their cell proliferation inhibitory effects. The radiosensitizing effects were also investigated using a colony-forming assay. The extent and frequency of DNA damage were determined using γH2AX staining, a marker for DNA damage, between four groups: control, black soybean exosomes alone, radiation alone, and a combination of both.
Results: The mean size of the exosomes was less than 200 nm. Absorption of the exosome were observed in very high frequency in MIApaca-2 cells. The exosomes obtained from approximately 20 black soybeans exhibited much higher tumor growth inhibitory effects than the solution of black soybeans without exosomes. The exosomes also showed radiosensitizing effect in response to 6 Gy of ionizing radiation.
Conclusions: These findings together represent that the plant-derived dietary exosomes from black soybeans may have potential to be a novel strategy for cancer cell growth inhibition and radiosensitization.

#3655 Dose-dependent anti-proliferative activity of a bioactive hemp-derived extract REPYR-SC1 against prostate cancer.

Joel Costoya[1], Joaquin J. Jimenez[2]

[1]Department of Biochemistry and Molecular Biology, University of Miami Miller School of Medicine, Miami, FL,[2]Dr. Phillip Frost Department of Dermatology and Cutaneous Surgery, University of Miami Miller School of Medicine, Miami, FL

In the US approximately 1 in 8 men are diagnosed with prostate cancer, and metastatic cases account for the majority of prostate cancer-related mortality. Prostatic cancer is the second leading cause of cancer death in men, harboring a 32% 5-year survival rate. Current treatments utilize a combination of androgen deprivation therapy, androgen signaling receptor inhibitors and chemotherapy. Despite these improvements, castration-resistance and chemotherapy resistance remain a significant obstacle to sustained remission and signify a need for novel therapeutic approaches. Immunotherapies and the discovery of new anti-neoplastic agents are current modalities of considerable interest. We explore the use of REPYR-SC1, a novel hemp extract, as an anti-cancer, immunomodulatory agent following the pre-clinical evidence demonstrating anti-neoplastic efficacy of cannabinoid derivatives and their potential immunoactivity. C4 cells were used to model prostate cancer, HPrEC prostate epithelial cells as a non-cancerous control, and CTLL-2 cytotoxic T lymphocytes were chosen as a quantifiable measure of immunomodulatory capability. REPYR-SC1 was administered at 0, 0.1, 0.5, 1, and 5 µL/mL and cultured with C4, HPrEC and CTLL-2 cells for 24 and 48 hours. Morphological assessment was performed by light microscopy, pre- and post-treatment. Subsequent to this manual cell counts were performed pre-and post-treatment, followed by trypan blue exclusion assay. Only viable cells were included in the cell count. REPYR-SC1 produced a significant dose- and time-dependent reduction in proliferation ($p<0.001$) in prostate cancer C4 cells and CTLL-2 cells. At a dose of 1 and 5 µL/mL at the 24- and 48-hour mark, full inhibition of proliferation was observed in C4 cells. HPrEC cells showed minimal susceptibility with 20% inhibition observed for 5 µL/mL at 48 hours. CTLL-2 cells showed significant susceptibility with complete inhibition of proliferation observed at a dose of 1 and 5 µL/mL at 48 hours. REPYR-SC1 exhibited measurable immunomodulatory effects against T-lymphocytes in vitro, and selective anti-neoplastic activity versus prostate cancer cells. In conclusion, REPYR-SC1 demonstrated evidence of potential for prostate cancer inhibition and warrants further investigation.

#3656 A-ring analogs of Andrographolide inhibit wnt1 signaling and exhibit potent anticancer activity in breast and colorectal cancer models.

Rushika Raval[1], Selina Xi[1], Ruirui Liu[1], Abigail Yee[1], Aileen Pak[1], **Edward Njoo**[1], Gary Johanning[2], Feng Wang-Johanning[2]

[1]Chemistry, Aspiring Scholars Directed Research Program (ASDRP), Fremont, CA,[2]SunnyBay Biotech, Fremont, CA

The natural product andrographolide, a labdane diterpenoid extracted from the plant Andrographis paniculata, has been extensively studied as an anticancer therapeutic, and is putatively known to function through covalent inhibition of NF-kB: a transcription factor at the crossroad of a myriad of cell signaling pathways that modulate tumor survival and metastasis. Functionalization of the C-19 hydroxyl has been shown to alter the primary mode of action from inhibition of NF-kB to modulation of the Wnt/β-catenin signaling pathway. With a systematic series of 12 silyl and trityl ether analogs of Andrographolide, we evaluated their antiproliferative activity in MDA-MB-231 (triple-negative breast cancer), MCF-7 (metastatic breast adenocarcinoma), HCT-116 (human colorectal carcinoma), and HT-29 (colorectal adenocarcinoma) cell lines. These compounds displayed greater potency than the parent compound, andrographolide. We observe unique potency in HCT-116 with the chloro butyl analog (IC 50 = 0.32μM; 24 hr), and the chloro trityl analog (IC50 = 7.32μM; 24 hr). In MDA-MB-231, the chloro butyl analog exhibits an IC50 of 10.11 μM, and chloro trityl exhibits an IC50 of 2.88 μM. Trityl ether analogs in an NF-kB SEAP reporter cell experiment show inhibition of SEAP expression in a dose dependent fashion. Additionally, upon administration of trityl ether analogs, in a Wnt/β-catenin reporter cell assay, we observe decreased luciferase expression at 10 μM. After investigating the activities of this series of compounds in connection to NF-κB and β-catenin inhibition, two putative mechanisms of action previously reported as the cellular targets of andrographolide or its analogs, we find that subtle modifications to C-19 functionalization can greatly affect the in vitro biological profile of these compounds. Notably, the trityl analog displayed significant inhibition of SEAP-coupled NF-κB activity, and diminished antiproliferative activity with coadministration of CHIR99021 compared to the TPS (triphenylsilyl) analog with the only difference being the single substitution of a carbon to a silicon atom. This study underscores the potentially complex polypharmacology of andrographolide and its analogs and highlights the importance of further examination of the lead compounds from this work in other analogous *in vitro* and *in vivo* cancer cell models.

#3657 Preclinical discovery of proscillaridin A glycan analogs for the *in vitro* and *in vivo* treatment of solid tumors.

Shreya Somani[1], Lekhya Menta[1], Gary Johanning[2], Feng Wang-Johanning[2], **Edward Njoo**[1]

[1]Aspiring Scholars Directed Research Program (ASDRP), Fremont, CA,[2]SunnyBay Biotech, Fremont, CA

Cancer persists as one of the leading causes of mortality in the US, accounting for over 2 million new cases and 611,000 deaths in 2024. In parallel, several small-molecule drugs are currently in development for the treatment of malignancies. Within those, natural products, their synthetic analogs, or other derivatives, account for about 50% of all FDA-approved anticancer small molecules. Several naturally-derived cardiac glycosides, including digoxin, digitoxin, and proscillaridin A, have been originally identified as cardiomyocyte modulators and are currently being investigated for their anti-cancer properties. These cardiac glycosides are generally classified into cardenolides and bufadienolides, which bear butenolide and pyrone D-ring functionality, respectively, and have exhibited remarkable in vitro toxicity in various cancerous cell lines. As simple modifications on steroidal small molecules have demonstrated success in augmenting bioavailability or enhancing downstream biological activities, we sought to prepare synthetic analogs of proscillaridin A, a bufadienolide isolated from the genus Scilla. We synthesized five analogs of proscillaridin A bearing acetate esters, silyl ethers, or dimethyl ketals to investigate how ketalization, acetylation, and/or silylation of the A-ring allylic glycoside might alter its anti-cancer properties. The antiproliferative activity of these compounds was evaluated alongside proscillaridin A and two model cardiac glycosides — digoxin and digitoxin — across several breast, colorectal, liver, and ovarian cancer cell lines. Through a diverse panel of cell viability and cytotoxicity experiments, reporter assays, and cell cycle and protein marker analysis by flow cytometry, we find that ketalization of the glycan of proscillaridin A provides similar, and in some cases enhanced, in vitro potency. Subsequently, to evaluate the preclinical applicability of these compounds in inhibiting solid tumor growth, we found that direct, intraperitoneal injection of proscillaridin A and its analogs demonstrated reasonably potent antitumor activity in a murine mammary cancer model, albeit with dose-limiting ADMET properties. This study establishes the foundation for further in vitro and in vivo evaluations of cardiac glycosides for the treatment of cancer.

#3658 C-4 analogs of podophyllotoxin inhibit tubulin polymerization: A generalizable platform for the discovery of antimitotic therapeutics for cancer.

Shreya Somani[1], Stella Yang[1], Lekhya Menta[2], Yining Xie[1], Anna Gribok[1], Evy Hsen[1], **Edward Njoo**[1], Gary Johanning[3], Feng Wang-Johanning[3]

[1]Chemistry, Aspiring Scholars Directed Research Program (ASDRP), Fremont, CA,[2]Aspiring Scholars Directed Research Program (ASDRP), Fremont, CA,[3]SunnyBay Biotech, Fremont, CA

Antimitotic agents, such as podophyllotoxin and its derivatives, act through a ubiquitous mechanism of action by targeting the most fundamental mechanisms of cell division, and have demonstrated broad clinical potential as anticancer therapeutics. Given the pharmacological importance of the C-4 hydroxyl on podophyllotoxin, we sought to establish a structure-activity relationship between chemical modification and in vitro potency. We previously reported that increased C-4 sterics of podophyllotoxin esters have minimal effect on cell-free tubulin polymerization, yet decrease in vitro potency against human colon cancer cells. In this study, the antiproliferative activity of 26 novel carbonate, carbamate, and silyl ether podophyllotoxin analogs was evaluated for inhibition of in vitro cell viability, cell cycle arrest, cell-free tubulin polymerization, immunofluorescence imaging, and docking models. In human and murine colorectal cancer (HCT-116, HT-29, CT-26), lung cancer (A549, Calu-1), triple-negative breast cancer (MDA-MB-231 P), liver carcinoma (Hep G2), ovarian adenocarcinoma (SK-OV-3), and embryonic kidney cells (HEK-293), the carbonate analogs exhibited greater antiproliferative activity when compared to their carbamate counterparts, while the silyl ether analogs performed the poorest. Most notably, the t-butyl carbonate exhibited the most potent activity with IC50 at or below single digit nanomolar ranges, while the carbamates exhibited IC50 values greater than 42 nM. Correspondingly, the most potent analogs also exhibited potent cell cycle G2/M arrest by flow cytometry, with t-butyl carbonate causing arrest to the greatest percentage (69.2%), affirming tubulin inhibition as the primary mechanism of action. However, those differences were not reflected in the cell-free biochemical assay, where the best carbonates and carbamates showed similar percentages of tubulin inhibition (85.78% and 85.28% respectively), and no correlation was observed between C-4 substituent and tubulin inhibition. Additionally, in silico modeling revealed a minimal difference in each analog's binding affinity, providing further evidence that C-4 functionalization does not directly alter a compound's ability to bind to tubulin. Collectively, our results suggest that absolute binding to tubulin is not the primary determinant of biological activity for C-4 analogs of podophyllotoxin across a broad panel of cancer cell lines, and that the impact of structural changes at C-4 on biological potency is agnostic to logP and steric bulk. Altogether, the structure-activity relationship described enables future development of podophyllotoxin-based antimitotic agents for cancer.

#3659 Heterogeneous expression and cancer-selective regulation of endogenous membrane TRAIL by quercetin across various human cancer cell lines.

Erin Marie Thorpe[1], Candece L. Gladson[2], Michael Kalafatis[1], Center for Gene Regulation in Health and Disease (GRHD), Cleveland State University, Cleveland, OH,

[1]Chemistry, Cleveland State University, Cleveland, OH,[2]Department of Cancer Biology, Cleveland Clinic, Cleveland, OH

We have recently shown that several human glioblastoma cell lines (M059K, T98G, A172), as well as normal human astrocytes, possess endogenous tumor necrosis factor-related apoptosis-inducing ligand (TRAIL). In addition, we demonstrated that the flavonoid quercetin promotes the trafficking of endogenous membrane TRAIL (mTRAIL) to the plasma membrane in glioblastoma cells, where it can interact with death receptors already present on the surface of neighboring cancer cells and trigger apoptosis through both the extrinsic and intrinsic pathways. In contrast, although normal human astrocytes also express endogenous mTRAIL, quercetin treatment did not enhance its trafficking to the plasma membrane or induce apoptosis. Together, these observations suggest that quercetin selectively activates mTRAIL-mediated apoptosis in cancer cells but not in normal cells (*Thorpe et al., Cancers* 2025, 17, 3197; https://doi.org/10.3390/cancers17193197). The present study explores whether mTRAIL expression and responsiveness to quercetin extend across a broader spectrum of human cancer and non-malignant cell lines. Western blotting and flow cytometry were used to evaluate mTRAIL expression in a panel of human cancer and normal cell lines, including breast cancer (MCF-7, BT-20, HCC1937), melanoma (A375, MeWo, WM164), Burkitt lymphoma (RA-1, DG-75, Daudi), normal fibroblasts (08398), and additional models currently under investigation. Endogenous mTRAIL was detected in several malignant and non-malignant lines, including MCF-7, HCC1937, A375, RA-1, Daudi, and 08398 fibroblasts, but was absent in BT-20, MeWo, WM164, and DG-75. In RA-1 and A375 cancer cells, flow cytometry further confirmed that quercetin treatment increased cell-surface mTRAIL in a concentration-dependent manner, resulting in apoptosis. Collectively, including data from our previously published findings, endogenous mTRAIL expression was detected in 8 of 12 human cancer cell lines (67%) and in all 3 non-transformed cell lines (100%), indicating that expression may vary among cancer cell lines but appears to be consistent in normal cells. Overall, these findings support a role for quercetin in promoting mTRAIL trafficking and presentation at the plasma membrane, ultimately resulting in the demise of neighboring cancer cells. Ongoing studies aim to elucidate the functional significance of endogenous mTRAIL expression across various cell types and to define the molecular mechanism by which quercetin promotes mTRAIL trafficking to the plasma membrane of malignant but not normal cells, with the goal of establishing its potential therapeutic relevance across different cancer types.

#3660 Network pharmacology reveals functional components and molecular mechanisms of andrographis combined with lactoferrin in pancreatic cancer treatment.

Yuan Li[1], Wenhao Weng[2], Ajay Goel[1]

[1]Beckman Research Institute of City of Hope, Monrovia, CA,[2]Shanghai Children's Hospital, School of Medicine, Shanghai, China

Background: Pancreatic cancer (PC) remains the most lethal malignancies, underscoring the need for novel therapeutic strategies. Natural plant-derived bioactive compounds have garnered increasing attention as potential anticancer agents due to their safety, affordability, and ability to target multiple pathways regulating cellular growth. Network pharmacology has emerged as a powerful approach to elucidate the multi-target and multi-pathway mechanisms of various bioactive compounds, offering theoretical insights into their synergistic therapeutic potential in complex diseases. Among natural agents, Andrographis (Andro) and Lactoferrin (Lf) have shown potent anticarcinogenic properties. However, their potential synergistic interactions and the underlying mechanisms remain largely unexplored.

Methods: In this study, we investigated the synergistic anticancer effects of Andro and Lf on PC cell lines (MIA-PaCa-2 and BxPC-3), and explored growth-regulatory pathways underlying their combined activities. Cell viability, migration, and invasion assays were performed to evaluate the antiproliferative and anti-invasive activities. Using Network pharmacology and pathway enrichment analyses, we further identified key targets and signaling pathways associated with the synergistic effects of these two compounds in PC. Subsequently, the findings from cell-culture experiments were validated using patient-derived 3D tumor organoids.

Results: The combined treatment with Andro and Lf demonstrated marked synergistic anti-tumor activity, significantly suppressing cell viability, proliferation, migration, and invasion in PC cells. Network pharmacology identified 13,778 disease-related targets and 164 putative drug targets, with 148 overlapping targets between PC and the combination treatment were deciphered. Notably, AKT1 emerged as a central node, indicating strong associations between PC progression and the pharmacological activity of Andro and Lf. Pathway enrichment analyses further indicated that the synergistic effects of the combination were predominantly linked to the PI3K-AKT signaling pathway (P<0.05) and accompanied by a significant reduction in intracellular calcium levels. Consistently, AKT1 expression was significantly higher in PC tissues compared with normal tissues in the TCGA dataset (FC = 1.24, P<0.05). Finally, in 3D organoid models, the combined treatment showed stronger anticancer activity, significantly reducing organoid number and size (P<0.05), highlighting its therapeutic potential.

Conclusion: Our study provides evidence that the synergistic anticancer effects of Andro and Lf in PC are mediated via the PI3K-AKT signaling pathway and modulation of intracellular calcium levels, highlighting their promise as a combinatorial therapeutic strategy.

#3661 Discovery of Spondias mombin flavonoid rutin as a novel DNA methyltransferase 1 inhibitor and potential agent to treat triple negative breast cancer in patients of West African ancestry.

Afees John Olanrewaju[1], Elyssa Fraser[2], Joseph Enya[3], Leviticus Arietarhire[3], Ezekiel Olugbogi[4], Toluwanimi Afolabi[5], Oladimeji Soremekun[1], Michael Hall[2], Ozichi Amobi[2], Victor Chinedu[2], John Khalaf[6], Jonathan De Anda[7], Shawnee Angeloni[2], Ubaldo Soto[6], Eileen J. Brantley[8]

[1]Anatomy, (Eureka Research Lab), Babcock University, Ilishan-Remo, Nigeria,[2]Basic Science, Loma Linda University Health, Loma Linda, CA,[3]Anatomy, Babcock University, Ilishan-Remo, Nigeria,[4]Biochemistry, Babcock University, Ilishan-Remo, Nigeria,[5]Anatomy, Olabisi Onabanjo University, Ilishan-Remo, Nigeria,[6]Department of Basic Sciences, Loma Linda University Health, Loma Linda, CA,[7]Department of Pharmaceutical and Administrative Sciences, Loma Linda University Health, Loma Linda, CA,[8]Loma Linda University Health, Loma Linda, CA

Women of West African (WA) ancestry disproportionately experience poor breast cancer outcomes, even when diagnosed with the estrogen receptor (ER)-positive subtype. Recent chromatin accessibility analyses reveal ancestry-specific upregulation of DNA methyltransferase1 (DNMT1), with elevated DNMT1 levels in WA patients correlating with worse survival. Given the traditional use of *Spondias mombin* in WA populations for breast cancer, and the known epigenetic activity of flavonoids, we investigated the therapeutic potential of its major flavonoid, rutin and sought to delineate a probable mechanism of anticancer action. Seventeen breast cancer-related molecular targets were screened using molecular docking and Molecular Mechanics/Generalized Born Surface Area binding energy calculations. Rutin's binding interactions were analyzed in detail using 2D/3D interaction mapping, hydrogen-bond profiling, and stability metrics. Rutin demonstrated strong potential binding affinity to 10 of 17 breast cancer targets, with the most favorable interaction observed with DNMT1, surpassing those with HER2, mTOR, AKT1, and EGFR. Docking analyses identified multiple stabilizing hydrogen-bond interactions within the DNMT1 catalytic pocket, suggesting direct inhibition of enzymatic activity. Rutin also engaged key regulators of proliferation (CDK4, Cyclin D1), angiogenesis (VEGF-A), and DNA repair (BRCA1/2), indicating a multi-targeted anticancer profile. The strong DNMT1binding supports a mechanism in which rutin may relieve methylation-dependent silencing of tumor suppressor genes, whose reduced expression associates with poor survival, particularly among patients of WA ancestry. Colony-forming assays reveal that rutin exhibits potent antiproliferative activity in breast cancer cells, particularly those derived from patients of WA ancestry. Quantitative PCR analyses show that rutin inhibits DNMT1 gene expression in cells derived from patients of WA ancestry. Our in-silico findings identify rutin as a high-affinity DNMT1inhibitor with multi-pathway anticancer potential, supporting a role for flavonoid-mediated epigenetic reprogramming in reducing breast cancer disparities. Our in vitro findings suggest that rutin inhibits DNMT1 to ultimately suppress TNBC cell proliferation. These results justify further mechanistic validation in ancestry-derived breast cancer models and support the development of *S. mombin*-derived flavonoids as low-toxicity, ancestry-relevant therapeutic candidates.

#3662 Activity profiling of natural compounds identifies potent chemotypes active in parental and drug-resistant lymphoma models.

Filippo Spriano[1], Francesca Ghirga[2], Deborah Quaglio[2], Mattia Mori[3], Alberto J. Arribas[1], Bruno Botta[2], Francesco Bertoni[1]

[1]Institute of Oncology Research, Universita della Svizzera italiana, Bellinzona, Switzerland,[2]Department of Chemistry and Technology of Drugs, Sapienza University of Rome, Rome, Italy,[3]Department of Biotechnology, Chemistry and Pharmacy, University of Siena, Siena, Italy

Background. Despite the big improvements achieved during the years, too many patients affected by lymphomas still succumb to their disease. Plants represent an extremely rich source of structurally diverse secondary metabolites, which can provide novel active compounds. Thus, we screened a curated library of 37 natural (mostly plant-derived) and nature-derived compounds in cell lines derived from marginal zone lymphoma (MZL), including those with acquired resistance to targeted agents. The library consisted of molecules selected through a cheminformatics approach for their diversity, and spanned 16 chemical classes, including anthranoids, flavonoids, chalcones, triterpenes, alkaloids, acetophenones, benzophenones, coumarins, and a dibenzofuran derivative.
Methods. The library was screened for anti-proliferative activity in 6 MZL lymphoma-derived models (VL51, and 3 BTK/PI3K/BCL2 inhibitors (i) resistant; Karpas1718, and BTKi/PI3Ki resistant). Cells were treated with each compound at 0.4 µM, 4 µM, and 40 µM for 72 hours. Cell viability was assessed using an MTT assay, normalized to DMSO controls. Data were analyzed by class and by individual compound across doses and cell-line subgroups, using a ≥30% reduction in proliferation as the threshold for activity.
Results. At 0.4 µM, most compounds displayed minimal inhibition, with only vismione B (anthranoid) showing partial activity. At 4 µM, modest reductions were observed in selected chalcones and in usnic acid (dibenzofuran). At 40 µM, clear class- and compound-dependent effects emerged. The most active compounds, osajin (flavonoid), ursolic acid (triterpene), usnic acid (dibenzofuran), cordoin, and 4,4′-O-methoxy-chalcone, reduced viability to <25% across all models. These compounds were also validated in a dose-dependent study. By class, chalcones, flavonoids and anthranoids were among the most active chemical classes. A comparison between parental and resistant sublines revealed that most active compounds retained their activity in both settings, indicating resistance-independent mechanisms of action. Some of the tested flavonoids showed preferential activity in VL51 rather than Karpas1718. Finally, selected compounds were tested against the CB-33 lymphoblastoid cell line, with a particular focus on usnic acid (benzofuran), which demonstrated more cytotoxicity in lymphoma cells than in the non-lymphoma cell line.
Conclusions. This screen of structurally diverse natural compounds identified chalcones, flavonoids, and anthranoids as the most active classes in lymphoma models. The reproducible, dose-dependent activity of osajin, ursolic acid, usnic acid, cordoin, and 4,4′-O-methoxy-chalcone across all models highlights them as promising lead scaffolds for further mechanistic studies and medicinal chemistry optimization toward novel anti-lymphoma agents.

#3663 Antiproliferative screening in B cell lymphoma: Ghanaian medicinal plants and their phytochemical correlates.

Filippo Spriano[1], Alberto J. Arribas[1], Alberto Furlan[2], Johnson Nketiah[3], Barbara Z. Anibea[3], Andrea Cavalli[2], Afua A. Mensah[1], Dorcas Osei-Safo[3], Francesco Bertoni[1]

[1]Institute of Oncology Research, Universita della Svizzera italiana, Bellinzona, Switzerland,[2]Institute of Research in Biomedicine, Universita della Svizzera italiana, Bellinzona, Switzerland,[3]Department of Chemistry, University of Ghana, Accra, Ghana

Background. Lymphomas remain a major cause of morbidity and mortality, with patients relapsing due to resistance to treatment and cumulative toxicity. Over 60% of anticancer drugs are derived from plant-derived natural products (NPs) or their derivatives. NPs add 3D-rich scaffolds that broaden chemical space and engage “hard” targets. Semi-synthesis around NP cores can enhance potency, selectivity, and pharmacokinetics, preserving novel mechanisms orthogonal to current agents, which help bypass or delay resistance. Here, we have studied NPs derived from 10 Ghanaian individual plant species and 2 defined mixtures for their anti-tumor activity in marginal zone lymphoma (MZL) models, including derivatives with secondary resistance to BTK, BCL2, and PI3K inhibition.
Methods. We screened 48 samples (single species, mixtures, purified compounds, fractions, extracts) in VL51, SSK41, Karpas1718parental and their resistant derivatives (VL51 ibrutinib resistant, SSK41 venetoclax resistant, and Karpas1718 idelalisib resistant) at 10 and 1 µg/mL for 72 h (MTT). Activity was defined as ≥30% inhibition of proliferation. Selected chemotypes were assigned by LC/MS-guided isolation and NMR.
Results. The samples’ activity was heterogeneous, with 7% of all readouts active at 1 µg/mL and 30% at 10 µg/mL. The most consistent and potent inhibition was observed for *Dichapetalum heudelotii* root fractions (DOS-19/20/21/22) and *Xylopia aethiopica* fruit fractions (DOS-34/45/47). DOS-20 contained stilbenoids including (E)-combretastatin A-1, combretastatin B-1, and heudelotols, and produced a strong and broad inhibition of proliferation at 10 µg/mL. DOS-34 and -47, enriched in ent-kaurane diterpenoids, exerted strong inhibition of proliferation at 10 µg/mL, with a clear loss of activity at 1 µg/mL, indicating a steep dose-response behavior. The single compound hexyl-9-oxodecanoate (DOS-8) exhibited higher activity at both 10 and 1 µg/mL in SSK41 venetoclax-resistant cells than in parental cells. Similarly, the single compound isomeranzin, derived from *Clausena anisata*, and the *Xylopia* + *Bambusa* precipitate showed higher activity in SSK41 venetoclax-resistant cells. Subfractions from column chromatography of a mixture of *Aloe vera* and *T. officinale* showed preferential activity in SSK41 cells and Karpas1718, with higher activity in Karpas1718 idelalisib-resistant cells than in parental cells.
Discussion. We observed a strong chemotype-activity pattern: stilbenoids and ent-kaurane diterpenoids were the most potent profiles, while alkaloids exhibited narrower, context-specific effects; fatty ester-rich samples were mostly inactive. The sharp dose dependence of *Dichapetalum* and *Xylopia* fractions with activity in resistant and TP53-defective models suggests that they are priority leads for mechanism-of-action studies and optimization against drug-resistant B-cell lymphomas.

#3664 A novel 4-herb traditional Chinese medicine formula inhibits metastasis of triple-negative breast cancer.

Longling Wang[1], Julia K.M. Lee[2], Judy Y.W. Chan[2], Zhong Zuo[1], Kenneth K.W. To[1]

[1]School of Pharmacy, The Chinese University of Hong Kong, Hong Kong, China,[2]Institute of Chinese Medicine, The Chinese University of Hong Kong, Hong Kong, China

Background and Aim: Breast cancer is the most common cancer in women worldwide. Triple-negative breast cancer (TNBC) is the most aggressive breast cancer subtype with high metastatic capacity and dismal prognosis. Accumulating evidence suggests that Traditional Chinese Medicine (TCM) is a promising strategy for cancer treatment. Our team previously reported that a TCM formula consisting of *H. diffusa, A. paniculata, A. senticosus,* and *C. sinensis* exhibited a potent antitumor effect in a metastatic breast cancer mouse model. The formula was shown to reduce metastatic lesions in the lungs and livers of experimental mice. Recently, we modified this herbal formula by substituting *C. sinensis* with *G. lucidum* (a potent immunostimulatory herb) with an aim to improve the antitumor and antimetastatic efficacy. This study aimed to (i) investigate this modified formula (hereafter called GHAA) systematically both *in vitro* and *in vivo*, and (ii) elucidate its mechanism of action by bioinformatics analysis.
Method: Morphological and chemical authentications of the herbs were accomplished in accordance with the Chinese Pharmacopoeia. The anticancer effect of GHAA or its 4 individual herb extracts was evaluated in the TNBC cell line by MTT assay. The synergistic anticancer effect was analyzed by the SynergyFinder software. Anti-migration and -invasion effects were evaluated by wound healing and invasion assays, as well as in the zebrafish xenograft model. RNA sequencing was conducted in TNBC cells treated with GHAA or its individual herbs to elucidate the differentially expressed genes and altered pathways following treatment. The transcriptomic signatures induced by GHAA or its individual herbs were queried against the Connectivity Map database to elucidate their possible mechanism of action. The antitumor and anti-metastatic efficacy of GHAA was also investigated in nude mice bearing TNBC tumor xenografts *in vivo*.
Results: GHAA inhibited TNBC proliferation in a concentration-dependent manner *in vitro* (IC_{50} ~ 1 mg/mL). Simultaneous combination of GHAA and doxorubicin was mildly synergistic. GHAA induced apoptosis, but it had no effect on cell cycle regulation. Also, GHAA was shown to significantly inhibit TNBC migration and invasion, and metastasis in the zebrafish model. RNA-seq analysis revealed that ribosomal biogenesis is the top altered biological process by GHAA. Using the connectivity mapping approach, the most potent herb (*A. paniculata*; IC_{50} ~ 0.2 mg/mL*)* within GHAA was found to share a highly similar transcriptomic signature as cathepsin inhibitors, implying its mechanism of action. Finally, GHAA also displayed significant antitumor and anti-metastatic efficacy in TNBC-inoculated nude mice without inducing notable toxicity.
Conclusion: The findings advocate clinical evaluation of GHAA for the treatment of metastatic TNBC.

#3665 Oleuropein, a phenolic compound from olive leaves, exerts cytotoxicity and peroxiredoxin induction in MDA-MB-231 breast cancer cells.

Giovanna Kalin, Adam Vaz, Shelley A. Phelan

Biology, Fairfield University, Fairfield, CT

Extra virgin olive oil, a foundational element of the Mediterranean cuisine, has been widely associated with numerous health benefits, including the prevention of degenerative diseases and the promotion of longevity. A major bioactive component of the olive tree is oleuropein, a phenolic compound predominantly found in olive leaves and fruit. Oleuropein has been well-characterized for its potent antioxidant and anti-inflammatory properties, as well as its potential anticancer effects demonstrated in both animal and cell-based models. In this study, we investigated the effects of oleuropein on the human triple-negative breast cancer cell line MDA-MB-231. Cells were treated with oleuropein at concentrations of 50, 200, and 400 µg/mL, or 70% ethanol control. We assessed cell viability using the MTS assay, and cytotoxicity and apoptosis using a Caspase 3/7 activity. We found the highest concentration of oleuropein to induce a 3-fold decrease in viable cell density and an 8-fold increase in apoptosis. We also examined the effect of oleuropein on the expression of the peroxiredoxin (Prdx) gene family, which encodes thiol-specific antioxidant proteins known to protect cells from oxidative damage and that we previously demonstrated to be induced by oleuropein in MCF-7 cells. We found significant induction of Prdx gene expression in MDA-MB-231 cells by oleuropein, with a marked induction of Prdx1 with the 400 ug/ml treatment. Current research is aimed at measuring Prdx protein expression in oleuropein-treated cells, as well as the effect of Prdx suppression on oleuropein susceptibility. Together, these findings suggest that oleuropein exerts dose-dependent anticancer effects in MDA-MB-231 cells that result in a robust peroxiredoxin antioxidant protein response. Further exploration of the mechanism of action of oleuropein in MDA-MB-231 cells will provide important insights into its pro-oxidant effects and potential therapeutic applications.

#3666 Antitumor effects of coffee diterpenes, kahweol acetate and cafestol, on taxane-resistant and neuroendocrine prostate cancer cells.

Tomohiro Hori, Hiroaki Iwamoto, Taiki Kamjima, Hiroshi Kano, Makino Tomoyuki, Renato Naito, Hiroshi Yaegashi, Kazuyoshi Shigehara, Takahiro Nohara, Kouji Izumi, Atsushi Mizokami

Department of Integrative Cancer Therapy and Urology, Kanazawa University Graduate School of Medical Science, Kanazawa, Japan

Background: Epidemiological studies have reported that higher coffee consumption is associated with a reduced risk of prostate cancer. Kahweol acetate and cafestol, major diterpenes found in unfiltered coffee, have shown antitumor activity in prostate cancer cells. However, their effects on treatment-resistant subtypes, including taxane-resistant castration-resistant prostate cancer (CRPC) and neuroendocrine prostate cancer (NEPC), remain unclear. Therapeutic options for these aggressive variants remain extremely limited, highlighting the need for novel agents. We aimed to investigate the antitumor potential and underlying mechanisms of kahweol acetate and cafestol in these refractory prostate cancer models.
Methods: We used docetaxel-resistant (DU145-TxR, PC-3-TxR) and cabazitaxel-resistant (DU145-TxR/CxR, PC-3-TxR/CxR) prostate cancer cell lines, which were established from their respective parental DU145 and PC-3 cells. In addition, the neuroendocrine prostate cancer cell line NCI-H660 was included. Cells were treated with kahweol acetate and/or cafestol (10-100 μM). Cell proliferation and migration were evaluated. Synergistic effects were analyzed using the combination index-isobologram method. Apoptosis induction and cell cycle distribution were evaluated by flow cytometry. Expression of apoptosis-related (cleaved-caspase-3, cleaved-PARP, Bcl-2, Bcl-xL) and EMT-related (Snail, Slug) proteins was examined by western blotting.
Results: Both kahweol acetate and cafestol significantly inhibited proliferation and migration in all resistant and NEPC cell lines in a dose-dependent manner. Combined treatment (30 μM each) produced synergistic inhibition. Flow cytometry demonstrated an increased sub-G1 population and a reduced G2 phase, suggesting apoptosis induction. Western blotting revealed increased cleaved-caspase-3 and cleaved-PARP expression, along with decreased anti-apoptotic Bcl-2 and Bcl-xL levels. EMT markers Snail and Slug were also downregulated, indicating suppression of migratory potential.
Conclusions: Kahweol acetate and cafestol exert strong antitumor effects in taxane-resistant and neuroendocrine prostate cancer cells through synergistic induction of apoptosis and inhibition of EMT. Given their efficacy at clinically achievable concentrations, these coffee-derived diterpenes represent promising candidates for novel therapeutic approaches in treatment-resistant prostate cancer.

#3667 Neohesperidin dihydrochalcone: A novel natural inhibitor of ferroptosis.

Bomi Han, Yi-Xi Gong, Seonghye Son, Eui Man Jeong

Jeju National University, Jeju, Korea, Republic of

Ferroptosis, a form of regulated cell death characterized by the iron-dependent accumulation of lipid peroxides, is increasingly recognized as a critical pathogenic mechanism in various human diseases. Given the significant implication of ferroptosis in pathology, there is an urgent need to identify novel chemotypes with anti-ferroptotic activity. Recently, natural products have garnered attention as safe and effective sources for ferroptosis regulators. In this study, we identified Neohesperidin dihydrochalcone (NHDC), a flavonoid sweetener derived from citrus fruits, as a potent inhibitor of ferroptosis. We demonstrated that NHDC significantly restored cell viability in HT-1080 cells treated with Erastin, a System Xc– inhibitor. Mechanistically, NHDC treatment effectively mitigated the accumulation of lipid reactive oxygen species (ROS) and modulated the expression of ferroptosis-related proteins, including SLC3A2, SLC7A11, and PTGS2. Furthermore, NHDC exhibited a protective effect against ferroptosis induced by Sulfasalazine (SAS), another System Xc– inhibitor, by reverting SAS-induced lipid ROS levels. Interestingly, NHDC showed selectivity in its protective mechanism, distinguishing its activity from RSL3-induced ferroptosis pathways. Collectively, our findings demonstrate that NHDC acts as an effective anti-ferroptotic agent by targeting System Xc– inhibition. This study provides valuable insights into the therapeutic potential of NHDC as a natural candidate for the treatment of ferroptosis-related diseases.

#3668 Targeting apoptotic machinery using methanolic extracts of *Carpobrotus edulis* to suppress pancreatic cancer growth.

Lesetja Motadi[1], Ronald Makalapetlo[2]

[1]University of Johannesburg, Johannesburg, South Africa,[2]Biochemistry, University of Johannesburg, Johannesburg, South Africa

Pancreatic cancer remains a formidable global health challenge. Current cancer treatments, such as chemotherapy are expensive and limited. Consequently, investigating alternative anticancer treatments, such as medicinal plants, is crucial. This study aimed to investigate the potential anticancer properties of a crude methanolic extract and isolated compounds from *Carpobrotus edulis* by targeting apoptotic machinery in pancreatic cancer cells (MIA PaCa2). Multiple assays, including Alamar blue, ATP, Hoechst staining, Caspase 3/7 activity, DNA fragmentation, and RT-qPCR, were conducted to assess apoptosis induction. The crude methanol and isolated compounds did not affect the MRC-5 non-cancerous cell line. Mechanistic investigations confirmed that the crude extract activated the extrinsic TNF-mediated apoptosis pathway, evidenced by a significant increase in TNF expression and caspase 3/7 activity, leading to DNA and nuclear fragmentation, chromatin condensation, and the formation of apoptotic bodies. The loss of cell confluence, supported by non-significant(p>0,05) downregulation of STAT3, further suggested inhibited cell growth. While some changes were observed in the expression of p53, Bak1, and Fas for both the crude extract and isolated compounds, these were not statistically significant (p>0,05). Protein-ligand docking studies of the identified 7,9-Ditert-butyl-oxaspiro [4.5] deca-6,9-diene-2,8-dione and 1-octadecanol proved the compounds as having high affinity for the selected ligands: TNFR, FADD, p53, Bak1, and STAT3. Future research will focus on the further purification and investigation of the most potent isolated compound.

#3669 Oleuropein downregulates MITF via direct PKA inhibition and ERK-mediated turnover in melanoma.

Ingyu Lee, Jihye Kim, Yi-Xi Gong, Eui Man Jeong

Jeju National University, Jeju, Korea, Republic of

The Microphthalmia-associated Transcription Factor (MITF) acts as a molecular rheostat in melanoma, governing the switch between proliferative and invasive phenotypic states. Since constitutive activation of the PKA-CREB axis drives high MITF levels to sustain tumor proliferation, targeting this pathway offers a promising therapeutic strategy. Here, we elucidate the mechanism by which oleuropein modulates MITF stability and expression in melanoma and normal melanocyte models. In B16F10 melanoma cells characterized by aberrant PKA signaling, oleuropein directly inhibited PKA catalytic activity, leading to reduced CREB phosphorylation and subsequent transcriptional suppression of MITF. Furthermore, oleuropein triggered ERK1/2 activation, accelerating MITF protein turnover. Consequently, oleuropein dismantled the hyper-proliferative transcriptional program through dual upstream and downstream regulatory mechanisms. Crucially, oleuropein reduced basal MITF levels in normal human melanocytes and effectively blunted MITF spikes induced by α-MSH or forskolin. This suggests that oleuropein functions as a potent inhibitor of the PKA-CREB axis, preventing pathological signaling amplification under both basal and hyperactivated conditions. In conclusion, by targeting PKA catalytic activity and promoting ERK-dependent degradation, oleuropein effectively attenuates aberrant MITF expression. These findings position oleuropein as a promising modulator of melanoma phenotypic plasticity with potential therapeutic applications.

#3670 Beta-lactams, structural mimics of natural products, as anti-pancreatic cancer agents: A pilot study.

Debasish Bandyopadhyay[1], Tushar Debnath[1], Attrayo Mukherjee[2], Jonathan Rock[1], Omar Espino[1], Vivek Kumar Kashyap[3], Subhash C. Chauhan[4]

[1]Sch. Integr. Bio. Chem. Sc., The University of Texas Rio Grande Valley, Edinburg, TX,[2]School of Biotechnology, Kalinga Institute of Industrial Technology (KIIT), Bhubaneswar, India,[3]The University of Texas Rio Grande Valley, McAllen, TX,[4]The University of Texas Rio Grande Valley, Mc Allen, TX

Around 95% of pancreatic tumors harbor mutations in codons G12, G13, and Q61 of the *KRAS* gene. Thus, there is a significant unmet need for the development of selective KRAS inhibitors. Alternatively, the four-membered cyclic amides, commonly known as β-lactams, are found in nature. Since their discovery, beta-lactam antibiotics have played a central role in fighting against bacterial infections. However, the 'upgradation' of β-lactams from one generation to another is required for drug resistance, which is predominantly due to bacterially produced β-lactamase enzymes that hydrolyze the highly strained β-lactam ring because of tremendous angular strain. We hypothesize that, as cancer cells do not produce β-lactamase enzymes, the β-lactam ring's stability should be higher in tumor environments. With appropriate chemical modifications, β-lactams should inhibit proteins responsible for the proliferation, angiogenesis, and metastasis of various cancers, including hepatobiliary-pancreatic carcinomas (HPCs). HPCs include hepatocellular carcinoma (HCC), biliary tract cancers (BTCs), and pancreatic cancer (PanCa), which are highly challenging to treat and manage. As a part of our ongoing research in developing small molecule inhibitors from natural sources through chemical modifications (semi-synthetic) and/or by appropriate structure-based design and synthesis of structural mimics of natural products, we have successfully carried out computer-assisted design, multi-step synthesis, and *in vitro* anti-pancreatic cancer evaluation of a small series of β-lactams as KRAS inhibitors. There are a few methods for synthesizing the beta-lactam core unit, and we used the [2+2] ketene-imine cycloaddition (Staudinger) reaction followed by derivatization to synthesize the target 2-azetidinones. Further, MTT and apoptosis assays, cell cycle analysis, gamma-H2AX (phospho-Ser139) staining, and BrdU incorporation studies were conducted. Most of the products in this series demonstrated excellent (*in vitro*) activity in pancreatic cancer cell lines. The newly synthesized β-lactams demonstrated hundreds- to thousands-fold higher activity than the positive control, gemcitabine, in PANC-1 cells. Comparison of IC_{50} values in pancreatic cancer cells (PANC-1) and normal pancreatic epithelial cells (NPC) shows that almost all compounds exhibit 3-359 times greater selectivity for PANC-1 than for NPC. The *in silico*, and *in vitro* validated β-lactams could successfully serve as an entry point for clinical trials after appropriate *in vivo* evaluation. The work will significantly strengthen the fight against pancreatic cancer and undoubtedly foster a collaborative environment for future research.

#3674 The impact of race/ethnicity on survival in secondary triple negative breast cancer.

Ana Isabel Jacinto, Theresa Keegan, Qian Li, Fran Maguire, Candice Sauder

UC Davis Comprehensive Cancer Center, Sacramento, CA

Objective: To identify if treatments used for secondary triple negative breast cancer are associated with survival differences by race/ethnicity.
Background: Survival in women with secondary breast cancer, and those with triple negative breast cancer (TNBC), is worse for young women, especially non-Hispanic (nH) Black women. We hypothesize this is related to treatment received.
Methods: Females, aged 15-50 years, diagnosed with a TNBC during 2003-2019 were identified using the California Cancer Registry. Multivariable logistic regression compared characteristics of secondary vs primary TNBC. Multivariable Cox proportional hazards regression models evaluated associations of secondary vs primary TNBC on overall survival (OS) and breast cancer specific survival (BCSS). Analyses were stratified by race/ethnicity.
Results: Of 682 women with a secondary TNBC, 48.5% were nH White, 11.3% were nH Black, and 31% were Hispanic. All women with a secondary TNBC (vs primary TNBC) were more likely to receive a mastectomy and non-anthracycline based chemotherapy. NH White women were less likely than women of other races/ethnicities to have axillary lymph node dissections. Hispanic and nH White women with a secondary (vs primary) TNBC experienced worse OS and BCSS, which was not seen in nH Black and Asian/Pacific Islander women (Figure 1).
Conclusion: While treatments were similar for secondary vs primary TNBCs by race/ethnicity, Hispanic and nH White women with secondary TNBC experienced worse survival. Our findings suggest that tumor biology, rather than treatment, differs in secondary TNBC, warranting different treatment algorithms to improve outcomes.

Figure 1: Multivariable Adjusted Cox Proportional Hazard Ratios for Overall Survival and Breast Cancer Specific Survival for Secondary compared to Primary Triple Negative Breast Cancer by Race/Ethnicity

Overall Survival	Breast Cancer Specific Survival	
#3675 Identifying determinants of molecular testing for advanced non-small cell lung cancer in the rural United States.

Dena Rhinehart, Amanda L. Blackford, Kristen Marrone, Craig Pollack, Josephine Feliciano

Sidney Kimmel Comprehensive Cancer Center at Johns Hopkins University, Baltimore, MD

Background: Targeted therapies for non-small cell lung cancer (NSCLC) have led to population level improvements in mortality and can double overall survival for some patients with sensitizing mutations. Up to 60% of patients with advanced NSCLC may be eligible for these treatments, and US national oncology guidelines recommend molecular testing for patients with advanced disease. However, patients in the rural US are less likely than urban counterparts to receive molecular testing to determine eligibility for targeted therapies. The most rural populations also face twice the NSCLC mortality rate than the most urban populations, in part due to reduced access to guideline concordant care. Understanding the determinants of and processes involved in testing in the rural US is critical to develop strategies to deliver this care to this population with disproportionately high NSCLC mortality rates. In this study, we are examining patient level and systems level determinants of molecular testing in the rural US.

Methods: Utilizing the SEER-Medicare database linked to federal housing assistance, we have identified a cohort of patients diagnosed with advanced NSCLC between 2014-2019 using the Surveillance, Epidemiology, and End Results (SEER) cancer registry program and Medicare database linked with data from the US Department of Housing and Urban Development. Individuals were 66 to 95 years old at diagnosis and continuously enrolled in fee-for-service Medicare for at least 12 months before diagnosis and either to death or six months after diagnosis. Molecular testing, as evidenced by epidermal growth factor receptor (EGFR) testing was identified via claims using HCPCS codes 81235, 81275, 81276, 81400-8, 81415, 81455, 81504, and 81540. We are also surveying multidisciplinary providers (pathologists, proceduralists, oncologists, nursing) to identify health system barriers and facilitators to molecular testing in the rural Mid-Atlantic. The survey questions were developed using the Consolidated Framework for Implementation Sciences (CFIR) 14-question survey as a guide.

Results: We identified 8713 individuals with advanced NSCLC residing in a rural area at the time of diagnosis in the SEER-Medicare database. The overall rate of EGFR testing was 21.1%. Individuals tested were younger (75.1 v 76.3 years), more likely to be married (36.6% v 32.8%), did not originally qualify for Medicare due to disability (12.1% v 18.6%), did not have concurrent Medicaid coverage (13.9% v 23.3%) and had fewer comorbidities (Charlson score of 0, 46.2% v 40.6%), compared to those who did not have EGFR testing ($p < 0.001$ for all). Provider survey responses are ongoing.

Conclusions: This ongoing study is identifying specific rural US populations in greatest need of efforts to expand molecular testing for NSCLC as well as implementation barriers and facilitators to testing from a multidisciplinary perspective.

#3676 Social disparities in the extension of endocrine therapy among premenopausal breast cancer survivors in Denmark.

Kirsten M. Woolpert[1], Lene Mellemkjar[2], Soren Friis[3], Mette Norgaard[1], Bent Ejlertsen[4], Deirdre Cronin-Fenton[1]

[1]Department of Clinical Epidemiology, Aarhus University and Aarhus University Hospital, Aarhus N, Denmark,[2]Institute of Cancer Epidemiology, Danish Cancer Society, Copenhagen, Denmark,[3]Danish Cancer Institute, Danish Cancer Society, Copenhagen, Denmark,[4]Danish Breast Cancer Group, Rigshospitalet, Copenhagen University Hospital, Copenhagen, Denmark

Introduction Despite universal access to oncology care, social disparities in cancer survivorship persist in Denmark. For premenopausal women with estrogen receptor-positive breast cancer, decisions regarding extending endocrine therapy beyond five years often depend on estimated individual recurrence risk and treatment tolerance. We examined whether social disparities are associated with the initiation of extended endocrine therapy among Danish breast cancer survivors who were recurrence-free at five years post-diagnosis.

Methods We included all women registered in the Danish Breast Cancer Group clinical database who were premenopausal at diagnosis with a first primary, estrogen receptor-positive, stage I-III invasive breast cancer diagnosed during 2008-2011. We further restricted the population to those who initiated adjuvant endocrine therapy and were alive, recurrence-free, and residing in Denmark five years after diagnosis. Extended endocrine therapy was defined as cumulative coverage with endocrine therapy for at least one year beyond the initial five years of treatment. Using the unique personal registration number assigned to all Danish residents, we linked patients across nationwide registries to obtain information on cohabitation, marital status, employment, income, and education, measured at or before endocrine therapy initiation. Associations between social characteristics and treatment extension were estimated using logistic regression, adjusted for patient age at diagnosis, and reported as odds ratios (ORs) with 95% confidence intervals (CIs).

Results Among 1,911 premenopausal patients diagnosed during the study period, 1,136 (57%) continued endocrine therapy beyond five years. Treatment extension varied across all assessed social characteristics. Women living alone at endocrine therapy initiation were less likely to extend (OR = 0.64; 95% CI, 0.51-0.79) compared with those cohabiting with a partner. Similarly, unmarried women (OR = 0.70; 95% CI, 0.55-0.90) and those who were divorced or widowed (OR = 0.67; 95% CI, 0.52-0.87) had lower rates of extension compared with married women. Survivors who were unemployed (vs employed; OR = 0.66; 95% CI, 0.52-0.83) or in the lowest quartile of household income (vs highest; OR = 0.72; 95% CI, 0.55-0.94) also had reduced odds of treatment extension. Finally, women with short education had 0.79 (95% CI, 0.61-1.02) times the odds of extension compared with those with long education.

Conclusions Our study suggested differences in the uptake of extended endocrine therapy according to social characteristics. Future work will build on these findings to evaluate how social and clinical factors together influence long-term treatment adherence and recurrence outcomes, with the aim of informing more equitable survivorship care.

#3677 Supporting communities through open dialogue on cancer care and addressing food insecurity: Partnerships with local YMCAs.

Rosa Barahona[1], Elena Nieves[2], Marya Shegog[3], Brenda Hernandez[4], Letech Caldera-Huerta[1], Lourdes Baezconde-Garbanati[5]

[1]USC Keck School Medicine, Los Angeles, CA,[2]USC Norris Comprehensive Cancer Center, Los Angeles, CA,[3]Lazarex Cancer Foundation, Danville, CA,[4]Weingart YMCA, Los Angeles, CA,[5]USC Keck School of Medicine, Los Angeles, CA

Background: A December 2024 USC Dornsife study found ~25% of LA County households faced food insecurity. The Lazarex Cancer Foundation, in partnership with USC NCCC and local YMCAs, supports communities experiencing cancer disparities and food insecurity. We provide welcoming, culturally responsive spaces for diverse and vulnerable groups to discuss cancer concerns and receive food support. Our goal is to advance cancer knowledge and offer free food by meeting individuals where they are with linguistically appropriate, culturally aligned information. Through YMCA partnerships, we've expanded access to cancer programs, resources, and services that improve outcomes across the cancer disparities continuum.

Methods: From October 2021 to October 2025, Lazarex Cancer Wellness HUBs conduct ongoing outreach across multiple LA County YMCAs and community and faith-based partners. This partnership enables extensive outreach through wellness hubs, giving community members access to food, education, and connections to cancer support services that address key social determinants of health. Content includes screening guidelines, the importance of diverse clinical trial participation, self-advocacy strategies, trustworthy health information, and food access.

Results: Over 8.6 million pounds of free food have been provided. We continue offering this service alongside cancer prevention information and connections to local resources. Food is also delivered to seniors and families lacking transportation or who feel unsafe in public spaces. More than 12,000 individuals across 148 zip codes have been served, with WELA Y completing 2,600+ safe deliveries. The Weingart YMCA has become a model for similar efforts across LA County.

Conclusion: We developed a community outreach model that enables consistent engagement in diverse, vulnerable communities, offering culturally tailored cancer information. These efforts aim to reduce cancer disparities and food insecurity by increasing awareness, knowledge, and access to quality care and trustworthy resources. The Lazarex Cancer Wellness HUB demonstrates an effective approach to empowering individuals as informed advocates for cancer prevention, navigation, advanced care options, and food access.

#3678 Capturing Latino health disparities: Lessons from mail and community-based population health surveys in California.

April P. Vang[1], Juanita E. Quino[2], Angelica M. Rolon[1], Alexa Morales Arana[1], Julie H. T. Dang[3], Moon S. Chen[3], Primo N. Lara[3], Laura Fejerman[4], Luis G. Carvajal-Carmona[1]

[1]The Health Equity Science and Community Research Laboratory (THE LCC Lab), Genome Center, UC Davis, Davis, CA,[2]University of Southern California, Los Angeles, CA,[3]University of California Davis Comprehensive Cancer Center, UC Davis, Sacramento, CA,[4]Public Health Sciences, UC Davis, Davis, CA

Background: Latinos face significant cancer health disparities and remain underrepresented in research. To address regional needs, the University of California Davis Comprehensive Cancer Center (UCDCCC) conducts regular Catchment Area Population Assessments (CAPAs) to inform outreach and engagement strategies. Our purpose was to understand best approaches for capturing Latino health needs responses and to understand breast and cervical cancer screening rates and risk factors.
Methods: This cross-sectional study compared two CAPA survey methodologies used from July 2019 to March 2020: a mail-based approach using probabilistic sampling of residential addresses versus a community-based approach using bilingual coordinators for in-person interviews. Comparisons were made on catchment population representativeness and breast and cervical cancer screening outcomes.
Results: The study included 361 Latino participants (255 community-based, 106 mail-based) across 16 of 19 UCDCCC catchment counties. Mail-based participants were significantly older, more educated, and had higher household incomes than community-based participants. Despite the differences in key demographics of participants in the two survey modalities, our results were inconclusive on whether up-to-date breast and cervical cancer screening rates differed between the two groups. Time since the last routine check-up, primarily among community-based participants, emerged as a key predictor of screening adherence.
Conclusions: Mail-based methods captured more affluent Latinos, whereas community-based methods reached more underserved populations. Each method introduced distinct sampling biases, but together they provided a more balanced representation of the catchment area. **Impact**: Mail- and community-based survey methods enhances the representativeness of Latino health data and supports more equitable research recruitment strategies.

#3679 Trends and disparities in hepatitis C virus-associated hepatocellular carcinoma mortality in the United States, 1999-2023.

Sophia Ahmed[1], **Fareed Baksh**[2], Elangovan Krishnan[3], Arfa Assad[1], Muhammad Uzair[4], Areesha Nawaz[5], Oshaz Fatima[6], Subhan Saleem[1]

[1]Medicine, Allama Iqbal Medical College, Lahore, Pakistan,[2]Internal Medicine, Community Health Systems - Flowers Hospital: Dothan, Alabama, US, Dothan, AL,[3]AIM DOCTOR, Thiruverkadu, India,[4]Medicine, Liaquat Univeristy of Medical & Health Sciences, Jamshoro, Pakistan,[5]Medicine, Dow Medical College, Karachi, Pakistan,[6]Medicine, King Edward Medical University, Lahore, Pakistan

Chronic hepatitis C virus (HCV) infection is a major driver of hepatocellular carcinoma (HCC) in the United States, where HCC incidence and mortality have doubled over the past 25 years. Despite the effectiveness of direct-acting antivirals, HCV-related HCC remains substantial, reinforcing the need for sustained surveillance and early detection. This study, adhering to STROBE guidelines, analyzed deaths related to HCV-associated HCC from 1999 to 2023 using CDC-WONDER data. Deaths were identified via ICD-10 codes (B17.1, B18.2, C22.0), with demographic categorization by place of death, age, gender, race, census region, and urbanization. Age-adjusted mortality rates (AAMRs) were calculated per 100,000 population. Joinpoint regression assessed trend changes, reporting Average Annual Percent Change (AAPCs) with 95% CIs. Statistical analyses were performed using Joinpoint software, Microsoft Excel, and CDC-WONDER mapping tools. From 1999 to 2023, 50,760 U.S. deaths were attributed to HCV-associated HCC. AAMRs increased from 0.19 in 1999 to 0.43 in 2023. Among deaths with place-of-death data, most occurred in medical facilities (38.7%) or at home (35.0%). Joinpoint analysis showed increasing mortality from 1999 to 2012, stable rates through 2016, and a decline to 2023 (AAPC 2.52%). Female AAMRs rose from 0.07 to 0.17, peaking in 2013 before declining (AAPC 2.57%). Male AAMRs increased from 0.31 to 0.73, with early surges, peaking through 2016, then declining (AAPC 3.29%). Mortality was highest in NH Whites, followed by NH Blacks. NH Whites rose until 2013, then declined (AAPC 5.00%), while NH Blacks showed early sharp increases and declined after 2016 (AAPC 4.30%). Metropolitan areas had higher AAMRs than non-metropolitan areas, with both rising until the mid-2010s followed by declines (AAPC: 4.46% and 6.03%, respectively). Across regions, AAMRs rose until the mid-2010s, driven by sharp early increases in the Northeast (32.1%) and steady growth in the Midwest, South, and West (8-10%). Mortality was highest in ages 55-64 and 65-74, both showing sharp increases from 2013 to 2017 followed by declines (AAPC –3.94%). HCV-related HCC mortality has declined since the early 2010s but remains uneven across sex, race, and geography. Males, Black individuals, and urban areas bear the highest burden. These findings underscore the need to strengthen HCV testing, antiviral treatment uptake, and timely HCC surveillance in the high-risk populations.

#3680 Attitudes, beliefs, and perceptions of clinicians on AI-assisted digital health interventions for oncofertility education.

Bhakthi Sahgal, Alvaro Rivera-Andrade, John F. Russell, Ornsiree Junchaya, Pavani Chalasani, Naomi Seiler

George Washington University, Washington, DC

Background: Fertility preservation counseling is a critical component of cancer care, yet patients often face disparities and barriers to timely, comprehensible information. Digital and AI-enabled educational tools may help expand access and standardize communication, but little is known about how frontline clinical staff perceive their acceptability, utility, trustworthiness, or appropriateness. Understanding these perspectives is essential to ensure emerging technologies promote, rather than exacerbate, inequities in oncofertility care.
Methods: This prospective qualitative study will be conducted at two cancer centers representing different tiers of institutions, an NCI-designated and a non-NCI-designated, to capture diverse organizational contexts and care delivery environments. Semi-structured interviews will be completed with multidisciplinary clinical leadership and staff, including directors, oncologists, reproductive endocrinologists, advanced practice providers, oncology nurses, and oncology social workers involved in oncofertility-related communication. Interview guides will draw on patient-centered communication frameworks, human-centered design principles, and implementation-science constructs related to acceptability, utility, trustworthiness, and appropriateness. Sessions will be audio-recorded, transcribed, and analyzed in NVivo using a hybrid deductive-inductive thematic approach to identify patterns related to trust, usability, privacy, accessibility, cultural relevance, and perceived clinical value.
Expected Outcomes: This study will generate insights into how clinical teams perceive and would engage with digital and AI-enabled fertility preservation education tools within onco-fertility settings. Findings will underline the factors influencing their acceptability, perceived utility, and trustworthiness across different institutional contexts. The analysis will highlight key design and implementation considerations that can inform the responsible development and deployment of digital tools supporting oncofertility communication across both NCI-designated and non-NCI cancer centers.
Implications: Findings will inform the equitable design and implementation of patient-centered, clinician-endorsed, culturally responsive digital health interventions for fertility preservation. Results will guide responsible digital tool adoption in oncology communication workflows and support improvements in patient engagement, care quality, and equity across diverse cancer care settings.

#3681 Optimizing genetic/genomic health communication in cancer prevention through video development.

Elena B. Taylor[1], Charite N. Ricker[2], Daisy Hernandez[2], Itzya Ulloa[2], Rosa Barahona[3], Lourdes Baezconde-Garbanati[2]

[1]USC Norris Comprehensive Cancer Center, Los Angeles, CA,[2]Keck School of Medicine of USC, Los Angeles, CA,[3]USC, Los Angeles, CA

Introduction: The Engagement Optimization Unit (EOU) of the USC Center for Optimizing Engagement in Colorectal Cancer Patients (COPECC), in partnership with the Patient Engagement Unit (PEU) and the Community Genetics Navigation Specialists (CoGENES) program, sought to improve educational materials for Hispanic participants in the ENLACE study before they received genetic testing results. Because colorectal cancer (CRC) incidence is rising in adults under 50 and is a leading cause of cancer death among Hispanic men, the team aimed to reduce disparities by providing clearer, more engaging information. Early listening groups (n=25) indicated a strong preference for video-based education, prompting development of a short film explaining the purpose and importance of genetic testing.

Methods: The film was created in collaboration with the USC School of Cinema. The team identified four Key Messages to be woven into the film that outlines the purpose and meaning of genetic testing and design. A film visual outline was produced with patient interviews, content and order of graphic animations. Production work included preparation and actual filming of participants that provided relatable testimonials and cancer team clinicians that provide professional credibility about the purpose and meaning of genetic testing.

Results: Focus groups had previously been conducted to better understand the preferred modality for presenting education materials. Individual comments specifically regarding the video revealed that there was a preference for the video format (5 focus groups 6/8 ,1/3, 3/3, 6/12/ and 3/3 comments specifically stated this preference). Based on this data as well as the literature, an 8-minute film was produced as an optimized format to present the information. The film content included testimonials by three participants, medical professionals (genetic counselor and physician) further explaining the importance of genetic testing, and animated graphics supporting the key messages being delivered. The film was assessed for logical information and content flow, and identification of key messages within the film, and relatability. Two language specific videos were created, one in Spanish and one in English - adding captions, animation, narration, and dubbing in both languages. The film is to be used in an education intervention comparing materials provided to cancer patients prior to receiving their genetic testing results.

Conclusion: Based on previous research, this video will improve our understanding and retention of key genetic messages in colorectal cancer. The video has incorporated elements including information with visual movement, supported by captions and narration to deliver this information on genetic testing to the ENLACE participants. The creation of this video provides, at the very least, an alternative to education delivery mechanism (besides static written information).

#3682 Nationwide epidemiologic and economic burden analysis of neurologic disorders associated with cancer treatment.

Ilaha Huseynli[1], Yiran Xu[2], Russell C. Jeter[2], Stephen N. Housley[1]

[1]School of Biological Sciences, Georgia Institute of Technology, Atlanta, GA,[2]Department of Mathematics & Statistics, Georgia State University, Atlanta, GA

Background: Neurologic disorders associated with cancer treatment (CIND) are common dose-limiting toxicities of many chemotherapies. They can persist long after treatment, impair function, and quality of life. Despite their import, large scale data on incidence, dose-response, and health care utilization and economic burden is limited. Objective: Quantify the epidemiology of CIND, stratified by cancer status, agent, and route of administration, evaluate clinical and treatment-related risk factors, measure health care utilization and economic cost burden, all in a nationwide cohort.
Methods: Using longitudinal IBM Marketscan claims data, we applied multi-tier drug matching to identify adults with incident chemotherapy and classify cancer and neurologic status using ICD 9 neoplasm and neurologic codes. Patients were categorized as having same day or incident neuropathy relative to the cancer diagnosis or first chemotherapy dispensing date. CIND cumulative incidence and time to first event were assessed at 3-month intervals. We modeled adjusted odds and hazards of CIND by cancer status and chemotherapy route and evaluated dose-response in multivariable Cox model adjusted for age, sex, and comorbidities.
Results: Across three cohorts (totaling ~ 3.1M patients), CIND incidence was highest in cancer patients receiving chemotherapy (40.4%) compared to cancer patients alone (34.1%) which was higher still relative to the general population (12%). Higher mean incremental daily dose was significantly associated with increased CIND hazard, with oral agents showing HRs per 1-SD from 1.09-2.23 (bexarotene, capecitabine, hydroxyurea, mercaptopurine, tretinoin; all $p \leq 0.046$) and IV methotrexate showing HR 1.34 (95% CI 1.00-1.79; $p=0.048$). Most CIND events occurred within one year of the last dose, indicating substantial on treatment and delayed CIND risk. Compared with IV administration, oral chemotherapy was associated with a modestly lower hazard of CIND (HR 0.862). Older age and comorbidities (hypertension, peptic ulcer, depression, chronic pulmonary disease, diabetes, and coagulopathy) provide additional independent risk. Healthcare burden analyses revealed opioid dispensing, CIND-directed pharmacotherapy, and rehabilitative services were more frequently used in chemotherapy recipients, accompanied by 51-fold higher per-patient costs (~$53k) relative to general population.
Conclusion: In this nationwide cohort, CIND is common, often delayed, and shaped by route of administration, indication, dose intensity, and patient comorbidity. CIND care concentrates substantial utilization and financial burden in chemotherapy exposed populations, underscoring the need for dose optimized regimens, proactive surveillance, and better supportive care strategies.

#3683 The breast cancer survivorship experience of Korean American women: A qualitative study.

Seulgi Ryu[1], Dongmi Kim[1], Yeeun Kim[1], Wonshik Chee[2], Eun-Ok Im[1]

[1]School of Nursing, The University of Texas at Austin, Austin, TX,[2]Department of Kinesiology and Health Education, College of Education, The University of Texas at Austin, Austin, TX

Background Breast cancer is the most frequently diagnosed cancer among women in the United States. A recent sharp increase in breast cancer was observed among Asian American women, and breast cancer is the most prevalent cancer among Korean American women. There remains a significant gap in research exploring the breast cancer survivorship experience of Korean American women. This study aims to explore the survivorship experiences of Korean American breast cancer survivors.

Methods This is a part of a larger study that evaluated a technology-based coaching/support program among Asian American breast cancer survivors. Only the qualitative data from 10 Korean American breast cancer survivors over the 3-month interventions were included in this analysis. Data were collected through online logs, where all interactions between participants and interventionists were recorded. The online logs included an average of 1,029 lines (range: 428-2149) of text per participant. The data were analyzed using a thematic analysis.

Results Five prominent themes were identified. First, “self-directed coping strategies with pain” were identified; the participants reported several ways to manage pain, such as medication or gaining support through assistive methods (e.g., cuffing therapy, sauna, and acupuncture), which were relevant to Asian cultural aspects. Second, “resilience in survivorship” was enhanced through participation in the culturally tailored intervention. While the participants were motivated to contribute meaningfully to the research, they experienced less pain and were encouraged to exercise more to reduce pain. Third, “challenges of living with and beyond cancer” were noted; the participants reported challenges related to physical or emotional symptoms, a language barrier, being obliged to be filial to their parents, being stigmatized for their illness, lacking time for themselves, and an unsupportive family. Fourth, “resilience and growth through illness” were identified; the participants reported that their families became stronger after the diagnosis, and they became more proactive, finding meaning in their lives. They provided support to other cancer patients or those in need and were grateful to their peers or family for their support. Finally, “positive adaptation and empowerment” were identified; the participants were actively seeking behaviors/strategies to improve their physical or emotional challenges, such as changing their diet, exercising, and focusing on other activities (e.g., travel or finding a new hobby).

Conclusions Even though Korean American breast cancer survivors faced multiple challenges, they had more proactive attitudes and were resilient in their survivorship journey. This study also contributes to the evidence that culturally tailored interventions can empower survivors to cope with illness and enhance their ability to navigate their survivorship journey.

#3684 Socioeconomic and clinical predictors of survival in patients with squamous cell tonsillar cancer.

Shama Karanth[1], Pamela Sandow[2], Mihika Shinde[1], Nimish Valvi[3], Kathryn Hitchcock[1], Cesar Migliorati[2], Dejana Braithwaite[1]

[1]University of Florida, Gainesville, FL,[2]University of Florida College of Dentistry, Gainesville, FL,[3]Ball State University, Muncie, IN

Background: Tonsillar cancer represents a distinct and understudied subset of head and neck malignancies with rising incidence, largely driven by human papillomavirus (HPV), associated oropharyngeal cancer. Understanding the roles of clinical characteristics and socioeconomic factors is critical for optimizing early detection and improving outcomes in this population. This study aimed to identify key demographic, clinical, and socioeconomic predictors of treatment delay and overall survival (OS) among patients with tonsillar cancer.

Methods: We conducted a population-based retrospective cohort study using the Surveillance, Epidemiology, and End Results (SEER) database (2010-2021), including individuals aged 20-85+ years with primary tonsil cancer. Data were extracted using SEER*Stat version. The primary endpoint was OS. Multivariable Cox proportional hazards regression and machine learning models enhanced with Shapley additive explanations (SHAP) were used to assess prognostic factors and model interpretability. Model performance was compared with random survival forest (RSF) analyses.

Results: Among 6,148 patients with Stage I-IV tonsillar squamous cell carcinoma, 1,457 (23.7%) deaths occurred during follow-up (median overall survival [OS], 46 months; interquartile range [IQR], 18-85 months). Nearly half (47.5%) presented with stage IV disease, and most were male (84.3%). Regarding treatment, 2,574 (42%) received chemoradiation alone, while 1,381 (22.5%) underwent combined chemoradiation and surgery. The cohort was predominantly non-Hispanic (NH) White (81%), followed by Hispanic (7.1%), NH Black (6.6%), and Other/Unknown (5.3%). In adjusted Cox models, poorer survival was independently associated with stage IV (HR, 2.21; 95% CI, 1.72-2.47), tumor size >40 mm (HR, 2.09; 95% CI, 1.73-2.54), older age (HR, 2.71; 95% CI, 2.22-3.31), distant metastases (HR, 3.47; 95% CI, 2.78-4.32), rural residence (HR, 1.28; 95% CI, 1.10-1.50), low household income (HR, 1.17; 95% CI, 1.04-1.33), and NH Black race (HR, 1.57; 95% CI, 1.33-1.88). The random survival forest demonstrated good discrimination (C-index 0.715), comparable to that of the Cox model (0.759). SHAP analysis identified metastasis, stage, nodal involvement, income, rurality, and race/ethnicity as key predictors.

Conclusion: In this large, population-based study of squamous cell carcinoma of the tonsil, nearly half of the patients presented with advanced disease, and socioeconomic disadvantage was strongly associated with poorer survival. Machine learning analysis identified metastasis, disease stage, nodal involvement, and social factors as key predictors, suggesting that integrating clinical and social context into prognostic models may guide targeted early detection and precision survivorship strategies to reduce disparities.

#3685 A case of rapid progression from Stage I to Stage IV in an MSI-H/EMAST African American colorectal patient.

Mudasir Rashid[1], Hassan Brim[1], Rabia Zafar[1], Christine Nembhard,[1], Sudhir Varma[2], Hassan Ashktorab[1]

[1]Howard University Hospital, Washington, DC,[2]Hithru, New Jersey, NJ

Colorectal cancer (CRC) remains a leading cause of cancer mortality. While most cases arise sporadically, familial risk contributes to about 30%, underscoring the need to assess family history during screening. Microsatellite instability (MSI) is a well-established diagnostic and prognostic biomarker, but elevated microsatellite alterations at selected tetranucleotide repeats (EMAST) remain poorly characterized, particularly among African American patients.We report a 59-year-old African American female with hypertension, hyperlipidemia, and congenital hearing and speech impairment who presented with rectal bleeding. Colonoscopy revealed a 7 cm mass in the transverse colon and a 15 mm sigmoid adenoma. Pathology confirmed a stage I (pT2N0M0) adenocarcinoma that rapidly progressed to stage IV with liver metastasis within one year. Immunohistochemistry showed loss of MLH1 and PMS2 with retained MSH2 and MSH6; MSI testing was MSI-high (BAT26), and EMAST was positive for RBM47.Whole-genome sequencing revealed dense intronic indel clusters in **MSH3**, suggesting MutSβ dysfunction consistent with EMAST. We also identified 21 deleterious missense variants across DNA-repair, immune, and transcriptional pathways (e.g., **ZAP70, MSH4, ESR1, ACVR1B, LMNA**). CNV gains were enriched in duplication-rich loci such as 11p15.5, 11q14, 13q31-q22, and 20q11-q13, overlapping oncogenic clusters (**IGF2/H19, DNMT3B, SRC, BCL2L1, E2F1**). Additionally, 19 frameshift and stop-gain mutations (e.g., **GRIK2, NOS3, WNT16**) introduced premature termination codons.STR profiling demonstrated bidirectional instability—18 expansions and 28 contractions across 46 intronic loci—confirming a pervasive EMAST pattern driven by MSH3 deficiency. This case illustrates a rare, aggressive MSI-H/EMAST CRC with rapid progression, extensive genomic instability, and dual MSI-EMAST features. Findings highlight the biological aggressiveness of combined MSI-H/EMAST tumors and emphasize the need for genetic counseling, molecular surveillance, and targeted precision strategies in underrepresented populations.

#3686 Insights into smoking cessation support for lung cancer patients: A multi-site survey of patient perspectives post-diagnosis.

Lyric R. Li[1], Jo-Ann Persson[2], Aahna Shah[3], Krishna S. Gunturu[4]

[1]Frank H. Netter M.D. School of Medicine at Quinnipiac University, North Haven, CT,[2]Center for Cancer Care, Griffin Hospital, Derby, CT,[3]The Loomis Chaffee School, Windsor, CT,[4]Hartford Healthcare Medical Group Specialists, LLC, Hartford, CT

Background: Although extensive research demonstrates that quitting smoking after a cancer diagnosis—regardless of stage—improves treatment outcomes and quality of life, 30% of patients continue smoking. This study explored differences between lung cancer patients who smoke post-diagnosis and the general smoker population and examined the gap between evidence and patient perspectives by surveying perceived benefits, barriers, and views on cessation support across two community oncology sites in Connecticut.

Methods: We conducted a cross-sectional survey at two clinical sites, recruiting participants during routine visits. The survey assessed demographics, smoking history, perceived benefits and barriers, prior cessation resource effectiveness, comfort and priorities for clinician discussion, concerns about stigma or financial influence, and knowledge and confidence. Most items used 5-point Likert scales and were summarized descriptively. Items were dichotomized (1-3 vs. 4-5) per prespecified rules; items where “1” indicated highest importance/challenge were inverted for consistency. Data was managed in REDCap.

Results: Sample: N=40; age 68.1±6.9; 55.0% female; 40.4±11.6 years smoking; 13.3±8.7 cigarettes/day; 27.9±22.4 pack-years. Only 7.5% rated current cessation resources as effective.

While 55% felt comfortable discussing cessation, 35% wanted more frequent discussions, and 32.5% wanted oncology teams to address cessation even without explicit survival framing. Concerns included fear that disclosure could affect treatment/resources (37.5%) and finances (27.5%). Knowledge and confidence were moderate (67.5% felt informed and confident).

Top internal barriers were withdrawal (52.5%) and reliance on smoking for stress relief (42.5%); external barriers were less common (17.5% lacked knowledge of resources; 17.5% felt rushed/unsupported). Leading motivators: preventing other smoking-related diseases (80%), improving cancer treatment effectiveness (75%), and enhancing daily comfort (62.5%). Additional drivers included a sense of control (40%) and being a role model (42.5%). *Percentages reflect item-level endorsement (agree/strongly agree); totals do not sum to 100% because multiple selections were allowed.*

Conclusions: Patients reported reasonable knowledge and confidence but low perceived effectiveness of current resources, with many desiring more frequent, nonjudgmental discussions. Stigma and fear of negative consequences may suppress disclosure, limiting support. Internal barriers—especially withdrawal and stress coping—predominated. Future implementation priorities include routine, stigma-aware oncology conversations emphasizing ongoing benefits of quitting; proactive withdrawal management with evidence-based pharmacotherapy; and clear messaging to reduce disclosure fears and foster engagement.

#3687 Establishing a data-driven oncology research ecosystem in sub-Saharan Africa: The Medserve-LUTH Cancer Centre (MLCC) research unit experience.

Adedayo Joseph[1], Anthonia Sowunmi[2], Muhammad Habeebu[2], Bolanle Adegboyega[2], Adewumi Alabi[2], Eben A. Aje[2], Temitope Andero[2], Godwin Uwagba[2], Chidiebere Agbakwuru[2], Bukola Oshikanlu[2], Ayodeji O. Ojetunde[2], Samuel Adeneye[2], Nusirat Adedewe[2], Michelle Mangongolo[2]

[1]Lagos University Teaching Hospital, Nigeria, Nigeria,[2]Medserve-LUTH Cancer Centre, Lagos University Teaching Hospital, Lagos, Nigeria

Background: Sustainable cancer research capacity is critical to advancing evidence-based oncology in low- and middle-income countries (LMICs). Historically, Africa has contributed less than 2% of global cancer research output, largely due to inadequate infrastructure, fragmented data systems, and limited clinical research training. The Medserve-LUTH Cancer Centre (MLCC) Research Unit, established in 2020 in Lagos, Nigeria, was designed as a translational research hub within a high-volume clinical environment to bridge this gap through coordinated clinical studies, data science integration, and workforce development.
Methods: The MLCC Research Unit implements a hybrid academic-industry model incorporating electronic data capture, protocol-driven registries, and cross-disciplinary training. The unit supports investigator-initiated and multicentre studies across all oncologic speciality areas, with a common focus on radiation oncology. Emerging areas of innovation have included pediatric radiation oncology, hypofractionated radiotherapy and financial navigation. Key operational metrics including active studies, research personnel, partnerships, and outputs were analysed to assess growth and impact between 2020 and 2025.
Results: Since inception, the MLCC Research Unit has supported 73 ongoing or completed studies spanning clinical, operational, and implementation research. The team has expanded from 2 to 14 trained personnel, including 5 research associates, 7 research assistants and 2 interns. Collaborative partnerships were established with institutions in over 18 countries, and passive collaborations with 207+ international academic partners, facilitating data sharing and joint publications. 127 peer-reviewed manuscripts and 118 conference abstracts have been produced. Research data generated at MLCC have contributed to regional literature, radiotherapy policy discussions, regional clinical trials (e.g., HYPOAfrica, ARETTA), and national and regional pediatric oncology protocols. Integration of internal quality-assurance audits was initiated in 2021 to improve data completeness.
Conclusion: The MLCC Research Unit demonstrates that structured, locally led oncology research ecosystems can thrive in LMIC contexts when aligned with clinical workflow and supported by digital infrastructure and capacity-building programs. This model offers a replicable framework for developing sustainable cancer research capacity across sub-Saharan Africa, linking local data generation to global cancer control priorities.

#3688 Use of targeted therapies in lung cancer following medicare's national coverage determination for next-generation sequencing.

So-Yeon Kang[1], Patrick Roney[2], Jaeil Ahn[2], Tania Lobo[2], Carole Gresenz[3], Arnold Potosky[2], Anita Kinney[4], Marc D. Schwartz[5]

[1]Georgetown University, Washington, DC,[2]Georgetown University Medical Center, Washington, DC,[3]Georgetown University McCourt School of Public Policy, Washington, DC,[4]Rutgers University School of Public Health, Piscataway, NJ,[5]Lombardi Cancer Center, Washington, DC

Background: Despite its clinical importance and growing utilization, access to genomic testing remains uneven, with insurance coverage emerging as a persistent barrier. The Centers for Medicare & Medicaid Services (CMS) implemented a National Coverage Determination (NCD) in March 2018 for genetic testing using next-generation sequencing (NGS). Implementing nationally standardized coverage policy is expected to promote the use of targeted anticancer therapies with proven efficacy. However, whether this policy change increased the use of genomically targeted therapies, which often require testing results for reimbursement, remains unclear. We evaluated the association between the NCD and the use of oral targeted anticancer therapies among Medicare beneficiaries with lung cancer, a disease characterized by a high prevalence of actionable mutations.

Methods: We conducted a retrospective cohort study using SEER-Medicare Part D claims from 2016-2020. Medicare beneficiaries aged ≥65 with lung cancer were followed for up to 12 months after diagnosis. The primary outcome was initiation of Medicare Part D-covered oral targeted therapies. Key exposures included (1) diagnosis before vs. after the NCD and (2) whether the beneficiary lived in a region whose Medicare Administrative Contractor (MAC) had NCD-equivalent NGS coverage before 2018. Multivariable logistic regression models adjusted for demographics (age, sex, race/ethnicity), clinical factors (stage, comorbidity, and initial cancer therapy), geographic region, urbanicity, and neighborhood socioeconomic indicators.

Results: The cohort included 30,855 beneficiaries with a diagnosis of lung cancer. Overall use of targeted therapies declined over time (7.3% before vs. 6.8% after the NCD). The NCD was not significantly associated with targeted therapy use (p=0.78). However, regional variation was substantial. Compared with beneficiaries in regions with pre-existing NCD-equivalent NGS coverage, those in regions without such coverage had lower baseline targeted therapy use (OR=0.77; 95% CI: 0.62-0.97; p=0.02). Following the NCD, regions that previously lacked NGS coverage experienced a greater increase in targeted therapy use relative to regions with prior coverage (interaction OR=1.24; 95% CI: 1.03-1.51; p=0.03).

Conclusions: Medicare's NCD for NGS was not associated with an overall increase in targeted therapy use among beneficiaries with lung cancer, but it reduced regional disparities linked to earlier differences in NGS coverage standards. These findings highlight how pre-existing local coverage policies can shape downstream access to precision oncology treatments even after national policy changes.

#3689 Lurbinectedin plus atezolizumab vs durvalumab maintenance in ES-SCLC: A comparative clinical and economic analysis.

Manaswini Krishnakumar[1], Suma Sri Chennapragada[2], Arpana Ashok[2], Aswanth Reddy[2]

[1]Saint Vincent Hospital, Worcester, MA,[2]Mercy Hospital, Fort Smtih, AR

Background Extensive-stage small cell lung cancer (ES-SCLC) treatment has evolved with improving survival with addition of immunotherapy treatment. Recently, the IMforte trial reported better survival outcomes by adding lurbectindin maintenance with atezolizumab after induction therapy. This approach challenges the current widely used durvalumab-based regimen (CASPIAN trial) for treatment of ES-SCLC. We aim to analyze the survival outcomes, toxicity, tolerability, and cost-effectiveness of these regimens.
Methods: Data from IMforte and CASPIAN trials were directly extracted from published primary manuscripts and associated supplementary materials and synthesized descriptively. Survival outcomes, including overall survival (OS) and progression-free survival (PFS), were analyzed from trial data. Adverse events (AEs), tolerability, and cost-effectiveness using the incremental cost-effectiveness ratio (ICER) per quality-adjusted life-year (QALY) were compared.
Results: In IMforte maintenance lurbinectedin plus atezolizumab yielded a median OS of 13.2 months vs. 10.6 months for atezolizumab (HR 0.73, p=0.017) and PFS of 5.4 months vs. 2.1 months (HR 0.54, p<0.0001). CASPIAN reported a median OS of 12.9 months with durvalumab (vs. 10.5 months for EP; HR 0.75, p=0.0032) and PFS of 5.1 months (vs. 5.4 months; HR 0.80). Patients in both trials received induction with a chemotherapy immunotherapy combination. Grade 3/4 AEs were higher in IMforte's combination (38% vs. 22%), and the CASPIAN trial reported similar grade 3/4 AEs between treatment arms. IMforte trial showed more myelosuppression (e.g., anemia 8%, neutropenia 7%) and CASPIAN more immune-related AEs (20% vs. 3%). Cost analysis revealed IMforte's ICER at $1,071,238/QALY versus CASPIAN durvalumab at $165,182/QALY, both exceeding the $150,000/QALY threshold but with durvalumab closer to cost-effectiveness. Our institutional drug acquisition cost was calculated to be $319,735 for atezolizumab plus lurbectinidin (12 months) vs $111,312 for duvalumab(12 months) maintenance, approximately.
Conclusions: The IMforte combination offers superior PFS and potentially longer OS than CASPIAN's durvalimab-based regimen, but with increased bone marrow toxicity and significantly higher costs. CASPIAN's regimen is more cost-effective, making it a viable option in resource-constrained settings, and lurbenectin can be used as a following line of treatment after progression on durvalumab. The IMforte trial did not allow a crossover; hence, it is unknown if early introduction of lurbecnectin for ES-SCLC will better survival rather than when used as a subsequent line treatment. These findings inform treatment selection for ES-SCLC, balancing efficacy, safety, and economic considerations.

#3690 The impacts of prior authorization policy reforms on breast cancer treatment.

Margot Eliza Hutchins[1], Alyce Adams[1], Lin Ma[1], Alison Kurian[2], Mina Satoyshi[2]

[1]Department of Health Policy, Stanford Cancer Institute, Stanford, CA,[2]Stanford Cancer Institute, Stanford, CA

Prior authorization (PA) is a widely used cost-containment tool that requires third-party approval for coverage of medical tests and treatments. This process is time-intensive for physicians and is frequently associated with delays in patient care; in cancer care, almost 80% of oral chemotherapies require PA, and most cancer patients undergoing PA report delays of two or more weeks. The burden of prior authorization is a growing concern, and major recent changes in state and federal policy aim to streamline and expedite PA. However, the impact of these policies on cancer care remains unclear. Using data from the Oncoshare database (2012-2020), we evaluate how two California laws (SB 866 and SB 282, passed in 2012 and 2014) affect medication utilization and time to treatment among breast cancer patients using a quasi-experimental design. While we observed no significant changes in medication utilization, both laws were associated with reductions in time to treatment. These findings suggest that PA reform improves timely access to cancer therapies.

#3691 Comparing perspectives on HPV vaccination strategies across jurisdictions with and without school-entry requirements: A qualitative study of key informants in the U.S. and territories.

Erika Escabi-Wojna[1], Natalie M. Alamo[1], Mariola Acosta-Rullan[2], Grace Velez-Crespo[3], Pamela C. Hull[4], Maria E. Fernandez[5], Vivian Colon Lopez[1]

[1]University of Puerto Rico Comprehensive Cancer Center, San Juan, Puerto Rico,[2]Icahn School of Medicine, New York, NY,[3]Puerto Rico Science, Technology and Research Trust, San Juan, Puerto Rico,[4]UK Markey Cancer Center, Lexington, KY,[5]UTHealth Houston School of Public Health, Houston, TX

Introduction: HPV is the most common sexually transmitted infection in the United States (U.S.) and the leading cause of cervical and other HPV-related cancers. Despite an FDA-approved HPV vaccine available for over two decades, vaccination rates remain suboptimal, varying by state and ethnicity. While some jurisdictions require HPV vaccination for school entry, most rely on non-mandatory approaches. This study explored how policy contexts, specifically the presence or absence of school-entry requirements, shape strategies, barriers, and facilitators to HPV vaccination.
Methods: We conducted semi-structured interviews with nine key informants (KIs) from six U.S. jurisdictions between May and August 2024. KIs had at least three years of experience in health or vaccination policy and knowledge of HPV vaccination strategies. Seven participants represented jurisdictions with HPV school-entry requirements, and two represented jurisdictions without. Interviews were audio-recorded, transcribed, and coded using a mixed deductive-inductive approach. Verbal data were compared by theme in Dedoose.
Results: KIs from jurisdictions with school-entry requirements emphasized provider recommendation and reframing HPV vaccination as cancer prevention as effective strategies. Those without school-entry requirements highlighted starting vaccination at age nine and using educational materials. Participants from jurisdictions with school-entry requirements reported that the policy increased vaccination rates, improved access, and convinced hesitant parents. KIs from jurisdictions without this policy described resistance that has prevented its adoption, noting that opposition was often aimed at requirements themselves rather than the vaccine, reflecting opposition to government involvement in health decisions. In both policy contexts, misinformation fueled by social media was a major barrier. KIs described the COVID-19 pandemic as a setback that contributed to ongoing vaccine fatigue and skepticism. They noted general exhaustion with vaccine discussions, while some observed that the pandemic polarized attitudes. All KIs emphasized community engagement through trusted messengers and culturally appropriate outreach in building vaccine confidence.
Conclusions: Policy context shapes HPV vaccination framing, delivery, and accessibility. Jurisdictions with school-entry requirements reported better uptake, attitudes, and access, while those without requirements relied on non-mandatory approaches to navigate cultural and political sensitivities. Comparative insights can guide context-specific implementation approaches to enhance HPV vaccination and reduce cancer outcomes. Funding: NCI grant #R01CA232743. Declaration of Generative AI: The authors used AI for editing suggestions.

#3692 Accelerating global impact in translational cancer research: Lessons from 15 years of the EU TRANSCAN initiative.

Valentina Trapani[1], Katarina Bibova[2], Estela Cepeda[3], Giusi Condorelli[4], Liron Even-Faitelson[5], Charlotte Gudewicz[6], Sebastian Hueckesfeld[7], Anabela Isidro[8], Emma Ito[9], Fei-Fei Liu[9], Hubert Misslisch[7], Elisa Nannicini[10], Floriane Nguyen[11], Martin NovaK[2], Silvia Paradisi[12], Giulia Piaggio[13], Ines Rey Hidalgo[11], Maria Romero[14], Hugo Soares[8], **Giandomenico Russo**[15]

[1]Alliance Against Cancer, UniCamillus-Saint Camillus International University of Health and Medical Sciences, Roma, Italy,[2]Slovak Academy of Science, Bratislava, Slovakia,[3]Fundacion Cientifica de la Asociacion Espanola Contra el Cancer, Madrid, Spain,[4]Italian Ministry of Health, Roma, Italy,[5]Chief Scientist Office, Ministry of Health, Jerusalem, Israel,[6]Institut National du Cancer, Boulogne-Billancourt, France,[7]DLR Projekttrager, Bonn, Germany,[8]Agencia De Investigacao Clinica E Inovacao Biomedica, Lisbon, Portugal,[9]Canadian Institutes of Health Research - Institute of Cancer Research, Toronto, ON, Canada,[10]Regione Toscana, Firenze, Italy,[11]FICYT - Fundacion para el Fomento en Asturias de la Investigacion Cientifica y la tecnologia, Oviedo, Spain,[12]Istituto Superiore di Sanita, Roma, Italy,[13]Alliance Against Cancer (Alleanza Contro Il Cancro), Istituto Nazionale Tumori Regina Elena, Roma, Italy,[14]Alliance Against Cancer, Italian Ministry of Health, Roma, Italy,[15]Alliance Against Cancer, Roma, Italy

Efficient and sustainable collaboration among cancer research funders is critical to addressing the growing complexity of cancer prevention, diagnosis, and treatment. Over the past 15 years, the TRANSCAN initiative, encompassing TRANSCAN, TRANSCAN-2, and TRANSCAN-3, has built a mature and flexible model for aligning translational cancer research funding across Europe and beyond. Supported in its last two phases by the EU ERA-NET co-funding scheme, TRANSCAN promotes convergence between national and regional priorities, and EU-level strategic goals. Since 2011, TRANSCAN has pioneered two innovative features: the integration of public and private funders into a single coordinated framework, and the targeted support of small investigator-driven research consortia. Each participating organization contributes in line with its national strategies and available resources to jointly launch Transnational Calls (JTCs) covering a broad range of translational cancer research topics. The current phase, TRANSCAN-3, coordinated by the Italian Ministry of Health, brings together 31 funding agencies from 20 different countries, including non-European partners such as Canada and Taiwan. The initiative also places strong emphasis on engaging early-career researchers and patient representatives, fostering inclusiveness and shared ownership of the research agenda. A new phase, TRANSCAN-4, is currently being planned, reflecting the continued strategic importance of transnational coordination in cancer research. Between 2011 and 2025, TRANSCAN received approximately €8 million from the European Commission to support its activities and management. During this period, the network successfully implemented 11 JTCs that mobilized a total of €148 million in national and regional funding. In addition, the European Commission co-funded two of these calls, directly supporting research projects with a further €12 million. Altogether, 141 small- to mid-sized consortia, involving 723 research groups, have been funded. These focused, transnational collaborations complemented larger EU-funded cancer consortia and contributed to high-impact translational results. Beyond financial coordination, TRANSCAN has strengthened capacity building, cross-border networking, stakeholder engagement, and long-term strategic alignment among funders. The TRANSCAN initiative demonstrates the value of sustained transnational cooperation in cancer research funding. Its bottom-up, inclusive, and mixed public-private model has significantly advanced the EU and international cancer research landscape in line with the EU Mission on Cancer and Europe’s Beating Cancer Plan. This long-term cooperation model offers a blueprint for future alignment of national and regional, public and private programs to achieve collective impact. More information is available at: www.transcan.eu.

#3693 Barriers and challenges to women leadership in medical research and how to overcome them.

Adriana Albini[1], Elisabetta Vercesi[2], Eva Negri[3], Giovanni Corso[1], Sonia Levi[4], **Douglas McClain Noonan**[5]

[1]IEO - European Institute of Oncology, Milan, Italy,[2]Fondazione Onda, Osservatorio nazionale sulla salute della donna e di genere ETS, Milan, Italy,[3]Department of Medical and Surgical Sciences, Universita di Bologna, Bologna, Italy,[4]Vita-Salute San Raffaele University, Milan, Italy,[5]IRCCS MultiMedica, Sesto San Giovanni, Italy

Women in leading positions in medical research remain underrepresented and face systemic barriers to career advancement, including implicit biases and stereotypes. To explore these issues, and envisage feasible solutions, we conducted a cross-sectional qualitative study using a 33-item questionnaire. The survey was completed by 82 Italian senior academic female researches with an h-index higher than 60 in biomedical research. Major fields of study were biology, neurosciences, immunology, metabolism, genomics, pharmacology and oncology/cancer biology. This cohort offers insights into the experiences, struggles, and achievements of highly successful women in medical research. Findings reveal persistent gender biases and societal expectations slowing or hindering women's career progression, with only 17% of respondents expressing satisfaction with gender parity in opportunities within the field Almost all (91%) reported challenges with work-life balance and lack of institutional support, many respondents emphasized the underrepresentation of women in leadership, with 74% highlighting the need to increase female participation in decision-making roles. Additionally, 61% advocated for promoting more women to senior positions toward achieving gender equality in the field. 89%, experienced at least one gender-related obstacle during their career while 42% were tempted to resign from their professional role. These results highlight the persistent structural and cultural obstacles that even top-performing women face in the field. Targeted strategies such as mentorship, education to counteract bias, flexible work policies, and equitable promotion policies are required for empowerment and to foster a more inclusive environment for current and future generations of women scientists. The study also highlights the resilience, dedication, and motivation of women academic medical researchers. Their sense of responsibility, passion for science, and the search of both personal and social support systems are crucial factors contributing to their persistence in the field, encouraging younger women to pursue a career in medical research.

#3694 Development of a DCE-based classification tree to enhance shared decision-making in patients with advanced prostate cancer.

Pranav Prakash[1], Jennifer A. Wenzel[2], Winter M. Thayer[3]

[1]Johns Hopkins University, Baltimore, MD,[2]Johns Hopkins University School of Nursing, Baltimore, MD,[3]School of Nursing, Johns Hopkins University School of Nursing, Baltimore, MD

Prostate cancer remains one of the most prevalent cancer types in the United States. The extensive range of available treatment options and diverse care pathways often creates significant uncertainty and anxiety for patients navigating the decision-making process. Each patient, along with their support network, tends to have unique priorities regarding treatment, such as financial stability, alleviating symptoms, or extending survival. There is a need for effective tools to help shared decision-making. The Cancer Health Aid to Manage Preferences and Improve Outcome through Navigation (CHAMPION) trial is a randomized controlled study designed to evaluate whether Community Patient Navigators (CPNs), equipped with mobile health tools, can improve patient confidence and satisfaction during cancer treatment decision-making, and enhance collaboration between patients and healthcare practitioners. Within the CHAMPION trial, a nested study, Cancer Preference Reflection and Elicitation for Family Support (C PREFS), utilizes discrete choice experiments (DCEs) to examine and quantify patient preferences when considering treatment options for advanced prostate cancer. DCEs involve presenting participants with hypothetical scenarios and asking them to indicate their preferred choices. The primary objective of this project is to develop a classification tree, which serves as a model for decision-making, informed by interview data collected from patient-supporter dyads. Advanced prostate cancer patient-supporter dyads were interviewed about disease and treatment history, beliefs about medical treatment, and symptomatic characteristics of the cancer. Patients continue to be recruited at the Johns Hopkins Sidney Kimmel Comprehensive Cancer Center. Eligible patients who consent to participate in the study will complete future visit surveys and DCEs that will be used to validate the classification tree. This study is thus contributing towards development of a classification tree capable of accurately predicting the treatment preferences of advanced prostate cancer patients. The resulting tool has the potential to serve clinicians and patients by supporting shared decision-making processes and ensuring that treatment recommendations are closely aligned with individual patient values and preferences.

#3695 The Artemis Project: A patient-led global research consortium advancing prevention-focused breast cancer innovation.

Fran M. Visco[1], Jayanta Debnath[2], Daniel Douek[3], Stephen J. Elledge[4], Silvia C. Formenti[5], Michele S. Garfinkel[1], Cyrus M. Ghajar[6], Patricia K. Haugen[7], Christopher I. Li[6], Herbert Kim Lyerly[8], **Michelle Tregear**[1], Alana L. Welm[9], Frank J. Calzone[10]

[1]National Breast Cancer Coalition, Washington, DC,[2]UCSF - University of California San Francisco, San Francisco, CA,[3]Human Immunology Section, NIAID, NIH, Bethesda, MD,[4]Harvard Medical School, Boston, MA,[5]Weill Cornell Medicine, New York, NY,[6]Fred Hutchinson Cancer Research Center, Seattle, WA,[7]Independent advocate, Sioux Falls, SD,[8]Professor, Duke University (Columbus, OH), Durham, NC,[9]University of Utah Huntsman Cancer Institute, Salt Lake City, UT,[10]Self-employed consultant, Westlake Village, CA

Purpose: The National Breast Cancer Coalition (NBCC), established in 1991, is a collaboration of activists, survivors, grassroots groups and national organizations united to end breast cancer through action and advocacy. Despite progress in certain areas, neither breast cancer incidence nor global mortality have significantly declined. In response, NBCC launched the Artemis Project in 2010, an advocate-led initiative focused on primary prevention of breast cancer and prevention of metastasis, designed to foster new collaborations among researchers and advocates. The project is a response to the fact that despite billions of dollars invested in research that has led to some effective treatments, we still do not know how to prevent or cure breast cancer.
Artemis process: The Artemis Project is a collaboration to identify urgent gaps, set milestones, and co-develop research solutions to primary and metastasis prevention. Unlike traditional research development pipelines, Artemis integrates trained patient advocates as equal partners in priority setting, research design and oversight. Advocates identify the participants and choose the issues. Collaborations form at the annual meeting among researchers and advocates who often would not have met otherwise.The annual Artemis meeting brings participants together to explore new ideas, develop innovative projects towards Artemis's goals, and outline work plans for 12-18 months after the meeting. Online meetings are held throughout the year for the groups to interact and to report progress. Seed funding for some projects has been provided by NBCC. NBCC schedules webinars throughout the year on relevant topics for Artemis participants.
Selected Artemis outcomes: The first Artemis project led to an ongoing initiative to develop a breast cancer prevention vaccine, with a plan in place to move to a Phase I trial by mid-2026. The vaccine, consisting of 6 self-antigens overexpressed in breast cancer, is being developed under a contract with the NCI Prevent Program. DNA Land, an effort stemming from another Artemis project, has recruited over 33,000 individuals who have consented and contributed genomic and matched phenotypic data to underpin bioinformatics studies supporting prevention-focused breast cancer research.Additionally, researchers participating in Artemis have formed many collaborations that have grown into externally funded research efforts, including a project to eliminate disseminated tumor cells.
Conclusions: Now 15 years in, the Artemis Project has created a durable, advocate-led ecosystem that unites researchers, clinicians, and advocates to pursue transformative prevention solutions rather than incremental advances. This model is adaptable across disease research areas.

: Adoptive Cell Therapy 1
Poster Session

#3699 The "Preservation & Expansion" process: A key milestone for enhancing accessibility of autologous tumor-infiltrating lymphocyte therapy by enabling long-term cryopreservation of seed cells.

