Results: A total of 143,961 patients were included, and stage IV disease accounted for 76%. GI cancers comprised 36% of the cohort, followed by lung (25%) and breast (11%). *KMT2C* mutations occurred in 5.3% overall, most frequent in cervical (14%), endometrial (11%), urinary tract (8.6%) and breast cancer (8.4%). African American patients showed slightly higher prevalence versus non-AA both overall (5.6% vs 5.2%, p=0.089) and in GI cancers (5.4% vs 4.6%, p=0.013). In PBC-treated patients, median rwOS was longer in *KMT2C*^{mut} vs *KMT2C*^{wt} across all cancers (19.6 vs 16.7 mo, p=0.038), endometrial (42.3 vs 31.9 mo, p=0.03), head and neck (28.4 vs 13.3 mo, p=0.02), and GI (18.9 vs 15.7 mo, p=0.006). Within the GI group, colorectal cancers (CRC) had the largest impact (median rwOS of 51.0 vs 25.3 months, p=0.01). In CRC, rwPFS for *KMT2C*^{mut} vs *KMT2C*^{wt} were Not Reached vs 16.7 months (p=0.001), respectively. AACR Genie was analyzed to validate these results. A total of 1,551 CRC cases were included, with 8% harboring *KMT2C* mutations. CRC *KMT2C*^{mut} had improved rwOS compared to *KMT2C*^{wt} following PBC (Not Reached vs 57.5 months, p=0.005). This effect appeared specific to PBC, with no difference after irinotecan-based therapy.
Conclusion: *KMT2C* mutations are linked to improved survival after platinum chemotherapy, particularly in CRC and other GI cancers, supporting *KMT2C* as a predictive biomarker. Laboratory studies to define the mechanistic basis of this association are underway.

#3991 BRAF N486_P490del and fusions as distinctive gene alterations in pancreatic ductal adenocarcinomas: Analysis of C-CAT and AACR Project GENIE data.

K. Ochi[1], C. Morizane[1], K. Shiraishi[2], T. Koyama[1], K. Sunami[3], R. Kitadai[1], Y. Okuma[1], T. Shiraishi[2], E. So[1], Y. Goto[1], S. Hakui[1], K. Fujisaki[1], K. Onuma[1], Y. Komori[1], D. Yamashige[1], M. Okada[1], S. Harai[1], Y. Maruki[1], Y. Kawamoto[1], Y. Nagashio[1], S. Hijioka[1], H. Ueno[1], T. Okusaka[1];

[1]National Cancer Center Hospital, Tokyo, Japan, [2]National Cancer Center Research Institute, Tokyo, Japan, [3]National Cancer Center Hospital, Department of Laboratory Medicine, Japan

Backgrounds: *BRAF* genomic alterations (GAs) have been identified in various tumors and are categorized into three distinct classes. Based on their impact on RAS-independent kinase activity, class 1 (monomer) and class 2 (dimer) are significant treatment targets and class specific regimens are being developed. However, the distribution of these classes across different primary sites has not yet been clarified. In patients with pancreatic cancer (PC), class 2 *BRAF* GAs have occasionally been encountered in clinical practice. Because precision oncology is limited in PC, *BRAF* GAs are precious target. To elucidate the patterns of *BRAF* GAs in PC, we investigated two extensive databases. Methods: We analyzed the Japanese nationwide C-CAT data and the AACR Project GENIE data. *BRAF* GAs were annotated using OncoKB and AlphaMissense and classified into three classes based on the published literature. Results: In the C-CAT data (N=107,714), as summarized in the table, *BRAF* GAs (n=3559, 3.3%) were frequently observed in thyroid, skin, and colorectal cancers, but these were mainly class 1(mostly V600E). In contrast, PC showed a distinct profile: among 11,959 patients with PC, *BRAF* GAs were detected in 230 (1.92%), Class1 was relatively rare (15.6%) and 60.4% (139/230) were class 2. These were mainly composed of in-frame deletions (n=97), with N486_P490del (n=79) and fusions (n=28). In GENIE data (N=250,018), 1.6% (169/10,730) of patients with PC harbored *BRAF* GAs. Although proportion of V600E was higher than that in C-CAT (19.5%), class 2 was dominant (63%, 108/169), such as fusions(n=48) and N486_P490del (n=28). Among *BRAF* N486_P490del positive solid tumors, pancreas was dominant primary site in both C-CAT (82%, 79/96) and GENIE (52%, 28/53). Conclusions: Class 2 *BRAF* GAs, especially N486_P490del and fusions, are distinctive alterations in patients with PC, and the development of class 2 specific targeted therapies is urgently needed.

#3992 Leveraging Ultima Genomics ppmSeq WGS-cfDNA to accurately detect clonal evolution over sequential blood biopsies.

Elizabeth E. Martin[1], Julian Hess[1], Carrie Cibulskis[1], Mendy Miller[1], Brian P. Danysh[1], Chip Stewart[1], Elena Helman[2], Ilya Soifer[2], Doga C. Gulhan[3], Dejan Juric[4], Doron Lipson[2], Gad Getz[1]

[1]Broad Institute of MIT and Harvard, Cambridge, MA,[2]Ultima Genomics, Tel Aviv, Israel,[3]Krantz Family Center for Cancer Research and Dept. of Pathology, Massachusetts General Hospital, Boston, MA,[4]Krantz Family Center for Cancer Research and Dept. of Pathology, Massachusetts General Hospital, Cambridge, MA

Comprehensively modeling tumor evolution is important for cancer diagnosis, treatment, and minimal residual disease (MRD) monitoring. Liquid biopsies enable non-invasive sampling of tumor DNA during a patient's cancer treatment. Accurate detection of low allele fraction somatic variants in circulating tumor DNA (ctDNA) has clinical importance for cancer detection and monitoring. Current ctDNA panel sequencing methods lack the breadth of variants captured in whole genome sequencing (WGS) and cannot fully track tumor clones over time. Moreover, deep and accurate cell-free DNA (cfDNA) sequencing is challenging due to constraints of low tumor fraction in the blood and the high cost of WGS sequencing.

Ultima Genomics (UG) developed paired plus-minus sequencing (ppmSeq) technology, a whole-genome duplex sequencing approach that lowers observed error rates and allows for a high yield of duplex molecules. Using UG's deep WGS ppmSeq, we developed our mutation calling algorithms to enable sensitive detection of somatic variants in cfDNA samples, allowing us to track clonal populations over time. To test whether we could identify shared clonal populations in patient sequences between other platforms and ppmSeq technology, we collected post-mortem tissue specimens from 12 patients of various cancer types (breast, cholangiocarcinoma, etc.) and 38 pre-mortem cfDNA samples from the same patients. First, these patients' data were sequenced with existing Illumina sequencing technologies (WES) and then on the UG sequencing platform for both tissue and ppmSeq.

We sequenced the ppmSeq data to an average depth of 135x (range 104x to 208x) and achieved an average duplex proportion of 38% (range 31% to 44%). For all patients' tissue and cfDNA samples that were sequenced with both ppmSeq WGS (UG) and WES (Illumina), we reconstructed phylogenetic trees to determine the life history of the cancer using our PhylogicNDT suite of tools. Phylogenies reconstructed from ppmSeq WGS cfDNA identified many more mutations and richer trees than those reconstructed from WES of the same cfDNA samples. We compared the cfDNA ppmSeq phylogenies with those constructed from WGS of the same patient's tissue samples and identified the same clonal populations, enabling us to match clones from the blood to the tissue and track the progression of individual clones.

The identification of large clonal populations in ctDNA sequenced with Ultima Genomics' ppmSeq approach is an improvement over methods with lower sensitivity and coverage; moreover, this approach can identify clonal populations that change over a given treatment course. This more accurate inference of cancer evolution information could enable us to better guide therapies and identify novel mechanisms of resistance that would have been missed with prior methods.

#3993 Artificial intelligence-integrated analysis of the gut microbiome in early- and late-onset colorectal cancer among populations at increased risk using clinical, genomic, and social determinants data.

S. Manjarrez[1], F. Carranza[1], B. Waldrup[1], X. Qi[1], A. L. Cruz Gomes[1], D. O. Garcia[2], A. Maldonado[2], J. Karmouch[1], R. Jenq[1], PE-CGS Network, E. Velazquez-Villarreal[1];

[1]City of Hope National Medical Center, Duarte, CA, [2]University of Arizona, Tucson, AZ

Early-onset colorectal cancer (EOCRC) is rising globally and disproportionately affects populations at increased risk. The gut microbiome has been implicated in colorectal cancer development, yet its relationship to early- versus late-onset disease within these communities remains unclear. This study aimed to characterize microbiome differences across age-defined CRC subgroups using an AI-enabled, multi-domain analytical framework.We analyzed 2,715 colorectal cancer (CRC) tumor samples from patients in our NIH Cancer Moonshot COPECC PE-CGS Network and public data repositories. Within this cohort, stool samples were collected from 23 patients diagnosed with CRC. Microbial profiling was performed using 16S rRNA sequencing and complemented by whole-exome sequencing, RNA sequencing, clinical variables, and social determinants of health (SDOH). Mutation frequencies across different populations were evaluated using the AACR Project GENIE database. Conversational artificial intelligence platforms (AI-HOPE) were used to integrate and query multi-omics and SDOH data, enabling identification of patterns associated with age at onset.EOCRC cases demonstrated lower microbial richness compared with late-onset CRC. Distinct differences in microbial composition and relative abundance were observed when stratifying by genetic ancestry, mutation frequency, gene fusions, copy number variation, clinical features, and SDOH factors. AI-guided integration further highlighted age-specific microbial profiles that aligned with multi-omic alterations.These findings reveal notable microbiome differences between early- and late-onset CRC in populations at increased risk. This preliminary work underscores the utility of artificial intelligence-supported integrative analysis and highlights the need for larger comparative studies to determine whether specific microbial signatures contribute to variations in CRC onset and outcomes.

#3994 Differences in the mutational landscape across race and sex highlight distinct TP53-associated risk in multiple myeloma.

C. Ugwu[1], N. Ubah[2], M. Megiso[1], A. Uriepero Palma[1], T. Verinumbe[1], A. Chachua[1], S. King[1], A. Neely[1], E. Obomanu[1], A. Taneja[3], A. Turki[4];

[1]Jefferson Einstein Philadelphia Hospital, Philadelphia, PA, [2]Montefiore St Luke Cornwall Hospital, Newburg, NY, [3]Sidney Kimmel Comprehensive Cancer Center, Jefferson Einstein Philadelphia Hospital, Philadelphia, PA, [4]Marienhospital University Hospital, Ruhr-University Bochum, Germany

Background:
Complex health disparities involving race, sex, and genomics have been described in multiple myeloma (MM) (Tebuka E et al. Blood Gl. Hem. 2025). Large genomic studies have highlighted the impact of the mutational landscape (Maura F et al. JCO 2024; Schavgoulidze A et al. Blood 2024); however, the role of gene-gene interactions, including those involving TP53 alterations, has not yet been extensively examined by race and sex.

Methods:
Using a large, multi-institutional targeted sequencing dataset from the AACR GENIE v18 cohort, we analyzed 1,020 patients with MM (White n=839; Black n=181). Patients with at least one successfully profiled gene were included. Co-occurrence analyses were restricted to mutation-bearing patients. Clinical features, mutation burden, and fraction of genome altered were compared using Wilcoxon and Fisher tests. Differences in co-occurrence distributions were evaluated with Mann-Whitney U tests. Overall survival was assessed using multivariate Cox models, including interaction terms for TP53 with race and sex.

Results:
Age differed between Black and White patients (median 63.5 vs 66 years; p=0.002) but not between males and females. Mutation burden and fraction of genome altered were comparable across groups (p>0.16). No individual mutation frequency differences remained significant after correction for multiple testing.

In contrast, the landscape of gene-gene interactions with TP53 varied substantially by race (p=0.027) and sex (p=0.038). White patients showed numerous TP53-associated co-mutations, including TP53-TET2 (11.1% vs 0%), -FAT1 (10.2% vs 0%), -KRAS (8.3% vs 0%), -DNMT3A (7.4% vs 0%), -DIS3 (6.5% vs 0%), -BRAF (5.6% vs 0%), and TP53-TRAF3 (4.6% vs 0%). Black patients exhibited more NRAS-centered co-mutations, including NRAS-KRAS (7.41% vs 1.35%) and NRAS-CYLD (6.17% vs 1.57%). The NRAS-centered pattern was present in both sexes, with females showing slightly higher NRAS frequency and stronger clustering with DNMT3A and TET2. Examination of sex subgroups also showed the highest proportion of TP53 co-mutations among White males (16.6%) compared with White females (10.3%, p=0.009).

Overall survival did not differ by race (p=0.83) or sex (p=0.11). TP53 mutation was associated with significantly shorter survival (p=0.0018), with a significant interaction between TP53 status and sex (p=0.0078). TP53-mutated males had the poorest outcomes.

Conclusions:
These findings underscore the importance of gene-gene interactions in MM and their relevance to understanding health disparities. The absence of TP53 co-mutational patterns among Black patients is notable and may have implications for future trial design and risk-stratification strategies.

: Biomarkers That Change Management: Predicting Therapy Benefit, Progression, and Metastatic Risk Minisymposium

#4015 Whole-genome duplication predicts metastasis risk and timing across human cancers.

J. Xu, H. Walch, M. Perry, C. Fong, J. Jee, K. Pichotta, A. Price, A. L. Richards, C. Bandlamudi, M. Donoghue, N. Schultz, W. K. Chatila;
Memorial Sloan Kettering Cancer Center, New York, NY

Introduction:
Whole-genome duplication (WGD) is a pervasive event in cancer evolution, conferring tolerance to large-scale genomic alterations and reshaping selective pressures. While WGD is linked to aneuploidy and poor prognosis, its impact on metastatic risk across cancer types remains unclear. We evaluated whether WGD detected in the primary tumor predicts subsequent metastasis risk and timing in a pan-cancer cohort.
Methods:
We analyzed 33,349 tumors across 29 cancer types profiled by MSK-IMPACT (2014-2024). Metastatic site and timing were derived from NLP-based annotations integrating pathology and radiology reports. Analyses were restricted to stage I-III primary tumors without prior metastasis. Landmark analyses at 1 and 3 years compared distinct metastatic sites among patients with sufficient follow-up, excluding cancer types with fewer than 50 eligible patients at the 3-year landmark. Within each cancer type, nonparametric cumulative incidence functions were estimated with death as a competing event. WGD was inferred from FACETS allele-specific copy numbers, defining WGD-positive as >50% of autosomes with major copy number ≥2.
Results:
In total, 6,434 primary tumors met inclusion criteria, comprising 5,170 WGD- and 1,264 WGD+ cases. Across cancer types, WGD+ tumors showed a significantly higher likelihood of metastasis within three years compared with WGD- tumors (60.4% vs. 42.0%, $p<0.001$), a pattern consistent within individual cancer types. WGD+ tumors also exhibited a greater metastatic burden, with a higher proportion of patients developing metastases to ≥3 sites (20.4% vs. 11.3%, $p<0.001$). WGD+ tumors were more likely to develop brain metastases overall (4.7% vs. 2.6%, $p=0.003$). One-third (32.2%) of WGD+ tumors lacked TP53 alterations, indicating genome doubling can arise independently of canonical TP53 loss. WGD significantly predicted metastatic progression in both TP53-altered (HR=1.10, $p=0.043$) and TP53-wildtype tumors (HR=1.38, $p<0.001$), with a larger effect size observed in the TP53-wildtype subset.
Conclusions:
In this pan-cancer, primary-only analysis, WGD emerged as an early and consistent predictor of metastatic progression across tumor types, with effects persisting in TP53-wildtype disease. These findings position WGD as a unifying hallmark of cancer progression and highlight how large-scale genomic-clinical integration can reveal key determinants of tumor evolution.

#4016 Tissue-based homologous recombination deficiency status prediction in patients with breast, ovarian, and pancreatic cancers.

P. Safabakhsh, D. Tolkunov, B. Overstreet, M. Lefterova, L. Lawrence;
Guardant Health, Palo Alto, CA

Introduction: Homologous recombination deficiency (HRD) is a predictive biomarker of response to PARP inhibitors and other DNA damage response (DDR)-targeting therapies across cancer types. HRD can be detected by identifying mutations in *BRCA1/2* or other homologous recombination repair (HRR) genes, or through copy number (CN) or single nucleotide variant (SNV)-based signatures associated with genomic instability. While genomic instability status (GIS) is an FDA-approved biomarker for ovarian cancer treatment, comprehensive tissue-based GIS detection across multiple cancers is still limited. We developed and validated a tissue-based GIS predictor integrating CN and SNV signatures for breast, ovarian, and pancreatic cancers.
Methods: We implemented an ensemble model to predict GIS using HRR gene deficiency to infer SNV and CN signatures associated with HRD. The model was trained on clinical samples processed on Guardant360 Tissue (Guardant Health, Palo Alto, CA), incorporating select HRD-associated COSMIC single base substitution (SBS) signatures (v3.4) and genomic scarring features such as loss-of-heterozygosity (LOH). The aggregate model was evaluated on an independent cohort of clinical breast, ovarian, and pancreatic samples with tumor purity ≥ 20%. *BRCA1/2* or *PALB2* biallelic loss and strict wildtype status in 14 HRR genes were used as orthogonal labels to assess sensitivity; while a cohort wildtype for an expanded set of pathogenic or likely pathogenic variants in HRR genes was used to estimate specificity.
Results: The GIS model achieved an overall AUC of 0.98, with sensitivity of GIS detection of 90% in breast cancer, 91% in ovarian cancer, and 80% in pancreatic cancer. GIS detection in HRR-negative samples was < 3% in all three cancer types. Prevalence of GIS detection among clinical samples was 256/803 (32%) in breast cancer, 56/107 (52%) in ovarian cancer, and 40/214 (19%) in pancreatic cancer. Among patients with GIS detected, 75% of breast cancers, 39% of ovarian cancers, and 67% of pancreatic cancers did not harbor pathogenic *BRCA1/2* or *PALB2* mutations.
Conclusions: We present a tissue-based genomic instability detection method demonstrating strong performance in breast, ovarian, and pancreatic cancers. Prostate cancers, which also commonly exhibit HRD, showed a distinct genomic scarring signature and are being actively investigated for future incorporation into the GIS model.This comprehensive biomarker expands HRD testing beyond HRR mutations to capture a broader patient population who may benefit from DDR-targeting therapies.

#4017 Integrated multi-omics approaches in resectable hepatocellular carcinoma with microvascular invasion for revealing therapeutic target.

J. So, I. Kang, W. Kwon, S. Lee;
Omics & Real-world Data-driven AI for Precision Medicine Lab, Seongnam, Korea, Republic of

Introduction: Hepatocellular carcinoma(HCC) with microvascular invasion(MVI) has the traits of aggressive and rapid proliferation rate and penetration along blood vessels. Therefore, MVI is one of the clinical features of liver cancer with a high risk of recurrence and a poor prognosis. There is a need to explore biomarkers and customized drugs for early diagnosis of MVI.
Methods: Using gene expression of resected human HCC samples (Discovery cohort, n=240), we identified a transcriptomic signature predictive of MVI. Subsequently, we performed integrated analyses using data from the cancer dependency map (DepMap) project, including multi-omics based cancer-specific molecular characterization, compound-based drug sensitivity screening, and integrative *in-silico* prediction approaches to investigate determinants of MVI. The resulting MVI-predictive transcriptomic signature was validated across multiple independent cohorts (TCGA-LIHC, n=373; KOREA, n=188; TOKYO, n=183; MODENA, n=78; ZHONGSHAN, n=159).
Results: The MVI 1,028 genes signature was identified in the discovery cohort, and its predictive performance was robustly validated in the independent validation cohort (AUC = 0.889, $p < 0.01$). Multi-omics analyses revealed aggressive tumor biology associated with the MVI signature and highlighted specific biomarkers.
Conclusions: Integrative multi-omics profiling of resectable HCC with MVI reveals biomarkers for the diagnosis of MVI and therapeutic target. This target will increase the therapeutic effect and play a key role in the precision medicine.

#4018 Stromal immune composition significantly contributes to adenomatous polyp recurrence or progression to cancer.

M. Dehankar[1], L. A. Boardman[1], D. O'Brien[2], E. A. Thompson[3], J. M. Kachergus[3], J. Shi[3], A. Abyzov[1], M. Suvakov[1], R. P. Graham[1], C. Wang[1];

[1]Mayo Clinic, Rochester, MN, [2]Ambry Genetics, Aliso Viejo, CA, [3]Mayo Clinic, Jacksonville, FL

Background: Most colorectal cancer (CRC) arises from polyps and is mainly prevented by polypectomy. The most important polyps to manage with colonoscopy are those with highest CRC risk- namely, advanced polyps (> 1cm, villous histology or high-grade dysplasia (HGD). Yet, 48% of advanced polyps recur within 1 to 3 years of removal, and up to 5% of advanced polyps under surveillance still progress to CRC. We performed this pilot study to investigate molecular and microenvironment heterogeneities of polyps and how they might impact their clinical behavior.

Methods: GeoMx spatial transcriptomics was performed on FFPE tissues from three different polyp outcome phenotypes (POPs) including the polyp that does not recur (POP-NR), that recurs following polypectomy but cured by colonoscopy (POP-R) or the polyp despite polypectomy develops CRC at the polypectomy(ies) site (POP-CRC). Normal colon and polyp with low or HGD from the index polyp were assessed from 6 patients with POP-NR, 9 with POP-R and 12 with POP-CRC with a minimum of 2 follow up colonoscopies at 3-year intervals. Epithelium was identified as PanCK positive, and stroma identified as PanCK negative and positive nuclear staining. Cell type deconvolution was implemented using single-cell adult human intestinal tract catalogue (Elmentaite *et al.,* https://www.gutcellatlas.org/). Differential gene expression (DEG), cell type abundance and functional enrichment analyses was performed using linear mixed effects model, and observations with p-value < 0.05 and log2FC >= |1| are reported.

Results: The greatest number of DEGs were identified in stroma of the index POP-CRC compared to POP-NR polyps (n = 17 down and 11 upregulated genes), followed by epithelium of the index POP-CRC vs POP-NR polyps (n = 10 down and one upregulated gene(s)). Between the index POP-CRC and POP-R, epithelium showed downregulation of 7 genes, and upregulation of no genes. In stroma two genes were down and none upregulated. Four genes were downregulated in stroma of the index POP-R vs POP-NR polyp and 3 in epithelium, and one gene was upregulated in stroma and another in epithelium. *MZT2B* was upregulated in stroma of both the index POP-R (log2FC = 1.09, p-value = 0.0014) and POP-CRC (log2FC = 1.29, p-value = 0.0001) and has been implicated as a prognostic marker associated with worse prognosis in certain cancers. IgM and IgA plasma cells, proximal progenitors, MMP9+ inflammatory macrophages and myofibroblasts were found to be downregulated in epithelium of index POP-CRC and POP-R compared to POP-NR polyps; while microfold cells were downregulated in stroma of index POP-CRC and POP-R compared to POP-NR polyps.

Conclusions: The stromal microenvironment and less so, epithelial features present in the index polyp differ based on a polyp's future clinical behavior. The polyp-immune interaction warrants further study as a potential prevention target against polyp progression.

#4019 Clinical validation of WES-based HRD scoring and its prognostic value for PARP inhibitor maintenance therapy in ovarian cancer.

D. Kyung[1], K. Han[2], Y. Cha[1], W. Ko[1], H. Roh[1], N. Park[2], C. Lee[2], S. Kim[2], T.-Y. Kim[2];
[1]IMBDx, Seoul, Korea, Republic of, [2]Seoul National University Hospital, Seoul, Korea, Republic of

Background: Homologous recombination deficiency (HRD) predicts PARP inhibitor (PARPi) sensitivity in ovarian cancer. We evaluated the clinical and analytical performance of a WES-based genomic profiling assay generating HRD scores and BRCA status, and assessed its prognostic value for PARPi maintenance.
Methods: We included 81 consecutive patients with epithelial ovarian cancer (FIGO I-IV) who had received PARPi therapy between 2017-2024 at Seoul National University Hospital. After tumor purity estimation and microdissection, formalin-fixed, paraffin-embedded (FFPE) surgical tumor tissues and matched blood were analyzed using the CancerProfiler™ WES panel. HRD scores were derived from genomic scar metrics (LOH, TAI and LST) following the scarHRD algorithm. Germline and somatic BRCA1/2 variants were profiled concurrently. HRD-high status was defined at ≥42 and ≥50. Tumor purity and fraction were estimated from WES data and incorporated into HRD computation to ensure quantitative stability.
Results: Median age was 56; 96% had high-grade serous carcinoma and 94.8% FIGO III-IV disease. Optimal cytoreduction (<1 cm residual) was achieved in 61%, and 52% received neoadjuvant chemotherapy. By the WES panel assay, a total of 46 patients had germline or somatic BRCA mutations. HRD-high status was observed in 77.8% at ≥42 and 66.7% at ≥50; the ≥50 cutoff showed a stronger association with germline BRCA (OR 3.15; p=0.021). Among 73 PARPi maintenance recipients (52 first-line and 23 second-line), HRD ≥50 showed differential predictive value by NAC. In first-line recipients, PFS was similar between HRD-high and -low after NAC (15.3 vs 11.3 mo, p=0.77) but markedly longer in HRD-high without NAC (median not reached vs 7.66 mo, p=0.001). This pattern persisted in the second-line setting (NAC: 19.48 vs 6.49 mo, p=0.049; no NAC: 17.78 vs 2.43 mo, p<0.001). BRCA mutation predicted benefit only in NAC-treated first-line patients (17.7 vs 4.5 mo, p=0.007) and not elsewhere. HRD-high was an independent predictor of longer PFS (first-line HR=0.26, p=0.02; second-line HR=0.20, p=0.029). In multivariable analyses, the predictive value of PARP inhibitors was BRCA-dependent only in the first-line setting (HR=0.09, p=0.001), with no significant association observed in the second-line (HR=0.28, p=0.226). By contrast, HRD-high status remained a consistent independent predictor in both first- (HR=0.26, p=0.02) and second-line therapy (HR=0.02, p=0.029), emerging as the sole significant determinant after recurrence.
Conclusions: HRD ≥50 is a robust predictor of PARPi benefit—particularly in treatment-naïve tumors—whereas BRCA status shows limited and NAC-dependent predictive value. These findings support prospective multi-center validation of WES-based HRD assays as scalable alternatives to array-based platforms.

#4020 Utility of CA19-9 for prediction of asymptomatic pancreatic cancer among patients with new onset diabetes.

J. Fahrmann[1], C. Lopez[2], E. Irajizad[1], S. Chari[1], J. Vykoukal[1], R. Spencer[1], J. B. Dennison[3], E. J. Koay[3], F. McAllister[3], M. P. Kim[1], J. Rinaudo[4], P. A. Hart[5], W. E. Fisher[6], S. Van Den Eeden[7], B. Wu[1], Z. Feng[8], S. M. Hanash[3], A. Maitra[9];
[1]The University of Texas MD Anderson Cancer Center, Houston, TX, [2]Fred Hutchinson Cancer Center, Seattle, WA, [3]UT MD Anderson Cancer Center, Houston, TX, [4]National Cancer Institute, Bethesda, MD, [5]The Ohio State University Wexner Medical Center, Columbus, OH, [6]Baylor College of Medicine, Houston, TX, [7]Kaiser Permanente Northern California, Oakland, CA, [8]Fred Hutchinson Cancer Research Center, Seattle, WA, [9]NYU Grossman School of Medicine, New York, NY

Purpose: New-onset diabetes (NOD) is an early indicator of pancreatic ductal adenocarcinoma (PDAC). There remains a need to establish biomarkers that can reliably identify NOD patients at risk of having occult PDAC. Here, we assessed the predictive performance of single timepoint CA19-9 as well as an established algorithm that considers repeat CA19-9 testing for risk prediction of PDAC among a prospective cohort of patients with NOD.
Methods: CA19-9 was assayed in 6,516 serially collected pre-diagnostic plasma samples collected from 2,121 NOD patients from the Consortium of Chronic Pancreatitis Diabetes and Pancreatic Cancer (CPDPC)-initiated NOD study who completed the 3-year study follow-up period. The specimen set included 25 pre-diagnostic samples from the 12 PDAC cases diagnosed during study follow-up. We applied a single threshold (ST) method, which considers CA19-9 levels at a single time point, as well as a previously established parametrical empirical Bayes (PEB) algorithm [referred to as $PEB^{CA19\text{-}9}$], which considers prior CA19-9 results, with 'case' calls made based on pre-specified cutoffs corresponding to 1% 1-year risk. Resultant CA19-9 continuous data as well as case calls were provided to the EDRN Data Management and Coordinating Center as part of a Prospective-sample-collection-Retrospective-Blinded-Evaluation (ProBE)-compliant Phase 3 biomarker validation study. Sensitivity, specificity, population-level positive predictive value (PPV), and negative predictive value (NPV) are reported.
Results: The 3-year incidence of PDAC in the NOD cohort was 0.57%. At the patient level, CA19-9 yielded sensitivity of 83.3% at 97.2% specificity, with respective PPV and NPV of 14.7% and 99.9%. Sensitivity for early-stage (I-II) disease was 100%. In a subset of patients, CA19-9 first tested 'positive' at a median (interquartile range [IQR]) of 7 months (4 to 14 months) prior to clinical PDAC diagnosis. Of the two PDAC cases missed by CA19-9 using the ST method, one (diagnosed with stage III PDAC) was detected using the $PEB^{CA19\text{-}9}$ algorithm.
Conclusion and Relevance: In the setting of adult new onset diabetes, CA19-9 is a readily available and promising biomarker that can be leveraged for earlier detection of an underlying pancreatic cancer.

#4021 Precision diagnostics for early melanoma detection using spatial biology and AI guided image analysis.

Y.-C. Kao[1], S. X. Tan[1], X. Tan[2], H. Oey[1], K. J. Lee[1], T. Vallius[3], R. Pelletier[4], A. Causer[5], C. Zhou[1], D. Smit[1], J. O'Neill[1], A. Xiong[6], B. O'Brien[7], A. Collins[7], P. K. Sorger[8], H. Soyer[1], K. Khosrotehrani[1], Q. Nguyen[2], M. S. Stark[1];
[1]Frazer Institute, The University of Queensland, Dermatology Research Centre, Brisbane, Australia, [2]QIMR Berghofer Medical Research Institute, Brisbane, Australia, [3]Harvard Medical School, Brookline, MA, [4]Laboratory of Systems Pharmacology, Harvard Program in Therapeutic Science, Harvard Medical School, Boston, MA, [5]Institute for Molecular Bioscience, the University of Queensland, Brisbane, Australia, [6]QIMR Medical Research Institute, Queensland, Australia, Brisbane, Australia, [7]Sullivan Nicolaides Pathology, Brisbane, Australia, [8]Harvard Medical School, Winchester, MA

Accurate diagnosis of melanoma is particularly challenging, as malignant lesions often resemble benign naevi. The gold standard for diagnosing melanocytic lesions relies on the examination of morphological cell features using hematoxylin and eosin (H&E) stained tissue samples. This process however is often subject to variability, lacking the sensitivity to precisely define cell types with a high degree of accuracy. This project aims to overcome histopathological limitations by accurately defining transcriptional cell states, indicative of invasive potential, in benign and malignant lesions. We propose that this will enable more precise definitions of true melanomas in a sea of benign or indolent lesions, which constitute the bulk of excised lesions sent for diagnosis. To identify these “hidden” cell states, we performed spatially resolved whole transcriptome profiling (Visium CytAssist) of whole lesions using a large progression series of samples (n=75): ranging from healthy skin, naevi (benign and low to high grade dysplastic naevi), melanoma *in situ*, T1a melanomas, and melanoma arising from pre-existing naevi. To enable deconvolution of the Visium ‘spots’, we performed Single Cell RNA sequencing on healthy skin, naevi and thin melanomas, to determine marker genes specific to each cell type present in human skin. This analysis revealed a change of melanocyte cell states along melanoma progression, from conventional naevus to T1a melanomas. We further identified naevus and melanoma-specific signatures which can be spatially resolved, enabling classification of lesions as “benign” or “malignant”, as well as identifying previously hidden regions of malignant potential. We further utilised single cell resolved Xenium (transcriptomic) and Orion (proteomic) platforms to validate the spatial expression of benign and malignant genes and to finely characterise immune cell populations within the tumour microenvironment. Additionally, all specimens have been assessed for a panel of 361 cancer genes, facilitating a comprehensive characterization of the mutational profile driving melanoma progression. By integrating the molecular data with spatial gene expression analysis, we have developed an innovative deep learning model that enhances diagnostic precision for melanoma based on H&E-stained slides. Together, we have defined melanocyte cell states across melanoma progression and uncovered key tumour-microenvironment interactions. We envision that these data will permit AI-guided diagnosis to accurately delineate benign and malignant melanocytic lesions.

#4033 Chemical trapping of inactive GRB2 dimer unveils a novel cancer vulnerability by coupling replication stress to anti-tumor immunity.

Z. Ahmed[1], D. E. Jones[2], J. A. Tainer[1];
[1]UT MD Anderson Cancer Center, Houston, TX, [2]University of Arkansas, Little Rock, AR

Growth Factor Receptor-Bound protein 2 (GRB2), a critical signal transduction adaptor, has been an elusive therapeutic target due to its ubiquitous SH2/SH3 domains, despite prior clinical evidence (e.g. a striking 75% complete remission in AML patients using liposomal antisense GRB2 RNA) supporting the high value of its inhibition. We overcame this long-standing "undruggable" challenge by leveraging our discovery that the GRB2 dimer is its auto-inhibited form with a unique druggable interface. We will report the structure-guided discovery and optimization of small molecule GRB2 inhibitors (GRB2i) that act by stabilizing this inactive dimer. Combining experimental structural biochemistry and AI-Machine Learning (AI-ML) refinement across chemical space, we have developed potent clinical leads. Our data reveal GRB2i primarily targets cancer-critical DNA Damage Response (DDR) pathways, rather than canonical GRB2 roles in cell growth and proliferation. Specifically, our GRB2i chemically induces catastrophic Homologous Recombination (HDR) deficiency and replication fork instability. This vulnerability renders cancer cells exquisitely sensitive to PARP inhibitors and other DNA damaging agents. Importantly, we show that GRB2i activates the cGAS/STING pathway, triggering the release of pro-inflammatory cytokines and creating a significant immune destruction liability for cancer cells. These collective results unveil a novel structure-guided strategy for small molecule GRB2 inhibition, demonstrating its potential as a single agent or strategic combination therapy to enhance anti-tumor immunity and exploit a central cancer vulnerability.

#4034 Computational ranking-guided discovery of Plexin-B2 as a driver of circulating tumor cell clusters and AI-facilitated neutralization to prevent and inhibit metastasis.

F. Tong[1], M. Veit Acosta[1], Y. Sun[2], Y. Jia[3], G. Hu[4], H. Liu[1];

[1]Northwestern University - Chicago, Chicago, IL, [2]Northwestern Univ. Feinberg School of Medicine, Chicago, IL, [3]Northwestern University, Chicago, IL, [4]Tufts University, Boston, MA

Our previous studies and other works demonstrate that multicellular circulating tumor cell (CTC) clusters are up to 50 times more efficient than single CTCs in mediating viable metastasis (*Cancer Discovery*, 2018, 2023). Yet, the molecular targets underlying this phenomenon and the CTC cluster interactions with immune cells remain poorly understood. To uncover key mediators of CTC clustering and metastatic progression, we developed a computational ranking pipeline integrating adhesion network analysis and metastasis-free survival modeling. This analysis prioritized Plexin-B2 (PLXNB2) as a top-ranked transmembrane protein associated with poor distant metastasis-free survival and enriched expression in CTC clusters from patients with advanced breast cancer. Functional studies demonstrated that loss of PLXNB2 (Plxnb2) markedly reduces both homotypic tumor-tumor and heterotypic tumor-myeloid (monocyte) cluster formation, thereby suppressing spontaneous metastasis *in vivo*. Mechanistically, PLXNB2 engages SEMA4C on tumor cells and SEMA4A on myeloid cells to drive intercellular adhesion and metastatic colonization. Integrative proteomic and pathway network analysis further identified downstream PLXNB2 signaling effectors regulating cell adhesion and stemness plasticity, corroborating its importance as a central hub for clustering. To therapeutically block PLXNB2 functions in metastasis, we obtained 106 anti-PLXNB2 monoclonal antibodies (mAbs) for functional screening and optimization, both computationally and experimentally. Using artificial intelligence (AI)-driven structural platforms and language models, we assessed the IgG binding and neutralizing possibilities in clustering and proliferation assays. Experimental screen of top candidates revealed that several antibodies effectively disrupted both homotypic tumor-tumor and heterotypic tumor-monocyte clustering. Furthermore, we implemented an AI-guided structural modeling workflow to predict the PLXNB2-IgG complex, identify active binding residues, and optimize antibody-antigen energetics for enhanced affinity and neutralization. Together, these findings identify PLXNB2 as a key molecular regulator of CTC clustering and metastatic seeding and establish a framework for structure-guided antibody engineering to therapeutically target CTC cluster-driven breast cancer metastasis.

#4035 SWELL1 controls epigenetic methylation, mitochondrial metabolism, and anti-tumor immunity in IDH-mutant gliomas.
H. Cheng, J. Chen, J. Huang, W. Liu, Z. Qiu;
Johns Hopkins University, Baltimore, MD

Diffuse gliomas account for the majority of adult brain malignancies with limited therapeutic options. Among them, isocitrate dehydrogenase (IDH)-mutant (mIDH) gliomas occur in the majority of diffuse low-grade gliomas with signatures of epigenetic hypermethylation, disrupted mitochondrial metabolism, and an immunologically “cold” microenvironment. Thus, identifying novel mediator that links these processes is critical for developing new treatments. Here, we identified SWELL1 (also known as LRRC8A) as a critical mediator for the mIDH glioma progression. SWELL1, the essential component of the volume-regulated anion channel (VRAC), has been linked to glucose metabolism, glutamate-mediated neuron toxicity, and ATP-induced microglial activation. In our study, SWELL1 knockout (SKO) in primary mouse mIDH gliomasphere cells resulted in increased epigenetic methylation, together with loss of cellular stemness transcriptional programs. Moreover, metabolomic and Seahorse analyses revealed loss of TCA cycle metabolites and decreased mitochondrial respiration in SKO gliomasphere cells, leading to loss of cell growth activities. These findings were further validated using patient-derived TS603 gliomasphere cells and the analysis of a recently published single-cell RNA-sequencing (scRNA-seq) dataset, in which tumors with low SWELL1 mRNA expression exhibited loss of proliferation and increased inflammation signatures. We further performed orthotopic xenograft model using mouse gliomasphere cells and found that mIDH SKO tumors progress slower with prolonged mouse survival. Within the tumor microenvironment, SKO tumors exhibited a profound immune-reactive phenotypes, with increased microglial and tumor-associated macrophage antigen presenting activation, as well as T cell cytotoxic activation. Importantly, orthotopic tumoral VRAC inhibition with an FDA-approved drug dicumarol phenocopied the genetic knockout, extended survival, and synergized with anti-PD-1 checkpoint blockade, significantly boosting anti-tumor efficacy. Our study identifies SWELL1 as a novel, targetable mediator that couples mitochondrial metabolism and epigenetics to oncogenic progression and immune exclusion in mIDH gliomas, providing a strong preclinical rationale for targeting VRAC as potential IDH-mutant glioma therapeutics.

#4036 Deciphering regulatory drivers of lineage plasticity and resistance to antibody-drug conjugates in urothelial bladder cancer.

Jiaqian Luo, Sizhi P. Gao, Jacob E. Tallman, Fengshen Kuo, Merve Basar, Cansu Yol, Syed M. Alam, Hui Jiang, Xinran Tang, Doris X. T. Zheng, Jordan E. Eichholz, Alejandra Lopez Rojas, Ecenur Turkay, Jonathan E. Rosenberg, Gopakumar Iyer, Eugene J. Pietzak, David B. Solit, Hikmat Al-Ahmadie

Memorial Sloan Kettering Cancer Center, New York, NY

Urothelial bladder cancer (UC) displays significant phenotypic heterogeneity, with ~ 30% of tumors exhibiting variant histologic features such as micropapillary, plasmacytoid, squamous, neuroendocrine, and sarcomatoid differentiation. Many of these histologic variants are often associated with aggressive behavior and reduced response to targeted therapies. Emerging clinical data suggest that lineage plasticity may underlie resistance to antibody-drug conjugates (ADCs), including enfortumab vedotin (EV), a Nectin-4-targeting ADC now standard in advanced UC. However, the mechanistic link between lineage transitions, ADC target expression, and ADC sensitivity remains incompletely understood. To study the regulatory mechanism, we conducted integrative genomic and transcriptomic profiling on 341 macrodissected bladder tumor specimens encompassing conventional UC and diverse histologic variants. A subset of mixed histology tumors was further profiled using spatial transcriptomics (10x Genomics Visium) to evaluate intratumoral heterogeneity. Regulon activity was inferred using transcriptomic data. Functional validation of candidate regulators was conducted in bladder cancer cell lines and patient-derived organoids using CRISPR/Cas9-mediated knockout and overexpression.We identified two dominant transcriptional categories across the histologic subtypes. Tumors with plasmacytoid, micropapillary, or nested histology retained a luminal urothelial signature and consistently expressed ADC targets such as NECTIN4, TACSTD2 (Trop-2), and ERBB2 (HER2). In contrast, tumors with squamous, sarcomatoid, or neuroendocrine features showed loss of urothelial identity, downregulation of these ADC targets, and activation of lineage-alternative transcriptional programs. Spatial transcriptomics confirmed marked intratumoral heterogeneity, showing spatially differential lineage program and ADC target expression. Master regulator analysis discovered a core luminal transcriptional program governed by FOXA1, GATA3, and PPARG, which was progressively silenced in variant histologies. These tumors concurrently activated alternative lineage-specific regulators, including ASCL1 and NEUROD1, consistent with neuroendocrine reprogramming. Perturbation of these regulators in organoid and cell line models modulated Nectin-4 expression and altered sensitivity to EV in vitro. This study establishes lineage reprogramming as a central mechanism regulating ADC target expression and ADC response. Lineage regulators represent tractable modulators of ADC response and support the development of rational combination strategies to overcome plasticity-associated resistance. Ongoing studies using multi-omics and functional modeling aim to further define lineage regulatory networks and inform targeted therapeutic strategies.

#4037 Pharmacological inhibition of eIF4A1 suppresses leukemogenesis via specifically rewiring amino acid biosynthesis.

Xiaoxu Zhang[1], Honghai Zhang[1], Lei Dong[2], Alexandra Huang[3], Xueer Wang[1], Lili Ren[1], Hongjie Bi[4], Sean O'Leary[3], Rui Su[1]

[1]Beckman Research Institute of The City of Hope, Monrovia, CA,[2]UT Southwestern Center, Dallas, TX,[3]University of California Riverside, Riverside, CA,[4]Harbin Medical University, Harbin, China

Acute myeloid leukemia (AML) is an aggressive blood malignancy with a dismal 5-year survival rate below 30%. Dysregulation of mRNA translation is a hallmark and a driver of tumorigenesis, including leukemogenesis. However, the precise contributions of translation factors to AML pathogenesis and their potential as therapeutic targets remain poorly understood. Here, we identify eukaryotic translation initiation factor 4A1 (eIF4A1) as a promising vulnerability of AML; genetic depletion or pharmacological inhibition of eIF4A1 markedly suppresses AML initiation and progression via reprogramming amino acid metabolism. Through unbiased multi-omics analysis, we identified eIF4A1 as the most highly expressed translation factor in AML. Notably, eIF4A1 expression was significantly elevated in AML cells and patient samples compared to healthy controls. eIF4A1 knockout (KO) dramatically inhibited AML cell proliferation, suppressed mitochondrial respiration, and reduced global translation intensity *in vitro* and substantially delayed AML progression *in vivo*. While eIF4A1 is traditionally studied within the cap-binding eIF4F complex, our other findings uncover a novel eIF4F complex-independent mechanism. BioID-MS assays, coupled with the validation of PLA assays and co-IP assays, revealed the robust RNA independent proximity of eIF4A1 and mRNA stabilizer Y-box binding protein 1 (YB-1). Integrative RNA-seq and proteomics demonstrated phosphoglycerate dehydrogenase (PHGDH) as a functionally essential target of eIF4A1. Moreover, metabolic profiling combined with isotope tracing (^{13}C) orthogonally confirmed the crucial role of eIF4A1 in rewiring *de novo serine* metabolism, in which PHGDH serves as the rate-limiting enzyme. Gene specific CLIP-qPCR verified the direct binding of both eIF4A1 and YB-1 to PHGDH mRNA. Furthermore, the KO of either eIF4A1 or YB-1 accelerated *PHGDH* mRNA decay. Collectively, these findings suggest an eIF4F-independent mechanism of eIF4A1: eIF4A1 cooperates with YB-1, stabilized *PHGDH* mRNA and reprogrammed amino acid metabolism in AML. Zotatifin, an FDA-approved eIF4A1 inhibitor, administered intraperitoneally (0.5 mg/kg; twice weekly for five weeks), dramatically reduced the leukemia burden and significantly prolonged survival of AML mouse models *in vivo* (immunodeficient xenograft model: 63 *vs.* 150 days median survival for PBS *vs.* Zotatifin, $P = 0.0006$; immunocompetent bone marrow transplantation model: 40 *vs.* 75 days, $P = 0.001$). Moreover, Zotatifin demonstrated strong synergistic activity with the YB-1 inhibitor SU056 in eradicating AML both *in vitro* and *in vivo* ($P < 0.0001$), primarily by disrupting amino acid biosynthesis. Overall, our findings identify eIF4A1 as a key regulator of AML pathogenesis and metabolic homeostasis. Targeting eIF4A1, particularly with Zotatifin, represents a promising therapeutic strategy for AML.

#4038 Anti-ROR2 therapies target cancer stem cells in triple-negative breast cancer.

E. M. Ghia, C. Huang, R. A. Shatsky, G. F. Widhopf II, D. Elson, J. Xian, S. Zare, A. M. Wallace, B. A. Parker, T. J. Kipps; University of California, San Diego, La Jolla, CA

ROR1 and ROR2 are developmentally restricted, structurally related cell surface proteins expressed during embryogenesis but absent in adult tissues. Many cancers, including breast cancer, aberrantly express ROR1/ROR2. We hypothesize that ROR1 and ROR2 mark triple-negative breast cancer (TNBC) stem cells (CSCs) and mediate cancer stemness, epithelial-mesenchymal transition (EMT), metastasis, and resistance to reactive oxygen species (ROS) triggered by radiation or chemotherapy via ROR1/ROR2 signaling. Patient-derived xenografts (PDX) in immunodeficient NOD-scid gamma (NSG) mice (N=7) enabled direct comparison of TNBC tissue and early-passage (T1) PDX using oligonucleotide-barcoded antibodies and single-cell RNA-seq. PDX retained high proportions of $ROR2^+$ TNBC cells with variable or absent ROR1. $ROR2^+$ cell abundance in T1 PDX matched biopsy and showed enriched stemness, EMT, and upregulated ERK1/2, NF-κB, NRF2 target genes (FDR<0.0001). Extreme limiting dilution assays showed 1,000 or 50,000 $ROR2^+$, but not ROR2-negative, cells, formed secondary PDX tumors ($p<0.0001$). APR-246, an investigational anti-cancer agent, promotes cell death via p53 restoration/ROS generation. We generated a high-affinity, humanized monoclonal antibody (mAb) specific for human ROR2 (h6E6) that could block ROR2 signaling, analogous to the capacity of our previous anti-ROR1 mAb (zilovertamab) to block ROR1 signaling. Observing that the vast majority of $ROR1^+$ TNBC co-express ROR2, we hypothesized that targeting $ROR2^+$ TNBC cells with h6E6 mAb could synergize with APR-246 to reverse CSC properties, inhibit PDX engraftment, and overcome resistance to oxidative stress induced by therapy. *In vitro*, h6E6 treatment enhanced TNBC PDX cell sensitivity to APR-246 versus isotype control (hIgG1) ($p<0.005$). In NSG mice with $ROR2^+$ TNBC PDX, intravenous h6E6, compared to control hIgG1, reduced expression of cancer stemness and EMT genes, as well as ERK1/2, NF-κB, and NRF2 pathway targets (FDR<0.0001), and caused a 5-fold reduction in NQO1, the main NRF2 downstream target, and increased sensitivity to APR-246 ($p<0.001$). By integrating rigorous experimental controls in both *in vitro* and *in vivo* studies using early-passage PDX, our work demonstrates that anti-ROR2 antibody therapy, combined with redox-modulating agents like APR-246, can effectively target CSC-driven disease persistence and therapy resistance in TNBC, supporting future clinical trials of h6E6 targeting $ROR2^+$ TNBC.

#4039 Deletion of peroxiredoxin 3 (PRX3) impairs mitochondrial bioenergetics and tumor growth in mesothelioma, supporting the first in human clinical testing of the PRX3 inhibitor RSO-021.

V. Gibson[1], J. Dzialo[2], C. Poile[2], J. Rogel[2], A. Habibovic[1], K. Butnor[1], S. Duloo[2], J. Spicer[3], D. A. Fennell[2], **B. Cunniff**[1];
[1]University of Vermont, Burlington, VT, [2]University of Leicester, Leicester, United Kingdom, [3]King's College London, London, United Kingdom

Aggressive tumors, including mesothelioma, generate high levels of reactive oxygen species (ROS) to support rapid growth and proliferation. To survive under increased oxidative stress, tumor cells upregulate antioxidant expression and activity, including the mitochondrial hydrogen peroxide (H_2O_2) scavenging enzyme peroxiredoxin 3 (PRX3). PRX3 is overexpressed in many cancers and promotes proliferation, survival and chemoresistance, highlighting it as a promising therapeutic target in oncology. Here we demonstrate that genetic deletion of PRX3 via CRISPR/Cas9 in the H-MESO-1 human mesothelioma cell line impairs mitochondrial bioenergetics and suppress mesothelioma tumor growth. PRX3 knockout (PRX3 KO) cells displayed significantly reduced oxygen consumption rates, extracellular acidification rates, and elevated mitochondrial ROS (mROS), indicating PRX3 deficient cells exist in an energetically compromised state. PRX3 deletion also decreased proliferation, colony formation and 3D spheroid growth in Matrigel. In vivo PRX3 KO cells failed to form tumors in SCID mice, whereas control cells generated substantial tumor burden. RNAseq-based gene set enrichment analysis of PRX3 KO cells supported the observed phenotypes including downregulation of oxidative phosphorylation, glycolysis and E2F and MYC targets. Re-expression of PRX3 in PRX3 KO cells partially rescued these phenotypes, reducing mROS, improving mitochondrial function, and enhancing colony formation. In a first-in-human phase 1 trial treating patients via weekly local intrapleural administration with RSO-021, the clinical formulation of the covalent PRX3 inhibitor thiostrepton (TS), at 90 mgs was well tolerated leading to disease control in 67% of patients at 12 weeks and was associated with tumor reductions (NCT05278975). Functional genomic screening identified SLC7A11, a cystine/glutamate transporter, as a mediator of resistance to PRX3 inhibition. Targeting PRX3, especially in combination with SLC7A11 inhibition, represents a promising approach for treating aggressive and treatment-resistant forms of cancer. Collectively, these findings identify PRX3 as a key regulator of redox metabolism, mitochondrial function, and mesothelioma tumorigenesis, and establish RSO-021 as a novel first-in-class PRX3 inhibitor with significant therapeutic potential in oncology. Phase 2 testing of RSO-021 is ongoing.

#3979 Targeting nicotinamide metabolism with NAMPT-inhibitor OT-82 potentiates venetoclax in preclinical models of pediatric and adult acute myeloid leukemia.

M. Haber[1], M. Karsa[1], P. Connerty[1], A. Karsa[1], D. Spurling[1], G. Pomilio[2], V. Litalien[2], J. Xie[3], L. C. Cheung[4], R. S. Kotecha[4], O. Chernova[5], A. V. Gudkov[6], R. B. Lock, PhD[1], M. D. Norris[7], A. H. Wei[2], D. Moujalled[2], K. Somers[3];
[1]Children's Cancer Institute Australia, Sydney, Australia, [2]Walter and Eliza Hall Institute, Melbourne, Australia, [3]Children's Cancer Institute, Sydney, Australia, [4]The Kids Research Institute Australia, Perth, Australia, [5]Oncotartis, Inc, Buffalo, NY, [6]Roswell Park Comprehensive Cancer Center, Buffalo, NY, [7]Children's Cancer Institute Australia, Randwick, Australia

This study evaluates whether targeting the heightened dependence of acute myeloid leukemia (AML) on nicotinamide metabolism can be therapeutically exploited to inhibit AML progression and mitigate venetoclax resistance. AML continues to have poor survival outcomes in children and adults. While the BCL-2 inhibitor venetoclax has revolutionised the treatment of adult AML, there are increasing reports of inherent and acquired resistance to venetoclax. Emerging evidence implicates metabolic reprogramming and increased dependence on the activity of nicotinamide phosphoribosyltransferase (NAMPT), the rate limiting enzyme in the cellular nicotinamide biosynthesis pathway, in AML progression and venetoclax resistance. We evaluated the efficacy of the clinical-stage NAMPT inhibitor OT-82 alone and in combination with venetoclax against AML cell lines *in vitro* and primary AML bone marrow patient samples *ex vivo* by resazurin reduction-based viability, synergy, live/dead and apoptosis assays. Xenograft models derived from 7 pediatric and 9 adult AML patients were treated with OT-82 or venetoclax or their combination in a Single Mouse Trial design to assess therapeutic benefit across a diverse AML panel. PDXs encompassed *KMT2A*-rearranged, *FLT3*-mutant, *TP53*-deficient, and epigenetically altered subtypes, reflecting the heterogeneity of human AML and included venetoclax-refractory cases. OT-82 demonstrated potent single-agent activity against AML cell lines *in vitro* and primary patient samples from *de novo* and relapsed/refractory AML patients *ex vivo* with nanomolar IC50s. The drug induced apoptosis in leukemia cells while sparing normal progenitors. Strong synergy was observed between OT-82 and venetoclax. *In vivo*, OT-82 potentiated venetoclax and venetoclax/azacitidine in a venetoclax-resistant pediatric AML cell line xenograft model, significantly extending survival of mice treated with OT-82/venetoclax or OT-82/venetoclax/azacitidine in comparison to the single agents or venetoclax/azacitidine. Extending in vivo efficacy testing to 16 additional AML PDXs in Single Mouse Trial format demonstrated that OT-82 significantly delayed AML progression across the AML PDX panel ($p=0.0051$), as well as the individual adult and pediatric AML PDX panels ($p=0.0185$, $p=0.0009$, respectively). The OT-82 and venetoclax drug combination induced the most pronounced survival extensions, achieving maintained complete responses in 4/7 and 7/9 pediatric and adult AML PDXs, respectively, including high-risk cases and those with resistance to single agent venetoclax. In conclusion, this study establishes NAMPT inhibition by OT-82 as a promising metabolism-targeting strategy to overcome venetoclax resistance and supports clinical translation of OT-82 in combination with venetoclax in adult and pediatric AML.

#3980 Non-canonical CAR T cell states correlate with durable therapeutic responses in multiple myeloma patients.

K. Wu[1], K. Law[1], S. Kwek[2], M. Arias-Badia[2], A. Lyu[1], R. Wolters[2], A. Lea[2], M. Clark[2], C. Liu[2], Y. Li[1], R. Owens[1], L. Trieu[1], A. Tran[1], M. Bridge[1], Z. Fan[2], A. Cheung[2], J. Wolf[2], A. Portuguese[1], J. Gauthier[1], T. Martin[2], J. Eyquem[2], L. Fong[1];
[1]Fred Hutchinson Cancer Center, Seattle, WA, [2]UCSF, San Francisco, CA

Background: Chimeric antigen receptor (CAR) T cells targeting B-cell maturation antigen (BCMA) have exhibited unprecedented efficacy with >70% initial response rate in patients with relapsed/refractory multiple myeloma (RRMM), which led to FDA approval of 2 CAR T products: ciltacabtagene autoleucel (cilta-cel) and idecabtagene vicleucel (ide-cel). However, long-term clinical outcomes vary markedly in RRMM patients. Prior studies have shown that specific states of CAR T cells, immature myeloma phenotype and hostile tumor microenvironment (TME) are associated with rapid relapse, but much remains to be elucidated regarding how CAR T cells evolve, persist and interact with host immunity over time in patients with distinct clinical outcomes.
Methods: We acquired longitudinal bone marrow (BM) and peripheral blood mononuclear cells (PBMC) samples from 22 RRMM patients receiving 4 different anti-BCMA CAR T products, including cilta-cel (n=7), ide-cel (n=5), BB21217 (n=1) and orva-cel (n=9). The frequency and cell states of CAR and non-CAR T cells were assessed using flow cytometry and single-cell multi-omics (scRNA-seq).
Results: At 1-month post-infusion, the frequency of CAR T cells in BM was significantly higher in durable responders (DR, PFS$\geq$12mo) than transient responders (TR, PFS<12mo) (p=0.04). Single-cell transcriptomic profiling further demonstrated CAR T cells in DR patients were significantly enriched in memory-like and proliferative states with less exhaustion phenotype. After 1 month, the frequency of persisting CAR T declined in all patients, but DR patients had significantly higher frequencies of CAR T cells than TR ($p<0.0001$). By 6 months, persisting CAR T cells in DR patients predominantly exhibited a non-canonical state (T persisters) possessing high expression levels of AP1 genes, NF-κB regulators, and effector cytokines as well as low level of exhaustion-related genes. By single-cell TCR tracking, these T persisters transitioned from multiple cell states at early timepoints. In DR patients, classical monocytes within the BM exhibited less immunosuppressive phenotype post CAR T infusion.
Conclusions: Favorable clinical outcomes in RRMM patients are associated with greater expansion and persistence of CAR T. Durable responses are also associated with non-canonical CAR T cell states as well as a less immunosuppressive tumor microenvironment. These results provide insights into the determinants of durable clinical responses with anti-BCMA CAR T cells for RRMM.

#3981 A bivalent molecular glue linking lysine acetyltransferases to oncogene-induced cell death.

M. N. Nix[1], S. Gourisankar[2], S. Nettles[3], K. Bowman[4], H. Yang[4], B. G. Dwyer[5], R. C. Sarott[3], H. Abuzaid[3], M. Martinez[3], A. Krokhotin[3], L. Chen[3], M. M. Davis[3], D. Fernandez[1], T. Zhang[3], M. R. Green[4], S. M. Hinshaw[3], N. S. Gray[3], G. R. Crabtree[3]; [1]Stanford University, Stanford, CA, [2]Stanford Cancer Institute, Stanford, CA, [3]Stanford School of Medicine, Stanford, CA, [4]UT MD Anderson Cancer Center, Houston, TX, [5]Stanford Schoool of Medicine, Stanford, CA

Cancer therapies that activate cell death are critical to avoid relapse. Approximately 30% of diffuse large B cell lymphoma (DLBCL) cases, the most common non-Hodgkin lymphoma, fail standard-of-care treatment regimens, highlighting the need for new death-promoting targeted therapies. Here, we introduce a gain-of-function small molecule modality that kills DLBCL cells at sub-nanomolar potency (IC_{50} = 0.8 nM) through induced proximity. These bivalent compounds, Lysine Acetyltransferase Transcriptional/Epigenetic Chemical Inducers of Proximity (KAT-TCIPs), leverage the endogenous activity of the co-activating KATs E1A Binding Protein p300 (p300) and CREB-Binding Protein (CBP) to drive the transcription of death-promoting genes normally repressed by oncogenes. Specifically, KAT-TCIPs recruit p300/CBP to genomic loci controlled by the master transcriptional repressor BCL6, dysregulated in ~40% of DLBCL cases, and rapidly reprogram the epigenome to promote BCL6-dependent cell cycle arrest and apoptosis. We report the first X-ray co-crystal structure of a TCIP molecule bound to p300 and BCL6, which guided the optimization of our lead KAT-TCIP, TCIP3. Additional biophysical characterization of TCIP3 revealed its function as a molecular glue that cooperatively seeds ternary complexes on chromatin. This compound exhibits robust preclinical efficacy *in vivo*. It ablates germinal center B cells, which are naturally enriched for BCL6 expression, in immunized mice (5 mpk bid dosed intraperitoneally) relative to vehicle controls. Additionally, TCIP3 eliminates tumors in DLBCL cell line-derived xenograft models within 11 days at the same dose. Notably, this molecule spares healthy lymphocytes and fibroblasts in cytotoxicity analyses. Collectively, our findings establish KAT-TCIPs as powerful tools for co-opting the malignant function of oncogenic drivers to activate robust cell death, with implications for precision epigenetic therapies.

#3982 FGFR1+ cancer-associated fibroblasts contribute to the failure of CAR-T cell therapy in B-cell lymphoma through the secretion of TGFβ.

N. Di Siervi, M. Revuelta, G. Medico, G. G. Inghirami, L. Cerchietti;
Weill Cornell Medicine, New York, NY

Despite significant advancements in chimeric antigen receptor (CAR) T-cell therapies targeting CD19 for relapsed B cell malignancies, over 50% of lymphoma patients do not achieve sustained remission. The roles of cancer-associated fibroblasts (CAF) in reprogramming lymphoma microenvironments and their relationship with CAR T-cell response are becoming increasingly evident. Evidence suggests that TGFβ-activated stromal gene signatures are enriched in immunosuppressive lymphoma microenvironments (LME) and in non-responder CAR T-cell patients (Cerchietti. Cancer Discovery 2021, Locke. Nature Medicine 2024). In previous studies using pre-clinical lymphoma models, we demonstrated that FGFR1 inhibition in CAFs can reverse extracellular matrix compositional changes and increase the secretion of several monocyte chemoattractant proteins, thereby promoting the infiltration of anti-lymphoma macrophages and inducing anti-tumor effect in $FGFR1^{neg}$ lymphoma cells (Di Siervi. Cancer Research 2024). We report now that $FGFR1^{+}$ CAF are a consistent source of TGFβ. We discovered that TGFβ secretion in CAF is tightly regulated by FGFR1 activity. Genetic downregulation and pharmacological inhibition of FGFR1 (SSR128129E, FGFR1i) in three different activated fibroblast models led to a significant decrease in TGFβ transcription, expression, and secretion ($p < 0.005$). We developed a patient-derived xenograft (PDX) model from a B-cell lymphoma patient refractory to CD19 CAR T cell therapy, that we use to test the effect of pharmacological FGFR1 inhibition to the anti-tumor effect of human CD19-CAR T cells. Compared to vehicle, FGFR1i significantly reduced circulating tumor cells and increased circulating CAR T-cells ($p < 0.005$). These findings correlated with a reduced tumor burden and increased CAR T cell infiltration in the intrasplenic tumors.To further characterize CART-cell function, we analyzed exhaustion phenotype. We observed a significant reduction in exhausted $CD4^{+}$ and $CD8^{+}$ T-cell populations ($PD1^{+}$ $LAG3^{+}$) in the CART plus FGFR1i group ($p< 0.05$). Moreover, mice treated with the combination exhibited improved overall survival compared to those treated with CAR T cells alone ($p< 0.05$) or FGFR1i alone ($p < 0.05$). To test whether these results were specific for CD19-CAR T cells, we conducted similar experiments using BAFFR-CAR-T cells. Consistently, the combination of BAFFR-CAR T cells and FGFR1i increased CAR T cell expansion ($p < 0.005$), reduced T-cell exhaustion ($p < 0.05$), and improved overall survival compared to FGFR1i ($p < 0.005$) and CAR T cell therapy alone ($p < 0.005$). In conclusion, our findings suggest that the multifactorial changes induced by FGFR1i rewire the immunosuppressive LME, enhancing CAR T-cell infiltration, expansion, and antitumor activity.

#3983 Condensate dynamics drive adaptive METTL3 inhibitor resistance.

The RNA methyltransferase METTL3, catalyzing N^6-methyladenosine (m^6A) modification, is implicated in oncogenesis. METTL3 inhibitors have shown potent anti-tumor efficacy across diverse preclinical models and are being tested in early-phase clinical trials. However, how cells fundamentally and dynamically respond to disruption of the m^6A RNA methylation machinery and what drives resistance to the catalytic inhibition of METTL3 remains unknown. Using genome-wide CRISPR sensitization and resistance screens in sensitive and resistant cancer models, we identify the nuclear m^6A-reader YTHDC1 as a critical determinant of METTL3 inhibition response. Genetic depletion of *YTHDC1* markedly sensitizes cells to METTL3 inhibitor (METTL3i) treatment *in vitro* and *in vivo* across solid and hematologic cancers, and its overexpression drives primary resistance.

A YTHDC1-condensate imaging screen identified YTHDC1 interactor PABPN1, a PAXT complex component and a resistance hit from our CRISPR screen, as a negative regulator of YTHDC1 condensate dynamics. PABPN1 overexpression restores METTL3i sensitivity in resistant models, whereas its loss induces resistance, highlighting that the state of YTHDC1 nuclear condensates functionally mediate METTL3i response.

Mechanistically, catalytic blockade of METTL3 remodels YTHDC1 condensates, increasing their intensity, size, and number while reducing their biophysical dynamics in sensitive cancer models and patient samples. In contrast, healthy human blood cells retain dynamic condensates, and resistant cancers display static condensates. Integrating direct RNA nanopore m^6A mapping, bulk-RNAseq and quantitative proteomics in YTHDC1-overexpression model, we find that residual m^6A modification persist on transcripts, and YTHDC1 drives restoration of MYC/BCL-2 programs upon METTL3 inhibition. Furthermore, YTHDC1 enhances binding to *MYC* and *BCL-2* mRNAs under METTL3i treatment, preserving their translation despite global m^6A loss. Accordingly, MYC overexpression phenocopies YTHDC1-mediated resistance to METTL3i, confirming its functional relevance. Therapeutically, co-targeting with a newly developed YTHDC1 inhibitor or the clinically approved BCL-2 inhibitor venetoclax synergistically enhances METTL3i efficacy *in vitro* and *in vivo* in clinically relevant models including AML patient-derived xenografts.

Together, these findings uncover adaptive reorganization of the m^6A machinery across hematologic and solid cancers. The YTHDC1 pathway and its condensate state act as predictive biomarkers and enhancers of therapeutic efficacy in METTL3-targeted cancers. Combinatorial targeting of METTL3 and YTHDC1/BCL-2 as a strategy to overcome therapeutic resistance.

#3984 Lymphotoxin alpha induces myeloid differentiation and programmed cell death in myeloid leukemic stem cells resulting in deep and sustained remission in vivo.

Frequent relapse driven by resistant leukemic stem or progenitor cells (LSC) represents one of the major challenges in acute myeloid leukemia (AML) therapy. Based on the concept of cytokine-induced myeloid differentiation as observed during emergency granulopoiesis of healthy hematopoeitic progenitors, we dissected individual cytokines for their effect on myeloid differentiation of LSCs.We identified that cytokines from the TNF family potently induced cellular differentiation in LSCs from a range of different genetic backgrounds of AML. The induction of this differentiation program is driven, at least in part, by the activation of programmed inflammatory cell death and subsequent release of pro-inflammatory cytokines such as IL-1beta. Mechanistically, we identified that TNFR receptor 1 (TNFR1)-mediated signaling induces Receptor-interacting protein kinase 3 (RIPK3) dependent cell death of LSCs upon loss of the pro-survival protein TNFR associated factor 2 (TRAF2). TNF family cytokines such as Lymphotoxin alpha (LTα3) efficiently repress leukemia by depleting TRAF2 from the intracellular pool of LSCs via activation of both TNFR1 and TNFR2. Competitive and simultaneous recruitment of TRAF2 to both TNFR1 and TNFR2 results in the failure of LSCs to generate a robust pro-survival signaling complex I at the proximal portion of TNFR1. This results in RIPK3-dependent inflammatory cell death of LSCs.Of note, in contrast to conventional therapies, LTα3 exerted only minimal toxicity on the healthy hematopoiesis but instead promoted hematopoietic progenitors. This cytokine-induced propagation of healthy progenitor cells mimics the process observed during emergency granulopoiesis. Exposure of healthy primary human bone marrow progenitors to LTα3 resulted in propagation of healthy progenitors cells. Co-treatment of malignant and healthy progenitor cells from AML patients within the same culture repressed the malignant LSCs but propagated the healthy progenitors. Accordingly, this tumor-suppressive mechanism can be harnessed to simultaneously clear malignant progenitors cells and promote healthy hematopoiesis.In mouse model systems, genetic deletion of the TNF superfamily member gene lymphotoxin alpha (Lta) blocked cell death and accelerated leukemogenesis. In patient-derived xenograft mouse models, exposure to recombinant LTα3 resulted in deep and sustained remissions. Leveraging this endogenous tumor-suppressive mechanism may de-couple treatment efficacy on malignant cells from undesired bone marrow (BM) suppression.

#3985 MED12L: A novel player in platelet dysfunction in myeloid neoplasms.

M. Brindisi[1], L. Crisafulli[2], M. Zampini[1], M. G. Liturri[1], A. Campagna[1], L. B. Lanino[3], M. Ubezio[1], G. Todisco[4], G. Maggioni[1], A. Russo[1], M. Bacci[1], N. Manes[1], E. Riva[1], D. [1]IRCCS Humanitas Research Hospital, Rozzano (MI), Italy, [2]Institute for Genetic and Biomedical Research, Milan Unit, CNR, Milan (MI), Italy, [3]Yale University, New Haven, CT, [4]Humanitas University, Pieve Emanuele (MI), Italy, [5]HOCH Health Ostschweiz, Cantonal Hospital St. Gallen, St. Gallen, Switzerland

Myeloproliferative neoplasms (MPN) impose substantial clinical burden through thrombotic complications and leukemic progression, representing the main determinants of patient morbidity and mortality. These clonal malignancies arise from somatic mutations in hematopoietic stem cells (HSC), most commonly *JAK2*-V617F. Despite therapeutic advances, molecular mechanisms underlying aberrant megakaryopoiesis and pathologic thrombocytosis remain unmet. This study investigates Mediator complex subunit 12-like (MED12L), a functionally uncharacterized protein, in normal and malignant hematopoiesis, identifying a novel regulatory function in platelet (PLT) turnover dynamics. In *JAK2*^{V617F} mice genetic ablation of the transcription factor *Pbx1* resulted in amelioration of thrombocythemia and erythrocytosis. Transcriptomics analysis of their stem/progenitor cells uncovered downregulation of *Med12l*. Conversely, in *JAK2*^{V617F} mice, *Med12l* was upregulated in common Megakaryocyte (Mk)-Erythroid progenitors and in committed Mk (but not erythroid) precursors, rising the hypothesis that MED12L dysregulation contributes to aberrant PLT homeostasis in myeloid malignancies. To assess the functional significance of MED12L in the hematopoietic system, we studied *Med12l* knockout (KO) mice and performed systematic hematopoietic characterization under steady-state and stress conditions. We also generated *Med12l* KO/*Jak2*^{V617F} compound mutants (JM mice) to assess the impact of MED12L absence in vivo in an MPN setting. Clinical validation utilized MPN and myelodysplastic syndrome cohorts. Our investigations reveal a previously unrecognized role for MED12L in regulating PLT lifespan and turnover. Blood analysis of *Med12l*-KO mice demonstrated an altered PLT compartment, with increased mean PLT volume, distribution width, area, internal complexity, and elevated surface integrin expression with respect to WT. These findings indicate impaired PLT maturation, supported by a higher frequency of reticulated PLT and increased mitochondrial and endoplasmic reticulum content. *In vivo* PLT depletion with anti-GPIbα antibody revealed impaired recovery kinetics in KO mice, with delayed bone marrow Mk-primed HSC and Mk-committed progenitor expansion. Critically, *in vivo* biotinylation studies definitively established accelerated platelet clearance in MED12L absence. Importantly, in *JM* mice the absence of MED12L counteracted thrombocytosis, a hallmark of MPN, without affecting erythrocytosis. Consistently, scRNA-seq from MPN patients showed a higher proportion of MED12L-expressing platelets compared to healthy donors; similarly, in patients affected by myelodysplastic syndrome we observed a strong correlation between the expression of MED12L in CD34^{+} cells and platelet features.This study uncovers MED12L as a novel player in platelet biology, highlighting its potential as a therapeutic target in myeloid neoplasms.

#3997 Elucidating broad cell-cell interactions via 3D super-cell graphs for prostate cancer risk stratification.

Y. Zhao[1], S. Chow[1], R. Yan[1], R. Serafin[1], E. Baraznenok[1], L. D. True[1], P. Lal[2], A. Madabhushi[3], J. T. Liu[1];

Prostate cancer treatment decisions rely heavily on the examination of 2D histology sections. However, because these sections provide limited sampling of tissue volumes without 3D glandular and cellular context, interpretation can be misleading and ambiguous. We have developed a slide-free 3D pathology method that generates volumetric datasets that mimic the appearance of H&E staining. Using these 3D pathology datasets, we have shown that computational analysis of 3D histomorphometric features describing glandular and nuclear morphology offer better prognostic value than analogous 2D features. However, given that the spatial organization of cells in 3D remains largely unexplored, we investigate whether quantifying 3D cell–cell interactions can further enhance prognostication.
To analyze 3D cell–cell interactions, we first applied a deep-learning segmentation model (Cellpose) to identify all cell nuclei from H&E-analog 3D pathology datasets, and then extracted 3D histomorphometric features from those nuclei, including shape descriptors, texture metrics, and contextual features. Since directly modeling the interactions between millions of cells in 3D is both computationally prohibitive and prone to overfitting, we grouped spatially adjacent and morphologically similar cells into “supercells”, reducing the data to approximately 10% of the original cell count (with exponentially less cell connections) while preserving the overall structure of the cell interactions. Leiden clustering based on nuclear histomorphometric features was used to group these supercells into broad cell types. We then constructed 3D supercell graphs using k-nearest neighbors, where each supercell is represented as a node and edges indicate supercell interactions.
To evaluate the prognostic value of these 3D supercell graphs, we generated graphs for a cohort of 76 archived prostatectomy specimens with known 5-year biochemical recurrence (BCR) outcomes. Quantitative features extracted from the 3D supercell graphs were used as inputs to a LASSO model with 5-fold cross-validation, achieving an AUC of 0.745 ± 0.06 for predicting 5-year BCR. 3D histomorphometric features previously derived from cancer glands and nuclei masks yielded an AUC of 0.751 ± 0.08. Combining all of these features yielded an AUC of 0.837 ± 0.05. In parallel, we are assessing whether end-to-end graph neural network (GNN) learning provides additional prognostic value compared with traditional machine classifiers based on 3D supercell graph features, especially in a low-shot regime with limited cohort sizes.
In summary, based on H&E-analog 3D pathology datasets, we have introduced 3D supercell graphs as a data-efficient method to capture broad cell interactions within the tumor microenvironment, showing that these 3D supercell graph features are of prognostic value.

#3998 AI-driven spatial analysis of 1100 head and neck squamous cell carcinoma patients H&E slides uncovers three subtypes with markedly distinct tumor microenvironments and survival patterns.

S. Biswas[1], A. Stemmer[1], S. Patiyal[1], E. Shulman[1], C.-P. Day[1], T.-H. Chen[2], M.-H. Yang[3], D.-T. Hoang[1], E. Ruppin[4];
[1]Cancer Data Science Laboratory, Center for Cancer Research, National Cancer Institute, Bethesda, MD, [2]Department of Oncology, Taipei Veterinary Hospital, Taipei, Taiwan, [3]Institute of Clinical Medicine, National Yang Ming Chiao Tung University, Taipei, Taiwan, [4]Cedars-Sinai Medical Center, Los Angeles, CA

Background: The spatial organization of the tumor microenvironment (TME) is a critical determinant of tumor progression and patient outcomes in head and neck squamous cell carcinoma (HNSC). However, spatial transcriptomics (ST) technology remains limited by high costs and tissue requirements, which restrict its application to large clinical cohorts and hinder biomarker translation.
Methods: We trained a deep learning model on a HNSC ST cohort comprising 21,466 spots from 10 slides to predict spot-level spatial gene expression directly from *H&E*-stained histology slides. We validated the model's performance and robustness across two independent HNSC ST cohorts consisting of 11,485 spots from 8 slides covering diverse anatomical sites and sample types.
Results: We first demonstrated that our model robustly predicts spatial expression of 2,772 genes (Pearson $r > 0.4$ for predicted vs. actual ST gene expression) across all three ST cohorts. Second, we applied it to infer the spatial gene expression for 1,145 patients from two independent datasets (TCGA-HNSC, n = 445; HANCOCK, n = 700). Third, spatial clustering of inferred TCGA-HNSC profiles identified 11 shared spatial clusters representing TME composition within each patient. Fourth, hierarchical clustering of these TME compositions revealed three distinct patient subgroups, termed *SpatioStates*, each associated with unique biological features and survival patterns. The *Proliferative SpatioState*, dominated by hyperproliferative-hypoxic programs, represents an aggressive tumor niche associated with poor overall survival. In contrast, the *Immune-Activated SpatioState* exhibits strong inflammatory signaling and robust immune-cell engagement, reflecting active antitumor immunity and showing significantly improved prognosis compared with the *Proliferative SpatioState* (HR = 0.66, p = 0.023) after adjustment for age and stage. Meanwhile, the *Metabolic SpatioState* is characterized by high oxidative phosphorylation and stress-response pathways corresponding to metabolically adaptive tumor regions with intermediate survival outcomes. Remarkably, these *SpatioStates* are consistently repeated in the independent HANCOCK cohort, maintaining significant prognostic discrimination between *Proliferative* and *Immune-Activated SpatioStates* (HR = 0.46, p = 0.005), underscoring the robustness and generalizability of our model.
Conclusions: This study establishes the first scalable computational framework for inferring prognostic spatial TME architecture from routine *H&E* slides in HNSC. The identified *SpatioStates* demonstrate robust survival stratification across independent cohorts, thereby facilitating large-scale spatial profiling and establishing a foundation for integrating spatial biology into clinical biomarker development.

#3999 Pan-cancer prediction of response to immune checkpoint blockade from histopathology.

Braun[7], J. Lee[8], H. Joo[9], H. Kim[9], A. Osipov[4], R. A. Figlin[4], J. Bar[10], I. Barshack[10], C.-P. Day[1], S. Hannenhalli[1], K. Sargsyan[4], A. B. Apolo[2], K. D. Aldape[11], M.-H. Yang[12], M. B. Atkins[13], Z. A. Ronai[9], E. Ruppin[1];

[1]National Cancer Institute - Cancer Data Science Laboratory (CDSL), Bethesda, MD, [2]National Cancer Institute - Genitourinary Malignancies Branch, Bethesda, MD, [3]National Yang Ming Chiao Tung University, Hsinchu, Taiwan, [4]Cedars-Sinai Medical Center, Los Angeles, CA, [5]Taipei Veterans General Hospital, Taipei, Taiwan, [6]Brigham and Women's Hospital, Boston, MA, [7]Yale School of Medicine, New Haven, CT, [8]Sungkyunkwan University, Suwon, Korea, Republic of, [9]Cedars-Sinai Medical Center, Jim and Eleanor Randall Department of Surgery, CA, [10]Sheba medical center, Ramat Gan, Israel, [11]National Cancer Institute, Bethesda, MD, [12]National Yang Ming Chiao Tung University, Taipei, Taiwan, [13]Georgetown Lombardi Comp. Cancer Center, Washington

Background: Immune checkpoint blockade (ICB) has transformed cancer therapy, yet only a subset of patients benefit, underscoring the need for robust, generalizable biomarkers capable of identifying tumors with sufficient immune activation. Although numerous immune-related gene signatures and transcriptomic approaches have been proposed, most lack pan-cancer robustness and fail to generalize across independent cohorts. To address this gap, we derived TIME_ACT, an unsupervised 66-gene tumor immune activation (“hotness”) signature that integrates immune infiltration, inflammatory activity, and spatial TIL density. This signature accurately predicts tumor hotness across diverse cancer types, forming a robust pan-cancer measure of immune activation.
Methods: TIME_ACT was evaluated across 22 publicly available pre-treatment ICB transcriptomic cohorts (n=1,416) spanning seven cancer types. To enable prediction from pathology, TIME_ACT scores were inferred from H&E slides using Path2Omics, a recently published deep-learning model trained on TCGA, and validated in nine new histopathology cohorts from different medical centers and populations (n=459).
Results: TIME_ACT accurately identifies immune-hot tumors across eight TCGA cancer types (AUC 0.96-1.00) and two external datasets (AUC 0.96-0.98). TIME_ACT genes were consistently enriched in T cells, B cells, and dendritic cells at single-cell resolution. Spatial analyses shows that TIME_ACT-high regions co-localize with lymphocyte-dense niches adjacent to the tumor epithelium. Across 22 transcriptomic ICB cohorts, TIME_ACT robustly predicted response (mean AUC 0.74; mean OR 5.49). Importantly, histopathology-inferred TIME_ACT scores achieve strong performance across nine multi-centric cohorts (mean AUC 0.73; mean OR 5.07), matching transcriptomic-based prediction levels and importantly, outperforming direct slide-based models.
Conclusions: TIME_ACT is a robust pan-cancer tumor immune activation signature that predicts ICB response directly from the readily available tumor pathology slides. Upon further prospective testing and validation, it offers an exciting new way for further democratizing precision immunotherapy.

#4000 A large-scale, multi-target deep learning model for virtual genomic profiling in colorectal cancer.

E. N. Bergstrom, T. Wu, M. Chatzianastasis, T. Tran, A. Rosenfeld, R. Burns, A. Jurdi, H. Costa, F. Zhang;
Natera, Inc., Austin, TX

Molecular profiling of tumor biopsies is the cornerstone of precision oncology, guiding therapy selection and prognostic assessment. Computational analysis of routine H&E slides offers a complementary approach that can accelerate insights and optimize downstream molecular testing. Recent advances in computational pathology have demonstrated that deep learning models can infer molecular features directly from digital H&E images, termed virtual genomics. However, most studies in colorectal cancer (CRC) have been constrained by limited cohort sizes and single-target prediction frameworks, restricting their clinical relevance and generalizability. Here, we present a transformer-based deep learning framework designed for large-scale, single- and multi-task virtual genomic profiling in CRC. Trained on 45,155 patients with matched digital H&E images, whole-exome sequencing (WES), and circulating tumor DNA sequencing for molecular recurrence monitoring, we validated all results on an external cohort from The Cancer Genome Atlas (TCGA, n=422 CRC patients). We embedded all images using H-optimus-0 and trained a transformer-based multiple instance learning aggregation head for downstream virtual genomic predictions. We trained individual models to predict genes found in the MSK-IMPACT505 cancer gene panel and a single model that predicts all genes simultaneously. Individual models predicted 379 mutated genes with an internal area under the receiver operating curve (AUROC)>0.7. We validated 254 of these genes within TCGA with an AUROC>0.7. Training a multi-task learning model to predict all genes simultaneously improved the AUROC for 85% of the genes. Based on NCCN guidelines in CRC, we further trained individual models to predict MSI status, BRAF V600E, KRAS G12D/V/G13D, and POLE/POLD1 exonuclease mutations with AUROCs of 0.96, 0.92, 0.83, and 0.83, respectively. For the BRAF, KRAS, and POLE/POLD1 mutations, we observed continued benefit from increasing cohort size from as small as 10 mutated cases up to the maximum positivity within our cohort, suggesting that we have not reached the full performance potential for these mutations. Finally, virtually-imputed BRAF mutations stratified minimal residual disease (MRD) risk better than the WES-derived genomic mutation status revealing that the model was capturing MAPK pathway activation rather than single mutation status. The virtual genomic algorithm advances virtual genomic profiling in CRC, demonstrating scalable and potentially generalizable prediction of hundreds of genomic alterations from routine histology. Beyond serving as a low-cost pre-screening tool to guide molecular testing, the virtually imputed biomarkers capture pathway-level activity that better correlates with clinical outcomes such as MRD risk, underscoring its potential to transform precision oncology through image-based genomic insight.

#4001 AI-driven spatial cell classification and tumor-infiltrating lymphocyte (TIL) patch analysis reveal spatial immunoarchitecture in arsenic-associated bladder cancer.

S. Singhal[1], A. Dikshit[2], S. Singhal[1], K. L. Gardner[3];

[1]University of North Dakota, Grand Forks, ND, [2]Bio-Techne Corporation, Newark, CA, [3]Vagelos College of Physicians & Surgeons, New York, NY

The integration of artificial intelligence (AI) with digital pathology provides unprecedented opportunities to decode the spatial complexity of tumor-immune interactions. We developed an AI-driven spatial pathology framework that combines multiplex fluorescence in situ hybridization (mFISH) and deep-learning-based digital histopathology to classify cells and identify tumor-infiltrating lymphocyte (TIL) patches in bladder tumors. Formalin-fixed paraffin-embedded samples were analyzed using RNAscope mFISH targeting three arsenic-responsive genes - *NKIRAS2, AKTIP,* and *HLA-DQA1.* Whole-slide images were co-registered with H&E slides and processed using nuclear segmentation and a convolutional neural network for automated cell-type classification. AI-assisted spatial clustering and TIL patch detection algorithms quantified immune-tumor proximity, heterogeneity, and neighborhood context at micron-level resolution. The AI model achieved >92% accuracy in distinguishing tumor, stromal, and lymphocytic populations. Quantitative mapping revealed that low-grade tumors contained densely packed TIL clusters with a mean inter-TIL distance of <30 µm, reflecting robust immune infiltration. In contrast, high-grade tumors exhibited a >3-fold reduction in TIL patch density and increased spatial separation between lymphocytes and tumor boundaries, consistent with immune exclusion. Spatial co-expression of *NKIRAS2-AKTIP* was enriched in immune-cold regions, while *HLA-DQA1* expression correlated with higher TIL density and active immune interfaces. Pathway enrichment analysis of TIL-proximal regions highlighted upregulation of inflammatory and oxidative stress pathways, whereas immune-depleted zones showed activation of DNA repair and cell proliferation signatures. Gradient-based quantification of TIL patch density and co-expression topology stratified tumors into immune-inflamed, immune-intermediate, and immune-cold phenotypes that correlated with histologic grade and exposure signatures. This integrative approach bridges molecular multiplex imaging with spatial computational pathology, establishing a scalable framework for digital immune landscape mapping. Our findings highlight how environmental exposures reshape tumor-immune architecture and demonstrate the potential of AI-guided pathology for precision immunoprofiling and exposure-related cancer risk assessment.

#4002 Peritumoral collagen microarchitecture is differently prognostic of biochemical recurrence across populations in prostate cancer.

A. Subramanian[1], N. Tokuyama[2], T. Pathak[2], P. Lal[3], A. Madabhushi[2];
[1]Georgia Institute of Technology, Atlanta, GA, [2]Emory University, Atlanta, GA, [3]University of Pennsylvania, Philadelphia, PA

Background
Extracellular matrix remodeling contributes to prostate cancer progression, yet race-associated differences in collagen architecture and their relationship to biochemical recurrence (BCR) remain poorly understood. We investigated whether collagen microstructure features differ between African American (AA) and European American(EA) men who had undergone radical prostatectomy, and whether population-specific collagen signatures carry prognostic value in the post-surgical setting.
Methods
We analyzed H&E-stained whole-slide images from radical prostatectomy specimens representing 101 AA and 101 EA men. Collagen fibers within the peri-tumoral region were computationally extracted using a deep-learning-based image-analysis pipeline, followed by quantification of 19 collagen morphology and texture features spanning structural (orientation, length, curvature, thickness, density, tortuosity, branching, intersection angles), spatial (inter-fiber distance), and textural (texture entropy and Haralick metrics) categories. The dataset was randomly divided into an 80% training set and a 20% independent test set, with equal representation of AA and EA patients in the test subset. Within the training set, population-specific prognostic features were identified using univariate median-threshold survival analysis ($p<0.05$). Multivariate Cox models were then trained separately using AA-derived and EA-derived feature subsets, and model performance was evaluated exclusively on the held-out test set to prevent data leakage.
Results
Nine collagen features were prognostic in AA patients, indicating more irregular collagen texture, greater fiber twisting, and higher variation in fiber orientation and curvature—suggesting a more disrupted stromal environment. In contrast, only five features were prognostic in EA patients, largely corresponding to differences in collagen density, fiber spacing, and overall stromal compactness. Only the collagen orientation variability feature was shared across both groups, underscoring the distinct tumor remodeling patterns in AA versus EA patients. The prognostic value was not retained when each population specific features was applied to the other population. In the full cohort, the AA-specific features demonstrated significant association with BCR (HR = 4.09, 95% CI: 1.09-15.34, p = 0.0243), whereas the EA-specific features did not (HR= 0.96, 95 % CI: 0.31-2.98, p = 0.9408).
Conclusion
Peri-tumoral collagen architecture differed markedly between AA and EA patients, influencing which features predicted BCR. Only AA-derived collagen patterns remained prognostic across groups, highlighting the need for population-aware prognostic approaches.

#4078 Vagal sensory neuronal inflammatory memory promotes gastric tumorigenesis through ILC2-mediated epigenetic signaling and the CGRP/Ramp1 axis.

Yi Zeng[1], Puran Zhang[1], Ruhong Tu[1], Feijing Wu[1], Xiaofei Zhi[2], Jin Qian[1], Biyun Zheng[1], Hualong Zheng[1], Shuang Li[1], Hiroki Kobayashi[1], Yosuke Ochiai[1], Masahiro Hata[1], Juli Lin[1], Junya Arai[1], Leah B. Zamechek[1], Timothy C. Wang[1]

[1]Columbia University Irving Medical Center, New York, NY,[2]Nantong University, Nantong, China

Background: Mammalian tissues can “remember” prior inflammatory or injurious events and respond more rapidly to later stimuli. Whether vagus-derived sensory neurons encode such experiences and convert them into tumor-promoting signals remains unknown. We show that inflammatory memory within vagal sensory neurons drives gastric regeneration and tumorigenesis through ILC2-mediated epigenetic reinforcement and CGRP/RAMP1 signaling.

Methods: Gastric injury was induced by high-dose tamoxifen (HDT) or *Helicobacter pylori* infection/eradication. Orthotopic (ACKP) and spontaneous (Iqgap3-CreERT2; $KRAS^{G12D}$) tumor models assessed memory-driven initiation. Trpv1-Cre; hM3Dq and Trpv1-Cre; DTA mice enabled chemogenetic activation or ablation of nodose ganglion (NG) neurons. An AAV-C-Fos-tTA/TetO-Cre-DTA TRAP system labeled and ablated neurons activated during the first injury. Ramp1 was deleted in gastric stem cells (Iqgap3-CreERT2; $Ramp1^{flox}$), and $IL25R^{+}$ ILC2s were depleted genetically or pharmacologically. Chromatin of sorted NG neurons was analyzed by ChIP-qPCR for H3K4me3 enrichment at memory loci.

Results: Prior injury produced persistent “neuronal memory” marked by expanded $CGRP^{+}$ fibers that accelerated mucosal recovery but enhanced metaplasia and tumorigenesis. Activation of $Trpv1^{+}$ NG neurons was required; activation mimicked memory, while ablation or vagotomy abolished it. TRAP tracing showed reactivated neurons during reinjury overlapped with and exceeded those from the first; ablating the initial cohort erased the phenotype. MRI and c-Fos in the brainstem revealed stronger vagal signals after reinjury, indicating peripheral memory transmission to the central axis. During memory formation, subsets of sensory terminals directly innervated gastric isthmus stem cells; anterograde and retrograde tracing verified bidirectional connectivity, providing a structural basis for rapid signal recall. Memory neurons released CGRP acting on $Ramp1^{+}$ isthmus stem cells; deleting or antagonizing Ramp1 suppressed dysplasia and tumorigenesis. $IL25R^{+}$ ILC2s infiltrated the isthmus and maintained NG memory via IL-5-triggered CGRP release, Wnt5a-guided terminal attraction, and IL-13-induced SMYD4 with enhanced H3K4me3 in NG neurons. These cues reinforced the feedback sustaining the memory state.

Conclusions: We identify a vagal sensory neuronal inflammatory memory circuit linking prior injury to gastric tumor initiation. ILC2-mediated IL-13/SMYD4/H3K4me3 signaling stabilizes memory within NG neurons, while CGRP/RAMP1 and neuro-epithelial contacts transmit it to the mucosa, forming a neuro-epigenetic feedback loop driving inflammation-associated gastric cancer.

#4079 Unique mechanism of MASLD-associated hepatocarcinogenesis: LSEC-derived CXCL9 facilitates T-cell exhaustion in steatotic tumor microenvironment.

N. Ohtani[1], T. Kamiya[1], K. Echizen[1], Y. Nonaka[1], Y. Yukawa-Muto[1], H. Fujii[1], S. Itoh[2], N. Kawada[1];

[1]Graduate School of Medicine, Osaka Metropolitan University, Osaka, Japan, [2]Graduate School of Medical Sciences, Kyushu University, Fukuoka, Japan

In recent years, the incidence of hepatocellular carcinomas (HCC) associated with MASLD (Metabolic dysfunction-associated steatotic liver disease) and MASH (Metabolic dysfunction-associated steato-hepatitis), has continued to rise, although that of viral HCC declines because of the development of anti-viral drugs. However, combination therapy with atezolizumab plus bevacizumab in non-viral liver cancers, including MASLD-related cases, has shown no clear clinical benefit (Cheng et al., J Hepatol 2022), and monotherapy with anti-PD-1/PD-L1 antibodies has even exacerbated disease (Pfister et al., Nature 2021). These findings suggest that mechanisms of HCC development in steatotic MASLD-related liver fundamentally differ from HCCs of other etiologies. In this study, we sought to elucidate the unique mechanisms driving MASLD-associated hepatocarcinogenesis, with a focus on how exhausted T cells arise within the highly steatotic tumor microenvironment. We employed chemical carcinogenesis mouse models of MASLD-associated liver cancer previously established by our group (Yoshimoto et al., *Nature* 2013), alongside patient-derived samples. Multiplex assay for plasma profiling of healthy controls, MASLD/MASH patients, and MASLD/MASH-related liver cancer patients revealed a high level of CXCL9 specifically in the MASLD/MASH-related cancer group. Consistently, CXCL9 levels were increased in samples of our MASLD-related mouse models. Notably, blockade of the CXCL9-CXCR3 axis reduced T-cell trafficking from lymph nodes to the liver and, surprisingly, markedly suppressed tumor formation. Pharmacologic inhibition of lymphocyte migration revealed similar effects. Because CXCL9 expression was predominantly upregulated in liver sinusoidal endothelial cells (LSECs) in the MASLD-HCC model, we generated LSEC-specific CXCL9-knockout mice, which also consistently exhibited reduced tumorigenesis. Although CXCL9 is generally considered a favorable chemokine that recruits cytotoxic T cells to enhance anti-tumor immunity in other cancer types, it plays a detrimental role in MASLD-associated HCC. Our results suggest that LSEC-derived CXCL9 recruits T cells from lymph nodes, but these T cells rapidly undergo exhaustion in the steatotic microenvironment, ultimately promoting cancer progression. To further dissect this process, we performed single-cell TCR sequencing of $CD8^+$ T cells from lymph nodes and liver tissues. We will present the pseudotime analysis of the clonal trajectory, which may suggest the unique mechanisms underlying MASLD-associated HCC development.

#4080 The neural bridge: Stress-remodeled enteric nervous system (ENS) in the colitis-cancer transition.

X. Zhou, C. Chen, H. Choi, J. Liu, S. Chi, N. Tran, M. Ciorba, S. A. Stewart, **X.-Y. He**;
Washington University School of Medicine in St. Louis, St. Louis, MO

Chronic stress, driven by environmental and psychosocial factors, disrupts systemic homeostasis and adversely affects cognitive function, behavior, and the cardiovascular, gastrointestinal (GI), and immune systems. It is closely associated with GI disorders and can exacerbate inflammatory bowel disease (IBD), a known precursor to colorectal cancer (CRC). Effective repair of the colonic epithelium is essential for favorable long-term outcomes in IBD patients, who frequently experience chronic GI injury. Moreover, disruption of gut homeostasis is linked to conditions such as obesity, diabetes, and colitis, all of which may contribute to tumorigenesis. Although multiple mechanisms are implicated in gut homeostasis, a key regulator is the enteric nervous system (ENS), an extensive network of neurons and enteric glial cells (EGCs) that innervates the GI tract. EGCs act as signaling hubs, modulating intestinal motility, immune responses, and epithelial barrier function by releasing factors that influence neighboring cells in response to environmental changes. In Crohn's disease, for example, a reduced glial network is correlated with impaired mucosal healing. Therefore, understanding the mechanisms that facilitate gut homeostasis of significant therapeutic importance, as defective mucosal repair can lead to fibrosis and increased risk of GI adenocarcinoma. To address the role of stress in colitis, a pre-cancer disease, we used a physical restraint model from our previous work, which induces a leaky gut phenotype in mice. In a dextran sodium sulfate (DSS)-induced colitis model, we further found that stress significantly delayed colitis healing, with the accumulation of p16+ senescent enteric glial cells (senEGCs). The senEGCs, which no longer proliferate but remain metabolically active, secrete a diverse array of cytokines, growth factors, and proteases, collectively known as the senescence-associated secretory phenotype (SASP), resulting in inhibiting intestinal organoid outgrowth. Remarkably, either pharmacological intervention with senolytics drug (dasatinib and quercetin) or genetic ablation of senescent cells in INK-ATTAC mice fully reverses stress-impaired colitis recovery. Colitis-associated cancer (CAC), a CRC subtype linked to IBD, carries a high mortality rate: within 30 years of disease onset, over 20% of IBD patients develop CAC, and more than half of these cases result in death. Inflammation also plays a role in the development of sporadic CRCs. In two established CAC models, we found restraint stress increased colorectal tumor number by two-fold relative to controls and enhanced tumor innervation. Given that perineural invasion is a strong and independent prognostic indicator in CRC, our findings provide new insights into the systemic influence of stress on CRC development and open avenues for novel therapeutic strategies to improve CRC treatment outcomes.

#4081 A multimodal single-cell atlas reveals a pathogenic epithelial-myeloid circuit driving HNSCC progression.

C. Nam[1], H. Zhao[2], E. Salman[2], D. Arnaudov[2], U. K. Sinha[2], Y. Park[3], **D.-C. Lin**[2];

[1]Keck School of Medicine of USC, Los Angeles, CA, [2]University of Southern California, Los Angeles, CA, [3]Yonsei University Health System, Seoul, Korea, Republic of

In this study, we performed single-cell RNA sequencing (scRNA-seq) on 167 samples from patients with head and neck squamous cell carcinoma (HNSCC), including distal normal tissues, premalignant lesions, peri-tumor regions, primary tumors, lymph node metastases, and distant metastatic or recurrent tumors. This comprehensive atlas allowed us to profile the full spectrum of immune and stromal populations across the continuum of HNSCC progression. By integrating transcriptional states, cellular compositions, and intercellular communication networks, we uncovered key features of the dynamically evolving tumor microenvironment and identified stage-specific mechanisms that shape tumor development, metastatic competence, and therapeutic resistance.

A central finding was the discovery of a previously unrecognized intratumoral monocytic subset, which we termed Tumor-Reprogrammed Monocyte (TrMo). TrMo cells are markedly enriched in tumor tissues and strongly associated with adverse pathological features and poor patient survival. We also delineated major epithelial heterogeneity programs—including cell-cycle activation, hybrid epithelial-mesenchymal transition (hEMT), and epithelial senescence (EpiSen)—and validated these states in patient-derived organoid models. Notably, normal tissues were dominated by high EpiSen scores, whereas tumors exhibited diverse and spatially organized transcriptional programs.

Using co-association analyses, we identified a robust multicellular module composed of hEMT cancer cells, TrMo cells, myofibroblastic CAFs, regulatory T cells, and Endo_C3-RGCC endothelial cells. Spatial transcriptomic profiling confirmed the physical co-localization of this module in tumor tissues, highlighting a coordinated, tumor-promoting niche.

To investigate its functional relevance, we focused on the bidirectional communication between hEMT tumor cells and TrMo cells. Spatial data demonstrated their intimate juxtaposition in situ, while in vitro co-culture experiments revealed a reciprocal signaling loop. TrMo cells enhanced EMT features in cancer cells by activating the EGFR pathway, whereas hEMT tumor cells induced TrMo activation through CD44-dependent cues. Using patient-derived tumor organoids, we further validated this reciprocal circuit and showed that disrupting either EGFR signaling in tumor cells or CD44 signaling in monocytes attenuated the tumor-promoting phenotypes.

Together, these findings define a pathogenic epithelial-myeloid signaling axis that emerges early in HNSCC progression, becomes reinforced in advanced disease, and represents a promising therapeutic vulnerability. Our work provides a comprehensive multi-modal atlas of the HNSCC microenvironment and establishes a mechanistic framework for targeting multicellular tumor niches that drive aggressive behavior and treatment failure.

#4082 The gut microbiota influences chronic sleep deprivation-induced colorectal cancer progression and treatment response.

M. C. Hernandez[1], Y. Yang[2], C. Jobin[1];

[1]University of Florida College of Medicine, Gainesville, FL, [2]University of Florida Department of Medicine, Gainesville, FL

BACKGROUND: Sleep deprivation (SD) is common among cancer patients and a known disruptor of immune regulation and microbiota balance. We hypothesize that SD-induced bacterial dysbiosis promotes carcinogenesis and reduces 5-Fluorouracil (5-FU) efficacy by creating an immunosuppressive tumor-microenvironment (TME).

METHODS: Chronic SD and fecal microbiota transplant (FMT, $5*10^7$ CFU single oral gavage) mouse models were used to evaluate murine colorectal cancer using MC38 cancer cells. Tumor growth and 5-FU response were assessed. TME immune cell infiltration, tumor gene expression of circadian rhythm (CR) genes, inflammatory, and immune markers were compared between SD and controls.

RESULTS: Chronic SD exposure increased *PER2*, *CRY1*, *CRY2* and decreased *BMAL1* CR gene expression compared to non-SD mice. Chronic SD mice experienced a significant increase in tumor volume (endpoint mean 734 mm^3 SD vs 476 mm^3 non-SD, p=0.0002), remodeled TME via a significant increase in Ly6G+ Neutrophils (0.0366) and CD19+ B cells (0.0163). This was associated with a decrease in *TNFα*, *IL1β* and *IL17A* gene expression. FMT from SD mice to recipient non-SD mice conferred greater MC38 tumor volume (endpoint mean 1086 mm^3 SD vs 618 mm^3 non-SD, p=0.0092) and a pro-inflammatory TME via increase in IL6+ producing Ly6G+ Neutrophils and *IL-6* mRNA accumulation in the tumor ($p < 0.0001$). Interestingly, SD mice exhibited larger tumor volumes (endpoint mean 2241 mm^3 SD vs 1033 mm^3 non-SD, p=0.0059), and fewer cytotoxic and effector immune cells and markers following 5-FU treatment. Gene expression analysis revealed altered *IL17a* (p=0.0195*), IL6* (p<0.0001), *IFNγ* (p=0.0366), and *CD27* (p=0.0228) mRNA accumulation. FMT from SD donor mice to recipient non-SD mice exhibited impaired 5-FU response as seen with higher tumor volume (endpoint mean 1055 mm^3 SD vs 630 mm^3 non-SD, p=0.0033), decreased infiltration of CD4 and CD8+ T cells in the TME along with decreased gene expression of *TNFα* (p= 0.0296) and *IL6* (p=0.0485) in the tumor.

CONCLUSION: Chronic SD promotes carcinogenesis, disrupts circadian rhythm regulation, and weakens chemotherapy efficacy through microbiota-driven immune dysregulation. These findings identify SD as a modifiable factor influencing cancer outcomes and highlight the gut microbiota as an important mediator of this pathology.

#4083 The impact of obesity-induced changes in adipose tissue on ovarian cancer progression.

Sofia Howe, Emily Rodriguez, Mikella Robinson, Carrie Danielle House

San Diego State University, San Diego, CA

Obesity, characterized by excessive accumulation of body fat, is increasingly prevalent and is recognized as a risk factor for ovarian cancer. Omental adipose tissue is the initial metastatic niche for ovarian cancer cells, providing a conducive microenvironment enriched in fatty acids and cytokines that facilitates tumor migration and proliferation. Elevated NF-κB signaling associated with obesity is well-documented to aberrantly influence cancer cell behavior, potentially enhancing the tumor-supportive characteristics of adipose tissue. Despite this established link, the role of specific adipose cell populations in NF-κB-mediated ovarian cancer metastasis, particularly omental preadipocytes which are progenitors to mature adipocytes, remains unclear. Previous studies in our lab identified Insulin-like growth factor-1 (IGF-1), secreted by preadipocytes, as an activator of NF-κB that promotes extracellular matrix (ECM) remodeling and metastasis. Therefore, we hypothesize that preadipocytes from obese omental tissue contribute to ovarian cancer progression through IGF-1 mediated enrichment of NF-κB signaling. To test this, we used in vitro co-culture and in vivo co-injection models with human ovarian cancer cell lines to compare adipocytes and preadipocytes in supporting ovarian cancer during isolation stress-inducing conditions. Our findings revealed that mature adipocytes and preadipocytes generate tumors and activate NF-κB at similar levels. However, when we compared co-injections of GFP labeled cancer cells with isolated omental preadipocytes from high or normal BMI donors, we found that high BMI preadipocytes enhanced early tumor growth and reduced survival of mice. Tumors from high BMI exhibited increased phosphorylation of p65 (Rel A), suggesting that the obese adipose microenvironment may modulate NF-κB signaling dynamics to support tumor growth. We further assessed SOX2 and FN1 expression in GFP positive sorted cells and found a significant decrease in SOX2 expression and increased FN1 levels, suggesting reduced cancer cell stemness and enhanced proliferative, ECM-remodeling programs. To assess IGF-1 secretion, we utilized co-culture studies and found increased IGF-1 levels from high BMI preadipocytes. Our findings highlight the critical role of obesity-induced alterations in omental adipose tissue, particularly in preadipocytes, with IGF-1 signaling as a key factor that may drive metastasis. Ongoing studies aim to interrogate IGF-1 dependent NF-κB activation for ECM-remodeling and metastatic growth using knockdown models. These results will be further validated in an obesity-induced mouse model to assess whether IGF-1 is required to drive ECM remodeling and metastasis. This study provides valuable insight into how obese adipose tissue influences tumor biology, potentially guiding the development of therapeutic strategies for obese ovarian cancer patients.

#4084 Dissecting myeloid-driven mechanisms of immunotherapy resistance in prostate cancer bone metastases.

A. Lyu[1], Z. Fan[2], M. Clark[2], A. Lea[2], R. Wolters[2], L. Qiu[2], K. Tucker[1], L. Trieu[1], Y. Li[1], A. Tran[1], A. Muralidhar[1], E. Van Allen[3], L. Fong[1];

[1]Fred Hutchinson Cancer Center, Seattle, WA, [2]University of California San Francisco, San Francisco, CA, [3]Dana-Farber Cancer Institute, Boston, MA

Background: Patients with metastatic castration-resistant prostate cancer (mCRPC) are generally refractory to immune checkpoint inhibitors (ICIs), particularly those with bone metastases, the most frequent site of disease progression (70-90%). The bone marrow (BM) harbors diverse immune populations, with myeloid cells comprising >70% of its cellular compartment. Among these, neutrophils, known mediators of ICI resistance across multiple malignancies, predominate, whereas macrophages, including *SPP1*-high tumor-associated macrophages (*SPP1*^{hi}-TAMs), are relatively sparse, implicating neutrophils as potential key drivers of ICI resistance. However, their role in human mCRPC bone metastases remains poorly characterized. We hypothesize that single-cell characterization of immunosuppressive neutrophil subsets can find new therapeutic opportunities to enhance immunotherapeutic efficacy.

Methods: We performed single-cell profiling of prostate cancer biopsies across disease stages and tumor sites, including bone metastases, as well as bone samples from tumor-free patients who underwent hip replacement surgery. To validate these findings, we also employed a murine intraosseous CRPC model, combining multi-omic single-cell analyses with functional assays and mechanistic studies.

Results: Single-cell profiling of patients revealed abundant neutrophil populations in the bone compared to other soft tissues, with distinct subsets corresponding to developmental trajectories. Among mature neutrophils, an inflammatory subset expressing elevated *IL1B* expression (*IL1B*^{hi}-mNeu) was significantly enriched in mCRPC bone metastases versus tumor-free bone tissues and expressed elevated immunosuppressive transcriptional programs. Multi-omic analyses of the intraosseous CRPC murine model identified an analogous *Il1b*^{hi}-mNeu population that suppressed CD8^{+} T cell function in co-culture. *In vivo* studies showed that targeting *Il1b*^{hi}-mNeu with a CXCR1/2 antagonist or adoptive transfer of these neutrophils into CRPC-bearing mice demonstrated that *Il1b*^{hi}-mNeu are key drivers of ICI resistance in intraosseous CRPC. Pathway analyses implicated pro-tumor inflammatory signaling as a major mechanism, in particular through IL-1β-mediated pathways. Pharmacologic inhibition of IL-1R diminished *Il1b*^{hi}-mNeu -mediated CD8^{+} T cell suppression *in vitro* and improved ICI responsiveness *in vivo*.

Conclusions: Our studies identify a distinct mediator of immunotherapy resistance in prostate cancer bone metastases. We demonstrate that mature inflammatory neutrophils (*IL1B*^{hi}-mNeu) are enriched in human mCRPC bone metastases and drive ICI resistance through IL-1R signaling. These findings suggest that targeting these cells and their signaling pathways could represent promising therapeutic strategies for overcoming ICI resistance in advanced prostate cancer.

#4087 Senescent cancer cells facilitate metastasis by adhesion-mediated clustering and immune modulation.

S. Anvar[1], C. Maharjan[1], Z. Chen[2], J. D Somers[2], Z. Jin[1], H. Kates[3], S. H. Ramirez[1], A. M. Andrews[1], B. M. Runyon[1], M. E. Carelock[1], Y. Zhang[2], J. Liu[4], W. Zhang[1], L. Cui[2];
[1]University of Florida, College of Medicine, Gainesville, FL, [2]University of Florida, College of Pharmacy, Gainesville, FL, [3]University of Florida, Health Cancer Institute, Gainesville, FL, [4]University of New Mexico, Alnuquerque, NM

Therapy-induced senescence (TIS) occurs following cytotoxic stress and has previously shown to promote tumor metastasis through senescence-associated secretory phenotype (SASP) of stromal cells in the tumor microenvironment, however, whether senescent cancer cells directly participate in metastatic dissemination remains unclear. Here, we report that therapy-induced senescent breast cancer cells actively promote metastatic seeding by physically adhering to parental breast cancer cells and forming circulating senescent-parental cell clusters. Senescence was induced in MDA-MB-231 cells with doxorubicin (39 nM, 7 days) or in 4T1 cells via irradiation (50 Gy, 7 days) and confirmed by X-gal staining, NIR-BG2 senescence probe activity, and increased p16 and SASP expression. RNA-seq revealed upregulation of migration, motility, and adhesion pathways of senescence cells with specific increases in ICAM1, JUP, CLDN1, and CLDN7. Functionally, senescent cells were able to migrate independently, but the presence of both senescent and parental cells in co-culture significantly enhanced migration of both cell types in trans-well and wound healing assays. Hanging-drop aggregation produced large mixed clusters in co-culture, whereas parental cells alone formed scattered microcolonies. Direct adhesion assays showed parental tumor cells preferentially attached to senescent cells versus the substrate, with individual senescent cells binding multiple parental cells. In vivo, orthotopic co-injection of senescent and parental MDA-MB-231 cells in NSG mice resulted in significantly increased lung metastasis. Early tail-vain tracking revealed greater initial lung seeding when co-injected parental cancer cells with senescent MDA-MB-231 in NSG mice and 4T1 cells in NSG and BALB/c mice models, respectively. Interestingly, in immune competent BALB/c mice, metastatic progression sustained over time. These findings reveal a previously unrecognized mechanism in which senescent cancer cells cooperate with parental cancer cells through cell-cell adhesion mediated clustering to facilitate early metastatic colonization. Ongoing studies examine the functional role of ICAM1 and JUP, and the involvement of the immune system as a second phase of metastasis following dissemination, where senescent cells may reshape the microenvironment to promote tumor cells survival. These results suggest that targeting senescent cell adhesion and immune programs may suppress early dissemination and metastatic relapse following cancer therapy.

#4088 Extracellular matrix rigidity controls breast cancer metastasis via TYK2-mediated mechanotransduction.

Z. Hu[1], H. E. Majeski[1], A. Mestre-Farrera[1], S. Cai[2], A. Lalezarzadeh[1], Y. Zhang[1], K.-I. Arimoto[1], D.-E. Zhang[1], H. M. Piwnica-Worms[2], L. Fattet[3], J. Yang[1];

[1]UC San Diego, La Jolla, CA, [2]UT MD Anderson Cancer Center, Houston, TX, [3]Centre de Recherche en Cancerologie de Lyon, Lyon, France

Mechanical cues from the extracellular matrix (ECM) regulate various cellular processes. In breast cancer, increased tumor stiffness is associated with elevated metastasis risk and poor survival. Whether and how the soft extracellular matrix (ECM) of normal mammary tissues actively suppresses malignant progression is poorly understood. Here, we identify TYK2 as an essential mechanosensitive metastasis suppressor that preserves epithelial integrity specifically under low ECM stiffness. Using human and mouse basal-subtype mammary acini and multiple triple-negative breast cancer (TNBC) patient-derived organoid models, we show that genetic depletion or pharmacologic inhibition of TYK2 potently induces EMT, disrupts basement membrane, and drives multicellular invasion under soft physiological stiffness. Importantly, this mechanotransduction pathway is independent of canonical interferon/JAK/STAT signaling, as neutralizing type I interferons or inhibiting JAK1/2 or STAT3/5 did not alter stiffness-dependent EMT and invasion. Mechanistically, TYK2 localizes to the plasma membrane via IFNAR1 binding under low stiffness, which retains the EMT transcription factor TWIST1 in the cytoplasm. Increasing ECM stiffness causes TYK2 to disperse into the cytoplasm, leading to nuclear translocation of TWIST1 and EMT activation. In vivo, TYK2 knockdown or systemic inhibition with the clinical TYK2 inhibitor deucravacitinib markedly increased local invasion and significantly enhanced lung metastasis in MCF10DCIS and TNBC patient-derived xenografts, while leaving primary tumor growth unchanged. Supporting a mechanosensory role of TYK2, normal human breast epithelium exhibited strong membrane-localized TYK2, whereas invasive breast cancers displayed diffuse cytoplasmic TYK2, mirroring the high-stiffness phenotype observed in vitro. These findings uncover TYK2 as a ECM rigidity-dependent epithelial safeguard that actively suppresses EMT and metastatic progression in basal-subtype breast cancer. By demonstrating that TYK2 blockade or loss unleashes invasion and metastasis in multiple xenograft and patient-derived TNBC models and that normal breast epithelium relies on membrane-anchored TYK2 for mechanotrasnduction, this work reveals a fundamental stiffness-governed epithelial defense mechanism. Given the increasing clinical use of TYK2 inhibitors for autoimmune diseases, these results raise important considerations for patient monitoring and metastasis risk.

#4089 Immunosuppressive cellular topography and genomic adaptations sustain colorectal cancer metastasis to the brain.

A. Sathe[1], M. Zhang[1], X. Bai[1], J. Kang[1], R. Meka[1], H. Sun[1], M. Humayun[2], X. Wang[2], S. M. Grimes[1], A. Khan[1], M. Liu[1], A. S. Luksik[3], M. Lim[1], C. K. Petrisch[1], C. M. Jackson[3], H. Vogel[1], J. Shen[1], R. D. Kamm[2], M. Gephart[1], S. Han[1], H. P. Ji[1];
[1]Stanford University School of Medicine, Stanford, CA, [2]Massachusetts Institute of Technology, Cambridge, MA, [3]Johns Hopkins University School of Medicine, Baltimore, MD

Colorectal cancer metastases to the brain (CRC-BMets) are lethal and resistant to immunotherapy and radiation. The cellular and molecular adaptations that sustain CRC-BMets remain poorly defined. The objective of our study was to identify the tumor-intrinsic and microenvironmental programs that support metastatic growth in the brain. To understand these mechanisms as they operate in the patient's metastatic niche, we performed sequencing and imaging-based spatial transcriptomics on 51 patients, including a subset with paired primary tumors and longitudinal radioresistant tumors. Using patient-derived three-dimensional co-culture systems, microfluidic assays and single-cell sequencing, we experimentally perturbed the intercellular interactions that promote tumor growth in the metastatic niche.Metastatic tumor cells showed significantly elevated chromosomal instability and activation of RNA-processing, stress-response, and junctional remodeling pathways compared with paired primary tumors. After radiation therapy, resistant clones retained their copy-number alterations and displayed increased epithelial-mesenchymal transition and transcriptional plasticity. Spatial mapping revealed that tumor cells proliferated preferentially in endothelial-rich regions. Tumor cells acted as multicellular ligand hubs (*MIF*, *GDF15*, *PRSS3*, *SEMA3C*) reinforcing tumor-supportive interactions with multiple surrounding microenvironmental cell types in the metastatic niche. Adjacent brain parenchyma expressed astrocytic and glial activation, together with angiogenic and matrix-associated pro-tumor features. CRC-BMets reconstructed a stromal microenvironment dominated by macrophages and fibroblasts in proximity to tumor cells, with sparse lymphocytes. This conserved macrophage-fibroblast neighborhood promoted angiogenesis and extracellular matrix remodeling, with increased regulatory T cell and exhaustion gene signatures. Macrophages expressed high levels of *SPP1*, predicted to orchestrate a matrix remodeling immunosuppressive program via interactions with corresponding receptors on neighboring cells. In a microfluidic device, CRISPR deletion of *SPP1* reduced macrophage mobility in the presence of tumor cells. When co-cultured with a CRC-BMet patient-derived spheroid and fibroblasts, *SPP1* knockout led to reduced expression of lipid-metabolism related genes in macrophages and disrupted tumor-promoting interactions. Together, these findings indicate that CRC-BMets are maintained by spatially organized tumor-intrinsic adaptations and multicellular stromal programs that persist after radiotherapy. These tumor genomic adaptations, multicellular ligand hubs, and an SPP1-dependent macrophage-fibroblast axis define targetable vulnerabilities in this aggressive metastatic site.

#4090 ADAR1 acts as a metastatic switch by sustaining survival programs in breast cancer brain metastasis..

T. Sposito, E. Klacking, J. Pham, R. Sasik, I. Van der Werf, N. Kfoury-Beaumont, T. Beaumont, V. Goodwill, A. A. Khalessi, T. Whisenant, C. Jamieson;
University of California San Diego - UCSD, San Diego, CA

Background: Essential for preventing autoinflammation, adenosine deaminase acting on double-stranded RNA (ADAR1) has been widely implicated in tumor progression and immunotherapy resistance. However, its role in the establishment and progression of metastasis remains unexplored. High-grade breast cancer (BC) patients harboring ADAR1 overexpression have been correlated with a worse prognosis and reduced survival, suggesting that ADAR1 activation may also play a role in BC stem cells transformation. This project focused on the brain niche, one of the most aggressive and least studied sites for BC metastasis.
Methods: We investigated ADAR1 dependencies in BC brain metastasis (BC-BrM) using single-cell RNA sequencing (scRNA-seq) of orthotopically derived triple-negative breast cancer (TNBC) BrM. The model was generated by intra-cerebroventricular implantation of TNBC cells carrying a nanoluc-GFP reporter for tracing ADAR1 activity into *Rag2γc*$^{-/-}$mice. Data from this mouse model were compared with scRNA-seq and imaging of metastatic patient samples.
Results: When TNBC cells were implanted into the mouse brain to form BrM, we observed upregulation of the tumor extracellular matrix (ECM) and JAK/STAT-driven inflammatory response, together with the activation of the WNT/β-Catenin pathway and ADAR1, compared to non-implanted TNBC cells. Consistent with these findings, we observed acorrelation between nuclear ADAR1 and WNT/β-Catenin activation in human tumors. As a readout for increased β-Catenin stability, we detected a marked inhibition of its negative regulator, GSK3β, in samples with high nuclear ADAR1/β-Catenin levels.
Sc-RNA seq analysis of patient samples identified a cluster with high ADAR1 level characterized by fast dividing cells and activation of Protein Arginine Methyltransferase 1 (PRMT1), a driver of *de novo* fatty acids synthesis in BC cells. This cluster positively correlated with cancer cell proliferation programs, lipid remodeling and suppression of inflammatory stimuli. ADAR1 downregulation in the mouse model confirmed a decrease in PRMT1 across several clusters and revealed a reduction in the metastatic drive of the tumors, by impairing cell-cycle progression, ECM deposition and lipid remodeling. Finally, we identified a highly stressed cluster, predominantly composed of ADAR1 KD cells, characterized by endoplasmic reticulum stress, a robust unfolded protein response, and an apoptotic signature.
Conclusions: Our findings identify ADAR1 as a critical “metastatic switch” that enables BC cells to coordinate proliferation and stress adaptation programs required for survival in the brain microenvironment. ADAR1 loss destabilizes metastatic proteostasis ultimately leading to programmed cell death. This study uncovers a key dependency of BC-BrM on ADAR1, highlighting it as a promising therapeutic target for disrupting the metastatic niche.

#4091 KPC1 regulates mesenchymal reprogramming in metastatic melanoma through ubiquitin-dependent degradation of ZEB1.

Yusuke Nakano[1], Matias A. Bustos[1], Kelly Chong[1], Yoshinori Hayashi[1], Aaron Ciechanover[2], **Dave S.b. Hoon**[1]

[1]St. John's Cancer Institute, Santa Monica, CA,[2]The Rappaport Faculty of Medicine and Research Institute, Halifa, Israel

Background: Advance stages of metastatic melanoma (MM) transitions reversibly between melanocytic and mesenchymal (MES)-like cell states, enabling invasion, therapeutic resistance, and immune evasion. While transcriptional regulators of this plasticity are well described, the role of post-translational control remains underexplored. The ubiquitin E3 ligase KPC1 (RNF123) regulates NF-κB signaling through p105 processing, but its contribution to melanoma cell-state transitions is unknown. We investigated whether KPC1 regulates MES reprogramming through ubiquitin-dependent modulation of ZEB1, a central MES transcription factor.
Methods: We integrated bulk RNA-seq, single-cell RNA-seq, and proteomic datasets from TCGA-SKCM, GSE115978, and PXD006003. Deconvolution (BayesPrism, CODEFACS) was used to derive melanoma-cell-specific expression profiles, and Monocle3 was applied to reconstruct pseudospatial trajectories. Functional validation included siRNA knockdown, qRT-PCR, Western blotting, cycloheximide chase, MG132 treatment, ubiquitination assays, and wound-healing migration assays. Multiplex immunofluorescence (mIF) on a clinically annotated stage III/IV melanoma FFPE tissue microarray (n = 110) assessed protein-level associations and clinical relevance.
Results: Across TCGA and scRNA-seq datasets, KPC1 expression showed a strong inverse association with MES gene signatures and was lowest in melanoma cells enriched for MES pathways. Trajectory analysis demonstrated that MES progression accompanied a continuous decline in KPC1. KPC1 knockdown did not change ZEB1 mRNA but markedly increased ZEB1 protein, indicating post-transcriptional regulation. Loss of KPC1 delayed ZEB1 degradation in CHX-chase assays, reduced ZEB1 ubiquitination, enhanced CDH2 expression, suppressed CDH1, and increased cell migration. Proteasome inhibition further confirmed that ZEB1 turnover is KPC1-dependent. In melanoma patient samples, low KPC1 protein co-localized with high ZEB1 and CDH2 and predicted significantly shorter overall survival. Combined evaluation of KPC1, ZEB1, and CDH2 improved prognostic resolution beyond individual markers.
Conclusions: KPC1 functions as a post-translational suppressor of MES-like reprogramming in metastatic melanoma by promoting ubiquitin-dependent degradation of ZEB1. Loss of KPC1 stabilizes ZEB1, activates MES transcriptional and phenotypic programs, and correlates with poor clinical outcomes. These findings identify KPC1 as a key regulator of melanoma cell-state plasticity and supports its potential utility as a theragnostic target.

#4092 Tumor cell JAG1 promotes lymph node metastasis and predicts recurrence in lymph node positive breast cancer patients.

B. Gordon[1], S. Youn[1], B. Swaminathan[1], N. Obacz[1], R. Vadakath[1], P. Teneqexhi[1], I. Alvarez-Lopez[2], M. Rezola[2], S. Manzano[2], Z. Telletxea[2], Z. Xu[3], Z. Chen[3], E. Er[1], L. Naiche[1], M. Munoz Caffarel[2], **J. Kitajewski**[3];

[1]University of Illinois Chicago, Chicago, IL, [2]Biogipuzkoa Health Research Institute, Donostia-San Sebastian, Spain, [3]University of Illinois Cancer Center, Chicago, IL

Lymph node metastasis is a “canary in the coal mine” in breast cancer, acting as a distinct prognostic indicator of aggressive disease. In preclinical models, invasion of tumor cells into lymphatics and lymph nodes is promoted by LECs that are active participants in the promotion of tumor cell invasion. It remains unclear how breast tumors interact with LEC cell signaling pathways to transverse lymphatic endothelium. Better understanding of specific and clinically actionable mechanisms that tumor cells use to promote lymphogenous metastasis are needed to reduce disease progression to distant organs. Expression of the Notch ligand JAG1 has long been associated with poor prognosis in patients, and JAG1 has been established to have critical roles in lymphatic specification and development. Using mouse models, we report that JAG1 expression in tumor cells actively promotes lymph node metastasis. JAG1 expression in tumor cells promotes progression through multiple stages of the lymphogenous metastatic cascade, including lymphovascular invasion into peritumoral lymphatic vessels, entry to mammary lymphatic collecting ducts, invasion into the subcapsular sinus of the lymph node, and overt nodal metastasis. To understand the underlying mechanisms of JAG1-driven metastasis, we determined that exposure of LECs to JAG1, either by JAG1-expressing tumor cells or tethered exogenous ligand, disrupted lymphatic barrier integrity and increased tumor cell migration across LEC monolayers in vitro. JAG1-stimulated transendothelial tumor migration could be suppressed with a Notch4-inhibiting antibody, but was not affected by treatment with a canonical Notch inhibitor. We demonstrated that JAG1 expression in tumor cells promotes VEGFR3 activity in LECs. JAG1-dependent lymph node metastasis can be suppressed with two distinct soluble VEGFR3 antagonists in vivo. In human synchronous breast and lymph node samples from node positive patients, we demonstrate that tumor cells in the lymph node are enriched in JAG1 compared to the primary tumor. Enrichment of JAG1 in lymph nodes was clinically meaningful, as JAG1 levels in the node, but not the primary tumor, predicted disease recurrence post-lumpectomy, which suggests that molecular workup of sentinel lymph nodes may be informative in lymph node positive patients. These data provide a novel mechanism by which tumor cells regulate cell behaviors in nearby lymphatic endothelium to promote invasion and lymphogenous metastasis.

#4093 Lipocalin-2 drives brain metastatic progression through reciprocal tumor-microenvironment interactions in lung cancer.

D. He[1], Y. Zhu[2], J. Zhang[1], W. Zhuang[1], H. Bai[1], J. Wang[1];

[1]State Key Laboratory of Molecular Oncology, Department of Medical Oncology, National Cancer Center/National Clinical Research Center for Cancer/Cancer Hospital, Chinese Academy of Medical Sciences & Peking Union Medical College, Beijing, China,

[2]Department of Radiation Oncology, Sichuan Clinical Research Center for Cancer, Sichuan Cancer Hospital & Institute, Sichuan Cancer Center, Affiliated Cancer Hospital of University of Electronic Science and Technology of China, Chengdu, China

Background: Brain metastasis (BM) is a leading cause of death in lung cancer patients, and the brain's unique microenvironment is key to metastatic initiation and progression. However, the molecular mechanisms of tumor microenvironment crosstalk in lung cancer BM remain unclear. Lipocalin-2 (LCN2) is associated with inflammation and cancer, but its specific role in lung cancer BM is undefined.
Methods: Single-cell sequencing analysis was conducted on BM specimens from patients with lung cancer BM, and data mining of public databases was performed to identify key molecules. Cell lines with stable LCN2 knockdown or overexpression were constructed using lentiviral transduction. Transcriptome sequencing and immunofluorescence assays were applied to verify the in vitro functions of LCN2, including its regulatory effects on downstream signaling pathways and cellular behaviors. For in vivo studies, murine models of lung cancer BM were established via brain orthotopic injection and intracardiac injection of tumor cells. Bioluminescence imaging and multiplex immunofluorescence staining was utilized to investigate the role of LCN2 in BM tumor initiation and progression, as well as its interaction with brain microenvironmental components.
Results: LCN2 was upregulated in BM compared to primary tumors, correlating with shorter intracranial disease-free and overall survival and plasma LCN2 was higher in BM patients. LCN2 is dispensable for BBB transmigration but is essential for promoting tumor growth within the brain microenvironment. LCN2 promoted intracranial tumor growth and upregulates VEGF-A via the JAK2/STAT3 signaling pathway to facilitate angiogenesis in lung cancer BM. More importantly, LCN2 bound to SLC22A17 on astrocytes to activate the JAK2/STAT3 signaling pathway and induce CCL2 secretion, which recruited macrophages that secreted IL-1β to upregulate LCN2 in tumor cells via the IL-1R-NF-κB signaling axis. Inhibition of IL-1β-IL-1R and JAK2/STAT3 signaling by IL-1R inhibitor anakinra combined with STAT3 inhibitor SH4-54 an suppress LCN2-driven tumor progression.
Conclusions: Tumor-derived LCN2 orchestrates a brain-specific metastatic program through dual mechanisms: a paracrine loop involving astrocyte activation and macrophage recruitment and a tumor-intrinsic angiogenic pathway via SLC22A17-JAK2-STAT3-VEGF-A signaling. These mechanistic insights suggest that LCN2 may serve as both a therapeutic target and a prognostic biomarker in lung cancer BM.

#4060 SOX2 is a master regulator of classical squamous cell carcinoma.
R. Falter, Y. Song, X. Zhang;
University of Utah Huntsman Cancer Institute, Salt Lake City, UT

Classical squamous cell carcinoma is defined by recurrent 3q amplification and overexpression of the lineage-specific transcription factor SOX2. However, the extent to which SOX2 contributes this molecular subtype remains incompletely understood. Here, we identify SOX2 as a master regulator of the classical SCC subtype through integrated analysis of chromatin accessibility, transcription factor binding, 3D chromatin interactions, and gene expression. Across TCGA and cell line datasets, classical SCCs exhibit SOX2 copy number gain, focal amplification, and elevated expression. Dependency analyses reveal that classical SCC cell lines are uniquely sensitive to SOX2 loss, which we functionally validate using SOX2 CRISPRi, resulting in impaired proliferation and reduced SOX2 protein levels. ATAC-seq following SOX2 depletion demonstrates that SOX2 is required to maintain chromatin accessibility at thousands of regulatory elements. Regions that lose accessibility upon knockdown show the strongest SOX2 ChIP-seq binding and are enriched for SOX2 motifs. Conversely, SOX2 overexpression in SOX2-low non-classical SCC lines is sufficient to induce chromatin opening at newly bound enhancers, supporting a direct pioneer factor role for SOX2. HiChIP profiling reveals that SOX2 loss disrupts enhancer-promoter chromatin loops, whereas SOX2 overexpression creates new interactions at target genes. SOX2-dependent looping events overlap strongly with SOX2-driven accessibility changes. Finally, transcriptomic analyses show that SOX2-regulated enhancer-promoter interactions activate pathways enriched in classical SCC. Genes associated with SOX2-driven loops and accessibility changes exhibit the strongest expression alterations.Together, these data demonstrate that SOX2 is both necessary and sufficient to activate classical SCC epigenomic and transcriptional programs. By functioning as a pioneer factor that controls chromatin accessibility, chromatin looping, and downstream oncogenic expression, SOX2 emerges as a central regulator of classical SCC.

#4061 Single cell transcriptomic analysis of T-SCLC patients identifies PHOX2B as a factor in NE transformation.

A. Sabet[1], M. Wang[1], S. Rakhade[2], A. Quintanal-Villalonga[1], E. Redin[1], C. M. Rudin[1], J. Chan[1];
[1]Memorial Sloan Kettering Cancer Center, New York, NY, [2]Herbert Irving Comprehensive Cancer Ctr., New York, NY

Lung neuroendocrine (NE) transformation is a molecular process by which non-small cell lung cancers (NSCLCs) transdifferentiate into small-cell lung cancer (SCLC). This transition involves coordinated histological and molecular reprogramming. NE transformation is frequently observed in EGFR-mutant LUAD, occurring in up to 15% of patients treated with EGFR targeted therapies. Whereas LUAD is typically driven by activating oncogenic mutations that hyperactivate the MAPK signaling, SCLC is defined by near-universal inactivation of the tumor suppressor genes *TP53* and *RB1*. Although concurrent loss of *TP53* and *RB1* appears to be a prerequisite for NE transformation, this genetic background alone is insufficient to induce the phenotypic switch. In this project, we aim to identify molecular drivers that promote NE transformation in *TP53/RB1*-deficient LUAD tumors.We conducted single cell transcriptomic profiling on a cohort of 47 tumors and patient-derived xenografts (PDXs) from 24 patients with transformed or combined NE histology. Our analysis identified high levels of *PHOX2B* in transformed SCLC (T-SCLC) cases versus non-transformed SCLC and LUAD. *PHOX2B* is a neural crest transcription factor (TF) and acts a known oncogenic driver in neuroblastoma. In two EGFR-mutant LUAD cell lines with concurrent inactivation of *TP53* and *RB1*, we found that PHOX2B overexpression induced upregulation of NE markers such as SYP. Furthermore, we observed a pronounced decrease in EGFR signaling along with MAPK (ERK) and YAP activity. ChIP-seq analysis revealed *PHOX2B* binding to the EGFR promoter, suggesting that PHOX2B may act as a transcriptional repressor of EGFR. Despite these changes, PHOX2B overexpression did not drive full morphologic NE transformation *in vitro* or *in vivo*. Moreover, PHOX2B knockout in *de novo* as well as T-SCLC cell lines did not substantially reduce NE marker expression. Our research uncovers a previously unidentified role for *PHOX2B* in NE differentiation. They suggest that *PHOX2B* likely primes cells for transformation by shutting down EGFR signaling, which may represent a necessary but insufficient factor for NE transformation. Future work will investigate the molecular mechanism by which PHOX2B contributes to NE differentiation and cooperates with other factors to drive plasticity.

#4062 MBD4 regulates FOXA1 lineage-specific enhancers to promote prostate tumorigenesis and progression.

X. Chen, J. A. Villa-Pulgarin, J. Wu, U. Chan, A. Orgel, J. Owiredu, A. Yadav, A. Sboner, C. E. Barbieri;
Weill Cornell Medicine, New York, NY

BACKGROUND: Like many cancers, prostate cancer (PCa) relies on tissue- and lineage-specific transcription factors essential for normal tissue function and tumor progression. A key master factor is the androgen receptor (AR), which regulates prostate tissue identity and differentiation, maintaining normal, growth-suppressive, prostate-specific luminal programs via androgen response elements (AREs). However, during tumorigenesis, AR is co-opted to drive oncogenic transcription programs, including the reprogramming factors like FOXA1 and HOXB13. Despite AR's critical role, the mechanisms and functional implications of both its oncogenic and growth-suppressive programs in PCa remain incompletely understood. We hypothesized that the previously known methyl-CpG reader and DNA repair protein, MBD4, safeguards these lineage trajectories by restraining pioneer factor engagement.
METHODS: We performed an epigenetic-focused CRISPR screen (2,508 genes) in an LNCaP ARE-activated model to nominate the regulators of AR programs. We engineered MBD4 knockout and inducible overexpression models and profiled chromatin and transcription by ATAC-seq; CUT&RUN (AR, FOXA1, H3K27ac, H3K4me3, H3K27me3); and RNA-seq across AR^+ and AR^- lines. Proliferation and lineage-identity programs were also evaluated in normal mouse prostate organoids. Clinical relevance was assessed using multi-cohort patient transcriptomes and cancer-dependency datasets.
RESULTS: MBD4 emerged as a gatekeeper of the AR/ARE-mediated growth-suppressive program. MBD4 loss increased chromatin accessibility and enhancer acetylation at FOXA1-enriched loci, with FOXA1 binding expanding upon loss and decreasing with MBD4 overexpression. MBD4 localized to AR/FOXA1 enhancers and limited FOXA1 engagement. Functionally, MBD4 knockout accelerated proliferation in AR^+ lines (e.g., LNCaP, MDA-PCa-2b) and slowed growth in AR^- lines (e.g., PC3, DU145). In normal mouse prostate organoids, MBD4 disruption biased luminal epithelial identity programs and reprogrammed enhancer architecture. Across patient cohorts, MBD4 expression and dependency patterns tightly tracked with AR status/lineage, linking lineage context to chromatin plasticity.
CONCLUSIONS: MBD4 acts as a gatekeeper of the AR/ARE-mediated growth-suppressive program by limiting lineage-specific enhancers and restraining FOXA1 engagement. Loss of MBD4 promotes FOXA1-driven reprogramming and lineage plasticity, nominating the MBD4-FOXA1 axis as a potential therapeutic target.

#4063 Oral small-molecule condensate modulator (c-mod) inhibits MYC activity and demonstrates robust anti-tumor activity across diverse tumor models.

J.-G. Ren, D. Baumann, A. Talbot, T. Durand-Reville, I. Klein, **A. Boija**;
Dewpoint Therapeutics, Inc., Boston, MA

MYC is a key oncogenic driver that is commonly overexpressed or amplified across a wide spectrum of human cancers. Despite its therapeutic relevance, MYC has remained difficult to target pharmacologically due to its intrinsically disordered structure and dependence on dynamic biomolecular interactions. MYC forms transcriptional condensates to drive oncogene expression, suggesting that it might be inhibited by this mechanism. Using a condensate-focused screening approach, we previously identified first-generation MYC condensate modulators (c-mods) capable of disrupting MYC condensates and suppressing MYC-dependent transcription. Here we describe the profile of our orally bioavailable MYC Development Candidate (DC) with improved pharmacological properties, potency, and selectivity. This compound reduces MYC condensates, represses MYC-driven gene expression, and selectively inhibits the growth of MYC-addicted cancer cells by inducing apoptosis and cell-cycle arrest. Broad in vitro activity has been observed across multiple solid tumor types. In animal models, oral administration of our DC produces robust anti-tumor responses with an emerging tolerability profile supportive of continued development. Preclinical biomarker studies further demonstrate modulation of MYC pathway activity in vivo. Together, these findings position MYC condensate modulation as a promising therapeutic strategy for MYC-driven cancers.

#4064 NSD3 is a critical cofactor that enables fusion oncoprotein-driven 3D genome reorganization and activation of oncogenic transcriptional programs.

Y.-H. Chen, K. Sampat, I. D. Yonchev, C. E. Hawkins, C. Ponne, **K. P. Eagen**;
Baylor College of Medicine, Houston, TX

Fusion oncoprotein transcription factors such as BRD4-NUT reprogram chromatin organization to activate oncogenic transcriptional programs, yet the mechanisms by which they reshape gene regulatory architecture remain poorly understood. BRD4-NUT and NUT variant fusions drive NUT carcinoma, an aggressive squamous malignancy with a median survival of only 6.5 months. Although BRD4-NUT induces *de novo* tumor formation by reorganizing chromatin to activate pro-growth transcriptional programs, the chromatin-level mechanisms underlying this process have not been established. Here, we identify the chromatin regulator NSD3—also a recurrent NUT fusion partner—as a critical cofactor required for fusion oncoprotein-mediated chromatin reorganization and transcriptional regulation. Using CUT&RUN chromatin profiling, we show that NSD3 is highly enriched within BRD4-NUT chromatin “megadomains”, where it deposits histone H3K36me2 and stabilizes BRD4-NUT binding to chromatin. NSD3 also promotes the stability of BRD4-NUT nuclear condensates. Hi-C analysis reveals that loss of NSD3 attenuates the long-range chromatin interactions that link BRD4-NUT megadomains both within (*cis*) and between (*trans*) chromosomes, demonstrating that NSD3 is required for 3D genome reorganization by a fusion oncoprotein. Through these chromatin regulatory functions, NSD3 sustains expression of BRD4-NUT target genes, including *MYC* and MYC-regulated transcriptional networks. NSD3 depletion reduces proliferation and promotes differentiation of BRD4-NUT+ cells. Together, these findings identify NSD3 as a mechanistic cofactor co-opted by a fusion oncoprotein to integrate chromatin architecture, 3D genome topology, and transcriptional activation. This work reveals a generalizable model in which wild-type chromatin regulators are hijacked by fusion oncoproteins to establish oncogenic transcriptional and gene regulatory states, and it nominates NSD3 as an actionable vulnerability for therapeutic strategies targeting fusion-driven cancers.

#4065 EcDNA-borne structural variants drive oncogenic fusion transcript amplification.

H. Yi[1], S. Zhang[1], J. Swinderman[2], Y. Wang[1], V. Kanakaveti[1], K. L. Hung[1], I. T. Wong[1], S. Srinivasan[1], E. J. Curtis[1], A. Bhargava-Shah[1], R. Li[1], M. G. Jones[1], J. Luebeck[3], C. Bailey[4], Y. Zhao[1], J. Belk[1], K. Kraft[1], Q. Shi[1], X. Yan[1], S. K. Pritchard[1], K. S. Mahajan[1], F. Liang[1], M. Jamal-Hanjani[5], D. W. Felsher[6], L. Gilbert[2], V. Bafna[3], P. S. Mischel[1], H. Y. Chang[7];
[1]Stanford University School of Medicine, Stanford, CA, [2]Arc Institute, Palo Alto, CA, [3]University of California at San Diego, La Jolla, CA, [4]The Francis Crick Institute, London, United Kingdom, [5]University College London (UCL) Cancer Institute, London, United Kingdom, [6]Stanford Hospital, Stanford, CA, [7]Amgen, Stanford, CA

Extrachromosomal DNA (ecDNA) amplifications are key drivers of human cancers. Here, we show that ecDNAs are major platforms for generating and amplifying oncogene fusion transcripts across diverse cancer types. By integrating analysis of whole genome and transcriptome sequences from tumor samples and cancer cell lines of a wide variety of tissue types, we reveal that ecDNAs have the highest rate of oncogene fusion events of any copy number alteration. Focusing on the most common ecDNA fusion hotspot, we find that fusion of the 5' end of the long noncoding RNA gene, *PVT1*-with exon 1 joined to diverse 3' partners-confers increased RNA stability, potentially via an SRSF1-dependent mechanism, and enhances MYC-dependent transcription and cancer cell survival. These results demonstrate that ecDNA fosters genome instability and frequent oncogene fusion formation in cancer.

#4066 Epidemiology meets epitranscriptomics: Uncovering a novel *TERT*-antisense transcript regulated by RNA methylation and its role in cancer cell growth and proliferation.

B. Papenberg[1], O. Florez-Vargas[1], M. Ho[1], K. Forsythe[1], C.-H. Lee[1], S. M. Mbulaiteye[2], P. J. Batista[3], L. Prokunina-Olsson[1]; [1]National Cancer Inst. Div. of Cancer Epidemiology & Genetics, Bethesda, MD, [2]National Cancer Inst. Div. of Cancer Epidemiology & Genetics, Rockville, MD, [3]National Cancer Inst. Center for Cancer Research, Bethesda, MD

Human telomerase reverse transcriptase (TERT) maintains telomeres at chromosome ends and its dysregulation contributes to human health conditions. Multiple GWAS signals are detected within the *TERT* genomic region at chr 5p15.33. As a potential proxy for these signals, we investigated a highly polymorphic variable number tandem repeat (VNTR)2-1 within intron 2 of *TERT*, with 57-143 copies of a 42 bp repeat unit per allele. Functional annotation predicted an antisense intronic transcript with a variable-length open reading frame (2,505-5,211 bp; 834-2,038 aa).

Within this *TERT*-antisense transcript, we predicted N6-methyladenosine (m6A) consensus motifs in each 42 bp repeat. The consensus repeats and m6A-deficient variants of VNTR2-1 were cloned into a m6A-deficient dual-luciferase reporter vector (m-psiCHECK-2) and expressed in the bladder cancer cell line UMUC3. Transient treatment with STM2457, an inhibitor of the m6A writer METTL3, reduced reporter expression, confirming that m6A motifs within VNTR2-1 are methylated by METTL3.

VNTR2-1 expression was experimentally validated by 5'-RACE/Nanopore-seq in UMUC3. Additionally, RNA-FISH further visualized the transcript, showing co-localization with ribosomes and suggesting translation potential.

We explored potential peptides produced from VNTR2-1 transcript by analysis of public mass spectrometry datasets using PepQuery and identified several unique VNTR2-1 peptide fragments in human tumors. Next, we cloned a synthetic FLAG-tagged gene containing three VNTR2-1 consensus repeats with native Kozak sequence and translation start/stop codons. Western blotting confirmed the translation of the VNTR2-1 peptide that was ablated by start codon mutation, suggesting that the native Kozak sequence is sufficient for VNTR2-1 translation. These results support VNTR2-1 as a peptide-producing transcript.

RNA-seq following VNTR2-1 overexpression revealed upregulation of pathways related to DNA replication and cell cycle, while CRISPR-Cas9 knockout (V2.1KO) produced reciprocal downregulation of these pathways. To determine whether these transcriptional shifts translated to functional differences, we measured proliferation of UMUC3 as well as the lung cancer cell line A549 using xCELLigence Real-Time Cell Analysis. Overexpressing cells exhibited accelerated growth compared with wild type, whereas V2.1KO cells proliferated more slowly, mirroring the pathway-level changes. BrdU incorporation assays further corroborated impaired DNA replication in V2.1KO cells.

In summary, we identified a novel antisense transcript produced by VNTR2-1 within a *TERT* intron that functions as a lncRNA and/or translated peptide to modulate cell proliferation, potentially contributing to cancer and other disease-related phenotypes.

[1]St. Jude Children's Research Hospital, Memphis, TN, [2]Universite de Nantes, Nantes, France, [3]Dana-Farber Cancer Institute, Boston, MA, [4]Broad Institute, Cambridge, MA, [5]UCSF - University of California San Francisco, San Francisco, CA

Cancer cells are dependent on the control of transcription for maintenance of the malignant cell state. EP300 and CBP are paralogous, commonly expressed, master epigenetic enzymes, whose activity controls normal and malignant transcription. Here, using a cancer-wide integrative chemical-genetic analysis, we find enhanced dependency on EP300 compared to CBP in most cancer lineages, including osteosarcoma (OS). OS is a highly lethal malignancy of bone and has enhanced dependency on EP300, compared with CBP. To take advantage of selective pharmacology targeting EP300 alone that spares CBP in untransformed cells and thereby reduces toxicity, we used the EP300-targeted degrader JQAD1. We identify a specific genetic subgroup of OS, marked by dysregulation of the PI3K-AKT-mTOR pathway, that is both genetically dependent on EP300 and uniquely sensitive to EP300 degradation. Expression of constitutively active AKT in insensitive OS cells induces sensitivity to JQAD1, driven by physical relocalization of EP300, CBP and H3K27ac to genetic subtype-enriched dependency loci. Mechanistically, combinations of AKT inhibitors and JQAD1 suppress the growth of AKT-dysregulated OS. These observations extend across >850 cancer cell lines, where multiple AKT inhibitors, including the FDA-approved capivasertib, positively combine with EP300 degraders in a manner mechanistically dependent on control of protein synthesis. Finally, combination treatment is synergistic in AKT-dysregulated, orthotopic OS xenografts. These findings reveal genetic and transcriptional determinants of EP300 degrader function in high-risk OS and provide a foundation for biomarker-directed investigation of co-targeting of EP300 and AKT for therapeutic gain across cancers marked by enhanced protein translation.

#4025 Sequential cell free DNA analysis reveals genetic heterogeneity in patients with relapsed neuroblastoma enrolled in the SIOPEN-ITCC BEACON study.

Y. Iddir[1], C. Bobin[1], A. Saint-Charles[1], J. Masliah-Planchon[1], M. Gambart[2], E. Saberi-Ansari[1], A. Colaprico[1], A. Bellini[1], C. Butterworth[1], V. Attignon[3], D. A. Tweddle[4], J. R. Tall[5], D. Hughes[5], R. Weston[6], A. Vilaplana[7], L. Chesler[8], L. Moreno[7], S. George[9], **G. Schleiermacher**[1];

[1]Institut Curie, Paris, France, [2]Toulouse University Hospital, Toulouse, France, [3]Centre Leon Berard, Lyon, France, [4]Newcastle University, Newcastle, United Kingdom, [5]The Institute of Cancer Research, London, United Kingdom, [6]Birmingham University, Birmingham, United Kingdom, [7]Vall d'Hebron Institute of Research, Barcelona, Spain, [8]The Institute of Cancer Research, Sutton, Sutton, United Kingdom, [9]The Institute of Cancer Research, Sutton, United Kingdom

Background: Outcome for high-risk neuroblastoma following relapse remains poor, with an urgent need to increase understanding of the biology to develop effective (combination) therapies.
Aims : To characterize tumor-specific molecular alterations for patients enrolled in the SIOPEN-ITCC BEACON trial (EudraCT 2012-000072-42, evaluating different backbone chemotherapy regimens +/-bevacizumab in high risk refractory/relapsed NB) and to analyze resistance mechanisms based on sequential cfDNA.
Methods: Samples were collected from 191 BEACON patients. Tumor samples were available for 73 patients (2:diagnosis, 24:refractory; 47:relapse), and liquid biopsies for 182 patients (1-6 samples per patient, mean: 3). cfDNA lcWGS (low coverage Whole-genome sequencing), cfDNA WES (Whole-exome sequencing or targeted panel-sequencing was conducted on all plasma samples, with paired germline analyses.
Results: Molecular analysis of 63 tumor samples (41 large NGS-panel and 22 WES), , identified MYCN amplification in 17 cases, and mutations in RAS/MAPK/P53 pathway genes in 24% of patients, with 17.5% harboring an *ALK* mutation. cfDNA quantity at enrollment in BEACON did not correlate with disease burden (SIOPEN score), but showed correlation with outcome (HR p=0.02). From plasma samples obtained at inclusion and analyzed by WES, a mean of 35[5-96] SNVs were shared with tumor samples, while 31[7-73] and 11[2-29] SNVs were unique to tumor and plasma, respectively. cfDNA specific SNVs frequently targeted genes of pathways in cell-to-cell and cell-to-extracellular matrix connections. Sequential cfDNA quantities and ctDNA content evaluated by WES were measured for 139 patients, and showed distinct dynamics correlating with disease status. Notably, cfDNA quantity increases were associated with the emergence of new mutations in all analyzed cases, including alterations in genes of the RAS/MAPK pathway such as *HRAS*. Evidence of clonal hematopoiesis during treatment was observed in 40% of cases. Fragment size and nucleosome footprint analyses for inference of transcription factor and overall expression profiles is ongoing.
Conclusions: In refractory/relapsed high-risk neuroblastoma patients, 1/4 had at least one mutation in RAS/MAPK/p53 pathway genes, which might correlate with poorer survival. 53% of SNVs observed in tumor were detectable in plasma, and plasma-specific SNVs were observed in all cases. This finding underscores the value of plasma sample collection during follow-up to study tumor heterogeneity and clonal evolution.

#4026 Spatial T-cell receptor profiling uncovers barriers to T-cell engagement and shared tumor-reactive clonotypes in high-risk neuroblastoma.

Y. Jiang[1], W. Yu[2], S. Pedersen[1], J. Eagles[1], A. Thadi[2], A. Naranjo[3], N. B. Collins[4], S. DuBois[4], R. Bagatell[2], B. D. Crompton[5], K. Tan[2], T. J. Pugh[1];

[1]UHN Princess Margaret Cancer Centre, Toronto, ON, Canada, [2]Children's Hospital of Philadelphia, Philadelphia, PA, [3]University of Florida, Gainesville, FL, [4]Dana-Farber Cancer Institute, Boston, MA, [5]Dana-Farber Cancer Inst., Boston, MA

Background: Survival for patients with high-risk neuroblastoma (NB) is ~50%. While T-cell infiltration correlates with improved outcomes in some pediatric cancers, T-cell diversity, spatial organization, and antigen specificity remain poorly characterized. We integrated bulk T-cell receptor (TCR) sequencing, spatial transcriptomics, and spatial TCR profiling in NB patients from the Children's Oncology Group phase 3 trial ANBL1531, which evaluated 131I-metaiodobenzylguanidine therapy during frontline induction.
Methods: We applied hybrid-capture TCR sequencing to paired biopsy and resection FFPE tumors (10 samples from 5 patients), longitudinal PBMCs (84 samples from 33 patients), and cfDNA (14 samples from 12 patients). Using shared TCRs across sample types and timepoints, we designed a Xenium panel with 377 genes and 100 TCRα/β/γ/δs, enabling spatial mapping across 1.90 million cells (median 138,742, range 17,175-715,510 cells per tumor). We predicted TCR specificity using MixTCRpred, and inferred sequence convergence using GLIPH2 against a database of reference TCRs (4,146 known specificities, 595,689 controls, 16,888 NB from the Precision oncology for young people cohort).
Results: PBMC TCR repertoires showed biphasic dynamics, with diversity contracting mid-therapy (Shannon mean 476→151) then recovery post-therapy (413; p=0.0006, linear mixed-effects model), likely corresponding to chemotherapy-driven lymphopenia. In tumors, TCR diversity declined between biopsy and resection while hyperexpanded clonotypes increased (mean 30→59%), indicating potential selective clonal enrichment. Spatial profiling of the 10 tumors revealed immune-tumor compartmentalization, with macrophage-enriched barriers segregating immune cells from clusters of tumor cells. Spatial TCR profiling enabled in situ α/β chain pairing, identifying four TCRα/β clonotypes (all $CD8^+$ effector memory) not resolvable by bulk sequencing. One clonotype with predicted NY-ESO-1 specificity expanded from biopsy to resection (2.22→4.92% of all T cells), suggesting antigen-driven clonal proliferation. Despite this expansion, clonotype spatial positioning remained unchanged, indicating that microenvironmental architecture constrains T-cell localization. GLIPH2 identified 8 NB-restricted TCR sequence motifs shared across 3-7 NB patients. These motifs occurred in individuals with convergent MHC alleles, suggesting recognition of common NB-associated antigens.
Conclusions: Integrated TCR and spatial profiling revealed macrophage-mediated compartmentalization and restricted T-cell localization. Clonotypes predicted to be tumor-reactive also expanded during therapy. Shared NB-specific TCR motifs suggest convergent antigen recognition and targets for immunotherapy.

#4027 Co-targeting GPC2 and B7-H3 with CAR T cells achieves durable responses in preclinical high-risk neuroblastoma and medulloblastoma models.

P. M. Schurch[1], B. Draper[2], V. P. Zecchino[1], H. Pan[1], B. Nelson[1], A. M. Giudice[1], J. B. Foster[1], L. K. Donovan[2], K. R. Bosse[1]; [1]Children's Hospital of Philadelphia, Philadelphia, PA, [2]University College London, London, United Kingdom

Glypican 2 (GPC2) is highly expressed in pediatric cancers including high-risk neuroblastomas and medulloblastomas, and GPC2 CAR T cells are now in phase 1 trials (NCT05650749, NCT07087002). However, durable responses are limited by heterogeneous antigen expression, treatment-induced antigen loss, and poor CAR T persistence. In neuroblastoma, interconvertible adrenergic (ADRN) and mesenchymal (MES) states further complicate targeting, as state switching downregulates GPC2 and GD2, whereas B7-H3 remains consistently expressed. B7-H3 is also abundant across other GPC2$^+$ cancers, supporting a dual GPC2.B7-H3 CAR strategy. To approach GPC2.B7-H3 dual CAR T cell targeting, we engineered seven GPC2/B7-H3 co-targeting bicistronic CAR constructs containing CD28, 4-1BB, or OX40 costimulatory domains and either two (dual, d1-3) or one (parallel, p1-4) CD3-ζ signaling domain. Among these, d1 and p2 were prioritized because they drove strong activation of Jurkat NFAT-GFP CAR T cells in co-cultures with isogenic NALM-6 cells expressing either or both antigens and showed superior cytokine secretion in human CAR T co-incubation assays compared with single-antigen B7-H3 (B) or GPC2 (G) CARs. *In vivo*, dual-targeting CAR T cells - double-transduced (B/G) or expressing d1 or p2 - achieved potent clearance of COG-N-453x neuroblastoma PDXs, with 16-week cure rates of 83.3%, 83.3%, and 100%, exceeding single CARs (B, 57.1%; G, 0%). Human CAR T cell persistence was detected in bone marrow and spleen of cured mice at 16 weeks, suggesting a role of enhanced T cell persistence in durable remissions. In the aggressive COG-N-561x model, only bicistronic CARs d1 and p2 achieved durable 14-15-week cures (d1, 100%; p2, 71.4%), surpassing double-transduced (B/G, 33.3%), co-administered (B+G, 20%), or single CARs (B, 20%; G, 0%). Upon rechallenge, only d1 and p2 cohorts rejected tumors and remained tumor-free long-term (d1, 71.4%; p2, 60%), again with persistent CAR T cells in bone marrow and spleen through the 36-week study endpoint. Finally, across *in vitro* medulloblastoma models, repeat tumor-stimulation assays confirmed superior activity of d1 and p2. In an aggressive orthotopic group 3 medulloblastoma 7316-10374 xenograft model where 100% of GPC2 CAR-treated mice relapsed, the p2 CAR outperformed d1 and the single B7-H3 CAR, with 16-week cure rates of 100%, 71.4%, and 60%, respectively, confirming the superiority of dual GPC2.B7-H3 targeting and a potential advantage of parallel CD3ζ-sharing designs. Altogether, GPC2.B7-H3 bicistronic CARs induced durable and curative responses across neuroblastoma and medulloblastoma models, nominating this approach as a next-generation GPC2 CAR T strategy for clinical testing.

#4028 Surface localized nuclear envelope proteins define a therapeuticvulnerability in MYC-driven Group 3 medulloblastoma.

S. K. Singh[1], Y. Suk[1], M. A. Rossotti[2], J. Ibanez-Vega[3], M. Shaikh[1], Y. Chen[4], H. Patel[1], L. Escudero[1], A. Delaidelli[5], A. Khanna[1], S. Slassi[1], C. Barba Bazan[1], E. Apel[1], S. Custers[1], S. Grewal[6], W. Maich[1], L. Asselstine[1], D. McKenna[1], Y. Xiao[7], W. Gwynne[8], J. Moffat[7], H. Suzuki[9], P. H. Sorensen[10], R. Truant[1], K. Henry[11], E. Sotillo-Pineiro[12], C. Venugopal[1], C. L. Mackall[13], G. Krenciute[3]; [1]McMaster University, Hamilton, ON, Canada, [2]NRC, Ottawa, ON, Canada, [3]St Jude Children's Research Hospital, Memphis, TN, [4]Stanford Cancer Institute, Stanford, CA, [5]BC Cancer Agency, Vancouver, BC, Canada, [6]Michael G. DeGroote School of Medicine at McMaster University, Hamilton, ON, Canada, [7]The Hospital for Sick Children, Toronto, ON, Canada, [8]McMaster University, Georgetown, ON, Canada, [9]National Cancer Center Japan, Tokyo, Japan, [10]BC Cancer Research Centre, Vancouver, BC, Canada, [11]University of Ottowa, Ottowa, ON, Canada, [12]Stanford University, Stanford, CA, [13]Stanford Hospital, Stanford, CA

Medulloblastoma (MB) is the most common malignant pediatric brain tumor and is comprised of four molecular subgroups (WNT, SHH, Group 3, and Group 4). Regardless of subgroup, MB patients are treated with the same standard of care (SoC) (surgical resection, chemotherapy, craniospinal irradiation) that can lead to lifelong neurocognitive deficits in survivors. A subset of Group 3 MBs harbors focal amplifications of the MYC oncogene (MYC-G3MB) that invariably lead to disease recurrence which currently remains incurable. Therefore, there is an urgent need for development of therapies that are safe for the vulnerable developing brain while exerting potent anti-tumor efficacy against therapy-resistant subtypes. Here, we identify nuclear envelope (NE) proteins LBR and TMPO to be highly expressed in MYC-G3MBs in contrast to normal tissue and human neural stem cells (hNSCs), and a context-specific mislocalization of NE proteins to the plasma membrane (PM), only in MYC-G3MBs. NE protein expression correlated to worse MB patient prognosis and survival and was significantly enriched in recurrent tissue compared to the patient matched primary samples. High resolution microscopy and transcriptomic analysis implicated hyperproliferative cell states and endogenous chromosomal instability to drive NE deformation and the creation of DNA double strand break-capturing nuclear envelope tubules (dsbNETs), critical recently described factors in genome stability that mediate the repair of rapidly accumulating DNA damage in cancers such as MB. CRISPR Cas9-mediated endogenous tagging of LBR and TMPO revealed exposure of N-termini to the extracellular matrix and linked ER or ER-like vesicles to be directly trafficked to the cell surface in MYC-G3MBs. We developed single domain antibodies (sdAbs) specific to the N-terminus of LBR and TMPO and engineered second generation chimeric antigen receptor (CAR) T cell mono (LBR or TMPO) and bispecific (LBR and TMPO) therapies. We demonstrate the potent anti-tumor efficacy of NE protein-targeted CAR T cell therapies in patient derived xenograft models (PDX) of MYC-G3MBs. We present nuclear envelope proteins aberrantly mislocalized to the plasma membrane exclusively in G3MB as a novel class of cancer-selective therapeutic targets, for the development of a new class of CAR T cell therapies for treatment-refractory childhood MB.

#4029 Neuronal activity-regulated mechanisms promoting growth of diffuse hemispheric glioma, H3G34-mutant.

K. R. Taylor[1], **S. H. Wu**[1], R. Drexler[1], G. A. V. Cruzeiro[2], I. Liu[2], A. E. Ivec[1], L. Ni[1], C. A. O. Biagi, Jr.[2], P. J. Woo[1], M. Su[1], Y. Byun[1], M. Filbin[2], M. Monje[1];

[1]Stanford University, Stanford, CA, [2]Dana Farber Boston Children's Cancer and Blood Disorders Center, Boston, MA

Neuronal activity robustly drives glioma progression, mediated via paracrine and synaptic mechanisms and offering novel therapeutic avenues for a disease with a devastating prognosis. While the activity-dependent regulation of diffuse midline glioma, H3K27-mutant (DMG-H3K27) and IDH-wildtype glioblastoma has been investigated thoroughly, the interaction of neurons with diffuse hemispheric glioma, H3G34-mutant (DHG-H3G34) remains to be elucidated. Recent transcriptomic analyses suggest a distinct cell-of-origin for DHG-H3G34, demonstrating these tumors primarily resemble early interneuron lineage cells. In the healthy context, neuronal progenitor cells are highly responsive to neuronal activity during development. We previously reported a proliferative response of patient-derived DHG-H3G34 cultures to active neurons *in vitro*, yet the key neuronal mechanisms governing the progression of DHG-H3G34 are unknown. Here, we explored the neuronal activity-dependent mechanisms that drive DHG-H3G34 growth. We found that activity-induced DHG-H3G34 proliferation in neuron-glioma co-culture is abrogated in the presence of a voltage-gated sodium channel blocker (tetrodotoxin) that prevents action potentials or an AMPA receptor inhibitor, confirming that activity-dependent mechanisms drive DHG-H3G34 malignant cell proliferation and raising the possibility of AMPAR-mediated synaptic mechanisms. Immuno-electron microscopy in two independent patient-derived models demonstrated multiple types of synaptic structures in DHG-H3G34 xenografts, including neuron-to-glioma synapses. Preliminary electrophysiological recordings of xenografted DHG-H3G34 cultures confirmed the presence of spontaneous and stimulation-evoked inward currents consistent with excitatory postsynaptic currents (EPSCs). Further optogenetic stimulation of both glutamatergic cortical projection neurons and GABAergic neurons promoted the proliferation of DHG-H3G34 xenografted cells within the stimulated circuits *in vivo*. Activity-regulated conditioned media harvested from optogenetically stimulated acute cortical slices induced DHG-H3G34 proliferation in monoculture, thus confirming paracrine signaling as one key mechanism in driving tumor growth. Subsequent proteomic analysis of active conditioned media indicated multiple novel proteins of interest including neuronal cell adhesion molecule (NrCAM) and neurofascin (NFASC). Both paracrine factors increased proliferation and migration in multiple DHG-H3G34 cell lines. Overall, these findings suggest that DHG-H3G34 gliomas integrate into neural circuits and leverage both conserved and tumor-type-specific activity-regulated mechanisms. Continued investigation into these activity-dependent mechanisms of glioma growth aims to identify potential therapeutic strategies for these lethal brain cancers.

#4030 Targeting MYB with REM-422 for the treatment of pediatric T-cell acute lymphoblastic leukemia - A report from the Pediatric Preclinical Testing Consortium (PIVOT).

R. B. Lock[1], K. Evans[1], B. Watts[1], M. Agoncillo[1], C. M. Smith[1], S. Neuhauser[2], T. M. Stearns[2], E. L. Jocoy[3], J. Kwon[4], J. H. Chuang[4], S. Levin-Furtney[5], B. A. Teicher[6], C. Kung[5], C. J. Bult[2], M. A. Smith[6];

[1]Children's Cancer Institute, Lowy Cancer Research Centre, School of Clinical Medicine, UNSW Medicine & Health, UNSW Centre for Childhood Cancer Research, UNSW Sydney, Australia, Sydney, Australia, [2]The Jackson Laboratory for Mammalian Genetics, Bar Harbor, ME, [3]The Jackson Laboratory, Sacramento, CA, [4]The Jackson Laboratory for Genomic Medicine, Farmington, CT, [5]Remix Therapeutics, Watertown, MA, [6]National Cancer Institute, Bethesda, MD

Introduction: While survival rates for pediatric acute lymphoblastic leukemia (ALL) have improved dramatically over the past 60 years, outcomes remain poor for certain patients, particularly those with relapsed/refractory T-cell ALL (T-ALL). MYB is a transcription factor involved in the regulation of hematopoietic stem and progenitor cells, which exhibits strong dependency in lymphohematopoietic neoplasms. REM-422 is an orally available small molecule degrader of *MYB* mRNA that is currently being evaluated in Phase 1 clinical trials (NCT06118086 and NCT06297941). Therefore, it was of interest to test the *in vivo* activity of REM-422 against the PIVOT pediatric ALL patient-derived xenografts (PDXs).

Methods: *MYB* mRNA expression was assessed via RNA sequencing and expressed as fragments per kilobase of transcript per million mapped reads (FPKM, Rokita *et al*., *Cell Rep*., 2019). MYB protein expression was assessed by immunoblotting using a MYB monoclonal antibody (clone D2R4Y). For *in vivo* efficacy testing in NSG mice, REM-422 was administered at 5 mg/kg via oral gavage, daily for 3 weeks. A single mouse trial design (1 vehicle control, 1 drug treated mouse per PDX) was used for testing across pediatric ALL PDXs. Standard PIVOT methods were used to assess event-free survival (EFS). Stringent objective response (OR) measures modeled after the clinical setting were also used to evaluate activity (Houghton *et al*., *Pediatr. Blood Cancer*, 2007).

Results: *MYB* mRNA expression was significantly higher in 90 pediatric ALL PDXs (mean 153 FPKM, range 16.0-321) compared with 154 PDXs derived from pediatric solid tumors (mean 4.0 FPKM, range 0.04-240, $P<0.001$), with no significant differences in expression between pediatric ALL subtypes. *Ex vivo* exposure of 2 PDXs to REM-422 for 6-24h resulted in almost complete ablation of MYB protein levels. REM-422 was well tolerated in NSG mice, with no overt signs of toxicity or weight loss >5%, and with all intended doses administered. In the efficacy study, 28 of 30 planned PDXs were evaluated. REM-422 extended mouse median EFS by 20.7 days compared with vehicle control-treated mice ($P<0.0001$). While REM-422 extended survival in both the T and B-lineage PDXs, the 10 T-lineage PDXs (Treated-Control [T-C] 33.0 days, T/C 3.6, $P<0.0001$) exhibited a better overall response compared with the B-lineage PDXs (T-C 19.4 days, T/C 2.5, $P=0.0004$). Moreover, REM-422 elicited ORs in 8/10 T-lineage (2 Partial Responses [PRs], 3 Complete Responses [CRs] and 3 Maintained CRs [MCRs]) compared with only 2/18 B-lineage (1 PR, 1 MCR) PDXs.

Conclusions: REM-422 exhibited potent single-agent *in vivo* activity against a large panel of pediatric T-ALL PDXs, supporting its potential clinical evaluation in this disease. Future research directions will include efforts to identify effective combinations with targeted and/or standard-of-care drugs.

: Precision Prevention: Advances in Early Detection and Risk Assessment Minisymposium

#4069 Therapy-associated clonal hematopoiesis and risk of hematologic malignancy after primary cancer treatment.

K. M. Barnao[1], R. L. Kelly[1], W. Zhou[2], I. Chan[3], Y. Cao[4], K. L. Bolton[3], M. J. Machiela[1];
[1]National Cancer Institute, Rockville, MD, [2]Leidos Biomedical Research Inc., Frederick, MD, [3]Washington University School of Medicine, St. Louis, MO, [4]Washington University in St. Louis, St Louis, MO

Clonal hematopoiesis (CH) is the age-related expansion of hematopoietic stem cells, driven by single nucleotide variants (SNVs) or insertions and deletions (indels) in driver genes (clonal hematopoiesis of indeterminate potential, CHIP) or large-scale mosaic chromosomal alterations (mCAs). Both CHIP and mCAs are associated with increased hematologic malignancy risk. Prior studies have suggested cancer therapies may select for CH clones with DNA damage response mutations (e.g., CHIP in *TP53)*. While therapy-related CHIP is recognized, the contribution of cancer treatment to mCA prevalence and the relationship of treatment-induced mCAs to subsequent cancer risk remains poorly understood. We investigated how exposure to cancer therapy may promote the acquisition or expansion of mCAs and consequently increase susceptibility to subsequent hematologic malignancies.Using genomic data from UK Biobank participants, we detected CHIP and mCAs in individuals with (N=24,607) and without prior cancer (N=453,763), classified as likely cancer therapy-exposed (hereafter referred to as exposed) or unexposed. We identified 422 exposed individuals who subsequently developed a hematologic malignancy. Logistic regression models, adjusted for age, age^2, sex, smoking status, and genetic similarity, were used to compare CH prevalence between exposed and unexposed groups, and between participants in the exposed group who did and did not develop hematologic malignancies.Autosomal mCAs were detected in 5.2% of therapy-exposed individuals compared to 3.0% of unexposed individuals (OR=1.2, 95% CI=[1.1-1.3], p=9.6×10^{-6}). CHIP was also enriched among therapy-exposed participants (7.6% vs. 4.5%; OR=1.4, 95% CI=(1.3-1.5), p=3.4 ×10^{-40}). 17.5% of therapy-exposed individuals who developed incident hematologic malignancies harbored mCAs, compared with 3.7% who did not develop a hematologic malignancy (OR=4.9, 95% CI=[3.8-6.4], p=1.9×10^{-32}), with notable enrichment of mCAs highly associated with hematologic malignancies (e.g., chromosome 9 p-arm copy-neutral loss of heterozygosity (chr9pCNLOH), chr14qCNLOH, and chr13q Loss). CHIP was observed at a frequency of 18.0%, compared to 6.3% of those who did not progress (OR=2.9, 95% CI=[2.2-3.7], p=8.3×10^{-16}).These findings demonstrate that cancer therapy is associated with increased frequency of detectable CHIP and autosomal mCAs, with enrichment of mutations commonly observed in hematologic malignancies. Importantly, these events were detectable prior to diagnoses of a therapy-related hematologic malignancy, highlighting their potential as early indicators of hematologic malignancy risk in cancer survivors. Identifying high risk autosomal mCAs in this population could inform precision risk stratification and guide targeted surveillance strategies for individuals at risk of subsequent therapy-related hematologic malignancies.

#4070 *APC* mosaicism and colibactin-associated signature as key factors in unexplained colorectal polyposis.

K. Driouch[1], Z. Tariq[1], A. Dardenne[2], M. Dhooge[3], J. Netter-Coti[4], M. Le Mentec[1], S. Farelly[3], M.-C. Gorenstein[4], I. Bieche[1], A. Chansavang[3], E. pasmant[1], C. Colas[1], O. Trabelsi-Grati[1], B. Buecher[1];
[1]Institut Curie, Paris, France, [2]Hopital Saint-Antoine, Paris, France, [3]Hopital Cochin, Paris, France, [4]Hopital Europeen Georges Pompidou, Paris, France

Background: Colorectal adenomatous polyposis is usually linked to genetic predisposition, and affected patients should receive genetic counselling and germline testing. In *APC*-associated polyposis, the absence of a suggestive family history does not exclude the diagnosis, given the frequency of *de novo* mutations. *APC* mutations may arise postzygotically, resulting in a somatic mosaicism in a significant fraction of patients who show no germline *alterations*. However, a substantial proportion of patients remain genetically unexplained, suggesting that additional mechanisms, possibly environmental or microbial, may contribute to disease onset and progression. Growing evidence suggests that gut microbiota (especially *pks*$^+$ *Escherichia coli* that produce the colibactin) may induce characteristic DNA mutations thus contributing to the disease.

Methods: In this study, 125 patients with unexplained colorectal adenomatous polyposis were included. Next-generation sequencing was performed on 337 polyps and 173 healthy tissues. Somatic mosaicism was diagnosed when a same *APC* pathogenic mutation was identified in ≥ 3 neoplastic lesions or in healthy biopsies and in ≥ 1 colonic lesion (n=60 patients). Colibactin-associated *APC* variants were identified and the presence of *pks*$^+$ bacteria was explored by qPCR. Finally, the clonal architecture of each lesion was inferred by classifying all mutations as clonal or subclonal.

Results: APC somatic mosaicism was identified in 22 patients (36.7% of assessed cases). Most mosaic variants were not detectable in blood, except in two patients who showed low-level germline mosaicism. Overall, 94.4% of neoplastic lesions carried a somatic *APC* variant; those without *APC* mutations often harbored alterations in other driver genes such as *KRAS, BRAF, CTNNB1* or *RNF43.* Several *APC* mutations showed patterns characteristic of exposure to colibactin, produced by *pks*$^+$ bacteria, including the recurrent splice-site mutation c.835-8A>G. Nearly 19% of lesions displayed mutations fitting the colibactin-associated signature. PCR testing for pks$^+$ bacteria was positive in 22% of samples, but there was no concordance between pks$^+$ PCR positivity and colibactin-related mutations, suggesting that exposure may be past or transient. The clonal analyses indicated that mosaic and colibactin-associated *APC* mutations are early, clonal events detected in multiple polyps. A rare case of transmission of a mosaic *APC* variant to offspring confirmed the early acquisition and possible involvement of germline cells. In contrast, mutations in other driver genes tend to appear later, as subclonal alterations.

Conclusion: Overall, the findings suggest that somatic *APC* mosaicism explains one third of unexplained colorectal adenomatous polyposis. Moreover, early-life exposure to colibactin-producing bacteria may also contribute to disease initiation and progression in some patients.

#4071 The impact of patient biology on racial disparities in breast cancer outcome.

J. DeWitt, D. Jiminex-Tovar, S. Haricharan, E. Oropeza, M. Raghunathan;
San Diego State University, San Diego, CA

Hormone receptor positive (HR+) breast cancer is the most common subtype of breast cancer diagnosed globally. Despite effective targeted therapies, HR+ breast cancer remains a leading cause of cancer-related death in women. Long-standing epidemiological research identifies significantly worse outcomes for Black women diagnosed with HR+ breast cancer relative to White women. While structural factors such as access to healthcare and education level contribute to this outcome disparity, it persists even in analyses where these factors are controlled. In-depth analyses of the somatic molecular biology that may underlie these outcome disparities are hampered by a lack of datasets that represent Black patient populations. Here, we generate a HR+ breast cancer patient transcriptomic dataset that overrepresents Black women and controls for access to healthcare and education level. We find that signatures relating to the tumor microenvironment, i.e. collagen deposition and prognostically unfavorable T-cell landscapes are enriched in HR+ tumors from Black women. Importantly, we find, using experimental model systems *in vitro* and *in vivo*, that race-aligned collagen deposition patterns are at least partially attributable to tumor cell-intrinsic signaling and critical for Black breast cancer metastasis. We also find that unfavorable T-cell signatures in HR+ tumors from Black women, which have previously been attributed to race and ancestry, are more strongly poverty-aligned. Using multiple independent datasets, we identify STAT4 as a potential master regulator of this poverty-associated tumor immune signature. Together, these findings provide new evidence that somatic molecular biology of breast cancer patients can be modified by multiple structural factors such as self-identified race and poverty burden to promote poor patient outcomes. Integrating an understanding of structural factors into molecular cancer research is critical for implementing truly personalized, and maximally effective, oncology systems.

#4072 Single-cell pathology of the normal breast uncovers occult cytomorphologic signatures that signal future cancer risk and etiologic origins.

M. Abubakar[1], S. M. Lawrence[2], J. D. Hughes[3], S. Fan[1], K. Mutreja[2], R. M. Pfeiffer[1], G. L. Gierach[1], B. Jenkins[3], J. E. Henry[4], M. A. Duggan[5];

[1]National Cancer Institute, Bethesda, MD, [2]Leidos Biomedical Research, Frederick, MD, [3]Johns Hopkins Bloomberg Sch. of Public Health, Baltimore, MD, [4]Indiana University, Indianapolis, IN, [5]University of Calgary, Calgary, AB, Canada

Background: Malignant transformation involves progressive changes in cellular morphology. However, the point along the early carcinogenesis trajectory when these changes first signal cancer risk and etiologic origins remains unknown. **Methods:** In this prospective cohort study of 3,415 healthy women who donated normal breast tissue (NBT) to the US-based Susan G. Komen Tissue Bank (KTB) between 2009-2019, machine learning algorithms were used to characterize 72,237,858 cells in digitized histologic sections of NBTs. Occult alterations in epithelial nuclear area, perimeter, chromasia, nuclear contour irregularity, epithelial nuclear density, and stromal cellular density defined three cytomorphologic signatures that were denoted by their histogenesis i.e., epithelial, stromal, and mixed (epithelial and stromal). Associations of cytomorphologic signatures with subsequent breast cancer (BC) incidence were assessed using multivariable Cox proportional hazard regression with age as timescale and left truncated at study entry. Analyses were performed overall and by tumor subtype (estrogen receptor-positive (ER+) and ER-). **Results:** After a median follow-up of 6 years (range:1-16 years) post-donation, 104 previously healthy women developed BC. Women with the stromal (hazard ratio (HR) and 95% confidence interval (CI) = 3.01 [1.56-5.80]; *P*=0.001), epithelial (HR= 2.28 [1.31-3.96]; *P*=0.003), or mixed (HR= 2.18 [1.18-4.03]; *P*=0.010) signatures in their NBT had more than double the risk of BC than those without any signature. RNA sequencing analyses revealed the stromal signature to be characterized by heightened expression of inflammation, angiogenesis, and epithelial-to-mesenchymal transition genes. Etiologically, the stromal signature was associated with younger age, Black race, multiparity, contraceptive pill use, and BC family history, and in subtype-specific analysis, it was most strongly predictive of aggressive, ER- BC (HR= 9.04 [3.22-25.39]; *P*<0.0001). The epithelial signature (reflecting age-related epithelial functional decline) demonstrated contrasting etiologic profile from the stromal signature, and was most strongly associated with future ER+ BC, particularly when detected in stroma-poor/adipose-rich microenvironments (HR= 7.04 [1.49-33.19]; *P*=0.01). The mixed signature, which was subtype-agnostic in its BC predictive value, was characterized by heightened expression of wound response genes, shorter (-3 years) latency to BC diagnosis than the epithelial and stromal signatures (*P*<0.0001), and by its association with obesity and older age (>25 years) at first childbirth. **Conclusion:** Oncogenic processes may imprint occult cytomorphologic signatures in breast tissues long before cancer diagnosis, with implications for BC risk prediction, targeted prevention, and early interception strategies.

#4073 Deep plasma proteomics for early-stage breast cancer detection.

A. Horrmann[1], Y. Travadi[1], J. Carey[1], K. Mallery[1], E. Boytim[2], G. Schaap[1], C. Rungkittikhun[1], K. Kamalanathan[1], N. R. Bristow[1], C. Galeano-Garces[1], A. Groth[1], A. R. Hesch[1], **P. Advani**[3], J. Hwang[2], B. R. Konety[1], J. M. Drake[1];
[1]Astrin Biosciences, St. Paul, MN, [2]University of Minnesota, Minneapolis, MN, [3]Mayo Clinic, Jacksonville, FL

Annual breast cancer screening is a critical piece of women's health. While mammography remains the gold standard, increased breast density leads to decreased sensitivity, underscoring the need for more sensitive and accessible screening methods. Liquid-based biopsies for early breast cancer detection are emerging but currently remain out of reach for clinical use. Recent data on nucleotide assessment from plasma in breast cancer have been mixed with 87% sensitivity for late-stage disease (stage 3-4) but only 20% sensitivity for early-stage disease (stage 0-2). Proteomics is an exciting area for early cancer screening where improvements in sample preparation and equipment have enabled major advances in early cancer detection. This is particularly true for a deep proteome assay as proteins can be identified which are 8-9 orders of magnitude less abundant than the most common plasma proteins. This study evaluates the presence of breast cancer using label-free shotgun mass spectrometry-based proteomics on less than 1 ml of plasma from 1,259 women classified as either healthy or newly diagnosed treatment naïve breast cancer patients with a focus on early-stage disease. We trained using a cohort of 845 women, comprising of 466 healthy and 379 with breast cancer and validated on 397 women (195 healthy and 202 breast cancer) using a protein-based machine learning classifier to distinguish these groups. All plasma samples were processed in a blinded manner coupled with semi-quantitative, label-free mass spectrometry (MS)-based analysis. The median number of proteins detected per patient across breast cancer and healthy individuals was 7,064 and 7,054, respectively. The validation performance achieved 92.3% specificity for healthy controls and an overall sensitivity of 92.6% with an AUC of 0.975 (95% CI: 0.961-0.987) for breast cancer patients. Sensitivity broken down by clinical stage (0-IV), molecular subtypes (HR+/HER2+, HR-/HER2+, HR+/HER2-, and HR-/HER2-) and pathological subtypes (LCIS, DCIS, ILC, and IDC) were ≥85% and indistinguishable across all stages and subtypes. Gene set enrichment analyses (GSEA) identified pathways including epithelial-to-mesenchymal transition (EMT) and PI3K-AKT signaling as enriched in the breast cancer samples, highlighting that our test can identify cancer-related proteins in early-stage patients. Overall, we have developed a highly sensitive blood-based assay that utilizes deep proteomic profiling to identify distinctive cancer specific signatures in women who are undergoing screening for breast cancer. This work enables us to develop a protein-based classifier from plasma for early detection of breast cancer and enhances screening strategies for women with dense breasts who are at average or high-risk based on family history, specific genetic mutations such as BRCA1/2, race, or other factors.

#4074 Non-invasive early detection of cancer-predisposing liver diseases using genome-wide cfDNA fragmentomes.

Akshaya Vijaya Annapragada[1], Zachariah Foda[1], Hope Orjuela[1], Carter Norton[1], Shashi Koul[1], Noushin Niknafs[1], Sarah Short[1], Keerti Boyapati[1], Adrianna Bartolomucci[1], Dimitrios Mathios[2], Michael Noe[1], Chris Cherry[1], Jacob Carey[3], Alessandro Leal[3], Bryan Chesnick[3], Nic Dracopoli[3], Jamie Medina[3], Nicholas Vulpescu[1], Daniel Bruhm[1], Sarah Bacus[4], Vilmos Adleff[1], Amy Kim[1], Steve Baylin[1], Greg Kirk[1], Andrei Sorop[5], Razvan Iacob[5], Speranta Iacob[5], Liana Gheorghe[5], Simona Dima[5], Katherine McGlynn[6], Manuel Ramirez-Zea[7], Claus Feltoft[8], Julia Johansen[8], John Groopman[1], Jillian Phallen[1], Rob Scharpf[1], Victor Velculescu[1]

[1]Johns Hopkins University School of Medicine, Baltimore, MD,[2]Washington University School of Medicine, St Louis, MO,[3]DELFI Diagnostics, Baltimore, MD,[4]Seqbiomarque, Brea, CA,[5]Fundeni Clinical Institute, Bucharest, Romania,[6]National Cancer Institute, Bethesda, MD,[7]Institute of Nutrition of Central American and Panama, Guatemala City, Guatemala,[8]Copenhagen University Hospital, Copenhagen, Denmark

INTRODUCTION: Liver disease occurs on a continuum from steatosis to fibrosis, cirrhosis and ultimately hepatocellular carcinoma (HCC), with a 30% lifetime risk of HCC among those with cirrhosis (LCr). If identified early, steatosis and fibrosis are potentially reversible, and in LCr, surveillance can reduce cancer morbidity and mortality. Despite these benefits, conventional LCr detection modalities are invasive or have limited performance. We previously demonstrated that cost-effective liquid biopsies of genome-wide cell-free DNA (cfDNA) fragmentomes enable early detection of HCC. Here, we use these technologies to detect liver steatosis, fibrosis, and cirrhosis towards improved pre-cancer intervention and HCC surveillance.

METHODS: We performed low-coverage, whole genome sequencing of plasma cfDNA from separate Discovery (n=423) and Validation (n=221) cohorts including individuals with no known liver disease (n=397), chronic liver disease and early fibrosis (n=91) including viral hepatitis and metabolic associated steatotic liver disease, or advanced fibrosis/cirrhosis (n=156). We computed genome-wide fragment length, coverage, and repeat element features (DELFI and ARTEMIS), cross-validated a machine learning classifier for fibrosis and LCr detection in the Discovery Cohort and evaluated the locked model in the Validation Cohort. We then performed whole methylome sequencing (n=28) and cell-type deconvolution to reveal mechanisms of change to cfDNA fragmentomes in LCr.

RESULTS: Individuals with early liver disease/fibrosis and advanced fibrosis/cirrhosis were detected with high performance (AUC=0.90, 95% CI=0.86-0.95 and AUC=0.95, 95% CI=0.93-0.98, respectively) in the Discovery Cohort. At an 80% specificity locked cutpoint, Validation Cohort sensitivity was 70.8% (90% CI=52.3%-87.5%) for early liver disease/fibrosis and 90.1% (90% CI=84.4%-94.4%) for advanced fibrosis/cirrhosis. The model displayed low cross-reactivity for other fibrotic origin conditions including benign lung nodules or chronic pancreatitis (median scores 0.087 and 0.068 respectively vs. 0.55 for LCr, $p<0.0002$). The approach outperformed the existing fibrosis index FIB-4, detecting 5.07x (95% CI=3.03-17.35) and 1.2x (95% CI=1.18-1.32) more cases of early liver disease/fibrosis and advanced fibrosis/cirrhosis in simulations. cfDNA methylome deconvolution revealed increased contributions of liver endothelium ($p=0.00016$) and blood monocytes ($p=5.2\times10^{-5}$) and decreased contribution of hepatocytes ($p=0.00035$) with shorter fragment lengths in LCr.

CONCLUSIONS: A cfDNA fragmentome biomarker enabled early detection of liver disease including LCr and reflected both liver-derived and immune-cell related changes. These analyses may enable accessible early detection of pre-cancer conditions with potential to improve liver disease management and early detection of HCC.

#4075 Enhanced early detection of pancreatic cancer using a multi-analyte liquid biopsy approach.

Leighton[1], R. Malta[1], M. Nabiyouni[1], C. Fraire[1], G. Guler[2], S. Dhillon[1], C. (. Coruh[1], M. Peters[1], S. Chowdhury[1], E. Nilson[1], S. Quake[3], W. Volkmuth[2], S. Levy[1];

[1]ClearNote Health, San Diego, CA, [2]ClearNote Health, San Mateo, CA, [3]Stanford University, Stanford, CA

Background: Pancreatic ductal adenocarcinoma (PDAC) has a 5-year survival rate of less than 12% due to late diagnosis when curative options are limited. Early detection, especially stage I-II disease, could improve survival, but current non-invasive tests lack enough sensitivity. Multi-analyte liquid biopsies that combine genomic, epigenomic, and glycan data show promise for better detection. We developed a prediction model for the early detection of pancreatic cancer by integrating epigenomic and genomic features with haplotype information and CA19-9 biomarker levels, achieved a markedly more sensitive predictor.

Methods:

We employed a training set of 162 pancreatic cancer patients and 983 non-cancer patients. Cell-free DNA was isolated and employed to perform 5-hydroxymethylcytosine (5hmC) profiling, low pass whole-genome sequencing (WGS) and genotyping. CA19-9 biomarker levels were also measured in plasma. The resulting 5hmC gene-based changes, fragment size differences, and genotyping coupled with CA19-9 levels, were used for logistic regression model building. The prediction model performance was validated in an independent validation cohort of 1,445 individuals, consisting of 259 pancreatic cancers and 1,186 non cancer with several high-risk features including diabetes, family history, genetic predisposition and heavy smokers. Cancer performance was measured through sensitivity and specificity metrics and 95% confidence intervals (CIs).

Results:

After training the prediction model to optimize feature selection, the final model was locked at a specificity threshold of 97.75% and used to score an independent clinical cohort in a blinded manner. In the independent validation cohort, the multi-analyte model achieved an overall sensitivity of 82.6% (95% CI: 77.45%-87.04%) and importantly, early-stage sensitivity (n=138) was 76.8% (95% CI: 68.87%-83.57%). These measures point to an increase of sensitivity of > 8-15% compared to an earlier version of the assay. Test specificity was 97.45% (95% CI: 96.41%-98.29%), consistent with the pre-established 97.75% training specificity, highlighting robust performance across datasets.

Conclusions:

The multi-analyte model demonstrated strong early-stage PDAC detection while maintaining high specificity. By integrating orthogonal biological features such as epigenomics, genomics and CA19-9 levels, we have been able to improve PDAC detection performance, ensuring that the breadth of oncogenic development can be detected through an early detection blood test.

#4042 Tumor-tailored ionizable lipid nanoparticles facilitate IL-12 circular RNA delivery for enhanced lung cancer immunotherapy.

Y. Xu[1], S. Xu[2], B. Li[3];
[1]Baylor College of Medicine, Houston, TX, [2]UTSW, Dallas, TX, [3]University of Toronto, Toronto, ON, Canada

mRNA-based immunotherapies are hindered by systemic toxicity and transient expression, necessitating frequent dosing. This is especially problematic for potent cytokines like Interleukin-12 (IL-12), whose use is limited by severe adverse effects.
To address this, we developed a platform using circular RNA (circRNA), which offers more sustained protein expression than linear mRNA. A high-throughput combinatorial method (Ugi reaction) was used to screen for ionizable lipids to deliver circRNA to lung tumors. The lead LNP, H1L1A1B3, showed a fourfold increase in circRNA transfection efficiency over the ALC-0315 standard. H1L1A1B3 LNPs were also dual-functional, acting as an immune adjuvant by potently activating NF-κB and IRF innate immune pathways. This LNP was loaded with circRNA encoding IL-12, providing significantly delayed decay in protein expression.
Therapeutic efficacy was validated in two lung cancer models. In a subcutaneous LLC1 model, a single intratumoral injection of H1L1A1B3-circRNA-IL-12 LNPs delayed tumor progression. Combined with an anti-PD-L1 checkpoint inhibitor, this induced robust tumor regression. Immunological profiling revealed a profound remodeling of the tumor microenvironment (TME), including an eightfold increment in $CD45^+$ leukocytes and enhanced infiltration of $CD8^+$ and $CD4^+$ T cells, increasing the $CD8^+$/Treg ratio.
Second, in an orthotopic HKP1 NSCLC model, a single intratracheal administration of the IL-12 circRNA LNPs effectively suppressed lung tumor growth. This local delivery resulted in sustained serum IL-12 and IFN-γ for at least five days but did not cause systemic liver toxicity (normal AST/ALT levels). The treatment successfully recruited immune cells, including $CD8^+$ T cells, to the lung tumors.
In conclusion, this work presents a tumor-tailored, dual-function LNP (H1L1A1B3) that efficiently delivers stable IL-12 circRNA and provides intrinsic immunostimulatory effects. The platform enables sustained, localized cytokine expression, remodeling the TME to be immunologically "hot." These results highlight the potential of this LNP-circRNA platform to advance RNA drug delivery, offering a potent and safer immunotherapeutic strategy for lung cancer by overcoming systemic toxicity and transient expression hurdles.

#4043 A novel TAM-targeted therapeutic for rare and aggressive solid tumors.

F. H. Barnett[1], J. James[2], S. Premeau[1], R. R. Crum[1], A. Basbaum[1], R. Schmidt[1];
[1]Resolute Science, Inc., San Diego, CA, [2]Corvid LLC, San Diego, CA

A hallmark of aggressive tumors is the dense infiltration of tumor-associated macrophages (TAMs), which often constitute 30-50% or more of the total cells within a tumor. TAMs foster an immunosuppressive microenvironment and promote resistance to chemotherapy, immunotherapy, and radiation. They also facilitate macrophage vascular mimicry, a non-endothelial microcirculation in hypoxic tumor regions as described by Barnett et al., 2016. Resolute Science, Inc. has developed macrophage-targeted conjugates (MAC-TACs), a novel class of synthetic drug conjugates that exploit TAM biology and the TAM microcirculation for targeted delivery of payloads to tumor cells. By targeting TAMs rather than tumor cells, this platform bypasses resistance from tumor heterogeneity and receptor evolution. Our lead candidate, RS-5, an MMAE-conjugated MAC-TAC, has shown near-complete to complete regressions in 22 studies across 10 solid tumor models, including CDX, syngeneic and PDX models. MAC-TACs comprise four components: a receptor targeting ligand, backbone, linker, and payload. This modular design enables the development of therapeutic and imaging molecules, including radiopharmaceuticals. MAC-TACs target an overexpressed receptor found on TAMs. Immunohistochemical analysis reveals a high and relatively uniform expression of the TAM-targeted receptor across a range of metastatic tumor types, including sarcoma, melanoma, bladder, prostate, pancreatic and gastric cancers. In vitro and in vivo studies demonstrate selective uptake by TAMs, which internalize and release the payload to adjacent cancer cells. Receptor expression correlates with therapeutic response. A complete response was observed in a doxorubicin-resistant soft tissue sarcoma (STS) PDX model. In a second PDX STS model, a near-complete response was observed over two months of treatment. In an A375 melanoma CDX model, a near-complete response was also observed. In an intracranial U87MG glioma model, RS-5 demonstrated a 79% increase in median survival, and in an HT1080 luciferase brain metastasis model, a 100% increase in median survival was observed. Across studies, body weight and hematologic/chemical parameters remained within normal ranges. RS-5 exhibits a favorable PK/PD profile; MTD and DRF are complete, and 4-week toxicology studies are underway.These preclinical results support broad clinical utility, particularly for TAM-rich tumors. A first-in-human dose-escalation study is planned for the summer of 2026.