Zhou He, Xingming Ma, Feng Yin, Shanshan Liang, Wenjia Zhuang, Hui Yan, Huajun Jin

Shanghai Juncell Therapeutics Co., Ltd, Shanghai, China

Background: Tumor-infiltrating lymphocyte (TIL) therapy has shown promising efficacy in advanced solid tumors. However, its autologous nature poses a major limitation due to the ineligibility of many patients with advanced disease for repeated tumor resections, leading to a loss of potential treatment opportunities. To overcome this challenge, we developed a “Preservation & Expansion” strategy, in which TIL seed cells are generated from initial tumor tissue and cryopreserved for on-demand expansion into final products (FP) upon treatment need.
Objective: This study aimed to validate the feasibility of expanding FPs from cryopreserved TIL seed cells after various storage durations.
Methods: Tumor tissues were processed and initially cultured to generate seed cells. Seed cells generated from tumor tissues were either immediately expanded (G0) or cryopreserved for 3 days (G3D), 1, 2, 3, or 6 months (G1M-G6M), or 1 or 2 years (G1Y, G2Y) prior to expansion. Cell viability was assessed at the seed, intermediate, and FP stages. Phenotypic analysis (CD3+, CD8+, CD4+, CD56+) was performed on both seed cells and FPs, while functional analyses, including IFN-γ secretion and cytotoxicity via real-time cell analysis (RTCA), were conducted on the FPs.
Results: Viability of cells derived from various tumor tissues post-thaw was comparable across different cryopreservation durations, with the following results (%): G0: 79.7±6.4; G3D: 80.9±5.1; G1M: 81.0±5.8; G2M: 80.2±3.9; G3M: 81.3±4.7; G6M: 81.0±5.3; G1Y: 80.4±5.6; G2Y: 80.8±4.8. Moreover, no significant differences in cell viability were observed during the REP culture phase at various time points. Phenotypic characterization by flow cytometry revealed similar profiles among seed cells cryopreserved for different durations and their corresponding final cellular products. Furthermore, cryopreservation duration had minimal impact on the effector functions of the final products, as evidenced by well-maintained levels of IFN-γ secretion and cytotoxic activity across all groups. IFN-γ secretion levels (ng/ml) were: G0: 14.5±7.0; G3D: 15.0±4.2; G1M: 13.4±5.0; G2M: 14.8±5.0; G3M: 16.5±5.0; G6M: 16.5±5.0; G1Y: 16.9±5.0; G2Y: 20.4±5.0. Cytotoxicity assessed by RTCA (%) was as follows: G0: 76.8±7.9; G3D: 78.1±4.3; G1M: 78.3±8.9; G2M: 77.4±9.0; G3M: 79.2±8.3; G6M: 79.9±3.7; G1Y: 77.2±8.7; G2Y: 83.2±3.6.
Conclusion: TIL seed cells can be effectively expanded into functional FPs with consistent viability, phenotype, cytokine secretion, and cytotoxicity after long-term cryopreservation up to two years. These results validate the "Preservation & Expansion" process as a robust and feasible approach to improve the accessibility and practicality of autologous TIL therapy by decoupling tumor resection from treatment timing.

#3700 Engineering iPSC-derived NK cells with autocrine feeder signaling to enhance cytotoxic function.

Yi-Chen Sun[1], Zhi-Qian Lin[2], Chieh-Min Wang[2], Yun-Yi Yang[3], Yi-Ping Yang[2], **Kai-Feng Hung**[4]

[1]Taipei Tzu Chi Hospital, The Buddhist Tzu Chi Medical Foundation, New Taipei City, Taiwan,[2]Taipei Veterans General Hospital, Taipei, Taiwan,[3]Kang Chiao International School, New Taipei City, Taiwan,[4]National Yang Ming Chiao Tung University, Taipei, Taiwan

Natural killer (NK) cells are key effectors in cancer immunotherapy, but their clinical translation is hindered by limited cell expansion and persistence. Feeder-based expansion systems using tumor-derived K562 cells achieve robust cell proliferation but raise safety concerns. To address these challenges, we generated human induced pluripotent stem cell (iPSC)-derived NK cells endowed with self-feeder properties and autocrine signaling that promote cell expansion and functional activation while minimizing oncogenic risk. Specifically, iPSCs were differentiated into hematopoietic progenitors (iHPCs) under defined conditions and subsequently matured into NK (iNK) cells. The self-supporting iNK cells were then established by viral transduction to express CD86, 4-1BB ligand (4-1BBL), and interleukin-21 (IL-21) bispecific antibodies engineered in a single-chain variable fragment (scFv) format. We showed that the optimized hybrid differentiation protocol yielded highly pure (92.1% $CD56^+$) NK cells that expressed early activation markers ($CD161^+$) but remained phenotypically immature ($CD94^+$ 2.2%, $CD16^+$ 17.7%), consistent with an early-stage but lineage-committed NK phenotype. The engineered self-supporting iNK cells exhibited robust expression of CD86, 4-1BBL, and IL-21 bispecific scFv. Co-culturing the self-supporting iNK cells with primary NK cells isolated from peripheral blood prolonged the viability of the primary NK cells beyond the typical two-week lifespan, indicating self-feeder supportive function. Importantly, the self-supporting iNK cells exhibited enhanced cytotoxicity against K562 cells and retained their cytolytic function even after repeated re-challenge with K562 targets. In conclusion, the engineered iNK cells demonstrated dual functionality, acting both as feeder cells and as cytotoxic effectors against target cancer cells. These self-supporting iNK cells with autocrine feeder signaling hold potential to advance NK cell-based cancer immunotherapy.

#3701 Safety and efficacy of CAR T-cell therapy in CNS lymphoma: A meta-analysis.

Ahmad Shawabkeh[1], Muaath I. Alsufi[1], Homam AbuHashesh[1], Heba Khreisat[1], Zaid Muhanna[1], Salma Salman[2], Ahmad Obeid[1], Layan AlDaher[1], **Jehad Yasin**[1]

[1]School of Medicine, University of Jordan, Amman, Jordan,[2]School of Medicine, Ain Shams University, Ain Shams, Egypt

Background: The efficacy and safety of Chimeric Antigen Receptor T-cell (CART) therapy in Central Nervous System Lymphoma (CNSL) remain uncertain, given the limited representation of CNS involvement in pivotal CAR T-cell trials. This meta-analysis synthesized data from studies evaluating outcomes in both primary (PCNSL) and secondary CNS lymphoma (SCNSL) cohorts treated with CART.

Methods: A comprehensive search was performed across PubMed, Scopus, Web of Science, and clinical registries up to June 2025. Studies reporting efficacy or toxicity outcomes in CNSL following CART therapy were included. Proportions were stabilized using the Freeman-Tukey double arcsine transformation and pooled using inverse variance weighting. Between-study heterogeneity was estimated with the DerSimonian-Laird method, and τ^2 confidence intervals were calculated via the Jackson approach. Random- or fixed-effects models were applied based on $I^2 \geq 50\%$ or $< 50\%$, respectively. Publication bias was assessed using Egger's regression. Subgroup and multiple meta-regression analyses evaluated moderators including CNS category (PCNSL, SCNSL, or Both) and publication year.

Results: Data from thirty-nine studies encompassing 1,457 participants were meta-analyzed. The pooled overall response rate (ORR) was 0.75 [95% CI: 0.70-0.79; $I^2 = 52.2\%$]. Complete response (CR) rate was 0.52 [95% CI: 0.46-0.58; $I^2 = 63.0\%$], and partial response (PR) rate 0.18 [95% CI: 0.14-0.22; $I^2 = 50.40\%$]. No significant publication bias was detected. Meta-regression indicated no significant effect of publication year or CNS category on ORR. Cytokine Release Syndrome (CRS) occurred in 83.8% [95% CI: 79.1-88.2; $I^2 = 71.4\%$], with grade ≥3 CRS in 5.74% [95% CI: 3.21-8.76; $I^2 = 62.1\%$]. Immune Effector Cell-Associated Neurotoxicity Syndrome (ICANS) was reported in 44.4% [95% CI: 35.9-53.1; $I^2 = 86.5\%$], with severe (grade ≥3) events in 16.8% [95% CI: 11.9-22.4; $I^2 = 74.3\%$].

Conclusions: CART therapy achieves robust response rates in CNS lymphoma, with efficacy comparable between PCNSL and SCNSL. Neurotoxicity remains frequent but manageable, and severe CRS events are infrequent.

#3702 No impact of dexamethasone on CAR-T cell expansion in vitro and in patients with RRMM.

Lelisa Gemta[1], **Lawrence P. Andrews**[1], Matthew J. Frigault[2], Binod Dhakal[3], Jacalyn Rosenblatt[4], Michael R. Bishop[5], Sigal Shachar[1], Jenny Mu[1]

[1]Arcellx, Rockville, MD,[2]Massachusetts General Hospital, Boston, MA,[3]Department of Medicine, Medical College of Wisconsin, Milwaukee, WI,[4]Beth Israel Deaconess Medical Center, Harvard Medical School, Boston, MA,[5]David and Etta Jones Center for Cellular Therapy, University of Chicago, Chicago, IL

Chimeric antigen receptor (CAR)-T cell therapy is an effective treatment for relapsed/refractory multiple myeloma (RRMM). The Phase 1 trial of anitocabtagene autoleucel (anito-cel), an autologous D-Domain BCMA-directed CAR-T cell therapy, demonstrated a 100% overall response rate and a median progression free survival rate of 30.2 months, with a median follow-up of 34 months (Bishop et al., 2024). No delayed neurotoxicities were observed (Kaur et al., 2025), such as parkinsonism or cranial nerve palsies reported in up to 10% of real-world ciltacabtagene autoleucel (cilta-cel)-treated patients and associated with elevated absolute lymphocyte count (ALC) indicative of CAR-T cell hyper-expansion as a major risk factor (Lim et al., 2025). Pre-emptive intervention using dexamethasone (Dex) based on ALC has been proposed to limit uncontrolled expansion and prevent delayed neurotoxicity (Turner et al., 2025). However, in patients with large B-cell lymphoma treated with axicabtagene ciloleucel in ZUMA-1, prophylactic steroids did not hinder CAR-T cell expansion (Cohort 6; Oluwole et al., 2021). Thus, further investigation of the impact of Dex on CAR-T cell expansion and function is warranted.

In the Phase 1 study of anito-cel (n=38), 66% of patients received Dex to treat cytokine release syndrome (CRS) events. Patients requiring Dex intervention showed higher soluble BCMA levels at screen, indicative of greater tumor burden. No patients received prophylactic Dex. Consequent Dex use did not suppress CAR-T cell expansion below levels observed in non-Dex-treated patients (ALCmax: 1.39 [0.82-3.07] vs 1.01 [0.49-1.28] k/ul). Differences in CAR-T cell activation-associated cytokines were observed between Dex and non-Dex-treated patients.

The increase of CAR-T cell expansion in patients with higher tumor burden, who required intervention with steroids, is consistent *in vitro* when CAR-T cells were stimulated with a high BCMA density cell line (H929) compared to a low BCMA density cell line (Raji). For these *in vitro* studies, surrogate versions for anito-cel (D-Domain), cilta-cel (VHH) and idecabtagene vicleucel (scFV) were generated and the impact of Dex on CAR-T cell phenotype and functionality was assessed. Treatment with Dex did not impact CAR-T cell expansion, cytolytic activity, CAR expression, CD4:CD8 ratio or differentiation/activation state. While Dex did not impact CAR-T cell expansion (D-Domain 4.8 vs 4.4; VHH 5.4 vs 4.3; scFV 5.3 vs 4.9 fold expansion), Dex treatment decreased IL-2 production, *in vitro*, making it an effective CRS treatment.

While increased ALC and rapid CAR-T cell expansion within the first 28 days has been identified as a biomarker for delayed neurotoxicities, these data suggest that high dose steroids may not be an efficacious intervention for ALC restraint. Instead, Dex treatment is likely to curb proinflammatory cytokines and thus is an appropriate intervention for CRS management.

#3703 Sentinel lymph node-derived CD45$^+$ cells combined with low-dose radiotherapy and PD-1 blockade as a next-generation adoptive cell therapy in head and neck cancer.

Pardis Mohammadzadeh[1], Tomoya Kurokawa[1], Kelsey Decker[1], Peter Vo[1], Prakriti Sen[1], Riley N. Jones[2], Sayuri Miyauchi[2], Santiago Fassardi[1], Anais Zourelidis[1], Robert Saddawi-Konefka[3], Joseph A. Califano[1]

[1]Gleiberman Head and Neck Cancer Center, Moores Cancer Cencer, University of California San Diego, San Diego, CA,[2]Department of Radiation Medicine & Applied Scienes, and Moores Cancer Center, University of California San Diego, San Diego, CA,[3]Department of Head and Neck Cancer Surgery, University of California San Diego, San Diego, CA

Purpose: Head and neck squamous cell carcinoma (HNSCC) is the seventh most common cancer globally, representing roughly 6% of all malignancies. Each year it accounts for an estimated 660,000 new diagnoses and over 325,000 deaths, with incidence projected to rise by nearly 30% by 2030. Despite advances in surgery, radiation, and immunotherapy, patients with HPV-negative HNSCC continue to face poor outcomes, with five-year overall survival rates often below 55%. Adoptive cell therapy (ACT) in solid tumors remains limited by the scarcity of tumor-reactive T cells and their functional exhaustion after expansion. The sentinel lymph node (SLN), the initial site of tumor antigen presentation and T-cell priming, may provide a rich and minimally exhausted source of tumor-specific lymphocytes. Here, we evaluated the immunologic and therapeutic advantages of SLN-derived leukocytes over those from tumor tissue in an orthotopic model of HPV$^-$ HNSCC.

Methods: CD45$^+$ immune cells isolated from donor SLNs, NSLNs, tumors, or SLNs preconditioned with low-dose tdRT (4 Gy) in the 4MOSC1 murine model were adoptively transferred into syngeneic tumor-bearing recipients to evaluate their therapeutic potential. Recipient groups included untreated controls, preconditioned mice with 4 Gy tdRT, or a single PD-1 blockade (PD1i) dose before ACT. Phenotypic and functional characterization was performed using flow cytometry, multiplex immunofluorescence, ELISA, and CITE-seq to evaluate cell populations, activation, exhaustion, clonal overlap, and tissue distribution.

Results: SLN-CD45$^+$ populations were enriched in activated CD4$^+$/CD8$^+$ T cells with elevated CD69, CD137, and IFN-γ expression compared with tumor-derived counterparts. mIHC confirmed higher densities of activated T cells in SLN and tumor regions after SLN-CD45$^+$ transfer. TCR analysis revealed substantial overlap between SLN and tumor clonotypes, suggesting selective enrichment of tumor-reactive clones. Functionally, ACT with SLN-CD45$^+$ cells induced greater tumor regression and survival benefits than ACT from tumor source, even without lymphodepletion or expansion in culture. Notably, cryopreserved SLN-derived cells retained comparable efficacy to freshly isolated ones. Preconditioning recipients with 4 Gy tdRT or PD1i further improved intratumoral infiltration, activation, and persistence of transferred cells without added toxicity.

Conclusions: The sentinel lymph node provides a potent, readily accessible reservoir of tumor-reactive immune cells for ACT. Combining SLN-derived ACT with tdRT and PD1i significantly enhances therapeutic efficacy in HPV$^-$ HNSCC. These findings highlight the translational potential of leveraging tumor-draining lymphoid niches as tumor-primed immune reservoirs for next-generation ACT in solid tumors.

#3704 Long-term *ex vivo* expansion of functional CAR-T cells using the biomimetic AeroCyte-based artificial antigen-presenting cell platform.

Yu-Tsueng Liu, Mindy Yin, Guixin Shi

AeroCytek, Inc., San Diego, CA

Strategies to sustain CAR-T cell persistence in vivo include enriching stem-like products, repeated infusions of engineered cells, and improving the tumor microenvironment. Peripheral T lymphocytes exhibit remarkable self-renewal, with studies showing up to 10^{41}-fold expansion in syngeneic mice over 10 years (Nature, 2023; 614:762), and similar potential ex vivo, though technical barriers persist. Here, we assessed a biomimetic phospholipid microbubble platform (AeroCyte) designed as artificial antigen-presenting cells (aAPCs) to support long-term ex vivo CAR-T cell expansion. AeroCyte-J, coated with appropriate ligands, mimics natural cell-to-cell (juxtacrine) interactions for T cell stimulation and undergoes spontaneous dissolution in media. We hypothesized this system would enhance ex vivo production of stem-like T cells and enable repeated dosing to overcome hostile in vivo conditions.

$CD4^+$ T cells were isolated from human blood using anti-CD4-conjugated AeroCyte and activated with anti-CD3/CD28-conjugated AeroCyte (AeroCyte-J328) for two weeks, then restimulated biweekly for about 6 months, achieving up to 10^{16}-fold expansion. Notably, expansion was absent without AeroCyte-J328. Next, three CAR-T cell lines targeting GD2, HLA-A2, or CD19, which were generated from a vial of frozen PBMCs from a different donor, were expanded over seven biweekly cycles using AeroCyte-J328. The expanded cells were $CD3^+$ and included both $CD4^+$ and $CD8^+$ subsets. CAR-T cells from each stimulation cycle were evaluated for target-specific cytotoxicity by co-culturing them for three days without IL-2 with GFP-expressing Raji cells ($CD19^+$, HLA-$A2^-$, $GD2^-$) and T98G cells ($CD19^-$, HLA-$A2^+$, $GD2^+$). Using the number of target cells co-cultured with non-transduced PBMCs as the baseline control (set at 100%), all three CAR-T cell types demonstrated target specificity, particularly at lower effector-to-target (E:T) ratios, as determined by flow cytometry or fluorescence microscopy. Reproducibility was confirmed by expanding CAR-T cell lines derived from one of three additional donor PBMC samples across four biweekly cycles, which produced consistent and comparable results.

Long-term expansion depended on continuous aAPC stimulation and is attributed to intrinsic T cell self-renewal rather than malignant transformation, given that expansion is AeroCyte-J328-dependent and the improbability of simultaneous malignant transformation across independent cultures. Additional preclinical and clinical validation of this simple and robust platform could make CAR-T therapy more accessible and affordable, as well as enable improved treatment of solid tumors, for example through repeated dosing.

#3705 Integration of affinity-dependent modulation and CD5/TRAC knockout generates fratricide-resistant and highly cytotoxic anti-CD5 CAR-T cells.

Seojeong Kim[1], Jeong Hoon Jeong[2], Jihyun Park[3], Youngho Lee[2], Hyung Cheol Kim[2], Hyoung Jin Kang[4], Matthew H. Porteus[5], Steven Feldman[5], Youngil Koh[4]

[1]Seoul National University, Seoul, Korea, Republic of,[2]Curocell Inc., Daejeon, Korea, Republic of,[3]Seoul National University Hospital, Seoul,[4]Seoul National University Hospital, Seoul, Korea, Republic of,[5]Stanford University, Stanford, CA

CD5-positive T-cell malignancies, including T-cell acute lymphoblastic leukemia and peripheral T-cell lymphoma, remain challenging to treat due to severe fratricide during CAR-T manufacturing and a lack of effective therapeutic options. Previous work generated two anti-CD5 CAR-T constructs (CAR5) containing unique CD5 binders with distinct affinities, designated A2CAR5 (high affinity) and C7CAR5 (low affinity), to evaluate how binding strength influences CAR-T cell functionality. A2CAR5 exhibited robust antigen engagement but suffered from severe fratricide accompanied by excessive cytokine release, whereas C7CAR5, with lower affinity, largely avoided fratricide while retaining potent cytotoxicity both in vitro and in vivo. However, attempts to improve the functionality of either construct through CD5 knockdown resulted in only limited enhancement. The present study builds upon these findings by applying CD5 and TRAC gene editing to the high-affinity CAR5 to further enhance its efficacy and safety. A comparative evaluation of A2CAR5 and C7CAR5 with CD5 knockout (KO) was conducted to assess affinity-dependent function, while a CD5/TRAC double knockout (dKO) was designed to develop an optimized allogeneic CAR5 platform. Since allogeneic CAR-T cells may exhibit limited persistence following infusion, achieving potent initial activity is critical for therapeutic success. CD5 KO effectively abolished fratricide in A2CAR5 cells, normalizing IFN-γ and TNF-α secretion to levels comparable to those of non-transduced T cells. Surface marker analysis revealed that fratricide led to a progressive increase in the proportion of CAR^+ cells over time, whereas CD5 KO eliminated this abnormal enrichment, reduced exhaustion marker expression, and preserved a favorable memory phenotype. Following CD5 KO, A2CAR5 consistently demonstrated superior functional performance compared to C7CAR5, exhibiting stronger cytotoxic activity specifically against $CD5^+$ target cells and greater functional persistence under repetitive antigen exposure. To achieve efficient disruption of both CD5 and TRAC, a sequential targeting approach was adopted, which proved more effective and consistent than conventional double knockout methods. In conclusion, these findings indicate that CD5 knockout reduces fratricide and limits T-cell exhaustion, supporting the development of optimized allogeneic CAR5 cells through the integration of binder design and gene editing. Future work will incorporate AAV6-mediated CAR knock-in at the TRAC locus to further enhance genomic precision and product consistency.

#3706 Impact of number of IL-2 infusions and product out of specification status on outcomes of tumor infiltrating lymphocyte therapy for melanoma.

Mohamed A. Aboelatta[1], Jeffrey E. Johnson[1], Jabra G. Zarka[1], Matyas Benada[2], James W. Jakub[3], Roxana S. Dronca[3], Ruqin Chen[3], Mahesh Seetharam[4], Deepti Behl[1], Svetomir N. Markovic[1], Lisa A. Kottschade[1], Heather N. Montane[1], Matthew S. Block[1], Anastasios Dimou[1], Robert R. McWilliams[1], Paula Gill[1], Yi Lin[1], **Arkadiusz Z. Dudek**[1]

[1]Mayo Clinic, Rochester, MN,[2]Charles University, Hradec Kralove, Czech Republic,[3]Mayo Clinic, Jacksonville, FL,[4]Mayo Clinic, Scottsdale, AZ

Background: High-dose interleukin-2 (IL-2) is administered after tumor-infiltrating lymphocyte (TIL) infusion to promote in-vivo expansion and persistence, yet optimal dosing and the clinical significance of out-of-specification (OOS) TIL products remain unclear. We investigated the impact of number of infused IL-2 doses and manufacturing OOS status on outcomes in metastatic melanoma treated with commercial TIL therapy.

Methods: We retrospectively analyzed 31 patients treated across three Mayo Clinic sites. Planned IL-2 was 600,000 IU/kg every 12 hours for ≤6 doses; actual dosing varied based on clinical tolerance. Patients were grouped as low (0-2) vs high (≥3) IL-2 doses. TIL products were classified as within-specification or OOS per commercial release criteria. Survival associations were evaluated using Kaplan-Meier and multivariable Cox regression.

Results: In our 31-patient cohort, the median age was 59 years (range 17-77), 58% were male, and 84% had ECOG 0. At TIL infusion, M-stage distribution was M1a 6%, M1b 10%, M1c 61%, and M1d 23%. LDH was elevated above the upper limit of normal in 42%. The median number of IL-2 infusions was 4 (range 0-6); 58% of patients received ≥3 doses, while 2 patients (6%) received none. Out-of-specification (OOS) TIL products occurred in 6 patients (19%). Best responses included complete response (26%) and partial response (23%), for an overall response rate of 48% and a disease-control rate of 61% (CR + PR + SD). Among responders, the median duration of response was 84 days (95% CI 73-95). At data cutoff, the median follow-up was 253 days (95% CI 137-370). The most common grade 3/4 toxicities occurring >14 days after TIL infusion were lymphopenia (39%), anemia (16%), and thrombocytopenia (10%). Median progression-free survival (PFS) was 99 days (95% CI 73-125) with 20 progression events, and median overall survival (OS) was 193 days (95% CI 32-354) with 13 deaths. Number of infused IL-2 doses was dependent on patients tolerability. Receiving ≥3 IL-2 doses was associated with improved overall survival (394 vs 101 days; $p < 0.001$) and a trend toward longer progression-free survival (110 vs 59 days; $p = 0.055$). OOS products predicted inferior PFS (30 vs 110 days; $p = 0.003$) and showed a trend toward worse OS (120 vs 394 days; $p = 0.079$). In multivariate analysis, ≥3 IL-2 doses independently improved PFS (HR 0.20, 95% CI 0.06-0.69; $p = 0.011$) and OS (HR 0.09, 0.02-0.36; $p = 0.001$), while OOS status increased risk of progression (HR 8.10, 2.24-29.25; $p = 0.001$) and death (HR 6.16, 1.35-28.20; $p = 0.019$).

Conclusions: Higher number of infused doses IL-2 and meeting commercial TIL release criteria were independently associated with improved outcomes.

#3707 Durable remission of high-risk and refractory neuroblastoma by PHOX2B derived peptide-HLA directed CAR T cells: An IND enabling study.

Muzamil Y. Want[1], Richa Kapoor[1], David Groff[1], Keelan O'Reilly[1], Liron Grossmann[1], Alvin Farrel[1], Rebeca A. Ventura[2], Peiyao Li[1], Quinlen Marshall[2], Jenny pogoriler[3], Daniel Martinez[3], Matt Beasley[4], Ben Kiefel[4], Mark Yarmarkovich[5], John Maris[1]

[1]Division of Oncology and Center for Childhood Cancer Research, Children's Hospital of Philadelphia, Philadelphia, PA,[2]University of Pennsylvania, Philadelphia, PA,[3]Children's Hospital of Philadelphia, Philadelphia, PA,[4]Myrio Tx, Melbourne, Australia,[5]NYU Langone Health, New York, NY

Effective cellular therapies for solid tumors are limited by the lack of tumor-specific antigens. We previously showed that non-mutated self-peptides from essential intracellular neuroblastoma (NB) oncoproteins are presented by common HLA allotypes, enabling selective targeting (Nature 2023). Here, we report IND-enabling studies of second-generation PHOX2B PC-CAR T cells incorporating a 4-1BB costimulatory domain. A GMP-grade lentiviral vector encoding the PHOX2B peptide-HLA-specific CAR was produced at CHOP and used to transduce healthy donor and patient T cells. PHOX2B expression and epitope heterogeneity were analyzed across solid tumors, NB xenografts, and cell lines by RNA-seq, IHC, and a PHOX2B scFv assembled with klickmer detecting the QYNPIRTTF/HLA complex. Safety was evaluated using the X-scan and sCRAP cross-reactivity algorithms integrated with experimental testing across 25 normal HLA-A24/23 primary cell lines and HLA-matched PHOX2B negative cancers. Functional activity was assessed via IncuCyte based cytotoxicity, multiplex cytokine profiling, and T-cell activation/proliferation by flow cytometry. Efficacy was tested in four HLA-A24/23 NB xenografts (including chemotherapy-resistant models) and one non HLA-A*24:02/23:01 NB control in NSG MHC-I/II deficient mice receiving a single ~7×10^6 PC-CAR T-cell infusion. Longitudinal expansion, immunophenotype, and transcriptional states were characterized by flow cytometry and single-cell RNA-seq. PHOX2B was highly expressed in all neuroblastomas and pheochromocytomas and not expressed in other cancers. Klickmer staining revealed variable epitope density correlating with PC-CAR T cell activation. PHOX2B PC-CAR T cells mediated potent, dose-dependent killing of HLA-A24/23 neuroblastomas, sparing antigen-negative non-HLA-A24/23 cancer cells unless peptide-pulsed. Antigen engagement triggered proliferation, effector cytokine release, and IFN-γ dependent upregulation of HLA-I, significantly increasing antigen density. No cross-reactivity was detected in co-culture assays. A single dose of PC-CAR T cells induced complete regression (>50 days) across all xenografts. One relapse in each of two models either regressed spontaneously with re-emergence of PC-CAR T cells or after re-treatment. Responses were durable >120 days, whereas PHOX2B+ non-HLA-A24:02/23:01 controls showed progressive disease. Expansion peaked at day 14 with $CD8^+$ effector-memory predominance transitioning to central-memory persistence. PHOX2B-directed PC-CAR T cells show stringent specificity, potent cytotoxicity, and curative efficacy in preclinical patient-derived NB models. These IND-enabling data supported the ongoing first-in-human/child Phase 1 trial (NCT07007117), validating PHOX2B as a lineage-restricted immunotherapeutic target in high-risk neuroblastoma.

#3708 Improving antitumor T cell therapy with membrane-tethered engineered cytokine agonists.

Diana Gumber[1], Saul Priceman[2], Christine E. Brown[3], Leo D. Wang[1]

[1]Immuno-oncology, City of Hope National Medical Center, Duarte, CA,[2]Keck School of Medicine of USC, Los Angeles, CA,[3]City of Hope National Medical Center, Duarte, CA

Chimeric antigen receptor (CAR) T cell therapy has demonstrated marked success in the control of hematological malignancies. However, the hostile milieu and chronic antigen exposure in the tumor microenvironment contribute to the induction of exhaustion and loss of efficacy of CAR T cells in the treatment of solid tumors.

Overcoming T cell exhaustion is essential for improving immunotherapeutic efficacy in the treatment of solid tumors. One strategy focuses on engineering CAR T cells that generate a supportive local immune environment through expression of activation and survival-promoting proteins. Specifically, interleukin-2 (IL2) is an attractive candidate as it is a potent stimulator of proliferation and effector function in T cells. However, the therapeutic application of systemic IL2 is associated with life-threatening complications and T cell exhaustion. To address these toxicities, we have developed membrane-tethered engineered cytokine agonists (MECAs), which are cell-surface constrained proteins that transduce a defined subset of cytokine-mediated signals to promote T cell function without toxicity or T cell exhaustion.

Here, we evaluate the influence of MECAs on the proliferation and cytotoxicity of CAR T cells in a glioblastoma-targeting model. IL13Rα2-targeting CAR T cells co-expressing the MECAs demonstrated improved cytotoxic function and proliferation in recursive challenge in in vitro models. Preliminary results demonstrate that MECA-expressing CAR T cells are not toxic in an in vivo orthotopic glioma model. Additionally, the CAR T cells co-expressing MECA had greater anti-tumor activity compared to CAR only T cells.

Exhaustion of antigen-specific T cells is a central challenge across multiple cancer immunotherapy modalities. The proposed MECAs have the potential to revolutionize immunotherapy by providing effective and widely applicable orthogonal signals that improve the proliferation and effector activity of adoptively transferred CAR T cells.

#3709 A first-in-class Erythrocyte-anti-PD-1 conjugate overcomes immunotherapy resistance across pan-solid tumors: A phase I trial.

Xiaoqian Nie[1], Liu Yang[2], Kurban Mattursun[3], Zheling Chen[2], Xiaofei Gao[1]

[1]Westlake University, Hangzhou, China,[2]Zhejiang Provincial People's Hospital, Hangzhou, China,[3]Westlake Therapeutics, Hangzhou, China

Background: Despite the success of immune checkpoint blockade (ICB), most patients fail to respond or eventually develop resistance due to insufficient efficacy or immune-related toxicities. We developed αPD-1-Ery, an erythrocyte-PD-1 antibody conjugate in which anti-PD-1 antibodies are covalently linked to erythrocyte membranes. Unlike conventional antibodies, αPD-1-Ery selectively accumulates in the spleen, where it efficiently engages and activates T cells, leading to reductions in immunosuppressive myeloid cells. These coordinated effects remodel the immune landscape, reprogram the tumor microenvironment, and suppress tumor growth in ICB-resistant models. Based on these findings, we initiated a phase I investigator-initiated trial of αPD-1-Ery in patients with advanced solid tumors that had progressed on prior PD-1/PD-L1 therapy (NCT06026605).

Methods: This first-in-human study evaluated the safety, tolerability, pharmacokinetics (PK), and preliminary efficacy of αPD-1-Ery monotherapy. Eligible patients had histologically confirmed solid tumors progressing on prior PD-1/PD-L1-containing regimens. αPD-1-Ery was administered intravenously every 21 days at dose levels of 2×10^{11} or 3×10^{11} cells per infusion. Safety was assessed per NCI-CTCAE v5.0, and efficacy per RECIST v1.1.

Results: As of October 31, 2025, 14 heavily pretreated patients with 11 tumor types were enrolled. No dose-limiting toxicities or TRAEs > grade 3 occurred, and no severe immunotoxicities were observed. αPD-1-Ery showed encouraging anti-tumor activity, with a DCR of 78.6% (11/14) and an ORR of 42.9% (6/14), including 1 CR and 5 PRs. Responses were more pronounced at the higher dose level (ORR 57.1%, 4/7), supporting a dose-dependent effect. Median PFS was 5.5 months, and the 12-month OS rate was 71.4%, indicating durable benefit. PK analysis demonstrated dose-proportional exposure, with mean Cmax values of 2,711 and 5,107 cells/μL for the low and high doses, respectively. Tmax ranged from 0.5 to 48 hours, and engineered erythrocytes persisted for 7-21 days. Free antibody levels remained <5%, confirming in-vivo stability and spleen-targeted delivery. Biomarker analysis identified a spleen-associated myeloid signature: responders had higher baseline circulating PMN-MDSCs and showed rapid post-treatment declines compared with non-responders, consistent with spleen-mediated myeloid modulation.

Conclusion: αPD-1-Ery is safe, well tolerated, and demonstrates encouraging anti-tumor activity in ICB-resistant solid tumors. Erythrocyte-drug conjugates represent a novel therapeutic class for overcoming resistance to checkpoint blockade, with broad implications for cancer treatment and drug development.

#3710 Adapting and validating a humanized mouse model for testing of immune-shielded genetic modifications in therapeutic cells.

Mino Yakoub, Katrin Ridders, Henning Jelten, Audrey Holtzinger, Matthias Austen, Claudia Wrzos

Evotec International GmbH, Gottingen, Germany

Introduction: Allogeneic transplantation of “off-the-shelf” cell therapies offers a transformative approach for treating a wide range of diseases, including various oncological diseases. However, host-mediated immune rejection ‘’Allogeneic rejection’’ remains a critical barrier to therapeutic success. To address this, immune shielding strategies have been developed to evade immune detection, necessitating robust in vivo models for evaluating their protection from immune cells. Many in vivo models fall short in mimicking the human host immune milieu. We have established a model that incorporates multiple transplantation sites for therapeutic cells, such as under the kidney capsule of the mice. Additionally, we have characterized relevant readouts for the evaluation of the survival of immune-shielded therapeutic cells and monitoring allogeneic rejection.
Methods: We utilized the immunodeficient BRGSF mice. These mice were humanized using CD34+ from distinct human donors, resulting in the BRGSF-HIS mice (purchased from Genoway). We transplanted these mice with therapeutic stem cell-derived cells. Post-transplantation, mice received human FLT3 ligand to enhance human myeloid cell development. At the end of the study, blood, spleen, and kidney tissues are collected for flow cytometry, MSD cytokine profiling, and histology. Other functional readouts were performed during the in-life phase.
Results: The model was validated by transplanting wild-type (non-immune shielded) stem cell-derived therapeutic cells under the kidney capsule of BRGSF-HIS mice. In addition, a subset of BRGSF-HIS mice serves as a control group and does not undergo transplantation. The BRGSF-HIS were tested by flow cytometry of blood and spleen to confirm the presence of all the human immune cells essential for allogeneic rejection, including CD4/CD8 T-cells, NK cells, B-cells, monocytes, and M1/M2 macrophages. A comparative analysis was performed on both transplanted and non-transplanted BRGSF-HIS, focusing on the assessment of immune cells and cytokines in the blood and spleen. The transplanted mice exhibited a pronounced pro-inflammatory phenotype in T-cells, characterized by increased CD4+ and CD8+ TEMRA and CD69+ populations, elevated Th1 subsets, and reduced Th2 cells. We observed a tendency for a shift of splenic M2 to M1 macrophages in the transplanted mice. Systemic immune activation was further demonstrated by increased levels of pro-inflammatory cytokines found in both plasma and spleen samples. Histological assessment of immune infiltration at the transplantation site revealed a high abundance of human T-cells, accompanied by macrophages.
Conclusion: We developed a model to evaluate allogeneic rejection of immune-shielded therapeutic cells, assess their survival, and analyze immunophenotyping resulting from transplantation, as well as human host immune infiltration.

#3711 Enriching CD8+ and CD4+ neoantigen-reactive tumor infiltrating lymphocytes by cell surface marker-based sorting.

Lisa M. Kenney, Nivedita Ratnam, Abraham A. Hakim, Juliette Rault-Wang, Steven A. Rosenberg, Frank J. Lowery

Surgery Branch, National Cancer Institute, Center for Cancer Research, National Institutes of Health, Bethesda, MD

Introduction: Adoptive cell transfer (ACT) of tumor-infiltrating lymphocytes (TIL) is FDA-approved for metastatic melanoma and is under investigation for metastatic epithelial cancers. Identifying neoantigen-reactive TIL currently requires time- and resource-intensive testing against patient-specific neoantigens, enabling selection only at the culture level. Cell-surface markers capable of isolating tumor-relevant $CD8^+$ and $CD4^+$ TIL could eliminate the need for personalized sequencing and screening.
Methods: Single-cell RNA/TCR sequencing of mixed population of neoantigen-specific and bystander TIL derived from pooled cultures from a metastatic GI cancer lesion with known reactivity identified CD103 as the top marker of tumor-relevant $CD8^+$ TIL and CD31 as a bystander marker. Similar analysis of bulk TIL from another GI malignancy lesion derived from a different patient identified PD-1 and ADGRG1 as $CD4^+$ enrichment markers and CD69 and KLRB1 as depletion markers. Markers were tested for their ability to enrich tumor-relevant $CD8^+$ and $CD4^+$ TIL from pooled epithelial cancer fragments (11 retrospective and 5 prospective $CD8^+$ samples; 10 retrospective $CD4^+$ samples). Following culture in IL-2 in GREX100 flasks for 21 days, TIL were sorted based on expression of CD103 and CD31 for the $CD8^+$ TIL and PD1, ADGRG1, CD69 and KLRB1 for the $CD4^+$ TIL. Sorted populations were expanded using rapid expansion protocol (REP) and evaluated for neoantigen reactivity by upregulation of 4-1BB and/or OX40 expression and IFN-γ release via ELISpot. Single-cell TCR sequencing of populations was done to identify and confirm neoantigen specificity. Group comparisons were performed using non-parametric paired t-tests.
Results: Across retrospective and prospective samples, $CD103^+CD31^-$ $CD8^+$ TIL showed mean neoantigen reactivity of 19.3% and 18.3% and median enrichment of 5.7x ($p = 0.0244$*) and 8.1x over bulk $CD8^+$ TIL. Single-cell TCR sequencing confirmed enrichment in retrospective samples ($p = 0.0312$*) and validated 1-3 unique neoantigens per patient. Among 10 patients with $CD4^+$ neoantigen-specific responses, $CD4^+$ bulk TIL showed a mean reactivity of 13.8%, with 1-5 neoantigens validated per patient. $CD4^+CD69^-PD\text{-}1^+$ selection produced a 2.2x median increase in reactivity ($p = 0.0195$*) and superior capture of neoantigen-specific TCRs vs $CD4^+$ Bulk ($p = 0.0039$**). Overall 14 of 16 patient samples studied for $CD8^+$ reactivity showed enrichment by $CD103^+CD31^-$ while 9 of 10 patient samples studied for $CD4^+$ reactivity showed enrichment with $CD4^+$ $CD69^-PD1^+$.
Conclusion: Selection of $CD103^+CD31^-$ cells enriches tumor-relevant $CD8^+$ TIL, while $CD4^+CD69^-PD\text{-}1^+$ most effectively enriches $CD4^+$ TIL. Clinical-scale sorting using these markers could generate neoantigen-enriched TIL without patient-specific screening, expanding treatment feasibility for patients with more rapidly progressing disease.

#3712 Pleiotropic oxidized carbon nanozymes reprogram CAR T cell metabolism to enhance persistence through redox modulation.

Kevin Song[1], Yue Hu[2], Paul Derry[2], Thomas Kent[2], Xiaotong Song[3]

[1]University of Houston, Houston, TX,[2]Texas A&M University, Houston, TX,[3]Texas A&M Univ. Health Science Center (Houston, TX), Houston, TX

Adoptive CAR T cell therapy faces major challenges in solid tumors due to chronic antigen stimulation, oxidative stress, and metabolic exhaustion. We recently developed Pleozymes, pleiotropic oxidized carbon nanozymes that function as synthetic redox mediators with multiple enzymatic activities, including superoxide dismutase-like scavenging and NADH/NAD^+ interconversion. Pleozymes are 3-8 nm oxidized carbon nanoparticles synthesized from coconut-derived activated charcoal and exhibit broad redox potential and mitochondrial localization, enhancing both oxidative phosphorylation and glycolysis in mammalian cells. To investigate their role in T cell metabolic resilience, we treated GPC3-targeted CAR T cells with Pleozymes during chronic co-culture with GPC3-positive HCC Huh7 cells over repeated stimulation cycles. Cell proliferation, apoptosis, exhaustion marker expression, and memory subset differentiation were assessed by flow cytometry and metabolic assays. Pleozymes markedly enhanced CAR T cell expansion and viability across repeated tumor challenges. Apoptotic rates were reduced, and expression of exhaustion markers TIM-3 and LAG-3 decreased significantly. Pleozymes promoted differentiation toward T stem cell memory (TSCM) and central memory (TCM) phenotypes, indicating improved persistence potential. Metabolic profiling indicated elevated total ATP levels and enhanced NAD^+-dependent catabolic activity, consistent with concurrent activation of glycolysis, fatty acid β-oxidation, and tricarboxylic acid (TCA) cycle flux. Collectively, these findings demonstrate that Pleozymes act as metabolic cofactors that restore redox balance and sustain bioenergetic flexibility in CAR T cells. By mitigating exhaustion and enhancing memory differentiation, Pleozymes offer a novel, non-genetic strategy to improve CAR T cell persistence and antitumor efficacy in solid tumor settings.

#3713 Fluorescence potency assays for evaluating HER2 CAR T-cell-mediated killing in cancer cells.

Danny Flanigan, Nathalie Opdam - van de Laar, Denise Sullivan, DANIEL MILLARD, STACIE CHVATAL

Axion BioSystems, Atlanta, GA

Introduction Harnessing the potent cytotoxicity of chimeric antigen receptor T (CAR-T) cells has revolutionized cancer immunotherapy. A key factor influencing CAR-T cell efficacy is target antigen density on cancer cells. Human epidermal growth factor receptor 2 (HER2), overexpressed in various cancers like ovarian and lung carcinomas, is a promising target for CAR-T cell therapy. Traditional cytotoxicity assays generally provide only static endpoint measurements and often rely on 2D cell culture models, which fail to capture the structural complexity of tumors in vivo—a factor crucial to CAR-T cell efficacy. Live-cell imaging offers a solution by enabling non-invasive, real-time monitoring of cytotoxicity. Therefore, this study aims to explore the dynamics of CAR-T cell-mediated cytotoxicity against cancer cells with varying HER2 expression levels, comparing outcomes between 2D and 3D cell culture models using the Omni platform by Axion BioSystems. Methods Monolayers and spheroids of SKOV3 (ovarian carcinoma) and A549 (lung adenocarcinoma) cells, tagged with GFP, were exposed to HER2 CAR-T cells at different Effector:Target (E:T) ratios. Using the Omni platform, hourly brightfield and fluorescent images were captured over 72 hours to assess cancer cell growth and cytotoxicity and quantify the cytolysis of fluorescent target cells. Percent cytolysis of the target cells was calculated by comparing the green fluorescent intensity of treated wells to no treatment control wells. Results As expected, A549 cells treated with CAR T-cells exhibited dose-dependent decrease in fluorescence confluency (%), with near-complete cell lysis observed in the 5:1 E:T ratio group at 160 hours. Immune cell-mediated killing was assessed by applying HER2-targeted CAR T-cells to both SKOV3-GFP and A549-GFP spheroids. SKOV3-GFP spheroids treated with CAR T-cells showed a dose-dependent decrease in fluorescence intensity, with higher E:T ratios (2:1, 5:1, and 10:1) resulting in approximately 75% reduction in fluorescence intensity by 72 hours. In contrast, A549 spheroids only exhibited significant killing at 5:1 and 10:1 E:T ratios, while minimal decreases in intensity were observed at other ratios. Conclusion The Omni platform enables real-time monitoring of CAR T-cell interactions with target cells, providing key insights into the cytotoxic potential of these engineered immune cells. Fluorescent metrics were used to track immune cell-mediated killing, with changes in fluorescence confluency and intensity reflecting the extent of target cell death. Results showed that the potency of CAR T-cell-mediated cytolysis was dose-dependent, with higher E:T ratios leading to greater target cell killing. SKOV3-GFP spheroids, which overexpress HER2, were more susceptible to HER2 CAR T-cell-mediated killing, while A549-GFP spheroids with low HER2 expression required higher E:T ratios for effective cytolysis.

#3714 Immunopeptidomic discovery of fetal WNT-associated antigen NKD1 enables HLA-A2+ restricted TCR-T therapy for MSS mCRC.

Jaeyop Lee, Swara Patel, Inaki Etxeberria, Elizabeth Benitez, Jura Pintar, Andres Rettig, Christopher Cowley, Stefanie Gerstberger, Kathleen Luckett, Asha Saxena, Zita Aretz, Tatyana Korontsvit, Zhuoning Li, Kevin Soares, Emmanouil Pappou, T. Peter Kingham, William Jarnagin, Philip B. Paty, Martin R. Weiser, Michael D'Angelica, Julio Garcia-Aguilar, Jinru Shia, Mara Monetti, Christopher A. Klebanoff, Karuna Ganesh, David A. Scheinberg

Memorial Sloan Kettering Cancer Center, New York, NY

T cell-engaging therapies have achieved limited success in microsatellite stable (MSS) metastatic colorectal cancer (mCRC), in part because of a paucity of truly cancer-specific targets. Systematic interrogation of the immunopeptidome, the repertoire of peptides presented by human leukocyte antigen (HLA) class I molecules, can expand the pool of druggable antigens beyond conventional surface receptors. Nonetheless, both neoantigenic driver mutations and recently described oncofetal peptides are rare or absent in most CRCs. Our recent work shows that mCRC cells adopt a highly stereotyped fetal-like phenotype, characterized by activation of a developmental WNT signaling program that is further enriched in metastasis-initiating cells and conserved across diverse patients. We hypothesized that this transcriptional reprogramming generates a cancer-specific, developmentally fixed HLA-I ligandome that can be exploited for T cell therapy. Using an integrated platform for systematic collection and multimodal profiling of matched normal colon, primary tumor, and metastases from patients undergoing CRC surgery, we established ex vivo patient-derived organoids (PDOs) that faithfully capture patient-specific CRC cell states and provide an effectively inexhaustible source of tumor cells for immunopeptidomic discovery and functional validation. In HLA-$A2^+$ PDOs, representing the most common HLA allele, immunopeptidomic analyses identified recurrent presentation of peptides derived from fetal WNT program genes, in particular NKD1, that are prevalent across mCRC PDOs from HLA-$A2^+$ patients and undetectable in healthy tissues. These peptides were immunogenic in vitro, eliciting robust reactivity from healthy donor T cells and supporting their suitability as therapeutic targets. Moreover, naive $CD8^+$ T cells engineered with NKD1-specific T cell receptors (TCRs) showed strong cytokine activation and potent, antigen-dependent cytotoxicity against mCRC PDOs without detectable off-target activity, consistent with a favorable therapeutic index. Together, these data nominate NKD1 as a conserved antigen in mCRC and support the clinical advancement of an NKD1-directed TCR-T cell product as a first-in-class precision therapy for patients with MSS mCRC.

#3715 Epigenetic and signaling-based engineering enhances CAR-T cell function in oculo-cerebral lymphoma.

Marion Alcantara[1], Jaime Fuentealba[1], Silvia Menegatti[1], Anne-Laure Privat[1], Lisseth Silva[1], Kyle Raymond[1], Daniel De Murat[1], Valentine Pottez Jouatte[1], Lamia Lamrani[1], Zelia Gouveia[1], Denis Malaise[2], Carole Soussain[1], Sebastian Amigorena[2]

[1]Institut Curie, Saint-Cloud, France,[2]Institut Curie, Paris, France

Patients with PCNSL, an aggressive B-cell malignancy confined to the central nervous system (brain, cerebrospinal fluid, spinal cord and/or eye), face poor outcomes, particularly upon relapse. Although CD19-directed CAR-T cell therapies have transformed the treatment of systemic B-cell malignancies, their application in PCNSL has been constrained by neurotoxicity concerns in pivotal studies. Recent data demonstrate feasibility and safety in this setting; however, more than half of patients eventually relapse, highlighting the need for more persistent CAR-T cells capable of functioning within the immunosuppressive CNS microenvironment. To address this, we first evaluated a panel of second-generation CD19 CARs, including ITAM-tuned “1XX” variants, using a 3D spheroid model of PCNSL. T cells expressing the (SJ25C1)1XX-CAR format demonstrated the highest antitumor activity. To further improve their durability, we knocked out SUV39H1, a histone methyltransferase that limits memory T cell differentiation through histone H3 lysine 9 trimethylation (H3K9me3), an epigenetic mark associated with chromatin compaction. The resulting (SJ25C1)1XX-CAR SUV39H1 KO T cells showed enhanced cytotoxicity in vitro, and superior tumor control and survival in an orthotopic PCNSL xenograft model compared to conventional second-generation CAR-T cells. To further test persistence, we established an ocular lymphoma rechallenge model. Following initial tumor clearance by both edited and non-edited 1XX CAR-T cells, only SUV39H1 knockout CAR-T cells maintained long-term protection upon rechallenge in the contralateral eye. Ex vivo spleen analysis confirmed their accumulation and enrichment in memory precursors ($CD27^{+}KLRG1^{-}$) with elevated Ki67 expression, indicating enhanced proliferative potential. Altogether, our study supports the clinical translation of a next-generation cell therapy for PCNSL based on epigenetically reprogrammed, signaling-optimized CAR-T cells. We are currently developing a GMP-compatible manufacturing process incorporating the RQR8 marker/safety switch to enable rituximab-mediated elimination in the event of unexpected toxicity, in preparation for a future phase I/II clinical trial.

#3716 Regulatory immunotherapy utilizing activated natural killer cells and antitumor response for hepatocellular carcinoma.

Ola Sayed Ahmed[1], Refaat Gabre[2], Amr Iamail Abdelraouf[3], Hisham Imam[4], Maha Genhia[2]

[1]Cancer Biology, National Cancer Inst., Cairo, Egypt,[2]Biotecnology, Facutly of Science- Cairo University, Cairo, Egypt,[3]Surgical, National Hepatology and Tropical Medicine Research Institute, Cairo, Egypt,[4]Biomedical, Niles, Cairo, Egypt

Background: Hepatocellular carcinoma (HCC) is among the most prevalent and fatal cancers globally, but viable therapeutic alternatives are scarce. Natural killer (NK) cells are components of the innate immune system that exhibit significant anti-cancer properties. Recent findings indicate that activation with interleukins IL-15 and IL-18 promotes the production of NK cells exhibiting augmented effector capabilities and potential “memory-like” characteristics. This study examined the cytotoxic efficacy of IL-15/18-stimulated NK cells against human HCC tissue in vitro.
Methods: NK cells were collected from healthy donors and patients with HCC, followed by in vitro activation with IL-15 and IL-18. The cytotoxic efficacy of activated NK cells was assessed in co-culture with human HCC cells. This study demonstrated that IL-6 and IL-1α participated in regulating the anti-tumor efficacy of IL-15/18-activated NK cells.
Results: The results indicate that NK cells from patients with HCC and healthy donors exhibited comparable expression levels of both activating and inhibiting NK cell receptors. The expansion of NK cells from HCC patients was inferior compared to that of healthy donors in response to IL15/18 ($p < 0.001$ on day 5). In vitro, NK cells from both groups of persons exhibited significant cytotoxicity against HCC targets, and this was associated with the inhibitory effects of activated NK cells on the production of IL-6 and IL-1alpha. Lower levels of spontaneous HCC formation were observed in a spontaneous model of HCC after IL-15/18 activated NK cells that trafficked to the liver ($p < 0.01$).
Conclusion: IL-15/18-activated NK cells from both healthy donors and HCC patients exhibit comparable levels of anti-tumor efficacy against HCC cells. These results indicate that IL-15/18 activation augments the therapeutic efficacy of NK cells, endorsing their application as a promising immunotherapeutic approach for hepatocellular carcinoma.

#3717 DLL3-targeted *in vivo* CAR-T therapy of small cell lung cancer with lipid nanoparticles and circular RNA.

Yishan Ma[1], Jingsheng Cai[2], Yufei Xia[1], Xiaonan Huang[1], **Mantang Qiu**[2]

[1]Chinese Academy of Sciences, Beijing, China,[2]Peking University People's Hospital, Beijing, China

Background: The survival of small cell lung cancer (SCLC) is discouraging, necessitating the development of novel targets and effective therapeutic approaches. Delta-Like Ligand 3 (DLL3) represents a promising target for the treatment of SCLC, with ongoing vigorous therapeutic strategies, including DLL3-targeted chimeric antigen receptor-T (CAR-T) cell therapy. Here, we report DLL3-targeted in vivo CAR-T therapy constructed by circular RNA (circRNA) and antibody-conjugated lipid nanoparticles (LNP), yielding promising therapeutic potential for treating SCLC.

Methods: Circular RNAs (circRNAs) are covalently closed single-stranded RNAs that are resistant to exonuclease-mediated degradation. Compared with linear mRNA, circular RNA is more stable and efficient as translate templates, thus circRNA has been considered as “the next generation” of mRNA. RNA-LNPs were prepared via microfluidic mixing an aqueous solution of the circRNA and an ethanolic solution of the lipid components at a ratio of 3:1. LNPs were conjugated with purified rat anti-mouse CD5 (CD5-LNP) or IgG (IgG-LNP) via SATA-maleimide chemistry reaction to obtain antibody conjugated LNP-circRNA.

Results: We have previously reported a highly efficient TREM1/DAP12-based novel multiple-chain CAR structure. In current study, we successfully synthesized and validated the feasibility of circRNA encoding DLL3-targeted CAR. To quantify the percentage of CAR-T cell in vivo, LNPs were intravenously injected into 8-week-old mice. CAR T cells in the immune organ and peripheral blood were characterised via flow cytometry 24h post injection. CD5-conjugated LNP showed a significant higher CAR-T percentage in peripheral blood (~15%) and immune organs (~12% in lymph node, ~16% in spleen, and 22% in thymus) compared to non-targeted LNP (unconjugated LNP and IgG-conjugated LNP). We further analysed the CAR-T cell duration in vivo. CD5-targeted LNP were intravenously injected into 8-week-old mice at dose of 30 ug RNA per mice. Immune organ and peripheral blood were isolated and characterised via flow cytometry at each time point. We observed that the CAR expressing T cells reached peak at 24h, then completely diminished after 5days. Lastly, using mice subcutaneous and orthotopic models, we demonstrated the efficacy of circRNA-based CAR-T therapy in SCLC tumor eradication, significantly extending survival. By Day 28 post-injection, 3/4 mice in the experimental group remained alive, whereas all in the control group had perished by Day 21. No significant increase of liver toxicity (indicated by AST and ALT) among the indicated groups, suggested favorable safety profile.

Conclusion: Leveraging antibody-conjugated LNP and circRNA, we have effectively engineered DLL3-targeted CAR-T cells in vivo, which shows effective cytotoxicity against SCLC. This research offers a promising avenue for advancing SCLC and in vivo CAR-T therapeutics.

#3718 CAR Detection Reagents - Pioneering advances in CAR T analytics.

Stephan Wilmes, Desire Missing, Anja Brauchle, Nadine Borgelt, Johanna Mullers, Monika Winkels, Larissa Mockel, Michaela Niemoller, Dagmar Hau?ler-Kuballa, Franziska Antonia Bertram, Olga Goldbach, Dominik Poschen, Astrid Imann, Silvia Ruberg, Anijutta Appelshoffer, Fabio El Yassouri, Marsilius Mues, Volker Nolle, Andreas Bosio, Christian Dose, Anne Richter

Miltenyi Biotec B.V. & Co. KG, Bergisch Gladbach, Germany

Chimeric Antigen Receptor (CAR) T cell therapies have transformed cancer treatment, offering targeted and effective options for patients with hematologic B-cell malignancies, including leukemias, lymphomas and multiple myeloma. Their precision in targeting and eliminating cancer cells has positioned them as a promising approach in cellular immunotherapy. Accurate detection of CAR expression is essential for research, pre-clinical applications, clinical manufacturing, and patient immunomonitoring. To address these needs, we developed CAR Detection Reagents optimized for flow cytometric analysis of CAR-engineered T and NK cells, ensuring exceptional quality and specificity. Our recombinant antigen-based CAR Detection Reagents mimic CAR interactions with tumor cells, targeting key cell surface antigens such as CD19, BCMA, CD22, MSLN, CD123, B7-H3, HER2, and CD33. We also created anti-CAR antibodies for CD19 FMC63 and GD2 14G2a CARs, along with linker-specific antibodies for G4S- and Whitlow-linkers, commonly used in commercial CAR T cell products. All these reagents feature an engineered human IgG1 Fc region to prevent Fcγ receptor binding, ensuring background-free analysis. Available in various conjugates (e.g., fluorophores, biotin), they offer superior performance and flexibility in panel design. Our flow cytometric analysis demonstrated bright and specific staining with low background on primary CAR T/NK cells and model cell lines, crucial for reliable CAR T cell enumeration in product manufacturing and patient monitoring. CAR Detection Reagents are also applicable for magnetic activated cell sorting (MACS). In immunomonitoring post-adoptive cell transfer, rapid isolation of CAR T cells from blood or PBMCs can be critical, as CAR T cells in these samples can be present in very low numbers falling below the detection limit. Magnetic enrichment substantially enhances analytical sensitivity, ensuring long-term monitoring of CAR T cell persistence, vital for assessing treatment efficacy and patient response. Furthermore, MACS-purified CAR T cells can undergo deep phenotyping and functional assays. Detecting CAR T cells in tissue samples is essential for understanding their distribution and activity within the body. This capability allows researchers and clinicians to assess CAR T cell infiltration and therapeutic impact at tumor sites, offering insights into treatment effectiveness and resistance mechanisms. Using fluorescence microscopy, we demonstrate precise detection and enumeration of CD19 FMC63 CAR T cells with a FMC63-targeting anti-CD19 CAR antibody in fresh-frozen and PFA-fixed tissue samples from treated mice. This approach enhances our understanding of CAR T cell dynamics *in vivo*. In summary, these versatile CAR Detection Reagents are invaluable tools for advancing CAR T cell research and clinical therapies. AI tools were used to improve this abstract.

#3719 From gene to bedside: Mayo Clinic's first-in-house BAFF-R CAR-T.

Yan Luo[1], Shaohua Guo[1], Yaqing Qie[2], Martha E. Gadd[2], Tanya Hundal[2], Hemant S. Murthy[3], Mohamed A. Kharfan-Dabaja[3], Hong Qin[4]

[1]Department of Cancer Biology, Mayo Clinic Florida, Jacksonville, FL,[2]Regenerative Immunotherapy and CAR-T Translational Research Program, Mayo Clinic Florida, Jacksonville, FL,[3]Division of Hematology and Medical Oncology, Department of Internal Medicine, Mayo Clinic Florida, Jacksonville, FL,[4]Department of Immunology, Mayo Clinic, Rochester, MN

Chimeric antigen receptor (CAR)-T cell therapy has revolutionized the treatment of B-cell malignancies. Despite the clinical success of CD19-targeted approaches, relapsed/refractory (R/R) disease—often driven by antigen loss or immune escape—remains a major challenge. To overcome this, we developed a novel CAR-T cell therapy targeting BAFF-R, a receptor consistently expressed in chronic lymphocytic leukemia (CLL) and other B-cell malignancies. We developed a new anti-BAFF-R monoclonal antibody and engineered the MC10029 CAR construct using its scFv. Antigen-specific cytotoxicity was validated in both in vitro and in vivo models, including Nalm-6 (leukemia) and Z138 (lymphoma), and CD19-knockout tumor cells to model (R/R) disease. MC10029 CAR-T cells were generated from healthy donors and CLL patients, and their cytotoxicity was evaluated against MEC-1, a CLL cell line, as well as autologous CLL patient tumor samples. These studies demonstrated potent and specific antitumor efficacy. We transitioned to clinical-grade production, using GMP-compliant lentivirus to manufacture MC10029 CAR-T cells under regulatory guidelines. With FDA IND approval, we initiated a Phase 1 clinical trial to evaluate safety and dosing. Our first patient, treated with a low-dose, single infusion, achieved a complete metabolic response within 2 months. The therapy is well tolerated, with no severe advent events such as cytokine release syndrome or neurotoxicity, supporting both the safety and efficacy of the therapy. Conclusion: This study represents Mayo Clinic's first homegrown CAR-T cell therapy, developed entirely in-house—from antibody discovery and CAR design to GMP manufacturing and clinical trial—marking a significant step toward personalized, next-generation immunotherapy for B-cell malignancies.

#3720 Nectin-4-targeted CAR-NK cells exhibit potent antitumor activity against bladder cancer.

Mohammad Mousaei Ghasroldasht, Piyush K. Agarwal

Department of Surgery, Section of Urology, University of Chicago, Chicago, IL

Background: Bladder cancer (BC) remains a major clinical challenge due to frequent recurrence and limited durable responses to current therapies such as Bacillus Calmette-Guérin (BCG) immunotherapy and cisplatin-based chemotherapy. Natural Killer (NK) cell therapy has recently emerged as a promising immunotherapeutic approach, particularly when combined with Chimeric Antigen Receptor (CAR) technology to enhance tumor recognition and cytotoxicity. Nectin-4, an adhesion molecule highly expressed in BC, represents a strong therapeutic target for CAR-engineered NK cells. In this study, we aimed to target bladder cancer using Nectin-4-specific CAR-NK cells.
Methods: Nectin-4-specific CAR-NK cells were generated via lentiviral transduction, and CAR expression was confirmed by fluorescence microscopy. The cytotoxic activity of CAR-NK and unmodified NK cells was evaluated against Nectin-4-positive (SW780) and Nectin-4-negative (T24) bladder cancer cell lines using LDH release and CCK-8 viability assays at early time points. A 3D spheroid model was used to assess CAR-NK cell attachment, infiltration, and long-term cytotoxicity. Gene expression profiling following co-culture was performed to evaluate activation and apoptosis-related pathways. An in vivo xenograft model was used to validate the in vitro findings.
Results: Nectin-4 CAR-NK cells demonstrated significantly enhanced cytotoxicity compared with parental NK cells within 4 hours of co-culture with SW780 cells, as assessed by LDH and CCK-8 assays. In 3D spheroid models, CAR-NK cells showed stronger attachment and affinity for Nectin-4-positive tumor spheroids during short-term co-culture and exhibited higher cytotoxicity after prolonged exposure compared with unmodified NK cells. Gene expression analysis revealed increased activation markers and cytotoxic mediators in CAR-NK cells, along with upregulation of apoptosis-related genes in target tumor cells following treatment.
Conclusions: Engineering NK cells with a Nectin-4-specific CAR markedly enhances their ability to recognize and eliminate Nectin-4-positive bladder cancer cells. These findings support the potential of Nectin-4 CAR-NK therapy as a targeted immunotherapeutic strategy for bladder cancer. Future development of multi-targeted CAR-NK constructs designed to modulate the tumor microenvironment may further improve efficacy and overcome immune resistance.

#3721 Anti-tumor function and long-term persistence of KSQ-001EX, a SOCS1-edited eTIL® therapy, independent of IL-2 co-administration.

Dipen Sangurdekar[1], Erica Tobin[1], Karrie Wong[1], Ashish Yeri[1], Alex Smashnov[1], Kelly Bowen[1], Giorgio Sarkis[1], Violetta Medik[1], Hsinyi Lu[2], Sevinj Isgandarova[2], Michelle Carrasco[1], Patricia Harris[1], Cara L. Haymaker[2], Micah Benson[1], Anna Truppel-Hartmann[1], Rodabe N. Amaria[2]

[1]KSQ Therapeutics, Lexington, MA,[2]UT MD Anderson Cancer Center, Houston, TX

Tumor Infiltrating Lymphocyte (TIL) therapy is an autologous adoptive cell therapy for cancer involving the isolation, *ex vivo* expansion, and infusion of polyclonal T cells from a patient's own tumor. Seeking to improve clinical efficacy and durability of TIL therapy, we developed KSQ-001EX, a CRISPR/Cas9 engineered TIL (eTIL®) therapy with inactivation of the SOCS1 gene to enhance T cell persistence and anti-tumor functionality. KSQ-001EX is being investigated in a phase 1/2 clinical study (NCT06237881) in patients with advanced solid tumors. Metastatic melanoma patients received lymphodepleting chemotherapy followed by KSQ-001EX without IL-2 in Cohort 1 (n=4) or with high-dose IL-2 in Cohort 2 (n=8), at a dose range of 0.5-10e9 cells (median 5.25e9). KSQ-001EX was directly monitored in blood and tissue samples via indel tracking of the SOCS1 gene locus. Correlative analyses were performed by integrating patient baseline characteristics, drug product (DP) manufacturing data, multi-modal and single-cell characterization of tumor starting material, KSQ-001EX DP, post-infusion PBMCs and on-treatment tumor tissue biopsies. All 12 KSQ-001EX DPs were enriched in CD8+ T cells, exhibiting a "Young TIL" phenotype with a median of 39% CD27+ cells and low expression of exhaustion markers. All DPs showed strong polyfunctionality and cytotoxicity against redirected lysis targetcell lines. Infused cell dose, particularly absolute dose of CD27+ KSQ-001EX cells, predicted post-infusion engraftment, expansion, persistence, and infiltration of KSQ-001EX in tumor tissue at day 28, and was the strongest factor associated with clinical activity. Clonal tracking of T cells in post-infusion blood revealed similar expansion of KSQ-001EX clones before day 9 and after day 21 across most patients and between cohorts, with top infiltrating clones in tumor correlating with clonal expansion in blood at day 28. To further understand the contribution of IL-2 to KSQ-001EX engraftment, persistence and function, cytokines and phenotypic characteristics of peripheral blood CD8+ T cells post-infusion were compared between Cohort 1 and Cohort 2. While no differences were observed in the frequency or activation state of CD8+ T cells between Cohorts, elevated expression of TOX in CD8+ T cells and increased frequencies of Treg were observed in Cohort 2 (with IL-2) between day 9-28 post infusion. In conclusion, higher infused CD27+ KSQ-001EX dose is associated with favorable expansion kinetics and persistence. KSQ-001EX engraftment, function and long-term persistence in absence of IL-2 at lower doses than traditionally used with unmodified TIL suggest the beneficial effects of SOCS1 inactivation. Based on these collective data, we confirm the functional enhancement introduced by SOCS1 deletion. Further investigation of eTIL in the absence of IL-2 and higher DP doses is warranted.

#3722 Preclinical development and evaluation of CD87-directed CART for colorectal cancer.

Andrea Feci[1], Trevor Baybutt[1], Robert Carlson[1], Emmett Grover[1], Jagmohan Singh[1], Ross Staudt[1], Miao Cao[1], Edoardo Manca[1], Jasmine Alvarez[1], Scott A. Waldman[2], Adam Snook[3]

[1]Thomas Jefferson University, Philadelphia, PA,[2]Chair, Dept. of Pharm. & Exp. Therapeutics, Thomas Jefferson University, Philadelphia, PA,[3]Sidney Kimmel Cancer Center at Thomas Jefferson University, Philadelphia, PA

Background: Chimeric antigen receptor T-cell (CAR-T) therapy has shown success in hematologic malignancies; however, its efficacy in solid tumors, including colorectal cancer (CRC), remains limited by poor tumor penetration, an immunosuppressive microenvironment, antigen heterogeneity, and a risk of on-target/off-tumor toxicities. CD87, the receptor for the urokinase plasminogen activator (uPAR), has emerged as a promising target, given its near-universal overexpression in CRC, and its near absence in normal tissues, except certain myeloid cells. Recent studies on the elimination of senescent myeloid cells in mice have supported the safety of CD87-directed CAR-T cells *in vivo*. Here, we pursued safety and efficacy studies of human CD87-directed CART (CART87) for use in CRC. We employed a Jurkat NFAT-Lucia reporter platform to functionally screen and optimize human CD87-specific CAR designs, then advanced the top candidates into CARTs for testing against a panel of CRC cell lines. Moreover, we employed bioinformatics to identify potential risks associated with targeting CD87 in humans.

Methods: To assess the potential safety of targeting CD87, we analyzed public bulk and scRNAseq datasets from human and mouse tissues. Furthermore, we quantified CD87 surface expression in human blood leukocyte populations and assessed their susceptibility to CART87. To optimize the CAR87 design, we employed a Jurkat NFAT-Lucia reporter assay, which measured CAR activation upon stimulation with recombinant uPAR and CD87-expressing cells. Constructs with high tonic signaling and non-specific activation by CD87-negative cells were eliminated. We then engineered CD87-directed CAR-T cells (CART87) and assessed their activity against CD87-positive CRC cell lines compared with CD87-negative HEK293 cells and CD87 knockout (KO) cells.

Results: scRNAseq analysis of bone marrow, whole blood leukocytes, and organ tissues revealed that CD87 mRNA expression is restricted to mature monocyte-lineage cells, with murine organs/tissues showing analogous results. Correspondingly, CD87 surface expression by flow cytometry was largely restricted to mature myeloid lineage cells. The Jurkat-NFAT reporter system enabled rapid comparison of single-chain variable fragments (scFv), structural and signaling domain configurations, and identified lead construct #3 (CAR87.3). CART87.3 demonstrated specific and potent cytolytic activity *in vitro* against CD87-positive CRC cell lines T84, SW480, LS174T, and DLD1.

Conclusions: This work identifies CD87 as a safe, selectively-expressed target antigen for the development of CAR-T therapy in CRC. The *in vitro* results support the advancement of human CART87 towards *in vivo* validation. Furthermore, we describe the rational design of a CART87 construct using a high-throughput strategy that could be broadly applied in CAR design for other target antigens.

#3723 Evaluation of *ex vivo* CAR-T cell cytotoxicity and infiltration using multimodal 2-D and 3-D imaging approaches.

Catherine McManus, John G. Foulke, Meghan Sikes, Luping Chen, Hyeyoun Chang, Fang Tian

ATCC, Manassas, VA

Background: Chimeric antigen receptor T (CAR-T) cell therapy has revolutionized cancer treatment, particularly for hematologic malignancies. Beyond CD19 and CD20, BCMA (B-cell maturation antigen)-targeted CAR-T therapies have become a major focus, especially for multiple myeloma. In fact, BCMA is considered one of the most validated targets in plasma cell malignancies. In pursuit of improving the efficacy and number of applications of this therapy, sensitive and robust cytotoxicity assays are required to efficiently evaluate different CAR constructs, effector-to-target cell ratios, and immune effector cells ex vivo. Furthermore, as CAR-T cell therapy is now under active investigation for the treatment of solid tumors, there is an urgent need for models that mimic the complexity of 3-D tumor environments.

Methods and results: In this study, we engineered two luciferase-GFP dual reporter cancer cell lines, Raji-GFP-Luc2 and NCI-H929-GFP-Luc2, and demonstrated their use in a streamlined combined bioluminescence and live imaging assay. Notably, Raji-GFP-Luc2 and NCI-H929-GFP-Luc2 endogenously express high levels of the two FDA-approved CAR-T target antigens, CD19 and BCMA, respectively. Using these lines in co-culture with mock and targeting CAR-T cells, we tracked reporter cancer and CAR-T cell interactions by fluorescence live imaging. Fluorescence quantification clearly demonstrated that CAR-T cells killed cancer cells at higher levels compared to mock controls in both 2- and 3-D co-culture. We then evaluated dose-dependent cancer cell killing by targeting CAR-T cells in 2- and 3-D by luciferase assay. Importantly, we found that quantification of either transgene yields comparative results despite utilizing distinct assays and readouts. Finally, we embedded reporter cancer cell spheroids in 3-D matrices and performed time-lapse imaging of CAR-T cell infiltration. Bioluminescence assay of the embedded spheroids confirmed increased cancer cell killing by targeting CAR-T cells in a solid tumor model.

Conclusions: Overall, our dual reporter cancer cell lines are powerful and effective tools for assaying CAR-T cell cytotoxicity. Furthermore, our multimodal imaging platform integrates bioluminescence and live fluorescence imaging to quantitatively and visually assess CAR-T cell cytotoxicity. With scalability and sensitivity, this assay provides an avenue for standardizing CAR-T cytotoxicity testing and will aid in the expansion and improvement of this promising therapy.

#3724 Exogenous IL-2 administration promotes circulating T-cell levels, persistence and therapeutic efficacy of allogeneic UCART20x22 in a B-cell lymphoma mouse model.

Shipra Das[1], Hana Cho[1], Marco Rotondi[2], Isabelle Chion-Sotinel[2], Margaux Sevin[2], Vivian Dai[1], Jean-Charles Epinat[2], Roman Galetto[2], Laurent Poirot[2], Adrian Kilcoyne[1]

[1]Cellectis, Inc., New York, NY,[2]Cellectis, Paris, France

Background: Non-Hodgkin's lymphoma (NHL) ranks as the sixth most common cancer among women and the seventh among men in the United States, with B-cell lymphomas constituting 80-85% of cases. Diffuse large B-cell lymphoma (DLBCL) is the predominant subtype. Despite significant advances in the treatment of B-NHL, significant unmet need remains for patients who are chemorefractory, relapse following autologous CD19 CAR-T or are unable to access autologous CD19 CAR-T because of supply, cost or other constraints. Off the shelf engineered allogeneic CAR-T offers a potential additional therapeutic option for patients. Advanced editing technology such as TALEN allows TRAC knockout to mitigate the risks of GvHD and also allows for the investigation of multiple alternative targets such as CD20 and CD22, to treat patients who may have antigen escape following previous treatment. While engineering technology can overcome the challenges of allogeneic therapy, efforts must still be made to further enhance expansion and persistence to allow for deep and durable responses. Clinical evidence suggests that the IL-2 cytokine, a potent T-cell growth factor essential for the proliferation of activated T cells, when combined in low-dose with CAR T-cell therapies improves pharmacokinetics and anti-tumor efficacy without compromising safety.

Method: NSG mice were engrafted with Daudi-luc-GFP cells on D-7. UCART20x22 (bi-specific TALEN®-engineered allogeneic T-cells targeting both CD20 and CD22), or vehicle were infused on D0. IL-2 was infused intraperitoneally after UCART20x22 administration as per different test regimens. Bioluminescence imaging was performed at regular intervals during the study to assess tumor control. UCART20x22 expansion and persistence was also measured at different timepoints.

Results: IL-2 administration significantly increased circulating T-cell levels and prolonged T-cell persistence. Increased tumor control was observed when low-dose UCART20x22 was combined with exogenous interleukin 2 (IL-2). No relapse was observed up to day 50 in the concomitant IL-2 treated mice. These responses were observed even when the IL-2 treatment regimens were delayed respect to UCART20x22 infusion, although the intensity of T cell responses were less strong than upon concomitant treatment. No adverse effect were observed, as measured by body weight assessment over time. Additionally, there were no clinical signs of treatment-related morbidities in any of the treatment groups.

Conclusion: The results of the *in vivo* studies support the use of IL-2 to improve the therapeutic outcomes of UCART20x22 in terms of depth and durability of disease response. This is currently being investigated in the NatHaLi-01 clinical study for R/R B-cell lymphomas, aiming to optimize response rates and durability of response in this patient population.

#3725 Stem cell-derived allogeneic anti-CD19 CAR-iNKT cell therapy GT719 for relapsed/refractory B cell malignancies.

Dehui Zou[1], Wei Liu[1], Yan Yu[1], Huimin Liu[1], Yi Wang[1], Sisi Feng[2], Xiaona Xu[2], He Zhang[2], Ershao Zhang[2], Jiang Li[2], Jingman Wang[2], Jing Hao[2], Ning Wang[2], Huipin Zheng[2], Yin Cheng[2], Jun Cui[2], Jingwei Sun[2], **Yarong Liu**[2]

[1]State Key Laboratory of Experimental Hematology, National Clinical Research Center for Blood Diseases, Haihe Laboratory of Cell Ecosystem, Institute of Hematology & Blood Diseases Hospital, Tianjin, China,[2]Grit Biotechnology, Shanghai, China

Background: Adoptive cell therapy, particularly CAR-T therapy, has transformed the treatment of hematologic malignancies, but autologous products remain limited by high cost, long manufacturing, and insufficient functional T cells in heavily pretreated patients. These challenges underscore the need for off-the-shelf allogeneic approaches. Invariant natural killer T (iNKT) cells are an attractive cell platform because they recognize lipid antigens via the non-polymorphic CD1d molecule, avoiding graft-versus-host disease (GvHD). CAR-engineered iNKT cells also provide multimodal tumor killing, tumor microenvironment modulation, enhanced infiltration, and natural bone marrow homing. However, their scarcity in peripheral blood poses manufacturing challenges. To address this, we developed GT719, an allogeneic anti-CD19 CAR-iNKT therapy generated through in vitro differentiation of cord blood-derived $CD34^+$ hematopoietic stem cells. Rational CAR design and optimized manufacturing enable scalable production capable of treating thousands of patients per batch. Extensive preclinical studies show that GT719 eliminates malignant B cells through coordinated CAR-, invariant TCR-, and NK receptor-mediated cytotoxicity and selectively depletes immunosuppressive macrophages and myeloid-derived suppressor cells.

Study Design and Methods: Based on promising preclinical results, a first-in-human investigator-initiated clinical trial (NCT06948981) has been launched to evaluate the safety, toxicity, dose-limiting toxicities (DLTs), and recommended treatment dose of GT719 for patients with relapsed or refractory CD19-positive B cell malignancies, including both B cell non-Hodgkin lymphoma (B-NHL) and B cell acute lymphoblastic leukemia (B-ALL). This open-label *Trial in Progress* begins with two single-patient acceleration cohorts testing doses of 5×10^7 and 1×10^8 cells per patient, followed by a classical 3+3 dose-escalation design testing doses of 5×10^8 and 1×10^9 cells per patient. Enrolled patients undergo a standard lymphodepletion regimen consisting of cyclophosphamide and fludarabine from Day -5 to Day -2, consistent with protocols used for autologous CAR-T therapies. GT719 is administered intravenously on Day 0, and the primary safety observation window for DLTs extends from Day 1 to Day 28. Adverse events are assessed for incidence and severity according to CTCAE version 5.0. Although the trial is ongoing, we anticipate presenting preliminary safety and efficacy data for GT719 at the meeting. Clinical trial registration number: NCT06948981

#3729 A biologically grounded predictor of neoadjuvant breast cancer therapy response from tumor transcriptomics and histopathology.

Thomas Cantore[1], Danh-Tai Hoang[2], Lipika Ray[1], Amos Stemmer[3], Tiangen Chang[1], Saugato Rahman Dhruba[2], Eldad David Shulman[1], Emma M. Campagnolo[3], Joo Sang Lee[3], Salomon M. Stemmer[4], Stephen-John Sammut[3], Yuan Yuan[5], Stan Lipkowitz[6], Sheila Rajagopal[3], Carlos M. Caldas[7], Nishanth Ulhas Nair[6], Eytan Ruppin[8]

[1]NIH-NCI, Bethesda, MD,[2]National Cancer Institute - Cancer Data Science Laboratory (CDSL), Bethesda, MD,[34]Rabin Medical Ctr. Inst. of Oncology, Petach Tikva, Israel,[5]Cedars-Sinai, Los Angeles, CA,[6]National Cancer Institute, Bethesda, MD,[7]University of Cambridge, London, United Kingdom,[8]National Cancer Institute, Rockville, MD

Background. While expression-based signatures inform adjuvant therapy in breast cancer (BC), no approved molecular biomarkers exist for the neoadjuvant setting, where early prediction of response could guide treatment. Identifying such biomarkers is challenging given the molecular heterogeneity of breast cancer, where multiple malignant subtypes may coexist within a tumor and influence therapy response.

Methods. We developed *BRIDGE*, a computational framework that deconvolves the pretreatment bulk tumor transcriptome to estimate molecular subtype composition and predict pathological complete response (pCR) to neoadjuvant therapy. BRIDGE was trained on 9 transcriptomics datasets and tested on 23 independent ones spanning different subtypes, composing one of the most variable multi-cohort validations to date. Six additional datasets with pre-treatement H&E slides and response data were analyzed to evaluate histology-based predictions.

Results. Analyzing measured BC transcriptomics, BRIDGE outperformed surrogate implementations of established commercial signatures (Oncotype DX, MammaPrint, RORS) in ER+/HER2− tumors, where these assays are clinically approved in the adjuvant setting. It also outperforms other transcriptomic signatures in subtypes where validated predictive biomarkers are limited. In ER+/HER2− patients, it yields an ROC-AUC of 0.79 with a high Odds Ratio (OR = 7.4); in HER2+ disease, an AUC of 0.78 (OR = 7.2); and in TNBC, an AUC of 0.71 (OR = 4.4). We further developed BRIDGE-Slide, which applies BRIDGE to pre-treatment histopathology slides via deep learning-inferred transcriptomics. BRIDGE-Slide outperforms direct slide-to-response models, underscoring its potential as a first-of-its-kind, fast, low-cost biomarker. Finally, spatial transcriptomics shows that BRIDGE-derived subtype assignments form spatially cohesive regions aligned with canonical molecular features, reinforcing its biological interpretability.

Conclusions. BRIDGE is a biologically grounded framework for neoadjuvant BC response prediction, validated on a rich set of diKerent patients cohorts. Its histopathology based version opens the door for fast and low cost prediction in the neoadjuvant setting, upon further prospective testing and validation.

#3730 Spatial determinants of TILs in immunotherapy sensitivity of patients with non-small cell lung cancer (NSCLC).

Miguel Lopez de Rodas Gregorio[1], Ravi Kamble[2], Matthew Blair[1], Yao Nie[2], Marghoob Mohiyuddin[2], Sowmi Utiramerur[2], Kurt Alex Schalper[1]

[1]Pathology, Yale School of Medicine, New Haven, CT,[2]Roche, Pleasanton, CA

Immune checkpoint blockers (ICB) targeting T-cell co-inhibitory receptors such as PD-1 and CTLA-4 provide clinical benefit to a subset of patients with non-small cell lung cancer (NSCLC). The abundance and functional state of tumor-infiltrating lymphocytes (TILs) have been proposed as immunotherapy biomarkers. However, the role of the spatial arrangement and distribution of TILs in immune evasion and immunotherapy sensitivity remains less explored. We used multiplexed quantitative immunofluorescence to measure and spatially map major TIL subpopulations (CK, CD4, CD8 and CD20), candidate tumor-antigen specific T-cells (CK, CD8, CD39 and PD-1) and T-cell functional differentiation states (CD4, CD8, TOX, TCF7) in consecutive tissue microarray sections from baseline NSCLCs in three retrospective cohorts treated with frontline chemotherapy (CTX, n=156), first line ICB (1L-ICB, n=56) or ICB as second or subsequent treatment line (2L+-ICB, n=68). We studied the spatial characteristics of TILs using computational metrics of cell heterogeneity and clustering, and their association with clinicopathologic variables and treatment-specific outcomes. We identified five spatial metrics significantly associated with overall survival (OS) only in the 1L-ICB patient population. A high Morisita-Horn Index (spatial diversity) of CD8+ or CD20+ TILs and CK+ cancer cells in the stromal tissue compartment, and a high Ripley's k (Rk) function (spatial clustering) of CD8+ T-cells in the total tissue area were associated with shorter OS (HR=1.57, CI:1.09-2.28; HR=1.42, CI:1-2.01; HR=1.38, CI: 1.03-1.83; respectively). In contrast, a high Rk function of CD8+ T-cells and the Moran's Index (MI, spatial autocorrelation) of CD20+ TILs measured within the cancer cell nests were significantly associated with longer OS (HR=0.58, CI:0.35-0.95; HR=0.44, CI:0.23-0.84, respectively). Tumors with high Rk values for CD8+ TILs in the cancer cell compartment had a higher density of inactive effector T-cells (CD8+ PD1- CD39-) and bystander-like effector T-cells (CD8+ PD1+ CD39-) than tumors with low CD8+ Rk. Tumors with high MI of CD20+ TILs in the cancer cell area showed higher densities of inactive effector T-cells, progenitor-like effector T-cells (CD8+ TOX+ TCF7+) and lower levels of candidate tumor antigen-specific effector T-cells (CD8+ PD1+ CD39+) than tumors with low MI of CD20+ TILs. There was a significant association between higher MI of CD20+ TILs and advanced age (≥65). The spatial arrangement of TILs in baseline tumor samples is associated with distinct local T-cell responses and frontline immunotherapy outcomes in patients with NSCLC. Increased clustering of CD8+ and CD20+ TILs within the cancer cell nests is independently associated with favorable survival in this population. This supports a strong biomarker potential for the integrated analysis of TILs incorporating spatial features.

#3731 Development of a gene expression predictor for bevacizumab response.

Yi Ren[1], Chee Yit Lim[1], Yaw Chyn Lim[2], Joseph W. Foley[1], Raymond Tsang[1], Wan Qin Chong[3], Boon Cher Goh[3], **Joshua K. Tay**[1]

[1]Department of Otolaryngology, National University of Singapore (NUS), Singapore, Singapore,[2]NUS Centre for Cancer Research (N2CR), National University of Singapore (NUS), Singapore, Singapore,[3]Department of Haematology-Oncology, National University Cancer Institute, Singapore, Singapore

Background: Bevacizumab, an anti-vascular endothelial growth factor (VEGF) monoclonal antibody, inhibits tumor angiogenesis and is used to treat several advanced-stage cancers, such as glioblastoma, ovarian, lung, and colorectal cancers. More recently, it has been incorporated into treatment regimens for locally advanced nasopharyngeal carcinoma (NPC). Despite its widespread adoption, no reliable biomarker has been developed to predict the treatment outcome. Moreover, bevacizumab treatment carries risks such as bleeding, hypertension, and proteinuria. Therefore, selecting patients for bevacizumab addition to already intensive chemotherapy regimens remains a clinical challenge.

Methods: We obtained 19 formalin-fixed paraffin-embedded (FFPE) biopsies from a completed phase 2 clinical trial (NCT01309633) for locally advanced NPC, where patients received bevacizumab prior to standard concurrent chemoradiation. Based on haematoxylin and eosin (H&E) identification, tumor epithelial regions were isolated by laser-capture microdissection, with biological replicates when available. RNAseq libraries were prepared with an in-house RNAseq technique optimized for FFPE tissues. Differential expression between complete response (CR, n=11) and partial response (PR, n= 8) tumors was assessed, and a bevacizumab response gene signature was derived. Gene signature scores were computed using single-sample gene set enrichment analysis (ssGSEA) and gene set variation analysis (GSVA).

Results: After quality control, 37 tumor epithelial libraries were analyzed (21 CR and 16 PR). We identified 58 differentially expressed genes (p.adj<0.05), with 44 upregulated in PR. These genes were related to extracellular matrix remodelling, vascular endothelia, and immune response. GSEA using cell-type signature gene sets or Curated Cancer Cell Atlas gene sets from MSigDB showed enrichment of inflamed fibroblasts, endothelial, and stromal cell types in PR, and cell-cycle programs in CR. Therefore, the 44-gene panel was used as a gene signature to predict reduced response to bevacizumab. Both ssGSEA and GSVA scores robustly separated PR from CR (p<0.001). These findings suggest that stromal/vascular inflammation in the tumor epithelial regions is associated with reduced bevacizumab response.

Conclusions: In this study, we derived a 44-gene tumor epithelial signature that predicts reduced response to bevacizumab in locally advanced NPC and confirmed its performance with ssGSEA and GSVA. The signature captures stromal, endothelial, and immune-inflammatory programs within tumor epithelial regions and informs patient selection for anti-angiogenic therapy. Our current work includes validation in independent patient cohorts across multiple cancer types to improve clinical utility and generalizability.

#3732 Time-series deep learning radiomics for predicting post-radiotherapy rib fractures in non-small cell lung cancer.

Yijun Chen[1], Michael Farris[1], Ariel Choi[1], Nga Thi Thanh Nguyen[1], Amanda Goetz[1], Corbin A. Helis[1], Fei Xing[2], Liang Liu[2], Qing Lyu[3], Christopher T. Whitlow[3], Christina K. Cramer[1], Michael D. Chan[1], Dan Bourland[1], Michael T. Munley[1], Jeffrey S Willey[1], **Yuming Jiang**[1]

[1]Radiation Oncology, Wake Forest University School of Medicine, Winston Salem, NC,[2]Cancer Biology, Wake Forest University School of Medicine, Winston Salem, NC,[3]Radiology, Wake Forest University School of Medicine, Winston Salem, NC

Background and purpose: Rib fracture is a recognized clinical complication in medically inoperable patients with non-small cell lung cancer (NSCLC) undergoing stereotactic body radiotherapy (SBRT), leading to diminished quality of life and delayed recovery. This study aimed to develop and validate a deep learning model for predicting post-radiotherapy rib fracture using time-series CT radiomics.
Material and methods: This study retrospectively collected CT scans from 67 NSCLC patients, comprising 1,605 individual ribs as separate instances. We proposed a novel Knowledge-aware Temporal Mixture of Experts (KA-TMoE) model that integrates radiomics from sequential CT scans to estimate fracture risk for each rib. Model performance was evaluated using area under the curve (AUC), sensitivity, specificity, and F1 score. Model interpretability was achieved using SHapley Additive exPlanations analysis, which attributed predictive value to each input feature.
Results: The KA-TMoE model demonstrated strong predictive performance, achieving favorable AUC in the validation cohort (0.792). The DeLong test confirmed statistically significant improvements over ablation variants, underscoring the importance of integrating temporal data and domain knowledge. High sensitivity (0.85) and specificity (0.78) reflected a well-balanced trade-off, surpassing alternative approaches. Whitney U tests further supported its robustness, which showed significant differences in output distributions across cohorts. Among the top 20 most influential features, half originated from three-month postoperative radiomics, emphasizing the critical role of temporal information.
Conclusion: The KA-TMoE model provides a robust, accurate framework for predicting rib fractures after SBRT in NSCLC patients. Its predictive power enables personalized risk assessment, better patient management, and optimized clinical prognosis.

#3733 Optimizing NGS-based biomarkers for mismatch repair and proofreading deficiency.

Jan Budczies[1], Klaus Kluck[1], Michael Menzel[1], Daniel N. Kazdal[2], Matthias Kloor[3], Albrecht Stenzinger[4]

[1]University Hospital Heidelberg, Heidelberg, Germany,[2]Institute of Pathology, University Hospital Heidelberg, Heidelberg, Germany,[3]Applied Tumor Biology, Heidelberg University Hospital (UKHD), Heidelberg, Germany,[4]Heidelberg University Hospital (UKHD), Heidelberg, Germany

Testing for mismatch repair and proofreading deficiency (MMRD and PRD) in cancer tissues supports the guidance of immunotherapies and the screening for cancer predisposition syndromes. As more and more patients are receiving molecular tumor diagnostics based on broad sequencing approaches, there is an opportunity to integrate MMRD/PRD testing with the testing for clinically actionable mutations. To reach this aim, there is a need to optimize the NGS-based biomarkers and cutpoints. We analyzed whole exome sequencing (WES) of 1487 patients from the TCGA cohorts of colorectal, stomach, and endometrial cancer (COADREAD, STAD, and UCEC). PCR-based testing and detection of deleterious mutations in POLE or POLD1 served as reference for MMRD and PRD status, respectively. MSI scores were derived from paired tumor-normal (T/N) and from tumor-only (T-only) data using MSIsensor and MSIsensor-pro, cutpoints were optimized by maximizing the balanced accuracy. Missense mutation burden, indel burden, and counts for 96 mutation types were determined from the somatic mutation calls. Using a training-test split (70% vs. 30%), elastic net classifiers were trained and validated for the prediction of MMRD and PRD status. With MSI scores from T/N data a close to perfect separation of mismatch repair deficient from proficient tumors was achieved in the pooled COADREAD/STAD/UCEC cohort (AUC=0.99, optimal cutpoint=2.1%), while MSI scores from T-only data performed less perfect (AUC=0.94, optimal cutpoint=6.7%). The performance of MSI scores from T-only data improved when analyzed separately in COADREAD, STAD, and UCEC which can be explained by differing optimal cutpoints of 12.4%, 3.3%, and 5.6%, respectively. Combining missense and indel burden permitted a close to perfect separation of mismatch repair deficient for proficient tumors. Tumors simultaneously exhibiting MMRD and PRD formed a distinct cluster in UCEC, but not in COADREAD and STAD. Both MMRD and PRD were reflected by characteristic signatures in the partition of the mutations to 96 mutation types. We compared the performance of the following three classifier types to separate tumors with respect to MMRD and PRD: (1) based on MSI scores, (2) combining missense mutation and indel burden, and (3) based on the 96 mutation types. Overall, the three classifiers performed similarly and allowed a good separation in almost all comparisons. Separating proofreading-deficient from -proficient tumors when MMRD was present was the only task that was achieved by none of the classifiers. Simulation studies investigating tumor purity showed that classifiers based on missense mutation/indel burden and mutation types outperformed MSI scores for low tumor purities. The study opens new avenues for MMRD and PRD detection in the setting of clinical WES. We are currently investigating which of the NGS-based markers perform satisfactorily when gathered with large sequencing panels instead of WES.

#3734 Early-onset low-grade adverse events as predictive biomarkers in advanced NSCL: A multi-treatment cohort analysis.

Dung-Tsa Chen[1], Andreas N. Saltos[1], Zachary Thompson[1], Junmin Whiting[1], Sebastian Viracacha[1], Timothy I. Shaw[1], Ignacio I. Wistuba[2], Jhanelle E. Gray[1]

[1]Moffitt Cancer Center, Tampa, FL,[2]UT MD Anderson Cancer Center, Houston, TX

Purpose: This study aims to assess whether early-onset, grade 1 (G1) and low-grade (LG) treatment-related adverse events (TrAEs) can serve as predictive markers for favorable survival outcomes in advanced non-small cell lung cancer (NSCLC) across different treatment modalities.

Methods: We analyzed data from 577 NSCLC patients across 11 cohorts treated at Moffitt Cancer Center: 5 immunotherapies (n=383), 3 targeted therapies (n=88), and 3 chemotherapies (n=106). Data for analysis used AE data derived from Common Terminology Criteria for Adverse Events (CTCAE v4-5), treatment response including comparison of responder (complete response (CR) and partial response (PR)) versus non-responder (stable disease (SD) and progressive disease (PD)) and comparison of disease control (DC: CR/PR/SD) versus PD using Wilcoxon two-sample test, progression-free survival (PFS) and overall survival (OS) using Kaplan-Meier survival curve with log-rank test. Our analytic approach leveraged multiple AE parameters to develop a set of innovative AE biomarkers. Early-onset G1/LG TrAEs were defined as those occurring within 30 days of treatment initiation.

Results: Early-onset AE analysis across all treatment types revealed that (a) Immunotherapy had lower frequency of G1 and LG TrAEs compared to chemotherapy and targeted therapy; (b) higher frequency of G1 and LG TrAEs were associated with better treatment response in immunotherapy (responder vs non-responder with p=0.047 (G1) and 0.069 (LG); DC vs PD with p=0.005 (G1) and 0.018 (LG)), but no significant results in chemotherapy and targeted therapy; (c) For patients who did not encounter HG non-treatment related AEs (non-TrAEs), if they frequently experienced G1 and LG TrAEs, their survival outcomes tended to be better compared to the ones with less or no AE experiences in immunotherapy (median PFS: 5.5 vs 3.5 months with p=0.03 for G1 and 5.5 vs 3.3 months with p=0.015 for LG; median OS: 18.2 vs 12.2 months with p=0.008 for G1 and 16.1 vs 12.2 months with p=0.04 for LG). Please note that non-TrAEs represent a strong surrogate for compromised baseline health status. Without proper adjustment, this factor may confound the observed association between early-onset G1 and LG TrAEs and survival outcomes. For in chemotherapy and targeted therapy, both G1 and LG TrAEs did not show significant survival association.

Conclusion: G1 and LG TrAEs within 30 days of therapy initiation were associated with better treatment response and improved survival in advanced NSCLC, especially in immunotherapy-treated patients. These findings support the use of early-onset G1/LG TrAE profiles as potential predictive biomarkers.

#3735 Septin9 isoforms as biomarkers of taxane response in breast cancer.

Jycole E. M. Bush[1], Jacob Essif[1], KATE LATHROP[2], April Risinger[1]

[1]UT Health Science Center at San Antonio, San Antonio, TX,[2]Mays Cancer Center, San Antonio, TX

Microtubule-targeting agents (MTAs), including the taxane paclitaxel, are widely used for the treatment of breast cancer. However, there are no clinically validated biomarkers to predict taxane response. Emerging evidence implicates septins, a conserved family of GTP-binding cytoskeletal proteins, key regulators of growth, migration, invasion, and taxane response of breast cancer cells in vitro. Notably, isoforms of septin9 (SEPT9) have opposing roles with SEPT9_i1 promoting migration, epithelial-mesenchymal transition and paclitaxel resistance whereas SEPT9_i2 is associated with decreased oncogenic phenotypes and may serve a protective role. We tested the hypothesis that septin9 isoform expression in breast tumors correlates with the response of breast cancer patients to taxane chemotherapy regimens in both retrospective and prospective clinical studies. In a retrospective analysis we found a significant increase in post-metastatic survival time of taxane-treated patients whose tumors expressed the highest levels of SEPT9_i2 mRNA. Notably, this correlation was only observed in women diagnosed with triple-negative breast cancer (TNBC) that rely most heavily on response to taxanes as they are not co-administered with targeted therapeutics. In a prospective study of neoadjuvant taxane response, women with a complete pathological response to taxane-based chemotherapy regimens had significantly lower expression of SEPT9_i1 mRNA in their tumors than non-responders. Furthermore, majority of tumors that did not respond fully to taxanes in neoadjuvant settings had increased SEPT9_i1 mRNA expression in the residual tumor after treatment. Finally, we validated a SEPT9_i1 specific antibody for immunohistochemistry and SEPT9_i1 mRNA correlated with protein in breast biopsies. Ongoing experiments in the laboratory are elucidating the mechanism by which expression of septin9 isoforms regulates response to taxane chemotherapy using isogenic cell line and tumor models. This work is uncovering a reciprocal relationship between expression of oncogenic and tumor suppressive isoforms and identifying alternative chemotherapeutic options for treatment of tumors with unfavorable septin expression profiles.

#3736 C3C: A biomarker for extracellular cathepsin activity and ADCs.

Marina Crespo-Bravo, Nicholas Willumsen, Morten Karsdal

Nordic Bioscience, Herlev, Denmark

Background: Antibody-drug conjugates (ADCs) combine the specificity of monoclonal antibodies with the potent cytotoxicity of small-molecules payloads. While classical ADCs rely on antigen binding, internalization and intracellular linker cleavage in the lysosomes recent studies show that certain tumors exhibit extracellular cathepsin activity capable of cleaving ADC linkers in the tumor microenvironment (TME) and creating a peritumoral “drug halo” that enhances bystander killing even in antigen-low or antigen-negative TME. For this reason, identifying tumors with high extracellular cathepsin activity may be critical for optimizing ADC efficacy and patient stratification.
Methods: We developed and investigated the potential of C3C, an ELISA-based biomarker that measures type III collagen fragments generated by cathepsins. Since the same cathepsins responsible for cleavage type III collagen and generating C3C also cleave commonly used peptide ADC linkers, we hypothesize that C3C could provide and non-invasive readout of cathepsin activity in the TME. We measured C3C in serum from patients with colorectal cancer (CRC) (n = 10), pancreatic ductal adenocarcinoma (PDAC) (n = 10) and non-small cell lung cancer (NSCLC) (n = 10) and compared to healthy controls (n = 26). To assess biological specificity, we also measured C3-HNE, a biomarker reflecting neutrophil elastase-driven inflammation.
Results: We found significantly elevated levels of C3C compared to healthy individuals in patients with CRC ($p = 0.03$), PDAC ($p = 0.006$) and NSCLC ($p < 0.001$). In contrast, C3-HNE showed no correlation with C3C in any indication, suggesting that C3C does not simply reflect general inflammation but instead captures cathepsin activity implicated in extracellular ADC linker cleavage.
Conclusion: The results suggest that C3C is a promising biomarker for identifying cathepsin-rich TMEs that may support payload release and potent bystander activity of ADCs. Furthermore, C3C could be used to select patients more likely to benefit from cleavable-linker ADCs representing a potential tool for both drug development and clinical precision oncology.