#4044 GPNMB CAR-T cells target both glioblastoma and the tumor microenvironment to relieve immune suppression.

Sheila Kumari Singh[1], Neil Savage[1], Muhammad Vaseem Shaikh[1], Shan Grewal[1], Franz J. Zemp[2], Nick Mikolajewicz[3], Joanna Pyczek[4], Hinda Najem[5], Jeffrey Wei[3], Shawn C. [1]McMaster University, Hamilton, ON, Canada,[2]Southern Alberta Cancer Research Institute, Calgary, AB, Canada,[3]University of Toronto, Toronto, ON, Canada,[4]University of Calgary, Calgary, AB, Canada,[5]Northwestern University, Chicago, IL,[6]Sick Kids Research Institute, Toronto, ON, Canada,[7]UHN Princess Margaret Cancer Centre, Toronto, ON, Canada

Glioblastoma (GBM) remains uniformly lethal, driven by profound intratumoral heterogeneity, and an immunosuppressive tumor microenvironment (TME) dominated by tumor-associated macrophages (TAMs). The identification of novel therapeutic targets is crucial for advancing promising therapies that address both tumor and TME. Here, we identify glycoprotein non-metastatic melanoma protein B (GPNMB) as a clinically relevant surface marker expressed on both GBM cells and TAMs. Genetic loss of GPNMB in GBM models reduced tumor cell proliferation, delayed intracranial tumor growth, and altered transcriptional programs linked to immune regulation and leukocyte activation, indicating GPNMB sustains both tumor fitness and an immunosuppressive niche. We generated both anti-human and anti-mouse GPNMB CAR-T cells showing potent activity: In orthotopic patient-derived xenografts, GPNMB CAR-T therapy induced complete tumor remission; murinized GPNMB CAR-Ts similarly produced sustained tumor control in syngeneic GBM models. In a humanized mouse model of recurrent GBM, anti-human GPNMB CAR-T therapy drove tumor regression in most animals despite a highly suppressive myeloid-rich TME. An integrated central nervous system myeloid single-cell RNA-sequencing atlas revealed GPNMB$^+$ macrophages are enriched for lipid transport, and GPNMB expression correlates with immunosuppressive gene signatures. Consistent with this, GPNMB was preferentially expressed by immunosuppressive macrophages, and GPNMB CAR-Ts selectively eliminated immunosuppressive over pro-inflammatory macrophages in vitro and in vivo. Collectively, these data establish GPNMB CAR-T therapy as an extremely promising therapy inducing complete GBM remission in PDXs and immunocompetent models by simultaneously targeting GPNMB+ tumor cells and immunosuppressive macrophages.

#4045 Collagen binding enhances anti-CTLA4 therapy in recurrent glioblastoma.

L. Barr[1], J. Takei[1], C. Wang[2], O. Iwaloye[1], K. Furudate[3], H. Ichie[1], S. Tsuzuki[1], J. Ishihara[2], S. Osuka[1];
[1]University of Alabama at Birmingham, Birmingham, AL, [2]Imperial College London, London, United Kingdom, [3]UT MD Anderson Cancer Center, Houston, TX

Recurrent glioblastoma (rGBM) is an aggressive malignant brain tumor, with a median survival of 6 months. rGBM establishes an immunosuppressive tumor microenvironment (TME) driven by regulatory T cells (Treg) and exhausted T cells (Tex). Since both Treg and Tex highly express CTLA4, antagonistic CTLA4 antibodies (αCTLA4) were considered promising therapeutic agents. Despite this rationale, clinical trials showed no survival benefit in rGBM, likely due to poor tumor penetration of αCTLA4. Therefore, technology to enhance αCTLA4 delivery in rGBM tissue is critically needed. rGBM acquires treatment resistance through alteration of extracellular matrix (ECM) proteins in the tumor microenvironment (TME). Our lab proposes utilizing this ECM change as a reservoir to accumulate αCTLA4. We focused on COL I & III, which are minimally expressed in the normal brain but highly upregulated in rGBM. We created CBD-αCTLA4 by fusing αCTLA4 with the collagen-binding domain (CBD) of von Willebrand factor (vWF), leveraging vWF's selective binding to COL I & III at sites of vascular disruption, inflammation, and tumors while sparing normal organs with COLI&III high expression. In syngeneic rGBM murine models, CBD-αCTLA4 showed greater accumulation than αCTLA4 using confocal microscopy and biodistribution assay. Single-cell RNAseq showed CBD-αCTLA4 reduced Treg and Tex populations within rGBM tumors, thereby transforming the immunosuppressive TME and facilitating the recruitment of type 1 conventional dendritic cells (cDC1s) into the tumor. Survival analysis in our models revealed CBD-αCTLA4 treatment (100μg i.v., twice) prolonged survival by 140% with a 14% CR rate in rGBM mice models, while αCTLA4 (non-CBD) treatment showed no survival extension. For clinical translation, we developed a humanized CBD-αCTLA4 (CBD-Ipilimumab) and validated its efficacy in 3D human GBM slice cultures, demonstrating decreased Treg cells in human tumor tissue. Furthermore, CBD-ipilimumab significantly prolonged survival in peripheral blood mononuclear cell (PBMC)-humanized mice bearing human rGBM tumors. Collagen-binding αCTLA4 achieved enhanced intratumoral accumulation, reversed the immunosuppressive profile, and elicited potent antitumor effects in rGBM. Our results suggest that CBD-αCTLA4 holds significant promise as an innovative immunotherapy for rGBM. Moreover, this collagen-targeting platform has broad implications, as it can be extended to other antibody-based therapeutics for brain tumors.

#4046 A novel DLL3 trispecific T cell engager antibody integrating the CD2/CD58 co-stimulatory pathway demonstrates superior antitumor efficacy and balanced safety profile.

Cheng Luo[1], Devin Liu[1], Yingyu Li[1], jingjing Nie[1], Na Li[1], Fan Zhou[1], Xin Wang[1], Yang Xin[1], Mingzhu Shao[1], Tingting Yang[1], Hai Huang[1], Cheng Chen[1], Mingrui Du[1], Jiashun Cai[1], Li Chen[1], **Yu Liang**[2]

[1]Probio, Inc, Nanjing, China,[2]Probio, Inc, Pennington, NJ

As a clinically validated therapeutic modality, T-cell engager (TCE) antibodies showed great success in hematological tumors. However, they still face a number of challenges in effectively treating solid tumors, including a lack of tumor-specific targets, insufficient T cell infiltration of some tumors, and immunosuppressive forces within the tumor microenvironment (TME) leading to T cell anergy and exhaustion. These challenges contribute to the narrow therapeutic window of TCEs in treating solid tumors and partially explain why no solid tumor-targeting TCE received regulatory approval until the DLL3-targeting tarlatamab became the first (and only to date) in 2024. To address the aforementioned challenges, a number of approaches are being explored and tested clinically, including those integrating a co-stimulatory moiety into the TCE to prevent or revert T cell exhaustion and promote sustained proliferation of the infiltrated T cells within the TME. Amongst co-stimulatory pathways, those mediated by CD28 and 4-1BB have been the most extensively explored, even though recent studies have shown that they are often associated with excessive toxicity or paradoxical immunosuppression. In contrast, the CD2-CD58 axis offers a promising alternative based on a few possible modes of actions, including promoting a balanced T cell co-stimulation at both the priming and effector stage, and stabilizing immunological synapse. Therefore, to further enhance the efficacy, persistence, and safety of conventional TCEs targeting DLL3 and other solid tumor targets, we designed a novel class of DLL3xCD3xCD2 trispecific antibodies based on an internally developed CD3 VHH antibody with cyno cross-reactivity. These trispecific TCEs were evaluated in a suite of *in vitro* functional assays whereby they demonstrated superior potency in tumor cell killing and sustaining T cell proliferation compared to the parental bispecific TCE (DLL3xCD3) and tarlatamab, especially at low E/T ratios, which mimics the scarcity of T cell infiltration into the TME of solid tumors. Additionally, this enhanced tumor cytotoxicity was accompanied by an increased, but balanced, cytokine profile with a reduced release of proinflammatory cytokines (TNFa, etc.), and an insignificant level of tumor antigen-independent T cell activation or cytokine release. For *in vivo* studies, these trispecific TCEs demonstrated a favorable IgG-like pharmacokinetics profile and greater antitumor activity than clinical benchmarks in two human PBMC-reconstituted CDX models (SHP77 and NCI-H82). In summary, the incorporation of a CD2 co-stimulatory moiety into a DLL3-targeting TCE leads to a novel, next-generation TCE with improved efficacy and safety profiles in preclinical studies. IND-enabling studies are ongoing with the potential to advance it to clinical studies in the near future.

#4047 CBP/p300 and PARP inhibitor combination treatment synergistically enhances anti-tumor efficacy in models of advanced prostate cancer.

O. I. Richter[1], S. Sardar[1], X. Zhang[2], J. D. Kindrick[2], L. Ravindranath[1], C. H. Chau[3], C. J. Thomas[2], C. McNair[4], X. A. Su[1], A. Sharp[5], J. de Bono[5], K. Frese[6], W. D. Figg[3], K. E. Knudsen[7], A. A. Shafi[1];

[1]Uniformed Services University of the Health Sciences, Bethesda, MD, [2]National Center for Advancing Translational Sciences, Bethesda, MD, [3]National Cancer Institute, Bethesda, MD, [4]Thomas Jefferson University Kimmel Cancer Center, Philadelphia, PA, [5]The Institute of Cancer Research, London, United Kingdom, [6]CellCentric Ltd., Cambridge, United Kingdom, [7]Parker Institute for Cancer Immunotherapy, San Francisco, CA

Metastatic castration-resistant prostate cancer (mCRPC) is a uniformly fatal disease which has displayed resistance to many single-agent therapies, underscoring the need for novel combination therapies. Histone acetyltransferases CBP/p300, which act as androgen receptor (AR) coactivators, are often upregulated in mCRPC. Elevated CBP/p300 levels are associated with reduced progression-free and overall survival in prostate cancer patients. Our recent work has demonstrated that CBP/p300 play important roles in regulating DNA repair, particularly homologous recombination, and that inhibition of CBP/p300 may sensitize mCRPC to existing therapeutics. A Phase 1/2a study investigating a CBP/p300 inhibitor, CCS1477, alone and in combination regimens is currently underway. However, research into CCS1477 combination treatments is highly limited, necessitating further investigation into combination therapies and markers of sensitivity to improve outcomes for mCRPC patients. We hypothesized that combination treatment using CBP/p300 inhibitors (CBP/p300i) with PARP inhibitors (PARPi) would enhance anticancer effects by synergistically impairing DNA damage repair in cancer cells. Using preclinical 2D and 3D models, including patient-derived explants, we evaluated the functional impacts of targeting CBP/p300 and PARP pathways in combination. We found that this combination therapy was significantly more effective than either monotherapy at reducing cell growth both *in vitro* and *ex vivo*. Importantly, a comprehensive screen with clinically relevant PARPi revealed that combination of CBP/300 and PARP inhibition demonstrate synergy across several PCa cell lines. To assess the utility of CBP/p300 and PARP combination therapy in patients, we treated PCa patient-derived explants (PDEs) from a racially diverse cohort with CBP/p300i and PARPi. Ki67 staining revealed decreased proliferation in combination therapy-treated tissue, supporting the findings from 2D models. To investigate genomic alterations that may underlie differential treatment responses, we performed whole-exome sequencing (WES) on tissues from our PDE cohort. This analysis identified distinct germline and somatic variants that segregated with treatment responders versus non-responders. Spatial transcriptomics will identify molecular signatures distinguishing responders from non-responders, advancing precision medicine in diverse populations. Our findings indicate that CBP/p300 inhibition in combination with PARPi may have stronger anti-tumor effects than single-agent therapies. Analysis of patient-derived models provides insight into the patient subsets most likely to benefit from this combination therapy, supporting its potential as a novel therapeutic approach to improve outcomes for mCRPC patients.

#4048 3D bioprinted cancer models for drug screening versus 2D and *in vivo* models: A comparison study.

Aurelie Cadiou[1], Eva-Laure Matera[2], Doriane Mathe[1], Marine Fellmann[1], Jerome Guitton[3], Kamel Chettab[4], Christophe Marquette[4], Charles Dumontet[2]

[1]Antineo, Lyon, France,[2]CRCL, Lyon, France,[3]Hospices Civils de Lyon, Lyon, France,[4]University of Lyon, Lyon, France

3D models are increasingly used to perform preclinical drug screening. 3D bioprinted models offer a promising alternative to better mimic the in vivo setting. In this work we compared molecular characteristics and drug sensitivity of two HER2 positive human cancer lines, the breast cancer model BT-474 and the ovarian cancer model SK-OV-3. Both models were a) cultured in classical 2D systems, with analyses during the exponential growth phase; b) bioprinted using a fibrinogen/alginate/gelatin bioink and characterized at different time points; c) implanted subscutaneously in CB17-SCID mice and treated once tumors were established (median volume #100 mm3). All models were compared using RNA sequencing. Drug sensitivity was evaluated against HER2 specific agents (lapatinib, trastuzumab-emtansine) and paclitaxel in 2D and 3D models and against paclitaxel in tumor models. Tumor bearing mice were treated with different paclitaxel doses ranging between 2.5 mg/kg (ineffective) to 30 mg/kg (T/C ratio of 0.4). Paclitaxel accumulation in tumor cells was quantified in all models exposed to various concentrations of drug. IC50 values were found to be approximately 3 to 10-fold higher in 3D models than in 2D models for all treatments tested. Analysis of 3D models at different time points using non disruptive (Presto Blue) or disruptive (flow cytometry analysis) methods showed active proliferation of tumor cells up to 40 days after bioprinting, as documented by Ki67 staining. In a standard assay objects were printed on day 0, exposed to treatments on day 4 and analyzed up to day 11. Addition of cancer associated fibroblasts (CAFs) in the bioink reduced sensitivity of tumor cells to therapy. Coculture with adipocytes or in the presence of adipocyte conditioned medium also showed reduced sensitivity to therapy. Tumor cell concentrations of paclitaxel was quantified by mass spectrometry at various time points and concentrations in the 2D and 3D settings as well as in in vivo tumor models. RNA profiling of the different models identified a category of genes which were highly expressed in the 2D setting only, while genes specifically expressed in in vivo models tended to be also more highly expressed in 3D models. Differentially expressed genes were confirmed using RT-qPCR and are currently being explored at the proteomic level. Gene Ontology analysis suggested that genes involved in cell adhesion, focal adhesion and extracellular-matrix receptor interactions tended to be less expressed in 2D models. These results suggest that 3D bioprinted models better mimic the in vivo situation than 2D models and should be systematically used in the preclinical drug screening process of novel agents, in order to reduce and better choose relevant murine models.

Background: Glypican-3 (GPC3) is a highly specific and promising tumor-associated antigen. Adoptive cell therapies for solid tumors face significant hurdles including poor T-cell trafficking and limited persistence. To address these challenges, we initiated an iterative design process for GPC3-targeted STAR-T cells (YTS102). Our initial enhanced construct (v2) incorporated the chemokine receptor CXCR2 to improve tumor trafficking. We further optimized the construct to enhance T-cell expansion and persistence, leading to a v3 version armored with membrane-bound IL-15 (mbIL-15).
Methods: The STAR-T platform utilizes a high-affinity GPC3-specific scFv (GC33) fused to TCR constant domains. Preclinical evaluation was conducted through comprehensive in vitro (cytotoxicity, cytokine secretion, migration) and in vivo (Huh-7 and MKN45 xenograft models) assays to validate the functional attributes of each engineered construct. A first-in-human, investigator-initiated phase I trial (NCT05344664) was also conducted to evaluate the safety and preliminary efficacy of both v2 and v3 GPC3 STAR-T cells in patients with heavily pretreated, GPC3-positive advanced solid tumors.
Results: Preclinical studies confirmed the distinct advantages of each design. The CXCR2-armored v2 STAR-T cells showed enhanced chemokine-mediated migration, while the mbIL-15-armored v3 construct demonstrated superior proliferation, persistence, and potent serial killing ability. Both constructs mediated robust anti-tumor efficacy in xenograft models. In the phase I study, 7 evaluable patients (6 gastric cancer, 1 hepatocellular carcinoma) received STAR-T cell therapy (either v2 or v3). The safety profile was manageable; cytokine release syndrome (CRS) occurred in 6/7 patients (3 Grade 1-2; 3 Grade 3), and Grade 2 ICANS was observed in one patient. Encouraging clinical activity was observed, with an objective response rate (ORR) of 42.8% (3/7) and a disease control rate (DCR) of 71.4% (5/7).
Conclusion: Iterative engineering of GPC3-targeted STAR-T cells with functionalities to enhance tumor trafficking (CXCR2) and persistence (mbIL-15) results in potent anti-tumor activity. Early clinical data demonstrate a favorable safety profile and promising efficacy in heavily pretreated patients with GPC3-positive solid tumors. These findings validate our optimization strategy and support the continued clinical development of YTS102 as a promising therapeutic for solid tumors.

#4007 The cellular architecture of the infused T cell predicts efficacy of autologous tumor-infiltrating lymphocyte therapy (LM-103) in acral melanoma.

Chao Zhang[1], Jilong Yang[1], Xiangchun Li[2], Kexin Chen[2], Hongru Shen[2]

[1]Department of Bone and Soft Tissue Tumor, Tianjin Medical Univ. Cancer Inst. & Hosp., Tianjin, China,[2]Department of Epidemiology and Biostatistics, Tianjin Medical University Cancer Institute & Hospital, Tianjin, China

Acral melanoma (AM), the predominant melanoma subtype in Asia, shows poor response to immune checkpoint inhibitors, underscoring the need for alternative immunotherapies. An investigator-initiated trial evaluates autologous tumor-infiltrating lymphocyte (TIL) therapy (LM-103) in four Chinese patients with advanced AM, achieving a 75% disease control rate and one durable complete response. To define determinants of therapeutic outcome, integrated single-cell RNA sequencing (scRNA-seq) and T-cell receptor sequencing (TCR-seq) are performed on infused TIL products, tumors, and longitudinal peripheral blood. Single-cell profiling reveals marked heterogeneity within the infused products, including naïve, regulatory, follicular helper (Tfh), cytotoxic, and multiple exhausted T-cell states. Responders demonstrate striking enrichment of Tfh and intermediate exhausted (TEX_int) $CD8^+$ T cells, whereas the non-responder product is dominated by terminally exhausted subsets. Pseudotime analysis supports a conserved exhaustion continuum in which TEX_int cells occupy a plastic, functionally competent intermediate state.Cell-cell communication modeling shows that responder products contain a densely connected signaling ecosystem driven by Tfh- and TEX_int-mediated costimulatory pathways, such as CD40, CD70, and FASLG. In contrast, non-responder products exhibit sparse, immunosuppressive networks dominated by TGFβ and MIF signaling. TCR integration demonstrates higher clonality within Tfh and TEX_int subsets in responders.Longitudinal tracking reveals that the complete responder maintains stable high clonality after infusion. Notably, a dominant clonotype enriched in the TEX_int population of the infused product persists in peripheral blood and later adopts a progenitor-like exhausted (TEX_prog) state. This finding provides direct in vivo evidence that intermediate exhausted T cells can differentiate into a progenitor-like state after adoptive transfer, establishing a durable, self-renewing reservoir capable of sustaining long-term anti-tumor immunity.These results define the cellular and clonal architecture underlying successful TIL therapy in AM. Durable benefit is determined not by the size of the infused product but by the presence and persistence of coordinated Tfh-TEX_int ecosystems that seed long-lived progenitor-like immunity. These insights offer mechanistic biomarkers and provide a foundation for optimizing TIL manufacturing for melanoma subtypes refractory to current immunotherapies.

#4008 A novel, first in class chimeric antigen receptor dendritic cell platform driving broad and durable antitumor immunity in solid tumors.

S. L. Namen[1], G. Pandey[2], T. Naismith[1], C. Willoughby[1], L. Longtine[1], U. Panni[2], C. F. Lichti[2], K. Singhal[1], M. Griffith[3], **C. DeSelm**[1]; [1]Washington University School of Medicine in St. Louis, St. Louis, MO, [2]Washington University in St. Louis, St. Louis, MO, [3]Washington University, St. Louis, MO

Chimeric Antigen Receptor Dendritic Cells (CAR-DCs) represent a new class of immunotherapy designed to overcome the key limitations of CAR-T and immune checkpoint blockade (ICB) in solid tumors. By engineering conventional dendritic cells (cDCs) with a tumor-targeting CAR delivered via non-integrating mRNA, we have harnessed the intrinsic ability of DCs to cross-prime a broad repertoire of antitumor CD8+ T cells. This approach merges the precision of CAR technology with the natural antigen-presenting potency of DCs, enabling broad immune activation by inducing polyclonal $CD8^+$ T-cell responses that extend beyond CAR-restricted epitopes. To enable clinical advancement, we have developed a scalable human manufacturing process that reliably produces >300 million CAR-DCs, overcoming a longstanding barrier to the translational deployment of DC-based therapies. Immunotherapies such as CAR-T and ICB have transformed hematologic cancer treatment but remain ineffective in many solid tumors due to finite target antigens and dependance on pre-existing tumor-reactive T cells. To overcome these challenges, we engineered type I conventional DCs with a CAR recognizing B7-H3, a clinically relevant solid and liquid tumor antigen. In vitro, B7-H3 CAR-DCs displayed enhanced uptake of diverse tumor antigens, maturation, and superior cross-presentation of tumor derived antigens to $CD8^+$ T cells, driving potent cytotoxic T-cell activation. In vivo, using a C57BL/6 syngeneic 1956 sarcoma model comprised of 75% B7-H3$^+$ and 25% B7-H3$^-$ tumor cells, untreated mice exhibited progressive disease. In contrast, both intratumoral and intravenous administration of B7-H3 CAR-DCs induced complete to almost complete tumor regression and confer durable protection upon rechallenge, demonstrating the establishment of robust, target-independent immunity. Analysis of tumor-draining lymph nodes (tdLNs) revealed that B7-H3 CAR-DCs delivered substantially greater amounts of tumor antigen to tdLNs. Correspondingly, transcriptional profiling of tdLN $CD8^+$ T cells revealed signatures of enhanced activation, increased proliferative potential, and a shift toward memory formation which are hallmarks of efficient cross-priming. Mass spectrometry of MHC-I-cross presented peptides and tetramer analyses demonstrated CAR-DCs generated a broad expansion of endogenous tumor neoantigen-specific $CD8^+$ T cells, confirming strong and effective diversification of the antitumor T-cell response. Together, these results position mRNA-engineered CAR-DCs as a first-in-class, translationally ready cell therapy platform that integrates antigen specificity, broadening of the antitumor T-cell response, durable memory formation, and GMP-compatible large-scale manufacturing thereby supporting rapid advancement toward IND-enabling studies and clinical evaluation in solid tumors.

#4009 Decoding the medulloblastoma surfaceome prioritizes the oncofetal antigen GPC2 for potent CAR-T cell therapy.

D. Usta[1], W. Gwynne[2], Y. Suk[3], Y. Chen[1], M. T. Radosevich[4], D. Chernova[4], Y. Feng[4], E. Nasajpour[4], M. Trissal[5], R. Poetschke[5], A. Delaidelli[6], C. Dunham[7], L. Labanieh[4], J. van der Lugt[8], S. Nierkens[8], M. G. Filbin[9], C. Petrisch[4], P. H. Sorensen[10], K. Ryan[4], C. Venugopal[3], E. Sotillo-Pineiro[4], C. L. Mackall[11], S. K. Singh[3], **S. Heitzeneder**[4];

[1]Stanford Cancer Institute, Stanford, CA, [2]McMaster University, Georgetown, ON, Canada, [3]McMaster University, Hamilton, ON, Canada, [4]Stanford University, Stanford, CA, [5]Dana-Farber Boston Children's Cancer and Blood Disorders Center, Boston, MA, [6]BC Cancer Agency, Vancouver, BC, Canada, [7]BC Children's Hospital, Vancouver, BC, Canada, [8]Princess Maxima Center, Utrecht, Netherlands, [9]Dana-Farber Cancer Institute, Boston, MA, [10]British Columbia Cancer Research Centre, Vancouver, BC, Canada, [11]Stanford Hospital, Stanford, CA

Key determinants for efficacious CAR-T antigens remain near absence in vital tissues and that antigen levels in clinical specimens exceed CAR-T detection thresholds. CAR-T cells meeting these criteria have demonstrated clinical benefit in aggressive pediatric brain tumors, as seen in H3K27M-mutant diffuse midline glioma responding to GD2-directed CAR-T cell therapy. Medulloblastoma (MB) is a devastating childhood brain tumor, for which standard-of-care is fails in 30% of patients, and leaves many survivors with debilitating long-term effects. Survival rates of recurrent disease reside below <10%. Increasing cure rates and diminishing treatment-related morbidity necessitates targeted therapies, but success using CAR-T cells in MB has been limited by a dearth of suitable cell-surface targets. We profiled the CAR-T antigen landscape of MB through integrating unbiased surfaceome analysis from tumor and normal tissue transcriptomes and quantitative antigen density mapping of candidate targets on n= 24 MB tumor biopsies across all molecular subtypes. We found that MB closely resembles prenatal brain and credentialled oncofetal antigens as the predominant target pool in MB. A quantitative flow cytometry-based assay to precisely quantify antigen densities of candidate targets in clinical specimens prioritized GPC2 as the top candidate. GPC2 antigen densities ranged from ~1700-24500 molecules/cell across MB subgroups (mean: 6374 +/-4968). Because antigen density greatly influences CAR-T potency, we previously engineered GPC2-CAR-Ts tuned towards clinical densities on neuroblastoma and demonstrated that cJUN-overexpression (OE) augments their potency by lowering antigen detection thresholds (Heitzeneder et. al, 2022). Here, we employ orthotopic xenograft models and locoregional CAR-T delivery to study the interplay between GPC2 antigen density and CAR potency and to inform a phase-1 trial design. We found that both GPC2-CAR-T constructs (+/-cJUN) achieved durable disease control against GPC2-intermediate GR4-MB (ICB1299: ~9000 mol/cell and MBT375, a newly established PDX: ~6500 mol/cell). In a highly aggressive, MYC-amplified, GPC2-high GR3-MB model (SU_MB002: ~18800 mol/cell), recurrence occurred in 3/5 mice post GPC2-CAR, whereas repeated dosing or cJUN-OE significantly improved persistence and long-term anti-tumor control. In a GPC2-low, GR3-MB model (HDMB03: ~3000 mol/cell) used to further dissect antigen detection limits, only cJUN.GPC2-CAR-T cells maintained anti-tumor responses. This work informed an ongoing phase-1 clinical trial at Stanford (NCT07087002), currently testing repeated, locoregional GPC2-CAR-T infusions and is planned to employ cJUN overexpression in patients with recurrent/refractory MB, aiming to provide a targeted treatment option for this devastating malignancy.

#4010 NK-TCR cells: A next-generation platform expanding NK-cell therapeutic potential.

N. Uprety, B. Liu, R. Basar, R. Shrestha, F. Reyes Silva, M. Daher, K. Rezvani;
UT MD Anderson Cancer Center, Houston, TX

Background: Adoptive transfer of engineered natural killer (NK) cells has emerged as a promising strategy for solid and hematologic malignancies; however, the absence of a physiological T-cell receptor (TCR) limits the spectrum of antigens for targeting and prevents recognition of intracellular targets. To address this challenge, we developed a n NK-TCR platform that enables stable expression of fully functional TCRs in NK cells without inducing alloreactivity or GvHD. Using this system, we generated two lead NK-TCR products targeting the intracellular tumor antigens NY-ESO-1 and PRAME, with additional TCRs in development.
Methods: Primary human NK cells were engineered to express either an NY-ESO-1-specific TCRα/β receptor or a PRAME TCRα/β receptor recognizing target peptides presented on HLA-A*02:01. Both products incorporated the full CD3 signaling complex (ζ, ε, γ, δ) and a chimeric CD28-CD3ζ costimulatory module, and IL-15 to support activation and in vivo persistence. Each NK-TCR cell product was evaluated independently for in vitro for cytotoxicity, cytokine production, proliferation and serial-killing capacity against multiple tumor cell lines, including Saos-2 (osteosarcoma), A375 (melanoma), U266B1 (multiple myeloma), and THP-1 (AML).
Results: NY-ESO-1-TCR NK cells showed potent antigen specific activity, efficiently eliminating Saos-2, A375 and U266B1 cells, with strong cytokine production, sustained serial killing and superior persistence relative to non-transduced NK cells. The PRAME TCR NK cells showed equally strong activity against U266B1, Saos2, and A375 cells. In vivo, NY-ESO-1 TCR NK cells mediated rapid tumor regression and prolonged survival in multiple myeloma xenograft models, with durable persistence and no signs of exhaustion or toxicity. PRAME TCR NK cells achieved similarly superior in vivo activity in a U266B.1 Multiple Myeloma model compared to non-engineered controls. Based on the strength of these findings, NY-ESO-1-TCR NK cells are now under evaluation in multiple myeloma with a separate study in synovial sarcoma, and PRAME TCR NK cells have entered clinical evaluation for AML and melanoma. Together, these data establish NK-TCR platform as a next-generation cellular therapy approach with broad applicability and the capacity to extend NK-cell therapies to intracellular antigen targets.

#4011 Universal T cell therapy screening library in preclinical models of CAR T cell therapy.

A. Eapen, L. Wu, L. Moser, B. Quach, W. Gamal, K. Rodrigues, K. C. Tsui, Z. Good, T. Roth;
Stanford University School of Medicine, Stanford, CA

Currently approved T cell therapies fail to induce a durable remission for many of the patients who receive them, highlighting a pressing need to improve patient outcomes. To comprehensively explore genetic strategies to enhance function of engineered T cells, we have developed CRISPR-All, a combinatorial genetic perturbation language capable of simultaneously inducing natural gene overexpression, gene knockouts, and gene knockdowns, as well as new synthetic sequences such as chimeric antigen receptor (CAR) binders or signaling domains and synthetic gene sequences. Using CRISPR-All, we have created a T cell therapy “meta-library”, termed CRISPR-All Cell Therapy Universal Screening (CACTUS), collated from a comprehensive review of literature on effector function-enhancing genetic modifications in both native and engineered human T cells. In CACTUS2, we also included perturbations informed by clinical dataset analysis of patients receiving CD19-CAR or bispecific CD19/CD22-CAR therapy. We introduced the CACTUS2 library into primary human T cells along with a CD19-28Z CAR (axi-cel) and performed an in vitro assay in which edited CAR T cells are chronically stimulated over the course of 14 days via repetitive co-culture with target human leukemia or lymphoma cell lines (NALM6, Toledo, JeKo-1). Top hits across these screens emerged as synthetic chimeras of overexpressed genes. The large-scale analysis of perturbations relevant to T cell fitness in cancer models empowered by the CRISPR-All screening method is an important step in improving CAR T cell therapeutic designs for enhanced therapeutic outcomes.

#4012 Triple disruption of *CCDC6*, *CBLB*, and *ASB2* promotes the therapeutic efficacy of Glypican 3 targeted T cells.

Azlann Arnett[1], David Steffin[1], Antonino Montalbono[1], Nisha Ghatwai[1], Amy Courtney[1], Gabriel Barragan[1], Magda Magda Esparza Cerda[1], Michael Wood[1], Marie Pouzolles[1], Kshitij Rai[2], Frederic D. Bushman[3], Dimitrios L. Wagner[4], Andras Attila Heczey[5]

[1]Baylor College of Medicine, Houston, TX,[2]Rice University, Houston, TX,[3]Department of Microbiology, University of Pennsylvania, Philadelphia, PA,[4]Center for Cell and Gene Therapy, Baylor College of Medicine, Houston, TX,[5]Seattle Children's Research Institute, Seattle, WA

Viral insertions of chimeric antigen receptor (CAR) cassettes into specific genes can lead to clonal expansion of the resulting CAR T cell population and complete remission of cancer. Viral integration events provide a unique opportunity to study regulators of CAR T proliferation and function. We analyzed the clonal dynamics of twelve patients enrolled in our glypican 3 (GPC3) CAR T cell and IL15 GPC3 CAR T cell clinical trials using VDJ transcripts from single cell RNA sequencing of products and peripheral blood samples. One patient with hepatocellular carcinoma (HCC) treated with IL15 CAR T cells had a remarkably expanded clone. At peak expansion $14.7x10^9$ CAR^+ T cells were circulating in the patient based on flow cytometry. Expansion was accompanied by grade 3 cytokine release syndrome requiring activation of the inducible caspase 9 safety switch which rapidly eliminated all CAR T cells as measured by flow cytometry and completely resolved related symptoms. Response assessment with 3D imaging decreased the primary liver mass and either eliminated or significantly reduced the size all metastatic tumors. Alpha-feto-protein tumor marker (half-life ~ 1 week) decreased from 14500 to 760 over 5 weeks. To determine whether viral integration was associated with this clone we performed whole genome integration analysis. Sonic abundance of intronic integrations in CBLB, CCDC6 and an exonic integration in ASB2 closely mirrored abundance of the expanded clone. We validated these integrations were present in the clonally expanded IL15 CAR T cells using targeted single cell DNA sequencing. Viral integrations can disrupt gene function through the creation of chimeric transcripts. We identified CAR CBLB, CAR ASB2, and IL15 CCDC6 chimeric transcripts in our single cell RNA sequencing. Transcriptomic analysis revealed a unique gene regulatory program. Seurat clustering identified three clusters enriched for the expanded clone. Two clusters were associated with rapidly dividing cells expressing significantly higher levels of TYMS, PCNA, and CDK1. While the last cluster expressed transcription factors associated with T cell function ZNF683 and RUNX2. In a model of HCC, simultaneous knock out of these genes, or combinatorial knockout of CBLB and CCDC6 using base editing led to increased CAR T cell expansion and anti-tumor activity. To our knowledge this is the first report of integration driven clonal expansion seen in solid tumor CAR T therapy. As an integration in CBL was previously associated with clonal expansion, our CBLB finding suggests integration in this gene family may lead to clonal growth. We identified CCDC6 a gene with unknown function in T cells, as a regulator of CAR T proliferation. These results demonstrate the impact of multiple genetic disruptions in CAR T cells resulting in robust expansion and antitumor activity and support the careful implementation of these perturbations to enhance patient outcomes.

: AACR Project GENIE: Genomic Characterization
Poster Session

#4096 A pan-pediatric gene-regulatory network analysis reveals druggable dependencies across pediatric solid tumors.
Daniel Lee[1], Abid A. Reza[2], Syed A. Bukhari[2], Jun S. Wei[2], Hsein-Chao Chou[2], Xinyu Wen[3], Andrew S. Brohl[4], Javed Khan[5]

[1]FDA, Silver Spring, MD,[2]NIH, Bethesda, MD,[3]Programmer/Analyst, Dept. of ABCC, NIH, Bethesda, MD,[4]Moffitt Cancer Center, Tampa, FL,[5]National Cancer Institute, Bethesda, MD

Background: Pediatric tumors often co-opt normal developmental gene-regulatory programs, with errors in lineage-restricted progenitors that halt or reverse differentiation. Because these cancers arise within restricted developmental windows, display fetal-like programs, and carry relatively few driver mutations compared to adult tumors, we hypothesized that a pan-pediatric, transcriptome-inferred gene-regulatory network (GRN) analysis will discover lineage-specific regulons that anchor each tumor to a developmentally arrested state, which would identify actionable biomarkers and therapeutic targets.
Methods: We analyzed 2541 bulk RNA-seq from 35 pediatric cranial and extracranial solid-tumor samples, after batch correction. We inferred a pan-pediatric GRN from gene expression data, integrating networks inferred by ARACNe-AP and GENIE3 into a consensus GRN across all tumor types. We used a one-vs-rest strategy to identify tumor-specific differentially expressed genes (DEGs) within the regulons. Using hypergeometric tests, we quantified transcription factor (TF) activity and their regulons across tumors by assessing the enrichment of tumor-specific DEGs within each regulon. To map genes to drugs, we queried drug libraries, including Mechanistic Interrogation PlatE, Profiling Relative Inhibition Simultaneously in Mixtures, ChEMBL, DrugBank, and DrugCentral. We filtered druggable genes among TFs, their regulon members, and their interactors using log fold change and adjusted p-values, and ranked candidates in 19 tumors with DepMap data by using effect size.
Results: We identified 281 enriched TFs across tumors. The functional enrichment analyses showed that TF programs are usually restricted to specific tumor classes, mirroring their developmental cell-of-origin and highlighting candidate tumor-specific biomarkers. Examples include neurodevelopmental and neural-crest-related TFs (e.g., PHOX2B, ASCL1, and SOX10) in neuroblastoma (NB) and muscle-lineage TFs (e.g., MYOG, MYOD1, and PAX3/7) in fusion-positive rhabdomyosarcomas (FP-RMS). Our analysis suggests that TFs behave as robust, tumor-type-specific expression signatures and can distinguish tumors that may be histologically similar but arise from different developmental lineages. Furthermore, we used our TF-centric approach to identify known and new drug targets, such as SIX1, RRM2, AURKA, and BIRC5 in FP-RMS, and ACVR2B & BMPR1B in NB.
Conclusions and Future Directions: A unified GRN framework analysis of pan pediatric solid tumors resolves lineage-specific regulons associated with tumorigenesis and yields a ranked set of druggable genetic dependencies. *In vitro* and *in vivo* validation studies are currently underway.

#4097 cBioPortal for cancer genomics.

Resnick[7], Trevor J. Pugh[6], Chris Sander[9], Jianjiong Gao[1], Nikolaus Schultz[1], Ethan Cerami[2]

[1]Memorial Sloan Kettering Cancer Center, New York City, NY,[2]Dana-Farber Cancer Institute, Boston, MA,[3]The Hyve, Utrecht, Netherlands,[4]SE4BIO, Houten, Netherlands,[5]Caris Life Sciences, Irving, TX,[6]University Health Network, Toronto, ON, Canada,[7]Children's Hospital of Philadelphia, Philadelphia, PA,[8]Bilkent University, Ankara, Turkey,[9]Harvard Medical School, Boston, MA

cBioPortal is a widely used platform for interactive visualization and analysis of large-scale multimodal cancer datasets. It provides cohort exploration tools, such as OncoPrint, mutation “lollipop” plots, survival and enrichment analyses, detailed patient-level views, and integrated variant annotations to support interpretation.

The public instance of cBioPortal (https://www.cbioportal.org) serves >40,000 unique visitors globally each month. It hosts data from >500 studies, all also available through the cBioPortal Datahub. In 2025, we added 38 new studies (~35,000 samples). We also added Tumor Break Load (TBL) scores across PCAWG, CCLE, and all 32 TCGA Pan-Cancer Atlas studies. More than 99 cBioPortal instances are deployed at institutions and companies worldwide.

cBioPortal partners with AACR Project GENIE to provide access to the GENIE cohort in a dedicated instance (https://genie.cbioportal.org). Users can explore >268,000 clinically sequenced samples from 20 institutions, as well as GENIE Biopharma Collaborative (BPC) cohorts with detailed clinical annotations, including NSCLC (~2,000 samples), colorectal cancer (~1,500), and breast cancer (~1,200), with more to come.

Over the past year, cBioPortal progressed along two complementary directions. First, we introduced a chat-based interface for natural-language data exploration, reflecting ongoing efforts to utilize AI, specifically large language models, to augment traditional query and visualization workflows in cBioPortal. Second, we released several core platform enhancements: 1) we improved the performance for large cohorts by switching the backend database from MySQL to ClickHouse, an OLAP (Online Analytical Processing) database; 2) the Plots tab can now visualize variant allele frequencies, connect multiple samples from the same patient, and has more flexible categorical sorting; 3) variant interpretation has been strengthened through integration of AlphaMissense predictions; 4) we released a redesigned About page highlighting the year’s accomplishments and future roadmap. It is worth noting that many of these features were developed using AI-assisted technologies, which are increasingly standard practice in software engineering.

cBioPortal is open source (https://github.com/cBioPortal) and developed collaboratively by groups at Memorial Sloan Kettering Cancer Center, Dana-Farber Cancer Institute, Children’s Hospital of Philadelphia, Princess Margaret Cancer Centre, Bilkent University, SE4BIO, and The Hyve. We welcome contributions from the cancer research community.

#4099 Genomic and clinical landscape of 10,000 Korean pan-cancer patients reveals molecular determinants of prognosis and therapeutic response: K-MASTER program.

Ji Yoon Lee[1], Jisoo Hong[2], Kyong Hwa Park[3], Soohyeon Lee[3], Jwa Hoon Kim[3], Ju Won Kim[3], Ji Won Lee[3], Yonghwa Choi[2], Doyoon Kim[2], Yoonji Kim[2], Woo Young Jang[2], Jiwon Kim[1], You Jin Song[1], Dayoung Lee[1], Hyeonmin Jeong[1], Wooseok Lee[1], Yoon Ji Choi[3], Jason K. Sa[1]

[1]Korea Univ. College of Medicine, Seoul, Korea, Republic of,[2]oncoMASTER, Seoul, Korea, Republic of,[3]Korea Univ. Medical Center, Seoul, Korea, Republic of

Precision oncology relies on molecular characterization of the tumors to guide individualized therapy. Although large-scale precision oncology programs have revealed profound insights into the molecular complexity of human cancers, their direct clinical impact remains incompletely defined. Building upon our prior work, we expanded the K-MASTER program, one of the world's largest East Asian pan-cancer cohorts, integrating deep molecular profiling with long-term clinical outcomes. We analyzed 10,000 Korean patients with advanced malignancies, combining molecular aberrations with eight years of survival, treatment modalities, and therapeutic response data. Comparative analyses with the Western cohort, including AACR-GENIE, uncovered ancestry-specific molecular disparities. Furthermore, we developed a unified metric, the Molecular-Prognostic Index (MPI), to systematically quantify and compare the prognostic impact of individual genomic alterations at both pan-cancer and individual tumor levels. Using this framework, we identified key alterations and pathways shaping patient survival and therapeutic sensitivities. Korean cancer patients exhibited distinct molecular features, including frequent *CDKN2A* loss and mismatch repair deficiency-related mutational signatures. Prognostic modeling revealed that actional alterations curated in OncoKB and *APC* mutations conferred favorable clinical outcomes, whereas mutations in *TP53, CDKN2A, KRAS,* and *SMARCB1* were significantly associated with poor survival across multiple tumor types. Machine-learning-based analyses further identified DNA damage repair deficiency and chromosomal instability as robust predictors of response to platinum-based chemotherapy and immune checkpoint blockades. Collectively, these results provide unprecedented insights into the complex molecular and clinical landscape of Korean advanced cancers, establish a population-specific framework for precision oncology therapy, and provide mechanistic and prognostic insights essential for global translation of genomic medicine.

#4100 Large language models for tumor genomic interpretation.

Jennifer Yu[1], Madison Darmofal[2], Michele Waters[2], January Choy[2], Thinh N. Tran[2], Chenlian Fu[1], Leah Morales[1], Kaicheng U[1], Ross L. Levine[2], Nikolaus Schultz[2], Michael F. Berger[2], Quaid Morris[2], Justin Jee[2]

[1]Tri-Institutional Computational Biology & Medicine, Weill Cornell Medicine, New York, NY, [2]Memorial Sloan Kettering Cancer Center, New York, NY

Introduction: Algorithms trained on real-world data aid in tumor genomic prediction tasks, such as identifying cancer driver mutations and inferring cancer type. The extent to which generalist large language models (LLMs) trained on large natural language corpora can replace or supplement such domain-specific algorithms with zero-shot inference is unknown.
Methods: We evaluated the zero-shot performance of proprietary (GPT-5, o3-mini, GPT-4o and Claude 3.7 Sonnet), open weight (DeepSeek and Qwen3) and domain-specialized medical (MedGemma) LLMs on three tasks: (i) Distinguishing tumor-somatic mutations from clonal hematopoietic (CH) variants in patients with matched tumor-whole blood profiling (N=37,179 patients; 54,807 samples), (ii) Classifying oncogenic variants using the OncoKB dataset as a positive control (N=10,489 patients; 10,752 samples; 13,470 variants), and (iii) Predicting cancer type from tumor genomic profiles in the multi-institution AACR GENIE dataset (N=97,074 patients; 102,791 samples).
Results: Multiple LLMs approached the accuracy of MetaCH, a supervised model for distinguishing somatic tumor mutations from CH variants. o3-mini achieved the highest accuracy for distinguishing oncogenic driver from benign passenger mutations. Among patients with non-small cell lung cancer and mutations in *KEAP1*, those with VUSs classified as oncogenic by GPT-5 had worse overall survival than those with VUSs classified as benign. GPT-5, o3-mini, and Claude 3.7 Sonnet had accuracy approaching that of a supervised model, GDD-ENS, at classifying 34 cancer types using tumor genomic profiles. Ensemble approaches combining prediction results from GPT-5 and GDD-ENS improved cross-institutional generalizability and performance by an average of 20%. In their reasoning, LLMs discussed clinically relevant genomic features consistent with feature importances from GDD-ENS.
Conclusion: Without task-specific training, LLMs achieved performance comparable to specialized supervised models across all tasks.

F1 score comparison across three cancer genomics prediction tasks.

	Mutation status(Tumor-somatic vs. CH)	Oncogenic Variants(Benign vs. Oncogenic)	Cancer Type(34 types)
GPT-5	0.94	0.80	0.49
GPT-4o	0.96	0.75	0.32
o3-mini	0.93	0.82	0.43
Claude 3.7 Sonnet	0.95	0.79	0.43

#4102 EGFR mutation subtype modifies the clinical impact of TP53 functional loss on brain metastasis and survival in lung cancer.

Lexi Li[1], Yiye Wong[2], Nathan Yan[3], J. Nicholas Bodor[4], **Yunyun Zhou**[4]

[1]Homestead High School, Cupertino, CA,[2]The Kings Academy, Sunnyvale, CA,[3]The Harker School, San Jose, CA,[4]Fox Chase Cancer Center, Philadelphia, PA

Background:
Brain metastasis (BM) is common in EGFR-mutant non-small cell lung cancer (NSCLC). Exon 19 deletion (Ex19del) and L858R, the two predominant EGFR sensitizing mutations, differ in biological behavior, therapeutic response, and CNS relapse patterns. TP53 is the most frequent co-mutation in EGFR-mutant disease, has been associated with increased metastatic potential and CNS progression, but its subtype-specific effects in the BM setting remain unclear. We examined whether TP53 functional loss differentially influences BM risk and post-BM survival in EGFR subtypes.
Methods:
We analyzed NSCLC patients from MSK-IMPACT cohort and GENIE BPC cohort. Aim 1 (BM risk): time-to-BM Cox models evaluated associations of EGFR subtype, TP53 status, and their interaction with BM at presentation and BM during follow-up, adjusting for demographics, smoking, and stage. Aim 2 (post-BM prognosis): Among patients with radiographically confirmed BM or CNS, overall survival (OS) from BM diagnosis was evaluated using multivariable Cox models adjusting for BM timing, local intracranial therapy, systemic treatment generation, and extracranial metastatic burden.
Results:
Among 152 patients, time-to-BM analyses similarly showed shorter BM-free survival for TP53 functional loss (adjusted HR=1.65, P=0.11). Among 836 patients with BM, TP53 functional loss predicted worse OS (adjusted HR=1.97, P=0.05), and this adverse effect differed markedly by EGFR L858R and Ex19del subtype (interaction P=0.047). In Ex19del tumors, TP53 loss had a modest association with poorer OS, whereas in L858R tumors it was strongly associated with worse outcomes (median OS 34.7 vs 48.2 months). Results were consistent across cohorts and robust to exclusion of low-VAF TP53 variants.
Conclusions:
TP53 functional loss has distinct clinical implications across EGFR mutation subtypes, conferring both higher risk of brain metastasis and significantly worse post-BM survival in L858R compared with Ex19del disease. These findings reveal important subtype-specific heterogeneity within EGFR-mutant NSCLC and support integrating TP53 status into BM risk assessment and management strategies.

#4103 Dynamic co-mutation patterns and therapeutic implications in BRAF-altered malignancies: Evidence from AACR Project GENIE.

Mohamed M. Khamis[1], Vivek Subbiah[2], Mohamed Gouda[3]

[1]Mercy Hospital St. Louis, St Louis, MO,[2]Sarah Cannon Research Institute, Nashville, TN,[3]The University of Texas MD Anderson Cancer Center, Houston, TX

Background: BRAF gene alterations result in persistent activation of the MAPK signaling cascade, a well-established oncogenic driver across diverse tumor types. A comprehensive pan-cancer analysis of BRAF alteration types (mutations, CNAs, and fusions), co-mutation landscapes, and actionability in large cohorts remains limited.
Methods: We utilized AACR Project GENIE v18.0-public to characterize BRAF alteration prevalence, co-mutations, and actionability. OncoKB levels (L1-L4) defined actionability, and serial samples were analyzed for clonal evolution.
Results: Among 204,292 samples, BRAF alterations were detected in 23,363. BRAF mutations were identified in 12,860 samples (7,359 with V600 and 5,501 with non-V600 variants). Prevalence was highest in thyroid cancer (44.9%), melanoma (38.0%), and histiocytosis (33.5%). V600 variants predominated in thyroid cancer (97.2%; 98.4% in papillary and 99.2% in anaplastic) and melanoma (76.7%), while non-V600 variants were enriched in NSCLC (73.3%), endometrial (98.5%), and bladder cancer (96.6%). BRAF copy number alterations (CNAs) were present in 10,274 samples, with the highest prevalence in breast (85.9%), esophagogastric (70.3%), and ovarian (69.6%) cancers. BRAF fusions occurred in 1,153 samples, with the highest prevalence in glioma (16.8%) and prostate cancer (14.2%). Tumor-centric actionability was high in histiocytosis (93.5% actionable), thyroid cancer (91.9%), and melanoma (79.3%), and was substantial in colorectal cancer (50.6%) and glioma (31.6%). Alteration-centric analysis confirmed L1 evidence as highest level for V600 alterations across solid tumors and for fusions (e.g., KIAA1549-BRAF in glioma). Non-V600 alterations showed L2-L4 evidence as highest level (e.g., MEK inhibitors in histiocytoses; investigational RAF inhibitors). Non-V600 tumors showed significantly higher co-mutation burden, with 40 genes enriched, including RTK/RAS (KRAS: 18.5% vs 1.3%; NF1: 18.7% vs 3.6%), chromatin remodeling (ARID1A: 20.1% vs 7.3%), and PI3K/AKT (PIK3CA: 19.8% vs 8.8%). Co-mutation analysis revealed a substantial fraction of events with OncoKB evidence, particularly in RTK/RAS, chromatin, and PI3K/AKT pathways, creating opportunities for rational combination strategies. Serial analysis of 2,314 samples from 1,072 patients demonstrated dynamic evolution of co-mutations, supporting serial profiling to identify emerging therapeutic targets.
Conclusions: This study represents the most extensive pan-cancer analysis of BRAF alterations, highlighting their prevalence, co-mutation, and actionability patterns. Non-V600 tumors exhibit higher genomic complexity and actionable co-mutation burden, which could inform combination strategies. The dynamic evolution of co-mutation underscores the need for serial profiling to uncover emerging therapeutic vulnerabilities.

#4104 The genomic landscape of skin adnexal carcinomas in the AACR GENIE database: Implications for precision cancer medicine.

Valbert Oliveira Costa Filho[1], Mariana Macambira Noronha[1], Pedro Robson Costa Passos[1], Carlos Diego Holanda Lopes[2], Giuseppe G. F. Leite[3], Carlos Wagner de Souza Wanderley[4], Sam D. Saibil[5], Danielle Calheiros Campelo Maia[1], Erick F. Saldanha[2]

[1]Universidade Federal do Ceara, Fortaleza, Brazil,[2]Princess Margaret Cancer Centre, University Health Network, Toronto, ON, Canada,[3]Division of Infectious Diseases, Department of Medicine, Escola Paulista de Medicina Universidade Federal de Sao Paulo, Sao Paulo, Brazil,[4]Brigham and Women's Hospital, Harvard Medical School, Boston, MA,[5]Department of Medicine, University of Toronto, Toronto, ON, Canada, Toronto, ON, Canada

Skin adnexal carcinomas (SAC) are rare and heterogeneous malignancies. These group of tumors differentiate from skin appendageal, such as hair follicles and sebaceous glands, and are molecularly and clinically distinct from keratinocyte carcinomas. Recurrent or metastatic SACs are aggressive tumors with poor survival outcomes, and limited available therapeutic options. Here we leveraged the AACR GENIE database to uncover the genomic landscape of SAC. Genomic data from samples classified as SAC according to the World Health Organization classification were selected from the AACR GENIE 1.8 dataset and annotated using the OncoKB^{TM} database. Tumor mutation burden (TMB) values were provided by the AACR team, with classification defined as low (<2 mut/Mb), intermediate (2 to 16 mut/Mb), and high (>16 mut/Mb). Mutational signatures were generated and matched to the COMISC database. A total of 224 samples were retrieved, including primary (73.7%, n=165) and metastatic (26.3%, n=59) tumors. Clinicodemographic analysis revealed 53.6% (n=120) female and identified race distribution as white (73.2%; n=164), Asian (10.3%; n=23), black (5.4%; n=12) and non-specified (11.1%; n=25). Extramammary Paget disease was the most common subtype (48.7%; 109), followed by tumors with apocrine/eccrine (32.6%; n=73), sebaceous (17.4%; n=39), and follicular differentiation (1.3%; n=3). The median number of mutations per sample was 4 (IQR 2-3). The most frequently mutated genes were *TP53* (45%), *PIK3CA* (20%), *KMT2C* (17%), *ERBB2* (17%), and *NOTCH1* (12%). The main altered pathways involved RTK-RAS (54.9%), TP53 (48.7%) and PI3K (37.1%). The most frequent copy number losses were in *CDKN2A* (11.8%) and *CDKN2B* (10.5%). The main copy number gains were observed in *ERBB2* (8.7%) and *MYC* (8.1%). The most frequent actionable mutations annotated by OncoKB^{TM} occurred in *PIK3CA* (Level 1; 17%), *ERBB2* (Level 1; 12%), *CDKN2A* (Level 4, 4.9%), *PTCH1* (Level 3A, 4.5%), and *ARID1A* (Level 4, 4%). Actionable *BRAF* mutations were detected in 2.2% of patients (0.4% Level 1 and 1.8% Level 2), whereas *KRAS* Level 1 mutations were observed in 3.6% of patients. The median TMB was 2.7 mut/Mb (IQR 0.85-6.83), 38.8% (n=87) samples had low TMB, 48.6% (n=109) had intermediate TMB, and 12.5% (n=28) had high TMB. Three COSMIC mutational signatures were matched: SBS2 (activity of APOBEC family of cytidine deaminases), SBS6 (defective DNA mismatch repair), and SBS7b (ultraviolet exposure), dominating 37.4%, 36.9%, and 25.7% of tumors, respectively. Our study profiled the largest cohort of SACs reported to date and identified a subset of patients with high TMB and actionable genomic alterations, including Level 1 alterations per OncoKB. These findings highlight the relevance of genomic profiling in SACs to inform clinical decision making, enable clinical trial matching, and improve the biological understanding of these rare malignancies.

#4105 Distinct age associated genomic landscapes in colorectal, pancreatic, small bowel, and anal cancers: A pan gastrointestinal analysis of 34,000 tumors from AACR Project GENIE v18.0.

Ahmed Abdelhakeem[1], Nency Ganatra[2], Dina Elantably[1], Tayo Adeoye[1], Nayef H. Abdel-Razeq[1], Mosalem M. Osama[3], Hani M. Babiker[1]

[1]Mayo Clinic Florida, Jacksonville, FL,[2]Department of Internal Medicine, Baptist Hospitals of Southeast Texas, Beaumont, TX,[3]Saint Luke`s Cancer Institute, Kansas City, MO

Background: Early-onset gastrointestinal (GI) cancers are increasing globally, yet the genomic basis for age-related differences across multiple tumor types remains poorly defined. We leveraged AACR Project GENIE v18.0 (N≈34,000 GI tumors) to characterize molecular distinctions by age in colorectal, pancreatic, small bowel, and anal cancers with sufficient early-onset representation.
Methods: Clinical and genomic data were extracted and tumors classified into early-onset (<50 years) and late-onset (≥50 years). Mutation frequencies were compared by cancer type and age group, focusing on recurrent drivers, DNA repair, Wnt signaling, RAS/MAPK, chromatin remodeling genes, and targetable alterations.
Results: Early-onset colorectal cancer (N=5,724) showed increased Wnt/β-catenin pathway alterations: APC (+4.9%), TCF7L2 (+4.1%), and TP53 (+5.0%), while late-onset tumors (N=15,807) were enriched for BRAF (−5.4%), RNF43 (−1.9%), and GNAS (−1.1%), indicating divergent tumorigenic pathways. Early-onset pancreatic cancer (N=890) exhibited significantly lower frequencies of canonical drivers—KRAS (−24.7%), TP53 (−15.6%), CDKN2A (−6.9%), SMAD4 (−6.0%)—with enrichment of MEN1 (+3.5%), TSC2 (+3.0%), ATRX (+2.0%), DAXX (+1.9%), and CTNNB1 (+2.4%), consistent with fusion-driven, hereditary, and chromatin remodeling biology. Small bowel cancer (N=99) in early-onset patients demonstrated enrichment in DNA damage response and MAPK/RAS genes including BRCA2 (+7.2%), NF1 (+7.4%), FBXW7 (+8.8%), FLT4 (+6.5%), ARAF (+6.4%), and ALK (+5.1%), whereas late-onset tumors (N=538) were enriched for KDR (−5.1%) and MGA (−5.2%). Early-onset anal cancer (N=62) showed elevated MGA (+7.8%), WHSC1/NSD2 (+6.9%), PBRM1 (+6.2%), FANCA (+5.2%), ERCC5 (+6.2%), and MSH6 (+5.9%), highlighting chromatin remodeling and DNA repair pathways potentially related to HPV biology; late-onset tumors (N=464) had enrichment in ATM (−5.6%), PTEN (−5.5%), STK11 (−5.2%), APC (−5.2%), and KMT2C (−5.0%), reflecting age-associated genomic instability.
Conclusions: This pan-GI age-stratified analysis reveals distinctive oncogenic programs in early-onset GI cancers characterized by Wnt/TP53-driven colorectal, fusion- and chromatin remodeling-driven pancreatic, DNA damage response/MAPK-driven small bowel, and chromatin-immune DDR signatures in anal cancers. These findings underscore the need for age-tailored precision oncology and support routine genomic profiling in early-onset GI malignancies to identify targetable alterations enriched in younger patients.

#4106 Pan cancer enrichment of homologous recombination repair (HRR) gene alterations in 101,240 tumor samples from AACR Project GENIE: Implications for tumor-agnostic PARP inhibitor expansion.

Ahmed Abdelhakeem[1], Nency Ganatra[2], Dina Elantably[1], Tayo Adeoye[1], Nayef H. Abdel-Razeq[1], Osama M. Mosalem[3], Hani M. Babiker[1]

[1]Mayo Clinic Florida, Jacksonville, FL,[2]Baptist Hospitals of Southeast Texas, Beaumont, TX,[3]Saint Luke's Cancer Institute, Kansas City, MO

Background: PARP inhibitors are restricted to a subset of BRCA-associated cancers, but homologous recombination repair (HRR) deficiency signifies a broader genomic vulnerability that may extend therapeutic opportunities across diverse malignancies. We utilized AACR Project GENIE v18.0-public to define the pan-cancer prevalence of HRR gene alterations.
Methods: Somatic mutation and clinical sample data from GENIE v18.0-public were analyzed. HRR genes included BRCA1, BRCA2, ATM, CHEK2, PALB2, RAD51B/C/D, RAD51L1, BARD1, BRIP1, and core FANC genes. HRR alteration rates were calculated by tumor type using unique samples; only de-identified aggregate results are reported.
Results: Among 101,240 tumors, HRR gene alterations were frequent in multiple non-BRCA-associated cancers. Highest rates were seen in sialoblastoma (100%), large cell medulloblastoma (50%), malignant glomus tumor (50%), lung cancer (46.0%), infantile fibrosarcoma (42.9%), liver (40%), kidney (40%), non-melanoma skin (36.9%), colorectal (36.6%), melanocytoma (34.2%), biliary tract (33.3%), bladder (31.5%), and ovarian/fallopian tube (30.2%). Notably, lung, bladder, hepatobiliary, renal, gastrointestinal, and some sarcoma subtypes showed HRR mutation prevalence equal or higher than current PARP indications, yet lack FDA approval.
Conclusions:HRR alterations are widespread across solid tumors, often surpassing rates in cancers eligible for PARP treatment. These findings support expanding tumor-agnostic HRR genomic testing beyond BRCA-linked malignancies and warrant prospective trials of PARP inhibitors in HRR-enriched tumor types such as lung, bladder, hepatobiliary, renal, gastrointestinal, and pediatric/rare cancers. Impact: Large-scale genomic profiling from AACR Project GENIE demonstrates that HRR gene alterations are common across diverse solid tumors, with prevalence in multiple cancer types surpassing those currently eligible for PARP inhibitor therapy. These findings support broad implementation of HRR genomic testing in routine molecular diagnostics and provide a rationale for expanding PARP inhibitor use beyond BRCA-associated malignancies. The data justify prospective tumor-agnostic clinical trials of PARP inhibitors in HRR-enriched cancers such as lung, bladder, hepatobiliary, renal, gastrointestinal, and select pediatric and rare tumors; this could transform therapeutic decision-making and accelerate development of synthetic lethality-based targeted therapies

#4107 Factors associated with early treatment discontinuation in the AACR Project GENIE Biopharma Collaborative (BPC) non-small cell lung cancer (NSCLC) cohort.

Dany Hamze, Sanjay Mishra, Aleenah Mohsin, Sarah Minuit, Ece Gamsiz Uzun, Jeremy L. Warner

Brown University, Providence, RI

Background: Early treatment discontinuation in NSCLC is frequent and is associated with worse outcomes. We sought to identify clinical and genomic factors associated with early discontinuation among patients with NSCLC treated with immune checkpoint inhibitors (ICIs) or tyrosine kinase inhibitors (TKIs), now central to most NSCLC treatment strategies. We used the AACR Project GENIE BPC registry, which captures granular drug exposures along with other clinical and genomic variables.

Methods: Data were obtained from the BPC NSCLC v2.0 cohort on May 19, 2025. Patients receiving ICIs or TKIs were included if the identified drugs had different start and end dates. Early discontinuation thresholds were first clinically estimated, then empirically defined using 1) Gaussian Mixture Models and 2) Classification and Regression Tree analysis, with consensus cutoffs of 3.0 and 4.3 months for TKIs and ICIs, respectively. Multivariable logistic regression (MLR) was applied to evaluate associations between early discontinuation and: sex; stage; drug class; oncogenic driver mutations in *EGFR*, *ALK*, *KRAS*, and *BRAF*; and line of therapy (first-line [1L] vs later-line). Because the cohort predates wider first-line ICI adoption, most ICI exposures in BPC occur in later lines.

Results: 910 of 1846 (49%) treatment episodes were included. By our definition, early discontinuation occurred in 420 (46%) of these. In MLR, TKI exposure (OR 0.17, 95% CI 0.12-0.24) and receiving TKI or ICI as 1L treatment (OR 0.56, 95% CI 0.39-0.78) were inversely associated with early discontinuation. Stage IV was associated with a trend towards early discontinuation (OR 1.56, 95% 0.94-2.65). Conversely, the presence of an *EGFR* mutation trended away from early discontinuation (OR 0.72, 95% CI 0.48-1.07). The final model demonstrated good discrimination with an AUC of 0.74. Calibration analysis showed excellent agreement between predicted and observed probabilities.

Conclusions: Receiving TKIs in any line and ICI treatment in 1L were inversely associated with early discontinuation, suggesting differential tolerability. *EGFR* mutation status demonstrated a trend toward lower discontinuation risk, independent of TKI exposure or line of therapy. Stage IV trended towards a higher early discontinuation risk, which could reflect early progression of disease while on treatment. Limitations include: 1) the exclusion of episodes with a single dose or a clinical trial medication (both are recorded with the same start/end date in BPC); 2) a lack of ground truth for discontinuation reasons; 3) unknown cross-episode interactions in patients with multiple treatment episodes; and 4) unmeasured confounders, such as social determinants of health (SDOH). Despite these limitations, our findings highlight distinct factors that may inform individualized strategies and warrant further investigation.

#4109 Pan-cancer landscape of IDH1/2 mutations with a focus on non-small cell lung cancer: Insights from the AACR GENIE Registry.

Zhaohui L. Arter, Cathleen Park, Misako Nagasaka, Sai-Hong I. Ou

UCI Health, Orange, CA

Background: IDH1 and IDH2 mutations are oncogenic drivers across several tumor types. Their prevalence, mutational spectrum, and co-alteration profiles in Non-Small Cell Lung Cancer (NSCLC) remain incompletely defined. Given the availability of approved IDH1 and IDH2 inhibitors, characterizing these mutations has potential therapeutic relevance.
Methods: We queried the AACR GENIE v18 database (n=250,018 tumor samples) to assess IDH1/2 mutation frequency, subtype distribution, associated histologies, co-mutations and survival outcomes in NSCLC.
Results: IDH1 and IDH2 mutations were identified in 5,380 (2.2%) and 2,761 (1.1%) patients, respectively. IDH1 mutations—primarily R132H (50.4%) and R132C (20.6%)—were enriched in gliomas (42.6%), cholangiocarcinoma (6.0%), lung adenocarcinoma (4.8%), and melanoma (4.4%). IDH2 mutations—mainly R140Q (20%) and R172K (9.8%)—were most frequent in AML (20.3%), colorectal cancer (7.4%), and NSCLC (5.9%). Among 30,454 NSCLC patients, IDH1 and IDH2 mutations occurred in 1.2% and 0.7%, respectively. EGFR co-mutations were found in 83 (21.8%) of IDH1- and 39 (22%) of IDH2-mutant NSCLC. KRAS co-mutations were seen in 170 (44.5%) of IDH1- and 51 (29%) of IDH2-mutant NSCLC (Table). Across major oncogenic subgroups, IDH co-mutations occurred in 1.04% (IDH1) and 0.60% (IDH2) of EGFR L858R, 1.18% and 0.13% of EGFR E746_A750del, and in 2.01% and 0.81% of KRAS G12C, respectively. Among 1,846 patients with available survival data, the median overall survival (OS) was 14.7 months for stage IV KRAS G12C+/IDH1/2- patients compared with 9.7 months for KRAS G12C+/IDH1/2+ (P = 0.02).
Conclusions: In stage IV KRAS G12C-mutant NSCLC, IDH1/2 co-mutations were linked to shorter median OS. These findings, along with the frequent co-alterations of IDH1/2 with EGFR and KRAS, warrant further study of targeted and combination strategies.

Table: IDH1/2 Co-Alterations in NSCLC

Feature	IDH1 (n=366)	IDH2 (n=199)
EGFR co-mutations	83 (21.8%)	39 (22%)
L858R / E746_A750del	19 / 18	11 / 2
KRAS co-mutations	170 (44.5%)	51 (29%)
G12C / G12V / G12D	62 / 28 / 24	25 / 15 / 4
G12A / G12F / G12S / G12R	10 / 2 / 2 / 1	2 / 2 / 1 / 1
Other KRAS variants	41	6

#4110 Genomic vulnerabilities and clinical behavior of metaplastic breast cancer through integrated registry and GENIE analysis.

Ahmed Shatta[1], Diego F. Chamorro[2], Blessie Elizabeth Nelson[1], Bora Lim[1]

[1]UT MD Anderson Cancer Center, Houston, TX,[2]University of Pittsburgh Medical Center, Pittsburgh, PA

Background: Metaplastic breast cancer (MpBC) is a rare and highly heterogeneous subtype of breast cancer, predominantly triple-negative and characterized by chemoresistance, early relapse, and poor survival. Despite its classification within the triple-negative breast cancer (TNBC) spectrum, the clinical behavior and molecular landscape of MpBC remain poorly defined, limiting the development of targeted therapeutic strategies.
Methods: Clinical MpBC cases from MD Anderson Cancer Center (2014-2025) were annotated for subtype, stage, and survival. Genomic data from the AACR GENIE MpBC cohort (v16.1; n=258) were evaluated for pathogenic mutations and copy-number alterations. Variant frequencies, hotspot patterns, and mutual exclusivity were assessed using Fisher's exact test. Analyses were performed in R, with statistical significance defined as $p<0.05$.
Results: Among 105 MpBC cases in the MDACC registry, 92.9% were TNBC, with an overall mortality rate of 34.3%. HER2-positive disease was rare (3.5%) but demonstrated the highest proportional mortality (50%). ER-positive tumors ≥10% (3.5%) had a 25% mortality rate, whereas ER/PR low-positive (<10%) tumors exhibited clinical outcomes similar to TNBC. Notably, mortality was observed even among early-stage patients, underscoring aggressive tumor biology that is independent of stage. Genomic analysis of 258 MpBC cases (267 samples) from GENIE identified recurrent *TP53* mutations (57%), including canonical hotspot variants (R248Q, R175H, R273C), consistent with pervasive genomic instability. *PIK3CA* alterations (34%), driven predominantly by H1047R, were frequently mutually exclusive with *TP53* mutations ($p=0.043$), suggesting distinct molecular subclasses with differential oncogenic drivers. Additional recurrent alterations in chromatin regulators (*KMT2C* 17.1%, *KMT2D* 10.5%) and copy-number gains involving *AGO2* (22.9%), *RAD21* (20.4%), *RECQL4* (19.8%), and *MYC* (19.4%) highlight potential vulnerabilities in DNA repair, replication stress response, and transcriptional regulation. Genomic profiling of the institutional MpBC cohort is ongoing.
Conclusion: These integrated clinical and molecular findings reinforce MpBC as a major contributor to mortality within the TNBC population despite its rarity and nominate PI3K/AKT pathway alterations, genomic instability, and epigenetic deregulation as potential therapeutic targets. These findings further support the need for biomarker-driven precision oncology trials, including basket-style designs and rare-tumor initiatives, to advance targeted therapies for rare, aggressive breast cancer subtypes.

#4111 Comprehensive multi-omics characterization of colorectal cancer in a community catchment population.

Brigette Waldrup[1], Francisco Carranza[1], Yuxin Jin[1], Yonatan Amzaleg[1], Mackenzie Postel[2], David W. Craig[3], John D. Carpten[3], Boudoir Salhia[4], Charite N. Ricker[5], Julie O. Culver[5], Carmen E. Chavez[6], Mariana C. Stern[7], Lourdes Baezconde-Garbanati[7], Heinz-Josef Lenz[5], Enrique I. Velazquez-Villarreal[3]

[1]City of Hope, Beckman Research Institute, Department of Integrative Translational Sciences, Duarte, CA,[2]University of Southern California, Keck School of Medicine of USC, Department of Translational Genomics, Los Angeles, CA,[3]City of Hope Comprehensive Cancer Center & Beckman Research Institute, Department of Integrative Translational Sciences, Duarte, CA,[4]University of Southern California, USC Norris Comprehensive Cancer Center and Keck School of Medicine of USC, Department of Translational Genomics, Los Angeles, CA,[5]University of Southern California, Keck School of Medicine & USC Norris Comprehensive Cancer Center and Keck School of Medicine of USC, Department of Translational Genomics, Los Angeles, CA,[6]University of Southern California, USC Norris Comprehensive Cancer Center, Los Angeles, CA,[7]University of Southern California, USC Norris Comprehensive Cancer Center & Keck School of Medicine of USC, Department of Population and Public Health Sciences, Los Angeles, CA

Introduction: Colorectal cancer (CRC) remains a leading cause of cancer mortality and disproportionately affects Hispanic and Latino populations in the United States, who remain underrepresented in genomic research. To address this gap, we performed a comprehensive multi-omics analysis to identify biological and genetic factors contributing to CRC disparities, including somatic alterations, gene expression programs, and genetic similarity (NASEM terminology for genetic ancestry).

Methods: Through the Cancer Moonshot PE-CGS Network, we analyzed 204 paired primary CRC tumor/normal samples from individuals in the Los Angeles catchment area. For comparison, 3,920 Non-Hispanic White (NHW) CRC samples were evaluated using public datasets, including AACR Project GENIE. DNA exome sequencing was used to assess somatic mutations, copy number alterations, gene fusions, and genetic similarity. RNA sequencing profiled differential gene expression, pathway activity, and immune signatures. Analyses followed NASEM best practices for the use of race, ethnicity, and genetic ancestry in genomics research.

Results: Genetic similarity analysis identified a high prevalence of Peruvian-from-Lima-like (1KG-PEL-like) similarity among Hispanic and Latino patients. Higher 1KG-PEL-like similarity was associated with microsatellite stability status, younger age at diagnosis, and left-sided tumor location. Somatic analysis revealed significant alterations in APC, TP53, KRAS, and other CRC-associated genes, with notable differences in mutation frequencies compared with NHW samples. Copy-number profiling identified amplifications in drug-targetable loci, and fusion analysis detected clinically relevant events including ALK, FGFR1, RAF1, and enriched PTPRK fusions in tumors with the highest 1KG-PEL-like similarity. Transcriptomic analyses demonstrated distinct pathway activation and immune-related expression programs compared with NHW CRCs.

Conclusion: This study provides one of the most comprehensive multi-omics characterizations of CRC in an underrepresented population. By integrating genetic similarity with somatic, structural, and transcriptional features, these findings reveal biologically meaningful patterns that may contribute to CRC disparities. This work establishes a foundational framework for future investigations and supports the development of ancestry-informed precision oncology strategies.

#4112 Identification of NTRK missense mutations in glioblastoma multiforme: Insights from AACR Project GENIE and structural-functional analyses.

Jehad A. Yasin[1], Muaath I. Alsufi[1], Ahmad Shawabkeh[1], Abdallah Al-Ramadi[1], Mohammad Alghaniem[1], Layan AlDaher[1], Reger Mikaeel[2]

[1]School of Medicine, The University of Jordan, Amman, Jordan,[2]Department of Pathology and Immunology, Washington University School of Medicine, Saint Louis, MO

Background: Neurotrophic tyrosine receptor kinase (*NTRK*) alterations are oncogenic drivers in diverse malignancies; however, their relevance in glioblastoma multiforme (GBM) is incompletely defined. While *NTRK* fusions have been well characterized, the prevalence, pathogenicity, and potential clinical impact of *NTRK1/2/3 missense mutations* in GBM remain largely unexplored. Using the AACR Project GENIE registry (v18.0), we profiled *NTRK* missense variants in GBM and integrated survival and structural analyses to evaluate their functional significance.
Methods: Data from 7048 GBM samples (6523 patients) were curated. Post-sequencing overall survival (OS) was assessed by exploratory Kaplan-Meier (KM) and univariate Cox regression. Pathogenicity and structural consequences were evaluated through AlphaMissense, REVEL, LoGoFunc, PROVEAN, MutPred2, and DynaMut on AlphaFold-predicted structures.
Results: Missense mutations in *NTRK1* (1.8%), *NTRK2* (1.3%), and *NTRK3* (1.3%) were rare. Four variants were consistently detected in the extracellular domain: *NTRK2* p.Y359D (0.23%), *NTRK2* p.G344D (0.21%), *NTRK1* p.H298Q (0.25%), and NTRK1 p.P302S (0.23%). In NTRK1, 15/16 patients carried both p.H298Q and p.P302S together, while isolated p.H298Q (n = 1) or p.P302S (n = 0) events were rare. A similar pattern was observed in NTRK2 p.Y359D/p.G344D mutants, where p.Y359D and p.G344D co-occurred in 14/15 patients, indicating co-mutation enrichment. KM analysis suggested a trend toward improved OS for p.Y359D (p = 0.047) and H298Q (p = 0.037). Cox regression pointed to protective effect of p.H298Q (HR = 0.32, 95% CI: 0.103-0.992). AlphaMissense classified p.Y359D and p.G344D as 'likely pathogenic' and p.H298Q/p.P302S as 'likely benign', whereas PROVEAN predicted all four as deleterious. DynaMut suggested destabilization for p.Y359D (ΔΔG –2.48 kcal/mol) and increased flexibility, while it demonstrated stabilization for p.H298Q (ΔΔG +0.261 kcal/mol), consistent with its gain-of-function classification by LoGoFunc, and low REVEL score of 0.104. MutPred2 analysis signaled functional impact for p.Y359D, which showed a high pathogenicity score (0.923; REVEL score = 0.910) with coordinated disruption of regulatory motifs and mechanistic changes, including gain of loop structure, loss of a sulfation site at p.Y359, altered ordered interfaces, and perturbed metal binding.
Conclusions: This analysis suggests that previously underrecognized NTRK missense mutations may be present in GBM and could have functional relevance; however, these findings should be interpreted cautiously given the study's retrospective registry design, reliance on tumor-only sequencing (with potential germline or passenger variants), incomplete clinical and molecular covariates, lack of multiple-testing adjustment, and the absence of experimental validation.

#4113 Distinct clinical, molecular and multi-omics biomarkers in early-onset head and neck squamous cell carcinoma.

Joab O. Odera[1], Rong Jiang[2], Morgan C. Byrd[1], Oyomoare L. Osazuwa-Peters[3], Nosa Osazuwa-Peters[1]

[1]Duke University School of Medicine, Durham, NC,[2]Head and Neck Surgery & Communication Sciences, Duke University School of Medicine, Durham, NC,[3]Department of Population Health Science, Duke University School of Medicine, Durham, NC

Background Early-onset head and neck squamous cell carcinoma (EOHNSCC) incidence is rising globally, often independent of traditional risk factors such as tobacco and alcohol. Whether EOHNSCC harbors distinct molecular and multi-omics signatures compared to typical-onset HNSCC (TOHNSCC) remains poorly understood.

Methods We analyzed The Cancer Genome Atlas (TCGA) Firehose Legacy and AACR GENIE datasets to compare EOHNSCC (18-49 years) and TOHNSCC (>49 years) HNSCC. Features included somatic mutations, copy number alterations (CNAs), structural variants, gene fusions, DNA methylation, mRNA expression, and protein expression. HNSCC onset group differences were assessed for significance using Fisher's exact and Wilcoxon rank sum tests ($p < 0.05$). Pathway enrichment leveraged GO, KEGG, Reactome, and CORUM databases. Multivariable logistic regression evaluated associations between EOHNSCC and clinical covariates.

Results Across both datasets, our study cohort was composed of 2,472 individuals with HNSCC ($N_{AACR\ GENIE}$= 1,961; N_{TCGA}=511). In AACR GENIE, EOHNSCC patients were more likely female (aOR = 1.49, 95% CI: 1.09-2.02), non-white (aOR = 1.99, 95% CI: 1.38-2.83), and had lower mutation burden (aOR = 0.44, 95% CI: 0.29-0.64). However, in TCGA, EO-HNSCC patients had lower histological grade tumors (G3 vs G1 aOR = 0.38, 95% CI: 0.14-1.00), more likely to receive neoadjuvant therapy (aOR = 17.02, 95% CI: 3.32-101.65), and had little to no prior smoking history (reformed vs non-smoker: aOR = 0.28, 95% CI: 0.13-0.57). Molecular markers in TCGA for EOHNSCC was characterized by concurrent mutation and mRNA overexpression in *GDNF, FRYL, KIAA0586, CADPS, MYF5*, and *DCTN1*, enriched in hypoxia-related pathways. Integration of CNAs and expression highlighted *ASH2L* and *SERPIND1*, which are associated with cell cycle regulation signaling. Methylation-driven expression involved motility genes (*SPIPM6, SPAG6, ODAD3, RSPH4A*), enriched in cilium movement and DAP12 signaling. *HSPA2* hypomethylation was correlated with *HSPA2* CNA and upregulated mRNA expression, linked to cancer invasion and metastasis. Genes with mRNA-protein concordance included *NOTCH1, SYK, SERPINE1, IRS1, CHEK2, EIF4E*; associated with translation initiation. In AACR GENIE, EOHNSCC showed higher KCNIP1 mutation, while TOHNSCC was enriched for *NOTCH1, FAT1, KMT2D*, and *PIK3CA*. Of note, *FAT1* was the only gene mutated in both datasets; consistently in TOHNSCC.

Conclusions EOHNSCC exhibits distinct multi-omics signatures involving hypoxia, cell motility, cell cycle regulation, cancer metastasis, and translation initiation. Candidate biomarkers include *GDNF, ASH2L, SPAG6, HSPA2, EIF4E* and *KCNIP1*. Minimal overlap across datasets underscores the need for validation and exploration of prognostic and therapeutic implications.

#4114 Population-based patterns of human papillomavirus infections and cervical cancer incidence, driver mutations and overall survival.

S. Ahmed Hussain[1], Chunqiao Tian[2], Christopher Tarney[1], Thomas Beltran[3], Pouya Javadian[1], Ryan McLaughlin[4], Paulette Mhawech-Fauceglia[5], Doris M. Benbrook[6], Sean Cronin[1], Zachary Kopelman[1], Colin Sitler[3], Leslie M. Randall[7], John Chan[8], Daniel Kapp[9], Chad A. Hamilton[10], Charles A. Leath[11], Christina Washington[12], Kathleen Moore[12], Kristen Bunch[1], Nicholas Bateman[2], Thomas P. Conrads[13], G. Larry Maxwell[13], Kathleen M. Darcy[14]

[1]Walter Reed National Military Medical Center, Bethesda, MD,[2]The Henry M Jackson Foundation for the Advancement of Military Medicine, Bethesda, MD,[3]Womack Army Medical Center, Fort Liberty, NC,[4]Uniformed Services University of the Health Sciences, Bethesda, MD,[5]Aurora Diagnostics, Las Vegas, NV,[6]OU Health Stephenson Cancer Center, Oklahoma City, OK,[7]Mid-Atlantic Gynecologic Oncology and Pelvic Surgery Associates, Falls Church, VA,[8]California Pacific Medical Center, San Fransisco, CA,[9]Stanford University School of Medicine, Stanford, CA,[10]The Ochsner Cancer Institute, New Orleans, LA,[11]University of Alabama at Birmingham, Birmingham, AL,[12]Oklahoma University Health Sciences Center, Oklahoma City, OK,[13]Women's Health Integrated Research Center, Falls Church, VA,[14]Henry M. Jackson Foundation, Bethesda, MD

Background: Human papillomavirus (HPV) infection is the primary cause of cervical carcinoma. Variations in HPV prevalence, tumor genomic alterations, and survival outcomes across population groups remain incompletely characterized. Understanding the interplay of viral and host tumor biology is essential to optimize prevention and treatment in cervical cancer.

Methods: High-risk HPV prevalence was evaluated in non-Hispanic White (NHW), non-Hispanic Black (NHB), and Hispanic (HSP) females aged 18-59 years using the National Health and Nutrition Examination Survey (NHANES, 2005-2016). Age-adjusted incidence of cervical cancer was evaluated using data from 21 regions in SEER (2004-2020). Somatic driver mutations were analyzed in tumors from patients with cervical cancer using the Genomics Evidence Neoplasia Information Exchange (GENIE v16.0). Overall survival was examined using Kaplan-Meier and Cox regression models among stage I-IV cervical cancer cases in the National Cancer Database (NCDB, 2004-2020).

Results: Among 11,033 NHANES participants, high-risk HPV prevalence was similar in White and Hispanic women but higher in Black women (2.1-fold higher odds of any HPV infection; 1.5-fold higher odds of HPV16/18). Fig 1A shows the higher distribution of high-risk HPV genotypes individually and concurrent high-risk infections in NHB patients compared with either HSP or NHW patients. Data from SEER shows that age-adjusted incidence of cervical cancer was higher in both HSP and NHB patients compared with NHW patients. Rates declined in all groups from 2004-2000 (Fig 1B). Fig 1C displays somatic mutations in tumors from 595 cervical cancer patients in GENIE. BRD4, ERBB3, MTOR, and GRM3 mutations were more frequent in NHB than NHW patients. ERBB3, CIC, PIK3R1, and PI3K pathway alterations were enriched in NHB compared with HSP patients, whereas SMARCA4, CIC, KDM5C, and RANBP2 mutations were more common in White than Hispanic patients. In 117,170 NCDB cases, 5-year survival was 76% for HSP, 69% for NHW, and 60% for NHB patients (Fig 1D, $p<0.0001$). Compared with HSP women, mortality risk was 40% worse for NHW and 91% worse for NHB patients ($p<0.001$).

Conclusions: Differences in HPV infection pattern are linked with cervical cancer incidence, somatic mutations, and survival, reflecting biologic and clinical heterogeneity across populations. Integrating viral genotyping with incidence rates and tumor molecular profiling may inform precision prevention, risk assessment, and personalized treatment to improve outcomes for all patients.

Translational Relevance: This study links viral, incidence, genomic and survival data across multiple national datasets to reveal population-level variations in cervical cancer. These insights support efforts to enhance HPV vaccination, early detection, and individualized prevention, screening and therapeutic decision-making.

#4116 Clonal trajectories of chronic lymphocytic leukemia and Richter transformation over the patients' lifespan.

Ian Marquez-Lopez[1], Aleix Real[1], Nuria Russinol[1], Nicholas Williams[2], Romina Royo[3], Markus van Roosmalen[4], Heribert Playa-Albinyana[1], Juan Antonio Pineyroa[1], Melika Bashiri[1], Pablo Mozas[5], Armando Lopez-Guillermo[5], Julio Delgado[5], Dolors Colomer[1], Ruben van Boxtel[4], Jyoti Nangalia[2], Elias Campo[1], Ferran Nadeu[1]

[1]IDIBAPS, Barcelona, Spain,[2]Wellcome Sanger Institute, Cambridge, United Kingdom,[3]Barcelona Supercomputing Center, Barcelona, Spain,[4]Princess Maxima Center for Pediatric Oncology, Utrecht, Netherlands,[5]Department of Hematology, Hospital Clinic, Barcelona, Spain

Richter transformation (RT) is a rare but clinically challenging event in the evolution of chronic lymphocytic leukemia (CLL), characterized by transformation of CLL into an aggressive lymphoma, commonly diffuse large B-cell lymphoma. Although the molecular profiles of CLL and RT are well characterized, their evolutionary trajectories remain uncertain. A better understanding of CLL and RT dynamics could enable earlier identification and intervention in high-risk patients. Thus, our aim was to trace CLL/RT clonal histories over the lifespan of the patients through tumor phylogenies.
To that aim, we applied primary template-directed amplification-based single-cell whole-genome sequencing to 5 patients, analyzing 349 single cells from up to 6 sequential time points spanning up to 19 years from CLL diagnosis to RT. A bioinformatic workflow that integrates existing algorithms with an in-house PTA-artifact filtering strategy was developed to optimize the sensitivity and specificity of the variant calling. A median sensitivity of 87.7% was obtained for point mutations at a sequencing depth of ~20×, with only ~5% of cell-specific artifacts remaining.
Our analyses revealed an increased mutational burden from normal B-cells to CLL and from CLL to RT explained by the combination of therapy-related and cell-intrinsic mutational processes. In addition, a high intratumor heterogeneity was detected both in terms of somatic mutations and copy number alterations, which was not previously captured by bulk sequencing. The phylogenetic reconstruction revealed remarkable intrapatient parallel genomic evolution. This was exemplified by the independent acquisition of multiple del(13q) in 3 cases, del(9p21) in 2 cases, or 7 LOH(17p) in 4 different phylogenetic clades with distinct *TP53* mutations in 1 patient.
Next, we used clock-like mutations to time the acquisition of genetic drivers, the diversification steps between CLL and RT, and their clonal bursts, which are indicative of periods of rapid proliferation. These analyses revealed that initial CLL genetic drivers were acquired up to 30 years before diagnosis. However, abrupt clonal bursts were not triggered by these genetic drivers, suggesting that cell-extrinsic factors such as B-cell receptor stimulation or microenvironmental changes could initiate the expansion of CLL. On the other hand, RT diversifies from the CLL early, including before CLL diagnosis. However, these clones follow a years-long process of clonal evolution in which the acquisition of high genomic complexity at advance stages facilitates their final outgrowth.
Overall, this study provides a roadmap of the origin, early diversification steps, and evolution of CLL and RT with potential clinical implications for early detection and intervention, while providing a framework for the study of the evolution of other hematological and solid tumors.

#4121 Incorporation of cut-point robustness in the discovery and evaluation of molecular cancer biomarkers using SCRIBE (Survival Cut-point Reporting and Integrative Biomarker Evaluation).

Miguel Lopez de Rodas Gregorio[1], Barani Kumar Rajendran[1], Javier Ramos Paradas[1], Carlos E. de Andrea[2], David L. Rimm[3], Hongyu Zhao[4], Kurt Alex Schalper[1]

[1]Pathology, Yale School of Medicine, New Haven, CT,[2]Pathology, Clinica Universidad de Navarra, Pamplona, Spain,[3]Yale School of Medicine, New Haven, CT,[4]Yale School of Public Health, New Haven, CT

Precision oncology relies on the use of biomarkers for matching cancer patients with specific therapies aiming to maximize efficacy and minimize toxicity. Although a large number of candidate biomarkers are reported, only few of them show adequate performance in independent studies and are implemented clinically. Major limitations of molecular biomarker studies in oncology include the utilization of individual cohorts and the selection of single, and arbitrary cut-points to stratify patients that increase the risk of false discovery and data overfitting. To address this challenge, we introduce a novel concept for biomarker discovery, development, prioritization and validation incorporating the cut-point robustness along ranges of consecutive cut-points as a critical parameter. We also report SCRIBE, a novel and user-friendly automated computational tool for simultaneous analysis, and discovery of biomarkers and their impact along cut-point ranges in independent datasets. To illustrate the performance of our approach, we used SCRIBE to assess the biomarker potential of the mRNA expression levels of 13 HLA class II antigen-presentation machinery genes in baseline tumor samples from three independent cohorts of patients with lung adenocarcinoma. Our analysis identified *HLA-DQB1* as the HLA class-II gene with the most robust prognostic association. The analysis of two cohorts identified the optimal cut-point range between the 44^{th} and 57^{th} percentiles. To define a single cut-point, we selected the percentile with the strongest hazard ratio effect, which corresponded to the 49^{th} percentile. We applied this cut-point to the three cohorts and found that higher levels of *HLA-DQB1* were significantly associated with longer overall survival. Using Cox proportional hazard models including *HLA-DQB1* and stage, both features were significantly and independently associated with survival in the cohorts. Finally, we performed an unsupervised discovery analysis of the whole transcriptome incorporating the cut-point robustness and identified genes with prominent and previously unreported association with prognosis in patients with lung adenocarcinoma. Notably, *AVEN* emerged as the top gene with a dramatic negative survival effect. We provide a novel conceptual framework for biomarker studies incorporating the cut-point robustness as a key property. We also provide a novel integrative computational tool for automated analysis of multiple biomarkers incorporating relevant cut-point ranges and other properties to enhance the impact of biomarker studies. We envision SCRIBE as a valuable tool for researchers and clinicians seeking to improve the reproducibility and applicability of biomarker studies and to support the development and clinical use of existing and novel biologically driven anti-cancer therapies.

#4122 Identification of molecular signatures in pancreatic ductal adenocarcinoma through multiomics.

Benjamin Miao[1], Tung-Shing Mamie Lih[2], Yingwei Hu[2], Hui Zhang[2]

[1]Johns Hopkins Univeristy, Baltimore, MD,[2]Johns Hopkins University School of Medicine, Baltimore, MD

Pancreatic ductal adenocarcinoma (PDAC) is among the deadliest malignancies, with a dismal five-year survival rate. Despite continuous efforts to study its molecular signatures, the high degree of tumor-associated cellular heterogeneity in PDAC introduces extraneous microenvironmental components that complicate analysis. In recent years, multi-omics approaches have shown promise in deconvoluting cellular composition and enabling more specific, comprehensive cancer profiling. To better characterize PDAC, in this study, we analyzed transcriptomic and proteomic data from 140 tumor tissues with 67 paired normal adjacent tissues, along with single-cell RNA sequencing data from 73 tumor tissues. Using this integrative approach, we successfully attributed molecular signatures to distinct cell-type populations. Overall, we found 59 tumor-cell derived PDAC molecular signatures and evaluated them for functional relevance, prognostic value, and potential therapeutic implications. Among these, we identified molecular targets associated with increased tumorigenic activity and immunosuppression. Moreover, survival analysis of protein phosphorylation and overall expression informed prognostic significance for potential targets. Notably, we found that several phosphorylation changes correlate with poor patient survival, suggesting potential paths for therapeutic intervention by targeting protein post-translational modifications. Our study provides a detailed understanding of PDAC through characterization of key tumor-specific signatures that could serve as potential targets to help improve clinical outcomes for this disease.

#4123 Dissecting the baseline tumor microenvironment in mNSCLC by transcriptional profiling identifies tumor microenvironmental conditions predictive for immunotherapy response.

Lilian van Vlerken-Ysla[1], Arash Nabbi[2], Zhou Zhu[3], Ross Stewart[4]

[1]Early Oncology Translational Medicine, AstraZeneca, Gaithersburg, MD,[2]Early Oncology Data Sciences and AI, AstraZeneca, Mississauga, ON, Canada,[3]Early Oncology Data Sciences and AI, Astrazeneca, Gathersburg, MD,[4]Early Oncology Translational Medicine, Astrazeneca, Cambridge, United Kingdom

Background: The MYSTIC trial (NCT02453282), a phase 3 study of durvalumab ± tremelimumab vs. standard of care (SOC) chemotherapy in 1L metastatic NSCLC, did not meet its primary endpoint of overall survival (OS) in the intent-to-treat (ITT) population. This analysis aimed to identify whether baseline tumor-immune microenvironment (TME) features were predictive for either favorable or poor response to durvalumab (D) ± tremelimumab (T) treatment in this patient population.
Methods: RNA sequencing was performed on baseline tumor samples from 185 patients in the MYSTIC biomarker-evaluable population (BEP). Non-negative matrix factorization (NMF) was used to resolve distinct clusters based on the expression of the top 10% most variable protein-coding genes. The resulting clusters were analyzed for differences in clinical outcomes, genomic alterations, immune cell composition, pathway activity, and T-cell and B-cell repertoire.
Results: NMF identified four distinct clusters within the MYSTIC BEP population of which two clusters were notably characterized by tumor immune grouping. Cluster 1 (20% of patients) exhibited hallmarks of a pro-inflammatory TME, with high T-cell signatures, macrophage infiltration, and expression of checkpoint inhibitors. Patients in this cluster treated with D+T experienced a prolonged survival (mOS 19.78 months) compared with patients on this treatment in any of the other three clusters (HR 0.39, 95%CI 0.15-1). Cluster 1 was also enriched for patients with PD-L1≥50%. Cluster 3 (20% of patients) displayed features associated with immune suppression, including high granulocyte and Treg infiltration, low macrophage signature, and enrichment of TGFbeta and stemness pathways. These patients experienced worsened survival outcomes when treated with D+T (mOS 2.17 months), compared to other clusters (HR 3.13, 95%CI 1.48-6.6). Most notably, patients in cluster 3 had significantly worsened survival on D+T compared to patients in cluster 1 (HR 6.15, 95%CI 2.02-18.8). The remaining two clusters could be characterized by histology, with Cluster 2 (35% of patients) characterized by non-squamous histology and enrichment for STK11 and MYC alterations, and Cluster 4 (25% of patients) characterized by squamous histology, aggressive proliferation signatures, and enrichment for TP53, MLL2, PTEN, and PIK3CA alterations. Neither of these two clusters drove notable impact to D+T treatment.
Conclusions: NMF clustering of baseline MYSTIC tumor samples revealed distinct TME profiles linked to divergent immunotherapy responses. A pro-inflammatory cluster predicted benefit with D+T, while a suppressive cluster aligned with poor outcomes. Findings suggest response depends not just on overall immune infiltration but on the specific immune cell composition within the TME.

#4124 Cancer stem cells and where to find them: Their trajectories and implications in cancer evolution.

Zixuan Lan[1], Philip Awadalla[2]

[1]Molecular Genetics, University of Toronto, Toronto, ON, Canada,[2]Molecular Genetics, University of Oxford, Oxford, United Kingdom

Cancer cells are heterogeneous within and among biopsies and can be perceived as a hierarchical structure defined by growth potential, in which more stem-like cells are at the apex. Cancer stem cells (CSCs) thus represent a distinct subset of cancer cells with stemness properties that play a pivotal role in tumour growth, recurrence, and metastasis. How and where CSCs originate remain somewhat controversial as differentiated cells may also regain stemness-like properties through dedifferentiation, and CSC phenotypes can vary among patients and cancer types. To systematically identify and trace potential CSC populations in lung adenocarcinoma (LUAD), we implemented an integrative computational framework that leverages both genomic and transcriptomic features from single-cell RNA sequencing (scRNA-seq) datasets from LUAD patients. By reconstructing developmental trajectories, we defined differentiation states within malignant compartments and detected rare cancer cell subsets as candidate CSCs in each biopsy. We then inferred copy number variations (CNVs) for individual malignant cells and generated phylogenetic trees based on CNV patterns to reconstruct clonal evolution. Our analyses revealed that CSC-like cells not only emerged as early ancestral clones but also arose later during tumour evolution, exhibiting similar stemness programs but undergoing dedifferentiation. We also explored their spatial organization with Visium spatial transcriptomics, and we observed that CSC-like states localized to spatially variable regions and were found near immune and stromal niches, suggesting microenvironmental influences on stemness. Finally, through deconvoluting bulk RNA-seq data and performing survival analysis, we derived a stemness signature capable of stratifying patient disease outcomes. In summary, this integrated multi-modal analysis provides insights into the identity, evolutionary dynamics, spatial distribution, and clinical relevance of CSCs in LUAD. Our approach offers a foundation for identifying CSC-driven mechanisms of tumour progression in LUAD and other cancers, and new biomarkers for prognosis and therapy response.

#4125 Goblet cell appendiceal adenocarcinoma is molecularly distinct from other histologic subtypes: Insights from large-scale genomic, transcriptomic, and organoid modeling.

Saikat Chowdhury[1], Ichiaki Ito[1], Samuel Rivero-Hinojosa[2], Chia-Mei Young[1], Eleanor A. Fallon[3], Beth A. Helmink[1], Taylor Neilson[1], Vasily Aushev[2], Sacha El Khoury[1], Abdelrahman MG Yousef[4], Mahmoud Mohamad Gamal Yousef[5], Shruti Sharma[2], Robert Lentz[2], Adham Jurdi[2], Paul F. Mansfield[1], Keith Fournier[1], Yuan-Hung Lo[1], Michael G. White[1], John Paul Shen[1]

[1]UT MD Anderson Cancer Center, Houston, TX,[2]Natera, Inc., Austin, TX,[3]Roswell Park Comprehensive Cancer Center, Buffalo, NY,[4]University of New Mexico Health Sciences Center, Albuquerque, NM,[5]Upstate Medical University, New York, NY

Background: Appendiceal Adenocarcinoma (AA) is a rare cancer, though recent data indicate a rising incidence, now exceeding 1 per 100,000 individuals annually. Goblet cell adenocarcinoma (GCA) of the appendix, which accounts for ~15% of all AA, is associated with worse survival than non-goblet AA. To elucidate the unique tumor biology of GCA, we systematically compared the genomic and transcriptomic landscapes of GCA versus non-GCA AA, identifying GCA-specific driver mutations and dysregulated pathways that distinguish GCA from other AA histologic subtypes.

Methods: Whole-exome sequencing (WES) data from 1,202 AA tumors were generated as part of the standard workflow for personalized, tumor informed circulating tumor DNA testing (Signatera^{TM}), including 385 patients with GCA, 450 with mucinous, 206 with enteric-type, and 161 with signet ring cell histology. Transcriptomic profiling was available for 63 tumors (n=25 GCA, 38 non-GCA) using Altera^{TM} tumor genomic profiling test (Natera, Inc.). Isogenic organoids with gene knock-out (KO) were generated using CRISPR/Cas9 in a *KRAS/GNAS* co-mutant murine tumor.

Results: There were striking differences in the somatic mutation landscapes between GCA and non-GCA tumors, with frequent *mutations in KRAS (73.4%), TP53 (39.5%), and GNAS (36%)* in non-GCA tumors. In contrast, GCA did not harbor a single gene mutation in more than 20% of the cohort. In GCA, the most commonly mutated gene was *ZFP36L2* (18%), a zinc finger protein that binds and stabilizes mRNA transcripts, and has previously been reported to inhibit cell proliferation. Other commonly mutated genes in GCA included *TP53* (17%) and *SMAD4* (10%), with only 10% of tumors harboring *KRAS* mutations. Transcriptional regulators such as *WTAP* (9%), *SOX9* (8%), *ARID1A* (7%), *MLLT4* (7%), *KMT2D* (7%), and *KMT2B* (4%) were also frequently altered. Performing Gene Set Enrichment Analysis (GSEA) on the differentially expressed genes between GCA and non-GCA tumors revealed that the bile acid and adipogenesis pathways were upregulated in GCA. Survival analysis showed worse OS in GCA vs non-GCA AA (94.7 months vs not reached; HR 3.51, 95% CI 2.67-4.63; $p < 0.0001$). To explore the potential significance of *ZFP36L2,* organoids derived from *ZFP36L2* KO showed decreased doubling time and allowed propagation of the organoid culture without doxycycline-induced expression of GNAS^{R201C}, a known oncogenic driver in AA. Transcriptomic analysis comparing *ZFP36L2* KO to parental lines showed enrichment for androgen response, EMT, TNFα, Wnt, Hedgehog, KRAS, and TGFβ signaling.

Conclusion: Clear molecular differences between GCA and the more common mucinous AA were observed. It is clear that strategies for developing new drugs for AA must treat GCA as a distinct entity and not merge these patients with other histological subtypes, as has frequently been done previously.

#4126 Quantification of step-specific selection reveals ordered acquisition of driver mutations in colon cancer.

Kira A. Glasmacher, Jeffrey Peter Townsend

Yale University, New Haven, CT

Colorectal cancer is a leading cause of cancer mortality worldwide. Colon adenocarcinoma develops through sequential evolutionary steps originating in adenomatous polyps. Many driver mutations of colon cancer and their relations have been hypothesized. However, quantitative timing and strength of selection across specific stages of progression remains unknown. Somatic single nucleotide variants from colon adenomas and adenocarcinomas were analyzed using a step-specific likelihood model that treats adenoma formation and malignant progression as consecutive steps within a shared evolutionary trajectory. Analyses were stratified by *POLE*/*POLD1* mutation and DNA mismatch repair (MMR) status to evaluate background-specific effects. We identified mutations under positive selection during initial formation of adenomas and later in malignant progression to adenocarcinomas, and also quantified how each successive driver changes selection on the next. Many trends of step-specific selection emerged that were consistent across *POLE*/*POLD1*-mutant and MMR-deficient tumors, such as high early selection on *APC* and strong late selection on *CTNNB1* and *TP53*. However, step-specific selection varied across the steps of progression in mutants of other genes, including *KRAS*, *BRAF*, and *FBXW7*. Inferred evolutionary trajectories point to early disruption of WNT and TGF-β signaling, followed by later acquisition of TP53, MAPK, and PI3K pathway mutations. These findings provide a data-driven, high-resolution temporal sequence of the selective pressures shaping tumorigenesis. They identify potential biomarkers for early detection, and reveal how polymerase and mismatch-repair backgrounds alter evolutionary paths by purely altering gene- and site-specific mutation rates. Consistency with experimentally identified early drivers (*APC*, *KRAS*) and late drivers (*TP53*) validates the approach and demonstrates its suitability for extending step-specific analyses to many additional cancer types. Ultimately, such high-resolution evolutionary trajectories enable precision-medicine targeted drug treatments to be exquisitely tailored to individual patients and facilitate treatments that not only target extant variants but also anticipate additional therapies that could be useful to forestall or prevent the next driver mutation and consequent burgeoning tumor burden.

#4127 Inferring transcriptomic programs from circulating tumor DNA methylation signatures in small cell lung cancer using RRBS and EM-seq.

Yuanxin Xi[1], Allison Stewart[2], Lixia Diao[1], Qi Wang[1], Li Shen[1], Runsheng Wang[2], Alberto Duarte[2], Alexa Halliday[2], Kavya Ramkumar[2], Robert Cardnell[2], Bingnan Zhang[2], Carl M. Gay[2], Lauren A. Byers[2], **Jing Wang**[1]

[1]Bioinformatics and Computational Biology, UT MD Anderson Cancer Center, Houston, TX,[2]Thoracic/Head & Neck Medical Oncology, UT MD Anderson Cancer Center, Houston, TX

Background: Small cell lung cancer (SCLC) exhibits profound epigenetic remodeling and transcriptional plasticity, yet tissue scarcity limits multi-omic profiling. Circulating tumor DNA (ctDNA) methylation analysis via reduced representation bisulfite sequencing (RRBS) or enzymatic methyl-seq (EM-seq) provides a minimally invasive window into tumor biology. However, the relationship between ctDNA methylation features and transcriptomic states such as epithelial-mesenchymal transition (EMT) or neuroendocrine (NE) differentiation remains poorly defined but may serve as means to monitor patient therapeutic response.
Methods: We analyzed matched ctDNA methylation RRBS and bulk RNA-seq data from N = 43 SCLC patients collected at baseline. CpG methylation levels were quantified and mapped to gene bodies, promoters, and distal regulatory regions. To capture functional methylation signatures, CpG sites were ranked by their correlation with RNA expression of the corresponding genes and by feature importance predicting expression levels or calculated transcriptomic scores (e.g., EMT, MYC, ASCL1/NEUROD1 subtype indices). High-ranking CpG sites were aggregated into gene-level and pathway-level signatures, followed by GO and KEGG enrichment analyses to identify key regulatory networks. These were further evaluated in SCLC patients treated longitudinally with frontline chemotherapy.
Results: Genome-wide ctDNA methylation profiles predicted bulk RNA-seq-derived gene expression as well as predefined score metrics (such as EMT score, NE score) with high concordance (Wilcoxon $R^2 = 0.63 \pm 0.07$, $p < 0.001$). Ranking analysis revealed that predictive CpG sites were enriched in enhancer and promoter regions associated with EMT regulators and NE lineage genes. Functionally, GSEA further linked high NE scores to activation of Hedgehog signaling, and EMT scores to enrichment of G2/M checkpoint pathways, suggesting distinct regulatory programs underlying SCLC phenotypes.
Conclusions: Integrative analysis of ctDNA methylation and transcriptomic data reveals that ranked, functionally annotated CpG features can accurately infer gene expression programs and biological states in SCLC. These approaches provide a mechanistic framework to interpret ctDNA methylation signatures and enable noninvasive characterization of tumor subtypes and therapeutic resistance in SCLC patients.

#4128 Proteomic signatures of tumorigenicity, immune evasion, and multidrug resistance in a murine T-cell lymphoma with CNS/ocular tropism.

Ori Braitbard[1], Jacob Hochman[2]

[1]The Department of Bioinformatics, Jerusalem College of Technology, Jerusalem, Israel,[2]Alexander Silberman Institute of Life Sciences, The Hebrew University of Jerusalem, Jerusalem, Israel

Background: The S49 T-cell lymphoma and its derivative sublines provide a powerful model to dissect how T cell lymphomas acquire tumorigenicity, evade immune surveillance, develop multidrug resistance, and disseminate to the CNS and eyes. The malignant suspension growing line T-25 contrasts with three derivatives: an immunogenic non-tumorigenic adherent T-25-Adh cell line, a tumorigenic revertant Rev-2-T-6, and a MDR1 overexpressing HU-1 cell line, which is drug-resistant yet non-tumorigenic in adults (derived from T-25-Adh). Rev-2-T-6 and HU-1 cell lines are capable of CNS/ocular metastasis in neonates.
Methods: We used label-free quantitative proteomics to define programs that underlie these divergent phenotypes. Biological triplicates of T-25, T-25-Adh, Rev-2-T-6, and HU-1 cells were analyzed and compared by high-resolution LC-MS/MS, and proteins were quantified using MaxQuant LFQ. We quantified 3,500 proteins across all lines with high reproducibility.
Results: Unsupervised clustering and PCA showed tight triplicate clustering, with T-25 clearly separated from the other variants; HU-1 and T-25-Adh clustered together, and Rev-2-T-6 occupied an intermediate position, consistent with its partial revertant phenotype. Compared to T-25 cells, HU-1, Rev-2-T-6, and T-25-Adh showed 17, 19, and 29 significantly regulated proteins, respectively. HU-1 was enriched for cAMP-related, nuclear envelope, and RNA-processing proteins, together with marked MDR1 overexpression. It showed reduced MHC-I heavy chains and ribosomal components. This is consistent with immune evasion and altered mitochondrial function in a multidrug-resistant yet non-tumorigenic background. Rev-2-T-6 up-regulated cAMP and DNA-replication factors down-regulating MHC-I and mitochondrial enzymes, supporting proliferative, glycolysis-shifted “revertant” state. T-25-Adh displayed down-regulation of cell-cycle and oxidative phosphorylation proteins, defining an adherent, immunogenic, non-tumorigenic program.
Conclusions: The present proteomic atlas of S49-derived lymphoma lines reveals shared and lineage-specific signatures of malignancy, immune escape, and drug resistance. Loss of antigen presentation and mitochondrial metabolism, together with activation of cAMP and proliferative programs, characterizes tumorigenic cells, whereas the immunogenic adherent phenotype is associated with reduced proliferation, metabolic down-shifting, and enhanced adhesion/immune pathways. MDR1 up-regulation in HU-1 decouples drug resistance from tumorigenicity while preserving CNS/ocular tropism. These data nominate antigen-processing machinery, cAMP signaling, mitochondrial metabolism, and ABC transporters as biomarkers and therapeutic targets in CNS-tropic lymphomas and provide a framework for comparative analyses with human T-cell malignancies.

#4129 Spatial single-cell transcriptomic profiling reveals distinct immune and stromal landscapes across TIL/PD-L1-defined TNBC subtypes.

Kyungsoo Kim[1], Soong June Bae[2], Yoonjin Cha[2], Yoonwon Kook[2], Ah Yoon Kim[2], Jee Hung Kim[2], Sung Gwe Ahn[2], Joon Jeong[2]

[1]Yonsei University, Seoul, Korea, Republic of,[2]Gangnam Severance Hospital, Seoul, Korea, Republic of

Purpose:
Triple-negative breast cancer (TNBC) displays marked heterogeneity in immune contexture, influencing response to immune checkpoint blockade. We aimed to characterize spatial and cellular differences among TNBC subtypes stratified by tumor-infiltrating lymphocytes (TILs) and PD-L1 expression using single-cell spatial transcriptomics.
Experimental Procedures:
We analyzed 36 TNBC cores using the Xenium platform (~5,000 genes per cell) and annotated major cell populations, including epithelial, fibroblast, and immune cells. Each core was classified into four TIL/PD-L1 subtypes ($TIL^+PD\text{-}L1^+$, $TIL^+PD\text{-}L1^-$, $TIL^-PD\text{-}L1^+$, and $TIL^-PD\text{-}L1^-$) based on histologic TIL density (≥30%) and PD-L1 CPS (≥10). Pairwise intercellular distances between tumor and stromal/immune cells were computed within a 50-μm radius to quantify spatial immune exclusion and stromal remodeling.
Results:
Distinct spatial and transcriptional profiles were observed among subtypes. $TIL^+PD\text{-}L1^+$ tumors exhibited dense immune infiltration and upregulation of antigen-presentation and T-cell activation genes in both $CD4^+$ and $CD8^+$ subsets. In contrast, $TIL^+PD\text{-}L1^-$ tumors showed prominent desmoplastic stroma and reduced immune-cell proximity, accompanied by fibroblast enrichment of *POSTN*, *FBLN1*, and *SFRP2*, suggesting extracellular-matrix remodeling that may hinder immune infiltration. Epithelial cells in $TIL^+PD\text{-}L1^-$ cores displayed higher expression of *XBP1*, *FOXA1*, and *MLPH*, indicating epithelial plasticity and potential immune evasion. Spatial mapping further revealed that tumor margins in $TIL^+PD\text{-}L1^-$ cores contained more aggressive epithelial phenotypes than corresponding cores in $TIL^+PD\text{-}L1^+$ tumors.
Conclusions:
Single-cell spatial transcriptomics delineated distinct immune and stromal architectures across TIL/PD-L1-based TNBC subtypes. The $TIL^+PD\text{-}L1^+$ subtype represents an immune-active microenvironment, whereas the $TIL^+PD\text{-}L1^-$ subtype demonstrates stromal-driven immune exclusion. These findings provide spatial evidence that combined assessment of TILs and PD-L1 can stratify TNBC patients by their potential responsiveness to immunotherapy.

#4130 Single-cell multi-omic characterization of gastric intestinal metaplasia reveals potential genetic, epigenetic and isoform signatures of lesions at high risk for GC progression.

Dongin Lee[1], Xiangqi Bai[1], Sue Grimes[1], Kyungtae Lee[1], Yan Wang[1], Charlotte Wong[1], Anuja Sathe[1], Ignacio Wichmann[1], Youlim Kim[2], Rithika Meka[1], Renee Long[1], Allison Im[1], Billy Lau[1], Robert Huang[1], Hanlee P. Ji[1]

[1]Medicine, Stanford University School of Medicine, Stanford, CA,[2]Microbiology and Immunology, Stanford University School of Medicine, Stanford, CA

Worldwide, gastric cancer (GC) is the fifth most common malignancy and the third leading cause of cancer-related deaths. Gastric intestinal metaplasia (GIM) is a precursor lesion of GC. However, only a small number of GIM lesions progress to GC. A key challenge is identifying the genomic, molecular and cellular features of GIM that predict their risk of becoming invasive cancer. Once these features are identified, one could “intercept” patients at high risk for developing GC. We conducted a single-cell multi-omic analysis of endoscopic biopsies of GIM lesions. These patients underwent GC risk evaluation using a two-biopsy approach. We used the pathology results to determine a clinical risk stage based on the Operative Link on Gastric Intestinal Metaplasia Assessment (OLGIM). Clinical stages include I and II which are low risk versus III and IV which are high risk. Each biopsy underwent single cell RNA-seq and single cell assay for transposase accessibility of chromatin (ATAC). Therefore, we had both of these genomic readouts for each cell. In addition, we used single cell long read sequencing to identify transcript isoforms and mutations. Overall, we obtained the following single cell cell features of GIM which included: (1) gene expression, (2) chromatin accessibility, (3) copy number aberrations, (4) somatic variants, and (5) isoform expression. We compared the single cell genomics features between high-risk and low-risk groups. For example, we observed that key genes specifically expressed in intestinal-like stem cells, which are linked to potential gastric cancer-initiating cells—such as *CDH17*, *SI* and *CPS1*—were more highly expressed among the high-risk group, which also exhibited increased chromatin accessibility at the same genes. Furthermore, we detected differential isoform usage of gastric-related genes between the two groups, which implies that isoform changes are related to GC progression. These findings provide genomic, molecular and cellular features of GIMs that are associated with high risk of developing GC.

#4131 Multi-omics characterization of PRMT5 inhibition identifies vulnerabilities for combination therapy in MTAP-deleted cancers.

Eliana Destefanis[1], Blanka Bordas[1], Jose C. Martinez[2], Samar Sayedyahossein[1], Samuel Moffitt[1], Enakireru M. Erhumuoghene[1], Daniel Dominguez[2], Kathleen M. Mulvaney[1]

[1]Fralin Biomedical Research Institute, Virginia Tech Cancer Research Center, Washington, DC,[2]University of North Carolina, Chapel Hill, NC

Homozygous deletion of CDKN2A on chromosome 9p21 is the most frequent genomic loss in cancer and often extends into the adjacent MTAP gene. This co-deletion occurs in ~10% of tumors (>200,000 cases annually in the U.S) and is particularly enriched in aggressive malignancies such as glioblastoma (GBM), malignant peripheral nerve sheath tumors (MPNST), pancreatic ductal adenocarcinoma (PDAC), and non-small cell lung cancer (NSCLC). In these tumors, MTAP loss leads to intracellular accumulation of its substrate methylthioadenosine (MTA), which partially inhibits protein arginine methyltransferase 5 (PRMT5) by competing with its methyl donor S-adenosyl-methionine (SAM) at the active site, reducing its ability to symmetrically dimethylate arginine residues (SDMA). This creates a synthetic-lethal dependence on residual PRMT5 activity and has driven the development of MTA-cooperative PRMT5 inhibitors, which show encouraging preclinical activity and single-agent response rates of 21-29% in early clinical trials in the advanced, refractory setting. We therefore hypothesized that defining the molecular consequences of PRMT5 inhibition could guide patient stratification and inform rational combination strategies capable of enhancing therapeutic efficacy and preventing resistance. To test this, we performed multi-omics profiling, including short- and long-read transcriptomics and whole-cell proteome mass spectrometry, across MTAP-deleted NSCLC, GBM, and PDAC models, integrating these data with in-house and publicly available datasets to define PRMT5-dependent methyl events and their downstream molecular consequences. Transcriptomic and proteomic analyses revealed strong and consistent pathway-level alterations across models following PRMT5 inhibition, including activation of MAPK signaling, a compensatory program validated to synergize with PRMT5 inhibitors in vitro and in vivo. Across eight distinct PRMT5 methyl-enrichment mass spectrometry studies, we identified 180 PRMT5 substrates enriched mainly for proteins involved in RNA metabolism and pre-mRNA splicing, including multiple snRNP-associated components of the spliceosome. We therefore examined the splicing consequences of PRMT5 inhibition and observed widespread increases in intron retention and reductions in exon skipping, with enrichment of splicing alterations in transcripts involved in DNA damage repair across models. Overall, this study provides a comprehensive substrate map of PRMT5 and characterizes the transcriptional, proteomic, and splicing programs activated upon its inhibition across MTAP-deleted GBM, NSCLC, and PDAC models. These findings highlight pathway and splicing-associated vulnerabilities as targets for rational combination strategies and establish a mechanistic framework to guide biomarker development and future therapeutic exploration.

#4132 Landscape of allele-specific expression in prostate cancer reveals recurrent, stage-specific events in AR signaling and resistance pathways.

Margaret Tsui[1], Kevin Hu[1], Hanbing Song[2], Sarah Hsu[1], Rebecca Chen[1], Lorraine Nuniz[1], Julia Pham[1], Chih-Hao Chang[1], Keliana Hui[1], David Quigley[3], Jingjing Li[4], Franklin Huang[1]

[1]Division of Hematology and Oncology, Dept. of Medicine, University of California San Francisco, San Francisco, CA,[2]University of California San Francisco, San Francisco, CA,[3]Urology, University of California San Francisco, San Francisco, CA,[4]Neurology, University of California San Francisco, San Francisco, CA

The effects of cis-regulatory alterations in prostate cancer (PCa) are insufficiently characterized, presenting an opportunity to discover driver genes and therapeutic targets. To comprehensively study these effects, we identify genes undergoing allele-specific expression (ASE) in localized PCa and metastatic castration-resistant PCa (mCRPC) samples. By defining recurrent ASE events across prostate tissue and tumor-enriched ASE, we develop CASEDI, a computational framework for prioritizing cancer drivers by integrating ASE and clinical data. CASEDI reveals genes showing recurrent ASE and altered expression in PCa, including AR-regulated and oncogenic ACSM1. mCRPC samples show enrichment of ASE in DNA repair, resistance pathways, and oncogenes and increased frequency of monoallelic expression (MAE) compared to localized tumors. We define an mCRPC gene signature based on MAE status that identifies a subgroup of localized patients with worse prognosis. Using ASE analysis, we expand the landscape of cis-regulatory events in PCa to inform the identification of additional therapeutic targets.

#4133 Single cell multi-omics enables molecular dissection of gastric cancer subtypes.

Junha Cha[1], Anuja Sathe[1], Yan Wang[2], Susan M. Grimes[3], Hanlee P. Ji[2]

[1]Stanford University School of Medicine, Stanford, CA,[2]Stanford University, Stanford, CA,[3]Medicine, Stanford University, Stanford, CA

Gastric cancer (GC) has different histopathological subtypes that include intestinal, diffuse, and mixed. These subtypes are identified based on histologic cell morphology and are clinically informative, more so than molecular subtypes. Namely, histologic subtypes differ in prognosis, rates of metastasis and treatment response. However, many questions remain about the genomic features that distinguish each histologic subtype. Integrating single-cell datasets is particularly challenging at the molecular level due to technical variation. We developed an integrative data set combining in-house and public multi-omics datasets - they include bulk sequencing, scRNA-seq, spatial transcriptomics, and proteomics. The scRNA-seq data included 208 tumors from 118 patients. This single cell data was harmonized to reduce the effects of batch variability. For analysis, we developed a computational pipeline incorporating generalized linear models, non-negative matrix factorization for meta-program identification, sample-level pseudo-aggregation and network-based gene expression analysis. This pipeline enabled gene-wise dissection, pathway-centric interpretation of malignant transcriptional programs and systematic quantification of cell state dynamics across integrated cohorts. We identified distinct tumor-intrinsic gene expression programs across subtypes. The intestinal and mixed tumors expressed immune-associated programs, while the MSI tumors exhibited elevated cell-cycle signaling compared to MSS. In the tumor microenvironment, the diffuse subtype showed reduced B-cell differentiation but increased dendritic cell abundance, whereas intestinal subtype was enriched for T-cell subtypes, including regulatory T cells with immunosuppressive potential. From the single cell results, we determined that TIGIT expression was significantly elevated among CD8 and regulatory T cells. This result was confirmed with multiplexed immunofluorescence staining on an independent set of 142 GCs. Fibroblast-driven interactions dominated diffuse tumors, while intestinal and mixed tumors displayed immune-mediated “hot tumor” phenotypes.

Overall, our study showed that the analysis of an integrated, harmonized single-cell data from GC revealed malignant and microenvironmental programs distinguishing subtypes. Our results provided some subtype-specific vulnerabilities and provides insight into potential future therapeutic targets.

#4134 A long-read sequencing and phylogenetic framework for improved detection and timing of overlapping and repetitive somatic structural variations.

Anton Goretsky[1], Yuelin Liu[1], Ayse Keskus[1], Tanveer Ahmad[1], Chi-Ping Day[2], Erin K. Molloy[3], Mikhail Kolmogorov[1]

[1]Cancer Data Science Laboratory, National Cancer Institute, National Institutes of Health, Bethesda, MD,[2]National Cancer Institute, National Institutes of Health, Bethesda, MD,[3]Department of Computer Science, University of Maryland, College Park, College Park, MD

Despite their accuracy in identifying single nucleotide variants (SNVs), current short-read sequencing technologies struggle to resolve repetitive regions and complex structural variants (SVs), as the reads are simply too short to span such challenging genomic segments. Mapping issues in homologous regions, the high barrier to accurate phasing, and other limitations increasingly point to long-read sequencing as a method to overcome these challenges. Here we develop a computational framework for harmonization and joint analysis of different variant types in the evolutionary context. We particularly focus on structural variants, as they have significant functional consequences and play a large role in driving cancer initiation and progression. As such, we explore the application of long-reads to improve precision breakpoint calling for structural variants in highly repetitive regions, demonstrating their efficacy in resolving complex structural variants. We use this framework to profile 23 subclones of a mouse melanoma cell line, characterized with distinct growth phenotypes and treatment responses. Uniquely, our framework reveals recurrent amplifications of putative driver genes across different lineages caused by independently acquired structural variants, suggesting parallel evolution. In addition, our approach revealed gradual and lineage-specific methylation changes associated with aggressive clonal phenotypes. We show our set of phylogeny-constrained variant calls along with openly released sequencing data can be a valuable resource for the development of new computational methods.

#4135 Site-specific oral microbiome patterns in Puerto Rican head and neck cancer patients.

Gabriela N. Garcia Quinones[1], Jaleniz Suarez Perez[2], Orlando Castro Ortiz[3], Maria Sanchez Vazquez[3], Jonathan Hernandez Agosto[1], Filipa Godoy Vitorino[2], Magaly Martinez Ferrer[1]

[1]Pharmaceutical Sciences, University of Puerto Rico Medical Sciences Campus, San Juan, Puerto Rico,[2]Department of Microbiology and Medical Zoology, University of Puerto Rico Medical Sciences Campus, San Juan, Puerto Rico,[3]Cancer Clinical & Translational Research, University of Puerto Rico Comprehensive Cancer Center, San Juan, Puerto Rico

Introduction: Head and neck cancers (HNCs) are the seventh most common cancer globally and the sixth most prevalent in Puerto Rico. They are also the eighth leading cause of cancer deaths among Puerto Rican men. Understanding HNC development and prognosis in this population is vital. The oral microbiome plays a significant role in HNC, as previous studies have shown that microbial dysbiosis can affect diagnosis and treatment. *However, little is known about the oral microbiome patterns in Puerto Rican HNC patients and their stability in response to clinical factors.* Therefore, the objective of this study is to determine the bacterial communities associated with HNC in Puerto Rican patients.
Methods: Genomic DNA was extracted from 79 histologically confirmed HNC tumor samples from Puerto Rican patients, followed by HPV genotyping and microbiome analyses using 16S rRNA gene amplicon sequencing. Data were deposited in Qiita/Deblur for quality control and bioinformatics analyses. Downstream analyses, including alpha and beta diversity, taxonomic characterization, and biomarker analyses, were conducted using QIIME2, MicrobiomeAnalyst, and Random Forest.
Results: Although beta diversity was similar across different anatomic sites, a significant difference was observed between the larynx and the oropharynx ($P = 0.041$, $FDR = 0.355$). The larynx consistently demonstrated lower richness and Shannon diversity compared to the oropharynx, hypopharynx, and oral cavity. Furthermore, Random Forest models showed weak discriminatory power ($MDA < 0.05$) for all six metadata variables analyzed: anatomic location, surgery, HPV status, radiotherapy, and chemotherapy. This was observed despite the contributions from various phyla, including *Bacillota_A*, *Deinococcota, Pseudomonadota*, and *Bacteroidota*, as well as genera such as *COE1, Duncaniella, Escherichia, Paramuribaculum*, and *Aggregatibacter.*
Conclusions: The oral microbiome of Puerto Rican HNC patients appears highly resilient, with significant variations in richness and diversity primarily linked to the laryngeal anatomical site. To enhance predictive accuracy for overall, cancer-specific, and disease-free survival, future studies will systematically correlate the microbiome's composition with clinical HNC characteristics. This will be accomplished by employing an array of survival-based machine learning methodologies, including penalized Cox regression (Elastic Net), Random Survival Forests, and Gradient Boosted Survival models (XGBoost-Cox). This work promises to unlock the microbiome's potential as a powerful tool for improving patient prognoses.

#4136 Pan-cancer transcriptomic signatures of immune checkpoint blockade response and machine learning-based prediction across TIGER cohorts.

Junqing Zhang[1], Hongru Shen[2], Yajing Bi[2], Xiangchun Li[2]

[1]Tianjin Medical University, Tianjin, China,[2]

Immune checkpoint blockade (ICB) can induce durable remission in a subset of patients with advanced cancer, but accurately identifying responders before treatment is essential to maximize clinical benefit and avoid unnecessary immune-related toxicities. To address this need, we systematically analyzed bulk RNA-seq cohorts from the Tumor Immunotherapy Gene Expression Resource (TIGER) encompassing multiple tumor types treated with ICB, and developed a machine learning-based framework for response prediction in a pan-cancer, multi-cohort setting.

We included cohorts of glioblastoma, head and neck squamous cell carcinoma, non-small cell lung cancer, renal cell carcinoma, gastric cancer, and several melanoma datasets, with all samples annotated as responders or non-responders. Within each cohort, we performed differential gene expression analysis between responders and non-responders and applied Hallmark gene set enrichment to define key biological pathways associated with ICB response. On this basis, we extracted transcriptomic features and trained support vector machine (SVM) classifiers. Model performance was assessed by repeated 10-fold cross-validation within cohorts and further examined using leave-one-dataset-out (LODO) validation and cross-dataset testing among melanoma cohorts.

Across tumor types, responders exhibited a highly consistent immune-activation landscape, including marked up-regulation of interferon-γ/α responses, allograft rejection, and TNF-NF-κB and IL6-JAK-STAT3 inflammatory signaling, together with metabolic reprogramming involving oxidative phosphorylation and cholesterol homeostasis. Non-responders more frequently showed enrichment of cell-cycle and proliferation pathways (G2M checkpoint, E2F targets) and epithelial-mesenchymal transition, with tumor type-specific patterns in melanoma and renal cell carcinoma. SVM models achieved good discrimination, with many within-cohort areas under the ROC curve (AUCs) exceeding 0.7 and some approaching 0.9, while maintaining practically useful performance in cross-cohort evaluations.

Collectively, this study delineates shared immune and metabolic programs associated with ICB benefit and tumor type-dependent resistance features, and proposes a transcriptome-machine learning prediction framework applicable across multiple cancers and cohorts, providing a solid data and methodological foundation for further optimization of immunotherapy response prediction using advanced representation learning approaches.

#4137 The acidic tumor microenvironment facilitates colorectal cancer liver metastasis through LPL lactylation-mediated reprogramming of macrophage cholesterol metabolism.

Yifan Zheng, Zhengyu Wei, Zhengran Zhou, Peishan Hu

The Sixth Affiliated Hospital of Sun Yat-sen University, GuangZhou, China

Colorectal cancer liver metastasis (CRLM) remains a major challenge in clinical treatment, with its recurrence and poor prognosis closely linked to tumor microenvironment (TME) reprogramming and immune cell dysfunction. As core immunoregulatory cells in the CRLM microenvironment, tumor-associated macrophages (TAMs) undergo significant metabolic reprogramming during disease progression; however, the mechanism by which metabolic reprogramming regulates TAM phenotype and promotes tumor metastasis has not been fully elucidated.A multi-omics strategy integrated single-cell RNA sequencing (scRNA-seq) and ICGC-ARGO/GEO transcriptomic data to analyze metabolic dynamics in CRLM lesions. TAMs were stratified into high (HCTAM), medium, and low (LCTAM) subgroups by cholesterol metabolic activity. Spatial transcriptomics (ST) verified spatial gene expression and metabolic activity, and in vitro functional experiments validated gene functions and regulatory relationships.Cholesterol metabolic pathways were abnormally upregulated in CRLM lesions, with TAMs exhibiting the highest cholesterol metabolic activity among immune and stromal cells. HCTAMs had significantly elevated M2 polarization scores, localized to late-stage macrophage differentiation, and co-expressed multiple M2 markers. Five machine learning algorithms identified lipoprotein lipase (LPL) as significantly overexpressed in HCTAMs, with high LPL expression independently associated with advanced CRC stages and poor overall survival. Mechanistically, lactate dehydrogenase A (LDHA) was significantly upregulated in HCTAMs, and TAM cholesterol metabolic was activity positively correlated with TME acidosis scores. ST confirmed LPL enrichment in acidotic regions, and multiplex immunofluorescence showed LPL colocalization with pan-lactylation. Lactate-induced lactylation modification regulated the expression of LPL . Transcriptomic analysis revealed significant EMT pathway enrichment in CRC cells of high-LPL group. In vitro experiments confirmed LPL colocalization with M2 TAM marker CD163; TAM LPL knockdown reduced cholesterol levels and downregulated M2 polarization markers. Co-culture experiments showed LPL-knockdown TAMs inhibited the invasion and migration of CRC cells and downregulated EMT-related marker expression.In conclusion, this study confirms that the acidic microenvironment in CRLM lesions drives LPL overexpression in TAMs through lactate-dependent lactylation modification. This effect maintains high cholesterol metabolic activity in TAMs and promotes their M2 polarization, further enhancing CRC cell EMT progression and invasiveness, ultimately exacerbating CRLM development.

#4138 Integrative computational and experimental analysis identifies carcinogenic effects of 1,4-Phenylenediamine in hepatocellular carcinoma via PI3K/AKT-MAPK and JAK/STAT signaling pathway.

Liuxian Ban[1], Ran Ding[2], ZhiQing Long[2]

[1]University of Hong Kong, Shenzhen Hospital, Shenzhen, China,[2]Sun Yat-sen University Cancer Center, Guangzhou, China

Hepatocellular carcinoma (HCC) is strongly influenced by environmental chemical exposures, among which 1,4-Phenylenediamine dihydrochloride (1,4-PDD) may act as a potential carcinogenic agent. In this study, we employed a network toxicology framework to systematically elucidate the molecular mechanisms linking 1,4-PDD exposure to HCC development. Differentially expressed genes and putative targets associated with 1,4-PDD were identified by integrating toxicogenomic databases, transcriptomic profiles, and protein-protein interaction networks. A multi-algorithm machine learning pipeline-combining random forest, LASSO regression, and support vector machines was implemented to refine and prioritize key targets with high stability. These targets were subsequently used to construct a prognostic model via multivariate Cox regression, which demonstrated robust predictive performance in independent validation cohorts. Mechanistic analyses indicated that the key targets were predominantly enriched in oncogenic signaling pathways, particularly the p-AKT, p-MEK, p-ERK1, and p-STAT3 axes, suggesting that 1,4-PDD exposure may promote malignant progression by activating PI3K/AKT-MAPK and JAK/STAT signaling cascades. Overall, this study delineates system-level toxicological mechanisms of 1,4-PDD in HCC and presents a molecular prognostic model with potential translational value for assessing chemical exposure-related liver cancer risk.

#4139 Resource allocation deconvolution for pathway analysis.

Junhao Wang, Yifei Wang, Tianshu Michael Bao, Yong Li

Baylor College of Medicine, Houston, TX

Background: Traditional pathway analysis mainly focuses on comparing pathway activity among different samples, ignoring how pathways share and compete for a limited transcriptional "budget."
Methods: We present PathwaySpectra, a framework that characterizes the transcriptional budget allocation and competitive landscape of pathways at the single-sample level. It can flexibly integrate standard annotations and user-defined gene sets and can be easily extended to various data types and disease scenarios.
Results: In an immune checkpoint inhibitor (ICI) cohort, PathwaySpectra revealed previously unannotated high-efficiency modules whose budget shares positively tracked clinical response, as well as low-efficiency modules enriched in progressive disease. Using composition-aware models with covariate adjustment, these associations remained robust. Compared to common supervised pathway scores, PathwaySpectra not only demonstrates the ability to distinguish response-related signals but also to identify previously unknown related signals. The competition view further suggested a reallocation of budget from immune-effective to inefficient pathways in non-responders, potentially constraining resources for productive immune activation.
Conclusions: PathwaySpectra offers a complementary perspective beyond standard pathway activity metrics, enabling budget-based, sample-by-sample pathway analysis and supporting custom gene sets for research targeting specific questions, thereby facilitating the discovery of pathway-level therapeutic response biomarkers.

#4140 *In silico* analysis of Lacunae cornuta phytochemical against high-risk HPV targets.

Solomon Owumi[1], Esther M. Pius[1], Oluwaseun M. Owolabi[1], Ifeoluwa O. Alabi[1], Victor O. Eso[1], Sanusi A. Abdullah[1], Hikmah A. Abdulganiyu[1], Jesutosin O. Babalola[1], Chima Amadi[2], Chinedum Udekwu[3], Adegboyega K. Oyelere[4], E. Oluwabunmi Olapade-Olaopa[5], Olorunseun O. Ogunwobi[3]

[1]Biochemistry, University of Ibadan, Ibadan, Nigeria,[2]Dedra Nutraceuticals and Biotechnology Initiative, Abuja, Nigeria,[3]Chemistry and Biochemistry, Michigan State University, Lansing, MI,[4]Chemistry and Biochemistry, Georgia Institute of Technology, Atlanta, GA,[5]Surgery, University of Ibadan, Ibadan, Nigeria

High-risk Human Papillomavirus (hrHPV) particularly HPV 16 and 18 is the primary etiological agent for cervical carcinogenesis, a disease disproportionately impacting women globally and a leading cause of morbidity and mortality. hrHPV encode oncoproteins that disrupt cell cycle regulation, inhibit apoptosis, and facilitate malignant transformation. *Launaea cornuta* (LC) is a medicinal plant known to contain flavonoids, terpenoids, and phenolic acids. Traditionally valued for its anti-inflammatory, antiviral, and anticancer properties, LC has demonstrated bioactivity in various preclinical models, indicating its potential applicability in the management of HPV-related pathologies. We used Network Pharmacology to identify molecular targets in hrHPV-induced cervical cancer. Bioinformatics analyses showed that LC phytochemicals interact with key genes—CASP3 (caspase-3), BCL2 (B-cell lymphoma 2), and HIF1A (hypoxia-inducible factor 1-alpha) —linked to apoptosis and hypoxic response. Molecular docking simulations assessed the binding affinities of LC-derived compounds to hrHPV oncoproteins (E6 and E7) and hub genes. Protein structures were taken from databases, and docking scores were used to estimate inhibitory effects. NP analysis identified CASP3, BCL2, and HIF1A as central genes implicated in the pathogenesis of hrHPV-induced cervical cancer. These genes represent critical nodes linking viral oncogenesis, apoptosis regulation, and cellular adaptation to hypoxia. Several LC phytochemicals exhibited strong binding affinities to hrHPV E6/E7 oncoproteins and the hub genes. MD analysis showed that several LC phytochemicals—such as stigmasteryl methyl ether, Tricyclo(20.8.0.0(7,16))triacontane, 1(22), 7(16)-diepoxy, and tremulone—demonstrated strong binding affinities (-5.9 to -8.4 kcal/mol) with E6, E7 oncoproteins and hub genes, indicating potential for viral inactivation or inhibition of oncogenic function. LC phytochemicals may inhibit oncogenic mechanisms driven by hrHPV through targeted interactions with both viral and host cell proteins, thereby facilitating apoptosis and reducing tumor progression. Their therapeutic potential
is highlighted by the modulation of critical pathways involving CASP3, BCL2, and HIF1A. The in-silico evaluation of LC phytochemicals demonstrates promising inhibitory activity against hrHPV E6 and E7 oncoproteins and key molecular targets involved in cervical cancer. Further research is necessary to translate these findings into clinical applications.

#4141 Multimodal single-cell analysis of systemic immune remodeling induced by cytoreductive nephrectomy combined with immune checkpoint inhibitors in metastatic renal cell carcinoma.

Suebin Park[1], Byungjin Hwang[2]

[1]Department of Clinical Drug Discovery and Development, Yonsei University College of Medicine, Seoul, Korea, Republic of,[2]Department of Biomedical Sciences, Yonsei University College of Medicine, Seoul, Korea, Republic of

Background: The role of cytoreductive nephrectomy (CN) in metastatic renal cell carcinoma (mRCC) remains uncertain in the immuno-oncology era. Ongoing trials such as PROBE (NCT04510597) and NORDICSUN (NCT03977571), focus on deferred CN versus no CN, but neither includes an upfront CN arm. To address this gap, we performed a multimodal single-cell analysis comparing the immunological effects of upfront CN, deferred CN, and no CN in combination with ICIs.
Methods: We performed multimodal single-cell sequencing integrating bulk RNA-seq, scRNA-seq, CITE-seq, and TCR-seq on peripheral blood mononuclear cell (PBMC) samples obtained from five patients undergoing CN and ICI therapy in different treatment orders. Eleven PBMC samples collected across treatment time points were pooled, genotyped, and demultiplexed using SNP-based assignment, followed by normalization and processing with the Seurat workflow. Bulk RNA-seq and genotyping enabled donor identification and transcriptomic profiling, while single-cell transcriptomic, surface proteomic, and TCR clonotype data were jointly analyzed to characterize cellular components, immune activation states, and clonal dynamics associated with CN in combination with ICI therapy.
Results: We analyzed 133,943 cells and identified 16 immune cell types. Immune composition differed by the sequencing of cytoreductive nephrectomy (CN) and ICI therapy. In the upfront CN group, CN increased memory B cells, classical monocytes, and NK cells, and these changes persisted during nivolumab plus ipilimumab treatment. In the deferred CN group, CN also expanded NK cells but additionally increased $CD8^+$ effector memory T cells. Transcriptomic, ADT, and TCR analyses revealed distinct immune states and clonal expansion patterns contributing to systemic immune remodeling.
Conclusions: This study reveals that CN combined with ICIs exerts different immune effects depending on whether CN is performed upfront or deferred. While both approaches increased NK cells, B- and T-cell responses differed between groups. Our multimodal single-cell analysis further identified distinct transcriptional, proteomic, and clonal changes associated with each approach. Although the optimal timing of CN remains uncertain, these findings highlight the need for further investigation to refine patient selection and guide CN integration with ICI therapy in mRCC.

#4142 Metabolic transition analysis from dormancy to awakening in breast cancer.

Javier Villela Castrejon[1], Herbert Levine[2], Jason T. George[3]

[1]Translational Cancer Research, Texas A&M University, Houston, TX,[2]Northeastern University, Boston, MA,[3]Texas A&M University, Houston, TX

Dormancy and late relapse remain pressing challenges in ER+ breast cancer. Mechanistically, dormancy can reflect a cellular quiescence of micrometastatic cells or tumor-mass dormancy constrained by angiogenic or immune bottlenecks. A long-standing hypothesis is that dormant disseminated tumor cells (DTCs) reside in a glycolysis-high, mesenchymal-like state, whereas successful awakening requires a transition toward an epithelial, OXPHOS-dependent phenotype.
Here, we test this hypothesis using a catabolic-anabolic AMPK/HIF-1/MYC regulatory model with four phenotypic states (OXPHOS, Warburg, hybrid W/O, and glutamine-reliant Q), each with distinct metabolic signatures. We integrated these signatures with longitudinal experimental and relevant clinical intervention datasets, including viral infection-induced awakening model, clinical endocrine-therapy time courses, and dormancy models. In addition, three complementary epithelial-mesenchymal transition (EMT) metrics were integrated to assign a consensus epithelial, hybrid, or mesenchymal phenotype to each sample to connect the intrinsic relationship of EMT with metabolic phenotype and dormancy status. Across models, we uncover marked metabolic diversity during cancer awakening, including transitions from quiescent, glycolysis-dependent or mesenchymal-biased states toward hybrid W/O metabolic configurations characterized by coordinated changes of AMPK and HIF-1, altered ROS source balance, and re-engagement of epithelial and proliferative signaling pathways. These metabolic and transcriptional transitions reveal the molecular features associated with dormancy exit and may provide new opportunities to therapeutically prevent awakening and late metastatic relapse.

#4143 Integrative analysis of XPC and VEGFA as risk biomarkers in T-cell lymphoma: A case-control study.

Faten Awwad[1], Lama M. Bani Salameh[1], Laith N. AL-Eitan[2], Nour Abdo[3], Sohaib Al-Khatib[4]

[1]Faculty of Medicine, Jordan University of Science & Technology, Irbid, Jordan,[2]Department of Biotechnology and Genetic Engineering, Faculty of Science and Arts, Jordan University of Science & Technology, Irbid, Jordan,[3]Department of Public Health, Faculty of Medicine, Jordan University of Science & Technology, Irbid, Jordan,[4]Department of Pathology and Laboratory Medicine, Faculty of Medicine, Jordan University of Science & Technology, Irbid, Jordan

Introduction: T-cell lymphoma (TCL) is a rare and aggressive type of non-Hodgkin lymphoma (NHL) that accounts for around 12% of all cases and shows variable clinical and molecular features. Germline single-nucleotide polymorphisms (SNPs) have been increasingly recognized as modulators of cancer risk. However, the role of such genetic variants in TCL in a non-western population remains largely unexplored. Therefore, we aimed to investigate the relationship between XPC, VEGFA and TNFAIP8 SNPs and the risk of developing TCL in an Arab population.
Methods: A total of 31 TCL patients and 289 matched healthy controls were recruited from King Abdullah University Hospital (KAUH), Females represented 32.3% (n=10) of patients and 61.3% (n=146) of controls, with mean ages of 44.1 and 43.2 years, respectively. Genomic DNA was extracted from formalin-fixed paraffin-embedded (FFPE) tissue samples for lymphoma cases and from peripheral blood samples for controls. Selected SNPs were genotyped using a sequencing protocol, and significant ones were identified using adjusted p-values and the Bonferroni false discovery rate (FDR) correction. We validated our findings using the GEO cohort (GSE6338) and performed linear modeling of microarray data to identify differentially expressed genes, applying a cutoff of log2FC > 0.5. All analyses were conducted in R version 4.4.3.
Results: The primary cohort showed that XPC rs2228001G>T was associated with higher TCL risk in both the co-dominant [TT: OR 2.353; 95% CI 1.01-5.59; p=0.0471] and recessive models [TT: OR 2.811; 95% CI 1.29-6.08; p=0.0084]. VEGFA rs3025039C>T also showed a strong association with increased risk in the co-dominant [TT: OR 19.091; 95% CI 4.70-78.99; p=0.00003], dominant [OR 3.227; 95% CI 1.36-7.75; p=0.0076], and recessive [OR 15.333; 95% CI 3.94-60.06; p=0.00006] models. Conversely, TNFAIP8 rs1045241C>T showed a protective effect in the co-dominant [OR 0.158; 95% CI 0.02-0.56; p=0.0141], dominant [OR 0.382; 95% CI 0.14-0.92; p=0.0446], and over dominant models [OR 0.152; 95% CI 0.02-0.53; p=0.0116]. In the validation dataset (GSE6338), VEGFA showed significant upregulation (LogFC=0.598; adj. p=0.000795), while XPC showed no significant change (LogFC=0.090; adj. p=0.457).
Conclusion: This study identifies VEGFA rs3025039 as a potential genetic risk factor for T-cell lymphoma in the Jordanian population. Gene expression analysis further confirmed upregulation of VEGFA in TCL validation cohort, suggesting a possible role in disease progression. These findings provide the first evidence in an Arab population cohort linking specific SNPs and gene expression changes to TCL risk, offering potential targets for population-specific personalized therapies.

#4144 Immunotherapy response predictors in colorectal cancer: A multi-omics approach.

Joaquin Pedro Merlo[1], Marco Adrian Scheidegger[2], Ada G. Blidner[2], Alejandro Cagnoni[2], Gabriel A. Rabinovich[2], Karina Marino[1]

[1]Instituto de Biologia y Medicina Experimental (IBYME) - CONICET. UADE - INTEC, Buenos Aires, Argentina,[2]Instituto de Biologia y Medicina Experimental (IBYME) - CONICET, Buenos Aires, Argentina

Predicting immunotherapy (IT) outcomes remains a clinical challenge as approved biomarkers show limited efficacy. Although aberrant glycosylation has been linked to tumor progression, its role in predicting IT outcomes is underexplored. With the goal of aiding in patient stratification, we integrated genomic, transcriptomic and glycomic data to explore the predictive capacity of glycoimmune genes. Using unsupervised machine-learning methods and cross-validation with two independent cohorts, we developed the GlycoImmune Signature (GIS), an 18-gene expression signature associated with improved response to IT and survival outcomes. We applied the GIS to colorectal cancer (CRC) samples from TCGA-COAD and characterized their immune infiltration and proteomic profiles. MSI-H patients and predicted responders (TIDE algorithm) showed higher GIS scores ($p<0.0001$). High GIS-scoring (GISH) patients exhibited a “hot” tumor microenvironment (TME) and upregulation of immune-related signatures compared to low GIS-scoring (GISL) cases. Interestingly, approximately 40% of MSI-L/MSS patients were GISH, suggesting that the GIS may identify patients who might respond to IT but are not currently considered by clinical guidelines. Single-cell transcriptomics data of CD45+ and tumor cells (GSE200997) of treatment-naïve samples were aggregated per patient to generate pseudobulk profiles and classify them into GISH and GISL. GISH tumors showed an enrichment of effector CD8+ T cells and reduced infiltration of Tregs and Th17 cells, confirming previous findings. Mapping these GISH and GISL-associated cell states onto cells from patients treated with IT (GSE205506) revealed that GISH-associated effector CD8+ T cells were more cytotoxic and prevalent in responders, while those from GISL patients expressed exhaustion markers (*LAG3, PDCD1, CTLA4, EOMES, TOX).* In turn, GISH-associated Tregs showed the loss of regulatory markers (*FOXP3, CTLA4*, *TIGIT*). To translate our transcriptomic marker into a proteomic one, we analyzed proteomic data from GISH patients in TCGA-COAD, finding 29 upregulated proteins associated with immune response and cell killing, and 9 downregulated proteins associated with metabolic reprogramming. Among the former, six proteins present relevant biological roles and are highly expressed in CRC tumors, which could serve as cost-effective clinical readouts. Overall, these findings position the GIS as a multi-omics surrogate of IT response in CRC and highlight its potential to expand patient eligibility for immunotherapy.

#4145 Genome-wide metabolic modeling identifies key modifiers of precancerous LUSC evolution.

Neel Sanghvi, Thomas Cantore, Chi-Ping Day, Sanna Madan, Nishanth Ulhas Nair, Eytan Ruppin

National Cancer Institute, Bethesda, MD

Background: Metabolic alterations drive tumorigenesis, yet few metabolic cancer drivers have been established. The squamous cell carcinoma subtype of lung cancer (LUSC) is particularly underserved, with few, potentially harmful treatment options and overall poor prognosis. Here, we aim to discover actionable modifiers of tumorigenesis through a systematic, genome-scale metabolic analysis of human lung samples. We identify metabolic genes whose knockout (KO) may drive carcinogenesis and, critically, those whose KO may revert (pre)cancerous states back to the healthy lung.

Methods: We analyzed bulk transcriptomes from 122 normal, precancerous, and cancerous samples spanning the LUSC evolutionary spectrum. First, sample-specific metabolic states were modeled in-silico using iMAT (Zur et al., 2010) on the HumanGEM model. Second, gene KOs were simulated with rMTA (Valcárcel et al., 2019) to estimate their oncogenic risk and back-to-normal reversion potential. Third, top scoring genes in both categories were corroborated by independent and orthogonal validations: a mouse gene-null phenotype dataset (KnockOut Mouse Project), differential expression in a separate LUSC precancer progressors vs regressors cohort, the Dependency Map (DepMap), and an LLM/AI-enhanced literature review. Corroborated, top-scoring genes were finally mapped to small molecule inhibitors via the DrugBank database.

Results: Reassuringly, top predicted risk genes (KO → progression) emerging from the metabolic modeling analysis were associated with greater cancer incidence in null allele mice (Wilcoxon $p = 0.02$), downregulated in LUSC precancer lesions that progressed to cancer ($p < 0.0094$), and associated with tumor suppressive activity in literature ($p < 0.01$), compared to background genes. Conversely, top reversion genes (KO → regression) were downregulated in LUSC precancer samples that regressed to normal ($p < 0.04$), overlapped with genes whose KOs lowered cancerous growth in the DepMap (odds-ratio/OR > 1.6, $p < 0.0083$), and were associated with oncogenic activity in literature ($p < 0.01$). Top validated reversion genes were enriched in glutamine and glucose usage pathways (OR > 7, padj < 0.09). Top risk-mitigating inhibitors included antiviral Lamivudine (*CMPK1*), antidepressant Phenelzine (*AOC3, GPT1/2*), and antihyperlipidemic Statins (*ABCB1*).

Conclusions: Genome-scale metabolic modeling analysis of LUSC samples uncovered several gene KOs and drugs that may revert precancerous metabolic states to non-cancerous ones. Although these genes and drugs warrant further experimental testing, top candidates were prioritized through and supported by multiple independent computational analyses. This work paves the way for a new class of treatments that may bring tumors closer to a non-cancerous homeostasis instead of the standard-of-care cell killing that too often leaves resistant residual disease.

#4146 Melanocytic transcriptional state is an independent marker of survival in metastatic melanoma.

Ziyin Huang[1], Kristen E. Rhodin[2], Rami Al-Rohil[3], Viviana Geron[2], Arul M. Chinnaiyan[1], Margaret H. O'Connor[2], Christina Vadala Angeles[1], Smita K. Nair[2], Georgia M. Beasley[2], Matthew K. Iyer[1]

[1]University of Michigan, Ann Arbor, MI,[2]Duke University, Durham, NC,[3]University North Carolina, Chapel Hill, NC

Introduction: Advanced cutaneous melanoma shows substantial heterogeneity in clinical outcomes, even among patients classified within the same clinical stage. Understanding the molecular drivers underlying this heterogeneity is critical for advancing treatment strategies. Previous studies have identified distinct melanoma transcriptomic states - Tirosh *et al.* and Balderson *et al.* have agreed on a four-subtype model defining “Undifferentiated”, “Neural Crest”, “Transitory”, and “Melanocytic” states. However, their biological and clinical relevance remains unclear. Here we profiled in-transit melanoma (ITM) using digital spatial RNA profiling to associate melanoma transcriptomic states with overall survival (OS) and acral melanoma (AM) status.
Methods: Digital spatial profiling (Nanostring GeoMx Whole Transcriptome Atlas) was performed across a tissue microarray constructed from patients with ITM diagnosed from 1990-2020. After filtering poor quality areas of interest (AOIs), we processed the data using noise correction and quantile normalization. We applied Principal Component Analysis (PCA) to define melanoma subtype signatures by ranking genes contributing to each of the first four PCs. We performed gene set enrichment analysis using GSEA with significance defined as an adjusted p-value < 0.05. Association between gene or gene-set expression and OS was evaluated using optimal expression cutoffs to define high and low groups, with a minimum group size of 20%. Cox proportional hazards models were then used to assess survival differences between groups.
Results: We analyzed a cohort of 84 patients (116 AOIs) with ITM passing QC. PCA of transcriptional profiles revealed distinct transcriptional states. The PC1 axis differentiated Transitory from Undifferentiated melanoma, PC2 reflected immune cell infiltration, PC3 corresponded to stromal cells and Neural crest-like melanoma, and PC4 associated with Melanocytic melanoma. We derived gene sets from the PCA results and associated the expression of each gene set with OS. Across a cohort of treatment-naïve ITM, high expression of the melanocytic state conferred a median overall survival difference of 7.59 years (melanocytic ‘high’=5.16 years vs ‘low’=12.75 years, log-rank p=0.0024) and independently associated with poor survival in multivariate analysis. AMs showed higher melanocytic state gene expression compared to non-acral cases. These findings were validated in external datasets, supporting that the melanocytic state predicts poor prognosis.
Conclusion: The melanocytic transcriptional state was independently associated with worse overall survival in patients with metastatic melanoma and was enriched in acral melanoma, suggesting that assessment of the melanocytic state may have value for clinical risk stratification.

#4147 CEDAR: A comprehensive database of curated cancer epitopes and receptors.

Zeynep Kosaloglu-Yalcin[1], Ibel Carri[2], Nina Blazeska[2], Randi Vita[2], Daniel Marrama[2], Hannah K. Carter[3], Morten Nielsen[4], Alessandro Sette[2], Bjoern Peters[2]

[1]La Jolla Institute for Immunology, San Diego, CA,[2]La Jolla Institute for Immunology, La Jolla, CA,[3]UC San Diego, La Jolla, CA,[4]Technical University of Denmark, Lyngby, Denmark

The identification of immunogenic cancer epitopes, including patient-specific neoepitopes and shared tumor-associated antigens (TAAs), is a critical foundation for advancing effective cancer immunotherapies. To provide the community with a centralized data source for this research, the Cancer Epitope Database and Analysis Resource (CEDAR, cedar.iedb.org) offers the most extensive and actively updated collection of experimentally validated cancer epitope and receptor data. Currently, CEDAR hosts data from 6,242 publications, encompassing 152,636 T Cell Assays, 143,715 B Cell Assays, and 4,394,087 MHC Ligand Assays, covering 666 distinct restricting MHC alleles.

CEDAR's comprehensive catalog includes neoepitopes, oncoviral epitopes, and TAAs, storing both positive and negative immune responses across human, mouse, and other species. The central element of the database is the experimental data validating these tumor molecule interactions; assay information is meticulously reported, including the specific assay types (e.g., ELISpot, tetramer staining, mass spectrometry) used to confirm T cell, B cell, and MHC binding/presentation. Furthermore, the database stores T and B cell receptors known to specifically recognize these epitopes.

The strength of the CEDAR lies in its rigorous and transparent curation process. All entries are curated by PhD-level scientists following a publicly available curation manual that outlines specific, consistently applied rules for data extraction, validation, and annotation. Curators use extensively validated workflows that combine automated text-mining with detailed manual review to ensure completeness and accuracy. Data is annotated in a highly structured way using community-supported ontologies, such as Uniprot, the Disease Ontology, and The Ontology for Biomedical Investigations (OBI), among others. This high degree of standardization ensures data accuracy, maximizes interoperability, and enables users to perform highly granular queries, filtering by species, MHC molecules, cancer pathology, antigen type, and specific source antigens.

As an integral and freely accessible companion site to the Immune Epitope Database (IEDB), CEDAR serves as a critical foundation for basic and translational immuno-oncology research. It provides the high-quality, trusted experimental data necessary for validating predictive models, designing targeted therapeutics, and exploring the landscape of tumor immunity.

#4151 Phone-based portable slide digitization system for AI-enabled histopathology.

Sergii Domanskyi[1], Todd Sheridan[2], Javad Noorbakhsh[1], Jeffrey H. Chuang[3], **Jill Carol Rubinstein**[4]

[1]The Jackson Laboratory for Genomic Medicine, Farmington, CT,[2]Hartford Healthcare, The Jackson Laboratory for Genomic Medicine, Farmington, CT,[3]The Jackson Laboratory, Farmington, CT,[4]Hartford Healthcare, UCONN School of Medicine, The Jackson Laboratory for Genomic Medicine, Farmington, CT

In traditional histological analysis, pathologists view glass slides using light microscopy. Increasingly, slides are being digitized with high-resolution scanners. Digital pathology has great potential to mitigate disparity in access to specialized cancer care and allows application of artificial intelligence (AI)-based tools for analysis, but digitization costs can be prohibitive. We developed a phone-based system to digitize, visualize, and automate analysis using video capture and image stitching to generate whole slide images, overcoming the innate limitation in phone lens field of view. Our system provides digital pathology capability without need for specialized equipment. A cell phone with attached microscope lens is placed on a custom, 3-D printed rig with light source for smooth video capture across transilluminated slides. We demonstrate system efficacy using Apple iPhone 16 pro + Sandmarc lens. The Telepath is our original app, using 5x optical zoom, locked exposure, fixed white balance, and continuous autofocus to capture video with consistent lighting and color at 60 frames per second. Overlapping images are extracted and aligned with Scale Invariant Feature Transform descriptors and Fast Library for Approximate Nearest Neighbor matcher. After illumination correction, images are stored in TIFF format. Numerical tile-level AI-features are extracted with CTransPath and used to train classification models. The Telepath was used to digitize 24 histology slides prepared from PDX melanoma specimens. Video capture required 0.5 to 2 minutes/slide based on tissue size. Final resolution was 0.57 microns per pixel with average file size of 20 MB. Pathologist review confirms subjective image quality is ample for review. An automatic tumor detection model trained on images digitized on a commercial scanner was tested on images digitized on The Telepath, achieving recall 0.943 ± 0.096, precision 0.763 ± 0.25, accuracy 0.891 ± 0.047, fpp (size-adjusted fpr) 0.094 ± 0.046. We present a portable, affordable, AI-enabled digital pathology system that takes specimens from glass slides to annotated digital images. Given the portability and speed of the system, we envision such applications as direct upload of images to the medical record for secondary or centralized pathology review, automated assessment of prospective donor organs during procurements, and both permanent and frozen section analysis of surgical specimens for such tasks as tumor margin assessment and detection of lymph node metastases. The Telepath dramatically decreases financial and temporal barriers to the implementation of digital pathology, with potential to mitigate disparity in access to specialty care and open the door to broader application of AI-based tools.

#4152 Identification and phenotypical evaluation of androgen receptor indifferent phenotype in treatment-naïve primary prostate cancer cases.

Tessa Tolson[1], Beatrice Knudsen[2], Wei Zhang[3], Mason Hovinga[2], Chance Walker[2], Galaxy Yang[4], Erika Egal[3], Yosep Chong[5], Michael Freeman[4], Yi Qiao[1]

[1]Department of Biomedical Informatics, University of Utah, Salt Lake City, UT,[2]Department of Pathology, University of Utah, Salt Lake City, UT,[3]Huntsman Cancer Institute, Salt Lake City, UT,[4]Cedars Sinai Health System, Los Angeles, CA,[5]The Catholic University of Korea Uijeongbu St. Mary's Hospital, Uijeongbu, Korea, Republic of

INTRODUCTION: High-grade, locally advanced primary prostate cancer (PC) carries an increased risk of metastatic progression. The Androgen Receptor indifferent (ARi) phenotype is characterized by low PSA expression despite high expression of AR and has been noted in CRPC where it is considered to be induced by treatment. We sought to examine primary, treatment-naïve PC cases for evidence of ARi.

METHODS: We applied digital pathology and multiplexed, single-cell resolution tissue staining techniques to a locally advanced PC patient cohort with 27 patients and computational RNA expression analysis to the TCGA prostate cancer dataset (TCGA-PRAD). Thus, we first quantify AR and PSA protein expression levels in cells and then identify tissue regions with >30% AR+ cells and <30% PSA+ cells as ARi cases. The PC regions we analyzed include seminal vesicle invasion (SV), lymph node metastasis (LN), extracapsular extension (ECE), perineural invasion (PNI), cribriform (CRIB), and non-cribriform (HGNC). For computational analysis of the TCGA bulk RNA sequencing data, we stratify patients according to high AR / low PSA (ARi-cohort) and high AR / high PSA (AR responsive, or ARr-cohort) and perform differential expression and gene set enrichment analysis accordingly.

RESULTS: Pathologically, we identified ARi phenotype in one or more tissue samples from 5 out of 27 patients. ARi is more frequent in LN compared to SV; and within the prostate, HGNC exhibited more ARi than CRIB. Computational analysis of the TCGA-PRAD cohort (n=500) revealed that ARi patients, compared to AR-responsive patients, are enriched in epithelial-mesenchymal transition (EMT), stem-like, and ONECUT2-induced gene signatures. Moreover, we demonstrate that ARi phenotype is strongly associated with the Prostate Cancer Subtype 1 (PCS1) and PAM50 Basal subtype, consistent with the aggressiveness of the disease.

CONCLUSION: We identified the ARi phenotype in two cohorts of primary PC patients using both tissue staining with single cell resolution and computational analysis of bulk RNA expression. We further characterized this phenotype using published gene signatures and determined its relationship to PCS and PAM50 subtypes. Furthermore, we propose that the presence of the ARi phenotype can be assessed quickly by clinical immunohistochemistry with AR and PSA antibodies followed by quantification of positive ARi cells (as defined by a high AR:PSA ratio). Moving forward, we will perform single cell RNA expression analysis on the cohort we performed tissue staining to further validate the presence and behavior of ARi phenotype in primary PC, expand into other cohorts, as well as evaluate treatment strategies likely to elicit a response in these cells according to their transcriptomic phenotypes.

#4153 Advancing precision oncology through tumor digital twins: A versatile ViT-determined margin-consistent model for lung adenocarcinoma histopathologic subtyping in hematoxylin-eosin images.

Meghdad Sabouri Rad[1], Mohammad Mehdi Hosseini[1], Muhammad Hassaan Khalid[2], Saverio J. Carello[1], Michel R. Nasr[1], Rossana Kazemimood[3], Ola El-Zammar[1], **Bardia Rodd**[1]

[1]SUNY Upstate Medical University, Syracuse, NY,[2]University of Texas Health Science Center at Houston, Houston, TX,[3]Pathology, University of Texas Health Science Center at Houston, Houston, TX

Background: Digital twin frameworks in oncology require a stable, patient-specific histologic representation of tumor architecture. However, current LUAD subtyping models are vulnerable to stain and scanner variability, domain shift, and poor probability calibration. We investigate whether a state-space/Transformer hybrid with attention and margin-aware training can generate a robust, calibrated “morphology twin” suitable for integration into future tumor digital-twin systems.
Methods: A uniform patch-aggregation WSI pipeline was implemented with identical tiling, Macenko normalization, augmentations, and optimization across all backbones. From 143 FFPE H&E WSIs in BMIRDS-LUAD, we extracted 203,226 tissue patches (224×224 at 20×). Patches were encoded using ResNet50/101, ViT-L, or a state-space/Transformer hybrid (MambaVision). Slide-level predictions were produced via gated-attention MIL and a linear classifier whose logit gaps define decision margins. Training employed cross-entropy combined with a supervised representation term, without handcrafted harmonization or test-time adaptation. Internal development used a WSI-stratified split across five LUAD growth patterns. Zero-shot external evaluation used WSSS4LUAD. Endpoints included accuracy, subtype-specific AUC, feature-margin concordance, internal-to-external performance drop, calibration (ECE/Brier), and run-to-run variability across 10 seeds.
Results: On BMIRDS-LUAD, MambaVision+attention achieved 96.40±3.32% accuracy with ROC-AUC ≥0.99 across all subtypes and strong feature-margin alignment (τ=0.88 train / 0.64 validation). Errors were largely confined to mixed-pattern or low-quality slides. Zero-shot transfer to WSSS4LUAD yielded 83.69±7.76% accuracy—the smallest performance drop (–12.71 points) among all backbones. Calibration improved in-site and out-of-site (ECE/Brier: 0.043/0.098 internal; 0.087/0.154 external), with statistically significant gains over ResNet and ViT baselines. Variability across seeds narrowed (3.32% vs 6.12% for ResNet50), indicating enhanced training stability.
Conclusions: This framework addresses key LUAD subtyping failure modes—cross-site instability, overconfident boundary errors, and limited reproducibility. By integrating state-space modeling, Transformer attention, and margin-consistent learning, it produces a calibrated morphology twin that preserves subtype discriminability under domain shift and provides more trustworthy WSI-derived probabilities. While not a complete cancer digital twin, it forms a robust histologic module for integration into next-generation multimodal and temporal LUAD digital-twin systems.

#4154 Graph theoretic spatial heterogeneity analysis of multiplexed immunofluorescence images enables quantitative differentiation of HGSC precursor lesions in the fallopian tube.

Thomas Jacob[1], T. Rinda Soong[2], Shikhar Uttam[3]

[1]University of Pittsburgh School of Medicine, Pittsburgh, PA,[2]Pathology, University of Pittsburgh, Pittsburgh, PA,[3]Computational and Systems Biology, University of Pittsburgh, Pittsburgh, PA

Background: p53 signatures, serous tubal intraepithelial lesions (STILs), and serous tubal intraepithelial carcinomas (STICs) represent the precursor spectrum of high-grade serous carcinoma (HGSC), with STICs identified in 50-60% of HGSC cases. These lesions harbor TP53 mutations and exhibit similar genomic alterations to invasive HGSC, yet only a subset of these progress to malignancy. Studies suggest a close to a decade long latency period between STIC formation and invasive disease, creating a critical window for intervention. However, the factors determining malignant transformation remain poorly understood and quantified. Critically, the immune microenvironment of these precursors remains quantitatively uncharacterized. Specifically, we lack quantitative metrics associating lymphocytes, immunosuppressive cells, and immune checkpoint expressions in p53 signatures, STIL, and STIC lesions that are concordant with HGSC risk. Quantitative understanding of whether immune escape mechanisms are established early or develop during progression could identify microenvironment biomarkers that predict risk of individual lesions becoming invasive.

Method and Results: Toward this goal, we have developed a spatial heterogeneity analysis (SHEAN) framework for multiplexed immunofluorescence (mIF) that utilizes graph-theoretic representations of fallopian precursor tissue samples to identify quantitative spatial immune signatures that (1) characterize and distinguish normal epithelium (Norm), p53 signatures, STICs, and HGSCs from each other; (2) are sensitive to TP53 mutation status; and (3) can differentiate STICs based on their flat (FLAT) and budding, loosely adherent or detached (BLAD) status. These statistically significant features, confirmed at the image level, include signatures associated with degree of infiltration into, and interaction between T-lymphocytes, M2 polarized macrophages, and epithelial cells. SHEAN also achieved a cross-validated area under the ROC curve (AUROC) of 87.4% in discriminating Norm, p53 signatures, STICs, and HGSCs based on a bootstrapped model that included 53 normal, 68 p53 signatures, 73 STIC, and 32 HGSC regions and used an XGBoost classifier.

Conclusions: SHEAN allows the quantification of immune spatial metrics of the HGSC precursor microenvironment, providing an interpretable, spatially informed model capable of discriminating between lesion categories and enabling the reliable stratification of HGSC risk.

#4155 Development of a virtual Cyclin E1 biomarker using Deep Learning from H&E slides for predicting Cyclin E1 overexpression in gynecological malignancy.

Jeannette Fuchs[1], Kenneth To[2], Christopher Jackson[2], Lawrence Schobs[2], Rohan Lyons[2], Rafay Azhar[2]

[1]Translational Medicine, Debiopharm International S.A., Lausanne, Switzerland,[2]ViewsML, Vancouver, BC, Canada

The purpose of this study was to develop and validate a virtual immunohistochemistry (vIHC) algorithm capable of predicting Cyclin E1 (CCNE1) protein expression from hematoxylin and eosin (H&E)-stained whole-slide images in gynecological malignancy encompassing primarily high-grade serous ovarian carcinoma (HGSOC) and uterine serous carcinoma (USC). CCNE1 is a key cell-cycle regulator whose gene amplification (copy number ≥6) correlates strongly with protein overexpression (H-score >50) and enhanced sensitivity to WEE1 inhibitors. Conventional IHC requires precious tissue and additional laboratory processing; the ViewsML virtual biomarker platform derived from routinely available H&E slides provides a scalable alternative to accelerate patient selection for targeted therapy.

H&E and matched Cyclin E1 IHC whole-slide images were provided by Debiopharm. Sixty paired digital slides (40 HGSOC and 20 USC) were analyzed. The dataset was divided into training (n=45), validation (n=6), and testing (n=9) cohorts. ViewsML utilized neural network models trained to learn morphological and nuclear features predictive of Cyclin E1 expression intensity (0-3+). Model performance was evaluated using per-cell sensitivity, specificity, and concordance with physical IHC intensity and H-score classifications, including ROC AUC metrics. Concordance between predicted and true Cyclin E1 expression was evaluated through nuclear localization distinguishing weak, moderate, and strong staining patterns, allowing quantitative assessment of Cyclin E1-positive tumor fractions across HGSOC and USC.

In conclusion, this study demonstrates the feasibility of an AI-driven virtual biomarker for Cyclin E1 that can predict protein overexpression directly from H&E slides. The virtual IHC approach conserves valuable tissue and accelerates biomarker screening for patient selection, facilitating improved enrichment for Cyclin E1-associated therapeutic trials. Future applications include integration with multiplex virtual markers to further enhance clinical applicability.

#4156 Comprehensive 40-marker cyclic IF panel for spatial profiling of head and neck squamous cell carcinoma.

Danielle Fails, Alyssa Hernandez, Mike Spencer

Bethyl Laboratories, Montgomery, TX

Introduction

Head and neck squamous cell carcinoma (HNSCC) incidence has increased by at least 23 % globally over the last ten years and is predicted to continue to rise by 30 % annually. Treatment for HNSCC often includes a multidisciplinary approach (i.e., chemotherapy + surgery) but success rates are still limited with less than half surviving more than two years post-treatment (Nieszporek et al., 2025). Significant improvements in the number of biomarkers that can be screened at once, while preserving tissue integrity, have been made over the last decade. These staining and imaging improvements have contributed to the identification of novel therapeutic targets while limiting the egregious use of precious tissues. This study aimed to interrogate the tumor microenvironment of head and neck squamous cell carcinoma using the same tissue slice using a fully automated cyclic IF system.

Methods

Two panels of 20 biomarkers each were designed using immune markers, tissue architectural markers, and specific targets of interest in head and neck squamous cell carcinoma. *Panel 1* was comprised of I/O markers (CD3, CD4, CD8, FoxP3, CD56, CD20, CD68, CD11c, aSMA, PD-L1, PD-1, CD45, CD27, CTLA-4, CD19, PCNA, CD14, CD16, SOX10, CD79a) while *Panel 2* was largely comprised of discovery markers (ALDH2, IL-8, CK17, MMP9, MAGE-A4, EpCAM, EGFR, CK14, CK19, CK5/6, p53, CD44, ZEB1, ZEB2, beta-Catenin, E-Cadherin, Vimentin, COL1A1, COL4A1, FAP). Optimization was achieved using FFPE tissue microarrays containing normal and cancerous skin tissues. Pre-processing steps were done in the Epredia© PT Module using Tris-EDTA ph9 solution, at 100°C, for 1 hour. Panel 1 was stained first followed by Panel 2 without removal of the tissue from the instrument. Automated immunofluorescent staining and imaging of the samples was performed on the Lunaphore COMET™ system.

Results

The sequential staining of two 20-plex protein panels on the same tissue demonstrates the COMET's capability of maximizing the number of biomarkers that can be evaluated. This protocol significantly reduces the use of tissue necessary, helps maintain tissue integrity for downstream processing (i.e., H&E staining), and minimizes costs by reducing chip and reagent use.

Conclusions

This comprehensive interrogation of the HNSCC tumor landscape with the use of high-plex, fully automated sequential immunofluorescent staining highlights many of the capabilities of the latest spatial technologies. In using this approach, deeper dives of tumor microenvironments can be achieved with minimal tissue use while keeping reagent and material costs low. References: 1.

#4157 Spatial immune profiling of solid tumors by complementing H&E with a novel 17-plex immunofluorescence approach.

Richard Van Krieken, Jaspreet Kaur, Xun Li, Naveen Dakappagari, Jennifer Bordeaux

Navigate BioPharma Services, Inc., Carlsbad, CA

Background: Spatial biology has increasingly leveraged “spatial neighborhoods” to integrate how cells are organized and interact, yet standards for defining and identifying these neighborhoods are still developing. Multiplex fluorescence immunohistochemistry (fIHC) offers detailed profiling of immune and tumor cell states, while hematoxylin and eosin (H&E) staining remains a gold standard for visualizing tissue and cellular morphology. We validated a 17-plex fIHC assay on the Orion™ (RareCyte) platform and aligned the fIHC with same slide H&E images to improve fidelity of cellular neighborhoods identification across breast, lung, prostate, melanoma, and colorectal cancers.
Methods: We developed a generalizable workflow to align same-slide H&E and 17-plex fIHC Orion images for assessment of cellular neighborhoods through integration cell phenotyping (via fIHC) with tissue architecture (via H&E). The 17-plex fIHC assay includes antibody-fluorophore conjugates targeting Granzyme B, Ki67, CD3e, CD20, CD4, CD163, CD8a, PD-L1, NKp46, PD-1, LAG3, FOXP3, CD11b, CD138, SOX10, Cytokeratin, and Hoechst nuclear stain. Slides were first stained and imaged by fIHC, followed by H&E staining and imaging on the Orion. Cell phenotyping and slide registration were performed on HALO® (Indica Labs).
Results: Integrating H&E with multiplex fIHC supported identification of spatial themes, including regions with enriched tumor-infiltrating lymphocytes, immune deserts, and mixed/transitional zones populating the tumor/stroma interface. This approach improves interpretability of these patterns by connecting cell phenotypes with tissue architecture morphology, supporting identification of microenvironments with greater consistency.
Conclusions: Combining H&E with multiplex fIHC enables anatomically informed mapping of cellular neighborhoods across multiple tumor types. This discovery-oriented workflow improves interpretability of spatial patterns, is adaptable to diverse datasets and pipelines, and may yield new insights into the immune microenvironment to inform next-generation therapies.

#4158 Cell lines as quality controls for Quantitative Continuous Scoring (QCS) of IHC stained samples.

Ana Hidalgo-Sastre[1], Tze Heng Tan[1], Nicolas Giraldo[2], Nathalie Harder[1], Sophia Varriano[3], Andrew Kunihiro[3], Guenter Schmidt[1], Hadassah Sade[1], Yeoun Jin Kim[3], Marlon Rebelatto[3], **Mark Gustavson**[3]

[1]AstraZeneca, Munich, Germany,[2]AstraZeneca, Barcelona, Spain,[3]AstraZeneca, Gaithersburg, MD

Background: Effectively measuring therapeutic target expression is critical in oncology for precise and accurate patient selection. Target expression is often measured by immunohistochemistry (IHC) using visual pathology scoring; however, digital pathology-based Quantitative Continuous Scoring (QCS) has emerged as a more precise and accurate alternative[1]. Given that IHC assays and whole slide image (WSI) scanners have known variability, we designed a proof-of-concept study to evaluate the applicability of using cell lines as quality controls for QCS scoring of IHC stained samples.
Methods: A panel of cell lines (N=10) were selected to represent a broad range of target expression and cultured as cell pellets into a Formalin-Fixed Paraffin Embedded (FFPE) Cell Micro Array (CMA) for downstream IHC analysis with QCS. The CMA was sectioned (4 µm) and stained with a target antibody according to standard protocols. The stained slides were scanned at 40x, and images were analyzed using a trained QCS deep-learning based QCS model that quantifies membrane staining intensity (SI).
Results: Cell line controls showed highly consistent QCS staining intensity (SI) scores through the entire CMA block (n=40 sections). SI from triplicates run on the same day were compared among each other or across days with a coefficient of variation (CV) <10% for each cell line, demonstrating a high level of precision and reproducibility through the entire cell line pellet. Additionally, cell density was also consistent throughout the FFPE block. Moreover, we observed highly significant correlation (R=0.98) between QCS SI and mass-spectrometry results, thus demonstrating specificity for assessing target expression in cell lines. Finally, early experiments with contrived assay variability showed the ability of cell lines to track the 32% contrived variability observed in tissue and correct that variability to 7%, thus supporting the use of cell lines to potentially improve IHC/QCS precision and reproducibility.
Conclusion: These data support the feasibility of using cell lines as qualitative controls for QCS scoring of IHC stained samples. Given that heterogeneity of expression is not a significant factor like it is in tissue, cell lines provide consistent expression throughout the entire block with a high degree of precision and reproducibility. These data thus support the potential for integrating cell line controls into the quality assurance pipeline for QCS-based IHC measurements in the laboratory setting. Further, cell line quality controls could also be used for bridging and comparability, thus enabling efficient and robust development of QCS assays.[1] Kapil et al. “HER2 quantitative continuous scoring for accurate patient selection in HER2 negative trastuzumab deruxtecan treated breast cancer”. Nature Sci Rep. 2024 May 27;14(1):12129.

#4159 Automated robust normalization and context-aware rescue of TReg cells from multiplex immunofluorescence.

Joao Paulo Oliveira da Costa, Alina Ainbinder, Kenneth Trieu, Henry Reinhart, Yury Sheikin

Pathology, Takeda Pharmaceutical Company Ltd. (U.S.), Cambridge, MA

CCR8^{+}FoxP3^{+} regulatory T cells (Tregs) are a key immunosuppressive subset in solid tumors, but their accurate quantification in multiplex immunofluorescence (mIF) is hindered by slide-to-slide staining variability, dim FoxP3 signal, and background-driven CCR8 false positives. We developed a fully automated, background-aware R pipeline for robust cross-slide calling of CCR8^{+}FoxP3^{+} cells from HALO single-cell data across NSCLC, CRC, GEJ, and HNSCC.Single-cell intensities for CCR8 and FoxP3 were transformed using inverse hyperbolic sine and normalized per slide using robust z-scores (rz) computed from medians and MADs, with fallbacks when FoxP3^{-} or CCR8^{-} reference populations were sparse. FoxP3 positivity was reassessed using a two-stage approach: (i) “soft” FoxP3 calls integrating HALO labels with high-rz outliers, and (ii) a strict rescue rule in which each cell’s FoxP3 rz was evaluated against the empirical FoxP3^{-} distribution, requiring both a minimum rz floor and low FoxP3 background-z, preventing inflation of false positives.
CCR8 calling used a spatially explicit background model: slides were partitioned into fine spatial bins, and CCR8 background medians and dispersions were estimated from local CCR8^{-} cells, with smoothing across sparse regions. This produced a background z-score (bg_z) and a background-adjusted CCR8 rz (rz_bg). From these, we defined a lenient background-aware CCR8 call and a strict CCR8 keeper enforcing strong evidence and artifact filters (cytoplasm completeness, CK negativity, nucleus quality).
Final CCR8^{+}FoxP3^{+} assignments used a FoxP3-aware rule: FoxP3^{+} cells were evaluated with lenient CCR8 criteria to recover dim true positives, whereas FoxP3^{-} cells required the strict CCR8 keeper to prevent spurious double-positive inflation. Agreement analyses showed that the strict CCR8 criteria substantially reduced Halo-only artifacts while adding very few “rescued-only” events. Conversely, FoxP3 soft-rescue recovered dim nuclei primarily in low-background regions.
Processing was optimized using Arrow to avoid loading full datasets into memory, enabling analysis of >10 million cells on a standard workstation. The combined FoxP3 normalization, empirical rescue, and CCR8 background-aware gating produced stable distributions across indications and improved both sensitivity and specificity for CCR8^{+}FoxP3^{+} Treg quantification.

#4160 Ensuring pathologist alignment to safeguard data integrity in multi-centre oncology IVD/CDx clinical trials.

Lindsey Bennie, Bethany Montgomery, David Ribeiro

ARC Regulatory, Belfast, United Kingdom

Background: Multi-centre oncology clinical trials increasingly rely on digital pathology and distributed specialist review, resulting in a heightened risk of inter-pathologist variability. Without robust alignment, differences in tissue interpretation can skew patient inclusion, compromise assay performance, and ultimately threaten the validity of clinical investigations for In Vitro Diagnostic (IVD) and companion diagnostic (CDx) development. Objective: To demonstrate the critical importance of pathologist alignment and the impact of structured interpretation guidance on assay concordance in a multi-reviewer setting.

Methods: ARC Laboratories evaluated the effect of pathologist alignment using a gastric cancer cohort (n=20). FFPE samples were stained with a CLDN18 antibody (Ventana CLDN 18 43-14A) on the BenchMark UltraPlus platform. In Phase 1, two independent, CLDN18-trained gastrointestinal pathologists assessed tumor content, tumor positivity, and percentage tumor involvement without a pathology manual or consensus meeting. In Phase 2, both pathologists underwent an alignment process including a pre-read, defined pathology interpretation manual, and agreement meeting before reassessment.

Results: In the unaligned phase, pathologists agreed on tumor positivity in only 8/20 cases. Tumor content and percentage tumor interpretation differed by up to 50%, resulting in assay performance that would not meet validation acceptance criteria. Following alignment, concordance increased substantially: 18/20 cases met agreement for tumor positivity, and differences in tumor content estimation decreased to ≤20%. Under these conditions, the assay met all required validation parameters and was deemed suitable for use in clinical trials.

Conclusion: This study highlights that even highly trained subspecialist pathologists can exhibit significant variability without structured alignment tools. A defined pathology manual and consensus process markedly improve concordance and are essential for ensuring assay validity in multi-centre or digitally enabled IVD/CDx trials. ARC's findings underscore that systematic pathologist alignment is not optional—it is a foundational requirement for generating reliable, regulatory-ready clinical data.

#4161 Validation of the ViewsML vIHC platform for biomarker classification and intensity binning: A pilot collaboration with Histowiz's PathologyMap platform.

Akash Parvatikar[1], Patrick Savickas[1], Chris Lee[1], Jeffrey Shek[1], Kenneth To[2], Christopher Jackson[2], Lawrence Schobs[2], Rohan Lyons[2], Rafay Azhar[2]

[1]HistoWiz, Long Island City, NY,[2]ViewsML Technologies Inc., Vancouver, BC, Canada

The purpose of this study was to validate ViewsML's Virtual Immunohistochemistry (vIHC) platform, a system that generates virtual biomarker predictions based on H&E whole slide images. This collaboration with Histowiz's PathologyMap platform enables evaluation of vIHC deployment across the PathologyMap database, demonstrating its potential as a scalable and practical alternative for biomarker discovery workflows. Board-certified anatomic pathologists procured 50 lung carcinoma cases for analysis. Formalin fixed paraffin embedded (FFPE) blocks were cut to 4 µm in quadruplicate onto positively charged slides. Each slide was stained with a GLP-regulated H&E stain and digitally scanned on a Leica AT2 onto the Histowiz PathologyMap platform. Slides were then de-stained and re-stained on a Leica BOND Rx platform with CD68, αSMA, and Pan-CK immunohistochemistry markers, and re-scanned. The resulting whole slide images (WSIs) were processed by ViewsML to train AI models to predict IHC expression from H&E images. For each biomarker, paired H&E and IHC WSIs were first spatially registered to ensure precise alignment. The paired data were randomly divided into training (75%), validation (10%), and test (15%) sets. Supervised machine-learning models were trained to predict IHC expression intensity from the corresponding H&E image, using the corresponding physical IHC as supervision. Evaluation was performed on the hold-out test set to verify performance. Once trained, these models enable biomarker predictions directly from a single standard H&E slide. The virtual markers demonstrated high classification performance, with per-cell ROC-AUC values of 0.94 for CD68, 0.92 for PanCK, and 0.95 for SMA. The model predicted per-cell stain intensity across millions of cells, preserving biological variability across expression ranges and tissue compartments.This collaboration validates ViewsML's virtual staining as a reliable computational alternative to physical IHC, capable of both qualitative and quantitative biomarker assessment. Integration with Histowiz's digital pathology infrastructure demonstrates the feasibility of embedding vIHC within scalable workflows for biomarker research, WSI repository annotation, and assay standardization. These findings support further multi-institutional expansion of ViewsML to enable robust, reproducible, and cost-efficient biomarker evaluation.

#4162 AI-based detection and scoring of TROP2 expression in IHC-stained NSCLC specimens.

Jeff Lock, Adam Hsiung, Kevin Gallagher, Harry Nunns, Nam Tran, Ben Ovadia, Arezoo Hanifi, Qingyan Au

Neogenomics Laboratories, Inc., Aliso Viejo, CA

Lung cancer is the leading cause of cancer-related deaths in the United States and non-small cell lung cancer (NSCLC) accounts for approximately 85 percent of all lung cancer cases[1,2]. Trophoblast cell-surface antigen 2 (TROP2), a transmembrane glycoprotein that normally serves as a Ca^{2+} signal transducer linked to cell growth, proliferation, and migration, is frequently observed in NSCLC and elevated expression levels are associated with increased metastatic risks and poor prognostic outcomes. Due to the adverse effects of TROP2 on NSCLC, as well as on many other common cancers, strategies such as antibody-drug conjugates (ADCs) and CAR-NK cells targeting TROP2 expressing tumors have emerged as areas of active investigation and therapeutic development. To serve these efforts, we present an end-to-end workflow for the quantification of TROP2 expression in NSCLC specimens that consists of an IHC staining assay optimized for the detection of TROP2 in FFPE tissue sections together with AI-based image analysis routine for the automated scoring of TROP2 tumor expression in whole-slide image (WSI) specimens. Our analysis algorithms were highly concordant to manual interpretation by pathologists when evaluated using Pearson's correlation coefficient, demonstrating both accurate tumor identification and TROP2 expression scores. By integrating our TROP2 IHC assay with algorithmic image analytics, we offer a comprehensive, scalable solution for discovery-based research efforts and clinical drug trials focused on TROP2 in NSCLC.

#4163 A general-purpose AI foundation model for spatial proteomics.

Andrew H. Song[1], Anurag Vaidya[2], Muhammad Shaban[1], Yuzhou Chang[1], Huaying Qiu[1], Yao Y. Yeo[1], Guillaume Jaume[1], Wenrui Wu[1], Qin Ma[3], Sizun Jiang[1], Faisal Mahmood[1]

Standard spatial proteomics (SP) pipelines for biomarker discovery have traditionally relied on cell segmentation followed by single-marker thresholding or rule-based mechanisms to assign cell phenotypes. However, this often suffers from a laborious process of manual annotations and neglects cell states characterized by the coordinated expression of multiple markers as a function of the cellular spatial organization. Moreover, converting the preprocessed cells to actionable biological insights on the cohort level is time-consuming due to its iterative nature of hypothesis generation and testing. We sought to build an AI foundation model trained on a large body of spatial proteomics datasets to address these challenges and further accelerate crucial spatial biology tasks in a platform-agnostic manner.

We present KRONOS, a foundation model for spatial proteomics that operates directly on segmentation-free multiplex image patches. KRONOS extends the self-supervised learning recipe proven to be successful for several pathology foundation models to spatial proteomics, by employing a Vision Transformer architecture that can flexibly handle the variable number of protein markers and simultaneously encode the protein expression levels and the known biological properties of the protein. The training dataset for KRONOS consists of 47 million single-marker patches spanning 175 protein markers, 16 tissue types, eight fluorescence-based imaging platforms, across five different institutions. This diverse and large-scale dataset allows KRONOS to learn rich, low-dimensional image representations that effectively capture spatial protein expressions jointly across different markers.

We evaluate KRONOS across a diverse range of downstream tasks, including cell phenotyping, tissue artifact detection, and patient stratification, and across diverse disease types such as lymphoma, renal cell carcinoma, and skin cancer. Across these tasks, KRONOS consistently outperforms other pathology (UNI) and spatial proteomics foundation model (CA-MAE) baselines, underscoring the importance of a domain-specific model trained on a large corpus of data. Specifically for cell phenotyping, we show that KRONOS is data-efficient and requires only a few cell annotations, addressing a major bottleneck in spatial proteomics where cell-level annotations are expensive to produce, slow to generate, and difficult to reuse across datasets. Furthermore, KRONOS allows “reverse image search” for identifying similar spatial patterns and biological concepts within and across patient cohorts, facilitating the discovery of clinically relevant tumor microenvironments and protein biomarkers.Together, these results position KRONOS as a general-purpose, foundation model for spatial proteomics that streamlines analysis, reduces annotation burden, and unlocks new opportunities for spatial biomarker discovery.

#4164 Implementation of a diffusion-based color checker for histological image batch correction.

Arman Petrosyants[1], Vaagn Chopuryan[2], Vasiliy Minkov[2], Anna Belozerova[2], **Alexander Bagaev**[2], Viktor Svekolkin[2], Aleksandr Sarachakov[2]

[1]Research Center for Digital Engineering and Innovation, Moscow, Russian Federation,[2]BostonGene Corporation, Waltham, MA

Introduction: Inconsistent tissue preparation, staining, and scanning introduce non-biological variations (batch effects) in histological images. These variations cause machine learning models to learn spurious, site-specific features instead of true pathological patterns, leading to inflated internal performance and poor generalizability and hindering clinical adoption. Current stain normalization methods, such as statistical (Reinhard), color deconvolution (Macenko, Vahadane), and generative adversarial networks, rely on relative normalization to an arbitrary "gold standard," a fundamental limitation. Simple methods often distort important morphological details, while advanced techniques still fail to remove all site-specific signatures.
Methods: We introduce a novel generative AI tool for histological image batch correction using a context-aware Stable Diffusion inpainting model to generate a dynamic localized color checker directly on whole slide images (WSIs). The model was trained to inpaint digital representations of a physical color checker (i.e., NIST Traceable Color Transmission Calibration Slide) onto the masked WSI region, preserving the WSI's original color space and establishing a context-aware standard without external references. Trained using 117 Huron and 119 Polaris scanner IHC and H&E WSIs with ground truth scans using the physical NIST color checker, the model enabled subsequent color extraction and image correction to a desired color space. Validation was performed using 78 Huron and 79 Polaris holdout WSIs. The mean-pooled embeddings derived from the Hibou pathology foundational model were used to predict the WSI's original scanner.
Results: The proposed method mitigated batch effects by transforming the task from simple normalization into a sophisticated form of image restoration. The model uses its powerful learned prior to reconstruct the image as it should appear under ideal, standardized conditions, mitigating site-specific batching.Prior to correction, this classifier achieved an AUC-ROC of 0.99, indicating the presence of strong, non-biological scanner-specific patterns (batch effects). After normalization, the performance of the same classifier dropped (AUC-ROC = 0.53), confirming the elimination of scanner-specific artifacts.
Conclusion: The AI image analysis model offers a robust solution to batch effect challenges in computational pathology, eliminating the need for a reference image during IHC and H&E WSI interpretation. Moving beyond relative color matching, this approach delivers color standardization. By improving robustness to technical batch effects and ensuring AI pathology models are trained on true biological signals, this approach is poised to accelerate the deployment of pathology foundational models across preclinical, translational, and clinical trial settings.

#4165 Advancing high-plex spatial proteomics using cleavable fluorophores and automated multiplex cycling.

Alyssa Hernandez, Danielle Fails

Bethyl Laboratories, Inc., Montgomery, TX

Introduction:
Understanding the spatial distribution of proteins within tissue microenvironments is essential for studying immune responses, tissue organization, and disease processes. High-plex spatial proteomics enables detailed mapping of multiple biomarkers on a single tissue section, but traditional methods can be limited by spectral overlap and fluorophore stability. Parahelia's automated staining workflow delivers a gentle heating step designed to maintain tissue structure over multiple staining rounds.
Methods:
Human formalin-fixed paraffin-embedded (FFPE) tissues were used to develop a high-plex workflow integrating Spatomics' CFP technology with automated staining and imaging by using the Parhelia Spatial Station and the Phenoimager HT. Numerous protein targets can be stained using CFPs, which generates strong, localized fluorescence through an HRP-catalyzed reaction between the CFT and nearby residues. After imaging, the fluorescent tags are efficiently cleaved and HRP is deactivated, allowing repeated cycles without compromising tissue quality or antigenicity. The Parhelia Spatial Station enables multiple samples to be processed simultaneously, automating fluid handling and antibody staining through gentle capillary laminar flow to standardize workflow and minimize variability, while the Phenoimager provides high-resolution, quantitative imaging across cycles.
Results:
Iterative staining and cleavage cycles produced clean signal reset between rounds with consistent biomarker detection maintained throughout the workflow. Imaging confirmed distinct signals for all targets, supporting the robustness and reproducibility of the workflow. The combined use of Spatomics' CFP chemistry, the Parhelia Spatial Station, and the Phenoimager HT enabled repeated staining and imaging on the same FFPE section, allowing a diverse set of protein markers to be visualized within a single slide. Consolidating multiple cycles into one tissue section reduced the number of slides required and increased the amount of spatial information obtainable from limited samples.
Conclusion:
This study demonstrates combining Spatomics' CFP patented chemistry with automated staining and high-resolution imaging. This workflow maintains tissue integrity, sensitivity, and reproducibility, offering a robust platform for spatial biomarker discovery and translational oncology research.

#4166 Molecular diagnosis of lung tumors with a history of pancreatic cancer: Spatial profiling-based differential markers and functional insights into invasive mucinous adenocarcinoma.