#3737 BXQ-350: A novel biologic that targets dysregulated sphingolipid metabolism and normalizes key anti-tumoral and pro-tumoral sphingolipids in newly diagnosed metastatic colorectal carcinoma patients (mCRC).

Gilles H. Tapolsky, TARIQ ARSHAD, Michael Gazda, Jackson Bond, Nikhil Wilkins, James Beach

Bexion Pharmaceuticals, Covington, KY

Background: Dysregulated sphingolipid metabolism is common to many cancer types, including mCRC, and leads to elevated concentrations of specific sphingolipids, including pro-tumoral gangliosides (GM3), lactosylceramides (LacCer), glucosylceramides (GluCer) and sphingosine-1-phosphate (S1P) and lower concentration of anti-tumoral ceramides. In mCRC patients, several studies have shown elevated concentrations of the pro-tumoral sphingolipids are associated with a worse prognosis and poor survival. Therefore, targeting dysregulated sphingolipid metabolism and returning sphingolipid metabolism to homeostasis could be a promising therapeutic approach. BXQ-350 is a nanovesicle of Saposin C, an allosteric activator of sphingolipid metabolism, that affects dysregulated sphingolipid metabolism. BXQ-350 lowers GM3, LacCer, GluCer and S1P levels while it also increases ceramide levels promoting a return to homeostasis and an anti-tumoral environment. In a single agent Phase 1 study, BXQ-350 was safe and well-tolerated (no DLT, no MTD) and showed signs of activity. Among patients with PFS > 6 months, there were 4 recurrent CRC patients: 1 patient had a PFS of ~12 months, 2 of ~18 months, and 1 is still on study after 7 years.
Method: BXQ-350 is being investigated in a Phase 1b/2a study in combination with mFOLFOX7 and Bevacizumab as SoC in newly diagnosed mCRC patients (NCT05322590) to assess the efficacy and safety of BXQ-350.The Phase 1b/2a is a safety dose escalation part to establish the RP2D exploring 1.8 and 2.4 mg/kg BXQ-350 in combination with SoC. Primary objectives are to assess safety and preliminary efficacy of BXQ-350 in this combination. Secondary objectives include longitudinal analysis of several biomarkers, including sphingolipid profiling.
Results: A total of 32 evaluable patients were enrolled, and all 32 patients have completed SoC treatment schedule plus BXQ-350. Amongst these 32 patients, 21 (66%) are alive and in active follow-up. The disease control rate was 94% (30 pts had SD, PR or CR). As of September 2025, ORR was 59% and PFS was 10.6 months. Analysis of sphingolipid profiles shows that BXQ-350 significantly (> 50%) and durably lowers plasma levels of GM1-3, LacCer, GluCer and S1P while increasing Cer levels (> 50%); furthermore, statistically significant associations between LacCer, Cer, Cer/S1P and Glu/Cer levels and survival were observed.
Conclusions: BXQ-350 was safe and well tolerated in combination with SoC in 1L mCRC. Ongoing monitoring of patients suggests that BXQ-350 may provide a clinical benefit to 1L mCRC patients in combination with FOLFOX 7 + Bevacizumab. Basal and longitudinal analysis of sphingolipid showed that BXQ-350 impacts plasma levels of critically important sphingolipids and associations between key sphingolipids and survival were noted.

#3738 Characterization of TAG-72, a glycan-based ADC target and its pan-tumor expression profile.

Joseph D. Schonhoft, Martijn H. den Brok, Marleen H. van Stevendaal, Thaddeus J. Unger, Lieke W. Wouters, Luc M. Zijlmans, Renate van Daalen, Raffaella Rossin, Marc Robillard, Keith Orford

Tagworks Pharmaceuticals BV, Nijmegen, Netherlands

Background: Tumor-Associated Glycoprotein 72 (TAG-72) is a cancer-specific glycoepitope displayed on mucins and expressed across epithelial cancers, predominantly adenocarcinomas. Initially studied using the B72.3 and CC49 antibodies, TAG-72-expressing cancers lack optimal therapeutic approaches. TGW101, a novel antibody-drug conjugate (ADC) targeting non-internalizing TAG-72, incorporates a CC49-derived diabody and a DAR4 MMAE payload linked via a trans-cyclooctene-based linker that enables controlled cleavage following administration of a tetrazine small-molecule trigger. This ADC-trigger system is currently in phase I clinical development (NCT06959706) for select solid tumors that frequently express TAG-72. Here we present characterization of the TAG-72 glycoepitope, the development of fit-for-purpose TAG-72 IHC assays for patient selection, estimates of its prevalence across solid tumors, and its overlap with established predictive biomarkers used in standard-of-care settings for populations with unmet need.
Methods: Glycan arrays were set up by GlycoDisplay, using engineered cells transfected with a range of probes containing mucin-like repeats. TAG-72 IHC assays were developed at NeoGenomics.
Results: A cell-based glycan array analysis revealed that the CC49-diabody binding requires clustered Thomsen-nouvelle (Tn) and/or sialylated-Tn (STn) glycans on the tandem repeat domain of specific cancer-associated mucins, including MUC1, 2, 5AC, 6, 13, and 17, suggesting it is co-dependent on macrostructural glycan conformation. Optimized IHC using both B72.3 and CC49 anti-TAG-72 clones revealed highly specific staining, with positive staining of the duodenum luminal mucosa (known to be moderate or low positive) and absent staining in the duodenum submucosa, muscularis, and other normal tissues including kidney. Both B72.3 and CC49 IHC clones demonstrated highly similar staining patterns. Additionally, TAG-72 staining was observed in CDX and PDX xenograft models where tumor regressions occurred following treatment with TGW101. Initial screening of tumor microarrays indicated expression across a wide range of solid tumors, with highest expression in adenocarcinomas and mucinous tumors. Scoring criteria, biomarker overlap, and estimated prevalence for both B72.3 and CC49 clones by indication will be presented.
Conclusions: TAG-72 is a tumor-associated glycoepitope consisting of STn and Tn glycans present on multiple mucin proteins. It is widely expressed in epithelial cancers, while almost entirely absent in normal tissues, making it an attractive therapeutic target. Current commercially available antibodies show excellent specificity using modern IHC techniques and could facilitate biomarker-driven clinical development for TAG-72-targeted therapies.

#3739 Isolation and characterization of pancreatic cancer-derived small extracellular vesicles as a novel liquid biopsy approach.

Ravi Kumar Paluri[1], Ashish Kumar[1], Yixin Su[1], Gregory L. Kucera[2], Ashish Manne[3], Jingyun Lee[1], Sangeeta Sing[1], Susy Kim[1], Cristina Furdui[4], Gagan Deep[5]

[1]Wake Forest Baptist Health, Winston Salem, NC,[2]Associate Professor, Dept. of Internal Med., Wake Forest University School of Medicine, Winston-Salem, NC,[3]Ohio State University, Columbus, OH,[4]Atrium Health Wake Forest Baptist, Winston Salem, NC,[5]Wake Forest University School of Medicine, Winston-Salem, NC

Background: A major challenge in managing pancreatic cancer (PanC) is late detection and the inability to identify non-responders early. Existing liquid biopsy approaches offer limited capacity to rapidly and noninvasively track the tumor's evolving molecular landscape, which is essential for overcoming therapy resistance and guiding targeted treatment. Small extracellular vesicles (sEV; <200 nm) circulate widely and carry cargo reflective of their cells of origin. Using our established methods for isolating tissue-specific sEV, we identified pancreas-specific surface markers, isolated circulating pancreas derived sEV ($sEV^{Pancreas}$), and evaluated their potential as a liquid biopsy platform.

Methods: We analyzed fresh-frozen PanC tissues (n=12) along with matched healthy samples. sEV were isolated from tissues, subjected to surface protein shaving, and analyzed using LC-MS/MS based on published methods. Proteomic data, combined with the Human Protein Atlas, were used to identify $sEV^{Pancreas}$. They were isolated from archived plasma samples of PanC patients (n=10) and healthy individuals (n=5) using biotin-tagged antibodies and streptavidin-coated magnetic beads. Isolated sEV/$sEV^{Pancreas}$ were characterized for size and concentration by nanoparticle tracking analysis (NTA), and for various biomarkers' expression using nano-flow cytometry, RT-PCR, RNA sequencing, and digital PCR.

Results: Prolyl 4-hydroxylase subunit beta (P4HB) and annexin A4 (ANXA4) were identified as pancreas-specific sEV surface markers. Nano-flow cytometry confirmed significantly higher levels of P4HB- and ANXA4-positive sEV in PanC plasma compared to healthy controls ($p<0.01$). Using these markers, we isolated $sEV^{Pancreas}$ from blood plasma samples of PanC patients and controls. NTA confirmed that the isolated vesicles were <200 nm in both groups. Notably, $sEV^{Pancreas}$ from PanC patients exhibited significantly higher expression of the PanC biomarker cholecystokinin A receptor ($p<0.01$) and lower levels of miR-320-5p, a microRNA associated with poor prognosis. RNA sequencing of $sEV^{Pancreas}$ revealed several upregulated (e.g., endosulfine-α, MUC12) and downregulated (e.g., DYNC1I2, POM121C) genes in the PanC group. Finally, KRAS copy number and mutation status was reliably assessed in $sEV^{Pancreas}$, highlighting the potential for KRAS mutational profiling.: we reliably characterized wild type and mutated KRAS status (G12D and G12V).

Conclusions. We demonstrate that pancreas-derived sEV can be selectively isolated from blood using newly identified pancreas-specific markers. These $sEV^{Pancreas}$ harbor distinct molecular signatures and reliably capture KRAS copy number and mutations, supporting their potential as a rapid, minimally invasive liquid biopsy platform. These findings lay the groundwork for sEV-based assays for treatment monitoring and response assessment.

#3740 OncoGraph: A patient-specific blood test using protein markers to monitor cancer recurrence and treatment response.

Mao Mao[1], Wenjian Wang[2], Qingqi Ren[3], Shiyong Li[1], Wei Wu[1]

[1]SeekIn, Shenzhen, Guangdong, China,[2]Sun Yat-sen Memorial Hospital, Sun Yat-sen University, Guangzhou, Guangdong, China,[3]Peking University Shenzhen Hospital, Shenzhen, Guangdong, China

Background: ctDNA-based MRD assays are increasingly used for post-treatment monitoring but remain costly and technically demanding, limiting global accessibility, particularly in low- and middle-income countries (LMICs). Protein tumor markers (PTMs) are inexpensive and clinically effective in select cancers (e.g., PSA for prostate, AFP for liver), but most malignancies lack disease-specific markers, and existing markers have restricted applicability with substantial inter-patient variability, limiting individualized monitoring. We developed OncoGraph, a patient-specific approach that identifies abnormally elevated PTMs and tracks their longitudinal dynamics to monitor recurrence and treatment response. This approach offers an affordable, scalable solution suited for LMIC healthcare systems.
Methods: Baseline blood samples from newly diagnosed cancer patients were analyzed by OncoSeek, a validated multi-cancer early detection assay quantifying a predefined panel of common PTMs (e.g., AFP, CEA). For individuals testing positive, PTMs exceeding internally validated thresholds were designated as patient-specific PTMs. These markers were longitudinally tracked after surgery or during therapy to monitor recurrence, response, or progression. Using OncoGraph, we evaluated postoperative recurrence in 24 liver cancer patients and treatment monitoring in 23 advanced lung cancer and 116 lymphoma patients receiving chemotherapy or targeted therapy.
Results: In liver cancer (n=24), 13 patients had elevated baseline PTMs (all AFP). After surgery, OncoGraph-positive patients had a higher recurrence rate (4/5 vs. 1/8) and shorter median recurrence-free survival compared with OncoGraph-negative patients (385 days vs. not reached; HR 12.8; $P < 0.01$).In advanced lung cancer (n=23), 17 patients carried PTMs elevated at baseline (CEA and/or CYFRA21-1). After a median of 44.5 days after treatment initiation (range, 31-63), patients with significant PTM decrease had longer median progression-free survival (438 vs. 191.5 days; $P < 0.05$).In lymphoma (n=116), only eight patients had baseline-abnormal PTMs (all CA125). After two treatment cycles, all eight showed marked OncoGraph decrease, fully concordant with interim PET/CT responses (partial or complete response) assessed after 2-4 cycles.
Conclusion: OncoGraph provides a patient-specific framework for PTM-based monitoring, addressing limitations of traditional PTMs through patient-specific marker selection. By selecting patient-specific informative PTMs and tracking their longitudinal dynamics, OncoGraph delivers early, clinically actionable signals of recurrence risk and treatment response across multiple cancer types. Its low cost, minimal technical requirements, and broad applicability make it a practical and scalable monitoring solution, particularly for LMIC healthcare settings.

#3741 Radiation-dendritic cell combination therapy drives systemic cellular immune shifts in liver cancer.

Melody Wu[1], Panwen Wang[2], Chen Wu[3], Ying Li[4], Christopher L. Hallemeier[5], Thomas D. Atwell[6], Nguyen H. Tran[7], Andre de Menezes Silva Corraes[7], Kevin Regan[7], Zuoyi Shao[7], Rayaan Kamal[7], Haidong Dong[8], Lewis R. Roberts[9], Sean Park[5], Yi Lin[10], Lionel Aurelien Kankeu Fonkoua[7]

[1]Medical Scientist Training Program, Mayo Clinic College of Medicine and Science, Rochester, MN,[2]Mayo Clinic - Department of Biomedical Informatics, Scottsdale, AZ,[3]Mayo Clinic Graduate School of Biomedical Sciences, Rochester, MN,[4]Mayo Clinic - Department of Quantitative Health Sciences, Jacksonville, FL,[5]Mayo Clinic - Department of Radiation Oncology, Rochester, MN,[6]Mayo Clinic - Department of Radiology, Rochester, MN,[7]Mayo Clinic, Rochester, MN,[8]Mayo Clinic - Department of Immunology, Urology, Rochester, MN,[9]Mayo Clinic - Department of Gastroenterology & Hepatology, Rochester, MN,[10]Mayo Clinic - Department of Hematology & Oncology, Rochester, MN

Introduction: Liver cancer remains a leading cause of cancer mortality globally with limited treatment options for patients (pts) with unresectable hepatocellular carcinoma [HCC] and intrahepatic cholangiocarcinoma [iCCA][1,2,3,4]. We hypothesize that combining the intratumoral dendritic cell (DC) vaccination after external beam radiotherapy (EBRT) without (phase I) and with (phase II) systemic atezolizumab and bevacizumab (atezo/bev for HCC) would enhance tumor-specific immunity and improve clinical outcomes, and present preliminary results from our phase I/II trial (NCT03942328).

Methods: Peripheral blood mononuclear cells (PBMCs) were collected at baseline (PRE), after radiation (EBRT), and after completion of DC without or with atezo/bev (POST). Single-cell RNA sequencing with TCR sequencing were analyzed using CellRanger v7.0.1, Immunopipe, Seurat v5.3.0, & Gene-set enrichment analysis (GSEA). Long EFS (EFS-L) is defined as >=12 months (mo) for phase I and >=18mo for phase II, and short EFS (EFS-S) below that.

Results: Seventeen patients have been analyzed to date (Phase I: n=8 [4 HCC, 4 iCCA]; Phase II: n=9 HCC). 674,106 cells were sequenced (146,843 PRE; 168,838 EBRT; 114,437 POST).

GSEA for EFS-L vs EFS-S were comparable at PRE, EBRT and POST between phase I and phase II. EFS-S was associated with enrichment of interferon alpha (IFNα; B naïve, monocytes, pDC, cDC2, NK, Treg, CD8 Tcm and Tem at PRE and POST; B intermediate, CD4 Tem and NK at EBRT) and reactive oxygen species (ROS; PRE: pDC, CD8 Tcm, Tem. EBRT: CD4 Tem. POST: CD8 T naïve Tem, CD4 Tcm & Tem, cDC2) pathways.

In contrast, EFS-L was associated with enrichment of WNT-β-catenin (WNT; CD14 mono at EBRT & POST, B intermediate at EBRT), TGFb (PRE: NK; EBRT: B intermed, CD4 Tem; POST: monocytes, CD4 naïve & Tem, pDC, cDC2), and angiogenesis (EBRT: NK; POST: monocytes, cDC2) pathways.

Interestingly, enrichment of protein secretion pathway in NK cells was associated with EFS-L, but among other cells were associated with EFS-S (PRE: CD16 mono, Treg; POST: CD16 mono, CD4 & D8 Tem).

Compared to phase I, addition of atezo/bev in phase II pts was associated with a significant increase in Gini coefficient ($p<0.0001$), suggesting expansion of certain TCR clones, along with a trend for increased Gini coefficient from Pre to Post in both phase I and II.

Conclusions: Preliminary analysis of this study combining EBRT with intratumoral DC vaccination +/- PD-L1/VEGF blockade identified distinct treatment-related changes in systemic cellular immune profiles. Enhanced TCR clonal diversity in phase II suggests added immunologic benefit from PD-L1/VEGF blockade. As accrual continues, integrated analyses will identify systemic immune correlates of clinical benefit and resistance to this multimodal immunotherapy approach.

#3742 Immune microenvironment rather than genomic alterations drives hyperprogression-related features in 11q13 amplified Chinese esophageal cancer.

Ling Deng

Guangzhou Medical University Affiliated Qingyuan Hospital (Qingyuan People's Hospital), Qingyuan City, China

Background: Immune checkpoint inhibitors (ICIs) have transformed the therapeutic landscape of esophageal cancer (ESCA), yet a subset of patients experience hyperprogressive disease (HPD) following immunotherapy. Previous studies have suggested that genomic alterations located on chromosome 11q13—including amplification of CCND1, FGF3, FGF4, and FGF19—may contribute to HPD. This study aimed to investigate whether 11q13 amplification in ESCA is associated with genomic features or distinct immune microenvironment characteristics that could help explain resistance to immunotherapy and the development of HPD.
Methods: Tumor samples from 341 ESCA patients were analyzed using a 733-gene next-generation sequencing (NGS) panel to characterize genomic profiles, including DDR pathway alterations, tumor mutation burden (TMB), and intratumor heterogeneity (ITH). Multiplex immunofluorescence (mIF) was also performed to evaluate key immune microenvironment components. Patients with and without 11q13 amplification were compared with respect to genomic alterations and immune cell infiltration.
Results: Among the 341 ESCA patients, 49.3% (168/341) exhibited 11q13 amplification. Genomic analysis revealed no significant differences between the 11q13-amplified and non-amplified groups in DDR pathway gene alterations, TMB, or ITH, suggesting that 11q13-associated immunotherapy resistance is unlikely to be driven by intrinsic genomic instability. In contrast, immune microenvironment profiling demonstrated marked differences: patients with 11q13 amplification exhibited significantly reduced infiltration of $FOXP3^+$ regulatory T cells (P=0.005) and $CD3^+CD4^+FOXP3^+$ T cells (P=0.03) in the tumor stroma, while showing significantly increased infiltration and density of $CD8^+PD\text{-}1^+$ T cells in the tumor parenchyma (P=0.01 for density; P=0.02 for positivity). These immune patterns are consistent with previously reported features associated with HPD, suggesting that immune dysregulation rather than genomic alterations may underlie hyperprogression in 11q13-amplified ESCA.
Conclusion: 11q13 amplification in ESCA does not correlate with DDR gene alterations, TMB, or ITH, but is strongly associated with distinct immune microenvironment features previously linked to HPD, including reduced stromal regulatory T cell infiltration and increased parenchymal $CD8^+PD\text{-}1^+$ T cell presence. These findings highlight the clinical importance of immune microenvironment dysregulation in 11q13-amplified ESCA and underscore the need for tailored therapeutic strategies for this molecular subgroup.

#3743 ddPLEX EGFR/KRAS/BRAF: A highly multiplexed droplet digital PCR (ddPCR) panel for ultra-sensitive NSCLC biomarker detection.

Surbhi Jain[1], Cailin Festog[1], Mai Ho[1], Cindy Li[1], Necip Mehmet[1], Ady Melendez-Molina[1], Toshiro Newsum[1], Prithwish Pal[1], Mina Rostamza[1], Yusuke Ono[2], Leisa Jackson[3], Brittany D'Alessio[3], Gunnar Johnson[3], Gary A. Pestano[3]

[1]Bio-Rad Laboratories, Hercules, CA,[2]Sapporo Higashi Tokushukai Hospital, Sapporo, Japan,[3]Biodesix, Inc., Louisville, CO

Biomarker testing for actionable oncogenic driver mutations is recommended in national and international guidelines based on the improved outcomes observed with use of targeted therapies in eligible patients with metastatic NSCLC. Here, we demonstrate the performance of the ddPLEX EGFR/KRAS/BRAF Mutation Detection Assay Kit, a research use only kit developed for the QX600™ Droplet Digital™ PCR (ddPCR) System. This kit is designed for the detection, discrimination and quantification of 37 actionable variants in the *EGFR*, *KRAS*, and *BRAF* genes in a single ddPCR well. It also has a companion total quantification well that quantifies *EGFR*, *KRAS* and *BRAF* genes in a mutation agnostic manner and allows for variant allele frequency (VAF) calculation. It provides same day results with a streamlined workflow, includes positive and internal controls and is compatible with plasma and formalin-fixed paraffin-embedded (FFPE) samples.

The analytical performance of the ddPLEX EGFR/KRAS/BRAF Mutation Detection Assay Kit was evaluated internally, and the findings are presented here. The results demonstrated an analytical sensitivity of 0.025%-0.1% in a background of 132 ng of human genomic DNA for all targeted variants. The assay had an analytical specificity of 100% when tested with 1000 copies input of each variant, one at a time, in a total of 132 ng of human genomic DNA. The mutant assay did not cross-react with any of the commonly reported mutations located in the same amplicon as *KRAS* G12C and *BRAF* V600E. The mutant assay was linear from 800 copies to 4 copies per reaction with a R^2 in the range of 0.94-0.99. The total quantification assay was also linear in the range of 1.3 ng to 53 ng of total DNA input with a R^2>0.99 for all three targets. With previously extracted and archived cell-free DNA from plasma and FFPE DNA that were tested with alternative PCR based methods, the ddPLEX kit had a concordance of 100% and 96.5%, respectively.

In conclusion, the ddPLEX EGFR/KRAS/BRAF Mutation Detection Assay Kit is sensitive, accurate, and efficient in time and cost for detecting clinically relevant NSCLC variants. Multiplexing maximizes information and reduces sampling bias from specimens with low nucleic acid quantities such as FFPE and plasma.

#3744 Peripheral immune indices predict pathologic complete response and residual cancer burden in inflammatory breast cancers.

Hui Gao[1], Ranjan Upadhyay[1], Angela Alexander[2], Angela N. Marx[3], Megumi Kai[3], Chelain R. Goodman[1], Azadeh Nasrazadani[4], Savitri Krishnamurthy[1], Anthony Lucci[5], Rachel M. Layman[1], Sadia Saleem[3], Vicente Valero[6], Michael C. Stauder[7], Susie X. Sun[8], Gary J. Whitman[9], Miral M. Patel[9], Huong C. Le-Petross[9], Chasity L. Yajima[3], Lily Villarreal[3], Heather Lopez[3], Bora Lim[1]

[1]UT MD Anderson Cancer Center, Houston, TX,[2]TRIUMPH Postdoctoral Fellow, UT MD Anderson Cancer Center, Houston, TX,[3]Breast Medical Oncology, UT MD Anderson Cancer Center, Houston, TX,[4]Azadeh Nasrazadani (Individual),[5]Professor, Dept. of Surgical Oncology, UT MD Anderson Cancer Center, Houston, TX,[6]Professor of Medicine, UT MD Anderson Cancer Center, Houston, TX,[7]Assistant Professor, UT MD Anderson Cancer Ctr., Houston, TX,[8]Breast Surgical Oncology, UT MD Anderson Cancer Center, Houston, TX,[9]Diagnostic Imaging, UT MD Anderson Cancer Center, Houston, TX

Background: Circulating immune profiles offer a noninvasive approach to monitor treatment response in breast cancer. Inflammatory breast cancer (IBC), although clinically distinct, shares resistance and immune evasion features among each other. To identify immune escape mechanisms and early predictors of response in IBC, we profiled longitudinal peripheral immune markers and evaluated their association with pathologic complete response (pCR) and residual cancer burden (RCB) across treatment regimens and subtypes and developed composite immune indices to improve prediction under class imbalance.

Methods: Peripheral blood samples (n=93) from patients treated with neoadjuvant or induction therapy for IBC were analyzed by multiparameter flow cytometry and annotated for subtype, regimen, pCR, and RCB. Group comparisons used Mann-Whitney U (pCR) and Kruskal-Wallis (RCB). Predictive models included logistic regression and random forest classifiers with class-weighting. Composite indices included CD8 Exhaustion, CD8 Memory, NK-ADCC scores derived from z-scaled components. Model performance was assessed using 5-fold cross-validation with AUC, PR-AUC, and calibration. Planned extensions include leave-one-regimen validation, temporal analyses, and external evaluation using a pre-registered pipeline.

Results: Univariate analyses identified significant associations between pCR and the CD8 Exhaustion Index ($p \approx 0.007$) and CD8 Memory Index ($p \approx 0.038$), with NK-ADCC trending ($p \approx 0.078$). Logistic regression and random forest models incorporating combined indices improved AUC from ~0.70 when individually associated, to ~0.92 ± 0.07 (5-fold CV), albeit with wide uncertainty due to only up to 5 pCR events. Individual markers linked to pCR included Stem_Memory_CD8, NKG2A_ADCC, and CTLA4_CD8, while CD56hi NK and NKG2A +CD56hi NK distinguished RCB gradients ($p<0.05$ before correction). No markers remained significant after FDR adjustment given sample size.

Conclusions: Peripheral immune signatures, particularly combined CD8 exhaustion, memory indices, NK ADCC were associate with higher pCR and lower RCB. Composite indices outperform single markers and capture the balance between immune activation and suppression. Ongoing cross-cohort validation will assess generalizability across regimens and subtypes. Severe class imbalance (~5/93 pCR) and small subgroup sizes constrain precision of our analysis. Findings are hypothesis-generating and warrant external validation in larger prospective cohorts.

#3745 Unveiling clear cell renal cell carcinoma heterogeneity associated with locally advanced disease using single nucleus multi-omics.

Pratik Shah[1], Anita Ng[2], Justin Wang[3], Houman Khalili[2], Tony Pham[4], Melissa Neumann[1], Xinhua Zhu[1], Annette Lee[5], Andrew Shih[2]

[1]Northwell Health Cancer Institute, New Hyde Park, NY,[2]The Feinstein Institute for Medical Research, Manhasset, NY,[3]College of Agriculture and Life Sciences, Cornell University, Ithaca, NY,[4]CUNY School of Medicine, Manhattan, NY,[5]ATL Consulting, Wayne, NJ

Clear cell Renal Cell Carcinoma (ccRCC) is the most common type of kidney cancer with diverse clinical courses that are driven by molecular and histological heterogeneity. Overall survival of ccRCC patients has improved significantly with the introduction of adjuvant therapies, including immunotherapy and tyrosine kinase inhibitors (TKI), particularly for patients at higher risk of recurrence post-nephrectomy. However, the response rate to these targeted therapies for those that relapse can vary greatly. To decipher the molecular underpinning of therapy responsiveness associated with advanced stage ccRCC, we performed single nucleus analysis of gene expression and chromatin dynamics on fresh post-nephrectomy tumor samples collected in 8 patients.

Upon comparing different ccRCC subpopulations between stage 3 (n=6) and stage 1 (n=2) patients, we observed large global transcriptional differences with an enrichment of a subset of metabolically active RCC cells with heightened *EDIL3* expression. Besides the increased distribution of this RCC subset in stage 3 patients, we have identified chromosomal regions in these cells that overlapped with 4 genome-wide association study (GWAS) hits for increased risk of ccRCC (Purdue et al., 2024). Among the clusters of ccRCC subsets discovered in this cohort, the gene signatures of *EDIL3*-ccRCC are significantly associated with lower survival time (OR= 4.65; P=1.9E4) in stage I-III TCGA-KIRC (n = 372). Intriguingly, these cells, as well as a *FOS* expressing ccRCC cluster, are also enriched in patients in our cohort that eventually relapsed. Together with the upregulation of ERK and RAS signaling compared to other tumor cells, the increased fatty acid metabolism in *EDIL3*-ccRCC may present an alternative signaling mechanism that can contribute to progression due to metastasis and disease recurrence. In silico prediction of drug responsiveness revealed an overall decrease of therapeutic sensitivity of *EDIL3*-ccRCC toward various EGFR inhibitors. In contrast, while *FOS*-ccRCC signature also appears to be associated with disease recurrence, these cells are highly sensitive to various TKI and Sunitinib in particular. These results suggest the potential to leverage the differential therapeutic vulnerability of ccRCC subpopulations to provide better combination therapies in the clinic.

With the goal of improving the conceptual framework for the design of adjuvant therapies, our study offers an in-depth characterization of ccRCC subpopulations that are associated with higher stages and disease progression, possibly through different druggable oncogenic pathways.

#3746 Single-cell liquid biopsy profiling in mCRPC receiving PSCA-targeted CAR-T cell therapy.

Doanna Minh Pham[1], Stephanie Nicole Shishido[1], Saul J. Priceman[2], Tanya B. Dorff[3], Peter Kuhn[4]

[1]USC - University of Southern California, Los Angeles, CA,[2]University of Southern California, Los Angeles, CA,[3]City of Hope Comprehensive Cancer Ctr., Los Angeles, CA,[4]Assoc. Professor, Dept. of Cell Bio., University of Southern California, Los Angeles, CA

Metastatic castration-resistant prostate cancer (mCRPC) represents an aggressive, treatment-refractory stage of prostate cancer with limited treatment options and poor prognosis. Chimeric antigen receptor (CAR)-T cell therapy has demonstrated success in hematological malignancies, but its efficacy in solid tumors is limited by tumor microenvironment (TME) barriers and tumor cell heterogeneity. In this study, we applied a single-cell enrichment-free liquid biopsy platform to monitor disease progression and CAR-T cell response in mCRPC patients enrolled in a Phase 1 clinical trial (NCT03873805). Using fluorescent whole-slide imaging (fWSI), we analyzed peripheral blood (PB) and bone marrow aspirate (BMA) from eight patients (four responders and four nonresponders) collected longitudinally before, during, and after therapy. Two key findings emerged: 1) lymphodepletion mobilized circulating tumor cells (CTCs) from bone marrow into PB, altering compartment-specific cellularity regardless of response, and 2) clearance of clonal CTCs after CAR-T cell infusion occurred in responders but not in nonresponders. Single-cell analyses further revealed that PB and BMA captured distinct CTC subtypes, underscoring the complementary value of both compartments for monitoring. This multi-omic analysis leverages high-resolution single-cell liquid biopsies to characterize circulating rare cells, such as CTCs and their subtypes, to correlate them with clinically observed responses to CAR-T cell therapy in mCRPC.

#3747 Discovery and functional characterization of enhancer hijacking oncogene rearrangements in NSCLC using Hi-C sequencing of FFPE tumors.

Kristin Sikkink, Blake Skrable, Sid Selvaraj, Alex Hastie, **Anthony Schmitt**

Arima Genomics, Carlsbad, CA

INTRO: Molecular profiling of solid tumors has revealed many targetable biomarkers; in NSCLC, ~50% of patients harbor such biomarkers (EGFR mutations or ALK fusions). However, limited precision therapeutic options exist for the remaining ~50%. To address this need, we aimed to identify and functionally characterize novel tumor-driving genomic mechanisms involving known oncogenes using Hi-C sequencing of FFPE NSCLC tumors.
METHODS: FFPE NSCLC tumors (n=97) were retrospectively selected from Stage III/IV patients whose prior CGP showed no EGFR/RAS mutations or gene fusions (“driver-negative”). Hi-C sequencing was performed by Arima Genomics, and rearrangements, gene fusions, and CNVs were identified with Arima-SV pipeline. Oncogenes within ~1 Mb of a rearrangement (“oncogene rearrangements”) were evaluated for potential enhancer hijacking events by analyzing breakpoint-crossing 3D regulatory interactions with putative enhancers at rearrangement partner loci. Functional characterization of rearranged oncogene activation was assessed by IHC.
RESULTS: 95/97 (98%) Hi-C libraries passed QC and were deeply sequenced and analyzed. 35/95 (37%) of tumors had oncogene rearrangements involving 47 oncogenes. 26/95 (27%) tumors carried 33 rearranged oncogenes linked to response to targeted therapies (Level 1/2 therapeutic response evidence; OncoKb), including BRAF (1), ERBB2 (3), FGFR1 (9), FGFR2 (2), FGFR3 (2), NRG1 (4), NTRK1 (1), NTRK2 (1), RET (5), ROS1 (2), KRAS (2), and PIK3CA (1). 3/95 (3%) tumors had PD-L1 rearrangements. 8/95 (8%) tumors had 11 rearranged oncogenes of lower-level significance, such as PIK3CB (1), CCND1 (3), BCL6 (1), and MYC (2), CLDN18 (3), and HRAS (1). 23 had sufficient tissue remaining for further functional characterization and a corresponding commercially available IHC test for protein expression. 11/23 (48%) were expressed in >10% of the tumor cells, including FGFR1 (2/9, 22%), ERBB2 (2/3, 66%), NTRK1 (0/1, 0%), NTRK2 (1/1, 100%), ROS1 (0/2, 0%), CLDN18 (0/1, 0%), BCL6 (1/1, 100%), MYC (2/2, 100%), and CCND1 (3/3, 100%). Lastly, we observed that 10/11 (91%) rearrangements with both features of enhancer hijacking ((1) strong breakpoint-crossing oncogene 3D interactions and (2) partner locus enhancers) were expressed at the protein level, versus only 1/12 (8%) lacking one or both features.
CONCLUSIONS: These data demonstrate the capability of Hi-C to detect rearranged oncogenes and predict their exogenous expression. Many activated rearranged oncogenes correspond to targets of FDA-approved or standard-of-care therapies, albeit potentially activated by a mechanism different than those well-established (point mutations or gene fusions). Further studies are needed to determine whether such oncogene rearrangements confer therapeutic susceptibility or serve as other predictive biomarkers or drug targets.

#3748 A proportion of shared mutations in lung squamous cell carcinoma provides insights that may guide therapeutic approaches.

Jaewoong Lee[1], Jun Hyeok Lim[2], Lucia Kim[3], Woo Kyung Ryu[4], Hyun-Tae Shin[5], In-Jae Oh[6], Sabin Park[1], Yoo Duk Choi[7], Semin Lee[1], Jeong Seon Ryu[8]

Lung squamous cell carcinoma (LUSC) frequently arises within a genetically altered epithelium, yet the clinical significance of the cancerized field remains unclear.To investigate its biological and prognostic significance, we performed whole-exome and transcriptome analyses on precancer, primary tumor tissues, and their matched normal tissues from 76 LUSC patients. We defined the proportion of shared mutations (PSM) between precancer and corresponding tumor samples, which negatively correlates with poor recurrence-free survival and overall survival. Interestingly, high PSM was associated with early chromosomal instability, tobacco-related mutational signatures, and upregulation of metabolic and proliferative genes such as *RRM2* and *TIMMDC1*. Furthermore, molecular features of RRM2 and TIMMDC1 were enriched in the independent non-recurrence group. Additionally, copy number variations and gene expression patterns differed significantly between the PSM-low and PSM-high groups, suggesting the presence of clonal evolution within a cancerized field. These results demonstrate that PSM serves as a novel biomarker for prognosis and reveals key early events in the progression of LUSC.

This study was supported by a grant (RS-2022-NR-071926 and RS-2018-NR031072) from the National Research Foundation of Korea (NRF).

#3749 Integrative multiomics and functional studies to identify biomarkers of AOH1996 sensitivity across AML subtypes.

Hamsini Kala[1], Dana Abou Abbas[2], Robert J. Hickey[3], Linda H. Malkas[4], Caroline M. Li[1], Robert G. Lingeman[1], Guido Marcucci[2], Le Xuan Truong Nguyen[2], Brian Ball[5], Amanda Blackmon[5], Melissa Ronan[6], Jennifer Roth[7], Matthew G. Rees[7]

[1]Beckman Research Institute of The City of Hope, Duarte, CA,[2]City of Hope, Duarte, CA,[3]City of Hope National Medical Center, Duarte, CA,[4]City of Hope National Medical Center, Sylmar, CA,[5]PS Hematology, City of Hope National Medical Center, Duarte, CA,[6]Broad Institute of MIT and Harvard, Cambridge, MA,[7]Broad Institute, Cambridge, MA

Acute myeloid leukemia or AML encompasses diverse molecular subtypes driven by distinct transcriptional and genetic programs that influence therapeutic response. AOH1996 which is a PCNA-dependent replication stress pathway inhibitor has demonstrated preclinical activity in AML. However biomarkers that may predict sensitivity across heterogeneous AML subgroups remain undefined. We first applied integrative multiomic analysis to begin defining the molecular contexts in which AOH1996 may be most effective. Transcriptomic, genomic, and proteomic datasets from PRISM, DepMap, and other curated subtype annotations were integrated with AOH1996 response metrics also known as AUC. Initial analyses focused on quantitative assessment of MYC RNA expression relative to AOH1996 sensitivity using a quadrant based visualization framework, and ongoing multi-omic analyses incorporating mutational backgrounds. Pathway activity scores, and protein level features are being used to explore broader biomarker patterns across AML models. Guided by these computational findings we are developing complementary in vitro studies in a panel of molecularly annotated AML models to functionally probe AOH1996 response, with planned readouts broadly focused on cell growth, cell cycle behavior, and stress associated phenotypes consistent with replication stress and innate immune pathway engagement. Preliminary computational results reveal subtype dependent variation in the relationship between MYC expression and AOH1996 response which aligns with MYC's established role in driving transcriptional load and replication stress and nominating MYC expression as a biologically plausible candidate biomarker. Together, this integrated multiomics and emerging experimental framework supports the feasibility of biomarker-guided evaluation of AOH1996 across AML subtypes and provides a foundation for future translational studies aimed at molecularly informed therapeutic stratification.

#3751 QVT Subscore: An interpretable radiomic panel of tumor vascularity reveals treatment-specific mechanisms-of-action (MoA) in NSCLC.

Haojia Li[1], Pushkar Mutha[2], Young Kwang Chae[3], Kai Zhang[1], Liam Il-Young Chung[3], Amogh Hiremath[1], Rhea Chitalia[1], Justin Yau[3], Omid Haji-Maghsoudi[1], Trishan Arul[1], Vamsidhar Velcheti[4], Anant Madabhushi[1], Nathaniel Braman[1]

Note: Black Arrow p<=0.05, White Arrow 0.05<p<0.1, — no trend					

Background: Tumor angiogenesis drives treatment resistance by fostering an immunosuppressive microenvironment. VEGF inhibitors (VEGFi) target the vasculature, while immune checkpoint inhibitors (ICI) do not address this mechanism directly. Quantitative Vessel Tortuosity (QVT) Score is a radiomic biomarker of vascularity previously shown to be associated with ICI response. Here, we introduce QVT Subscore, an interpretable panel that isolates distinct vascular attributes (e.g., branching, curvature, radius), enabling treatment-specific insight into vascularity MoA and vascular normalization.

Methods: QVT Subscores are derived by grouping the 910 QVT features comprising QVT Score into six biological categories, summarized by principal component analysis. The panel was evaluated in 557 patients from the phase 3 SWOG S0819 trial and a real-world ICI monotherapy cohort (n=147). QVT score/subscore changes from baseline to first on-treatment CTs were assessed by paired t-test and substratified by objective response (OR).

Results:While the mono-chemotherapy showed no vascularity changes, VEGFi regimens reduced QVT Score, with Branch and Curvature Subscores decreasing significantly but Vessel Volume unchanged. In contrast, ICI recipients exhibited significant increases in QVT Score and 5/6 Subscores, showing opposite changes to VEGFi in four subscores and differing effects on vessel Radius and Volume. VEGFi produced the greatest vascularity decrease in patients achieving OR, with milder decreases in non-OR. For ICI, OR showed negligible QVT change, while vascularity significantly increased in non-OR across all subscores except Radius.

Conclusions: The QVT Subscore panel captures granular tumor vascular remodeling from different treatments, providing mechanistically grounded insights into clinical trial arm performance. Future work will assess the panel’s potential for identifying regimens that benefit from adding VEGFi.

#3752 RNA editing deaminase activation as a dynamic marker to track hematopoietic stem cell fitness and leukemia evolution.

Inge van der Werf[1], Jessica Pham[1], Neha Katragadda[1], Kendale Wirtjes[1], Athena Mohebbi[1], Emma Klacking[1], Thomas Whisenant[2], Ludmil B. Alexandrov[2], Sheldon Morris[1], Catriona Jamieson[1]

[1]Sanford Stem Cell Institute, La Jolla, CA,[2]UC San Diego, La Jolla, CA

Myeloproliferative neoplasms (MPNs) are clonal hematopoietic stem cell-derived disorders that can evolve into acute myeloid leukemia (AML) at variable rates. Although JAK2 inhibitor therapies have improved outcomes, and variant allele frequency (VAF) monitoring informs therapeutic response, predicting if pre-leukemic stem cells will acquire self-renewal and transform into malignant leukemia stem cells (LSCs) remains a critical challenge. Our recent studies identified inflammatory responsive RNA-editing enzymes, ADAR1 and APOBEC3C as contributors of pre-leukemic stem cell (LSC) evolution. Given that MPNs are stem cell-driven disorders, we hypothesize that RNA-editing signatures mediated by these enzymes could serve as real-time indicators to track disease progression. This study aims to integrate driver mutation VAF, ADAR1 and APOBEC3C gene expression, and RNA-editing patterns into a comprehensive biomarker tool to evaluate MPN progression, predict therapeutic response, guide clinical decision making, and prevent transformation to leukemia.

We performed longitudinal 150-gene next-generation sequencing (NGS) analyses for 129 MPN patients with a median follow-up time of 958 days (range 0-4214). From this cohort, we selected four patients who were treated with the JAK2 inhibitors, progressed to sAML, underwent stem cell transplantation, and had cryopreserved peripheral blood and bone marrow mononuclear cells stored in our biorepository. For these patients, we had 15, 17, 24, and 31 sequential time points collected between 2013 and 2025. qPCR was performed on $CD34^+$ immunomagnetic bead-selected cells to measure ADAR1, APOBEC3C, STAT3, and JAK2 expression levels. During treatment, we observed dynamic changes in ADAR1, APOBEC3C, JAK2, and STAT3 expression levels. Notably, while VAF remained stable, both lactate dehydrogenase (LDH) and ADAR1 expression levels increased. Survival and self-renewal assays comparing time points with relatively low versus high ADAR1 expression revealed significantly increased colony counts at the high-expression time points. These findings suggest that ADAR1 expression may serve as a dynamic marker for both disease progression. Further single-cell RNA sequencing studies will delineate differences in HSCs and HPCs at sequential time points for four MPN patients that progressed to sAML.

#3753 Uncovering tumor microbial and immune biomarkers of immunotherapy response in lung cancer.

Lili Ma[1], Chao Cheng[1], Shwetha Vasanth Kumar[1], Spiridon Tsavachidis[1], Aaron P. Thrift[1], Joseph F. Petrosino[1], Hee-Jin Jang[1], Robert Taylor Ripley[1], Christopher I. Amos[2], Hyun-Sung Lee[1], Matthew B. Schabath[3], David C. Christiani[4], Yanhong Liu[1]

[1]Baylor College of Medicine, Houston, TX,[2]University of New Mexico Comprehensive Cancer Center, Albuquerque, NM,[3]Moffitt Cancer Center, Tampa, FL,[4]Harvard Medical School, Boston, MA

Background: Although immune checkpoint inhibitors (ICIs) have shown promise, fewer than half of advanced Non-Small Cell Lung Cancer (NSCLC) patients respond, and biomarkers such as PD-L1 and tumor mutational burden poorly predict response. The intratumoral microbiota directly interacts with cancer and immune cells, yet its relationship with immune subsets in ICI-treated NSCLC is unclear. We hypothesize that integrating tumor microbiota with immune features could improve prediction of response and patient stratification.

Methods: We analyzed total RNA-Seq data from 120 stage IV NSCLC patients whose tumor samples were collected prior to ICI therapy. Patients were classified as 30 responders or 82 non-responders,and progression-free survival was evaluated. A dual RNA-Seq approach profiled both host and microbiota: human reads were removed (Bowtie2), non-human reads classified (Kraken2). Microbial α-diversity (Chao1, Shannon), β-diversity (Bray-Curtis). Host immune profiling included differential expression (DESeq2) and immune infiltration (CIBERSORT), with group differences tested by t-test.

Results: We detected 273 microbial species. α- and β-diversity did not differ between responders and non-responders. Differences between responders and non-responders were mainly driven by Gram-negative taxa. Streptomyces was the only Gram-positive genus enriched in responders. Immune profiling showed that responders had higher expression of antigen-presentation genes, greater $CD8^+$ T-cell cytotoxicity, and upregulation of PD-1 and CTLA-4, whereas non-responders had impaired antigen presentation, reduced effector T cell activity, and a neutrophil-dominant suppressive axis with increased S100A8 and ARG1; GSVA indicated enrichment of neutrophil-mediated Gram-negative killing pathways.

Conclusions: As microbial signals in low-biomass lung tumor RNA-seq are susceptible to contamination, we removed taxa commonly associated with environmental sources. Notably, Streptomyces-a genus producing several anticancer natural products—remained more frequent in responders, suggesting a potential link to favorable outcomes. In addition, our results suggest that responders exhibit antigen presentation and activated effector T cells, yet also display high expression of PD-1 and CTLA-4, placing them in an inflamed but suppressed state that becomes responsive upon checkpoint inhibition. Conversely, non-responders are dominated by innate immune programs with suppressed adaptive immunity, and therefore fail to mount an effective antitumor response even when treated with immune checkpoint inhibitors. Machine learning approaches integrating immune-microbiome crosstalk are ongoing. If validated, these intratumoral microbial and immunological predictors could optimize patient selection for immunotherapy and support precision treatment strategies in NSCLC.

#3757 Establishment of 3D culture system of circulating tumor cells with immune cell evasion strategy.

Ji Eun Moon, **Jihyun Lee**, Soee Kim, Minseon Hwang, Jung Won Kim

Cytogen, Inc., Seoul, Korea, Republic of

Introduction
Circulating tumor cells (CTCs), are cancer cells shed from primary tumors, travel through the vasculature and give rise to metastatic lesions. CTCs have more advantages as a diagnostic tool compared with other liquid biopsy components such as cell-free DNA, because they contain all cellular components could provide more information of cancer cells. However, the number of CTC in the blood is very small, there are limitations in applying various kinds of analyses. Therefore, we have developed CTC 3D culture system for expanding number of CTCs after the enrichment of CTC with automated Smart Biopsy^{TM} Cell Isolator. In this study, a CTC-mimicking model with the cancer cell lines to establish a 3D culture environment suitable for CTC growth and a pilot test of CTC 3D culture with clinical samples were performed.
Method
To establish the 3D culture system with cancer cell lines, we spiked H358 (lung cancer), HCT116 (colon cancer) with peripheral blood mononuclear cells (PBMCs) (cell:PBMC ratio= 1:10 ~ 1:250) and initiated culture under 3D conditions. To retain only the minimal number of cancer cells required for growth we tested various approaches including dynamic culture and static culture. Then mixed cell suspension was embedded into the matrigel and incubated until growth. A pilot test for CTC 3D culture was performed with clinical samples of prostate cancer after the approval of institutional review board of Ewha Womans University Mokdong Hospital.
Result
We observed that immune cell movement increased both in frequency and speed when higher numbers of PBMCs were present within the gel. As a result, following significant PBMC migration out of the dome, cancer cells progressively expanded and formed small clusters. Starting with 100 cells per dome, cancer cell clusters reached approximately 100-150 μm in diameter by week 2. By recapitulating in vitro the key challenges encountered in clinical samples, such as extremely low number of CTCs and their susceptibility to immune-mediated elimination, our model enables systematic evaluation of these limitations and the identification of strategies to overcome them. Furthermore, pilot application of this system using clinical blood samples yielded promising preliminary results.
Conclusions
We have established the 3D CTC culture system with various kinds of in vitro tests for defining culture conditions that allow CTC-like cells to survive immune pressure and our culture system was validated with successful growth of CTC with ex vivo culture of clinical samples of prostate cancer.

#3758 Pilot study of the clinical correlation of CTC counts and AR-V7 expression with resistance to androgen receptor inhibitors in metastatic prostate cancer.

Jihyun Lee[1], Minseon Hwang[1], Soee Kim[1], Choung-Soo Kim[2], Jung Won Kim[1]

[1]Cytogen, Inc., Seoul, Korea, Republic of,[2]Department of Urology, Ewha Womans University Mokdong Hospital, Ewha Womans University School of Medicine, Seoul, Korea, Republic of

Introduction

Androgen receptor splice variant 7 (AR-V7) is a constitutively active isoform of the androgen receptor and has been associated with resistance to AR-targeting therapies and progression to metastatic prostate cancer (mPCa). However, tissue-based detection of AR-V7 is limited by the poor accessibility of metastatic lesions, particularly before and after treatment. To address this limitation, we developed a CTC-based AR-V7 detection system using CytoGen's Smart Biopsy™ CTC platform and investigated the clinical association of CTC counts and AR-V7 expression androgen receptor inhibitor (ARI).

Method

Peripheral blood samples (20 mL) from 12 mPCa patients were processed using the Smart Biopsy™ Cell Isolator for CTC enrichment. 5 samples from healthy donor were used as negative control of CTC counts by immunofluorescence and the cut-off of AR-V7 expression. CTCs were enumerated by immunofluorescence (IF), and AR-V7 transcripts were analyzed using droplet digital PCR (ddPCR)

Results

To investigate the clinical correlation of CTC counts and AR-V7 expression to the resistance of ARI, blood samples of mPCa patients were collected and CTC enrichment was proceeded with Smart Biopsy™ Cell Isolator. Number of CTC in all of 12 mPCa patients' samples were successfully counted by IF assay. 10 patients showed the high CTC burden (≥10 CTCs per 5mL of blood) and it was statistically significant correlation with the resistance of ARI. AR-V7 expression in CTC were also tested by ddPCR. 5 out of 12 mPCa patients showed AR-V7 positive CTC and 4 out of 5 patients were associated with ARI's resistance.

Conclusions

In this pilot study, CTC counts and/or AR-V7 detection in CTC showed the meaningful correlation to the resistance of ARI, suggesting that they may serve as potential diagnostic tools for predicting the treatment response of ARI.

#3759 Next-generation liquid biopsy for circulating tumor cell detection in metastatic prostate cancer.

Minzhi Sheng[1], Omar Alawamry[2], Shuyang Feng[3], Urban Emmenegger[4], Kristin Cimolini[1], Danny Vesprini[5], Andrew Loblaw[5], Laurence H. Klotz[6], Christopher S. Lim[7], Stanley K. Liu[1], Hon Sing Leong[1]

[1]Sunnybrook Research Institute, Toronto, ON, Canada,[2]Department of Medical Biophysics, University of Toronto, Toronto, ON, Canada,[3]Department of Urology, West China Hospital, Chengdu, China,[4]Department of Hematology and Oncology, Sunnybrook Health Sciences Centre, Toronto, ON, Canada,[5]Department of Radiation Oncology, University of Toronto, Toronto, ON, Canada,[6]Professor, Dept. of Surgery, Univ. of Toronto Sunnybrook HSC, Toronto, ON, Canada,[7]Department of Radiology, University of Toronto, Toronto, ON, Canada

Prostate cancer (PCa) is the most frequently diagnosed malignancy among Canadian men, and metastatic disease (mPCa) carries a poor prognosis. Liquid biopsy that analyzing circulating tumor cells (CTCs) provide a minimally invasive tool for disease assessment, yet commonly used CTC markers such as EpCAM show variable expression in PCa, especially in advanced or treatment-resistant settings. More reliable biomarkers are needed to improve CTC detection and patient stratification. We use monoclonal antibodies against STEAP1, a transmembrane protein highly overexpressed in PCa but minimally present in normal tissues, and integrated them into an imaging flow cytometry (imFC) CTC assay to detect and characterize CTCs. CTCs from localized and metastatic PCa patients were isolated using Ficoll density gradients and stained with DAPI, CD45, EpCAM, and STEAP1 antibodies. High-content images were analyzed through a computational pipeline incorporating machine-learning classification to identify and classify intact CTCs, CTC fragments, and tumor-derived extracellular vesicles (EVs) internalized by immune cells. STEAP1$^+$ CTCs were detected in most metastatic patients, including individuals who lacked detectable EpCAM$^+$ CTCs, highlighting the limitations of EpCAM-only assays. Patients with active disease exhibited higher STEAP1$^+$ CTC counts compared with those with localized or stable disease. Additionally, STEAP1$^+$ extracellular vesicles and CTC fragments were observed within CD45$^+$ immune cells, suggesting broader tumor-immune interactions measurable through this platform. We further extended this workflow to a clinical study evaluating treatment-associated changes in abundance of CTC expressed with different PCa biomarkers, PSMA, STEAP1, and STEAP2 in patients receiving Pluvicto therapy. In this study, CTCs were enriched using the Parsortix microfluidic capture platform. Early results indicate that STEAP-family markers remain detectable in patients with low or fluctuating PSMA expression, supporting their value in monitoring therapeutic response. Together, these findings position STEAP1, STEAP2 and PSMA as robust biomarkers for next-generation CTC-based liquid biopsy assays and demonstrate their potential to enhance diagnostic sensitivity and treatment monitoring in mPCa.

#3760 Spatial immune signatures predict outcomes in HPV-positive oropharyngeal cancer: Results of a clinical trial.

Nader Sadeghi[1], Alex Mlynarek[1], Marco Antonio Mascarella[2], Alan Spatz[3], Khalil Sultanem[4], William D. Foulkes[5], Severine Landais[6], Michael Hier[1], **Sabrina Wurzba**[7]

[1]McGill University, Montreal, QC, Canada,[2]McGill University Health Centre, Montreal, QC, Canada,[3]Director/Pathology, McGill University, Montreal, QC, Canada,[4]McGill University, Monteal, QC, Canada,[5]Professor, Depts. Medicine, Oncology, Human Genetics, & Ob & Gyn, McGill University, Montreal, QC, Canada,[6]Centre de recherche du CHU Sainte-Justine, Montreal, QC, Canada,[7]McGill University, Montreal, QC, Canada

Background: The incidence of Human Papillomavirus (HPV)-associated oropharyngeal cancer (OPC) has been increasing in recent years. While patients with HPV-positive OPC generally demonstrate more favorable outcomes compared to those with HPV-negative disease, a subset still experiences locoregional recurrence and distant metastasis. These clinical challenges underscore the need for a better understanding of the tumor microenvironment (TME) and its role in modulating treatment response. We hypothesized that the composition and spatial dynamics of the TME differ between complete responders and partial/non-responders, and these differences may serve as predictive biomarkers.

Methods: This retrospective study included patients with p16-positive OPC treated at two major cancer centers in Montreal between 2010 and 2023. Formalin-Fixed Paraffin-Embedded (FFPE) tissue blocks were retrieved, and tissue microarrays (TMAs) were constructed for high-dimensional immune profiling using imaging mass cytometry (IMC). Immune cell populations were analyzed across treatment response categories (complete vs. partial responders) and treatment stages (pre- vs. post-treatment). Deep learning-based cell segmentation was applied to quantify immune cell subsets, assess spatial architecture, and perform network and neighborhood analyses of the TME to identify potential predictive and prognostic immune signatures.

Results: Tissue specimens were obtained from HPV-positive (p16+) OPC patients, of whom 79.6% were male, with a mean age of 62.5 years. IMC revealed distinct immune landscapes between response groups. In complete responders, treatment induced a robust recruitment of anti-tumor immune cells (e.g., CD8+ T cells and B cells), suggesting an activated immune phenotype post-treatment. In contrast, non-responders exhibited enrichment of immunosuppressive or tumor-promoting cell types following therapy. Spatial co-localization and cell-cell interaction analyses further indicated that B and T cells interactions may contribute to therapeutic success.

Conclusion and Impact: This study provides novel insights into the spatial and cellular remodeling of the immune microenvironment in HPV-positive OPC before and after treatment. Our findings highlight the prognostic potential of IMC-based immune profiling and support the development of predictive biomarkers to guide the selection of patients who may benefit from neoadjuvant chemotherapy or immunomodulatory interventions.

#3761 Aneuploid primary cancers metastasize as diploid cancer stem cells.

Olufemi Emmanuel Akanni[1], Jerry Thomas Thornthwaite[2]

[1]Osun State University, Osogbo, Nigeria,[2]Cancer Research Institute of West Tennessee, Henderson, TN

The standard cancer treatment modalities have focused on destroying daughter cancer cells while having minimal effect on Cancer Stem Cells (CSCs). The details of the underlying mechanism by which CSCs metastasize in our sarcoma model are presented. To understand the fundamental process of metastatic disease, we used a chemically induced cancer model by painting the shaved distal thigh musculature of DBA/6J mice with 1.0% 3-methylcholanthrene in sesame oil. Approximately 90% of the mice developed an intramuscular tumor *in situ* within six months. The original chemically induced cancer cells were enzymatically dissociated into single cells, and 5×10^4 sarcoma cells in 0.1 ml were injected intramuscularly into new mice. Using our DAPI-Nuclear Isolation Medium and our high-resolution DNA flow cytometry, we generated DNA histograms of the tumor cell populations. When the primary tumors reached 2.0 cm in diameter, metastatic nodes in the lungs were detected using an India ink contrast stain after dissecting about 10 small 1.0 mm metastatic nodules and enzymatically dissociating the metastatic cancer cells into viable populations, as described above. The metastatic tumors were almost exclusively diploid, showing a normal total DNA content. When diploid metastatic tumors were transplanted intramuscularly, they grew as an aneuploid population containing both diploid cancer stem cells and aneuploid daughter cancer cells, with the same DNA Index, which served as a fingerprint of each original tumor. We could repeat this process many times. Our early observations revealed that the diploid population of an aneuploid cancer was the most virulent to metastasis. The diploid metastatic CSCs with their low S-phase would have a good chance of escaping the immune system, as their cell surfaces would appear normal. They would also be less affected by chemotherapy or radiation therapy because of their low S-phase. All excised lung metastases between 2 and 8mm in diameter maintained their diploid DNA histogram pattern, with only 1% aneuploidy. These diploid metastases, after enzymatic single-cell preparations, were either transplanted into the flank of a new mouse or placed in cell culture. Aneuploid cells began to emerge from the diploid cell populations, resulting in a DNA index equivalent to that of the original chemically induced sarcoma. These data indicate that cancer stem cells (CSCs) originate in the diploid portion of the primary aneuploid sarcoma, as only these diploid cells can evade the immune system and establish diploid lung metastases. The diploid CSCs still retained the capacity to transform into daughter aneuploid cells.

#3762 Genetic characterization of disseminated tumor cells of historical cryo-preserved bone marrow samples from primary breast cancer patients.

Anne Rohloff[1], Rui Pedro Lousa Das Neves[1], Christiane Driemel[1], Daniel Doerr[2], Oliver Hoffmann[3], Rainer Kimmig[3], Nikolas Hendrik Stoecklein[1], Sabine Kasimir-Bauer[3]

[1]Department of General, Visceral and Pediatric Surgery, University Hospital Duesseldorf, Duesseldorf, Germany,[2]Department of Endocrinology and Diabetology, University Hospital Duesseldorf, Duesseldorf, Germany,[3]Department of Gynecology and Obstetrics, University Hospital Essen, Essen, Germany

Background: Metastatic relapse is the leading cause of death in patients with hormone receptor-positive, HER2-negative primary breast cancer (BC). While some patients experience late relapse after more than 10 years, others relapse within 3-7 years, yet the biological mechanisms underlying this variability remain poorly understood. Disseminated tumor cells (DTCs) in the bone marrow (BM) are hypothesized to represent a clinically occult reservoir driving metastatic progression. In this study we characterized genomic alterations of DTCs to define their clonal relationship to matched primary tumors (PTs) and distinguish genomic features contributing to early versus late relapse.

Methods: Our study is based on a cohort of cryopreserved BM samples collected at diagnosis from 600 BC patients treated between 2006 and 2012 with more than 12 years of follow-up. From this cohort, we selected BM samples previously diagnosed as DTC-positive using a standardized immunocytochemistry assay. For this study, we established a workflow to detect and isolate DTCs from cryopreserved BM using the CellSearch® system. After thawing, up to 20 Mio mononuclear cells per sample were processed with CellSearch® for the detection of $EpCAM^+/DAPI^+/CK^+/CD45^-$ DTCs (CS-DTCs). Individual CS-DTCs were subsequently isolated, and their whole genomes were amplified using adapter-linker PCR. Low-pass next-generation sequencing (NGS) was performed to assess copy-number alterations (CNAs).

Results: Thus far, we detected and isolated CS-DTCs in 31/35 BM samples previously diagnosed as DTC-positive. In our initial CNA analysis, 75% of CS-DTCs displayed aberrant copy-number profiles characteristic of BC, whereas matched white blood cells showed normal genomic profiles. In one patient analyzed to date, we isolated 16 CS-DTCs demonstrating a shared clonal CNA pattern, however, individual CS-DTCs also harbored private CNAs. Additional BM samples and the corresponding PTs are currently being processed to enable direct comparison of DTCs with their matched primaries.

Conclusions: Our preliminary results demonstrate that this CellSearch®-based workflow enables reliable detection, isolation, and genomic characterization of single DTCs from long-term cryopreserved BM samples. This approach provides a robust platform for exploring clonal relationships between DTCs and PTs. The overall aim is to uncover mechanisms underlying minimal residual disease and relapse in BC.

#3763 CCR7 expression and spatial distribution in inflammatory breast cancer: A baseline characterization for therapeutic targeting.

Surbhi Shivhare[1], Caren Sanchez[1], Richard Larson[1], Lacey Dobrolecki[2], Michael Lewis[2], Jennifer Chen[3], Susanne Lin[4], Anastasiya Evdokimova[5], Daria Goncharova[5], Angela Alexander[6], Azadeh Nasrazadani[6], Rachel Layman[6], Bora Lim[6], Vicente Valero[6], Anthony Lucci[3], The MDACC Inflammatory Breast Cancer Team, Wendy A. Woodward[1]

[1]Department of Breast Radiation Oncology, UT MD Anderson Cancer Center, Houston, TX,[2]Lester and Sue Smith Breast Center, Baylor College of Medicine, Houston, TX,[3]Department of Breast Surgical Oncology, UT MD Anderson Cancer Center, Houston, TX,[4]Department of Veterinary Medicine & Surgery and Department of Translational Molecular Pathology, UT MD Anderson Cancer Center, Houston, TX,[5]BostonGene Corporation, Waltham, MA,[6]Department of Breast Medical Oncology, UT MD Anderson Cancer Center, Houston, TX

Purpose: Inflammatory breast cancer (IBC) is a rare, highly aggressive subtype marked by rapid proliferation, extensive angio-/lymphangiogenesis, and early metastasis. CCR7, a chemokine receptor involved in immune trafficking, promotes tumor migration toward lymphatics via CCL19/CCL21. This study provides an integrated genomic, protein, spatial, and functional evaluation of CCR7 in IBC to assess its therapeutic potential.

Methods: Clinical analysis used genomic data from HR+ HER2- and TNBC IBC compared with subtype-matched non-IBC. CCR7 expression was assessed in IBC and non-IBC cell lines by immunoblotting; ligand secretion (CCL19/CCL21) in tumor and stromal cells was measured by ELISA. CCR7 localization was evaluated using subcellular fractionation and IF, along with testing of a CCR7-blocking antibody. Multiplex IF was performed on BCM PDX models representing distinct CCR7 genomic and protein states. Functional studies included the CCR7 antagonist Navarixin, CCL19/21-induced migration assays, and generation of CCR7 CRISPR knockout clones.

Results: CCR7 CNAs occurred in both IBC and non-IBC but did not correlate with mRNA or protein levels. CCR7 protein was broadly expressed, with strongest membranous expression in A3250 and variable levels in IBC-3, SUM-190, and SUM-149. The blocking antibody reduced membranous CCR7 only in A3250, indicating subtype-specific accessibility. IBC cell lines did not secrete CCL19/CCL21, supporting reliance on stromal ligands, which varied by coculture. Across six BCM PDXs, CCR7 was consistently expressed, whereas ligand levels were heterogeneous; MBI-117 showed high CCL19/CCL21. Spatial profiling revealed $CCR7^+$ tumor cells aligned along $Podoplanin^+$ lymphatics with $CCL21^+$ stromal cells and $CD163^+$ macrophages enriched around $CCR7^+$ emboli. Navarixin reduced proliferation in IBC3 and SUM-190 by 96h, and CCL19/21 enhanced migration in A3250 and SUM-149. CCR7-KO SUM-149 clones were generated, with functional analyses ongoing.

Conclusion: CCR7 expression in IBC is independent of copy number and supported by a ligand-rich microenvironment that positions $CCR7^+$ tumor cells along lymphatics. Integrated genomic, spatial, and functional data support CCR7 as a therapeutic target in IBC, with studies ongoing.

#3764 Dynamic regulation and physical interaction of IGF1 and CYR61 in prostate cancer cells.

Greisha L. Ortiz Hernandez, Carmina Patrick, Jessica Wu, Susan L. Neuhausen

Population Sciences, Beckman Research Institute of The City of Hope, Duarte, CA

Prostate cancer (PCa) remains a leading cause of cancer-related mortality among men, with limited treatment options for advanced disease. Cysteine-rich angiogenic inducer 61 (CYR61), a matricellular protein with an insulin-like growth factor-binding domain, has been implicated in tumorigenesis, yet its role in PCa progression is incompletely understood. Given our published studies validating that silencing CYR61 impaired proliferation, migration, and PI3K/AKT signaling, while PI3K/AKT inhibition abrogated insulin-like growth factor-1 (IGF1)-induced CYR61 expression and proliferation, and the established involvement of IGF1 in PCa and its association with therapy resistance, this study specifically investigated the molecular interplay between IGF1 and CYR61. Our studies by confocal microscopy revealed that IGF1 induces nuclear CYR61 expression and translocation in a time-dependent manner across PC3, 22Rv1, and LNCaP cells, with maximal expression observed at 24 hours post-treatment. Immunoprecipitation assays also demonstrated a physical interaction between IGF1 and CYR61 in PC3 and HEK293T cells, suggesting direct or complex-mediated binding. These findings position CYR61 as a critical effector of IGF1 signaling and raise the possibility of extracellular interactions that modulate PCa progression. Ongoing studies using the AVEXIS system aim to define the IGF1-CYR61 interactome and identify additional binding partners, which may uncover novel therapeutic targets and biomarkers. Future directions include mapping these interactions in tumor microenvironment compartments and exploring combinatorial strategies integrating CYR61 inhibition with IGF1R or PI3K inhibitors to curb aggressive PCa.

#3765 Cost-effective targeted DNA mutation and gene expression change profiling in circulating tumor cells using new Droplet Digital PCR technologies.

Yoon-Tae Kang, Srikanth Perike, Adam Corner, Cynthia Shu, Andrew Prantner, Nathan Knapp, David Coe, Elizabeth Jordan Dreskin

Bio-Rad Laboratories, Hercules, CA

Introduction: Liquid Biopsies provide a less invasive method for cancer diagnosis and prognosis when compared to conventional tissue biopsies. Over the past two decades, fragmented tumor derived DNA (ctDNA) found in blood has been studied extensively and shown to contain tumor-specific gene mutations and distinct fragment patterns compared to non-tumor cfDNA, which are now employed to monitor the molecular status of patients with cancer. Similarly, Circulating tumor cells (CTCs) have recently evolved as promising biomarkers whose existence and quantity in blood have shown a close correlation to disease progression and recurrence potential. While initial studies on CTCs relied on their protein marker expression and enumeration, recent CTC studies at the molecular level revealed genomic mutations in Estrogen receptor 1 (ESR1) for breast cancer, and epidermal growth factor gene (EGFR) across various cancers. Along with ctDNA studies, detection of mutations and gene expression changes in CTCs can offer additional insights into drug efficacy evaluations and prognosis. However, the rarity of CTCs and lack of streamlined protocols utilizing cost-effective technologies for clinics present a crucial challenge.
Methods: For lung cancer, three non-small cell lung cancer cell lines with different EGFR mutations were prepared. For breast cancer, one epithelial breast cancer cell line (MCF7) with/without acquired tamoxifen resistance was prepared. Each CTC sample was prepared by spiking cancer cells into a total of 7.5 ml of whole blood from healthy donor at a concentration of up to 100 cells/ml. The Genesis Cell Isolation System efficiently captured CTCs based on size and deformability and the enriched CTCs were subsequently processed for simultaneous DNA and RNA extraction using the SingleShot Cell Lysis Kit. Either extracted gDNA or total RNA was used for mutation detection using ddPCR or gene expression studies upon cDNA synthesis, respectively. To determine the presence of specific EGFR/ESR1 mutations within the genomic DNA of captured cells, Droplet Digital PCR was performed using assays for EGFR/ESR1 mutation variants as well as known mutations PIK3CA p.E542K and GATA3 p.D336fs*17. For gene expression changes in breast cancer upon tamoxifen resistance, 6/7-multiplex gene expression assays with targeted representative genes were performed using a QX600 or a QX700, respectively.
Results: The streamlined combined protocol using the Genesis System and ddPCR facilitated sensitive detection of specific genomic DNA mutations as well as gene expression changes in CTCs upon drug treatment.Discussion and
Conclusions: ddPCR is a cost-effective approach for unlocking molecular information carried by CTCs in blood for liquid biopsy. Further studies using clinical specimens with larger sample sizes would facilitate the clinical use of the suggested protocol.

#3766 Depletion of circulating tumor cells using an automated device using non-hemolytic affinity based substrates.

Jayant Khandare[1], Yuvraj Patil[1], Prathamesh Jakka[1], Neha Mulye[1], Aditi Wadekar[1], Srusthi Parekh[1], Karan Kulkarni[1], Tulsi Yadav[1], Tanvi Deshpande[1], Harshal Padma[1], Rakshit Kamble[2], Aravindan Vasudevan[1]

[1]Actorius, Pune, India,[2]Actorius, Los Angeles, CA

Background: While 90% cases are associated with metastatic deaths, it is imperative to monitor early stage cancer patients for the presence of systemic disease to improve overall survival (OS) and PFS. In spite of complete remission, upto 25-50 % of CRC stage II-III and early breast cancer cases are known to relapse. Further, the existence of micro-tumors using radio-imaging tools is undetected due to limit of detection. Post curative intent therapies, accounting minimal residual cellular disease (MCRD), is represented by circulating tumour cells (CTCs). CTCs are known for their extravasation and invasiveness from primary sites to distant. Further they could evade immune systems, and thus there is need to design safer extracorporeal devices for the capture and depletion of CTCs especially overexpressing PD-L1. We designed an automated device to capture and remove CTCs from whole blood.
Methods: We designed an automated micro-processor operated fluidic device OncoMetastat, having cartridges for blood, reagent tubes, and a 3D-printed biocompatible spiral channel. The controller unit powers peristaltic pumps for blood circulation through the spiral channel (96 mm diameter × 6 [H] mm). It consisted an antibody and transferrin conjugated 2 mm glass beads. In addition, with 4 vibrators for micro-stirring of blood for enhanced CTC capture from 5 - 10 ml patients blood (n=54). WBC count, hemolysis and protein binding was measured. The beads were scanned for CTCs with $CK18^{+}$ve, DAP^{I+}ve with $CD45^{-}$ve) with an automated scanning ability and compared with OncoDiscover CTC enumeration platform approved by CDSCO India. We analyzed true positives, false negatives and sensitivity, specificity, PPV, NPV and accuracy.
Results: Retrospectively, 54 pan-cancer patients' blood including breast, CRC, prostate, lung were used to capture and deplete CTCs. OncoMetastat platform demonstrated capture efficiency of > 90%, compared to OncoDiscover. Auto-scanning demonstrated 100% efficiency of CTC imaging, compared to manual imaging. Leukocyte adhesion was low with anti-EpCAM and transferrin glass beads (2 ± 1 WBCs/per sample, n = 54). WBCs enumerated showed trends specific to cancer type (mean WBC count/ml of 4.9×10^6 - Breast CA, 3.9×10^6 - Rectal CA, 3.5×10^6- Prostate CA), showed decrease in WBC by 40% compared to healthy controls (mean of 6.9×10^6 WBCs/ml). Clinically insignificant hemolysis (<1%) and protein-binding (~1.5%) was noted. Vibration-assisted showed enhanced CTC sequestration (>90% cell capture efficiency. The sensitivity (94.4%), specificity (92.9%), PPV (94.4%), NPV (92.9%), accuracy (93.8%) was observed for CTC capture.
Conclusions: We showed depletion of CTCs with specificity and efficiency. Automated device demonstrate the ability to remove CTCs from whole blood as an extracorporeal device for enhancing cancer therapy outcome.

#3767 Detection of circulating tumor cells (CTCs) as a next-generation liquid biopsy for neuroendocrine tumors (NETs) by taking advantage of existing theranostic probes.

Michael Greenberg[1], Ezequiel Silva Nigenda[2], Julie Hallet[1], Omar Alawamry[1], Simron Singh[1], John Trant[2], Hon Sing Leong[1]

[1]Sunnybrook Research Institute, Toronto, ON, Canada,[2]University of Windsor, Windsor, ON, Canada

When neuroendocrine cells become cancerous, the resulting Neuroendocrine Tumours (NETs) can be challenging to detect. NETs are often asymptomatic, because they often lead to hormonal imbalances, which are associated with other diseases. In terms of biomarkers, NETs often overexpress Somatostatin Receptor 2 (SSTR2). This biomarker is the primary method of detecting and treating NETs and a specific molecule called DOTATATE is used for clinical PET scans and therapies to detect and combat this cancer in NET patients. DOTATATE compounds consist of two active components. The DOTA component is a metal chelator that carries the component detected by PET scan. The TATE component is a modified octreotate compound which binds to the Somatostatin Receptor 2 (SSTR2).Here, we offer the TATE-Cy5 probe, which takes advantage of the clinical use of DOTATATE for use in a blood test. Similar to DOTATATE, TATE-Cy5 also contains tyrosine-3-octreotate, meaning that it can to bind to SSTRs with equal effectiveness. However, instead of the DOTA chelator, TATE-Cy5 has a fluorescent Cy5 probe, which can be used to detect the presence of NETs because we hypothesize we can detect circulating tumor cells (CTCs) in patient blood samples. We predict that there are high numbers of CTCs that bind the TATE-Cy5 probe in patient whole blood samples according to disease severity.Results show that TATE-Cy5 binds to cell lines overexpressing SSTR2. Moving onto clinical samples, we also observe the presence of CTCs that bind TATE-Cy5 in whole blood samples from NET patients. We further subclassified CTCs as based on a combination of co-expressing biomarkers, CTCS that are positive for SSTR2, and tumours positive for both SSTR2 and EpCAM. With further testing, we will be able to use TATE-Cy5 to monitor patient treatment response over time.In summary, we have developed a novel and cancer specific CTC liquid biopsy that takes advantage of existing imaging probes in the form of DOTATATE. This technology has significant clinical implications because it can be used as a companion liquid biopsy for existing and emerging therapies.

#3768 Spatially resolved lineage and microenvironmental remodeling define metastatic progression in oral squamous cell carcinoma.

Chung Ji Llu[1], Hui-Wen Cheng[2], Li-Han Lin[2], Kuo-Wei Chang[3]

[1]Department of Oral and Maxillofacial Surgery, Mackay Memorial Hospital, Taipei, Taiwan,[2]Department of Medical Research, Mackay Memorial Hospital, Taipei, Taiwan,[3]School of Denstry, National Yang Ming Chiao Tung University, Taipei, Taiwan

Background: Lymph node metastasis is the strongest prognostic factor in oral squamous cell carcinoma (OSCC), yet the spatially coordinated cellular programs that drive metastatic evolution remain insufficiently defined. Conventional bulk and single-cell transcriptomic methods cannot preserve tissue architecture or resolve how malignant, stromal, and immune compartments interact *in situ*.

Methods: We performed Visium spatial transcriptomics on 20 OSCC tissue specimens, including normal epithelium, primary tumors without nodal metastasis (N^-), primary tumors with nodal metastasis (N^+), and metastatic lymph nodes. SpatialCpie was used to estimate intra-spot cellular composition, CellChat to infer intercellular signaling networks, and Monocle3 to reconstruct epithelial lineage trajectories across the metastatic continuum.

Results: Spatial mapping revealed that invasive tumor fronts contained mixed malignant epithelial, fibroblast, and immune populations, distinguishing them from more homogeneous tumor cores. Pseudotime analysis demonstrated a continuous epithelial lineage progression from normal to metastatic states, accompanied by increased epithelial plasticity and downregulation of differentiation-associated markers. Stromal profiling showed a shift toward matrix-remodeling fibroblast phenotypes positioned adjacent to invasive epithelial regions. Metastatic lymph nodes exhibited reduced cytotoxic T-cell signatures and expansion of B-lineage populations, indicating immune suppression within the metastatic niche. Integrated signaling analysis revealed a coordinated communication axis linking epithelial state transition, stromal activation, and immune remodeling during metastatic progression.

Conclusions: This spatially resolved framework identifies metastatic OSCC as a dynamically evolving multicellular ecosystem shaped by epithelial plasticity, stromal reprogramming, and immune adaptation. These findings provide mechanistic insight into the development of nodal metastasis and highlight microenvironmental features with potential biomarker and therapeutic relevance.

#3769 Predicting efficacy of curative-intent surgery in advanced gastric cancer: A biologically informed staging approach.

Yingying Wu, Zhenxin Wang, Hong Zeng, Yihong Sun, Zhaoqing Tang, Xuefei Wang

Zhongshan Hospital Fudan University, Shanghai, China

Background: Treatment strategies for advanced gastric cancer (GC) largely depend on the presence or absence of metastasis. However, a subset of patients with limited metastasis may still derive meaningful benefit from curative-intent surgery, challenging the traditional binary staging paradigm. Current assessments of metastasis rely on lesion volume and anatomical distribution, which oversimplify tumor biology. The degree to which patients with metastatic GC can benefit from surgery remains unclear. We therefore propose a serum-derived staging model that integrates systemic tumor-host interactions to define biological tumor stage and inform surgical decision-making in a biologically informed manner.

Methods: Advanced GC was stratified by metastatic burden into locally advanced GC (LAGC), limited metastatic GC (LMGC), and widely metastatic GC (WMGC). Cohort 1 included 179 patients receiving curative-intent surgery following preoperative systemic therapy (100 LAGC, 48 LMGC, 31 WMGC). Serum samples were obtained at baseline and preoperatively. Cohort 2, an independent dataset collected during a different period, included 149 patients (109 LAGC, 25 LMGC, 15 WMGC) with baseline serum samples. Systemic inflammatory profiles were characterized via Olink platform. Baseline samples from Cohort 1 served as the training set. Feature selection was performed using ordinal logistic regression, XGBoost, and SVM-RFE, followed by Elastic Net regression for model construction. Preoperative samples from Cohort 1 were used for internal validation, and Cohort 2 for external validation.

Results: Three inflammatory proteins, IL-22 RA1, HGF, and 4E-BP1, were significantly associated with metastatic burden and were incorporated into the tumor-induced perturbation score (TIPscore). Baseline TIPscore distinguished WMGC, the subgroup least likely to benefit from surgery, from LAGC and LMGC with an AUC of 0.812. Lower TIPscore was associated with improved overall survival (OS) ($p = 0.049$). In preoperative samples from Cohort 1, TIPscore outperformed conventional M0/M1 staging, increasing 1-year OS prediction AUC from 0.683 to 0.850 in advanced GC overall, and reaching 0.875 in the LMGC subgroup. Among LMGC patients receiving curative surgery, a lower post-treatment TIPscore predicted better OS ($p = 0.034$) and event-free survival (EFS) ($p = 0.015$). TIPscore was further validated in Cohort 2, achieving an AUC of 0.810 for distinguishing WMGC from LAGC and LMGC, and 0.711 for distinguishing WMGC from LMGC.

Conclusions: TIPscore is a biologically informed staging model that reframes metastatic burden as a continuous biological spectrum rather than a categorical variable. By precisely situating individual patients along this spectrum, TIPscore provides prognostic insight to guide surgical decision-making and may be particularly valuable in ambiguous clinical contexts such as LMGC.

#3770 DNA methylation-based model predicts occult lymph nodal metastasis for resectable NSCLC patients.

Long Jiang[1], Xing Li[2], Yanhua Chen[2], Changbin Zhu[2], Ziming Li[1]

[1]Shanghai Lung Cancer Center, Shanghai Chest Hospital, Shanghai Jiao Tong University School of Medicine, Shanghai, China,[2]Amoy Diagnostics Co., Ltd., Xiamen, China

Background: Patients with non-small cell lung cancer (NSCLC) harboring pathologic lymph nodal metastases (LNDM) (pN1-2) have substantially higher recurrence risks. However, 10~15% of patients staged as cN0 via preoperative CT have lymph node involvement confirmed by pathologic evaluation. Endobronchial ultrasound-guided transbronchial needle aspiration (EBUS-TBNA) improves preoperative nodal staging, but extensive sampling of multiple stations increases procedural risk and complexity. Thus, exploring LNDM biomarkers are needed. This was aimed to develop a tumor DNA methylation-based model to predict intrathoracic nodal metastases indicating more precised patient population receiving EBUS-TBNA evaluation.
Methods: Primary tumor tissue and paired preoperative plasma from 68 patients with resectable NSCLC was retrospectively collected (pN0=24, pN1=24, pN2=20, all pN2 were mediastinal nodal metastases). Tumor DNA was extracted and subjected for enzyme conversion and methylation sequencing (EM-Seq). Differentially methylated CpG sites associated with nodal involvement were identified by comparing pN0 vs pN1/2 (Wald test). A lymph-node-metastasis methylation score was constructed using LASSO regression and its performance assessed by ROC analysis. Promoter-localized differentially methylated sites were subjected to Gene Ontology (GO) and pathway enrichment analyses. Further validation of this model on preoperative plasma cell-free DNA is undergoing.
Results: Differentially methylated 6,745 CpG sites between pN0 and pN1/2 tumors ($p<0.05$) were disclosed. An 8-CpG methylation score discriminated patients with and without nodal metastases with an AUC of 0.962 (cut-off 2.0; sensitivity 1.0; specificity 0.841). The methylation score increased with pathologic nodal stage (median pN0=0.76, pN1=2.74, pN2=3.30, pN1 vs pN0 $p<0.01$, pN2 vs pN0 $p<0.01$, pN2 vs pN1 $p=0.26$). No correlation to primary tumor size ($r=-0.08$, $p=0.505$) was found, making it only LNDM relevant. Among differentially methylated loci, 28% (1,872 sites) were located in promoter regions. In node-positive tumors, enriched GO terms included epithelial cell polarity and cell-cell adhesion, whereas node-negative tumors showed enrichment of phenylalanine, tyrosine, and glycine/serine metabolism.
Conclusions: A DNA methylation model strongly associated with the presence and extent of intrathoracic nodal involvement was developed for resectable, cN0 NSCLC. This model has the potential to preoperatively identify patients who most warrant EBUS-TBNA. Its predictive performance in pre-treatment plasma is being validated, and plasma-based results will be presented at the AACR.

#3771 Monitoring tumor dynamics through circulating cancer stem cells in colorectal cancer patients.

Monika Pizon[1], Dorothea Schott[1], Ulrich Pachmann[1], Katharina Pachmann[2]

[1]Laboratory Dr. Pachmann, Bayreuth, Germany,[2]Laboratory Dr Pachmann, Bayreuth, Germany

Background:
Colorectal cancer (CRC) remains one of the most commonly diagnosed and lethal malignancies worldwide. Tumor recurrence and metastasis are major determinants of patient survival. Circulating cancer stem cells (cCSCs), a rare subpopulation of tumor cells present in peripheral blood, are believed to drive tumor growth, metastasis, and therapy resistance. While tumorsphere culture has been used to identify cancer stem cells from primary tumors or cell lines, we have established an effective method for detecting and characterizing circulating cancer stem cells in the blood of CRC patients.
Methods:
Metastatic and non-metastatic CRC patients were included in this study. For the detection of circulating cancer stem cells, we used a functional assay for tumorsphere formation (stemtrac®). Immunofluorescence and qRT-PCR were employed to assess surface marker expression and pluripotency-associated genes. Additionally, we report a case of a 40-year-old man with metastatic KRAS-positive CRC, who was longitudinally monitored using both circulating epithelial tumor cell (CETCs/CTCs) and cCSC analyses in correlation with clinical and imaging findings.
Results:
Patients with metastatic disease exhibited a significantly higher number of tumorspheres compared with non-metastatic patients (median: 48 vs. 15 spheres per 100 µl blood), suggesting a correlation between tumorsphere count and disease stage. Tumorspheres showed high expression of EpCAM and CD133, elevated ALDH1 activity, and upregulation of pluripotency genes such as SOX2, OCT4, and NANOG. No sphere formation was observed in healthy controls (n = 50). In the case study, fluctuations in CETCs/CTCs and cCSC levels reflected treatment response and disease activity, with sustained increases preceding clinical or radiological evidence of progression.
Conclusion:
This study demonstrates that tumor stem cells can be detected in peripheral blood from both metastatic and non-metastatic CRC patients. The number of tumorspheres derived from circulating cancer stem cells serves as an independent indicator of metastatic potential. Serial monitoring of CETCs/CTCs and cCSCs provides a non-invasive and dynamic tool for evaluating treatment efficacy and identifying early disease progression. A deeper understanding of the biology of circulating cancer stem cells may facilitate the development of more effective and personalized therapeutic strategies for colorectal cancer.

#3772 Exploring gene mutations of circulating tumor cells by Oxford nanopore adaptive sequencing implemented with a newly developed bioinformatic pipeline.

Ta-Hsien Lee[1], Jin-Ru Wang[2], Shiuan-Ru Hou[2], Ju-Chien Cheng[3], **Ching-Ping Tseng**[2]

[1]Department of Clinical Laboratory, Tri-Service General Hospital Penghu Branch, Penghu, Taiwan,[2]Department of Medical Biotechnology and Laboratory Science, Chang Gung University, Taoyuan, Taiwan,[3]Department of Medical Laboratory Science and Biotechnology, China Medical University, Taichung, Taiwan

Circulating tumor cells (CTCs) represent an important and easily accessible biological material for monitoring treatment response and early detection of patients with cancer. In this study, we aimed to develop a precision workflow combining immunomagnetic bead- and negative selection-based enrichment of CTCs with the Nanopore adaptive sequencing technology to detect mutations in cancer-relevant genomic regions and to understand the intrinsic properties of CTCs. PowerMag system which we developed in our previous studies was used to deplete leukocytes and enrich CTCs from blood sample followed by whole genome amplification. The amplified DNA was subject to Nanopore adaptive sequencing using the Oxford Nanopore GridIon device and the BED file to define 76 common cancer gene mutation target regions. A bioinformatic analytical platform was also developed in-house for efficient extraction of high-confidence reads. The confidence for the presence of mutated nucleotides was determined by implementing a logistic calculation based on the quality score of the indicated nucleotides. The workflow has been validated by using human peripheral blood leukocytes as the biological source of DNA. In addition, preliminary analysis of OECM-1 oral cancer cells spiked into human peripheral blood also reveals that CTCs enrichment followed by adaptive sequencing and the use of analytical tools developed in-house are applicable to identify cancer-associated gene mutation even with a few numbers of reads spanning the gene mutation regions. Taken together, the combined platform represents a new tool for real-time, cost-effective genomic profiling of rare CTCs, with potential applications in the clinical management of cancer patients.

#3773 ROR1 and PMEPA1 as combined predictive biomarkers for metastasis in triple-negative breast cancer: Multi-omics and clinical validation.

Hao Wang[1], **Linze Xu**[1], Song An[2], Yang Liu[1]

[1]Department of Hepatobiliary Cancer, Liver Cancer Center, Tianjin Medical University Cancer Institute & Hospital, National Clinical Research Center for Cancer, Key Laboratory of Cancer Prevention and Therapy, Tianjin's Clinical Research Center for Cancer, TianJin, China,[2]Department of Breast Oncology Surgery, Tianjin Cancer Hospital Airport Hospital, TianJin, China

Background: Triple-negative breast cancer (TNBC) remains the most aggressive subtype of breast cancer, characterized by high heterogeneity, early metastasis, and lack of effective targeted therapies. Early identification of high-risk patients is crucial for improving outcomes. Previously, we identified receptor tyrosine kinase-like orphan receptor 1 (ROR1) as a TNBC-specific extracellular vesicle (EV) marker capable of capturing tumor-derived EVs (2025 AACR #Abstract 2005). Building on this foundation, we conducted an integrated multi-omics and clinical validation study to uncover novel ROR1-associated molecules that could enhance the prediction of metastatic potential in TNBC.

Methods: EV proteomics were used to confirm TNBC-specific markers. scRNA-seq (GSE176078) and TCGA-BRCA bulk RNA-seq data were analyzed. hdWGCNA identified hub genes in epithelial-mesenchymal transition (EMT)-high invasive TNBC cells. LASSO, support vector machine (SVM), and random forest algorithms were applied to screen EMT-related metastasis genes. TCGA data were split (7:3) into training and validation sets, and AutoGluon machine learning with undersampling constructed the metastasis prediction model. For clinical validation, TNBC patients were categorized by metastatic status, immunofluorescence staining of PMEPA1 and ROR1 was performed on TNBC tumor tissues, with CKpan distinguishing tumor parenchyma from stroma.

Results: Proteomic and computational analyses identified PMEPA1 as a key metastasis-associated gene, showing the highest predictive performance (AUC) in the WeightedEnsemble-L2 model. In clinical samples, patients who later developed distant metastases exhibited significantly higher PMEPA1 and ROR1 expression than those who remained metastasis-free. Co-localization analysis showed both proteins enriched in $CKpan^{+}$ tumor regions. The combination of ROR1 and PMEPA1 improved predictive performance for TNBC metastasis compared to either marker alone, consistent with bioinformatics predictions. These findings suggest cooperative involvement of ROR1 and PMEPA1 in TNBC progression.

Conclusions: PMEPA1 is identified as a novel ROR1-associated molecule involved in TNBC metastasis. Co-expression of PMEPA1 and ROR1 serves as a robust predictor for metastatic progression. Integrating machine learning-based transcriptomic modeling with clinical validation provides a promising framework for early metastasis risk stratification in TNBC. Ongoing studies aim to elucidate the ROR1-PMEPA1 signaling axis as a potential therapeutic target.

#3774 Genomic landscape of acute myeloid leukemia in an African ancestry cohort: A pilot study.

Oluyemi Akinloye[1], Olayiwola Akianji Popoola[1], Olatunde Olugbenga Fakoya[1], Stella Samson Rwazuala[2], Nneka Nwanyiaru Osobukola[1], Michael Forster[3]

[1]Center for Genomics of NCDs and Personalized Healthcare (CGNPH), University of Lagos, Lagos, Nigeria,[2]Department of Haematology, Muhimbili University of Health and Allied Sciences, Dr es Salaam, Tanzania, United Republic of,[3]Department of Clinical Molecular Biology, University of Kiel, Kiel, Germany

Introduction: Acute myeloid leukemia (AML) is a diverse hematologic cancer that is distinguished by the uncontrolled growth and improper development of immature clonal myeloid cells. AML patients' age, performance status, comorbidities, genetics, and other clinical characteristics unique to leukemia, such as molecular classification, all influence their prognosis.
Methods: In a pilot mixed African sample (Tanzania and Nigeria), we explore and identify genomic mutations and their possible influence on the clinical outcome of AML in an African Ancestry population. A total of six participants were recruited for the pilot study: n=4 (67%) from Tanzania and n=2 (33%) with an age range of between 14-71 years, and (2)33% female and (4)67% females. Genomic DNA was obtained from blood samples of all participants; a DNA library was prepared with targeted selected genes associated with Leukemia and sequenced on an Illumina Next-generation sequencer.
Results: The study demonstrated numerous and diverse mutations in the African ancestry population. While CEBPA and BTK show 100% mutation, STAG2, CALR, BRAF, NOTCH1, and ZRSR2 demonstrated the lowest mutation (17%) in AML. A missense mutation predominates in
CSF3R, NRAS, BRAF, ASXL1, BTK, and CBL, while CALR and NOTCH1 had only in-frame deletions. In-frame driver mutations were found in FLT3 AML_3, while FLT3 and NOTCH1 were found only in AML_4. All samples had a mutation in SETBP1, CEBPA, and BTK. Pathogenic mutations were detected with a frequency of 67% in FLT3, 33% in NRAS and 17% in BRAF, NOTCH1, and CALR. The NRAS mutations identified in this study have been associated with cancers other than AML and stand out in our cohort, as both genetic modifiers of AML biology and therapeutic targets. BRCA1 and TP53 are the most common pathogenic mutated variants in the TCGA dataset. They both show robust therapeutic targeting potential.
Conclusions: The molecular signature identified in this African Ancestry population demonstrated genomic diversity in the African Ancestry population. Some of the genomic variations identified in this study are rarely documented in AML (NRAS; Gln61His, Gly13Asp: BRAF Val600Glu, Val640Glu). This is an indication of the need to review the genomic criteria for the diagnosis and management of AML, especially with more comprehensive data of the African Ancestry population. We describe various mutated genes with their potential therapeutic targets in AML, including DASATINIB (CBL), which shows promise as a therapeutic target for AML in the African Ancestry population. This study provides a basis for committing resources to a larger cohort and further exploring the genomic diversity and variants in an African Ancestry population.

#3775 Integrated CTC analysis to characterize tumor progression and enable broad multi-omics biomarker platforms for next-generation cancer Therapeutics.

Hyoyong Kim[1], Sehyung Pak[2], Dajeong Lee[3], Seung Hwan Son[3], Giho Seo[3], Kangwon Jang[1], Byung Hee Jeon[2]

[1]Cytogen, Inc., Seoul, Korea, Republic of,[2]CytoGen Inc., Seoul, Korea, Republic of,[3]Humic Inc., Seoul, Korea, Republic of

Background: Circulating tumor cells (CTCs) offer a minimally invasive approach to evaluate tumor progression, metastatic potential, and therapeutic response. CytoGen's SMART BIOPSY™ platform, based on high-definition HDM Chip technology, enables sensitive CTC capture from non-clinical and clinical samples. Establishing the translational value of CTC dynamics in non-clinical efficacy studies is essential for developing biomarkers that can support clinical trial design and IND filing.
Methods: To investigate the relationship between CTCs, tumor burden, and metastasis, xenograft models were generated using both non-metastatic and metastatic human cancer cell lines. Blood samples were collected longitudinally during tumor growth and after therapeutic intervention. CTCs were isolated using the SMART BIOPSY™ platform and evaluated by immunofluorescence (IF) to enumerate total CTCs and quantify target-marker-positive CTC populations. Tumor size and metastatic progression were assessed through imaging and necropsy to determine correlations with CTC dynamics.
Results: IF-based analysis demonstrated a clear correlation between CTC counts and tumor burden, with metastatic models consistently yielding higher CTC numbers than non-metastatic models. Importantly, therapeutic treatment that led to tumor reduction produced a significant decrease in target-marker-positive CTCs, indicating that SMART BIOPSY™ sensitively reflects pharmacodynamic changes. These findings validate the platform's reliability for monitoring tumor progression and early treatment response in non-clinical efficacy studies.
Conclusions: While this study focused on IF-based CTC characterization, the SMART BIOPSY™ platform is fully compatible with a broad multi-omics workflow, including scRNA-seq, FISH, NGS, immunofluorescence panels, and proteomics, enabling comprehensive biomarker discovery for metastasis and drug resistance. The translational insights obtained from non-clinical CTC analyses can be directly leveraged in IND filing, supporting patient stratification strategies and pharmacodynamic monitoring in early-phase clinical trials. Collectively, SMART BIOPSY™ provides a robust bridge that connects non-clinical efficacy studies with clinical drug development, establishing a versatile and expandable platform for next-generation oncology therapeutics.

#3776 Methodology and clinical validation of a centrifugation-free microfluidic isolation platform for circulating tumor cell clusters in cancer patients.

Jason Chia-Hsun Hsieh[1], Pei-Hung Chang[2], Tzu Keng Chiu[3]

[1]Chang Gung Memorial Hospital at Linkou, Taoyuan, Taiwan,[2]Chang Gung Memorial Hospital at Keelung, Taipei City, Taiwan,[3]Chang Gung University, Taoyuan, Taiwan

BACKGROUND: Circulating tumor cell (CTC) clusters are aggregates of tumor cells found in the peripheral blood and are typically linked to unfavorable clinical outcomes. However, current technologies capable of isolating, counting, or culturing these clusters without prior blood processing remain limited.
METHODS: We developed a microfluidic single-cell-picking system that enables isolation of cells without sample preparation or centrifugation, thereby preserving their native morphology and viability. Unlike conventional centrifugation or bead-based enrichment—which often compromises fragile clusters—this platform combines real-time fluorescence-activated droplet extraction with coordinate-guided picking to selectively retrieve single cells and intact clusters for downstream multi-omics investigation.
RESULTS: The system demonstrated a linear recovery efficiency of 93% ($R^2 = 0.9985$) and sustained higher levels of cell viability and metabolic function compared with magnetic bead-based techniques. In clinical testing, it distinguished cancer patients from healthy individuals based on CTC and CTC-cluster counts, underscoring its value for liquid biopsy applications and precision oncology.
CONCLUSION: This proof-of-concept work indicates that a gentle, preprocessing-free microfluidic strategy can effectively isolate and characterize both single cells and intact clusters, offering insights into metastatic biology and enhancing the potential of clinical diagnostic tools.

#3777 Spatial co-elevation of IGF1R and STMN1 associates with metastatic progression in osteosarcoma.

Piaopiao Luo, Xiaoqian Ma, Tairan Wang, Yiqing Wang, Xiang Nan

Anhui Medical University, Hefei, China

Background: Osteosarcoma metastasis remains the leading cause of patient mortality, and current therapeutic strategies offer limited benefit for metastatic disease. Identifying metastasis-associated signaling programs is essential for developing more effective interventions.
Methods: We integrated single-cell RNA sequencing, spatial transcriptomics, ligand-receptor interaction analysis, and functional assays to define molecular programs associated with osteosarcoma progression. Clinical cohorts were used to evaluate associations with metastasis and survival. In vitro and in vivo models were applied to validate mechanistic insights and therapeutic response.
Results: High IGF1R and STMN1 expression strongly correlated with distant metastasis and poor prognosis. Single-cell communication analysis revealed enhanced crosstalk between $STMN1^{+}$ osteosarcoma cells and cancer-associated fibroblasts (CAFs), predominantly driven by IGF-mediated signaling. Spatial transcriptomics confirmed the co-localization and coordinated upregulation of IGF1R and STMN1 in metastatic niches. Functional assays demonstrated that stromal IGF1/IGF2 activation of IGF1R increases STMN1 expression, and stronger spatial co-elevation of these molecules reflects enhanced coordination that facilitates tumor dissemination. Dual targeting of IGF1R and STMN1 significantly suppressed osteosarcoma invasion and metastatic outgrowth in both in vitro and in vivo models.
Conclusions: This study identifies the IGF1R-STMN1 axis as a mechanistically coherent and spatially reinforced driver of osteosarcoma metastasis. The spatial co-elevation of IGF1R and STMN1 marks metastatic niches and represents a promising therapeutic vulnerability, offering new avenues for improving outcomes in osteosarcoma.