Ryunosuke Fujii[1], Kousei Ishimura[1], Kazuhiko Shien[1], Shuta Tomida[2], Kenta Manabe[1], Shunsuke Mori[1], Kazuya Hisamatsu[1], Ryota Fujiwara[1], Atsushi Matsuoka[1], Ryo Yoshichika[1], Kazuhiro Okada[1], Yuma Fukumoto[1], Haruchika Yamamoto[1], Kumi Nakajima[1], Shin Tanaka[1], Hidejiro Torigoe[1], Ken Suzawa[1], Kentaroh Miyoshi[1], Mikio Okazaki[1], Seiichiro Sugimoto[1], Hirofumi Inoue[2], Kosei Takagi[3], Hidetaka Yamamoto[4], Shinichi Toyooka[1]

[1]Thoracic, Breast and Endocrinological Surgery, Okayama University Graduate School of Medicine, Dentistry and Pharmaceutical Sciences, Okayama, Japan,[2]Center for Comprehensive Genomic Medicine, Okayama University Hospital, Okayama, Japan,[3]Gastroenterological Surgery, Okayama University Graduate School of Medicine, Dentistry and Pharmaceutical Sciences, Okayama, Japan,[4]Pathology and Oncology, Okayama University Graduate School of Medicine, Dentistry and Pharmaceutical Sciences, Okayama, Japan

Background: Differentiating pancreatic cancer lung metastasis (PCLM) from primary lung cancer, particularly invasive mucinous adenocarcinoma (IMA), sometimes be difficult due to their pathological similarities such as mucin production. This study aimed to identify diagnostic markers for distinguishing IMA from PCLM and to elucidate the molecular pathogenesis of mucinous lung adenocarcinoma using spatial multi-omics analyses.
Methods: We performed spatially resolved transcriptomics by GeoMx digital spatial profiler on surgically resected lung tumors, from nine patients with a history of pancreatic cancer and three patients of IMA without such history. Multiple regions of interest (ROIs) were selected in tumor components from each sample. Based on GeoMx results, validation was performed by immunohistochemistry (IHC) on tissue specimens. Subsequently, functional analysis was conducted using the lung adenocarcinoma cell line.
Results: By spatial transcriptomics profiling, positive UGT2B15 and negative S100A4 were suggested as candidate markers for distinguishing IMA from PCLM. The expression status of these proteins were confirmed by IHC on tissue specimens. Transcription factor analyses suggested that HNF1A was involved in UGT2B15 expression in the IMA, and functional analyses using lung cancer cell lines also demonstrated these associations.
Conclusion: We identified UGT2B15 and S100A4 as potential candidate markers for distinguishing IMA from PCLM. The involvement of the transcription factor HNF1A in the expression of UGT2B15 in the IMA was suggested.

#4167 Virtual inference of collagen architecture from H&E to characterize stromal fiber morphology and organization in colorectal cancer.

Harsimran Kaur[1], Minh-Khang Le[2], Arkadiusz Gertych[2], Maha Guindi[2], Jun Gong[3], Alexandra Gangi[2], Kyle Coleman[2], Jane C. Figueiredo[4], Xiaoying Liu[5], Louis J. Vaickus[5], Keluo Yao[6], Ken S. Lau[7], **Joshua Jay Levy**[2]

[1]Vanderbilt University School of Medicine, Nashville, TN,[2]Cedars-Sinai Medical Center, Los Angeles, CA,[3]Cedars-Sinai Medical Center, Studio City, CA,[4]Samuel Oschin Comprehensive Cancer Institute, Los Angeles, CA,[5]Dartmouth-Hitchcock Medical Center, Lebanon, NH,[6]Cedars-Sinai, Los Angeles, CA,[7]Vanderbilt University Medical Center, Nashville, TN

Background: Collagen architecture is a key determinant of colorectal tumor progression, influencing immune exclusion, fibroblast differentiation, and tumor budding, and plays a central role in shaping the tumor microenvironment. Although image analysis algorithms exist to quantify collagen features such as fiber density, orientation, and organization, but typically require specialized stains like picrosirius red (PSR). Computational methods that infer collagen phenotypes directly from H&E slides could enable larger studies of spatial tumor matrix biology and support development of prognostic imaging biomarkers.

Methods: In this pilot study, four colorectal cancer slides were stained with H&E and imaged, then restained with PSR, and re-imaged. Co-registered stromal patches yielded 40,740 training/validation and 4,528 real PSR and H&E test image patch pairs. Two generative image-to-image translation models, pix2pix and a latent diffusion model were trained to generate virtual PSR (vPSR) patches from the H&E patches. The real PSR test patches paired with the H&E test patches served as reference. The virtual pix2pix (pix2pix-vPSR), diffusion (diffusion-vPSR) and real PSR test patches were processed to obtain collagen fiber masks. Subsequently, 108 collagen fiber density and orientation features were extracted from each mask and correspondence of the features extracted from pix2pix-vPSR and diffusion-vPSR collagen masks were compared with those extracted from real PSR collagen mask using Spearman correlation coefficients.

Results: Both models produced strong correlations with real PSR features, particularly for collagen area fraction ($r > 0.89$), high-density matrix fraction ($r > 0.86$), gap circle count ($r > 0.86$), fiber spine area ($r > 0.83$), coherency/anisotropy ($r > 0.82$), fractal dimension ($r > 0.82$), fiber angle ($r > 0.80$), and fiber length ($r > 0.80$). Diffusion-vPSR correlations ranked among the top 90% and exceeded pix2pix-vPSR correlations by an average $\Delta r > 0.07$, with the gains observed for fiber contour- and thickness-based features, including median length ($\Delta r > 0.20$), thickness variation ($\Delta r = 0.19$), and asymmetry indices ($\Delta r > 0.16$). Smaller improvements were observed for fiber entropy length, variability and for skew/kurtosis/gap statistics (Δr=0.07-0.11). Pix2pix correlations surpassed diffusion correlations in only 10% of features; primarily gap fiber density features ($\Delta r \leq 0.05$).

Discussion: This study demonstrates the feasibility of generating vPSR images from routine H&E slides to infer collagen architecture with high fidelity. Broader application and refinement across larger cohorts will clarify how collagen architecture shapes tumor behavior, recurrence risk, and patient outcomes, supporting further spatial biomarker development.

#4168 All-in-one digital pathology compares and contrasts the tumor microenvironment of renal cell carcinoma tissue with paired, patient derived tumoroids.

Levi Maston, Amber L. Ortiz

Indica Labs, Albuquerque, NM

AI-powered pathology advances translational research by shrinking the gap from discovery to diagnosis through highly performant analytical capabilities. Here, we utilize the HALO®/HALO AI quantitative image analysis platform to compare the tumor microenvironment (TME) of patient tumor samples and corresponding tumoroids. Tumoroids created (in vitro) from primary tumor tissue (in vivo) allow researchers in the field of oncology to more accurately replicate the TME of patient biological specimens. Tumoroids compared to 2-D cell culture are believed to better mimic the physiologically relevant environment by reducing the destruction of native tissue structure and cellular composition. We perform AI-powered image and spatial analysis on multiplexed immunofluorescent tissues incorporating biomarkers for immune subtypes and key features of tumoroids such as TME, cell proliferation, immune profile. The samples have been obtained from the BioStudies BioImage Archive under the study S-BIAD1661 containing samples of clear cell Renal Cell Carcinoma (ccRCC)[1]. By applying digital pathology techniques to these research approaches, we demonstrate a thorough and versatile analysis workflow to address the characterization of tumoroids and their corresponding patient samples and highlight the impact of these tools on research, discovery and diagnostics.

#4169 Reading the map: An invitation to the resources of the Human Tumor Atlas Network.

Adam Taylor[1], Ashley Clayton[1], Aditi Gopalan[1], Milen Nikolov[1], Thomas Yu[1], David Gibbs[2], Yamina Katariya[2], Dar'ya Pozhidayeva[1], Ino de Bruijn[3], Seluck Onur Sumer[3], Kristen Anton[4], Jennifer Altreuter[5], Alex Lash[5], Ethan Cerami[5], Nikolaus Schultz[3], Vesteinn Thorsson[2]

[1]Sage Bionetworks, Seattle, WA,[2]Institute for Systems Biology, Seattle, WA,[3]Memorial Sloan Kettering Cancer Center, New York, NY,[4]Dartmouth Health, Lebanon, NH,[5]Dana-Farber Cancer Institute, Boston, MA

Purpose: The Human Tumor Atlas Network (HTAN) sets out to map the cellular and molecular architecture of human tumors over space and time to advance precision oncology. The HTAN Data Coordinating Center (DCC) underpins this mission by standardizing, integrating, and distributing multimodal data; ensuring legacy and impact.
Methods: The DCC developed a scalable cloud ecosystem (Synapse.org, Google BigQuery, custom data portal) for data ingestion, governance, validation, and dissemination. A community-driven process, aligned with NCI standards, produced a consistent metadata schema that ensures interoperability across rich clinical and biospecimen information and all data modalities. The HTAN data portal provides a single landing page for users of HTAN data featuring filter-based search, visualization of imaging and single-cell datasets and detailed documentation. Data are disseminated via a tiered model, with imaging and dbGaP-controlled access sequencing data available from NCI Cancer Research Data Commons General Commons and open-access processed data on Synapse.org. Current work transitions to a modular LinkML data model, adds an AI-assisted curation interface, and includes a streamlined medallion architecture in BigQuery and portal enhancements.
Results: The first five years of HTAN (release v7.0) produced 334 TB of multimodal data (0.23M files) from 2,372 cases and 11,378 biospecimens, spanning >60 disease types and >25 assays. HTAN supports >3,400 unique global users a month. The most frequently accessed data includes scRNA-seq (1075 downloading users), multiplex imaging (197), and spatial transcriptomics (419). Analysis of dbGaP requests to-date (N=127) shows broad academic (75%) and industry use with research themes focused on genome instability (115 requests), immune evasion (52), and metastasis (49), often with multi-omic and AI-driven approaches.
Conclusions: HTAN has established a globally utilized, harmonized foundation for spatially resolved, multimodal cancer research. This enduring platform for community-driven discovery is built on robust data management and transparent access models. The next phase deepens integration of spatial and clinical data, expanding AI-readiness, and strengthening support for reuse and reproducibility. We invite researchers to engage with this resource.
ChatGPT 5, Gemini 2.5 Pro, & Claude Sonnet 4.5 were used to summarize usage metrics, conduct thematic analysis of dbGaP applications, and initial abstract drafting. All content was evaluated and approved by the authors.

#4170 An AI-driven multimodal workflow for enhancing late-phase clinical trial outcome prediction.

Inbal Gazy[1], Assaf Avinoam[1], Reva Basho[2], Jonathan Zalach[1]

[1]Imagene AI LTD, Tel Aviv, Israel,[2]Ellison Medical Institute, Los Angeles, CA

A major challenge in drug development is the gap between early-phase signals and late-stage success. Despite promising early-stage clinical trial readouts, fewer than 10% of drug candidates ultimately progress to regulatory approval, highlighting substantial gaps in predictive fidelity along the development pathway. This gap complicates decision-making, leading to increased development time, costs and risks. Key contributors to this challenge include the small sample sizes inherent to early-phase cohorts and the limited use of patient stratification, shown to be a contributing factor for higher success rates. Recent advances in artificial intelligence (AI) have introduced powerful tools that have the potential to support clinical trial progress evaluation. By integrating multimodal models with real-world data (RWD) within an AI-driven framework, Imagene AI is developing approaches to address the discrepancies between early and late-phase outcomes, and to support better evaluation of late-phase readouts, such as survival outcomes and biomarkers identification, based on early phase cohorts. In this study, we adopted a multimodal foundation-model strategy, built on a diverse set of foundation models. Among them, our digital pathology foundation model, CanvOI, played a central role in enabling prediction of large-cohort outcomes from small-cohort data. Models were trained on a limited sample set of Trastuzumab (Herceptin)-treated breast cancer patients with outcome data. We then generated Kaplan-Meier survival curves for this small cohort with and without an AI-augmented workflow and compared the results with published outcomes from a Phase III trial. Our findings show that the AI-augmented predictions better align with the Phase III clinical trial outcomes, suggesting that this approach has the potential to support more informed decisions using early-phase data. *ChatGPT was used for editing this abstract

#4174 hla2vec: Developing a HLA embedding space using probabilistic cross-reactive groups.

Isabel Quesada, Jordan Tagle, **Kyle Ellrott**

OHSU Knight Cancer Institute, Portland, OR

The genes in the major histocompatibility complex (MHC) that code for the Human Leukocyte Antigen (HLA) protein complex are some of the most diverse genes in the genome. And while some of the alleles such as HLA-A*02:01 are seen in almost 25% of the population, databases such as IMGT/HLA report nearly 20 thousand variants. In cancer populations, this produces a long tail of individuals who are unique within a sampled population. HLA class I typing for The Cancer Genome Atlas (TCGA) covered almost 10K individuals across 33 cancer types, and resulted in over 300 HLA alleles. Within this cohort alleles such as HLA-A*03, HLA-A*33, and HLA-A*2 have been associated with prognosis and immunotherapy response in various cancers. Not all HLA alleles are different, with some alleles observing similar binding patterns that can place them in cross-reactive groups (CREGs). And while this concept has traditionally been documented as a discrete set of documented alleles, from large scale experiments we can start to think of this as a probabilistic space representing probabilistic CREGs (pCREGs). Two alleles in a pCREG may only bind to some fraction, for example 90%, of the same peptides. Using this as a basis we can develop an embedding space where the distance between different HLA alleles is relative to their pCREG association. We have developed a method called HLA2Vec, which has been trained on the 15 million HLA/peptide binding experiments accumulated in the BigMHC dataset. In addition, we developed a benchmark to describe a new model's ability to identify CREGs. We have compared this method to other Protein Modelling Languages (PML), such as Evolutionary Scale Modeling (ESM) in their ability to identify pairs of HLAs that are likely to be in the same pCREG, and found the HLA2Vec to be much more accurate, while using many fewer parameters. With HLA alleles placed in this embedding space, we are able to cluster together smaller groups of individuals with near unique HLA alleles into larger subtypes, based on pCREG status, bringing together patients likely to have similar immune HLA binding patterns for statistical analysis. This analysis has been applied to TCGA data to group rare alleles into larger response groups. The next steps of this research are to see if this method for HLA embedding may also provide insights for developing similar embedding spaces for T Cell Receptor (TCR), and improve HLA pCREG conditional binding prediction.

#4175 Neoantigen-guided TCR discovery pipeline to improve specificity and reduce off-target toxicity in AML.

Pamella Borges[1], Martiela Freitas[1], Samee Ullah[1], Hussein A. Abbas[2], Dinler Antunes[1]

[1]Biology and Biochemistry, University of Houston, Houston, TX,[2]UT MD Anderson Cancer Center, Houston, TX

Identifying and engineering neoantigen-specific T cell receptors (TCRs) remains a major barrier to advancing adoptive immunotherapy for acute myeloid leukemia (AML), a malignancy characterized by a low mutational burden and, consequently, limited neoantigen availability. Recent studies have highlighted recurrent AML-associated mutations as promising sources of therapeutic neoantigens, arising from chromosomal alterations, motivating the development of new strategies to systematically discover and evaluate TCRs targeting antigens while minimizing off-target toxicity. We developed a structure-guided TCR discovery pipeline that designs neoantigen-specific TCRs, determines their presence within AML patient repertoires, and evaluates binding specificity and predicted safety. From the literature, we selected recurrent AML neoantigens restricted by HLA-A*02:01, including the TP53 Y220C peptide (VVPCEPPEV) and the NPM1 mutant peptide (AIQDLCVAV), both of which are among the most common TP53 hot-spot and the most frequent molecular alterations in AML. A melanoma-derived TCR-pHLA structure (PDB: 2BNQ) was used as an unbiased scaffold for inserting each AML neoantigen. ProteinMPNN, a deep learning-based protein sequence design, was then applied to redesign residues within CDR1-3, generating 50,000 candidate TCR sequences predicted to optimize interface complementarity and binding. Single-cell TCR-sequencing (scTCRseq) data were analyzed to extract paired α/β patient TCRs, with high-confidence receptors identified based on barcode redundancy and immune phenotype. Clustering of patient and designed TCRs using GLIPH2 revealed a dominant cluster comprising >90% of TP53-associated patient TCRs and two designed TCRs sharing a CDR3 motif, whereas no convergence was observed for NPM1 sequences. Three designed TCRs (two motif-convergent and one top-ranked by structural confidence) and the 62 patient TCRs from the convergent cluster were structurally modeled using TCRmodel2. All modeled TCRs are now being evaluated with STAG-LLM to predict binding specificity and interface similarity to the TP53-HLA complex. The top candidates will progress to molecular dynamics simulations to characterize contact fingerprints and evaluate potential off-target toxicity using CrossDome, which evaluates TCR cross-reactivity based on biochemical similarity between peptide-HLA ligands and predicts the off-target toxicity risk of T-cell-based immunotherapies. Initial results suggest structural and repertoire-based convergence toward recognition of TP53, supporting its relevance as an immunologic target for AML. By integrating rational TCR design, patient repertoire interrogation, and computational safety screening, this pipeline provides a scalable, reproducible framework for discovering neoantigen-specific, potentially low-toxicity TCR candidates for AML immunotherapy.

#4176 DAG-guided kernel learning framework to mitigate racial disparities in breast cancer.

Min-jeong Baek[1], Jieqiong Wang[2], Vimla Band[1], **Shibiao Wan**[1]

[1]Department of Genetics, Cell Biology and Anatomy, University of Nebraska Medical Center, Omaha, NE,[2]Department of Neurological Sciences, University of Nebraska Medical Center, Omaha, NE

As the second leading cause of cancer death among women in the United States, breast cancer (BC) mortality is disproportionately higher among Black women than among non-Hispanic White women. Artificial intelligence (AI) and machine learning (ML) approaches have been successfully applied to mitigate racial disparities in BC. For instance, previously we developed a multi-modal transfer learning (TL) framework that can help address health disparities by transfer knowledge learned on the majority group (e.g., non-Hispanic White women) to improve performance of AI/ML models for a minority group (e.g., Black women). However, these approaches integrate different omics data in a simplistic manner, but failed to capture the complex cross-omics interaction among them, leading to minor or modest performance improvement for reducing BC health disparities. To address these concerns, we propose a directed acyclic graph (DAG)-guided kernel learning framework to mitigate racial disparities in breast cancer. Specifically, we first encoded the cross-omics interaction knowledge into a DAG graph by a method called non-combinatorial optimization via trace exponential and augmented Lagrangian for structure learning (NOTEARS). Then, we hard-masked the learned graph to retain only biology-consistent projections. From these projections, we computed projection-specific RBF kernels to capture non-linear sample similarity, yielding interpretable, direction-aware kernels used for training a TL model equipped with a data augmentation (DA) method, which were used to reduce breast cancer disparities. By using three omics modalities (i.e., mRNA, miRNA, and DNA methylation) from The Cancer Genome Atlas (TCGA) BRCA cohorts of 1,085 female BC patients, we demonstrated that our proposed framework achieves remarkably better performance (using various performance metrics like ROC-AUC, PR-AUC, Accuracy, and F1-score) compared with state-of-the-art approaches for reducing BC health disparities in terms of time-specific Progression-Free Interval (PFI) predictions. In addition, our framework could quantify and identify multiple key cross-modality interactions to mitigate BC racial disparities. In summary, our proposed framework would provide a novel approach to explore cross-omics interactions for boosting a robust TL model performance to reduce health disparities in BC. We also believe our approach can be extended to mitigate racial disparities for other types of cancer.

#4177 Integrated meta-clustering reveals subtype-specific transcriptomic heterogeneity of pediatric low-grade glioma.

Bulidierxin Tuerhanbayi[1], Jieqiong Wang[2], **Shibiao Wan**[1]

[1]Department of Genetics, Cell Biology and Anatomy, University of Nebraska Medical Center, Omaha, NE,[2]Department of Neurological Sciences, University of Nebraska Medical Center, Omaha, NE

Pediatric low-grade glioma (pLGG) is the most common type of brain tumor in children, accounting for approximately 30% of all central nervous system tumors in children. pLGG has multiple molecular subtypes that differ in disease progression, recurrence patterns, and treatment responses. Conventional wet-lab approaches including molecular profiling and histopathological studies for pLGG characterization are time-consuming, costly, and laborious. Recently, methods based on artificial intelligence (AI) or machine learning (ML) have been widely used for pLGG molecular categorization, but most of them can only identify two or three pLGG subtypes. To more comprehensively characterize the molecular subtypes of pLGG and their potential biological and therapeutic significance, we develop an integrated meta-clustering approach to explore high-resolution molecular subtypes and their transcriptional heterogeneity for pLGG. Specifically, we first performed multiple rounds of random projection (RP) to generate dimension-reduced feature vectors from pLGG transcriptomics data, each of which was subsequently clustered by some conventional clustering algorithms including hierarchical clustering, K-means, and self-organizing maps, as base clustering methods. Then, to yield robust clustering performance, we integrated the clustering results of these RP-based individual clustering algorithms by adopting a weighted meta-clustering (wMetaC) approach. Results based on 543 pLGG patients suggested that our proposed approach demonstrated superior stability and discriminative powers for higher-resolution pLGG subtyping compared to conventional approaches. Based on consensus matrix analysis, we identified two major pLGG subtypes, with one further subdivided into three subgroups and the other into two. Then, we performed cluster-specific differential gene expression analysis, molecular pathway analysis, and gene-drug-disease association analysis. The results showed that the identified five subgroups exhibited significant subtype-specific transcriptomic heterogeneity. In summary, our meta-clustering approach demonstrates higher accuracy and robustness in identifying higher-resolution molecular subtypes of pLGG, revealing the molecular heterogeneity within pLGG and potentially providing new insights for more precise molecular subtyping and precision therapy.

#4178 Mapping the imputation-augmented somatic mutation landscape of 2,551 NSCLC patients highlights contrasting patterns across histologic subtype, smoking status, and ancestry.

Isam Mohd-Ibrahim, Zhuokun Feng, Yu Chen, Lauren Higa, Youping Deng

University of Hawai'i at Manoa, Honolulu, HI

Non-small cell lung cancer (NSCLC) is a genetic disease characterized by an abundance of somatic mutations. Within the many mutations that make up the somatic mutation landscape, a select few actively drive the development of cancer. Mutations in driver genes have gained import as therapeutic targets, biomarkers, and aides in understanding oncogenesis. Recent studies have also shown the preponderance of certain drivers in certain demographics, as is the case for the targetable EGFR mutations in female non-smokers of Asian descent. In this study, we attempt to add further clarity and definition to the somatic mutation landscape of NSCLC using 2,551 secondary DNA-sequencing data aggregated from various cohorts. We also utilized machine learning-based methods to impute smoking status and genetic ancestry to create a broad and deep cohort to identify unique associations between somatic features and specific populations. We aggregated and processed the genomic data into highly granular somatic mutation features and identified 87 significantly mutated genes (SMG), 48 of which are putatively novel driver genes. EAS (patients of East Asian ancestry) patients were found to have fewer SMG per patient and a significantly lower tumor mutation burden than patients of other genetic ancestries. This remained true even after stratifying the populations studied by smoking status and cancer subtype. Besides associations with EGFR, multivariable models also identified more frequent ATM and STK11 mutations in EAS patients. Unsupervised clustering on the 87 SMG and 109 mutational signatures identified 6 distinct clusters, including 2 previously identified distinct KRAS-featuring clusters. Common clinical features were observed within some clusters, for example, female EAS non-smokers were particularly enriched in one cluster. Cox regression models identified better survivability in EAS patients and patients with EGFR mutations, whereas patients with mutations in TP53, KEAP1, and BID had significantly poorer survival. The results from this study identify a clear disparity in the somatic mutation landscape of lung cancer patients of different ancestries, which should be taken into consideration in future studies. The results also highlight the benefits of utilizing large, heterogeneous datasets of a specific cancer type in driver gene discovery and the utility of integrating multiple somatic features. This study also emphasizes the benefits of data imputation, integrating 942 patients with otherwise unknown smoking status.

#4179 Three-dimensional spatial multi-omics of gastric tumor sections reveal hidden features beyond 2D analyses.

Inyeop Jang[1], Soyoung Im[1], Minji Kim[1], Seok-Jin Chung[1], Minsoo Lee[2], Soonyoung Lee[2], Jongseong Jang[2], Tae Hyun Hwang[1]

[1]Vanderbilt University Medical Center, Nashville, TN,[2]LG AI Research, Seoul, Korea, Republic of

Single-section spatial-omics frequently misses microanatomical context and is sensitive to sectioning variability. Recent 3D reconstruction studies highlight substantial heterogeneity within the tumor microenvironment obscuring true biology. Emerging platforms (e.g. Singular Genomics G4X) enable in-situ RNA/protein readouts at subcellular resolution on the same slide with fluorescent H&E, creating serialized spatial multi-omics. This work allows us to map transcript abundance at the subcellular level with x-y-z coordinates, integrating H&E, transcripts, and proteins on the thick tissues, enabling true 3D spatial multimodal tumor modeling.We profiled serial FFPE sections using the G4X system to jointly quantify targeted RNAs and proteins per slice. Across slices, we compared cell types, neighborhood enrichment matrices, and gene-set enrichment to measure inter-slice inconsistency. We then registered the serial sections into a common 3D frame, reconstructed a volumetric atlas, and identified 3D hotspots for exhausted T-cell programs. To directly visualize whether these patterns reflected true 3D structure, we acquired label-free 3D holotomography from the same serial sections, aligned them with the corresponding serial G4X data in a shared 3D space, applied AI-based single-cell segmentation, and mapped cell types defined by G4X RNA and protein expression back to their x-y-z coordinates.Serial 2D slices showed discordant cell-type compositions and neighborhood enrichments, indicating strong variability even within a single tumor block. In contrast, 3D reconstruction revealed a coherent exhausted T-cell domain that failed to reach statistical significance in any individual slice. Holotomography confirmed dense, continuous interfaces among T cells, extracellular matrix, and tumor cells across depth, supporting true biological continuity and demonstrating subcellular localization of transcripts and proteins in 3D.Our 3D spatial multi-omic approach shows that single-section analyses may miss clinically relevant immune niches, whereas integrated 3D RNA-protein-holotomography profiling recovers hidden signals. By mapping and combining the transcripts with proteins and the 3D holotomography at subcellular x-y-z coordinates in thin and thick tissues, we provide a practical workflow for volumetric tumor-immune profiling that can accelerate biomarker discovery and therapeutic targeting in gastric cancer and can be generalized to other cancer types."Generative AI was used only to edit this abstract's language. The authors are responsible for the study concept, data interpretation, and conclusions, and have approved the final version."

#4180 Protocol-specific and coverage-based RNA-seq metrics characterize RNA integrity signatures across cohorts.

Miyeon Yeon[1], Wonyoung Choi[2], Jin Young Lee[2], David Neil Hayes[3], Hyo Young Choi[4]

[1]Preventive Medicine, University of Tennessee Health Science Center, Memphis, TN,[2]University of Tennessee Health Science Center, Memphis, TN,[3]UTHSC Center for Cancer Research, Memphis, TN,[4]Preventive Medicine, University of Tennessee Health Science Center, Memphis, TN

Background: RNA degradation profoundly impacts transcript quantification and downstream biological interpretation. Existing RNA quality assessment methods are largely limited to poly(A)-selected mRNA-seq and do not generalize to total RNA-seq, resulting in inconsistent quality evaluations across sequencing protocols. We hypothesize that base-resolution RNA-seq coverage profiles capture protocol-specific quality signatures. By modeling unexpected variation in these coverage patterns, RNA-seq quality can be accurately assessed for both mRNA-seq and total RNA-seq (including frozen and FFPE samples) within a common analytical framework tailored to each protocol.
Methods: For both mRNA-seq and total RNA-seq, we quantify abnormal variations in per-base coverage by explicitly modeling degradation-related and other low-quality patterns. For mRNA-seq, specifically, we developed the Degradation Score (DS), which estimates the positional decay in read coverage along transcripts. For total RNA-seq, we introduced the window Coefficient of Variation (wCV), a variant of CV metric that captures coverage nonuniformity, reflecting the tendency of degraded samples to show elevated variability across gene bodies. We applied these metrics to over 2,600 RNA-seq profiles spanning multiple sequencing strategies and cohorts, including TCGA (mRNA-seq), CALGB (fresh frozen total RNA-seq), and ALCHEMIST (FFPE total RNA-seq).
Results: Across datasets, our coverage-based metrics showed stronger correlations with conventional QC measures ($|r|$=0.52-0.59 in mRNA-seq, 0.43-0.89 in total RNA-seq; $p<0.001$) than the correlations among themselves ($|r|$=0.24-0.44 in mRNA-seq, 0.44-0.88 in total RNA-seq; $p<0.001$). We also identified a set of samples in which conventional QC flagged high degradation but coverage profiles appeared intact, and vice versa, highlighting protocol-dependent discrepancies. Manual inspection confirmed markedly greater aberrant variability in samples with high DS (mRNA-seq) or high wCV (total RNA-seq). Using standardized within class sum of squares across RNA quality strata, we found that samples classified as high-quality by our metrics consistently preserved known subtype structure across normalization methods.
Conclusions: These protocol-specific, coverage-based measures provide a coherent and reproducible framework for evaluating RNA integrity across sequencing strategies and experimental conditions. Incorporating degradation-aware QC into RNA-seq pipelines improves interpretability, comparability, and biological fidelity of transcriptomic analyses in large cancer genomics studies.

#4181 De-risk targets through mechanism-enabled simulations in the Virtual Lab.

Krishna Bulusu, Katalin Szegner, Laszlo Merő, Eszter Szarka, Ivan Fekete, Maria Victoria Ruiz Perez, Csilla Hegedűs, Imre Gaspar, Gabor Kovacs, Kristof Szalay, Daniel Veres

Turbine Simulated Cell Technologies Ltd., Budapest, Hungary

Minimizing the risk of late-stage failure in drug discovery for novel targets remains a central challenge in translational research. Conventional preclinical perturbation datasets lack mechanistic insight and context specificity. Turbine's Virtual Lab offers access to simulations with mechanistic insights enabled by AI-guided virtual cell modeling to predict phenotypic and transcriptomic outcomes of genetic and pharmacological perturbations in preclinical models representative of patient heterogeneity. This framework enables systematic evaluation of target-disease linkage mechanisms, target liabilities, and combinatorial strategies to enrich preclinical decision-making data packages. We utilized our Simulated Cell technology to construct virtual replicates of more than 1,200 cancer cell lines by integrating large-scale omics data (CCLE) with a curated signaling network as prior knowledge. The virtual cell lines were trained on experimentally observed genetic (DepMap) and pharmacological perturbation data (GDSC2) to accurately represent their phenotypic responses, and on differential gene expression data (LINCS) to describe post-perturbation transcriptomic states. Benchmarking was performed against an unseen set of cell lines across all genes and selective essential genes only. Target assessment reports were generated by merging simulation-derived phenotypic and post-perturbation omics features with curated clinical intelligence, yielding an integrated view of signaling-level mechanisms of action, patient stratification strategies, combination potential, and initial safety assessments. The Simulated Cells accurately reproduced DepMap dependency outcomes, demonstrating a global test-set Pearson correlation of 0.90 across all genes. For selective essential genes only, we measured a cell-line wise 0.55 Pearson correlation. Replicate-level Pearson correlation is 0.78 for the same metric, while baseline (bias) models score only 0.23. Notably, the prospective validation hit rate stands at 70% for dependency predictions, also capturing novel dependencies not identified in DepMap. For a set of 10 in silico-identified targets, we observed a 50% shorter timeline from identification to in vivo validation and a 100% higher rate of in vitro validation compared with industry benchmarks. We have also established a Virtual Lab platform that provides easy, scalable, and interpretable access to these simulations. Turbine's target discovery platform combines mechanistic interpretability with strong concordance to experimental dependencies, bridging computational modeling and translational research. The Virtual Lab interface is user-friendly and optimized for adoption without any data science or AI expertise. This approach enables data-driven, de-risked, and accelerated target selection and portfolio advancement in oncology discovery.

#4182 Pan-cancer landscapes of transcriptional heterogeneity in metastatic tumors.

Ramyar Molania[1], Himisha Beltran[2]

[1]Dana-Farber Cancer Institute, Boston, MA,[2]Dana-Farber Cancer Institute, New York, NY

Metastasis, the spread of cancer from its original site to distant organs, is the leading cause of cancer-related mortality. A deeper understanding of the molecular mechanisms underlying metastatic progression is therefore of critical clinical importance. The availability of large-scale pan-cancer bulk RNA-seq datasets from both primary and metastatic tumors provides a unique opportunity to investigate the shared and distinct transcriptional features of metastasis. Furthermore, this creates an unprecedented opportunity to perform systematic analyses across metastatic tumors from diverse cancer types.However, our initial pan-cancer analysis demonstrated that several major confounding factors,most notably strong tissue background signals in metastatic samples, pose significant challenges for accurately comparing primary and metastatic tumors. We have previously established effective strategies to adjust for immune and stromal components in bulk transcriptomic data. Building on this foundation, we have recently extended our approach to address a key obstacle in studying metastasis: the overwhelming influence of tissue-of-origin signals at metastatic sites.To evaluate our method, we first performed in silico simulations of normal-tissue background correction using TCGA pan-cancer RNA-seq data. We further generated pseudo-bulk profiles from single-cell RNA-seq datasets spanning multiple cancer types, each exhibiting varying degrees of background tissue contamination. Across these datasets, our analyses demonstrate that this approach effectively removes confounding signals, thereby enabling more accurate transcriptomic comparisons between primary and metastatic tumors. Application of this method to large pan-cancer bulk RNA-seq cohorts revealed promising and novel biological insights, including both shared and cancer-type-specific transcriptional programs associated with metastatic progression.Our preliminary analysis indicates that multiple hallmark pathways, including oxidative phosphorylation and epithelial-mesenchymal transition (EMT), are broadly upregulated across metastatic tumors in pan-cancer datasets. In addition, we observe pronounced immunosuppressive signaling within the tumor microenvironment of metastatic lesions, suggesting that metabolic rewiring and immune evasion are coordinated features of metastatic disease.

#4183 Finding Goldilocks: How AI-powered covalent drug discovery removes the “un” from “undruggable”.

Johannes C. Hermann, Robert Everley, Han Wool Yoon, Rohan Varma, Karsten Krug, Daniel Erlanson, Chris Varma, Kevin R. Webster

Frontier Medicines, South San Francisco, CA

Covalent drugs offer a path to drugging hard targets to provide urgently needed novel cancer medications. Starting from small covalent fragments is efficient in principle but difficult in practice due to challenges distinguishing generic from specific reactivity and the influence of the reactive warhead on all other chemical properties. The Frontier™ Platform and covalent AI as a key pillar overcomes these challenges. Focused super large-scale experimental data generation relevant to covalent drug discovery has enabled the development of several powerful covalent AI algorithms. Their application falls into two different fields, firstly the better understanding of the proteome and proteins and potential covalent binding sites and secondly in advancing covalent chemistry. We detail strategic data generation through chemoproteomics experiments, quantum mechanics, experimental chemical property determination, and the leveraging of these data to inform covalent drug discovery for hard-to-drug targets. This includes the AI-driven characterization of covalent binding sites across nearly the complete human proteome. Covalent fragment hits have been identified for multiple difficult cancer targets including KEAP1, ADAR, DHX9, PTPN11, MYC, and many others (>75% of important cancer driver genes). Furthermore, we will highlight several novel AI covalent chemistry applications. We will present an algorithmically designed covalent fragment library for screening, covalent chemical property prediction algorithms, and details of our highly specialized AI-driven covalent drug design engine that autonomously ingests all relevant data for a given project and suggests optimized compounds to be synthesized. We show the impact of this approach for a historically undruggable transcription factor and cancer driver as an example. Undruggable targets across a variety of cancer target classes have become druggable leaning on advanced covalent drug discovery methods.

#4184 Multimodal deep learning framework for predicting clinically significant phenotypes in prostate cancer.

Priyanka Vasanthakumari[1], Mohamed Omar[2]

[1]Computational Biomedicine, Cedars-Sinai Medical Center, Los Angeles, CA,[2]Cedars-Sinai Medical Center, West Hollywood, CA

Prostate cancer is the most common non-cutaneous malignancy and the second leading cause of cancer-related death among men in the United States. Its clinical and biological heterogeneity poses major challenges for accurate outcome prediction and treatment planning. Traditional single-modality models often fail to accurately capture the risk of disease progression. Recent advances in artificial intelligence, particularly foundation models, enable the integration of heterogeneous data into unified representations of tumor biology, which can in turn uncover better predictive and prognostic features than what is possible with unimodal modalities.We develop a multimodal model that integrates histopathology whole-slide images (WSIs), transcriptomics, and clinical data to predict prostate cancer molecular and clinical phenotypes, enhancing both predictive accuracy and interpretability. The framework employs separate encoders for each modality: an image encoder adapted from foundation models CONCHv1.5 and TITAN, a text encoder based on ClinicalBERT for clinical data, and a transcriptomic encoder combining Gene2Vec embeddings with expression-level features projected into a shared latent space. The encoders are contrastively fine-tuned using pairwise alignment, with WSIs serving as the anchor modality based on paired data availability.The multimodal representations are evaluated on several downstream clinically significant prediction tasks, including Gleason grading, metastasis prediction, biochemical recurrence, and molecular alteration status such as TMPRSS2:ERG fusion and PTEN loss. The framework also provides interpretability by quantifying the contribution of each modality and visualizing attention distributions, highlighting joint feature representations that are important to each task.This study uses data from 632 patients with paired data from public and institutional repositories. Inter-modality fine-tuning between WSI and clinical text data yielded promising alignment results, with paired image-text samples achieving significantly higher similarity ranks than unpaired samples (mean p-value $\approx 10^{-29}$). Gleason grade multiclass classification downstream task achieved an overall test accuracy of 81.4% and a weighted F1 score of 79.6%.

#4185 A modular *in silico* triage pipeline for multi omic evaluation of surface protein targets across indications.

Satyajit Rajapurkar, Lena Eismann, Mariana Pereira, Theodore Groth, Mugdha Khaladkar, Kathrin Jansen, Edward Curry, Marica Speranza

GSK, Collegeville, PA

Antibody-Drug Conjugates (ADCs) have revolutionized oncology by coupling cytotoxic payloads with antibodies that selectively target malignant cells. However, balancing efficacy with toxicity continues to be a major challenge, especially when off-target expression in healthy tissues leads to adverse side effects. To address these limitations, we have developed a modular in silico triage pipeline that integrates multi-modal, multi-omic datasets to systematically evaluate candidate surface proteins for targeted bispecific therapy.Our pipeline evaluates candidate antigens based on their MS-based tissue protein expression patterns across diverse cell populations and tissues, enabling the identification of markers that are predominantly upregulated in cancer cells while maintaining low mRNA expression in critical normal tissues. This comprehensive approach supports the rational design of bispecific antibodies that can further enhance specificity by binding to two distinct antigens simultaneously. By streamlining the target selection process, this strategy promises to accelerate the development of more effective and safer therapeutic modalities across a range of cancer indications.Here, we detail the design, implementation, and validation of our *in silico* framework, providing a robust platform for rapid and flexible evaluation of potential surface protein targets for ADCs and beyond.

#4186 A novel integrated AI ML and COSMIC signature profiling approach resolving blast crisis CML heterogeneity into single patient level pan cancer actionable programs enabling repurposable therapies for relapsed refractory and metastasized cancers.

Zafar Iqbal[1], Abdulkareem AlGarni[2], Lubna Alnuaim[3], Sahrish Khan[4], Sohail Rao[5], Yaqob Taleb[6], Nasser Mohammed AlQahtani[7], Muhammad Alshuaibi[7], Essa Al Mansour[8], Mashael AlShuker[8], Azfar Athar Ishaqui[9], Giuseppe Saglio[10], Kaleem Ahmed[11], Rizwan Naeem[12], Masood A. Blast crisis CML (BC-CML) is a highly refractory and heterogeneous phase. We applied an integrated whole-exome sequencing (WES), COSMIC mutational signature, and machine-learning (ML) pipeline with AI-guided drug mapping to stratify BC-CML at single-patient resolution. In 19 BC-CML cases within 157 patients, WES revealed markedly elevated mutational burden, widespread chromosomal damage, and distinct molecular architectures. ML resolved three BC-CML subtypes enriched for unique COSMIC signatures and targetable pathways. Therapeutic mapping linked each subtype to repurposable FDA-approved agents, supporting a scalable precision-oncology strategy relevant to relapsed, refractory, and metastatic cancers.

Introduction

BC-CML represents a terminal stage where secondary mutations and genomic stress disrupt TKI response [1]. Shared oncogenic programs across myeloid and solid tumors support pan-cancer therapeutic repurposing [2]. A WES-ML-COSMIC strategy enhances molecular stratification beyond conventional staging [3]. We applied this framework to define actionable BC-CML subtypes.

Methods

A total of 157 patients (123 CP, 15 AP, 19 BC) were analyzed under IRB approval [4]. DNA was sequenced on Illumina NovaSeq, aligned to GRCh38 using BWA-MEM [5], processed through GATK and COSMIC/VEP [6]. PCA+scikit-learn enabled ML clustering [7]. COSMIC signatures were generated using SigProfilerExtractor [8]. PanDrugs guided drug repurposing [9].

Results

BC-CML displayed >2,500 somatic mutations and ~54% higher mutational burden than CP/AP with hotspots on chromosomes 1, 7, 17, and 19. ML defined three subtypes:

Cluster 1 (BRCA2/TP53): HR-deficiency; COSMIC S3/S5.

Cluster 2 (IDH1/2, TET2): epigenetic/metabolic dysregulation; S1/S2.

Cluster 3 (JAK2, CSF3R): cytokine/oxidative-stress signaling; S13/S18.

Drug mapping linked them to PARP/MDM2 inhibitors, IDH inhibitors/HMAs, and JAK inhibitors respectively.

Discussion

This integrated WES-ML-COSMIC framework translates BC-CML heterogeneity into discrete, targetable biological programs [2]. The three clusters reflect distinct evolutionary pressures—HR failure, epigenetic drift, and cytokine-driven oxidative stress—each linked to repurposable FDA-approved therapies [3]. This single-patient-level mapping supports a scalable precision-oncology model for relapsed, refractory, and metastatic cancers beyond BC-CML [4,9].

#4187 scOncoNet: Dual-graph attention network for program-aware *in-silico* gene perturbation in single-cell cancer data.

Tingyi Li, Yuanyuan Shen, Bin Baek, Xiaoqing Yu, Xuefeng Wang

H. Lee Moffitt Cancer Center, Tampa, FL

Identifying genes that functionally drive malignant programs in single-cell tumors remains difficult, particularly when CRISPR or Perturb-seq data are unavailable. Co-expression alone cannot separate correlation from regulatory influence, and existing analyses lack a framework that connects global molecular networks with patient-specific cellular programs. Current single-cell foundation models largely rely on gene-gene relationships while making limited use of the cell-cell structure intrinsic to tumor ecosystems. To address these gaps, we developed scOncoNet, a lightweight dual-graph attention network that integrates gene-gene and cell-cell structure, malignant meta-program supervision, and gene-to-program attribution to enable program-aware estimation of gene influence directly from patient scRNA-seq data. The model incorporates PPI networks to provide global molecular context for the gene encoder and constructs a program-aware cell graph blending local transcriptomic similarity with malignant program similarity. A two-layer architecture jointly learns gene and cell embeddings, with an attention mechanism that adaptively reweights cell-cell edges to highlight biologically meaningful transitions such as EMT or hypoxia. A program-prediction module anchors the cell embedding space to malignant programs, and gene impact scores combine PPI-informed gene embeddings with gradients that quantify each gene's influence on these programs, generating a mechanistic estimate of its potential effect on malignant states. Using an esophageal squamous-cell carcinoma (ESCC) single-cell dataset restricted to epithelial cells, we defined ESCC-specific malignant programs, including proliferation (*MKI67*), EMT (*VIM*), hypoxia (*CA9*), and immune evasion, and applied scOncoNet to prioritize candidate targets. Top-ranked genes were dominated by ESCRT and proteasome components, including multiple *CHMP* family members along with *VPS25, TSG101, PSMD14*, and *PSMC2*, reflecting core survival and vesicle-trafficking functions consistent with their pan-cancer essentiality. Compared with existing scRNA-seq-based approaches, scOncoNet shows stronger alignment between gene embeddings and malignant programs, enabling precise recovery of functional gene-program relationships. Across additional single-cell datasets, the model consistently preserved malignant program structure and generated stable target rankings. In summary, scOncoNet integrates global molecular networks with patient-specific cellular programs to identify functional gene drivers directly from tumor single-cell data. Its ability to reveal core cancer progression machinery and prioritize candidate CRISPR targets without perturbation experiments suggests utility for mechanistic studies and therapeutic target discovery in tumor types lacking perturbation datasets.

#4188 Breaks in the cancer immunity cycle correlate with response-predictive HNSCC immune microenvironment phenotypes.

Sarah R. Harrington[1], Daniel Uralov[1], Sophia Linguiti[1], Hannah Kenny[1], Parvesh Kumar[2], Janvi J. Shukla[1], Marianna Nicodemi[2], Ian Argento[2], Emma J. Anisman[1], Eloise Freitag[2], Adam J. Luginbuhl[1], Larry Harshyne[3], Zhao Lin[3], Alban J. Linnenbach[3], Ubaldo E. Martinez-Outschoorn[3], Joseph M. Curry[1]

[1]Department of Otolaryngology- Head and Neck Surgery, Thomas Jefferson University Hospital, Philadelphia, PA,[2]Sidney Kimmel Medical College, Thomas Jefferson University, Philadelphia, PA,[3]Department of Medical Oncology- Head and Neck Surgery, Thomas Jefferson University Hospital, Philadelphia, PA

Introduction

Head and neck squamous cell carcinoma (HNSCC) displays substantial immune heterogeneity that shapes response and prognosis to immune checkpoint inhibitor (ICI) therapy. Unlike biomarkers for response to ICI therapy, there is still no understanding of resistance mechanisms. To address this need, we performed baseline pathway enrichment analyses across TME subtypes and clinical outcomes. Using pairwise comparisons, we identified reproducible “breakpoints” within the Cancer Immunity Cycle (CIC) that inform future precision-therapeutic strategies.

Methods

Bulk RNA-sequences from TCGA HNSCCs HPV+ (n=94) and HPV- (n=415) and an our neoadjuvant ICI cohorts HPV+ (n=53) and HPV- (n=29) were assigned TME subtypes: Immune Enriched (IE), Immune Enriched Fibrotic (IEF), Fibrotic (F) and Depleted (D) using published signatures. Unbiased and supervised GSEA were performed, contrasting TME subtype pairs to identify enriched pathways mapping to CIC steps. Step activity was defined as Bioprocess Count × mean NES. Connectivity of CIRCOS plot chords, denoting interplay between steps, was quantified by shared processes × mean STRING signal for protein-protein interaction. CIRCOS plots were generated for TCGA and trial cohorts. Survival analyses used Cox and Kaplan-Meier models ($p<0.05$).

Results

HPV+ tumors exhibited a global reduction of stepwise CIC activities compared with HPV-tumors. As expected, CIC mapping revealed consistent low activity in antigen release (step 1) and antigen presentation (step 2), with variable loss of tumor cell killing (step 7) in F/D tumors. IE tumors maintained near-intact steps, IEF showed partial attenuation, whereas F showed breaks in steps 1-2, and D activity was minimal. CIC analysis revealed novel subpopulations within a given TME subtype, differentiated by survival. TCGA survival analyses showed statistically significant higher adaptive immune/TCR activity improved outcomes in IE tumors. In HPV- F tumors, a senescence/autophagy gene set linked to CIC predicted worse progression-free survival (HR=7.06, $p=0.03$). In contrast, HPV+ D tumors exhibited activity of a senescence gene set strongly associated with improved OS (HR=0.209, $p<0.001$). Phenotype-level survival (HPV-agnostic) showed significantly worse outcomes for F vs IE tumors. These patterns were reproducible in our clinical cohort. Future pathologic response to ICI mirrored CIC integrity, with higher response rates in IE/IEF, but did not reach statistical significance.

Conclusion

CIC modeling across independent cohorts reveals recurrent immune breakpoints in HNSCC, particularly in antigen release and presentation. This novel approach to parsing the TME and CIC activity may be valuable for predictive biomarker discovery, pertaining to response to ICI therapy.

#4189 Quantifying uncertainty in virtual spatial transcriptomics using Bayesian neural networks.

Thanosan Prathifkumar[1], Nehan Mohamed[2], Anvith Kakkera[3], Zarif Azher[4], Xiaoying Liu[5], Fred Kolling[3], Laurent Perreard[3], Scott Palisoul[5], Louis J. Vaickus[5], **Joshua Jay Levy**[6]

[1]Central Peel Secondary School, Brampton, ON, Canada,[2]Thomas Jefferson High School for Science and Technology, Alexandria, VA,[3]Dartmouth College Geisel School of Medicine, Hanover, NH,[4]California Institute of Technology, Pasadena, CA,[5]Dartmouth-Hitchcock Medical Center, Lebanon, NH,[6]Cedars-Sinai Medical Center, Los Angeles, CA

Introduction: Spatial transcriptomics (ST) enables whole-transcriptome profiling within intact tissue architecture but remains costly and batch-dependent. Deep-learning-based virtual RNA inference from hematoxylin and eosin (H&E) slides offers a way to collect ST at scale without profiling, yet the reliability of such predictions is unclear. Uncertainty may arise from assay noise, biological limits on what morphology can reveal, or variation in gene abundance across tissue structures. Uncertainty estimation complements accuracy by helping distinguish these sources and clarify why some genes are more challenging to infer. Here, we integrate virtual RNA inference with Bayesian neural networks (BNN) to quantify and characterize uncertainty in spatial transcriptomic predictions.
Methods: An in-house dataset of 65 paired H&E-stained colorectal and triple-negative breast cancer whole-slide images with matched Visium ST data yielded 289,569 spots and corresponding 512×512-pixel H&E patches for 991 spatially variable genes. Using 5-fold patient-level cross-validation, a BNN with Bayesian convolutional and multilayer perceptron layers was trained via variational inference, with Kullback-Leibler divergence regularizing weight distributions. During inference, predictive posterior sampling produced means and log-variances for each gene from image patches, enabling separation of epistemic (uncertainty reducible with more data or improved modelling) and aleatoric (irreducible noise driven by biological variability or assay limits) uncertainty. Gene set enrichment was used to characterize genes ranked by uncertainty.
Results: High epistemic uncertainty genes were enriched for signalling and regulatory pathways such as Histone H4-K12 acetylation and positive regulation of apoptosis. High aleatoric uncertainty mapped to stress-response programs including cellular response to ionizing radiation, medium-chain fatty acid biosynthesis, and myeloid cell activation. Low-uncertainty genes were dominated by stable metabolic and cell-cycle pathways, including aerobic respiration, electron transport, and mitochondrial NADH→ubiquinone transport.
Conclusion: These results suggest that the uncertainty framework highlights gene programs that are more amenable to histology-based inference, with metabolic pathways exhibiting the most reliable morphological association. Further algorithmic refinement and external validation will be key to establishing the utility of uncertainty modelling for cohort design in large-scale ST studies.

#4190 A scalable, proteome-wide protein profiling platform with absolute quantification of 1000 proteins to power oncologic drug discovery pipelines.

Jerid Robinson, Nathaniel Robichaud, Grant Ongo, Kiran Edwardson, Alyssa Rosenbloom, Narges Rashidi, Arya Tavakoli, Jeff Munzar, Milad Dagher

Nomic Bio, Montreal, QC, Canada

Proteomics has been constrained by flexibility, high costs, and inconsistent quantification. We present Omni 1000, a quantitative 1000-plex solution powered by nELISA technology—designed for broad, reproducible, and cost-effective protein measurement. Omni 1000 delivers 0.1 pg/mL sensitivity, 99.99% specificity, and dynamic range spanning 3-6 logs. With <10% CV, Omni 1000 ensures precision for discovery and translational applications.

Omni 1000 content was developed through a rigorous, data-driven strategy to achieve comprehensive proteome-wide coverage while retaining high-value markers. The foundation is built from two sources: (1) a curated set of Most Valuable Proteins (MVPs)—biomarkers selected heuristically based on prevalence in key signaling pathways, translational research, and validated endpoints; and (2) large-scale, high-plex proteomic datasets with disease-association. To optimize, we applied Minimum Redundancy Maximum Relevance (mRMR) to reduce overlap, reconstruction loss minimization to preserve signal from high-dimensional datasets, and prioritized MVPs. Each iteration was validated against key biological ontologies—achieving 92% MVP coverage, 100% Reactome level 0, >80% Reactome level 1, 100% pharma-relevant KEGG signaling pathways, and 100% MeSH disease classes.

For biomarker discovery, Omni 1000 makes large-scale and clinically relevant studies routinely achievable through significant cost-efficiencies and rapid readout with flow cytometry. In a study of plasma biobank samples, use of Omni 1000 successfully demonstrated early insights in detecting active rheumatoid arthritis immune signatures prior to onset of clinical symptoms.

In addition, Omni 1000's high-throughput capabilities were used to support a drug screening platform based on patient-derived tumor organoids. Use of Omni 1000 demonstrated insights on baseline donor heterogeneity and drug compound responses and resistances specific to patient tissue profiles, an effort to advance precision medicine.

Together, we demonstrate a novel 1000-plex solution, Omni 1000, with content balancing critical targets and biological breadth, and demonstrate real-world utility through two key applications: early detection of disease and high throughput drug development.

#4191 TP53 dysfunction drives immunometabolic rewiring via mTORC1 activation and autophagy suppression in colorectal cancer.

Eunseuk Lee, Dana Al-Assi, Randy Rueda-Rivera

RWJ Barnabas Health Community Med. Ctr., Toms River, NJ

The tumor suppressor protein p53 regulates both metabolism and immunity through its control of the mTORC1-autophagy axis; yet the mechanistic consequences of TP53 dysfunction in microsatellite-stable colorectal cancer (MSS CRC) remain unclear. We used an integrative transcriptomic approach that combined bulk RNA-seq (GSE146009), TCGA-COAD/READ (n = 647), and single-cell RNA-seq data (GSE108989), to investigate how TP53 loss alters metabolic-immune coupling in CRC. While p53 and autophagy were activated together in wild-type tumors, mTORC1 signaling remained restrained. This pattern preserved metabolic stability and supported a favorable $CD8^+/FOXP3^+$ immune ratio. In contrast, TP53-mutant and null tumors exhibited a decoupling of p53 from mTORC1, leading to sustained anabolic signaling, autophagy suppression, and upregulation of pro-inflammatory cytokines (IL1B, IFNG), which coincided with enrichment of $FOXP3^+$ regulatory T-cells and immune exclusion. Single-cell profiling confirmed that mTORC1 and autophagy remain co-activated across major T-cell subsets. However, immune-metabolic coordination was weaker in exhausted and regulatory populations. Principal-component and correlation analyses revealed two distinct axes, metabolic intensity and immune polarity, that describe TP53-dependent immunometabolic divergence.Taken together, the results suggest that TP53 dysfunction promotes linked metabolic and immune reprogramming through mTORC1 activation and autophagy suppression, resulting in a FOXP3-dominant, immune-cold tumor microenvironment.. This mechanistic insight provides a rationale for combining mTORC1 and autophagy inhibition with immune-checkpoint blockade in TP53-deficient MSS CRC.

#4192 Coordinated miRNA regulation of AR-PI3K/MAPK crosstalk and EMT in prostate cancer.

Fabiana Buono[1], William Lautert-Dutra[1], Dan Dion[2], Camila Morais Melo[1], Cheryl Crozier[2], Fabiano Pinto Saggioro[3], Rodolfo Borges dos Reis[4], Jeremy Andrew Squire[1], Jane Bayani[5]

[1]Department of Genetics, University of Sao Paulo, Ribeirao Preto Medical School, Ribeirao preto, Brazil,[2]Diagnostic Development, OICR - Ontario Institute for Cancer Research, Toronto, ON, Canada,[3]Department of Pathology and Forensic Medicine, University of Sao Paulo, Ribeirao Preto Medical School, Ribeirao preto, Brazil,[4]Department of Surgery And Anatomy, University of Sao Paulo, Ribeirao Preto Medical School, Ribeirao preto, Brazil,[5]Diagnostic Development / Department of Laboratory Medicine and Pathobiology, OICR - Ontario Institute for Cancer Research, Toronto, ON, Canada

Prostate cancer (PCa) progression and therapeutic resistance are critically dependent on the Androgen Receptor (AR) axis and major survival networks, including PI3K/AKT, MAPK, and epithelial-mesenchymal transition (EMT) programs. While individual microRNAs (miRNAs) have been implicated in these pathways, the broader miRNA-driven regulatory systems controlling these interconnected oncogenic axes remain poorly understood. We performed miRNA expression profiling in a clinically well-annotated PCa cohort and conducted an integrative analysis, identifying functional miRNA clusters through network correlation, pathway enrichment, and mapping to established oncogenic and EMT-related signature scores. Literature-based functional annotation was then combined with our miRNA findings to investigate correlations against key EMT transcription factors and tumour suppressors such as PTEN. We identified distinct miRNA clusters whose targets collectively converge on common oncogenic hubs, including AR-PI3K/MAPK-WNT/NOTCH signalling. With a role in EMT modulation, several miRNAs displayed strong negative correlations with EMT transcription factors, including miR-221-5p and miR-542-3p with SNAI2 (r ~ -0.5), and miR-378d and miR-449b-5p with ZEB2 (r ~ -0.7 and -0.4), supporting their functional involvement in suppressing EMT programs. Additionally, miR-542-3p, miR-449b-5p, and miR-302d-3p correlated inversely with PTEN (-0.7, -0.5, -0.5), suggesting their participation in PI3K/AKT pathway modulation. These findings align with the established tumour-suppressive roles of miR-206, miR-302d-3p, and miR-2110—previously linked to MAPK/ERK, AKT/mTOR, and FGFR/RTK-PTEN regulatory axes (Cancers 2024). Pathway enrichment analyses revealed that targeted pathways, including WNT, NOTCH1, PI3K/AKT, MAPK, ERBB2, and FGFR signalling, form an interconnected oncogenic network. Within this framework, miR-378d and miR-449b-5p exhibited strong negative correlations with ERBB2 (-0.7 and -0.5, respectively). Consistent with these molecular interactions, Correlation with Scote-derived oncogenic signatures, including ERBB2 activation and BRCAness, demonstrated that miRNA clusters strongly associate with genomic instability, proliferation, and therapy resistance phenotypes. Collectively, these findings suggest that the identified miRNA clusters function as integrated regulatory modules that simultaneously coordinate the suppression of AR signalling crosstalk with PI3K/MAPK activation and modulation of EMT. Their strong associations with Scote oncogenic signatures and EMT transcription factors underscore their potential as prognostic biomarkers and as targets for rational combination strategies aimed at disrupting AR-survival network crosstalk and overcoming therapeutic resistance.

#4193 Heterogeneous graph neural network meta-analysis of lung cancer and tuberculosis transcriptomic datasets reveals convergent host response networks.

Andrew Triska[1], Selvakumar Subbian[2], **Natarajan Ganesan**[3]

[1]School of Mathematics and Statistics, The Open University, Milton Keynes, United Kingdom,[2]Public Health Research Institute, Rutgers Health, New Jersey Medical School, Newark, NJ,[3]Biomedical and Anatomical Sciences, New York Institute of Technology, College of Osteopathic Medicine (NYITCOM) at Arkansas State University, Jonesboro, AR

Background: Granulomas, hallmark cellular structures of tuberculosis (TB), have similarities to lung tumors, creating a diagnostic and mechanistic interface between infection and malignancy. However, the comparative, genomewide transcriptional landscape between lung cancer and TB granulomas remains poorly characterized. We hypothesize that the lesions in pulmonary TB and cancer may encode convergent molecular programs that regulate the structure and/or function of cells within the lesions.
Methods: We performed a large-scale integrative meta-analysis of 450 RNA-seq samples from patients with lung cancer, TB patients, and healthy controls. Raw FASTQ files were processed to generate robust count matrices. Differential gene expression (DGE) was assessed using DESeq2, and co-expression networks were constructed via WGCNA with batch correction. To capture complex, non-linear relationships between genes, pathways, and clinical metadata, we developed a Heterogeneous Graph Transformer (HGT), a graph neural network that models multi-type nodes and edges, enabling the discovery of shared and disease-specific regulatory hubs.
Results: Heatmap analysis of the top 100 differentially expressed genes revealed distinct clusters with mixed modules indicative of convergent biology between lung cancer and TB granulomas. KEGG enrichment analysis revealed an overlap between immune and oncogenic signaling pathways, including NF-κB, PI3K-Akt, MAPK, Toll-like receptor, and PD-1/PD-L1 checkpoint pathways. Chromatin remodeling emerged as a common theme, with recurrent histone variants (H2AC, H3C, H4C) suggesting epigenetic plasticity. These shared hub genes implicate chronic inflammation and immune mimicry as mechanistic bridges between granulomas and cancer, making them potential biomarkers to distinguish TB vs lung cancer and/or therapeutic targeting.
Conclusions: This systems-level approach reveals a unique TB granuloma-lung cancer interface rooted in common mechanistic pathways, identifying candidate biomarkers and therapeutic targets for two of the world's most burdensome pulmonary diseases.

#4195 OncoGraphDB: Rapid projections of patient-level multimodal graph database facilitates efficient exploration of tumor subtypes and identifies new combinatorial biomarkers of patient outcomes and gene essentiality.

Jacob Pfeil[1], Amber Tse[2], Severiano Villarruel[1], Emily Rossi[3], Liqian Ma[1], Xi Zhao[1], Josue Samayoa[3], Kyle Halliwill[1]

[1]AbbVie Bay Area, South San Francisco, CA,[2]Former AbbVie Bay Area Employee, South San Francisco, CA,[3]AbbVie Inc., North Chicago, IL

Cancer ‘omics data are often analyzed in isolation of other related data modalities despite the potential for added benefit when analyzing a multimodal model. One strategy is to include all available data, but this approach may obfuscate the underlying signal if data modalities exist in the model that do not significantly contribute to the analysis. To enable efficient exploration of multimodal data, we developed the OncoGraphDB framework to rapidly project subgraphs of a larger, all inclusive, cancer omics knowledge graph. This enabled us to identify subspaces that maximally separate patients of interest using a user-defined metric (i.e. patient survival, drug response, or predicted gene essentiality). We found that across cancer indications, gene expression data provided the most single-mode information, which is consistent with several recently published studies. However, performance was improved when predicting prognosis and shared gene essentiality scores when additional data modalities were included in the analysis, including somatic mutation signatures and DNA methylation profiles. Agentic AI was then applied to the Neo4j graph framework to support interactive interrogation of the cancer -omics knowledge graph providing domain experts an exploratory data portal for hypothesis generation. Finally, we describe the gene expression and image classifiers for projecting new patient samples onto the graph to support N-of-1 reverse translation studies. The OncographDB platform facilitates efficient exploration of complex cancer databases and provides data analysis solutions for precision medicine applications.

#4196 Predicting self-antigen recognition of TCRs derived from tumor infiltrating CD8+ T cells via contrastive learning and T cell phenotyping.

Brinda Vijaykumar, Qiaomu Tian, Jack Prazich, Preet Joshi, Neel Patel, John Abel, Anthony Coyle, Daniel Pregibon

Repertoire Immune Medicines, Cambridge, MA

T cell receptor (TCR)-based immunotherapies leverage the ability of a TCR to bind with high specificity and selectivity to peptides derived from intracellular targets, including those overexpressed on tumors. Consequently, TCRs identified from tumor-infiltrating lymphocytes (TILs) that respond to antigens in the tumor microenvironment represent attractive substrates for TCR immunotherapy development. However, de-orphaning TCRs is exceedingly challenging given the diversity of TCR and target sequence space. Although multiplexed peptide-MHC (pMHC) staining assays have improved throughput of direct, *ex vivo* measurement of TCR-pMHC binding, they are limited by TIL sample quality, T cell infiltration, TCR repertoire diversity, and limited pMHC library size. Machine-learning based techniques may overcome these limitations by training models to predict TCR-pMHC interactions and then inferring TCR-pMHC binding on large databases collected in other contexts. Here, we applied a contrastive model of TCR-pMHC binding prediction (1) to 382 tumor samples from 9 indications containing 490,000 T cells. We found that 5,244/490,000 (~1.1%) of TCRs from this dataset were predicted to recognize one of the 4,438 pMHCs in our model training set. Of these, 1,949 were predicted to bind common viral peptides, an observation indicative of bystander recruitment and infiltration. An additional 2,549 TCRs were predicted to bind to Class I onco-antigens, including QLLALLPSL [PRAME], YLEPGPVTA [GP100] and GLYDGMEHLI [MAGEA10]. The model was able to capture TIL TCRs with diverse complementarity-determining regions (CDRs) as well as highly homologous sequences. TCRs predicted to bind self-antigens were phenotyped using Repertoire's DECODE™ platform (2), showing that cancer-specific TCRs tended to have a more cytotoxic and effector like phenotype compared to a memory-like signature on viral specific TCRs (e.g. TCRs specific to cytomegalovirus, Epstein-Barr virus, and influenza). These results demonstrate a way to computationally de-orphan TCR specificities and phenotypically characterize T cells in a high-throughput manner to further our understanding of the TCR landscape in cancer patients. Importantly, this strategy could enable the discovery of TCR sequences suitable for therapeutic development using existing datasets. Future work should focus on increasing the diversity of validated TCR-pMHC specificities and in-vitro validation of predicted TCR-pMHC interactions (as well as reported model performance metrics).1. Abel, John, et al. "REPTRA: Mapping Immune T Cell Receptor Activity from Full Sequences with a Debiased Contrastive Loss." bioRxiv (2025): 2025-10.2. Francis, Joshua M., et al. "Allelic variation in class I HLA determines CD8+ T cell repertoire shape and cross-reactive memory responses to SARS-CoV-2." Science immunology 7.67 (2021): eabk3070.

#4197 Multiomic dissection of KRAS signaling reveals targetable metabolic and DNA repair vulnerabilities in colorectal cancer.

Tom Cohen[1], Ashima Mehta[1], Adam Richardson[1], Monil Gandhi[1], Douglas Guzior[1], Kevin Cho[2], Ethan Stancliffe[1], Gary Patti[2]

[1]Panome Bio, St. Louis, MO,[2]Washington University in St. Louis, St. Louis, MO

Background: KRAS is among the most common oncogenic drivers in colorectal cancer and is historically “undruggable”; yet direct KRAS inhibitors are now entering clinical trials. The systems-level effects of KRAS modulation remain poorly characterized, limiting therapeutic insights. We applied integrated multiomic profiling to reveal mechanistic vulnerabilities that could enhance translational strategies.

Methods: Isogenic HCT-116 colorectal carcinoma cells (homozygous KRAS^G13D mutation vs. partial KRAS loss) were analyzed in biological replicates (n = 3-5) across transcriptomics (15,432 genes), proteomics (6,654 proteins), phosphoproteomics (10,034 phosphopeptides), and metabolomics (3,015 metabolites). Multi-layer data (>30,000 analytes) were integrated via pathway enrichment, correlation networks, and dimensionality reduction to identify core molecular modules downstream of KRAS.

Results: KRAS deletion produced broad molecular reprogramming: 640 transcripts, 74 proteins, 744 phosphopeptides, and 519 metabolites showed significant changes ($q<0.05$). Metabolomics was most perturbed (>17%), revealing increased mitochondrial respiration and branched-chain amino acid catabolism, alongside suppressed glycolysis. Downregulated signaling included collagen biosynthesis, EGFR, IGF transport, and IL-4/IL-13 pathways. Network integration distilled >30,000 features into <100 molecular modules, highlighting metabolic shifts in plasmalogen-associated lipid remodeling and altered phosphorylation of nuclear pore, ribosomal, and DNA repair proteins (ATRX, DAXX). These findings indicate vulnerabilities in oxidative metabolism, lipid metabolism, ribosome biogenesis, and genome stability.

Conclusions: This comprehensive multiomic analysis reveals that KRAS-driven colorectal cancer depends on coordinated control of metabolism, extracellular matrix signaling, and DNA repair pathways. KRAS attenuation shifts cells to oxidative metabolism while exposing vulnerabilities in lipid metabolism and DNA repair machinery. These findings suggest combinatorial therapeutic strategies integrating KRAS inhibition with metabolic or DNA damage-targeted therapies.

#4198 Integrative single-cell transcriptomics and computational docking identify CCL18 as an immunomodulatory target in prostate cancer.

Edwige Flore Gouegni[1], Gebre-Eziagbher Kiros[1], Renee Reams[1], Diana J. Wilke[2], Fredenburg Kristianna[3], Bodour Salhia[4]

[1]College of Pharmacy and Pharmaceutical Sciences, Institute of Public Health, Florida A&M University, Tallahassee, FL,[2]University of Florida, Gainesville, FL,[3]Department of Pathology, Immunology, and Laboratory Medicine, University of Florida, Gainesville, FL,[4]USC Norris Comprehensive Cancer Center, Los Angeles, CA

Background: Prostate adenocarcinoma (PRAD) remains a major cause of cancer morbidity in men, driven by cellular heterogeneity and immune evasion. Single-cell RNA sequencing (scRNA-seq) enables high-resolution profiling of tumor and immune states to uncover cell-specific therapeutic targets. This study integrates scRNA-seq, pathway enrichment, and molecular docking to identify immunomodulatory molecules with therapeutic potential in prostate cancer.
Methods: scRNA-seq data (GSE181294) from 34 PRAD and 5 normal samples (165,905 cells) were processed in Seurat for quality control, clustering, and annotation. Differential expression analyses across tumor, epithelial, and immune compartments were followed by GO/KEGG enrichment and pseudobulk validation. Expression and survival associations were evaluated using TCGA-PRAD via UALCAN. Candidate genes were prioritized through cell-cell communication modeling and validated in silico using structure-based molecular docking with curated ligand libraries.
Results: Seven major cell clusters were identified. Tumor cells showed enrichment of mitotic and chemokine pathways, while T/NK cells exhibited immune-suppressive signatures. CCL18 emerged as a key chemokine overexpressed across tumor and immune compartments and validated in TCGA data. Communication analysis identified CCL18-producing cluster 0 signaling through CCR1, CCR5, and CCR8. Docking revealed high-affinity ligands interacting with residues GLU-9 and ACT-101, supporting the druggability of CCL18.
Conclusions: Integrating single-cell analysis, pathway profiling, and docking highlights CCL18 as a promising therapeutic or vaccine target in PRAD. Its consistent tumor-immune expression and favorable binding properties support further experimental validation.
Keywords: scRNA-seq, prostate cancer, CCL18, immunotherapy, tumor microenvironment, molecular docking.

#4200 Exploring unrestricted antibiotic use gut microbiome imbalance and chemical carcinogens in liver and kidneys toxicity through computer modeling and *in vivo* study.

Solomon Owumi[1], Dooshima A. Bagu[2], Joseph Chimezie[3], Esther M. Pius[1], Uche O. Arunsi[4], Jesutosin O. Babalola[5], Ayomide P. Akomolafe[6], Chima Amadi[7], Chinedum Udekwu[8], Adegboyega K. Oyelere[9], E. Oluwabunmi Olapade-Olaopa[10], Olorunseun O. Ogunwobi[1]

[1]University of Ibadan, Ibadan, Nigeria,[2]Dooshima Bagu, Ibadan, Nigeria,[3]Joseph Chimezie, Ibadan, Nigeria,[4]Chemistry Biochemistry, Georgia Institute of Technology, Georgia Institute of Technology, GA,[5]Biochemistry, University of Ibadan, Ibadan, Nigeria,[6]University of Nebraska, Omaha, NE,[7]Dedra Nutraceuticals and Biotechnology Initiative, ABuja, Nigeria,[8]Chemistry Biochemistry, Michigan State University, East Lansing, MI,[9]Georgia Institute of Technology, Atlanta, GA,[10]Surgery, University of Ibadan, Ibadan, Nigeria

The gut microbiota, vital for human health, can be disrupted by antibiotics, which has been linked to diseases such as cancer. Contamination of food with Aflatoxin B_1 (AFB_1) and Diethylnitrosamine (DEN), both strong liver carcinogens, increases liver cancer risk. This study examines how unrestricted use of common antibiotics (Ampicillin and Ciprofloxacin) affects gut microbes, combined dietary exposure to AFB_1 and DEN, and the development of liver and kidney toxicity in rats. Molecular Docking (MD) and Network Toxicology were used to investigate how AFB_1, DEN, AMP, and CPX cause hepatorenal toxicity by interacting with key hub proteins involved in redox and protective cellular pathways. Ligand orientation and binding energies for STAT3 and EGFR were assessed using molecular docking. Gut microbial analysis shows that AMP and CPX induce antibiotic-driven dysbiosis, suppressing beneficial gram-positive bacteria like Lactobacillus and promoting the growth of opportunistic gram-negative bacteria such as Escherichia coli, Klebsiella pneumoniae, and Pseudomonas aeruginosa. These changes result in toxic metabolite production affecting the hepatic immune system. In the presence of carcinogens, AMP and CPX synergy may contribute to carcinogenesis in co-treated groups. STAT3, EGFR, MAPK8, IKBKB, MMP2, MET, and NOS2 were identified as important hub genes. AFB_1 (–8.5 kcal/mol), CPX (–7.8 kcal/mol), and AMP (–7.6 kcal/mol) showed high affinity for EGFR, indicating a possible synergistic role in EGFR signalling modulation. *In vivo* studies in male Wistar rats showed that co-treatment reduced body, liver, and kidney weights, raised serum hepatic transaminases, creatinine, and urea, decreased antioxidant enzymes, and increased inflammation markers, lipid peroxidation, alpha-fetoprotein, and caspase-3 activity, alongside reduced IL-10 in the liver and kidney. The data indicate that AMP and CPX cause gut dysbiosis and, together with AFB_1 and DEN, have a synergistic hepatorenal toxic effect that may be relevant in the onset of carcinogenesis.

#4201 Simulating trans-endothelial nanoparticle transport via macropinocytosis.

Marvin Skiba[1], **Hae-gyung T. Han**[2], Warren Chan[3]

[1]School of Materials Science and Engineering, Nanyang Technological University, Singapore, Singapore,[2]Harvey Mudd College, Claremont, CA,[3]Nanyang Technological University, Singapore, Singapore

Macropinocytosis is a key mechanism in transendothelial nanoparticle transport into solid tumours. It uses cell membrane ruffles to capture circulating nanoparticles. Endothelial cell ruffles cannot be independently and systematically varied *in vivo*, preventing parameter-specific analysis. We developed an *in silico* model that examines nanoparticle capture by macropinocytosis. We discover that nanoparticle capture rates rise steeply until saturating with ruffle number as well as ruffle turnover time. From our data we derive an equation describing the nanoparticle capture by macropinocytosis. This relationship reveals how ruffle dynamics govern nanoparticle capture efficiency.

#4206 The ancestry-transcriptome link: Machine learning predicts chemotherapy response in breast cancer.

Michelle Guevara-Nieto[1], Maria J. Lopez-Munevar[2], Carlos Orozco-Castano[3], Rafael Parra-Medina[4], Laura Fejerman[5], Valentina Zavala[6], Jone Garai[7], Jovanny Zabaleta[8], Alba L. Combita-Rojas[9], Liliana Lopez-Kleine[2]

[1]Pathology Department, Universidad Nacional de Colombia, Bogota, Colombia,[2]Universidad Nacional de Colombia, Bogota, Colombia,[3]Instituto Nacional de Cancerologia, Colombia, Bogota, Colombia,[4]National Cancer Institute, Bogota, Colombia,[5]UC Davis Comprehensive Cancer Center, Davis, CA,[6]Department of, University of California San Francisco, Santiago, Chile,[7]Stanley S. Scott Cancer Center, Louisiana State University Health Science Center, New Orleans, LA,[8]LSU Health New Orleans, New Orleans, LA,[9]Instituto Nacional de Cancerologia, Bogota, Colombia

Background: Breast cancer resistance to neoadjuvant chemotherapy (NAC) remains a major challenge in Latin America, where limited genomic representation restricts precision-oncology advances. Understanding how genetic ancestry interacts with transcriptomic features may uncover population-specific predictors of treatment response. We investigated the ancestry-transcriptome link using machine-learning models in Colombian breast cancer patients.
Methods: We analyzed 58 women with locally advanced breast cancer treated with NAC (29 responders, 29 non-responders) across five molecular subtypes. RNA-seq identified 339 differentially expressed genes (DEGs); the top 10% most variable DEGs (n=34) were retained following variance-stabilizing normalization. Predictors included clinical variables (tumor size, TNM stage, T-stage, N-stage, grade, clinical stage, treatment regimen, age, BMI, menopause), genetic ancestry fractions (Amerindian-AMR, African-AFR, European-EUR), and 34 DEGs. Recursive Feature Elimination did not improve model performance; therefore, all variables were included. Random Forest (500 trees) and XGBoost models were trained, with hyperparameter optimization via cross-validation.
Results: XGBoost achieved the highest performance (AUC = 0.90) using a learning rate of 0.05, depth 12, and 90% subsample/colsample. Across models, T-stage, age, and Amerindian ancestry consistently emerged as top predictors based on gain, coverage, and split frequency. Among transcriptomic variables, CACNA1D, CLEC3A, TFF1, and TTK showed strongest predictive contribution. Model robustness was confirmed through parameter variation and resampling strategies.
Conclusions: Machine-learning integration of ancestry and transcriptomic features accurately predicts NAC response in Colombian breast cancer patients. Amerindian ancestry, alongside key clinical variables and reproducible gene-expression signatures, influenced prediction performance, underscoring the importance of population-specific factors in treatment resistance. This ancestry-transcriptome framework provides a scalable, data-driven approach for advancing precision oncology in underrepresented Latin American populations.

#4207 Omics-aware patch aggregation via multimodal co-training with a scalable multi-omics encoder for slide-level prediction across an oncology biomarker panel.

Hwanil Choi[1], Tae Hyun Hwang[2], Soonyoung Lee[1], Jongseong Jang[1]

[1]Bio Intelligence Lab, LG AI Research, Seoul, Korea, Republic of,[2]Department of Surgery, Vanderbilt University Medical Center, Nashville, TN

Background: Whole-slide images (WSIs) are widely available, but matched multi-omics profiles are limited, especially when multiple modalities are required. We developed a multimodal learning framework that integrates RNA expression and DNA mutation with H&E WSIs, explicitly modeling partially observed omics to train an omics-aware patch aggregator for slide-level prediction.
Methods: An omics-aware patch aggregator was trained with a slide-level contrastive objective that aligns a Multi-Omics Encoder (MOE) and a Slide Encoder (SE). The MOE is a shared Transformer that tokenizes each omics modality, concatenates modality-specific tokens with omic-type encodings, and uses self-attention to capture cross-omic interactions, allowing new omics to be added without changing the architecture. The SE processes tens of thousands of patches per slide and incorporates patch coordinates via relative positional bias to emphasize spatially proximal regions. Multimodal pretraining used ~20,000 partially paired WSIs and multi-omics profiles from The Cancer Genome Atlas and Genotype-Tissue Expression projects.
Results: After multimodal pretraining, the omics-aware aggregator supported slide-level prediction across an oncology biomarker panel. For gene overexpression, area under the ROC curve (AUC) values were: LAG3 0.84, CLDN6 0.68, CD274 0.98, EGFR 0.74, ERBB2 0.72, ERBB3 0.69, CD276 0.82, VTCN1 0.72, TACSTD2 0.77, FOLR1 0.93, and MET 0.82. By tumor type and task, lung adenocarcinoma achieved AUCs of 0.70 for tumor mutational burden, 0.87 for EGFR mutation, and 0.62 for KRAS mutation; colorectal cancer 0.99 for microsatellite instability; breast cancer 0.95, 0.88, and 0.81 for ER, PR, and HER2 protein subtyping and 0.74 and 0.86 for TP53 and PIK3CA mutations; renal cell carcinoma 0.60 for PBRM1 and 0.74 for BAP1 mutations; and colon adenocarcinoma 0.88 for KRAS and 0.89 for TP53 mutations. Gene overexpression tasks used The Cancer Genome Atlas with five-fold cross-validation across four seeds; lung and colorectal models used Samsung Medical Center cohorts; breast subtyping used the BCNB cohort; and renal and colon tasks used Clinical Proteomic Tumor Analysis Consortium data.
Conclusions: An omics-aware patch aggregation framework co-trained with a scalable multi-omics encoder and WSIs enables accurate slide-level prediction for diverse biomarkers and tumor types and illustrates how partially paired multi-omics data can strengthen digital pathology models. AI was used for language editing only; authors are responsible for all content and approved the final version.

#4208 Machine learning models for predicting prostate cancer risk in Hispanic men.

Ricardo J. Rodriguez-Colon[1], Amaia V. Varela-Parrilla[2], Zinned C. Medina-Nieves[1], Maria M. Sanchez-Vazquez[1], Magaly Martinez-Ferrer[1]

[1]University of Puerto Rico Comprehensive Cancer Center, San Juan, PR,[2]Department of Biology, University of Puerto Rico, Rio Piedras Campus, San Juan, PR

Introduction: Hispanic men in the United States experience a notable prostate cancer (PCa) burden, with studies reporting higher rates of advanced-stage disease at diagnosis compared with non-Hispanic men. However, their genetic and sociodemographic profiles remain untargeted in current risk prediction approaches. These observations highlight gaps in current risk assessment strategies and the need for improved, population-relevant prediction tools. Machine learning (ML) applications in biomedical research have yielded valuable advances in the early detection and prediction of cancer risk. The aim of this study was to develop a ML model to predict PCa risk in Hispanic men leveraging data from the All of Us Research Program.

Methods: The study cohort included 20,172 Hispanic males, 220 PCa cases (1.1%) and 19,952 controls. Predictors included age group (≤40, 41-59, ≥60 years), family history of PCa, smoking status, drinking frequency and the rs10090154 genotype associated with PCa. Data were split 80/20 into training (n= 16, 138) and testing (n= 4,034) sets. To address class imbalance, class weights were applied. Logistic regression, random forest and XGBoost models were trained and evaluated. Models underwent a five-fold cross-validation with sigmoid calibration, and performance was assessed using ROC-AUC, PR-AUC, Brier score, precision recall and F1 score.

Results: Among the three models, the logistic regression model achieved the best balance of discrimination and calibration with a mean ROC-AUC of 0.872 (95% CI: 0.856-0.885), PR-AUC of 0.059 (95% CI: 0.045-0.074), Brier score of 0.0105 and an F1 score of 0.066. The model metrics were accuracy = 0.704, recall = 0.955 and precision = 0.034. Correspondingly, the false negative rate (FNR) was 4.5%, indicating that only 2 out of 44 true PCa cases were misclassified as controls, while the false positive rate (FPR) was 30.6%, meaning roughly one in three non PCa cases were incorrectly flagged as positive. Feature importance and odds ratio analyses identified Age ≥60 and family history of PCa as the most influential predictors for the model, followed by the rs10090154 genotype and former smoking status. Comparatively, the random forest (ROC-AUC= 0.851) and XGBoost (ROC- AUC= 0.858) models demonstrated similar discrimination but exhibited slightly lower calibration and interpretability compared with logistic regression.

Conclusions: A class-weighted, sigmoid-calibrated logistic regression model achieved accurate, interpretable and well calibrated PCa risk predictions. Despite the low observed case prevalence in the All of Us cohort, the model showed strong sensitivity and discrimination, supporting its utility for biomedical and clinical risk stratification in population-based precision health research. These findings highlight the potential of simple and interpretable ML models to improve early PCa risk assessment in Hispanic men.

#4209 A multi-variable machine learning model integrating stage, histology, grade, and treatment to predict mortality in salivary gland cancer: A SEER 2010-2021 population-based study.

Chiugo Okoye[1], Chinemerem Martlin Emeasoba[2], Chidi Obialo-Ibeawuchi[3], Olanipekun Ntukidem[4], Oboseh John Ogedegbe[5], Uchenna Amaechi[6]

[1]Northeast Georgia Health System, Inc., Gainesville, GA,[2]UAMS Northwest, Fayetteville, AR,[3]Walden Univeristy, Minneapolis, MN,[4]Trinity Health Ann Arbor, Yspsilanti, MI,[5]Tirnity Health Ann Arbor, Yspsilanti, MI,[6]Howard University Hospital, DC, WA

Background: Salivary gland cancers are rare, heterogeneous tumors with widely variable clinical outcomes. Current prognostic tools rely on limited clinicopathologic features and do not incorporate complex interactions between tumor biology and treatment patterns. We aimed to develop and validate a machine learning (ML) model integrating stage, histology, grade, tumor size, and treatment modalities to predict all-cause mortality using a large U.S. population-based cohort.

Methods: We identified patients with primary malignant salivary gland tumors in the SEER database (2010-2021). Variables included age, sex, race, AJCC stage, histologic subtype, tumor size, grade, nodal status, surgery, radiation, and chemotherapy. Missing data were imputed using iterative multivariate imputation. Models evaluated included logistic regression, random forest, gradient boosting, and XGBoost. Performance was assessed with 70/30 train-test split and temporal validation using diagnoses from 2010-2017 as training and 2018-2021 as testing. Model interpretability was examined using SHAP values.

Results: A total of 12,678 salivary gland cancer cases met inclusion criteria. XGBoost showed higher performance, with an AUC of 0.87 in the test set and 0.85 in temporal validation, outperforming logistic regression (AUC 0.76). Sensitivity, specificity, and PPV for high-risk classification were 0.81, 0.78, and 0.72, respectively. SHAP analysis identified stage, tumor size, histologic subtype, grade, and receipt of surgery as the most influential predictors of mortality. The model revealed nonlinear interactions between tumor grade and nodal status that were not captured by traditional regression.

Conclusion: We came up with a robust, interpretable machine learning model integrating key clinical, pathologic, and treatment variables to predict mortality in salivary gland cancer with high accuracy. This tool provides a strong framework for individualized risk stratification and may help decision-making regarding treatment intensity, surveillance, and survivorship care. Further prospective validation is warranted to support clinical adoption.

#4210 Transformer and pretraining on external ehr cohort boosts infection risk prediction in hematologic malignancies.

Banafshe Felfeliyan[1], **Natasha Markuzon**[2]

[1]AstraZeneca Canada, Mississauga, ON, Canada,[2]AstraZeneca, Waltham, MA

Infections are a major early driver of morbidity and mortality in hematologic malignancies, particularly in chronic lymphocytic leukemia (CLL), due to intrinsic immune dysfunction and therapy induced immunosuppression. Predicting infection risk and identifying contributors prior to treatment is warranted; meanwhile limited sample size in local EHRs limits our ability to predict them accurately. We demonstrate that an attention-based transformer pretrained on an external cohort (CLL), lymphomas, multiple myeloma (MM)) and finetuned on a local CLL cohort enhances infection risk prediction. We used multimodal genomic and clinical data (EHR, labs, treatment) from two independent datasets, Flatiron CLL Custom Spotlight (FCCS; n=1,725, USA) and DALYCARE (n=3,418; Denmark) that includes CLL, lymphomas, MM. In the absence of standard infection labels prescribed antibiotics served as a proxy; infection prevalence was 33.6% in FCCS and 64.4% in DALY CARE. After schema harmonization and temporal aggregation across four-time windows, we derived 389 features (FCCS) and 688 (DALYCARE), with 249 shared ones including treatment, demographics, labs, vitals, and omics info. Models were trained and evaluated to predict infection risk 24 week post first line treatment with 5fold cross-validation per cohort. Cross cohort generalization was assessed via self-supervised learning (SSL) pretraining on full DALYCARE followed by fine tuning on FCCS. On 249 shared features SSL pretraining on DALY-CARE increased C-index vs training only on FCCS, from 0.63±0.05 to 0.66±0.07, with consistent PR-AUC gain (0.42 ± 0.06 to 0.46 ± 0.1), indicating that knowledge transferred from a larger external cohort, even with mixed lymphoid subtypes, can mitigate performance loss when sample size is limited. Without DALYCARE pretraining and using the full FCCS feature set (389), the transformer reached a higher C-index (0.69 ± 0.02 vs 0.66 ± 0.07), suggesting richer cohort features- still outweigh pretraining benefits. The transformer also outperformed baselines: C-index 0.69 ± 0.02 (FCCS) and 0.68 ± 0.02 (DALYCARE) vs CoxPH 0.59 ± 0.03 and 0.57 ± 0.01; PR-AUC 0.73 ± 0.07 and 0.73 ± 0.04 vs LightGBM 0.60 ± 0.04 and 0.59 ± 0.06. Attention based interpretability scores, and permutation importance are aligned in both cohorts and with known risk factors, including del(17p), renal function markers (eGFR, K+, NA+), and prior infection history. Transformers transfer knowledge across external cohorts, outperform baselines in infection risk prediction, improved interpretability. While focused on CLL, this demonstrates that leveraging external cohorts and other diseases can improve local predictions when samples are limited. Future work will combine transferred prior knowledge with richer cohort features to further enhance performance.

#4211 AI-driven epigenomic profiling reveals early predictors of cutaneous squamous cell carcinoma risk in hidradenitis suppurativa.

Murali R. Kuracha[1], Sree Naga V. Kuracha[2], Aaren Vedangi[3], Radhakrishna Uppala[4], Lavanya Uppala[5], Venkata Duvvuri[1]

[1]Sirius Mindshare Academy, San Jose, CA,[2]Millard North High School, Omaha, NE,[3]Clinical research, KIMS ICON Hospital, Visakhapatnam, India,[4]Obstetrics and Gynecology, Beaumont Health, Royal Oak, MI,[5]School of Medicine, Creighton University, Omaha, NE

Background: Hidradenitis Suppurativa (HS) is a chronic inflammatory skin disease with a markedly increased risk of cutaneous squamous cell carcinoma (cSCC), including aggressive and often fatal variants. Although cSCC arises through ultraviolet injury, chronic inflammation, impaired wound repair, and smoking, its molecular drivers remain incompletely defined. Emerging evidence implicates epigenetic dysregulation, particularly DNA methylation, as an early indicator of carcinogenic potential. Our HS cohort contained no cSCC cases at recruitment, providing a unique opportunity to identify early epigenomic alterations preceding malignant transformation. Methods: Genome-wide DNA methylation was profiled in blood from 24 HS cases and matched controls using the Illumina MethylationEPIC array. Differentially methylated CpGs were identified through a rigorous bioinformatic pipeline and cross-referenced with cSCC datasets to define overlap with oncogenic pathways. Artificial intelligence approaches, including deep learning, Cox elastic-net survival modeling, random forest, and integrated AI/ML pipelines, were used to prioritize CpGs associated with cSCC risk. Results: We identified significant methylation alterations (FDR ≤ 0.05) at 32 CpG sites across 32 genes in HS, comprising 24 hypomethylated and 8 hypermethylated loci. All are previously implicated in cSCC and converge on canonical oncogenic pathways, including *EGFR/MAPK, p53, TERT, NOTCH* signaling, and DNA repair/chromatin remodeling. The cSCC tumor-trained Cox proportional hazards model (Cox model) demonstrated strong prognostic performance (C-index 0.78-0.84 across cross-validation). Applying this model to HS samples generated a continuous cSCC Epigenetic Prognostic Score (cSCC-EPS) that stratified HS patients into low-, intermediate-, and high-risk methylation phenotypes. SHapley Additive exPlanations (SHAP) analyses highlighted CpGs within *EGFR, DNMT1, TP53, NOTCH3, BRAF,* and *TERT* as the strongest contributors to cSCC predicted risk. This integrative AI-ML epigenetic pipeline identified HS patients with methylation profiles converging on high-risk cSCC tumor biology, suggesting a blood-based molecular window into early carcinogenic processes. Conclusions: HS patients harbor blood-based methylation signatures that mirror early epigenomic alterations seen in cSCC. This AI-integrated framework provides the first evidence that these biomarkers can predict malignant transformation in HS, positioning methylation profiling as a promising tool for early cSCC risk assessment.

#4212 Baseline peripheral blood scRNA-seq AI estimator framework predicts solid-tumor response and adverse events via molecular foundation models and cell-to-patient learning.

Pablo Moreno[1], **Marta Milo**[1], Ricardo Miragaia[1], Alex Proutski[1], Virginia Savova[2], Ikbel Achour[3]

[1]Astrazeneca, Cambridge, United Kingdom,[2]Astrazeneca, Waltham, MA,[3]Astrazeneca, Gaithersburg, MD

Introduction: Accurately identifying patients likely to benefit from therapy and at risk of adverse events from baseline blood samples, is an unmet need in oncology. We developed a translational AI estimator framework that predicts treatment response, adverse events (AEs), and molecular signatures from baseline PBMC single-cell RNA-seq, for solid tumors. We used baseline PBMC scRNA-seq counts (with optional cell-type annotations), pre-trained molecular foundation models (FMs) (scGPT v1.0 [1], scFoundation [2]), cell-to-patient Multi-Instance Learning (MIL) [3] with RECIST labels (CR/PR Responders; SD/PD Non-Responders), to predict responses. We fine-tuned downstream tasks, applied scVI-based data augmentation [4] to improve stability and generalization, with an interpretability layer linking predictions to cell types and gene programs.

Results: Using baseline PBMC scRNA-seq from patients with solid tumor treated with immunotherapy (103 patients, ~12,000 cells/patient), the estimator predicts treatment response from baseline blood across FM backbones and identifies an optimal downstream architecture. We used scFoundation with and without hierarchical attention and scGPT. For scFoundation without hierarchical attention, we observe learning with substantial loss reduction, discrimination of classes with AUC just below 0.8 and F1 scores ≈ 0.78. For scFoundation with hierarchical attention we observe similar performance with slightly worse accuracy with AUC ≈ 0.75 and F1 ≈ 0.70 . For scGPT, we observe learning (loss reduction), good discrimination of classes with AUC ≈ 0.75 and F1 scores just over 0.7. Validation scores are slightly worst in all cases. Results we reported so far are reflecting the ability of our framework to generalize, show competitive performance with differences attributable to hierarchical vs non-hierarchical aggregation. Data augmentation to improve training stability and preliminary AE risk modeling, prioritizing grade ≥3 events, are showing encouraging results. Molecular signatures are used to support mechanistic insight and biomarker explaining predictions.

Conclusions: Baseline blood single-cell signals combined with FM embeddings and cell-to-patient learning can predict treatment response in solid tumors and provide a path to AE stratification and signature discovery. Improvements can be made with larger dataset and interpretable biological rationales can be facilitated by this framework.

#4213 Generative genomics accurately predicts cancer gene expression.

Gregory Koytiger[1], Alice M. Walsh[1], Vaishali Marar[1], Kayla A. Johnson[1], Max Highsmith[1], **Alexander R. Abbas**[1], Andrew Stirn[2], Ariel Brumbaugh[1], Alex David[1], Darren Hui[1], Jeffrey Kahn[1], Sheng-Yong Niu[1], Liza J. Ray[1], Candace Savonen[1], Stein Setvik[1], Jeffrey T. Leek[1], Robert K. Bradley[1]

[1]Synthesize Bio, Seattle, WA,[2]Variational Bio, Seattle, WA

AI models capable of predicting experimental outcomes could accelerate biomedical research by circumventing fundamental constraints of laboratory experimentation and clinical trials. We developed GEM-1 (Generate Expression Model-1), a generative genomics framework that models the diversity of real-world gene expression experiments and accurately predicts future experimental results.

We trained GEM-1 using 470,691 bulk RNA-seq samples from 24,715 datasets in the NCBI Sequence Read Archive, spanning diverse tissues, diseases, and over 18,000 distinct perturbations. An automated metadata agent harmonized fragmented experimental descriptions using large language models. GEM-1 employs a deep latent variable model that partitions experimental metadata into biological, technical, and perturbational components, using pretrained foundation model embeddings to enable generalization to novel perturbations.

Testing on holdout data deposited after training, GEM-1 achieved pseudoreplicate-level accuracy (pearson correlation of gene rank across samples, r_gene, of 0.65-0.75) for previously observed contexts and maintained strong performance for completely novel genetic (r_gene = 0.58-0.63) and chemical perturbations (r_gene = 0.52-0.68). The model correctly predicted 63% and 70% of enriched gene sets for novel genetic and chemical perturbations, respectively. We extended GEM-1 to single-cell data using 41.5 million cells, achieving comparable performance to established models for cell type annotation while enabling interpretable biological feature inference.

We demonstrated clinical utility by generating synthetic cohorts that accurately recapitulated key biological phenomena: SYNTH-TEx (5,300 healthy tissue samples matching GTEx patterns), SYNTH-interferon (200 samples correctly modeling lupus interferon dysregulation), and SYNTH-cancer (10,523 samples exhibiting known molecular features of cancer). We show that GEM-1 can simulate novel perturbations on specific patient samples, an ability we term "reference conditioning".

This approach represents a significant advance toward AI systems that can predict experimental outcomes before physical experiments are conducted, shortcutting fundamental limitations in experimental speed and clinical trial recruitment and potentially revolutionizing drug development and personalized medicine.

#4215 A comparative assessment of machine learning models for predicting prostate cancer using PVT1 biomarkers and PSA.