#3778 Circulating tumor cell based *ex vivo* platform for characterizing circulating hybrid cell dynamics in multiple cancer types.

Chia-Liang Yen, Wan-Syuan Jian, Ting-Chun Liu, Pei Yu Chen, Shih-Pei Wu, Po-han Chen

CancerFree Biotech, Jersey City, NJ

Circulating hybrid cells (CHCs) arising from tumor-leukocyte fusion may contribute to metastasis and therapy resistance through enhanced DNA repair, immune evasion, and acquired migratory capacity. However, the prevalence, expansion dynamics, and clinical significance of CHCs across cancer types remain poorly characterized.Circulating tumor cells (CTC)-enriched samples from patients with breast cancer, NSCLC, and colorectal cancer were analyzed through extended ex vivo culture. CHCs were identified by dual pan-cytokeratin and CD45 immunofluorescence combined with morphological criteria. An AI-assisted image analysis platform is being developed for automated CHC quantification and characterization. A subset underwent parallel culture with cisplatin to assess chemoresistance and clinical correlations with treatment history and disease status were evaluated. Initial validation demonstrates reliable discrimination between immune cells and non-immune cells (potential CTCs/CHCs), enabling systematic quantification. Dual immunofluorescence staining revealed distinct CHC populations characterized by co-expression of epithelial (pan-CK^+) and hematopoietic ($CD45^+$) markers with large cell size. CHCs were rarely observed in early culture across all cancer types but became prominent by extended culture, indicating progressive enrichment over time. Complete quantitative analysis with statistical validation is ongoing. These findings establish extended ex vivo culture as a platform for investigating CHC biology, assessing drug sensitivity, and determining clinical relevance.

#3779 Plasma exosomes identify metastatic potential in early stage melanoma.

Lauren Emily Miller

Cell Biology & Physiology, Brigham Young University, Provo, UT

Exosomes are emerging as key players in cancer progression, facilitating local and distant interactions that contribute to tumor metastasis. Survival with malignant melanoma rapidly decreases following metastatic spread. Patients with a diagnosis of metastatic melanoma experience a five-year survival rate which decreases from 91.3% (no metastasis) to 16%. It is imperative that early detection of metastatic melanoma is implemented to improve survival rates. Known as “messengers of metastasis”, exosomes provide a reflection of their cell of origin, unveiling critical insights into tumor microenvironment maintenance and metastatic behavior. Using stage I patient samples with metastatic melanoma as well as a mouse model, we isolated exosomes from the local environment, such as the primary tumor, as well as through the bloodstream. From nanoparticle analysis, exosome concentration differed within the localized and systemic environments among stage I patients, further supporting our understanding of the heterogeneity among patient tumors, despite being classified in the same stage of cancer. Proteomic analysis of exosomes with mass spectrometry conveyed stark differences in the expression of proteins found in the localized, tumor environment and those found in the systemic environment of which plasma-derived exosomes were isolated. Eighteen proteins with known metastatic characteristics were statistically found to be uniquely expressed in the bloodstream or in the primary tumor. Interestingly, plasma-derived exosomes containing metastatic proteins were found in the patients with stage I melanoma. These proteins may serve as an early indicator of metastatic melanoma with further studies.

#3780 The role of KRT10 in cancer brain metastasis.

Bo Chen[1], Liyang Zhang[2], Karrie M. Kiang[3], Gilberto Ka Kit Leung[4]

[1]The University of Hong Kong, Hong Kong, Hong Kong,[2]Xiangya Hospital Central South University, Hong Kong, Hong Kong,[3]The University of Hong Kong, Hong Kong, China,[4]Univ. of Hong Kong, Hong Kong, Hong Kong

KRT10 is a keratin family protein that regulates epithelial structure and cellular differentiation. While the role of KRT10 in cancer metastasis has been previously reported, the specific mechanisms underlying its involvement remain unclear. In this study, we applied an integrated multi-omics strategy—including spatial transcriptomics and metabolomics—combined with in vitro assays to investigate the mechanism of KRT10 in non-small cell lung cancer (NSCLC) brain metastasis. We observed elevated KRT10 expression in NSCLC relative to normal tissues. Silencing KRT10 markedly reduced NSCLC cell migration and invasion. We then examined the tumor microenvironment and identified metastatic niches where KRT10 was concentrated. NSCLC cells interacted with pro-metastatic neutrophil extracellular trap (NET) DNA via KRT10, and the specific DNA sequences involved were subsequently confirmed. The predictive ability of KRT10 in metastasis was also explored. Overall, inhibiting KRT10 could serve as a potential therapeutic strategy to inhibit NSCLC cell brain metastasis.

#3782 High-sensitivity CD19⁺ cell enrichment enables rare mutation detection and MRD-focused liquid biopsy in chronic lymphocytic leukemia.

Yasser Abdelrahman, Junmei Wang, Yue Zhang, Pan Du, Binggang Xiang

Predicine, Inc., Hayward, CA

Background: Accurate TP53 mutation detection is critical for clinical trial enrollment and MRD monitoring in chronic lymphocytic leukemia (CLL), as TP53 disruption drives treatment resistance and guides eligibility and stratification in most CLL trials. Patients with TP53-aberrant disease are typically excluded from chemoimmunotherapy-based protocols and redirected to targeted-agent or high-risk studies, making reliable TP53 testing essential. However, targeted therapies can markedly suppress circulating CLL cells, reducing tumor fraction and compromising assay sensitivity. In line with the 2024 ERIC TP53 testing update recommending CD19⁺ B-cell enrichment for low-lymphocyte-count samples (≤10×10^9/L), Predicine developed and validated an immunomagnetic CD19⁺ enrichment workflow optimized to isolate rare CLL circulating tumor cells from whole blood under low-burden conditions.
Methods: Whole-blood samples were processed using an anti-CD19 immunomagnetic capture system. Because bead binding masks CD19 epitopes, enriched cells were quantified by flow cytometry using CD20 as a surrogate marker. Performance was evaluated across key analytical metrics, including cell viability, purity, ambient-temperature stability, intra- and inter-assay precision, and cross-site concordance. The workflow's impact on mutation detection was assessed using MEC-1 spike-in controls and CLL patient samples by comparing TP53 variant allele frequencies (VAFs) before and after enrichment. Refinements were implemented to minimize cell loss and erythrocyte carryover, ensuring scalability for clinical trial environments.
Results: The assay consistently yielded high-quality CLL cells with a median viability of 97.7% and substantially increased the tumor-cell fraction from 10.3% in PBMCs to 79.6% post-enrichment. B-cell enrichment was successful from whole blood stored at room temperature for at least four days. Precision studies demonstrated strong intra- and inter-assay reproducibility, and results were concordant across independent testing sites. Importantly, Enrichment significantly improved the sensitivity of mutation detection. In MEC-1 spike-in samples, the median TP53 VAF increased by 3.6-fold, while the CD19⁺ cell frequency increased by over 4-fold, highlighting robust tumor cell recovery and an enhanced signal-to-background ratio for NGS.
Conclusions: Predicine's validated CD19⁺ enrichment workflow enables efficient, reproducible recovery of rare CLL CTCs and fully aligns with ERIC 2024 recommendations for tumor-cell enrichment at low lymphocyte counts. This approach supports accurate TP53 mutation assessment under low-burden conditions and provides a trial-ready liquid-biopsy solution for MRD monitoring, early relapse detection, and biomarker-guided clinical trial enrollment in CLL.

#3786 Peripheral immune signature of dostarlimab in addition to standard of care definitive radiation in patients with medically inoperable endometrial cancer.

Liyun Chen[1], Rachel Furuya[2], Linda Odibo[2], Lulu Sun[3], David Mutch[2], Carolyn McCourt[2], Matthew A. Powell[2], Julie K. Schwarz[1], Jessika A. Contreras[1], Premal H. Thaker[2], Stephanie Markovina[1]

[1]Department of Radiation Oncology, Washington University in St. Louis, St Louis, MO,[2]Department of Gynecologic Oncology, Washington University in St. Louis, St Louis, MO,[3]Department of Pathology, Washington University in St. Louis, St Louis, MO

Upfront surgical staging is considered standard of care for patients with localized endometrial cancer. However, for patients with significant comorbidities surgery may be high risk or inadvisable. These patients can undergo definitive radiation therapy (RT) delivered with brachytherapy (BT) with or without external beam RT (EBRT). The tolerability and potential benefit of immunotherapy in this patient cohort is unknown. We performed a prospective Phase I trial of dostarlimab in conjunction with definitive RT for patients with medically inoperable endometrial cancer. Ten patients were enrolled. Dostarlimab was administered three weeks prior to the start of RT and then concurrently with RT for three cycles. Here we report the dynamics of circulating immune profiles to identify potential treatment-predictive biomarkers. Longitudinal analysis of paired peripheral blood mass cytometry (CyTOF) and soluble protein analytes (ELISA) was performed at baseline, on- and post-treatment timepoints. One cycle of neoadjuvant dostarlimab prior to RT was associated with increased serum type I interferon-induced chemokines (CXCL9, CXCL10, CXCL11) and IL-2 family cytokines (IL15, IL21), pivotal for immune cell activation and adaptive immune response. While the abundance of T cell populations in PBMCs remained mostly unchanged, effector memory CD4 and CD8 T cells had increased expression of Ki-67 and granzyme B, indicating a proliferative and cytotoxic phenotype. Initiation of RT was associated with multiple changes in plasma protein analytes including further increases in CXCL9/10, upregulation in inflammatory cytokines IL-1 and TNF, as well as cytokines with tumor-promoting potential CCL4, CCL7, and G-CSF. T cells expressing granzyme B and activation markers (CD38, HLA-DR) remained elevated, indicating sustained functional potential. CD11c+ DCs, monocytes, and Treg cells were also increased after RT. Notably, patients treated with BT+EBRT (n=3) compared to those with BT (n=7) had higher increase in DCs and monocytes as well as overall changes in cytokine expression during treatments, such as increased IL4 and IL10 associated with T cell function and decreased CCL2 and CXCL13. At 6-week post-treatment, cytokines elevated from baseline persisted in patients treated with BT+EBRT while less variations in cytokine profiles were observed in the group without EBRT. Lastly, we observed a sustained decrease in PD-1+ T cells after 1 cycle of dostarlimab but an increased frequency of LAG-3+ or Tim-3+ T cells at cycle 2 and 3 of dostarlimab with RT.
Taken together, the circulating immune profile demonstrated an association between the baseline and on-treatment immune activation signature with dostarlimab in addition to RT, highlighting the potential of this combination regimen to enhance therapeutic efficacy in patients with inoperable endometrial cancer.

#3787 The safety of PARP inhibitors combined with immune checkpoint inhibitors versus immune checkpoint inhibitor monotherapy: A systematic review, meta-analysis, and trial sequential analysis of randomized controlled trials.

Mus'ab Theeb Mustafa[1], Aws Khalid Abushanab[2], Ahmad Yousef Alazzam[2], Mahmoud Taysir Mousa[2], Ahmad Sa'ed[3], Noor N. Al-Bzour[4], Osama Wadah Rammaha[2], Zaher Mutaz Ashour[2], Hamza Muneer Alakhras[3], Yihea Mohammad Al-Mashaqbah[2], Ahmad Sami Othman[3], Nour Maher Mustafa[3], Renad Fawwaz Al Banawi[2], Anwaar Saeed[5]

[1]Prince Hamza Hospital, Amman, Jordan,[2]Faculty of medicine, Hashemite University, Zarqa, Jordan,[3]Jordan University Hospital, Amman, Jordan,[4]Jordan University of Science and Technology, Irbid, Jordan,[5]University of Pittsburgh, Pittsburgh, PA

Background: The combination of poly(ADP-ribose) polymerase inhibitors (PARPi) and immune checkpoint inhibitors (ICI) represents a promising strategy with potential synergistic effects. Preclinical studies suggest that PARPi-induced DNA damage may enhance tumor immunogenicity and augment the efficacy of ICI. Currently, this approach is being studied across multiple malignancies. However, the risk of additive adverse events remains a major concern. We conducted the first meta-analysis of randomized controlled trials (RCTs) to assess the safety of PARPi plus ICI versus ICI monotherapy.

Methods: We conducted a PRISMA-compliant systematic review, searching PubMed, Web of Science, and the Cochrane Library for RCTs comparing PARPi+ICI combination therapy against ICI monotherapy. The safety outcomes were serious adverse events (SAEs), immune-mediated adverse events (imAEs), treatment discontinuation, and specific treatment-related adverse events. Risk ratios (RR) and 95% confidence intervals (CI) were pooled using a random-effects model. Heterogeneity was assessed using the I^2 statistic. Finally, Trial Sequential Analysis (TSA) was performed to test the reliability of the pooled results and classify findings as conclusive, inconclusive, or suggestive.

Results: Six RCTs (DUO-E, KEYLYNK-008, ORION, SWOG 1929, MORPHEUS, and BAYOU) encompassing 1537 patients comparing PARPi+ICI with ICI monotherapy were included. The combination was associated with a significantly suggestive higher risk of SAEs (N=5; RR 1.77; 95% CI: 1.29-2.43; I^2=0%) and anemia (N=6; RR 3.27; 95% CI: 2.50-4.29; I^2=16%), neutropenia (N=5; RR 4.13; 95% CI: 2.35-7.27; I^2=18%), and significantly conclusive leukopenia (N=3; RR 3.93; 95% CI: 2.24-6.91; I^2=2%), vomiting (N=6; RR 3.47; 95% CI: 2.20-5.46; I^2=0%). Conversely, the combination led to a significantly inconclusive lower incidence of imAEs (N=3; RR 0.77; 95% CI: 0.61-0.98; I^2=0%). No significant differences were observed in discontinuation of the ICI component (N=5; RR 1.31; 95% CI: 0.85-2.02; I^2=0%, INC), diarrhea (N=6; RR 1.15; 95% CI: 0.81-1.64; I^2=5%), hypothyroidism (N=5; RR 0.77; 95% CI: 0.51-1.16; I^2=0%,), however they all were inconclusive.

Conclusions: The addition of PARPi to ICI therapy conclusively increases the risk of leukopenia and vomiting. Furthermore, our TSA found suggestive evidence for an increased risk of SAEs, anemia, and neutropenia. Conversely, while pooled analysis suggested a reduced risk of imAE, our TSA revealed this finding to be inconclusive and warrants further investigation. Similarly, the current evidence is inconclusive for the risk of ICI discontinuation or diarrhea. Based on these findings, watchful clinical monitoring and risk-benefit assessment are essential when considering this combination.

#3788 Integrated single-cell analysis identifies biomarkers associated with clinical benefit in patients with PD-L1 positive, advanced NSCLC treated with SBRT followed by atezolizumab plus tiragolumab.

Jii Bum Lee[1], Dong Kwon Kim[2], Sang Hoon Lee[2], Kyung Hwan Kim[1], Su-Jin Choi[2], Min Hee Hong[1], Byoung Chul Cho[1], Sun Min Lim[1]

[1]Yonsei Cancer Center, Yonsei University College of Medicine, Seoul, Korea, Republic of,[2]Yonsei University College of Medicine, Seoul, Korea, Republic of

Background: Prior studies have shown that the addition of SBRT to immunotherapy in oligometastatic non-small cell lung cancer (NSCLC) may improve clinical outcomes. SKYROCKET is a single-center, single-arm phase II study that evaluated whether SBRT combined with atezolizumab plus tiragolumab enhances anti-tumor efficacy in PD-L1-positive oligometastatic NSCLC.
Methods: Patients initially received SBRT to all oligometastatic sites, and subsequently received a fixed dose of 1200 mg IV of atezolizumab and 600 mg of tiragolumab every 3 weeks on day 1 of each 21-day cycle within 7 days of SBRT. The primary endpoint was investigator-assessed progression-free survival (PFS) from the start of SBRT. Secondary endpoints included PFS in PD-L1 high subset, objective response rate (ORR), overall survival (OS) and safety profile. Exploratory endpoints included characterization of immune remodeling and stromal dynamics via single-cell RNA sequencing (scRNA-seq) obtained from tumor biopsies at baseline (BL) and on-treatment (OT), and were further characterized as clinical benefit (CB, PR or SD ≥6 months) and no clinical benefit (NCB, PD or SD <6 months).
Results: A total of 41 patients were enrolled. At a median duration of follow-up of 9.8 months (IQR, 6.3-15.8), the median PFS at the start of SBRT was 9.3 months (95% CI, 6.0-NR). In patients with PD-L1 high (≥ 50%), the median PFS was 11.4 months compared to 6.4 months in patients with PD-L1 low (<50%) expression (P = 0.029, HR, 0.39, 95% CI, 0.16-0.95). Of the 39 patients with measurable lesion, the ORR and DCR was 56% and 92%, respectively. No new safety adverse events were seen with the addition of SBRT to atezolizumab plus tiragolumab. ScRNA-seq of paired BL and OT (n=3) and single-time point (n=2) identified CD8 progenitor-exhausted (T_{PEX}) and terminally exhausted (T_{EX}) subsets. CD8 T_{PEX} cells markedly expanded after treatment, with target engagement evidenced by high TIGIT and PD-1 expression in CD8 T_{PEX}/T_{EX} subsets. Pathway analyses showed enhanced T-cell activation and TCR signaling. CD4 Tregs were reduced in the CB group but increased in the NCB group. Pseudotime analysis showed T_{EM} cells in CB preferentially transitioned into $CXCL13^{+}$ helper states, while NCB skewed toward Treg differentiation. The CB group showed reduced Treg suppression and NECTIN-TIGIT signaling, whereas NCB maintained proliferative $CTLA4^{high}$/$TIGIT^{high}$ Tregs supported by ICAM/Galectin-CTLA4 pathways.
Conclusion: In PD-L1 positive oligometastatic NSCLC, atezolizumab plus tiragolumab after completion of SBRT improves PFS with manageable safety profile. Combination therapy boosts cytotoxic/helper T-cell programs in CB, whereas persistent ICAM/Galectin-CTLA4-driven Tregs underlie resistance to treatment.

#3789 Treatment with ACR-2316, a potential first- and best-in-class WEE1/PKMYT1 inhibitor, combined with anti-PD-L1 induces complete tumor regression with durable immune memory.

Taronish Dubash[1], Joelle Baddour-Sousounis[1], Amira Elbakry[1], Jessica Hopkins[1], Subodh Kumar[1], Yingchun Spring Liu[1], Ahmed Youssef[1], Kate Rappard[1], Ignacio Arribas Diez[2], Georgia Mista[2], Marc Isaksson[2], Francisco Santana[1], Luka Romero[1], Zachary Best[1], Nina Lipjankic[2], Anna-Maria Alves[1], Daphne Garcia-Lopez[1], Portia Lombardo[1], Calvin Yang[1], Emma Ahrman[2], Valentina Siino[2], Magnus E. Jakobsson[2], Helen Nilsson[2], Ayesha Murshid[1], Lei Shi[1], Caroline Wigerup[2], Michail Shipitsin[1], Joon Jung[1], David Proia[1], Kristina Masson[1], Peter Blume-Jensen[1]

[1]Acrivon Therapeutics Inc., Watertown, MA,[2]Acrivon AB, Medicon Village, Lund, Sweden

Introduction: ACR-2316 is a potent and selective dual WEE1/PKMYT1 inhibitor rationally designed using Acrivon's generative phosphoprotemics AP3 platform. Currently advancing in a Phase 1 clinical study in AP3-identified solid tumor types, ACR-2316 was engineered for superior single-agent activity and high selectivity resulting in potent DNA damage and complete tumor regression across preclinical *in vivo* models. This study demonstrates that ACR-2316 not only damages the nuclear and mitochondrial genomes, but also stimulates the innate immune system, leading to complete tumor regression and lasting immune memory in mice when combined with PD-L1 blockade.

Results: To investigate the mechanisms of immune activation by ACR-2316, we performed AP3-based proteomic profiling of xenograft tumors from ACR-2316 treated mice and observed strong upregulation of innate immune signaling pathways, including type I interferon. These findings were further validated at the cellular level, where ACR-2316 treatment led to the activation of double stranded RNA and DNA sensing machinery RIG-I, MDA5 and cGAS. Furthermore, we found evidence of mitochondrial DNA fragmentation with ACR-2316 treatment, suggesting that this may serve as an additional immune sensor.In a syngeneic colorectal cancer model, ACR-2316 monotherapy resulted in dose-dependent tumor growth inhibition. In combination with anti-PD-L1, ACR-2316 exhibited striking synergy, leading to complete tumor regression in mice. To assess the durability of this response, tumor cells were re-injected into tumor-free mice that were previously treated with the combination therapy. All animals remained tumor-free for over 200 days through four sequential tumor re-challenges, demonstrating strikingly robust and durable immune memory. To dissect the mechanism of this durable immunity, we systematically depleted key immune cell subsets in tumor re-challenged mice. While depletion of either $CD4^+$ or $CD8^+$ T cells alone did not enable tumor growth, co-depletion of both subsets resulted in tumor formation. This suggests that the immune memory generated by the combination treatment of ACR-2316 and anti-PD-L1 is co-dependent on both $CD4^+$ and $CD8^+$ T cell subsets.

Conclusions: Our findings reveal the dual role of ACR-2316 in inducing tumor intrinsic DNA damage and promoting immune activation through multiple immune sensing mechanisms, resulting in permanent immune memory co-dependent on CD4+ and CD8+ T cell subsets. This provides a strong rationale for combining ACR-2316 with immune checkpoint inhibitors in the clinical setting. ACR-2316 is in a phase 1 monotherapy trial and has already shown initial clinical activity with tumor shrinkage and a confirmed partial response during dose escalation across solid tumors predicted by our AP3 platform to be sensitive to ACR-2316.

#3790 Combined inhibition of myeloid cell PI3Kγ and regulatory T cell integrin αvβ8 promotes durable tumor suppression.

Erpei Wang[1], Giuliana Mognol[2], MOHAMMAD AMJAD[2], Hui Chen[2], Mark Paradise[2], Dean Sheppard[3], judith Varner[2]

[1]University of California, San Diego, San Diego, CA,[2]University of California, San Diego, San diego, CA,[3]University of California, San Francisco, San Francisco, CA

The immunosuppressive tumor microenvironment (TME) remains a critical barrier to effective immunotherapy. Immune suppressive myeloid cells and regulatory T cells can each prevent effective anti-tumor immune responses. The integrin αvβ8 promotes immune evasion by serving as a key activator of latent TGF-β in regulatory T cells, while the lipid kinase PI3Kγ promotes immunosuppressive signaling in myeloid cells. Genetic and pharmacological inhibition of PI3Kγ stimulates integrin αvβ8 expression on regulatory T cells both in mouse models of cancer and in patients enrolled in cancer clinical trials. Inhibition of either αvβ8 or PI3Kγ significantly suppressed head and neck tumor growth, suggesting they each play important roles in modulating anti-tumor immunity. To gain mechanistic insights into the impacts of these therapeutic approaches, we performed single-cell RNA sequencing (scRNA-seq) on HPV+ HNSCC tumors from wild-type (WT) and PI3Kγ knockout (KO) mice, with or without anti-αvβ8 treatment, to investigate the individual and combined impacts of PI3Kγ inhibition and αvβ8 blockade in the TME. RNA velocity and cell-cell communication inference analysis was performed to uncover dynamic regulatory interactions among cell populations. Antagonism of integrin αvβ8 led to increased CD8+ T cell infiltration and a reduction in TGF-β-responsive transcriptional programs. PI3Kγ inhibition promoted a proinflammatory shift in myeloid cells, characterized by diminished M2-like polarization and enhanced antigen presentation, and increased CD8+ T cell recruitment. Together combined inhibition of αvβ8 and PI3Kγ reversed T cell exclusion and promoted durable tumor suppression.

#3791 Cry1 inhibition reverses resistance to T cell-based immunotherapy by promoting anti-tumor immunity.

Tae Woo Kim[1], Oh Se Jin[2]

[1]Department of Convergence Medicine, Korea Univ. College of Medicine, Seoul, Korea, Republic of,[2]Korea university, Seuol, Korea, Republic of

T cell-based immunotherapy, including immune checkpoint blockade (ICB), has dramatically changed the paradigm of cancer treatment. However, many cancer patients do not achieve durable responses to immunotherapy, and resistance to these treatments remains a major clinical challenge. We previously showed that immune pressure imposed by immunotherapy selects for immune-resistant tumors that acquire both tumor cell-intrinsic and tumor cell-extrinsic refractoriness through NANOG-driven transcriptional upregulation of HDAC1. In this study, we identify CRY1 as a pivotal NANOG-dependent effector that integrates these refractory traits. In $NANOG^{high}$ tumor cells, CRY1 stabilizes Cyclin A and MCL1, thereby promoting cancer stem cell-like properties and resistance to cytotoxic T lymphocyte (CTL)-mediated killing, a process that depends on HDAC1-mediated epigenetic silencing of APC3 and TRIM17. In parallel, CRY1 suppresses CXCL10 expression via HDAC1-dependent transcriptional repression, leading to reduced recruitment of $CD8^+$ T cells into the tumor microenvironment (TME). Importantly, pharmacological inhibition of CRY1 synergizes with anti-PD-1 antibody treatment and adoptive CTL transfer to reduce tumor growth by converting immune-resistant tumors into an immune-sensitive state. Thus, our findings implicate CRY1 as a central molecular target for controlling $NANOG^{high}$ tumors and provide a rationale for combining CRY1 inhibitors with T cell-based immunotherapy to reverse the complex refractoriness of tumors.

#3792 EGFR promotes immune evasion and resistance to immunotherapy in *NF1* mutant melanoma.

Milad Ibrahim[1], Irineu Illa-Bochaca[2], Tara Muijlwijk[1], Ines Delclaux[2], KATHERINE VENTRE[2], George Jour[2], Shi Qiu[3], Agrima Dutt[1], Paola Angulo salgado[1], Amanda W. Lund[4], Markus Schober1[2], Iman Osman[2]

[1]NYU Langone Medical Center, New York, NY,[2]NYU Langone Health, New York, NY,[3]NYU Langone Health, NYU Langone Health, NY,[4]NYU Langone Health Perlmutter Cancer Ctr., New York, NY

Background: Immune checkpoint inhibitors (ICIs) have greatly improved survival rates in melanoma patients, including those with melanomas driven by deactivating mutations in the *NF1* tumor suppressor gene. However, primary or secondary resistance occurs in 50-60% of cases. Moreover, *NF1*-mutant melanoma patients with co-occurring *BRAF* or *NRAS* mutations generally do not respond to BRAF and/or MEK inhibitors, leaving them without effective treatment options. Gaining a better understanding of the mechanisms behind ICI resistance in *NF1*-mutant melanomas, along with identifying more effective treatment strategies, remains an unmet clinical need.

Methods: We compared melanoma cells and their surrounding cell types in 22 *NF1*-mutant and 20 *NF1* wild-type human melanoma tissues using single-cell spatial transcriptomics and highly multiplexed immunohistochemistry. We inferred communication networks between melanoma cells and the microenvironment using Cell-Chat. Finally, we tested how EGFR inhibitors affect the tumor growth and the immune microenvironment in syngeneic mouse models using flow cytometry.

Results: *NF1*-mutant melanoma cells are enriched in pathways related to epithelial-to-mesenchymal transition and immune evasion pathways mediated by significantly increased expression of *EGFR, NGFR, VEGFA, TGFB1,* and *TGFB3*. These cells are more closely associated with cancer-associated fibroblasts (CAFs), and their microenvironment contains significantly more inflammatory CAFs that are enriched in EGF signaling. Conversely, there was less CXCL9 signaling from CAFs to T cells in *NF1*-mutant melanoma microenvironment. This *NF1*-mutant immunosuppressed microenvironment results in significantly less infiltration of T cells which were also less proliferative and exhibit lower cytotoxic activity compared to *NF1* wild-type melanoma, possibly due to the reduced expression of HLA antigens on the surface of *NF1*-mutant melanoma cells. Higher levels of EGFR were detected in ICI resistant *NF1*-mutant melanoma patients and correlated with reduced antigen presentation and T cells infiltration. Pharmacological inhibition of EGFR restored antigen presentation and immune cell responses in *NF1*-mutant melanoma syngeneic mouse model, both alone and in combination with anti-PD1 antibodies.

Conclusion: Our results reveal that hyperactive EGFR signaling promotes immune evasion and immunotherapy resistance in *NF1*-mutant melanoma patients and suggest that EGFR inhibitors may improve ICI treatment outcomes in *NF1*-mutant melanomas with increased EGFR activity.

#3793 Preventing nk cell activation in the damaged liver induced by cabozantinib/pd-1 blockade increases survival in hepatocellular carcinoma models.

Satoru Morita[1], Tomofumi Ando[2], Hiroto Kikuchi[2], Atsuyo Morita[2], Tatsuya Kobayashi[2], Grace Birch[3], Ryota Tanaka[4], Aya Matsui[2], Zhiping Ruan[2], Peigen Huang[2], Alexei Hernandez[5], Erin M. Coyne[5], Sarah M. Shin[5], Robin Kate Kelley[6], Mark Yarchoan[5], Stefan Halvorsen[7], Slim Sassi[7], Mari Mino Kenudson[8], Shadmehr Demehri[4], Rizwan Romee[3], Won Jin Ho[5], Dan Duda[2]

[1]Surgery, Keio University School of Medicine, Tokyo, Japan,[2]Radiation Oncology, Harvard Medical School/Massachusetts General Hospital, Boston, MA,[3]Bone Marrow Transplant and Cellular Therapy Program, Dana Farber Cancer Center, Harvard Medical School, Boston, MA,[4]Visiting Staff, MGH/Harvard Medical School, Charlestown, MA,[5]Oncology, Johns Hopkins University School of Medicine, Baltimore, MD,[6]UCSF - University of California San Francisco, San Francisco, CA,[7]Center of Computational and Integrative Biology (CCIB), Massachusetts General Hospital and Harvard Medical School, Boston, MA,[8]Pathology, Harvard Medical School/Massachusetts General Hospital, Boston, MA

The addition of anti-VEGF antibody treatment to immune checkpoint blockade (ICB) has increased the efficacy of immunotherapy in advanced hepatocellular carcinoma (HCC). Despite an initial promise, adding multitargeted kinase inhibitors of VEGFR with ICB has failed to increase survival in HCC. To reveal the mechanisms underlying treatment failure, we studied the effects of cabozantinib/ICB using orthotopic murine HCC models with or without liver damage. We monitored tumor growth and liver function, recorded survival outcomes, and performed immune profiling studies for intra-tumoral and surrounding liver. Cabozantinib/ICB treatment led to tumor regression and significantly improved survival in mice with normal livers. However, consistent with the clinical findings, combination therapy failed to show survival benefits despite similar tumor control when tested in the same models but in mice with liver fibrosis. Moreover, preclinical and clinical data converged, showing that activating immune responses by cabozantinib/ICB treatment induced hepatoxicity. Immune profiling revealed that combination therapy effectively reprogrammed the tumor immune microenvironment and increased NK cell infiltration and activation in the damaged liver tissue. Surprisingly, systemic depletion of NK reduced hepatotoxicity elicited by the combination therapy without compromising its anti-cancer effect, and significantly enhanced the survival benefit even in mice with HCC and underlying liver fibrosis. These findings demonstrate that preventing NK activation allowed for maintaining a favorable therapeutic ratio when combining ICB with cabozantinib in advanced HCC models.

#3794 ACR246, a first-in-class 5T4 antibody-drug conjugate (ADC), showed promising anticancer efficacy in preclinical models and patient with esophageal cancer.

Xi Jiao[1], **Zhenwei Miao**[2], Na Zhuo[1], Panpan Zhang[1], Jifang Gong[1], Feng Wang[2], Yan Dai[3], Li Yang[2], Wu Yao[2], Shanhui Weng[2], Johannes Nippgen[2], Lin Shen[1]

[1]Peking University Cancer Hospital & Institute, Beijing, China,[2]Hangzhou Adcoris Biopharma Co., Ltd., Hangzhou, China,[3]SIP LifeLink Oncology Research Institute, Suzhou, China

Background: Advanced esophageal squamous cell carcinoma (ESCC) poses a significant therapeutic challenge, particularly after progression on first-line immune checkpoint inhibitors. The oncofetal antigen 5T4 represents a promising target due to its high expression in ESCC and limited presence in normal tissues. ACR246 is an investigational anti-5T4 ADC composed of a fully human IgG1 monoclonal antibody conjugated to a topoisomerase I inhibitor via a stable cleavable linker, with a drug-to-antibody ratio of 8.
Methods: Proteomic sequencing of tumor and adjacent tissues from ESCC patients was performed to compare 5T4 protein levels and estimate immune infiltration. The antitumor efficacy of ACR246 was assessed across a panel of preclinical models, including cell lines, patient-derived organoids (PDOs), and xenografts (PDXs) of gastroesophageal cancer. Its efficacy was benchmarked against a 5T4-Deruxtecan (DXd) ADC and chemotherapy in these models. 5T4 expression level in PDX and PDO tissues was assessed by immunohistochemistry (IHC) to correlate with response. The synergistic potential of ACR246 with anti-PD-1 was investigated in 5T4-positive ESCC PDO-PBMC co-cultures and a murine ESCC model expressing human 5T4, with tumor microenvironment changes analyzed by flow cytometry. A clinical case from a heavily pretreated ESCC patient is included.
Results: Proteomics confirmed significantly elevated 5T4 protein levels in ESCC tumors versus adjacent tissues. High 5T4 expression correlated with reduced infiltration of CD4+ T cells, CD8+ effector memory T cells, and dendritic cells, indicating an immunosuppressive milieu. *In vitro* studies showed that ACR246 exhibited high specificity for 5T4-expressing cancer cells and demonstrated superior activity over irinotecan in multiple gastroesophageal cancer PDOs. In PDX models of gastroesophageal cancer (n=9), ACR246 achieved significant tumor growth inhibition, with efficacy positively correlating with 5T4 expression. Remarkably, ACR246 outperformed the 5T4-Dxd ADC across these PDX models. Furthermore, ACR246 combined with anti-PD-1 showed enhanced antitumor activity in ESCC PDO-PBMC co-cultures and murine ESCC models, accompanied by increased IFN-γ+ CD8+ T cells and reduced M2-like macrophages. Finally, a 5T4 positive, anti-PD-1-refractory ESCC patient (NCT06238401) receiving ACR246 (3.6 mg/kg) achieved a confirmed partial response (cycle 4) with 51% reduction in the volume of target liver and lymph node metastatic lesions. No grade ≥ 3 treatment-related adverse events (TRAEs) were observed during the treatment period.
Conclusion: Integrated preclinical and clinical data establish ACR246 as a promising therapeutic for 5T4-positive ESCC and support its broader evaluation in other 5T4-expressing solid tumors.

#3795 Crept-618: First GalNAc-siRNA targeting CREPT reverses HCC immune evasion and synergizes with anti-PD-1.

Jianghua Li[1], **Alex Zou**[2], He Yang[1], Jiayu Wang[1], Weihua Yang[1], Zhijie Chang[3], Jun Li[1]

[1]Tsinghua University, Beijing, China,[2]UC Berkeley, Berkeley, CA,[3]Tsinghua University, Berkeley, China

Purpose: Immune checkpoint inhibitors (ICIs) achieve responses in only approximately ~20% of hepatocellular carcinoma (HCC) patients due to immunologically “cold” tumors characterized by poor T-cell infiltration. We identify CREPT—overexpressed in HCC and linked to worse survival (HR=2.722, P=0.0018) and ICI non-response (higher expression in non-responders; GSE215011, P<0.01)—as a dual driver of tumor proliferation and immune silencing. We present CREPT-618, the first GalNAc-conjugated siRNA targeting CREPT.

Experimental Procedures: CREPT expression was analyzed in TCGA, GEO, CPTAC databases and validated by immunohistochemistry in a 104-patient HCC tissue microarray. Functional roles were tested via CREPT knockdown in HCC cell lines (LM3, Huh7, Hep3B and Hepa1-6) using proliferation, migration, and invasion assays. In vivo efficacy was assessed in humanized orthotopic implantation mouse models with or without anti-PD-1 combination. The underlying mechanism was studied using RNA-seq, ATAC-seq, ChIP-seq, and scRNA-seq. CREPT-618 was tested for potency (no transfection), specificity, PK, biodistribution (Cy5/LC-MS), and GLP toxicology in mice, rats, and monkeys.

New, Unpublished Data: CREPT recruits the SIN3A-HDAC1/2 complex to the CCL5 promoter, leading to chromatin compaction (ATAC-seq) and silencing IFN-γ/IRF1-induced CCL5 transcription (ChIP-seq). CREPT loss increased CCL5 secretion (3.7-fold, P<0.001), driving CD8+ T/NK infiltration (2.8-fold, P<0.01; scRNA-seq)—prevented by CCR5 blockade, confirming CCL5 dependence. CREPT-618 achieved potent, specific silencing (IC_{50} 0.046-1.628 nM; RNA-seq/PCA validated) with liver-focused PK (Cmax ~200 μg/g, T½ ~70 h). In orthotopic HCC, monotherapy modestly suppressed growth across 3 batches (IHC target engagement confirmed), while combination with anti-PD-1 drove synergistic 78.3% tumor regression (P<0.001) and a 5.1-fold increase in cytotoxic CD8+ T cells. CREPT-618 was well-tolerated up to 100 mg/kg (rodents) and 30 mg/kg (monkeys).

Conclusion: CREPT drives HCC growth and immune evasion by repressing CCL5, blocking T-cell recruitment via the CCL5-CCR5 axis. CREPT-618—the first siRNA targeting CREPT—silences this oncogenic hub, restores CCL5 signaling, converts “cold” tumors to “hot”, and synergizes with anti-PD-1. These preclinical data will enable a first-in-human trial; preliminary human safety and CREPT knockdown data will be presented at AACR.

#3796 Targeting midkine with HBS-101 enhances chemotherapy and immunotherapy response in TNBC via immune activation and oncogenic pathway suppression.

Baskaran Subramani[1], Megharani R. Mahajan[1], Panneerdoss Subbarayalu[2], Zhenming Xu[1], Neelam Mukherjee[1], Gangadhara R. Sareddy[1], Hareesh B. Nair[3], Ratna K. Vadlamudi[1], Suryavathi Viswanadhapalli[1]

[1]UTHSA, San Antonio, TX,[2]UT Health San Antonio Greehey Children's Cancer Res. Inst., San Antonio, TX,[3]Texas Tech University Health Science center, El Paso, TX

Background: Triple-negative breast cancer (TNBC) is an aggressive subtype with high recurrence and resistance to standard therapies. Midkine (MDK), a heparin-binding growth factor that functions as a cytokine, is overexpressed in TNBC and promotes tumor progression, immune evasion, and chemoresistance. We recently developed HBS-101, as a first-in-class small-molecule MDK inhibitor and demonstrated its therapeutic efficacy in preclinical TNBC models. This study evaluates whether MDK inhibition enhances chemo and immunotherapy efficacy as well as the mechanistic understanding of combination therapy effects.
Methods: TNBC cell lines were treated with HBS-101 alone or in combination with chemotherapy (doxorubicin and paclitaxel), and assessed for viability, apoptosis, and synergy. 3D organoids derived from patient-derived xenografts (PDX) were employed to examine the ex vivo effects of combination therapy. The efficacy of HBS-101 with chemotherapy and immunotherapy (PD-L1 inhibitor) was evaluated using human and murine cell line-derived xenograft (CDX) models of TNBC respectively. In vivo, orthotopic TNBC tumors were established in immunocompetent mice and treated with combination treatments. Tumor growth, and immune cell infiltration were analyzed using xenograft models. RNA-seq was performed on HBS-101 treated cells to identify changes in immune and apoptotic pathways. Molecular and immunological effects were examined using RT-qPCR, Western blotting, flow cytometry, and immunohistochemistry.
Results: Combination treatment with HBS-101 and chemotherapy produced synergistic anti-tumor activity in TNBC models, significantly reducing 2D and 3D cell viability, stemness, and tumor growth relative to monotherapies. Similarly, combining HBS-101 with immunotherapy also yielded strong synergistic effects in syngeneic TNBC models, outperforming individual treatments. Mechanistic studies revealed that HBS-101 disrupted MDK-mediated signaling pathways, including STAT3, thereby sensitizing tumor cells to treatment and enhancing immune activation. Combination therapy also increased infiltration of CD8 positive T cells and macrophages, accompanied by elevated levels of IFN-gamma and granzyme B. RNA-seq analysis showed upregulation of immune and apoptotic pathways and suppression of immunosuppressive signals. These molecular changes correlated with reduced tumor burden, and increased apoptosis, supporting the mechanistic synergy of MDK inhibition in combination therapy.
Conclusion: MDK inhibition with HBS-101 enhances the efficacy of chemo-immunotherapy in TNBC by disrupting oncogenic signaling and promoting immune activation. These findings support the therapeutic potential of HBS-101 as part of a combination strategy to overcome resistance and improve outcomes in TNBC.

#3797 A novel tritherapy overcoming the immune suppressive tumor microenvironment elicits robust antitumor activity.

Brian G. Morreale[1], Andrea Monell[1], Han Yu[2], David B. Sykes[3], Jonathan F. Lovell[4], Michael J. Nemeth[1], Scott I. Abrams[5]

[1]Department of Immunology, Roswell Park Comprehensive Cancer Center, Buffalo, NY,[2]Department of Biostatistics and Bioinformatics, Roswell Park Comprehensive Cancer Center, Buffalo, NY,[3]Center for Regenerative Medicine, Massachusetts General Hospital, Boston, MA,[4]Department of Biomedical Engineering, University at Buffalo, Buffalo, NY,[5]Roswell Park Cancer Institute, Buffalo, NY

Immune checkpoint inhibitors (ICIs), such as those that engage PD-1 on cytotoxic $CD8^+$ T cells, can improve survival outcomes across multiple solid cancer types. However, in several cancers, such as triple-negative breast cancer (TNBC), the use of these agents is effective in limited subsets of patients. It is thought that this limitation is tied to numerous barriers which inhibit their efficacy, including the immune suppressive tumor microenvironment (TME) and a low infiltration of antigen (Ag)-specific $CD8^+$ T cells. Myeloid-derived suppressor cells (MDSCs) constitute a prominent immune suppressive component of the TME and are produced in response to tumor-derived factors. MDSCs consist of immature myeloid subpopulations that inhibit the proliferation or effector functions of cytotoxic $CD8^+$ T cells. To overcome this obstacle of immune suppression, our laboratory has developed a novel approach to target MDSC 'biogenesis' in the bone marrow to mitigate their production and bolster novel immunotherapies. We identified a metabolic susceptibility in MDSCs, which mitigates MDSC function using agents known as dihydroorotate dehydrogenase (DHODH) inhibitors. DHODH inhibitors block *de novo* pyrimidine metabolism and are being used as an anti-AML therapy to promote the maturation of myeloid progenitors common to both leukemic cells and MDSCs. This anti-MDSC approach boosted ICI activity, which significantly diminished tumor growth and metastasis; however, tumors persisted. To achieve more effective tumor response, we turned to the concept of epitope-specific immunization (ESI). We hypothesized that not only does DHODH blockade 'reprogram' MDSCs, but a peptide-based ESI approach targeting an endogenous tumor Ag in combination with our anti-PD-1/anti-MDSC regimen would result in greater tumor reduction by activating and expanding low frequencies of Ag-specific $CD8^+$ T cells. We optimized a tri-therapy regimen consisting of our anti-PD-1/anti-MDSC regimen with an ESI to boost intra-tumoral T cells. We showed that such a novel tri-therapy regimen caused significant antitumor responses, substantially more so compared with the single- and double-agent controls, which correlated with an increase in intra-tumoral Ag-specific $CD8^+$ T cells. To further demonstrate that this tri-therapy enhanced T cell function, we integrated an 'add-back' approach. We isolated $CD8^+$ T cells from tri-therapy-treated mice and showed following adoptive transfer that they significantly reduced tumor growth compared to $CD8^+$ T cells derived from vehicle or the dual-agent combination controls. Altogether, our results suggest that a novel multi-modal strategy that concurrently reduces MDSCs, overcomes T cell exhaustion, and expands tumor-reactive $CD8^+$ T cells, has important therapeutic implications to improve outcomes against ICI-refractory tumors.

#3798 *In vivo* results of AGX101, a TM4SF1-directed tubulin inhibitor conjugate, in combination with immune checkpoint inhibitors.

Shou-Ching Jaminet, Paul Jaminet, **Glen J. Weiss**

Angiex, Cambridge, MA

Introduction: TM4SF1 (Transmembrane-4 L-Six-Family-Member-1) is an endothelial marker with critical roles in angiogenesis, as well as a tumor cell antigen that contributes significantly to invasion and metastasis. TM4SF1 is upregulated 20-fold in angiogenic tumor vascular endothelium compared to normal vasculature endothelium and exhibits a unique nuclear internalization pathway. AGX101 is a novel tubulin inhibitor conjugate specifically directed against TM4SF1, delivering a potent maytansinoid payload directly to the nucleus of cells within the tumor microenvironment resulting in three mechanisms of action (MoAs): (1) activation of tumor immune surveillance, (2) tumor blood supply deprivation, and (3) direct tumor cell killing.
Methods: TM4SF1 expression was assessed using immunohistochemistry. Safety and pharmacokinetics of AGX101 were evaluated in non-human primates (NHP), with escalating doses to determine the highest non-severely toxic dose (HNSTD). Efficacy studies were also conducted in mouse models, enabling assessment of the minimum effective dose (MED) needed to engage each of the three MoAs. The combination of HNSTD and MED enables calculation of a therapeutic index (TI). The potential for synergy with immune checkpoint inhibitors (ICIs) was also investigated.
Results: Notable cancers with high TM4SF1 scoring intensity include lung cancer, kidney cancer, ovarian cancer, GI cancers, and breast cancer. In NHP, AGX101 exhibited a favorable safety profile.In preclinical efficacy studies, monotherapy demonstrated robust efficacy through each of the three MoAs in mouse syngeneic models including CT26 colon carcinoma and human tumor xenograft models including MIA PaCa-2 pancreatic cancer. Measured by exposure, TI was large. In syngeneic mouse models the effects of ICIs were potentiated by the AGX101 murine surrogate AGXB01, suggesting potential synergy. High response rates (RR) were achieved including CT26 with 71% RR for AGXB01+anti-CTLA-4 antibody vs 13% for anti-CTLA-4 alone; Renca mouse renal cancer model with 80% RR for AGXB01+anti-CTLA-4 antibody vs 20% for anti-CTLA-4 alone. In B16F10 mouse melanoma, a non-responsive model, AGXB01+ anti-PD-1 antibody or anti-CTLA-4 antibody ~doubled survival time vs either monotherapy of AGXB01 or anti-PD-1 antibody or anti-CTLA-4 antibody. In rechallenge experiments, 38 of 39 mice that had been rechallenged after tumor-free responses successfully eradicated new tumors without drug retreatment, demonstrating a durable immune response.
Conclusion: AGX101 represents a promising new approach in cancer therapy. The preclinical data suggest that AGX101 could provide a significant therapeutic benefit by novel and differentiated mechanisms of action, namely selectively targeting the tumor vasculature and potentiating ICIs. Further clinical development of AGX101 is ongoing.

#3799 HER3 inhibition sensitizes metastatic colorectal and pancreatic cancer to immunotherapy.

Chao Wei[1], Moeez Ghani Rathore[2], Elizabeth Bryson[1], Kimberly Curry[3], Jennifer Baek[3], Jordan M. Winter[4], Rui Wang[3]

[1]Case Western Reserve University School of Medicine, Cleveland, OH,[2]Case Comprehensive Cancer Center, Cleveland, OH,[3]Case Western Reserve University, Cleveland, OH,[4]UH Cleveland Medical Center, Cleveland, OH

INTRODUCTION: Metastatic colorectal cancer (mCRC) and pancreatic cancer (mPC) demonstrate 5-year survival rates of 14% and 3%, respectively, with over 70% patients developing distant metastases in the liver. Immune checkpoint inhibitors (ICIs) exhibit significant efficacy in some solid tumors and MSI CRC but have limited therapeutic benefit in MSS mCRC/mPC. This project aims to identify potential novel combination strategies to overcome ICIs resistance in mCRC/mPC. We previously discovered that liver endothelial cells activate HER3 signaling in cancer cells through NRG1 and LRG1 ligands, promoting metastatic growth via distinct AKT/RSK pathways. This study investigates whether inhibiting HER3 pathway can enhance immunotherapy efficacy in mCRC/mPC, especially MSS tumors.

METHODS: Metabolic changes in CRC/PC cells and tumors were first determined by LC-MS and ELISA for key metabolites, and then further assessed by *in vitro* assays, including Seahorse FX and TMRE, in the context of HER3 activation and/or inhibition. Phosphorylation activation of HER3 and downstream metabolic enzymes were evaluated by Western blotting and IHC staining using murine/patient tumor tissues. We developed syngeneic, orthotopic CRC/PC liver metastases by hepatic injection of murine CRC and PC cells (MSI or MSS), and assessed T cell infiltration and activation by IHC staining and flow cytometry. More importantly, therapeutic efficacy was assessed by treating these models with HER3 inhibitor sapitinib and/or anti-PD-1 antibodies.

RESULTS: LC-MS analysis revealed that mCRC/mPC exhibited significantly elevated glycolytic metabolites compared to primary tumors, with HER3 inhibition reversing this metabolic reprogramming. HER3 activation enhanced phosphofructokinase 2 (PFK2)-S483 phosphorylation and increased lactate secretion in CRC/PC cells. In murine CRC/PC liver metastases, *HER3* KO tumors showed decreased lactate, which reduced exhaustion of $CD8^+$ T cells, determined by decreased expression of TOX, and increased cytotoxic $CD8^+$ T cells, determined by increased Granzyme B levels. Most importantly, the combination of HER3 inhibition with anti-PD-1 significantly extended survival in CRC/PC liver metastases (both MSI and MSS), and achieved ~40% complete response rate, which is markedly superior to monotherapies.

CONCLUSIONS: We identify a novel HER3-PFK2-lactate metabolic axis that promotes immunosuppression in CRC/PC liver metastases. Targeting this pathway sensitizes CRC/PC liver metastases to checkpoint blockade, offering a promising strategy to extend immunotherapy benefits beyond the limited patient population currently responsive to ICIs.

#3800 Combinational effects of VC2-GMCSF oncolytic virus and paclitaxel in end-stage breast cancer animal model.

Reza Ghavimi, Leila Rahimian, Vladimir Chouljenko, Harikrishnan Mohan, Ojasvi Dutta, Md Mehedi Hasan, Jeongha Lee, Minori Kojima, Jose Sezar Menk, Konstantin Kousoulas

Louisiana State University, Baton Rouge, LA

Resistance and metastasis continue to make breast cancer a clinical challenge. VC2-GM-CSF drives antitumor immunity; paclitaxel remodels tumor environment to boost immune infiltration. Thus, combined use may yield superior therapeutic benefit over the use of either agent alone. This study investigates the potential synergistic interactions of VC2-GM-CSF with paclitaxel using the murine 4T1 breast cancer model in vitro and in vivo. In vitro, 4T1 cells were treated with paclitaxel alone or in combination with VC2-GM-CSF, and cell viability was assessed by MTT assay. Viral entry was quantified using a flow-cytometric assay. We further explored the in vivo antitumor effect of combined VC2-GM-CSF and paclitaxel in an orthotopic 4T1 stage IV metastatic model of breast cancer. Established 4T1 tumors in BALB/c mice were treated intratumorally with VC2-GM-CSF combined with paclitaxel. On day 31, tumors and lungs were collected for histopathological evaluation. Flow cytometric quantification of lymphocytes infiltrating the tumors was performed for $CD45^+$, $CD3^+$, $CD4^+$, and $CD8^+$ cells. The combined treatment was substantially more effective in inducing dose-dependent decreases in the viability of 4T1 cells and cell death than either single therapy in vitro. Flow cytometric entry assays showed that paclitaxel does not impair the entry of VC2-GM-CSF into cancer cells. In vivo, the combination significantly reduced primary tumor growth compared with the control treatment. Flow cytometry and immunohistochemistry analyses indicated increased T-cell infiltration in tumors after combination therapy. Together, these results demonstrate an enhanced antitumor effect resulting from the complementary cytotoxic and immunomodulatory mechanisms of paclitaxel and oncolytic virotherapy.

#3801 Synergistic therapy by combination of a plant virus immunomodulator and IL-12 against murine ovarian cancer.

Xinyi Deng[1], Jessica Fernanda Affonso de Oliveira[2], Nicole F. Steinmetz[1]

[1]UC San Diego, La Jolla, CA,[2]University of California San Diego - UCSD, San Diego, CA

Cowpea Mosaic Virus (CPMV) is an immunostimulatory agent that can induce antitumor immunity by reversing the immunosuppressive tumor microenvironment (TME) upon intratumoral treatment. In situ injection of CPMV activates and recruits innate immune cells which initiate tumor cell killing and antigen processing, ultimately launching systemic and adaptive antitumoral immunity. IL-12 is a promising proinflammatory cytokine that facilitates antigen processing and promotes T cell proliferation. CPMV primarily activates innate immune cells while IL-12 plays a key role in the adaptive immune response; therefore, we hypothesized that the synergistic combination of CPMV and IL-12 would be beneficial for reducing tumor burden. We tested our study using a murine ovarian carcinoma model. Mice were inoculated with bioluminescent tumor cells. Tumor burden was monitored using bioluminescence, body weight, and circumference. Survival was established based on humane endpoints. Our data show that the combination of CPMV + IL-12 outperforms the single-arm treatment. Robust efficacy is demonstrated for the combination group. In ongoing studies, we are deciphering the mechanism of action through immunological investigation. This work was funded in part through grants from NIH: R01 CA224505 and R01 CA274640.

#3802 Adaptive cd73 upregulation undermines parp inhibitor efficacy and creates a therapeutic opportunity for combined blockade in advanced prostate cancer.

Ping xie[1], Jie Fan[1], Hui Tang[1], Longzhen Song[2], Bin Zhang[1]

[1]Northwestern University Feinberg School of Medicine, Chicago, IL,[2]Department Medicine, Northwestern University Feinberg School of Medicine, Chicago, IL

Metastatic castration-resistant prostate cancer (mCRPC) remains a major cause of cancer-related mortality in the male population. While poly(ADP-ribose) polymeraseinhibitors (PARPi) are approved for selected mCRPC patients with homologous recombination repair (HRR) deficiencies, combinations with PD-1/PD-L1 inhibitors immunotherapy have demonstrated limited efficacy in unselected populations. To investigate the immunomodulatory effects of PARPi in an unbiased manner, we performed bulk RNA sequencing on HRR-proficient MyC-CaP cells treated with PARPi Olaparib or control vehicle. Pathway enrichment analysis revealed a marked upregulation of CD73 (NT5E), an emerging immune checkpoint ectoenzyme that generates extracellular adenosine, suggesting an adaptive mechanism that undermines PARPi efficacy and enables unwanted immunosuppression. CD73 induction by PARPi was confirmed in both human and mouse prostate cancer cell lines, with more pronounced effects in the HRR-compromised PTEN knock-out (KO) cells. Mechanistically, Olaparib-driven CD73 expression was mediated through the DNA damage-activated ATR-CHEK1-IRF1 and TGF-β1-AKT signaling pathways. Concurrently, PARPi enhanced tumor cell immunogenicity by activating the type I interferon pathway and antigen presentation machinery. *In vivo*, combining Olaparib with CD73 blockade therapy delayed tumor growth, improved T-cell infiltration, and augmented antigen-specific $CD8^+$ T-cell effector function across HRR-proficient and PTEN KO prostate cancer models. These findings highlight PARPi-induced CD73 upregulation as a novel resistance mechanism and support PARPi plus CD73 blockade as a promising therapeutic strategy for mCRPC, irrespective of HRR status.

#3803 The unique presentation of four immunotherapy toxicities in a single patient.

Orianna Guarisma-Lugo[1], Roderick Brice[1], Samuel Ramirez[1], Winston W. Tan[2]

[1]Hematology-Oncology, Mayo Clinic Florida, Jacksonville, FL,[2]Assistant Professor, Dept. of Hem./Onc., Mayo Clinic Florida, Jacksonville, FL

Medical advancements with immunotherapy have cured some patients with previously incurable metastatic renal cancer. We present the case of a 74-year-old male metastatic renal cancer patient who received only one dose of the combination of ipilimumab with nivolumab. In response to his treatment, he developed autoimmune hepatitis, myasthenia, myositis, and myocarditis. Although these serious side effects are considered to rarely occur, they can quickly become life-threatening and even fatal. These immune-related adverse events (irAEs) may further develop into secondary life-threatening symptoms such as respiratory failure due to advanced myasthenia; cardiotoxicity of myocarditis with possible cardiogenic shock, cardiac arrest, and severe heart failure; and liver failure consequently from autoimmune hepatitis. Furthermore, the ability for physicians to detect immunotherapy toxicity early is extremely important in intervening in a timely manner to avoid lethal conditions for the patient. With patients receiving immunotherapy, communication, collaboration, and multidisciplinary care are essential. Any subtle or sudden changes in their health status or symptoms should prompt further investigation. It is our purpose to highlight this patient to raise awareness of toxicity to significantly reduce the fatality rates and increase the therapy’s success rate in the years to come.

#3804 Engineering CAR macrophages in combination with anti-tumor therapies to suppress brain metastasis.

Shih-Ying Wu, Abhishek Tyagi, Eleanor Cecile Smith, Ravindra Pramod Deshpande, Jee Won Kim, Kounosuke Watabe

Wake Forest University School of Medicine, Winston Salem, NC

Brain metastases pose a significant clinical challenge for patients with HER2-positive breast cancer, with up to 50% of those with metastatic disease developing CNS involvement. Although HER2-targeted therapies such as trastuzumab deruxtecan (T-DXd) have improved systemic outcomes, their limited penetration across the blood-brain barrier (BBB) leaves the brain as a sanctuary site for recurrence. Innovative strategies are urgently needed to overcome BBB restrictions and effectively treat HER2-positive brain metastases.To address this, we leveraged the unique ability of macrophages to cross the BBB and perform phagocytic and immune-modulatory functions. We engineered chimeric antigen receptor macrophages (CARMA) to express tumor antigen-specific scFv and activate down-stream signaling to enhance anti-tumor immunity. We hypothesize that CARMA can penetrate the BBB, exert potent anti-tumor activity, and synergize with tumor antigen-targeted therapy and T-DXd to improve outcomes in brain metastases. In preclinical models, CARMA demonstrated strong antigen-specific phagocytosis and significant suppression of brain metastases. Notably, CARMA exhibited minimal neurotoxicity compared to CAR-T cells and induced a bystander killing effect mediated by cytokines upregulation upon tumor antigen engagement.To further enhance efficacy, we evaluated a combination strategy of CARMA and T-DXd to synergize antibody-dependent cellular cytotoxicity (ADCC) with macrophage-mediated phagocytosis. Our results showed that this combination dramatically suppressed brain metastases. These findings position CARMA as a promising immunotherapy platform for HER2-positive breast cancer brain metastases, offering potential to overcome BBB limitations and improve patient outcomes through multi-modal synergy.

#3805 Enhancing anti-tumor immunity via *in vivo* LNP delivery of a universal chimeric adapter protein to activate innate immune cells through T cell engagers.

Kevin Carbajal, Warren Anderson, Matthias Schroff, **Maximilian Richter**

Inceptor Bio, Durham, NC

T cell engagers (TCEs) have achieved remarkable successes both in liquid and solid tumors. However, relapses tend to occur in a significant fraction of patients, driven by antigen escape or T cell exhaustion. Currently, TCEs are unable to engage innate immune responses and thereby fail to leverage the innate immune system's crucial support functions, such as inducing a pro-inflammatory environment and promoting antigen spread and T cell licensing against tumor neoantigens.
Here we describe a chimeric adaptor protein that renders innate immune cells engageable by existing T cell engagers. This T cell engager receptor (TCE-R) is comprised of an extracellular domain that is recognized by all CD3-targeting TCEs, and a set of intracellular signaling domains that drive innate cell effector function upon TCE binding. Following initial administration of the TCE alone to induce tumor debulking, TCE-R is delivered in vivo using mRNA encapsulated in a lipid nanoparticle (LNP) allowing trafficking of pro-inflammatory innate immune cells to the tumor, inducing a broader TCE-driven anti-tumor response.
In a monocyte cell line stably expressing TCE-R, we have demonstrated TCE-mediated phagocytosis of target cancer cells as well as TCE-driven induction of pro-inflammatory signaling pathways. Further, TCE-R delivered as an LNP-encapsulated mRNA to primary human macrophages and dendritic cells in vitro resulted in expression of TCE-R on the cell surface, demonstrating the ability to deliver the transgene to relevant lineages of the innate immune system. Lastly, in vivo delivery of TCE-R LNP to innate immune cells in immune competent Balb/c and immunocompromised NSG mice has been demonstrated through surface expression of the human TCE-R on multiple myeloid cell lineages.
Taken together, our data lay the foundation to endow any anti-CD3 TCE with the ability to engage innate immune cells, recruit them to the tumor site, activate them in situ, and to leverage new effector functions to aid, broaden, and expand TCE-driven T cell responses ultimately leading to antigen spread, T cell licensing and durable remission.

#3807 Engineering and preclinical development of a differentiated EGFR/PDL1 bispecific ADC for the targeted therapy of solid tumors.

Liang Zhu, Chen Chuan, Mei Tian, Dandan Liu, Jiyuan Tian, Lisha Dong, Yongxin Shang, Rongmei Yan, Kezhen Ye, Liang Tian, Jian Peng, Zhenping Zhu

Earendil Labs, Wilmington, DE

Both EGFR and PDL1 are well-established therapeutic targets for a broad range of malignancies. Nevertheless, their therapeutic efficacy remain limited, as many patients are either refractory to or develop resistance during the course of treatment. EGFR and PDL1 are frequently co-expressed in multiple tumors, where they play key roles in promoting tumor progression and immune evasion. Notably, PDL1 expression is modulated by EGFR signaling, and the significant crosstalk between EGFR and PDL1 signaling has been reported. In this study, we developed a bispecific antibody (bsAb) targeting both EGFR and PDL1. The bsAb demonstrated enhanced binding avidity towards PDL1+/EGFR+ cancer cells, with higher efficiency of internalization, and more potent EGFR-directed blockade of PD1/PDL1 interaction. Several bsAb ADCs were generated by conjugating with various cytotoxic payloads. *In vitro* data demonstrated that the lead bsADC induced potent antitumor activity and strong bystander killing activity. Importantly, no Immunotoxicity was observed on PDL1+ human antigen-presenting cells. *In vivo* efficacy studies demonstrated that the lead bsADC achieved superior antitumor activity compared with MRG003 analog (an anti-EGFR ADC) and the clinical-stage PDL1V analog (an anti-PDL1 ADC) in multiple CDX models.

#3808 Regulation of PD-L1$^+$ tumor associated macrophages by collagen expressing myCAFs and luminal progenitors in endocrine-resistant breast cancer.

Nirmal Das[1], Cheng-Han Hsieh[2], Rumela Chakrabarti[2]

[1]University of Miami Miller School of Medicine, Miami, FL,[2]Department of surgery, University of Miami Miller School of Medicine, Miami, FL

Endocrine resistance is a major clinical obstacle that undermines the effectiveness of hormone-based therapies and drives disease progression. Around 15-20% of ER+ breast cancers are intrinsically endocrine resistant and an additional 40-50% acquire resistant during treatment, leading to metastatic progression. The five-year survival rate of these patients drops to 20-25%, while many of them progress to TNBC, a very aggressive subset of breast cancer.Recently, we demonstrated that PD-L1$^+$ tumor-associated macrophages (TAMs) are a central mediator for endocrine resistance and are recruited by Dll1-mediated Notch signaling. However, regulation of the PD-L1$^\pm$TAMs in endocrine resistance is not completely understood. Single-cell RNA sequencing (scRNA-seq) followed by cell chat communication analysis depicts that PD-L1$^+$ TAMs are regulated by myCAFs (Myofibroblasts, a type of cancer-associated fibroblasts) and LPs (Luminal progenitors). CD61+ luminal progenitor cells are linked to tumor heterogeneity and enriched with tumorigenic potential, serving as a cell of origin for breast cancers. Mechanistic studies reveal myCAFs are enriched in collagen, which is further corroborated in endocrine-resistant breast cancer patients' samples and ER+ mouse mammary tumors stained with trichrome and SMA staining. Closer investigation also shows that these SMA+ myCAFs are in close proximity to PD-L1$^+$ TAMs, aiding juxtracrine signaling. Further analysis highlights that myCAFs which are high in collagen signaling, are mediating interaction with PD-L1$^+$ TAMs through APP-CD74 and Col1a1/Col4a1/Col4a2/Col6a3 crosstalk. Detailed analysis on CD61$^+$ LPs, on the other hand, by scRNA-seq show that LPs crosstalk to PDL1$^+$ TAM through APP-CD74 signaling as well. APP (Amyloid precursor protein) is a transmembrane protein that is often correlated with worse clinical outcomes. Functionally, PD-L1$^+$ TAMs augments LP activity, as seen by increasing sphere number. Detailed investigation shows that these PD-L1$^+$TAMs are CD74$^+$ and IFN-γ responsive. Moreover, co-culture of PD-L1$^+$ TAMs treated with FDA approved drug Milatuzumab, a CD74 inhibitor, resulted in fewer and smaller tumor spheres, underscoring the crucial function of CD74 in mediating this crosstalk. Analysis of downstream regulators confirm that CD8$^+$ T cells are exhausted, suggesting a strongly immune-suppressive TME. Together, we identified a complex cell signaling network between myCAF-luminal progenitor expressing APP and collagens with CD74$^+$/PD-L1$^+$ TAMs in endocrine resistant tumors, identifying novel actionable vulnerabilities in these breast cancer patients.

#3809 Bax activation promotes immune activity and synergizes with PD-L1 blockade immunotherapy against mutant KRAS-driven lung cancer.

Abu Syed Md Anisuzzaman, **Xingming Deng**

Emory University, Atlanta, GA

The mutant KRAS-driven non-small cell lung cancers (NSCLC) frequently co-occurring mutations of LKB1 or p53 exhibit varying degrees of resistance to conventional treatments and anti-PD-L1 immunotherapy. It is urgently needed to develop new strategies to improve the outcome of these diseases. We have recently discovered that small molecule Bax activator CYD-2-11 targets the S184 structural pocket in the C-terminal tail of Bax, thereby activating its proapoptotic activity with potent antitumor activity against lung cancer. Here we further found that, in addition to apoptotic cell death, CYD-2-11 also induces cytosolic DNA and activation of cGAS-STING-TBK1-IRF3 pathway, thereby upregulating PD-L1 and producing interferons (IFN alpha and IFN beta) and chemokines (CCL5 and CXCL10). The combination of CYD-2-11 with anti-PD-L1 synergistically enhances intratumor CD3+ total T cells, CD8+ cytotoxic T cells and CD44+ memory/effector T-cells in association with reduction of regulatory T cells (Tregs), exhausted $CD8^{+}$T cells and $Gr\text{-}1^{+}$ $CD11b^{+}$ and $CD49d^{+}$ MDSCs, which contribute to increased immunity leading to the synergistic suppression of lung tumor growth and prolonged survival in genetically engineered mutant KRAS-driven lung cancer mouse models that are resistant to anti-PD-L1 immunotherapy. These findings provide preclinical evidence for the mechanism-driven combination of small molecule Bax activator with anti-PD-L1 as an effective strategy for lung cancer therapy, especially for those mutant KRAS-driven lung cancers that are resistant to PD-L1 blockade immunotherapy.

#3810 Intratumoral (IT) ruxotemitide (LTX-315) in combination with pembrolizumab in patients with unresectable advanced melanoma refractory to PD-1/PD-L1 therapy: Final results from the ATLAS-IT-05 study.

Stephane Dalle[1], Adi Diab[2], John M. Kirkwood[3], Miguel F. Sanmamed[4], Laurent Mortier[5], Marta Nyakas[6], Thomas Urban Marron[7], Maciej Gil[8], Oystein Rekdal[8], Karim A. Benhadji[8], Caroline Robert[9]

[1]Centre Hospitalier Universitaire de Lyon, Lyon, France,[2]UT MD Anderson Cancer Center, Houston, TX,[3]Vice Chairman For Clinical Res., Dept. of Medicine, University of Pittsburgh Medical Center, Pittsburgh, PA,[4]Clinica Universidad de Navarra, Pamplona, Spain,[5]Hopital Claude-Huriez, Universite de Lille, Lille, Lille, France,[6]Oncology, Oslo University Hospital, Oslo, Norway,[7]The Tisch Cancer Institute, New York, NY,[8]Lytix Biopharma AS, Oslo, Norway,[9]INSERM U981 (Gustave Roussy), Fontenay aux Roses, France

Background: Advanced unresectable cutaneous melanoma refractory to prior immunotherapy is associated with poor prognosis and limited treatment options. Ruxotemitide, an oncolytic peptide, induces immunogenic cell death and remodels the tumor microenvironment to enhance antitumor immunity. Preclinical and early clinical data support synergistic activity with PD-1 blockade. This Phase 2 study evaluated intratumoral (IT) ruxotemitide in combination with pembrolizumab in patients with unresectable advanced or metastatic melanoma accessible for IT injection after prior checkpoint inhibitor (CPI) failure.
Methods: This was an open-label, single-arm Phase 2 study enrolling adults with stage IIIB-IV (M1b) cutaneous melanoma and at least one injectable lesion (cutaneous, subcutaneous, lymph node, or intramuscular). Patients received IT ruxotemitide (up to seven injections during the first 29 days) in combination with pembrolizumab 200 mg IV every 3 weeks until disease progression or for up to 24 months. The primary endpoint was objective response rate (ORR) per RECIST v1.1. Secondary endpoints included duration of response (DoR), progression-free survival (PFS), and safety.
Results: Twenty-three patients were enrolled, with a median age of 68 years (range, 42-91 years). Over half (52.1%) of pts had received three or more prior lines of therapy, and all had previous CPI treatment. Twenty-two patients were evaluable for efficacy. ORR was 13.6% (80% CI, 5.1-27.9). The clinical benefit rate was 36.4%. All responses were durable, lasting more than 24 months. Median PFS was 6.3 months. The safety profile was consistent with known effects of IT immunotherapy and pembrolizumab. The most common treatment emergent adverse events (TEAEs) were injection-site reactions (95.7%), fatigue (30%), pruritus (26.1%), hypotension (26.1%), and anemia (21.7%). No TEAEs led to treatment discontinuation.
Conclusions: IT ruxotemitide plus pembrolizumab demonstrated durable antitumor activity and manageable safety in heavily pretreated patients with CPI-refractory advanced or metastatic melanoma with injectable disease. These findings support further clinical evaluation of this combination in melanoma.

#3811 Exploring immunomodulatory tumor-derived vaccines targeting triple negative breast cancer cells.

Marcio C. Bajgelman[1], Karina Thomaz[1], Daniela Mizobuti[1], Susana Ramalho[2], Sophie Derchain[1]

[1]Brazilian Biosciences National Laboratory, Brazilian Center for Research in Energy and Materials, Campinas, Brazil,[2]Women's Hospital - CAISM, University of Campinas, Campinas, Brazil

Breast cancer remains a major public health concern and is the leading cause of cancer-related deaths among women. Triple-negative breast cancer (TNBC) is the subtype with the poorest prognosis, and due to its phenotypic characteristics, no effective treatment is currently available for most diagnosed patients. This underscores the urgent need for novel therapeutic strategies. In this project, we explore antitumor vaccines generated from genetically modified TNBC cells expressing the immunomodulatory ligands TNFSF 4-1BBL and OX-40L. TNFSF ligands have the ability to costimulate T cells, enhancing their activation and proliferation. Previous studies from our group demonstrated that such vaccine combinations can increase T-cell proliferation, boost interferon-gamma production, inhibit regulatory T cells, and enhance T cell-mediated antitumor cytotoxicity, leading to a long term antitumor immunity and preventing tumor recurrence in cured and rechallenged animal models. Here, we generated antitumor vaccines derived from human TNBC cells, which were obtained after neoadjuvant chemotherapy from a patient sample provided by the CAISM-UNICAMP biobank. These cells were genetically engineered to express OX-40L and 4-1BBL, and the resulting tumor cell-based vaccines were evaluated in vitro for their antitumor potential. We observed that the vaccines enhanced immune responses in T lymphocytes from both autologous and allogeneic TNBC vaccines. Experimental assays confirmed that these tumor-derived vaccines induced elevated production of immunomodulatory cytokines and improved the antitumor T cell-mediated cytotoxicity. Our findings support the potential of this strategy as a promising immunotherapy approach for TNBC.

#3812 A novel 'Seed-and-Boost' immunotherapy drives potent TCR-T cell expansion, tumor infiltration, and durable tumor control.

Kar Wai Tan[1], Kan Xing Wu[1], Jin Wei Tan[1], Melissa Wirawan[1], Yovita Purwanti[1], Ana Dios[2], Fan Zhao[2], Natasha Girgis[2], Alessandra Nardin[1], Evan W. Newell[3], Anish Suri[2], Steven N. Quayle[2], **Michael Fehlings**[1]

[1]ImmunoScape Pte Ltd, Singapore, Singapore,[2]Cue Biopharma Inc., Boston, MA,[3]Fred Hutchinson Cancer Center, Seattle, WA

Background: While TCR-engineered T cell therapies show promise in solid tumors, long-term efficacy is limited by insufficient in vivo expansion and persistence. Current strategies also face significant challenges in manufacturing and clinical management. We present a novel strategy combining low-dose TCR-T cells (Seed) with a TCR-targeted cytokine biologic (Boost) to drive selective in vivo expansion, enhance tumor infiltration, and sustain tumor-specific responses. We demonstrate this by targeting WT1-positive solid tumors using WT1-specific TCR-T cells plus CUE-102, a clinically validated ImmunoSTAT™ fusion protein enabling controlled TCR engagement and delivery of IL-2 to WT1-specific T cells.

Methods: We generated a highly specific dual HLA (HLA-A:02:01 and HLA-A:02:07) targeting TCR against the $WT1_{37-45}$ antigen. Preclinical characterization of this TCR, engineered into human primary T cells, included potency assessment against various WT1-positive cancer cell lines and testing for antigen cross-reactivity and HLA alloreactivity. WT1-specific TCR-T cells were combined with CUE-102 to assess specific TCR-T cell expansion, anti-tumor efficacy, tumor infiltration, and long-term efficacy both in vitro and in various xenograft models using WT1-expressing ovarian and pancreatic cell lines.

Results: WT1-specific TCR-T cells demonstrated potent in vitro cytotoxicity against HLA-A*02:01 and HLA-A*02:07 WT1-positive cancer cell lines. In addition, we observed a favorable safety profile with no antigen cross-reactivity or HLA alloreactivity. In combination with CUE-102, we observed high potency and sustained anti-tumor cell efficacy at very low effector to target cell ratios and a vigorous selective in vivo expansion of WT1-specific TCR-T cells. In xenograft models of WT1-positive ovarian and pancreatic cancers, the combination therapy led to significantly higher numbers of circulating TCR-T cells, enhanced tumor infiltration, and robust tumor control even at very low TCR-T cell doses, compared to TCR-T cell monotherapy. Furthermore, in animals with higher tumor burden, the combined treatment resulted in sustained tumor regression and significantly extended survival.

Conclusion: Our data demonstrate that boosting with CUE-102 triggers robust in vivo expansion and activation of engineered TCR-T cells seed, resulting in effective anti-tumor responses, T cell persistence, and prolonged survival without additional cell engineering. This approach offers a potentially transformative solution for long-term benefits in solid tumor patients and can address cell therapy manufacturing and clinical management challenges by enabling the infusion of fewer seed TCR-T cells, eliminating the need for systemic IL-2 administration, and potentially avoiding toxic conditioning regimens.

#3813 Synergistic immunomodulation by Tumor Treating Fields combined with immunotherapy across solid tumors: A systematic review with translational relevance to pancreatic ductal adenocarcinoma..

Douaa Albelal, Hari Krishnareddy Rachamala, Hani Babiker

Hematology and Oncology, Mayo Clinic Florida, Jacksonville, FL

Background: Pancreatic ductal adenocarcinoma (PDAC) remains highly lethal due to aggressive biology, stromal desmoplasia, and profound immunotherapy resistance. Tumor Treating Fields (TTFields) disrupt mitosis and induce immunogenic cell death (ICD), type I interferon signaling, and microenvironment remodeling, providing a rationale for combining TTFields with immune checkpoint inhibition. This is the first systematic review to comprehensively synthesize mechanistic and clinical evidence for TTFields immunotherapy combinations across solid tumors, with emphasis on their translation relevance to PDAC.
Methods: A systematic search of PubMed, Scopus, Web of Science, Embase, Cochrane Library, and ClinicalTrials.gov was conducted through October 26, 2025, following PRISMA 2020 guidelines. Eligible studies evaluated TTFields combined with immunotherapy. Two reviewers independently screened and extracted data using Covidence. Evidence was summarized narratively by tumor type, study design, and immunotherapeutic approach.
Results: Thirty-seven studies met criteria, including preclinical and clinical investigations across glioblastoma, NSCLC, mesothelioma, PDAC, and other tumors. Preclinical models consistently showed that TTFields trigger ICD hallmarks such as calreticulin exposure, HMGB1 and ATP release, and activate STING/type I interferon pathways, enhancing dendritic-cell maturation and T-cell and NK-cell function. Across in vivo models, TTFields combined with PD-1 or CTLA-4 blockade, vaccines, or other immunotherapies reduced tumor growth and increased lymphocyte infiltration. Clinical evidence, although early-phase and heterogeneous, indicates the combination is feasible, with toxicity dominated by low-grade skin reactions and no excess immune-related adverse events. In glioblastoma, adding TTFields to pembrolizumab and temozolomide showed numerically improved survival. The LUNAR phase 3 trial in metastatic NSCLC demonstrated an overall survival advantage when TTFields were added to systemic therapy, including immunotherapy. Evidence in PDAC remains preliminary, but the ongoing PANOVA-4 study combining TTFields with atezolizumab and chemotherapy highlights emerging translational relevance.
Conclusions: TTFields enhance antitumor immunity when combined with immunotherapy across solid tumors. In PDAC, these mechanisms may help counteract the immunosuppressive microenvironment. Ongoing gastrointestinal trials will clarify optimal combinations, biomarkers of response, and the clinical role of TTFields-based immunomodulation.

#3817 Fusions and rearrangement detection in gastrointestinal and lung tumors leveraging low-pass whole-genome sequencing based Hi-C chemistry.

Darren S. Sigal[1], David Jacob Hermel[2], Alex R. Hastie[3], Anthony Schmitt[3]

[1]Scripps Clinic and Scripps Cancer Center, La Jolla, CA,[2]Scripps Health, La Jolla, CA,[3]Arima Genomics, San Diego, CA

Introduction: Molecular profiling in solid tumors has enabled the detection of actionable oncogenic drivers that guide targeted therapy. While point mutations in genes such as *EGFR* and *KRAS* are well established, gene fusions that activate key signaling pathways have become increasingly important therapeutic targets. Although RNA sequencing remains the gold standard for fusion detection, clinically relevant events are still missed. This study evaluates the ability of Hi-C whole-genome sequencing to improve detection of actionable fusions and structural rearrangements in solid tumors.
Methods: All cases had molecular testing such as FISH, DNA panel sequencing, and/or RNA transcriptome sequencing as part of clinical care. Hi-C sequencing is a novel whole-genome DNA assay optimized for structural variant detection from FFPE tissues. Its chemistry captures linked read pairs that originate near each other in both three-dimensional and linear genomic space. This increases breakpoint coverage, amplifies rearrangement signals, and allows detection of fusions obscured by non-unique or complex genomic regions.
Results: A total of 60 solid tumor cases were evaluated, the majority of which were gastrointestinal—including pancreatic adenocarcinoma, gastric cancer, and colorectal cancer. Hi-C sequencing was first applied to detect known fusions and rearrangements (12 cases) like *ALK, FGFR2, ROS1, NTRK3,* with 100% concordance with FISH (8 cases), whole transcriptome (1 cases), and DNA panel sequencing (3 cases), and able to detect fusion partner in all cases. Next it was used to successfully identify actionable or potentially actionable structural variants across the cohort (48 cases) which had no targetable driver genes detected by NGS. Hi-C detected targetable gene fusions involving *NRG1* in three cases, and *PRKCB* in another case. Additional rearrangements were detected proximally to genes whose overexpression may be linked to tumor progression like *NRG1, KRAS, NOTCH3*, and *CHST9*.
Conclusions: Hi-C sequencing shows strong potential as a complementary tool for molecular classification of gastrointestinal and other solid tumors. By detecting gene fusions and rearrangements—including those missed by conventional testing—Hi-C may expand the number of patients who can be matched to targeted therapies.

#3818 A robust RNA-seq solution for severely degraded FFPE samples: The PredicineWTS Tissue NGS platform.

Min Wang, Yasser Abdelrahman, Guanglong Jiang, Yong Huang, Pan Du, Binggang Xiang

Predicine, Inc., Hayward, CA

Background: Formalin-fixed, paraffin-embedded (FFPE) tissues remain essential resources for cancer research and the discovery of clinically relevant biomarkers. However, RNA extracted from FFPE samples is often highly degraded, chemically modified, and fragmented, posing major challenges for transcriptomic analyses, including gene expression profiling and RNA fusion detection. To address the need for a robust RNA-seq method capable of handling severely degraded RNA, we developed the PredicineWTS Tissue platform, which integrates optimized extraction chemistry with a proprietary RNA-seq pipeline tailored for FFPE RNA.
Methods: The PredicineWTS Tissue platform employs a proprietary extraction protocol that simultaneously isolates DNA and RNA from a single FFPE section, maximizing material utility for multi-omics applications. The RNA-seq workflow supports inputs as low as 10 ng and tolerates extreme degradation, including DV200 values down to 10%. A customized bioinformatics pipeline enables comprehensive expression profiling and detection of RNA fusions and splicing variants. DNA isolated during extraction is preserved for downstream genomic assays, enabling integrated analyses. Performance validation was performed using commercial reference materials.
Results: The platform showed strong performance on heavily degraded FFPE RNA. High-quality libraries were generated from samples with DV200 values as low as 10%, achieving approximately 93% uniquely mapped reads, 90% exonic reads, and detection of ~19,000 genes. Expression accuracy correlated strongly with an independent third-party company's results (Pearson $r \geq 0.94$). Fusion detection sensitivity was evaluated using titrated Seraseq material (50%, 20%, 10%, and 5% tumor purity), and all expected fusions were detected down to the 10% tumor purity, supporting sensitivity for low-abundance events relevant to cancer biomarker discovery. DNA recovered during extraction showed yield and quality comparable to leading extraction methods, further supporting workflow versatility.
Conclusion: PredicineWTS Tissue assay provides a powerful and reliable RNA-seq solution of severely degraded FFPE samples. By enabling robust expression profiling and sensitive fusion detection at low RNA quality and input, the platform advances biomarker discovery and supports integrated multi-omics studies. Its performance with archival and challenging FFPE material positions it as a valuable technology for precision oncology and translational research.

#3819 Validation of TruSight Oncology Comprehensive for detecting and reporting clinically relevant mutations.

Mauro Chavez, Silvia Chan, Stewart Comer, Gajalakshmi Dakshinamoorthy, Dan Schmidt, Giang Howard, Lisa Tulathimutte, Martin Martchovsky, Carey Davis, Eileen de Feo, Denise Perry

Illumina Lab Services, Illumina, Inc., San Diego, CA

Comprehensive genomic profiling (CGP) is transforming cancer diagnostics by enabling the detection of a wide range of actionable biomarkers and immunotherapy response signatures in a single test. TruSight Oncology Comprehensive (TSO Comp) is a qualitative *in vitro* diagnostic test that evaluates both DNA and RNA from formalin-fixed, paraffin-embedded (FFPE) tissue and analyzes 517 cancer-associated genes with known clinical relevance in one integrated workflow. This study presents the verification and validation of TSO Comp with added laboratory developed test (LDT) claims by conducting accuracy, analytical specificity, and precision (inter and intra run repeatability) studies. Assay performance was assessed using 19 cell lines, contrived and Seraseq® reference materials, and 41 clinical samples to detect the following variant classes: small variants (SNVs, MNVs and indels), fusions/splice variants, Tumor Mutational Burden (TMB), Copy Number Variants (CNVs), and Microsatellite Instability (MSI). The latter two, along with 31 additional fusions and two additional splice variants, were validated as part of the LDT. Overall, the study resulted in 99.4% positive percent agreement (PPA) rates and >99.9% negative percent agreement (NPA) rates for small variants. 100% PPA was estimated across 17 CNVs, 41 fusions/splice variants, and two MSI positives. Furthermore, 100% NPA was estimated for all evaluated samples considered for CNV, fusions/splice variants, and MSI status. TMB scores between reference results and TSO Comp were highly correlated, with R^2 = 0.97. The LoD for CNVs resulted in 100% detection rates for ≥ 2.6 fold change (i.e., 5 copies) in gene amplification when measured across five replicates of four clinical samples. Three contrived cell lines with replicates were used to establish the LoD of 20% tumor content for MSI. In addition, 23 healthy donor samples resulted in 100% analytical specificity for CNV and MSI. All variants and MSI status resulted in ≥ 98.8% inter and intra runs concordance across nine clinical and one Seraseq reference material with replicates.This study demonstrates how TSO Comp can be extended to include additional variant claims with high sensitivity and specificity as an LDT while maintaining clinical interpretation and reporting of cancer mutations central to the CGP of FFPE. Indeed, TSO Comp significantly reduces the burden of validating certain variant classes (e.g. study size was reduced by a minimum factor of two) and allows laboratories to validate and report on additional claims as cancer diagnostics knowledge evolves.

#3820 Concordance analyses of a rapid, targeted, and comprehensive genomic profiling panel for the detection of guideline-recommended biomarkers in non-small cell lung cancer.

Amanda Williamson[1], Hardik Parikh[2], Jon Williams[3], Jie An[2], Erin DeBlasi[2], Alison Roos[4], Leandra Blann[5], Luca Quagliata[6], Mark Tomilo[7], Marcia Eisenberg[8], Brian Caveney[8], Taylor J. Jenson[1], Shakti Ramkissoon[1], Eric Severson[1]

[1]Labcorp, Durham, NC,[2]Labcorp, Buffalo, NY,[3]Labcorp, San Diego, CA,[4]Thermo Fisher Scientific, Phoenix, AZ,[5]Thermo Fisher Scientific, Houston, TX,[6]Thermo Fisher Scientific, Basel, Switzerland,[7]Thermo Fisher Scientific, Ann Arbor, MI,[8]Labcorp, Burlington, NC

Targeted therapies and immunotherapies have improved survival in non-small cell lung cancer (NSCLC). For advanced and early-stage disease, clinical guidelines emphasize timely biomarker results to optimize outcomes. Laboratories face challenges in meeting expanding biomarker demands while conserving tissue and maintaining turnaround times suitable for clinical use and trial enrollment. This study evaluated concordance between the targeted Oncomine™ Precision Assay (OPA), a rapid, low-input NGS panel, and the OmniSeq® INSIGHT (OSI) comprehensive genomic profiling (CGP) assay and assessed OPA's feasibility for expedited biomarker reporting in routine practice. We retrospectively selected 200 advanced NSCLC samples with residual nucleic acid previously tested by OSI. DNA and RNA were re-run using OPA on the Genexus instrument with inter-assay controls. Concordance analyses focused on DNA variants in *BRAF*, *EGFR*, *ERBB2(HER2)*, *KRAS*, and *MET*, and RNA fusions in *ALK*, *MET*, *RET*, *ROS1*, and *NTRK1-NTRK3*. Sensitivity and specificity of OPA relative to OSI were calculated. Workflow metrics including ease-of-use and hands-on time were also evaluated.In a preliminary cohort of 37 samples, OPA showed Assay-QC pass rates of 95% (DNA) and 100% (RNA). Five samples that failed OSI RNA QC passed OPA, though no additional fusions were detected; these were excluded from concordance calculations. Averaged sequencing metrics were 1.07M DNA mapped reads and 125,180 RNA fusion mapped reads. Inter-assay controls were 100% concordant for SNV/Indels (20/20) and fusions (44/44). In the clinical cohort, OPA showed 96.7% for SNV/Indels (29/30), 100% for CNVs (3/3) and fusions (2/2). Specificity was 99.89%, with one potential false positive possibly below OSI's limit of detection (LOD). Turnaround time was 1 day with <1-hour hands-on time. OPA demonstrated high concordance with OSI for a defined set of actionable NSCLC biomarkers. While not all clinically relevant biomarkers (e.g., TMB, MSI, or genes outside the OPA panel) were assessed, results showed strong analytical agreement for overlapping targets. CGP assays like OSI remain the standard for broad biomarker testing in advanced NSCLC, but OPA's rapid turnaround and low-input requirements offer a practical option for timely detection of select actionable biomarkers, making it a useful complement to CGP when time or tissue is limited.

#3821 Clinical utility of a urine-based urothelial cancer test in equivocal upper tract lesions: improving malignancy detection and minimizing unnecessary URS.

Paolo Piatti[1], Yap Ching Chew[1], Farah Toullier-Garcia[1], Ernest Kaufmann[2], Kilian Rothlin[2], Philipp Baumeister[2], Agostino Mattei[2], Christian Fankhauser[2]

[1]Pangea Laboratory, Tustin, CA,[2]Luzerner Kantonsspital, Lucerne, Switzerland

Background and Objective: Upper tract urothelial carcinoma (UTUC) is a rare but aggressive malignancy that often requires diagnostic ureterorenoscopy (URS), an invasive procedure associated with infection, ureteral injury, and potential tumor seeding. In patients with equivocal imaging, deciding whether to perform URS is challenging and may lead to unnecessary procedures. A non-invasive and accurate diagnostic tool is therefore needed to improve risk stratification. Bladder CARE™, a urine-based epigenetic assay with high accuracy for bladder cancer and UTUC, received FDA Breakthrough Device Designation in December 2023. This study evaluated its diagnostic performance in patients with equivocal upper-tract lesions, with the goal of confirming malignancy and reducing unnecessary URS in selected cases.

Material and Methods: Between December 2023 and August 2025, urine samples from 46 patients with suspected UTUC were analyzed using Bladder CARE™. All patients subsequently underwent URS, with nephroureterectomy performed when malignancy was confirmed. Results were classified using the Bladder CARE Index (BCI): positive (> 10), low positive (2.5-10), and negative (< 2.5). Sensitivity, specificity, PPV, and NPV were calculated using histopathology from URS and/or nephroureterectomy as the reference standard. Associations between BCI and tumor grade were also assessed.

Results: Patients had a mean age of 70 years (16 female, 30 male); 24 were UTUC-positive and 22 negative. Mean BCI was significantly higher in UTUC-positive cases vs negatives (85.8 vs 1.7). The positive category showed excellent performance (93% sensitivity, 100% specificity, PPV 100%, NPV 95%), supporting its use to avoid URS in appropriately selected patients. Low-positive results also detected a substantial proportion of cancers but with lower certainty (86% sensitivity, 69% specificity), making URS evaluation appropriate for these cases. Bladder CARE™ detected 88% of low-grade and 100% of high-grade tumors, and 90% of Ta and 100% of T1-T3 tumors. Cytology detected only 2 of 19 UTUC cases. Mean BCI values were higher in high-grade vs low-grade tumors (111.7 vs 54.2) and in T1-T3 vs Ta lesions (136.7 vs 56.0), indicating correlation with tumor aggressiveness.

Conclusion: Bladder CARE™ demonstrated strong diagnostic accuracy with potential to modify the UTUC management pathway. A positive result may allow direct progression to definitive treatment without diagnostic URS, reducing morbidity and expediting care. The correlation between BCI and tumor grade/stage may further support treatment selection, including kidney-sparing approaches or neoadjuvant therapy. While multicenter validation is needed, this non-invasive assay represents a promising advance in UTUC diagnostics and clinical decision-making.

#3822 Enabling multiomic analysis in cell-free DNA tubes by addressing the impact of pre-analytical factors.

Shuting Zhao, Teng-Kuei Hsu, Francis Apolinario, Aurora Martinez-Horta, Yizhen Zhong, Aditya Rao, Jimmy Lin, Richard Bourgon, Tanya Moreno, Ofer Shapira, Kang Li

Freenome, Brisbane, CA

Background: Cell-free DNA (cfDNA) tubes are widely adopted for genomic liquid biopsies because they allow delayed processing after blood collection while ensuring cfDNA stability. However, it remains poorly understood whether other analytes, especially plasma proteins, are stable in cfDNA tubes when subjected to preanalytical stresses during delayed processing. This study investigates the effect of time and temperature variations during transit on protein profiles in samples collected in Streck cfDNA tubes, and a computational method to mitigate the impact.

Methods: We collected blood from 10 healthy donors into Streck cfDNA tubes. Plasma was separated at varying time points and after exposure to different temperature conditions to simulate shipping stress. A total of 2,903 proteins were measured using an immuno-proteomic profiling platform to assess changes in protein abundance. We also assessed a computational regression approach to correct for preanalytical impact on protein levels measured by a bead-based multiplex immunoassay and determine the effect size change of biomarker candidates in a clinical cohort (cancer n=105 vs. control n=538).

Results: Using a 20% abundance change cutoff, we observed that over half of the proteins (1,574) remained stable over prolonged time and temperature exposure. While 351 proteins showed negative bias, the majority of perturbations (978) were concentration increases, with proteins from blood cells overrepresented. Some proteins, such as Macrophage Migration Inhibitory Factor (MIF), were highly correlated with plasma hemoglobin (Hb) level, indicating a red blood cell (RBC) lysis effect. Other proteins, such as Epidermal Growth Factor (EGF), were more correlated with plasma potassium (K) level, suggesting broader lysis effects involving other blood cell types. Using the independent clinical cohort, we confirmed that MIF and EGF levels were highly correlated with Hb and K, respectively. The regression results showed that the Hedges' g effect size for MIF between case and control groups increased from 0.184 to 0.468 after Hb-regression, and the EGF Hedges' g increased from 0.318 to 0.467 after K-regression, demonstrating the power of this computational method to unmask potential protein biomarkers.

Conclusions: Preanalytical variables significantly impact plasma proteomic profiles in cfDNA tubes, especially for proteins that are associated with blood cells. The protein abundance changes in response to preanalytical stresses in cfDNA tubes can confound analyses and lead to false findings. Our results demonstrate that leveraging preanalytical markers like K and Hb allows for computational mitigation of this variability. Implementing robust sample quality control and computational correction strategies is essential to ensure the reliability of plasma proteomic measurements from samples collected in cfDNA tubes.

#3823 Genomic landscape of resectable hepatocellular carcinoma defined by tissue based whole-exome sequencing.

Jie Hu[1], **Haoran Tang**[2], Cancan Jia[2], Feng Xie[2], Yue Zhang[2], Jian Zhou[1]

[1]Liver Cancer Institute, Zhongshan Hospital, Fudan University, Shanghai, China,[2]Huidu (Shanghai) Medical Sciences, Ltd., Shanghai, China

Introduction: Hepatocellular carcinoma (HCC) is the seventh most common malignancy worldwide. Recent advances, including immune checkpoint inhibitors and anti-VEGFR therapies, have improved outcomes for HCC patients, especially in the adjuvant setting after surgical resection. However, many patients still experience disease recurrence and develop treatment resistance, and the molecular biomarkers underlying these events remain poorly defined. Here, we report a retrospective translational study using tissue-based whole-exome sequencing (WES) to investigate molecular biomarkers in patients with resectable HCC.
Methods: In this retrospective study, 88 patients with surgically resected HCC were enrolled. Tumor tissue samples collected at the time of surgery were submitted for molecular profiling using PredicineWES+, a whole-exome sequencing (WES) assay with boosted sequencing in 600 tumor-relevant genes. Matched normal tissue samples also underwent WES to rule out germline variants.
Results: Across 88 patients, PredicineWES+ identified 14,042 somatic mutations and 951 copy number variations. The median tumor mutation burden was 2.41 muts/Mb (range, 0.48-9.74 muts/Mb). The most frequently altered genes were TP53 (70%), TERT (41%), RB1 (25%), and CTNNB1 (22%), with TP53 and RB1 predominantly affected by copy number loss and most TERT variants occurring in the promoter (including 30 C228T events). TP53 alterations were slightly more prevalent in Barcelona Clinic Liver Cancer (BCLC) stage C than in earlier stages, but without statistical significance. No significant associations between TP53, TERT, RB1, or CTNNB1 alterations and prognosis were observed.
Conclusion: Comprehensive tissue-based WES profiling in resectable HCC revealed a characteristic genomic landscape, highlighting the complexity of molecular drivers underlying recurrence and resistance in HCC and underscore the need for integrative biomarker strategies in tumor genomics to refine risk stratification and guide adjuvant therapy.

#3824 Cross-cohort robust detection of colorectal cancer using a minimal junction-based platelet RNA panel.

Jin Sun Choi[1], Ji Won Park[2], Yewon Kim[3], Sangick Park[4], Dahyun Park[3], Eunhye Chai[3], Hyo Jun Kim[2], Seung Chul Heo[1], Seung-Yong Jeong[2], TaeJin Ahn[3], Rumi Shin[1]

[1]SMG-SNU Boramae Medical Center, Seoul, Korea, Republic of,[2]Seoul National University Hospital, Seoul, Korea, Republic of,[3]Foretell My Health, Inc., Seoul, Korea, Republic of,[4]Handong Global University, Pohang, Korea, Republic of

Background:
Tumor-educated platelets (TEPs) incorporate cancer-derived RNA signals and represent a promising minimally invasive platform for early cancer detection. However, gene-level TEP signatures such as the widely used 921-gene panel often exhibit reduced performance across heterogeneous cohorts. Because platelet RNA predominantly reflects regulated splicing events rather than transcriptional abundance, exon-exon junction features may provide higher biological specificity and improved stability against hematologic variability. In this study, we aimed to identify representative exon-exon junction alterations in platelet RNA that distinguish CRC from healthy controls.
Methods:
We analyzed public platelet RNA-seq data (132 CRC and 21 healthy samples; NIH BioProject PRJNA737596) and a prospective clinical cohort (44 CRC and 96 healthy samples), both of which contained a substantial proportion of early-stage CRC (stage I-II, ~52%). Junction-level read counts were quantified, normalized, and filtered based on differential expression, reproducibility, and independence from hematologic indices. A 10-junction panel was selected using logistic regression modeling, and support vector machine (SVM) classifiers were trained and validated using stratified, independent subsets. Performance of the 10-junction model was compared with an identically preprocessed model based on the previously reported 921-gene TEP panel. Functional annotation of the 10 junctions was conducted to assess mechanistic relevance.
Results:
The 10-junction panel demonstrated consistently strong diagnostic performance across cohorts. In the public validation set (n=68), the model achieved a sensitivity of 89.4%, specificity of 85.7%, and an AUC of 0.912. In the clinical validation set (n=75), sensitivity was 87.5%, specificity 93.3%, and AUC 0.959. Detection of early-stage CRC was robust in both datasets (AUC 0.903 and 0.956 in the public and clinical cohorts, respectively). Notably, the junction-based model outperformed the 921-gene panel in the clinical cohort (AUC 0.959 vs. 0.895). Functional enrichment analysis indicated involvement of vesicle trafficking, autophagy, and platelet-immune signaling pathways, consistent with known mechanisms of platelet reprogramming in cancer.
Conclusions:
A compact junction-based TEP RNA panel enables accurate detection of CRC, including early-stage disease, and demonstrates superior cross-cohort robustness compared with conventional gene-level approaches. Its small feature set, strong biological coherence, and consistent performance highlight its potential as a scalable and cost-efficient liquid biopsy for CRC screening. Multi-institutional prospective validation is warranted.