Pragyan Kadel[1], Rachel E. Bonacci[2], Emmanuel Owusu Asante-Asamani[3], Olorunseun O. Ogunwobi[4]

[1]Data Science, Clarkson Univ., Potsdam, NY,[2]Biology, Michigan State University, East Lansing, MI,[3]Mathematics, Clarkson Univ., Potsdam, NY,[4]Michigan State University, East Lansing, MI

Prostate cancer (PCa) is one of the leading causes of cancer-related deaths among men, especially in populations of African ancestry. While prostate-specific antigen (PSA) testing is the most common diagnostic tool, its low specificity results in overdiagnosis and overtreatment. Recent studies have shown that specific exons of the PVT1 gene, such as exon 4A, exon 4B and exon 9, may serve as promising biomarkers to improve PCa risk stratification when combined with PSA levels. Building on this work, our study evaluates the predictive accuracy of machine learning techniques in identifying patients with any prostate cancer or high-grade prostate cancer on data from 108 multiracial men with elevated PSA. We explore different combinations of these features using logistic regression and support vector machines (SVMs).We found no single best method across all population groups and endpoints. The optimal classifier varied based on the specific prediction task. For predicting any cancer in the general population, the best performing model was Logistic Regression (F1-score of 0.72) when PSA is combined with PVT1 exon 4a. For cancer grade prediction in the general population, SVM achieved the best performance (F1 score of 0.93) using PSA, PVT1 exon 4a and PVT1 exon 9. For predicting the risk of any cancer among Men of African Ancestry (MoAA) Logistic Regression achieved the best accuracy (F1 score of 0.89) by combining PSA with PVT1 exon 4a.Our results show that combination of PVT1 biomarkers with PSA improves the accuracy of risk prediction across different populations and endpoints. Additionally, Logistic Regression provides more accurate predictions of any cancer whereas SVMs perform better for predicting high grade cancer. Future work will focus on evaluating our models on larger clinical data

#4216 Interpreting PLMs for cancer discovery: High attention hotspots predict pathogenic mutation positions and novel drug binding sites.

Sophia J. Pribus[1], Gowri Nayar[2], Russ Altman[3]

[1]Stanford University School of Medicine, Stanford, CA,[2]Biomedical Informatics, Stanford University, Stanford, CA,[3]Bioengineering, Stanford University, Stanford, CA

Computational proteomics has revolutionized cancer research, guiding targeted experimental exploration to accelerate protein-based mechanistic discovery. Protein Language Models (PLMs) enable scalable, resource-efficient study; through large-scale training on only primary protein sequences, PLMs generate vector representations of protein structure that have been shown to capture biochemical and structural properties. A core component of PLMs is the attention mechanism, which specifically captures long-range interactions across a protein sequence in attention matrices. Using the previously unexplored attention matrices generated by the Evolutionary Scale Modelling 2 (ESM-2) PLM, we developed a novel method to identify High Attention (HA) residues, the specific residues that ESM-2 assigns the most attention to early in training. We found that HA residues had interpretable links to biological function across the human proteome, including proximity to active sites and conservation across protein families. We further used AlphaMissense pathogenicity predictions and TCGA-labeled pathogenic variant positions to determine that HA residues predict protein regions with high pathogenic risk. Finally, we explored the utility of HA residues for novel binding site discovery, an open challenge in cancer research. Using Uniprot and Biolip annotations, we confirmed that HA residues were spatially proximal to previously-known binding sites. We then used SiteMap to predict the bindability of HA residue regions in both annotated and unannotated proteins. We identified multiple cancer protein examples where HA residues identified regions with previously undiscovered high bindability and thus potential novel therapeutic utility. In summary, our work demonstrates the biological interpretability of PLM representations and offers a valuable method to prioritize functionally relevant protein residues for targeted biomedical research.

#4217 Multi-modal modeling of genomic, histopathologic, and lab data predicts survival after hepatectomy in oligometastatic colorectal cancer.

Divya Koyyalagunta, Stefanie Gerstberger, Marion Liu, Chenlian Fu, Simran Chhabria, Madison Darmofal, Kevin Michael Boehm, Justin Jee, Michele Waters, Vinod P. Balachandran, Kevin Soares, Alice C. Wei, Jeffrey A. Drebin, T. Peter Kingham, William R. Jarnagin, Jinru Shia, Francisco Sanchez-Vega, Michael I. D'Angelica, Karuna Ganesh, Quaid Morris

Memorial Sloan Kettering Cancer Center, New York, NY

Background: Oligometastasis is an intermediate stage of metastatic progression with limited spread and organ involvement, where curative treatment remains possible. In colorectal cancer (CRC), ~10% of patients present with liver-limited oligometastatic disease and undergo hepatectomy with curative intent. However, there is an unmet need for pre-operative predictive biomarkers that can distinguish long-term survivors from patients who relapse shortly after hepatectomy and thus did not benefit from surgery. To improve clinical decision-making for oligometastatic CRC, we aimed to develop a machine learning (ML) model to reliably predict post-hepatectomy outcomes using routinely collected clinical data.
Methods: We analyzed 284 CRC patients treated at Memorial Sloan Kettering Cancer Center who had liver-confined oligometastatic disease and underwent metastatic resection via partial hepatectomy. Four data modalities were collected: clinical features; MSK-IMPACT targeted exon sequencing; histopathology features from whole slide images; and laboratory values collected within 30 days pre-hepatectomy. We trained an XGBoost ML model with nested cross-validation to predict which patients would achieve overall survival greater than three years after hepatectomy.
Results: An ML model trained on genomics, histopathology and lab data achieved the highest predictive performance (AUROC = 0.75, SE = 0.03), with comparable performance using only genomics and lab data (AUROC = 0.73, SE = 0.04). Combining ML-predicted risk with the established Clinical Risk Score (CRS) for CRC recurrence showed a modest increase in prognostic discrimination (CRS C-index = 0.606, CRS + ML C-index = 0.635). Lab and histopathology variables contributed most to model predictions, and an elevated systemic inflammation index ((platelets × neutrophils) / lymphocytes) was associated with worse prognosis, consistent with prior work. We further found that deep deletion in dual-specificity phosphatase DUSP4, a regulator of MAPK signaling, was significantly associated with improved long-term survival (log-rank p = 0.016).
Conclusions: A multi-modal ML model using pre-operative genomic, histopathologic, laboratory, and clinical data can predict long-term survival following hepatectomy in oligometastatic CRC. This study offers a strategy for integrating routinely collected data to improve clinical decision making and risk stratification for resection of oligometastatic disease.

#4218 ProteoBridge: Bridging skipped sections via histology-based protein prediction.

Minji Kim[1], Sunho Park[2], Seock-Jin Chung[1], Inyeop Jang[1], Jean R. Clemenceau[1], Soyoung Im[3], Eric Sha[1], Hwanil Choi[4], Soonyoung Lee[4], Jongseong Jang[4], Sam C. Wang[5], Tae Hyun Hwang[1]

[1]Section Surgical Research, Vanderbilt University Medical Center, Nashville, TN,[2]Surgical Section Research, Vanderbilt University Medical Center, Nashville, TN,[3]College of medicine, The Catholic University, Suwon, Korea, Republic of,[4]LG AI Research, Seoul, Korea, Republic of,[5]University of Texas Southwestern Medical Center, Dallas, TX

Background: The progress of spatial multimodal platforms has enabled high-resolution mapping of various types of molecular and morphological characteristics within a tissue. Proteins influence cellular phenotypes and the organization of the tumor microenvironment, with their abundance and patterns highly correlated in adjacent serial sections. Spatial Multimodal platforms such as Singular Genomics G4X, which capture H&E-stained images, multiplexed protein expression, and targeted RNA transcriptomics from the same tissue slide, now create a foundation for three-dimensional (3D) spatial multimodal profiling and 3D tumor microenvironment modeling. However, comprehensive multiplex protein imaging across entire tissue stacks is costly, labor-intensive, and impractical, leading to sparse proteomic sampling that limits accurate 3D reconstruction.Methods: We developed ProteoBridge, a deep learning-based framework that predicts protein expression patterns across serial tissue sections to densify the proteomic information needed for 3D molecular modeling. For each tissue stack, the model was trained on the first section, which contains H&E, multiplex protein images, and RNA transcriptomics. The inputs include H&E tiles and RNA transcriptome data, while the outputs are multi-channel protein maps for the same field of view. The combination of targeted RNA transcriptomics and H&E stained morphology helps define cell types and states, allowing the model to learn morphology-to-protein relationships based on transcriptional programs. The training focused on reducing mean absolute error across protein channels to establish histology-protein correspondences for unmeasured sections.Results: We evaluated ProteoBridge on tissue stacks with multiple profiled sections. Image-level similarity between predicted and measured protein maps was assessed. Using single-slide supervision, ProteoBridge accurately reproduced marker intensities and preserved cross-plane consistency, capturing both intensity values and spatial organization of proteins.. By filling in skipped planes, ProteoBridge generates a more continuous 3D representation of the tumor proteome suitable for downstream 3D molecular modeling and visualization.Conclusion: ProteoBridge requires only routine H&E staining on the remaining sections in a stack to infer protein intensities across serial planes, reducing cost and turnaround time while expanding effective proteomic coverage. Using the G4X platform's multimodal data and extending protein predictions to unmeasured areas allows for cost-effective 3D reconstruction of the tumor proteome, enhancing molecular modeling of the tumor microenvironment and its heterogeneity.Generative AI assisted only with language editing of this abstract. The authors retain sole responsibility for the scientific content and conclusions, having reviewed and approved the final version.

#4219 Predicting immunotherapy response in patients with hepatocellular carcinoma from clinical and textual features using AI techniques.

Anwaar Saeed[1], Meghana Singh[1], Yuming Shi[1], Alireza Tojjari[1], Vaishnavi Balaji[2], Lakshya Sharma[3], Azhar Saeed[4], Thant Hoe[2], Yuxi Zhang[2], **Sola Adeleke**[2]

[1]Department of Medicine, Division of Hematology & Oncology, University of Pittsburgh Medical Cancer & UPMC Hillman Cancer Center, Pittsburgh, PA,[2]Curenetics Ltd, London, United Kingdom,[3]School of Medicine, University of St Andrews, Scotland, United Kingdom,[4]University of Vermont Medical Center, Colchester, VT

Background:
Immunotherapy (IO) improves survival in advanced hepatocellular carcinoma (HCC), yet under 30% of patients respond to treatment. Existing biomarkers have shown limited predictive accuracy. Machine learning (ML) and natural language processing (NLP) techniques could be used to develop prediction models that support personalised treatment. We aimed to develop and evaluate machine learning models that predict response to IO in patients with HCC.
Methods:
We retrospectively analyzed data from 302 patients with HCC treated with immunotherapy at UPMC Hillman Cancer Centre between December 2014 and December 2023. Five machine learning models were developed to predict immunotherapy response including logistic regression, random forest, XGBoost, support vector machine and multi-layer perceptron. Models were initially trained using 20 clinical features, then models were expanded to include 50 combined clinical and text-embedded features. Radiological and clinical notes were processed using a natural language processing (NLP) model to generate text embeddings. Data was split into training (80%) and test (20%) sets. Shapley Additive Explanations (SHAP) was used to interpret the prediction models.
Results:
Of the 302 patients, 215 (71%) had stable disease and 87 (29%) had progression. The best-performing model was the Random Forest classifier incorporating both clinical and NLP-derived features (AUC 0.77, Precision: 0.72, Recall 0.72). Model performance marginally decreased when restricted to clinical variables alone (AUC 0.71, Precision: 0.70, Recall 0.70). Key predictors of response to immunotherapy included lower alpha-fetoprotein (AFP), liver function tests within normal range (AST, ALT, ALP, albumin, bilirubin), higher total protein and lower grade of ECOG performance status. 142 patients had first-line IO treatment with atezolizumab and bevacizumab (Atezo/Bev) and 57 patients had durvalumab and tremelimumab (Durva/Treme). A subgroup analysis showed that model performance for patients receiving Atezo/Bev (test AUC-ROC 0.97) was superior to those receiving Durva/Treme (test AUC-ROC 0.66). However, there was no statistically significant difference in predicted mean response between the two IO regimens (Atezo/Bev 0.55, Durva/Treme 0.64, T-statistic: -1.54, p-value 0.13).
Conclusions:
This study demonstrates that ML models integrating both clinical and NLP-derived features can accurately predict IO response in patients with HCC. Key predictors of disease progression included AFP, liver function blood tests and ECOG performance status. Future work will externally validate these results on larger datasets, with the aim of developing generalizable and clinically useful predictive models.

#4220 Predicting high-risk colorectal polyps using pre-colonoscopy features: Machine learning model development and validation.

Basheer Qolomany, Mrinalini Deverapall, Adeyinka O. Laiyemo, Zaki A. Sherif, Hassan Brim, Hassan Ashktorab

Dept. of Medicine, Howard University College of Medicine, Washington, DC

Background: Advanced colorectal polyp risk stratification typically relies on colonoscopy and/or pathology findings, but there is interest in whether there are non-invasive features visible prior to colonoscopy that can identify which patients are at higher risk. Such a tool could help in clinical decision-making, enabling colonoscopy surveillance to be reserved for those most likely to have high-risk polyps and avoiding unnecessary procedures in those at lower risk.

Methods: We developed machine learning models to predict high-risk polyps using demographic, lifestyle, and comorbidities. Patients with villous/tubulovillous adenoma, high-grade dysplasia, ≥10 mm in size, and/or ≥3 polyps per procedure were considered as having High-risk polyps (HRP), while all others were considered to be Low-risk polyps (LRP). The data set consisted of 4,681 patients from 2014 - 2022 (internal validation; 2018 HRP, 2,658 LRP) and 1,562 patients from 2023-2024 (external validation; 769 HRP, 793 LRP). Models utilized were neural networks, random forest, SVM, Naive Bayes, logistic regression, decision trees, KNN, and XGBoost.

Results: The neural network achieved the best internal performance (ROC-AUC 0.7764, PR-AUC 0.75, accuracy 0.72). However, external cohort performance reduced (ROC-AUC 0.67, accuracy 0.66), suggesting overfitting or feature drift. Less complex models such as Naive Bayes, SVM, and XGBoost, while weaker internally (ROC-AUC 0.54-0.59), demonstrated stronger external performance (ROC-AUC 0.52-0.63, accuracy ~0.53-0.60). This suggests that predictive signal in pre-colonoscopy features exists but is moderate and very sensitive to temporal and cohort variation. Model interpretability analysis using SHAP values revealed that the main variables driving predictions were age, smoking status, sex, occupation, race, and indication for colonoscopy. Additional contributors included family history of colorectal cancer in first-degree relatives, BMI, and several clinical/lifestyle factors such as ASA use, NSAID use, and alcohol use. These results highlight that while traditional clinical risk factors dominate prediction, sociodemographic variables also carry important signal.

Conclusions: HRP prediction based on non-invasive pre-colonoscopy features is feasible but challenging. Performance degradation upon external validation highlights the importance of real-world generalizability and practice or demographic change effects. These findings highlight both clinical utility potential and limitations of pre-colonoscopy risk prediction, and suggest that multimodal data sources (e.g., genomics, microbiomics, imaging, social determinants) may be required to achieve clinically meaningful performance.

#4221 CAPTYN, a six-variable machine-learning model predicting clinical benefit of atezolizumab-bevacizumab in hepatocellular carcinoma: Development and external validation in IMbrave150.

Gae Hoon Jo[1], Sohyun Hwang[2], Bernhard Scheiner[3], Won Suk Lee[4], Beodeul Kang[4], Jung Sun Kim[4], Ho Yeong Lim[4], Chansik An[5], Dong Yun Kim[6], Inyoung Kim[7], Dong-hyuk Heo[7], Matthias Pinter[3], Beom Kyung Kim[6], Chan Kim[4], Hong Jae Chon[4]

[1]Department of Life Science, CHA University, Seongnam, Korea, Republic of,[2]Department of Pathology, CHA Bundang Medical Center, Seongnam, Korea, Republic of,[3]Division of Gastroenterology and Hepatology, Department of Medicine III, Medical University of Vienna, Vienna, Austria,[4]Department of Medical Oncology, CHA Bundang Medical Center, Seongnam, Korea, Republic of,[5]Department of Radiology, CHA Bundang Medical Center, Seongnam, Korea, Republic of,[6]Department of Internal Medicine, Yonsei University College of Medicine, Seoul, Korea, Republic of,[7]Theragen Bio Co., Ltd., Seongnam, Korea, Republic of

Background: Current prognostic models for hepatocellular carcinoma (HCC) treated with atezolizumab plus bevacizumab (AB) rely on limited variables and lack prospective validation. We aimed to develop and externally validate a machine-learning model integrating multiple clinical variables to predict clinical benefit to first-line AB in advanced HCC.
Methods and Results: This multicenter study included 637 patients with unresectable HCC from three hospitals and one phase III prospective trial (IMbrave150), grouped into four AB cohorts. The training set comprised patients from CHA Bundang Medical Center (Korea, n=301) and the Medical University of Vienna (Austria, n=53), while external validation used IMbrave150 (n=99) and Severance Hospital (Korea, n=184) cohort. Clinical benefit (CB) was defined as CR, PR, or SD with PFS ≥6 months by RECIST v1.1; all other cases were classified as non-clinical benefit (NCB). Among 14 candidate variables, nine were identified by univariable Cox regression for OS and PFS. A recursive elimination procedure maximizing five-fold cross-validated AUC for NCB classification identified six optimal predictors—CRP, AFP, platelet, total bilirubin, lymphocyte, and neutrophil—which were used to train an XGBoost classifier, termed CAPTYN. In the training set, CAPTYN achieved an AUC of 0.93. SHAP-based interpretation showed that elevated CRP, AFP, and total bilirubin and reduced lymphocyte counts contributed to NCB, whereas platelet and neutrophil counts exhibited U-shaped associations. In external validation, CAPTYN achieved AUCs of 0.70 (95% CI, 0.59-0.81) in IMbrave150 cohort and 0.67 (0.59-0.75) in Severance cohort, outperforming CRAFITY, ALBI, and CRAPT-M (DeLong's test $p<0.05$). Calibration was acceptable (Brier score=0.22 and 0.24, respectively), and CAPTYN significantly stratified OS and PFS (IMbrave150 cohort: both $p<0.001$; Severance cohort: $p=0.012$ for OS, $p=0.009$ for PFS), whereas comparator models failed to discriminate PFS. Subgroup analyses across demographics and disease features in IMbrave150 consistently showed higher hazard ratios (>1.5) for OS and PFS in CAPTYN-predicted NCB patients.
Conclusion: CAPTYN, a six-variable machine-learning model predicting CB to AB, was externally validated using a prospective trial and a real-world cohort, providing calibrated, interpretable probabilities that may inform individualized treatment decisions.

#4222 Early prediction of engraftment outcomes in hematopoietic cell transplantation using neural ordinary differential equations.

Parham Habibzadeh

Department of Medicine, University of Pittsburgh, Pittsburgh, PA

Background: Engraftment failure after allogeneic hematopoietic cell transplantation (HCT) is a complex event that traditional models struggle to predict due to dynamic interactions among microbiome composition, immune recovery, and clinical risk factors, especially with missing or irregular data. Neural Ordinary Differential Equations (Neural ODEs) address these limitations by treating patient trajectories as continuous-time evolutions, enabling effective learning from such sparse and irregularly sampled measurements where traditional discrete-time networks often fail.
Methods: A synthetic cohort of 1,000 HCT patients over 42 days, modeling dynamic features (e.g. gut bacterial abundance, immune cell numbers) and static risk factors (e.g. age, HHV-6 status, conditioning intensity, initial microbiome diversity) was generated. Microbiome dynamics were governed by Lotka-Volterra equations, capturing predator-prey interactions between beneficial and pathogenic bacteria populations. Literature-derived parameters governed immune trajectories, ensuring biological plausibility. For prediction, a neural ODE framework that learns continuous-time dynamics from discrete, irregularly sampled data, enabling smooth visualization and extrapolation was utilized. The model was trained on only the first 3-7 days of data with class-weighted loss. Feature importance was assessed via permutation analysis.
Results: Validation of the synthetic cohort (N=1,000) confirmed clinically realistic recovery trajectories; for instance, patients receiving myeloablative conditioning engrafted later (mean 20.8 days) than those receiving reduced-intensity conditioning (14.8 days). On this validated cohort, the neural ODE model achieved strong early prediction of Day 42 outcomes using only the first 3 days of data (AUC=0.96; recall=93.8%; precision=88.2%). Permutation feature importance analysis revealed that while early neutrophil dynamics were critical, the dynamics of the abundance of specific beneficial commensals and initial microbiome diversity were dominant predictive signals, outweighing static clinical factors.
Conclusions: Neural ODEs provide a mechanistically grounded framework for learning from sparse, irregularly sampled longitudinal data while maintaining biological interpretability. Beyond HCT, this approach shows promise for dynamic prediction in cancer research where traditional recurrent architectures struggle with irregular time series. The continuous-time parameterization enables smooth trajectory interpolation offering advantages over standard discrete-time neural network models.

#4223 AI-based prescreening of clonal hematopoiesis in patients with liver disease using Sysmex XN hematology analyzer data.

Jeongmin Park[1], Dahyun Kim[1], Ja Min Byun[2], Hyunsoo Cho[2], Eun Ju Cho[2], Youngil Koh[2]

[1]Cancer Research Institute, Seoul National University College of Medicine, Seoul, Korea, Republic of,[2]Seoul National University Hospital, Seoul, Korea, Republic of

Clonal hematopoiesis (CH) is characterized by the clonal expansion of blood cells harboring somatic mutations and is commonly observed with aging. Although CH is known to induce hemogram alterations, differentiating it using standard complete blood count (CBC) metrics alone is challenging, highlighting the need for multidimensional hematologic profiling. To address this, this study leverages expanded CBC parameters from the Sysmex XN analyzer, incorporating broader optical measurements, to explore whether they improve CH detection. Given prior evidence linking CH to liver pathology, this study focuses on the relationship between CH and liver disease. Associations between the two have been demonstrated in large-scale cohorts such as the UK Biobank, and CH-driven macrophage activation has been implicated in the progression of NAFLD, NASH, cirrhosis, and hepatocellular carcinoma. However, liver diseases—including cirrhosis—produce characteristic CBC alterations, making CH discrimination particularly difficult. This motivates evaluating whether an AI model can detect CH-related signals despite liver disease-induced hematologic changes. At Seoul National University Hospital, with support from Sysmex, raw outputs from XN analyzers have been prospectively archived since 2022, covering 146 parameters, including reportable items and research indices. Using these data, 2,173 CBCs from 303 patients with liver diseases were analyzed using diverse machine- and deep-learning methods. Initial models were trained on the first test data per patient. To capture the longitudinal dynamics of CH, features were reconstructed from all repeated tests per patient (mean, standard deviation, maximum, minimum), and a soft-voting ensemble combining logistic regression, LightGBM, and CatBoost was developed, yielding stable performance. A deep-learning MIL model was applied to aggregate repeated CBC measurements across patient time points and capture instance-level contributions, complemented by an autoencoder to compress correlated features into latent clusters and improve model stability. With first-visit data only, logistic regression achieved precision 41.0%, recall 51.6%, F1 0.457; CatBoost achieved precision 39.2%, recall 93.5%, F1 0.552. When summary statistics with soft voting model were used, performance improved to precision 72.2%, recall 80.0%, F1 0.759. Within the MIL framework, analysis of model-weighted instances revealed distinct activation patterns in autoencoder-derived latent clusters associated with liver diseases, offering a novel interpretability perspective beyond traditional feature-importance analysis. This algorithm provides practical guidance to identify CH from CBC data in patients with liver disease, enabling prescreening prior to precision diagnostics and supporting timely diagnosis and improved management.

#4224 Artificial intelligence-derived analysis of wearables-derived biometrics to characterize physiologic response to chemotherapy in solid organ cancers.

Alexander Zhu[1], Lizi Zhang[2], Yuhang Zhang[2], Alexandra Potter[1], Bryan Rettner[1], Alisha Keshwani[1], Alina Keshwani[1], Nicole Hu[1], Anton Melki[1], Zhengyu Fang[2], Meghan McCarthy[1], Jacob Baird[1], Aubrey Pope[1], Samuel Schwartz[1], Quiana Guo[1], Michael Lanuti[1], Xiao Li[2], Chi-Fu Jeffrey Yang[1]

[1]Massachusetts General Hospital, Boston, MA,[2]Case Western Reserve University, Cleveland, OH

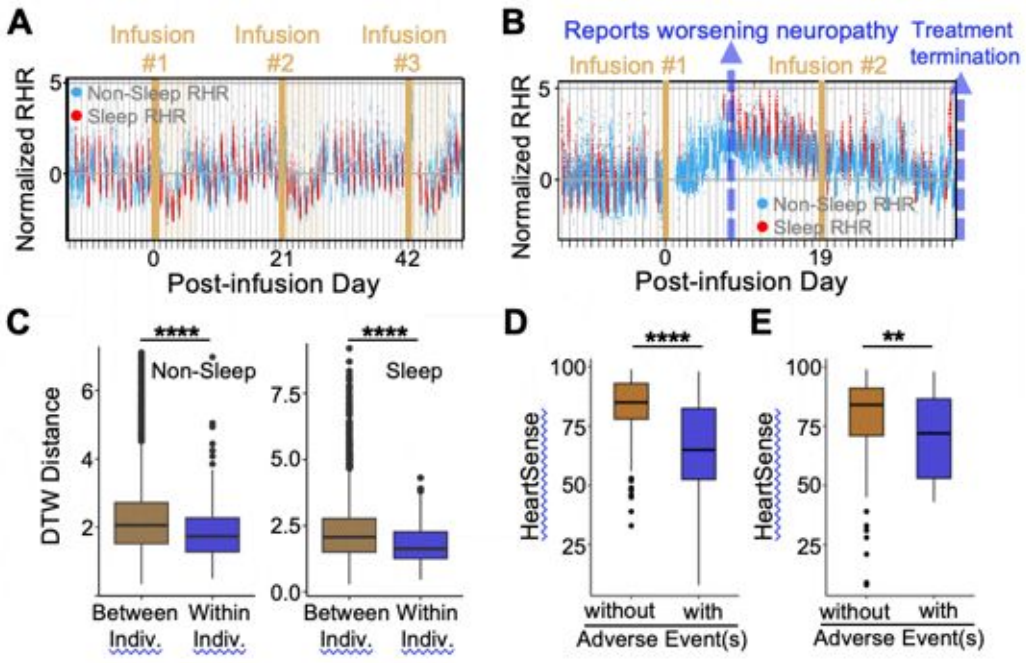
Objective: (1) To use wearable-derived biometrics to examine the relationship between physiologic patterns and adverse events during chemotherapy for solid organ cancers. (2) To use machine-learning analysis of these physiologic patterns to predict adverse events.

Methods: Patients with solid organ cancers receiving systemic therapy were enrolled in an ongoing trial evaluating the effects of chemotherapy/ immunotherapy on physiologic patterns. Patients continuously wore a Fitbit for >5 days before and during treatment. We analyzed intra- and inter-personal variation in normalized daily average resting heart rate (RHR) across cycles. We developed a novel, personalized, baseline-referenced statistical framework based on the Change-of-Heart machine learning algorithm, "HeartSense," which standardizes each participant's RHR against their own baseline during sleep and non-sleep periods, generating a score that quantifies daily physiologic stability. Higher scores reflect RHR patterns consistent with pre-treatment baseline and lower scores indicate greater deviation from baseline. We compared lowest HeartSense scores by patients who experienced adverse events vs those who did not in cycle 1. We also examined whether scores from cycle 1 were associated with adverse events in cycle 2.

Results: A total of 54 cancer patients who underwent ≥1 cycle of systemic therapy were included in analysis. Distinct physiologic patterns emerged during therapy. One patient showed cyclic decreases in heart rate after each infusion with recovery to baseline (Figure A), while another exhibited progressive physiologic disruption preceding treatment termination (Figure B). Intrapersonal variation in sleep and non-sleep RHR was significantly smaller than interpersonal variation (Figure C). Lower median HeartSense scores within a cycle were significantly more likely to experience adverse events (Figure D). Lower scores were also associated with adverse events in cycle 2 (Figure E).

Conclusions: Patients exhibit distinct physiologic changes in resting heart rate during systemic therapy and deviation from normal patterns may indicate treatment-related adverse events. Our novel machine learning algorithm identified that lower scores—reflecting abnormal physiologic regulation—were linked to a higher risk of adverse events both during and after the current treatment cycle, suggesting that chemotherapy-related toxicity can be preceded by early physiologic warning signals.

Figure. Evaluating Physiologic Patterns Among All Cancer Patients Undergoing Systemic Therapy. Data from 54 patients undergoing systemic therapy are presented. Figures 1A and 1B show two example patients who underwent adjuvant chemotherapy. Each panel represents a single patient's normalized resting heart rate (RHR). Each panel shows a single patient's normalized resting heart rate (RHR), separated into sleep (blue) and non-sleep (orange) periods. **Figure 1A** is an example of a patient who underwent lobectomy followed by 4 cycles of adjuvant chemotherapy (pemetrexed/cisplatin). The patient wore the watch during the first 3 cycles of adjuvant chemotherapy (the patient did not wear the watch during cycle 4). The blue-shaded regions highlight periods immediately following the date of chemotherapy infusion where the patient exhibited similar decreases in RHR, each lasting approximately 7 days. **Figure 1B** is an example of a patient who underwent lobectomy followed by 2 cycles of chemotherapy (pemetrexed/carboplatin). Eight days after the cycle #1 infusion date, the patient reported worsening neuropathy. After cycle #2, the patient reported further severe worsening of neuropathy, with difficulty pushing buttons and driving their car. The patient discontinued chemotherapy after cycle #2. **Figure 1C.** Boxplot showing intrapersonal and interpersonal variation in resting heart rate (RHR) across systemic therapy cycles. RHR (normalized at the individual level using HeartSense) collected during each systemic therapy cycle was analyzed using dynamic time warping (DTW). The DTW distance, representing the temporal similarity in RHR patterns, was calculated for all pairwise comparisons of cycles, either between individuals or within the same individual, and summarized separately for non-sleep and sleep periods. **Figure 1D.** Boxplot summarizing the worst HeartSense score per cycle calculated by the HeartSense algorithm, stratified by whether the patient experienced adverse event(s) during that cycle. **Figure 1E.** Similar to 1D. However, instead of stratifying by whether adverse event(s) occurred in that cycle, the plot is stratified by whether adverse event(s) occurred in the subsequent cycle. Significance was assessed using a two-sided Wilcoxon rank-sum test (*P<0.05; **P < 0.01; *** P<0.001; **** P<0.0001).



#4225 AI-driven *de novo* design of humanized nanobodies targeting KLK2 for prostate cancer immunotherapy.

Fengze Jin, Puja Singh, Hanyong Chen, Christopher Warlick, **Yibin Deng**

Department of Urology, University of Minnesota Medical School, Minneapolis, MN

Conventional monoclonal antibodies (mAbs) are widely used in cancer therapy but are limited by large size (~150 kDa), structural complexity, and high production costs, motivating the development of alternative antibody formats. Single-chain variable fragments (scFvs), derived from mAbs, retain antigen-binding specificity and affinity while offering a smaller molecular size (~25 kDa), enabling applications such as chimeric antigen receptor (CAR)-T/NK cells and/or bispecific T/NK cell engagers (BiTEs or NKCEs) for immunotherapy. However, scFvs face challenges including structural instability, linker-dependent functionality, and aggregation-prone hydrophobic residues, which limit their therapeutic efficacy. In contrast, single-domain antibodies (sdAbs), derived from the variable antigen-binding domain of heavy-chain-only antibodies (VHHs) and commonly known as nanobodies (~15 kDa), overcome these limitations. Importantly, nanobodies can access cryptic or conformational epitopes—such as deep cavities that are inaccessible to conventional mAbs or scFvs—providing a stable, highly versatile, and clinically attractive biotherapeutic modality for cancer immunotherapy. Traditional methods to develop nanobodies rely on targeting protein-immunized camelids or high-throughput experimental nanobody display systems, including bacteria, phage, ribosome, or yeast display. These approaches are time-consuming, labor-intensive, camelid-derived (with potential immunogenicity), and restricted in library diversity. Moreover, affinity maturation and specificity optimization require multiple iterative rounds of experimental selection—often taking months to years—and may still fail to produce high-affinity nanobodies against difficult targets. To address these challenges, we developed and integrated multiple artificial intelligence (AI) platforms for target-guided humanized nanobody backbone design, soluble protein sequence generation, and enhanced target-nanobody complex prediction and screening. These platforms enable *de novo*, conformational epitope-based nanobody design, generating diverse, high-affinity, and highly specific candidates entirely *in silico,* with experimental validation achievable within weeks to months depending on the target. As a proof-of-principle, we have applied our AI platforms to design humanized nanobodies targeting kallikrein-related peptidase 2 (KLK2), a clinically validated, prostate cancer-specific cell surface protein, and are experimentally engineering the top-designed candidates into T/NK cell engagers and CAR-T/NK cells to evaluate their ability to eliminate KLK2-expressing prostate cancer cells.

#4226 Machine learning based classification of breast cancer using lifestyle and clinical risk factors in Puerto Rican women.

Jorge E. Martinez-Jimenez[1], Sol V. Perez-Martir[1], Doralis de Leon-Vazquez[1], Nelly A. Arroyo[2], Julie Dutil[1]

[1]UPR - Comprehensive Cancer Center, San Juan, PR,[2]Ponce Health Sciences University, Ponce, Puerto Rico

Globally, breast cancer incidence has increased by more than 20 percent and mortality has increased by 14 percent making it a significant public health challenge. Effective prevention and screening strategies require improved early risk assessment tools, especially for understudied populations. Current risk models are predominantly trained on European descent populations, resulting in suboptimal and uneven performance in admixed populations. Our goal was to compare how current machine learning (ML) methods perform to classify breast cancer status in a Puerto Rican population. We used a structured dataset of lifestyle, demographic, reproductive, and established epidemiological risk-factor variables from a Puerto Rican cohort of 1393 woman. Data was preprocessed using systematic data cleaning, removal of outcome-leaking features, normalization of categorical labels, imputation of missing values, and encoding of non-numeric variables. The final dataset was split using a stratified train-test strategy to preserve case-control balance, followed by model development using multiple supervised algorithms. Logistic Regression, Decision Tree, Random Forest, Gradient Boosting, XGBoost, LightGBM, and CatBoost models were trained and compared using stratified 10-fold cross-validation and standardized performance metrics. After hyperparameter tuning with randomized search, the CatBoost classifier achieved the strongest performance on the held-out test set, with a ROC-AUC of 0.8009, PR-AUC of 0.8285, F1-score of 0.7239, and balanced accuracy of 0.7342, outperforming both traditional models and other boosting algorithms. Model interpretability was assessed using SHapley Additive exPlanations (SHAP) and permutation-based feature importance, which consistently identified influential predictors including menopausal status, smoking history, polygenic risk score, age, and number of sisters with breast cancer, among other risk factors. These findings confirm that gradient-boosting approaches, particularly CatBoost, effectively capture nonlinear interactions in multidimensional health data while maintaining interpretability. Overall, this work demonstrates the feasibility and utility of integrating machine learning to predict breast cancer risk using non-genetic and genetic risk factors in a Puerto Rican population.

#4227 Independent validation of the immunotherapy response model using real-world Moffitt Cancer Center cohort.

Isis Yanina Narvaez-Bandera, Alyssa Pybus, Tosin Jolaogun, Paulo C. Morais Lyra, Jeremy Goecks

Machine Learning, Moffitt Cancer Center, Tampa, FL

Immune checkpoint blockade (ICB) has revolutionized cancer therapy, yet many patients derive limited benefit or experience adverse effects. Thus, it becomes crucial to identify when a patient is likely to respond well to ICB treatment, thereby guiding treatment decisions and improving outcomes. Although several studies have applied machine learning (ML) to clinical and laboratory data to predict ICB response, independent validation in large, real-world cohorts remains limited. This gap, driven in part by the small number of available cohorts, restricts model generalizability and hinders broader clinical use. To expand on the most promising model, published as a logistic regression-based immunotherapy-response score (LORIS), we performed external validation using data collected at Moffitt Cancer Center.We analyzed 2,090 patients with advanced melanoma (n=908), non-small cell lung cancer (NSCLC; n=878), and renal cell carcinoma (RCC; n=304) treated with ICB at Moffitt between 2011-2025. The six clinical and laboratory features used in the original LORIS model—age, cancer type, prior systemic therapy, albumin, neutrophil-to-lymphocyte ratio, and tumor mutational burden—were extracted from patient records. Two validation strategies were implemented. First, we evaluated the published LORIS model by directly applying its coefficients to the Moffitt data; no retraining was performed, and all patients were used exclusively for testing, both within each cancer type and in a combined pan-cancer cohort. Second, to assess model reproducibility, we trained a new logistic regression model using an 80/20 train-test split of the Moffitt cohort and compared its performance with LORIS. All evaluations used 1- and 6-month pretreatment windows, with model performance quantified by AUC. Feature contributions were examined to identify predictors driving response.ICB response prediction performance varied substantially across diseases. The highest performance was observed in RCC, where achieved an AUC of 0.85 (1-month pretreatment) and 0.84 (6-month pretreatment). Melanoma showed moderate performance (AUC 0.71-0.74), while NSCLC had lower performance (AUC 0.53-0.55), contributing to the reduced discriminative ability of our pan-cancer model (AUC 0.56-0.61). Incorporating Programmed Death-Ligand 1 (PD-L1) did not consistently improve predictions and in several settings decreased performance. Model performance was similar between 1-month and 6-month pretreatment windows.This large-scale real-world validation confirms partially reproducible predictive signals for RCC and melanoma but highlights limitations in NSCLC and heterogeneous cohorts. Our findings underscore the need for expanded multimodal approaches to improve clinical applicability of ICB response prediction.

#4228 Validation of the CLL treatment infection model (CLL-TIM) in patients with newly diagnosed chronic lymphocytic leukemia (CLL).

Raphael Mwangi[1], Tait D. Shanafelt[2], Soren Basnet[1], Emily L. West[1], Owen Keegan[1], Timothy G. Call[3], Yao Yuan[3], Bryan Alexis Vallejo[3], Paul J. Hampel[3], Lindsey E. Roeker[3], Yucai Wang[4], Saad J. Kenderian[4], Sara J. Achenbach[5], Aaron D. Norman[6], Kari G. Rabe[5], Neil E. Kay[3], James R. Cerhan[6], Curtis A. Hanson[7], Susan L. Slager[3], Sameer A. Parikh[3]

[1]Division of Computational Biology, Mayo Clinic, Rochester, MN,[2]Department of Medicine, Division of Hematology, Stanford University, Stanford, CA,[3]Division of Hematology, Mayo Clinic, Rochester, MN,[4]Mayo Clinic, Rochester, MN,[5]Division of Clinical Trials and Biostatistics, Mayo Clinic, Rochester, MN,[6]Division of Epidemiology, Mayo Clinic, Rochester, MN,[7]Department of Laboratory Medicine and Pathology, Mayo Clinic, Rochester, MN

Prognostic indices such as the CLL International Prognostic Index (CLL-IPI) and the International Prognostic Score for Early-stage CLL (IPS-E) can predict time to first treatment (TTFT) in patients with early-stage CLL. Their ability to predict risk of infection - a leading contributor to morbidity and mortality in CLL - remains uncertain. The CLL-TIM is a machine-learning model developed in Europe that integrates clinical, laboratory, and infection-related data to predict TTFT or infection risk within 2-years of diagnosis, Receiver Operating Characteristic - Area Under the Curve (ROC-AUC) 0.74; Agius et al., *Nat Comm* 11, 363 2020. We conducted the first validation of CLL-TIM in a US cohort of newly diagnosed CLL patients and compared its performance with the CLL-IPI and IPS-E indices. Adults with newly diagnosed CLL (2000-2020) were identified through the Rochester Epidemiology Project using International Classification of Disease (ICD) codes; all diagnoses were confirmed. We replicated the variable selection from the original CLL-TIM model and applied it to our cohort. The primary endpoint was a 2-year composite of either TTFT or incident infection (defined as having blood cultures drawn). Model performance was evaluated using ROC-AUC consistent with the original CLL-TIM methods. CLL-IPI and IPS-E performance was assessed using time-dependent ROC-AUC; pairwise differences in discrimination were tested using DeLong. We identified 454 CLL patients with a median age of 72 years [range, 30-97], 166 (37%) were female, Rai Stage was 0-II in 399 (92%) patients. IGHV genes were unmutated in 130/305 (42%) patients and TP53 disruption (either del17p by FISH or *TP53* mutation) was present in 24/329 (8%) patients. At 2-years, 55 (12%) patients received CLL therapy, and 56 (12%) patients had an infection. The 2-year composite endpoint was observed in 94 (21%) patients. The ROC-AUC was 0.74 (95% CI 0.68-0.80) for CLL-TIM, 0.69 for CLL-IPI (95% CI 0.63-0.75, p=0.11 compared to CLL-TIM) , and 0.68 for IPS-E (95% CI 0.62-0.74, p=0.02 compared to CLL-TIM). We also evaluated the ROC-AUC using all the prognostic models for each individual endpoints. The corresponding ROC-AUC for TTFT at 2 years were 0.79, 0.74, and 0.76 for CLL-TIM, CLL-IPI, and IPS-E, respectively; and for infection at 2 years were 0.68, 0.57, and 0.52, respectively. This is the first validation of the CLL-TIM in a US-based cohort of newly diagnosed CLL patients. Although the CLL-TIM model exceeded the minimally meaningful discrimination threshold (AUC >0.7) for individual patient-level risk prediction, there was no statistical difference in AUC between CLL-TIM and CLL-IPI, suggesting either model can predict the composite endpoint at 2 years. Most of the observed discrimination was driven by prediction of TTFT rather than infection, underscoring the need to develop more infection-specific risk models for newly diagnosed CLL.

#4229 AI based explainable survival modeling for advanced non small cell lung cancer.

Kang Qin[1], An Qin[2], John V. Heymach[1]

[1]MD Anderson cancer center, Houston, TX,[2]Loyola University Chicago, Chicago, IL

Background: Accurate individualized prognostication in advanced non-small cell lung cancer (NSCLC) is hindered by nonlinear interactions among clinical and biological variables. Integrating interpretable artificial intelligence (AI) with classical survival modeling may enhance predictive precision while preserving transparency.
Methods: A real-world cohort of 62 608 advanced NSCLC patients with 52782 observed death events was analyzed. Prognostic variables significantly associated with overall survival (OS) were identified using univariate Cox proportional-hazards regression ($p < 0.05$). Feature refinement was achieved through LASSO-regularized Cox modeling with 5-fold cross-validation ($\lambda = 0.00176$) and stability selection (≥ 0.7), producing a 20-feature prognostic signature. These variables were then used to train and benchmark 18 regression and ensemble machine-learning algorithms for continuous OS prediction. Model performance was evaluated using R^2, RMSE, MAE, calibration plots, and decision-curve analysis (DCA). Feature interpretability was assessed with SHAP (Shapley Additive Explanations) to quantify the direction and magnitude of each predictor's effect.
Results: All 20 variables remained significant in multivariate Cox analysis. Chemotherapy, systemic therapy, and surgery were independent protective factors, whereas age, tumor size, metastatic burden, liver/bone metastasis, regional nodal involvement, and N stage predicted worse outcomes. Ensemble gradient-boosting models outperformed linear baselines ($R^2 \approx 0.15$ vs. 0.10; RMSE ≈ 18 months). LightGBM achieved the highest accuracy ($R^2 = 0.155$; MAE = 11.9 months) with excellent calibration and the greatest net benefit on DCA. SHAP analysis identified chemotherapy, diagnosis year, organ metastatic number, and age as dominant determinants of predicted survival, with strong reproducibility across folds (Spearman $\rho > 0.9$).
Conclusions: A transparent Cox-LASSO-LightGBM-SHAP framework established a robust, biologically consistent 20-factor prognostic signature for advanced NSCLC. The model achieved high predictive accuracy, clinical calibration, and interpretability, revealing treatment modality, metastatic extent, and temporal therapeutic progress as principal survival drivers. This interpretable AI framework enables credible, individualized survival prediction and bridges data-driven modeling with clinical oncology.

#4233 Transcription factor c-Maf drives Th17-dependent activation of CD8⁺ T cells to sustain anti-tumor immunity.

Ching Tung Wu, Shi-Chuen Miaw

National Taiwan University College of Medicine, Taipei City, Taiwan

Within the tumor microenvironment (TME), Th17 cells exhibit a dual role in tumor progression. Although IL-17A, IL-17F, and IL-21 have been reported to exert anti-tumor effects, the intrinsic mechanisms underlying Th17-mediated tumor suppression remain poorly understood.The transcription factor c-Maf is a known regulator of cytokine production in CD4⁺ T-cell subsets. To investigate its role in tumor immunity, we generated mice with c-Maf-deficient CD4⁺ T cells (). In both subcutaneous tumor models and an orthotopic colorectal cancer model induced by AOM/DSS treatment, mice developed significantly larger tumors than littermate controls, demonstrating that c-Maf expression in CD4⁺ T cell is critical for anti-tumor immunity. Analysis of tumor-infiltrating lymphocytes (TILs) from MC38 tumor-bearing mice showed a marked reduction in Tbet⁺ and IFN-γ⁺ Th1 cells, as well as RORγt⁺, IL-17A⁺, and IL-21⁺ Th17 cells. Although CD8⁺ T cells expressed comparable levels of c-Maf in both genotypes, mice displayed significantly reduced CD8⁺ T-cell cytotoxicity, including lower expression of CD107a, granzyme B, and IFN-γ. These findings indicate that c-Maf deficiency diminishes anti-tumor Th1 and Th17 responses and impairs CD8⁺ T-cell function within the TME. To directly assess the role of c-Maf in Th1 and Th17 cells, we performed adoptive transfers of OT-II⁺ Th1 or Th17 cells. Transfer of c-Maf-deficient Th17 cells resulted in significantly impaired tumor control compared to WT Th17 cells, whereas Th1 cell transfer showed no genotype-dependent differences. This indicates that c-Maf selectively enhances the anti-tumor activity of Th17 cells. Furthermore, transfer of WT OT-II⁺ Th17 cells increased CD8⁺ T-cell cytotoxicity in recipient mice, suggesting that c-Maf ⁺ Th17 cells promote CD8⁺ T-cell activation. Consistent with this, neither WT nor c-Maf-deficient Th17 cells controll tumor growth when transferred into Rag1$^{-/-}$ mice lacking T and B cells, demonstrating that the anti-tumor activity of Th17 cells requires CD8⁺ T cells. Mechanistically, co-culture experiments revealed that the CD8⁺ T-cell cytotoxic enhancement mediated by WT Th17 cells was abolished upon blockade of either IL-17A or IL-21. These results indicate that c-Maf promotes anti-tumor immunity by regulating IL-17A and IL-21 production in Th17 cells, thereby enabling robust CD8⁺ T-cell activation. In summary, our findings identify c-Maf as a critical transcriptional regulator in Th17 cells that sustains anti-tumor immunity through a cytokine-dependent mechanism that augments CD8⁺ T-cell cytotoxic function.

#4234 Glycan-based site specific ADC achieves sustained tumor control through Improved payload delivery and immune activation.

Liu Chih-Chun, Tsai Yi-Chien, Huang Jing-Rong, Lo Fei-Yun, Pei Yu, Hsu Ren-Yu, Tu Tzu-Hsuan, **Chen Ya-Chi**

OBI Pharma Inc,, Taipei, Taiwan

Antibody-drug conjugates (ADCs) achieve potent tumor killing but often limited to induce durable antitumor immunity. The Glycan conjugated platform enables site-specific glycan conjugation, enhancing pharmacokinetics (PK) and intratumoral payload delivery versus conventional cysteine-based ADCs. We hypothesized that this improved payload delivery capability by the Glycan conjugated ADC (OBI-902) would potentiate immunogenic cell death (ICD) and sustains antitumor immune activation relative to a cysteine-conjugated ADC (OBI-992).

Efficacy and immune profiling were evaluated in LL2 syngeneic tumors overexpressing human Trop2. Intratumoral payload, and ICD markers (calreticulin, HSP70, HSP90) were assessed post-treatment. Tumor, lymph node, and blood immune subsets were analyzed by multiparametric flow cytometry, and serum cytokines quantified for systemic immune activation. OBI-902 demonstrated durable tumor growth inhibition and enhanced ICD in the tumor microenvironment, findings that were superior to those observed with OBI-992. Serum IFN-γ, IL-12, and TNF-α elevations indicated systemic immune activation.

In tumors, OBI-902 increased $CD4^+$ and $CD8^+$ T-cell and B-cell infiltration while reducing MDSCs. It also expanded cDC1s and upregulated their MHC-II expression, supporting improved antigen presentation. In tumor-draining lymph nodes, OBI-902 expanded progenitor-exhausted $CD8^+$ T cells yet functional state while limiting terminal exhaustion. Peripheral immune profiling corroborated that OBI-902 increased T-cell proportions and reduced MDSCs. At study endpoint, OBI-902 sustained $CD8^+$ T-cell functionality with higher CX3CR1 and lower CD39 expression, indicating preserved cytotoxicity and T-cell fitness. This readily accessible peripheral immune signatures may serve as pharmacodynamic biomarkers in clinical settings.

The Glycan conjugated platform ADC (OBI-902), enabled by its more stable linker-payload design that delivers greater payload to the tumor, achieved sustained ICD induction and a profound reprogramming of T-cell exhaustion, driving robust innate and adaptive immune activation. These results highlight the Glycan conjugated platform as a next-generation ADC technology and strongly support its combination with immune checkpoint blockade in future clinical studies.

#4235 Cell-level spatial transcriptomics detection of microenvironmental STAT1-expressing plasma cells in colorectal cancer recurrence by G4X.

I-Chuang Liao[1], **Minh-Khang Le**[1], Vivek Pujara[1], Haley Jun[1], Devanshi Pratiher[1], Jane C. Figueiredo[2], Nathalie Nguyen[1], Chintda Santiskulvong[1], Angie Laguna[1], Yi Zhang[1], Keluo Yao[1], Joshua Jay Levy[1]

[1]Cedars-Sinai Medical Center, Los Angeles, CA,[2]Samuel Oschin Comprehensive Cancer Institute, Los Angeles, CA

Introduction: STAT1 mediates interferon signaling and immune responses with diverse roles in cancer. In colorectal cancer (CRC), plasma cells are critical immune mediators, and STAT1 expression in these cells may reflect their functional status. Lower STAT1-expressing plasma cells have been linked to a weakened anti-tumor immune response that facilitates tumor escape. Understanding this relationship could reveal novel prognostic biomarkers and therapeutic targets for CRC.

Materials and Methods: Thirty CRC samples underwent G4X spatial profiling, each with a manually selected 4.5 × 4.5 mm² capture area targeting key histological features, resulting in spatial gene expression profiles for a 360-gene panel for 3,088,252 cells. Tissue sections were processed following the G4X spatial transcriptomics protocol enabling RNA detection at subcellular resolution. Manual pathology annotation was performed by a collaborating pathologist, identifying regions including cancer, dysplasia/cancer in situ, benign epithelium, interface, muscularis, and stroma. Cancer-associated cells were defined by two criteria: (1) spatial localization within annotated cancer regions, and (2) absence of canonical epithelial and malignant epithelial markers (CEACAM5, EPCAM, MUC12). Differential expression analyses identified associated cell markers, and the proportions of cell types expressing these markers were quantified. Cell-level regression models incorporated random patient intercepts and clinical covariates (age, gender, microsatellite status, T and N stage), followed by sample-level univariate analyses across all 30 samples to assess associations between STAT1-positive cell clusters and clinical recurrence.

Results: Differential expression analysis identified STAT1 as the top upregulated gene in cancer-associated cells (log2 fold-change = 2.11; adjusted $p < 0.001$). Clustering of STAT1-positive cancer-associated cells revealed 10 distinct cell clusters, including 5 cancer-associated fibroblast subtypes, tumor-associated macrophages, mixed T cells, 2 epithelial-like cells, and plasma cells. Regression analyses consistently indicated a negative association between proportion of STAT1-positive plasma cells and colorectal cancer recurrence (OR = 0.19; 95% CI = 0.03-1.13; $p = 0.068$).

Conclusion: STAT1-expressing plasma cells in the colorectal cancer microenvironment are significantly associated with recurrence risk. These findings support further validation efforts through immunohistochemistry in a larger study cohort, demonstrating the promise of leveraging spatial transcriptomic insights to inform routine pathology for patient stratification.

#4236 The metabotropic Glutamate receptor-1 is a glutamatergic checkpoint that integrates with TCR to augment anti-tumor CD8⁺ T cell activation, metabolism and effector function.

Salvador Gonzalez Ochoa[1], Maria Teresa P. de Aquino[1], Thomas W. Hodo[1], Thanigaivelan Kanagasabai[1], Muna A. Mohammed[2], Jane Tonello[1], Alla Ivanova[1], Anil Shanker[3]

[1]Department of Biochemistry, Cancer Biology, Neuroscience and Pharmacology, Meharry Medical College, Nashville, TN,[2]Department of Biomedical Sciences, Meharry Medical College School of Graduate Studies, Meharry Medical College, Nashville, TN,[3]The Office for Research and Innovation, Meharry Medical College, Nashville, TN

Background: Glutamate receptors (GluRs), classically linked to neuronal signaling, are also recognized as key immunomodulators. T cell activation requires precise coordination of TCR-driven signaling microclusters and calcium-dependent pathways that shape T cell effector function. Emerging evidence shows that glutamatergic cues influence T cell metabolism, activation, and fate, yet their role within TCR signaling remains poorly defined. Here, we show how GluR-TCR interactions govern CD8⁺ T cell activation and function, particularly within the metabolic and functional constraints of the tumor microenvironment.
Methods: Tumors and lymphoid tissue single-cell suspensions were analyzed for the expression of ionotropic (GluA3, NR1, NR2B) and metabotropic (mGluR1, mGluR5) receptors on CD4⁺ and CD8⁺ TILs by flow cytometry. CD8⁺ T cells were activated with anti-CD3/CD28 or PMA/ionomycin ± IL-2 in the presence or absence of NBQX (GluA3) and CPCCOEt (mGluR1) inhibitors. Expression of glutamate transporters, viability, and extracellular glutamate were assessed by fluorometric assays. CPCCOEt-treated cells were analyzed for mGluR1-TCR colocalization and phosphorylation of TCR-signaling proteins by confocal microscopy and flow cytometry. Metabolic activity was measured by Seahorse XF96 (OCR/ECAR). Intracellular Ca^{2+} dynamics were evaluated using Fura-2 AM ratiometric imaging. CD8⁺ T cell proliferation was assessed by CFSE, and cytotoxicity was tested in vitro and in vivo using a pulmonary metastasis model; activated CD8⁺ T cells ± antagonists were transferred retro-orbitally.
Results: We found that mGluR1 and GluA3 are expressed at higher levels in T cells compared with other immune cell lineages, and their expression increases during CD8⁺ T cell activation. Conversely, pharmacologic inhibition with CPCCOEt significantly impaired CD8⁺ T cell activation, disrupting mGluR1 colocalization with the TCR-Vβ8.1 in the cell membrane and reducing phosphorylation of key proteins involved in TCR-driven signaling, metabolic pathways, inducing a pronounced dysregulation of Ca^{2+} flux. Functionally, CPCCOEt-treated CD8⁺ T cells showed a reduction in proliferation to levels resembling naïve T cells and a marked decrease in cytotoxic activity. In vivo, these impairments translated into an increased burden of secondary metastatic pulmonary nodules, highlighting the essential role of mGluR1 signaling in sustaining effector CD8⁺ T cell function and antitumor immunity.
Conclusion: These findings identify mGluR1 as a critical glutamatergic checkpoint that integrates with the TCR to augment CD8⁺ T cell activation, metabolism, and effector function. Its disruption collapses signaling strength, Ca^{2+} responses, and cytotoxic competence, revealing a potential target to boost T cell potency in solid tumor microenvironments.

#4237 Immunofluorescence-based adaptive immune subtypes in an association with long-term disease-free interval in the Carolina Breast Cancer Study Phase III.

Qichen Wang[1], Timothy Patrick Sheahan[1], Alyssa Joy Cozzo[2], Sarah Christine Van Alsten[2], Ebonee Nicole Butler[1], James Stephen Marron[3], Katherine A. Hoadley[4], Melissa A. Troester[1]

[1]Department of Epidemiology, Gillings School of Public Health, University of North Carolina at Chapel Hill, Chapel Hill, NC,[2]Lineberger Comprehensive Cancer Center, University of North Carolina at Chapel Hill, Chapel Hill, NC,[3]Department of Statistics and Operations Research, College of Arts and Science, University of North Carolina at Chapel Hill, Chapel Hill, NC,[4]Department of Genetics, Lineberger Comprehensive Cancer Center, University of North Carolina at Chapel Hill, Chapel Hill, NC

Adaptive immune subtype defined using bulk RNA expression has been associated with lower risk of breast cancer recurrence. In the context of intralesional heterogeneity, these estimates may not capture relevant localized patterns of immune infiltration. We aimed to 1) compare bulk RNA-based and immunofluorescence (IF)-based immune subtypes to better characterize the tumor immune microenvironment and 2) evaluate associations between spatially-resolved adaptive immunophenotypes defined using IF and breast cancer recurrence. We analyzed 1,665 invasive breast cancer tumors from the population-based Carolina Breast Cancer Study Phase 3, using 5,276 1-mm tumor microarrays cores (up to 4 per tumor). Six adaptive markers (PD-1, CD3, CD4, CD8a, CD8, FOXP3) were quantified by multiplex IF. Core-level adaptive immune subtypes (adaptive-high vs adaptive-low) were defined with k-mean clustering of HALO-estimated percent-positive cells for each marker. Participant-level immune subtypes were defined using k-means clustering on weighted averages of core-level marker values, weighted by total cell count. Tumors were labeled as 'consistent' if all cores matched the participant-level subtypes. As a comparison, we also performed k-mean clustering using only CD8 percent positive (high vs low) on tumor level. Percent agreement was calculated comparing IF (multi-marker) with bulk RNA-based adaptive classifiers (previously defined). We used Cox models to estimate associations between adaptive subtype and 10-year disease-free interval (DFI) stratified by estrogen receptor (ER) status, and adjusted for age, race, and stage. We observed 65% agreement between participant-level IF and RNA adaptive classifiers. Multi-marker IF-defined adaptive-low tumors had worse 10-year DFI [ER+: Hazard Ratio (HR) 1.54, 95% Confidence Interval (CI) 1.07-2.22; ER-: HR 1.72, 95% CI 1.11-2.68]. CD8-low cluster showed a similar association among ER+ tumors [HR 1.52, 95% CI 1.06-2.19], no association among ER- tumors [HR 1.31, 95% CI 0.83-2.06]. RNA-based associations were stronger than those for IF [HR_{RNA} 2.00, 95% CI 1.48-2.70, non-adaptive vs. adaptive, overall]. Exposure misclassification may have attenuated associations because tumors with inconsistent multi-marker adaptive-high IF subtype were significantly associated with worse 10-year DFI compared to those were consistent [HR 1.83, 95% CI 1.18-2.85]. Overall, adaptive immunity is prognostic in breast cancers, but misclassification of adaptive response is a concern for biomarker development. Use of multiple markers reflecting the adaptive immune community may partially overcome intralesional heterogeneity, but bulk profiling masks spatial characteristics. Ideal immune biomarkers for prognosis must be reproducibly measured and sensitive to detect the most impactful immune characteristics.

#4238 Cytokine expression within the different categories of tumor-infiltrating lymphocytes in primary cutaneous melanoma: an immunohistochemical study.

Thato Ntuli[1], Benny Mosoane[1], Tebogo Marutha[2], Rahaba Marima[2], **Zodwa Dlamini**[2], Meshack Bida[1]

[1]Department of Anatomical Pathology, University of Pretoria, Pretoria, South Africa,[2]Pan African Cancer Research Institute (PACRI), University of Pretoria, Pretoria, South Africa

Background:
Melanoma is a highly aggressive skin malignancy with an incidence exceeding 3 per 100 000. Tumor-infiltrating lymphocytes (TILs) are often linked to better prognosis and tumor regression, reflecting an active host immune response. However, melanoma can evade immune attack, so inflammatory cells are not always effective or tumor-directed. This study evaluated tumor necrosis factor (TNF) and interferon-gamma (IFNγ) expression in primary cutaneous melanoma across different TIL categories to determine whether these infiltrates act as active responders or passive bystanders.
Methods: We performed a cross-sectional study using archival primary cutaneous melanoma tissue from the University of Pretoria (2014-2020). Skin punch biopsies, local excisions, and wide excisions were included. Immunohistochemistry for TNF and IFNγ was performed on formalin-fixed, paraffin-embedded sections. Three pathologists independently graded TILs as negative, non-brisk, or brisk and assessed cytokine expression.
Results: Sixty-six patients met inclusion criteria. TIL grades were: negative (39.4%), non-brisk (33.3%), and brisk (27.3%). Overall, 31.8% of melanomas were TNF-positive. TNF expression occurred in 16.7% of brisk TIL cases, 41% of non-brisk cases, and 15% of TIL-negative tumors. IFNγ expression showed a clearer gradient: brisk TILs were IFNγ-positive in 89% of cases, non-brisk in 64%, and TIL-negative in 15%. Extensively pigmented melanomas tended to show low cytokine expression, although numbers were small and firm conclusions could not be drawn.
Conclusion
TNF and IFNγ expression broadly correlated with TIL grade in primary cutaneous melanoma. Brisk TILs were strongly associated with high IFNγ expression, non-brisk TILs showed more modest cytokine levels, and TIL-negative tumors were largely cytokine-poor. These findings suggest functional heterogeneity among inflammatory infiltrates. Larger, ideally multicenter studies including more heavily pigmented melanomas and clinical outcome data are needed to clarify the prognostic and potential therapeutic implications of these cytokine patterns.

#4239 Aging turns B cells into drivers of CD8⁺ cells that weaken tumor defenses.

MONICA BODOGAI[1], Bongsoo Park[2], Fatima-Zohra Braikia[3], Kumaraswami Konda[1], Arya Biragyn[1]

[1]Immunoregulation Section, Laboratory of Molecular Biology and Immunology, National Institute on Aging, Baltimore, MD,[2]Epigenetics and Stem Cell Aging Unit, Translational Gerontology Branch, National Institute on Aging, Baltimore, MD,[3]Gene Regulation Section, Laboratory of Molecular Biology and Immunology, National Institute on Aging, Baltimore, MD

Despite aging being a major risk factor for cancer, the effect of age-induced immune dysregulation in tumor control is poorly understood. While CD8⁺ T cells are central to antitumor immunity, aging changes their phenotype and interactions with other immune cells. Using multiparameter flow cytometry, functional assays. single-cell RNA sequencing, and ATAC-seq, we identify a phenotypically and epigenetically distinct CD8⁺ T cell population (DP8) that accumulates with age in mice and possibly in older humans. DP8 cells exhibit a non-exhausted CD101⁺CXCR6⁺CD39⁺CD73⁺ phenotype. Mechanistically, DP8 differentiation is driven by aging B cells, as aged—but not young—B cells induce DP8 identity and B cell deficiency prevents their emergence. Functionally, DP8 cells suppress CD4⁺ T cell activation and promote tumor progression, and tumors expressing CXCL16 selectively recruit DP8 cells into the tumor microenvironment where they impair antitumor immunity. We propose that DP8 cells are attractive therapeutic targets, as DP8-like cells appear to also increase in older humans, including in late onset breast cancer. In aged mice, the depletion of DP8 cells or their inducer B cells efficiently reverses tumor growth even when anti-PD1 therapy fails.

#4240 Differential impact of short and long-term hypoxia on effector T cell dysfunction.

Maria Villalba-Esparza[1], Ana Lledo-Delgado[2], Shruti S. Desai[1], Adam Aguirre-Ducler[1], Daniel Boiarsky[3], Boyu Huang[1], Samuel M. DeFina[1], Javier Ramos-Paradas[1], Kurt A. Schalper[1]

[1]Pathology, Yale University, New Haven, CT,[2]Immunobiology, Yale University, New Haven, CT,[3]Medical Oncology, Yale University, New Haven, CT

Background: Limiting T cell dysfunction is crucial for improving immunotherapy outcomes in patients with solid tumors, including non-small cell lung cancer (NSCLC). Hypoxia can occur in the tumor microenvironment (TME) and induce tumor infiltrating lymphocytes (TILs) adaptations, yet the impact of sustained hypoxia on human effector T cells remains poorly understood.

Methods: Using Imaging Mass Cytometry (IMC), we simultaneously mapped 36 markers for cancer cells (DNA, H3, CK, Vimentin, PD-L1, PD-L2, FGL1, CD47, β2M), immune cells (CD3, CD4, CD8, CD20, CD56, CD68, CD45RA, CD45RO, FOXP3, DC-Lamp), functional states (LAG-3, PD-1, TIM-3, VISTA, TBET, EOMES, TOX1/2, TCF7, CD25, CD27, CD137, GZB, ARG1, KI67 and CC3) and hypoxia (HIF1α, CA9) in 114 pre-treatment NSCLCs from two independent cohorts of patients treated with chemotherapy (Cohort 1, n=61) or PD-1 axis blockers (Cohort 2, n=53). Single-cell segmentation enabled the study of the relationship between hypoxia and effector T cell states. To assess functional changes, human PBMCs from healthy donors and *in vitro* expanded TILs obtained from primary human NSCLCs were exposed to recurrent TCR stimulation for 6 days under normoxia (21% O_2) or hypoxia (1% O_2). Longitudinal changes in effector T cell phenotype and function were evaluated by flow cytometry, scRNA/ATACseq, migration and cancer cell killing assays.

Results: In primary NSCLCs, hypoxic $CD8^+$ TILs showed heterogeneous distribution, higher activation and dysfunction markers (CD25, PD-1, LAG-3, TIM-3, TOX1/2, GZB, KI67), and distinct association with patient outcomes. Under normoxia, short-term (1 day) stimulation increased activation, cytokine production and cancer cell killing, followed by progressive acquisition of a dysfunctional state during intermediate (3 days) and long-term stimulation (6 days) characterized by increased markers of dysfunction, proliferation, reduced cytokine production, and impaired migration and cytotoxicity. Under hypoxia, short-term stimulation did not alter the T cell phenotype but reduced TNFα production, migration and tumor killing capacity compared to normoxia. However, prolonged T cell stimulation under hypoxia (3-6 days) led to a distinct phenotype with reduced dysfunction markers, increased cytokine production, and improved migration and killing. Differences were noted between PBMCs and TILs. Long-term stimulation under hypoxia showed distinct transcriptomic and epigenetic changes supporting specific mechanisms underlying the observed responses.

Conclusions: Hypoxia modifies the activation and functional profile of effector TILs in NSCLC. Short and long-term hypoxia induces opposite phenotypic, functional and molecular changes on effector T cells during recurrent TCR stimulation. These results expand our understanding of the dynamic role of hypoxia on human T cell dysfunction with prominent biological and translational implications.

#4241 Anti-tumor antigen CD8 T cells infiltrating M3 uveal melanoma metastases are detectable in the blood.

Sol Y. Nunez, Rachele Sintini, Camille Jamet, Setareh Aflaki, Abdoulaye Soumare, Pascale Mariani, Manuel Rodrigues, Marc-Henri Stern, Olivier Lantz, Ana I. Lalanne

Institut Curie, Paris, France

Introduction: Uveal melanoma (UM) is the most common cancer of the eye in adults. 30-40 % of UM become metastatic with preferential tropism to the liver. UMs with loss of one copy of chromosome 3 (M3) are the most prone to metastasize. Current treatments for metastatic UM (mUM) remain largely ineffective. A better understanding of tumor-specific $CD8^+$ T cell responses is essential for the development of new immunotherapies.

Methods: Tumor-infiltrating and blood $CD8^+$ T cells of mUM patients were studied using multicolor tetramer staining and spectral flow cytometry, VDJ single-cell RNA sequencing (VDJ-scRNAseq) and bulk TCR sequencing (TCRseq) for alpha and beta chains.

Results: Analysis of the immune infiltrate of UM metastases revealed the presence of numerous CD8+ T cells in all disomic 3 (D3) (n=15) and M3 (n=22) metastases. In only 12 out of 22 M3 metastases, CD8+ T cells co-expressed CD39 and PD-1 markers, associated with tumor reactivity, as compared to the juxta-tumoral tissue (p=0.0003). VDJ-scRNAseq analysis evidenced increased expression of genes related to chronic activation (*HAVCR2*, *LAG3* and *TOX)* and large clonal expansions of $CD39^+PD1^+CD8^+$ T cells, which were the only proliferating cells in the tumor bed. The tumor antigen (Ag) specificity of $CD39^+PD1^+CD8^+$ T cells was confirmed by staining with tetramers loaded with the tumor associated Ag, Melan-A, while the CMV-specific $CD8^+$ T cells did not co-express CD39 and PD1. A coordinated immune response in the liver and the blood in matched metastasis-blood samples was revealed by a strong positive correlation (Rpea=0.7366, p=0.0017, n=15) between the proportion of memory Melan-A-specific $CD8^+$ T cells in the blood and $CD39^+PD\text{-}1^+CD8^+$ T cells in metastases. Notably, only metastatic patients harbored a significantly higher percentage of memory Melan-A-specific CD8+ T cells as compared to healthy donors (n=9, p=0.0133) and primary UM patients (n=13, p=0.0096), confirming the localized nature of the immune response in the eye, reported by our team (JEM, 2024). To explore if tumor-reactive $CD8^+$ T cells of other tumor-Ag specificities could also recirculate, we performed scRNAseq and scTCRseq analysis of four M3 metastases along with bulk TCRseq for alpha and beta chains in the blood. A large proportion (between 18% and 42%, depending on the patient) of the most expanded $CD39^+PD1^+CD8^+$ TCR clones (≥ 3 cells) from the metastasis were also found in the circulation at the time of liver resection. The stage of the disease when these expanded metastasis-reactive clones appear in the blood and their Ag specificity are currently under investigation.

Conclusions: A subset of M3 mUM patients exhibit an anti-tumor Ag response in liver metastases which was also detectable in the blood. Further characterization of these tumor-Ag specific $CD8^+$ T cells and identifying their Ag specificities may lead to novel biomarkers of metastatic disease as well as novel therapeutic targets.

#4242 IRF8 regulates T cell differentiation and anti-tumor effector function.

Zainab Tiamiyu[1], Dakota Poschel[2], Aaron Behdadnia[1], Kendra Fick[1], Patrick Czabala[3], Yang Zhao[1], Dafeng Yang[3], Sergie BOMBIN[4], Kebin LIU[3]

[1]Biochemistry and Cancer Biology, Augusta University, Augusta, GA,[2]Medical College of Georgia, Augusta, GA,[3]Augusta University, Augusta, GA,[4]Georgia Cancer Center, Augusta, GA

Interferon regulatory factor 8 (IRF8) is a myeloid cell lineage-specific transcription factor that also regulate B cell differentiation under physiological conditions. Under pathological conditions such as cancer, IRF8 acts as a negative regulator of myeloid-derived suppressor cells (MDSCs) to regulate anti-tumor immunity. However, the function of IRF8 in regulation of the adaptive immune response in the tumor microenvironment is incompletely understood. We therefore aimed at building a single cell atlas of IRF8-regulated immune cell differentiation in the tumor microenvironment using genome-wide single-cell multiomics. Unsupervised clustering in combination with maker-based annotation identified 12 major cell subpopulations in tumor-infiltrating leukocytes. IRF8 deficiency resulted in increased myeloid-derived suppressor cells (MDSCs) and memory T cells, but decreased plasmablasts, dendritic cells, and effecter T cells. Pathway enrichment analysis indicates that IRF8 primarily regulates multiple metabolic pathways in plasmablasts. In addition, IRF8 deficiency enhances TCR signaling, MTOC1 signaling, IFNγ signaling, and T cell dysfunction in tumor-infiltrating effector T cells, but not in memory T cells. This hyperactivation is correlated with increased activation of apoptosis pathways in effector T cells. Our findings determine that IRF8 regulates the plasmablasts-effector T cell axis in the tumor microenvironment, and loss of IRF8 expression leads to decreased plasmablasts and hyper activation and dysfunction of effector T cells, resulting in effector T cell elimination and tumor immune escape.

#4243 Mutational-signature adjusted models reveal HLA-mediated depletion of antigenic mutations in non-small cell lung cancer (NSCLC).

Amy Lauren Cummings[1], Andy Han[2], Seung J. Park[3], Sai S. Kollapaneni[3], Daniel Li[3], Arjan Gower[3], Maria Antonia Velez Velez[3], Aaron Lisberg[3], Jonathan W. Goldman[4], Edward B. Garon[5]

[1]UCLA Health, Los Angeles, CA,[2]Department of Medicine, Division of Hematology/Oncology, UCLA - University of California Los Angeles, Los Angeles, CA,[3]UCLA - University of California Los Angeles, Los Angeles, CA,[4]UCLA David Geffen School of Medicine, Santa Monica, CA,[5]Asst. Prof., Dept. of Hem./ Onc., University of California (UCLA), Santa Monica, CA

Background: Quantifying immune editing in human tumors is challenging because observed mutation patterns reflect both mutational processes and selection. Whether HLA class 1 genotypes uniformly influence which somatic mutations persist remains unclear.
Methods: Whole-genome sequencing (WGS) from CPTAC NSCLC tumors with matched blood and adjacent normal lung underwent germline single nucleotide polymorphism (SNP), somatic single nucleotide variant (SNV), HLA typing, neoepitope prediction, and mutational signature decomposition using established pipelines. SNP/SNVs were annotated with codon position, resulting amino acids, and evolutionary similarity metrics (BLOSUM62, PAM250, Miyata, Atchley, Grantham). Four-digit HLA alleles were collapsed into recognized supertypes; neoepitopes with IC50 ≤150 nM were considered high-affinity. Models of expected nonsynonymous mutations were created using the GRCh38 reference, mutational signature, and tumor mutation burden and compared to observed SNP/SNVs using cosine similarity. Statistical significance was assessed using ANOVA and generalized linear models with FDR correction.
Results: 219 cases (111 LUAD, 108 LUSC) were processed successfully. Median SNPs were 862.3, SNVs were 103.8 with an associated median of 62.5 predicted neoepitopes (4.9 high-affinity) per case. Amino acid substitutions arising from the third codon position (N=96) had higher similarity than those from position 1 and 2 (N=226), ($p<0.001$). SBS4 dominated 167 (76.3%) tumors; in blood, SBS5 and SBS58 characterized 152 (69.4%) and 55 (25.1%) cases, respectively. Codon-position biases differed across signatures, with SBS4 showing relative depletion of position-3 substitutions compared to SBS5 and SBS58 ($p<0.001$). Signature-based modeling demonstrated cosine similarity >0.90 with higher cosine similarity in SBS4 compared to SBS5 and SBS58. ANOVA comparisons of amino acid substitutions revealed multiple supertypes (A02, B27, B44) with relative depletion of anchor substitutions and high-affinity neoepitopes with these substitutions (FDR<0.05).
Conclusion: Germline SNPs exhibit strong evolutionary constraint, whereas somatic SNVs show minimal intrinsic codon-position bias, supporting the hypothesis that cancer mutagenesis is a random process. Controlling for mutational signature uncovers HLA-specific immune editing, demonstrating that antigenic mutations are selectively depleted in specific HLA contexts. This signature-conditioned framework provides a clinically actionable platform for improving neoantigen prediction and immuno-oncology translation.

#4244 Investigating the spatial immune tumor microenvironment of dermatofibrosarcoma protuberans.

Maryam Al-Ghezi[1], Malia Rettig[1], Christopher P. Loo[2], Rashi Yadav[2], Wesley Yu[3], Joshua M. Moreau[1]

[1]Cell, Developmental and Cancer Biology, Oregon Health & Science University, Portland, OR,[2]Cancer Early Detection Advanced Research Center, Oregon Health & Science University, Portland, OR,[3]Department of Dermatology, Oregon Health & Science University, Portland, OR

Dermatofibrosarcoma Protuberans (DFSP) is a rare, locally aggressive cutaneous sarcoma driven by the COL1A1-PDGFB fusion. While its molecular drivers are well-defined, the DFSP tumor immune microenvironment remains poorly characterized. Understanding immune-stromal interactions in DFSP may reveal opportunities to complement surgical resection with immunotherapy or targeted approaches. We performed spatial transcriptomics on 16 DFSP patient samples using 10X Genomics Visium v2 (n=12) and Visium HD (n=4), integrated with single-cell RNA sequencing. Our analysis revealed distinct tumor, stromal, and immune populations with high PDGFB-high tumor cells spatially segregated from infiltrating immune compartments. We identified transcriptionally distinct cancer-associated fibroblast (CAF) subsets, including populations enriched for extracellular matrix remodeling and inflammatory signatures that may modulate local immunity. Immune profiling uncovered spatially heterogeneous T cell and macrophage infiltration, with distinct immune-rich and immune-desert zones across patients. Notably, we observed tertiary lymphoid structure (TLS) formation in multiple samples, characterized by elevated TLS signature scores and spatial co-localization of B and T cell markers. CXCL13 and CCL19 emerged as key chemokines defining TLS-associated immune-stromal communication networks. Using cyclic immunofluorescence, we validated the spatial organization of TLS-associated immune niches, confirming co-localization of CD3+ T cells, CD20+ B cells, and CD68+ macrophages within TLS-enriched regions at protein level. This work provides the first spatial immune atlas of DFSP, revealing organized lymphoid structures and CAF-mediated immune regulation that could inform combination strategies targeting PDGFR signaling alongside immune checkpoint or stromal modulation.

#4245 The Immune strategies to convert cold to hot tumors and overcome resistances.

Yang-Xin Fu

tsinghua University, Beijing, China

Cold tumors evade immunotherapy through limiting T cell priming inside draining LN or infiltration into TME. Here, we have developed sequential strategies to overcome the limitation. Firstly, we have developed new mRNA vaccine expressing membrane cytokines with shared or mutated antigens to more and better prime tumor specific T cells (TST) without toxicity. Secondly, we generated tetramer forms of NGR that fusing into Fc-pro-IL2 that selectively targeted CD13 enriched on TME for more IL-2 to rejuvenate dysfunctional T cells. Unexpectedly, cis-delivery of IL-2 on CD13 on tumor vessels can bridge the cross-talk between tumor vessels and TST. Activated T cells can remodel tumor vessels to allow more infiltration. To sustain their anti-tumor activities, we have sequentially delivered tumor-activating cytokines (pro-IL2) guided by anti-PD-1 antibody (anti-PD-1-pro-IL2) or radiation-activating TLR agonists to help DC-T cell interaction inside TME to sustain T-cell effector function. Together, we have sequential strategies converting cold to hot tumors and then simultaneously reinvigorates TIL to overcome the limitations of current immunotherapies.

#4248 Characterization of T-cells in ER$^+$ breast tumors and their matching adjacent tissue reveals that classical exhaustion markers are not indicative of T-cell function.

Diana Savage[1], Edward Buchel[2], Afshin Raouf[1]

[1]Department of Immunology, University of Manitoba, Winnipeg, MB, Canada,[2]Department of Surgery, University of Manitoba, Winnipeg, MB, Canada

The manipulation of patients' tumor-infiltrating T-lymphocytes (TIL) as a form of immunotherapy has shown promising results in the treatment of select cancers; however, limited benefit has been observed in treating invasive estrogen receptor-expressing (ER$^+$) breast tumors. The development of a dysfunctional, exhausted-like T-cell phenotype in the tumor microenvironment has been linked to immunotherapy failure, but the intrinsic and extrinsic factors that result in its development remain poorly understood. We previously showed that breast tumor-adjacent tissue (TAT), located over three centimeters from the primary tumor, contains an inflammatory signature and, therefore, hypothesized that it may be a reservoir of tumor-reactive T-cells. Further, the comparative study of TILs and TAT-T-cells may reveal important information about the mechanisms of TIL exhaustion and how to overcome them. ER$^+$ breast tumor and matching TAT samples were collected from patients undergoing mastectomy procedures, from which the breast cancer cells (BCC), TIL-CD3$^+$ and TAT-CD3$^+$ T-cells were obtained. The cytotoxic CD8$^+$ subset from each CD3$^+$ T-cell sample was isolated and examined for the expression of exhaustion and activation markers and then placed in a three-dimensional co-culture assay with the autologous BCCs. Here, BCC viability and T-cell exhaustion marker expression were assessed and conditioned media was collected for cytokine analysis. Interestingly, the TIL-CD8$^+$ T-cells expanded more rapidly than the TAT-CD8$^+$ T-cells; however, the TAT-CD8$^+$ T-cells were more effective in eliminating autologous BCCs. The enhanced reactivity of the TAT-T-cells was further corroborated with enhanced secretion of activating cytokines such as interferon gamma. T-cells with an increased expression of exhaustion marker TIM-3 (T cell immunoglobulin and mucin-domain containing-3) prior to co-culture were less effective in eliminating BCCs. Further, in co-cultures, up to a 9-fold increase in the expression of exhaustion marker LAG-3 (lymphocyte activation gene 3) was observed in select TIL- and TAT-CD8$^+$ T-cells. Interestingly, the expression of PD-1 (programmed cell death protein 1), the most frequently studied marker in the context of T-cell dysfunction, remained low and unchanged. To our knowledge, this is the first detailed study of the CD8$^+$ T-cells that reside in ER$^+$ breast tumors and their adjacent tissues. We have observed that TAT contains CD8$^+$ T-cells with enhanced reactivity against autologous BCCs despite having a similar exhaustion marker profile as the TIL CD8$^+$ T-cells. Interestingly, our findings also suggest that TIM-3 and LAG-3 may contribute to T-cell exhaustion in ER$^+$ breast tumors and that blocking these receptors might be more effective than blocking PD-1 as immunotherapy.

#4249 High-throughput discovery of MART1-specific TCR-peptide interactions using a Jurkat NFAT Reporter-K562 antigen-presenting cell system and single-cell adaptive immune receptor profiling.

Alex Chenchik[1], Debbie Deng[1], Kitt Paraiso[1], Guido Stadler[2], Ben Yellen[2]

[1]Cellecta, Inc., Mountain View, CA,[2]Celldom, San Carlos, CA

In this study, we developed a high-throughput workflow for identifying MART1-specific T cell receptor (TCR)-peptide interactions relevant to melanoma immunotherapy. Jurkat NFAT-GFP reporter cells expressing individual candidate MART1-TCRs (n=10 to 20) were co-cultured with K562 artificial antigen-presenting cells (APCs) engineered to express a MART1 120-peptide, tumor-associated library in a single-chain trimer (peptide-B2M-HLA-A) format. TCR activation was quantified using the CellDom Microwell EliSpot platform, where GFP expression and IL-2 secretion signaled productive antigen engagement. Cells from positive wells were harvested, and DriverMap adaptive immune receptor (AIR) bulk and single-cell TCR-Seq assays and subsequent NGS analysis were performed to identify the cognate TCR epitopes.To improve epitope presentation, we introduced a G2C substitution in the G4S linker of the single-chain trimer, which enhanced HLA surface expression and increased Jurkat activation compared with the wild-type construct. MART1-TCRs showed differential reactivity across the MART peptide panel, enabling ranking of functional affinity and identification of cross-reactive peptide candidates. Both the bulk AIR DNA and bulk AIR RNA assays show clonotypes that are expanded in MART1 vs Day 0 (control) or DMSO control. On Day 9, approximately 12 clonotypes are expanded at 250x compared to Day 0 in the MART1-stimulated sample. With the single-cell AIR assay, the MART1-stimulated samples showed overrepresentation of clones, whereas there was no clonal overrepresentation in the DMSO control plate.This end-to-end platform shows TCR-peptide interactions with bulk and & single-cell NGS readout, which could enable identification of therapeutic TCR candidates, and provide a scalable method for characterizing antigen specificity for cancer immunotherapy applications.

#4250 Sirt2 dictates TCR activation thresholds through post-translational control of LCK conformational state.

Imene Hamaidi[1], Pingyan Cheng[2], Soo Young Jun[1], Min-Hsuan Wang[3], Min Zhang[4], Odesha Taylor[4], Luis Lopez-bailon[5], Ismail Can[6], Bin Fang[4], Anders Berglund[1], Bradford Perez[7], Ben Creelan[4], Andriy Marusyk[4], Virginia Shapiro[6], Haitao Ji[4], Jose R. Conejo-Garcia[5], Sungjune Kim[1]

[1]Mayo Clinic Florida, Jacksonville, FL,[2]TuHURA Biosciences Inc, Tampa, FL,[3]Taipei Veterans Generation Hospital, Taipei, Taiwan,[4]H. Lee Moffitt Cancer Center, Tampa, FL,[5]Duke University School of Medicine, Durham, NC,[6]Mayo Clinic, Rochester, MN,[7]Florida Cancer Specialists & Research Institute, Trinity Cancer Center, Tampa, FL

BACKGROUND: Tumor-specific T cells are often characterized by reduced TCR signaling due to central and peripheral tolerance pathways that limit their responsiveness. These signals are further weakened by insufficient co-stimulation and active co-inhibitory pathways, collectively establishing a high threshold for activation. The integration of antigen recognition with co-stimulatory and inhibitory cues ultimately determines whether a T cell becomes activated or remains tolerant. Early TCR signaling must therefore be precisely regulated to prevent autoreactivity while still supporting protective immunity. Although phosphorylation and ubiquitination are well-established regulators of proximal TCR signaling, additional post-translational mechanisms remain less defined. SIRT2, a cytosolic NAD^+-dependent deacetylase with emerging roles in immune regulation, has not been examined in the context of TCR signaling.

METHODS: We evaluated proximal TCR signaling events in wild-type and SIRT2-deficient T cells using flow cytometry, immunoblotting, calcium flux assays, and RNA-sequencing. SIRT2-associated pathways were defined by mapping its interactome and acetylated substrates through mass spectrometry and immunoprecipitation. We screened LCK post-translational modifications by mass spectrometry and assessed SIRT2 enzymatic activity using an HPLC-based deacetylase assay. Conformational effects of LCK modification were examined using fluorescence-polarization binding assays and AlphaFold structural modeling. SIRT2 was deleted in human tumor infiltrating lymphocytes (TILs) via CRISPR/Cas9, and the impact of SIRT2 targeting was tested in lung cancer patient-derived xenograft models reconstituted with autologous TILs.

RESULTS: SIRT2 deficiency amplified proximal TCR signaling, leading to elevated phosphorylation of early signaling mediators and increased calcium flux in both naïve and anergic T cells. Loss of SIRT2 also altered thymic selection dynamics and expanded TCR repertoire diversity. Mechanistically, SIRT2 interacted with and deacetylated LCK, the initiating kinase of proximal TCR signaling. Mass spectrometry identified lysine K228 in the LCK linker region as a SIRT2-regulated deacetylation site that governs LCK conformation and kinase activity. Functionally, SIRT2 inhibition in exhausted mouse and human TILs restored TCR signaling capacity and improved anti-tumor responses.

CONCLUSION: Here we identify SIRT2-regulated deacetylation of LCK as a previously unrecognized mechanism that sets the strength and threshold of proximal TCR signaling. Accordingly, SIRT2 targeting reverses the exhausted phenotype of tumor-reactive T cells.

#4251 Th7R cells: CD4⁺ T-cell partners that drive Tpex-mediated antitumor immunity in the tumor microenvironment.

Shota Takei, Ou Yamaguchi, Satoshi Yamasaki, Atsuhito Mouri, Ayako Shiono, Yu Miura, Kosuke Hashimoto, Hisao Imai, Kyoichi Kaira, Ichiki Yoshinobu, Hiroyuki Nitanda, Tomoyuki Hishida, Katsuhisa Horimoto, Hiroshi Kagamu

Saitama Medical University International Medical Center, Hidaka, Japan

Background: Precursor-exhausted CD8⁺ T cells (Tpex) are self-renewing, stem-like CD8⁺ T cells that give rise to terminally exhausted (Tex) cells and maintain long-term antitumor immunity. Within the tumor microenvironment (TME), Tpex localize to tertiary lymphoid structures (TLSs) and high endothelial venules (HEVs) and trigger the CD8⁺ T-cell burst after PD-1 blockade. However, the CD4⁺ T-cell subsets that support Tpex generation and maintenance remain unclear. We previously identified Th7R cells, a Th1-like CD4⁺ T-cell subset (CCR4⁻CCR6⁺, expressing IL7R and TCF7) in lung cancer, associated with immune checkpoint inhibitor (ICI) responsiveness. Th7R and Tpex share stem-like signatures, suggesting a potential partnership.
Objective: To test whether Th7R cells function as CD4⁺ partners sustaining Tpex and long-term antitumor immunity, and to evaluate the antitumor efficacy of Th7R adoptive transfer.
Methods: We analyzed 55 early-stage lung cancer patients undergoing resection and 20 stage II-III patients treated with neoadjuvant anti-PD-1 therapy. Peripheral blood, tumor-infiltrating lymphocytes (TILs), and lymph node T cells were profiled by mass and imaging mass cytometry to assess the spatial and numerical relationship between Th7R and Tpex. In a mouse MCA205 model, CCR4⁻CCR6⁺ Th7R cells sorted and expanded from tumor-draining lymph nodes were adoptively transferred to evaluate antitumor effects and their impact on TILs.
Results: Patients with high preoperative Th7R frequency showed better disease-free survival. Th7R—but not other CD4⁺ subsets—decreased after tumor resection, indicating tumor antigen-driven expansion. In neoadjuvant cases, complete or major pathological responders had higher proportions of Th7R cells. Th7R and Tpex showed a positive correlation in both blood and lymph nodes. Imaging mass cytometry showed Th7R cells located near Tpex within TLSs. In mice, Th7R transfer induced tumor regression and specifically expanded both Tpex and Tex subsets.
Conclusion: Th7R cells are numerically and spatially associated with Tpex and crucial for sustaining long-term antitumor immunity. They may promote asymmetric Tpex division, maintaining renewal and effector supply. Th7R adoptive transfer, alone or with ICIs, represents a promising approach to enhance durable antitumor immunity.

#4252 Tumor extracellular vesicles prime B cells which promote tumor control and epitope spreading to T cell neoantigens.

Georgia Lattanzi[1], Zihan Guo[2], Kendrick Nguyen[1], Ferdinando Pucci[2], Daniel Hollern[1]

[1]Salk Institute For Biological Studies, La Jolla, CA,[2]Oregon Health & Science University, Portland, OR

Advanced solid malignancies are still a major clinical challenge due to their high lethality and limited response to existing therapies. Effective cancer immunotherapy requires T cell recognition of tumor neoantigens, and generation of a durable and robust cytotoxic response Recent studies demonstrate that B cells play a critical and previously underappreciated role in shaping anti-tumor immune responses in neoantigens-rich tumors by coordinating with T cells. However, how B cells respond to tumor neoantigens and regulate T cell responses are still not fully elucidated. By using engineered tumor cell lines expressing neoantigens with different affinity for cognate B cells either on tumor extracellular vesicles (tEVs) or as soluble proteins, we showed that tEVs and neoantigen-specific B cells are required for tumor control. We observed that tEVs-neoantigens are brought into the tumor draining lymph node where they bind and activate B cells. Using single cell RNA-sequencing and flow cytometry we showed that tEVs-neoantigens promote cognate B cells activation either through a germinal center reaction or through extrafollicular response. Notably, activated B cells not only mount direct anti-tumor responses, but also promote epitope spreading to linked T cell neoantigens, thereby broadening the immune response and improving tumor clearance. Epitope spreading consists of the diversification of tumor neoantigens recognized by the immune system and holds significant promise for improving cancer therapies. By co-expressing B and T cell neoantigens on the same tEV we observed extensive and prolonged B-T cells interaction using intravital microscopy, increased activation of CD4 T follicular cells, maintenance of progenitor CD8 T cells and tumor clearance. Thus, B cell response to co-expressed tEV neoantigens enhances the breadth of immune responses by facilitating specific anti-tumor T cell responses. By elucidating how B cells contribute to epitope spreading and tumor control, this research reveals new immunological principles and sets the base for next-generation cancer immunotherapies that harness both humoral and cellular arms of the immune system, offering new strategies to overcome tumor heterogeneity and therapy resistance.

#4253 Integrating neoantigen immunogenicity and tumor clonality for predicting immunotherapy response.

Ko-Han Lee, Timothy Sears, Maurizio Zanetti, Hannah K. Carter

University of California San Diego, La Jolla, CA

Background: Cancer immunotherapy has transformed treatment, yet response rates remain suboptimal. Immunogenic neoantigens—tumor-specific peptides eliciting T-cell responses—represent promising biomarkers, but current predictors have critical limitations: they focus predominantly on MHC-I while neglecting MHC-I/II coordination, and rely on tumor mutation burden (TMB), which lacks immunogenicity specificity and ignores tumor heterogeneity. We developed NeoPrecis, a computational framework integrating immunogenicity prediction with tumor subclonal architecture to improve immunotherapy response prediction.

Methods: NeoPrecis comprises two modules capturing mutation-centric and tumor-centric immunogenic contexts. NeoPrecis-Immuno models wild-type to mutant peptide distance to estimate T-cell recognition likelihood, incorporating amino acid embeddings, MHC-binding motifs, positional factors, and peptide sequences. The model was pre-trained on TCR-binding data for peptide-TCR cross-reactivity discrimination, then fine-tuned on T-cell assay data. NeoPrecis-Landscape integrates MHC-I and MHC-II immunogenicity predictions with PyClone-inferred subclonal structure. For each subclone, immunogenicity is computed as the product of its MHC-I and MHC-II scores. Tumor-level immunogenicity is then calculated as the weighted average of all subclonal scores, with weights determined by subclone prevalence.

Results: NeoPrecis-Immuno outperformed PRIME, ICERFIRE, and DeepNeo on an independent gastrointestinal cancer dataset with validated CD4+/CD8+ T-cell assays. Its interpretable architecture quantifies allele-specific contributions via allele benefit scores, which showed significant prognostic associations in melanoma ($p=0.04$) and NSCLC ($p=0.01$) independent of specific mutations. Across five melanoma and three NSCLC cohorts, NeoPrecis-Landscape outperformed TMB in stratifying ICI responders, particularly in melanoma and heterogeneous NSCLCs. Homogeneous, heavily immunoedited NSCLCs (predominantly smoker tumors) showed reduced neoantigen-based predictive power.

Conclusion: NeoPrecis provides an interpretable framework for neoantigen immunogenicity assessment. By integrating tumor subclonal structure, it outperforms TMB in predicting ICI response, especially in melanoma and heterogeneous NSCLCs with low immunoediting. Poor performance in immunoedited tumors suggests immune evasion mechanisms may dominate ICI response in these contexts.

#4254 Tapasin inhibits MHC I-presentation of a low affinity peptidome which elicits a unique population of highly effective CD8 T cells, in multiple mouse cancers.

Purva Pundeer[1], Joseph Dempsey[1], Adam T. Hagymasi[1], Jeremy Balsbaugh[2], Tatiana Scheglova[1], Ion Mandoiu[2], Pramod K. Srivastava[1]

[1]Immunology, University of Connecticut Health Centre, Farmington, CT,[2]University of Connecticut, Storrs, CT

Neoepitopes are generated from tumor-specific mutations that make tumors targets for CD8 and CD4 T cells. We and others have reported that a significant proportion of neoepitopes which elicit CD8 T cell mediated tumor control in vivo (such as Ccdc85cMUT in the BALB/c Meth A sarcoma and PLK1MUT in the C57BL/6 MC38-FABF colon carcinoma) bind MHC I with low to extremely low affinities (IC_{50} of 500- 50,000 nM) (Srivastava PK 2024 J. Clinical Investigation). The protein Tapasin facilitates the loading the MHCI with peptides that bind MHCI with high affinity. This high affinity immunopeptidome is a key to defense against acute viral infections. We observe that paradoxically, the Tapasin-sculpted immunopeptidome becomes a barrier in control of cancers. Genetic ablation of Tapasin in cancer cells (Meth A fibrosarcoma and 4T1 triple negative breast cancer of BALB/c mice and MC38-FABF colon carcinoma of C57BL/6 mice) leads to highly immunogenic cancer variants that fail to form tumors at challenge doses at which Tapasin-proficient parental tumors readily form tumors. The immune response elicited by Tapasin-deficient tumors is fully active even against the Tapasin-proficient parental tumors. The immunopeptidome of Tapasin-deficient tumors is dominated by low affinity pMHC I complexes. Mass spectrometry analysis of the MHC I presented peptidome shows 760 peptides presented by Tapasin-proficient cells and 1175 peptides by Tapasin-deficient cells. Of this, 500 peptides are shared between the parental and Tapasin-deficient cells. The unique peptidome of Tapasin-deficient cells shows a greater diversity of low affinity peptides (~700 peptide with predicted IC_{50} >2,000 nM in Tapasin deficient cells as compared to ~250 such peptides in Tapasin proficient cells). The low affinity immunopeptidome engages a pool of CD8 T cells with profound anti-cancer activity mediating robust tumor control of Tapasin-proficient parental tumors in adoptive transfer assays. The CD8 T cell repertoire elicited by Tapasin deficient tumors is highly cytotoxic and less exhausted as compared to the CD8 T cells elicited by Tapasin-proficient parental tumors. Lower expression of Tapasin in human cancers is significantly associated with better survival. These observations suggest that ablation of Tapasin can be used for immunotherapy of human cancers.

#4256 Long-read RNA sequencing and immunopeptidomics reveal transcriptomic aberrationneoantigens as targets for T cell immunotherapy in diffuse glioma.

Kenan Zhang[1], Megan Benz[1], Kelly M. Hotchkiss[2], Lin Lin[2], Sarah Quackenbush[2], Aroa Elortza Payros[3], Mark Pieterse[3], Wigard Kloosterman[3], Jeroen Kneppers[3], Mustafa Khasraw[4]

[1]The Preston Robert Tisch Brain Tumor Center, Duke University, Durham, NC,[2]Duke University, Durham, NC,[3]CureVac Netherlands B.V., Amsterdam, Netherlands,[4]Duke Cancer Institute, Durham, NC

Background: Diffuse Glioma (DG) exhibits low tumor mutational burden and limited responsiveness to immunotherapy, suggesting that antigen sources beyond canonical mutation-derived neoantigens are required to support effective antitumor T-cell responses. Transcriptomic aberrations, such as aberrant splicing, fusion transcripts, etc., generate extensive tumor-specific sequences. However, conventional short-read RNA sequencing captures only the sequences overlapping the neojunctions (NJs), thereby substantially underrepresenting this rich source of actionable neoantigens.

Methods: Nanopore long-read RNA sequencing was performed on 11 diffuse glioma tissues. Public data from 6 normal cortices was included as a control. A pipeline was composed to construct the whole-length transcriptome, identify novel transcripts with transcriptomic aberrations, translate peptides, and predict neoantigen candidates. Data-independent acquisition (DIA) proteomics was performed on 4 matched samples to verify the transcription of these novel transcripts and analyzed via DIA-NN. Immunopeptidome data were acquired from 5 matched samples and screened by NeoDisc, a computational pipeline accessing neoantigens based on the functionality of the antigen processing and presentation machinery.

Results: DGs demonstrated a significantly greater burden of both a larger number and higher expression of novel transcripts with transcriptomic aberration compared to normal cortex, indicating transcriptomic aberration as a tumor-enriched source of antigenic diversity. Novel transcripts consist of 8.08% of the total transcriptome in the DG cohort compared to 7.06% in the cortex cohort. Across the 4 DG samples with matched DIA proteomics, hundreds of novel transcripts per sample were identified after filtering for expression and coding probability. Approximately 30-40% of these transcripts showed evidence of translation supported by the DIA proteomics, with ongoing refinement for the high-confidence translated set. Neoantigen prioritization further identified hundreds of high-confidence candidate peptides per tumor with strong predicted HLA binding and immunogenicity features. To verify HLA-mediated peptide presentation as a further validation, DDA and DIA immunopeptidomics spectra for HLA-I and HLA-II have been collected.

Conclusions: Transcriptomic aberration neoantigens represent a biologically authentic and targetable antigen class in diffuse glioma. Integrating whole-length transcriptomics, DIA proteomics, and immunopeptidomics provides a disease-relevant and scalable framework for neoantigen discovery in low-mutation tumors. Cohort expansion and early T-cell functional validation of prioritized neoantigen candidates are undergoing to assess their therapeutic relevance.

#4257 F5446 epigenetically reprograms T cells to boost CEA CAR T cell immunotherapy efficacy in human colorectal cancer metastasis.

Kendra Fick, Patrick Czabala, Zainab Tiamiyu, Dafeng Yang, Kebin Liu

Augusta University, Augusta, GA

Chimeric Antigen Receptor (CAR) T cell therapy emerges as a promising cell-based immunotherapy for human cancer; however, it has shown little efficacy in solid tumors. Recent studies have shown that SUV39H1 decreases CAR T cell persistence and knocking out SUV39H1 increased CAR T efficacy in tumor-bearing mice. Analysis of human colon cancer liver metastases scRNA-seq datasets revealed that histone methyltransferases of H3K9me3 are upregulated in colon tumor and expressed in subsets of T cells in liver metastases of human colon cancer patients. To overcome human colon cancer resistance to CAR T cell immunotherapy, we have developed a SUV39H1-specific small molecule inhibitor F5446. Previously, we found that H3K9me3 promotes differentiation of T_{ex} cells and targeting H3K9me3 is an effective approach to increase $IFN\gamma^{hi}$ $T_{ex\text{-}int}$ cells to reinvigorate CTL functionality to suppress colon cancer liver metastasis. Based on this data, we hypothesize that F5446 is effective in increasing persistence of CAR T cells to suppress metastatic human colon cancer growth in NSG mice. A phase I clinical trial for α-CEA CAR T cell immunotherapy found it is well tolerated in patients with colorectal cancer with modest efficacy. Based on this, we generated second and third generation α-CEA CAR T plasmids for lentivirus transduction of primary T cells. We utilize an experimental liver metastasis model to induce liver metastasis of human colorectal cancer in a humanized mouse model. Mice are then treated with one dose of α-CEA CAR T cells and treated every three days with F5446 until endpoint. Extracted tumors are digested and the CAR T cell phenotypes (memory, effector, naïve, or exhausted) are determined via flow cytometry. We anticipate that F5446 will increase the persistence of CAR T cells in the liver metastases compared to CAR T therapy alone. F5446 is a promising conjunctive treatment with CAR T cell therapy to increase efficacy in solid tumor colon cancer.

#4258 In vivo genome-scale enhancer screen decodes T cell fate decisions in the tumor.

Keely Y. Ji[1], Alex Chang-Yu Chen[1], Laura Hinojosa[2], Bolutito Babatunde[2], Daniela Martinez[1], Thomas J. LaSalle[1], Maria Zschummel[1], Marc A. Schwartz[1], Ferhat Ay[2], Debattama Sen[1]

[1]MGH/Harvard Medical School, Boston, MA,[2]La Jolla Institute for Immunology, La Jolla, CA

During chronic infection and cancer progression, T cells enter a dysfunctional state called exhaustion, posing a significant challenge to disease control and immunotherapy outcomes. Previously, we and others have shown that T cell exhaustion is a differentiation process regulated at the epigenetic level. Exhausted T cells share a conserved program of chromatin accessibility landscapes across chronic infections and tumors (core exhaustion program) that is imprinted in early T cell differentiation. However, it remains unclear whether and which open chromatin regions within the core exhaustion program play a causal role in driving the exhausted state. We hypothesize that the core exhaustion program contains transcriptional enhancers that regulate T cell persistence and differentiation in exhaustion, preventing reinvigoration of function. To test it, we leveraged our novel enhancer editing platform called Systematic Non-coding element Interrogation by Paired sgRNAs (SNIP-R), a pooled CRISPR-based enhancer deletion platform optimized for kilobase-scale perturbation in primary T cells. We performed the first in vivo genome-scale enhancer deletion screen on ova-specific $CD8^+$ T cells (OT-1) in OVA-expressing tumors. We identified networks of regulatory elements in the core exhaustion program that regulate T cell persistence and subset formation in the tumor. Validation studies from the screen showed that deleting one such regulatory element 100kb upstream of the *Klf6* gene (*Klf6-100kb*) in T cells improved tumor control. *Klf6-100kb* perturbed T cells strongly outcompeted control populations and had increased generation of effector-like T cells in the tumor compared to control perturbations. Together, we showed that the core exhaustion program contains causal regulatory elements underlying T cell exhaustion and pinpointed new targets for developing next-generation adoptive T cell therapies.

#4259 Peripheral T cell methylome reveals accelerated systemic immune aging in early lung cancer.

Yu-Ching Wang[1], Shu-Yung Lin[2], Yi-Jhen Huang[3], Sheng-Yao Su[3], Yi-Chieh Wu[3], Jin-Shing Chen[4], Shuenn-Wen Kuo[4], Mong-Wei Lin[4], Chong-Jen Yu[4], Hsing-Chen Tsai[3]

[1]Taiwan International Graduate Program in Molecular Medicine, National Yang Ming Chiao Tung University, Taipei, Taiwan,[2]Department of Internal Medicine, National Taiwan University Hospital, Taipei, Taiwan,[3]Graduate Institute of Toxicology, National Taiwan University, Taipei, Taiwan,[4]Department of Surgery, National Taiwan University Hospital, Taipei, Taiwan

The immune landscape in cancer patients is shaped by dynamic interactions between systemic and local tumor immune responses. While the intratumoral immune microenvironment has been extensively studied, systemic immune alterations, especially in early-stage cancers, remain poorly understood. DNA methylation governs T cell functional and differentiation states, and aberrant patterns have been linked to immune dysfunction. We hypothesized that peripheral blood T cells in early lung cancer exhibit reactive DNA methylation remodeling in response to the presence of cancer. To test this, we profiled circulating CD3+ T cells from 63 patients with early-stage lung cancer (stages I and II) and 70 healthy individuals using Illumina Infinium MethylationEPIC arrays. We identified 824 differentially methylated regions (7373 CpG sites) in T cells from lung cancer patients versus non-cancer controls. Gene ontology analysis revealed promoter hypermethylation in T cell activation and differentiation pathways. Epigenetic clock analysis revealed accelerated biological aging in patient-derived T cells, independent of chronological age. Transcriptomic profiling by RNA-seq further demonstrated enrichment of senescence-associated gene networks. Consistently, deconvolution analysis using MethylCIBERSORT revealed an enrichment of late-differentiated T cell subsets. Similar observations emerged from pseudotime trajectory analysis, which showed peripheral T cells, which shift toward senescent-like states at the in early lung cancer. The extent of senescence correlated with promoter hypermethylation in co-stimulatory gene loci. Furthermore, hypermethylated gene promoters were enriched for binding motifs of the E26 transformation-specific (ETS) transcription factor family, implicating a regulatory role of DNA methylation in T cell state transitions. Finally, using cohort splitting and 10-fold cross-validation, we identified a five-gene immune-derived methylation signature that distinguished early-stage lung cancer from non-cancer subjects with high accuracy (training AUC = 0.953; validation AUC = 0.894). This study reveals previously unrecognized systemic T-cell epigenetic reprogramming in early-stage lung cancer, characterized by senescence features and impaired activation potential, and establishes a framework for developing immune-derived methylation biomarkers for early lung cancer detection.

#4260 Deciphering the dysfunctional immunological synapse in acute myeloid leukemia through microfluidic.

Sofia Titah[1], Clara Lewuillon[1], Faruk Azam Shaik[2], Aurelie Guillemette[1], Eva Gez[1], Nathalie Jouy[3], Laure Goursaud[1], Celine Berthon[1], Salomon Manier[1], Carine Brinster[1], William Langue[4], Tzung Hsuen Khoo[4], Alexandre Poulain[4], Sophie Dabo[4], Dominique Collard[2], Bruno Quesnel[1], Loic Lemonnier[5], Mehmet Cagatay Tarhan[2], Yasmine Touil[1]

[1]Univ. Lille, CNRS, Inserm, CHU Lille, UMR9020-U1277 - Canther - Cancer Heterogeneity, Plasticity and Resistance to Therapies, Lille, France,[2]Univ. Lille, CNRS, Centrale Lille, Junia, Univ. Polytechnique Hauts-de-France, UMR 8520 -IEMN 10 -Institut d'Electronique de Microelectronique et de Nanotechnologie, Lille, France,[3]UMS 2014/US4, Lille, France,[4]Laboratoire Paul Painleve - CNRS UMR 8524, Lille, France,[5]Laboratory of Excellence, Ion Channels Science and Therapeutics, Villeneuve d'Ascq, Lille, France

Minimal residual disease (MRD) in acute myeloid leukemia (AML) arises from residual leukemic cells that resist chemotherapy and evade immune surveillance, notably through the PD-1/PD-L1 immune checkpoint. These persistent cells are the main source of relapse. Our working hypothesis is that alterations in calcium signaling, a key regulator of T-cell activation, contribute to PD-1/PD-L1-mediated immune escape in AML. The project aims to characterize the calcium signaling signature associated with PD-1/PD-L1 axis activation during the formation of the immunological synapse (IS) between T cells and leukemic cells from AML patients, to better understand immune dysfunction and therapy failure.

To facilitate interactions between rare T cells and leukemic cells, we utilize microfluidic devices that enable controlled cell-cell contact and real-time monitoring of calcium dynamics. An AI-based algorithm performs real-time analysis of IS formation, processing about 100 events per image every five seconds. Calcium fluctuation data are extracted and mathematically modeled to quantify responses and classify patient-derived T cells as “responders” or “non-responders” using machine learning.

Immunofluorescence is used to identify key molecular components at the IS, while RT-qPCR quantifies the expression of calcium-regulating genes such as ORAI, STIM, and NFAT isoforms in both T cells and leukemic cells. Our first results reveal altered calcium mobilization in AML-derived $CD8^+$ T cells compared with healthy donors, along with PD-1-dependent inhibition of store-operated calcium entry linked to reduced ORAI1 activity.

Ongoing single-cell RNA sequencing (scRNA-seq) analyses aim to identify transcriptional profiles of T-cell subpopulations, both at rest and during IS formation. By integrating functional calcium signatures and transcriptomic data, we seek to uncover signaling pathways responsible for impaired IS formation in AML. Ultimately, this work will identify molecular targets within the calcium signaling network that could be modulated to restore the cytotoxic activity of exhausted $CD8^+$ T cells against therapy-resistant leukemic cells.

#4261 High-sensitivity HLA-I immunopeptidome profiling from limited clinical PBMC samples.

Anamarija Pfeiffer[1], Lucy Yang[1], Arthur Viode[1], Daniel Redfern[1], **Yuehan Feng**[1], Daniel Green[2], Cheryl McAlpine[2]

[1]Biognosys AG, Schlieren, Switzerland,[2]Greywolf Therapeutics, Oxford, United Kingdom

Background

Human leukocyte antigen (HLA) molecules are central to immune surveillance, presenting antigenic peptides from self and non-self proteins to T cells, and directing adaptive immune responses. Assessment of HLA-presented peptides is increasingly critical in oncology, both for understanding tumor immunogenicity and for guiding immunotherapy strategies. Peripheral blood mononuclear cells (PBMCs) offer a minimally invasive and clinically accessible matrix for such analyses, enabling serial sampling and longitudinal monitoring in clinical trials.

Application of the immunopeptidomics profiling (IMPX) to PBMC samples has demonstrated clinical relevance, as exemplified by its use in the GRWD5769 trial where pharmacodynamic modulation of the immunopeptidome was observed in patients treated with an ERAP1 inhibitor (ESMO 2024, ASCO 2025). Despite these advances, isolating HLA-associated peptides from limited PBMC material remains technically challenging, underscoring the need for more sensitive and robust methods suitable for routine use in clinical settings.

Methods

We developed and optimized an unbiased immunopeptidomics (IMPX) workflow utilizing native lysis and magnetic bead-based immunoprecipitation to isolate HLA class I associated peptides. Lysis and pulldown parameters were systematically refined to maximize recovery and specificity of HLA complexes from limited input material across diverse sample types, including cell lines, tumor tissues, and PBMCs. Downstream liquid chromatography-mass spectrometry (LC-MS) conditions and data processing pipelines were further optimized.

Results

To evaluate the performance of the workflow under clinically relevant conditions, a ramping experiment was conducted using 1 to 10 million PBMCs, reflecting cell yields commonly obtained from trial samples. Incorporation of mild detergent (n-dodecyl β-D-maltoside, DDM) during immunopeptide elution from HLA complexes significantly improved overall recovery, particularly at inputs of ≤5 million PBMCs. Following optimization of both the biochemical and computational pipelines, up to 2,300 HLA class I-associated peptides were confidently quantified from as few as 1 million PBMCs. When 5 million PBMCs were used as input, more than 9,500 unique HLA-bound peptides were identified.

In summary, this high-sensitivity, optimized immunopeptidomics platform enables comprehensive class I HLA profiling from minimal PBMC input, supporting its translational application as a pharmacodynamic readout in clinical studies.

Poster Session

#4266 CAR-T-cell monitoring using specific multimers: a fast and specific method allowing uniform evaluation.

Elizabeth Epps[1], Kivin Jacobsen[2], kevin Lenogue[2], Liselotte Brix[2]

[1]Immudex, USA LLC, Philadelphia, PA,[2]Immudex, ApS, Copenhagen, Denmark

CAR-T cell immunotherapy is used successfully against refractory hematological and solid cancer. Cellular Monitoring of CAR-T cells is important both for validating expression of the CAR construct in the transduced T cells prior to infusion, and persistence of the CAR-T cells in the blood of the recipient. CAR expression is often detected by fluorochrome conjugated antibody against a structural part of the CAR construct, and not the specific target for the CAR interaction. We have developed a flexible platform to manufacture direct CAR-T cells detecting multimer reagents, CAR-Dextramer® allowing detection of CAR-T cells of different specificities and affinities Activation of chimeric antigen receptor T (CAR-T) cells are critical for ensuring therapeutic efficacy in adoptive immunotherapy. CAR-T cell activation requires two signals: antigen recognition through the CAR and co-stimulation via intracellular interactions, and by stimulatory molecules such as interleukins. Control of activation and continuous monitoring are essential to optimize potency to improve clinical outcomes in hematologic and solid tumors immunotherapy.
We have developed CAR-T cell activation reagents based on the CAR-Dextramer® scaffold, that contain said stimulatory molecules. These reagents can be used to evaluate the ability of the transduced CAR-T cells to be stimulated or expanded through the specific interaction with its cognate target, and costimulatory signals.

#4267 *In vivo* evaluation of autologous anti-BCMA CAR-T therapy in PBMC-humanized SDKO mice reveals donor-specific immune responses.

Alba Matas-Cespedes[1], Jiwon Yang[2], Kushal Prajapati[3], Destanie Rose[2], Oanh Pham[2], Michael Lehmann[3], Tom McKevitt[1], Georgina Cornish[1], Richard Stebbings[1], James G. Keck[2], **Ilian Radichev**[2]

[1]Clinical Pharmacology and Safety Sciences, AstraZeneca, Cambridge, United Kingdom,[2]Innovation and Product Development, The Jackson Laboratory-West, Sacramento, CA,[3]Clinical Pharmacology and Safety Sciences, AstraZeneca, Gaithersburg, MD

Introduction: Autologous CAR-T therapies targeting B-cell maturation antigen (BCMA) have shown remarkable clinical success in treating multiple myeloma (MM). However, accurate prediction of patient-specific efficacy and adverse events - such as cytokine release syndrome (CRS), immune effector cell-associated neurotoxicity syndrome (ICANS) and Immune effector cell associated hemophagocytic lymphohistiocytosis-like syndrome (IEC-HS) - remains a significant and ongoing challenge. To address the need for personalized screening of CAR-T immunotherapies, we developed and tested a novel humanized mouse model using the NSG-SGM3-IL15-DKO (SDKO) strain, optimized for PBMC engraftment. This model is a new potential preclinical tool to assess individualized CAR-T efficacy and toxicity *in vivo*.

Methods: We evaluated autologous anti-BCMA CAR-T therapy in vivo using five human PBMC donors in the context of an established $BCMA^+$ tumor. For this, SDKO mice were injected intravenously with 1×10^6 MM.1S-luc cells, a model cell line for multiple myeloma. Ten days post-tumor injection, mice were randomized based on their tumor burden and injected with 3×10^6 PBMCs. Four hours later, mice received either PBS, 5×10^6 autologous untransduced T cells (UT), or 5×10^6 autologous anti-BCMA CAR-T cells. Tumor burden and body weight were monitored over 28 days. Blood samples were collected at SD1, SD2, SD5, SD15, SD21 and SD28 to assess human cell engraftment and plasma cytokine levels and tissues retrieved for histopathology.

Results: Autologous CAR-T cells induced rapid and potent tumor regression with low toxicity, whereas UT cells failed to control MM.1S-luc tumors across all donors, with tumor progression even more severe than that observed in the PBS group. However, donor-dependent variability was observed: Donors 0935 and 1295 showed reduced CAR-T expansion, and 0935 failed to achieve complete tumor clearance. Transient tumor resurgence occurred in most CAR-T treated mice, except Donor 5263, where tumors were rapidly and permanently eliminated. In contrast, tumors metastasized to bone marrow in PBMC and UT groups. Cytokine profiling revealed both donor-dependent (IL-9, IL-12p70, IL-12p40) and donor-independent (IL-2, IL-4, IL-5, IFNγ, TNFα, IL-13) secretion patterns. Notably, IL-10 exhibited a unique dynamic: a modest spike at SD1 followed by a CAR-T-dependent decline, while PBS and UT groups showed very high IL-10 levels at SD5, suggesting a link to uncontrolled tumor burden and immune dysregulation.

Conclusion: Our results demonstrate that the SDKO PBMC humanized mouse model has the potential to be a valuable tool for preclinical CAR-T testing, enabling patient-specific evaluation of efficacy and safety, and paving the way for safer CAR-T cells in the clinic.

#4268 Armored allogeneic Epstein-Barr virus specific T cells expressing a multi-functional B7-H3 chimeric antigen receptor exhibit improved persistence, expansion and performance in solid tumor models.

Marvin Chew[1], Pei Yun Teo[1], Joanna Koh[1], Jin Wei Tan[1], Lindsay Kua[1], Richard Ong[1], Fiona Wong[1], Angeline Goh[1], Qingfeng Chen[2], Cliona Rooney[3], Ivan Horak[1], Kar Wai Tan[1], **Lionel Low**[1]

[1]Research and Development, Tikva Allocell Pte. Ltd., Singapore, Singapore,[2]Institute of Cell and Molecular Biology, A*STAR, Singapore, Singapore,[3]Baylor College of Medicine, Houston, TX

Allogeneic chimeric antigen receptor (CAR)-T cells can address the high costs and poor availability associated with autologous CAR-T therapies. However, the development of these “off-the-shelf” are challenged with risks of graft-versus-host disease (GvHD) and allogeneic rejection by the patient’s immune cells. Furthermore, whilst remarkable successes have been achieved in the treatment of hematological malignancies, strategies targeting solid tumors face further challenges including tumor trafficking, antigen heterogeneity, chronic antigen stimulation and an immunosuppressive microenvironment.

To address these challenges, we employed allogeneic Epstein-Barr virus specific T cells (EBVSTs) that have been well tolerated in clinical trials. With a narrowed TCR repertoire, EBVSTs have lower GvHD potential. EBVSTs also express higher levels of CD74 and CXCR4 and can better migrate towards tumors cells. Allogeneic rejection by T/NK cells involves the activation of caspases. We show that armoring CAR-EBVSTs with an engineered serine protease inhibitor, SerpinB9(CAS), increases survival in mixed lymphocyte reactions and humanized mice models. Interestingly, we observed that the armored CAR EBVSTs are also resistant to activation induced cell death induced by chronic antigen stimulation.

B7-H3 is an attractive CAR target due to its overexpression in multiple solid tumors, and tumor stroma, with limited expression in normal tissues. We expressed an engineered V_{HH}-based B7-H3 CAR in our armored EBVSTs (B7H3.CAR-EBVSTs) and observed potent efficacy against various cell-line and patient derived xenografts *in vivo* models. Importantly, we showed that B7-H3 CAR also targets B7H3+ myeloid derived suppressor cells (MDSCs) and alloreactive T cells in co-culture experiments, further enhancing survivability in the presence of these immunological challenges.

Lymphodepletion is an essential preconditioning step prior to CAR-T infusion to ensure efficient engraftment of the cells. However, adverse effects of lymphodepletion include severe cytopenia and increased risks of opportunistic infections. We show that a constitutive IL-7 receptor (IL-7) synergized with SerpinB9(CAS) to boost proliferation in the presence of allogeneic challenge, potentially reducing or removing the need for lymphodepletion.

EBV infection has been associated with epithelial cancers including gastric and has been reported to upregulate B7-H3 in nasopharyngeal cancer (NPC). With partial HLA matching, B7H3.CAR EBVSTs can potentially mediate bispecific targeting of B7-H3+, EBV+ tumors in patients. Thus, our armored B7H3.CAR-EVBSTs present an attractive strategy that can overcome significant challenges and improve efficacy in solid tumors, strongly supporting its future development for evaluation in clinic.

#4269 Structure-guided protein engineering and humanization of GPC1-targeted nanobody CAR T cells for treating pancreatic cancer.

Hsi En Tsao, Mitchell Ho

National Cancer Institute, Bethesda, MD

Glypican-1 (GPC1) is a heparan sulfate proteoglycan that is overexpressed in pancreatic ductal adenocarcinoma (PDAC). We previously developed GPC1 CARs using the dromedary VHH nanobody D4 and the mouse monoclonal IgG antibody HM2, which recognize a membrane-distal epitope and a membrane-proximal epitope, respectively. Here, we integrate structural modeling with CAR functional data and animal experiments to define how epitope position and CAR geometry jointly determine GPC1 CAR efficacy. Modeling of CAR ectodomains incorporating CD8 or IgG4 hinges and CD8 or CD28 transmembrane (TM) domains indicated that only specific combinations yield an intermembrane spacing comparable to that of the TCR-pMHC immune synapse for a given epitope. These geometric predictions aligned with functional data in which D4-IgG4H-CD28TM CAR T cells rapidly regressed tumor bioluminescent in a T3M4 intraperitoneal PDAC model. Together, these results support a model in which epitope spatial location on GPC1 and CAR hinge/TM architecture are key design parameters for GPC1-targeting CAR T cells. To facilitate clinical development of D4 CAR T cells, humanization of the VHH D4 is highly desirable, although humanization of nanobodies such as VHHs is not well established. In addition to the CDR grafting to the nearest germline framework as we described previously for humanization of rabbit and mouse antibodies, we used AI-predicted structural models from multiple platforms to compare both the spatial geometry and sequence similarity of predicted D4 framework and CDR regions with available antibody and nanobody structures. Humanized constructs with the highest humanness scores, geometry, and similarity scores were back-mutated to preserve critical residues in the nanobody framework sequences and were then evaluated for GPC1 binding affinity and cell-surface binding. Using this AI-assisted, structure-guided strategy, we aim to generate clinically suitable humanized VHH nanobody scaffolds for GPC1 CAR T therapy and other nanobody-based clinical applications.

#4270 Enhanced solid tumor rejection using IF-BETTER gated CAR T cells for the treatment of hepatocellular carcinoma.

Leena Halim, Michael Lopez, Michel Sadelain

Columbia Institute for Cell Engineering and Therapy, Vagelos College of Physicians and Surgeons, Columbia University Irving Medical Center, New York, NY

CAR T cell therapy has demonstrated remarkable success in treating hematological malignancies but has been, to date, far less effective against solid tumors. Several common obstacles limiting the activity of CAR T cells in solid tumors have been identified, including low and/or heterogeneous target expression, insufficient T cell functional persistence, T cell exclusion and microenvironmental suppression. We address here the former, focusing on the targeting of glypican-3 (GPC3) in hepatocellular carcinoma (HCC). GPC3 is a GPI-anchored protein that is commonly but heterogeneously expressed in HCC, ranging from of 10^4 to 10^2 molecules per cell in a panel of HCC tumor cell lines. Whereas conventional CARs are efficacious against tumors expressing several thousand GPC3 molecules per cell, they consistently fail in the lower range of GPC3 expression. To overcome this limitation, we adopted an IF-BETTER gating strategy by co-targeting a second antigen that is broadly expressed in order to increase CAR T cell avidity for the tumor and CAR T cell persistence, depending on the structure of the associated chimeric costimulatory receptor (CCR). In contrast to an OR gate, wherein two antigens are targeted by either two CARs or a dual-specific CAR, the second antigen in an IF-BETTER gate does not on its own elicit cytotoxicity and therefore does not have to be as restricted to tumor cells as the CAR target. We identified IL1RAP as a potential CCR target and paired the GPC3 CAR, incorporating the GC33 scFv and the 1XX signaling module to extend CAR T cell persistence, with CCRs providing different costimulatory signals. We investigated the paired GPC3-1XX CAR/IL1RAP CCRs in vitro and in vivo, targeting tumor cell lines with a range of GPC3 expression levels. The GPC3-1XX + IL1RAP-CCR configuration preserved on-target GPC3-restricted cytotoxicity while increasing CAR T cell proliferation and maintaining cytotoxicity after repetitive stimulations, in contrast to control CAR T cells lacking the CCR. In vivo, GPC3-1XX CAR + IL1RAP CCR T cells showed significantly improved tumor control, intratumoral infiltration and survival, most pronounced in the setting of low GPC3 expression. In summary, combining calibrated 1XX CAR signaling with IL1RAP-gated costimulation increases GPC3 CAR T cell persistence and reduces antigen escape. These data support the clinical translation of an IF-BETTER gated strategy targeting GPC3 in hepatocellular carcinoma.

#4272 Glutamic-oxaloacetic transaminase 2 (GOT2) as a dual-functional enhancer for CAR-T cell metabolic fitness.

Xiangyi Fang[1], Shadab Kazmi[2], Andre Kelly[2], Xiaoling Jin[3], Alison Jaccard[4], Nathaniel W. Snyder[5], Alexander A. Shestov[2], Saba Ghassemi[2], Roddy S. O'Connor[2]

[1]Department of Bioengineering, University of Pennsylvania, Philadelphia, PA,[2]Department of Pathology and Laboratory Medicine, University of Pennsylvania, Philadelphia, PA,[3]Center for Cellular Immunotherapy, University of Pennsylvania, Philadelphia, PA,[4]Department of Cancer Biology, University of Pennsylvania, Philadelphia, PA,[5]Lewis Katz School of Medicine, Temple University, Philadelphia, PA

CAR-T cell therapy has transformed the treatment landscape for hematologic malignancies, yet its efficacy in solid tumors remains challenged. Aspartate is one of the most critically depleted metabolites in the solid tumor microenvironment; its deficiency impairs T cell proliferation, redox balance, and mitochondrial fitness. GOT2, a mitochondrial enzyme in the malate-aspartate shuttle, plays a critical role in T cell metabolism, as it catalyzes the conversion of oxaloacetate to aspartate. In doing so, GOT2 also helps maintain redox balance and energy production. In addition to its canonical role in aspartate biosynthesis, recent studies in cancer cells suggest that GOT2 regulates fatty acid metabolism through the activation of the transcription factor PPARδ. In T cells, PPARδ is shown to regulate the formation of central memory phenotype and long-term survival. In this study, we examined whether GOT2 overexpression enhances CAR-T cell metabolic fitness and antitumor activity. We found that GOT2-overexpressing CAR-T cells (CART19-GOT2) exhibit superior cytolytic function in both in vitro hypoxic conditions and in vivo tumor models. In xenograft models of NALM6 leukemia, CART19-GOT2 was able to sustain tumor control and prevented regrowth even after rechallenge. Compared to standard CART19 cells, CART19-GOT2 show enhanced mitochondrial respiration and spare respiratory capacity, indicating better mitochondrial fitness. GOT2 overexpression also elevated intracellular aspartate levels in CAR-T cells in normal growth conditions and under hypoxic stress. Using isotypically labeled nutrients as tracers, we found that aspartate is replenished through a cooperative interplay of fuels in primary human T cells, with glutamine serving as the preferred substrate. Collectively, these findings indicate that GOT2 overexpression is a promising strategy for metabolic enhancement of CAR-T cells for solid tumor immunotherapy.

#4273 Environmental conditioning during CD19-CAR T cell manufacturing impacts antitumor potency in a subcutaneous NALM6 tumor model.

Candy Garcia[1], Anita J. Zaitouna[2], Abriel Czachorowski[3], Lauren Kucharczyk[3], Natalie Czeryba[3], Philip Edward Lapinski[4], Andrea Hodgins-Davis[3], Thomas Sullivan[1], Yelena Bronevetsky[1], NINGCHUN LIU[3], Sheri Barnes[5], Shannon Eaker[6], Scott Wise[3], James Lim[1]

[1]Xcell Biosciences, San Francisco, CA,[2]Covance Inc., Ann Arbor, MI,[3]Labcorp, Ann Arbor, MI,[4]Laboratory Corporation of America, Ann Arbor, MI,[5]Laboratory Corporation of America, Chapel Hill, NC,[6]Xcellbio, SAN FRANCISCO, CA

Chimeric Antigen Receptor (CAR) T cell therapy has transformed outcomes for hematologic malignancies, yet optimizing manufacturing conditions remains critical to improving potency and consistency. We previously demonstrated that culturing CAR-T cells under physiological oxygen and pressurized conditions improved persistence and efficacy in a disseminated NALM6 human ALL model.In this study, we investigated whether these optimized manufacturing conditions similarly improve antitumor activity in a subcutaneous NALM6 xenograft model. CD19-targeted CAR-T cells were expanded under three conditions: standard CO_2 incubation (21% O_2 + 0 PSI), mild hypoxia with hyperbaric pressure (15% O_2 + 5 PSI), reflecting arterial and peripheral blood environments, and hypoxia with hyperbaric pressure (5% O_2 + 5 PSI), modeling the solid tumor and bone marrow microenvironments. After a 10-day tumor stage, a dose of 2.5e6 CAR+ T cells achieved complete tumor clearance in all conditions at 20 days post T cell dose, with faster tumor regression under 5% O_2 + 5 PSI conditions (7 days post T cell dose) compared to normoxia or mild hypoxia (10 days post T cell dose). These *in vivo* outcomes were consistent with enhanced *in vitro* functional activity, characterized by greater cytoxicity at CAR-T-to-effector ratios under 1:30 and increased cytokine production. This consistency mirrors our previous findings in the disseminated model, where CAR-T cells cultured under physiologically relevant conditions demonstrated the *in vitro* characteristics predictive of *in vivo* efficacy. Preliminary findings show enhanced potency and persistence under 5% O_2 + 5 PSI conditions. To determine whether these manufacturing advantages are sustained at lower CAR-T doses, a dose titration study is currently in progress, with complete results forthcoming.These data highlight the potential of physiological manufacturing with the GMP AVATAR Foundry to enhance CAR-T function and lower effective doses, supporting scalable next-generation cell therapies.

#4274 CAR-T cells with GPC3-inducible gene circuits for targeting hepatocellular carcinoma.

Kin Ching Tsang[1], Yuqing Deng[1], Pinghui Zhu[1], Chenzi Zhang[1], Jianwei Ren[2], Bo Feng[1]

[1]School of Biomedical Sciences, The Chinese University of Hong Kong, Hong Kong, China,[2]Centre for Regenerative Medicine and Health, Hong Kong Institute of Science & Innovation, Hong Kong, China

Despite the remarkable success of chimeric antigen receptor (CAR) T-cell therapy in hematologic malignancies, its application to solid tumors such as hepatocellular carcinoma (HCC) remains limited by insufficient tumor-specific activation and systemic toxicity from constitutive immunostimulation. To overcome these challenges, we engineered anti-glypican-3 (GPC3) CAR T cells incorporating inducible gene circuits that enable spatially and temporally controlled activation within the tumor microenvironment. Utilizing a lentiviral delivery system, we generated GPC3-specific CAR T cells exhibiting potent antigen-dependent cytotoxicity against HepG2 cells *in vitro* and significant tumor regression in immunodeficient xenograft models. To achieve precise antigen-gated regulation, we implemented a synthetic Notch (synNotch) receptor system and systematically characterized its induction dynamics and kinetics using a Jurkat T-cell reporter platform. Through single-chain variable fragment (scFv) screening, we identified an optimized anti-GPC3 scFv that conferred high sensitivity and specificity for HCC-associated GPC3. Subsequent engineering refinements, including deletion of the negative regulatory region (NRR) and incorporation of a SyNthetic Intramembrane Proteolysis Receptor (SNIPR) architecture, substantially enhanced receptor responsiveness, yielding robust, GPC3-dependent transgene expression with minimal basal leakage. Functional validation in both two-dimensional co-cultures and three-dimensional tumor spheroids confirmed that the optimized anti-GPC3 SNIPR system drives potent, target antigen-restricted transgene activation exclusively upon engagement with GPC3-positive tumor cells. Collectively, these findings establish a modular and tunable platform for inducible CAR T-cell therapy in HCC, demonstrating that synthetic gene circuits can enforce stringent spatial control over T-cell activation in the anti-GPC3 context. This approach holds significant promise for improving the therapeutic index of CAR T-cell therapy in HCC by simultaneously enhancing antitumor efficacy and mitigating off-tumor toxicity.

#4275 Combining circular RNA and a silicon membrane-based cell engineering approach to create CAR-Ts with membrane bound IL-2 and IL-12.

Armon Sharei[1], Zhihui Song[1], Sophia Hirsch[2], Eleni Rogers[3], Darby Kreienberg[3], Alec Barclay[3], Andrew Larocque[3], Anil Narasimha[3]

[1]Portal Biotechnologies, Inc., Watertown, MA,[2]Portal Biotechnologies, Watertown, MA, MA,[3]Portal Biotechnologies, Watertown, MA

Cell delivery is crucial for cell therapy and drug development, and we have developed a novel mechanoporation technology that allows efficient delivery of a wide range of cargoes to primary cells and cell lines. This technology uses a silicon membrane to temporarily deform cells, creating pores that enable cargo diffusion into the cells. Importantly, this method minimizes disruption to normal gene expression and maintains cellular integrity. It is compatible with various cell types and has been successfully applied in both cell therapy and drug discovery. At Portal, we have successfully delivered CRISPR/Cas9 RNPs, mRNAs, circular RNAs, and siRNAs into T cells, B cells, NK cells, and monocytes. For instance, we achieved over 85% GFP expression and B2M deletion in naive T cells after simultaneous delivery of mRNA and CRIRPR-RNPs. Additionally, we demonstrated the functional expression of a CD19 CAR and membrane-bound IL-2 by delivering two circRNAs. Early data from iPSCs and HSCs show significant potential for stem cell engineering and differentiation. Using a clinical-scale prototype, we have achieved delivery of over $1x10^9$ T cells per minute, resulting in more than 50% knockout efficiency and 90% GFP expression after 7 days of T cell expansion.Our platform also addresses a major barrier to drug development by enabling the delivery of cargoes that are otherwise impermeable to cells, such as small molecules, peptides, PROTACs, DELs, antibodies, and probes. We have successfully delivered a variety of cargos with over 80% efficiency while maintaining high cell viability. The technology has been tested in several cell types, including cancer cell lines, human immune cells, and stem cells. The simplicity of the mechanical delivery method facilitates scalability and integration with liquid handlers for high-throughput applications. This enables rapid and automated screening of molecules previously incompatible with live cell assays, improving drug discovery efficiency. Overall, Portal's technology offers a scalable, cost-effective solution with the potential to significantly advance both cell therapy and drug discovery. By reducing manufacturing time and cost, it seamlessly integrates into existing clinical and industrial equipment, supporting the development of next-generation cell-based treatments that could revolutionize the treatment of diseases with high unmet clinical needs.

#4276 Synecta™ T1 cell-derived nanoparticles and Flowfect® continuous flow transfection enhance non-viral engineering efficiency and manufacturing scalability of CD19-directed CAR-T cells for hematologic malignancies.

Chiquita Hanindya[1], Christopher Abraham[2], Maria Lai[2], Peter Keller[1], Kevin Gutshall[2]

[1]BlueWhale Bio, Philadelphia, PA,[2]Kytopen, Cambridge, MA

Background: Autologous CAR-T cell therapies have transformed outcomes in B-cell lymphomas, leukemias, andother indications, yet manufacturing duration, cost, process variability, and dependence on viralvectors continue to limit broader adoption. Improved processes are essential to deliver moreeffective cell therapies and enable broader adoption. Efficient non-viral gene editing requiresactivation that preserves viability and stem-like phenotypes, unlike CD3/CD28 activators, and adelivery system that achieves high editing efficiency without compromising cell health.BlueWhale Bio's Synecta™ T1 cell-derived nanoparticles (CDNPs) mimic physiologic APC signalingvia membrane-bound OKT-3, CD86, 4-1BBL, IL-7, and IL-15/IL-15RA. Kytopen's Flowfect Tx®continuous flow cell engineering technology maximizes yields of engineered cells, whileprocessing hundreds of billions of cells in minutes. Here we present the synergies of thesetechnologies to enhance CRISPR-mediated knock-in (KI) of a CD19-CAR at the TRAC locus.

Methods: Primary healthy donor (HD) human T cells were activated for 2-3 days with Synecta T1 orcomparator activation technologies and then gene-edited using Flowfect Tx® platform to deliverCas9/sgRNA RNP and a CD19-CAR HDR template. KI and knock-out (KO) efficiency, viability,activation, CD4/CD8 ratio, and expansion were quantified through Day 8. Parallel experimentsevaluated Synecta T1 activation immediately after Flowfect Tx transfection in naïve T cells.

Results: Synecta T1 induced >90% CD69$^+$CD25$^+$ activation while preserving CD3 expression. By Day 8, Tcells activated with Synecta and transfected Flowfect Tx® platform achieved >40% CD19-CAR KIand >90% TRAC KO, exceeding comparator activation technologies (<25% KI) and improving bothKI and KO efficiencies. Synecta T1 supported >80% viability and >5-fold expansion, yielding thehighest CAR-positive cell numbers, while maintaining a favorable CD4/CD8 profile. In the naïveworkflow, delivering RNP with a nanoplasmid HDR donor first and then activating with SynectaT1 increased KI-positive cells and expansion compared with unstimulated control, producingmarkedly higher CAR$^+$ output.

Conclusions: Synecta T1 and Flowfect Tx® platform enable efficient non-viral genome editing and rapidexpansion, supporting a streamlined, non-viral manufacturing approach for CD19-CAR-T cells. Byimproving KI and KO efficiency, Synecta T1 enhances CRISPR-based editing and supports targetedCAR insertion under endogenous promoters. Together, these technologies deliver a scalable workflow that achieves effective therapeutic doses quickly while preserving cell fitness. Futurestudies will evaluate activation strategies aligned with Day-2 or Day-0/1 Flowfect Tx® transfection.

#4277 AQP3 NOT gating mitigates lethal on-target off-tumor pulmonary toxicity of MSLN-directed CAR-T cells in ovarian cancer.

Minghua Xiang[1], Wei Mu[2], Bingbing Zhao[3], Jundong Li[4], Qinglei Gao[1], Huayi Li[4]

[1]Department of Obstetrics and Gynecology, Tongji Hospital, Tongji Medical College, Huazhong University of Science and Technology, Wuhan, China,[2]Department of Hematology, Tongji Hospital, Tongji Medical College, Huazhong University of Science and Technology, Wuhan, China, Wuhan, China,[3]Department of Obstetrics and Gynecology, Guangxi University Cancer Hospital, Nanning, China,[4]Department of Gynecologic Oncology, Sun Yat-sen University Cancer Center, Guangzhou, China, Guangzhou, China

Background: Mesothelin (MSLN) is overexpressed across multiple solid tumors and represents a promising therapeutic target. However, MSLN-directed chimeric antigen receptor (CAR)-T cells have been associated with lethal pulmonary on-target off-tumor toxicity. Here, we implemented a “NOT” logic-gating strategy to engineer dual-input MSLN/AQP3 lung-Specific Attenuated Functionally Engineered (lung-SAFE) CAR-T cells that retained potent antitumor activity against ovarian cancer while preventing fatal pulmonary toxicity.
Methods: A phase I trial (NCT05141253) was ongoing to evaluate the safety of MSLN-directed CAR-T cells in patients with solid tumors. Human MSLN (hMSLN) knock-in NCG mice bearing SKOV3 xenografts received intravenous MSLN-CAR-T cells and were longitudinally monitored for signs of toxicity. Major organs and peripheral blood were collected at moribund stages. MSLN expression, CAR-T cell infiltration, and lung injury were analyzed. Integrated analyses of in-house single-cell ovarian cancer datasets and publicly available single-cell lung datasets were performed to identify candidate inhibitory targets, which were subsequently validated in vitro and in vivo. CAR-T cell activation and cytotoxicity were assessed using flow cytometry, cell lysis assays, and cytokine quantification in co-culture supernatants.
Results: In the phase I trial, two patients with ovarian cancer experienced fatal pulmonary toxicity following MSLN-CAR-T cell infusion. To elucidate the underlying mechanism, we generated hMSLN knock-in NCG mice, which faithfully recapitulated the lethal pulmonary injury observed in patients. This toxicity was mediated by MSLN expression on alveolar cells and CAR-T cell-driven immunopathology. To overcome this limitation, we integrated single-cell transcriptomic analyses of ovarian cancer and healthy lung tissues to identify molecules selectively enriched in alveolar cells but minimally expressed in ovarian cancer cells. Cross-validation in cell lines, organoids, and human tissue specimens identified AQP3 as the most selective target. We then engineered a dual-input MSLN/AQP3 lung-SAFE CAR-T cells, wherein AQP3 delivered an inhibitory signal to suppress MSLN-CAR-T cell activation in the lung. The resulting lung-SAFE CAR-T cells maintained potent cytotoxicity against MSLN+ ovarian cancer cells while sparing AQP3+ alveolar cells in vitro.
Conclusions: This study established hMSLN knock-in NCG mice as a robust preclinical platform to evaluate the safety of MSLN-targeted CAR-T cells, identified AQP3 as a key molecular switch to mitigate their pulmonary toxicity in ovarian cancer, and introduced a generalizable framework that integrated single-cell transcriptomics with “NOT” logic-gating design for precision control of organ-specific CAR-T cell toxicity, advancing the safer translation of CAR-T cell therapies for solid tumors.

#4278 Regulatory T cell inspired engineering of CAR-T cells enhances anti-tumor efficacy in solid tumors.

Avik Chattopadhyay, Erin O'Connor, Leonardo M. R. Ferreira

Department of Pharmacology and Immunology, Medical University of South Carolina, Charleston, SC

Chimeric antigen receptor (CAR)-T cells have revolutionized treatment for hematologic malignancies. Yet, their efficacy against solid tumors remains limited due to the immunosuppressive tumor microenvironment (TME), characterized by nutrient deprivation, hypoxia, and lactate accumulation. Regulatory T cells (Tregs) thrive under such conditions due to expression of the transcription factor FOXP3, which enhances their intratumoral fitness. Leveraging this biology, we engineered effector CAR-T cells to overexpress FOXP3 and evaluated their therapeutic potential in melanoma. *In vitro*, CAR-T cells targeting the melanoma-associated antigen TRP1 efficiently killed B16F10 melanoma cells, with FOXP3 overexpression modestly reducing cytotoxicity. We next tested $CD4^+$, $CD8^+$, or total CAR-T cell subsets in immunocompetent C57BL/6 mice bearing B16F10 melanomas. *In vivo* NanoLuc luciferase imaging revealed superior persistence of FOXP3-expressing CAR-T cells compared to control CAR-T cells. Strikingly, while conventional CAR-T cells exhibited minimal tumor control, FOXP3 overexpression produced divergent outcomes: $CD4^+$ or $CD8^+$ CAR-FOXP3-T cells alone unexpectedly accelerated melanoma growth, whereas total CAR-FOXP3-T cells significantly delayed tumor progression. Mechanistic analyses revealed that FOXP3 overexpression did not alter the extent of CAR-induced T cell activation but did protect CAR-T cells from activation-induced cell death. Further characterization revealed that total CAR-FOXP3-T cells were predominantly $CD8^+$, leading us to hypothesize that supplemental $CD4^+$ CAR-T cells could enhance anti-tumor activity. Indeed, co-administration of $CD4^+$ CAR-T cells and total CAR-FOXP3-T cells resulted in sustained control of melanoma growth *in vivo*, indicating a synergistic interaction between the two cell populations. Our findings provide proof-of-concept for novel CAR-T cell therapy design principles to overcome barriers in solid tumor immunotherapy and inform the development of next-generation cellular therapies.

#4279 A PSMA-targeted CAR-T cell engineered with a CD16A signaling domain mitigates cytokine output while retaining antitumor activity in prostate cancer models.

Parv Barot, Hittu Matta, Sunju Choi, Gong Songjie, Bryant Bravo, Elton Zho, Hsing-Yu Wu, Sam Lin, Zhuoyue Yang, Preet M. Chaudhary

Jane Anne Nohl Division of Hematology and Center for the Study of Blood Diseases, USC Norris Comprehensive Cancer Center, Los Angeles, CA

Introduction: Adoptive transfer of Chimeric Antigen Receptor (CAR) T cells has demonstrated limited efficacy in solid tumors, partially attributable to excessive cytokine release driven by synthetic co-stimulatory domains and functional suppression within the tumor microenvironment. The purpose of this study was to engineer a Prostate-Specific Membrane Antigen (PSMA)-targeted CAR incorporating CD16A, an innate immune receptor with a distinct signaling profile to determine if this alternative architecture supports robust antitumor function while attenuating cytokine output.
Procedures: A lentiviral vector encoding a humanized J591-derived anti-PSMA single-chain variable fragment (scFv) fused to CD16A transmembrane and intracellular signaling domains (PSMA-CD16A CAR) was constructed, omitting canonical co-stimulatory domains (e.g., 4-1BB, CD28). Primary human T cells were transduced and evaluated for in vitro activity using a luciferase-based cytotoxicity assay against $PSMA^+$ LNCaP targets. Cytokine secretion (TNF-α, IFN-γ, IL-2) was quantified by ELISA following co-culture. In vivo antitumor efficacy was assessed in NSG mice bearing subcutaneous LNCaP xenografts (n=5 per group), utilizing untransduced T cells and tumor-only groups as controls.
Results: PSMA-CD16A CAR-T cells demonstrated antigen-dependent cytotoxicity in vitro, mediating efficient lysis of LNCaP cells. Compared with untransduced T cells, CAR-T cells exhibited enhanced killing potency while maintaining an attenuated cytokine secretion profile; levels of TNF-α, IFN-γ, and IL-2 were stable and sufficient to support effector function without supraphysiological spikes. In vivo, PSMA-CD16A CAR-T treatment significantly improved tumor control and prolonged survival. Median overall survival (OS) was 97 days in the CAR-T cohort reaching the study endpoint, compared to 71 days (±8) in untransduced T cells, representing a 36.6% survival increase. Three of five CAR-T treated mice survived to the maximal observation period with observed tumor regression with complete response. While survival was ultimately limited by xeno-reactive graft-versus-host disease (GvHD) inherent to the NSG model, tumor burden was significantly reduced compared to controls.
Conclusions: We report the successful generation of a PSMA-directed CAR relying exclusively on CD16A signaling. This construct preserves potent antitumor function while exhibiting a moderated cytokine profile. These findings support CD16A-based signaling as a viable alternative to conventional co-stimulatory domains. Ongoing work focuses on expanded functional characterization and evaluation in immunocompetent models to further assess safety, efficacy and persistence.

#4280 Restoration of LAT signaling via the ALA-CART platform promotes metabolic resiliency and persistence of AML CAR T cells.

Catherine Danis, Amanda J. Novak, Etienne Danis, Angie Vazquez, Michael Yarnell, Lillie Leach, M. Eric Kohler

University of Colorado Anschutz Medical Campus, Aurora, CO

Despite therapeutic advancements, the majority of patients with relapsed and/or refractory (r/r) acute myeloid leukemia (AML) have very poor prognoses and limited treatment options. While Chimeric Antigen Receptor (CAR) T cell therapy has transformed the treatment of r/r B-cell acute lymphoblastic leukemia (ALL), inducing remissions in up to 90% of patients, yet clinical trials of 2nd generation CAR T cells for patients with r/r AML have not replicated this success. Post-CAR T cell relapses in ALL are common and limit the long term efficacy of this therapy. Mechanisms driving ALL relapses after CAR T cells, such as short duration of activity and antigen modulated escape, have illuminated vulnerabilities of 2nd generation CAR T cells, such as exhaustion, poor persistence, and low antigen sensitivity. The mechanisms underlying AML progression after CAR T cells are not well defined, however, it is likely that similar barriers must be overcome to improve CAR T cell responses in patients with r/r AML.

We recently demonstrated the Linker for Activation of T cells (LAT) is inefficiently engaged in ALL-directed CAR T cells, particularly when antigen levels are low. Through a novel Adjunctive LAT-Activating CAR T (ALA-CART) platform, LAT activity and downstream signaling were restored and ALA-CART cells demonstrated enhanced potency, expansion, and persistence. We hypothesized that CD33-directed ALA-CART cells would similarly show improved potency and persistence in pre-clinical models of AML. Despite exhibiting decreased effector function in vitro, 33ALA-CART cells demonstrated increased efficacy in multiple AML xenograft models. 33ALA-CART cells had greater in vivo expansion and were effective at lower doses than CD33BBz CAR T cells. 33ALA-CART cells showed similar potency as CD33-28z CAR T cells, however, demonstrated enhanced persistence relative to both CD33BBz and CD33-28z CAR T cells. In rechallenge experiments, 33ALA-CART cells demonstrated enhanced expansion and leukemia clearance. Interestingly, the enhanced persistence of 33ALA-CART was strongly correlated with increased mitochondrial activity, a feature associated with long-lived memory T cell subsets and persistence. Consistent with this, RNA-sequencing analysis demonstrates that ALA-CART cells have increased potential for mitochondrial biogenesis and a reduced capacity for glycolysis relative to 2nd generation CAR T cells. Together, these data suggest that increased signaling through LAT results in enhanced metabolic capacity, potentially contributing to the enhanced proliferative, functional, and persistence capacity of 33ALA-CART cells in vivo.

Through restoring LAT activity and downstream signaling, the ALA-CART platform provides a rational strategy to enhance multiple facets of CAR T cell function and represents a promising approach to improve the efficacy of AML-directed CAR T cell therapy.

#4281 Armoring ROR1 CAR T cells with IL18 improves CAR T cell function and cytotoxicity against pancreatic cancer cell-lines *in vitro* and *in vivo*.

Bal Krishna Chand Thakuri, Saule Nurmukhambetova, Tri Tran, Ngoc Tran, Peirong Hu, Pradyot Dash, Rimas J Orentas, Alun Carter

Miltenyi Biotec, Gaithersburg, MD

ROR1 (Receptor tyrosine kinase-like Orphan Receptor 1) is a tumor-associated antigen widely expressed in solid tumors and is a promising target for CAR T cell therapy in pancreatic cancer. Cell-based immunotherapy has met with limited success due in part to the immunosuppressive tumor microenvironment (TME). Here we demonstrate that armoring our previously described[1] ROR1 CAR T cell product with interleukin-18 (IL18) enhanced expansion, persistence, and antitumor efficacy against pancreatic cell lines both *in vitro* and *in vivo*.

ROR-1-specific CAR-T cells were generated in human T cells using lentiviral vectors (LV) expressing a second generation CAR alone, CAR+ constitutive IL-18, or CAR+NFAT-IL18. IL18-ROR1 CAR T cells expanded 1.5 fold more, preserved naïve phenotype, and had reduced LAG3 expression (37% vs 81%) vs CAR. *In vitro* armored CAR cytotoxicity, determined by xCelligence tumor co-culture assays, was equal to or greater than CAR alone against ROR1(+) tumor cell lines. In an AsPC-1 mouse xenograft model, each CAR construct exhibited anti-tumor efficacy, with IL-18 expressing CARs displaying significantly greater tumor control. The constitutive IL18-CAR completely cleared tumor at day 28 post-T cell infusion and showed increased persistence throughout the study when compared to ROR1 CAR-T lacking IL-18 (Fig.1). CAR+NFAT-IL18 similarly controlled tumor growth compared to UTD.

In summary, IL18 armored CAR T cells significantly improved the expansion, persistence, and antitumor efficacy of ROR1 CARs in pancreatic cancer xenograft models. Importantly, NFAT-promoter-based regulation of ROR1 CAR T may offer a viable approach to regulating potential toxicity while retaining boosted IL-18 induced activity. This armoring strategy may offer a promising approach solid tumor indications and warrants further preclinical and translational investigation.

#4283 CD3-positive allogeneic CAR T-cells: A novel platform with persistence, BiTE-capture, and no alloreactivity.

Tanya Hundal[1], Yan Luo[2], Yaqing Qie[1], Martha E. Gadd[1], Shaohua Guo[1], Mohamed A. Kharfan-Dabaja[3], Hong Qin[4]

[1]Regenerative Immunotherapy and CAR-T Translational Research Program, Mayo Clinic, Jacksonville, FL,[2]Department of Cancer Biology, Jacksonville, FL,[3]Blood and Marrow Transplantation and Cellular Therapy Program, Mayo Clinic, Jacksonville, FL,[4]Department of Internal Medicine, Mayo Clinic, Jacksonville, FL

Several allogeneic CAR T-cell therapies are in clinical trials to evaluate safety, many of which rely on CRISPR/Cas-based genome editing. However, the Cas enzyme's random repair mechanism elevates the risk of undesired, off-target effects, posing a challenge for safe allogeneic CAR T-cell generation. To mitigate the risk of therapy-related oncogenesis, we sought to pursue an alternative safe strategy to manufacture allogeneic CAR T-cells distinct from the preexisting ones in the clinic. We have developed a CRISPR RNA (crRNA) targeting T-cell receptor beta constant (TRBC) gene, which in conjunction with AsCas12a Ultra enzyme, causes site-specific editing by eliciting a predictable microhomology-mediated end joining (MMEJ) DNA repair pathway, which mitigates off-targeting risk. Targeted amplicon sequencing was employed to evaluate off-targeting and repair mechanisms. Graft versus host alloreactivity as well as CAR T persistence was evaluated using immunocompromised mice. In vivo tumor challenge study was conducted for over 3 months. Engraftment confirmation was done using immunohistochemistry and flow cytometry. Interestingly while evaluating the edited T-cells, we sequestered a unique T-cell population that showed TCR disruption yet remained CD3-positive and did not cause in vivo alloreactivity. These CD3-Retained, Allogeneically Functioning T-cells (CRAFT-cells) showed a similar growth rate as unedited T-cells and were then used as a platform to produce CD19-targeted CAR T-cells and BAFF-R-targeted CAR T-cells. When compared to the standard CD3-disrupted allogeneic CAR T-cells, CRAFT CAR T-cells displayed an equally robust cytotoxicity while possessing a safer genomic profile. CRAFT CAR T-cells could function as effector cells for bispecific T-cell engager (BiTE) and induce CD3-dependent cytotoxicity against tumor cells. Pertinently, CRAFT CAR T-cells as opposed to CD3-disrupted CAR T-cells, were present in mouse xenografts without alloreactivity. Having the onset of MMEJ-directed repair and minimal off-targeting, positions this CRAFT crRNA to generate safer allogeneic CAR T-cells with an overall reduced genotoxic profile in a clinical setting. This unique CRAFT CAR T-cell population displays in vivo persistence. Additionally, CRAFT CAR T can be combined with BiTE therapy, offering a promising and potentially more durable alternative to preexisting ex vivo allogeneic CAR T-cell therapies.

#4284 FT839: A next-generation, off-the-shelf CAR T cell uniquely engineered with a dual CAR system targeting CD19 and CD38 for the treatment of hematological malignancies and autoimmune diseases without conditioning chemotherapy.

Alex J. Garcia[1], Shilpi Chandra[1], Soheila Shirinbak[1], Mark Jelcic[1], Brian Groff[1], Spas Markov[1], Alma Gutierrez[1], Angela Gentile[1], Miguel Meza[1], Karina Palomares[1], Carissa Dege[1], Bjoern Gaertner[1], Ramzey Abujarour[1], John Goulding[1], Tom Lee[1], Karl-Johan Malmberg[2], Maksim Mamonkin[3], Jode Goodridge[1], Martin Hosking[1]

[1]Fate Therapeutics, San Diego, CA,[2]Oslo University Hospital, Oslo, Norway,[3]Vagelos College of Physicians and Surgeons, Columbia Univerisity, New York, NY

Autologous chimeric antigen receptor (CAR) T cell therapies have revolutionized treatment of hematological malignancies and are showing promising results in autoimmune settings. Despite these successes, widespread accessibility to autologous CAR T-cell therapy is challenged by manufacturing complexities, high cost, lack of on-demand drug product availability and the requirement for intensive conditioning-chemotherapy. Moreover, single antigen targeting often fails to address the complex and heterogenous nature of such diseases. FT839 is an off-the-shelf, uniformly engineered, 13-point edited iPSC-derived CAR T cell therapy that overcomes these challenges, delivering potent and flexible multi-antigen targeting with broad patient accessibility.Mediated by its dual CAR system targeting CD19 and CD38 to eliminate malignant and aberrant immune cells, in preclinical studies FT839 exhibited selective elimination of autoimmune disease drivers like B cells, plasma cells and activated T cells as well as hematological cancer cells of lymphoma/leukemia and myeloma origin with profound potency ($p<0.01$). The comprehensive targeting strategy and the depth of activity was further extended when combined with the monoclonal antibody (mAb) rituximab or the T cell engager (TCE) epcoritamab facilitated through the expression of high affinity/non-cleavable Fc receptor (hnCD16) and CD3ε fusion receptor (CD3FR), respectively ($p<0.01$). Furthermore, FT839 features Sword and Shield^{TM} technology, designed to promote functional persistence by directly targeting and evading alloreactive host immune cells. In allogeneic settings with HLA-mismatched donor PBMCs or primed allogeneic T cells designed to quickly eliminate non-host cells, FT839 showed enhanced persistence (21x, $p<0.0001$ vs control), limited alloreactive cell expansion (0.25x, $p<0.0005$ vs control), and durable tumor control (>18x greater cytotoxicity vs control). FT839 has also been engineered with the chemokine receptor CXCR2, and a TGFβ signal redirection receptor to improve trafficking to sites of pathological activity and to counter the suppressive effect of TGFβ, respectively (6.5x greater tissue potency, $p<0.005$). With Sword and Shield^{TM} technology, FT839 obviates the need for conditioning chemotherapy, reducing patient burden and maximizing access. Armed with CD19 and CD38 targeting CARs and the ability to functionally combine with approved therapeutic mAbs and TCEs, FT839 selectively and uniquely eliminates heterogeneously populated disease-driving immune cells. Collectively, FT839 is a scalable, cost-effective, and uniform off-the-shelf CAR T-cell therapy for the broad treatment of hematological malignancies and autoimmune diseases.

#4286 B7-H3 hypoimmune chimeric antigen receptor T cells overcome immune rejection and retain antitumor activity against cholangiocarcinoma.

Chiara Camillo[1], Xiaomeng Hu[1], Giulia Cattaneo[1], Liti Zhang[1], Erica Daniels[1], Luigi Liguori[2], Eduardo Tejeda-Polanco[1], Maoyang Qi[1], Enrica Quattrocchi[1], Francesco Sabbatino[3], Sonja Schrepfer[1], Cristina R. Ferrone[1]

[1]Cedars Sinai Medical Center, Los Angeles, CA,[2]University of Salerno, Fisciano, Italy,[3]University of Salerno, S.Anastasia, Italy

Background. Intrahepatic cholangiocarcinoma (ICC) is a rare, aggressive liver cancer, with limited treatment options and poor survival. Because surgery is the only curative option, but most patients present with advanced disease, novel therapies are urgently needed. CAR-T cell therapy has revolutionized hematologic cancer treatment, but its application in solid tumors is limited.We investigated an allogeneic “off-the-shelf” hypoimmune (HIP) CAR-T platform designed to overcome barriers that hinder CAR-T efficacy in solid tumors. Targeting B7-H3, aberrantly expressed in ICC, the HIP CAR T cells demonstrated promising activity in vitro and in vivo studies. These findings support the potential of allogeneic HIP B7H3 CAR-T cells to improve antitumor responses in advanced ICC.
Methods: Immunohistochemical staining of an ICC tumor vs normal tissue. Generation of HIP T cells with disrupted B2M, CIITA, and TRAC genes using CRISPR-Cas9 editing. In addition, CD47 and anti-B7H3 CAR were expressed using lentiviral transduction. These allogeneic HIP B7H3 CAR T cells were compared to allogeneic WT B7H3 CAR T cells (TCR-/-) that only expressed the anti-B7H3 CAR. HIP phenotype characterization was analyzed by flow cytometry. Killing assay performed with xCELLicence real-time system. BLI for tumor growth.
Results: Immunohistochemistry of human ICC tumors showed strong membrane and cytoplasmic B7-H3 expression compared to normal liver tissue. The B7-H3 epitope recognized by mAb 376.96 was highly expressed in ICC2, ICC3 and hCAF cell lines. B7-H3 CAR T specifically recognized and eliminated ICC targets in vitro. Lentiviral constructs engineering produced both WT and HIP allogeneic CAR T cells with high editing efficiency: TCR knockout in 91% (WT) and 89.8% (HIP) and HLA-I and HLA-II knocked out in 93.3% and 98.7% of HIP B7-H3 cells. CD47 overexpression was restricted to the HIP B7-H3 cells (47.3%). In co-culture assay T cells, NK cells, and macrophages, HIP cells showed protection from adaptive and innate immune clearance. Impedance cytotoxicity assays confirmed that HIP B7-H3 CAR T cells maintained full antitumor activity, matching WT B7-H3 CAR T cell killing rate. HIP CAR-T cells are now validated in in vivo ICC model.
Conclusion: Our findings showed that allogeneic HIP B7-H3 CAR T cells can be efficiently engineered, maintain protection from adaptive and innate immune rejection, and retain full cytotoxic activity against ICC tumors. By combining the tumor-specific activity of B7-H3 CAR-T cells with the immune-evasive properties of HIP cells, this approach offers a promising and widely applicable allogeneic “off-the shelf” therapy for ICC, providing a strong rationale for further preclinical translational studies.

#4287 Cell killing dynamics and heterogeneity in engineered T-cells measured in live CellCage enclosures.

Shawn Levy[1], Richard Yau[1], Shreya Deshmukh[1], JangKeun Kim[2], Jiwoon Park[2], Yanping Yang[3], Makenzie Sacca[1], Shan Sabri[1], Christopher E. Mason[2], Moonsoo M. Jin[3]

[1]Cellanome, Inc., Redwood City, CA,[2]Weill Cornell Medicine, New York, NY,[3]Houston Methodist Research Institute, Houston, TX

Predicting CAR-T clinical efficacy remains a central challenge to the cell therapy field. Existing potency assays generally rely on bulk endpoints and may fail to capture cellular heterogeneity and dynamic interactions governing *in vivo* efficacy. We developed a technology to reveal CAR-T functional heterogeneity at single-cell resolution. Using CellCage Enclosures™, we encapsulated thousands of CAR-T cells at single-cell density with NALM-6, HeLa, and A549 targets across 1:10 and 25:1 E:T ratios in one experiment, enabling parallel cytotoxicity assessment under diverse conditions. Studies with AIC100, a preclinical ICAM1 CAR-T product, revealed striking heterogeneity: individual CAR-T cells exhibited killing at 55% compared to 80% with multiple cells working together. Optimal activity required both CD4+ and CD8+ CAR-T cells within the same microenvironment, suggesting critical cooperative mechanisms, which were product-specific, and impactful to clinical efficacy. A second CD19-targeting CAR-T product against NALM6 targets showed individual cells could kill effectively (50-60%), though cytotoxicity still improved to more than 80% with multiple effectors—but at different E-T ratios. Interestingly, CD8+ CAR-T killing was enhanced ~30% by non-transduced CD4+ T-cells lacking the CAR construct entirely, demonstrating that therapeutic potency can be modulated by cell-extrinsic factors independent of antigen recognition or cytokine secretion. This approach profiles thousands of cellular interactions per experiment, revealing that CAR-T activity emerges from complex cell-intrinsic properties and microenvironment factors unpredictable from bulk measurements. Each product exhibits unique cellular dynamics requiring individual optimization. The CellCage platform enables identification of potent CAR-T subpopulations and quantification of functional heterogeneity, providing a path toward predictive potency assays and rational optimization of cellular therapeutics.

#4288 Use of a 50-marker mass cytometry intracellular cytokine staining panel reveals unforeseen functional diversity within cell therapy products and unmasks potential efficacy 'saboteurs'.

Lauren Tracey[1], Michael Cohen[1], Laura Polanco[2], Erika Smith-Mahoney[3], David King[1], Amedeo Cappione[1], Anna Belkina[2], Christina Loh[1], Jennifer E. Snyder-Cappione[3]

[1]Standard BioTools, Markham, ON, Canada,[2]Boston University Chobanian and Avedisian School of Medicine, Boston, MA,[3]Boston University Chobanian and Avedesian School of Medicine, Boston, MA

Cell-based therapies have proven to be highly effective against certain cancers, yet improvements are needed to extend these successes to a wider variety of malignancies. Single-cell functional assessment of cell therapy products is customarily limited to Th1 cytokines (such as IFN-γ) and the cell survival/proliferative mediator IL-2, overlooking the cellular heterogeneity of CAR T products. This heterogeneity includes diverse antigen-experienced αβ T cells previously differentiated into distinct lineages (for example, Type 1, 2, 17, Treg) and innate T cell populations (iNKT, MAIT, γδ T), with many of the latter pre-programmed to exert immunosuppressive and/or cell repair effector functions. This diversity introduces potential “saboteur” cells with off-target effects that may undermine therapeutic efficacy. Surface marker profiling is insufficient for functional characterization, yet traditional flow cytometry lacks resolution for certain intracellular targets, particularly immunosuppressive cytokines. Mass cytometry (CyTOF™ technology) overcomes this technical limitation, providing superior intracellular signal resolution in the context of large panel analyses, a prerequisite of deep functional assessment of single cells. We hypothesized that there are sizeable proportions of saboteur T cells in cell therapy products that exert functions after stimulation that act in direct opposition to the therapeutic intention of the drug. To assess this, we developed a 50-marker CyTOF intracellular cytokine staining (ICS) panel with 24 functional readouts. This enabled clear detection of individual human T cells producing immunosuppressive cytokines such as IL-10, IL-13 and TGF-β, and measured the composite cytokine responses of both T cells in peripheral blood mononuclear cells (PBMC) and cell therapy products. Our data revealed an unforeseen prevalence of T cells that cross dogmatic lineage paradigms when stimulated. For example, after mitogen stimulation, approximately 30% of T cells from both peripheral blood and a cell therapy product produced the TGF-β-inducing cytokine amphiregulin (AREG), often concurrently with IFN-γ within the same cells. In addition, using the CyTOF ICS panel on TCR-stimulated T cell populations revealed peptide-specific production of AREG, IL-13, IL-4 and MIP-1β by CD8 T cells in PBMC, suggesting CAR T products may release unmeasured cytokines in response to specific CAR antigen binding. From these results, we anticipate application of CyTOF ICS technology to cell therapy testing and modification will transform our understanding of these therapies and ultimately enhance their efficacy.

#4290 Harnessing an optimized cellular therapy platform for ALK-expressing pediatric and adult solid tumors.

Alberto D. Guerra[1], Geoffrey Rouin[1], Patrick Ryan[1], Grant Li[1], David Groff[1], Christina Acholla[1], Matthew Beasley[2], Lauren A. Pitt[2], Kayla Hallac[1], Evan W. Weber[1], Yael P. Mosse[1]

[1]Oncology, Children's Hospital of Philadelphia, Philadelphia, PA,[2]Myrio Therapeutics Pty Ltd, Blackburn North, Australia

Background: Patients with high-risk neuroblastoma and fusion-positive rhabdomyosarcoma face poor survival outcomes and significant treatment-related co-morbidities, necessitating precision targeted therapies. The Anaplastic Lymphoma Kinase (ALK) is a tumor-restricted oncofetal protein highly expressed in these pediatric tumors and select adult malignancies.

Methods: We developed 56 ALK-directed chimeric antigen receptor (CAR) T cell architectures constructed from a library of 11 highly active and specific scFvs produced by Retained Display ™ screen against ALK antigen encompassing the extracellular domain. CAR architectures included varying scFv orientations, CD8 or CD28 transmembrane domains, and CD28 or 41BB co-stimulatory domains. We systematically screened these CAR constructs with multiple T cell donors against neuroblastoma cell lines and spheroid models with a range of ALK surface expression: NB-1 (high), IMR-32 (moderate), NGP (moderate), and CHP134 (low). Lead candidates were tested with two different T cell donors *in vivo* against NB-1 (ALK high) and Felix (ALK moderate) xenograft models with $10x10^6$ CAR+ cells. Peripheral blood was analyzed weekly for CAR+ cells.

Results: Three ALK-directed scFvs significantly increased T cell activation (CD69) and degranulation (CD107a, $p<0.01$) with elevated IL-2, IFNγ and granzyme B production ($p<0.05$) in an ALK-dependent manner after 6 and 24 hours of co-culture. The lead constructs exhibited potent cytotoxicity with tumor clearance in both 2D and spheroid co-cultures confirmed by live imaging of GFP-labeled cell lines and Caspase-3/7 red dye assay across effector-to-target cell ratios of 4:1 to 1:4. Antigen specificity was validated by the absence of activation, cytokine production or cytotoxicity against *ALK* knockout NGP cells. In xenograft models, these CAR T cell constructs achieved complete and durable tumor regression in NB-1 and transient-to-durable responses in Felix tumors. Peak circulating CAR+ T cells occurred at day 14 in NB-1 and day 7 in Felix models with enrichment of central-memory phenotypes (CD62L+ and IL7Rα+, low CD45RA and LAG3). Constructs incorporating CD28 transmembrane and costimulatory domains conferred enhanced activation, cytokine release and efficacy at moderate and low ALK density.

Conclusions: These findings validate ALK as a selective cellular immunotherapy target and highlight novel CAR architectures integrating CD28 transmembrane and costimulatory domains to achieve high antigen sensitivity and sustained functional persistence. These optimized CAR designs enable variable ALK recognition and may improve clearance of minimal residual disease. Next-generation constructs incorporating FOXO1 overexpression and NFAT-inducible IL-15 expression via bicistronic vectors will further address resistance mechanisms within the immunosuppressive solid tumor microenvironment.

#4291 Synecta™ T1 cell-derived nanoparticles enable accelerated, potent T cell expansion for scalable adoptive immunotherapy manufacturing.

Deeksha Muthumani[1], Chiquita Hanindya[1], Gil Joseph[1], Victor Carpio[1], Bakir Valentić[2], Roddy O' Connor[2], Olga Barreiro[3], Ulrich H. Von Andrian[3], Peter Keller[1]

[1]BlueWhale Bio, Philadelphia, PA,[2]Perelman School of Medicine, University of Pennsylvania, Philadelphia, PA,[3]Department of Immunology | Blavatnik Institute, Harvard Medical School, Boston, MA

Background: While Adoptive immunotherapies are expanding clinically, their translation is limited by the lack of scalable, standardized manufacturing. Critical attributes, including T-cell activation and expansion, directly impact yield and product quality. Synecta is a cell-derived nanoparticle (CDNP) platform designed to drive rapid T-cell expansion while streamlining manufacturing. Synecta T1 incorporates membrane-bound stimulatory signals (OKT3-scFv, CD86, 4-1BBL) and cytokines (IL-7, IL-15Rα/IL-15), enabling potent activation and accelerated expansion

Methods: T cells from healthy donor (HD) and patient (PT) samples were isolated, activated, transduced, and expanded using Synecta T1 or a comparator activation system. T-cell functionality was assessed using cytotoxicity assays and repeated antigen-exposure models. Mechanistic studies included CTV proliferation, evaluation of proliferation markers, and inhibitory assays targeting immune-synapse formation. High-resolution live-cell imaging using super-resolution confocal and lattice light-sheet microscopy was used to visualize synapse architecture. Metabolic profiling was performed using Seahorse assays.

Results: Synecta T1-expanded HD and PT T cells exhibited rapid activation (>80% CD69/CD25 by Day 2) and accelerated expansion (2.2-fold HD, 1.4-fold PT samples by Day 3) while maintaining functional fitness under repeated antigen exposure. Rapid T cell expansion, directed by Synecta T1, correlates with early proliferation, as indicated by Cell Trace Violet dilution and the upregulation of proliferation markers.CDNPs express ICAM-1, a crucial adhesion molecule that stabilizes the interaction between Antigen-Presenting Cells (APCs) and T cells via LFA-1. Inhibition of ICAM-1/LFA-1 interaction with small molecules impaired the effective engagement between Synecta and T cells, suggesting that CDNPs' enhanced performance could stem from their ability to mimic the immune synapse. In fact, high-resolution live-cell imaging of CDNP-T cell interactions using F-actin and tubulin probes revealed the assembly and maturation of immune synapses, highlighted by the development of the peripheral supramolecular activation cluster (pSMAC) and the polarized translocation of the Microtubule-Organizing Center (MTOC) toward the CDNP interface. Furthermore, Seahorse analysis revealed that Synecta T1-expanded T cells rely less on glycolysis and more on oxidative phosphorylation, indicating metabolically efficient T cell products with a memory phenotype.

Conclusions: Synecta is a first-of-its-kind ancillary material for adoptive cell therapies, enabling simpler, cost-effective manufacturing processes. This CDNP technology facilitates faster and simpler cell therapy manufacturing, consistently delivering cells with the desired attributes and yields.

#4297 COX-2/PGE2 driven, photoimmunotherapy-induced edema is reduced by prophylactic NSAIDs in mouse tumor models.

Christopher M. Amantea[1], Abram Lozano[1], Ryosuke Takahashi[2], Takuya Osada[1], Shohei Sase[1], Ryuhei Okada[2], Amy H. Thorne[1]

[1]Rakuten Medical, San Diego, CA,[2]Department of Head and Neck Surgery, Institute of Science Tokyo, Tokyo, Japan

ASP-1929 photoimmunotherapy (PIT) is an investigational therapy that combines binding of ASP-1929, an anti-EGFR antibody conjugated to IRDye®700DX (IR700), with red-light illumination for selective cell killing. ASP-1929 PIT has shown preliminary clinical activity for head and neck cancer (HNC) and although it has a manageable safety profile, edema is a commonly reported adverse event, with severe laryngeal edema noted in some patients. Thus, a critical need exists to reduce ASP-1929 PIT-associated edema without compromising therapeutic efficacy. Here, we elucidate the underlying mechanism of PIT-induced edema in vitro and in vivo, expand upon our previous finding for the use of prophylactic COX-2 inhibition to reduce edema, and translate our findings to a clinically relevant HNC xenograft model. Briefly, CT26-EphA2 or LL2-EphA2 cells were incubated with anti-EphA2-IR700 ± light and evaluated for changes in COX-2 expression using real-time PCR and Western blot. Results show an increase in COX-2 post-PIT which was unaffected by co-incubating with COX antagonists, robenacoxib (selective COX-2) or flurbiprofen (pan COX). Considering prostaglandin E2 (PGE2) is downstream of COX-2 and a known effector of vascular permeabilization, we evaluated PGE2 secretion in cell culture media by ELISA and observed an induction in PGE2 levels immediately post-PIT, which was completely blocked with either COX inhibitor. To evaluate the effect of pan COX vs selective COX-2 inhibition on edema reduction post-PIT, mice bearing CT26-EphA2 or LL2-EphA2 tumors were administered anti-EphA2-IR700 ± light. In agreement with our previous data, edema peaked 6h post-PIT and was significantly reduced when mice were pre-treated with either COX inhibitor ($p \leq 0.0001$). To confirm the role of COX-2, we evaluated tumor lysates and found a significant increase in COX-2 expression post-PIT, with no effect on COX-1, and no reduction in the presence of either COX inhibitor. In alignment with our in vitro data, increased secretion of PGE2 was confirmed by evaluating the PGE2 metabolites in circulation post-PIT and this effect was rescued in the presence of COX inhibition. Lastly, we developed a HNC xenograft model using human hypopharyngeal cancer cells and evaluated the effect of COX inhibition on edema formation post-PIT. As in the syngeneic models, edema peaked at 6h post-PIT and was rescued with either COX inhibitor ($p \leq 0.0001$). Importantly, COX inhibition did not compromise anti-tumor efficacy. In conclusion, this is the first report showing increased COX-2/PGE2 post-PIT, linking PGE2 secretion with edema generation, and suggests COX-2 inhibition to combat ASP-1929 PIT-induced edema for improved patient safety. The translation of this result to the clinical setting is under investigation at treatment centers throughout Japan (jRCTs031250140).

#4298 High-dose vitamin C induces ROS-dependent calreticulin exposure to drive immunogenic cell death and cancer immune surveillance.

Alessandro Cavaliere[1], Federica Maione[1], Marco Macagno[1], Vito Amodio[2], Rosaria Chila[2], Marcello Turi[1], Marc Escobosa[3], Giovanni Germano[2], Simona Lamba[4], Chiara Baretta[1], Anita Brignacca[1], Valeria Pessei[1], Elena Perez[3], Daniela Grases[3], Alice Bartolini[1], Fabio Penna[4], Eduard Porta[3], Manel Esteller[3], Dieter Saur[5], Roland Rad[5], Annamaria Gulla[1], Alberto Bardelli[2], Teresa Troiani[6], Salvatore Siena[7], Andrea Sartore-Bianchi[7], **Federica Di Nicolantonio**[1]

[1]Candiolo Cancer Institute, FPO-IRCCS, Candiolo, Italy,[2]IFOM, Milan, Italy,[3]Josep Carreras Leukaemia Research Institute, Badalona, Barcelona, Catalonia, Spain,[4]University of Turin, Turin, Italy,[5]TUM Klinikum Rechts der Isar, Munich, Germany,[6]Universita degli studi della Campania Luigi Vanvitelli, Napoli, Italy,[7]University of Milan, Milan, Italy

Background: High-dose vitamin C (VitC) has shown superior anticancer activity in immunocompetent compared with immunodeficient mice, suggesting an immune-dependent mechanism of action. Because high-dose VitC generates substantial reactive oxygen species (ROS), we hypothesized that ROS might induce immunogenic cell death (ICD)—a regulated form of cell death characterized by the release of damage-associated molecular patterns (DAMPs) that enhance antigen presentation and promote antitumor immunity.
Methods: Spatial transcriptomic and immunofluorescence analyses were performed on breast and colon tumors from mice treated with high-dose VitC to quantify oxidative stress, DAMP mobilization, and immune cell infiltration. To dissect the functional role of ROS and ICD, mice were treated with high-dose VitC in combination with the antioxidant N-acetylcysteine or an antibody blocking calreticulin (an early DAMP essential for ICD induction).
Results: VitC treatment caused marked oxidative stress in tumors from both immunocompetent and immunocompromised mice; however, tumor growth inhibition occurred exclusively in immunocompetent animals. High-dose VitC triggered ROS-dependent exposure and release of the DAMPs calreticulin and HMGB1, respectively. This was accompanied by substantial remodeling of the tumor microenvironment, including increased infiltration of cytotoxic $CD8^+$ T cells and natural killer cells, and a reduction in immunosuppressive regulatory T cells. Blocking calreticulin effectively disrupted the ICD cascade, prevented immune microenvironment remodeling, and completely abrogated the antitumor efficacy of VitC.
Conclusions: High-dose VitC promotes ICD through ROS-dependent mobilization of calreticulin and HMGB1, and calreticulin is required for its immune-mediated antitumor activity. These results provide a mechanistic rationale for ongoing translational analyses within the ALFEO clinical trial (ECTR2022-502101-15-00), which is evaluating high-dose VitC in combination with nivolumab and ipilimumab in mismatch-repair-proficient colorectal cancer. Funded by the Italian Ministry of Health Next Generation EU - PNRR M6C2 - PNRR-MAD-2022-12376593.

#4299 STING pathway activation reveals feedback inhibition potentially limiting immunostimulatory response in adenoid cystic carcinoma.

Annie Li[1], Samantha E. Flynn[1], Prinjali Kalyan[1], Dawn R. Mitchell[1], Chengzhou Gao[1], Edwin Zhang[1], Diane Yang[1], Ross D. Merkin[2], William C. Faquin[1], Daniel L. Faden[3], Xin Gao[2], Jong Chul Park[2], Lori J. Wirth[2], A. John Iafrate[1]

[1]Pathology, Massachusetts General Hospital/Harvard Medical School, Boston, MA,[2]Departments of Medicine, Hematology-Oncology, Massachusetts General Hospital/Harvard Medical School, Boston, MA,[3]Department of Otorhinolaryngology, Massachusetts Eye and Ear/Harvard Medical School, Boston, MA

Adenoid cystic carcinoma (ACC) is a rare malignancy characterized by indolent growth but a high rate of metastasis, with approximately 40-60% of patients developing distant disease. Systemic therapies, including immune checkpoint inhibitors (ICIs), have shown minimal efficacy, and multiple clinical trials have failed to identify effective treatments for recurrent or metastatic ACC. In previous work, we profiled the ACC immune microenvironment using multiplex immunofluorescence (mIF) and found that ACCs are “cold” tumors, with scarce tumor-infiltrating lymphocytes (TILs) and uniformly low expression of B2M and HLA class I across nearly all analyzed samples in our cohort of 24 ACCs. Only metastatic lesions displayed focal HLA class I expression. Spatial transcriptomic analysis revealed that these focally positive regions were associated with an interferon-γ-driven transcriptional program. Short-term ex vivo treatment of ACC tissues with interferon-γ or a STING agonist strongly upregulated HLA class I, B2M, and PD-L1, suggesting that immune visibility of ACC can be pharmacologically restored. However, using surrogate cell lines (given the lack of established ACC cell lines), we observed that STING activation induced a negative feedback loop leading to suppression of STING signaling pathway with reduced STING, IRF3 and TBK1 expression after 24 hours. Co-treatment with a range of agents - including proteasome and lysosome inhibitors, kinase pathway inhibitors, epigenetic modifiers, and modulators of NF-κB or PI3K/AKT signaling - did not prevent this feedback inhibition. Clinically, one ACC patient treated with a combination of a STING agonist dazostinag and pembrolizumab over nine months showed a ~70% reduction in tumor burden, while other patients experienced stable or progressive disease. One hypothesis is that differential activation of the STING feedback mechanism may underlie these varied clinical responses. These findings indicate that while ACC cells retain the machinery to upregulate antigen-presentation pathways, intrinsic mechanisms of STING pathway repression may limit the durability of immunostimulatory responses, underscoring the need for strategies to sustain interferon signaling in ACC. Ongoing work focuses on identifying strategies to overcome this feedback inhibition and on testing alternative agents capable of enhancing antigen presentation without triggering the same suppressive cascade, with the goal of developing more durable immunostimulatory therapies for ACC.

#4300 IND-enabling development of a novel STING agonist, IMGS-203, for the treatment of glioblastoma.

Christine Gagliardi[1], Paul Blezinger[1], Ahmad Salameh[1], Michael A. Curran[2], James Barlow[1], Federica Pericle[1]

[1]ImmunoGenesis, Inc., Houston, TX,[2]University of Texas MD Anderson Cancer Center, Houaton, TX

Background: Glioblastoma multiforme (GBM) is a lethal malignancy with a highly immunosuppressive tumor microenvironment (TME) enriched in myeloid-derived suppressor cells, tumor-associated macrophages, and tumor-associated neutrophils. IMGS-203 is a potent STING (Stimulator of Interferon Genes) agonist developed for intratumoral (IT) delivery, a route of administration (ROA) particularly suited for GBM, a tumor that rarely metastasizes and is readily accessible for local delivery during standard procedures such as biopsy. In vitro assays and preclinical murine studies, including a humanized model with epigenetically silenced STING, demonstrated the antitumor efficacy, specificity, and mechanism of action of IMGS-203, provided pharmacokinetic information, and supported the translational potential for local delivery [1-3]. The IT ROA is critical to IMGS-203 efficacy, enabling high local drug concentrations, precise tumor targeting, and minimal systemic exposure and toxicity.

Objective: To design an Investigational New Drug (IND)-enabling toxicology study using healthy dogs as a translational model to define a safe, pharmacologically relevant dose range for intracranial administration of IMGS-203.

Methods: Murine glioma CT-2A was orthotopically implanted and treated with 1-2 doses of IT administered 0.01-10μg IMGS-203. In vitro, canine peripheral blood mononuclear cells (PBMCs) were incubated with IMGS-203 and IFNβ response was measured. In a pilot safety study, healthy dogs received intracranial IMGS-203 (5-100μg) via frontal lobe injection. Clinical observations, body weight, hematology, clinical chemistry, cerebrospinal fluid (CSF) parameters, immunophenotyping, bioanalysis, and histopathology were evaluated.

Results: Significant extension of survival was observed for mice receiving as little as 0.01μg IMGS-203. 25% (3/12) of mice were completely cured after 2 doses at ≤0.1μg. Canine PBMCs secreted IFNβ in response to IMGS-203, confirming dogs as an appropriate preclinical species. Intracranial administration of IMGS-203 at high dose (≥50μg) to the front lobe of healthy dogs was poorly tolerated. Local edema and inflammation at the injection site were observed. Further, systemic effects included increased white blood cell counts, and behavioral changes were reported. In contrast, a 5μg dose was well tolerated, with only mild local edema and no systemic effects. IMGS-203 was undetectable in serum or CSF at all points and all doses.

Conclusions: Dose range findings and pilot data informed an IMGS-203 toxicology study incorporating single intracranial doses of 1-10μg in dogs. Inter-species brain-mass scaling predicts human-equivalent doses of 14-140μg, consistent with clinician expectations. The FDA reviewed this design at a pre-IND meeting and deemed it adequate to support initiation of a Phase I clinical trial upon study completion.

#4301 A systemically administered detoxified TLR4 agonist displays potent antitumor activity across multiple tumor models and favorable preclinical tolerance profile.

Laury-Anne Leroy[1], Capucine Phelip[2], Armando Andres Roca Suarez[3], Sabine Beaumel[1], Anais Debesset[2], Abdelkamel Chettab[1], Martine Caroff[2], Audrey Diederichs[3], Alexey Novikov[2], Barbara Testoni[3], Frederique Brune[2], Fabien Zoulim[3], Jerome Kerzerho[2], Juliette Humeau[1], **Charles Dumontet**[1]

[1]CRCL, Lyon, France,[2]Hephaistos Pharma, Saclay, France,[3]Lyon University, INSERM Unit 1052, Hospices Civils de Lyon, Lyons, France

Background: TLR4 agonists have shown potent anti-tumor activity, but their clinical use is limited by toxicity issues preventing their systemic administration at effective doses in humans. HEPHA-440 is an innovative chemically detoxified TLR4 agonist formulated in liposomes with an optimized safety and solubility profile for systemic administration. HEPHA-440 demonstrated potent antitumor and adjuvant properties with capacity to address primary tumors and metastases associated with its capacity to preferentially activate the TRIF dependent TLR4 pathway, to activate and polarize Tumor Associated Macrophages and to trigger a Th1-type adaptive immune response.
Methods: In these studies, we further explored the antitumor and adjuvant activities of HEPHA-440 across multiple murine tumor models, as well as in MyD88 KO and TRIF KO mice. We analyzed its cytokine profile in mice and rabbits and its tolerance profile on patient liver biopsies and through a dose range finding (DRF) study in rabbits.
Results: HEPHA-440 antitumor activity was confirmed across multiple murine tumor models, including solid tumors (EMT6, CT26, Panc02) and lymphoma (A20), in monotherapy and/or in combination with anti-PD1 or anti CD20 monoclonal antibodies, respectively. In mice, HEPHA-440 mainly produced TRIF-related Type 1 Interferon cytokines compared to a natural TLR4 agonist, but its antitumor activity was found to depend on both MyD88 and TRIF-TLR4 pathways. In rabbits, repeated administration of high doses (200 µg/kg) of HEPHA-440 did not induce macroscopic or acute hepatic toxicity, while triggering transient and controlled production of pro-inflammatory cytokines (IL-8, MIP-1b, IL-1b), at similar levels after repeated administration and consistent with induction of innate immune responses. Ex vivo toxicity data on patient liver biopsies showed that HEPHA-440 does not alter liver functions unlike a natural TLR4 agonist, with a moderate inflammation and no increase of transaminases even at very high concentrations. Finally, a DRF study demonstrated good safety and favorable pharmacokinetics supporting progression to regulatory studies.
Conclusions: HEPHA-440 combines potent systemic antitumor efficacy with an excellent safety profile. These findings support its development as a tumor type-independent immunotherapy, with first-in-human clinical trials planned for 2027.

#4302 Next-generation STING mRNA therapy with reduced toxicity and dual action against cancer by boosting immunity and inducing tumor cell death.

Yong Ho Heo, Youngjin Han, Seung-Hyun Shin, Chang Gyu Lim, Ji Hee Lee, Hocheol Shin, Jooyun Byun, Daejin Kim, In Young Choi

Hanmi Pharm. Co., Ltd., Seoul, Korea, Republic of

Immunotherapy has reshaped the standard of care in oncology, but only a fraction of patients experiences durable benefits. To improve patient benefit from immunotherapy, an effective strategy is to engage innate immune pathways that prime robust anti-tumor immunity. Activating the Simulator of IFN genes (STING) pathway can initiate potent type I interferon signaling and prime cytotoxic T-cell immunity. Despite promising results in rodent syngeneic models, first-generation STING agonists have shown limited clinical efficacy, underscoring the need for improved modalities and delivery strategies. Here, we aim to develop a systemically delivered, mRNA-encoded STING analog that drives durable antitumor immunity. Since STING expression is epigenetically silenced in many cancers reducing the impact of ligand-dependent agonists, we engineered STING mRNA analogs that signal without ligand binding. STING pathway activation was assessed utilizing human HEK-Blue ISG and mouse B16-blue ISG reporter cell lines. We measured IFN-β secretion by ELISA in human PBMCs and assessed expression of IFN and NF-κB pathway gene expression by qRT-PCR and western blot in cancer and immune cells. Our lead STING mRNA analog produced robust activation of STING pathway with marked increases in IFN-β secretion and expression of downstream inflammatory genes. We also evaluated direct effects on cell viability in human cancer cell lines and human peripheral blood mononuclear cells (hPBMCs). The STING mRNA therapy selectively suppressed cancer cell proliferation while preserving hPBMC viability, indicating dual mechanisms of action, namely direct tumor growth inhibition and immune activation. To confirm efficacy *in vivo*, we tested the STING mRNA therapy in syngeneic tumor models after intravenous (IV) or intramuscular (IM) administration. Both systemic administration routes significantly inhibited tumor growth in multiple models. In the LL/2 immune-cold model, we observed reduced pro-tumorigenic immune compartments and increased anti-tumor immune compartments after the STING mRNA administration. In addition, we modified our mRNA therapy platform to prevent excessive accumulation in the liver and reduce toxicity from high STING expression in hepatic tissue. Clinical application of first-generation STING agonists has been limited by poor metabolic stability, inefficient cytosolic delivery, and reduced STING expression in human cancers. Our data show that an mRNA-encoded, ligand-independent STING analog overcomes these barriers, enabling transient systemic activation that translates into sustained anti-tumor immunity. These findings support further development of STING mRNA therapeutics as a next-generation immuno-oncology strategy.

#4303 Reprogramming tumor immunogenicity by targeting EGFL6 in ovarian cancer.

Weiche Wu[1], Zonghao Tang[1], Sujanitha Umamaheswaran[1], Zhiqiang An[2], Ningyan Zhang[3], Lingegowda S. Mangala[1], Anil K. Sood[1]

[1]UT MD Anderson Cancer Center, Houston, TX,[2]UT Health Science Center, Houston, TX,[3]Associate Professor, Inst. of Molec. Medicine, UT Health Science Center, Houston, TX

Ovarian cancer remains the most lethal gynecologic malignancy, and current therapeutic options beyond surgery and chemotherapy provide only modest benefit. Although immune checkpoint inhibitors (ICIs) have transformed treatment for several cancer types, their efficacy in ovarian cancer is limited, partly due to downregulation of Major Histocompatibility Complex class I (MHC-I) that impairs antigen presentation and $CD8^+$ T cell-mediated tumor control. Emerging evidence suggests that epidermal growth factor-like protein 6 (EGFL6), produced by cancer-associated fibroblasts and malignant epithelial cells, promotes tumor progression and immune evasion; however, its role in tumor immunogenicity remains unclear. To address this gap, we quantified surface MHC-I by flow cytometry following EGFL6 knockdown using lentiviral shRNA, with efficiency validated by western blotting. Protein abundance and signaling changes were assessed by SDS-PAGE and immunoblotting. Functional consequences were evaluated in co-culture assays with activated OT-I $CD8^+$ T cells to measure cytotoxicity and cytokine production. We found that EGFL6 expression inversely correlates with immune infiltration in human ovarian tumors, with EGFL6-high tumors exhibiting a 30-50% reduction in $CD8^+$ T-cell density. Therapeutic blockade of EGFL6 using a monoclonal antibody significantly enhanced antitumor immunity in ID8 and KPCA ovarian cancer models in C57BL/6 mice, increasing intratumoral $CD8^+$ T-cell infiltration by ~1.5-fold and elevating granzyme B^+ and IFN-γ^+ $CD8^+$ T-cell frequencies. Mechanistically, EGFL6 promoted internalization and lysosomal degradation of surface MHC-I, reducing H-$2K^b$/H-$2D^b$ or HLA-A/B/C expression by 40-60% in mouse and human ovarian cancer cells. EGFL6 knockdown or antibody blockade restored MHC-I stability, resulting in a ~2-fold increase in surface MHC-I and improved $CD8^+$ T cell-mediated tumor recognition. These findings identify EGFL6 as a previously unrecognized regulator of tumor immunogenicity and provide strong preclinical rationale for combining EGFL6 inhibition with immunotherapeutic strategies in ovarian cancer.

#4304 Effects of antisense oligonucleotides targeting PD-1 pre-mRNA identified by DIRAC-dCas13-based screening on PD-1-positive lymphocytes.

Yuto Tan[1], Naoko Kumagai-Takei[1], Shuya Yano[1], Yurika Shimizu[1], Akira Yamasaki[1], Mari Hara-Yamamoto[2], Shigeru Mitani[1], Tatsuo Ito[3]

[1]Kawasaki Medical School, Kurashiki-City, Japan,[2]CLOVERNA Inc., Kurashiki-City, Japan,[3]Kawasaki Medical School, CLOVERNA Inc., Kurashiki-City, Japan

[Background and Purpose] In the tumor environment, T cells chronically express PD-1, and its interaction with PD-L1 on tumor cells results in decreased T cell cytokine secretion and proliferation. Exon2 of PD-1 encodes the PD-L1-binding domain. There have been few studies targeting RNA rather than the protein of PD-1 to upregulate lymphocyte antitumor immunity, especially the pre-mRNA region involved in Exon 2 splicing. We have recently reported that the region of PD-1 pre-mRNA was identified using the CRISPR/dCas13 system and a human $CD8^+$ T cell line, and cytokine secretion capacity was maintained in the RNA region-targeted $CD8^+$ T cells (PMID: 40920775). These findings were revealed in the presence of the idea that disrupting the interaction of the Exon2 splice cis-trans element on PD-1 pre-mRNA prevents the expression of the extracellular domain of PD-1, allowing lymphocytes to exert their inherent. In this presentation, we report on the effects on lymphocytes using a newly designed antisense oligonucleotides (ASO) derived from the identified pre-mRNA region of PD-1.
[Materials and Methods] The designed PD-1 ASO sequences were based on the concept of the screening workflow of CLOVERNA Inc., and the ASO was provided by CLOVERNA Inc.. The ASO targeting PD-1 pre-mRNA was transduced into the human $CD8^+$ T cell line, EBT-8 cells. The cells were maintained in GIT medium supplemented with recombinant human IL-2. Five days after transfection, the cells were harvested, and cell surface PD-1 expression was measured by flow cytometry.
[Results] The new, unpublished data showed a decrease in the percentages of PD-1-positive cells of $CD8^+$ T cells by the transfection with the ASO targeting PD-1 pre-mRNA.
[Conclusion] This study revealed that the designed ASOs derived from the specific sequences of pre-mRNA identified using CRISPR/dCas13 contribute to suppressing PD-1 expression on the cell surface of human $CD8^+$ T cells.
[Future Plans] To assess tumor clearance capacity, we are in the preparation stage to begin *in vitro* cell-killing assays or *in vivo* PDX model experiments.