#3825 Integrating CpG-level methylation and transcriptomics for high-resolution cancer epigenetics.

Chao Dai, Guanglong Jiang, Ziqi Zhu, Giancarlo Bonora, Yong Huang, Kemin Zhou, Pan Du

Predicine, Inc., Hayward, CA

Background: Promoter hypermethylation is a key mechanism for silencing tumor suppressor genes in cancer. While whole-transcriptome sequencing (WTS/RNA-seq) is widely used to study cancer biology, high-resolution integration of methylation and expression data remains challenging. Conventional differential methylation region (DMR) approaches aggregate signals across promoters, potentially obscuring fine-scale regulatory effects.
Methods: We analyzed three pairs of parental and sotorasib-resistant NSCLC cell lines using PredicineEpic genome-wide DNA methylation profiling and PredicineWTS RNA-seq. Instead of promoter-level aggregation, we quantified fragment-level methylation changes at individual CpG sites within promoter regions. Correlations between CpG-specific methylation alterations and differential gene expression were evaluated across varying TPM $\log_2$ fold-change thresholds. In addition, more than 50 FFPE tissue biopsies from multiple cancer types were profiled with PredicineEpic and PredicineWTS to systematically assess the relationship between DNA methylation and gene expression.
Results: CpG-level methylation changes showed stronger inverse correlations with gene expression than promoter-level averages. For genes with $\log_2FC \geq 4$, CpG fragment beta differences correlated with expression changes at $R = -0.92$ ($n = 7$, $p = 0.001$). Similar trends were seen at lower thresholds: $\log_2FC \geq 3$ yielded $R = -0.63$ ($n = 22$, $p = 0.001$), whereas promoter-level beta differences showed no significant correlation. Consistent patterns of stronger CpG-level correlations were also observed across all tissue biopsy datasets.
Conclusions: High-resolution CpG-level methylation analysis provides greater sensitivity for linking epigenetic alterations to transcriptional changes than conventional promoter-level approaches. Fragment-level methylation profiling can reveal critical transcriptional regulatory events and may have important applications in liquid biopsy and biomarker discovery.

#3826 Systematic assessment of histomorphologic and immunohistochemical features in metastatic castration-resistant prostate cancer biopsies.

Elnaz Mahmoudabadi[1], Erolcan Sayar[1], Peter S. Nelson[1], Michael Schweizer[2], Funda Vakar-Lopez[3], Lawrence True[3], Jakob Valk[3], Maria Tretiakova[3], Nancy Y. Greenland[4], Deepika Sirohi[4], Bradley A. Stohr[4], Jeffry P. Simko[4], Michael C. Haffner[1], Chien-Kuang Cornelia Ding[4]

[1]Division of Human Biology, Fred Hutchinson Cancer Center, Seattle, WA,[2]Division of Clinical Research, Fred Hutchinson Cancer Center, Seattle, WA,[3]Department of Laboratory Medicine and Pathology, University of Washington, Seattle, WA,[4]Department of Pathology, University of California San Francisco, San Francisco, CA

Background: Metastatic castration-resistant prostate cancer (mCRPC) represents a heterogeneous disease spectrum. While many tumors remain androgen receptor (AR)-driven, others undergo lineage plasticity toward neuroendocrine prostate cancer (NEPC). The significance of intermediate or mixed phenotypes—such as tumors with co-expression of AR and neuroendocrine (NE) markers or lacking all lineage markers—remains poorly defined. We sought to systematically characterize histomorphology and immunohistochemistry (IHC) in real-world mCRPC biopsies.
Methods: 117 mCRPC biopsies from two institutions were retrospectively reviewed and classified by tumor morphology on H&E. IHC was performed for NKX3.1, AR, synaptophysin (SYP), insulinoma-associated protein 1 (INSM1), and Ki-67. Expression was semi-quantitatively scored using H-scores (0-300), and Ki-67 was reported as the percentage of tumor nuclei with positive staining.
Results: Histologic distribution included 44 adenocarcinomas, 53 poorly differentiated carcinomas, 15 NEPC, and 5 mixed subtypes. Using H-score >40 as a cutoff, adenocarcinomas frequently expressed NKX3.1 (93%) and AR (100%), with limited NE marker expression (13% for INSM1 and 46% for SYP). Poorly differentiated carcinomas most often retained NKX3.1 (80%) and AR (84%), while NE marker expression was less common (SYP 27%, INSM1 26%). Mixed tumors demonstrated co-expression across lineages, (AR 100%, NKX3.1 100%, SYP 80%, INSM1 50%). NEPC showed diffuse NE differentiation (SYP 85%, INSM1 75%) with rare NKX3.1 or AR positivity (8% and 0%, respectively). High H-scores (>200) were enriched in NKX3.1 (83%) and AR (92%) positive adenocarcinomas, while majority NEPC showed high SYP expression and high Ki-67 proliferation index. Low H-score (<40) are seen across all four IHC markers in 1 poorly differentiated carcinoma and 2 NEPC.
Conclusions: This study provides one of the first systematic, standardized assessments of mCRPC biopsy morphology and IHC marker expression. NKX3.1 and AR predominated in adenocarcinoma and poorly differentiated carcinomas, whereas SYP and INSM1 reliably identified neuroendocrine carcinomas. Mixed subtypes exhibited overlapping lineage features. Ki-67 indicated differences in tumor proliferation across subtypes. These findings highlight the morphologic and immunophenotypic heterogeneity of mCRPC and emphasize the need for integrated pathologic evaluation to refine diagnosis and support translational research.

#3827 Cyclic immunofluorescence (CyCIF) staining for highly multiplexed circulating tumor cell (CTC) imaging using the Genesis Cell Isolation System with Celselect Slides.

Yoon-Tae Kang[1], Floyd Watkins[2], Dominique Winston[2], Marta Gonzalez-Plasky[2], Adam Corner[1], Nathan Knapp[1], David Coe[1], Elizabeth Jordan Dreskin[1]

[1]Bio-Rad Laboratories, Hercules, CA,[2]Bio-Rad Laboratories, Ann Arbor, MI

Introduction: Blood-based liquid biopsy enables the analysis of CTCs, which is providing a less invasive method for cancer monitoring compared to tissue biopsy methods. Immunofluorescent (IF) staining of CTCs can identify expression of protein markers associated with cancer origin, progression and metastasis. However, conventional IF imaging is limited to 4-5 markers at a time due to the spectral overlap, hindering in-depth insights into disease status and tumor heterogeneity. CyCIF is a method for performing highly multiplexed IF imaging via repeated cycles of imaging and fluorescence inactivation, thus enabling multiple biomarker studies from the same sample, which is crucial for studying extremely rare cells, such as CTCs. Here, we demonstrate on-system CyCIF on CTCs captured using the Genesis Cell Isolation System with Celselect Slides.

Methods: To run a CyCIF, two destaining buffers and a custom Genesis protocol were prepared. Contrived CTC samples were prepared by spiking breast cancer cells (MCF7) into whole blood from a healthy donor. The samples were processed following the Genesis Enumeration protocol with either Indirect Stain Kit or Indirect Stain Kit. The stained Celselect slides were imaged then destained following a two-step-destaining protocol (destaining and stripping) using hydrogen peroxide and low pH stripping buffer. Upon checking the destaining performance, the slide was re-stained and imaged again using the same antibody panel or a new panel. Hydrogen peroxide can deactivate fluorophores through irreversible chemical oxidation and intentionally erase fluorescent signals. Mild stripping buffer works by disrupting antibody-antigen interactions to remove antibodies, allowing the membrane to be re-probed for different proteins.

Results: The slide was stained using a standard CTC panel (CK/CD45/DAPI), destained and restained using the same CTC panel. At each step, the slide was scanned and analyzed using the BioTek Lionheart (Agilent) and its Gen5 software under the same exposure time and conditions (LUTs) Over 82 percent of spiked cancer cells were initially captured and stained using the test panel. Upon destaining with the optimized protocol, 90.32% of these cells were detained. Restaining with the same panel resulted in detection of over 85% of the originally captured CTCs. This demonstrates effective on-system CyCIF demonstration for rare cell studies with minimal cell loss.

Discussion and Conclusions: By combining CTC capture with a custom protocol, we present a cost-effective, efficient, and powerful solution for multiplexed protein marker expression studies on CTCs. This chemistry and protocol can be applied to multiple CTC staining panel applications using one Celselect slide across many sample types, thus maximizing the results with a limited sample type and volume for liquid biopsy.

#3828 Signatera HRD score enables high accuracy classification of homologous recombination deficiency.

Kimberly Zhu, Carly B. Scalise, Rojin Safavi, Annette Angus, Matthew Rabinowitz, Catalin Barbacioru, Ahmet Zehir

Natera, Inc., Austin, TX

Homologous recombination deficiency (HRD) is known to predict patient response to poly (ADP-ribose) polymerase (PARP) inhibitors and platinum agents, yet reliable detection remains difficult in patients who lack pathogenic variants in canonical homologous recombination repair genes. For these cases, HRD status can be assessed by the genomic “scars” caused by genomic instability, such as loss of heterozygosity (LOH), telomeric allelic imbalance (TAI), and large-scale state transitions (LST). However, current approaches have limited sensitivity, especially in specimens with low tumor purity. Here, we describe the development and performance of Signatera HRD score, an algorithm that uses tissue-based whole-exome and -genome sequencing (WES and WGS) data to determine HRD status. The algorithm integrates somatic single nucleotide variant (SNV) and copy number variant (CNV) features within a probabilistic framework to infer genomic scarring with high sensitivity and specificity. The underlying model was trained on WES and WGS data from 1,600 tumors of multiple cancer types. From genome-wide copy-number profiles of these tumors, non-negative matrix factorization identified 22 distinct and recurrent CNV signatures. Of these 22 signatures, 9 correlated with LOH and broader genomic instability and were retained as HRD features. The CNV signatures, combined with established single-base substitution (SBS) and insertion and deletion (ID) mutational signatures adjusted for tumor purity, were then fed into a machine learning classification model to predict HRD status. We retrospectively evaluated the performance of Signatera HRD score model in a cohort of 206 patients who underwent bespoke, mPCR-NGS tumor testing (Signatera^{TM}) with orthogonally determined HRD status. Initial performance (measured as the area under the curve [AUC]) was 0.8, but increased to 0.92 by adjusting the CNV signatures for the ploidy of each sample. Incorporating established SBS and ID mutational signatures further improved the discriminative power of the model to an AUC of 0.97. Using an HRD-status threshold derived from the training set of patients, the model achieved 94.4% sensitivity at 94.2% specificity in the evaluation cohort. Feature-importance analyses indicated that mutational signatures were the dominant contributors to model performance. In conclusion, Signatera HRD score is a tissue-based model that combines ploidy-adjusted CNV signatures with SBS/ID mutational signatures to reliably predict tumor HRD status, achieving performance comparable to or better than established genomic-scar metrics such as LOH, TAI, and LST. By leveraging widely available NGS data, this approach can expand access to HRD assessment and help identify patients more likely to benefit from PARP inhibitors without requiring specialized scar assays.

#3830 Diagnostic potential of salivary miR-300 and miR-340-5p in oral cancer among Pakistani patients.

Muhammad Jawad Khan, Andleeb Zahra, Ghulam Rabia, Syeda Aba Ali, Afraz Ahmad Raja, M. Qaiser Fatmi

Department of Biosciences, COMSATS University Islamabad, Islamabad, Pakistan

Oral cancer is a significant global health concern, ranking as the sixth most common cancer worldwide. The metastasis of oral squamous cell carcinoma (OSCC) is influenced by a combination of environmental, demographic, and genetic factors, including specific genes and miRNAs. Among demographic factors, age, socio-economic status, lifestyle, and pre-existing diseases play important roles, while genetic factors, such as the differential expression of miRNAs and their target genes, are critical in disease progression. Given their differential expression, miRNAs and their target genes hold potential as diagnostic biomarkers. This study aimed to detect and profile the expression of miRNAs and their target genes in the Pakistani population. We conducted a meta-analysis of 318 miRNAs and their differentially expressed target genes. From this pool, significant miRNAs and genes were identified through *in silico* functional enrichment, pathway, and network analyses. Our analyses highlighted a set of differentially expressed genes regulated by miR-300 and miR-340-5p. To further investigate the dysregulation of these target genes, network analysis was performed using Cytoscape. We then assessed the expression of miR-300, miR-340-5p, and their target genes ALB, CDH1, CDKN1A, and BCL2 in saliva samples from oral cancer patients and healthy controls. Receiver operating characteristic (ROC) analysis was conducted to evaluate the diagnostic potential of these miRNAs, and the area under the curve (AUC) was calculated for each. Our expression and network analyses revealed that miR-300 and miR-340-5p were significantly downregulated in cancer patients. These results indicate that miR-300 and miR-340-5p possess strong diagnostic potential for oral cancer, with AUC values of 0.827 and 0.704, respectively. Overall, our findings demonstrate that miRNAs and their target genes exhibit robust discriminatory capacity, supporting their potential as biomarkers for oral cancer.

#3831 Validation of blood tumor mutation burden in Labcorp Plasma Complete.

Vito Caropreso[1], Kenneth C. Valkenburg[1], Robert Summersgill[1], Amy Meltzer[1], James R. White[1], Ellen Verner[1], Jennifer B. Jackson[1], John Pruitt[2], Deborah Boles[2], Eric Severson[2], Marcia Eisenberg[2], Brian Caveney[2], Taylor Jensen[2], Shakti Ramkissoon[2]

[1]Labcorp, Baltimore, MD,[2]Labcorp, Durham, NC

Introduction: Tumor mutation burden (TMB) is an important and clinically relevant genomic signature for guiding physicians towards immunotherapies for their cancer patients. Blood TMB (bTMB) represents a potential method to measure TMB in cancer patients via blood-based liquid biopsy testing. Labcorp Plasma Complete™ (LPC) is a laboratory developed test (LDT) that analyzes circulating tumor DNA (ctDNA) to identify genomic alterations in cancer without the need for an invasive tumor tissue biopsy. In this study, we demonstrate that LPC can successfully and reproducibly report bTMB using a cohort of 84 clinical plasma samples compared to an orthogonal LDT.

Methods: Sequencing libraries were generated using 25ng of cell-free DNA (cfDNA) from 84 unique plasma samples originating from individuals diagnosed with varying solid cancer types. bTMB values from LPC were compared to bTMB values from an orthogonal test. A subset of 6 samples with a range of bTMB values reported by the orthogonal test were processed in triplicate across multiple operators and sequencing instruments to demonstrate reproducibility of the bTMB value reported by LPC. The standard deviation and average positive and negative agreement (APA and ANA) of the bTMB values were assessed based on bTMB-high and bTMB-not high status between all evaluable replicates. Specificity was assessed in 20 non-cancerous plasma samples to determine how many observations had a higher bTMB value than the established limit of blank.

Results: Concordance of bTMB values between LPC and the orthogonal test demonstrated a Pearson correlation coefficient of 0.78. LPC reported bTMB values from 0-37.13 mutations/Mb and samples were categorized as bTMB-high if the value was ≥7 mutations/Mb by LPC and ≥15 mutations/Mb by the orthogonal. Lower bTMB values were categorized as bTMB-not high, resulting in a positive percent agreement (PPA) of 100% and negative percent agreement (NPA) of 97.5%. Samples processed for reproducibility purposes demonstrated a 100% APA and 100% ANA with an average standard deviation of 0.94 mutations/Mb.

Conclusions: Utilizing the highly trained bTMB algorithm, LPC can produce accurate and reproducible bTMB values. The addition of this molecular signature to LPC will help guide physicians towards immunotherapy options, and the added utility will enable a more comprehensive precision oncology strategy for cancer patients.

#3832 Utilization, challenges, and outlook of cell of origin classification by immunohistochemistry in DLBCL: A U.S. survey of oncologists and pathologists.

Anthony Hesser[1], Dorian Cohen[1], **Gary Gustavsen**[1], Barbara Furtado[2], Brad Thomas[2], Shady Gendy[2]

[1]Health Advances LLC, Newton, MA,[2]AstraZeneca Oncology, Gaithersburg, MD

Background: Cell of Origin (COO) classification in treatment-naïve (TN) diffuse large B cell lymphoma (DLBCL) is universally recommended across guidelines as an essential prognostic tool, yet some patients are never tested or receive equivocal results that prohibit classification. We sought to determine what barriers to COO classification exist and what could mitigate these barriers.
Methods: Double-blinded phone interviews with 8 oncologists and 10 pathologists informed current practices, challenges, and survey design. A double-blinded, online survey of 60 oncologists who treat DLBCL and 60 pathologists (26 board-certified in hematopathology) who perform COO classification was conducted from September 29 to October 10, 2025. Respondents were from a mix of academic and community-based settings in the United States.
Results: We found that oncologists view COO as a valuable tool that provides prognostic insight and a more comprehensive diagnosis, with 54% of oncologists incorporating COO classification into treatment decision-making for some patients and an additional 32% of oncologists incorporating COO for all patients. Survey results suggest that 83% of TN DLBCL patients in the US are tested for COO, with 90% of US practices using immunohistochemical (IHC) techniques. Oncologists and pathologists prefer IHC due to its accessibility, fast turnaround time, and relatively low cost. Gene expression profiling (GEP), while offering more granular classification, is less common due to higher costs and taking 4-6 days longer to return results. 89% of US oncologists were confident using IHC results for treatment selection as they consider the IHC-GEP concordance sufficient. Although IHC is routine, 10-15% of samples initially yield equivocal results due to challenges with all three Hans algorithm markers, particularly with CD10 and MUM1, citing variability in staining protocols, ambiguity in scoring weakly positive cells, and difficulty interpreting focal versus diffuse signal. After secondary review, only ~3% of samples remain equivocal and another ~6% are unreportable due to inadequate sample quality or quantity. The potential for oncologists to use pathology results is impeded by missing information in the report, lack of a COO classification in the top-line diagnosis, and variation in report structure, even among pathologists at the same institution.
Conclusion: IHC is a widely used, reliable method for COO classification in TN DLBCL with 86% of oncologists using the results for treatment decisions. Our findings suggest that developing consensus guidelines for standardized pathology reports and developing educational materials to reinforce the clinical implications of COO and guide handling of equivocal results will help mitigate testing barriers and increase the proportion of patients receiving actionable COO classifications.

#3833 Development of a novel extracellular vesicle-based biomarker approach for pediatric high-grade glioma.

Adriana Fernandez Garcia, Poorvi Iyer, Pablo Ashi, Kosuke Funato

Biochemistry and Molecular Biology, University of Georgia, Athens, GA

Pediatric high-grade gliomas (pHGGs) account for 20% of childhood brain tumors and are associated with poor survival rates. Currently, pHGG detection relies on Magnetic Resonance Imaging (MRI), a costly and time-consuming procedure. Extracellular vesicles (EVs) carry molecular markers indicative of their cellular origin and can be isolated from various biofluids, offering an alternative approach. Recent studies showed that pHGGs contain cells that molecularly and morphologically resemble radial glia (RG), a type of neural progenitor. Given that RGs are normally exclusive to the developing brain, we hypothesized that EVs secreted from RG-like glioma cells (RG-EV) serve as a pHGG biomarker. However, there are no established molecular markers to specifically detect RG-derived EVs. To address this, we first identified a combination of surface markers to differentiate EVs derived from RG-like glioma cells from those of non-RG cells. We next validated the expression of these markers in patient-derived cell lines. Our analysis of EVs showed that pHGG cells secrete a significantly higher proportion of RG-EV compared to human astrocytes (88.88 ± 7.69% vs 0.57 ± 0.28%; $p < 0.0001$), along with other tumor-associated markers, including targets of chimeric antigen receptor (CAR) T cell therapy such as disialoganglioside GD2 (73.46 ± 11.75% vs 0.32 ± 0.07%; $p < 0.001$). Taken together, our findings showed that RG-derived EVs can be specifically isolated and detected by the combination of markers, distinguishing pHGG cells from non-malignant astrocytes. This work establishes a basis for developing a novel EV-based diagnostic biomarker approach for pHGGs.

#3834 Performance validation of a next generation sequencing myeloid assay on an integrated nucleic acid purification and sequencing system.

Amanda Weaver, Ubaradka Sathyanarayana, Hayden Tomazin, Gary Pestano

Biodesix, Inc., Louisville, CO

The large diversity of myeloid neoplasms requires in-depth characterization of genetic abnormalities, including single-nucleotide variants (SNVs), small insertions and deletions (INDELs), and fusions and translocations for diagnosis and management. NGS can identify mutations associated with myeloid disorders to diagnose specific subtypes or identify a personalized and patient-specific treatment. We validated a targeted NGS myeloid assay for use in our CAP/CLIA accredited clinical laboratory. The myeloid NGS panel can identify up to 45 key DNA targets and 34 fusion driver genes covering over 800 unique fusions. The assay utilizes an automated purification system and sequencer with an on-board bioinformatics pipeline and report generation capabilities. This automated workflow has a turnaround time of approximately 24 hours from loading of the test specimen on the purification system to results ready for review. All steps were hands-off except for sample loading and transfer of the nucleic acid purification plate to the sequencer. Commercially available reference materials consisting of contrived DNA and RNA from cell lines with SNVs, INDELS, and fusions common to myeloid disorders were used for analytic sensitivity and precision studies. Precision was evaluated in triplicate over 2 instruments, 3 days, 2 operators, and 3 runs. For analytic specificity, ten normal healthy donor DNA and RNA were extracted from blood collection tubes designed to stabilize nucleic acid. For accuracy, 8 peripheral blood lymphocytes specimens from patients with a variety of myeloid disorders were extracted and assayed on both the myeloid panel under validation and a reference NGS myeloid panel. The 8 myeloid specimens' primary diagnosis was chronic myeloid leukemia (n=3) and myelodysplastic syndrome (n=5). For accuracy, the NGS myeloid assay panel had 100% concordance to the reference NGS myeloid panel. All ten normal healthy donors had no variants detected indicating high specificity. Limit of detection was established as ≥5% Variant Allele Frequency (VAF) for DNA and ≥250 fusion mapped reads for RNA fusions. For precision, the %CV between all conditions was 4.8-28.6% for the 23 DNA variants and 17.9-36.0% for the 9 fusion variants. Our data supports the use of this targeted myeloid NGS assay and the integrated purification/sequencer system for the detection of genetic lesions in myeloid neoplasms. The streamlined workflow accelerated result generation, enabling faster treatment decisions. Automation reduces the need for qualified operators and facilitates efficient clinical management of patient samples for disease diagnosis and treatment guidance. Additionally, availability of timely results can benefit patients by enabling earlier treatment decisions. These qualities support the use of this system in clinical settings for more efficient management of patients' disease.

#3835 The expression of Napsin A by immunohistochemistry in colorectal adenocarcinomas: An observational study.

Cawekazi Cingo[1], Rahaba Marima[2], Tebogo Marutha[2], **Zodwa Dlamini**[2], Benny Mosoane[1]

[1]Department of Anatomical Pathology, University of Pretoria, Pretoria, South Africa,[2]Pan African Cancer Research Institute (PACRI), University of Pretoria, Pretoria, South Africa

Background:
Distinguishing primary colorectal adenocarcinoma from metastatic pulmonary adenocarcinoma can be challenging in small biopsies, particularly when tumors are mucin-rich or poorly differentiated. Napsin A is widely used as a marker of pulmonary adenocarcinoma, yet scattered reports suggest it may sometimes be expressed in non-pulmonary primaries, including colorectal cancer. We set out to see how often napsin A is expressed in colorectal adenocarcinomas in our setting and to gauge how much of a diagnostic trap it may pose.
Methods:
We retrospectively reviewed 107 colorectal adenocarcinoma samples using formalin-fixed, paraffin-embedded tissue blocks. Napsin A immunohistochemistry was performed using polyclonal and monoclonal antibodies. Three pathologists independently reviewed the slides; napsin A was considered positive when granular cytoplasmic staining was present in at least 1% of tumor cells. For each case, we recorded tumor differentiation, histological subtype, and CDX2 status.
Results:
Of the 107 tumors, 83 (77.6%) were moderately differentiated, 18 (16.8%) poorly differentiated, and 6 (5.6%) well differentiated. Histological subtypes included not otherwise specified (84.1%), mucinous (6.5%), signet ring (6.5%), and a small number of other variants. All cases were CDX2 positive, supporting a colorectal origin. Napsin A staining was observed in only 1/107 cases (0.9%) of poorly differentiated signet-ring adenocarcinoma, confined to the monoclonal antibody; none showed positivity with the polyclonal antibody.
Conclusion:
In this series, napsin A expression in colorectal adenocarcinoma was uncommon but not absent. Thus, a napsin A-positive metastatic adenocarcinoma could still represent a colorectal primary, especially in unusual histological subtypes. Our findings support cautious use of napsin A, always alongside morphology, a broader immunohistochemical panel, clinical data, and, where possible, molecular work-up. A larger multicenter dataset would help clarify generalizability and whether specific colorectal carcinoma subtypes are more prone to napsin A expression.

#3836 IGF system genes as colorectal cancer biomarkers in Puerto Rico.

Hilmaris Centeno-Girona, Camille Zenon-Melendez, Sheila Natalie Lopez Acevedo, Ingrid Montes-Rodriguez, Elba V. Caraballo-Rivera

University of Puerto Rico Comprehensive Cancer Center, San Juan, Puerto Rico

Introduction: Colorectal cancer (CRC) disproportionately affects Hispanic/Latino (H/L) populations; however molecular biomarkers remain understudied in this population. While individual IGF-axis have been explored as CRC biomarkers, comprehensive transcriptomic evaluation of the complete IGF system, including IGFs, receptors, and binding proteins, for stage-specific detection remains limited, particularly for H/L living in Puerto Rico. This study aimed to characterize transcriptomic dysregulation of the IGF system in CRC and evaluate individual genes and multi-gene signatures as diagnostic biomarkers to discriminate tumor from normal tissue and differentiate early-stage from advanced-stage disease.

Methods: RNA was extracted from 28 tissue samples (15 CRC cases, 13 controls) from the Puerto Rico Familial Colorectal Cancer Registry (PURIFICAR) using QIAGEN RNeasy Kit. RNA sequencing was performed on Illumina NextSeq 550. Differential gene expressions were analyzed using DESeq2 (adjusted $p<0.05$, log2FC>1). Pathway enrichment was analyzed using the Reactome database. Logistic regression models (crude and age and BMI-adjusted) estimated odds ratios for gene associations, overall and by CRC stage. ROC analysis determined diagnostic performance: AUC, sensitivity, and specificity. An IGF system multi-gene signature score was developed using the uncorrelated differentially expressed IGF genes (IGF1, IGF2, IGFL2, IGFL4). Significance was set at $p<0.05$.

Results: Our results show dysregulation of the IGF system across CRC stages, with IGF2 and IGF1R consistently upregulated and stage-specific IGFBP expression patterns. The multi-gene signature demonstrated good CRC discrimination (AUC: 0.831, $p=0.002$), with superior performance in advanced disease (AUC: 0.894, $p=0.002$). Among individual genes, IGFBP5 showed highest crude accuracy (AUC: 0.856, $p=0.020$), which improved when adjusted for age and BMI (AUC: 0.964, 92.3% sensitivity/specificity, $p<0.001$). IGFL4 showed excellent discrimination in advanced-stage models (adjusted AUC: 1.00, OR: 6.03, $p<0.001$). Early-stage detection was particularly strong for IGFBP5 and IGFL2 (adjusted AUC>0.94). Enriched pathways included IGF1R-SHC signaling and platelet activation in advanced disease.

Conclusion: This transcriptomic analysis identifies IGFBP5 and a multi-gene IGF signature as potential stage-specific biomarker candidates for CRC in H/L in Puerto Rico. Further validation in larger cohorts is warranted to determine whether IGF system genes can improve CRC detection.

#3840 Detection of minimal residual disease in colorectal cancer patients after surgery through circulating tumor DNA profiling.

Luis Maya Janssen[1], Ekaly Apagnha[1], Flavio de Alencar Teles Barreto[1], Andre Araujo de Medeiros Silva[2], Mayra Veloso Ayrimoraes Soares[1], Joao Batista de Sousa[2], **Fabio Pittella-Silva**[1]

[1]Laboratory of Molecular Pathology of Cancer, Faculty of Health Sciences, University of Brasilia, Brasilia, Brazil,[2]Division of Colorectal Surgery, Brasilia University Hospital, University of Brasilia, Brasilia, Brazil

Accurate identification of minimal residual disease (MRD) after curative-intent resection remains a critical unmet need in colorectal cancer (CRC). Given the narrow postoperative window during which current adjuvant chemotherapy (ACT) improves outcomes, rapid and reliable biomarkers are essential to guide timely treatment decisions. Here, we assess the prognostic performance of a targeted liquid-biopsy mutation panel for postoperative ctDNA detection to identify MRD and support ACT decision-making in CRC. We performed targeted sequencing using a Thermo Fisher Scientific NGS platform (Ion S5 Oncomine based panel) to assess more than 200 hotspot mutations across key CRC-associated genes. All samples were sequenced to a mean depth of ~50,000× using 10-20 ng of cfDNA, enabling detection of variants with a VAF >0.05%. ctDNA was evaluated before and after treatment in 49 patients with resectable stage I-III CRC (32 colon, 17 rectal), with blood samples collected at baseline and again 4 weeks after surgery or neoadjuvant therapy. Baseline ctDNA alterations were detected in 75% of patients (37/49), with higher detection rates in stage III (78%; 21/27) compared with stage II (69%; 11/16) and stage I (67%; 4/6). Across all baseline-positive samples, 76 mutations were identified in 10 genes, predominantly *TP53* (n=26), *APC* (n=14), *KRAS* (n=10), and *PIK3CA* (n=6), with a median VAF of 0.97% (range 0.05-17.9%). Post-treatment ctDNA positivity was observed in 57% of patients (28/49), indicating persistent MRD. A reduction in VAF after treatment occurred in 30% (15/49), including 9 patients with >50% decreases, consistent with a partial molecular response but ongoing subclinical disease. Conversely, 27% (13/49) showed increased VAF, suggesting inadequate treatment response and a higher risk of relapse. Complete ctDNA clearance occurred in 24% of patients (12/49), 8 with colon cancer and 4 with rectal cancer, all of whom remain event-free for at least 12 months. Up to date, one rectal cancer patient remains ctDNA-negative for 18 months. Finally, 18% of patients had no detectable mutations at either time point, underscoring the need for further assay refinement to improve detection sensitivity in this subgroup. In conclusion, postoperative ctDNA positivity identified patients with persistent molecular disease, while ctDNA clearance correlated with short-term event-free outcomes. These findings support the use of ctDNA profiling as a practical tool to guide postoperative treatment decisions.

#3841 Prognostic significance of PI3K-AKT pathway alterations identified by ctDNA sequencing in metastatic castration-resistant prostate cancer.

DongSoo Kyung[1], Yongjun Cha[1], Chang Wook Jeong[2], Seung-hwan Jeong[2], Chel Lee[3], Won Yeong Ko[1], Jee-Soo Lee[4], Moon-Woo Seong[4], Cheol Kwak[2], Tae-You Kim[5]

[1]IMBdx, Seoul, Korea, Republic of,[2]Urology, Seoul National University Hospital, Seoul, Korea, Republic of,[3]Pathology, Seoul National University Hospital, Seoul, Korea, Republic of,[4]Laboratory Medicine, Seoul National University Hospital, Seoul, Korea, Republic of,[5]Internal Medicine, Seoul National University Hospital, Seoul, Korea, Republic of

Background: Aberrations in the PI3K-AKT pathway are key drivers of castration-resistant prostate cancer (CRPC), promoting therapeutic resistance and poor outcomes. As these alterations become increasingly relevant for targeted therapy, defining their prevalence and prognostic value through noninvasive genomic profiling is essential. We therefore assessed PI3K-AKT pathway alterations in metastatic CRPC using high-depth circulating tumor DNA (ctDNA) sequencing.
Methods: A total of 127 patients with mCRPC underwent high-depth ctDNA sequencing using the AlphaLiquid®100 assay, covering PI3K-AKT pathway genes and homologous recombination repair genes. Paired PBMCs were available for 87 patients, while 40 underwent plasma-only profiling with our machine learning-based model applied to remove CHIP-related variants. For orthogonal comparison, PTEN immunohistochemistry (IHC) was performed using a mouse monoclonal antibody (clone 6H2.1, M3627, Dako). ctDNA metrics were evaluated with baseline clinical data and overall survival (OS), and outcomes were compared between PI3K-AKT-altered and wild-type disease.
Results: Among 127 patients (median age, 66 years), high-grade tumors were common (Gleason ≥8 in 71.7%), with advanced clinical T3-T4 disease in 78.7%, nodal involvement in 59.8%, and synchronous metastasis in 58.3%. The median PSA at diagnosis was 53.7 ng/mL, and 33.1% had undergone prior surgery. Somatic ctDNA alterations were detected in 91.3% (median 3; range 0-47), with substantial heterogeneity in variant types and tumor fractions (median 0.98%; range 0.05-79.6%). PTEN pathogenic mutations were found in 9.4% and activating *PIK3CA* and *AKT1* alterations in 7.9% and 0.8%. PTEN loss by IHC was present in 46.9% (30/64), with the overall 54.7% concordance with PTEN pathogenic mutations in cfDNA. Baseline clinical features were similar between PI3K-AKT-altered and wild-type tumors, except for higher T3-T4 disease ($p<0.001$). PTEN IHC loss was not associated with overall survival (OS) in the full cohort (HR 1.47, 95% CI 0.36-6.06) or in synchronous metastasis (HR 2.41, 95% CI 0.37-15.55). In contrast, PTEN pathogenic mutations detected via ctDNA were associated with inferior OS in the overall cohort (HR 3.19, 95% CI 0.90-11.37; $p=0.073$) and showed significant impact in synchronous metastasis (HR 4.91, 95% CI 1.29-18.67; $p=0.019$). A similar trend was seen for PIK3CA and/or AKT1 mutations (HR 3.25, 95% CI 0.95-11.16; $p=0.061$).
Conclusion: PTEN pathogenic mutations identified through ctDNA sequencing were strongly associated with worse overall survival in mCRPC and outperformed PTEN IHC in prognostic value. These results underscore the utility of ctDNA profiling for detecting PI3K-AKT pathway alterations and its potential to inform targeted treatment strategies in mCRPC.

#3842 Non-invasive cfDNA methylation profiling for prediction of PD-L1 tumor proportion score status in NSCLC.

Wei Tian, Anton Valouev, Kunwar Singh, Matthew Ellis, Katie Quinn, Tingting Jiang, Martina Lefterova, Justin Odegaard, Darya Chudova

Guardant Health Laboratory, Redwood City, CA

Background: Programmed death-ligand 1 (PD-L1) expression, measured by tumor proportion score (TPS), guides immunotherapy (IO) selection in NSCLC. However, tissue-based PD-L1 immunohistochemistry (IHC) is often limited by insufficient tissue, sampling bias and intratumoral heterogeneity. cfDNA methylation signatures enable non-invasive measurement of tumor-derived epigenetic signals and may be able to capture PD-L1-associated biology from a simple blood draw. We developed a cfDNA methylation-based predictor to identify patients with low PD-L1 TPS (<50%), a group more likely to benefit from IO combination regimens rather than IO monotherapy.

Methods: cfDNA methylation profiles of >500 plasma clinical patient samples, each with paired tumor PD-L1 IHC data, were analyzed across thousands of regulatory regions. A regularized logistic regression model was trained to predict samples with PD-L1 TPS <50%. Model performance was evaluated on an independent test cohort (N=90) by comparing predicted calls with IHC-based PD-L1 TPS measurements.

Results: The cfDNA methylation predictor for identifying PD-L1 TPS <50% cases achieved >50% sensitivity, 87% specificity, and >90% positive prediction value (PPV). Model performance was consistent across NSCLC histologies (LUAD and LUSC) and remained robust at tumor fractions as low as 0.05%. Approximately 70% of liquid biopsy samples were evaluable, supporting the feasibility of cfDNA methylation analysis for the majority of clinical samples.

Conclusions: Our methylation-based PD-L1 low predictor enables non-invasive detection of NSCLC cases with tissue PD-L1 TPS <50%, offering a potential alternative when tissue is limited or not available. Further investigation is warranted to determine whether an epigenetic PDL1 IHC trained classifier can support treatment decisions by identifying NSCLC patients more likely to require IO chemotherapy combination therapy.

#3843 Sequencing full-length mRNA in whole blood of breast cancer patients for antibody-drug conjugate therapy selection.

Jacob Bradley[1], Gabriel Benitez[1], Mark Barnett[1], Oliver Eve[1], Ivalya Ivanova[1], Katrina Morris[1], Alice Seguret[1], Ahmad Zyoud[1], John Davey[1], Yuanyuan Cheng[1], Amy Robinson[1], Arran Turnbull[2], Mike Dixon[2], Han-Yu Chuang[1], Rick Hockett[1], **Richard Kuo**[1], Pamela N. Munster[3]

[1]Wobble Genomics, Edinburgh, United Kingdom,[2]Western General Hospital, Edinburgh, United Kingdom,[3]UCSF - University of California San Francisco, San Francisco, CA

Identifying biomarkers for selection of therapeutics is a critical unmet need. For many existing treatments, particularly antibody-drug conjugates, there are limited or only partially effective options for determining efficacy. For example, breast cancer therapy selection requires accurate quantification of tumour HER2 expression, but current HER2 testing methods, primarily based on IHC and ISH, lack the precision to distinguish HER2 status in HER2 low and ultra-low patients. When determining HER2 ADC eligibility, the lack of reliable HER2 quantification can lead to under- or over-treatment. Developing an accurate and reliable HER2 quantification method will enable safer and more effective HER2 ADC utilization.We have developed a novel platform that leverages long-read sequencing to capture full-length mRNA and generate isoform-level expression profiles. We processed 30 tumor biopsies and 50 whole blood samples from breast cancer patients, as well as blood samples from 50 control patients. By integrating the tumor and blood transcriptome data, we characterized the expression of 61,537 genes from the Ensembl reference, including 1,223 cancer-related genes, such as HER2 (based on COSMIC Cancer Gene Census, established ADC targets and HER2-expression related gene sets) to identify novel splice junctions and other features with the potential to act as diagnostic biomarkers for ADC targets including HER2. We identified 17,114 novel splice junctions from novel RNA isoforms (not previously reported in the Ensembl reference human transcriptome annotation) across 5,423 genes that were found at 5-50% prevalence within our cancer patient cohort. This included 1,381 novel splice junctions found within 357 of the cancer-related genes, including 12 novel splice junctions in HER2 representing potential alternative receptor structures. Comparative analysis of combined feature sets in samples with different HER2 statuses demonstrate potential for developing a liquid biopsy method of characterising cancer receptor profiles for informing suitable ADC therapies. Our novel approach utilizing full-length RNA sequencing enables more comprehensive characterization and precise quantification of tumor-associated expression of HER2 and other cancer-related genes, providing new insights into transcript diversity and expression patterns that are critical for improving diagnostic accuracy, refining treatment selection, and ultimately enhancing patient outcomes.

#3844 Longitudinal ctDNA monitoring in melanoma using highly multiplexed USE-PCR incorporating bespoke targets enables real-time detection of treatment response and recurrence.

Hunter Miller[1], Annalara Fischer[1], Melissa Hall[2], Michael E. Egger[3], Kavitha Yaddanapudi[4], Lucien Jacky[5], John Alvarado[5], Aaron Aguiar[5], Nathaniel Clark[5], Paul Belitz[5], Jeremy Myslinski[5], **Jerrod Schwartz**[5], Paul Flook[5], Mark Linder[1]

[1]Department of Pathology and Laboratory Medicine, University of Louisville, Louisville, KY,[2]Health Brown Cancer Center, University of Louisville, Louisville, KY,[3]Department of Surgery, Health Brown Cancer Center, University of Louisville, Louisville, KY,[4]Department of Medicine, Department of Microbiology and Immunology, Health Brown Cancer Center, University of Louisville, Louisville, KY,[5]ChromaCode, Inc., Carlsbad, CA

Purpose: Circulating tumor DNA (ctDNA) is a promising biomarker for real-time monitoring of treatment response and recurrence, but current sequencing-based assays are limited by cost, TAT, performance on difficult regions, and sampling frequency. Universal Signal Encoding PCR (USE-PCR) is a highly multiplexed digital PCR chemistry that enables >30 tumor-informed targets to be measured per reaction. We evaluated its performance in a longitudinal melanoma cohort with dense serial sampling.

Methods: Tumor/ctDNA sequencing identified subject-specific variants, including challenging GC-rich loci such as *TERT* c.-124C>T. Multiplexed, tumor-specific USE-PCR panels were designed using Apollo, an automated cloud-based workflow. Panels flexibly incorporated additional targets and were compatible with low-shedding ctDNA. Plasma cfDNA and matching PBMC samples were collected from 8 melanoma subjects at high density (up to 20 timepoints per patient over ~2 years). Plasma ctDNA VAF trajectories, corrected for PBMC, were quantified on a commercial dPCR platform and compared with clinical course and treatment events. Analytical validation included sensitivity, precision, linearity, specificity, cross-platform performance, and robustness with low DNA input (<10 ng).

Results: USE-PCR detected distinct molecular phenotypes including clear treatment response (rapid VAF decline), molecular recurrence (0→5%→15% VAF within ~80 days), stable disease (VAF ~0), and mixed responses with target-specific fluctuations often preceding clinical progression or therapy change. An average of four variants were measurable per subject. Sampling at ~20-day intervals uncovered rapid, low-level shifts in ctDNA, including subclonal SNVs at <0.2% VAF, not achievable with quarterly surveillance. Detection was reliable down to 80 ppm with ≤14 SNV targets, strong precision (CV <15%), and linearity over 4 logs. The platform was robust on GC-rich and historically difficult NGS targets, including the *TERT* promoter, maintained performance with low cfDNA input (<10 ng), and allowed seamless addition of new variants (e.g. *BRAF* V600E/K, *NRAS* Q61) for longitudinal monitoring.

Conclusions: USE-PCR is a rapid (median TAT < 6 hrs), low-cost, and highly scalable platform for tumor-informed ctDNA monitoring, enabling high multiplexing, compatibility with difficult genomic loci, and frequent sampling suitable for real-time clinical management. High-density longitudinal data reveal molecular patterns aligned with disease activity supporting USE-PCR for dynamic treatment response assessment and recurrence monitoring. Processing of a larger cohort is in progress to enable prospective clinical validation.

#3845 Enhancing MRD detection through an ultrasensitive ctDNA test: Insights from real-world clinical data.

Rachel Marty Pyke, Steven Dea, Sherif El-Refai, Fabio C. P. Navarro, Charles W. Abbott, Yi Chen, Janet Lai, Gabor Bartha, John M. Lyle, Jason Harris, Vijay Gunuganti, **Sean M. Boyle**, Richard O. Chen

Personalis, Inc., Fremont, CA

There is a need for more sensitive circulating tumor DNA (ctDNA) tests that can achieve earlier detection of disease. The NeXT Personal Dx (NPDx) ctDNA MRD test utilizes a bespoke panel of up to ~1800 variants to achieve ultrasensitive detection down to ~1 part per million (PPM) of ctDNA with high analytical specificity (>99.9%). Here, we describe the real world performance from more than 5,000 patients profiled using NPDx. In this analysis we examined performance in a variety of real world testing situations and in the ultrasensitive range below 100PPM and 10 PPM, the latter of which has not been previously characterized.

Overall, the median limit of detection (LOD) across all timepoints was 1.90 PPM (IQR:1.53-2.70 PPM) across 15 different cancer types. This performance was achieved with a relatively low median cell free DNA (cfDNA) input of 12ng (range 2-30 ng). 45.3% of tests were ctDNA positive overall. The NPDx tests performed well with challenging FFPE tumor samples (low tumor DIN <=3.4 or tumor fraction <=20%), achieving low LODs (median = 2.38 and 2.33 PPM, respectively). NPDx also achieved a median LOD of 3.78 PPM on low TMB tumors (<=0.98 mutation/MB). With ultra-low cfDNA inputs (<=5ng, 11.98% of cohort), NPDx achieved a median LOD of 2.31 PPM.

Next we looked at performance in the ultrasensitive ranges below 100 PPM and 10 PPM. 40.2% of detections were in the ultrasensitive range below 100 PPM. Notably, 36.6% of all ultrasensitive detections were found to be <10 PPM (14.7% of detections overall), which aligned well with data from published NeXT Personal clinical studies (Lung - 42.5% in RWD, 40.5% in Black et. al 2025; Breast - 37.5% in RWD, 42.2% in Garcia-Murrillas et. al 2025). Detection rates <10 PPM were consistent across cfDNA input amounts down to 2 ng. For those patients who had sustained ctDNA positivity after a ctDNA negative timepoint, 49% had their first MRD+ detection <10 PPM.

Two case studies demonstrate the clinical value of detections below 10 PPM in patient management. A 68-year-old female with squamous NSCLC underwent left upper lobectomy and MRD monitoring with NPDx. After three negative results, two low-level positives (6.2 and 9 PPM) prompted PET imaging that revealed a surgical-site recurrence. ctDNA rose to 80 PPM on the day of imaging, and radiation therapy led to ctDNA clearance. A 67-year-old female with colorectal cancer treated with FOLFOX + Avastin achieved ctDNA clearance and remained negative for over a year. Following a treatment break, low-level ctDNA positivity (1 and 3 PPM) preceded imaging-confirmed recurrence and chemotherapy was resumed. These cases highlight how NeXT Personal detections <10 PPM can guide earlier clinical interventions in real-world practice.

These data demonstrate the consistent performance of NPDx in challenging real world conditions with limited inputs. The data also indicate the importance of detections below both 100 PPM and 10 PPM in the clinical setting.

#3846 Short double-stranded cfDNA: A novel precision biomarker class for cancer diagnostics.

Mirko Sonntag[1], Zhoutao Zhang[1], Denise Leupold[1], Jan Mueller[1], Yevhen Vainshtein[1], Christina Hartwig[1], Georg F. Weber[2], Kai Sohn[1]

[1]In-Vitro Diagnostics, Fraunhofer IGB, Stuttgart, Germany,[2]University Clinics Erlangen, Erlangen, Germany

Background: Cancer diagnostics relies on highly specific and sensitive biomarkers to detect early stages in cancer progression as well as recurrence of disease (MRD). However, current approaches often fail to fulfill these needs, however, liquid biopsy based on cell-free DNA (cfDNA) and in particular short double-stranded cell-free DNA (footprint DNA) holds great promise for improvements. Derived from interaction of regulatory proteins including transcription factors at DNA-binding motifs, footprint DNA comprises genome-wide DNA footprints from plasma samples. Selective enrichment and quantitative analyses of footprint DNA reveal significantly different signatures for complex diseases diagnostics including various cancer types.
Methods: Footprint DNA of more than 200 plasma samples from various tumor types, including colorectal cancer and pancreatic ductal adenocarcinoma, as well as non-cancer controls were analyzed by high-throughput sequencing followed by bioinformatic peak identifications to generate a comprehensive reference annotation for genome-wide liquid footprint sites. Additionally, quantitative evaluation of footprint DNA from individual patient samples was used to differentiate between clinical conditions and benchmarking against standard of care diagnostics.
Results: Peak calling revealed approximately 8.6 million different peaks in about 6.5 million footprint regions. 3.3 million peaks overlap with annotated transcription factor bindings sites (TFBS). Moreover, 33,675 promotor regions, 55,406 CTCF sites and more than 100,000 enhancer binding regions are covered by footprint DNA signals. We also found that footprint DNA at defined genomic loci semi-quantitatively correlated with physiological markers like ALT or urea from major organ systems including liver or kidney. In a proof-of-concept cohort, differential footprint DNA biomarkers distinguished between clinical conditions, notably also closely related cancer types of colorectal cancer and pancreatic ductal adenocarcinoma (PDAC). Even same organ diseases (SOD) like pancreatitis and PDAC could be specifically discriminated using footprint DNA biomarkers.
Conclusion: Footprint DNA bears strong potential for cancer diagnostics, demonstrated by disease and cancer discrimination as well as differentiation between same organ disease. Footprint DNA enrichment sets the groundwork as identification platform of discriminatory footprint DNA biomarkers, which allows panel-based cancer detection for clinical applications. This opens new possibilities in early cancer detection and monitoring of minimal residual disease (MRD). Comprehensive footprint annotation will therefore provide a strong basis for the diagnostic of cancer and other complex diseases.

#3848 Urine cell-free DNA methylation-based deconvolution identifies tumor-specific cell types in localized urinary tract cancers.

Ze Zhang[1], Rashad Nawfal[1], Gunsagar Gulati[1], Damien Vasseur[1], Ji-Heui Seo[1], Hunter Savignano[1], Razane El Hajj Chehade[1], Karl Semaan[1], Tamara Merhej[2], John Canniff[1], Noa Phillips[1], Ning Shen[3], Phillip Adams[1], Ilana Epstein[1], Jack Horst[1], Alexis Zinselmeier[1], Rachel Throwbridge[1], Gwo-Shu Mary Lee[1], Jamil Azzi[4], Michelle S. Hirsch[4], Martin Kathrins[4], Timothy N. Clinton[4], Matthew Mossanen[4], Keegan Korthauer[3], Toni K. Choueiri[5], Matthew L. Freedman[1], Sylvan C. Baca[1]

[1]DFCI/Harvard Medical School, Boston, MA,[2]Harvard Medical School, Boston, MA,[3]Department of Statistics, The University of British Columbia, Vancouver, BC, Canada,[4]Brigham Women's Hospital, Boston, MA,[5]Dana-Farber Cancer Institute, Boston, MA

Background: Urine is a promising liquid biopsy source for non-invasive detection and monitoring of cancers of the urinary system, which currently lack screening tools for early diagnosis. Cell-free DNA methylation immunoprecipitation sequencing (cfMeDIP-seq) is a well-established tool to profile enriched 5-methylcytosine (5mC) signals in cell-free DNA (cfDNA). Recently, the *decemedip* computational framework was developed to enable cell-type deconvolution from cfMeDIP-seq data, providing a strategy to infer tumor- and immune-derived cfDNA contributions.

Methods: We designed a customized urinary cancer cfMeDIP-seq deconvolution panel and integrated it with the *decemedip* framework to estimate the proportions of nine cell types, including immune subsets (B cells, $CD4^+$ T cells, $CD8^+$ T cells, monocytes, neutrophils, and natural killer cells) as well as tumor-specific signatures for prostate, kidney, and urothelial cancers. Urine cfDNA from 54 patients at Dana-Farber Cancer Institute was profiled by cfMeDIP-seq, comprising 19 localized bladder cancers (BLCA), 18 localized renal cell carcinomas (RCC), 9 localized upper tract urothelial carcinomas (UTUC), and 8 non-cancerous kidney disease cases. Deconvolution was applied to infer cell-type composition across these groups.

Results: RCC samples exhibited significantly higher kidney cancer-derived cfDNA signal than BLCA and UTUC ($p = 3e-06$), while urothelial cancers showed significantly higher urothelial cancer-derived signal compared to RCC ($p = 1e-05$). The kidney-to-urothelial cancer cfDNA signal ratio distinguished RCC from urothelial cancers with an AUC of 0.984. In the bladder cancer cohort, five patients with low urothelial cancer signal had received neoadjuvant therapy, suggesting that deconvolution captures treatment-related changes. Excluding these cases further improved the discriminatory performance (AUC = 0.987). RCC patients also demonstrated significantly higher kidney cancer-derived signal than those with non-cancerous kidney disease ($p = 0.03$), supporting the utility of this approach for benign-malignant differentiation.

Conclusions: Urine cfDNA deconvolution via cfMeDIP-seq enables detection of tumor-specific signals and profiling of immune cell composition across localized urinary cancers. This noninvasive liquid biopsy approach demonstrates potential for early detection, disease subtyping, minimal residual disease assessment, and treatment response monitoring and warrants validation in larger prospective cohorts.

#3849 Frequent monitoring of NSCLC immunotherapy using an mDETECT liquid biopsy reveals unexpected complexity and opportunities.

Mihaela Mates[1], Andrew Robinson[1], Harriet Feilotter[2], Sofia Genta[1], Keira Frosst[3], Keira Parr[3], Garrett Baron[1], **Christopher R. Mueller**[3]

[1]Kingston Health Sciences Centre, Kingston, ON, Canada,[2]Toronto General Hospital, University Health Network, Toronto, ON, Canada,[3]Queen's University, Cancer Research Institute, Kingston, ON, Canada

The methylation DETEction of Circulating Tumour DNA (mDETECT) assay is a targeted DNA methylation-based Next Generation Sequencing liquid biopsy designed to detect cancer-specific methylation patterns. We have developed a version of our mDETECT assay that sensitively and quantitatively monitors Non-Small Cell Lung Cancer (NSCLC). This targeted approach assesses 23 differentially methylated genes in NSCLC patients covering 229 CpGs. Our assay has a 95% sensitivity at 95% specificity with an AUC of 0.95.

We conducted a pilot observational study to frequently measure tumour dynamics in patients undergoing first-line pembrolizumab monotherapy for metastatic NSCLC. 19 participants were recruited prior to the initiation of immunotherapy and followed using the mDETECT NSCLC assay. 40 mL of blood was collected pre-treatment then weekly or biweekly after treatment initiation with some patients being followed for up to 2.3 years. In total we collected 226 samples (median 11.8 timepoints per patient). Radiological assessment was performed approximately every three months as per the standard of care.

The primary aim of the study was to determine if overall survival (OS) could be predicted with the mDETECT assay within the first 6 weeks of treatment. Patients were divided by short (< 1 year), medium (1-4 years), and long term (> 4 years) OS. Patients with short OS showed constant or increasing mDETECT levels and never dropped below 80% of their pre-treatment mDETECT level. Patients with long OS showed an immediate decrease within the first 6 weeks of treatment and generally reached undetectable levels. Patients with medium OS showed a slower decline and a higher plateau than the long OS patients. These patterns, while derived from a small pilot cohort, suggest the mDETECT assay can determine within weeks if a patient is responding to immunotherapy. Continued monitoring revealed progression in some initially responding patients, with increasing mDETECT levels detected 4-6 months in advance of radiological progression.

Frequent assessment of tumour burden by a liquid biopsy such as mDETECT offers the opportunity to rapidly determine a patient's response to therapy and potentially modify treatments earlier than with radiology alone and on an ongoing basis. These findings support the feasibility and potential clinical utility of integrating methylation-based ctDNA monitoring into immunotherapy management workflows and justify further prospective validation in a larger study.

#3850 Liquid biopsy-based monitoring of disease status in patients with HPV-positive oropharyngeal carcinoma (OPSCC).

Jens Peter Klussmann[1], Oliver Siefer[1], Zurwa Merrjam Uzun[1], Jannik Johannsen[1], Dustin Firmenich[1], Nora Wuerdemann[2], Ernst J.M. Speel[3], Julie George[4]

[1]Department of Otorhinolaryngology, Head and Neck Surgery, University of Cologne, Cologne, Germany,[2]Medical Oncology, University of Cologne, Cologne, Germany,[3]Department of Pathology and Clinical Bioinformatics, Erasmus Medical Center, Rotterdam, Netherlands,[4]University of Cologne, Cologne, Germany

Introduction: The incidence of HPV-associated oropharyngeal carcinoma (HPV+ OPSCC) is increasing worldwide. In cases of tumor recurrence, distant metastases are often already present, which complicates curative tumor treatment. It is therefore of highly critical to collect molecular parameters to monitor the response of patients to therapy.
Material/Method: The aim of this study is to establish an HPV-specific blood-based analysis (liquid biopsy) to enable both early diagnosis and monitoring of disease progression. To this end, our clinical biobank includes >1800 circulating tumor DNA (ct-DNA) samples from> 300 patients with HPV-associated OPSCC at the time of initial diagnosis, during tumor treatment, as part of clinical follow-up care, and in the event of tumor recurrence.
Results: In a cohort of 434 longitudinally collected ctDNA samples from 53 patients with HPV+ OPSCC quantitative PCR (qPCR) and digital droplet PCR (ddPCR) was performed probing for E6 HPV-16 DNA sequences. In all cases, the HPV status was confirmed by p16-IHC, HPV16 DNA PCR for E6 and L1, and determination of the viral load in the tumor. There was a high concordance between qPCR- and ddPCR-based detection of HPV E6 ($P<0.001$), with ddPCR yielding higher sensitivity and specificity (>80%). HPV-16 ctDNA levels significantly correlated with tumor stage and tumor volume ($P<0.05$). In individual cases, a positive HPV ctDNA signal could be determined months before the diagnosis of tumor recurrence.
Discussion: ddPCR-based quantification of ct-HPV16-E6 DNA in blood is a promising diagnostic method to monitor therapy response and tumor progression in patients with HPV+ OPSCC. Prospective clinical studies are warranted to clinically validate ct-HPV16-E6 DNA as a quantitative biomarker for therapeutic efficacy and longitudinal disease monitoring.

#3851 Ultrasensitive ctDNA monitoring predicts early response of immunotherapy in recurrent metastatic non-small cell lung cancer.

Kishen R. Patel[1], Bailiang Li[2], Charles W. Abbott[2], Cristina Naceur-Lombardelli[1], Sadegh Saghafina[3], Sevasti Galani[1], James R. M. Black[1], Wing Liu[1], Nicola Steele[4], Gillian Price[5], Shobhit Baijal[6], Dean Fennell[7], Matthew G. Krebs[8], Tanya Ahmad[1], Alexandra Pender[9], Siow M. Lee[1], Mariam Jamal-Hanjani[1], Nicholas McGranahan[1], Allan Hackshaw[1], Sean Michael Boyle[2], Richard O. Chen[2], Charles Swanton[3], Crispin T. Hiley[1]

[1]University College London (UCL) Cancer Institute, London, United Kingdom,[2]Personalis, Inc., Menlo Park, CA,[3]The Francis Crick Institute, London, United Kingdom,[4]The Beatson West of Scotland Cancer Centre, Glasgow, United Kingdom,[5]Aberdeen Royal Infirmary, Aberdeen, United Kingdom,[6]The University Hospital Birmingham NHS Trust, Birmingham, United Kingdom,[7]Leicester Cancer Research Centre, Leicester, United Kingdom,[8]The Christie, Manchester, United Kingdom,[9]Royal Free Hospital, London, United Kingdom

Background: Circulating tumor DNA (ctDNA) offers a minimally invasive approach for response monitoring of cancer immunotherapy treatment and early prediction of therapeutic outcomes. However, the clinical utility of ctDNA-based liquid biopsy faces a critical challenge: reliable ctDNA detection in low-shedding tumors and in patients with low molecular residual disease (MRD) following treatment response. We employed an ultrasensitive ctDNA assay to address this technical limitation, enabling precise longitudinal monitoring essential for optimizing IO therapy.

Methods: We analyzed longitudinal plasma samples from 41 patients with non-small cell lung cancer (NSCLC) [adenocarcinoma (n=19), non-adenocarcinoma (n=22)], who received IO monotherapy (n=33) or combined IO and chemotherapy (n=8) in the *Deciphering Anti-tumour Response and Resistance With INtratumour Heterogeneity (DARWIN 2)* trial nested within the TRACERx study. Using NeXT Personal®, an ultra-sensitive personalized liquid biopsy approach, we tracked up to ~1,800 patient-specific somatic variants per case across 233 plasma samples.

Results: The median limit of detection across all tests was 1.52 parts per million (PPM), enabling ctDNA detection across six orders of magnitude (range 2.1-309,673 PPM), with 21% of positive ctDNA detections in the ultrasensitive range (<100 PPM), with that increasing to 28% while on treatment. Histological subtype had no impact on detection with this assay. Early molecular response (mR), defined as either >50% reduction in ctDNA or sustained ctDNA negativity from pre-treatment baseline to the subsequent plasma sample (median interval: 43.5 days), was significantly associated with improved clinical outcomes. Patients achieving early mR exhibited superior progression-free survival (PFS; HR = 0.33, 95% CI 0.14-0.77, $p = 0.010$) and overall survival (OS; HR = 0.31, 95% CI 0.14-0.70, $p = 0.005$). All patients with complete response by RECIST criteria achieved early mR (sensitivity = 100%). Conversely, disease in all patients lacking mR progressed within 15 months. Furthermore, durable molecular complete response (dmCR), defined as ctDNA negativity maintained for ≥180 days, was strongly associated with improved survival outcomes (2-year PFS: 50% vs. 9%, HR = 0.31 95%CI 0.11-0.90, $p = 0.032$; 2-year OS: 86% vs. 13%, HR = 0.06, 95% CI 0.01-0.48, $p = 0.007$ for dmCR vs. non-dmCR, respectively).

Conclusions: Early ctDNA kinetics serve as a robust predictor of long-term immunotherapy outcomes in patients with advanced NSCLC. The ability to detect ultra-low ctDNA levels allowed for accurate assessment of minimal residual disease, irrespective of lung cancer histology. These findings establish ultrasensitive ctDNA monitoring as a valuable tool for precise, real-time evaluation of immunotherapy response, with implications for clinical decision-making.

#3852 Ultrasensitive AI-driven framework for MRD detection based on multidimensional cfDNA features.

Yunfei Shi[1], Hao Zhang[2], Zexiao Lin[3], Ningyou Li[2], Maolong Wang[4], Hua Bao[2], Jinfeng Zhang[2], Zhili Chang[2], Yong Ge[5], Peng Li[6], Pan Wang[7], Liang Huang[8], Xiangming Liu[9], Lu Han[10], Wangming Ji[11], Teng Sun[9], Dujun Hua[2], Xunbiao Liu[2], Mingya Wang[2], Baihan Zhu[2], Dongqin Zhu[2], Xue Wu[2], **Haimeng Tang**[12], Hao Zhang[9], Yang Shao[13]

[1]The First Affiliated Hospital of Kunming Medical University, Kunming, China,[2]Geneseeq Research Institute, Nanjing Geneseeq Technology Inc., Nanjing, China,[3]Department of Medical Oncology, The Third Affiliated Hospital of Sun Yat-sen University, Guangzhou, China,[4]Department of Thoracic Surgery, Qingdao University Affiliated Hospital, Qingdao, China,[5]Department of Thoracic Surgery, Affiliated Hospital of Xuzhou Medical University, Xuzhou, China,[6]Department of General Surgery, The First Medical Centre, Chinese People's Liberation Army (PLA) General Hospital, Beijing, China,[7]Cancer Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing, China,[8]Beidahuang Group General Hospital, Branch 1, Harbin, China,[9]Affiliated Hospital of Xuzhou Medical University, Xuzhou, China,[10]The First Medical Centre, Chinese People's Liberation Army (PLA) General Hospital, Beijing, China,[11]PLA Rocket - Force Characteristic Medical Center, Beijing, China,[12]Geneseeq Technology Inc., Toronto, ON, Canada,[13]Nanjing Geneseeq Technology Inc., Nanjing, China

Minimal residual disease (MRD) detection is essential for postoperative risk stratification and recurrence prediction in cancer, yet current fixed-panel assays exhibit limited sensitivity and specificity, particularly in tumor-naïve settings. We developed Shielding Ultra, a pan-cancer MRD assay targeting hotspot mutations across 2,365 cancer-related genes. Leveraging ultra-deep unique molecular identifier-based sequencing and AI-driven bioinformatics, the assay integrates somatic mutations, copy number variations (CNVs), and fragmentomic (Frag) features to enable multidimensional MRD assessment within a unified workflow. Analytical validation established a detection limit of 0.0048% and demonstrated 94% sensitivity in late-stage preoperative plasma, with approximately 99% specificity in healthy controls. Tumor-naïve analysis achieved 98.9% concordance with tumor-informed workflows following multimodal integration, supporting applicability when tumor tissue is unavailable. Clinical validation across colorectal, cholangiocarcinoma, and lung cancer cohorts confirmed strong prognostic performance at early postsurgical timepoints while maintaining high specificity. In colorectal cancer, MRD positivity showed a robust association with relapse, yielding hazard ratios up to 32.47 and achieving longitudinal sensitivity of up to 90.9% during postoperative surveillance. In lung cancer, recurrence detection sensitivity was 51.5% at one week after surgery and increased to 72.7% with the addition of one-month postsurgical sampling. Across cancer types, multimodal cfDNA integration strengthened detection performance and enabled reliable identification of MRD across diverse clinical contexts. These findings demonstrate that Shielding Ultra enables sensitive and specific MRD detection through the integration of multidimensional cfDNA features and AI-based algorithms. Its strong prognostic performance across multiple malignancies and compatibility with tumor-naïve workflows support its utility for postoperative risk stratification and personalized disease management.

#3853 Genomic profiling of circulating tumor DNA in endometrial cancer in Asia: A-TRAIN study.

Hiroki Tamura[1], Yuki Kojima[2], Kazuki Sudo[3], Wan Zamaniah Wan Ishak[4], Marcelo S. Imasa[5], Arb-aroon Lertkhachonsuk[6], Ryoka Miki[7], Hiroshi Yoshida[8], Shinji Kohsaka[2], Yukari Nagasaka[1], Ryunosuke Machida[9], Tetsuya Sasaki[10], Tomomi Hata[9], Kenichi Nakamura[9], Kan Yonemori[9]

[1]National Cancer Center Hospital, Tokyo, Japan,[2]National Cancer Center Japan, Tokyo, Japan,[3]National Cancer Center Hospital - Japan, Tokyo, Japan,[4]University Malaya Medical Centre, Kuala Lumpur, Malaysia,[5]St. Lukes Medical Ctr., Quezon City, Philippines,[6]Faculty of Medicine Ramathibodi Hospital, Bangkok, Thailand,[7]Life Technologies Japan Ltd, Tokyo, Japan,[8]Gastrointestinal Oncology Division, National Cancer Center Hospital, Tokyo, Japan,[9]National Cancer Center Hospital , Tokyo, Japan,[10]Clinical Research Support Office, National Cancer Center Hpspital, Tokyo, Japan

Background: Endometrial cancer affects more than 420,000 women worldwide, with approximately 40% of cases occurring in Asia. Recently, endometrial cancer is now more precisely categorized through molecular subtyping, which has improved prognostic assessment and guided treatment strategies. In this study, we identified molecular subtypes of endometrial cancer in Asian patients using comprehensive genomic profiling of liquid biopsy samples, circulating tumor DNA (ctDNA).
Methods: This is an Asian multicenter prospective observational study conducted by five institutions in Japan, Malaysia, Philippines, Taiwan, and Thailand (NCT05099978, ClinicalTrials.gov). Eligible patients had histological diagnosis of endometrial cancer with metastatic or recurrent disease. Genomic profiling was conducted by AmpliSeq HD custom panel (Thermo Fisher Scientific), targeting 23 genes (752 amplicons), designed using AmpliSeq Designer to cover on genes and hotspot mutation regions associated with endometrial cancer. This panel can identify (1) full-length in following genes: *ARID1A, ARID1B, B2M, CCNE1, CTCF, JAK1, PIK3R1, PTEN, RB1, RPL22, SMARCB1, SMARCA4* and *TP53*, (2) hotspot mutation or region in following genes: *AKT1, BRAF, CTNNB1, ERBB2, KRAS, MET, MYC, PIK3CA, POLE* and *PPP2R1A*.
Results: From August 2022 to March 2024, a total of 60 patients with advanced endometrial cancer were enrolled, including 44 from Japan, 10 from Taiwan, 3 from Malaysia, 2 from Philippines, and 1 from Thailand. The median age was 59 (range, 31 to 79) years. Most cases were at relapse (36; 60.0%) at liquid biopsy. In terms of therapy, 10 (16.7%) of the subjects had received radiation prior to the liquid biopsy, and 33 (55%) of the patients had received chemotherapy prior to the liquid biopsy. Genomic alterations were detected in 75.0% (45/60), with a median number of 2 genomic abnormality per case (range, 0-12). The most frequently altered genes were *PTEN* (n=20, 33.3%), *TP53* (n=19, 31.7%), *PIK3CA* (n=19, 31.7%) and *CTNNB1* (n=14, 23.3%). CNV analysis excluded 18 samples with both low coverage depth and low uniformity, or low uniformity alone, resulting in a total of 42 cases analyzed. CNVs were detected in eight patients: 2 with *ERBB2* amplification, 2 with *PIK3CA* amplification, 2 with *MYC* amplification, and 2 with *CCNE1* amplification.
Conclusion: The comprehensive genomic profiling of liquid-based samples prior to treatment initiation may help guide personalized therapeutic strategies for Asian patients with advanced or recurrent endometrial cancer.

#3854 Plasma cell-free RNA transcriptome analysis reveals transcriptional dysregulation and immune remodeling in pancreatic ductal adenocarcinoma.

Gyuryang Park[1], Hyosil Kim[2], Tae Young Kim[1], Sung Joon Kim[1], Jin-Hwa Park[1], Baeki E. Kang[3], Jung Won Chun[1], Sung-Sik Han[1], Tae Min Kim[3], Sang Myung Woo[1]

[1]National Cancer Center - Korea, Goyang-si, Gyeonggi-do, Korea, Republic of,[2]Cancer Research Institute, College of Medicine, The Catholic University of Korea, Seoul, Korea, Republic of,[3]Department of Medical Informatics, College of Medicine, The Catholic University of Korea, Seoul, Korea, Republic of

Pancreatic ductal adenocarcinoma (PDAC) is a highly lethal cancer due to poor early detection and frequent treatment resistance. Current tumor markers, including carbohydrate antigen 19-9 (CA19-9), show limited diagnostic and prognostic accuracy, underscoring the need for efficient biomarkers. Cell-free RNA (cfRNA), which circulates in body fluids and can be obtained through a minimally invasive approach, reflects tumor- and tissue-specific gene expression, offering strong potential as a biomarker across various cancer types. In brief, whole blood samples were collected from PDAC patients (n=63) and healthy controls (n=8), followed by plasma isolation via centrifugation prior to cfRNA extraction. Cell-free nucleic acids were isolated using a standardized circulating nucleic acid protocol, and cfRNA purity was enhanced through additional DNase treatment and a cleanup step. Complementary DNA (cDNA) libraries were generated using a low-input, strand-specific RNA sequencing method and were paired-end sequenced on a high-throughput next-generation sequencing platform.cfRNA transcriptomic analysis identified 541 differentially expressed genes (adjusted $p < 0.05$, $|\log_2 FC| > 1$), of which 496 were upregulated and 45 were downregulated in PDAC compared with healthy controls. Although most genes were not correlated with tumor stage, a subset displayed progressive, stage-dependent expression changes. Such gradual increases or decreases across tumor stages may reflect tumor burden and disease advancement, suggesting their potential as molecular indicators of PDAC progression. Functional enrichment analysis revealed pathways related to extracellular matrix remodeling, immune regulation, and cell proliferation. Additionally, cfRNA deconvolution analysis inferred shifts in immune cell composition. Notably, the proportion of neutrophils increased from approximately 7-9% in healthy controls to 10-15% across PDAC stages, whereas naïve CD4 T cells showed a marked decline from about 26% to 10-15%, and naïve B cells decreased from roughly 13-14% to 5-10%. In contrast, regulatory T cells exhibited a relative increase across PDAC stages. Together, these alterations reflect an immune landscape progressively skewed toward immunosuppressive features in PDAC. These findings collectively suggest cfRNA transcriptomic profiling captures tumor-derived transcriptional dysregulation and systemic immune remodeling, highlighting its promise as a biomarker source and a longitudinal monitoring tool for PDAC. Funding: This work was supported in part by the National Cancer Center, Korea (No. 2510590).

#3855 Circulating DNA methylation signatures enable early detection of gastrointestinal cancers.

Ruo-Kai Lin, YAO-YU HSIEH

Taipei Medical University, Taipei, Taiwan

Background: Early detection of gastrointestinal cancers remains a major clinical challenge due to their asymptomatic early stages—particularly for pancreatic and liver cancers—combined with the limited sensitivity of current screening modalities, inadequate identification of high-risk populations, and persistent disparities in surveillance access. Given the high mortality associated with pancreatic and liver cancers and the substantial global incidence of colorectal cancer, more effective early diagnostic strategies are urgently needed.

Methods and Findings: We previously identified aberrant DNA methylation of *ZFP30* and *ZNF781* in circulating tumor DNA (ctDNA) from patients with pancreatic cancer, and aberrant methylation of *TMEM240* in patients with colorectal cancer, with *TMEM240* hypermethylation additionally associated with liver metastasis in gastrointestinal malignancies. In this study, we evaluated methylation levels of *ZFP30/ZNF781* and *TMEM240* in hepatocellular carcinoma (HCC) tumor tissues and matched adjacent normal tissues using qMSP, revealing significantly elevated methylation in all tumor samples. Aberrant methylation of these genes was also detected in plasma cell-free DNA (cfDNA) from patients with liver cancer. Analysis of TCGA Western cohorts further confirmed consistently increased methylation of these loci in pancreatic, colorectal, and liver cancers.

Validation: We validated these biomarkers in independent Asian (Taiwan) and Western (U.S.) cohorts comprising 101 gastrointestinal cancer cases—including pancreatic, colon, rectal, and liver cancers—and 350 cancer-free healthy subjects. Aberrant methylation of *ZFP30/ZNF781* and/or *TMEM240* was detectable across all gastrointestinal cancer types analyzed.

Results: Detection sensitivities were 93.8% for early-stage pancreatic cancer, 100% for late-stage pancreatic cancer, 90.62% for colon cancer, 99.0% for rectal cancer, and 90% for liver cancer, with a specificity of 98% in cancer-free controls.

Conclusion: These results demonstrate that circulating DNA methylation signatures of *ZFP30/ZNF781* and *TMEM240*provide a highly sensitive and specific non-invasive approach for detecting a broad spectrum of gastrointestinal cancers, supporting their potential utility as early detection biomarkers.

#3856 Detection of cfDNA shedding from advanced precancerous lesions.

Fei Lu, **Liliana Cerna**, Spenser Alexander, Noura Tbeileh, Esha Atolia, Dina Hafez, Eser Kirkizlar, Matthew Rabinowitz, Alexey Aleshin, Trupti Kawli

Natera, Inc., Austin, TX

Minimally invasive, blood-based tests for the detection of colorectal cancer (CRC) and advanced precancerous lesions (APLs) have emerged as a screening tool to aid in the early detection of cancer. While cell-free (cf)DNA detection of CRC has demonstrated high sensitivity and specificity, APL detection has been less successful. In an effort to understand these limitations, we evaluated the prevalence of APL cfDNA biomarkers from plasma samples. Formalin-fixed, paraffin-embedded (FFPE) or fresh frozen (FF) APL tissue and matched normal blood samples from 61 (FFPE n=27, FF n=34) individuals were obtained through biobanks. Whole-genome sequencing (WGS) data was used to design custom, research-use only, personalized, mPCR-NGS-based circulating tumor (ct)DNA assays. Matched plasma samples collected at the same time as tissue and whole blood collection were evaluated for the presence of circulating APL biomarkers in plasma. Sensitivity was calculated in FFPE and FF for the overall cohorts, by APL subtype, and lesion size. Because the subtype distribution differed from expected prevalence in screening trials (pmids 38477985, 40455622), a distribution was constructed to be representative of the final pivotal study so that a reflective sensitivity estimate could be calculated. Overall at a 90% specificity, APL plasma sensitivity adjusted for subtype incidence was 25% and 37% in matched FFPE and FF tissue samples, respectively. The lower plasma detection rate in FFPE samples could be due to the compromised tissue gDNA integrity and personalized mPCR assay design-ability with FFPE tissue preservation methodology. Median plasma sample variant allele frequencies (VAF) of detected samples was 3.6x10-5 and 1.4x10-5 for FFPE and FF, respectively. APL plasma sensitivity for was calculated for each APL subtype, including high-grade dysplasia (FFPE: 40%, N=10; FF: 38%, N=10), villous growth >25% (FFPE: 25%, N=8; FF: 38%, N=13), tubular adenomas >10 mm (FFPE: 25%, N=4; FF: 33%, N=3), and serrated lesions >10 mm (FFPE: 20%, N=5; FF: 50%, N=8). In general, sensitivity increased as lesion size increased (FFPE: 4-10 mm 20%, 11-20 mm 30%, 21-30 mm 50%, ≥31 mm 50%; FF: 4-10 mm 22%, 11-20 mm 47%, 21-30 mm 67%, ≥31 mm: 33%). In this study, we established a baseline of APL ctDNA shedding using a tissue-informed ctDNA assay that can be used for optimizing assays designed to detect APLs at expected levels in cell-free DNA.

#3857 Comprehensive profiling of circulating tumor DNA in blood enables sensitive detection and genomic characterization of HPV cancer and precancer.

Qin Wang[1], Samuli Eldorfs[1], Sangmi Sandra Lee[2], Yana Al-Inaya[1], Gjystina Lumaj[1], Eliana Epstein[3], Dipon Das[1], Emma Ricart[4], Harsharan Dhillon[5], Juniper Lake[5], Michael G. Drage[3], Shun Hirayama[6], Viktor Adalsteinsson[7], Benjamin T. Davis[3], Doga C. Gulhan[2], Daniel Faden[3]

[1]Otolaryngology-Head and Neck Surgery, Massachusetts Eye and Ear, Boston, MA,[2]Department of Biomedical Informatics, Harvard Medical School, Boston, MA,[3]Mass General Brigham, Boston, MA,[4]Harvard Medical School, Boston, MA,[5]Pacific Biosciences, Menlo Park, CA,[6]Wakayama Medical University, Wakayama, Japan,[7]Broad Institute, Cambridge, MA

Background: Human papillomavirus (HPV) causes six cancer types, yet five lack population-level screening. We have developed HPV-DeepSeek, a blood-based, multi-feature HPV whole-genome sequencing assay targeting circulating tumor HPV DNA (ctHPVDNA). HPV-DeepSeek has detected HPV+ oropharynx cancer years prior to clinical diagnosis, establishing the feasibility of blood-based HPV+ cancer screening. Here we extend testing to HPV+ anal cancer (HPV+AC) with well-defined precancer stages, to comprehensively assess blood-based detection of HPV+ cancer and precancer.
Methods: HPV-DeepSeek was applied to a pre-diagnostic cohort collected 2.8-8.6 years before HPV+AC diagnosis (N=6) and to a prospective cohort (SCAN-LITE, NCT06971276), comprising HPV+AC (N=10), anal intraepithelial neoplasia 3 (AIN3) (N=20), AIN2 (N=20), AIN1 (N=20), anal HPV-infection (N=20), anal HPV-negative with past HPV history (N=14), and healthy controls (N=60). For validation, 78 paired tissue samples were profiled with HPV-DeepSeek and 5 underwent PacBio long-read sequencing.
Results: 4/6 pre-diagnostic samples tested positive, with detection lead time 2.8 to 7.2 years before cancer diagnosis. In the SCAN-LITE study, the sensitivity for HPV+AC was 100% (10/10). Profiling ctHPVDNA detected HPV-human integration in 6/10 cases and HPV-HPV rearrangements in 8/10, which were validated in paired tissue. PIK3CA mutations were found in 2/10 cases, and CNVs were detected in 3/10 cases at the chr3q hotspot. In precancers, ctHPVDNA was detectable with decreasing positivity by disease severity: 32.5% in AIN3/AIN2 and 12.5% in AIN1/infection. 1/14 (7.1%) HPV-negative control tested positive and was later diagnosed with HPV-infection at follow-up. All healthy controls were negative, yielding 100% specificity. No HPV integration, PIK3CA mutations, or CNVs were detected in precancer. While HPV+AC primarily showed HPV16 (10/10) with one case also harboring HPV35, precancer exhibited diverse genotypes. 20 genotypes were detected, including 6 multi-genotype infections found exclusively in high-grade precancers (AIN3/2). Fragmentomics analysis revealed distinct length profiles across stages, particularly di-nucleosome peaks enriched in HPV+AC while depleted in precancer, reflecting HPV epigenetic changes during carcinogenesis.
Conclusions: HPV+AC is detectable in blood at and before clinical diagnosis. We also show, for the first time, that HPV precancer can be detected in blood, with increasing positivity as stages progress. Blood-based detection of HPV+ cancer hallmarks, including HPV integration, PIK3CA mutation, and CNV, differentiates cancer from precancer, while fragmentomics adds to stage-specific signatures. Together, these findings support the feasibility of blood-based HPV+ cancer and precancer screening with the potential of stage differentiation.

#3858 Methylation profiling of cell free DNA using EMSeq whole genome sequencing and a targeted methylome panel for classification of pediatric ocular and brain tumors.

Laura A. T. Kagami[1], David N. Buckley[1], Jesse L. Berry[1], Susan N. Chi[2], Xiaowu Gai[3], Erin Kiehna[4], Katrina O'Hollaran[1], Dejerianne Ostrow[1], Tom Rosenberg[2], Yan Chen Wongworawat[5], Liya Xu[1], Jaclyn Biegel[1]

[1]Children's Hospital Los Angeles, Los Angeles, CA,[2]Dana-Farber Cancer Institute, Boston, MA,[3]Medical College of Wisconsin, Milwaukee, MN,[4]Novant Health, Charlotte, NC,[5]Loma Linda University, Loma Linda, CA

Methylation profiling has become an increasingly valuable tool for brain tumor subclassification, especially when histologic evaluation is ambiguous and standard genetic assays are non-informative. While methylation profiling of tumor tissue is well-described, comparable analysis using cell free DNA is not yet established, especially in pediatric oncology.

We evaluated the feasibility of enzymatic methylation conversion (EMSeq) and either direct whole genome sequencing (WGS) or hybridization with a 123 megabase methylome panel (Twist BioScience). Both methods were performed on 13 samples from 12 patients with central nervous system (CNS) tumors or retinoblastoma (RB), including 10 cerebrospinal fluid (CSF) and three aqueous humor (AH) samples using 5 ng of cfDNA input. All 13 samples classified accurately with an in-house neural network model. To assess sensitivity, six CSF samples from two patients were further diluted for 1 and 2 ng input into each assay. Classification results remained consistent across dilutions, and no appreciable differences were observed between EMSeq WGS and the Twist assay.

We selected EMSeq WGS for further studies due to the ability to generate genome-wide copy number plots, unbiased CpG coverage, and faster turnaround time. Twenty-eight diagnostic and surveillance AH and CSF samples representing 13 embryonal tumors (medulloblastoma, atypical teratoid/rhabdoid tumors, embryonal tumor with multilayered rosettes, RB), five gliomas (low- and high-grade), four ependymomas, and six other CNS tumors were processed using EMSeq WGS. We compared copy number profiles generated from cfDNA EMSeq WGS to our clinically validated LBSeq4Kids platform, which combines low passage WGS (LP-WGS) to detect copy number alterations and a targeted sequencing panel to detect structural variants and fusions. In all cases, copy number profiles generated from EMSeq WGS were concordant with those from LBSeq4Kids LP-WGS.

Diagnostic AH samples, and CSF samples obtained via lumbar puncture, external ventricular drain, or ventriculoperitoneal shunt demonstrated methylation profiles concordant with their expected tumor classes. In contrast, samples obtained intraoperatively or at recurrence showed reduced classification accuracy, with some clustering with non-cancer control references. In our experience, depending on CNS tumor type and anatomic location, CSF samples obtained via intraoperative collections have rendered less reliable cfDNA data.

Herein we demonstrate that methylation profiling of cfDNA using EMSeq WGS is feasible and informative, expanding the diagnostic potential of liquid biopsy approaches to pediatric tumors. Integration of methylation analysis into our current LBSeq4Kids platform will enable comprehensive molecular profiling for diagnosis, subclassification, and disease monitoring.

#3859 Dynamic systemic immune modulation in metastatic neuroendocrine tumor (NET) patients treated with targeted alpha-emitter ^{212}Pb-DOTAMTATE AlphaMedix.

Alessandra Jordano Conforte[1], Izabela Tworowska[2], Sara Fonseca Costa[1], Marta Brzezinska[1], Amaia Martinez Usatorres[1], Noushin Hadadi[1], Sylvain Monnier-Benoit[1], Simona Pavan[1], Rouzbeh Esfandiari[3], Brian Hashemi[1], **Pedro Romero**[1], Ebrahim S. Delpassand[2]

[1]Novigenix SA, Epalinges, Switzerland,[2]RadioMedix, Houston, TX,[3]Excel Diagnostics & Nuclear Oncology Center, Houston, TX

Peptide receptor radionuclide therapy (PRRT) has been increasingly explored as a therapeutic strategy for multiple solid tumors, such as prostate cancer and somatostatin receptor-expressing GEP-NETs. While Lutathera (^{177}Lu-DOTATATE), a β-emitting PRRT, represents the current GEP-NETs standard of care. α-emitting PRRTs such as AlphaMedix (^{212}Pb-DOTAMTATE) are emerging as promising alternatives with distinct radiobiological characteristics. Ionizing radiation from PRRT not only induces DNA damage but also modulate the immune system, contributing to therapeutic response.We sought to identify evidence of systemic immunomodulation associated with α-emitter AlphaMedix treatment and to compare it with that elicited by Lutathera. Whole-blood immunotranscriptomes were analyzed using the LITOSeek platform to characterize immune signatures and pathways differentially activated by α- and β-emitting PRRTs. This approach elucidates the immunological mechanisms underlying α-particle therapy and uncovers potential biomarkers of treatment response.

Methods: Whole blood samples were collected with PAXgene Blood RNA tubes from GEP-NET patients before and throughout AlphaMedix or Lutathera treatment. Differential expression, over-representation analysis, digital cytometry, and trajectory identification were used to characterize treatment-induced regulation of peripheral immunotranscriptomes, immune cell composition, and heterogenous responses within the patient population.

Results: AlphaMedix therapy induced strong peripheral transcriptomic changes in patients achieving complete or partial response, detectable from 8 weeks after first infusion, and up to 6 months after end of treatment. AlphaMedix triggers similar transcriptomic changes throughout the treatment among patients responding to the therapy, which is stronger and different from patients treated with Lutathera. The ^{212}Pb radioligand therapy triggers early generation of ROS, DNA damage, apoptotic responses, inflammation and monocyte recruitment. The results reveal two waves of immunotranscriptome modulation, likely reflecting kinetics heterogeneity of immune activation between early and late responders. Lymphopenia, particularly affecting B cells, was observed in patients treated with either AlphaMedix or Luthatera, with more pronounced lymphopenia among patients treated with Lutathera.

Conclusions: Data-driven characterization of treatment-associated transcriptional changes in peripheral immune cells underscores immune modulation associated with clinical response to radioligand therapy. The translational potential of whole-blood RNA liquid biopsy is demonstrated with Immuno-Pharmacodynamic profiling of patient response to radioligand therapy, and identification of immune-related biomarkers of clinical response.

#3860 A low-cost bioassay for multi-cancer detection in cfDNA using quantitative methylation-specific PCR.

Emily Neaga, Sarah Falotico, Mayur Gurnani, Miguel Williams, Anthony Shuber

Harbinger Health, Cambridge, MA

Liquid biopsy multi-cancer detection tests hold significant promise to improve patient outcomes by enabling earlier intervention. However, emerging sequencing-based assays face practical challenges due to high costs, complex workflows, and long turnaround times. In contrast, quantitative methylation-specific PCR (qMSP) enables rapid turnaround times with low-cost, low-complexity, and scalable workflows, while accommodating flexible batch sizes and decentralized testing. Harbinger Health's proprietary methylation biomarkers were applied to Harbinger Health's proprietary qMSP method to enable low-cost multi-cancer detection. Harbinger Health's biomarkers are associated with the initiation of oncogenesis and are ubiquitously observed across multiple cancer types. This redundancy enabled the selection of six highly pan-cancer-informative methylation patterns, reducing the genomic footprint while largely maintaining cancer detection performance. Despite the informative nature of these biomarkers, background methylation from processes like aging can attenuate disease detection. To address this limitation, Harbinger developed a qMSP method that incorporates locked nucleic acid (LNA) blockers to suppress probe mishybridization to stochastically methylated somatic cell-free DNA (cfDNA), improving selectivity for defined methylation patterns in low abundance circulating tumor DNA (ctDNA). The qMSP panel underwent analytical validation during development and demonstrated high sensitivity, specificity, and reproducibility for detecting cfDNA fragments with defined methylation patterns. The panel was applied to 130 cfDNA samples obtained from the CORE-HH clinical study (NCT05435066), representing 62 non-cancer samples and 68 cancer samples across nine cancer types. Samples were selected to reflect a similar range of methylation signals observed in the CORE-HH study cohort. The cancer samples represented a balanced stage distribution. cfDNA samples were processed into bisulfite libraries and analyzed by qMSP using 5 ng of library per reaction. The cycle threshold (Ct) of each methylation marker was normalized to an internal reference assay and delta Ct values were used to measure methylation. Using target-specific detection thresholds established on 62 non-cancer samples to achieve an equivalent of 97% specificity, qMSP detected at least one positive target for 30 of 68 (44%) cancer samples. This work represents an initial proof of concept for a low-cost multi-cancer detection assay. qMSP reactions in this study cost less than $5 per sample and were completed in under five hours, addressing key barriers to population-scale implementation such as cost and turnaround time. Future refinements, including expansion of the marker panel, optimization of detection thresholds, and improved assay design, are expected to further improve clinical performance.

#3861 Low-cost detection of advanced adenomas in cfDNA using quantitative methylation-specific PCR.

Emily Neaga, Sarah Falotico, Mayur Gurnani, Miguel Williams, Anthony Shuber

Harbinger Health, Cambridge, MA

Removal of advanced adenomas during colonoscopy has been shown to significantly reduce colorectal cancer incidence and mortality. However, many patients recommended for colorectal screening remain unscreened due to the invasive nature of colonoscopy. Liquid biopsy cancer detection tests hold significant promise to improve patient outcomes by broadening access and enabling earlier intervention. However, the cost, complexity, and turnaround times of emerging sequencing-based assays present challenges for population-level adoption. To address these challenges, Harbinger Health applied a refined panel of methylation markers in a methylation-specific quantitative PCR (qMSP) assay. qMSP provides a rapid, low-cost, and scalable approach for advanced adenoma (AA) detection in cell-free DNA (cfDNA). Harbinger Health utilizes proprietary methylation biomarkers associated with the initiation of oncogenesis. Redundancy across these markers enabled the selection of six highly pan-cancer-informative methylation patterns that distinguish cancer from non-cancer cfDNA with a small genomic footprint. Harbinger Health developed a qMSP method that quantifies specific methylation patterns using probes that hybridize to highly methylated variants, combined with locked nucleic acid (LNA) blockers that suppress non-specific signal from partially methylated variants. This improved selectivity enables the detection of rare circulating DNA (ctDNA) variants within a heterogenous cfDNA background. The qMSP panel underwent analytical validation during development and demonstrated high sensitivity, specificity, and reproducibility. The qMSP panel was evaluated in a cohort comprised of 62 cfDNA samples collected from patients with no reported cancer in the CORE-HH clinical study (NCT05435066) and 38 commercially sourced cfDNA samples collected from patients with confirmed advanced colorectal adenomas. cfDNA samples were processed into bisulfite libraries and analyzed by qMSP at 5 ng of library per reaction. The cycle threshold (Ct) of each methylation marker was normalized to an internal reference assay and delta Ct values were used to measure methylation. Using target-specific detection thresholds established on 62 non-cancer samples to achieve an equivalent of 90% specificity, qMSP detected at least one positive target for 18 of 38 (47%) AA samples. This work demonstrates the use of qMSP to quantify highly informative methylation markers for AA detection in cfDNA. A six-marker panel effectively distinguished AA samples from non-cancer samples in a cohort of 100 cfDNA libraries. Notably, marker selection was not optimized for AA detection, and an expanded panel with AA-specific biomarkers is expected to further improve clinical performance. qMSP reactions in this study cost less than $5 per sample and exemplify a rapid, low-cost analytical method for the detection of advanced colorectal adenomas.

#3862 Convergent chromatin remodeling enables pan-aerodigestive detection of advanced malignancies in plasma cfDNA.

Axel Misael Hidalgo, Ayesha Hashmi, Jeff Szymanski, Pradeep Chauhan, Lilli Greiner, Faridi Qaium, Daniel J. Ma, David M. Routman, Katie M. Van Abel, Aadel A. Chaudhuri

Mayo Clinic, Rochester, MN

Background:
Liquid biopsy approaches for cancer detection often rely on tissue-specific methylation or fragmentation features to infer tumor origin. However, a pan-aerodigestive cancer detection strategy is clinically valuable given shared risk exposures, field cancerization, and frequent diagnostic ambiguity among lung, esophageal, and head & neck cancers. We hypothesized that advanced-stage disease exhibits convergent chromatin remodeling, producing a dominant malignancy-associated fragmentomic signal that supersedes subtler tissue-of-origin patterns.
Methods:
Whole-genome EM-seq (~15×) was performed on plasma cfDNA from 120 patients with stage III/IV aerodigestive cancers (lung, esophageal, head & neck; squamous and adenocarcinoma) and 60 age-matched controls. Four fragmentomic modalities were assessed: (1) genome-wide fragmentation in 5-Mb bins (DELFI-like), (2) NMF spectral components, (3) 4-mer end motifs, and (4) promoter-centric nucleosome scores (Griffin). All preprocessing occurred strictly within each training fold of a repeated stratified 10-fold CV (100 repeats) to prevent data leakage. No test-sample information was used in training. Hyperparameters were tuned only within training partitions. Random Forest classifiers were trained under this fully nested scheme.
Results:
The multimodal classifier robustly detected advanced aerodigestive malignancies with a mean AUROC 0.86 and AUPRC 0.94. However, modality dissection revealed a clear performance hierarchy: nucleosome positioning (Griffin) alone achieved AUROC 0.85 and AUPRC 0.93, nearly matching the full integrated model, whereas end motifs performed poorly (AUROC 0.61). Biological interpretation demonstrated prominent nucleosome depletion centered at promoters of proliferation-associated genes, indicating a convergent epigenetic state of promoter opening across late-stage aerodigestive malignancies.
Conclusions:
Advanced aerodigestive cancers exhibit a dominant, convergent chromatin remodeling signature detectable in plasma cfDNA, driven primarily by altered nucleosome positioning. In late-stage disease, this shared malignancy-associated fragmentomic signal outweighs tissue-of-origin-dependent patterns. These findings highlight the utility of nucleosome-based fragmentomics not merely for detection, but for resolving diagnostic ambiguity in patients with indeterminate masses and for monitoring total tumor burden in high-risk aerodigestive malignancies.

#3863 Enhanced cfDNA fragmentation-based treatment monitoring on the Ultima Genomics platform.

Laurel K. Millberg[1], Garrett Graham[1], Zachary Skidmore[1], Jordan Gumm[1], Kevin Jacobs[1], Ariel Jaimovich[2], Elena Helman[2], Bryan Chesnick[1], Roberto Olivares-Amaya[1], Timothy Mcdaniel[1], Sian Jones[1], Amoolya Singh[1], Lorenzo Rinaldi[1]

[1]Delfi Diagnostics, Palo Alto, CA,[2]Ultima Genomics, Freemont, CA

Introduction: Whole-genome analysis of cell-free DNA (cfDNA) fragmentation, such as DELFI-Tumor Fraction (DELFI-TF), has emerged as a powerful tool for monitoring therapeutic response in patients with late-stage cancer. In this study, we assessed the technical feasibility of the Ultima Genomics sequencing platform for a cfDNA fragmentation-based monitoring application.
Methods: The study consisted of two cohorts: 1) 48 longitudinal plasma samples collected from 16 stage IV lung cancer patients and 2) 4 tumor, normal, and matched plasma samples of varying tumor types from treatment-naive stage IV patients. cfDNA was sequenced using three methods: the Illumina NovaSeq6000 (mean depth: 11.8x) and the Ultima UG 100 using the standard approach (8 replicates per sample, 11.0x) or ppmSeq (174.6x). Fragmentation features and DELFI-TF were computed, and DELFI-TF values were compared against somatic variant allele frequencies (VAF) from a 500-gene targeted sequencing panel. WGS somatic variants were identified by filtering ppmSeq variant calls and used to categorize reads into two groups based on their likely origin: tumor or white blood cell (WBC). Fragmentation features were then calculated per group as well as for all reads combined.
Results: Ultima sequences were high quality, with 88.3% of bases >Q30 base quality and 99.0% of reads aligned on average. Fragment length distributions (FLDs) within the 100-220bp range (Pearson $R > 0.998$, $p < 1e\text{-}5$) and genome-wide fragmentation profiles (Pearson $R > 0.939$, $p < 1e\text{-}5$) were highly correlated between platforms. Limits of blank, with overlapping bootstrapped confidence intervals, and ctDNA detection (100% positive, 95.7% negative, and 97.4% overall percent agreement) were also consistent. Ultima-DELFI-TF correlated strongly with VAF (Pearson $R=0.979$, $p<1e\text{-}5$), showed high precision across replicates (median robust CV: 2.6%), and reflected longitudinal ctDNA patterns in treatment response. Classifying read origin by somatic variants from ppmSeq resulted in tumor-derived FLDs that displayed a higher proportion of short fragments than WBC-derived FLDs (p-value < 1e-5, KS test). When compared to a reference FLD derived from samples with undetectable ctDNA, the tumor-derived FLD deviated more from the reference distribution than the WBC-derived and combined FLDs (median KL-divergence of 0.227 [tumor], 0.078 [WBC], and 0.089 [combined]). The relative frequencies of 10 fragment end motifs were consistently elevated in the tumor-derived fragments across the whole cohort (all $p < 1e\text{-}5$, Chi-sq).
Conclusions: These data support the technical feasibility of implementing DELFI-TF on the Ultima platform. Combining DELFI-TF with Ultima ppmSeq enables the detection of tumor-originated reads and provides a path toward more sensitive disease detection.

#3864 Serial ctDNA monitoring in metastatic breast cancer using an ultrasensitive tumor informed structural variant based assay.

Mitchell J. Elliott[1], June Roh[1], Kareena Thakur[1], Sasha Main[2], Karen Howarth[3], Sofia Birkealv[3], Jennifer Yen[3], Volundur Hafstad[3], Wendy Levin[4], Vikash Kumar[1], Long Nguyen[1], Meredith Li[1], Scott Victor Bratman[5], Eitan Amir[1], Philippe L. Bedard[6], Lillian L. Siu[7], Hal Berman[8], David Cescon[9]

[1]Department of Medical Oncology and Hematology, Princess Margaret Cancer Centre, Toronto, ON, Canada,[2]Department of Medical Biophysics, University of Toronto, Toronto, ON, Canada,[3]SAGA Dx, Lund, Sweden,[4]SAGA Dx, Morrisville, NC,[5]The Governing Council of The University of Toronto, Toronto, ON, Canada,[6]UHN-Toronto General Hospital, Toronto, ON, Canada,[7]UHN Princess Margaret Cancer Centre, Toronto, ON, Canada,[8]Department of Pathology, Toronto General Hospital, Toronto, ON, Canada,[9]Princess Margaret Cancer Centre, Toronto, ON, Canada

Background: Circulating tumor DNA (ctDNA) dynamics correlate with treatment response in metastatic breast cancer (mBC), yet evidence generated using tumor-informed, ultrasensitive assays remains limited. In addition, the landscape of serial ctDNA monitoring across different receptor subtypes and through multiple lines of therapy remains poorly characterized. Furthermore, the performance of structural variant (SV) based ctDNA detection has not been established in this setting. Validating ctDNA as a reliable biomarker of response and progression in mBC, particularly across treatment transitions, could provide clinical utility.
Methods: We conducted a single-center retrospective study in patients with mBC receiving standard-of-care systemic therapy. Serial blood samples were collected prospectively at enrollment, radiographic restaging events (+/-30 days), and at disease progression. ctDNA was analyzed retrospectively using an ultrasensitive, whole genome sequencing (WGS)-based, tumor-informed SV digital PCR assay. Clinical data, real-world progression-free survival (rwPFS) across sequential lines of therapy, and overall survival (OS) were obtained from the medical record.
Results: Results were available for 28/100 patients (18 ER+/HER2-, 6 TNBC, 4 HER2+), contributing 120 evaluable timepoints (median 3 per patient, range 1-18) with a median follow-up of 12.2 months (range 2.0-16.3). Patients received a median of 2 lines of metastatic therapy (range 1-8). Orthogonally validated fingerprints contained a median of 13 SVs (range 4-16). ctDNA was detected in 77% (92/120) of all sampled timepoints, with 34% (31/92) of positives falling within the ultrasensitive range (variant allele fraction ≤0.01% or ≤100 ppm). Serial ctDNA monitoring closely mirrored each patient's treatment course. Notably, no radiologist-adjudicated progression occurred without a preceding rise in ctDNA from on-treatment nadir. Four patients (1 ER+/HER2-, 1 TNBC, 2 HER2+) had undetectable ctDNA with a median rwPFS of 27 months (range 20-40) and remain on therapy without rwPFS or OS events. Accrual is ongoing, with continued serial plasma collection and maturing rwPFS/OS data.
Conclusion: These preliminary findings demonstrate the feasibility of ctDNA monitoring in a real-world, heterogeneous mBC cohort using a tumor-informed, ultrasensitive SV-based assay. ctDNA dynamics closely tracked treatment response across sequential lines of therapy, and early signals suggest that ctDNA clearance below the ultrasensitive detection threshold is associated with prolonged disease control. The high proportion of timepoints within the ultrasensitive range underscores the relevance of assay sensitivity for metastatic monitoring. Updated results from the full cohort, including correlation with all matched radiographic restaging events will be presented.

[1]Johnson & Johnson, Spring House, PA,[2]Nuffield Department of Surgical Sciences, University of Oxford, Oxford, United Kingdom,[3]Kennedy Institute, University of Oxford, Oxford, United Kingdom,[4]Centre for Human Genetics, University of Oxford, Oxford, United Kingdom,[5]Kennedy Institute, University of Oxford; Weatherall Institute for Molecular Medicine, John Radcliffe Hospital, Headington, Oxford, United Kingdom,[6]Nuffield Department of Surgical Sciences, University of Oxford, Oxford, United Kingdom, Department of Urology, Oxford University Hospitals NHS Foundation Trust; NIHR Biomedical Research Centre, Oxford, United Kingdom,[7]Department of Cellular Pathology, Oxford University Hospitals NHS Foundation Trust, Oxford, United Kingdom

Background:
Non-muscle-invasive bladder cancer (NMIBC) are biologically heterogeneous tumors that are classified based on stage/grade alone, which does not provide an accurate separation as it misses underlying molecular phenotypes. The UROMOL molecular classification, derived from large-scale transcriptomic profiling of NMIBC (Lindskrog SV, et al. *Nat Commun*. 2021;12:2301), stratifies tumors into prognosis-associated biology with distinct molecular subtypes. The relationship between molecular states and tumor microenvironment (TME) composition remains poorly defined.
Methods:
We performed transcriptomic subtyping and single-cell-level TME profiling of NMIBC tumors (patient n=16, sample n=34, cell n = 108108). Tumors were classified into UROMOL subtypes using NMIBC classifier (Lindskrog SV, et al. *Nat Commun*. 2021;12:2301) based on aggregated gene expression profiles. We quantified epithelial, stromal, and immune populations, and assessed pathway activity using curated immune and stromal gene module scores.
Results:
3 UROMOL subtypes were observed: Class 1 (luminal papillary), Class 2a (basal-inflamed), and Class 2b (luminal-inflamed). Class 1 tumors (n=6, 17.6%) exhibited an epithelial-dominant, immune-cold TME characterized by ~80.1% epithelial cells (95% CI: 74-86.2%) and minimal immune infiltration, including T cells (~1.9%, CI: 0.5-3.3%), macrophages (~1.4%, CI: 0.5-3.3%), and fibroblasts (~8.4%, CI: 4.3-12.5%). This composition is consistent with differentiated luminal biology and may have favorable baseline prognosis. Class 2a tumors (n=9, 26.5%) displayed a distinct TME composition pattern, with an increase in T-cell (~4.8%, CI: 1.7-8.0%) and macrophage (~1.9%, CI: 0.6-3.1%) infiltration compared to Class 1, alongside increased fibroblast (~17.5%, CI: 9.6-25.3%) and endothelial (~8.1%, CI: 4.9-11.4%) content. These tumors showed increased effector and checkpoint activity, reflecting a more active immune microenvironment than class 1. Class 2b tumors (n=19, 55.9%) showed a heterogeneous immune-stromal landscape with pronounced fibroblast enrichment (~27%, CI: 19.7-34.4%) and extracellular matrix remodeling, alongside elevated immune infiltration, including T cells (~17.5%, CI: 15-20.0%) and macrophages (~11.2%, CI: 7.4-14.9%), this reflects an immune-active, fibroblast-rich TME architecture.
Conclusions:
UROMOL subtypes are defined by distinct TME architectures with differences in cellular composition from immune-cold, epithelial-rich Class 1 tumors to highly immune infiltrated Class 2b tumors enriched with T cells and fibroblasts. Given the limited sample size, these observations should be validated in a larger cohort.
This study demonstrates that UROMOL molecular classes of NMIBC are associated with distinct TMEs, revealing biologically meaningful differences in immune infiltration and stromal composition.

#3870 Deep learning-powered morphological analysis of acute myeloid leukemia.

Ezgi June Olgac[1], Meghan Burr[2], Minna Suvela[1], Daniela Mendoza-Ortiz[1], Ella Sinervuori[1], Heikki Kuusanmaki[1], Mika Kontro[1], Caroline Heckman[1]

[1]University of Helsinki, Helsinki, Finland,[2]Deepcell, Inc., Menlo Park, CA

In this study we demonstrate that deep learning-based analysis of single cell images can distinguish acute myeloid leukemia (AML) bone marrow (BM) mononuclear cells (MNCs) from healthy BM MNCs based on morphological features. We further show that differences in *ex vivo* drug responses to BCL2 inhibitor venetoclax links to shifts in morphology of venetoclax-sensitive (ven-sen) and -resistant (ven-res) AML. Our sample cohort consisted of cryopreserved BM MNC samples from 6 healthy donors and 12 donors with AML. The AML samples were selected based on ex vivo sensitvity to venetoclax (6 ven-sen + 6 ven-res). Moreover, 2 longitudinal sample pairs (diagnosis-relapse) from 2 AML patients were included in the cohort. The AML samples were from patients recruited to the NCT04267081 trial and healthy donor samples from patients undergoing hip replacement surgery. Samples were thawed, fixed with 2% paraformaldehyde, and stored at +4°C until the time of imaging. The samples were prepared in a single cell suspension and 25,000-50,000 brightfield images collected per sample using the high-resolution single cell imaging and sorting platform, REM-I (Deepcell). Imaging data were synced to REM-I's data suite Axon. Morphological analysis through Axon was carried out based on 115 dimensions of cell morphology; 51 human-interpretable, and 64 deep-learning features. Analysis parameters were set to random sampling with equal number of data points per sample. Differential morphology analysis on Axon yielded divergence scores (Range: 0-1) as a quantified measure of morphological distinction.Comparison of healthy samples (n=6) against pooled AML samples (n=12) demonstrated that healthy and AML BM cells are distinct in their morphology and map into different clusters in a uniform manifold approximation and projection (UMAP) graph. Differential morphology analysis between these sample groups highlighted deep-learning embeddings in the top 10 differential morphology features, with divergence scores ranging from 0.55-0.65. Additionally, an analysis comparing healthy samples (n=6) to ven-sen (n=6) and ven-res (n=6) AML, revealed that the two different AML sample groups were distinct in morphology from each other as well as from the healthy samples. Finally, in the analysis of two longitudinal AML patient sample pairs for morphological analysis of AML progression, we observed changes in morphology between the diagnosis and relapse samples. This anaysis also revealed a substantial morphological shift in the patient that had a higher change in *ex vivo* ven response between the diagnosis and relapse samples. Our study demonstrates that cutting-edge methods powered by deep learning can facilitate the analysis of morphological features of AML with high-dimensionality that cannot be achieved by methods that depend only on human perception. These results indicate that drug response and disease progression in AML are reflected by changes in cell morphology.

#3871 Molecular correlates of response and survival in a phase II trial of weekly carboplatin/paclitaxel plus cemiplimab (wCP+C) in advanced/metastatic mucosal head and neck squamous cell carcinoma (a/mHNSCC).

Mateus Trinconi Cunha[1], Fahad Rind[2], Priyanka Bhateja[1], Esmerina Tili[3], David Konieczkowski[4], Darrion Mitchell[4], Sujith Baliga[4], Sung Jun Ma[4], Simeng Zhu[4], Gogineni Emile[4], John Grecula[4], Nolan Seim[5], Catherine Harring[5], Lauren Miller[5], Abberly Lott Limbach[6], Kang Stephen[5], James W. Rocco[5], Christian Rolfo[7], Dukagjin Blakaj[4], Marcelo Bonomi[8]

[1]Head and Neck Medical Oncology, The Ohio State University Wexner Medical Center, Columbus, OH,[2]Clinical Trials Department, The Ohio State University Wexner Medical Center, Columbus, OH,[3]Anesthesiology, The Ohio State University Wexner Medical Center, Columbus, OH,[4]Radiation Oncology, The Ohio State University Wexner Medical Center, Columbus, OH,[5]Otolaryngology, The Ohio State University Wexner Medical Center, Columbus, OH,[6]Pathology, The Ohio State University Wexner Medical Center, Columbus, OH,[7]Medical Oncology, The Ohio State University Wexner Medical Center, Columbu, OH,[8]Head and Neck Medical Oncology, The Ohio State Universiy Wexner Medical Center, Columbus, OH

Background: a/mHNSCC exhibits poor prognosis and limited immunotherapy efficacy. Weekly low-dose chemotherapy may enhance immunogenicity while reducing toxicity. We conducted a phase II trial of weekly low-dose chemotherapy plus cemiplimab as first-line treatment in a/mHNSCC, with integrated genomic profiling to explore molecular correlates of outcome. Patients received weekly carboplatin (AUC 1) and paclitaxel (30 mg/m²) plus cemiplimab (350 mg q3w). Forty-two patients were enrolled from Dec 2021-Dec 2024. Median age was 68 (range 42-81); 38/42 were male, and 27 (64%) were HPV-positive. Median OS (27 events) was 16.4 months (95% CI, 12.6-23.9); median PFS (36 events) was 5.62 months (95% CI, 5.0-10.3). Objective response rate (ORR) was 43% (18/42, PR or CR). The treatment was well-tolerated. These results were previously presented at ESMO 2025. We aim to present an exploratory analysis of pathogenic genomic mutations in this cohort and their correlation with ORR, PFS, and OS.
Methods: Of the 42 enrolled patients, genomic analysis (Tempus xT/xF) was performed in 29. The 4 most prevalent pathogenic alterations were analyzed separately, while all genes with detected pathogenic alterations were grouped and analyzed by pathway or functional group, with time-to-event outcomes assessed via Kaplan-Meier and log-rank, and Cox models when appropriate. Prevalence of tumor mutations between responder groups (CR/PR versus PD as ORR) and extreme PFS groups (<3 versus >12 months) was performed with odds ratio. P-values< 0.05 were deemed statistically significant. Due to the hypothesis-generating nature of this report, p-value adjustments for multiple tests were not performed.
Results: Pathogenic alterations included TP53 (N=14), CDKN2A (N=11), TERT promoter (N=8), and FGF3/FGF4 copy number gains (CNG; N=17). Mutations in NOTCH pathway genes (NOTCH1/3, FBXW7; N=7) were enriched in patients with primary progression ($p = 0.02$) and those with PFS <3 months versus >12 months ($p = 0.03$). NOTCH alterations conferred inferior PFS (HR 3.6; 95% CI, 1.4-9.3; $p < 0.01$) and OS (HR 2.9; 95% CI, 1.05-8.0; $p = 0.04$). TERT promoter mutations were associated with worse OS (HR 4.9; 95% CI, 1.7-14.5; $p < 0.01$) and trended toward poor PFS (HR 2.2; 95% CI, 0.9-5.2; $p = 0.08$). FGF3/FGF4 CNGs also trended toward inferior PFS (HR 2.6; 95% CI, 0.9-7.4; $p = 0.08$) and were associated with worse OS (HR 2.5; 95% CI, 1.0-6.6; $p = 0.04$).
Conclusions: Weekly low-dose chemotherapy plus cemiplimab shows promising activity in a/mHNSCC. Exploratory genomic profiling suggests NOTCH pathway mutations may be markers of poor prognosis and resistance. TERT and FGF3/4 alterations may also confer inferior outcomes and warrant further study.

#3873 Molecular heterogeneity in non-muscle invasive bladder cancer reveals clinically divergent subtypes with contrasting Bacillus Calmette-Guérin response and clinical outcomes.

Jee-Woo Seo, Il-San Jeong, Yeo-Gyeong Yoon, Jae-Yoon Kim, Seon-Young Kim, Seung-Woo Baek, Seon-Kyu Kim

Korea Research Institute of Bioscience & Biotechnology (KRIBB), Daejeon, Korea, Republic of

Background: Non-muscle-invasive bladder cancer (NMIBC) is an early-stage, molecularly heterogeneous malignancy with diverse clinical outcomes from frequent recurrence to occasional progression. Unlike muscle-invasive bladder cancer (MIBC), NMIBC lacks a unified molecular subtype. Current classification systems provide biological insights but offer limited prognostic precision. Although recurrence and progression are often treated as a continuum, recurrent tumors commonly exhibit Bacillus Calmette-Guérin (BCG) resistance, whereas progressive tumors tend to respond to BCG, highlighting the need for a precise molecular classification.
Methods: By integrating ten previously established omics-based classifiers of NMIBC, we identified six clinically and molecularly distinct subtypes. Fifty representative genes per subtype (300 total), designated as the Molecular Heterogeneity of NMIBC 300-gene signature (MHN300), were selected to build an AutoML-based prediction model. The model was trained and validated across 11 independent NMIBC cohorts and 7 single-cell RNA-seq datasets. Each subtype underwent comprehensive molecular characterization, including transcriptomic and genomic analyses, and prognostic relevance was assessed using Kaplan-Meier and Cox regression analyses.
Results: Six molecularly and clinically distinct NMIBC subtypes (C1-C6) were defined through integration of ten prior classifiers. C1 exhibited early cell-cycle and uroplakin activity, whereas C2 showed pan-fibroblast TGF-β and EMT signaling. C3 combined strong immune and late cell-cycle programs, while C4 and C5 both featured late cell-cycle activation with opposing clinical behaviors; C4 showing favorable BCG response and prolonged progression-free survival (PFS, $P < 0.001$ by log-rank test), and C5 displayed a high-frequency recurrence NMIBC (24% with ≥2 recurrence per year, HR = 5.12, 95% CI 2.82-9.39, $P < 0.001$ by log-rank test), along with BCG resistance and endothelial enrichment in scRNA-seq. C6 demonstrated FGFR3 and early cell-cycle features. The MHN300 AutoML classifier achieved 0.88 accuracy and was validated across independent cohorts.
Conclusions: The MHN300 classifier refines the current molecular framework for NMIBC by resolving intra-subtype heterogeneity and delineating biologically coherent, clinically meaningful subgroups with distinct risks of recurrence and progression. This refined taxonomy provides a foundation for subtype-guided precision management of NMIBC.
Grant Support: This study was supported by grants from the Korea Research Institute of Bioscience and Biotechnology (KRIBB) Research Initiative Program (KGM5192423).

#3874 Phosphoproteomic subtyping and characterization of colorectal cancer by comprehensive phosphoproteomics of fresh frozen endoscopic biopsy specimens.

Jun Adachi[1], Hirokazu Shoji[2], Hidekazu Hirano[2], Yosui Nojima[3], Satoshi Muraoka[1], Yutaka Saito[2], Ken Kato[2], Narikazu Boku[4], Yukihide Kanemitsu[2]

[1]National Institute of -Biomedical Innovation, Health, and Nutrition, Osaka, Japan,[2]National Cancer Center Hospital, Tokyo, Japan,[3]The University of Osaka, OIsaka, Japan,[4]University of Tokyo, Tokyo, Japan

Background and Aims: Phosphorylation is a key post-translational modification that regulates protein activity, localization, and interactions. By mapping phosphorylation patterns, phosphoproteomics provides real-time insights into how cancer cells reprogram their signaling networks to promote growth, survival, metastasis, and therapy resistance. While conventional deep phosphoproteomics requires a relatively large amount of clinical samples, we have developed a highly sensitive method using endoscopic biopsy samples which can offer excellent quality for hosphoproteomic analysis. In this study we evaluated the phosphoproteomic landscape in fresh-frozen endoscopic biopsies from patients with colorectal cancer (CRC).
Methods: Endoscopic biopsy specimens were obtained from 102 treatment-naïve CRC patients and snap-frozen in liquid nitrogen within 20 seconds of collection. Ultra-deep proteome and phosphoproteome analyses were performed using tandem mass tag (TMT)-based multiplexing. Genomic profiling was conducted with a targeted, high-multiplex PCR-based next-generation sequencing (NGS) panel.
Results: Ultrasensitive mass spectrometry-based proteomics using 204 naïve colorectal cancer specimens and 204 normal tissue adjacent to the tumor (NAT) quantified an average of 23985 phosphorylation sites. Consensus clustering clearly divided colorectal cancer into subtype 1 (proliferative type, 33%), subtype 2 (EMT type, 25%), Subtype 3 (Metabolic type, 20%), and subtype 4 (Abnormal RNA splicing type, 21%). Kinase activity profiles were obtained from phosphoproteome data and kinases that are specifically activated or inactivated in each subtype were identified. While concordance between these phosphoproteomic subtypes and the consensus molecular subtypes (CMS) was low, sidedness was associated with different kinome activity of tumor and NAT.
Conclusions: This proof-of-concept study demonstrates that phosphoproteomic analysis can delineate CRC subtypes independent of CMS classification and provide detailed kinase activity landscapes. Our pioneering approach enables robust clinical phosphoproteomics from small endoscopic biopsies, offering a promising tool for monitoring therapeutic kinase activities and advancing precision oncology.

#3875 Identifying the tumor site of origin using molecular profiling with an AI-based classifier.

Carlos E. Zuazo, Michael J. Demeure, David R. Braxton, **Sourat Darabi**

Hoag Cancer Institute, Newport Beach, CA

Background: Identifying the primary site of origin for tumors in an accurate and timely manner is a critical step in treating cancer in an effective way. In cases of cancers of unknown primary, deep learning-based genomic classifiers that can improve diagnostic workflows and decrease inaccuracies have been validated for clinical use by previous studies, but reports of clinical utility are lacking. Use of molecular profiling for identification of site of origin has shown to be accurate in about 70-95% cases and can reveal actionable targets for treatment. We report our experience of consecutive cases where a commercial AI-based classification tool was used in routine practice at a high-volume community cancer center.

Methods: Patient tumors, initially classified as cancers where the primary site was uncertain, were subjected to molecular profiling and AI-based genomic classification (GPSai) capable of recognizing a set of 90 distinct primary tumor sites and many histological subclasses. Molecular profiling consisted of whole exome and whole transcriptome sequencing of FFPE tumor samples, along with other predictive biomarker assays performed by a commercial laboratory (Caris Life Sciences). The identification of targetable mutations was reported, but variants of unknown significance were excluded when reporting genomic alterations.

Results: We reviewed 320 samples from 313 patients between December 2022 and October 2025 who were profiled using GPSai, 77 (24%) of which were cancers with unknown primary. Those cases which were unable to be classified were further investigated by a molecular pathologist. Of the 243 (76%) samples that received a tumor type assignment by the classifier, non-small cell lung cancer was the most represented, with 41 of 243 (16.9%), followed by pancreatic adenocarcinoma, with 25 of 243 (10.3%), and colon cancer, with 21 of 243 (8.6%). The classifier also assigned classifications of miscellaneous rare cancer types (21 of 243, or 8.6%), including rhabdomyosarcoma, angiosarcoma, and thymic carcinoma. 161 of 313 (51.4%) patients were women, 152 of 313 (48.6%) were men, and 201 of 313 (64%) patients were 65 or older in age. Mutations were found in 173 of 320 (54%) samples, with the most common being in *TP53, KRAS,* and *TERT.* Further, 51 of 320 (16%) of samples analyzed had a high tumor mutational burden (TMB), 10 of 320 (3%) had a mismatch repair deficiency, and 45 of 320 (14%) samples were positive for *PD-L1* (SP142) and 53 of 320 (16.6%) for *PD-L1* (22c3)..

Conclusion: 243 of 330 (76%) patient samples were assigned a cancer diagnosis, which is consistent with the range reported in published studies to date (70-95%). Among those that could not be classified, targetable mutations were commonly found, including *KRAS* and *EGFR*. AI-based genomic classification of tumor site of origin is useful in clinical practice in identifying treatment options for patients.

#3876 Prognostic and predictive value of the Clearseq1-4 tumor microenvironment classification in localized and metastatic clear-cell renal cell carcinoma.

Benoit Beuselinck[1], Lisa Kinget[2], Edward Mctaggart[3], Octavie Demeulenaere[3], Edouard Roussel[4], Bram Boeckx[5], Jessica Zucman-Rossi[6], Gabrielle Couchy[6], Henri Vandermeulen[7], Liesbeth De Wever[7], Marcella Baldewijns[8], Agnieszka Wozniak[9], Diether Lambrechts[10], Stefan Naulaerts[11], Abhishek D. Garg[9], Annelies Verbiest[12], Maarten Albersen[4]

[1]UZ Leuven, Leuven, Flemish Brabant, Belgium,[2]General Medical oncology, UZ Leuven, Leuven, Flemish Brabant, Belgium,[3]Oncology, KULeuven, Leuven, Flemish Brabant, Belgium,[4]Urology, UZ Leuven, Leuven, Flemish Brabant, Belgium,[5]VIB, KULeuven, Leuven, Belgium,[6]INSERM, Paris, France,[7]Radiology, UZ Leuven, Leuven, Flemish Brabant, Belgium,[8]Pathology, UZ Leuven, Leuven, Flemish Brabant, Belgium,[9]KU Leuven, Leuven, Belgium,[10]Catholic University of Leuven, Leuven, Belgium,[11]Oncology, KULeuven, Leuven, Belgium,[12]UZ Antwerpen, Antwerpen, Belgium

PURPOSE: The ccrcc1-4 transcriptomic subtypes were previously identified on fresh frozen clear-cell renal cell carcinoma (ccRCC) samples and have proven their prognostic value post-nephrectomy/metastasectomy and predictive value for first-line vascular endothelial growth factor receptor-tyrosine kinase inhibitors (VEGFR-TKIs). We aimed to extend and validate the ccrcc1-4 classifier on formalin-fixed paraffin-embedded (FFPE) tissues and to validate its prognostic and predictive value across the RCC treatment landscape.

EXPERIMENTAL DESIGN: RNA sequencing of tumoral FFPE tissue was performed. A classifier called Clearseq was designed to determine ccrcc1-4 subtypes. Subtypes were correlated with outcome after surgical and systemic therapies. External validation was pursued as well as characterization at single-cell transcriptomic level.

RESULTS: A total of 668 tumoral samples (337 primary tumors and 331 metastases) from 364 patients were assigned into ccrcc1, ccrcc2, ccrcc3 and ccrcc4-tumors. The angiogenic ccrcc2-subtype had a favorable prognosis after nephrectomy in localized setting, after cytoreductive nephrectomy and upon metastasectomy with curative intent and was correlated with improved outcome on first-line VEGFR-TKIs. Ccrcc4-tumors were enriched for sarcomatoid features and had the largest treatment benefit on immune checkpoint blockade (ICB) treatment in any line, resulting in overall survival outcomes comparable to those of less aggressive subtypes. These findings were corroborated in a post-nephrectomy cohort, and external cohorts of metastatic patients treated with ICB and/or angiogenesis inhibitors.

CONCLUSIONS: We validated the Clearseq classifier to predict ccrcc1-4 molecular subtype on FFPE tissues and confirmed its performance with respect to previous biomarker findings for both surgical and systemic treatment approaches.

#3877 Integrative application of Lymphly reveals shared molecular landscape across B-cell lymphomas.

Dmitrii Snitkin, Pavel Zemskiy, Andrey Suponin, Mark Meerson, Ekaterina Nesterenko, Alexander Bagaev, Alexander Nesmelov, Konstantin Chernyshov, **Nikita Kotlov**

BostonGene Corporation, Waltham, MA

Background: We previously created Lymphly, a hierarchical framework that uses discrete genetic events to enhance diffuse large B-cell lymphoma (DLBCL) classification. However, the molecular relationships between DLBCL subtypes and the broader B-cell lymphoma landscape remain poorly delineated. Here, we evaluated if Lymphly can elucidate molecular patterns across B-cell lymphomas to inform therapeutic development and trial design.

Methods: Lymphly was used to classify a meta-cohort of ~1,500 DLBCL samples and ~2,000 samples with available molecular data across multiple non-DLBCL B-cell lymphoma diagnoses from internal and publicly available datasets. The samples were assigned canonical (EZB, MCD, BN2, N1) and newly identified subtypes (JS3, JS6), as well as TP53+ and MYC+ statuses. Integrative analyses of molecular and clinical parameters highlighted distinct genomic architectures and risk profiles that may constitute potential therapeutic targets.

Results: Lymphly revealed shared genetic and transcriptional features between non-DLBCL lymphomas and specific DLBCL subtypes in the study cohort, indicative of convergent molecular phenotypes between specific Lymphly subtypes and lymphoma diagnoses. Specific Lymphly subtypes dominated certain diagnoses, and samples within each subtype shared similar gene expression profiles. Subtype EZB was enriched among follicular (FL) and Burkitt (BL) lymphoma samples, reflecting their germinal-center origin (GCB). Many of the FL samples also showed BCL2 translocations, which were less common in BL samples. Subtype BN2, featuring mutations affecting *NOTCH2* and NF-κB signaling, was enriched among marginal zone and splenic marginal zone lymphoma samples. Subtype MCD, featuring alterations in MYD88 and CD79B, was enriched in primary central nervous system lymphoma and high-grade B-cell lymphomas. Newly classified subtypes JS6 and JS3 revealed additional links between DLBCL and other B-cell lymphoma entities: JS6, a GCB-like entity, was linked to primary mediastinal B-cell lymphoma, while JS3, an activated B-cell-like entity, overlapped with T-cell/histiocyte-rich large B-cell lymphoma and plasmablastic lymphoma.

Conclusions: Lymphly demonstrated applicability beyond DLBCL, capturing canonical and newly identified subtypes and shared molecular patterns across B-cell malignancies. Applying DLBCL genetic classification to other B-cell lymphomas revealed potential trajectories of transformation into DLBCL, with Lymphly subtypes reflecting their natural molecular counterparts within the DLBCL spectrum. By integrating an interpretable and a rule-based classification with cross-disease molecular insights, Lymphly is poised to translate these insights into data-driven strategies that optimize decision-making across all stages of diagnostic and treatment development.

#3878 ZEB1 expression in NEUROD1-positive and combined YAP1-dominant pulmonary neuroendocrine carcinomas is associated with a locally immunosuppressive microenvironment.

Noriko Takemura-Kobayashi[1], Kei Asayama[1], Rawya Mohamed Salih Ibrahim[1], Masahiro Maki[1], Ryota Matsuoka[1], Aya Shiba-Ishii[1], Ayako Suzuki[2], Yutaka Suzuki[2], Daisuke Matsubara[1]

[1]Department of Diagnostic Pathology, Institute of Medicine, University of Tsukuba, Ibaraki, Japan,[2]Department of Computational Biology and Medical Sciences, the University of Tokyo, Chiba, Japan

Background: Pulmonary neuroendocrine carcinomas (pNECs), comprising small cell lung carcinoma (SCLC) and large cell neuroendocrine carcinoma (LCNEC), are classified into four molecular subtypes based on the expression of ASCL1, NEUROD1, POU2F3, and YAP1. In non-small cell lung cancer, Zinc finger E-box binding homeobox 1 (ZEB1), a key regulator of epithelial-mesenchymal transition (EMT), is more frequently expressed in poorly differentiated carcinoma (large cell and pleomorphic carcinoma) than in adenocarcinoma and squamous cell carcinoma. ZEB1 expression in cancer cells is linked to the decreased CD8+ T-cells and PD-L1 mediated immunosuppression. However, the features of ZEB1-positive SCLC/LCNEC are poorly understood.
Aim: We investigated the expression of ZEB1 in pNECs and its association with tumor microenvironment.Methods: Western blotting was performed on pNEC cell lines (13 SCLC and 1 LCNEC: 8 ASCL1-dominant, 3 NEUROD1-dominant, 1 POU2F3-dominant, and 2 YAP1-domiant). Immunohistochemistry was conducted on surgically resected samples (33 SCLC and 46 LCNEC). Spatial transcriptome analysis was performed on one ZEB1-positive SCLC sample.
Results: Western blotting using pNEC cell lines showed EMT-like phenotype in NEUROD1- and YAP1-dominant cell lines (high ZEB1, E-cadherin loss). Vimentin was absent in NEUROD1-dominant but present in YAP1-dominant cell lines. ASCL1- and POU2F3-dominant cell lines were largely epithelial (low/absent ZEB1, E-cadherin retained), although a part of ASCL1-dominant cell lines expressed ZEB1. In the xenograft from a ZEB1-positive ASCL1-dominant cell line (H2081), the expression of ZEB1 and E-cadherin was mutually exclusive; ZEB1-positive area was NEUROD1-positve, whereas ZEB1-negative area was ASCL1-positive. Immunohistochemistry on whole-slide sections from surgically resected samples revealed that most ZEB1-positive pNECs were NEUROD1-positive or combined YAP1-dominant cases (combined with adenocarcinoma or squamous cell carcinoma), with localized ZEB1 expression, whereas POU2F3-dominant cases showed low or no expression of ZEB1. Vimentin was highly expressed in a few combined YAP1-dominant pNECs but negative in most cases. The ZEB1-positive area exhibited significantly reduced CD3+ and CD8+ T cells infiltration and, in spatial transcriptome analysis, increased tumor-associated macrophages (TAMs) infiltration than in the ZEB1-negative area in the same cases.
Conclusion: Focal expression of ZEB1 was observed in NEUROD1-positive and combined YAP1-dominant pulmonary neuroendocrine carcinomas. ZEB1-positive area was poor in CD3+ and CD8+ T cells and enriched in TAMs, suggesting that ZEB1-mediated EMT is associated with a locally immunosuppressive microenvironment.

#3879 SPP1-driven immunometabolic reprogramming of tumor-associated neutrophils in glioblastoma.

Matthew Alexander Abikenari[1], John Hyunkuk Choi[1], Ravi Medikonda[1], Lily Kim[1], Rohit Verma[2], Justin Liu[1], Adam Sjoholm[1], George Nageeb[1], Brandon Hwa-Lin Bergsneider[2], Caren Yu-Ju Wu[3], Kwang Bog Cho[1], Andrew Tran[1], David Bakalov[4], Matei Banu[1], Michael Lim[1]

[1]Neurosurgery, Stanford University School of Medicine, Stanford, CA,[2]Stanford University School of Medicine, Stanford, CA,[3]Taipei Chang Gung Memorial Hospital, Ghanghua, Taiwan,[4]Medical Scientist Training Program, University of Utah, Salt Lake City, UT

Introduction: Tumor-associated neutrophils (TANs) in glioblastoma (GBM) are heterogeneous and poorly captured by the classical N1/N2 dichotomy. We characterized TAN states relative to peripheral blood neutrophils (PBNs) and wondered if a discrete, targetable program drives their pro-tumoral phenotype.
Methods: Public scRNA-seq datasets were reanalyzed (GSM8380727, GSM8380728: TANs 15,000 cells; PBNs 10,000 cells; 36,601 genes). Standard Seurat workflow was applied (stringent QC; SCTransform; integration; PCA/UMAP; shared-nearest-neighbor clustering). Differential expression used Wilcoxon rank-sum with Bonferroni FDR (adj. $p<0.05$, $|\log2FC|>0.25$). Module scoring examined prespecified programs: antigen presentation/co-stimulation, interferon/cytotoxicity, lipid/stress adaptation. Functional enrichment and protein-protein networks were assessed via GSEA and STRING.
Results: Integration revealed six tumor-associated Neutrophil states beyond the classical N1/N2 paradigm. Among them, an SPP1+ (osteopontin-high) (avg log2FC ~10.7; adj. $p\approx0$) population was particularly transcriptionally associated with lipid processing genes (APOE, APOC1, APOC2) and chemokine master regulators (CCL3, CCL4) of immune cell recruitment and metabolic reprogramming. SPP1+ TANs featured repression of cytotoxicity pathways and induction of oxidative and lipid metabolism modules, pointing toward a shift from antimicrobial to tissue-remodeling and tumor-supporting activities. Network analysis revealed two large hubs: SPP1-APOE/APOC (lipid remodeling) and CCL3/CCL4 (immune signaling) that are bridged by metabolic stress genes (CTSB, EIF1B) into a cohesive immunometabolic circuit.
Conclusion: Single-cell analysis characterizes GBM TAN heterogeneity and implicates an SPP1-centered, APC-like neutrophil axis bridging lipid regulation (APOE/APOCs) and chemokine signaling (CCL3/CCL4). This osteopontin-driven axis establishes a mechanistic basis for TAN-mediated tumor support and nominates SPP1 and its lipid-chemokine network as actionable targets to reprogram TANs for anti-tumor activity.This is among the first studies to define an osteopontin-driven immunometabolic axis in pro-tumoral neutrophils, establishing a mechanistic framework for future neutrophil-targeted immunotherapies in glioblastoma.

#3880 Functional high risk multiple myeloma is unified by a highly proliferative signature on gene expression profiling.

Hashini Thilakaratne, Jessie Zhao, Daniel Wong, Tiffany Khong, Sridurga Mithraprabhu, **Nicholas E. Bingham**, Andrew Spencer

Australian Centre for Blood Diseases, Alfred Health - Monash University, Melbourne, Australia

Background: Multiple myeloma (MM) is a haematological malignancy with globally improving survival rates. Functional high-risk (FHR) MM, defined as progressive disease less than 18 months from diagnosis, has a median overall survival <3 years, but FHR patients are not identified by conventional prognostic scores nor by gene expression (GE) signatures, such as SKY92 (SkylineDx). Additionally, the biology of therapy resistance and aggressive behaviour in FHR myeloma is poorly understood. We sought to define the transcriptional features of FHR MM and identify molecular pathways that unify this aggressive phenotype.

Methods: The MMProfiler microarray was performed on RNA extracted from bone-marrow aspirate samples of consecutive newly diagnosed MM (NDMM) patients. SKY92 risk classification (high- vs standard-risk) and genome-wide expression data (~20,000 genes) was obtained. Data was normalised across all samples prior to dimensionality reduction techniques, differential gene expression (DGE) analysis and pathway analysis. Clinical data and survival outcomes were collected. DGE analysis cutoffs were adj $p<0.01$ and $|log2FC|>1.0$).

Results: Forty-eight patients were included, of whom 13 (27%) patients met criteria for FHR MM. FHR status was associated with inferior survival (3-year overall survival 58.7% versus 88%, p=0.018). Firth logistic regression demonstrated that R-ISS, R2-ISS and SKY92 classification were not significantly associated with FHR status (R-ISS OR 2.62; 95% CI 0.82-9.85; R2-ISS OR 2.08, 95% CI 0.94-5.64; SKY92 OR 3.55, 95% CI 0.96-16.03).

DGE analysis identified a 16-gene proliferative module upregulated in FHR MM (*MCM2, FOXM1, CDCA5, KIF14, UBE2T, TYMS, KIF4A, NCAPH, SAC3D1, FAM72C, KIF15, ZWINT, CDT1, OIP5, TPX2, CDC20*). These genes functionally converge on cell cycle progression and mitosis, and contain a significant *FOXM1*-driven mitotic program. Formal pathway enrichment confirmed activation of E2F targets, G2/M checkpoint, MYC targets, and DNA repair pathways, consistent with a unified high-proliferation phenotype in FHR MM. A 6-gene proliferative signature derived from the DGE set (*FOXM1* and targets *KIF14*, *ZWINT*, as well as *MCM2*, *UBE2T*, and *TYMS*) demonstrated strong discrimination of FHR status (AUC = 0.912; $p = <0.001$).

Conclusion: FHR MM is poorly identified by current prognostic algorithms. Biologically, we show FHR MM is defined by a cell-cycle driving transcriptional program, at the gene expression level suggestive of a *FOXM1*-driven program. This data suggests early progression in MM reflects a distinct biological state with increased cell-cycle and replication stress pathways. The 6-gene proliferative signature described here warrants validation as a diagnostic tool for FHR MM. The proliferative program seen in FHR MM may represent a novel therapeutic vulnerability, suggesting a role for cell-cycle targeting therapeutic approaches.

#3881 Heterogeneity in tumor microenvironment across MMR subtypes of endometrial cancer: Analysis from the ENGOT-EN6-NSGO/GOG-3031/RUBY trial.

Background: In RUBY Part 1 (NCT03981796), dostarlimab + carboplatin-paclitaxel (D+CP) significantly improved PFS and OS vs CP alone in pts with primary advanced or recurrent endometrial cancer (EC). Although MMR deficiency (dMMR) is a predictive biomarker for clinical response, benefit is also observed in the MMR proficient (MMRp) subgroup. Additional insights into the underlying biology and heterogeneity of these tumors are needed to inform potential drivers of response to D+CP.
Methods: RNA sequencing (RNASeq) and whole exome sequencing were performed on 400 tumor samples from RUBY Part 1. Tumors were categorized as dMMR or MMRp per the testing method used for study enrollment. Genomic alterations and RNAseq signatures associated with infiltrating cell types or oncogenic processes were analyzed.
Results: Unsupervised clustering of tumor transcriptional profiles revealed two distinct histological subtype-associated clusters. dMMR tumors were predominantly in the endometrioid cluster; MMRp tumors were distributed across both clusters. Gene signature analysis revealed significant enrichment for tumors with high immune cell signature scores in the dMMR subgroup (Table); however, considerable overlap was observed with a subset of MMRp tumors demonstrating similarly high signature scores. Conversely, signatures associated with tumor senescence and interferon-stimulated genes were enriched in the MMRp subgroup. Genomic analysis revealed frequent alterations in *TP53*, *PTEN*, *PIK3CA,* and *ARID1A*, with higher mutation rates of several genes (eg, *JAK1* and *RNF43*) observed in dMMR tumors, concomitant with higher tumor mutational burden.
Conclusions: These results highlight the molecular and transcriptomic heterogeneity of EC, providing hypotheses to explore the impact of tumor characteristics beyond MMR status on response to dostarlimab+CP in EC. Exploration of the association between these biomarkers and outcomes is ongoing.

Table: Gene signatures across MMR subgroups

Signature	***P* value (Wilcoxon)**	**Signature score higher in**	**Median dMMR/MSI-H**	**Median MMRp/MSS**
Tumor senescence_Combes	<0.001	MMRp/MSS	–0.66	0.27

#3883 Integrated morphometric and molecular classification of central nervous system cancers in 10 seconds using a unified platform with picosecond infrared laser mass spectrometry.

Alexa Nina Fiorante[1], Michael Woolman[1], David Munoz[2], Farshad Nassiri[3], Gelareh Zadeh[4], Sunit Das[2], Howard Ginsberg[2], **Arash Zarrine-Afsar**[3]

[1]University of Toronto, Toronto, ON, Canada,[2]Unity Health, St. Michael's Hospital, Toronto, ON, Canada,[3]UHN Princess Margaret Cancer Centre, Toronto, ON, Canada,[4]UHN Princess Margaret Cancer Centre, Toronto, ON, Canada, Toronto, ON, Canada

The World Health Organization (WHO) now advocates for an integrated approach in the diagnosis of Central Nervous System (CNS) cancers. However, the proposed WHO workflow is complex, relying heavily on multiple instruments—like genetic sequencers and immunohistochemistry scanners—with variable, often lengthy, turnaround times.
Leveraging the link between lipid metabolism and cancer, we demonstrate that Picosecond InfraRed Laser Mass Spectrometry (PIRL-MS) can profile the tissue lipidome in just 10 seconds, achieving over 80% sensitivity and specificity for CNS tumor type prediction. This was validated across a large cohort of 150 pediatric (3 morphometrically distinct types, 7 molecular classes) and 1,142 adult (24 morphometric, 8 molecular classes) brain tumour types. While initial results provided strong classification, falling short of robust diagnostic criteria, the ongoing incorporation of machine learning has increased sensitivity and specificity to over 94% in select cases. The capabilities of PIRL-MS to deliver a 10-second diagnosis—based on downstream phenomic (lipidomic) changes—for both morphologically and molecularly distinct tumor (sub)types (e.g., IDH mutation status, medulloblastoma subgroups) offers a clear path toward a unified diagnostic platform. This approach can integrate morphometric and molecular diagnoses on a single instrument in seconds, drastically reducing the need for tissue manipulation and lengthy preparation steps, a feat unmatched by current methods.

#3884 Multiplex immunofluorescence based spatial analysis of HER2 positive breast cancer patients treated with bintrafusp alfa: A translational pathology study.

Maria Gabriela Raso[1], Elizve N. Barrientos-Toro[1], June Li[1], Renganayaki K. Pandurengan[1], Harsh Batra[2], Ximing Tang[1], Diego Oliva Rico[1], Julia Mendoza Perez[1], Jill Schwartz Gomez[3], Senthil Damodaran[3], Alastair Thompson[4], Andreas W. Machl[5], Natalia Jacob[6], Jennifer Keating Litton[7], Rashmi Krishna Murthy[3], Cara L. Haymaker[1]

[1]Translational Molecular Pathology, UT MD Anderson Cancer Center, Houston, TX,[2]Pathology and Molecular Medicine, McMaster University, Hamilton, ON, Canada,[3]Breast Medical Oncology, UT MD Anderson Cancer Center, Houston, TX,[4]Baylor College of Medicine, Dan L. Duncan Cancer Center, Houston, TX,[5]Senior Scientist II, Translational Oncology, EMD Serono, Inc., Billerica, MA,[6]Merk SA, Buenos Aires, Argentina,[7]Division of Clinical Research, UT MD Anderson Cancer Center, Houston, TX

Purpose: To characterize spatial remodeling of the tumor immune microenvironment and to define therapy associated cellular and architectural changes in stage II and III HER2 positive breast cancer treated with Bintrafusp Alfa, a bifunctional antibody that combines PD-L1 blockade with a TGFβ trap.
Experimental Design: Formalin fixed paraffin embedded baseline and on treatment biopsies (TP2) from patients enrolled in the MD Anderson clinical trial NCT03620201 were analyzed across five Multiplex Immunofluorescence (mIF) panels that captured: (1) PD axis T cell states, (2) cytotoxic, memory, and regulatory T cell subsets, (3) tumor and myeloid checkpoints and metabolic ligands, (4) T cell co-stimulation and exhaustion markers, and (5) myeloid and neutrophil axes. Spatial analysis was performed using the SPIAT R package to quantify cell-type distributions, identify unsupervised spatial clusters, and define neighborhood compositions. Cases were classified as responsive or refractory based on composite TP2 spatial features such as cytokeratin (CK) fragmentation, intratumoral CD8 positive infiltration, checkpoint-rich interfaces, and mixed immune and tumor clustering.
Results: A subset of TP2 specimens showed clear spatial remodeling characterized by(i) fragmentation of CK architecture into smaller epithelial nests separated by broader stromal areas,(ii) increased infiltration of CD8 and CD3 T cells at tumor stroma interfaces and within epithelial nests,(iii) localized PD1, PDL1, OX40 positive, and ICOS positive immune niches with focal TIM3 expression, and(iv) closer proximity of macrophages and neutrophils to fragmented CK borders without widespread activation of myeloid subsets.These features were enriched in responsive tumors, forming mixed tumor and immune clusters and inflamed spatial neighborhoods. In contrast, refractory tumors retained cohesive CK nests, peripheral T cell rims, and limited checkpoint marker expression.
Conclusions: Combined PD-L1 and TGFβ inhibition with Bintrafusp Alfa promotes heterogeneous spatial reprogramming of the breast cancer microenvironment. Beneficial remodeling is characterized by mixed epithelial and immune clusters, intratumoral cytotoxic and memory T cell infiltration, and checkpoint rich interfaces, while refractory cases are defined by persistent epithelial cohesion and suppressive myeloid environments. Overall, spatial compartmentalization, checkpoint expansion, and immune clustering emerged as indicators of response intensity. Our findings stress the need to tailor interventions to the spatial context; immune excluded tumors may benefit from T cell priming or myeloid reprogramming, while inflamed responders might require maintenance of checkpoint inhibition to sustain tumor clearance.

#3885 Application of transcriptomic bladder-cancer subtypes to upper-tract urothelial carcinoma (UTUC) across international cohorts reveals racial differences and translational limitations.

Joshua M. Scurll[1], Henning Bahlburg[1], Tran Anh Thu (Wendy) Phung[1], John Heard[2], Mamoru Hashimoto[3], Kazutoshi Fujita[3], Daniel Luthringer[2], Toru Sakatani[2], Kaoru Murakami[2], Charles J. Rosser[2], Ewan A. Gibb[1], Peter C. Black1[1], **Hideki Furuya**[2]

[1]University of British Columbia, Vancouver, BC, Canada,[2]Cedars-Sinai Medical Center, Los Angeles, CA,[3]Kindai University, Osaka, Japan

Background and Objectives: Management of UTUC follows bladder cancer (BC) guidelines but could be refined. Molecular subtyping has yielded valuable insights into tumor biology and therapy response/resistance for muscle-invasive (MI) and non-MI (NMI) BC and could have similar value for UTUC. Like NMIBC, UTUC is predominantly luminal-papillary (LumP) in subtype, which has spurred more granular UTUC-specific classification schemes. Here, we investigated whether MIBC and NMIBC subtyping could be translated to UTUC.

Methods: Histologically confirmed FFPE UTUC nephroureterectomy specimens were retrospectively collected from Cedars-Sinai Medical Center (Los Angeles, USA) and Kindai University (Osaka, Japan). RNA-seq was performed on 126 tumors, which were classified using consensus-MIBC and UROMOL2021-NMIBC frameworks. Event-free survival (EFS) was estimated by Kaplan-Meier analysis, excluding cases with prior or concurrent BC.

Results: Of 126 UTUCs, 69 (54.8%) were NMI and 55 (47.3%) MI. The LumP subtype was most common (57%), enriched in NMI-UTUC (75%) versus MI-UTUC (36%), mirroring NMIBC vs. MIBC. Cedars-Sinai tumors were mainly NMI (59%), while Kindai tumors were mostly MI (58%), suggesting population differences. LumP enrichment in Cedars-Sinai (80% of NMI vs. 33% of MI) contrasted with more balanced distributions in Kindai (5/10 NMI, 7/15 MI), indicating potential race-specific variation.Within LumP-UTUC, all four UROMOL classes were represented, whereas non-LumP UTUCs were mostly UROMOL 2b. Stratification by LumP vs. other revealed opposing (but not significant) survival trends in NMI- and MI-UTUC: LumP had poorer 5-year EFS in NMI-UTUC but better outcomes in MI-UTUC. Further stratification of LumP NMI-UTUC by UROMOL class showed no significant EFS differences, although Class 2b tumors had comparably poor outcomes to LumP MI-UTUC. Pathologic T stage remained the strongest prognostic factor (EFS: Ta > T1 > T2 > T3/4; $p < 0.05$).

Conclusions: LumP prevalence in UTUC is largely driven by NMI tumors, recapitulating NMIBC biology. Subtype and stage distributions vary between Western and Asian cohorts, implying race-related molecular diversity. While BC-derived classifiers can categorize UTUC, their clinical interpretation does not directly translate. Tumor stage outweighs molecular subtype as the principal determinant of outcome.

#3886 A novel glioblastoma subtype classification using hallmark gene set signatures: Association between poor prognosis and TP53 downstream pathway.

Yu Jin Kim[1], Jeongman Park[2], Woo Young Kwon[3], Jaejoon Lim[4], Sung Hwan Lee[5]

[1]Department of Biomedical Science, College of Life Science, CHA University, Seongnam-si, Korea, Republic of,[2]Department of Medicine, Hallym University, Chuncheon-si, Korea, Republic of,[3]CHA University, Seoul, Korea, Republic of,[4]2Department of Neurosurgery, Bundang CHA Medical Center, Seongnam-si, Korea, Republic of,[5]CHA University, Seongnam-si, Korea, Republic of

Glioblastoma (GBM) is an extremely aggressive and treatment-resistant primary brain tumor with a markedly poor prognosis. Although various molecular subtypes have been proposed to improve diagnostic and therapeutic approaches, their translation into clinical practice remains limited due to ambiguous classification criteria resulting from intra-tumoral heterogeneity and low clinical relevance. In this study, RNA-seq data from GBM cell lines in the DepMap database and bulk RNA-seq datasets from The Cancer Genome Atlas (TCGA), the Chinese Glioma Genome Atlas (CGGA), PRJNA1051047, and in-house cohorts were utilized. Furthermore, GeoMx DSP data paired with matched in-house RNA-seq samples were examined to characterize spatial transcriptomic patterns. Using Hallmark single-sample Gene Set Enrichment Analysis (ssGSEA) module scores, GBM cell lines were divided into two new subtypes by Non-negative Matrix Factorization (NMF) consensus clustering. Differentially expressed gene (DEG) signatures derived from these clusters were then used to classify IDH-wildtype GBM samples from four independent cohorts into two groups—designated as CA (cytokine-active) and GA (growth-active) subtypes—via a Bayesian compound covariate prediction (BCCP) model. The CA subtype exhibited poorer survival outcomes and elevated enrichment of tumor-associated pathways, including IL2-STAT5 signaling, apoptosis, and inflammatory response. Notably, TP53 emerged as a prominent upstream regulator in the CA group, consistent with increased ssGSEA module scores of 10 TP53-related pathways in various curated datasets in four patient cohorts. GeoMx DSP analyses further compared TP53 expression and ssGSEA module scores across α-SMA, CD45, and CD31 annotated regions of interest (AOIs) categorized into CA and GA subtypes. While TP53 expression did not significantly differ between the two groups in any AOI category, the Hallmark TP53 signaling module score was specifically elevated in α-SMA AOIs of CA subtype, particularly around perivascular regions. Collectively, two clinically relevant subtypes were identified, with the CA subtype being strongly associated with poor prognosis and significant dysregulation of TP53 downstream pathways. These findings suggest that TP53 may play a potentially important role in the aggressiveness of GBM.

#3887 Multiple myeloma risk classification of CoMMpass using Consensus Genomic Staging identifies differences between patients with high and low African genetic ancestry.

Steven M. Foltz[1], Chaitanya R. Acharya[1], Alexander Gout[1], Yuxin Jin[2], David E. Avigan[3], Ravi Vij[4], Shaji Kunnathu Kumar[5], Sagar Lonial[6], Hearn Cho[1], Katie Wozniak[1], Jonathan J. Keats[7], Craig Cole[8], John D. Carpten[9], George J. Mulligan[1]

[1]Multiple Myeloma Research Foundation, Norwalk, CT,[2]Beckman Research Institute of The City of Hope, Duarte, CA,[3]Beth Israel Deaconess Medical Center, Boston, MA,[4]Washington University School of Medicine, St. Louis, MO,[5]Mayo Clinic, Rochester, MN,[6]Emory Winship Cancer Institute, Atlanta, GA,[7]TGen (The Translational Genomics Research Institute), Phoenix, AZ,[8]Karmanos Cancer Institute, Detroit, MI,[9]City of Hope, Duarte, CA

Background: Multiple myeloma is the second most common adult blood cancer and remains incurable, despite recent advances. The IMWG/IMS recently published updated risk criteria, Consensus Genomic Staging (CGS), combining genomic events with clinical measures to identify high-risk patients (Avet-Loiseau, et al. JCO 2025). We applied CGS risk criteria to baseline samples from the Multiple Myeloma Research Foundation CoMMpass Study (NCT01454297), a prospective, longitudinal observational study that enrolled more than1100 participants between 2011-2017.

Methods: We assessed patient risk following CGS criteria. Criteria 1: del(17p), with a cutoff of >20% clonal fraction, and/or TP53 mutation. Criteria 2: an IgH translocation including t(4;14), t(14;16), or t(14;20) along with 1q+ and/or del(1p32). Criteria 3: monoallelic del(1p32) along with 1q+ or biallelic del(1p32). Criteria 4: beta-2 microglobulin >= 5.5 mg/L with normal creatinine. Patients meeting one or more criteria were classified as High Risk. To test if risk showed association with genetic ancestry, we grouped patients into those with high African genetic ancestry and those with low African genetic ancestry. Genetic ancestry was measured using ADMIXTURE in comparison to 1000 Genomes.

Results: We evaluated the CGS risk status of 877 CoMMpass patients, finding 69.2% (573/828) to be Standard Risk (SR) and 30.8% (255/828) to be High Risk (HR). HR patients showed worse progression-free survival (median PFS 26.3 months vs. 42.5 months; log rank test, $p < 0.0001$) and overall survival (median OS 63.9 months vs. median not reached; $p < 0.0001$). 10.6% (91/858) of patients met Criteria 1, 10.7% (93/873) met Criteria 2, 5.6% (49/877) met Criteria 3, and 8.7% (73/835) met Criteria 4.

We found 14.2% (123/867) of patients to have high African-like genetic ancestry (AFR-high) and 85.8% (744/867) to have low African-like genetic ancestry (AFR-low). We observed significantly fewer HR patients within the AFR-high group (20%, 23/115) than in the AFR-low group (32.4%, 231/712) (Fisher's exact test, $p = 0.0065$). The AFR-high group met HR criteria at a lower rate across all criteria, but only with Criteria 3 was the difference significant (p-value = 0.03). Higher levels of creatinine in AFR-high patients may have impacted meeting the normal creatinine requirement of Criteria 4.

Conclusions: HR patients comprise 30.8% of CoMMpass subjects and show significantly worse PFS and OS than SR patients. AFR-high patients met HR criteria at a lower rate than AFR-low patients according to the CGS criteria. Clinical trials that utilize CGS criteria to determine patient eligibility may be challenged to enroll a representative patient population, including AFR-high patients. Screening and eligibility criteria should be carefully considered to mitigate potential enrollment disparities.

#3889 Genomic-immunophenotypic landscape of early-stage pulmonary carcinoid tumors and their prognostic implications.

Song Xu[1], Lingling Zu[1], Ning Zhou[1], Jingya Wang[2], Xiongfei Li[3], Haixiang Yu[4], Sibo Peng[1], Chunxia Su[5], Dingzhi Huang[2]

[1]Department of Lung Cancer Surgery, Tianjin Key Laboratory of Lung Cancer Metastasis and Tumor Microenvironment, Lung Cancer Institute, Tianjin Medical University General Hospital, Tianjin, China, Tianjin, China,[2]Tianjin Medical University Cancer Institute and Hospital, National Clinical Research Center for Cancer, Key Laboratory of Cancer Prevention on and Therapy, Tianjin's Clinical Research Center for Cancer, Tianjin, China., Tianjin, China,[3]Department of Thoracic Surgery, Shanghai Chest Hospital, Shanghai Jiao Tong University, Shanghai, China., Shanghai, China,[4]Department of Thoracic Surgery, China-Japan Union Hospital of Jilin University, Changchun, China, Changchun, China,[5]Department of Medical Oncology, Shanghai Pulmonary Hospital and Thoracic Cancer Institute, Tongji University School of Medicine, Shanghai, China, Shanghai, China

Background: Pulmonary carcinoids (PCs), encompassing atypical carcinoids (ACs) and typical carcinoids (TCs), represent a rare category of lung cancer characterized by low to moderate malignancy. However, there is a limited understanding of the genomic and immune characteristics associated with PCs on a global scale.
Methods: This study enrolled 126 surgically resectable PC patients, comprising 44 ACs and 82 TCs. Next-generation sequencing utilizing a 578-gene panel was conducted and immunohistochemical staining for PD-L1 and CD8 was also carried out.
Findings: The most frequently altered genes in PCs were identified as *EGFR* (n=16, 18%), *KMT2C* (n=11, 12%), *LRP1B* (n=10, 11%), *MEN1* (n=10, 11%), and *NOTCH2* (n=9, 10%). Dysregulation of the RTK/RAS, NOTCH, and PI3K pathways was commonly observed in these PCs. Our study unveiled that only 4.6% of the PC patients were identified as PD-L1 positivity, and TMB and CD8+ T cell infiltration were found to be low in early-stage PCs, as manifested by the “immune-excluded” or “immune-desert” microenvironment. We identified age, gender, TNM stage, tumor type, smoking status, TMB, and LRP1B mutation as indicators of poor prognosis. We found that for those surgically resectable early-stage PC patients with *LRP1B* mutation, patients exhibit an increased risk for tumor-related mortality and recurrence, and subsequently further proposed a molecular classification based on the status of LRP1B mutation.
Interpretation: We depicted the genetic and immune landscape of PCs and proposed a LRP1B mutation based molecular classification. Our research offers novel insights into the biological mechanisms of PCs which contributes to the individualized treatment for PC patients.

#3890 HDAC6 as a convergent oncogenic and immunoregulatory hub across multiple cancer types.

Chia-Wei Wu[1], Chia-Yi Hsu[2], Eing-Mei Tsai[2], **Tsung-Hua Hsieh**[1]

[1]Department of Medical Research, E-Da Hospital/E-Da Cancer Hospital, I-Shou University, Kaohsiung, Taiwan,[2]Department of Obstetrics and Gynecology, Kaohsiung Medical University Hospital, Kaohsiung, Taiwan

Histone deacetylase 6 (HDAC6) has emerged as a critical regulator of tumor progression across multiple malignancies. Our integrated analyses reveal that environmental phthalates (BBP, DBP) drive oncogenic processes in breast epithelial stem cells and ER-negative breast cancer by activating ER-EGFR-PKA or AhR-cAMP-PKA-CREB1 signaling, leading to HDAC6 upregulation, β-catenin/LEF1-TCF4 activation, epithelial-mesenchymal transition (EMT), and enhanced metastatic potential. Beyond breast cancer, clinical datasets and functional studies demonstrate that elevated HDAC6 expression correlates with advanced stage, higher tumor grade, and poor survival in lung cancer, oral squamous cell carcinoma (OSCC), and endometriosis-associated ovarian carcinoma (EAOC). Mechanistically, HDAC6 promotes tumor progression by regulating HIF-1α/BNIP3-mediated autophagy in lung cancer, driving AP-1-dependent IL-13 expression and M2 macrophage polarization in OSCC, and mediating ARID1A mutation-associated IL-10-driven immunosuppressive macrophage programming in EAOC. Importantly, pharmacologic HDAC inhibition (TSA, vorinostat) suppresses autophagy, reverses macrophage polarization, reduces EMT, and markedly inhibits tumor growth in relevant in vitro and in vivo models. Together, these findings position HDAC6 as a convergent oncogenic and immunoregulatory hub across environmentally induced, hormone-independent, and mutation-associated cancers, supporting HDAC6-targeted therapies as a promising strategy for limiting tumor progression and reshaping the tumor immune microenvironment.

#3891 Morphologic spectrum of bladder cancer variants and incidental prostate pathology in cystoprostatectomy specimens.

Shannon Carskadon[1], Aryan Joshi[2], Nilesh S. Gupta[3], **Nallasivam Palanisamy**[1]

[1]Urology, Henry Ford Health, Detroit, MI,[2]Biochemistry, Michigan State University, East Lansing, MI,[3]Pathology, Henry Ford Health, Detroit, MI

High-grade bladder cancer exhibits substantial morphologic heterogeneity, and several variant histologies show distinct biological behavior and therapeutic responsiveness. To define the full pathologic spectrum in cystoprostatectomy specimens, we analyzed 44 cases treated between 2010 and 2023.The cohort (mean age 67.1 ± 12.2 years) predominantly presented with advanced disease; pT3a was the most common stage (25%), and one-third showed invasion of≥pT3. High-grade urothelial carcinoma was the primary subtype (14 cases). True variants were frequent and included squamous differentiation (6), sarcomatoid (2), micropapillary (1), nested (1), giant-cell/pleomorphic (1), and small-cell carcinoma (1). Papillary carcinoma and CIS were reclassified into the high-grade urothelial category. Margin positivity occurred in 6 patients (13.6%), especially among aggressive variants such as squamous, sarcomatoid, and micropapillary carcinoma. Lymph-node metastasis was identified in 3 patients (6.8%), all with high-grade invasive disease.Incidental prostate adenocarcinoma was common, spanning Grade Groups 1-4 and often multifocal. These tumors were low-volume, organ-confined, and rarely showed adverse features such as extraprostatic extension, seminal vesicle invasion, or positive margins. Cribriform/glomeruloid patterns were uncommon. Additional findings included HGPIN, chronic inflammation, and treatment-related changes. Actual bladder cancer invasion into prostatic stroma (pT4a) was rare (one case). Significantly, incidental prostate cancer did not correlate with bladder cancer histology or stage, reflecting their biological independence.Variant histologies have direct therapeutic implications: sarcomatoid, micropapillary, and small-cell carcinoma are associated with aggressive behavior, higher positive-margin rates, and may warrant intensified systemic therapy or enrollment in variant-specific clinical trials. Accurate identification prevents under-treatment of high-risk patients. In contrast, the incidental prostate cancers were clinically silent and indolent; recognizing them avoids unnecessary PSA surveillance, misinterpretation of imaging findings, and prevents staging errors, especially in distinguishing incidental cancer from actual prostatic stromal invasion.Overall, integrated bladder-prostate pathologic assessment improves staging accuracy, guides risk-adapted management, and supports multidisciplinary decision-making. These findings underscore the biological and clinical significance of variant histology in bladder cancer, while confirming that incidental prostate cancer in cystoprostatectomy specimens is typically low-risk and does not influence bladder cancer outcomes.

#3895 Targeting RET fusions in sarcomas with vepafestinib, a 3rd generation RET inhibitor with superior blood-brain barrier penetration.

Ryan Cheng[1], Allan J. W. Lui[1], Tom Zhang[1], Christopher A. Febres-Aldana[2], Michael Trombetta[1], Qing Chang[1], Inna Khodos[1], Elisa de Stanchina[1], Igor Odintsov[3], Marc Ladanyi[1], Romel Somwar[1]

[1]Memorial Sloan Kettering Cancer Center, New York, NY,[2]National Cancer Institute, Bethesda, MD,[3]Brigham and Women's Hospital, Boston, MA

Background
RET fusions are known drivers across multiple cancer types. While the FDA-approved small-molecule RET inhibitors selpercatinib and pralsetinib yield overall response rates of ~50-80%, on- and off-target resistance mutations and CNS disease progression underscore the need for novel therapies. Vepafestinib is a RET inhibitor with enhanced specificity and potency against RET solvent-front (G810) and gatekeeper (V804) mutations. Preclinical models of brain metastases demonstrate superior CNS penetration and anti-tumor activity compared to selpercatinib. Here, we investigated the therapeutic potential of vepafestinib in RET fusion-driven sarcomas.
Methods
Patient-derived xenograft (PDX) and cell line models of a SPECC1L::RET-driven sarcoma were established from a brain metastasis. Isogenic cell line models expressing SPECC1L::RET were generated via CRISPR-Cas9 genomic editing of human mesenchymal stem cells (HMSC). Xenograft models were developed by implanting either PDX tissue or HMSC-RET cells into the subcutaneous flank of NOD *scid* gamma (NSG) mice. To model brain metastasis, HMSC-RET cells stably expressing a bioluminescent reporter were implanted into the cerebellum of NSG mice. Protein expression and phosphorylation were assessed by Western blotting. Cell growth was measured using a viability dye.
Results
We established a PDX (Sarc-01pdx), a patient-derived cell line (Sarc-01cl), and an HMSC line harboring the SPECCL1::RET fusion (HMSC-RET). Expression of SPECCL1::RET was confirmed by RT-PCR and Western blot. Vepafestinib effectively inhibited the growth of Sarc-01cl (IC50=0.09 μM) and HMSC-RET (IC50=0.21 μM), compared to the isogenic control (HMSC IC50=12.7μM), with dose- and time-dependent reductions in the phosphorylation of RET (Y905 and Y1062) and downstream effectors, including AKT and ERK1/2. While selpercatinib and pralsetinib also inhibited the growth of the RET fusion-driven sarcoma cells, they showed more off-target effects in the control HMSC cells relative to vepafestinib.In both PDX and cell line xenograft models, vepafestinib (50 mg/kg BID) caused tumor growth inhibition comparable to selpercatinib (10 mg/kg BID) and pralsetinib (15 mg/kg BID). Upon cessation of treatment, tumor recurrence was not observed in mice treated with vepafestinib, whereas regrowth was detected in 1/5 and 3/5 mice in the selpercatinib and pralsetinb groups, respectively. Intracranially, vepafestinib was significantly more effective than selpercatinib at blocking tumor growth (p=0.042) and improving survival (median: 56 vs 32 days, p=0.0025).
Conclusions
Our preclinical results support vepafestinib as a promising, CNS-active therapy for RET fusion-driven sarcomas. Vepafestinib is currently being evaluated in the ongoing phase 1/2 margaRET trial for advanced RET-altered solid tumors (NCT04683250).

#3896 MERTK inhibitor MRX-2843 sensitizes AML to venetoclax and azacitidine in preclinical models.

Aashis Thapa[1], Chloe Hope[1], Edward B. Henderson[1], Austre Y. Schiaffino Bustamante[1], Gianna Branella[1], Alejandro De Janon[2], Sunil Raikar[1], Xiaodong Wang[3], Stephen V. Frye[3], H. Shelton Earp[3], Shuichi Takayama[4], Deborah DeRyckere[1], Douglas K. Graham[1]

[1]Emory University, Atlanta, GA,[2]Georgia Institute of Technology & Emory University, Atlanta, GA,[3]University of North Carolina at Chapel Hill, Chapel Hill, NC,[4]Georgia Institute of Technology, Atlanta, GA

While many patients with acute myeloid leukemia (AML) have an initial favorable response to treatment with standard of care venetoclax, a BCL2 inhibitor, and azacitidine, a DNA methyltransferase inhibitor, sustained remissions remain elusive and new therapies are urgently needed. We identified MERTK (MER Receptor Tyrosine Kinase) as a potential therapeutic target in AML and developed MRX-2843, a first-in-class dual MERTK/FLT3 kinase inhibitor that is currently being tested in leukemia patients. Here we describe a novel therapy that combines MRX-2843 with venetoclax and azacitidine to provide enhanced therapeutic effects in preclinical AML models. In human AML cell line cultures (KG-1, OCI-AML5, and NOMO-1), treatment with the 3-drug combination (MRX-2843/venetoclax/azacitidine) reduced cell density compared to venetoclax/azacitidine. Mathematical modeling using the fractional product method revealed a synergistic interaction between MRX-2843 and venetoclax/azacitidine in 2 of the 3 cell lines and an additive interaction in the other. In all 3 cell lines, MRX-2843 synergized with venetoclax/azacitidine to increase induction of cell death compared to venetoclax/azacitidine alone. Furthermore, in all 3 cell lines, the 3-drug combination reduced levels of c-MYC protein compared to venetoclax/azacitidine. These findings reveal a potential mechanism of the enhanced therapeutic effects mediated by the 3-drug combination. The triple combination also provided enhanced therapeutic effects against the KG1 cell line in an AML organoid model system that mimics many features of the bone marrow microenvironment, including chemoprotection. These data support addition of MRX-2843 to current standard of care venetoclax/azacitidine to better target bone marrow disease. Indeed, the 3-drug regimen significantly reduced bone marrow disease burden and prolonged survival in immune-compromised mice inoculated with the KG1 AML cell line. After the first treatment cycle (28 days), the fraction of human CD45+ leukemia cells in the bone marrow was significantly reduced in mice treated with the 3-drug combination (8.5±5%, n=4) compared to vehicle (67±8%, n=5, $p<0.001$), MRX-2843 (41±9%, n=6, $p=0.0451$), or venetoclax/azacitidine (40%±8%, n=6, $p=0.0482$). Moreover, mouse survival was significantly prolonged by the triple combination (median survival > 150 days, 59.1% survival after 150 days of treatment) compared to MRX-2843 (median survival = 76.5 days, 0% survival at 150 days, $p<0.0001$) or venetoclax/azacitidine (median survival = 104.5 days, 4.6% survival at 150 days, $p<0.001$). Together these findings (i) implicate co-administration of MRX-2843, venetoclax and azacitidine as an effective strategy to treat AML, (ii) reveal a potential mechanistic basis for this strategy, and (iii) support evaluation of this novel 3-drug combination in future clinical trials.

#3898 Profiling tumor selectivity of state- and paralog-selective RAS inhibitors through a signaling inhibition index (SII).

Beau Baars[1], Ana Orive-Ramos[1], Matthew Emmett[2], Bijaya Gaire[1], Mathieu Desaunay[1], Ziyue Kou[1], Guangyan Li[2], Christos Adamopoulos[1], Stuart A. Aaronson[3], Shaomeng Wang[4], William R. Sellers[2], Tiphaine Martin[1], Evripidis Gavathiotis[5], Poulikos I. Poulikakos[1]

[1]The Tisch Cancer Institute, Icahn School of Medicine at Mount Sinai, New York, NY,[2]Broad Institute at MIT and Harvard, Cambridge, MA,[3]Icahn School of Medicine at Mount Sinai, New York, NY,[4]Department of Internal Medicine, Department of Pharmacology, University of Michigan, Ann Arbor, MI,[5]Albert Einstein College of Medicine, Bronx, NY

The landscape of RAS-directed therapies has rapidly advanced following the advent of mutant-selective KRAS(G12C) inhibitors, driving the development of additional RAS-targeting agents, including mutant-selective (e.g. KRAS(G12C), KRAS(G12D)), as well as paralog- and state-selective compounds. Non-mutant- specific RAS inhibition can currently be achieved through three strategies: (i) guanine nucleotide exchange-OFF inhibitors (panRAS-GEF(OFF)i) that indirectly inactivate RAS by targeting SHP2 or SOS1, (ii) KRAS-OFF inhibitors (panKRAS(OFF)i) that spare NRAS and HRAS, and (iii) active-state RAS(ON) inhibitors (panRAS(ON)i) that directly block binding of effector RAF. Although these therapeutic modalities have shown promise, their clinical effectiveness and tolerability ultimately depend on achieving a high therapeutic index, defined as potent inhibition of oncogenic signaling in tumor cells with minimal effects on normal cells. To more robustly quantify tumor selectivity in preclinical models, we introduce the signaling inhibition index (SII), which measures the differential suppression of oncogenic signaling between RAS(MUT) and RAS(WT) cells, providing a more structured metric of tumor selectivity that has previously been poorly defined. Here, we evaluated the SII for state- and paralog-selective RAS inhibitors across diverse RAS(MUT) and RAS(WT) models. PanRAS-GEF(OFF)i exhibited neutral or negative SII, reflecting reduced MAPK suppression in KRAS(G12X) cells compared to wild-type cells. KRAS(G13D) models, especially with NF1 loss, showed low sensitivity. Combining SHP2 and MEK inhibition resulted in low tumor-selectivity, while RAS(Q61X) models were resistant due to MEK inhibitor-induced NRAS reactivation and altered SHP2 conformations. Consistent with these findings, analysis of DepMap SHP2-inhibitor sensitivity and dependency datasets showed that RAS(MUT) cell lines are not more sensitive than RAS(WT) cells to SHP2 inhibition, further underscoring the limited tumor selectivity of panRAS-GEF(OFF)-based approaches. In parallel, we assessed panKRAS(OFF)i and panRAS(ON)i potency/selectivity across a panel of RAS(MUT) and RAS(WT) cell line models. KRAS(OFF) inhibitors demonstrated higher selectivity, whereas active-state RAS(ON) inhibitors showed broader activity but narrow selectivity. Comparative analyses of published datasets revealed correlated sensitivity patterns across RAS inhibitor classes, indicating that therapeutic activity is largely restricted to the same subset of RAS(MUT) cancers. These findings highlight the importance of systemic SII quantification for therapeutic selectivity and for guiding the rational design and clinical implementation of next-generation RAS-targeted therapies.

#3900 Tegavivint, a first-in-class TBL1 inhibitor demonstrates potent activity in WNT-driven colorectal cancers.

Raffaella Soldi[1], Tithi Ghosh Halder[1], Jaeger Moore[1], Serina Ng[1], Jamie Cox[2], Taylor Bargenquast[1], Mahtab Youseffi[3], Julissa Simmons[3], Elena Ramirez[3], Aundrietta Duncan[3], Stephen Horrigan[3], Sunil Sharma[1]

[1]Honor Health Research Institute, Phoenix, AZ,[2]Honor Health Research Institute, Scottsdale, AZ,[3]Iterion Therapeutics, Houston, TX

Background. Tegavivint is a clinical phase investigational small molecule that disrupts Wnt/β-catenin signaling by targeting transducing beta-like protein 1 (TBL1), a critical mediator of nuclear β-catenin transcriptional activity. Unlike upstream Wnt inhibitors, tegavivint selectively impairs oncogenic transcriptional programs while sparing physiological Wnt functions, minimizing systemic toxicity. Preclinical studies and early-phase clinical trials have demonstrated that tegavivint suppresses tumor growth and enhances immune infiltration across multiple cancer models, including hepatocellular carcinoma and non-small cell lung cancer. Mechanistically, tegavivint promotes degradation of nuclear β-catenin, downregulates Wnt target gene expression, and modulates the tumor immune microenvironment. This mode of action is particularly relevant in colorectal cancer (CRC), where aberrant Wnt signaling, frequently driven by APC or CTNNB1 mutations, plays a central role in tumorigenesis. The present study investigates the potential therapeutic efficacy of tegavivint in CRC.

Methods. To evaluate the cytotoxic potential of tegavivint in CRC, we conducted the Broad PRISM screen. Annexin V analysis revealed dose- and time-dependent induction of apoptosis. To further elucidate the molecular consequences of treatment, transcriptomic profiling was performed in HCT15 cells. To investigate the influence of the tumor microenvironment on drug sensitivity, dose-response analyses were extended to CRC organoid models, including cell line-derived organoids co-cultured with fibroblasts, as well as patient-derived organoids (PDOs) containing endogenous stromal components. Last, Tegavivint was investigated in a combination drug screen to identify mechanisms of activity and potential synergies in 2D cells and PDOs.

Results. Tegavivint monotherapy exhibited robust antitumor activity across a spectrum of CRC preclinical models, including 2D cell lines, 3D spheroids, PDOs. RNA-seq analysis revealed marked transcriptional repression of Wnt/β-catenin signaling interacting genes along with induction of apoptotic programs, confirming the reprogramming of Wnt/b-catenin signaling and subsequent cell death by tegavivint. Furthermore, Tegavivint treatment induced apoptosis in responsive models, validating our initial mechanistic predictions and supporting its role as a targeted therapeutic agent in WNT-driven CRC. Tegavivint demonstrated synergistic activity when combined with VEGF-TKIs and pan-RAS inhibitors, while combination with other Wnt-inhibitors yielded no added activity.

Conclusion. These findings underscore the translational promise of Tegavivint as a therapeutic strategy in colorectal cancer, supporting its advancement toward clinical development to improve outcomes in WNT-driven disease subsets.

#3901 BGB-58067, a brain-penetrative MTA-cooperative PRMT5 inhibitor, demonstrates promising anti-tumor activity and favorable selectivity in tumors with MTAP-deletion.

Amy Jiang[1], Jinyan Chen[1], Xiaoxin Liu[1], Hongyu Chen[1], Huijun Kang[1], Jie Li[1], Haiying Li[1], Bo Zhang[1], Chenge Zhao[1], Hao Zhu[1], Xin Zhou[1], **Sanjia Xu**[1], Yibin Xu[2], Xing Zhou[1], Shifan Ma[1], Ming Fang[1], Min Xu[1], Lan Hua[1], Chuanxiu Yang[1], Yue Wu[1], Beibei Jiang[1], Xi Wu[1], Fan Wang[1], Ye Liu[1], Zhitao Wan[1], Jing Li[1], Jiyuan Zhang[2], Zhiwei Wang[1], Zhirong Shen[1], Yu Shen[1], Lai Wang[1], Xiaomin Song[1]

[1]BeOne Medicines, Beijing, China,[2]BeOne Medicines, Shanghai, China

PRMT5 was identified as a synthetic lethal target for cancers harboring homozygous deletion of the MTAP gene. MTA was found to accumulate in tumor cells with MTAP-deletion, which inhibited PRMT5 enzymatic activity and increased susceptibility to additional PRMT5 depletion. The homozygous MTAP-deletion was observed in 15% of all tumor types. MTA-cooperative PRMT5 inhibitors have been developed as potential antitumor therapies in tumor types with MTAP-deletion as they selectively bind and stabilize the catalytically inactive PRMT5/MTA complex to inhibit PRMT5 enzymatic activity. BGB-58067 is a highly potent and selective MTA-cooperative PRMT5 inhibitor with good brain penetration potential. BGB-58067 is highly selective for PRMT5 over other methyltransferase family members. It shows strong killing potency and good selectivity (>50-fold) in the cancer cell lines panel with MTAP-deletion over cell lines with MTAP-WT. BGB-58067 very weakly hits on normal hematological cells and demonstrates preferable selectivity (>30-fold) than competitors. BGB-58067 induces robust anti-tumor activity in multiple cell line-derived xenograft models. BGB-58067 demonstrates desirable pharmacokinetics properties and low DDI risk. It exhibits excellent unbound brain-to-plasma partition coefficient to support robust intracranial anti-tumor activity. BGB-58067 shows favorable nonclinical safety profile in the GLP studies, as well as good selectivity in an in vitro SafetyScreen87-off target profiling study. In conclusion, BGB-58067 demonstrates robust potency and selectivity, providing a favorable safety margin for patients, with high potential for the treatment of brain tumors and brain metastases.

#3902 WEE1 inhibition as a therapeutic strategy in triple-negative breast cancer: Evaluating single agent and combination activity of azenosertib in preclinical models.

Catherine Lee, **Alexandra Levy**, Mona Abed, Heekyung Chung, Olivier Harismendy, Doris Kim

Zentalis Pharmaceuticals, San Diego, CA

Background: WEE1 kinase maintains genomic integrity by regulating the G1/S and G2/M cell cycle transitions, allowing cells to repair damaged DNA before progressing to the next phase. Treating tumor cells with azenosertib, a highly selective oral WEE1 inhibitor (WEE1i), promotes premature cell cycle entry, accumulation of DNA damage, and ultimately cell death. While clinically meaningful activity has so far been observed in platinum-resistant ovarian cancer, we sought to explore vulnerability to WEE1 inhibition in other solid tumor types, such as breast. With over 300,000 new cases of breast cancer diagnosed each year in the United States, approximately 15-20% are triple-negative breast cancer (TNBC). TNBC is a particularly aggressive subtype with limited availability of targeted therapies for patients. Although recent approvals of immune checkpoint inhibitors and antibody-drug conjugates (ADCs) have improved outcomes in some patients with TNBC, many eventually experience disease progression, underscoring the continued need for new therapeutic strategies.

Methods: Using results from four *in vitro* pharmacogenomic drug screens in cell lines, we analyzed breast cancer models for sensitivity to WEE1i and potential molecular correlates, including subtype classification, mutation and expression of genes associated with replication stress, and pathway enrichment. *In vivo* efficacy of azenosertib was evaluated in a panel of ~10 TNBC xenograft models implanted subcutaneously in immunocompromised mice. Clinically relevant doses of azenosertib were tested as monotherapy treatments or in combination with current standard-of-care therapies for TNBC.

Results: When compared to non-TNBC breast, TNBC cell lines were significantly more sensitive to WEE1i *in vitro* and tended to have higher Cyclin E1 protein expression, a known marker of replication stress and vulnerability to WEE1i. *In vivo*, single agent azenosertib demonstrated moderate to strong efficacy in a panel of TNBC xenograft models. In models that were less sensitive to single agent azenosertib, combinations with sacituzumab govitecan (SG), trastuzumab deruxtecan (T-DXd), or datopotamab deruxtecan (Dato-DXd) enhanced tumor growth inhibition and prolonged duration of response beyond what was achieved with any of the agents alone.

Conclusions: We demonstrated *in vitro* and *in vivo* evidence that TNBC models are susceptible to WEE1 inhibition. Our findings suggest that azenosertib as a single agent, or in combination with standard-of-care therapies, may be a potential treatment strategy for TNBC and warrants further exploration.

#3903 SPEDOX-6: First-in-human Phase IB/IIA trial on soft tissue sarcomas.

C. J. Yu[1], leslie Wang[1], Kinsley Wang[1], Mengmeng Liu[1], Faqing Huang[2], Warren A. Chow[3], Xiaojiang Cui[4]

[1]Sunstate Biosciences, LLC, Pasadena, CA,[2]University of Southern Mississippi, Hattiesburg, MS,[3]University of California at Irvine, Irvine, CA, CA,[4]Cedars-Sinai Medical Center, Los Angeles, CA

Purpose: Soft tissue sarcomas (STSs) are extremely aggressive & deadly rare tumors with multiple subtypes. Early diagnosis is very difficult & STSs are frequently diagnosed only at advanced stages. DOX has remained the only standard of care in past 45 years with low efficacy and high dose-dependent cardiotoxicity. Better agents are urgently needed.
Methods: Our patented single protein encapsulation (SPE) platform allows encapsulation of small-molecule drugs by a single protein (albumins or globulins) to make new generation nanodrugs that have no artificial nanoparticles, no chemical modifications to drugs and proteins. SPEDOX-6 was successfully prepared by encapsulated 9 doxorubicin (DOX) molecules into the binding pockets of each native HSA molecule, which was confirmed and characterized by UV, fluorescence, membrane dialysis, size-exclusion HPLC and size distribution. SPEDOX-6 provides a novel approach for improving DOX's efficacy and reducing its side effects by targeting cancer cells with low neonatal Fc receptor (FcRn) levels.
Results: In mouse model, heart tissues' DOX was 4 to 8 times lower from SPEDOX-6 than from DOX, indicative of lower cardiotoxicity of SPEDOX-6. PK profiles of same dose for SPEDOX-6 and DOX shown that SPEDOX-6 has shown 48X increase of SPEDOX-6 total exposure upon its encapsulation. In rat model, the total exposure for SPEDOX-6 increases 7-17 times compared to DOX. SPEDOX-6's cardiotoxicity at 50 mg/kg was undetectable, in contrast to observable DOX's cardiotoxicity at 5-10 mg/kg. In mouse model efficacy study on HT-1080 (STS), SPEDOX-6 remarkably suppresses HT-1080 (the lowest FcRn) with 3 out of 10 mice tumor free. SPEDOX-6 at 30 mg/kg is significantly better than Doxil at 4 mg/kg (MTD) and DOX at 3.5 mg/kg (MTD) in inhibiting SK-ES-1 (Ewing sarcoma, with the highest FcRn) tumor growth, but SPEDOX-6 has less efficacy against SK-ES-1, relative to HT-1080. For MB-MDA-231 (TNBC, medium FcRn) model, SPEDOX-6 has shown superior anticancer efficacy in comparison to DOX. Combined with 3 mouse model studies, SPEDOX-6's antitumor efficacy displays an inverse relationship with the FcRn expression level, thereby providing a potential mechanism for SPEDOX-6 to effectively target tumors with low FcRn. IND (IND #: 152154) applications with 8 dosing escalation levels were approved by FDA and first-in-human phase IB was initiated at UCI and Cedar Sinai in June 2025 (NCT07064018). At present, initial dose (20 mg/m^2) with 3 patients (lung/pancreatic/cervical cancer) was completed and dose level 2 (40 mg/m^2) is underway with enrollment of 3 patients (2 STSs/ uterine cancer).
Conclusions: With Orphan Drug Designation of SPEDOX-6, only phase 2A trial is needed for full approval, granted by FDA. Superior clinical antitumor efficacy of SPEDOX-6 on STSs is expected to be achieved because a possible high dose at 310 mg/m^2 (> 4-folds DOX) can be used for treating patients without cardiotoxicity, which will save lots of lives.

#3904 SPOP drives AR-V7-mediated ARPI resistance in prostate cancer.

Joanina K. Gicobi[1], Susanna M. Gregory[2], Nicole A. Becker[2], Elizabeth A. Bering[2], Jacob J. Orme[1]

[1]Medical Oncology, Mayo Clinic, Rochester, MN,[2]Biochemistry and Molecular Biology, Mayo Clinic, Rochester, MN

Approximately 288,000 men are diagnosed with prostate cancer (PCa) in the United States each year, with cases expected to double by 2040. While metastatic PCa can be treated with androgen deprivation therapy (ADT) and AR pathway inhibitors (ARPI), it inevitably develops into treatment resistant, lethal disease. The most common ARPI resistance mechanism in PCa is the expression of AR splice variant AR-V7 that lacks the ligand binding domain and is constitutively active. Patients with PCa expressing AR-V7 experience inferior overall survival. Speckle-type POZ protein (SPOP) is an adaptor protein of the Cullin3-based E3 ubiquitin ligase that facilitates both degradative and non-degradative polyubiquitination of targets such as AR. Loss-of-function SPOP mutations occur in approximately 10-15% of prostate cancers, and *SPOP*-mutant PCa is a unique subtype that has been shown to be exquisitely sensitive to ADT and ARPI treatment. This sensitivity is mediated in part by increased androgen availability via upregulation of hydroxysteroid 17-beta dehydrogenase 4 (HSD17B4) and related steroid synthesis pathways, reduced AR degradation, and enhanced AR cofactor activity. The remarkable efficacy of ARPI in ADT-resistant *SPOP*-mutant prostate cancer is not well understood.We *hypothesized* a novel mechanism by which wild-type SPOP promotes AR-V7-mediated resistance to ARPI in PCa. This mechanism may explain the exceptional ARPI sensitivity of *SPOP*-mutant PCa, distinct from its susceptibility to ADT. We further proposed that clinical SPOP inhibition may broaden this enhanced ARPI susceptibility to the 85-90% of PCa expressing wild-type SPOP.Our *results* show that SPOP drives ARPI resistance in prostate cancer that can be reversed by SPOP inhibitor. Bulk RNA sequencing showed that SPOP inhibitor targets spliceosome machinery and more importantly, abrogated AR-V7 expression both at transcriptional and protein level. Further investigation revealed that wild-type SPOP ubiquitinates spliceosome regulator SFPQ, promoting AR-V7 alternative splicing and ARPI resistance. While SPOP loss is pathogenic in PCa, leveraging the weakness conferred by *SPOP* mutation in the 85% of patients with SPOP-wild type provides an innovative strategy to sensitize ARPI resistant disease to standard of care treatment and save lives.

#3905 A pan-TEAD inhibitor, SIGX2649, blocks Hippo-YAP/TAZ signaling pathway and suppresses solid tumor growth in preclinical studies.

Hualing Peng

Signet Therapeutics Inc, Shenzhen, China

The Hippo-YAP/TAZ signaling cascade is a critical regulator of tissue homeostasis, with TEAD transcription factors (TEAD1-4) serving as essential downstream effectors. Perturbation of Hippo signaling permits YAP/TAZ nuclear accumulation, leading to TEAD-mediated transcriptional programs that drive oncogenic processes such as tumor cell proliferation, resistance to apoptosis, drug resistance, and remodeling of the tumor microenvironment.

Here, we report the discovery of SIGX2649, a potent pan-TEAD inhibitor identified through AI-guided design and organoid-based screening. Leveraging generative AI and predictive AI models significantly accelerated lead identification and optimization during SIGX2649's development. SIGX2649 blocks palmitoylation of TEAD1/2/3/4, disrupts YAP/TAZ-TEAD protein interaction, and suppresses TEAD-dependent transcription. Notably, SIGX2649 displays a superior capacity to enhance the binding of the transcriptional repressor VGLL4 to TEAD relative to other multi-TEAD inhibitors, thereby further strengthening its pharmacological activity. Consequently, it inhibits proliferation across a spectrum of tumor models in vitro, including YAP-activated liver-cancer organoids and mesothelioma cells bearing LATS mutations and NF2 loss. In vivo, SIGX2649 exhibited robust antitumor efficacy in xenograft models, favorable pharmacokinetics, and minimal hepatic- or renal- targeted toxicity compared with other TEAD inhibitors under comparable efficacy. Combined with RAS-pathway inhibitors, SIGX2649 elicits pronounced synergistic responses in KRAS-mutant solid tumors.

The robust efficacy and considerable safety characteristics presented by SIGX2649 in preclinical trials support its potential to serve as a highly promising small-molecule therapeutic in future cancer treatment.

#3906 Small-molecule inhibitors as salvage therapy for CBFB::MYH11-associated acute myeloid leukemia.

Thuy An Nguyen[1], A S M Waliullah[1], Joshua Pei[1], Misha Padigala[1], Malena Nong[1], Nazifa Azam[1], Hien La[2], Nicholas Nguyen[1], Katelyn Do[1], Ramzia Ismailzada[1], Anna Bookstaver[1], Barbara Dziegielewska[1], Ly P. Vu[3], Nam Chu[4], Francine Garrett-Bakelman[5], Hong Zhu[6], Jeffrey W. Craig[1], Bon Q. Trinh[1]

[1]Department of Pathology, University of Virginia, Charlottesville, VA,[2]Biomedical Physics Program, Vietnam National University, Hanoi, Viet Nam,[3]Terry Fox Laboratory, Bristish Columbia Cancer Research Centre, Vancouver, BC, Canada,[4]Department of Cancer Biology and Genetics, Ohio State University, Columbus, OH,[5]Department of Biochemistry and Molecular Genetics, University of Virginia, Charlottesville, VA,[6]Department of Public Health Sciences, University of Virginia, Charlottesville, VA

Acute myeloid leukemia (AML) is an aggressive blood cancer and the most common form of acute leukemia in adults. Although chemotherapy with cytarabine and an anthracycline induces high remission rates, it often causes severe side effects, and relapse is common. These limitations highlight the urgent need for new treatment options, particularly for relapsed disease, where therapeutic resistance remains a significant obstacle. Genetic rearrangements are major drivers of AML, generating fusion proteins that disrupt normal hematopoietic regulation in about 20–40% of cases. Among these, CBFB::MYH11, resulting from chromosome 16 inversion or t(16;16) translocation, occurs in 10–15% of adult AML. This fusion protein sequesters RUNX1 in the cytoplasm, impairing core-binding factor function, blocking myeloid differentiation, and promoting leukemic cell survival. Thus, CBFB::MYH11 represents an attractive therapeutic target in AML, including in the setting of relapsed disease. Using a comprehensive virtual screening pipeline that integrates chemical structures from FDA-approved drugs, natural products, the ZINC22 database, and experimental compounds, we systematically identified lead compounds targeting the CBFB component of the CBFB::MYH11 fusion protein. To experimentally validate our cheminformatics-based predictions, we established multiple cytarabine-resistant AML cell lines, including CBFB::MYH11, to model therapy-induced resistance. In parallel, we isolated mononuclear cells from peripheral blood and bone marrow samples from AML patients with and without CBFB::MYH11 at both diagnosis and relapse, enabling direct comparison between in vitro and patient-derived resistance mechanisms. Treatment with the experimental compound SM1, one of the predicted top-binding candidates, selectively induced cell cycle arrest and apoptotic cell death in chemoresistant and chemosensitive AML cells harboring CBFB::MYH11, while sparing AML cells with other chromosomal aberrations. Both primary and relapsed AML patient cells harboring CBFB::MYH11 were similarly affected. We then established xenograft and patient-derived mouse models of AML to evaluate the therapeutic efficacy of SM1 *in vivo*. Ongoing studies will assess SM1's impact on animal survival and aim to extend both *in vitro* and *in vivo* analyses to additional lead compounds identified in our *in-silico* screening. The success of this study could enable the development of a small-molecule therapeutic toolkit for chemoresistant AML harboring CBFB::MYH11 and support future applications in other AML subtypes with oncogenic fusions.

#3907 Molecular determinants of response in laparoscopically triaged advanced ovarian cancer.

Sara Corvigno[1], Nicholas W. Bateman[2], Amma Asare[1], Chunqiao Tian[2], Jun Yao[3], Sean Cronin[2], Jonathan Ogata[2], Tamara Abulez[2], Kelly A. Conrads[2], Brian L. Hood[2], Joseph Celestino[1], Nicole D. Fleming[1], Kathleen M. Darcy[2], Amir A. Jazaeri[1], Shannon N. Westin[1], Christopher Tarmey[2], Thomas P. Conrads[2], George L. Maxwell[2], Sanghoon Lee[1], Anil K. Sood[1]

[1]Department of Gynecologic Oncology and Reproductive Medicine, UT MD Anderson Cancer Center, Houston, TX,[2]Gynecologic Cancer Center of Excellence, Department of Gynecologic Surgery and Obstetrics, Uniformed Services University of the Health Sciences, Walter Reed National Military Medical Center, Bethesda, MD,[3]Department of Molecular & Cellular Oncology, UT MD Anderson Cancer Center, Houston, TX

BACKGROUND: High-grade serous ovarian cancer (HGSC) is the most lethal gynecologic malignancy, marked by genomic instability, extensive peritoneal spread, and frequent recurrence despite initial chemosensitivity. Complete gross resection (CGR) at primary surgery is the strongest predictor of survival, yet it is not always achievable. Conventional imaging often underestimates disease burden and reliable molecular predictors of surgical and chemotherapeutic response are lacking. To address this, we performed a multi-omic analysis of tumors obtained during laparoscopic scoring procedures that triaged patients to primary tumor reductive surgery (pTRS) or neoadjuvant chemotherapy (NACT) followed by interval tumor reductive surgery (iTRS).

METHODS: Pre-treatment fresh-frozen tumor samples were collected from 40 patients across four groups: pTRS-CGR, pTRS-R1 (gross residual disease), iTRS-CGR, and iTRS-R1. Bulk RNA sequencing and multiplexed quantitative proteomics were performed to characterize transcriptomic and proteomic profiles. Integrative proteogenomic analyses identified concordant molecular signatures associated with treatment outcomes. Findings were validated in an independent multi-omic cohort of 30 HGSC patients treated with identical protocols.

RESULTS: Patients achieving pTRS-CGR had the most favorable overall survival (OS) (87.5 months, median OS), whereas iTRS-R1 had the poorest outcome (22.9 months, median OS). Multi-omic integration revealed distinct expression signatures across response groups. A total of 73 proteins and 229 transcripts were significantly upregulated in iTRS-R1 tumors compared to others, with strong proteomic-transcriptomic concordance (Spearman Rho=0.837, P<1E-4). Pathway analysis showed enrichment for primary cilium formation and cell anchoring in pTRS-CGR tumors, while iTRS-R1 tumors exhibited activation of oxidative phosphorylation, mitochondrial metabolism, and stress-adaptive signaling. Notably, EEF2K (Eukaryotic elongation factor 2 kinase), a key regulator of energy conservation and stress response, was markedly overexpressed in iTRS-R1 tumors. Validation confirmed elevated EEF2K in poor NACT responders with higher residual disease burden.

CONCLUSION: Laparoscopic triage effectively stratifies advanced HGSC for optimal surgical management, with pTRS-CGR achieving the best survival outcome. Multi-omic analyses highlight metabolic reprogramming as a hallmark of poor responders and identify EEF2K as a potential prognostic biomarker and therapeutic target. These data support biomarker-driven approaches to improve outcomes in advanced ovarian cancer.

#3908 Liquid biopsy-informed precision oncology clinical trial to evaluate the utility of ctDNA genomic profiling for therapy optimization in patients with advanced or metastatic solid tumors.

Amna Jamali[1], Jaime Wehr[1], Jenna VanLiere Canzoniero[1], Maria Fatteh[1], Katerina Karaindrou[1], Michael Conroy[1], Ilias Ziakas[1], Mohamed Sherief[1], Timsy Wanchoo[1], Faith Too[1], Lily Scharpf[1], Ruth Moges[1], Dana Petry[1], Kala Visvanathan[1], Ellen Verner[2], Amy Greer[2], Kory Kreimeyer[1], Jonathan Spiker[1], Rachel Karchin[1], Christine L. Hann[1], Vincent K. Lam[1], Joseph Christopher Murray[1], Josephine Feliciano[1], Kristen Marrone[1], Julie R. Brahmer[1], Ming-Tseh Lin[3], Taxiarchis Botsis[1], Hao Wang[1], Mark Sausen[2], Christopher D. Gocke[3], Rena Xian[3], Jessica Tao[1], Valsamo (Elsa) K. Anagnostou[1]

[1]Department of Oncology, Sidney Kimmel Comprehensive Cancer Center, Johns Hopkins School of Medicine, Baltimore, MD,[2]Labcorp, Baltimore, MD,[3]Department of Pathology, Johns Hopkins School of Medicine, Baltimore, MD

Background: Genomic profiling via liquid biopsies (LB) has advanced precision oncology decision-making; however, a major challenge is critically interpreting LB data to improve the selection and order of genotype-specific therapies.
Methods: We present updated results from the first planned analysis of an observational biomarker trial, aimed at assessing the clinical utility of serial LB in patients with advanced or metastatic solid tumors (NCT05585684). Primary endpoints assessed feasibility, prevalence of actionable alterations, and fraction of patients receiving genotype-matched therapies. Secondary endpoints encompassed progression-free survival (PFS), overall survival (OS), and concordance between LB and tumor next-generation sequencing (NGS). Serial LBs at baseline, early (1-3 weeks) on therapy, and at progression, employed a clinically validated 33-gene panel NGS assay (Labcorp Plasma Focus). Matched white blood cell (WBC) NGS was used to identify clonal hematopoiesis (CH)-derived variants. Mutation actionability was evaluated using a multi-resource programmatic approach, and levels of evidence (1-4) were assigned, followed by review at the Johns Hopkins Molecular Tumor Board (JH MTB).
Results: Among 50 patients, 45 baseline and 12 progression LBs were reviewed at MTB. JH MTB classified 72.5% (n=50) of baseline alterations as tumor-derived. In 19 patients with archival tissue NGS, 32 variants were detected in the baseline LB, of which 78.1% were also detected in tissue NGS. Furthermore, 23.2% (n=16) of LB alterations at baseline, 20.0% (n=6) early on-therapy, and 13.0% (n=3) at progression were CH derived. Upon MTB review, 29.2% variants at baseline, 21.9% at early on-therapy and 26.1% at progression were classified as actionable (58.8% level 1, 11.8% level 2, 11.8% level 3 and 17.6% level 4 evidence). Of 45 patients reviewed, 38 received therapeutic recommendations and 57.9% initiated recommended therapy. Patients treated with MTB recommended therapies had significantly longer median PFS and OS compared to those who received standard of care (p=0.027 and p=0.00062 respectively). MTB-recommended therapy selection was independently associated with PFS and OS, in multivariate analyses adjusting for clinical covariates including sex, smoking status, age, and prior lines of systemic therapy (p=0.043 and p=0.006, respectively). Subset of patients treated with genotype-matched MTB recommendations had significantly longer median PFS and OS compared to those who received standard of care (p=0.026 and p=0.0074 respectively).
Conclusion: Our findings emphasize the importance of precision oncology interventions driven by programmatic workflows within a multidisciplinary MTB, supported by comprehensive LB molecular information to guide therapy selection and improve patient outcomes.

#3909 SMARCA4 ablation mitigates distal-less homeobox 1 (*DLX1*)- driven oncogenicity in prostate cancer.

Ankita Bhattacharyya[1], Susanta Samajdar[2], Bushra Ateeq[1]

[1]Department of Biological Sciences and Bioengineering, Indian Institute of Technology Kanpur, Kanpur, India,[2]Aurigene Oncology Limited, Bangalore, India

Prostate cancer (PCa) is a molecularly heterogeneous malignancy with high prevalence and mortality rates in males across the globe. Several enhancer-driven oncogenic programs regulated by transcription factors (TFs) such as AR, FOXA1, MYC, and ERG contribute to PCa progression. Previously, elevated expression of DLX1, a homeobox TF, was reported to be oncogenic in PCa, and was established to be transcriptionally regulated by the AR/ERG/FOXA1 circuitry. While therapeutic inhibition using the BET inhibitor (BETi) and anti-androgen treatment was effective, the activation of alternate signaling cascades and bypass pathways often leads to drug resistance in PCa. To overcome BETi resistance in PCa, we employed a bottom-up approach to identify alternative therapeutic strategies. Given that the SWI/SNF chromatin remodeling complex, specifically SMARCA2/4, is a key regulator of the AR/FOXA1/ERG enhancer circuitry, here we explored the therapeutic efficacy of a dual PROTAC degrader targeting SMARCA2/4, in *DLX1*-high PCa. In silico analysis of a publicly available BRG1 ChIP-seq dataset showed peak enrichment at multiple sites on the *DLX1* promoter and along the *DLX1* gene body, implying its direct transcriptional control. In agreement, we noted the co-expression of *SMARCA4* in *DLX1*-high PCa patients in the TCGA-PRAD cohort as well as in the Indian PCa cohort. Mechanistically, we show that SMARCA2/4 PROTAC degrader treatment mitigates *DLX1* expression in ERG-fusion positive PCa as well as in Castration-Resistant Prostate Cancer (CRPC) models. Furthermore, cell-based functional assays using the PROTAC degrader confirmed a decrease in the proliferative, invasive, and migratory potential of PCa cells along with reduced foci formation capacity. Similarly, PROTAC degrader treatment of isogenic RWPE1 cells overexpressing *DLX1* showed reduced tumorigenicity, suggesting direct inhibition of DLX1 by the PROTAC degrader. Finally, we also observed remarkable inhibition of DLX1 in BETi-resistant PCa cells, suggesting the efficacy of SMARCA4 ablation in bypassing BETi resistance and mitigating DLX1-driven PCa oncogenicity.

#3910 AR copy number amplification and AR/KLK3 expression patterns reveal mechanisms of AR signaling inhibitor (ARSI) resistance and highlight the need for AR-directed therapeutic innovation in metastatic castration resistance prostate cancer (mCRPC).

Celine Robert-Tissot[1], Phuong A. Nguyen[1], Elisabeth A. Murphy[2], Yawei J. Yang[2], Evisa Gjini[1], Michaela Bowden[1]

[1]Flare Therapeutics, Cambridge, MA,[2]Caris Life Sciences, Irving, TX

Metastatic CRPC is predominantly driven by androgen receptor (AR) signaling. Despite second-generation ARSI, resistance remains a challenge and is associated with AR ligand-binding domain (LBD) mutations and AR copy number amplification (CNA). Prostate-specific antigen (PSA), encoded by kallikrein-related peptidase 3 (KLK3), serves as a key marker of AR transcriptional activity. We hypothesized that AR genomic alterations underpin variation in AR expression and activity and that real-world profiling would identify distinct AR/KLK3 expression-defined subgroups. From the Caris Prostate Cancer Database (N=17,429), 511 mCRPC patients treated with ARSI (Abiraterone and/or Enzalutamide) were identified. Whole exome and transcriptome sequencing (Caris Life Sciences) were performed on pre- and post-treatment tumor biopsies to assess AR alterations and RNA expression of AR and KLK3. Patients were stratified by AR CNA (CN>2) and pathogenic AR LBD mutations and categorized into four RNA subgroups: $AR^{hi}/KLK3^{hi}$, $AR^{hi}/KLK3^{lo}$, $AR^{lo}/KLK3^{hi}$, $AR^{lo}/KLK3^{lo}$. Associations with time on treatment (TOT) and overall survival (OS) were evaluated with Kaplan-Meier and log-rank tests. ARSI reduced AR wild-type (WT; mut–/CNA–) tumors and enriched for AR alterations, with AR CNA in 42–51% and AR mut in 3–10% of post-treatment samples. AR CNA+ and AR mut+ tumors showed significantly higher AR RNA and KLK3 RNA versus WT (all $p<0.05$). AR CN correlated with AR RNA ($\rho=0.77$, $p<0.0001$) and was associated with elevated KLK3 RNA ($p<0.0001$); AR RNA correlated with KLK3 RNA ($\rho=0.4$, $p<0.0001$). The dominant RNA subgroups were $AR^{hi}/KLK3^{hi}$ and $AR^{lo}/KLK3^{lo}$ (each 31%), followed by $AR^{lo}/KLK3^{hi}$ and $AR^{hi}/KLK3^{lo}$ (each 19%). AR CNA+ tumors were enriched in $AR^{hi}/KLK3^{hi}$ (55%), AR mut+ in $AR^{lo}/KLK3^{hi}$ (48%), and AR WT in $KLK3^{lo}$ (59%) subgroups. $AR^{lo}/KLK3^{hi}$ patients had the best ARSI response; $AR^{hi}/KLK3^{hi}$ and $AR^{lo}/KLK3^{lo}$ showed intermediate TOT, and $AR^{hi}/KLK3^{lo}$ the shortest. $AR^{hi}/KLK3^{hi}$ patients had worse OS versus $AR^{lo}/KLK3^{hi}$ (HR=2.79, 95% CI 1.05–7.42, $p=0.04$). AR CNA predicted shorter TOT versus AR WT (HR=1.94, 95% CI 1.17–3.22, $p=0.01$). AR CNA is the main driver of elevated AR signaling and reduced ARSI response, while AR mut is associated with lower AR expression and better outcomes. $KLK3^{lo}$ tumors, largely AR WT, show reduced AR dependence with limited benefit from AR-targeted therapies. These findings highlight a high-risk AR-driven subgroup defined by high AR expression and AR CNA. FX-111, a selective degrader of transcriptionally active, hormone-bound AR (AR_{ON}) in IND-enabling studies by Flare Therapeutics, offers a promising strategy to address this resistance. Ongoing analyses of AR/KLK3 subgroups aim to elucidate biological drivers of differential ARSI response.

#3911 Use of ALK inhibitors in patients with non-lung malignancies bearing *ALK* alteration prolongs treatment duration.

Vitor Abreu de Goes[1], Miguel Zugman[1], Koral Shah[1], Ali Moradi[1], Salvador Jaime-Casas[1], Yu Jun Li[1], Daniela V. Castro[1], Benjamin Mercier[1], Jadon Fann[1], JoAnn Hsu[1], George Zhang[1], Vicki Doctor[2], Amber Moran[2], Maurie Markman[2], Alexander Chehrazi-Raffle[1], Charles Nguyen[1], Sumanta Kumar Pal[1]

[1]Beckman Research Institute of The City of Hope, Duarte, CA,[2]Cancer Treatment Centers of America, Philadelphia, PA

Introduction

ALK inhibitors are known to produce deep and durable responses in selected cancer types. However, data on their agnostic use are scarce, and the rarity of *ALK* alterations hinders clinical trial feasibility. We evaluated real-world outcomes of these drugs in tumor types without current FDA approval.

Methods

We collected clinical and genomic data on patients who received off-label ALK inhibitors between January 1st, 2013, and December 31, 2024, through electronic medical records at a single institution. Descriptive analyses were used to summarize patients' characteristics and treatment patterns. We compared the time to treatment failure (TTF) on ALK-targeted therapy and on its prior line of therapy, as well as radiographic response as evaluated by the provider or radiology report.

Results

A total of 19 patients were included. The median age at therapy start was 62 years, with 63% Caucasian and 31% Asian. The most common histologies were sarcomas (5/19), papillary renal cell carcinoma (3/19), and gastric adenocarcinoma (2/19). Most patients (73%) had two or more metastatic sites at treatment start, usually harboring *ALK* fusions (62%) or point mutations (21%). ALK inhibitors were administered as third-line or later in 52% of patients, with alectinib being the most common (52%), followed by crizotinib (36%). Prior treatments often included chemotherapy (58%), other tyrosine kinase inhibitors (32%), and checkpoint inhibitors (21%). The median TTF with ALK therapy was 6.7 months (95% CI, 3.3 - 21.9), compared to 2.6 months (95% CI, 1.6 - 5.5) for the previous line. Among 15 patients on ALK inhibitors with imaging, 7 had partial responses, 4 had stable disease, and 1 achieved a complete response.

Conclusion

ALK inhibitors improved clinical outcomes in comparison with prior therapies across several malignancies. This supports the rationale for its agnostic use for tumors where clinical trials are not feasible.

#3912 NQO1 as a target to overcome therapy resistance in multiple myeloma.

Seungbin Han[1], Christina Verbruggen[1], Lenka Besse[2], Shilpa Kurian[1], Silvia Nerreter[1], Umair Munawar[1], Marietta Truger[3], Elena Gerhard-Hartmann[4], Andrej Besse[2], Ann-Sophie Hainold[1], Cornelia Vogt[1], Emma Besant[1], Nina Rein[1], Max Koppel[1], Xiang Zhou[1], Claudia Haferlach[3], Andreas Rosenwald[4], Christoph Driessen[2], Ondrej Slaby[5], Hermann Einsele[1], Leo Rasche[1], Markus Sauer[6], Johannes Waldschmidt[1], K. Martin Kortum[1]

[1]Department of Internal Medicine II, University Hospital Wuerzburg, Wuerzburg, Germany,[2]Clinics for Medical Oncology and Hematology, Cantonal Hospital St. Gallen, St. Gallen, Switzerland,[3]MLL Munich Leukemia Laboratory, Munich, Germany,[4]Institute of Pathology, University of Wuerzburg, Wuerzburg, Germany,[5]Masaryk University, Brno, Czech Republic,[6]Department of Biotechnology and Biophysics, University of Wuerzburg, Wuerzburg, Germany

Background: Overexpression of NAD(P)H:quinone oxidoreductase 1 (NQO1) has been linked to poor prognosis and therapy resistance in solid tumors, but its role in multiple myeloma (MM) remains unclear. Combination therapies including proteasome inhibitors (PIs), immunomodulatory drugs (IMiDs), and/or immunotherapies have improved outcomes in MM, yet most patients eventually develop resistant and relapse. We recently identified NQO1 overexpression across PI-resistant MM models and that high *NQO1* expression is associated with inferior outcome in PI treated MM patients. Hence, we here extend these findings in an independent MM cohort (n = 93) from our institution and in *NQO1* upregulated MM cell line models to examine how NQO1 affects MM immunotherapy targets and sensitivity to standard treatment regimens.

Methods: RNA-seq was performed on bone marrow-derived $CD138^+$ cells from 24 newly diagnosed MM (NDMM) and 69 relapsed/refractory MM (RRMM) patients, as well as MM cell lines. Surface density of immunotherapy targets was quantified via direct stochastic Optical Reconstruction Microscopy (*d*STORM). Sensitivity to PIs and IMiDs was assessed using AlamarBlue assays.

Results: In the MM RNA-seq cohort, *NQO1* expression was significantly higher in RRMM compared with NDMM ($p = 0.0002$), supporting an association of *NQO1* with treatment-exposed, advanced disease. Furthermore, overexpression of *NQO1* in MM cell lines led to an increased IC_{50} for bortezomib and carfilzomib, whereas IMiDs sensitivity remained intact. No upregulation of PI resistance-related genes was identified by RNA-seq. To test whether NQO1-dependent mechanisms are causative for PI resistance, NQO1-high MM cells were treated with NQO1 inhibitor ES936, which restored the sensitivity to both PIs to the wild type levels. In subsequent dSTORM analysis, no differences were observed in BCMA, SLAMF7, or GPRC5D, whereas CD38 surface density was significantly reduced in both NQO1-High myeloma cell lines. Consistent with the expression data, NQO1-overexpressing cells showed reduced sensitivity to CD38-directed therapies (daratumumab (Dara) and isatuximab (Isa). Notably, NQO1 inhibition with ES936 restored CD38 surface expression and rescued Dara and Isa responses, supporting that NQO1 is directly involved in CD38 downregulation and resistance to anti-CD38 antibodies. Of note, RNA-seq comparison of NQO1-high vs. WT MM models did not reveal changes in CD38 mRNA levels, pointing toward a post-translational mechanism, such as altered protein stability or trafficking.

Conclusions: NQO1 is upregulated in RRMM and functionally induces resistance to PIs and CD38-directed therapies which are widely used in current MM treatment. Inhibition of NQO1 with ES936 rescues CD38 expression, and restores PI sensitivity and anti-CD38 responses, supporting NQO1 as a promising target in treatment-exposed or relapsed MM.

#3913 Inavolisib demonstrates anti-tumorigenic effects in pre-clinical models of serous endometrial cancer.

Onc., University of North Carolina at Chapel Hill, Chapel Hill, NC

Objectives: Inavolisib is an oral selective PI3K inhibitor that has shown promising anti-tumorigenic activity in multiple pre-clinical models of cancer as well as breast cancer clinical trials, via promoting the degradation of mutated p110α, the catalytic subunit encoded by PIK3CA. The phosphatidylinositol 3-kinase (PI3K) signaling cascade is critically implicated in the tumorigenesis and progression of uterine serous carcinoma (USC), one of the most aggressive subtypes of endometrial cancer (EC). Given the urgent need to develop more effective treatment interventions for this highly lethal subtype of EC and that PI3Ka alterations are common in USC, we aimed to investigate the anti-tumorigenic and anti-invasive activities of inavolisib in serous EC cell lines.
Methods: The human serous EC cell lines, ARK1 and ARK2, were used in this study and treated with inavolisib (obtained from Genentech). Cell proliferation was evaluated by MTT assay. Cell cycle progression was examined by Cellometer. Cellular stress was evaluated by DCFH-DA assay and change in mitochondrial membrane potential was measured by JC-1 assay. Apoptosis was evaluated using a cleaved caspase-3 assay. Cell adhesion was evaluated using a laminin-1 assay, and cell migration was assessed by wound healing assay. Western immunoblotting was used to measure downstream protein expression related to cell cycle progression, cellular stress, and apoptosis.
Results: After 72 hours of treatment with inavolisib, the proliferation of ARK1 and ARK2 cells was inhibited in a dose-dependent manner (IC50: ARK1 674 nM, ARK2 2969 nM). Treatment of both cell lines with inavolisib significantly arrested the cell cycle at the G1 phase, increased intracellular reactive oxygen species levels, and decreased mitochondrial membrane potential compared with untreated cells ($p<0.05$). Inavolisib also significantly increased the activity of cleaved caspase-3 and reduced the expression of BcL-2 and MCL-1 in both cell lines. Moreover, inavolisib effectively decreased cell adhesion and migration at doses of 100 and 250 nM in the ARK1 and ARK2 cells ($p<0.05$). Western immunoblotting results demonstrated that treatment with inavolisib downregulated the expression of downstream targets of the PIK3CA/mTOR pathway (phosphorylated [p]-AKT, p-S6) and the cell cycle proteins CDK4 and cyclin D1 and upregulated the expression of the pro-apoptotic Bax and PDI proteins in both cells.
Conclusions: Inavolisib exhibits potent anti-tumorigenic and anti-invasive effects in serous EC cell lines, suggesting that this novel agent is a promising therapeutic option worthy of further exploration in the treatment of aggressive serous ECs.

#3914 Inavolisib exhibits anti-proliferative effects in pre-clinical model of endometrioid endometrial cancer.

Alexandra Diggs[1], Haomeng Zhang[2], Miller Singleton[3], Braxton Burnett[1], Kristen N. Taylor[4], Chunxiao Zhou[5], Victoria Lin Bae-Jump[6]

[1]University of North Carolina at Chapel Hill, Chapel Hill, NC,[2]University of North Carolina, Chaple Hill, NC,[3]UNC Lineberger Comprehensive Cancer Center, Chapel Hill, NC,[4]Gynecologic Oncology and Pelvic Surgery, Swedish Cancer Institute, Seattle, WA,[5]University of North Carolina, Chapel Hill, NC,[6]Assistant Professor, Dept. of Ob/Gyn, Div. of Gyn. Onc., University of North Carolina at Chapel Hill, Chapel Hill, NC

Objectives: Phosphoinositide 3-kinase (PI3K) is a key intracellular signaling enzyme that regulates cell growth, survival, and metabolism. Genetic alterations in the PIK3CA pathway are among the most common molecular events in endometrial cancer (EC), occurring in up to 80% of cases. Inavolisib is a highly selective PI3K-alpha inhibitor, and promotes the degradation of mutated p110α, the catalytic subunit encoded by PIK3CA. It has shown promising antitumorigenic activity in preclinical and clinical models of multiple solid tumors including endocrine resistant breast cancer. Endometrioid EC is the most common subtype of EC, one of the only cancers for which both incidence and mortality continue to rise. The backbone of its adjuvant treatment consists of a platinum-doublet, but new therapies are urgently needed. We aimed to investigate the effects of inavolisib on cell proliferation, cellular stress, apoptosis, cellular adhesion and migration in endometrioid EC cell lines.

Methods: The human endometrioid EC cell lines, HEC-1B and EC-023, were treated with inavolisib (supplied by Genentech). Cell proliferation was evaluated by MTT and colony formation assays. Cellular stress was evaluated by measuring levels of reactive oxygen species (ROS) via DCFH-DA assay and change in mitochondrial membrane potential via JC-1 assay. Cell cycle profile was evaluated by Cellometer. Apoptosis was evaluated using cleaved caspace-3 assay. Cell adhesion was evaluated using laminin-1 assay, and cell migration was assessed by wound healing assay. Western immunoblotting (WB) was used to measure downstream protein expression related to cell cycle progression, cellular invasion, and apoptosis.

Results: Inavolisib inhibited the cell proliferation and colony formation of HEC-1B and EC-023 cells, in a dose dependent manner (IC50: HEC-1B 7921 nM, EC-023: 310 nM). After 24 hours of treatment, inavolisib induced G1 cell cycle arrest in both cell lines. Treatment with inavolisib increased intracellular ROS levels and reduced mitochondrial membrane potential compared to control groups (all $p<0.05$). Importantly, inavolisib effectively decreased cell adhesive and migrative abilities in the HEC-1B and EC-023 cell lines (all $p<0.05$). WB supported these results, showing that treatment with inavolisib resulted in downregulation of the cell cycle regulatory proteins cyclin D-1, CDK2 and CDK4, inhibition of downstream targets of the PIK3CA pathway (phosphorylated [p]-AKT, p-44/42, and p-S6), and upregulation of the pro-apoptotic protein Bcl-xl, Bcl-2, and Mcl-1 in both cell lines.

Conclusions: Inavolisib demonstrated potent anti-proliferative and anti-invasive effects in endometrioid EC cell lines. Inavolisib may be a novel treatment strategy in EC, a cancer well-known for alterations in the PIK3CA/mTOR pathway.

#3915 From bench to bedside: A CNS penetrant and Omnipotent EGFR inhibitor, WSD0922-FU targeting primary mutations and the C797S acquired resistance mutation shapes the treatment landscape of EGFR mutant NSCLC.

Wei Zhong[1], Yue Liu[2], Carina Yu[2], Xiaolei Wang[2]

[1]Wayshine Biopharm, Corona, CA,[2]Wayshine Biopharm (Shanghai), Shanghai, China

The molecular landscape of EGFR-mutated non-small cell lung cancer (NSCLC) has evolved substantially with the widespread adoption of the third-generation covalent EGFR tyrosine kinase inhibitor (TKI) osimertinib as first-line therapy for tumors harboring classical EGFR mutations, along with the expanded use of next-generation sequencing (NGS). Consequently, patterns of acquired resistance have shifted: the once-predominant EGFR-T790M resistance mutation associated with first-generation EGFR TKIs has decreased in incidence, while EGFR-C797S has emerged as a major resistance mechanism following front-line third-generation EGFR TKI therapy. In parallel, increasing evidence highlights differential therapeutic responses to first-line third-generation EGFR TKIs between tumors with EGFR-L858R and EGFR-Ex19del mutations. Comprehensive genomic profiling through NGS continues to refine our understanding of the spectrum of classical, non-classical, and bypass resistance alterations, particularly those involving or co-occurring with C797S. Using paired tissue and plasma samples, we provide real-world evidence characterizing the molecular landscape of classical and non-classical EGFR mutations, as well as bypass signaling alterations that include C797S. We further describe the activity profile of WSD0922-FU, a molecule specifically designed to address the evolving EGFR mutational landscape, supported by translational data spanning preclinical to clinical studies. Our data demonstrate that WSD0922-FU exhibits potent activity not only against classical EGFR mutations and on-target resistance mechanisms following osimertinib—including C797S—but also against a range of non-classical EGFR alterations affecting both intracellular and extracellular domains (Q701L, E709X, L718X, G719X, S768I, V769M, L792X, V834X) as well as EGFRvIII. Collectively, these findings inform the clinical development strategy for WSD0922-FU as a potential first-line therapy for classical EGFR mutations, a second-line option for patients with CNS metastases after osimertinib, and a targeted treatment for tumors harboring C797S following osimertinib resistance.

#3916 A potent CDK7 inhibitor TY-2699a has the potential for combination with chemotherapy or immunotherapy in solid tumors.

Shengli Dong*, Apeng Liang*, Zhengfei Guo, Zhiyong He, Meihua Li, Xinlong Yang, Chao Zhou, Yu Yu, Hongqiang Li, Jian Zhu, Chengshan Niu, Shaoqing Chen, Jun Li, Yusheng Wu

TYK Medicines, Inc., Changxing, Zhejiang, China

Introduction: In recent years, PD-1 inhibitors and Trop2-ADC have been approved for the treatment of triple-negative breast cancer (TNBC). However, the efficacy of PD-1 inhibitor monotherapy is modest, benefiting only a small proportion of patients with TNBC. Chemotherapy remains the cornerstone of TNBC treatment; nevertheless, the risk of recurrence with these therapies remains high over time. Consequently, there is an urgent need to enhance the efficacy of immunotherapy and chemotherapy in patients with TNBC. TY-2699a, an orally active and highly selective CDK7 inhibitor developed by TYK Medicines, has shown monotherapy efficacy in TNBC (DCR 50%) and favorable tolerability, with lower gastrointestinal toxicity and manageable hematologic adverse events, supporting its potential for combination therapy in TNBC.

Results: In this study, we discovered that TY-2699a enhanced the efficacy of Gemcitabine and Nab-paclitaxel in TNBC HCC70 CDX mouse models when combined with TY-2699a, respectively. We observed that TY-2699a effectively killed EMT6 cells *in vitro* and improved PD-1 efficacy both *in vitro* and in an EMT6 syngeneic CDX mouse model. These findings warrant further investigation to determine whether TY-2699a enhances PD-1 efficacy in a TNBC 4T1 mouse model. Previously, we reported that TY-2699a is more potent than FDA-approved CDK4/6 inhibitors in head and neck squamous cell carcinoma (HNSCC). T-DXd (DS-8201) treatment achieved an ORR of 58.8% and a PFS of 20.5 months in patients with HER2-expressing salivary gland carcinoma (SGC). Our data suggest that TY-2699a and T-DXd act a synergistically effect on HNSCC Cal33 cells. Cetuximab is the only FDA-approved targeted therapy agent for HNSCC. Interestingly, we found that TY-2699a significantly enhanced the efficacy of Cetuximab in HNSCC FaDu cells both *in vitro* and in a CDX mouse model.

In summary, TY-2699a demonstrated antitumor efficacy as a monotherapy in TNBC, achieving a DCR of 50% with a manageable clinical safety profile. Beyond its role as a monotherapy, TY-2699a holds significant promise for use in combination therapies with chemotherapy or immunotherapy in TNBC and HNSCC. * Correspondence to: Shengli Dong and Apeng Liang.

#3918 *FGFR2* might be a promising therapeutic target for some types of carcinomas: Analysis of 1312 tumors with *FGFR2* abnormalities.

Hinano Nishikubo[1], DONGHENG MA[2], Tomoya Sano[2], Canfeng Fan[2], Daiki Imanishi[2], Takashi Sakuma[2], Yurie Yamamoto[2], Masakazu Yashiro[2]

[1]Molecular Oncology and Therapeutics, Osaka Metropolitan University Graduate School of Medicine, Osaka, Japan,[2]Department of Molecular Oncology and Therapeutics, Osaka Metropolitan University Graduate School of Medicine, Osaka, Japan

Background: Genetic abnormalities of the *fibroblast growth factor receptor 2* (*FGFR2*) gene, including amplification, fusions, and mutations, have been reported in various solid tumors. While molecular targeted therapies against *FGFR2* fusion have been proved to be useful in cholangiocarcinoma, the therapeutic significance of FGFR2 inhibitors remains unclear in other various solid cancers. Genomic and clinical information from solid tumor cancer gene panel testing cases is consolidated in the Center for Cancer Genomics and Advanced Therapeutics (C-CAT) database in Japan. This study aimed to utilize the C-CAT database to clarify the clinical-pathological significance of *FGFR2* abnormalities.

Materials & Methods: A total of 101,231 patients with solid cancer have been registered in the C-CAT database between June 2019 and June 2025. Of the 101,231 cases, 1312 cases with *FGFR2* gene abnormalities were analyzed. Tumor type distribution, co-mutations, and responses to FGFR inhibitors were evaluated. Disease control rate (DCR) was assessed in patients who received FGFR-targeted therapy.

Result: *FGFR2* alterations included amplification in 515 cases, fusion in 280 cases, and mutations in 568 cases. Their abnormalities were detected most frequently in the biliary tract (271 cases), esophagus/stomach (231 cases), and breast (211 cases). Amplification was frequent in the esophagus/stomach (205 cases) and breast (105 cases). *FGFR2* fusions are frequently detected in the biliary tract (163 cases), followed by breast (21 cases), pancreas (13 cases). Mutations were frequent in the uterus (111 cases), breast (89 cases), and biliary tract (86 cases). Among 1312 *FGFR2* alteration cases, *FGFR2* inhibitors were administered in 85 cases. Of the 85 cases, DCR was achieved in 49 cases, 44 cases of which were biliary tract cancer.

Conclusions: *FGFR2* might be a promising therapeutic target not only for cholangiocarcinoma with fusion but also for esophagus/stomach cancer and breast cancer with *FGFR2* alterations.

#3919 The emerging role of claudin 18.2 as a potential driver in gastric cancer progression.

Lisa Negro[1], Elisabetta Puliga[2], Emanuela Boccuni[2], Simona Corso[1], Silvia Giordano[1]

[1]Oncology, University of Turin, Turin, Italy,[2]Candiolo Cancer Institute - IRCCS, Torino, Italy

Gastric cancer (GC) represents one of the most impactful cancers on human health. Because of its strong aggressiveness and lack of resolutive therapies, researches are focusing their efforts on identifying novel molecular targets and new therapeutic strategies. Claudin 18.2 is a tight-junction protein expressed by the normal gastric epithelium. During malignant transformation, it is exposed on the whole tumor cell surface, becoming an accessible and druggable target. However, its role in tumor progression and proliferation is poorly investigated, partly due to the paucity of commercially available CLDN18.2-expressing cell lines. Taking advantage of our precious and molecularly annotated GC Patient-Derived Xenograft (PDX) platform, which includes approximately 200 primary cell lines and organoids, we assessed the Claudin 18.2 expression through RNA-Seq analysis, using the median expression value as the threshold for classification. The RNA-seq results were validated on representative PDXs using Real-Time-qPCR and Immunohistochemistry. Further, CLDN18.2 expression was evaluated in GC primary cell lines derived from low-, median-, and high-expressing PDXs (Real-Time-qPCR, Western Blot, and Immunofluorescence). For our analysis, we focused on four low-expressing (GTR181, GTR031, GTR498, GTR233), three median-expressing (GTR571, GTR797, GTR435), and three high-expressing (GTR789, GTR568, GTR816) CLDN18.2 cell lines. To explore the potential cell-autonomous role of CLDN18.2 as a driver in gastric cancer, we silenced the CLDN18.2 gene in median- and high-expressing cell lines. In high-expressing cells, CLDN18.2 silencing reduced cell proliferation compared with their wild-type counterparts, whereas no significant difference was observed in median-expressing cells, suggesting that high-expressing models are addicted to CLDN18.2. To further support the role of CLDN18.2 as a potential driver in high-expressing GC primary cell lines, we evaluated the cancer cell-autonomous sensitivity to Zolbetuximab - an anti-CLDN18.2 monoclonal antibody capable of inducing, in vivo, Antibody-Dependent Cellular Cytotoxicity (ADCC) and Complement-Dependent Cytotoxicity (CDC) - of low-, median-, and high-expressing models. High-expressing cell lines were highly sensitive, whereas sensitivity progressively decreased in median-expressing and low-expressing cells. These results suggest a potential CLDN18.2 dependency in high expressing GC cell lines, supporting a role for CLDN18.2 as a driver in GC proliferation. From a translational point of view, our preliminary data suggest that the efficacy of the anti-CLDN18.2 monoclonal antibody Zolbetuximab in high CLDN18.2-expressing tumor cells may be enhanced by the cancer cell-autonomous response, in addition to its established ADCC and CDC.

#3920 *PIK3CA* and *ARID1A* co-altered tumors are sensitive to AKT inhibitor, capivasertib.

Rian Engeldinger[1], Shirsa Udgata[1], Jordan Noelle Stoecker[1], Xingqi Shen[1], Ruchi Shah[1], Alexa Schmitz[1], Katherine A. Johnson[1], Cheri Pasch[1], Dustin A. Deming[2]

[1]Univ. of Wisconsin Madison Sch. of Med. & Public Health, Madison, WI,[2]University of Wisconsin Carbone Cancer Center, Madison, WI

Background: PIK3CA (PK) and ARID1A (AD) co-alterations occur in 1% of cancers. These cancers had enhanced sensitivity to PI3K inhibition with copanlisib (cop) in the MATCH trial arm Z1F. Given the recent FDA approval of the AKT inhibitor, capivasertib (capi), here we aim to evaluate the potential benefit of capi treatment in the setting of PK and AD alterations and the mechanism by which enhanced sensitivity might be occurring.
Methods: CRISPR/Cas9 was used to knockout AD from SW48PIK3CA-H1047R (SW48PK), and PIK3CAH1047R mutant locally advanced rectal cancer (LARC) patient-derived cancer organoids (PDCOs). PK or PKAD Colorectal (CRC), ovarian (OC), and renal (RC)PDCOs were obtained from the NCI repository and were treated with 2 μM capi for 48 hrs. Percent relative change in the longest diameter (PRC) was measured prior to and after treatment in(capi or control) and effect size was measured using Glass's delta (GD) . Western blot was used to determine levels of PI3K proteins (RPS6, AKT), apoptotic proteins (MCL-1, BCL-xL, Bax, Bims), and mTORC1 protein, PRAS40. Athymic nude mice were flank injected with SW48PK and SW48PKAD and treated with 100mg/kg capi (10% DMSO in 90% of 20% SBE-β-CD in saline) or vehicle b.i.d for 28 days or until moribund. Ki-67 and cleaved caspase-3 in these tumors were assessed by immunohistochemistry (IHC) and quantified as positive cells/high powered field (HPF).
Results: Capi treatment responses were observed in PKAD co-altered CRC PK (PRC 4.8%, GD 2.0), LARC-PK (0.5%, 0.9), OC-PKAD(10%, 1.03), RC-PKAD (1.52%, 1.52), and LARC-PKAD (2.91%, 1.78) PDCOs, indicating sensitivity across cancer types and enhanced sensitivity in co-altered lines relative to PK alone for LARC. Western blot showed greater reduction in p-RPS6 in LARC-PKAD by 6h compared to LARC-PK, but no significant differences were seen in 2D lines. p-AKT increased upon capi treatment across all 2D and 3D lines. Among apoptotic proteins, BCL-xL steadily increased over time in co-mutant cultures. Bims (cytotoxic isoform of Bim) had a stronger induction in 6h in LARC-PKAD compared to LARC-PK. Levels of p-PRAS40, MCL-1, Bax, and Bak remained largely comparable across lines. In vivo, PKAD tumors showed a significant tumor growth delay ($p = 0.01$) with capi treatment, while PK tumors did not ($p = 0.06$).
Conclusion: PIK3CA and ARID1A co-altered tumors have enhanced sensitivity to capi relative to PIK3CA mutant tumors, potentially through induction of Bims. Capi should be investigated further clinically in PIK3CA and ARID1A co-altered cancers. Additionally, further studies identifying novel drug combinations with capi are warranted to further enhance patient response

#3921 Periostin on tumor stromal cells might be associated with the malignant progression of patients with gastric cancer.

Canfeng Fan[1], Hinano Nishikubo[1], DONGHENG MA[2], Tomoya Sano[2], Daiki Imanishi[2], Takashi Sakuma[2], Yurie Yamamoto[2], Masakazu Yashiro[2]

[1]Osaka Metropolitan University, Osaka, Japan,[2]Osaka metropolitan university, Osaka, Japan

Periostin is one of matrix cellular proteins. It has been reported that the periostin in the tumor microenvironment might regulate the FAK signaling via the interaction with integrins expressed on cancer cells, resulting in the stimulation of proliferation and invasion. In gastric cancer (GC), the periostin has reported to be overexpressed in the tumor stroma, however, the role of periostin and the types of cells remains to be unclear. Then, in this study we examined the significance of periostin on the clinico-pathologic features of GC by immunohistochemical study, using 689 GC samples. Also, 4 GC cell lines were used to examine the effect of periostin on the proliferation and the invasion activity of GC cells by proliferation assay and invasion assay.The immunohistochemical study of periostin confirmed that the expression of periostin was frequently found on stromal fibroblasts in the tumor. High expression of periostin in the tumor stroma is associated with worse survival rates ($p < 0.001$, log-rank), deeper T invasion ($p < 0.001$), frequent lymph node metastasis ($p < 0.001$), distant metastasis ($p = 0.021$), higher recurrence rates ($p < 0.001$), and higher stage ($p < 0.001$). *In vitro* assays using GC cell lines demonstrated that periostin significantly promoted the invasion and migration ability of GC cells, but did not affect the proliferation activity.In conclusion, the periostin, which is mainly expressed on the tumor stromal fibroblasts, might be associated with the malignant progression of GC.

#3922 Polymeric delivery of TRAIL mRNA for inducing apoptosis in non-small cell lung cancer.

Gurkirat Singh Sandhu[1], Hasan Uludag[2]

[1]Faculty of Pharmacy & Pharmaceutical Sciences, University of Alberta, Edmonton, AB, Canada,[2]Department of Chemical and Materials Engineering, University of Alberta, Edmonton, AB, Canada

Tumor necrosis factor-related apoptosis-inducing ligand (TRAIL) activates death-receptor pathways to trigger caspase-dependent apoptosis, yet recombinant TRAIL has demonstrated limited activity in non-small cell lung cancer (NSCLC) because of rapid clearance and apoptotic resistance. Delivering TRAIL as messenger RNA (mRNA) may overcome these limitations, but mRNA therapeutics remain limited in oncology due to delivery inefficiencies, instability, and incomplete cytosolic release. This study evaluated biodegradable cationic lipopolymers for TRAIL mRNA delivery and examined whether combining TRAIL mRNA with small interfering RNAs (siRNAs) targeting anti-apoptotic mediators could strengthen apoptotic responses in resistant NSCLC settings. Biodegradable cationic lipopolymers were screened based on their delivery profiles. Nanoparticles were characterized by hydrodynamic diameter, zeta potential, and transmission electron microscopy (TEM). A549 lung adenocarcinoma cells were used for mechanistic studies, including multi-day viability assays, caspase-3/7 activity using the Caspase-Glo assay (24-72 hours), mitochondrial membrane potential analysis using tetramethylrhodamine ethyl ester (TMRE), nuclear morphology by Hoechst staining and confocal microscopy, DNA damage assessment by alkaline comet assay, and enzyme-linked immunosorbent assay (ELISA) for TRAIL protein detection. Additional NSCLC cell lines: Calu-3, H1975 GFP^+, and H1299 GFP^+ were used for viability-based bioassays to support mRNA-induced TRAIL activity.The selected polymer formed compact nanoparticles with 100-200 nm size and+15-40 mV zeta-potential. In A549 cells, TRAIL mRNA induced a clear time-dependent apoptotic response: viability declined progressively and reached approximately 40-50% at later time points with higher mRNA doses. Caspase-3/7 activity increased by ~2-fold at 24 hours and remained detectable at 48-72 hours. Confocal imaging showed mitochondrial depolarization together with condensed and fragmented nuclei, and comet assay confirmed DNA strand damage. siRNAs alone reduced viability but did not match the effect of TRAIL mRNA. In combination studies, siRNAs allowed lower TRAIL mRNA doses to achieve viability reductions comparable to higher-dose mRNA alone and maintained reduced viability further into the time course, improving both potency and duration of response.The delivery platform evaluated here supported effective TRAIL mRNA activity in A549 cells, and incorporating siRNAs further reinforced and prolonged the apoptotic response at reduced mRNA doses. These findings highlight a practical path toward combination nucleic acid strategies designed to counter apoptotic resistance in NSCLC.Portions of this abstract were drafted with the assistance of AI under the supervision and full scientific verification of the authors.

#3926 Serum soluble TREM2 predicts poor survival, mirrors surface TREM2 level on circulating M-MDSCs, and enhances MDSC-mediated suppression of T-cell proliferation in indolent B-cell lymphoma.

Hao-Yuan Wang[1], Po-Chun Liu[2], Fu-Chen Yang[2], Ching-Fen Yang[3], Chia-Ming Liang[4], Chia-Ying Wu[1], Chun-Kuang Tsai[1], Po-Shen Ko[1], Yao-Chung Liu[1], Nien-Jung Chen[2]

[1]Department of Medicine, Taipei Veterans General Hospital, Taipei, Taiwan,[2]School of Life Sciences, National Yang Ming Chiao Tung University, Taipei, Taiwan,[3]Department of Pathology and Laboratory Medicine, Taipei Veterans General Hospital, Taipei, Taiwan,[4]Department of Surgery, Taoyuan Branch of Taipei Veterans General Hospital, Taoyuan, Taiwan

Triggering receptor expressed on myeloid cells-2 (TREM2) is an anti-inflammatory surface receptor with a soluble isoform (sTREM2). Monocytic myeloid-derived suppressor cells (M-MDSCs) promote tumor growth, and our recent work shows that high surface TREM2 on circulating M-MDSCs predicts poor outcomes in diffuse large B-cell lymphoma. However, its role in indolent B-cell lymphoma remains unclear. This study investigated the clinical significance of serum sTREM2 and surface TREM2 on circulating M-MDSCs in treatment-naïve indolent B-cell lymphoma and explored immunomodulatory effects in murine models.

This prospective study enrolled 93 patients (2019-2025). Diagnoses included follicular lymphoma (*n*=54; 33 low-grade, 21 grade 3A), marginal zone lymphoma (*n*=21), lymphoplasmacytic lymphoma (*n*=6), small lymphocytic lymphoma (*n*=4), and mature B-cell neoplasms (*n*=8). Median age was 68; 46.2% were male; 58.1% had bone marrow (BM) involvement; 66.7% had Lugano stage IV; and 21.5% had high-risk IPI. Fourteen patients received active surveillance, and 79 received first-line therapy. The median serum sTREM2 level was 997 ng/L.

Normalized surface TREM2 on circulating M-MDSCs was calculated relative to paired healthy controls. ROC analysis identified 8.52% as the optimal cut-off. High surface TREM2 (>8.52%) was associated with inferior OS (*P*=0.031; 2-year OS: 84.6% vs 94.5%) and shorter time to next treatment (TTNT) (*P*=0.001; median: 48.69 months vs not reached [NR]). The TTNT disadvantage was observed in both active-surveillance patients (*P*<0.001; median: 16.87 vs 51.06 months) and those receiving first-line therapy (*P*=0.009; median: 48.69 months vs NR).

Serum sTREM2 levels increased across tertiles of normalized surface TREM2 (median: 694, 920, and 2,149 ng/L), with significant differences between lower and higher (*P*<0.001) and intermediate and higher groups (*P*=0.001).

ROC analysis identified 1,371 ng/L as the optimal serum sTREM2 cut-off. Elevated sTREM2 (>1,371 ng/L) predicted inferior TTNT (*P*<0.001; median: 48.69 months vs NR) and worse OS (*P*=0.002; median: 66.25 months vs NR).

To explore the functional roles of sTREM2, CellTrace Violet-labeled murine T cells were cocultured with WT or *Trem2*-knockout BM-derived MDSCs. Across varying MDSC:T-cell ratios, sTREM2 consistently suppressed T-cell proliferation, with stronger inhibitory effects at higher proportions of MDSCs, and the suppressive activity of sTREM2 was more pronounced with *Trem2*KO MDSCs than WT MDSCs.

In conclusion, elevated serum sTREM2 correlates with higher surface TREM2 on circulating M-MDSCs and predicts inferior survival in indolent B-cell lymphoma. Preliminary murine data suggest that sTREM2 augments MDSC-mediated suppression of T-cell proliferation, supporting a functional role for sTREM2 in lymphoma immunopathogenesis.

#3927 Analytical performance of a novel tissue-informed non-bespoke whole genome MRD detection assay.

David Delfosse, Alexander Fine, Daokun Sun, Akshay Kakumanu, Tristen Ross, Devika Singh, Ravin Poudel, Maryam Zand, Brian Reilly, Farzana Ahmed, Liv Parsons, Tuan Nguyen, Ena Shinnishi, Noel Vega, Hanna Tukachinsky, Chang Xu, Alex Robertson, Brett Wallden

Foundation Medicine, Inc., Boston, MA

Background: Detection of circulating tumor DNA (ctDNA) in early-stage cancer offers significant prognostic value and has potential for guiding clinical care decisions. However, achieving sufficient sensitivity for reliable detection at this stage is challenging. Personalized panels can increase turnaround time and operational complexity.To overcome these limitations, we developed a tissue-informed molecular residual disease (TI-MRD) laboratory developed test that does not use custom panels.
Methods: The TI-MRD assay defines a personalized tumor signature from whole genome sequencing (WGS) of tissue FFPE, and scans for this signature in cell-free DNA (cfDNA) from plasma, also sequenced using WGS. TI-MRD employs a novel algorithm using aneuploidy and somatic SNVs to define a tumor signature without requiring a matched normal sample. Samples from patients with early stage lung and colon cancer were used in a study for determining the lower limit of detection (LLoD) of the assay. The precision study also included samples from patients with breast, bladder, melanoma, ovarian, and pancreatic cancers. Analytical specificity of the assay was assessed using cfDNA from donors with no known history of cancer and a tumor signature derived from a panel of cancer FFPE samples.
Results: The LLoD for the TI-MRD assay was established using sample titrations ranging from > 44,000 PPM (> 4.4%) to 5 PPM and was based on a ≥ 95% probability of detecting tumor fraction (TF). LLoD for the TI-MRD assay was also evaluated as a function of tumor mutational burden (TMB), where the lowest TMB value tested was < 1 mut/Mb and the highest TMB value tested was > 9 mut/Mb. The titration data for estimating the analytical sensitivity for the TI-MRD assay demonstrated that the LLoD can be < 10 PPM. Reproducibility was determined by testing 6 replicates from 10 patients with TF values ranging from 380,000 PPM (38%) to 32 PPM. Precision was also evaluated as a function of cfDNA input mass (3.5 - 20ng) and FFPE input mass (10 - 220ng). Detection of ctDNA was highly reproducible across the range of cfDNA and FFPE input masses and was maintained across a 4-log range of TF values. The TI-MRD assay also achieved an empirical specificity of 100% from donors with no known history of cancer.
Conclusion: This TI-MRD assay demonstrated robust analytical performance with high sensitivity, reproducibility, and specificity for detecting ctDNA, highlighting the potential of this assay to guide therapeutic decisions in the early setting across many different cancer types.

#3928 Dynamic inflammatory biomarkers are associated with cancer cachexia in a prospective lung cancer cohort.

Elham Kazemian[1], Carlos David Cruz-Hernandez[2], Karen L. Reckamp[1], Puneeth Iyengar[3], Neil A. Bhowmick[4], Jane C. Figueiredo[5], Kamya Sankar[1]

[1]Cedars-Sinai Medical Center, Los Angeles, CA,[2]Cedars-Sinai Medical Center, Beverly Hills, CA,[3]Memorial Sloan Kettering Cancer Center, New York, NY,[4]Assoc. Professor, Dept. of Medicine, Cedars-Sinai Medical Center, Los Angeles, CA,[5]Samuel Oschin Comprehensive Cancer Institute, Los Angeles, CA

Background: Cancer cachexia is a multifactorial syndrome characterized by progressive skeletal muscle loss that affects approximately 40-50% of patients with non-small cell lung cancer (NSCLC)Despite its clinical impact, reliable biomarkers for early detection and risk stratification remain poorly defined.
Methods: In this prospective longitudinal study,we conducted an analysis of 27 patients with stage IV NSCLC from the SeroNet-CORALE cohort with at least two plasma samples collected between 2020-2023. Cachexia was defined according to international consensus criteria (weight loss >5% or >2% with BMI<20 kg/m2 over 6 months). We quantified 40 biomarkers using MesoScale Discovery platforms, including inflammatory cytokines, chemokines, metabolic hormones, angiogenic factors, and mitochondrial DNA. Firth penalized logistic regression models were used to evaluate associations between log2-transformed biomarker levels and cachexia status, with adjustment for age, sex, race, and treatment exposures.
Results: We enrolled lung cancer patients (65% female, mean age 65±10 years) with predominantly adenocarcinoma histology (89 percent), and the proportion classified as cachectic was 22 percent at diagnosis and 20 percent and 19 percent at the subsequent timepoints. Cachectic patients showed consistently lower BMI (21.0±2.0 vs 27.0±7.0 at T1; 21.8±4.9 vs 25.2±4.9 at T2). At T1, cachexia was strongly associated with elevated GDF15 (OR: 4.29, 95% CI: 1.04-29.74, p=0.044) and IL-15 (OR: 43.83, 95% CI: 2.39->999, p=0.007), while IL-4 demonstrated protective effects (OR: 0.09, 95% CI: 0.00-0.66, p=0.013). By T2, the biomarker profile had shifted, with significant associations emerging for elevated mtDNA (OR: 2.13, 95% CI: 1.07-7.69, p=0.022) and reduced levels of IL-5 (OR: 0.17, p=0.011), IL12/IL23p40 (OR: 0.44, p=0.010), and MDC (OR: 0.26, p=0.006). Longitudinal analysis revealed that baseline inflammatory biomarkers were associated with future cachexia risk. Elevated MCP-1 at baseline showed a strong, though non-significant, trend toward association with increased odds of cachexia at the 6-month follow-up (OR: 3.72, 95% CI: 0.91-42.70, p=0.070). In contrast, higher levels of MDC (OR: 0.19, 95% CI: 0.02-0.77, p=0.016) and TARC (OR: 0.28, 95% CI: 0.04-0.96, p=0.041) at baseline were significantly associated with reduced odds of cachexia at the subsequent timepoint.
Conclusion: This exploratory study reveals temporal variations in inflammatory profiles associated with cancer cachexia. While requiring validation in larger cohorts, the distinct biomarker patterns at different timepoints suggest cachexia biology may evolve from initial cytokine activation to later-stage mitochondrial and immune dysregulation. The association between baseline biomarkers and future cachexia development warrants cautious interpretation but may inform future research directions.

#3929 Prognostic significance of ctDNA in patients with metastatic uveal melanoma.

Andrew David Knight[1], Aleigha Lawless[2], Eric P. Wehrenberg-Klee[3], Genevieve Boland[2], Ryan J. Sullivan[4], Kamaneh Montazeri[2]

[1]Oncology, Mass General Cancer Center, Boston, MA,[2]Mass General Brigham, Boston, MA,[3]Invterventional Radiology, Massachusetts General Hospital, Boston, MA,[4]Harvard Medical School/Massachusetts General Hospital, Boston, MA

Background: Circulating tumor DNA (ctDNA) is an emerging prognostic biomarker in solid tumors. However, the independent prognostic value in metastatic uveal melanoma (mUM) remains incompletely defined. We evaluated the prognostic significance of baseline ctDNA as measured by the Signatera assay, assessed the relationship to known prognostic factors such as LDH and liver metastases, and the impact of ctDNA clearance while on treatment.

Methods: We retrospectively evaluated patients with mUM who had ctDNA collected within 30 days prior to treatment initiation. Kaplan-Meier (KM) and Cox proportional-hazard models were used to evaluate OS and PFS. Baseline ctDNA values were categorized into 3 tiers: Not-detected (ND), Low (<5 MTM/mL), and High (>5 MTM/mL). Multivariate Cox models were used to adjust for LDH (log-transformed) and liver metastases. Clearance of ctDNA was compared to persistently positive ctDNA. Patients treated with front-line tebentafusp were assessed as a prespecified subgroup.

Results: 41 patients had baseline ctDNA measurements taken prior to frontline treatment; 26 received front-line tebentafusp and 66% had detectable ctDNA. Higher ctDNA levels correlated with elevated LDH.

In the full cohort, detectable ctDNA was associated with shorter PFS (HR 3.07, 95% CI 1.14-8.30; p=0.027). In a 3-tiered stratification, high ctDNA (>5 MTM/mL) was predictive of shorter PFS (HR 4.65, 95% CI 1.62-13.4; p=0.004) and approached significance for OS (HR 4.60, 95% CI 0.97-21.8; *p*=0.055). On KM analysis, there was significant separation between the groups for both PFS (p=0.0048) and OS (p=0.011). As a continuous variable, higher ctDNA values (log-transformed) strongly predicted both PFS (HR 2.23, 95% CI 1.54-3.23; p<0.001) and OS (HR 3.26, 95% CI 1.79-5.92; p<0.001). In multivariate analysis, ctDNA remained independently prognostic of PFS (HR 1.75, 95% CI 1.06-2.87; p=0.028).

Clearance of ctDNA was associated with improved PFS (HR 0.25, CI 95% 0.08-0.76; p=0.015) and OS, with no deaths in the clearance group (HR not calculable).

In the tebentafusp-only subgroup, baseline ctDNA remained significant for OS (HR 2.47, 95% CI 1.30-4.66; p=0.005) and PFS (HR 1.83, 95% CI 1.22-2.74l; p=0.003). Clearance in this subgroup remained associated with improved PFS (HR 0.21, CI 95% 0.06-0.79; p=0.021) and OS (no deaths). Multivariate model trends were consistent with the full cohort but were limited by sample size.

Conclusions: Baseline and on treatment ctDNA measured using the Signatera assay are prognostic in patients with mUM. ctDNA results remained prognostic in the tebentafusp subgroup and after adjusting for LDH and liver metastases.

#3930 Developing a prognostic gene expression biomarker for re-irradiation in recurrent glioblastoma.

Brooke C. Braman[1], William C. Chen[1], Radhika Mathur[1], Akshara Vykunta[1], Vivian Tang[1], Nadeem Al-Adli[1], Joseph F. Costello[1], Minesh P. Mehta[2], Kanish Mirchia[1], Jacob S. Young[1], David R. Raleigh[1]

[1]University of California San Francisco, San Francisco, CA,[2]NRG Oncology, Philadelphia, PA

Introduction: Glioblastoma is the most common primary, malignant brain tumor. Despite aggressive treatment, the prognosis remains poor, and recurrence is nearly universal. Radiotherapy improves overall survival (OS) in patients with newly diagnosed glioblastoma (ndGBM). Re-irradiation (reRT) improves progression-free survival (PFS) when added to bevacizumab in recurrent GBM (rGBM), but an OS advantage in unselected populations has not been demonstrated. Here we test the hypothesis that gene expression profiling can identify glioblastomas with better prognosis after re-irradiation delivered at the time of disease recurrence.

Methods: A retrospective cohort of 98 IDH-wildtype, CNS WHO grade 4 GBM tissue samples (n=43 ndGBM, n=55 rGBM) from 83 patients who ultimately underwent reRT at the time of any tumor recurrence was analyzed using a barcode-based RNA hybridization platform with a custom 291-gene panel representing pathways underlying GBM growth and therapeutic response. Univariate analysis identified 60 genes associated with outcomes after reRT. A ridge regression model was trained using gene expression data to predict OS after reRT normalized to OS from diagnosis. Model outputs were mapped to reRT scores, which were dichotomized (high versus low) using the maximally selected rank statistic.

Results: The median time between RT courses was 19.9 mo. Median OS after reRT was 9.74 mo. Median OS after reRT for tumors with high versus low reRT scores was 12.5 versus 8 mo ($p<0.001$). The hazard ratio for death after reRT for tumors with low reRT scores compared to tumors with high reRT scores was 2.47 ([95% CI 1.47-4.16], $p<0.001$). Using only gene expression data from ndGBM, the median OS after reRT for tumors with high versus low reRT scores was 10.5 versus 5.7 mo ($p=0.022$; HR for low reRT scores: 2.20, [95% CI 1.09-4.45], $p=0.027$). Using only gene expression data from rGBM, the median OS after reRT for tumors with high versus low reRT scores was 16.82 versus 9.18 mo ($p=0.0014$; HR for low reRT scores: 3.55, [95% CI 1.55-8.17], $p=0.0028$). There were no differences in MGMT promoter methylation status or demographic characteristics between tumors with low versus high reRT scores. ReRT scores were calculated for a second cohort of 10 patients with spatially sampled ndGBM (n=6-19 samples/patient). By a mean-rating, one-way random effects, absolute agreement model, the intraclass correlation coefficient estimate for the reRT score was 0.89 ([95% CI 0.76-0.97], $p<0.001$), which indicates high score concordance for regionally distinct samples from within individual tumors.

Conclusions: Gene expression data from ndGBM or rGBM should be considered as a stratification variable for reRT clinical trials. The model reported here requires validation in additional cohorts to determine its prognostic value.

#3931 Immune cell profile changes in patients treated with tarlatamab for extensive stage small cell lung cancer in real world practice.

Dhauna Karam Prasad[1], Andre De Menezes Silva Corraes[1], Malvika Gupta[1], Audrey Ma[2], Chen Wu[1], Zuoyi Shao[1], Kevin Reagan[1], Rayaan Kamal[1], Ashley Potter[1], Abdullah Al-Ajmi[1], Syeda Mina[1], Sykler J. Taylor[1], Antonious Hazim[1], Anastasios Dimou[1], Kaushal Parikh[1], Mohammed Shanshal[1], Ailsa Luce[1], Anna Schwecke[1], Julian Molina[1], Aaron Mansfield[1], Katherine Smith[1], Lucy Holmes[1], Haidong Dong[1], Yi Lin[1], Konstantinos Leventakos[1]

[1]Mayo Clinic Cancer Center Minnesota, Rochester, MN,[2]Columbia University, New York, NY

Background: Tarlatamab, a Delta-like ligand (DLL3)/CD3-targeted bispecific T-cell engager (TCE) is FDA approved in patients (pts) with extensive stage small cell lung cancer (ES-SCLC), after progression on frontline chemoimmunotherapy. We aimed to evaluate the immune cell profile in pts who received this therapy in standard-of-care (SOC) practice with progression free survival (PFS) less than and greater than two months (mo).

Methods: Patients who received tarlatamab at Mayo Clinic Rochester and consented to immuno phenotyping of blood are included in the present study. Immune phenotyping was performed on whole blood by flow cytometry and analyzed by Kaluza. Data analysis was performed with Microsoft Excel and PRISM.

Results: Eighteen patients with median age 64 (range 37-79) were included in the study. 66% of our cohort were women and 83% had present or past history of smoking, with an average of 40 pack years (range 26-60). With a median follow-up of 2 months, the median PFS for the cohort was 1.5 mo (range 0.33-2.76 months). 61% (13/18) of patients had PFS <2mo. 39% (5/18) had PFS>2mo and of which, three patients had partial response with one maintaining stable disease and one patient with mixed response. At baseline (BL), there were no difference in T cell, CD4 or CD8 cell count between patients in the PFS<2mo and PFS>2mo groups. Patients with PFS<2mo had higher exhausted CD8 T cells compared to those in the PFS>2mo group (CD8+PD1+TIGIT+CD57+, PFS<3mo vs >3mo, cells/mL: 7.14±4.28, 1.58±1.37, p=0.009). Additionally, when analyzing the B-cell population, the PFS<2mo group had lower percentage of B cells compared to the group with PFS>2mo at baseline (6.0±7.5, 10.4±14, p=0.02). At day 7, the group with PFS<2mo had lower Treg compared to the group with PFS>2mo (2.88±1.38, 4.60±1.47, p=0.02). Also, the PFS<2mo group had an increase of B cells compared to the group with PFS>2mo at day 7(<2mo vs >2mo: 10.0±14, 4.37±3.07, p=0.04). Finally, the group with PFS>2mo had decrease in total monocytes (mono), classical mono, and immunosuppressive cells (PFS<2mo vs >2mo, Mono: 340±347, 253±106, p=0.04. Classical mono: 305±283, 155±109, p=0.02. CD14+HLA-DRneg: 105.8±96, 12±39, p=0.03) compared to the group with PFS<2mo by day 7. While no changes were seen between BL and day 7 for intermediate mono in PFS<2mo group, PFS>2mo group had decreased post treatment intermediate monocytes (BL vs day 7, cells/mL, intermed mono: 32.5±15,17.7±6.2, p=0.03).

Conclusion: In this study investigating the SOC outcomes of tarlatamab, early progression was associated with higher presence of exhausted CD8 T cells, B cells, and immunosuppressive monocytes. Analysis of additional patients will be shared at AACR meeting.

#3932 Spatial immune checkpoint profiling reveals predictive biomarkers of immunotherapy response in oral squamous cell carcinoma.

Shu-Han Yu[1], Chih-Hung Ye[1], Kah Yap Yi[1], Thien-Long Le[1], Le-Bao-Long Nguyen[1], Patrick Chun Theng Chong[1], Huai-Cheng Huang[2], Ruey-Lomg Hong[2]

[1]Institute of Biotechnology, National Taiwan University, Taipei, Taiwan,[2]Department of Oncology, National Taiwan University Hospital and College of Medicine, Taipei, Taiwan

Introduction: Oral squamous cell carcinoma (OSCC) remains a leading cause of cancer-related mortality in Taiwan. Despite the widespread use of surgery, radiotherapy, and chemotherapy, patient prognosis remains poor. Immunotherapy (IO) has demonstrated clinical benefit; however, only 15-20% of patients with recurrent or metastatic OSCC respond favorably. This underscores the urgent need for reliable biomarkers to guide patient selection and personalize treatment strategies.
Methods: To investigate immune checkpoint dynamics associated with IO outcomes, we integrated single-cell RNA sequencing (scRNA-seq) to define immune signatures predictive of treatment response. These findings informed the design of a customized Opal multiplex immunohistochemistry (mIHC) panel to spatially map immune cell populations and checkpoint molecules within the OSCC tumor microenvironment. Paired pre- and post-IO tumor specimens from 18 OSCC patients treated with anti-PD-1 therapy were analyzed using this panel. Spatial data were subsequently processed with AI-assisted computational profiling to quantitatively assess immune cell infiltration and checkpoint expression patterns in situ.
Results: Integrated analysis of scRNA-seq, mIHC, and AI-assisted spatial profiling identified seven immune checkpoint signatures significantly associated with improved survival, all representing distinct expression patterns within $CD8^+$ T-cell subsets. A risk scoring model integrating spatial immune cell densities with survival data successfully stratified patients into low- and high-risk groups, with the low-risk group demonstrating significantly longer overall survival (OS). Notably, the $LAG\text{-}3^-TIM\text{-}3^+PD\text{-}1^+CD8^+$ T-cell population was enriched in high-risk patients and displayed an immune-desert phenotype prior to IO treatment.
Conclusion: These results yield two key insights: (1) immune checkpoint signatures, not only PD-1/PD-L1 can be used to stratify OSCC patients with favorable survival outcomes, and (2) low-risk patients, they already have higher infiltrated T cells with the presence of co-inhibitory checkpoint molecules, whereas, the high-risk patients, post-IO treatment, they will have higher immune infiltation. Overall, our study highlights the prognostic value of integrated immune checkpoint expression profiling and supports the rationale for exploring combination immune checkpoint blockade strategies in OSCC.

#3933 sB7-H3 as a prognostic biomarker in osteosarcoma: Insights into clinical outcomes.

Lu Xie[1], **Yuwei Zhao**[1], Kunkun Sun[2], Yiyang Yu[1], Jie Xu[1], Yuhang Wang[1], Chenchen Yang[1], Hengyue Ma[1], Tingting Ren[1], Xiaodong Tang[1]

[1]Musculoskeletal Tumor Center, Peking University People's Hospital, Beijing, China,[2]Pathology Department, Peking University People's Hospital., Beijing, China

B7 homolog 3 protein (B7-H3), a member of the B7 checkpoint family, is aberrantly and consistently expressed on the membranes of various human cancer cells and is associated with poor prognosis. Emerging evidence also indicates that soluble B7-H3 (sB7-H3) correlates with adverse outcomes in multiple malignancies. In this study, we measured sB7-H3 levels in peripheral blood using an enzyme-linked immunosorbent assay (ELISA) from 100 newly diagnosed osteosarcoma (OTS) patients, both before and after neoadjuvant chemotherapy, and simultaneously assessed B7-H3 tissue expression via immunohistochemistry (IHC) analysis of surgical specimens. Our analysis showed significant associations between B7-H3 tissue expression and histopathological response to chemotherapy, with the H-score threshold >75 identifying patients with particularly poor prognosis ($p < 0.05$). Although no significant correlation was observed between tissue and circulating B7-H3 expression, we found that lower baseline sB7-H3 levels (pre-sB7H3 < 21.2425 ng/mL) predicted poor clinical outcomes. By integrating sB7-H3 levels with established prognostic indicators, including metastatic status and lactate dehydrogenase (LDH) levels, we developed a comprehensive prognostic model that demonstrated strong predictive accuracy for survival outcomes. Notably, pre-sB7-H3 levels were significantly associated with good histological responses ($p < 0.05$). Longitudinal monitoring during treatment revealed that dynamic changes in sB7-H3 levels positively correlated with disease progression ($p < 0.05$) and inversely correlated with good histological responses ($p < 0.05$). These findings highlight serum sB7-H3 as a clinically valuable biomarker in OTS, providing prognostic information both at diagnosis and throughout the course of treatment in a relatively convenient manner.

#3934 Apoptosis-inducing factor mitochondria-associated 2 (AIFM2) functions as an oncogenic driver and prognostic biomarker in oral squamous cell carcinoma.

Chung-Hsien Chou[1], Shu-Chun Lin[1], **Kuo-Wei Chang**[2]

[1]Oral Biology, National Yang Ming Chiao Tung University, Taipei, Taiwan,[2]Dentistry, National Yang Ming Chiao Tung University, Taipei, Taiwan

Head and neck squamous cell carcinoma (HNSCC), including oral squamous cell carcinoma (OSCC), is a prevalent malignancy with limited therapeutic success. Apoptosis-inducing factor mitochondria-associated 2 (AIFM2), also known as ferroptosis suppressor protein 1, has been implicated in ferroptosis regulation and cancer progression, yet its role in HNSCC/OSCC remains unclear. This study investigated the oncogenic functions, clinical relevance, and epigenetic regulation of AIFM2 in OSCC. Transcriptomic data from TCGA-HNSCC and in-house OSCC RNA-Seq datasets were analyzed to assess AIFM2 expression and clinical associations. Functional assays examined the effects of AIFM2 knockdown and overexpression on OSCC cell proliferation, migration, invasion, and drug responses. Bioinformatic prediction, luciferase reporter, and miRNA mimic assays were performed to identify microRNAs regulating AIFM2. A Light Gradient Boosting Machine (LGBM) model was employed to predict patient mortality risk. High AIFM2 expression correlated with advanced stage, poor differentiation, p16 negativity, and worse survival in HNSCC/OSCC. AIFM2 knockdown reduced migration and invasion, while overexpression enhanced proliferation, migration, and invasion but had minimal impact on sensitivity to cisplatin, palbociclib, or cold atmospheric plasma. Bioinformatic and experimental analyses identified miR-32-5p and miR-432-5p as direct suppressors of AIFM2, both downregulated in tumors. AIFM2-associated transcripts were enriched in pathways related to oxidative stress, lipid metabolism, and E2F targets. Furthermore, the AIFM2-associated gene expression signature generated by the LGBM model effectively stratified patients by prognostic risk. Collectively, these findings indicate that AIFM2 functions as an oncogenic driver in OSCC, promoting tumor progression and poor prognosis, and is epigenetically regulated by tumor-suppressive miR-32-5p and miR-432-5p, representing a potential prognostic biomarker and therapeutic target.

#3935 Peripheral T-cell receptor beta repertoire in breast cancer: Implications for prognosis and therapy-associated immune repertoire dynamics.

Ling-Ming Tseng[1], Chi-Cheng Huang[1], Ji-Lin Chen[2], Yi-Fang Tsai[1], Ta-Chung Chao[1], Wen-Chi Wu[1], Pei-Ju Lien[1], Yen-Shu Lin[1], Chin-Jung Feng[1], Yen-Jen Chen[1], Jiun-I Lai[1], Jen-Hwey Chiu[2], Chih-Yi Hsu[1], **Chun-Yu Liu**[1]

[1]Taipei Veterans General Hospital, Taipei, Taiwan,[2]National Yang Ming Chiao Tung University, Taipei, Taiwan

Purpose: Sequencing of the T-cell receptor (TCR) repertoire provides insight into host immune status and can serve as a biomarker of therapeutic response. This study aimed to comprehensively evaluate the relationships between peripheral TCR repertoire characteristics, clinicopathological parameters, survival outcomes, and treatment regimens in breast cancer.
Experimental Design: Peripheral blood from patients with early- or late-stage breast cancer was analyzed using the Oncomine™ TCR Beta-LR Assay, and matched tumor tissues were profiled with the Oncomine™ Comprehensive Assay v3. Patients were classified into three groups: (1) first-line surgery followed by adjuvant therapy, (2) neoadjuvant chemotherapy (NACT) followed by surgery, and (3) de novo or recurrent Stage IV disease. TCR diversity metrics including clonality, convergence, richness, and Shannon diversity were correlated with clinicopathologic features, genomic alterations, and overall survival using Pearson correlation, Kaplan-Meier, and Cox regression analyses.
Results: Among 856 enrolled patients, baseline TCR clonality was inversely correlated with both richness and Shannon diversity, while convergence showed a modest positive association with clonality. Higher clonality correlated weakly but significantly with patient age and tumor stage. Elevated baseline clonality was associated with poorer overall survival and remained an independent prognostic factor in multivariate Cox analysis. Patients harboring ARID1A mutations exhibited reduced TCR richness and lower Shannon diversity compared with wild-type counterparts. Treatment-specific analysis revealed that adjuvant chemotherapy, particularly taxane- or anthracycline-taxane-based regimens, induced peripheral T-cell clonal expansion and loss of diversity, with trastuzumab-associated changes confined to HER2-enriched but not luminal B2 subtypes. Similarly, NACT, especially anthracycline-taxane or platinum-containing regimens, promoted clonal expansion and reduced diversity, with HER2-targeted effects again restricted to HER2-enriched tumors.
Conclusion: Peripheral TCR clonality serves as an independent prognostic biomarker in Stage IV breast cancer. HER2-targeted therapies and specific chemotherapy regimens modulate immune repertoire dynamics in a subtype-dependent manner. These findings highlight that treatment type significantly influences TCR diversity and underscore the potential of integrating repertoire profiling with genomic and clinical data to guide personalized therapy in breast cancer.

#3936 IQGAP3 as a gatekeeper of epithelial integrity and prognostic biomarker in extrahepatic cholangiocarcinoma.

Naoki Rikiyama[1], Daisuke Douchi[1], Ming Zhu[1], Keigo Murakami[2], Mitsuhiro Shimura[1], Takehiko Saijo[1], Shusuke Migita[1], Shuichiro Hayashi[1], Hideaki Sato[1], Koetsu Inoue[1], Shuichi Aoki[1], Masahiro Iseki[1], Takayuki Miura[1], Shimpei Maeda[1], Hideaki Karasawa[1], Masaharu Ishida[1], Hideo Ohtsuka[1], Masamichi Mizuma[1], Kei Nakagawa[3], Shinobu Ohnuma[1], Atsushi Masamune[4], Toru Furukawa[2], Michiaki Unno[1]

[1]Department of Surgery, Tohoku University Graduate School of Medicine, Sendai, Japan,[2]Department of Investigative Pathology, Tohoku University Graduate School of Medicine, Sendai, Japan,[3]Division of Gastroenterological and Hepato-Biliary-Pancreatic Surgery, Department of Surgery, Tohoku Medical and Pharmaceutical University, Sendai, Japan,[4]Division of Gastroenterology, Tohoku University Graduate School of Medicine, Sendai, Japan

Background: Biliary tract cancer (BTC) is an aggressive malignancy for which reliable prognostic biomarkers remain scarce. Although recent efforts have advanced the molecular characterization of intrahepatic cholangiocarcinoma (iCCA), the biology of extrahepatic CCA (eCCA) is still insufficiently understood. IQ motif-containing GTPase-activating protein 3 (IQGAP3) is a scaffold protein involved in cytoskeletal regulation, cell-cycle control, and epithelial junctional stability. Because epithelial-mesenchymal transition (EMT) drives invasion and metastasis in BTC, we hypothesized that IQGAP3 may influence epithelial identity and clinical behavior in eCCA. This study sought to clarify the clinicopathological significance of IQGAP3 and examine its biological role using integrated pathological and functional analyses.

Methods: We retrospectively analyzed 100 patients who underwent curative resection for perihilar or distal CCA between 2016 and 2020. IQGAP3 expression was assessed by immunohistochemistry and quantified using QuPath-based H-scores; tumor regions were manually annotated in QuPath to ensure that H-scores reflected staining intensity exclusively in cancer cells. Associations with clinicopathological factors and overall survival (OS) were evaluated using standard statistical approaches. Functional studies were conducted in HuCCT1 and TFK-1 cells with shRNA-mediated IQGAP3 knockdown. RNA sequencing and gene set enrichment analysis (GSEA) were performed to identify transcriptional changes associated with IQGAP3 loss. Expression of epithelial markers, including E-cadherin (CDH1), was examined in cell models and resected tissues.

Results: High IQGAP3 expression was associated with significantly longer OS than low expression (median 102.7 vs 40.2 months; hazard ratio 0.51; 95% CI 0.30-0.88; $P = 0.017$). Low IQGAP3 levels correlated with lymph-node metastasis, advanced stage, and positive resection margins. Functional assays showed that IQGAP3 knockdown activated EMT-related transcriptional programs in both cell lines (normalized enrichment score 1.43 and 1.44; $P < 0.01$; false discovery rate $q < 0.25$) and reduced CDH1 expression, suggesting impaired epithelial cohesion. In clinical samples, IQGAP3 and CDH1 mRNA levels demonstrated a strong positive correlation ($r = 0.74$), supporting a biological link between IQGAP3 loss and disruption of epithelial integrity.

Conclusions: IQGAP3 plays a key role in maintaining epithelial identity in CCA. Its loss promotes EMT activation and is associated with more aggressive disease features, whereas high expression confers favorable prognosis in eCCA. IQGAP3 may serve as a practical biomarker for risk stratification and represents a potential target for strategies aimed at limiting EMT-driven tumor progression.

#3937 Investigation of inherited genetic variation for predictors of immune mediated colitis following immune checkpoint inhibitor (ICI) therapy of patients (pts) with melanoma.

Ahmad A. Tarhini[1], Zhihua Chen[2], Mohammad Ali Khaksar[1], Sandra J. Lee[3], F. Stephen Hodi[3], Tingyi Li[2], Howard Streicher[4], Vernon K. Sondak[5], John M. Kirkwood[6], Xuefeng Wang[2], Peter A. Kanetsky[7]

[1]Cutaneous Oncology and Immunology, H. Lee Moffitt Cancer Center, Tampa, FL,[2]Biostatistics and Bioinformatics, H. Lee Moffitt Cancer Center, Tampa, FL,[3]Dana-Farber Cancer Institute, Boston, MA,[4]National Cancer Institute, Rockville, MD,[5]Cutaneous Oncology, H. Lee Moffitt Cancer Center, Tampa, FL,[6]University of Pittsburgh Medical Center, Pittsburgh, PA,[7]Cancer Epidemiology, H. Lee Moffitt Cancer Center, Tampa, FL

Background: Immune mediated colitis is a common toxicity following ICI therapy of melanoma and can be life threatening. Therefore, predicting the risk of developing colitis may inform the treatment plan and clinical follow up. We hypothesize that inherited genetic variation is an important factor in predisposing pts to this immune related adverse event (irAE).
Methods: We conducted genome-wide genotyping on samples from 744 consenting pts enrolled in ECOG-ACRIN E1609 trial (NCT01274338) that tested ipilimumab. We used Illumina Infinium Global Screening Array v.3.0 + Multi-Disease BeadChip with 730059 designed loci. Genotypes were quality controlled, harmonized with the 1000 Genomes Phase 3 (1KGP3) genotypes, and imputed against the hrc-r1.1 reference panel using the Michigan Imputation Server 2, pipeline v2.0.6. We used logistic regression implemented in plink (v2.00a4LM glm with firth fallback) to estimate associations between inherited genetic markers and the occurrence of colitis, adjusting for genetic ancestry. We also calculated the value for 5 published polygenic risk scores (PRS) for inflammatory bowel disease (IBD) listed in PGS-Catalog v20240318 and tested the association with colitis in E1609 pts treating irAE grades as categorical (Kruskal-Wallis test) and as dichotomous (Wilcoxon rank-sum test) variables. IrAEs were graded using CTCAE v.4.
Results: There was no significant difference in distribution of the PRS across grade of colitis (Kruskal-Wallis) with any of the 5 PRS. However, all demonstrated stronger differences when irAE grades were dichotomized at >3 vs. other. PRS PGS004253 was most significant in association with grades 4-5 colitis (P = 0.01; AUC 0.73). This PRS (*Medha. Nature Commun 2024*) was trained in a non-melanoma European population that has a genetic ancestry similar to our melanoma study cohort (*Tarhini. AACR 2025*) and for which all markers in the PRS were available in our dataset. From our genome-wide association analysis, we identified 10 independent SNPs that were significantly associated with colitis irAE. When combined using log(OR) as weights, these SNPs were significantly associated with the severity of irAE grades, both across irAE grades (Kruskal-Wallis P = 2.5e-26) and when dichotomized as any colitis irAE vs. none (Wilcoxon P = 8.9e-30). In multivariable survival analysis adjusting for primary status (known, unknown) and sex (male, female), our 10-SNP PGS trended towards an association with survival outcomes.
Conclusion: Our results support an association between inherited genetic variation and the risk of colitis following ICI, including PRS for IBD selected based on inherited genetic similarity with the population used to train the PRS as well as a novel PRS score computed using 10 SNPs identified from our GWAS analysis.

#3938 Scalable AI-driven tumor-stroma ratio quantification for prognostic stratification in stage II-III colorectal cancer.

Wei Kit Tan[1], Marcia Zhang[1], Juha P. Vayrynen[2], Shuji Ogino[3], Mai Chan Lau[1]

[1]Bioinformatics Institute (BII), Agency of Science, Technology and Research (A*STAR), Singapore, Singapore,[2]Translational Medicine Research Unit, University of Oulu, Oulu, Finland,[3]Department of Pathology, Brigham and Women's Hospital, Boston, MA

Introduction: The tumor-stroma ratio (TSR), defined as the proportion of stromal content within the primary tumor, has been proposed as a prognostic histopathologic marker for colorectal cancer (CRC). Higher stromal content is often linked to poorer prognosis in stage II-III disease. However, TSR assessment remains manual and is prone to interobserver variability, while existing AI algorithms - often trained and tested on single-institution datasets - lack independent validation for generalizability. In this study, we developed an AI-driven TSR quantification model trained on the public Cancer Genome Atlas (TCGA) pathologist-annotated regions and validated it using predictions on (i) TCGA whole-slide images (WSI) and (ii) two large independent CRC cohorts (NHS/HPFS tissue microarray (TMA)).

Methods: We trained a SegFormer semantic segmentation model on 99,871 image tiles derived from pathologist-annotated regions (J.V.) from 469 TCGA H&E images spanning stage I-IV CRC. The model was trained to segment three major tissue categories: tumor, stroma, and others. For validation, we applied the model to 375 stage II-III CRC samples within the TCGA cohort (a subset of the 469 training images, evaluated beyond annotated regions) and to 537 NHS/HPFS TMA images. TSR was defined as the area of stroma divided by the sum of stromal and tumor areas. Patients were stratified into TSR-high and TSR-low groups using the cohort median as the cut-off. Prognostic associations were evaluated using Cox proportional hazard model.

Results: Computed TSR values range from 18.17% to 100% with a median of 88.56% for the NHS/HPFS cohort; and range from 11.72% to 99.87% with a median of 70.30% for the TCGA cohort. In the NHS/HPFS cohort, AI-derived TSR-high group showed significantly worse outcomes for overall survival (HR = 1.38; 95% CI = 1.06-1.81; P = 0.017) and CRC-specific survival (HR = 1.49; 95% CI = 1.03-2.15; P = 0.035). However, in the TCGA cohort, TSR stratification showed no significant prognostic value for either pathologist-annotated or WSI-AI-derived TSR for overall survival (HR = 1.12, 95% CI = 0.69-1.82; P = 0.647, and HR = 0.97; 95% CI = 0.59-1.60; P = 0.909, respectively) and CRC-specific survival (HR = 0.79, 95% CI = 0.40-1.58; P = 0.513, and HR = 0.88; 95% CI = 0.43-1.77; P = 0.723, respectively).

Discussion: While AI-derived TSR showed prognostic significance in the NHS/HPFS cohort, the lack of significance in TCGA suggests limited generalizability across cohorts. Notably, this is, to our knowledge, the first study to evaluate TSR using the well-established TCGA CRC dataset. These findings highlight the need to further dissect the stromal composition - through molecular staining or AI-driven profiling of immune populations, stromal subtypes, and tumor-immune spatial interactions - to capture the biological mechanisms underlying TSR and improve its robustness as a prognostic biomarker.

#3939 Circulating tumor cell analysis for early detection of minimal residual disease in oral cancer.

Xi Zhang[1], Sarj Vasani[2], Waqar A. Afridi[1], Danyelle A. Ferreira[1], Omar Breik[2], Gunter Hartel[3], Liz Kenny[2], **Chamindie Punyadeera**[1]

[1]Griffith University, Brisbane, Australia,[2]Royal Brisbane and Women's Hospital, Brisbane, Australia,[3]QIMR Berghofer Medical Research Institute, Brisbane, Australia

Background: The key clinical problem in detecting minimal residual disease (MRD) in oral cancer (OC) patients is the lack of sensitive, standardized tools to identify residual cancer cells that remain after treatment but are undetectable by conventional imaging or pathology. We aim to assess whether circulating tumor cells (CTCs) can serve as a biomarker for early detection of MRD.
Methods: This longitudinal observational study collected blood samples from 50 OC patients at baseline, and at one, three, and twelve months following surgery. CTCs were isolated using a spiral microfluidic device that leverages inertial microfluidic principles for separation. CTC was defined as either pan-cytokeratin (CK+) or cell-surface vimentin (CSV+), DAPI positive and CD45 negative. The presence of CTCs was compared between patients who experienced recurrence and those who remained disease-free.
Results: At one month, patients with recurrence showed significantly higher total CTC counts (mean 2.75 vs 0.61; $p = 0.0021$) and significantly elevated CTC phenotype positivity (cytokeratin positive (CK+) cell surface vimentin positive (CSV+): $p = 0.0001$). At three months, CTC differences further widened (mean 8.0 vs 0.91; $p = 0.0042$), with strong separation across multiple CTC cluster phenotypes, including CK-CSV+ ($p = 0.0001$) and CK+CSV+ ($p = 0.0003$). Significant CTC-based differences persisted at one year ($p = 0.0241$).
Conclusions: CTCs demonstrate strong promise as early biomarkers for MRD and impending recurrence in OC. Multiple markers exhibit statistically significant separation well in advance of conventional clinical detection, highlighting their potential for early intervention, supporting its integration into routine clinical practice for improved patient outcomes.

#3940 Persistent immune microenvironment changes associated with progression risk in Barrett's esophagus.

Hyun Young Park[1], Erin E. Grayhack[1], Ashten Omstead[1], Christopher Sherry[1], Alisha Khan[1], Catherine Lewis[1], Neda Dadgar[1], Kunhong Xiao[1], Gursimran Kochhar[1], Michael Landau[1], Douglas B. Stairs[2], Ali H. Zaidi[1], Patrick L. Wagner[1]

[1]Allegheny Health Network, Pittsburgh, PA,[2]Penn State Cancer Institute, Hershey, PA

Barrett's esophagus (BE) is the principal risk factor for esophageal adenocarcinoma (EAC). Since only a small number of patients with BE progress to high-grade dysplasia (HGD) or EAC, biomarkers of risk are in high demand. Our previous work identified alterations in the relative abundance of lamina propria lymphocyte and macrophage subsets in BE patients at initial diagnosis. In this study, we extended these findings by analyzing serial surveillance samples from these patients to assess the changes of these immune microenvironments over time. Formalin-fixed, paraffin-embedded tissue samples from patients with non-dysplastic BE undergoing endoscopic biopsy were examined. Initial diagnostic samples (n=58) and serial surveillance samples (n=78) from 58 unique patients were examined, among whom 25 were subsequently diagnosed with HGD or EAC ("progressors"), while 33 patients did not progress during at least 5 years of surveillance ("non-progressors"). Immunohistochemical staining was performed with antibodies specific for CD3 and CD8 (lymphocytes), CD68/CD86 co-positive ("M1- like") macrophages, and CD68/CD206 co-positive ("M2-like") macrophages. Regions of interest (ROI) selected from the lamina propria in the region of BE were subjected to digital image analysis, and subgroup comparisons of immune cell densities were carried out using Welch's t-test for the outcome of progression. In total, 3540 ROIs from non-progressors (1526 initial, 2014 follow-up) and 2994 ROIs from progressors (1077 initial, 1917 follow-up) were examined. Relative to non-progressors, progressor biopsies contained a markedly greater density of CD3+ lymphocytes (4586 vs. 2633, $p=0.0019$) and a significantly lower density of CD8+ lymphocytes (798 vs. 1359, $p=0.002$). Concomitantly, M1-like macrophages were significantly elevated in progressors (84.7 vs. 34.6, $p=0.003$), while M2-like macrophages were markedly decreased (35.5 vs. 80.3, $p<0.0001$) relative to non-progressors. The difference persisted at follow-up biopsy, (CD3+:1566 vs. 1228, $p<0.0001$; M1: 244 vs. 48.4, $p<0.0001$), whereas other immune cells changed (CD8+: 350 vs. 396, $p=0.096$ vs. M2: 66.5 vs 37.6, $p=0.0066$). The immune cell density suggests that there is an enduring feature of the BE microenvironment.The BE immune microenvironment demonstrates substantial differences in lamina propria lymphocyte and macrophage populations in patients who are destined to progress to HGD or EAC, relative to those who are not. These findings, which we show here to persist in serial biopsies over time, warrant further investigation to deepen our understanding of this altered immune microenvironment, both as a biomarker of progression risk and a potential target for immunomodulatory prevention strategies.

#3941 A RHO GTPase pathway signature as a potential prognostic biomarker and therapeutic target in bladder cancer.

Weiyi Gong[1], Chongwen Cao[2], Peng Wang[3], Shang-Jui Wang[4], Akshay Sood[5], Lingbin Meng[3], Qingqing Wu[6], Cheryl Lee[5], Anil Vasdev Parwani[6], Jenny Li[6], Xuefeng Liu[7]

[1]Comprehensive Cancer Center, Biomedical Sciences Graduate Program, The Ohio State University, Columbus, OH,[2]Comprehensive Cancer Center, The Ohio State University, Columbus, OH,[3]Department of Medicine, Wexner Medical Center, The Ohio State University, Columbus, OH,[4]Department of Radiation Oncology, Wexner Medical Center, The Ohio State University, Columbus, OH,[5]Department of Urology, Wexner Medical Center, The Ohio State University, Columbus, OH,[6]Department of Pathology, College of Medicine, The Ohio State University, Columbus, OH,[7]Department of Pathology, Urology and Radiation Oncology, Wexner Medical Center, The Ohio State University, Columbus, OH

Background: The RHO GTPase cycle regulates essential cellular processes, including proliferation, differentiation, senescence, and programmed cell death. However, many predicted downstream effectors of this pathway remain poorly characterized, and their prognostic relevance in bladder cancer (BLCA) is not well understood. This study aimed to develop a prognostic model for BLCA based on RHO GTPase cycle effector gene expression and to identify key effectors functionally involved in BLCA progression.
Methods: RNA-seq data and clinical information from The Cancer Genome Atlas (TCGA) and our James institutional cohort were analyzed. LASSO and Cox regression analyses were used to construct a prognostic gene signature associated with the RHO GTPase cycle. Patients were stratified into high- and low-risk groups based on this signature. Pathway enrichment analyses and therapy-response predictions were performed to compare biological features between risk groups. Candidate effector genes were functionally validated in BLCA cell lines using shRNA-mediated knockdown, followed by proliferation and colony-formation assays.
Results: The resulting gene signature reliably stratified patients into high- and low-risk groups, with Kaplan-Meier curves showing significantly reduced survival in the high-risk group. These findings were validated in our independent dataset. Among the signature genes, UACA, CLTC, and SNAP23 emerged as key candidates. Pathway enrichment indicated activation of YAP and EMT signaling in high-risk patients. Bioinformatic drug-prediction analysis identified PI-103 and PLX-4720 as potential therapeutic compounds for the high-risk group. Functional experiments demonstrated that knockdown of each signature gene significantly reduced proliferation and colony formation in BLCA cell lines and consistently induced a senescence-like morphology.
Conclusions: This study establishes a robust prognostic model for BLCA based on RHO GTPase cycle effector genes and highlights UACA, CLTC, and SNAP23 as potential prognostic biomarkers and promising therapeutic targets. Our findings provide a foundation for further investigation into RHO GTPase pathway effectors and their potential role in improving BLCA diagnosis and treatment.

#3942 NRF2 pathway activation predicts poor radiation response in laryngeal cancer: Insights from a large proteogenomic characterization study.

Kelly Gaudian, Harit Panda, Emily Wilkerson Zarbock, Kate Zhao, James Sun, Benjamin Wahle, Paul Zolkind, M. Ben Major

Washington University School of Medicine, St. Louis, MO

Patients with advanced laryngeal cancer often experience poor outcomes, and current clinical guidelines lack reliable predictive biomarkers. Preclinical cancer studies have implicated NRF2, a transcription factor that promotes antioxidant defense and metabolic reprogramming, in resistance to radiation therapy (RT). This study investigates whether activation of the NRF2 pathway influences clinical outcomes in larynx cancer patients receiving RT or surgery. We identified 135 larynx cancer patients who were treated at Siteman Comprehensive Cancer Center with either surgery and RT or surgery alone. Tumor samples were obtained from the WashU Head & Neck Tumor Center tissue bank and characterized using RNA sequencing, targeted exon capture sequencing, and mass spectrometry-based proteomics. Gene and protein expression profiling were used to independently calculate an NRF2 activity score, allowing the classification of tumors along a continuum of NRF2 activity. Kaplan-Meier analysis and Cox proportional hazards modeling were employed to compare disease-free survival (DFS) and locoregional failure (LRF) rates between NRF2-high and NRF2-low groups. In patients treated with surgery and RT, differential gene and protein expression analysis identified numerous NRF2-induced targets that were associated with locoregional failure. In those treated with radiation, NRF2-high patients had significantly worse outcomes than NRF2-low, with 5-year LRF rates of 51.0% and 17.1% (HR = 7.2, 95% CI: 2.0-25.7), and 5-year DFS rates of 25.4% and 50.7% (HR = 2.9, 95% CI: 1.3-6.2), respectively. Notably, NRF2-activity status was not significantly prognostic in the surgery alone cohort, indicating that NRF2 activation is specifically associated with radiation resistance. Ontological enrichment analyses identified upregulation of pathways associated with antioxidant response and dsDNA break repair in NRF2 high tumors, suggesting possible mechanisms of resistance. Discovery-based proteomics aligned closely with the gene expression data. Exon capture sequencing revealed 10 patients harboring driver mutations in NRF2 or KEAP1, 9 of which were categorized as NRF2 high from expression data. Logistic regression identified NRF2 score as the most predictive variable associated with outcomes for radiation-treated patients, followed by nodal involvement. These findings suggest NRF2 activation is associated with worse outcomes in patients receiving surgery and radiation, but not surgery alone. Future implications include validating NRF2 as a biomarker across data sets and the development and testing of NRF2-targeted therapies.

#3943 Morphology-derived spindle-cell gene signature in HPV+ HNSCC is linked to pEMT, molecular subtype, HPV integration, and recurrence-free survival.

Shaomiao Xia[1], Yvonne Xinyi Lim[2], Min Liu[2], Bailey Grab[3], Siddhi Patil[4], Shiting Li[3], Laura Rozek[5], Nisha J. D'silva[2], Maureen A. Sartor[6]

[1]Department of Computational Medicine and Bioinformatics, University of Michigan Medical School, Ann Arbor, MI,[2]University of Michigan School of Dentistry, Ann Arbor, MI,[3]Department of Computational Medicine and Bioinformatics, University of Michigan Medical School, Ann Arbor, MI,[4]Georgetown University, Washington, DC,[5]Oncology Department, School of Medicine, Georgetown University, Washington, DC,[6]Assistant Professor, Dept. of Bioinformatics, University of Michigan Medical School, Ann Arbor, MI

Spindle-shaped epithelial cells are frequently observed in HPV+ head and neck squamous cell carcinoma (HNSCC) cell lines and at invasive fronts in tumors, but how this morphology relates to transcriptional programs, aggressive phenotypes, and spatially organized niches remains unclear. This study aimed to understand the spindle phenotype by deriving a morphology-linked gene signature and testing its association with partial epithelial-mesenchymal transition (pEMT), HPV integration (HPVint) into the host tumor genome, tumor molecular subtypes (immune-strong, IMU vs highly keratinized, KRT), and patient recurrence-free survival (RFS), and by mapping this program *in situ* using spatial transcriptomics. We quantified cell morphology in two HPV+ HNSCC cell lines using cell aspect ratio, roundness, and circularity, and used bulk RNA-seq (n = 12) to identify genes differentially expressed in spindle-enriched conditions. We derived a 45-gene spindle-cell signature (SCS) and computed SCS and pEMT scores in 236 HPV+ HNSCC tumors from four cohorts: UM_FF (18), UM_FFPE (62), HVC (83), and TCGA (73). In parallel, we generated Nanostring CosMx 6k-plex spatial transcriptomics from four HPV+ tonsil tumors, clustered cells into major compartments, and projected SCS/pEMT scores and HPV gene expression onto tissue coordinates to characterize spatial niches. In HNSCC tumors, SCS scores are highly correlated with pEMT scores (Pearson's $r = 0.72$) despite sharing only two genes, indicating this signature robustly captures a pEMT-like program. KRT tumors had markedly higher SCS scores than IMU tumors in the pooled analysis ($p = 1.3 \times 10^{-9}$). Across four cohorts, SCS scores tended to be higher in HPVint+ than HPVint- tumors, with significant differences in three cohorts (p range 0.016-0.045) but not the HVC ($p = 0.21$), suggesting cohort-specific heterogeneity. Taken together, these patterns firmly link the spindle program to molecular subtype and suggest an association with HPVint. Survival analysis of 70 University of Michigan patients shows that patients with low SCS scores have significantly better RFS than those with high scores (Log-rank test, $p = 0.014$). We are incorporating CosMx data with these patterns to test the hypothesis that high SCS epithelial states preferentially occupy tumor-stromal interfaces and cancer-associated fibroblast-rich regions and are associated with distinct local immune architecture, defining a spatially restricted invasive niche. These analyses support that SCS captures an invasive state enriched in KRT and HPVint+ HNSCC and associated with poorer RFS. By connecting cell shape, transcriptional state, viral features, and spatial microenvironment, this study suggests morphology-derived biomarkers and spatial niches that may refine risk stratification and guide targeted therapeutic strategies in HPV-associated HNSCC.

#3944 The impact of diversity on transcriptional heterogeneity of skeletal muscle from pancreatic ductal adenocarcinoma patients.

Praveen Bhoopathi[1], Vignesh Vudatha[2], Arunima Punjala[2], Vashti Bandy[2], Anna Gibson[2], Dongyu Zhang[2], Katarzyna M. Tyc[3], Mikhail Dozmorov[3], Jeremy Ducharme[4], Martin Schonk[4], Brittney Poole[4], Sarah Judge[4], Leopoldo Fernandez[1], Andrew R. Judge[4], Jose G. Trevino[1]

[1]Surgery (Surgical Oncology) and Massey Comprehensive Cancer center, Virginia Commonwealth University - VCU, Richmond, VA,[2]Surgery (Surgical Oncology), Virginia Commonwealth University - VCU, Richmond, VA,[3]Department of Biostatistics, Virginia Commonwealth University - VCU, Richmond, VA,[4]Department of Physical Therapy and Myology Institute, University of Florida, Gainesville, FL

Objective: Cachexia plays a major role in the morbidity and mortality of pancreatic ductal adenocarcinoma (PDAC) patients. The objective of this study is to delineate the molecular pathways of muscle that contribute to cancer cachexia from surgically resected PDAC patients.
Methods: At surgical resection for PDAC, rectus abdominus muscle was sharply divided and shock frozen immediately for RNA-seq. Total RNA was extracted from the frozen tissue using standard protocols, and RNA integrity was confirmed prior to library preparation. The resulting high-quality RNA was then used for RNA sequencing (RNA-seq) analysis to find distinct variants in addition to a core transcriptional signature of roughly 13,007 frequently expressed transcripts, differential transcript expression was evaluated. KEGG pathways and MSigDB collections (Hallmark, Curated, GO signatures) were used in Gene Set Enrichment Analysis (GSEA), which uses both fold change and ranking of differentially expressed genes (DEGs) to find enriched biological pathways.
Results: Significant transcriptome variations in muscle tissue were found to be associated with patient race and survival. MSigDB gene sets comparing Black and White) patients revealed that the AA cohort had higher activation of pathways linked to inflammation, cardiomyopathy, and muscle atrophy/proteostasis. Three overlapping genes were found by cross-referencing these pathways with significant DEGs: CYP4B1, DDIT4 (upregulated in AA, significantly related with muscular atrophy/cachexia), and GINS1 (downregulated in AA, associated with proliferation). Additionally, eight genes including the physiologically significant genes ADAM28, SENCR, and MEG8 (related with muscle differentiation and tumor progression) were found to be substantially associated with overall survival.
Conclusion: RNA-seq and GSEA of muscle tissue provide critical insights into the systemic molecular alterations associated with PDAC. The identified pathways and genes, particularly those demonstrating racial and survival-associated heterogeneity (e.g., DDIT4, GINS1), represent potential biomarkers and therapeutic targets for addressing muscle dysfunction and cachexia in PDAC.

#3945 Serum detection of MUC1 and renin identifies circulating biomarkers for breast cancer prognosis.

Alakesh Bera[1], Hai Hu[2], COL Craig D. Shriver[3], **Meera Srivastava**[4]

[1]USUHS - Uniformed Services University of the Health Sciences, Bethesda, MD,[2]Chan Soon-Shiong Institute of Molecular Medicine at Windber, Windber, PA,[3]Uniformed Services University of the Health Sciences, Bethesda, MD,[4]Uniformed Services University, Potomac, MD

Background: Cytogenetic abnormalities involving multiple loci on the long arm of chromosome 1 are among the most frequent alterations in human breast carcinoma. To define their biological and clinical significance, we conducted a large-scale integrative genomic analysis across diverse breast cancer datasets.
Methods: Data from over 13,000 breast tumors (n = 13,146 samples; 12,229 patients across 30 studies) were analyzed using cBioPortal, including The Cancer Genome Atlas (TCGA). Copy number alterations, mRNA/protein expression, and clinical outcomes were evaluated. Comparative analyses with >100,000 samples across 35 other cancers (n = 105,424) determined specificity. Mutual exclusivity and co-occurrence analyses identified genetic interaction patterns relevant to tumor progression. Serum detectability of top candidates was evaluated.
Results: Eight genes particularly TRIM67, DISC1, REN, DNM3, ATP1B1, VSIG8, SPTA1, and MUC1 from different loci of 1q chromosome showed recurrent amplifications (12-15%) in breast tumors, significantly exceeding frequencies in pan-cancer datasets (~3%). These genes displayed low baseline expression in normal breast tissue but were highly expressed in tumors. Co-occurrence analyses revealed significant genetic interplay, including TP53 with MUC1/SPTA1/VSIG8 and PIK3CA with TRIM67/DISC1/REN, suggesting cooperative gain-of-function driving aggressive phenotypes. Among the eight amplified 1q genes, MUC1 and REN showed the strongest clinical relevance, as both encode secreted or shed proteins that were readily detectable in serum and have established associations with aggressive breast cancer biology. In contrast, DNM3 and ATP1B1 were detectable at lower abundance in serum-derived extracellular vesicles, supporting their potential as emerging but less established circulating markers.
Conclusions: Multi-locus amplifications contribute collectively to breast cancer progression through distinct gene interaction networks. This study identifies a core set of functionally relevant, serum-detectable gene products that may serve as biomarkers for prognosis, recurrence monitoring, and therapeutic targeting in aggressive breast cancer.

#3946 Association between MLK4 expression and colon cancer patient survival.

Nathan Kumar[1], Hitesh Kapoor[1], Piush Srivastava[2], Deepti Srivastava[2], Saket Jha[2], Sunil Kumar Singh[2], David Allison[3], Ajay Rana[2], Gerald Gantt[1]

[1]Division of Colon and Rectal Surgery, Department of Surgery, University of Illinois at Chicago, Chicago, IL,[2]University of Illinois at Chicago, Chicago, IL,[3]Department of Pathology, University of Illinois at Chicago, Chicago, IL

Background: Mixed Lineage Kinase 4 (MLK4) is a protein kinase from the serine/threonine kinase family functioning through the MAPK pathway. The association of MLK4 with colon cancer oncologic outcomes has not been well described. We aimed to investigate the molecular expression of MLK4 at both the protein and mRNA levels, its differential expression across stages, and the association with survival in cases of increased expression using the TCGA databases.

Methods: An *in-silico* analysis of MLK4 in colorectal cancers was performed using the TCGA database for stage-wise expression and overall survival analysis in 288 patients. A TMA of colon cancer and matched adjacent normal colon tissue, annotated with survival data and clinical stage (AJCC 8th edition), was used to investigate differential expressions of MLK4 in colon cancer. Laser Capture microdissection was performed with FFPE samples consisting of normal tissue and tumor. MLK4 RNA was quantified using organic extraction and RT-PCR techniques.

Results: IHC of MLK4 in 74 matched sample pairs revealed a significant ($p < 0.05$) increase in MLK4 expression (mean difference = 0.405, 95% CI = 0.2028 to 0.6080) in colon cancer compared to normal tissue. The correlation coefficient ($r = 0.4721$, $p < 0.0001$) suggested a moderate correlation between MLK4 levels in normal and tumor tissues. RT-PCR analysis in colon cancer specimens revealed a significant ($p<0.05$) increase in mRNA levels of MLK4 (mean difference = 2.139, 95% CI = 0.8789 to 3.400). High MLK4 expression showed a trend toward reduced overall survival compared with low expression (HR = 1.25, log-rank p = 0.079). Similarly, higher MLK4 methylation demonstrated a trend toward poorer overall survival in colon adenocarcinoma patients (HR = 1.54, 95% CI 0.96-2.47; log-rank p = 0.07).

Conclusion: Increased expression of MLK4, both transcriptionally and translationally, in colon cancer suggests involvement in colon tumor pathology. Cellular-level expressions and correlations of MLK4 kinase with survival can help elucidate the complex nature of colon cancer development and identify unknown prognostic markers.

#3950 Spatial transcriptomic dissection of microenvironmental drivers of NMIBC progression.

Jacob Alltucker[1], Yiling Shen[2], Suhyeon Choi[1], Pavithra Nedumaran[1], Andrew Martinez[1], Joseph Lownik[1], Huihui Ye[1], Hideki Furuya[1], Dan Theodorescu[3], Simon Knott[1]

[1]Cedars-Sinai Medical Center, Los Angeles, CA,[2]Tsinghua University, Beijing, China,[3]University of Arizona, Tucson, AZ

Background: High-grade non-muscle invasive bladder cancer (NMIBC) is an aggressive malignancy characterized by a high rate of progression to muscle-invasive bladder cancer (MIBC). Once muscle-invasive, the disease is associated with significantly worse overall survival. Thus, novel strategies for identifying therapeutic targets and biomarkers of progression are urgently needed. We utilized spatial transcriptomics to elucidate the tumor microenvironment states and cellular interactions that underlie progressive NMIBC. We hypothesized that progressive NMIBC is defined by distinct molecular and architectural compositions that converge on an MIBC-like phenotype.
Methods: We constructed tissue microarrays using transurethral resection specimens from 18 high-grade NMIBC patients who progressed to MIBC within 5 years and 27 risk-matched non-progressors, along with 52 MIBC cystectomy specimens. We then performed Xenium in situ expression analysis using a 5,000-gene panel with an additional 100 genes focused on stromal and immune signaling. Data were analyzed using single-cell variational inference with Leiden clustering-based cell typing, custom neighborhood (“niche”) evaluation, and computational workflows to characterize cellular interactions, transcriptional programs, and ligand-receptor signaling across progressor status and disease states.
Results: We generated a single-cell-resolution spatial transcriptomic atlas of over 4 million cells spanning NMIBC and MIBC tissues. Preliminary analysis revealed substantial intra- and inter-patient heterogeneity in both tumor-intrinsic transcriptional programs and microenvironment composition. Non-progressor tumors demonstrated increased immune activation signatures and enrichment of cytotoxic CD8+ T cells, while progressors showed enrichment of tumoral mTOR signaling and other oncogenic pathways. Ongoing work aims to define spatial niches and cellular interaction networks that differentiate progressive versus non-progressive disease and evaluate their alignment with MIBC-like architecture.
Conclusions: This study establishes the first single-cell spatial transcriptomic analysis directly comparing NMIBC progressors and non-progressors, providing a framework to define microenvironmental trajectories underlying progression to invasion. By leveraging high-resolution spatial transcriptomics to identify candidate biomarkers and potential drivers of invasion, this work may inform early risk stratification and microenvironment-targeted therapeutics aimed at preventing transition to MIBC.

#3951 Spatial mapping of B7-H3 mediated cellular plasticity in treatment naive pancreatic cancer.

Assya Legrini[1], Tengyu Zhang[1], Mari-Claire McGuigan[1], Colin Wood[1], Luke McNickle[1], Claire Kennedy-Dietrich[1], Ghazal Latifi[1], Yoana Doncheva[1], Josefina Vasquez[1], Hannah Morgan[2], Pamela McCall[2], Michail Doukas[3], Joanne Edwards[1], Nigel Jamieson[1]

[1]Univ. of Glasgow, Glasgow, United Kingdom,[2]Glasgow Tissue Research Facility, Univ. of Glasgow, Glasgow, United Kingdom,[3]Erasmus MC, Rotterdam, Netherlands

Pancreatic Ductal Adenocarcinoma (PDAC) remains one of the most lethal cancers, with only 20% of patients surviving 5 years post pancreatectomy. Despite rationale for targeting immune pathways, existing immunotherapies have provided minimal benefit to date. The immune checkpoint molecule, B7-H3, has emerged as a promising therapeutic target across solid tumours. However, its cellular origins, spatial context and clinical relevance in PDAC is poorly defined. This study aims to address this unmet need. An integrated spatial multi-omics strategy was applied across two treatment naïve PDAC cohorts. These FFPE tissue microarrays were divided into a test cohort (n=27), and a validation cohort (n=74). GeoMx regional proteomics (Bruker) was applied on section of the test cohort, while GeoMx regional whole transcriptome (Bruker), CosMx single cell 64-plex protein (Bruker) and CosMx 6K RNA (Bruker) assays were applied to serial sections of the validation cohort. Additional CosMx single cell whole transcriptome (WTx) data was generated from an Intraductal Papillary Mucinous Neoplasm (IPMN) whole section cohort (n=6). GeoMx samples were fluorescently stained with Syto13, PanCk, CD45 and αSMA, and masks were selected for PanCk+ve epithelium and tumour microenvironment (TME). CosMx samples were fluorescently stained for DAPI, PanCk, CD298/B2M, CD45 and CD68. Extensive clinicopathological data was available for all samples. Across regional protein and transcriptome profiling, B7-H3 expression was consistently elevated in TME and fibroblast enriched compartments compared to epithelium. Reduced epithelial expression significantly correlated with improved disease specific survival. B7-H3 ranked transcriptomic regional signatures revealed suppression of T-cell activation and antigen presentation pathways, alongside enrichment of fibro-inflammatory, myeloid and stromal signalling pathways. Single-cell spatial proteomics and RNA validated and resolved these signatures to discrete cellular niches. B7-H3 high tumours were characterised by dense clustering of fibroblasts, antigen-presenting macrophages and exhausted T-cell phenotypes, whereas B7-H3 low tumours demonstrated epithelial dominant clustering and increased spatial separation between B7-H3 enriched cell types and cytotoxic lymphocytes. WTx data further demonstrated graded B7-H3 expression variation from normal to dysplasia to IPMN cancer, highlighting spatial-temporal remodelling throughout oncogenesis.

Across all spatial platforms, B7-H3 consistently mapped within fibro-inflammatory and immunosuppressive niches, features strongly associated with aggressive disease and poor prognosis. Collectively, these findings establish B7-H3 as a robust spatial biomarker in PDAC and provide compelling biological rationale for therapeutic targeting of B7-H3 in a malignancy historically resistant to immune-based treatments.

#3952 Spatial multi-omics dissection of follicular lymphoma by GlycoScope-IN-DEPTH reveals a galectin-8L-driven complement-enriched, immune-exhausted microenvironment.

[1]Beth Israel Deaconess Medical Center, Boston, MA,[2]Massachusetts Institute of Technology, Boston, MA

Follicular lymphoma (FL), an indolent malignancy of germinal center B cells, accounts for ~40% of non-Hodgkin lymphomas. Although most patients experience slow progression, a subset undergoes transformation, and CD20-negative relapses pose a therapeutic challenge. FL is characterized by BCL2 overexpression and highly mannosylated surface immunoglobulins that engage lectins on antigen-presenting cells to sustain B-cell receptor signaling and promote immune evasion. Yet, a systematic understanding of glycan-mediated interactions within the FL microenvironment remains limited.

To address this gap, we developed GlycoScope, a multimodal spatial profiling platform that co-detects glycans and proteins at single-cell resolution in situ. Applying GlycoScope to tonsil, follicular hyperplasia (FH), and treatment-naive FL tissues, we identified selective enrichment of Galectin-8L in B cells, with significantly higher expression in FL. In tonsil and FH, Galectin-8L localized to the $BCL2^{+}$ mantle zone, whereas in FL it extended across both follicular center and mantle zones, suggesting its potential as a structural landmark to dissect the organization and local cellular architecture of lymphoid tissues.

Stepwise neighborhood analyses anchored on Galectin-$8L^{+}$ mantle-marginal zone rims revealed localized enrichment of checkpoint-expressing T cells with Galectin-$8L^{High}$ B cells. To further probe the functional states of these niches, we integrated GlycoScope with spatial transcriptomics on the same slide (GlycoScope-IN-DEPTH). Stratifying follicles by Galectin-8L expression showed that Galectin-$8L^{High}$ B cells adopt transcriptional programs enriched for immune synapse formation and complement activation, both positively correlated with Galectin-8L levels. CD4 T cells in the same cores exhibited terminal exhaustion, while macrophages displayed enhanced phagocytic and complement-cascade signatures, together indicating a coordinated, Galectin-8L–associated remodeling of the immune microenvironment.

Additional glycan-lectin imaging demonstrated that the distinct intrafollicular distribution of Galectin-8L potentiates interactions with its cognate lectin Galectin-8, which we found expressed on macrophages and T cells. These observations support a Gal8L-Gal8 interaction axis across B-T-macrophage compartments that orchestrates a complement-enriched, immune-exhausted microenvironment in FL.

Together, this integrated spatial framework highlights glycan-dependent immunoregulatory networks in FL and positions Galectin-8L as a functional landmark for mapping, and potentially targeting, dysregulated immune niches in lymphoid malignancy.

#3953 Assessing the role of immune aggregates as potential biomarkers of immunotherapy response in appendiceal adenocarcinoma (AA) using spatial proteomics.

Matt Lastrapes[1], Eleanor A. Fallon[2], Brenda Melendez[1], Bharat B. Singh[1], Davis Ingram[1], Khalida M. Wani[1], Lon W. Fong[1], Ashish Damania[1], Vivian Orellana[1], Nadim J. Ajami[1], Jillian Losh[1], Alexander Lazar[1], Kanwal Pratap Singh Raghav[1], John P. Shen[1], Melissa Taggart[1], Jennifer A. Wargo[1], Beth A. Helmink[1], Paul A. Scheet[1], Michael Geoffrey White[1]

[1]UT MD Anderson Cancer Center, Houston, TX,[2]Roswell Park Comprehensive Cancer Center, Buffalo, NY

Appendiceal adenocarcinoma is a rare tumor representing less than 1% of all gastrointestinal malignancies. Unfortunately, over 50% of AA patients present with stage IV disease with many patients being unresectable and with few systemic therapy options. Data from a recent clinical trial suggests improved overall survival on atezolizumab and bevacizumab combination therapy for patients with unresectable metastatic AA (NCT03074513). We previously studied general immune effects in a subset of these patients using spatial transcriptomics, suggesting immune aggregates like tertiary lymphoid structures (TLS) could be important biomarkers of response in AA. Here, we aim to characterize the landscape of immune aggregates using single-cell spatial proteomics to further understand potential biomarkers of immunotherapy response in AA. Single-cell spatial proteomics was performed on pre-treatment FFPE biopsies from eight trial participants using nanoString's CosMx Spatial Molecular Imager (SMI) with the 64-plex human IO protein panel. Data processing was done using nanoString's AtoMx platform and exported to the R package Seurat for analysis. Cell type annotations were obtained using CELESTA. Immune aggregates were manually identified and labeled using CosMx staining images and Napari. The profiled trial cohort (n=8) was grouped by clinical response, measured as whether a patient was alive (n=4) or deceased (n=4) at trial follow-up. Peritumoral immune aggregates were manually annotated across all patients using the CD45 staining images from AtoMx and Napari to add labels to cells. Overall, we detected 75 unique immune aggregates across 7 of the 8 patient samples profiled. At the tissue level, we identified higher Treg density ($p=0.085$, t-test) in deceased patients compared to living patients. Among cells in immune aggregates, there was a trend towards higher B cell ($p=0.14$) and fibroblast ($p=0.16$) density in aggregates from living patients. Neighborhood analysis performed within these structures uncovered 9 cellular neighborhoods, representing many components of tertiary lymphoid structures. Unsupervised clustering of immune aggregates according to cellular neighborhood composition resulted in the separation of aggregates with more germinal center B cells from others with more CD4+ and CD8+ T cells. With challenges in tissue collection and sequencing of AA surgical specimens, spatial proteomics provides a meaningful framework for studying the tumor microenvironment and treatment response in such tissues. The presence of mature immune aggregates in AA tumors suggests a potential role in driving response to immunotherapy, and work remains ongoing to further characterize these aggregates to best predict response to immunotherapy in future AA patients.

#3954 Identifying biomarkers of response in BRAF p.V600E mutant colorectal cancers (mCRC).

Gagandeep Brar[1], Brooke Rhead[2], Unnati Jariwala[2], Stamatina Fragkogianni[2], Amit Mahipal[3]

[1]City of Hope Comprehensive Cancer Ctr., Duarte, CA,[2]Tempus, Chicago, IL,[3]Case Comprehensive Cancer Center, Cleveland, OH

Background: *BRAF V600E* mutations occur in 8-12% of patients (pts) with mCRC and are associated with poor response to standard systemic therapies and low survival rates. However, a subset of pts with *BRAF V600E* mCRC have a more indolent course with response and survival rates similar to non-*BRAF* mCRC pts, suggesting that the impact of *BRAF V600E* as an oncogenic driver may be heterogeneous. Here, we explore the genomic and transcriptomic differences between responders (R) vs non-responders (NR) in *BRAF V600E* mCRC pts treated with first line (1L) systemic therapy.

Methods: The Tempus Lens Platform (Tempus AI, Inc., Chicago, IL) was used to query the Tempus multimodal de-identified database and establish and subsequently analyze a cohort of pts diagnosed with *BRAF-V600E* mCRC with xT (DNA) ± xR (RNA) testing prior to 1L chemotherapy ± bevacizumab (n=274). Pts with concomitant MSI-H/dMMR results were excluded. Pts with best response recorded at least 15 days after 1L start were classified as R (complete response/partial response/stable disease) vs NR (progressive disease). RNA expression data was normalized and quantified as transcripts per million (TPM), and compared using Wilcoxon rank-sum tests. Gene set enrichment analysis (GSEA) was performed on a curated collection of 50 gene sets defined by biological states or processes. Adjusted p-values (q-values) were computed for expression analyses using the Benjamini-Hochberg method. Landmark real world overall survival (rwOS) was defined as time from 1L treatment start +90 days until death or loss to follow up. Hazard ratio (HR) was calculated using Cox proportional hazard models and tested using a log-rank test.

Results: Patient demographics and tumor characteristics did not differ by response status, including tumor sidedness, number of metastases, location of metastases and therapy received. Median age was 64 and 59% were female in the overall cohort. The 90 day landmark rwOS analysis was longer in R vs NR (median 15.0 vs 8.8 months given survival to 90 days from 1L treatment start; HR 0.53; 95% CI [0.31-0.89, p=0.016]).Of the genes analyzed, *ARID2* (8.9% vs. 0%, p=0.006) and *FLCN* (5.4% vs. 0%, p=0.048) alterations were significantly enriched in NR (n=56) vs. R (n=96). Rs exhibited significantly higher expression of *STARD9* compared to NRs (q=0.046), as well as positive enrichment expression in the *Wnt* pathway (q=0.02) and negative enrichment in multiple pathways associated with cell proliferation, immune infiltration, angiogenesis and bile acid metabolism (q<=0.05).

Conclusions: Rs with *BRAF V600E* mCRC had improved survival outcomes and had minimal somatic and transcriptomic changes compared to NRs treated with 1L therapy at the gene level. Interestingly, GSEA revealed significant differences in Wnt, cell proliferation, immune infiltration, angiogenesis and bile acid metabolism pathways suggesting therapeutic implications that should be explored.

#3955 Spatial characterization of tumor-immune interactions in MMR-p and MMR-d among African American colorectal cancer patients using attention-based modeling.

Hassan Brim[1], Khushi Desai[2], Shweta Dixi[1], Justin Hong[2], Colles Price[3], Jonathan H. Chen[4], Nicolas Fernandez[5], Sara Sim[5], Sami Farhi[5], Rabia Zafar[1], Elham Azizi[5], **Hassan Ashktorab**[1]

[1]Howard University, Dist. of Columbia, DC,[2]Columbia, New York, NY,[3]Takeda Pharmaceutical Company Ltd., Deerfield, IN,[4]Northwestern University, Chicago, IL,[5]Broad, New York, NY

Background: Colorectal cancer (CRC) disproportionately affects African American individuals, who experience higher incidence and mortality than non-Hispanic White patients. Immune infiltration varies widely across CRC phenotypes, particularly between microsatellite instability (MSI) and microsatellite stable (MSS) tumors. Recent single-cell studies show that MSI tumors demonstrate stronger anti-tumor immunity, with coordinated variation between immune and malignant cell types, highlighting the need for spatial analyses to understand tumor-immune interactions.
Aim: To investigate spatial cellular organization in MSI and MSS tumors from African American patients using advanced computational and machine learning approaches to characterize immunomarker profiles. Methods: Spatially resolved single-cell transcriptomic profiling was performed using 10X Genomics Xenium 5k, which measures up to 5,000 genes in situ. Because such data require sophisticated processing, we employed machine learning innovations—including self-supervised learning—and robust artifact-correction tools to derive biologically meaningful signals. We introduce a pilot dataset of four CRC samples (2 MSI, 2 MSS) and present an analysis pipeline for preprocessing and annotating spatial CRC data using curated marker sets.
Results: Spatial profiling revealed distinct immune-tumor ecologies across phenotypes. MSS tumors showed depleted T/NK and B-cell populations, whereas MSI tumors exhibited higher immune-cell abundance and strong cytotoxic $CD8^+$ T-cell activity marked by elevated CXCL13, GZMA, GZMB, and GZMK expression. MSI samples also demonstrated activated T-cell programs supported by pro-inflammatory myeloid cells expressing CXCL10, consistent with an immune-hot, therapy-responsive microenvironment. In contrast, MSS tumors were fibroblast-driven and metabolically reprogrammed, characterized by high TGFB1, FAP, COL1A1, LDHA, and SLC2A1 expression, reflecting an immune-cold state with minimal T-cell infiltration. To analyze cellular communication, we applied AMICI—an interpretable attention-based model predicting a cell's gene expression from its spatial neighbors. AMICI revealed phenotype-specific interaction patterns, neighborhood length scales, and key genes mediating immune-stromal-tumor signaling.
Conclusion: This pilot study establishes an integrated spatial and computational framework for dissecting MSI-MSS differences in CRC among African American patients. Future work will expand AMICI-based analyses to further resolve neighborhood-driven phenotypes and cell-cell communication networks that shape immune infiltration and therapeutic response.

#3956 Spatial transcriptomic mapping of ER-positive breast tumors reveals immune pathway remodeling and resistance mechanisms following anti-PD-1 therapy.

Oliver J. De Sa[1], Megan Hopkins[1], Angel Arnaout[1], Arif Awan[2], Gregory Pond[3], Jane Bayani[1], Melanie Spears[1]

[1]Ontario Institute for Cancer Research, Toronto, ON, Canada,[2]Ottawa Hospital Research Institute, Ottawa, ON, Canada,[3]Assistant Professor, Dept. of Oncology, Department of Oncology, McMaster University, Hamilton, ON, Canada

Estrogen-receptor-positive (ER+) breast cancers (BCs) make up approximately 70%-80% of BC cases and demonstrate low lymphocyte infiltration, mutational burden, and modest objective response rates to immune checkpoint blockade (ICB), making them attractive candidates for novel immunostimulatory combination therapies. Here, we employ CosMx Single Cell Imaging (SMI) technology to spatially profile the transcriptional landscape of ~6000 targets in 9 ER+ BC patients, both pre- and post-treatment with the anti-PD-1 antibody Cemiplimab, to identify spatially resolved mechanisms of resistance and potential therapeutic targets. After quality control, ~3.1 million cells across 18 unique tissue sections were analyzed, allowing for robust characterization of immune, stromal, and epithelial cell niches with the ability to identify rare immune cell subsets at a high resolution. Comparing relative abundances of cell types of patients pre- and post-therapy, we see a high concordance of cell-types between tissue sections of the same patient. While 8/9 patients were dominated by Luminal A/B cancer epithelial cells, one patient had purely basal cancer epithelial cells, highlighting the value in spatial transcriptomic platforms for molecular subtyping in BC patients. To define metrics of patient response to Cemiplimab therapy, we quantified changes in tumor-intrinsic inflammatory/immune pathways and leveraged spatial information to calculate changes in tumor-infiltrating lymphocytes (TILs). 3/9 patients showed increased levels of type I/II IFN signaling in the tumor epithelium, 5/9 showed no change, and 1/9 showed a sharp decrease, coinciding with a unique increase in TNF-α signaling via NF-κB. 6/9 patients showed increases in TILs following therapy, defined as the fraction of tumor cells ≤ 0.1 mm from the nearest CD8 T-cell. The patient with the most pronounced decrease in TILs was the same patient who showed reduced IFN signaling previously, indicating agreement between response indicators, and suggesting upregulation of TNFa signaling via NFkB as a resistance mechanism to T-cell invasion. Our early work provides a comprehensive spatially resolved analysis of the mechanisms through which ER+ BCs resist ICB, suggesting that spatially mapped transcriptional programs can uncover actionable resistance pathways, and guide the design of next-generation immunotherapeutic combinations for ER+ BC.

#3957 Spatially derived transcriptomic predictors of immune checkpoint blockade outcome in advance gastric cancer.

Changjin Hong[1], Sunho Park[1], Jean R. Clemenceau[1], Minji Kim[1], Inyeop Jang[1], Seock-Jin Chung[1], Sung Hak Lee[2], Sam C. Wang[3], Tae Hyun Hwang[1]

[1]Section Surgical Research, Vanderbilt University Medical Center, Nashville, TN,[2]St. Mary's Hospital Pathology, The Catholic University of Korea, Seoul, Korea, Republic of,[3]Department of Surgery, University of Texas Southwestern Medical Center, Dallas, TX

Background: Advanced gastric cancer (GC) responds poorly to systemic therapy, including Immune Checkpoint Blockade (ICB), yet how the tumor microenvironment (TME) drives resistance remains unknown. We assembled the largest spatial transcriptomic dataset in Immune Checkpoint Blockade (ICB)-treated GC, derived signatures encoding spatial composition and their cellular functions and phenotypes, and validated these as outcome predictors across bulk, single-cell, and independent spatial cohorts.
Methods: Pre-treatment samples from advanced GC patients receiving ICB were profiled using spatial transcriptomics to derive spatial signatures that deconvolve immune, stromal, and tumor compartments and capture TME niches associated with ICB non-response. These spatial signatures were projected onto multiple external datasets, including four bulk RNA-seq cohorts, one single-cell RNA-seq cohort, two 10x Visium cohorts (27 GC samples), and one proteomic cohort, representing the largest integrated validation set for GC immunotherapy biomarkers to date.
Results: Spatial immune signatures in non-responders showed Th2, regulatory Th17, and a homing-lymphocytes program marked by VLA-4 and CXCR4, confirmed in scRNA-seq. Stromal signatures in non-responders included inflammatory CAF programs, complement system activation (C1S, C3, A2M, IL6ST), growth-factor signaling, and MHC-II antigen-presenting states. When projected onto bulk RNA-seq and proteomic cohorts, these spatial immune and stromal modules were consistently enriched in clinical non-responders and associated with inferior survival. In 10x Visium data, non-responder stroma exhibited a strong complement system, aligned with ECM remodeling and myofibroblast properties, and showed reduced neighboring T-cell infiltration. Spatial bivariate analyses localized MHC genes and M2-like $C1q^{+}$ macrophages to inflamed stromal niches. Additional non-responders, including an MSI-H case, retained Th2-dominant profiles, whereas responders revealed higher tumor-antigen expression and dendritic-cell activation.
Conclusion: Spatially derived transcriptomic signatures that incorporate functional states of the GC immune microenvironment robustly distinguish ICB non-responders across bulk, single-cell, and independent spatial datasets. These data nominate the inflammatory stromal niches, $C1q^{+}$ macrophage clusters, and skewed Th2 as actionable features of ICB resistance and potential therapeutic targets. Our results support incorporating spatial transcriptomics into pre-treatment assessment to refine patient selection, prioritize combination strategies that remodel the stromal-immune interface, and advance toward clinically deployable, GC-specific biomarkers for immunotherapy.

#3958 Spatial transcriptomic profiling of peritoneal metastases identifies multicellular programs in patient tumors undergoing pressurized intraperitoneal aerosol chemotherapy (PIPAC).

Heini Maaret Natri[1], Arianna L. Williams-Katek[1], Muhammad Talha Waheed[2], Tiana Li[3], Marwan Fakih[4], Mingye Feng[5], Amit Merchea[6], Sue Chang[7], Richard L. Whelan[8], Danielle Deperalta[8], Thanh H. Dellinger[2], Nicholas Banovich[1], Mustafa Raoof[2]

[1]Division of Bioinnovation and Genome Sciences, TGen (The Translational Genomics Research Institute), Phoenix, AZ,[2]Department of Surgery, City of Hope, Duarte, CA,[3]Department of Cancer Genetics and Epigenetics, City of Hope, Duarte, CA,[4]City of Hope National Medical Center, Duarte, CA,[5]Department of Immuno-Oncology, City of Hope, Duarte, CA,[6]Department of Surgery, Mayo Clinic, Jacksonville, FL,[7]Department of Pathology, City of Hope, Duarte, CA,[8]Department of Surgery, Northwell Health, New York, NY

Peritoneal Carcinomatosis (PC) is a metastatic cancer of the lining of the abdominal cavity, most often originating from the gastrointestinal or gynecological tracts. PC occurs in approximately 20% of colorectal cancer and 60% of ovarian cancer cases, with estimated 5-year survival rates as low as 6%.

Pressurized intraperitoneal aerosolized chemotherapy (PIPAC) is a locoregional drug delivery modality administered via a minimally invasive laparoscopic approach. PIPAC shows promise in the treatment of peritoneal metastasis in early trials on colorectal cancer (CRC) or appendiceal cancer (AC) in patients who cannot undergo cytoreductive surgery.

The spatial organization of the tumor microenvironment (TME) and the complex cellular interactions within profoundly shape biology and treatment response. Spatial transcriptomics offers an opportunity to characterize TME heterogeneity in its native architecture, allowing the identification of biomarkers, interactions, and gene expression programs as well as resistance mechanisms and new potential targets.

We performed image-based spatial transcriptomic profiling of 152 tissue samples, including 50 pre-treatment and 65 post-treatment metastatic tumors and 17 pre-treatment and 20 post-treatment tumor-adjacent normal tissue samples from 19 patients who participated in a Phase I trial on Oxaliplatin PIPAC. Through a comprehensive characterization of transcriptional profiles of a total of 1,249,711 cells, as well as cellular neighborhood and ligand-receptor interactions, we describe the heterogeneity of PC in its spatial context.

We have further characterized treatment-driven changes in pre- and post-treatment tumors of a subset of 7 patients who underwent PIPAC with mitomycin IP. Through cell-based niche and proximity analyses, we identify distinct shifts in the composition and architecture of treated tumors. Most notably, treatment resulted in an 87% decrease in the number of malignant cells, as well as an expansion of the plasma-barrier niche and an increased number of immune infiltrates. Further analysis revealed distinct differences in the abundance of specific cancer-associated fibroblast and immune subsets, demonstrating changes in TME architecture.

Overall, our results provide an invaluable characterization of PC in CRC and AC, garnering new insight into their architecture, cellular composition, and cell-cell interactions at baseline and in response to regional chemotherapy. Further analyses and follow-up studies can identify and validate new, actionable biomarkers to target these hard-to-treat tumors.

#3959 Novel methodology to explore glioma malignant transformation with spatial multi-omics.

Michal Polonsky[1], Jonathan Fox[1], Sheel Shah[2], Noa Hadas[1], Richard Everson[2], Long Cai[1]

[1]Biology and Biological Engineering, CalTech - California Institute of Technology, Pasadena, CA,[2]Neurosurgery, UCLA, Los Angeles, CA

Low-Grade Gliomas (LGG) generally have an indolent course and good prognosis after maximal safe resection; however, these tumors can progress into high grade gliomas through a poorly understood process of Malignant Transformation (MT). We sought to identify molecular drivers and cellular interactions predictive of MT, with the aim of informing early detection and providing new treatment targets. We developed a novel spatial multi-omics approach termed seqFISH+ which allows us to quantify the transcriptional states and DNA profiles of single cells within patient biopsies. With this approach, clones of cancer cells can be identified by shared DNA profiles, and matched with their transcriptional profiles and cellular interactions within the tumor microenvironments. We applied our experimental methodology to biopsies of 19 LGG patients as well as three Glioblastoma patients and compared the transcriptomic and genomic landscape of LGG patients which underwent MT to those that did not. We used a tailored gene panel to measure expression of 1150 genes and identified 12 cell types within the tumor biopsies encompassing malignant cell subtypes, immune cells and normal stromal cells. In addition to transcriptomic data, our novel pipeline allowed us to quantify hundreds of DNA loci within the same cells encompassing the entire genome at 3.3Mb resolution. Our final data set contained transcriptomic data of >600k single cells with matched DNA data for >200k cells. With our transcriptomic data we were able to identify known as well as novel gene markers associated with malignancy of LGG tumors. Our DNA data identified known chromosomal alterations such at 1p/19q deletion within malignant cells. As the location of the cells is left intact, we can now probe the spatial organization of the tumor-microenvironment and identify spatial signatures correlating with MT. DNA information will be used to identify individual cancer clones which contribute to progression. This information will enable us to identify clinically relevant molecular events and cellular interactions, which can be used as biomarkers for progression. With this highly multiplexed data we are constructing a comprehensive dictionary of cell intrinsic changes coupled with changes in the microenvironment to elucidate drivers of the MT process.

#3960 Spatially resolved transcriptomic signatures of gallbladder carcinogenesis from precursor to undifferentiated stages.

Yeseul Kim[1], Yoseob Lee[2], Harim Oh[1], You-Na Sung[1], Yoo Jin Lee[1], Yona Kim[1], Inho Park[3], Jinhyuk Bhin[2], Su-Jin Shin[3]

[1]Department of pathology, Korea University Anam Hospital, Seoul, Korea, Republic of,[2]Department of Biomedical Sciences, Yonsei University College of Medicine, Seoul, Korea, Republic of,[3]Department of pathology, Gangnam Severance Hospital, Seoul, Korea, Republic of

Background: Biliary intraepithelial neoplasia (BilIN) is recognized as a precursor lesion of gallbladder carcinoma. However, the transcriptomic alterations underlying the sequential process of carcinogenesis remain poorly understood. Moreover, the differentiation status of gallbladder carcinoma varies among patients, with some tumors exhibiting both differentiated and undifferentiated components within the same tumor. To elucidate key transcriptomic changes across this histologic spectrum, we performed spatial transcriptomic analysis on gallbladder tumor samples containing coexisting areas of normal epithelium, BilIN, differentiated carcinoma, and undifferentiated carcinoma to understand the molecular differences between lesions within individual patients.
Methods: A total of 59 regions of interest (ROIs) were selected from 13 patients, including normal (n = 11), dysplasia (n = 14), differentiated carcinoma (n = 22), undifferentiated carcinoma (n = 8), and metastatic lesions (n = 4). Spatial transcriptome profiling was performed using GeoMx Digital Spatial Profiling (GeoMx DSP) with EpCAM staining. The maximum size of each ROI was 750 × 625 μm, and each ROI included at least 200 cells. From GeoMx DSP-derived expression profiles, gene-expression dynamics were patterned via A-orthogonal nonnegative matrix factorization (AONMF), and epithelial-stromal crosstalk was inferred via weighted gene co-expression network analysis (WGCNA).
Results: Pathway enrichment analysis revealed bile acid metabolism and fatty acid metabolism were highest in normal spectrum and progressively diminished with histological worsening. From the differentiated spectrum, cell proliferation programs were upregulated, and the undifferentiated spectrum was characterized by EMT signature. Epithelial-stromal interaction analysis showed a TNC-ITGB1 axis in epithelial regions that activates TGF-β signaling in stromal cells within undifferentiated carcinoma. Patients harboring undifferentiated carcinoma exhibited distinct transcriptional patterns within the differentiated regions, showing increased HDGFL3 and decreased MMP1 expression compared with patients without progression to undifferentiated carcinoma, suggesting that HDGFL3 upregulation may represent an early molecular cue preceding dedifferentiation.
Conclusion: This study provides spatial transcriptomic insights into the sequential carcinogenic process of gallbladder tumorigenesis. EMT pathway is elevated in the undifferentiated spectrum in association with the TNC-ITGB1 axis, and HDGFL3 is upregulated in differentiated regions of patients harboring undifferentiated components. Thus, upregulation of HDGFL3 may serve as potential predictive biomarkers for the progression from BilIN to undifferentiated gallbladder carcinoma.

#3961 Identifying the molecular signature of infiltrating edge cells in glioblastoma as drivers of tumour invasion and recurrence.

Alyona Ivanova[1], Shamini Ayyadhury[2], Yanxia Ma[3], Xuehong Gui[3], Akshay V. Basi[3], Megan Yijun Wu[4], Trevor J. Pugh[5], David G. Munoz[6], Sungnam Cho[3], Tosin Oyewale[7], Lucas Schutz[7], Chibawanye I. Ene[3], Jared K. Burks[3], Sunit Das[8]

[1]University of Toronto, Toronto, ON, Canada,[2]PMGC, UHN, Toronto, ON, Canada,[3]MD Anderson, Houston, TX,[4]Lab Research Project Coordinator, The Hospital for Sick Children, Toronto, ON, Canada,[5]UHN Princess Margaret Cancer Centre, Toronto, ON, Canada,[6]St. Michael's Hospital, Toronto, ON, Canada,[7]Ariadne.ai, Heidelberg, Germany,[8]Asst. Professor, Dept. of Surgery, University of Toronto, Toronto, ON, Canada

Glioblastoma (GBM) is the most common malignant brain tumor in adults. Despite extensive research, there haven’t been remarkable gains in resolving the seeds of GBM recurrence, and the outcomes for many patients suffering from this devastating disease remain poor. Our knowledge on GBM heterogeneity is mostly restricted to the surgically resectable tumor core, while functional characterization of tumor cells at the infiltrating edge remains largely elusive due to the presence of normal functional brain tissue in the peritumoral lesion. Edge-derived cells exhibit larger capacity for infiltrative expansion and are the main drivers of treatment failure and tumor recurrence, making them action targets for novel treatment approaches.In this study, we present a first-of-its-kind integrative spatial investigation of GBM, combining two complementary spatial omics modalities high-definition spatial transcriptomics (ST - Visium HD) and spatial proteomics (SP - COMET) to achieve a comprehensive morphological, transcriptomic, and proteomic characterization of invasive tumor edge in situ. This multimodal spatial framework enabled to resolve the complex molecular landscape of the GBM periphery and to identify druggable biomarkers specific to edge-derived malignant cell populations.By integrating pathologically annotated H&E images with high-resolution spatial gene expression, we delineated patterns of tissue architecture and captured continuous gradients of gene expression across tumor-brain interface. Using NicheCompass, we dissected tissue hierarchies and spatially localized cellular processes within the infiltrative compartment of GBM. Through unsupervised phenotyping, we identified top spatially variable genes and active gene programs, revealing modules indicative of tumor cell hijacking of neuronal pathways. These findings align with previously described mechanisms of glioma-neuron synaptic coupling and formation of neurite-like tumor microtubes, consistent with enrichment of OPC- and NPC-like cellular states at tumor margin.Complementing the transcriptomic layer, SP was used to guide single-cell segmentation for ST analysis, infer cell types based on canonical phenotypic markers, and characterize cell state and function through protein-level profiling. This dual-modality approach allowed for precise spatial mapping of highly invasive edge cell populations and their functional states.By integrating multiple spatial omic layers, our study provides an unprecedented multimodal view of GBM invasion and identifies novel, spatially defined biomarkers that distinguish malignant edge-derived cells. These findings hold potential translational value as diagnostic and prognostic tools, enabling early assessment of treatment response and facilitating personalized therapeutic strategies aimed at mitigating GBM progression and recurrence.

#3962 Same-species multiplex IF with HCR™Gold IF: Cross-clone benchmarking using Abcam's oncology-validated primaries.

Wudy Yang[1], Randy Chen[1], Harry Choi[1], Aneesh Acharya[1], Will Howat[2]

[1]Molecular Instruments, Inc., Los Angeles, CA,[2]Abcam, Cambridge, United Kingdom

Background: Spatially resolved, multiplexed immunofluorescence (mIF) is essential for oncology research to profile tumor-immune architecture, track pathway activation, and stratify biomarkers in precious FFPE specimens. Conventional mIF is often limited by species constraints, secondary antibody cross-reactivity, and custom conjugations that slow panel development. Here, we present a plug-and-play workflow that pairs HCR™ Gold IF and Encoder reagents with Abcam's broad portfolio of primary antibodies to deliver robust same-species multiplexing with minimal optimization and rapid turnaround, streamlining setup from antibody order to imaging in about one work week.

Methods: The HCR™ HiFi Encoder binds with high affinity to the Fc domain of unmodified primary antibodies, forming a stable 1:1 complex without compromising antigen recognition. This encoding process is fully compatible with commonly used antibody buffers. Human cancer lines and FFPE tumor sections (e.g., lung, breast, colorectal) were processed using standard fixation/antigen retrieval, permeabilization, and blocking. Off-the-shelf Abcam primary antibodies were HiFi-encoded and detected with fluorophore-labeled HCR™ Gold amplifiers. Multiplexing was achieved by assigning orthogonal HCR™ initiators to each unmodified antibody, allowing simultaneous detection of multiple targets within a single sample. No primary conjugation or iterative stripping steps were required. Panels included oncology-relevant markers for epithelium (panCK), immune subsets (CD3, CD8, CD68), proliferation (Ki67), and stroma (a-SMA).

Results: Same-species multiplexing with Abcam primary antibodies produced high-contrast images that preserved expected subcellular/localization patterns across tumor cells, immune compartments, and stroma. Orthogonal Encoders minimized channel crosstalk and HCR™ Gold amplification yielded bright, linear signals suitable for quantitative comparisons across regions of interest. Replicate runs across tissues showed consistent signal-to-background and spatial patterns. Panel build time was markedly reduced; researchers can purchase Abcam antibodies and generate imaging-ready data in ~5 days, enabling rapid iteration of oncology panels and testing of alternative clones.

Conclusions: HCR™ Gold IF with Encoders provides a practical, cancer-focused solution for standardized, same-species multiplex IF using widely available Abcam primary antibodies. The enzyme-free, isothermal amplification preserves epitopes while delivering sensitive, reproducible signals, supporting robust characterization of the tumor microenvironment, pathway activity, and checkpoint expression from limited clinical material. This streamlined, plug-and-play approach lowers barriers to spatial biomarker studies and accelerates discovery and translational research.

#3963 Spatially Resolved Cell-Cell Communication Reveals Intra-tumoral heterogeneity in Small Cell Lung Cancer.

Tingxiao Gao, Jalal Kazan, Fatema Zohora, Gregory Schwartz, **Benjamin Lok**

Medical Biophysics, University of Toronto, Toronto, ON, Canada

Introduction: Small cell lung cancer (SCLC) is an aggressive neuroendocrine malignancy with a 5-year survival rate of only 7%. Despite ongoing advances, most patients derive limited benefit from existing therapies, underscoring the need to better understand mechanisms of SCLC progression and resistance. Cell-cell communication (CCC) through ligand-receptor (LR) interactions has been studied to have a key role in regulating process that influence tumor cell plasticity and spatial organization. We hypothesize that tumor-tumor CCC mediates heterogeneity within SCLC and contributes to its aggressive phenotype. Method: We generated spatial transcriptomic profiles from two SCLC circulating tumor cell-derived xenograft (CDX) samples at single-cell resolution using VisiumHD. Hematoxylin and eosin (H&E) staining confirmed the neuroendocrine morphology of each sample by an expert pathologist. We inferred CCC using CellNEST, a graph neural network model our lab developed to detect intercellular LR interactions directly from spatial transcriptomic data. Results: Across both CDX samples, we identified 380,790 high-confidence LR interactions at single-cell resolution. The five most frequently observed LR pairs were L1CAM-L1CAM (n=5430), MDK-PTPRZ1(n=5260), NECTIN1-NECTIN1(n=4172), VEGFA-NRP1 (n=2984) and GRN-SORT1 (n=2840). These LR pairs are biologically consistent with known pathways in SCLC, including those regulating cell adhesion, angiogenesis, and neuroendocrine differentiation. By spatially mapping these recurrent LR back to the tissue, we further revealed interesting region-specific communication patterns, suggesting that CCC contributes to transcriptionally and morphologically distinct tumor subregions. Discussion: This study provides spatially resolved characterization of tumor-tumor interactions in SCLC CDX models at single-cell resolution. By identifying highly recurrent LR interactions and mapping their spatial organization, we aim to uncover potential biological mechanisms underlie intra-tumoral heterogeneity. Ongoing work will expand this framework to larger SCLC cohorts to identify CCC-driven transcriptional programs and evaluate their potential as biomarkers and therapeutic targets to shed light on future therapeutic strategies for SCLC.

#3964 Spatial profiling of the neuroblastoma tumor microenvironment using seqFISH.

Christopher Riccardi[1], Michal Polonsky[2], Michael J. Zobel[1], Rebekah Kennedy[1], Melody Khoshneviszadeh[1], Anya Zdanowicz[1], Bruce Pawel[1], James Amatruda[1], Long Cai[2], Shahab Asgharzadeh[1]

[1]Children's Hospital Los Angeles, Los Angeles, CA,[2]California Institute of Technology, Pasadena, CA

Background: Neuroblastoma is the most common extracranial solid tumor of childhood, and high-risk disease remains difficult to treat. Increasing evidence suggests that interactions among tumor cells, immune populations, and stromal elements influence progression and therapeutic response. However, the spatial organization and subtype diversity of these populations within intact tumors remain poorly defined.

Methods: We applied seqFISH, a spatial transcriptomic platform, to eight regions of interest (ROIs) from fresh-frozen tumors of seven patients using a custom 2,514-gene panel, and to three ROIs from two tumors using a commercial 516-gene immuno-oncology panel. Tumor specimens represented a range of clinical risk groups and included primary, metastatic, MYCN-amplified, and post-therapy states. All samples were analyzed and integrated using the scVI Python package, a deep generative model that extracts latent embeddings from high-dimensional data while mitigating batch effects and preserving biologically relevant structure. To assign cell identities, we developed a novel joint-analysis algorithm that integrates seqFISH data with the NBAtlas single-cell RNA-seq reference (362,991 cells across 61 patients), enabling initial mapping of major neuroblastoma, immune, and stromal lineages, followed by refinement through spatial context, proximity relationships, and canonical marker gene expression. CAFs, TAMs, and T-cell populations were re-integrated separately to resolve subtype structure, and spatial statistics methods were used to identify cell-type associations occurring more frequently than expected by chance.

Results: We profiled over 450,000 spatially resolved cells and identified major cell types with high-confidence NBAtlas-guided assignments. Neuroblastoma tumor cells displayed proliferative signatures associated with clinical risk, mirroring patterns observed in NBAtlas. We resolved diverse stromal states - including vascular, inflammatory, interferon-stimulated, myofibroblastic, and tumor-like CAFs - and distinguished M1- and M2-like TAM subsets in situ. Spatial analyses revealed conserved neighborhoods, including enrichment of $CD4^+$ naïve/central-memory T cells adjacent to inflammatory CAFs and strong co-localization between vascular CAFs and endothelial cells.

Conclusion: By integrating seqFISH with a large neuroblastoma single-cell reference, we generate a detailed spatial map of the neuroblastoma tumor microenvironment. This combined approach enables refined identification of cellular subtypes and reveals reproducible microenvironmental structures that may influence tumor behavior and therapeutic vulnerability. Ongoing efforts include expanding sample size, incorporating *spatial* copy-number analysis, and applying this framework to additional pediatric solid tumors.

#3965 Spatialomics detection of neuroendocrine involvement in cancer tissue.

Scott T. Clarke, Chris Vonnegut, Leticia Montoya, Mae Voeun, Wenjun Zhou, Anna Cartier, Aleksey Rukavishnikov

Thermo Fisher Scientific, Waltham, MA

The study of neuroendocrine involvement observed in inflammation, neuronal damage, cancer, and neurodegenerative disease is an emerging field offering new opportunities of intervention and treatment of currently intractable disease. Cancer cells are known to invade the space surrounding neurons (perineuronal invasion) and derive pro-survival and anti-apoptotic benefits from the nerve fibers and their neurotransmitters, secreted amines and peptides. Formation of new neural tissue is a characteristic of cancer with poor prognosis. We present a spatial-omics approach of multiplexing immunohistochemistry (IHC) with mRNA in situ hybridization (ISH) detection to examine the microenvironment of neuroendocrine involvement and the biomarkers relevant to these tissues and infiltrating immune cells. We image both protein and mRNA abundance and distribution in FFPE tissue with neuroendocrine involvement. ISH detection uses single stranded branched DNA amplification scheme (ss-bDNA) for single molecule detection, while IHC detection uses direct antibody labeling for moderate and high abundant targets and enzymatic signal amplification for low abundant targets. We present protocol modifications with significant improvements minimizing incompatibility between IHC and ISH otherwise resulting in diminished or loss of signal. These modifications retain IHC and ISH signal, minimize auto-fluorescence, and shorten protocol time required for multiplexed workflows. We show multiplex IHC labeling of neural biomarkers such as S100B, CD56, glial fibrillary acidic protein (GFAP), chromogranin A (CgA) and synaptophysin in relevant tissue which are often over-expressed in non-endocrine structures and tissues of some tumors, and in neurodegenerative disease models. The presence of neural mRNA expression, combined with immune markers such as FoxP3 and PD-1, PD-L1 and proliferation markers of PCNA and Ki-67 in cancer tissue, reveal the neuroendocrine involvement in the tumor immune microenvironment. For Research Use Only. Not for use in diagnostic procedures.

#3966 *In situ* spatial multiomic profiling of breast cancer tissue utilizing the CosMx Spatial Molecular Imager.

Megan Hopkins[1], Oliver De Sa[1], Dan Dion[2], Vida Talebian[2], Jane Bayani[2], Melanie Spears[2]

[1]Diagnostic Development, Ontario Institute for Cancer Research, Toronto, ON, Canada,[2]Ontario Institute for Cancer Research, Toronto, ON, Canada

Breast cancer is a leading cause of cancer-related death among Canadian women. Advances in treatment have underscored the importance of tumor heterogeneity, and the diverse cellular composition of the tumor microenvironment across molecular subtypes. The evolution of single cell imaging technologies now allows researchers to incorporate spatial context when evaluating these complex cellular interactions, allowing cellular and sub-cellular resolution across the proteome and transcriptome. In this study, a 100-core tissue microarray (TMA) from 25 breast cancer tissue blocks spanning molecular subtypes was utilized. A single 5-micron section was subjected to two consecutive rounds of staining for CosMx SMI proteomic profiling using the 64-plex Immuno-Oncology assay followed by transcriptomic profiling using the 6K RNA assay. In total, 102 fields of view (FOVs) were profiled following the CosMx Multiomic Assay protocol (MAN-10201-04). After quality control of the protein assay, we profiled 175,139 cells identifying a mean of sixty-seven unique proteins per cell. With subsequent staining for the 6K RNA assay, 120,797 cells were profiled, using the overlaid FOV map for downstream data stitching, identifying a total of 6,176 genes, a mean of 365 unique genes per cell, and a mean of 556 transcripts per cell. To check concordance of cell typing, we identified HER2 as a consistent target between the clinically reported data, inclusion in the protein panel and inclusion (ERBB2) in the RNA panel. We found all core HER2 expression measured via the CosMx SMI matched the clinical annotations, and a strong correlation between HER2 protein expression and ERBB2 gene expression across the entire flow cell ($r=0.79$, $p=5.71e-23$). Conversely, Ki67 displayed a weak correlation ($r=0.13$, $p=0.201$), highlighting the importance of evaluating both metrics to discern a full picture of biological processes. CELESTA cell typing identified various structural cells expected to be found in breast tissue within the proteomic profiling (adipose, endothelial, epithelial, and vascular smooth muscle cells), along with various immune populations including B cells, CD4+, CD8+ T-cells, dendritic cells, natural killer cells, neutrophils, macrophages, and fibroblasts. These findings were corroborated in the transcriptomic data, with InSituType supervised clustering (BreastCancer_Wu.RData) revealing populations of cancer associated fibroblasts (CAFs), tumor associated macrophages (TAMs), tumor infiltrating lymphocytes (TILs), both naïve and memory B cells, along with basal, HER2+, Luminal A and Luminal B epithelial cell populations. In ongoing work, we continue to integrate proteomic and transcriptomic data to further investigate unknown cell populations found across the TMA and categorize fundamental differences in tumor epithelium interactions across molecular subtypes of breast cancer.

#3967 Spatial whole transcriptomic profiling of breast cancer tissue with CosMx Spatial Molecular Imager.

Megan Hopkins, Oliver De Sa, Dan Dion, Vida Talebian, Jane Bayani, Melanie Spears

Ontario Institute for Cancer Research, Toronto, ON, Canada

Spatial transcriptomics provides an opportunity to investigate the relationship between gene expression and tissue architecture, revealing new insights into cell-to-cell interactions that promote tumorigenesis, immune evasion, and other disease mechanisms. Here we employ the CosMx SMI Whole Transcriptome assay to profile 87 cores from a tissue microarray (TMA) of 25 breast cancer blocks spanning molecular subtypes. A single 5-micron section was stained following Bruker's published protocol (MAN-10184-06) with the Human Whole Transcriptome Panel (WTX), 19K-plex, utilizing 37,872 imaging barcodes to capture over 18,000 genes in the human protein-coding transcriptome. We analyzed 154,213 cells and identified 18,934 genes overall, with mean transcripts per cell of 926, and in the 90^{th} percentile identifying 2,060 transcripts per cell. Cells were assessed for quality control, normalized and cell-typed using InSituType with a reference profile of well-defined breast epithelial, stromal, and immune cells. We compared molecular subtyping of the cancer epithelium as assigned by InSituType with subtyping by histology, finding a high overall concordance between core-level subtype assignment and spatial single-cell assignments. Strikingly, basal cell types were present at high levels across all cores regardless of subtype, making up 98%, 64%, 50%, and 30% of triple negative, Luminal A, HER2, and Luminal B cores, respectively. HER2 enriched cells were the most unique, making up ~45% of HER2 core cells and <1% of cells in other cores. These results display the heterogeneity of tumor cell composition and emphasize the value of single-cell resolution in molecular subtyping when designing targeted therapeutics. We next investigated immune cell compositions of all cores and found Myeloid lineages to be the most dominant, followed by T and B cells. Immune cells were similar in composition across different subtypes, however, varied by their spatial distribution in the tumor, with the triple negative subtype displaying the highest level of tumor infiltration. In ongoing work, we continue to characterize inter- and intra- core heterogeneity to further understand how local immune niches and the surrounding microenvironment shape the initiation or suppression of tumorigenic programs.

#3968 Spatial transcriptomic features associated with response to neoadjuvant therapy in triple-negative breast cancer.

Shiqing Liao, Teia Noel, Joseph Lownik, Pavithra Nedumaran, Yoona Yang, Richard Mebane, Aagam Shah, Andrew Martinez, Akil A. Merchant, Simon Knott

Cedars-Sinai Medical Center, Los Angeles, CA

Background: The KEYNOTE-522 trial established pembrolizumab plus neoadjuvant chemotherapy as a standard for early-stage triple-negative breast cancer (TNBC) by significantly improving pathologic complete response (pCR) and event-free survival. Yet biomarkers predicting response and the biology underlying residual disease—particularly the divergent outcomes observed among patients with residual cancer burden class 2 (RCB2) from chemotherapy only and chemotherapy plus immunotherapy—remain poorly defined. We hypothesized that spatial cellular architectures at diagnosis, and their longitudinal remodeling with therapy, govern TNBC treatment response and resistance.

Methods: We performed single-cell resolution spatial transcriptomic profiling on 131 diagnostic biopsies, 161 resection specimens, and 38 metastatic lesions from patients treated with neoadjuvant chemotherapy with or without pembrolizumab, including 50 paired pre/post-treatment samples for longitudinal analysis. A 60-marker spatial proteomic panel provided cross-modality validation. Spatial features, including cell-type abundance, co-localization, tumor-immune interface structure, and niche organization, were evaluated across pCR versus non-pCR groups, RCB classes (0-3), and longitudinal transitions within each therapeutic arm.

Results: Across 6 pathologist-annotated histologic regions, we resolved 17 major cell types, 72 gene-defined subtypes, and 96 spatial communities. Early analyses highlight contrasting $CD8^+$ T-cell spatial states: intra-tumoral $CD8^+$ infiltration characterizes responders, whereas stromal-restricted $CD8^+$ localization, together with $CD33^+$ myeloid programs, marks non-response and T-cell exclusion. Additional cohort-specific variation was observed in fibroblast density, stromal architecture, and myeloid-lymphoid proximities. Integrating diagnostic and longitudinal spatial features, we are developing an interpretable spatial risk score to distinguish treatment response and RCB class.

Conclusions: This study represents one of the largest integrated spatial transcriptomic and proteomic analyses of TNBC neoadjuvant therapy to date. Emerging patterns suggest that cytotoxic T-cell access to tumor nests marks effective anti-PD-1 response, whereas fibroblast-driven stroma and myeloid-mediated exclusion underlie resistance. These insights provide a roadmap for designing combination therapies to overcome stromal and myeloid barriers to neoadjuvant immunotherapy.

#3969 Stereoseq spatial transcriptomics reveals cell-type contributions to prostate cancer metastasis.

Jonathan Panzer[1], Shannon Carskadon[2], Albert Levin[1], Sean Huang[3], Vikrant Kumar[3], Indra Adrianto[1], **Nallasivam Palanisamy**[2]

[1]Public Health Sciences, Henry Ford Health, Detroit, MI,[2]Urology, Henry Ford Health, Detroit, MI,[3]MIRXES Lab Private Limited, Singapore, Singapore

Prostate cancer remains a significant cause of morbidity and mortality among men, with African-American (AA) men experiencing a disproportionate disease burden. Although molecular profiling has advanced our understanding, the cellular origins and spatial microenvironmental transitions that drive malignant progression and metastatic potential remain incompletely defined. To characterize these transitions, we performed high-resolution spatial transcriptomic profiling on benign (n = 1) and malignant (n = 2) prostate tissues obtained from three AA men using STEREO-seq (SpaTial Enhanced REsolution Omics-sequencing), generating 83,144 cell-bins across all samples. Data were processed using the STEREO-seq Analysis Workflow (SAW v6.0) and analyzed with Stereopy and Seurat. Cell-type annotation was performed using Azimuth with the Prostate Cell Atlas as a reference, and stringent quality filters (>20% mitochondrial RNA or annotation confidence <0.5) resulted in 63,861 high-confidence annotations. Spatial niche characterization was performed using QUICHE (QUantitative InterCellular nicHe Enrichment) to define microenvironmental structure and cell-cell ecosystems. Compositional analysis revealed a pronounced expansion of club epithelial (CE) cells in malignant tissues, with enrichment correlating with tumor grade, accompanied by a marked reduction in fibroblasts. CE cells in high-grade lesions showed strong upregulation of LTF (avg_log2FC = 6.92, padj = 7.9×10^{-67}), while fibroblasts exhibited widespread loss of actin-associated genes (ACTG2, ACTA2, ACTB), indicating cytoskeletal disruption and microenvironmental remodeling. Basal epithelial cells displayed near-complete loss of KRT15 expression (avg_log2FC = -4.92, padj = 6.1×10^{-281}), suggesting depletion of structural epithelial populations and glandular destabilization. QUICHE analysis revealed distinct tumor-associated spatial niches highly enriched for CE cells, whereas fibroblast-rich niches dominated benign regions. Differential niche-level expression recapitulated global transcriptomic patterns, including loss of tumor suppressor gene activity, architectural breakdown of glandular structures, and activation of pathways implicated in invasion and metastasis. These findings highlight substantial shifts in cellular composition and spatial organization accompanying malignant transformation in prostate cancer. ST profiling identified CE-cell-driven niches and transcriptomic signatures strongly associated with metastatic potential, offering novel biomarkers and spatially defined cellular interactions that improve our understanding of PCa progression in African-American men. This spatially resolved framework provides a foundation for future studies aimed at dissecting microenvironmental drivers of metastasis and developing cell-type-specific therapeutic strategies.

#3970 Genome wide testing of archived ovarian and uterine carcinosarcoma FFPE tissue using FusionPlus Hi-C to determine HRD status.

Amanda Bradshaw[1], Christopher Elms[1], Mia Jeffris[2], Jon Belton[2], Williams Ricketts[2], Alex R. Hastie[2], **Michael Birrer**[1]

[1]Cancer Institute, University of Arkansas for Medical Sciences, Little Rock, AR,[2]Arima Genomics, Carlsbad, CA

Genomic rearrangements such as gene fusions and copy number variation are chromosomal abnormalities important in cancer, including diagnosis and treatment. Approximately 50% of ovarian cancers involve homologous recombination deficiency with characteristic genomic rearrangements. HRD tumors have been shown to respond well to PARPi treatments. PARPi are an approved treatment for cancers known to have abnormalities in DNA repair mechanisms including ovarian cancers. Ovarian and uterine carcinosarcoma is a rare and aggressive form of gynecologic cancer with few diagnostic and treatment options. Genetic testing and HRD assays are invaluable in cancer diagnosis and treatment. Molecular testing in lung and other solid tumors has led to the identification of driver mutations that can be targeted by new therapeutics. Detection of these fusion proteins by RNA sequencing is the current gold standard but evidence suggests that fusions are still missed for various reasons. This study aims to improve detection rate of targetable fusions and rearrangements in solid tumors, ovarian and uterine carcinosarcoma specifically, using a new method called Hi-C sequencing. The Hi-C assay has been promising in locating genomic abnormalities in various types of cancer. Hi-C sequencing is a whole genome DNA-sequencing assay for detection of structural variation based on unique Hi-C chemistry which leverages sequencing of linked pairs of reads which occur nearby one another in 3-dimensional and linear space, from FFPE samples. Linking reads amplifies the rearrangement signal by giving it many more read pairs spanning the breakpoint and also overcoming masked fusions resulting from breakpoints in non-unique sequences. This method is useful for a variety of specimen types and preservation methods as well as archival periods. Hi-C testing works well for formalin fixed paraffin embedded tissue which is important for solid tumor testing such as with carcinosarcoma. We used Hi-C testing on archived FFPE ovarian and uterine carcinosarcoma tissue to determine if it could be beneficial in future cases improving prognosis, and therapeutic choices, particularly in identifying HRD tumors and the use of PARPi treatments. Our data has shown that 7 out of 18 samples tested had aberrations involving genes potentially involved in HRD. These genomic aberrations included significant rearrangements, gene fusions, and loss-of-function in several genes involved in HRD including RAD51B, CHEK2, and FANCA1. These data suggest that Hi-C testing could be a valuable tool in the molecular classification of solid tumor cancers and provide earlier more thorough diagnosis and more precise treatment options for gynecologic carcinosarcoma with the notable benefits of being faster and lower cost, possibly advancing clinical research with the discovery of novel biomarkers and therapeutic targets.

#3971 Rapid antibody drug conjugate markers and RNA biomarkers in solid tumors using a hybrid Ultivue InSituPlex and Protease-Free RNAscope Workflow.

Patrick Savickas[1], AKASH PARVATIKAR[2], Jack Casey[2], Anushka Dikshit[3], AMAN TYAGI[2]

[1]Histowiz, New York, NY,[23]Bio-Techne Corporation, Newark, CA

Introduction: The spatial relationships between tumor cells, immune infiltrates, and the surrounding stroma—characterized by both protein expression and transcriptional activity—are critical determinants of therapeutic response and disease prognosis. Traditional spatial profiling approaches often require serial sections, compromising exact cellular co-localization, or utilize harsh processing steps that degrade target integrity. There is an urgent need for robust, high-throughput, single-slide methods to co-detect protein and RNA with high fidelity.

Methods: We developed and validated a novel, streamlined hybrid workflow combining Ultivue's highly multiplexed InSituPlex technology (protein detection) with Advanced Cell Diagnostics' (ACD) newly developed protease-free capability with RNAscopeTM in situ hybridization (ISH) workflow. This pairing is crucial: the protease-free ISH step prevents the degradation of critical cell surface epitopes required for robust downstream multiplex immunofluorescence (mIF) protein staining. A comprehensive panel was rapidly assembled, including key immuno-oncology protein markers for antibody drug conjugates (ex. HER2) via InSituPlex, co-detected with relevant transcriptional targets (e.g., cytokine mRNA, therapeutic target transcripts) via ISH. The assay was applied to FFPE tissue sections from Non-Small Cell Lung Cancer (NSCLC), Triple-Negative Breast Cancer (TNBC), and Gastric Cancer (GC) to demonstrate broad applicability.

Results: We successfully achieved simultaneous, high-resolution co-localization of up to 5 protein markers and 3 RNA transcripts within a single tissue section across all three heterogeneous cancer types. The protease-free pre-treatment maintained optimal tissue and epitope morphology, enabling exceptional signal-to-noise ratios for both protein and RNA channels. Critically, this combined multi-omic readout allowed for the precise spatial phenotyping of cell populations (e.g., CD8+ T cells co-expressing specific cytokine mRNA) and the assessment of spatial proximity between cells defined by combined protein/transcriptional signatures. The modularity of the Ultivue assay allowed for rapid assembly and substitution of antibody panels, enabling high-speed assay optimization.

Conclusion: This innovative, combined Ultivue InSituPlex and protease-free ACD ISH assay provides a powerful, single-slide platform for spatially resolved multi-omic analysis. It overcomes the technical limitations of traditional sequential staining, offering a high-throughput, high-fidelity tool that can be rapidly deployed for complex biomarker validation, detailed tumor microenvironment characterization, and improved patient stratification strategies in translational oncology and clinical trials.

#3972 Comprehensive immune landscape analysis of solid tumors using a 17-Plex immunofluorescence assay in clinical trials.

Jaspreet Kaur[1], Richard Van Krieken[1], Xun Li[1], Ying Huang[2], Lisa Kattenhorn[2], Naveen Dakappagari[1], Margaret E. McLaughlin[2], Jennifer Bordeaux[1]

[1]Navigate BioPharma Services, Inc., Carlsbad, CA,[2]Novartis BioMedical Research, Cambridge, MA

Background: The tumor micro-environment is highly complex; accumulating evidence indicates that immune cell composition and spatial distribution can contribute to disease progression and inhibition of antitumor immunity. There is a growing effort to leverage new technologies for in-depth analysis of the complexities within the tumor immune microenvironment. We validated a 17-plex, subcellular resolution, pan-immune cell panel to interrogate the immune cell types and their spatial organization in whole tissue sections.
Methods: We co-developed a 17-plex pan-immune cell immunofluorescence (IF) assay with RareCyte® utilizing the Orion™ platform to characterize immune cell populations and their functional states in formalin-fixed paraffin-embedded (FFPE) tissues from melanoma, breast, lung, prostate, and colorectal cancers. A single, 4-micron FFPE section was stained in one-step, using the intelliPATH™ FLX (Biocare Medical) with a cocktail of antibody-fluorophore conjugates targeting Granzyme B, Ki67, CD3e, CD20, CD4, CD163, CD8a, PDL1, NKp46, PD-1, LAG3, FOXP3, CD11b, CD138, SOX10, Cytokeratin, and Hoechst nuclear stain. Imaging was performed on the Orion™ platform, and data were analyzed using HALO® (Indica Labs).
Results: The assay enabled comprehensive spatial profiling of T, B, NK, and myeloid cell distributions within tumor and stromal compartments. Functional states of T cells (cytotoxic, regulatory, exhausted) and macrophage/B-cell niches were distinguished based on immune checkpoint and activation marker expression. Proximity analyses identified immune synapses and organized lymphoid structures, facilitating robust microenvironment characterization.
Conclusions: The Orion™ 17-plex pan-immune cell IF assay will enable comprehensive qualitative and quantitative analysis of the tumor microenvironment in clinical trial specimens. We anticipate that this approach will support the development of next-generation therapies by enabling detailed characterization of immune cell and tumor cell spatial biology across multiple cancer types.

#3973 A framework for antibody validation via spatial proteo-transcriptomics using the CellScape platform.

Tim Schunk[1], Tim Mandelkow[1], Shida Xiong[1], Jonas Raedler[1], Rodler Severin[1], Philipp Nuhn[1], Anne Letsch[1], Marion van Macklenbergh[1], Jan Weitkamp[1], Jakob Kohler[1], Arne Christians[2], Oliver Braubach[3], Steve Lott[3], Micaela Mathiak[1], Gavin Gordon[4], Bjorn Konukiewitz[1], Christoph Rocken[5], **Niclas Christian Blessin**[1]

[1]Universitatsklinikum Schleswig-Holstein, Kiel, Germany,[2]Bruker Spatial Biology,[3]Canopy Biosciences, St. Louis, CA,[4]Bruker Spatial Biology, St. Louis, CA,[5]Professor, Dept. of Pathology, Christian-Albrechts-University, Kiel, Germany

Spatial proteomics depends on antibody reliability, yet many antibodies used in routine diagnostics and research - particularly in conventional brightfield and multiplex fluorescence immunohistochemistry - are only subjectively or insufficiently validated, leading to potential false conclusions and limiting the use of spatial proteomics in large-scale clinical research studies.To address this limitation, we developed a fully automated - thus objective - deep learning-based framework for antibody validation. The in-situ staining patterns and interdependencies of various antibody clones for the same target were compared to the corresponding RNA expression pattern using a network of deep learning algorithms. For this purpose, a tissue microarray (TMA) was constructed from 50 different normal and 50 different neoplastic tissues including carcinoma entities, lymphomas, and other human neoplastic tissues from 1040 patients. All antibody clones were pre-tested in conventional brightfield IHC and assembled in 10- to 30-plex mfIHC assays using the CellScape™ Precise Spatial Proteomics platform (Bruker Spatial Biology, USA)to compare different antibody clones for the same target across 100 different human tissue types. The same TMA slide can then be used for spatial transcriptomics on the CellScape™ via HCR™ Gold (Molecular Instruments, Los Angeles, US) or on the CosMx® Spatial Molecular Imager (Bruker Spatial Biology, USA). A framework of different deep learning models (U-Net and DeepLab3^{+}) was developed for analysing protein and RNA expression. This spatial proteo-transcriptomics approach allows for both (i) the direct deep learning-based comparison of different antibody clones for the same target and (ii) an interpretation in view of the mRNA expression of the corresponding gene on a single-cell level across 100 different healthy and neoplastic tissues across the human body. Through the automatic assessment of every individual antibody clone, objective metrics such as fraction of expression on different tissue-compartments (%), accordance with other antibody clones for the same target (%), as well as correspondence with the RNA expression (%) were computed. Given that linear regression analysis showed an ultra-low signal deterioration across the different cycles (<1 %) - due to the novel EpicIF for gentle bleaching of the fluorochromes on the CellScape platform - a direct comparison of antibodies from different cycles was possible without cumbersome rearrangement of the antibodies for mfIHC panel creation. These findings highlight the potential of using an automated framework for antibody validation in favour of using publicly available non-spatial RNA expression libraries.In conclusion, here we present the first objective, pathologist reviewed, and fully automated deep learning-based framework for antibody validation using spatial proteo-transcriptomics.

#3974 Decoding cancer hallmarks through single-cell whole transcriptome imaging in invasive ductal carcinoma.

Claire Williams, **Patrick Danaher**, Megan Vandenberg, Martin Shelton, Mirko Corselli, Christine Kang, John Lyssand, Joseph Beechem

Bruker Spatial Biology, Seattle, WA

Tumor adaptation to microenvironmental stressors underlies key cancer hallmarks, including immune evasion, altered metabolism, angiogenesis, and uncontrolled proliferation. However, the spatial organization and cell-type specificity of these adaptations remain poorly characterized in intact tissue. To address this, we generated a spatially resolved, single-cell transcriptomic map of a grade II HER2+ invasive ductal carcinoma using the CosMx® Whole Transcriptome assay on the CosMx Spatial Molecular Imager (SMI). We assayed over 600,000 cells within a ~1 cm² FFPE tumor section. Spatial domain mapping and cell classification identified 37 distinct tumor, immune, and other stromal subtypes. Copy number analysis revealed clonal divergence across two tumor lobes and five transcriptionally distinct malignant clusters, suggesting spatially restricted evolutionary trajectories.

To investigate immune evasion, we characterized a robust T-cell infiltrate comprising 7.3% of cells. Spatial and transcriptional analyses revealed cytotoxic CD8+ T cells losing effector function and initiating exhaustion programs upon tumor entry. Tumor cells responded with localized activation of JAK-STAT, MHC-I, and NF-κB signaling, suggesting coordinated resistance to immune attack. These findings highlight spatially organized immune suppression and identify candidate mechanisms that may contribute to T-cell dysfunction in HER2+ breast cancer.

Next, we assessed tumor-induced metabolic reprogramming and angiogenesis, by modeling gene expression relative to vascular proximity. Hypoxia-related genes (e.g., HILPDA, VEGFA) were enriched in vessel-distal regions, while nutrient-associated genes (e.g., AZGP1, PLA2G2A) localized near vasculature. ELF3, a transcription factor associated with poor prognosis in HER2+ cancers, was unexpectedly upregulated in hypoxic zones. Cell cycle analysis revealed low-proliferation regions with stressor-specific transcriptional profiles, indicating localized growth constraints.

This dataset showcases the power of subcellular whole transcriptome imaging in resolving hallmark cancer behaviors directly within tissue context. This same data set could be re-interrogated for any/all of the hallmarks of cancer, even those that haven't been discovered yet. While derived from a single HER2+ breast cancer sample, the analytical framework we present, integrating spatial context with single-cell resolution, serves as a template for future studies investigating patient-specific tumor adaptations to microenvironmental stressors across diverse samples and clinical settings.

#3975 Spatially resolved multi-omics reveal metastatic ecosystem remodeling and immunomodulatory niches in HGSOC.

Yufeng He[1], Ce Luo[2], Yuanguang Meng[3], Zhe Zhang[3], Zexian Zeng[1]

[1]Peking-Tsinghua Center for Life Sciences, Academy for Advanced Interdisciplinary Studies, Peking University, Beijing, China,[2]Center for Quantitative Biology, Academy for Advanced Interdisciplinary Studies, Peking University, Beijing, China,[3]Department of Obstetrics and Gynecology, Seventh Medical Center of Chinese PLA General Hospital, Beijing, China

High-grade serous ovarian carcinoma (HGSOC) is the most lethal gynecologic malignancy. HGSOC spreads within peritoneal cavity via transcoelomic dissemination, and the greater omentum is a frequent site of metastatic tumor deposition. Embedded beneath the omental mesothelium, the fat-associated lymphoid clusters (FALCs, known as milky spots) serve as portals for early peritoneal metastasis. Yet how metastatic ecosystems differ from the primary tumor microenvironment, and are spatially organized around FALCs remains unclear. To address this, we profiled matched primary and metastatic tumor samples from 17 HGSOC patients using single-cell RNA sequencing with paired TCR/BCR profiling and spatial multi-omics including Visium HD spatial transcriptomics, multiplex CODEX imaging and spatial metabolomics. In FALC-rich regions within metastatic lesions, we identify a stereotyped architecture in which small aggregates of B cells and plasma cells are interlaced with $CD4^+$ and $CD8^+$ T cells and dendritic cells. Stromal regions between these FALCs and adjacent tumor border are highly infiltrated by *SPP1*$^+$*C1Q*$^+$ macrophages. We show that the B cells in metastasis mainly consist of IgG^+ and IgA^+ populations, and are class-switched and clonally expanded. Integrating spatial transcriptomics with histology, we found the abundance of the niche enriched for IgA^+ B cells associates with worse overall survival using a deep learning framework. Spatial metabolomics mapped spatial metabolic niches and showed that metastases shift toward glycolytic, lipid and phospholipid metabolism, whereas primary tumors retain more oxidative programs. Collectively, our findings provide a spatially resolved atlas of HGSOC metastasis and a foundation for spatially informed biomarker development.

#4051 BHB299: An AI/ML-optimized high avidity/low affinity CEACAM6-directed T cell engager for diverse solid tumors.
R. Henrici, K. Stephenson, R. Sanyal, M. Montgomery, M. Markova, A. Prater, B. Steurer, T. Park, D. Barreras, N. Huskey, J. Wojciak, J. Corbin, P. Greenside;
BigHat Biosciences, Inc., San Mateo, CA

Background: Solid tumors remain a major cause of global mortality, with millions of new cases annually. Despite a rapidly advancing standard of care, few patients achieve durable responses. CEACAM6 is a cell surface antigen expressed at extremely high levels on CRC (>85%), NSCLC (>50%), Gastric (>30%), Pancreatic (>30%) and a variety of other tumor types where it drives tumor metastasis and immune suppression through heterotypic interactions with adjacent cancer and infiltrating immune cells. CEACAM6 has historically been considered undruggable due to its moderate expression on healthy myeloid cells, which act as a peripheral antigen sink and a source of on-target/off-tumor dose-limiting toxicity.
Methods: A single domain VHH anti-CEACAM6 antibody was discovered and co-optimized alongside a CD3 binding domain for ultra-fast dissociation and developability using BigHat's proprietary AI/ML and cell-free protein synthesis (CFPS)-enabled platform. Comprehensive in vitro and in vivo studies of PK, PD, and safety were performed to support the candidacy of BHB299 for first-in-human evaluation.
Results: The resulting "2+1" T cell engager binds to cell surfaces with high CEACAM6 densities with high avidity and slow dissociation, but dissociates rapidly from myeloid cells with moderate target densities. This dynamic CD3 and CEACAM6 engagement selectively establishes an immunological synapse between tumor cells and T cells but not healthy myeloid cells, with >10,000x differential in IC50 in vitro using relevant models of cancer and whole blood from human donors. This avidity-based or "IF-BETTER" mechanism also eliminates sensitivity to soluble forms of CEACAM6, which may act as a decoy and antigen sink for high-affinity therapeutics. BHB299 also features a pH conditional CD3 agonist, which further enhances cell killing in the tumor microenvironment to reduce the risk of antigen escape due to low target expression. In vivo, BHB299 leads to complete responses or durable partial responses in multiple models of colon, rectal, lung, and pancreatic tumors, including metastatic PDX models of CRC and lung cancers. In safety studies in humanized mouse models and primates, no MTD was reached, consistent with a substantial therapeutic window.
Conclusion: BHB299 is a first-in-class CEACAM6-directed bispecific T cell engager for the treatment of diverse solid tumors, potentially up to 10% of all new cancers in the US each year. The molecule was engineered on BigHat Biosciences's AI/ML-powered antibody design platform to maximise tumor-specific target engagement. First-in-human studies are supported by the preclinical data package and are planned for 2026.

#4052 ENA101: A first-in-class bispecific T cell engager targeting a DARKFOX peptide presented by solid tumors.

T. Cornforth, C. Johnston, D. Howie, H. Adamson, R. Bergin, A. Black, L. Blackholly, E. Border, C. Cox, E. Denham, M. von Essen, V. Jefferson, L. Johnson, E. Lam, J. Lewis, M. Li, T. Lobry, H. McIntyre, I. Mount, J. Senra, M. Simpson, A. Stacey, E. Tye, M. Vologianni, **J. Dukes**;

Enara Bio, Oxford, United Kingdom

Background: Bispecific T cell engagers are an emerging immunotherapy for solid tumors, capable of potently redirecting polyclonal cytotoxic T cells to lyse tumor cells independent of their native specificity. This mechanism enables potent immune activation and has delivered landmark clinical benefit in solid tumors, exemplified by tarlatamab and tebentafusp, which achieved unprecedented efficacy even in immunologically 'cold' settings such as small-cell lung cancer and uveal melanoma. Progress in solid tumors is constrained by the limited availability of antigens with sufficient tumor specificity to ensure efficacy with a robust therapeutic window. To address this, we discovered and validated DARKFOX™, a novel cancer-specific Dark Antigen® encoded by an alternative open reading frame (altORF) of the canonical FOXM1 gene. DARKFOX is highly prevalent, tumor-specific, and homogeneously expressed within tumors, with a robustly presented HLA-A3 peptide (DARKFOX-A3). We have developed TCR-mimic antibodies with picomolar affinity for DARKFOX-A3 and incorporated them into our EnTiCE® T cell engager platform, engineered for best-in-class functional and manufacturability properties.

Methods: Antibodies specific for DARKFOX-A3 were generated from mice immunized with the antigen and subsequently affinity-matured in vitro to achieve high-affinity binding to the peptide-HLA complex. The optimized sequences were reformatted as single-chain variable fragments (scFvs) and engineered into Enara's EnTiCE® T cell engager platform. Proteins were expressed in mammalian systems and purified for use in functional assays, analytical characterization, and in vivo efficacy studies. Expression analyses were performed using RNA in situ hybridization.

Results: DARKFOX-A3-specific binders incorporated into Enara's optimized EnTiCE® half-life-extended T cell engager format achieved robust yields and high purity using a scalable mammalian expression system. ENA101 demonstrated pM binding affinity for DARKFOX-A3 and potently redirected and activated T cells, inducing cancer cell lysis with low-pM EC_{50} values across multiple DARKFOX-A3^{+} targets. In vitro co-culture assays with normal cell models, together with binding motif analyses, confirmed a highly specific pHLA binding profile. In vivo, ENA101 exhibited strong anti-tumor efficacy in xenograft models. Planned first-in-human studies are supported by expression data indicating high prevalence of DARKFOX across major tumor types, such as squamous NSCLC, enabling patient enrolment without antigen pre-screening.

Conclusions: ENA101 exhibits the hallmarks of a best-in-class bispecific T cell engager for solid tumors, including potent and highly specific redirection of T cell activity against antigen-positive cells across multiple tumor types. CMC activities and IND-enabling studies are currently in progress.

#4053 NRP1 drives a novel cross-presentation pathway exploitable by peptide-linked antibodies to redirect viral memory T-cells against solid tumors.

Anne V. Philips, Celine Kerros, Helen He, Lisa St. John, Noah Tubo, Ho Ngai, Qiyang Zhou, Chunhua Shi, Anthony Sump, Gheath Alatrash, **Jeffrey J. Molldrem**

UT MD Anderson Cancer Center, Houston, TX

Background: Although NRP1 is known to regulate tumor angiogenesis [1,2] and immune suppression [3,4], its role in antigen processing has not been defined. We discovered that NRP1 engagement triggers a previously unrecognized pathway enabling cross-presentation of exogenous peptides on MHC-I. We exploited this biology using a peptide-linked anti-NRP1 monoclonal antibody (5D6) to redirect antiviral $CD8^+$ T cells against NRP1-expressing tumors.
Methods: HLA-A2-restricted CMV, SARS-CoV-2, and tumor-associated peptides were chemically conjugated or recombinantly fused to 5D6 through a pH-sensitive cleavable linker. Internalization, trafficking, and antigen processing were evaluated by confocal microscopy and mass spectrometry. Functional cross-presentation was assessed using peptide-specific $CD8^+$ T cells in breast, lung and renal cancer cells *in vitro*, and in NSG mice bearing human carcinoma xenografts dosed with peptide-linked 5D6 followed by adoptive transfer of peptide-specific TCR-T cells.
Results: NRP1 ligation induced rapid antibody internalization into endosomal and lysosomal compartments, enabling efficient liberation of peptide cargo and high-density MHC-I cross-presentation on tumor cells. Pep-5D6-treated tumor cells were selectively killed by cognate $CD8^+$ T cells. *In vivo*, pep-5D6 followed by a single dose of peptide-specific TCR-T cells eradicated established tumors across multiple xenograft models within 1-4 weeks. These data reveal that NRP1 can function as a receptor for antigen delivery and cross-presentation, demonstrating its potential for therapeutic exploitation.
Conclusions: We identify a previously unrecognized NRP1-mediated cross-presentation pathway and introduce a first-in-class strategy that repurposes abundant viral memory T cells for targeted tumor elimination. This mechanistic insight defines new immunobiology for NRP1 and establishes a translational platform for redirecting pre-existing antiviral immunity toward NRP1-expressing cancers.

#4054 Tumor-activated PrimeBody biologics platform enables more potent CD47 targeting and superior therapeutic index in preclinical models.

A. Springer, S. Lai, C. Thanos, J. Humphrey, U. Eskiocak;
Voro Therapeutics, San Diego, CA

Systemic toxicities and dose-exposure limitations caused by target expression on normal tissues remain major barriers to effective cancer therapy. Tumor-activated masked biologics are a promising strategy to improve safety and efficacy, as highlighted by evolving clinical data with masked T-cell engagers (TCEs) and masked antibody-drug conjugates (ADCs). However, an optimized platform that balances protease specificity, systemic stability, and tumor release kinetics across diverse tumor types is lacking.VORO's PrimeBody biologics platform employs novel activation linkers that are rapidly cleaved in the tumor microenvironment but are stable in normal tissues, demonstrating substantially improved tumor-selectivity compared to clinical benchmarks. These linkers are coupled with novel, finely tuned affinity-based masking domains to precisely control target affinity and tumor-specific release kinetics. PrimeBody masking is ideal for novel, more potent CD47-targeted biologics to overcome safety limitations caused by ubiquitous CD47 expression in healthy tissues and simultaneously enable enhanced anti-tumor efficacy.VOR-101 is a masked, Fc-enhanced, high-affinity CD47 blocker that remains a latent prodrug until it is activated by proteolytic cleavage in the tumor microenvironment. In vitro, unmasked VOR-101 drives potent phagocytosis (EC_{50} ~20 pM) by primary human macrophages against epithelial cancer cell lines (DLD-1, HCT116, HT29, MCF-7, CAL27), while masked VOR-101 is inert (>2,000-fold higher EC_{50}). Ex vivo, VOR-101 is rapidly activated by human tumor surgical samples across all tested tumor types yet remains stable and intact in serum from healthy volunteers, cancer patients, and non-human primates for >14 days. In contrast, identical constructs engineered with clinical benchmark linkers exhibited significantly slower tumor activation and rapid serum degradation. Consequently, VOR-101 achieves >700-fold tumor-to-serum selectivity, a major improvement over the <25-fold selectivity observed with benchmark linkers currently in clinical development.In a translational hCD47/hSIRPα mouse model, magrolimab induced 50-60% depletion of red blood cells (RBCs) and exhibited poor systemic exposure (~10 nM). By contrast, VOR-101 at equimolar dosing achieved ~1 µM blood concentrations (~100-fold higher systemic concentration) while maintaining normal RBC counts. In xenograft models, VOR-101 induced durable complete responses that persisted well beyond the dosing period.Together, these findings demonstrate that VOR-101 (a tumor-activated, Fc-enhanced, high-affinity CD47 blocker) significantly improves the therapeutic index in preclinical models compared to clinical comparators. VOR-101 is advancing through IND-enabling studies with potential to exhibit single-agent activity in solid tumors.

#4055 Integrated CD2-costimulation on CD3 T cell engager EVOLVE platform yields differentiated and superior T cell effector profile.

E. Stewart, J. Zeiger, D. Ryan, R. Khalil, W. DeMaria, C. Brown, K. Ralph, A. Abduqadir, J. S. Myers, J. S. Fine, O. A. Sergeeva, S. Trombetta, S. Martomo;
EvolveImmune Therapeutics, Inc, Branford, CT

The EVOLVE platform utilizes a CD3 T-cell engager (TCE) with integrated CD2 costimulation to enhance the efficacy and durability of T cell responses. CD2 is a costimulatory receptor expressed on the majority of T cells in the tumor microenvironment (TME). We hypothesize that T cell co-engagement via CD3 and CD2 will result in superior T cell activation in the TME, conferring a greater anti-tumor effect. EVOLVE104, which recently entered the clinic, is a tri-specific molecule targeting CD3, CD2 and tumor antigen ULBP2/5/6. We showed previously that ULBP2/5/6, while minimally expressed on normal human tissues, is upregulated in solid tumors of squamous origin as well as in bladder cancer (1). In xenograft mouse models, EVOLVE104 showed significant tumor growth inhibition compared to bispecific TCE (2). In this study, we use a series of in vitro tests to compare T cell phenotypic and functional profiles after stimulation with EVOLVE104 or with other first generation bispecific TCE formats which lack integrated costimulation. We find that chronic stimulation of human peripheral blood-derived T cells with EVOLVE104 led to greater than a 30-fold increase in CD8+ T cell effector-to-naïve ratios compared to CD3 stimulation alone, demonstrating greater differentiation of T cells after exposure to EVOLVE. These EVOLVE104-stimulated effector cells showed two-fold or greater upregulation of activation markers such as CD25, CD69 and CD137 in a concentration-dependent manner after 24 hours when compared to bispecific TCE-treated T cells, with expression of these markers persisting through multiple rounds of stimulation. EVOLVE104-treated T cells also showed faster and sustained proliferation kinetics in chronic stimulation assays and TDCC assays. In this model, approximately 50% of effector CD8 T cells were proliferating by day 3 with EVOLVE104, compared to 20% with a bispecific TCE, which increased to >80% after multiple rounds of stimulation. Additionally, T cell function was maintained in vitro following chronic stimulation as measured by tumor cell killing of ULBP2/5/6+ tumor cells and by cytokine release in a mixed lymphocyte reaction assay. In conclusion, T cells stimulated with EVOLVE TCE platform with CD2 integrated costimulation shows differentiated and superior T cell phenotype with sustained tumor cell killing and cytokine production in vitro compared to T cells stimulated with TCE bispecific formats lacking CD2 costimulation. This study supports the hypothesis that the EVOLVE platform may provide deeper and more durable anti-tumor responses than first generation bispecific T cell engager formats. A first-in-human clinical dose escalation trial with EVOLVE104 is currently underway (NCT07217171).

#4056 Preclinical evaluation and safety of CBX-250 in acute myeloid leukemia: A bispecific T cell engager targeting Cathepsin-G peptide/HLA complex.

Jennifer Helble[1], Geraldine L. C. Paulus[1], Preethi Sankaran[1], Tanzila Rahman[1], Sarah Jaffe[1], Nga Sze Amanda Mak[1], Chunhua Shi[2], Jun Yan[2], Timothy Heffernan[2], Jeffrey Molldrem[2], Gheath Al-Atrash[2], Dmitri Wiederschain[1], Benjamin Lee[1]

[1]Crossbow Therapeutics, Inc., Cambridge, MA,[2]The University of Texas MD Anderson Cancer Center, Houston, TX

Acute myeloid leukemia (AML) presents a challenge for targeted immunotherapy due to the scarcity of tumor-specific surface antigens. An emerging strategy involves targeting peptide-HLA (pHLA) complexes derived from intracellular proteins. CG1 (FLLPTGAEA), a peptide derived from the Cathepsin G (CG) leader sequence presented by HLA-A*02:01, is selectively expressed on AML cells. CBX-250 has been developed as a TCR-mimetic (TCRm) bispecific T cell engager (TCE) antibody that binds to CG1/HLA-A*02:01 pHLA on AML cells and CD3 on T cells. We previously demonstrated that CBX-250 elicits in vitro killing of leukemia cells at sub-nanomolar EC_{50} levels. To further evaluate CBX-250 potency, we assessed a panel of CG1-positive U937 cell lines with varying levels of HLA-A*02:01 in T cell cytotoxicity assays. We observed comparable cytotoxicity across cell lines with target copy numbers ranging from 383-7930/cell, and notably, still observed robust killing of tumor cells with 33 target copies/cell. We also found that CBX-250 induced dose-dependent bystander killing of CG1/pHLA-negative cells only in the presence of CG1/pHLA-positive cells, highlighting the beneficial potency effects of CBX-250 in a tumor microenvironment with heterogenous target expression. To evaluate the safety of CBX-250, we assessed CBX-250-induced cytokine release in healthy donor HLA-A*02:01+ PBMCs and whole blood. We found no induction of cytokines in either PBMCs or whole blood when exposed to CBX-250, suggesting the risk for off-target adverse cytokine release is low. Although platelets likely do not present CG1, they can express high levels of class I HLA on their surface and may be potential targets for cross-reactivity with CBX-250. We found no increases in platelet activation following treatment with CBX-250, supporting the favorable safety profile of CBX-250. We assessed CBX-250 specificity by screening a library of >6,500 human proteins for off-target binding partners and found the only significant interactions were with CD3, one of its targets, and FCGR2A, an interaction which likely occurs through the Fc domain due to the high concentrations of CBX-250 tested. No other interactions were detected, indicating high specificity of CBX-250. To evaluate the pharmacology of CBX-250, serum pharmacokinetics (PK) and anti-drug antibody (ADA) formation were evaluated in naive male cynomolgus monkeys. The PK profile for IV and SC administration were consistent with IgG-like molecules, and the majority of the animals exhibited no ADA formation, suggesting minimal immunogenicity risks for CBX-250. Overall, our data demonstrate that CBX-250 is effective against a wide range of CG1/pHLA target densities and capable of mediating bystander killing. These features, combined with its encouraging safety profile, support clinical development of CBX-250. Phase 1 trial (NCT06994676) is ongoing.

#4057 Gastrointestinal tumor-associated target: A first-in-class therapeutic monoclonal antibody.

U. Goh[1], S. Kim[1], H. Kim[2], Y.-B. Kim[1];
[1]ReCerise Therapeutics, Seoul, Korea, Republic of, [2]Sungkyunkwan University, Gyeonggi-do, Korea, Republic of

Background:
Immune checkpoint blockade has improved outcomes in several cancers, but tumors with strongly immunosuppressive microenvironments, such as microsatellite-stable colorectal cancer (MSS-CRC), pancreatic cancer, and many hepatocellular carcinomas (HCCs), remain largely unresponsive. These tumors exhibit immune exclusion, impaired innate effector function, and dense tumor-supportive stroma. TM4SF5, a four-pass transmembrane glycoprotein enriched in gastrointestinal cancers, has been implicated in exclusion of effector lymphocytes, NK-cell dysfunction, and recruitment of tumor-associated macrophages (TAMs) and cancer-associated fibroblasts (CAFs), suggesting a central role in establishing an immunosuppressive tumor microenvironment (TME).
Methods:
A first-in-class monoclonal antibody was developed against native TM4SF5, recognizing the conformational extracellular epitope to disrupt TM4SF5-mediated signaling and immune-suppressive functions. Full-length TM4SF5 was reconstituted into a virus-like lipoparticle to maintain its native membrane conformation, enabling selection of TM4SF5-specific antibodies. A lead clone with high-affinity binding to both human and mouse TM4SF5 was Fc-optimized to generate the candidate RCT1213. RCT1213 was evaluated in vitro and in vivo for anti-tumor efficacy using patient-derived xenograft (PDX) tumor samples and TM4SF5-positive MSS-CRC cell line xenograft, respectively. Combination studies with immune checkpoint inhibitors (ICIs) assessed therapeutic interactions.
Results:
RCT1213 bound TM4SF5 with high affinity and attenuated TM4SF5-driven suppressive signaling in vitro PDX-derived tumors. Treatment with RCT1213 restored NK-cell activation and cytotoxic function, consistent with reversal of TM4SF5-mediated innate immune suppression. In MSS-CRC xenograft models, RCT1213 inhibited tumor growth and remodeled the TME, increasing immune-cell infiltration while reducing suppressive stromal and myeloid components. Combination therapy with ICIs yielded superior tumor control compared with either agent alone.
Conclusion:
Targeting TM4SF5 with RCT1213 alleviates TM4SF5-driven immunosuppression and restores innate effector function, resulting in robust anti-tumor activity in MSS-CRC models. These findings position TM4SF5 as an upstream immune-modulatory target and support RCT1213 as a first-in-class therapeutic candidate. IND-enabling studies are underway to advance RCT1213 into clinical development for MSS-CRC and other TM4SF5-expressing solid tumors.

#3988 Beyond G12C: Pan-cancer landscape and co-mutational architecture of rare RAS alleles across 211,526 patients.

N. Coleman[1], D. Hong[2];

[1]Trinity College Dublin, Dublin, Ireland, [2]UT MD Anderson Cancer Center, Houston, TX

Background: KRAS G12C has renewed interest in RAS biology, yet most RAS-mutant cancers harbor non-G12C variants whose therapeutic potential is uncertain and tissue-contextual. We aimed to map the prevalence, co-mutation signatures, and potential actionability of rare RAS alleles to inform next-generation clinical trial design.
Methods: We performed a pan-cancer analysis of AACR Project GENIE v.18, analyzing 250,018 tumor samples from 211,526 patients to quantify the prevalence of rare KRAS alleles (G12D/V/A/R, Q61, G13D), NRAS, and HRAS alleles by lineage, to define co-mutation signatures and assess clinical actionability.
Results: KRAS was altered in 32,946 tumors (16%; 35,614 patients). Rare KRAS alleles demonstrated strong codon-lineage patterns: G12D (9,457) and G12V (7,602) were the most common, each enriched across pancreatic adenocarcinoma (PDAC; 31.8%), colorectal cancer (CRC; 16.7%), and lung cancer (13.2%); G12A (1,542) occurred mainly in LUAD (41.4%) and CRC (20.5%), rarely in PDAC (1.36%); G12R (1,683) was highly pancreas-restricted (69%). G13D (2,596) was dominantly colorectal (55.9%). Q61X (2,279) occurred in PDAC (26%), LUAD (21%), and CRC (16%). HRAS mutations were rare (1,983 tumors <1%; 1,860), most frequently occurring in urothelial carcinoma (12.5%), thyroid cancer (6.3%), and HNSCC (2%). Codon-61 variants (Q61H/K/L/R; 461) accounted for 23.3% of all HRAS mutations, with enrichment in thyroid (22.8%), urothelial (17.4%), melanoma (6.3%), and HNSCC (6.1%); additional recurrent hotspots included G12 (234) and G13 (248). NRAS alterations were detected in 5,882 tumors (3%; 5,715 patients), most frequently in melanoma (1,440; 24.5%), CRC (565; 9.6%), and LUAD (300; 5.1%). Q61X accounted for 51% of all NRAS mutations, most commonly in melanoma (25%), CRC (10%), and LUAD (5%). KRAS-mutant tumors showed significant co-occurrence with TP53, SMAD4, CDKN2A, STK11, KEAP1, and APC (all $p<0.001$); KRAS was mutually exclusive with NF1, RB1, and PTEN (all $p<0.001$). HRAS-mutant tumors significantly co-occurred with NOTCH1, FGFR3, NF1, TERT, AKT1, ARID1A, PIK3CA, CDKN2A, CCND1, CDK4, and CDK6 (all $p\leq0.01$), with weaker associations for STK11, SMAD4, and TP53. NRAS-mutant tumors significantly co-occurred with CDKN2A, APC, BRAF, NF1, and TERT (all $p<0.001$) and were mutually exclusive with TP53, STK11, and PIK3CA.
Conclusions: Rare RAS alleles are common across solid tumors and show distinct codon- and lineage-specific architectures. KRAS alterations are broadly pan-epithelial, whereas HRAS and NRAS cluster within discrete niches. Co-mutation patterns differ, with KRAS linked to PDAC/LUAD/CRC tumor-suppressor pathways, HRAS to NOTCH1-FGFR3-PI3K-AKT-CDK signaling, and NRAS to BRAF, NF1, and TERT. These data support co-mutation-driven combinations and lineage-tailored therapeutic strategies for next-generation RAS-targeted approaches.

#3989 Mutant p53 neomorphic activities drive organ-specific metastatic programs through distinct transcriptional networks.

G. Efe[1], R. Navaridas[1], K. M. Cunningham[1], D. Hasson[2], C. Lu[3], J. J. Manfredi[2], C. L. Prives[4], A. K. Rustgi[1];
[1]Herbert Irving Comprehensive Cancer Center, New York, NY, [2]Icahn School of Medicine at Mount Sinai, New York, NY, [3]Columbia University Irving Medical Center, New York, NY, [4]Columbia University, New York, NY

Mutations in the tumor suppressor p53 correlate with poor prognosis and high metastasis rates, which account for more than 90% of cancer-related mortality worldwide. Our recent work (Cancer Discovery PMC10841313), highlights that mutant p53 may exhibit neomorphic gain-of-function properties, driving squamous cell carcinoma (SCC) metastasis beyond its classic role via wild-type p53 loss. While our previous work and emerging studies have highlighted the neomorphic gain-of-function activities of mutant p53 in promoting metastasis, the tissue-specific transcriptional programs that underlie metastatic organotropism remain underexplored.
To identify mutant p53-dependent mechanisms in facilitating organ-specific metastasis, we performed RNA-sequencing coupled with ChIP-sequencing on esophageal squamous cell carcinoma (ESCC)-derived lung and liver metastases harboring either mutant p53-R172H or p53 deletion. Analyses included differential gene expression (DEG), pathway enrichment, and comparisons between primary tumor and metastatic tumor transcriptomes. These studies were complemented by analyses of aero-digestive squamous cell carcinoma datasets from the AACR Project GENIE, TCGA, and tissue microarrays assessing mutant p53 in relation to patient survival and enriched molecular pathways.
Mutant p53 contributed to distinct transcriptomic shifts in liver versus lung metastases. In lung metastases, 618 genes were upregulated and 667 downregulated dependent upon mutant p53-R172H, with enrichment in distinct immune response programs. By contrast, liver metastases showed 1,320 upregulated and 1,355 downregulated genes, with strong downregulation of interferon and inflammatory response pathways. Our analyses exhibited minimal overlap between up- or downregulated genes across tissues (103 shared downregulated and 77 shared upregulated genes), highlighting organ-specific p53-mediated transcriptional control.
Furthermore, comparisons with primary tumors revealed subsets of DEGs uniquely dependent on p53-R172H across metastatic and primary contexts. Notably, only a small core set of genes (*Acot1*, *Ldhb*, *Bcat1*, *Il18rap*, *Kif6*, *Paqr4*, *Il1rl1 and Cdc20)* were upregulated in all three settings (primary, lung, liver), while most gene expressions were organ-specific.
Overall, our results reveal novel insights into the mechanisms underlying mutant p53-mediated metastatic organotropism. These data highlight the necessity of incorporating the organ specific context metastatic cancers into therapeutic strategies driven by mutant p53.

#3990 Real-world evidence of KMT2C mutation as a biomarker of sensitivity to platinum-based therapy in solid cancers.

Bruno Bockorny[1], Yingying Yu[2], Pedro Danielian[1], Yujing Jan Heng[1], Xiaohui Li[1], Stamatina Fragkogianni[2], Lisa Macera[2], Metamia Ciampricotti[2], Gerburg M. Wulf[1]

[1]Beth Israel Deaconess Medical Center, Boston, MA,[2]Tempus, Chicago, IL

Introduction: Epigenetic dysregulation, driven by alterations in the lysine methyltransferase 2C (*KMT2C*) gene, contributes to tumor growth. *KMT2C* is a putative tumor suppressor mutated in 7%-10% of solid tumors. Loss of *KMT2C* function impairs homologous recombination DNA repair, making tumor cells more susceptible to PARP inhibition. The study used a real-world dataset to assess if *KMT2C* mutations predict platinum-based chemotherapy (PBC) responsiveness and clinical outcomes in solid cancers.
Methods: The Tempus Lens Platform (Tempus AI, Inc., Chicago, IL) was used to query the Tempus multimodal de-identified database and establish and subsequently analyze a cohort of patients (pts) with solid cancers and Tempus xT (DNA) testing. Pts characteristics were compared using Chi-squared/Fisher's exact tests and/or Wilcoxon sum tests. Real-world overall survival (rwOS) and progression-free survival (rwPFS) were compared between *KMT2C*^{mut} vs *KMT2C*^{wt} and defined as the time from PBC initiation to death or loss to follow up (FU) and as the time from PBC initiation to first progression, death, or loss to FU, respectively. Median rwOS and rwPFS were estimated by Kaplan-Meier and compared using log-rank tests. Risk set adjustment was used to avoid immortal time bias due to left truncation. Findings were validated in the AACR Genie dataset for rwOS after PBC and non-PBC.