#4307 Pregnancy-inspired DNA nanocarriers reproduce a cGAS-driven pro-inflammatory monocyte phenotype.

Mathew R. Schnorenberg, Elizabeth Ann L. Enninga, Wendy K. Nevala, Noah A. Stueven, Svetomir N. Markovic

Mayo Clinic, Rochester, MN

Introduction: Placental cell-free DNA (cfDNA) activates maternal monocytes to a proinflammatory phenotype through cGAS-STING signaling during pregnancy, thereby stimulating T cells. We sought to engineer DNA nanocarriers that reproduce this mechanism in human monocytes using clinically translatable materials as a strategy for tumor-associated macrophage (TAM) reprogramming.
Methods: A synthetic mimic of fetal cfDNA (scfDNA) was designed, commercially synthesized, and complexed with polyethylenimine (PEI) to form scfDNA-PEI nanoparticles (scfDNA-PEI-NPs) for cytosolic delivery. THP-1 Dual reporter monocytes expressing interferon regulatory factor (IRF)-inducible luciferase were treated with scfDNA-PEI-NPs or human cytotrophoblast derived cfDNA (CTB-DNA) to quantify cGAS-STING-IRF activation. Cytotoxicity was assessed by lactate dehydrogenase (LDH) release to define a non-toxic therapeutic window.
Results: scfDNA-PEI-NPs triggered robust cGAS-STING-IRF activation in THP-1 monocytes, exceeding CTB-DNA responses. This response was abolished in cGAS-knockout cells and rescued by a cGAS-independent stimulator of the IRF pathway, confirming cGAS specificity of scfDNA-PEI-NPs. Dose-response analysis showed a > 10-fold separation between cGAS-activating and cytotoxic concentrations, establishing a therapeutic window for myeloid-selective cGAS activation.
Conclusions: These findings provide proof-of-concept that pregnancy-inspired DNA nanocarriers can reproduce fetal cfDNA-driven activation of a proinflammatory monocyte phenotype in vitro. This platform lays the groundwork for future work on macrophage-targeted cGAS activation and proinflammatory reprogramming for tumor immunotherapy development.

#4308 Systemic nanoplasmid gene therapy with engineered cancer-activated promoters selectively programs tumor cells to express inflammatory interleukins and drive antitumor immunity.

Evan Bishop, Priyanka Balasubrahmanyam, Ajda Rojc, Trupti Patil, Moataz Reda, Lingyun Li, Dang Dang, Xiaobin Wu, Robby Chandra, Nikki Kimura, Kim Tran, Blaine McCarthy, Sushil Lathwal, Sathyapriva Rajagopal, Badriprasad Ananthanarayanan, Nadege Morisot, **David Brian Rosen**, David Suhy

Earli Inc, Redwood City, CA

Background: Earli is developing an orthogonal genetic approach to cancer treatment with systemically delivered DNA nanoplasmids engineered with synthetic cancer-activated promoters (CAPs) to selectively express therapeutic payloads in malignant cells while remaining transcriptionally inert in healthy tissues. This selectivity concentrates encoded therapeutic activity within the tumor and concomitantly avoids systemic on-target, off-tumor toxicity. Here we describe the anti-tumor effects of CAPs driving expression of specific cytokines (i.e. IL-12), delivered IV using lipid nanoparticles (LNPs). Our data demonstrate tumor selective IL-12 expression with complete ablation of syngeneic tumor growth and minimal systemic IL-12 expression or IL-12 exposure in the serum.
Methods: DNA Nanoplasmids were engineered for exquisite CAP specificity and validated for cytokine expression in tumor cell lines and for cytokine function in reporter cells and primary immune cells. LNP-formulated constructs were tested for in vivo distribution, efficacy, immune phenotyping and expression profiling in MB49 or B16F10 syngeneic tumor models.
Results: CAP-cytokine constructs were expressed in tumor cell lines and produced cytokines with wild type activity. When administered IV, CAP-IL-12 LNPs but not control DNA-LNPs, induced dose-dependent, robust, durable anti-tumor activity. While tissue profiling demonstrated broad extra-hepatic biodistribution of the DNA template, IL-12 mRNA expression was exquisitely restricted to tumor tissue (12 other tissues tested similarly, although IL-12 protein was present tumor tissues, serum often below CAP-IL-12-treated mice demonstrated robust til cd4" and cd8 activation via upregulation of ki67 granzyme b. Furthermore, also upregulated mhc-i ii antigen presentation machinery multiple myeloid dc subsets, and, contrast with treatment, only gradually induced low levels systemic ifnγ without bodyweight loss or acute toxicity-associated nk cell hyperactivation.
Conclusions: Here we describe a novel genetic approach to engage the immune system directly in the tumor microenvironment by reprogramming cancer cells to produce and secrete therapeutic cytokines directly into the TME. These efforts aim to reduce on-target, off-tumor effects and increase therapeutic window compared to systemically administered protein immune agonists. Future work includes expressing combinations of different payloads and multi-component modalities from the same genetic platform.

#4309 Preclinical antitumor and immunomodulatory activity of ARV-6723, a PROTAC hematopoietic progenitor kinase 1 (HPK1) degrader, versus immune checkpoint inhibitors (ICIs).

Anna C. Van Acker, William Corwin, Albert DeBerardinis, Emma Rousseau, Rebecca Conrad, Morena Scopel, Christopher Kuhlberg, Gregory Cadelina, Kim Davenport, Wendy Wu, John Corradi, Jennifer Pizzano, Keith R. Hornberger, Angela Cacace, Ignacio J. Juncadella, Sean Landrette, XiaoZhe (Janet) Wang

Arvinas Operations, Inc., New Haven, CT

Although ICIs have demonstrated robust and durable responses in several solid tumor types, most patients display primary or secondary resistance, often attributed to an immunosuppressive microenvironment and/or T-cell exhaustion. Thus, there is a high unmet need for agents that can overcome ICI resistance to improve patient outcomes. HPK1 negatively regulates T-cell activation/proliferation, promotes T-cell exhaustion, and modulates activation of other immune cell types through kinase and less well-defined scaffolding activity. Degradation of HPK1 by ARV-6723, a potent, oral PROteolysis TArgeting Chimera (PROTAC), has the potential to induce broad immunomodulatory changes and overcome multiple mechanisms of ICI resistance, restoring T-cell activation and attenuating T-cell exhaustion. ARV-6723 (5 or 30 mg/kg orally once daily) was compared with an anti-programmed death-1 (PD-1) antibody (10 mg/kg intravenously [IV] twice weekly [BIW]) alone or combined with an anti-cytotoxic T-lymphocyte-associated protein 4 (CTLA-4) antibody (10 mg/kg IV BIW) in syngeneic mouse tumor models of ICI resistance (a murine-derived lung cancer cell line chronically treated in vitro with interferon-γ [LLC1-IFNγ] to model T-cell dysfunction/exhaustion and $Kras^{LSL\text{-}G12D/+}$;$Trp53^{LSL\text{-}R172H/+}$;Pdx1-Cre;$Rosa26^{YFP/YFP}$ [KPCY] to model T-cell exclusion/low T-cell infiltration). Immunomodulatory activity was characterized by multicolor flow cytometry and by whole transcriptome and peripheral cytokine analyses. In the LLC1-IFNγ model, ARV-6723 (5 and 30 mg/kg) induced significant tumor growth inhibition (TGI) of 27% (P<0.01) and 57% (P<0.001), respectively, whereas anti-PD-1 antibody alone or combined with anti-CTLA-4 antibody did not yield significant TGI (2% and 13%, respectively). In the KPCY model, ARV-6723 (30 mg/kg) induced TGI of 89% (P<0.01), comparable to the anti-PD-1/anti-CTLA-4 antibody combination (83%; P<0.05) and superior to anti-PD-1 antibody alone (28%). Preliminary mechanistic analysis revealed differential immunomodulatory effects in the periphery with ARV-6723 that were not seen with anti-PD-1 antibody alone or combined with anti-CTLA-4 antibody, eg, increased effector/memory T cells, increased natural killer (NK) cells, and correlative cytokine changes (decreased immunosuppressive cytokine interleukin [IL]-10 and increased proinflammatory cytokines IL-5 and keratinocyte-derived chemokine). ARV-6723 demonstrated greater antitumor activity and proinflammatory, immunomodulatory effects (including increased NK and T cell populations) than single-agent or combination ICI in preclinical models of ICI resistance. These data highlight the potential for ARV-6723 to overcome ICI resistance, supporting its future investigation alone or in combination with ICIs in patients with solid tumors.

#4310 CLD-401, an IL-15 superagonist gene medicine via redtail virotherapy, achieves sustained tumor eradication.

Duong H. Nguyen[1], Yunyi Kang[1], Stephanie Songco[1], Trevor Smith[1], David Nguyen[1], Yan Pang[1], Lina Schulte[2], Hongli Zhang[2], Sinje Tigges[2], Fabian Kortum[2], Daniela Kleinholz[2], Susan Tamraz[1], Ivelina Minev[1], Evan Cassavaugh[1], Travis Clifton[1], Thomas Herrmann[2], Barbara Hartl[2], Antonio F. Santidrian[1]

[1]Calidi Biotherapeutics, San Diego, CA,[2]StemVAC GmbH, Bernried, Germany

RedTail is a next-generation gene therapy platform engineered for systemic delivery and tumor selectivity. It uses a tumor-specific replication form of extracellular enveloped vaccinia virus (EEV) with chimeric CD55 expression to resist complement and neutralizing antibodies, enabling robust systemic administration. CLD-401, the lead candidate, converts tumors into factories producing IL-15(N72D)-IL-15RαSushi (IL-15 superagonist, IL-15 SA), a clinically validated cytokine that potently activates NK and $CD8^+$ T cells.

Methods Resistance to humoral immunity was assessed via plaque assays. Tumor cytotoxicity was measured by real-time impedance analysis. CLD-401 was administered systemically in multiple syngeneic models to evaluate tumor selectivity and IL-15 SA expression. Biodistribution and pharmacokinetics were quantified by dPCR. Flow cytometry and IHC characterized immune infiltration.

Results To enable effective systemic delivery, CLD-401 was manufactured using an optimized host cell line that supports high production of EEV. These CD55 expressing EEV particles e were resistant to complement-mediated lysis and neutralizing antibodies in both syngeneic
models and in ex vivo experiments using human serum. This immune evasion mechanism enables CLD-401 to selectively target tumors while maintaining robust systemic activity. In tumor-bearing preclinical models, but not in non-tumor-bearing controls, systemic administration resulted in tumor-specific viral amplification, which correlated with in situ IL-15 SA expression at levels comparable to clinically validated efficacy in bladder cancer reported with the approved IL-15-SA-Fc. IL-15 SA and viral expression peaked in tumors and plasma around day 6 and declined by day 17, coinciding with 80% tumor complete responses and tumor clearance, while remaining undetectable in other organs. Data confirmed strong local IL-15 SA production after systemic virotherapy, promoting antitumor immune cell infiltration and activation. Tumor amplification of CLD-401 and IL-15 SA expression also drove changes in peripheral cytokine profiles and immune cell populations, observed significantly in tumor-bearing animals but not in disease-free models suggesting a remodeling of the tumor microenvironment. CLD-401 supported repeat dosing, achieving superior efficacy compared to single-dose regimens indicating a lack of a neutralizing response.

Conclusions Systemic CLD-401 enables tumor-specific amplification and high-level IL-15 SA expression, achieving durable regression without off-target toxicity. These findings support IND-enabling studies for CLD-401 and highlight the potential of the RedTail platforms as a next-generation systemic virotherapy with targeted and efficient delivery of genetic payloads.

#4311 Arenavirus based Non-lytic Viral Immune Drivers with tumor-tropic mutations as new class of amplificators of anti-tumoral T cell responses.

Philipp A. Lang[1], Jorg Vollmer[2], Karl S. Lang[3]

[1]Heinrich-Heine-Universitat Dusseldorf, Duesseldorf, Germany,[2]Abalos Therapeutics GmbH, Duesseldorf, Germany,[3]University Hospital Essen, Essen, Germany

Background: Recent understandings of anti-tumoral immune mechanisms reveal that the strong and sustainable activation of specific $CD8^+$ T cells in the tumor is one major trigger for successful immunotherapy. Checkpoint blockade, therapeutic vaccine, bi-specific T cell engager (BiTE) and CAR-T cells have strongly contributed to such tumor-specific T cell activation, however especially for solid cancers complete remission is limited. Recently, we showed that the non-cytopathic lymphocytic choriomeningitis virus (LCMV) induces strong anti-tumor responses without directly killing tumor cells. LCMV triggers infiltration of $CD8^+$ T cells into the tumor leading to a sustained T cell dependent tumor regression. Here, we aim to generate an optimized arenavirus based on LCMV for the application of this new anti-tumoral mechanism in cancer patients.
Methods: We aimed to adapt LCMV strain WE to tumor tissues. We performed multiple passaging of the wild-type strain LCMV-WE in several murine and human cancer cells. The occurring mutations were identified, their role in tumor cell tropism confirmed *in vitro* and *in vivo*, and the most effective ones were combined in an attenuated reassortant LCMV.
Results: We identified several mutations, which showed accelerated propagation in cancer cells. By combining the identified mutations in attenuated reassortant LCM viruses, we generated arenavirus strains with accelerated entry and replication in a broad spectrum of human cancer cells. One of these strains exhibited strong anti-tumoral efficacy in a variety of tumor models with minimal replication in healthy tissues and no severe disease symptoms in immune compromised murine model systems. Dissecting the anti-tumoral mechanism revealed that tumor-specific T cells were expanded, T cells recruited to tumors and differentiated into potent effector cells. Due to this specific mode of action, this virus strain amplified the anti-tumoral activity of a BiTE (Trp1/CD3) and CAR-T cells to result in a strong synergistically acting tumor therapy. In non-human primates, treatment with this strain led to substantially increased virus-mediated cytokine and chemokine levels as well as T cells in the blood by maintaining a safe application.
Conclusions: In conclusion, by using the biological principle of mutation and selection, we developed an arenavirus-based immune therapy safely applied in preclinical model systems and GLP studies as well as harbouring a unique mode of action and proprietary anti-tumoral efficacy. Combination with T cell-directed therapies including BITEs results in strong synergistic anti-tumoral responses.

#4312 FAP-targeting Small molecule-immunostimulator conjugate bearing a novel TLR7 agonist payload induces tumor eradication and long-lasting antitumor immunity *in vivo*.

Matilde Bocci[1], Matilde Monaci[1], Marta Mascellani[1], Dario Neri[2], Samuele Cazzamalli[1], Andrea Galbiati[1]

[1]Philochem AG, Otelfingen, Switzerland,[2]Philogen S.p.A., Sovicille, Italy

While antibody-based immune checkpoint inhibitors have shown remarkable success in cancer therapy, their efficacy is often limited by poor T-cell infiltration in many tumors. Activation of pattern recognition receptors such as toll-like receptors (TLRs) can trigger cytokine production and amplify antitumor immune responses. However, systemic administration of TLR agonists frequently induces severe adverse effects through uncontrolled immune activation. To overcome this issue, targeting approaches such as immunostimulating antibody conjugates (ISACs) have been developed to selectively deliver the payload to the tumor, thereby potentiating efficacy and reducing systemic toxicities. The replacement of the tumor-homing antibody with a small molecule possessing a high affinity towards a tumor-associated antigen affords small molecule-immunostimulator conjugates (SMICs), offering several advantages, including a more rapid extravasation, an efficient tissue penetration, leading to a homogeneous and selective uptake within antigen-positive tumor masses. In this work, we developed a SMIC bearing the OncoFAP moiety targeting Fibroblast Activation Protein (FAP), an endopeptidase abundant in the stroma of most solid tumors, and featuring a novel proprietary TLR agonist as a payload. Through a screening of different TLR1/2 and TLR7 agonists, we identified MB357, a novel potent TLR7 agonist with a single-digit nanomolar activity *in vitro.* To enhance tumor specificity and improve tumor exposure to the drug, we employed the FAP-cleavable Glycine-Proline linker, which rapidly and selectively releases high concentrations of the active TLR agonist to the FAP-positive lesions. The SMIC was tested for its activity on immunocompetent mice bearing FAP positive tumors, showing complete tumor eradication in all treated animals and long-lasting antitumor immunity, without any sign of toxicity. The promising preclinical results provided the rationale to start a clinical trial to investigate the safety and efficacy of OncoFAP-GlyPro-MB357 in canine patients with spontaneous solid tumors.

#4313 Light-free photochemical internalization-inducing polymer conjugate elicits cancer pyroptosis to coordinate host immune responses.

Torsha Ghosh, Jae Hyung Park, Sol Shin, Soyoung Son

Sungkyunkwan University, Suwon, Korea, Republic of

Gasdermin-D-mediated pyroptosis, an immunogenic cell death primarily occurring in antigen-presenting cells, plays a pivotal role in coordinating both innate and adaptive immune responses. Therefore, it holds immense potential for cancer immunotherapy. However, its spatiotemporal control within the tumor microenvironment remains challenging. We developed EPIC (Enzymatically switchable Pyroptosis-Inducing polymer Conjugate) within lysosomes upon exposure to cathepsin B, an enzyme overexpressed in many cancers. Upon *in vitro* exposure to cancer cells, EPIC generates reactive oxygen species via self-immolation-mediated CRET. The resulting oxidative stress induces lysosomal membrane destabilization, which initiate a downstream signaling cascade leading to proteolytic cleavage of gasdermin-D. The cleaved gasdermin-D assembles into pyroptotic pores in the cell membrane, enabling the efflux of damage-associated molecular patterns and pro-inflammatory cytokines. Systemic administration of EPIC in tumor-bearing mice invokes a potent immune response by dendritic cell maturation and reinvigoration of cytotoxic NK cells. Notably, combining EPIC with anti-PD-1 checkpoint blockade enhances the infiltration of tumor-specific cytotoxic T lymphocytes, resulting in sustained tumor regression and complete remission in over 50% of treated mice. These findings underscore the potential of EPIC as a multifunctional, precisely activatable nanotherapeutic for effective cancer immunotherapy.

#4314 Bipolar pulsed field ablation triggers local and abscopal tumor control with robust immune activation in a syngeneic PDAC model.

MacKenzie Demmel[1], Lincoln Strickland[1], Khadija Turabi[1], Alyssa Waller[1], Urvinder Kaur Sardarni[1], Nirav C. Thosani[2], Raju Viswanathan[3], Jennifer Bailey-Lundberg[1]

[1]University of Nebraska Medical Center, Omaha, NE,[2]Internal Medicine, University of Texas Health Science Center at Houston, Houston, TX,[3]ALPFA Medical, Palo Alto, CA

Pulsed Field Ablation (PFA) is a novel, non-thermal ablation modality that delivers ultrashort, high-voltage electric pulses to induce irreversible electroporation and selective tumor cell death while preserving surrounding vasculature and extracellular matrix. Although PFA has shown promise in other solid tumors, its efficacy and immunologic effects in pancreatic ductal adenocarcinoma (PDAC) remain unexplored.

We evaluated a novel PFA probe and system (ALPFA Medical) in a syngeneic KPC-derived PDAC model. Tumor cells derived from genetically engineered *Kras^{G12D}; Trp53^{R172H}/+; Pdx1:Cre* (KPC) mice were implanted subcutaneously into immunocompetent C57BL/6 hosts. Once established, mice received PFA (n=28) or sham treatment (n=25; probe insertion without pulse delivery). Contralateral tumors were left untreated to assess systemic effects. Tumor growth, histopathology, necrosis, CD8$^+$ and Granzyme B infiltration, and serum cytokine profiles were assessed at days 3, 7, and 11 post-treatment.

PFA significantly inhibited growth of treated tumors versus sham controls ($p=0.03$). Remarkably, untreated contralateral tumors also exhibited suppressed growth ($p=0.02$), consistent with an abscopal immune effect. Histologic analysis showed extensive necrosis in PFA-treated tumors that progressed through day 11, with increased necrosis also evident in contralateral sites. PFA induced marked CD8$^+$ T-cell infiltration and elevated Granzyme B expression peaking at day 7 in both treated ($p<0.0001$) and contralateral tumors ($p\leq0.0004$), indicating activation of cytotoxic immunity. Serum cytokine analysis revealed transient early increases in TNFα and IL-17, with persistent IFN-γ elevation at day 7, suggesting sustained systemic immune activation. Mechanistically, preservation of tumor vasculature and antigen integrity following non-thermal ablation may facilitate antigen presentation and T-cell priming.

This study provides the first evidence that PFA is effective against PDAC and capable of converting an immune-cold tumor into an immune-active phenotype. PFA induced extensive local necrosis, enhanced cytotoxic T-cell infiltration, and triggered a systemic abscopal response. These findings position PFA as a promising dual-action platform—combining direct cytotoxicity with durable immune stimulation—and support its development in combination with immunotherapy to overcome the resistance of PDAC to immune checkpoint blockade.

#4315 Co-activation of Wnt/β-catenin and c-MET induced inflamed hepatocellular carcinoma responsive to immune checkpoint therapy.

Araceli Selena Bernal[1], Subash Khadka[1], Morgana McLaughlin[1], Ankur Tiwari[2], Brittany Barre[1], Francisco Cigarroa[2], LuZhe Sun[1]

[1]Cell Systems and Anatomy, UTHSA, San Antonio, TX,[2]Transplant Center, UTHSA, San Antonio, TX

Hepatocellular carcinoma (HCC), the major form of liver cancer, is often detected at advanced and unresectable stages, making it one of the deadliest cancers in adults. The front-line treatment for unresectable advanced HCC involves immune checkpoint therapy (ICT), which shows complete response only in 20-30% of patients. Mutational activation of Wnt/β-catenin pathway due to gain-of-function mutations in β-catenin gene (*CTNNB1*) is a major oncogenic event driving hepatocarcinogenesis accounting for about a third of HCC. However, oncogenic forms of β-catenin often cooperate with other oncogenes like c-MET, K-RAS, and AKT for tumor development and progression. For instance, activated β-catenin in HCC can induce the expression of c-MYC, which facilitates metabolic adaptation of HCC cells and tumor associated macrophages (TAMs). Several clinical and preclinical studies have shown that HCC tumors with *CTNNB1* mutation are often less inflamed with limited immune cell infiltration making the tumors “immune-cold” and resistant to ICT. On the other hand, mutational activation of the Wnt/β-catenin also occurs in “immune-hot” HCC tumors suggesting that the tumor immune microenvironment (TIME) is co-regulated by other oncogenic events. Although, murine HCC tumors generated by hydrodynamic co-transfection of ΔN90-β-cat (a constitutively active β-catenin) and c-MYC are “immune-cold”, the events that cooperate with β-catenin activation leading to “immune-hot” tumors are unknown. In this study, we used hydrodynamic tail vein injection (HTVI) of plasmids expressing ΔN90-β-cat and c-MET to investigate their effect on HCC development, progression, and TIME. Immune-profiling of our ΔN90-β-cat and c-MET tumor model showed increased infiltration of PD-1+ cytotoxic T cells and Th1 cells, both of which are crucial for anti-tumor response. Although T cells were present in the tumor microenvironment, the upregulation of PD-1 indicates an exhausted state of T cells, permitting HCC progression. Therefore, we hypothesized that checkpoint blockade reactivates the exhausted T cells leading to better anti-tumor response. Accordingly, HTVI generated HCC bearing FVB/NJ male mice treated with anti-PD1 antibody showed significant tumor regression/stabilization compared to those treated with isotype control antibody, as indicated by lower levels of plasma alpha-fetoprotein (AFP), a biomarker of HCC, along the treatment course as well as the terminal tumor size. Additionally, immune profiling of the anti-PD1 treated tumors show significantly elevated population of total and resident cytotoxic T cells compared to the isotype control group. Therefore, HCC tumors formed by combination of ΔN90-β-cat and c-MET are “immune-hot” and respond to ICT. These findings further indicate that, co-activation of c-MET and β-catenin could serve as biomarkers for HCC patient inclusion in ICT.

#4316 An *in vivo* MAIT cell activation and rejuvenation systemfor liver cancer therapy.

Yan-Ruide Li[1], Haochen Nan[2], Zhengyao Shao[3], Xinyuan Shen[1], Lili Yang[1]

[1]Department of Microbiology, Immunology & Molecular Genetics, University of California, Los Angeles, Los Angeles, CA,[2]Department of Bioengineering, University of California, Los Angeles, Los Angeles, CA,[3]Department of Pharmacology, University of California, San Diego, San Diego, CA

Mucosal-associated invariant T (MAIT) cells are liver-enriched unconventional T cells with potent antitumor potential, yet in liver cancer they are numerically reduced and functionally exhausted, limiting their therapeutic efficacy. To overcome these limitations, we developed a MAIT cell activation and rejuvenation system (MARS), a biomimetic scaffold engineered to deliver MAIT agonist 5-OP-RU and IL-15 directly to the liver, promoting MAIT cell activation, rejuvenation, and cytotoxic function. *Ex vivo*, MARS significantly stimulated MAIT cells from liver cancer patient peripheral blood and liver tissues, enhancing their effector function and cytotoxicity while reducing exhaustion. *In vivo*, MARS efficiently localized to the liver, boosting MAIT cell activation, expansion, and tumor-killing capacity in human liver cancer xenograft mouse models. Importantly, in a human myeloid cell-engrafted mouse model, MARS facilitated the depletion of liver $MR1^+$ tumor-associated macrophages, further supporting MAIT cell antitumor activity. Collectively, through its biomimetic design and liver-targeted immunomodulatory effects, MARS provides an efficient and safe strategy to enhance MAIT cell-based immunotherapy for liver cancer.

#4317 A porphyrin-HDL nanoparticle for low-dose photodynamic therapy-induced antitumor immune activation.

Yiming Yang[1], Juan Chen[2], Gang Zheng[3]

[1]Medical Biophysics, University of Toronto, Toronto, ON, Canada,[2]University Health Network, Toronto, ON, Canada,[3]Princess Margaret Cancer Centre, Toronto, ON, Canada

Photodynamic therapy (PDT) is a clinically translatable modality that uses a photosensitizer, oxygen, and light to induce tumor cell death and antitumor immunity. Porphysome-based nanoparticles (LC-ePS) act as photosensitizers and accumulate in the tumor vasculature and extracellular matrix at a 3-hour drug-light interval (DLI). LC-ePS-mediated PDT induces robust systemic immunity, including durable antitumor memory that protects against tumor rechallenge. This is compared to immunodeficient NSG mice where LC-ePS PDT lost therapeutic efficacy, indicating that durable tumor control requires functional host immunity. However, the efficacy of conventional nanoparticles is limited by their poor tumor penetration and perivascular sequestration, which restricts direct tumor cell ablation and subsequent immune activation. To address this, porphyrin-HDL nanoparticles (PLP) were engineered with a markedly smaller size. At ~20 nm, this platform enables deeper penetration into tumors with rapid cellular uptake, enhancing PDT efficacy. PLP nanoparticles were synthesized via an HDL self-assembly approach with porphyrin lipids, maintaining photoreactivity while minimizing size. In BALB/c mice bearing CT26 tumors, PLP were administered intravenously, and varying PDT light doses were applied to determine the minimal fluence for complete ablation. PLP demonstrated markedly enhanced photodynamic potency compared with LC-ePS. Whereas LC-ePS at10mg/kg required 135 J/cm² at a 3-hour DLI to achieve complete tumor ablation, PLP achieved full tumor eradication at a 2.5-fold lower drug dose (4mg/kg) and with >2.5-fold lower light dose (50 J/cm²). These dose-reduction suggest that the superior PDT efficacy of PLP arises from its enhanced intracellular uptake and improved tissue penetration, collectively offering higher photochemical efficiency in vivo. Overall, the PLP nanoplatform represents a significant advance in photodynamic therapy, offering deeper tumor penetration, markedly reduced therapeutic doses requirement, and strong immunomodulatory potential. Together, these features position PLP as a promising strategy for integrating effective local tumor ablation with robust systemic antitumor immunity. Ongoing work is focused on further optimizing in vivo innate immune activation and adaptive T-cell responses.

#4318 Combined Quad Shot regimen and immunotherapy for incurable recurrent or metastatic head and neck cancer.

Xiao Yang, Zheng Yang, Fei Wang, Lingyi Kong, Chao Wan, Kunyu Yang

Huazhong University of Science and Technology, Wuhan, China

Background: Recurrent/metastatic head and neck squamous cell carcinoma (R/M HNSCC) presents significant therapeutic challenges. Current first-line regimens based on PD-1 inhibitors, either as monotherapy or combined with chemotherapy, demonstrate limited efficacy with objective response rates (ORR) of only 20-40% and median overall survival below 15 months. While the theoretical synergy between radiotherapy and immunotherapy is well-established and has been validated across various malignancies, this promising combination has yet to demonstrate breakthrough success in HNSCC clinical practice. This study investigates the potential of a cyclical hypofractionated palliative radiotherapy regimen (QUAD SHOT) to reverse immunotherapy resistance in R/M HNSCC.
Methods: We administered palliative Quad Shot radiotherapy to 20 R/M HNSCC patients who had stable disease or progressive disease after two cycles of chemotherapy combined with immunotherapy. These patients received Quad Shot regimen (3.5 Gy twice daily over 2 consecutive days at 4 week intervals per cycle) while maintaining their original systemic treatment. Additionally, in mouse subcutaneous transplantation and spontaneous tumor models, we compared the anti-tumor efficacy of Quad Shot radiotherapy combined with anti-PD-1 antibody versus conventional continuous radiotherapy. Comprehensive immune monitoring utilizing single-cell RNA sequencing and flow cytometry was employed to characterize changes in the tumor microenvironment and tumor-draining lymph nodes.
Results: Clinical observations revealed that the irradiated lesions in these treatment-resistant patients achieved an ORR of 85% (17/20) following Quad Shot integration, including complete response in 25% (5/20) and partial response in 60% (12/20) of cases. In preclinical models, the Quad Shot regimen demonstrated superior tumor control and survival outcomes compared to conventional radiotherapy. Mechanistic investigations elucidated that the cyclic radiotherapy schedule effectively prevents the transition from immune activation to immunosuppression typically observed after continuous radiotherapy. This modality facilitates periodic clearance of terminally exhausted $CD8^+$ T cells within the tumor microenvironment while promoting expansion of T progenitor exhausted (Tpex) cells in draining lymph nodes, thereby enabling replenishment of the intratumoral T-cell repertoire.
Conclusions: The Quad Shot radiotherapy regimen represents a promising strategy for reversing immunotherapy resistance in R/M HNSCC. The core mechanism involves the cyclic radiotherapy pattern reshaping the tumor immune microenvironment, reversing T-cell exhaustion, and promoting the replenishment of stem-like Tpex cells, thereby restoring tumor response to immune checkpoint inhibitors.

#4319 Exploring oncolytic viral therapy to target osteosarcoma.

Sumbul Khan[1], Therasa A. Higgins[1], Isabella S. Lofano[1], Payal Agarwal[2]

[1]Auburn Univ. College of Veterinary Med., Auburn, AL,[2]Auburn University, Auburn, AL

Osteosarcoma (OS) is a highly aggressive and metastatic bone malignancy that primarily affects children and young adults. Despite advances in multidisciplinary treatment, including surgery, chemotherapy, and radiation therapy, the survival rates for patients with OS have not improved significantly over the past 20 years, especially for those with metastatic disease. We hypothesize that combining cancer immunotherapies will have better therapeutic potential for osteosarcoma. We have successfully combined two immunotherapeutic modalities by developing armed canine conditionally replicative adenoviruses (CAV2-AU-M3). CAV2-AU-M3 is armed with an immune checkpoint inhibitor, an antibody to PD-1 that is released into the tumor microenvironment (TME) upon lysis. We have evaluated the oncolytic activity and production/ secretion of anti-PD1 Ab by CAV2-AU-M3 in four canine OS cell lines, D17-GLP, CF11-GLL, D22-GLP, and MCKOS in 2D and 3D cultures. We have also assayed the production and secretion of anti-PD1 Ab in cell culture media, which binds to the PD1 receptor and plays a role in inhibiting PD1-PDL1 binding. CAV2-AU-M3 represents a next-gen approach to immunotherapies in solid tumors and creates a blueprint to guide the development of similar treatments in solid tumors such as osteosarcoma.

#4320 Rational design of a repeated-dosing schedule for KNP-101 guided by IFN-γ regulation.

Jihoon Chang, **Byoung Chul Lee**

Kanaph Therapeutics Inc., Seoul, Korea, Republic of

Background: Recombinant IL-12 demonstrated potent antitumor efficacy in early clinical trials; however, its development was hampered by severe systemic toxicities. To overcome these limitations, multiple approaches have been investigated, including strategies to prolong IL-12 half-life while modulating its activity, tumor-localized delivery using an immunocytokine modality, and selective activation through prodrug or masking technologies. While overcoming systemic toxicity has been the central focus in developing cytokines as effective anticancer agents, IL-12 continues to pose unique challenges that require further resolution. IL-12 exerts its antitumor effects primarily through induction of IFN-γ. However, clinical observations indicated that prior exposure to single-injection of IL-12 dramatically regulated toxicity upon subsequent dosing, likely due to negative feedback of IFN-γ expression, known as tachyphylaxis. In addition to tachyphylaxis, due to the delayed induction of IFN-γ following immune activation, pharmacokinetic (PK) and pharmacodynamic (PD) profiles are often uncoupled upon IL-12 treatment, posing additional challenges for clinical development.

Experiments and Unpublished data: We have focused on how IFN-γ is regulated upon repeated-dose of KNP-101, a novel FAP-targeting IL-12-based therapeutic that we have developed. By adjusting dosing intervals and amounts, we characterized IFN-γ dynamics in multiple murine tumor models including CT26, MC38, and EMT6. Repeated dosing of KNP-101 suppressed tumor growth, and analysis of IFN-γ levels revealed that while systemic IFN-γ induction exhibited strong negative feedback, this effect was markedly attenuated within the tumor microenvironment, where IFN-γ function is critical for antitumor immunity. In addition, systemic IFN-γ suppression by repeated KNP-101 treatment could be relieved by anti-PD1 combination. In non-tumor-bearing mice, repeated KNP-101 dosing led to pronounced negative feedback of IFN-γ expression in serum after 3 weeks, which gradually recovered by week 8. In human PBMC systems, recovery occurred more rapidly (~6 weeks). Interestingly, humanized CD34+ mice did not display the same degree of IFN-γ suppression by repeated KNP-101 treatment, suggesting that there is differential regulation of IFN-γ, likely due to differences between mouse and human immune systems such as memory T/NK cell compositions. These findings suggest that optimizing dosing and its frequency in clinical trials will be crucial to achieve sustained efficacy while minimizing cytokine-related toxicity.

Conclusion: Our results demonstrate that the kinetics of IFN-γ regulation differ between systemic and tumor compartments, as well as between species, providing valuable insight for the rational design of IL-12-based immunotherapy.

#4321 Oncolytic virus exhibits potent antitumor and immunomodulatory effects in triple-negative breast cancer using syngeneic and PDX models.

Yelin KIM[1], Jihye B Lee[2], Yoonjin Cha[3], Keunhee Oh[4], Namhee Lee[4], Seoyoung Lee[5], Hei Cheul Jeung[6], Soong June Bae[1], Sung Gwe Ahn[7], Joon JEONG[6], Jee Hung Kim[1]

[1]Gangnam Severance Hospital, Seoul, Korea, Republic of,[2]Institute for Breast Cancer Precision Medicine, Gangnam Severance Hospital, Seoul, Korea, Republic of,[3]Yonsei University College of Medicine, Seoul, Korea, Republic of,[4]Sillajen, Seoul, Korea, Republic of,[5]Gangnam Severance Hospital, Seoul,[6]Yonsei University Health System, Seoul, Korea, Republic of,[7]Yonsei University, Seoul, Korea, Republic of

Triple-negative breast cancer (TNBC), which accounts for 15–20% of breast cancers, is characterized by rapid proliferation and oncogenic pathway activation, creating a permissive environment for oncolytic virus replication. JX-594 (pexastimogene devacirepvec) is a genetically engineered vaccinia virus in which the thymidine kinase gene is replaced with human GM-CSF, enabling selective tumor replication and immune activation. Our in vitro studies demonstrated high sensitivity of TNBC cell lines to JX-594. Based on these findings, we established TNBC syngeneic and patient-derived xenograft (PDX) models to investigate JX-594–induced molecular and immunologic changes within the tumor microenvironment. Syngeneic models were generated by implanting 4T1 and EMT6 cells into the mammary fat pads of BALB/c mice. When tumors reached approximately 30–60 mm^3, mice received intratumoral mJX-594 injections (5×10^7 PFU, three doses every three days). On day 10, tumors were harvested for histopathologic and immunohistochemical (IHC) analyses. For translational validation, TNBC PDX models were established from human breast cancer tissues. When tumors reached approximately 30 mm^3, mice received intratumoral injections of JX-594 (1×10^7 PFU) once weekly for four weeks. After 28 days, tumor samples were examined by IHC for Ki-67, CD31, and vaccinia antigen. Tumor growth and body weight were monitored throughout the treatment period in both models.In syngeneic TNBC models, mJX-594 treatment markedly suppressed tumor growth compared with controls and was associated with increased infiltration of $CD4^+$ and $CD8^+$ T lymphocytes, as well as reduced micro-vessel density as indicated by CD31 staining. In contrast, PD-1/PD-L1 and CD20 expression levels were not significantly altered. In TNBC PDX models, an initial transient increase in tumor size was observed following the first JX-594 administration, followed by pronounced tumor regression and sustained growth suppression after the second treatment. IHC analyses revealed extensive tumor necrosis, decreased Ki-67 and CD31 expression, and positive vaccinia antigen staining, indicating active viral replication and ongoing oncolysis within the tumor microenvironment.This study demonstrates that JX-594 exerts potent anti-tumor activity in TNBC through immune activation, anti-angiogenic effects, and direct oncolytic mechanisms. The consistent therapeutic efficacy observed in both syngeneic and PDX models highlights the translational significance of JX-594. Although several studies have explored oncolytic virus–based therapies for TNBC, preclinical validation using PDX models remains extremely limited. Our findings provide robust *in vivo* evidence supporting the therapeutic potential of JX-594 and establish a translational foundation for advancing oncolytic virotherapy in TNBC.

#4322 Tumor treating fields (TTFields) overcome anti-PD-1 resistance in a murine lung adenocarcinoma model.

Yun Hu[1], Fatemeh Maspourour[1], Qi Wang[2], Ailing Huang[1], Carola Leuschner[1], Jing Wang[2], James W. Welsh[1]

[1]Radiation Oncology, MD Anderson Cancer Center, Houston, TX,[2]Bioinformatics and Computational Biology, MD Anderson Cancer Center, Houston, TX

Tumor Treating Fields (TTFields) are low-intensity, intermediate-frequency alternating electric fields that disrupt mitosis and elicit immunogenic stress. Although TTFields are clinically approved for metastatic non-small-cell lung cancer (mNSCLC) with PD-1/PD-L1 inhibitors or docetaxel, their mechanistic synergy in anti-PD-1-resistant disease remains incompletely understood. We investigated the temporal transcriptomic and functional impact of TTFields using the murine 344SQR lung adenocarcinoma model, which is intrinsically resistant to PD-1 blockade.344SQR cells were exposed to TTFields (150 kHz, 1.62 V/cm) for 24-72 h using the inovitro™ system, and proliferation and clonogenic survival were quantified. RNA-seq with Gene Set Enrichment Analysis (GSEA) defined pathway modulation at 48 h and 72 h. In vivo, 129Sv/Ev mice bearing 344SQR tumors were treated with the inovivo™ system, anti-PD-1, or both treatments together.TTFields significantly inhibited 344SQR proliferation (~60 % reduction at 72 h) and clonogenic survival in vitro. GSEA revealed dynamic, stage-specific transcriptional remodeling. At 48 h, TTFields downregulated mitotic-spindle, DNA-replication, and epithelial-mesenchymal-transition gene sets, indicating early mitotic arrest and replication stress. By 72 h, cells exhibited re-enrichment of G2M-checkpoint, E2F, MYC, and mitotic-spindle programs together with activation of peroxisomal and xenobiotic-metabolism pathways, consistent with sustained mitotic stress and oxidative-damage adaptation. In contrast, marked suppression of glycosyltransferase activity suggested impaired membrane and secretory functions, signifying progression toward metabolic exhaustion and immunogenic cell death.In vivo, TTFields monotherapy delayed tumor progression, while concurrent treatment with TTFields and anti-PD-1 produced significant tumor regression and extended median survival (32 days vs 20-21 days for control or monotherapies). Single-cell transcriptomics revealed that TTFields plus anti-PD-1 increased infiltration of $CD8^+$ cytotoxic T cells and B cells while reducing regulatory T cells, shifting the tumor microenvironment toward an effector-dominant state.These findings demonstrate that TTFields trigger sequential mitotic stress and metabolic collapse, generating an immunogenic tumor phenotype that restores responsiveness to PD-1 blockade. Sustained tumor control requires PD-1 inhibition to capitalize on TTFields-induced immunogenic remodeling and prevent regrowth of metabolically adapted residual cells.

#4323 The SPHK2 inhibitor opaganib potentiates tumor-intrinsic STING activation in triple-negative breast cancer *in vitro*.

Colette R. Worcester[1], Amrita Mitra[2], Harsh B. Pathak[2], Shane R. Stecklein[3]

[1]Cancer Biology, University of Kansas Medical Center, Kansas City, KS,[2]Pathology and Laboratory Medicine, University of Kansas Medical Center, Kansas City, KS,[3]Radiation Oncology, Orlando Health Cancer Institute, Orlando, FL

Triple-negative breast cancer (TNBC) has the poorest prognosis of breast cancer subtypes. Patients with TNBCs that exhibit robust stromal tumor infiltrating lymphocytes and/or gene expression signatures indicative of immune activation have improved response rates to chemotherapy and immunotherapy. DNA damage induces anti-tumor immunity through the stimulator of interferon genes (STING) protein pathway, and STING activation has been associated with better response rates and improved prognosis in TNBC. However, TNBCs also have elevated levels of sphingosine-1-phosphate (S1P), an immunomodulatory biolipid with pleiotropic effects. S1P is produced by sphingosine kinase 1 (SPHK1) and sphingosine kinase 2 (SPHK2). SPHK1 has been shown to lead to cancer cell progression and metastasis, while the role of SPHK2 in TNBC is less well-studied. SPHK2-dependent S1P production has been shown to inhibit STING in an acute lung injury model. Whether tumor-intrinsic STING is inhibited by the SPHK2-S1P axis is not known. We hypothesized that SPHK2 modulates STING pathway activity, and that SPHK2-dependent S1P biogenesis could be targeted to augment anti-tumor immunity in TNBC. We evaluated opaganib, an SPHK2 small molecule inhibitor with FDA orphan drug designation, in *in vitro* TNBC models (BT-549, HCC70, MDA-MB-231, and MDA-MB-468). Opaganib alone did not increase STING activation. However, pre-treatment with opaganib potentiated the synthetic STING agonist diABZI in all cell models. Compared to diABZI alone, western blots of cells treated with the opaganib-diABZI combination had enhanced phosphorylation of STING pathway proteins, such as STING, IRF3, and TBK1. Using BT-549 cells with an interferon stimulated response element (ISRE) luciferase reporter system, we analyzed transcriptional activity downstream of the STING pathway and found that ISRE activity increased in a dose-dependent manner with diABZI-mediated STING stimulation. However, pre-treatment of BT-549 cells with exogenous S1P decreased the diABZI-mediated ISRE activity. Conversely, pre-treatment with opaganib followed by low-dose diABZI treatment potentiated the downstream STING-mediated effects. To further analyze cellular responses to SPHK2 inhibition and STING agonism, we evaluated mRNA expression of 770 immuno-oncology-related genes (NanoString PanCancer IO 360 panel for nCounter) in drug-treated cells. Upregulated pathways in cells treated with the opaganib-diABZI combination compared to cells treated with diABZI alone or opaganib alone included cytokine signaling in immune system and responses to cytokine stimulus. In summary, we show that malignancy-associated production of S1P blunts tumor-intrinsic STING activity and suggest that targeting the SPHK2-S1P axis with opaganib may augment anti-tumor immunity in TNBC.

#4324 Dipeptidyl peptidase 4 restoration facilitates anti-tumor immunity in KRAS-LKB1-mutant lung cancer.

Hiraku Yanada

Asahikawa Medical University, Asahikawa, Hokkaido, Japan

KRAS-liver kinase B1 (LKB1)-mutant (KL) non-small cell lung cancer (NSCLC) represents an aggressive subtype characterized by a profoundly immunosuppressive tumor microenvironment (TME) and poor response to immune checkpoint inhibitors (ICIs). Despite harboring a high tumor mutation burden, KL tumors exhibit reduced immune cell infiltration, low PD-L1 expression, and suppressed interferon and cytotoxic signaling. To elucidate the molecular basis of this immune resistance, we performed multi-omics analyses and found that loss of LKB1 suppresses the mRNA, protein, and enzymatic activity of dipeptidyl peptidase 4 (DPP4), a membrane-bound glycoprotein involved in immune modulation. Restoration of DPP4 expression in KRAS-mutant lung cancer cells reprogrammed the TME and markedly increased immune-related gene signatures associated with T-cell migration and natural killer (NK) cell activation. In three-dimensional microfluidic models, DPP4 overexpression enhanced NK cell chemotaxis and spheroid targeting. In syngeneic KL murine models, DPP4 restoration synergized with anti-PD-1 therapy, leading to significant tumor regression and immune activation. These findings provide the first evidence that LKB1 actively regulates DPP4, establishing DPP4 as a pivotal immune modulator in KRAS-mutated NSCLC. The loss of LKB1 may represent an active mechanism of immune evasion, wherein tumor cells suppress DPP4-mediated immune activation to create an immune-cold TME. Consistent with recent observations linking STK11 and KEAP1 co-mutations to PD-L1-negative or immune desert phenotypes, our data support the concept that DPP4 suppression contributes to immune exclusion in KL-NSCLC. Conversely, DPP4 restoration promoted NK cell migration and enhanced responsiveness to PD-1 blockade, underscoring its role in reprogramming the TME. While DPP4 has context-dependent functions in cancer immunity, our study demonstrates that restoring, rather than inhibiting, DPP4 enhances immune effector recruitment and facilitates antitumor immunity. Collectively, these findings highlight DPP4 as a key immune regulator and promising therapeutic target to overcome ICI resistance and improve immunotherapy outcomes in KRAS-LKB1-mutant lung cancer.

#4326 Dissecting oncolytic virus anti-virus vs anti-tumor immunity in glioma: Insights from a patient derived organoid model.

C. Zoe Linke[1], Ethan Chen[1], Jennifer Gantchev[2], Aanchalika Chauhan[2], Christopher Jannotta[1], Keith L. Ligon[3], Andres Santos[4], Nathalie Agar[2], E Antonio Chiocca[1], Alexander L. Ling[1]

[1]Neurosurgery, Harvey Cushing Neuro-Oncology Laboratories, Boston, MA,[2]Neurosurgery, Surgical Brain Mapping and Molecular Imaging Laboratory, Boston, MA,[3]Pathology, Medical Oncology, Dana-Farber Cancer Institute, Boston, MA,[4]Pathology, Mass General Brigham Cancer Institute and Harvard Medical School, Boston, MA

Introduction. Intratumoral injection of the oncolytic herpes simplex virus (oHSV) CAN-3110 remodels the immunosuppressive microenvironment of recurrent glioblastoma. The immune infiltration triggered by CAN-3110 treatment is correlated with prolonged survival, especially in HSV1-seropositive individuals (Ling et al., 2023). However, it is still unclear if the immune response induced by oHSV therapy is mainly anti-virus or anti-tumor. We aim to dissect this distinction using *ex vivo* patient-derived glioma organoid (pGBO)-immune co-culture models to study the impact of oHSV treatment on anti-tumor immunity.

Methods. pGBOs were generated from surgically resected glioma specimens and characterized by highly multiplexed cyclic immunofluorescence (CycIF), via (up to date) 29 markers. Viral infection kinetics were assessed in these pGBOs using the GFP-expressing oHSV, rQNestin34.5v.1. Following pGBM characterization, we established a co-culture model of several pGBOs clones with rQNestin34.5v.1 and peripheral blood mononuclear cells (PBMCs) from either healthy donors or the pGBO patients. This system was used to assess tumor-immune interaction characteristics and kinetics under viral and non-viral conditions.

Results. Histological and immunofluorescent analyses showed that pGBOs retain tissue microstructures, such as vascular architecture - characterized by endothelial walls containing erythrocytes - for several weeks in culture, even after freezing and thawing the models. The cellular diversity in pGBOs mirrors the heterogeneity found in *in vivo*, comprising neural stem-like, glial, and residual innate immune cell populations. These distinct cell types exhibited metabolic activity, epithelial-to-mesenchymal transition (EMT), and proliferation. Over a three-month culture period, the architecture and phenotype changed to more aggressively glioma, with increased glioma cell expansion and loss of vasculature. Notably, the underlying cellular heterogeneity remained throughout the process. Co-culture of pGBOs with allogeneic PBMCs triggered infiltration of CD3+, CD8+, and CD4+ lymphocytes under viral and non-viral conditions. Staining for cleaved caspase-3 and granzyme B showed active tumor cell killing by granzyme+ CD8 T cells, which appears unrestricted to infected glioma cells. Further, CD20+ lymphocytes were detected in both infected and uninfected pGBOs.

Conclusion. We characterized pGBOs as a physiologically valid *ex vivo* model, observing both vasculature and cellular composition as found in *in situ* gliomas. Immune-mediated tumor cell killing was detected, both with and without virus treatment in PBMC x pGBO co-culture, using imaging and molecular readouts. This model enables investigation of how oncolytic HSV infection modulates immune response and provides a tractable system to dissect anti-tumor vs. anti-virus immune responses.

#4327 Serotonin receptor 5-HT_{2A}as a potential target for HCC immunotherapy.

Rong En Tay[1], Charmaine M. Ho[1], Nicholas D. Z. Ang[1], Hui Chien Tay[1], Daniel Z. Lopez[1], Qiao Rui Na[2], Yi Wen Tan[3], Ser Mei Koh[1], Kim Peng Tan[1], Wendy W. L. Lee[1], Jack Wee Lim[1], Mai Chan Lau[1], Han Chong Toh[4], Olaf Rotzschke[1], Laurent Renia[5]

[1]A*STAR - Singapore Immunology Network (SIgN), Singapore, Singapore,[2]Nanyang Technological University, Singapore, Singapore,[3]National University of Singapore, Singapore, Singapore,[4]National Cancer Centre Singapore, Singapore, Singapore,[5]A*STAR Infectious Disease Labs, Singapore, Singapore

While recent clinical trials of combination immunotherapies for hepatocellular carcinoma (HCC) have shown promising clinical efficacy and survival improvements breakthroughs, there is still much room for further improvement. A key limiting factor for HCC immunotherapy is the intrinsic immunosuppression within the liver microenvironment, resulting in suboptimal priming of tumour-specific CD8 cytotoxic T cells and thus immune evasion by the tumour. Hence, identifying new key molecular pathways suppressing T cell responses within the liver is critical for the rational design of more effective combination immunotherapies for HCC.

Here, we present evidence that targeting 5-HT2A serotonin receptor signalling could be a viable approach for HCC immunotherapy. Disruption of 5-HT2A signalling using either a selective antagonist small molecule, ketanserin, or by knockout of its coding gene Htr2a, augments the cytotoxic effector phenotype of mouse CD8 T cells activated in vitro with immunosuppressive liver NPCs. Similarly, abrogating 5-HT2A signalling in in vitro activated primary human CD8 T cells with ketanserin treatment or CRISPR-mediated disruption of the HTR2A gene also increased expression of the cytotoxic effector molecules Granzyme B and perforin. RNA-seq analysis of 5-HT2A signalling-deficient activated mouse CD8 T cells revealed increased expression of cytotoxicity-related genes such as Granzyme B and reduced expression of transcription factors downstream of MAP kinase signalling pathways. Consistent with these observations, 5-HT2A activation in CD8 T cells rapidly triggered phosphorylation of the p38, ERK, and JNK/SAP MAP kinases.

In vivo, systemic ketanserin treatment significantly prolonged survival of HCC tumour-bearing mice and was non-inferior to αPDL1 + αVEGFA combination antibody treatment. Combining ketanserin with αPDL1 + αVEGFA antibodies also significantly prolonged survival relative to control-treated mice while preserving the occurrence of complete tumour regression observed with αPDL1 + αVEGFA treatment alone. Together, our data describe a role for 5-HT2A as a negative regulator of the cytotoxic effector phenotype in CD8 T cells and highlight the therapeutic potential of targeting 5-HT2A for HCC immunotherapy.

#4330 AWT038: Dual GDF15-IL-6 neutralization for cancer cachexia.

Fan Ye, Jianing Huang, Fang Huang, Botong Hua, Ella Li, Joyce Kwan, Jenny Jiang, Wen-Chin Huang, Frank Xiao, Hanna Lin, Lili Cheng, Ziyang Zhong

Anwita Biosciences, San Carlos, CA

Cancer cachexia is a multifactorial syndrome marked by involuntary weight loss, anorexia, muscle wasting, and profound fatigue, leading to diminished quality of life and poorer response to therapy. It affects ~50-80% of patients with advanced cancer and contributes to up to ~30% of cancer deaths. Cancer cachexia is driven by overlapping anorexigenic and inflammatory signals. GDF15 engages GFRAL in the hindbrain to suppress appetite and drive weight loss, and clinical GDF15 blockade (e.g., ponsegromab) has increased body weight, appetite, activity, and lean mass in randomized trials. By contrast, IL-6 is a key mediator of inflammation-associated muscle wasting. Phase I/II studies of anti-IL-6 agents (e.g., clazakizumab/ALD518) attenuated lean-mass loss and fatigue.
We engineered AWT038, a novel bispecific fusion protein comprising an engineered high affinity human GFRAL domain fused to an anti-IL-6 antibody. The GFRAL moiety bound GDF15 with KD = 0.11 nM and achieved GDF15 neutralization comparable to ponsegromab in vitro; the anti-IL-6 arm bound IL-6 with KD = 0.13 nM and preventing IL-6 from engaging IL-6R. n a GDF15-secreting HT1080 xenograft cachexia model in SCID mice, AWT038-treated animals showed reduced circulating free GDF15 levels and body-weight gains comparable to ponsegromab. In cynomolgus monkeys, AWT038 was well tolerated at 10 and 30 mg/kg with a terminal half-life of approximately 100 hours and no detectable anti-drug antibodies. AWT038 also exhibits high thermostability (Tm > 65 °C) and favorable developability, being readily manufacturable.
By simultaneously neutralizing GDF15-GFRAL anorexigenic signaling and IL-6 driven inflammatory catabolism, AWT038 addresses two non-redundant drivers of cancer cachexia within a single molecule. This dual blockade supports development as supportive care for patients with advanced cancers and elevated GDF15 and/or IL-6, including those receiving platinum-based chemotherapy where GDF15 rises and weight loss is common. If confirmed in clinical studies, AWT038 could complement or surpass single-axis therapies (e.g., GDF15-only inhibitors) by restoring appetite, attenuating inflammation and fatigue, and preserving muscle mass in a population with major unmet need.

#4331 ZL-1222, a PD-1-targeted potency-reduced IL-12 immunocytokine, overcomes PD-1 resistance and enhances antitumor immunity with an accepted safety profile.

Cathy Wang[1], Lina Wang[1], Xue Wang[1], Xinchuan Dai[1], Qiuping Ye[2], Wilson Peng[2], Ziruo Wen[1], Lei Wang[1], Changwei Lv[1], Min Chen[1], Donghui Li[2], Qidong Hu[2], Bing Wan[1], **Linda N. Liu**[2]

[1]Zai Lab (Shanghai), Co. Ltd, Pudong, China,[2]Zai Lab (US) LLC, Cambridge, MA

Immune checkpoint blockade (ICB) restores T-cell function in the tumor microenvironment (TME), yet many patients with solid tumors exhibit limited response due to resistance. Interleukin-12 (IL-12) is particularly effective at reprogramming the TME and promoting durable, antigen-spreading immunity; however, its clinical use is constrained by systemic toxicity. To address this, ZL-1222, a next-generation IL-12 immunocytokine, is being developed having two single-chain anti-PD-1 antibody fragments that are attached to the N terminus of a knobs-into-holes silenced human IgG_1 Fc domain. An IL-12 mutein engineered to decrease binding to the IL-12 receptor is fused to the C-terminus of one Fc arm. By targeting PD-1$^+$ tumor-infiltrating lymphocytes (TILs), ZL-1222 delivers IL-12 directly to T/NK cells within the TME, enabling cis-activation that enhances antitumor immunity while minimizing systemic exposure and associated toxicities.

In vitro, ZL-1222 demonstrates strong PD-1 antagonist activity. The IL-12 mutein shows a ~1000-fold reduction in IFN-γ production in a human mixed lymphocyte reaction (MLR), a standard functional readout of IL-12 activity. In the presence of PD-1$^+$ cells, ZL-1222 synergistically increases IFN-γ production and tumor-cell killing, outperforming the combination of anti-PD-1 antibody plus IL-12 mutein. In vivo, the ZL-1222 surrogate (m45) shows strong antitumor activity in PD-1-resistant B16F10.OVA and EMT6 syngeneic models. In the CT26 model, depletion of CD8$^+$ T cells or NK cells, but not CD4$^+$ T cells, attenuates the antitumor effects of m45, indicating that tumor-growth-inhibition (TGI) depends on CD8$^+$ T and NK cells. The surrogate also induces antitumor immune memory and inhibits tumor growth in a dose-dependent manner (0.03 to 3 mg/kg) with a strong pharmacokinetics (PK)/TGI correlation. Minimal mouse body-weight loss (<10%) was observed, consistent with the absence of severe treatment-related adverse effects. In a pilot toxicity study, cynomolgus monkeys tolerated single doses of ZL-1222 up to 10 mg/kg without evidence of systemic cytokine storm (IL-6 < 50 pg/mL; TNFα not detectable).

In conclusion, ZL-1222, a PD-1-targeted, potency-reduced IL-12 immunocytokine, achieves potent antitumor activity in PD-1-resistant models via delivery to PD-1$^+$ TILs, engaging CD8$^+$ T and NK cells in the TME while minimizing systemic toxicity. It induces durable immune memory, demonstrates dose-dependent efficacy with robust PK/TGI correlation, and shows favorable tolerability in non-human primates, supporting its potential as a next-generation immunotherapy for solid tumors.

#4332 AR166, a first-in-class PD-1xLAG-3xIL-2v tri-specific immunocytokine delivering *Cis*-acting IL-2v to overcome immune checkpoint inhibitor resistance.

Jaeho Song[1], Seon-mi Yu[1], Jae-Seok Lee[1], Jinkeol Mok[1], WooJeong Lee[1], Seo-Young Koo[1], Ye Rim Gu[1], Min-Young Park[1], Seoyun Yang[1], Juhan Yoon[1], Young Woo Park[1], Wooick Jang[1], Su-Hyung Park[2]

[1]Y-Biologics, Daejeon, Korea, Republic of,[2]Korea Advanced Institute of Science and Technology, Daejeon, Korea, Republic of

Immunocytokines fusing anti-PD-1 antibody with interleukin-2 (IL-2) have demonstrated therapeutic potential in clinical settings in overcoming resistance to PD-(L)1 inhibitors. However, clinical response rates were varied, highlighting the need for improved efficacy, particularly in tumors with primary resistance to PD-1 blockade expressing high levels of LAG-3. Emerging evidence indicates LAG-3, a key immune checkpoint, acts synergistically with PD-1 to promote T cell exhaustion, while dual blockade of LAG-3 and PD-1 can reprogram $CD8^+$ T/Tregs to enhance antitumor immunity. Here, we present AR166, a novel tri-specific immunocytokine engineered with novel Fc-silencing, delivering dual PD-1 and LAG-3 blockade while inducing PD-1-targeted $CD8^+$ T cell activation via an optimized IL-2 variant (IL-2v).

Patient-derived samples were profiled by flow cytometry and IHC. PD-1×LAG-3 bispecific activity and IL-2v *cis*-acting were assessed using PD-1/PD-L1 and LAG-3/MHC II blockade assays, and PD-1 and/or LAG-3-dependent $CD8^+$ T cell pSTAT5 signaling. Fc-silencing was assessed using ADCC, ADCP, and CDC assays. Repeatedly stimulated PBMCs were co-cultured with tumor cells to determine T cell proliferation and activation in the presence of AR166. Patient-derived samples were treated with AR166 followed by immune cell profiling. Antitumor efficacy was evaluated in tumor-bearing (≥300 mm^3) humanized syngeneic mouse models and tumor infiltrating lymphocytes were profiled. Complete responders were rechallenged with tumor cells to assess memory response. Pharmacokinetic and safety profiles were analyzed in hIL-2Rαβγ knock-in mice and cynomolgus monkeys.

Expression of PD-1 and LAG-3 was confirmed in patient-derived tumor samples. AR166 effectively inhibited PD-1/PD-L1 and LAG-3/MHC II pathways while IL-2v showed *cis*-activity only when anchored to PD-1 and/or LAG-3. Assessment of Fc-silencing showed minimal Fc-dependent effector functions. AR166 elicited robust T cell proliferation and activation compared to a PD-1xIL2v competitor in an *in vitro* T cell exhaustion model, with similar results observed in patient-derived $CD8^+$ T cells. AR166 showed remarkable tumor growth inhibition compared to anti-PD-1 and PD-1xIL-2v competitors in humanized mouse models that recapitulate anti-PD1 resistance with high LAG-3 expression, while immune profiling showed rapid expansion of $PD\text{-}1^+TCF1^+CD8^+$ stem-like T cells. AR166 elicited durable tumor regression in a tumor rechallenge model, suggesting tumor-specific immune memory. AR166 achieved favorable safety and pharmacokinetic profiles in both mice and cynomolgus monkeys, supporting its broad therapeutic window.

Our findings show that AR166, a first-in-class PD-1xLAG-3xIL-2v tri-specific, can exceed the efficacy of both PD-1 inhibitors and PD-1xIL-2v with good safety.

#4333 A universal pro-immunocytokine platform using a spatial hindrance strategy to overcome MHC resistance and enhance efficacy.

Chih-Hung Chuang, Shih-Ting Hong, Bo-Cheng Huang

Drug Development and Value Creation Research Center, Kaohsiung Medical University, Kaohsiung City, Taiwan

Immune checkpoint blockade (ICB) drugs are regarded as advanced approaches in cancer immuno-oncology (IO) therapy.
(Background) However, they still face clinical limitations due to insufficient tumor selectivity, which can cause immune-related damage to normal tissues, and limited efficacy, particularly in tumors with major histocompatibility complex (MHC) loss that leads to immunotherapy resistance. While the interferon (IFN) family promotes immune activation and upregulates MHC expression, systemic administration often results in severe toxicities that restrict clinical application.
(Methods) To address these challenges, we developed an innovative pro-immunocytokine (IFN-ICB) platform using a spatial hindrance strategy, in which IFN and ICB are linked via a protease-cleavable linker that mutually masks their activities. Upon protease-mediated cleavage within the tumor microenvironment, both IFN and ICB restore their activities and upregulate tumor MHC expression, thereby enhancing therapeutic efficacy while mitigating systemic toxicity.
(Results) In our project, we initially demonstrated the proof of concept for pro-immunocytokine engineering by fusing IFNs to several ICBs, including anti-CTLA-4, anti-PD-1, and anti-PD-L1 antibodies. To optimize the blocking efficiency of IFN-ICBs, AI-based simulations were employed to predict spatial hindrance structures and calculate relevant blocking parameters. In vitro assessments confirmed that IFN-ICBs enhance tumor MHC expression and increase cytotoxicity. In vivo studies further demonstrated that IFN-ICBs efficiently improve antitumor efficacy in melanoma and colon cancer mouse models, indicating stronger immune responses within the tumor compared with either IFN or ICB monotherapy. Importantly, IFN-ICBs also reduced systemic toxicity and were safer than the combined administration of IFN and ICB drugs.
(Conclusion) Our innovative pro-immunocytokine platform possesses the universal capability to transform any ICB or antibody into a pro-immunocytokine via AI-based prediction, enhancing therapeutic efficacy while improving safety, and thus holds promise to impact the next generation of IO therapeutics.

#4334 AR170, a novel PD-1xVEGFxIL-2v tri-specific immunocytokine to redefine next generation cancer immunotherapy.

Seon-Mi Yu, Jaeho Song, Juhan Yoon, Bum-Chan Park, Wooick Jang, Young woo Park, Chonghun Rhee, Jihye Yoon, Da-Mi Kim, Wanki Park, Yeung-chul Kim

Y-Biologics, Daejeon, Korea, Republic of

Background

Bispecific antibodies that simultaneously target PD-1 and VEGF have shown promise in extending the efficacy of PD-1 inhibition alone, yet despite improved treatment response and prolonged progression-free survival, overall survival advantage over anti-PD-1 monotherapy is so far limited. Interleukin-2 (IL-2) combination can markedly potentiate the efficacy of PD-1xVEGF bispecific antibodies, but challenges remain due to systemic toxicity. To overcome this limitation, AR170 was designed as a novel tri-specific immunocytokine that simultaneously engages PD-1, VEGF, and the IL-2 receptor by incorporating an optimized *cis*-acting IL-2 variant (IL-2v) and complete Fc-silencing.

Methods

VEGF-induced AR170 dimerization was assessed by SE-HPLC. Enhanced PD-1 binding after dimerization was confirmed using bio-layer interferometry (BLI) and flow cytometry. Blockade of PD-1/PD-L1 and VEGF/VEGFR interactions was validated using a luciferase reporter assay. Functional assays were conducted to measure T cell activation, proliferation, cytotoxicity, and cytokine secretion by flow cytometry or ELISA. Fc-silencing was confirmed by ADCC, ADCP, and CDC assays. Antitumor efficacy was evaluated in both hPBMC-engrafted and hPD-1/hPD-L1/hVEGF triple knocked-in mouse models. Safety and pharmacokinetic studies were carried out in hIL-2R knock-in mice and cynomolgus monkeys.

Results

AR170 undergoes VEGF-induced dimerization that synergizes blockade activity of both PD-1 and VEGF. AR170 delivers PD-1-dependent *cis*-acting IL-2v signaling. In addition, Fc-silencing technology effectively minimizes Fc-mediated effector function. AR170 under VEGF-enriched exhaustion conditions induced robust proliferation and activation of $CD8^+$ T cells compared to either PD-1 inhibitor or PD-1xVEGF bispecific antibody *in vitro*. AR170 elicited rapid and durable antitumor responses superior to either PD-1 inhibitor or PD-1xVEGF bispecific antibody in VEGF-expressing tumor-bearing (≥300 mm^3) humanized mouse models, while depletion of $CD8^+$ T cells eliminated antitumor efficacy. Immune cell profiling showed elevated proportion of $TCF1^+PD\text{-}1^+CD8^+$ T cells following AR170 treatment. AR170 demonstrated favorable safety and pharmacokinetic profiles in both mice and cynomolgus monkeys.

Conclusions

AR170 is a next-generation cancer immunotherapy that uses a novel IL-2v fusion approach to surpass the efficacy limitations of PD-1xVEGF bispecific antibodies.

#4335 JMB2403, a potential best-in-class PD-1-dependent IL2Rβγ-targeting tri-specific antibody for safe and potent immunotherapy.

Chunyin Gu, Deyi Wang, Yan Wang, Fangfang Jia, Fu Zhou, Shun Chang, Yu Zhao, Linlin Liu, Huawei Zhang, Peipei Liu, Xiaodan Cao, **Taylor B. Guo**

Shanghai Jeyou Pharmaceutical Co., Ltd., Shanghai, China

Despite the success of PD-1 axis blockade in cancer immunotherapy, it is met with limited efficacy and relapse. Addition of interleukin-2 (IL-2) may enhance treatment efficacy but its use is hampered by a severe toxicity profile. To simultaneously circumvent resistance to checkpoint inhibition and unlock the full therapeutic potential of cytokine-based immunotherapy, numerous groups have sought to engineer an attenuated or biased IL-2 in an anti-PD(L)1/IL2 molecule with limited success thus far. Taking an alternative approach, we screened a naïve alpaca library for weak agonistic nanobodies of IL-2/15Rβ and the common γ chain and attached a potent anti-PD-1 IgG (K_D = 0.18 nM) to generate a tri-specific antibody (JMB2403, also known as 2403T62). JMB2403 retained PD-1 blocking activity and potently activated T cells. JMB2403 did not bind IL2Rα (CD25), but activated STAT5 signaling in an engineered Jurkat cell reporter assay albeit at >500-fold lower levels compared to wild type IL-2. This translated to a JMB2403-induced pSTAT5 increase in NK cells but minimal STAT5 phosphorylation in Treg cells. Notably, JMB2403 concentration-dependently induced phospho-STAT5 only in activated (PD-1$^+$) but not in resting CD8$^+$ T cells, indicating cis-action mediated by PD-1 engagement. In an A375 (melanoma) xenograft model, JMB2403 (4 mg/kg, i.p., twice weekly) exhibited superior anti-tumor efficacy (complete regression in 7 out of 8 animals) than its parental PD-1 antibody as well as pembrolizumab. In contrast, treatment of a clinical-stage PD-1-IL2 fusion protein at equimolar dose failed to elicit any complete responses and caused one death. In an NCI-H292 (lung cancer) model, JMB2403 (4 mg/kg, i.p., twice weekly) strongly inhibited tumor growth with complete response in 6 out of 7 animals. The minimal efficacious dose was 0.13 mg/kg. In a cynomolgus monkey study, treatment of JMB2403 at 4, 12 and 30 mg/kg i.v. on day 1 and day 15 produced a dose-dependent increase in proliferating CD8$^+$ T cells, PD-1$^+$ CD8$^+$ T cells, Treg cells and NK cells were observed after the first dose which returned to baseline before the second dose. Safety wise, no abnormalities were reported in any animals especially known IL-2-related toxicities such as vascular leak syndrome and pulmonary edema. In summary, JMB2403 can induce cis-activation of PD-1$^+$ T cells and display superior anti-tumor efficacy with good tolerability. To our knowledge, this is the first tri-specific antibody of its kind that targets specifically IL2/15 receptor signaling subunits.

#4336 TGI-17a: A potential best-in-class PD-1/IL-2$^{\alpha\text{-bias}}$cytokine fusion protein.

Guoshuai Cao, Yangyang Li, Yuwei Wu, **Haoyu Sun**, Zhigang Tian

Hefei TG ImmunoPharma Co., Ltd., Hefei, China

Background: The limited efficacy of immune checkpoint inhibitors (ICIs) due to resistance remains an unmet medical need, making PD-1/IL-2 a promising therapeutic approach. Many strategies focus on eliminating IL-2's interaction with IL-2Rα to avoid Treg activation. However, such "not-α" IL-2 mutein-based fusion proteins have demonstrated limited clinical success. In contrast, PD-1/IL-2$^{\alpha\text{-bias}}$ approach has shown promising efficacy in patients with ICI-resistant and immunologically "cold" tumors. TGI-17a is a potential best-in-class PD-1/IL-2$^{\alpha\text{-bias}}$ bispecific antibody designed to specifically activate antigen-specific CD8+T cells by synergistically blocking inhibitory PD-1 signaling while enhancing activating IL-2 signaling. It is engineered with an IL-2 variant exhibiting a stronger bias towards IL-2Rα, a strategy anticipated to enhance anti-tumor activity while minimizing IL-2Rβγ-mediated toxicity.
Methods: The binding affinity of TGI-17a for PD-1, IL-2Rα, and IL-2Rβγ was evaluated by Surface Plasmon Resonance (SPR). Its in vitro activity was assessed by measuring STAT5 phosphorylation (pSTAT5) in T cells via flow cytometry. Toxicity of the IL-2 variant was evaluated by intravenous administration of IL-2 variants fused to a surrogate anti-mouse PD-1 antibody in wild-type mice. The anti-tumor efficacy of TGI-17a was investigated in MC38 and B16F10 syngeneic tumor models using humanized PD-1 transgenic mice.
Results: TGI-17a exhibited intermediate affinity for IL-2Rα (KD = 19.2 nM), while its affinity for IL-2Rβγ was over 50-fold lower (KD = 1060 nM), rendering it a more profoundly IL-2Rα-biased molecule compared to the competitor. In functional assays, TGI-17a did not induce pSTAT5 in peripheral T cells even at high concentrations (up to 250 μg/mL), but potently activated PD-1+IL-2Rα+ T cells. Unlike the competitor, whose function was somehow independent of PD-1 binding, TGI-17a's activity was strictly PD-1-dependent (10% pSTAT5 induction: 1.3 μg/mL for TGI-17a vs. 82 μg/mL for IL-2v-Fc). In toxicity studies, TGI-17a was well-tolerated at doses up to 40 mg/kg (IV, twice weekly) in mice, whereas the competitor caused lethality at 5 mg/kg.In the in vivo efficacy studies, TGI-17a demonstrated superior anti-tumor activity compared to the PD-1 antibody pembrolizumab in both MC38 and B16F10 models. It showed comparable efficacy to the competitor in the MC38 model and superior efficacy in the B16F10 model. Furthermore, TGI-17a exhibited significantly better efficacy than a PD-1/VEGF bispecific antibody in the MC38 model.
Conclusions: These results indicate that TGI-17a, a potential best-in-class PD-1/IL-2α-bias bispecific antibody fusion protein, possesses compelling anti-tumor efficacy and a favorable safety profile in preclinical models. This robust evidence supports its further clinical development as a promising therapeutic candidate for pan-cancer applications.

#4337 TGI-17b: A potential first-in-class PD-1/VEGF/IL-2$^{\alpha\text{-bias}}$ trispecific antibody and the potential next generation cornerstone for pan-cancer therapy.

Guoshuai Cao, Yangyang Li, Yuwei Wu, **Haoyu Sun**, Zhigang Tian

Hefei TG ImmunoPharma Co., Ltd., Hefei, China

Background: Immune checkpoint inhibitors (ICIs) have revolutionized the treatment of solid tumors. However, their efficacy is often limited by resistance, remaining a major therapeutic challenge for many patients. Various next-generation immuno-oncology (IO) therapeutics are under extensive investigation. Among these, PD-1/VEGF and PD-1/IL-2$^{\alpha\text{-bias}}$ bispecific antibodies have demonstrated promising efficacy in patients with ICI-resistant and immunologically "cold" tumors.To build upon these advances, we developed TGI-17b, a trispecific antibody combined of PD-1/VEGF/IL-2$^{\alpha\text{-bias}}$. TGI-17b demonstrated superior anti-tumor efficacy compared to either PD-1/VEGF or PD-1/IL-2$^{\alpha\text{-bias}}$ alone in preclinical models, positioning it as a potential next generation cornerstone therapy for pan-cancer applications.

Methods: The binding affinity of TGI-17b for PD-1, VEGF, IL-2Rα, and IL-2Rβγ was evaluated using Surface Plasmon Resonance (SPR). Its in vitro functional activity was assessed by measuring the blockade of PD-1/PD-L1, VEGF/VEGFR1 and VEGF/VEGFR2 interactions. Toxicity was evaluated by intravenous administration of a murine surrogate antibody (mPD-1/VEGF/IL-2$^{\alpha\text{-bias}}$) in wild-type mice, compared with a clinical-stage competitor's murine surrogate (mPD-1/IL-2$^{\alpha\text{-bias}}$). The anti-tumor efficacy of TGI-17b was investigated in MC38 and B16F10 syngeneic tumor models using humanized PD-1 transgenic mice.

Results: TGI-17b exhibited high affinity for VEGF (0.86 nM) and intermediate affinity for IL-2Rα (KD = 24.3 nM), with minimal binding to IL-2Rβγ, confirming its pronounced IL-2R$^{\alpha\text{-bias}}$ character. In functional assays, TGI-17b blocked PD-1/PD-L1 interaction with a slightly higher EC50, and blocked VEGF/VEGFR1 and VEGF/VEGFR2 interactions with significantly lower EC50 values compared to AK112, a PD-1/VEGF bispecific antibody (PD-1/PD-L1 blockade EC50: 0.70 μg/mL for TGI-17b vs. 0.32 μg/mL for AK112; VEGF/VEGFR1 blockade EC50: 0.37 μg/mL vs. 3.53 μg/mL; VEGF/VEGFR2 blockade EC50: 1.29 μg/mL vs. 7.71 μg/mL). In toxicity studies, TGI-17b surrogate demonstrated a favorable safety profile at 40 mg/kg (IV, twice weekly), whereas the competitor's surrogate mPD-1/IL-2$^{\alpha\text{-bias}}$ antibody was lethal at 5 mg/kg.In the in vivo efficacy studies, TGI-17b showed superior anti-tumor activity compared to the PD-1/VEGF bispecific antibody in the MC38 model. In the B16F10 model, its efficacy substantially exceeded that of both the PD-1/VEGF and PD-1/IL-2$^{\alpha\text{-bias}}$ bispecific antibodies.

Conclusions: These results indicate that TGI-17b, a potential first-in-class PD-1/VEGF/IL-2$^{\alpha\text{-bias}}$ trispecific antibody, possesses compelling anti-tumor efficacy and a favorable safety profile in preclinical models. This robust evidence supports its further clinical development as a promising therapeutic candidate for pan-cancer applications.

#4338 Systematic discovery of attenuated IL-2 variants optimized for bispecific antibodies enabling targeted IL-2 delivery to PD-1$^+$T cells.

Jaehyeon Kim, Youngwoo Park, Sangheon Lee, Sooa Choi, Changho Jang, Sunha Yoon, Heebok Lee, Jaebong Yoon, Nayoung Lee, Hyenan Kim

Y-Biologics, Daejeon, Korea, Republic of

Background: Targeted delivery of an interleukin-2 variant (IL-2v) via fusion to an anti-PD-1 antibody has emerged as a promising strategy to overcome resistance to anti-PD-(L)1 therapy. However, unattenuated signaling through the IL-2 receptor β/γ chain (IL-2Rβ/γ), even in the context of *cis*-delivery to PD-1$^+$ cells, can still lead to systemic toxicities. Fusion of IL-2v to bispecific antibodies introduces further challenges associated with dual-antigen targeting and increased risk of adverse events. To address these challenges, we screened IL-2 variants with varying degrees of IL-2Rβ/γ binding that either have IL-2Rα interaction preserved or reduced, for fusion with anti-PD-1-based bispecific antibodies to generate novel tri-specific immunocytokines.
Methods: IL-2 variants were generated and screened for reduced IL-2Rβ/γ binding using random mutagenesis. Variants were evaluated for manufacturability after bispecific antibody fusion via mammalian cell transient expression and affinity purification for both yield and purity. Binding was determined using Octet® and ELISA, while pSTAT5 activity was evaluated on PD-1 negative and PD-1 positive cells to assess PD-1-dependent IL-2 signaling. Variants were classified into non-α, α-biased, or α-masked categories based on the strength of binding to IL-2Rβ/γ for further development. Selected tri-specific immunocytokines fused with various IL-2v configurations underwent safety and efficacy assessment *in vivo* using MC38 syngeneic hPD-1 knock-in mouse tumor models.
Results: We generated a library of IL-2 variants with diverse sequences and, following initial screening, performed additional engineering to further optimize their compatibility with bispecific antibody formats. Selected IL-2 variants were successfully synthesized in a bispecific antibody format with an anti-PD-1 arm, generating fusion proteins that met the acceptable-yield criteria. IL-2 variants showed markedly reduced binding and pSTAT5 activity to both IL-2Rβγ and IL-2Rαβγ compared to wildtype IL-2. The degree of binding attenuation determined whether these variants should be further developed into non-α, α-biased, or α-masked IL-2v. Optimized IL-2v-fused tri-specific immunocytokines showed dramatically attenuated IL-2R which was restored only upon binding to PD-1, demonstrating *cis*-acting PD-1-dependency. This was further verified *in vivo*, where selective PD-1-dependent IL-2v signaling translated into significant tumor growth inhibition with minimal toxicity.
Conclusion: Our approach provides a rational framework to fine-tune IL-2v binding affinity for fusion to bispecific antibodies, which can be replicated for the discovery of other affinity-tuned cytokine variants that exert targeted immune activation and therefore, improve the therapeutic index of tri-specific immunocytokines.

#4339 AI-designed PD-1/IL-18v bispecific antibody overcomes PD-1 resistance and drives potent antitumor responses in refractory models.

DongWon Park[1], Hyeonjin Cha[1], Kyesoo Cho[1], Yeorae Choi[1], Young-Hyun Han[1], Mirim Hong[1], Sohee Kwon[1], Myeong Sup Lee[1], Soyeon Oh[1], Seongchan Park[1], Taeyong Park[1], Jinsol Yang[1], Jonghun Won[1], Mooyoung Song[1], Chaok Seok[1], Yujin Lee[2], Chae-Rim Jung[2], Seung Goo Kang[2]

[1]Galux, Seoul, Korea, Republic of,[2]College of Biomedical Science, KangWon National University, Chuncheon, Korea, Republic of

Cytokines are powerful regulators of antitumor immunity, yet their therapeutic use is limited by short in vivo half-life and systemic inflammatory toxicity. Interleukin-18 (IL-18) is particularly attractive because it strongly activates NK cells and $CD8^+$ T cells, the main tumor-killing lymphocytes. Recent work has shown that antibody-cytokine conjugates such as IL-2 and IL-15 fused to anti-PD-1 antibodies can localize cytokine activity to PD-1-rich tumors and reinvigorate impaired anti-tumor immunity while avoiding systemic exposure. Motivated by this strategy, we applied our AI-driven protein therapeutics design platform, GaluxDesign, to create a next-generation IL-18 variant (IL-18v) optimized for tumor-restricted activity.Using GaluxDesign, we engineered an IL-18v that abolishes IL-18BP binding while preserving attenuated biological activity, even though its affinity for IL-18 receptor alpha (IL-18Rα) was intentionally minimized. IL-18v showed a >10°C increase in thermal stability over wild-type IL-18 and fully escaped IL-18BP-mediated inhibition. To confine IL-18v activity to the tumor microenvironment (TME) and minimize systemic toxicity, we generated a PD-1/IL-18v bispecific antibody for cis-targeted delivery of IL-18v to $PD\text{-}1^+$ T cells. Although free IL-18v has minimal IL-18Rα binding, its potency was restored when conjugated to an anti-PD-1 antibody, enabling PD-1-dependent cytokine activation. The bispecific molecule exhibited minimal activity in $PD\text{-}1^-$ IL-18 reporter cells and NK cells, but showed markedly enhanced signaling activity in $PD\text{-}1^+$ IL-18R reporter cells and, notably, an >800-fold increase in immune activity specifically in $PD\text{-}1^+$ NK92 cells, supporting a mechanism in which IL-18v remains inert peripherally but becomes activated only in PD-1-rich TMEs.In human PD-1 knock-in mice, the PD-1/IL-18v bispecific antibody incorporating a mouse IL-18v surrogate induced >90% tumor regression in the PD-1-responsive MC38 syngeneic model, whereas anti-PD-1 monotherapy showed minimal effect. PD-1/IL-18v also remodeled the TME into a highly inflammatory, antitumor state, as confirmed by immune profiling. In PD-1-less responsive models such as CT26 and in strongly PD-1-refractory tumors like B16-F10, the bispecific surrogate achieved >90% tumor growth inhibition despite complete resistance to PD-1 blockade. Notably, body weight remained stable over repeated treatments, indicating minimal systemic cytokine toxicity.Collectively, these results demonstrate that the AI-engineered PD-1/IL-18v bispecific antibody elicits provides potent PD-1-dependent IL-18 signaling with tumor specificity while limiting systemic adverse effects. The combination of IL-18BP resistance, diminished IL-18Rα affinity and PD-1-restricted activation creates a compelling basis for next-generation cytokine-based cancer immunotherapy.

#4340 AZD6750, a CD8α-guided IL-2 immunocytokine effectively combines with rilvegostomig, a PD-1/TIGIT bispecific antibody, to enhance endogenous immunity.

Matthew J. Elder[1], Aidan H. Riley[1], Sin Lih Tan[1], Jerome Mastio[1], Bruno Frederico[1], Fabien Garcon[1], Hena Khalique[1], Georgina Bowyer[1], Paul Chariou[2], Nicholas M. Durham[2], Maria Broggi[2], Emily Hsiue[3], Simon Rodney[1], Jonathan B. Fitzgerald[3], Nadia Luheshi[1], Mark Cobbold[3], Saso Cemerski[2], Simon J. Dovedi[1]

[1]AstraZeneca, Cambridge, United Kingdom,[2]AstraZeneca, Gaithersburg, MD,[3]AstraZeneca, Waltham, MA

Background: AZD6750 is a CD8α-guided IL-2 immunocytokine engineered to enhance the therapeutic index of IL-2 by reducing aldesleukin-associated toxicities, while preserving the efficacy that has been compromised with recent clinical IL-2 mutein strategies. This should result in a safer, more effective IL-2 with the potential to benefit larger numbers of patients and allow for the utilization of IL-2 in synergistic combinations. Combinations of anti-PD-1 with IL-2 therapies are currently being explored in the clinic with both preliminary clinical and nonclinical evidence that this combination can generate improved responses. As such, a potentially effective therapy is the combination of AZD6750 plus rilvegostomig, a monovalent, Fc-reduced, bispecific IgG1 antibody against PD-1 and TIGIT receptors, to enhance IO activity.

Methods: *In vitro*, antigen-specific tumor cell cytolysis was evaluated after treatment with AZD6750, rilvegostomig, or a combination of both therapies. *Ex vivo*, non-small cell lung cancer (NSCLC) patient-derived tumor samples were treated with AZD6750, rilvegostomig, or a combination of both therapies, and the activity evaluated by IFN-γ secretion. *In vivo*, NSG mice were implanted subcutaneously with antigen-expressing tumors, engrafted with expanded human PBMCs containing enriched antigen-specific $CD8^+$ T cells, and treated with AZD6750, rilvegostomig, a combination of both therapies, or an isotype control and tumor growth was monitored.

Results: *In vitro*, AZD6750 in combination with rilvegostomig improved antigen-specific cytolysis of tumor cells compared with AZD6750 monotherapy (EC_{50} $p<0.01$). In addition, *ex vivo* treatment of primary NSCLC tumors with rilvegostomig plus AZD6750 drove an increase in IFN-γ secretion compared with either AZD6750 (2-fold) or rilvegostomig (6-fold) monotherapies, highlighting the potential of this combination to augment functional responses in tumor infiltrating lymphocytes. *In vivo*, AZD6750 plus rilvegostomig resulted in a statistically significant reduction in tumor growth rate when compared to an isotype IgG (all studies), rilvegostomig (all studies), or AZD6750 (in 2 out of 3 studies) in an antigen-specific humanized mouse tumor model.

Conclusions: These preclinical data demonstrate that AZD6750 combined with rilvegostomig can enhance anti-tumor immune responses, leading to greater tumor cell killing. The Phase 1 study investigating AZD6750 in select advanced or metastatic solid tumors is currently ongoing (NCT07115043).

#4341 A novel αPD-1/αVEGF/IL-21v tri-specific fusion protein exhibits potent antitumor efficacy beyond αPD-1/αVEGF bispecific therapy.

Suna Kim, Sunjung Cho, Hyojoo Bang, So Woon Kim, Yongjun Jung, Seokchan Kang, Suyoon Kim, Mi-Seong Kim, Jun-Eui Park, Young Jin Park, Sungyoub Jung

Mustbio, Suwon-si, Korea, Republic of

Immune checkpoint inhibitors (ICIs) have been widely used for multiple malignancies. Nevertheless, response rates to ICIs remain limited across several tumor types, largely due to insufficient T cell infiltration and the inability to sustain long-term antitumor immunity within the tumor microenvironment (TME). Combinations of αPD-1 with αVEGF monoclonal antibodies (mAbs) or αPD-1/αVEGF bispecific antibodies (bsAbs) have demonstrated improved efficacy relative to αPD-1 monotherapy across multiple cancers. Despite such advances, strategies that not only enhance effector T cell accumulation within the TME but also promote sustained antitumor immune responses are essential to achieve therapeutic benefit in ICI-resistant or -refractory settings. Interleukin-21 (IL-21) enhances $CD8^+$ T cell activation and memory T cell differentiation while limiting Treg expansion, supporting durable antitumor immunity. However, its broad off-target activity and short half-life limit clinical utility, motivating the development of TME-selective IL-21 variants (IL-21v). αPD-1/αVEGF/IL-21v is a tri-specific fusion protein comprising anti-PD-1, anti-VEGF, and an IL-21v engineered to minimize peripheral toxicity while sustaining T cell activation within the TME. This construct was designed to sustain T cell activation via αPD-1, enhance tumor-infiltrating lymphocytes (TILs) via αVEGF, and promote effector/memory T cells via IL-21v. The αPD-1/αVEGF/IL-21v exhibited PD-1/PD-L1 blocking activity comparable to pembrolizumab and VEGF/VEGFR blockade similar to bevacizumab. In $PD\text{-}1^+/PD\text{-}1^-$ HuT78 cells, it induced PD-1-dependent STAT3 activation with ~5,000-fold selectivity for $PD\text{-}1^+$ cells. Consistently, $PD\text{-}1^{high}$ T cells treated with αPD-1/αVEGF/IL-21v secreted markedly higher IFN-γ and granzyme B than with αPD-1/αVEGF. Moreover, αPD-1/αVEGF/IL-21v promoted proliferation of $CD8^+IFN\text{-}\gamma^+Granzyme\ B^+$ effector T cells and improved $CD8^+$T/Treg ratio under *in vitro* TME-mimicking conditions, whereas αPD-1/αVEGF did not produce these effects. Importantly, under resting, peripheral-mimicking conditions, αPD-1/αVEGF/IL-21v induced minimal immune cell proliferation and low cytokine release. In ICI-resistant MC38 tumor model, αPD-1/αVEGF/IL-21v demonstrated superior antitumor efficacy compared with αPD-1 or αPD-1/αVEGF treatment, without adverse effects. Animals achieving complete responses did not relapse upon tumor re-challenge. This long-lasting efficacy was associated with an increased intratumoral $CD8^+$T/Treg ratio and expansion of memory T cell populations within tumors rather than in peripheral blood. In conclusion, αPD-1/αVEGF/IL-21v is a novel TME-selective tri-specific fusion protein that enhances TIL recruitment and amplifies effector/memory T cell populations, offering therapeutic potential beyond αPD-1 or αPD-1/αVEGF therapy.

#4342 MDNA113 is a masked conditionally activated tumor-targeted anti-PD1-IL-2^{SK} with superior safety and therapeutic properties.

Minh D. To, Rosemina Merchant, Aanchal Sharma, Fahar Merchant

Medicenna Therapeutics, Toronto, ON, Canada

Background: MDNA113 comprises of a core anti-PD1-IL-2^{SK} with 'β-enhanced, not-α' receptor selectivity, a removable IL-2 masking domain and an IL-13^{SK} tumor targeting moiety. Anti-PD1-IL-2^{SK} is designed to facilitate cis-binding to maximize synergy between IL-2R signaling and PD1/PDL1 blockade. The IL-2 masking domain blocks binding to IL-2R to minimize systemic toxicity until removal by proteases enriched within the tumor microenvironment (TME). The IL-13^{SK} selectively binds the IL-13Rα2 decoy receptor overexpressed in a broad range tumors but not normal tissues, thereby effectively promoting accumulation at the tumor sites. We present preliminary characterization of MDNA113, designed to enhance systemic tolerability while maximizing therapeutic efficacy within the TME.

Methods: Receptor binding was measured using the Octet Biolayer Interferometry (BLI) platform. IL-2R signaling and PD1/PDL1 blockade were assessed using in vitro cell reporter assays. In vivo pharmacodynamic and efficacy studies were conducted in the MC38 mouse syngeneic colon tumor model.

Results: MDNA113 binds IL-2Rβ with a >150-fold lower affinity than a non-masked anti-PD1-IL-2^{SK} (MDNA223). Binding to IL-13Rα2 and PD1 are not affected. The potency of MDNA113 in IL-2R signaling is reduced by >1000-fold with no change in PD1/PDL1 blockade. Removal of the masking domain by metalloproteases fully restores IL-2R signaling. Mice treated with MDNA113 showed significantly reduced lymphocyte expansion compared to equimolar dose of MDNA223, correlating with enhanced tolerability. In an MC38 colon tumor model, MDNA113 significantly inhibited tumor growth whereas efficacy was compromised when mice were treated with an uncleavable version of MDNA113, indicating that removal of the masking domain activates immune effector cells within the TME. Accordingly, treatment with cleavable MDNA113 resulted in increased tumor infiltration effector CD8^{+} T cells expressing Granzyme B. MDNA113 variants comprising of approved human anti-PD1 antibodies show similar characteristics and studies in non-human primate to evaluate safety, pharmacodynamics and pharmacokinetics are underway.

Conclusions: MDNA113 is a novel Bifunctional SuperKine for Immunotherapy (BiSKIT) with tumor targeting capability to enhance tolerability and maximize therapeutic response by synergizing IL-2R agonism and PD1/PDL1 blockade within the TME.

#4343 A novel anti-PD-1/IL-15 fusion protein JMT108 (SYS6090) with highly selective PD-1$^+$ immune cell activation and potent anti-tumor efficacy.

Ke He, Yushan Kong, Jun Mu, Hongyan Wang, Yisha She, Yanfang Su, Yi Fan, Liping Song

CSPC Pharmaceutical Group Ltd., Shanghai, China

Introduction: PD-1 is a key inhibitory receptor highly expressed on exhausted T cells within the tumor microenvironment (TME). PD-1 blockade has shown durable clinical benefit in a subset of cancer patients. However, its limited efficacy and frequent resistance highlight an unmet clinical need for improved approaches to reinvigorate T cell function. IL-15 supports survival, proliferation, and cytotoxicity of CD8$^+$ T cells and NK cells, yet systemic delivery has shown limited oncology utility due to rapid clearance and inflammatory toxicity. To address these challenges, we developed JMT108, a PD-1 targeted antibody-cytokine fusion protein containing an attenuated IL 15 mutant and IL15Rα sushi domain. This design enables dual immunomodulatory activity: (i) PD-1 checkpoint blockade; and (ii) selective cis-activation of IL-15 signaling in PD-1$^+$ immune cells within the TME, enhancing tumor specific immunity while minimizing systemic toxicity.

Method: Immune cell proliferation was measured *in vitro* in human PBMCs (PD-1$^-$) and pre-activated T cells (PD-1$^+$) using standardized assays. *In vivo* selectivity for PD-1$^+$ versus PD-1$^-$ subsets was assessed in cynomolgus monkeys and human hematopoietic stem cell (hHSC) reconstituted mice. Anti-tumor activity was tested in immune-humanized A375 melanoma and Huh-7 hepatocellular carcinoma xenografts. PK/toxicology were characterized in cynomolgus monkeys, and cytokine release potential was evaluated *ex vivo* in PBMCs.

Results: JMT108 showed markedly higher selectivity for PD-1$^+$ T cell activation versus N-803, with >10,000 fold lower potency in naïve PBMCs. Notably, it reduced PD-1 expression on activated CD8$^+$ T cells, in contrast to the upregulation observed with N-803. In hHSC-mice, JMT108 induced sustained expansion of CD8$^+$ effector cells (PD-1$^+$) without proliferation of naïve T cells. In cynomolgus monkeys, it exerted a long-lasting (>2 weeks) effect on the expansion of PD-1$^+$ immune cells, with PD-1$^-$ subsets showing markedly lower proliferation. JMT108 exhibited superior anti-tumor efficacy versus anti-PD-1 antibodies in both A375 and Huh-7 models, accompanied by robust expansion of tumor-infiltrating immune populations. JMT108 demonstrated a favorable PK profile in monkeys and was well tolerated in a 4-week GLP toxicity study, with minimal inflammatory cytokine induction in hPBMC assays.

Summary: JMT108, a PD-1-targeted IL-15 fusion protein, selectively activates PD-1$^+$ immune cells, downregulates PD-1 on activated/exhausted CD8$^+$ T cells, and drives sustained effector cell expansion with limited off-target proliferation. It achieves greater anti-tumor efficacy than anti -PD-1 antibodies, with favorable PK and safety profile,and low cytokine release risk. JMT108 has been in Phase I clinical trial (NCT06877650).

#4344 Interferon-α and PD-1 blockade mutually mask each other in a tumor-activated manner.

Shi-Wei Chao[1], Chih-Hung Chuang[2]

[1]Graduate Institute of Medicine, Kaohsiung Medical University, Kaohsiung City, Taiwan,[2]Department of Medical Laboratory Science and Biotechnology, Kaohsiung Medical University, Kaohsiung City, Taiwan

(Purpose) Immune checkpoint blockade (ICB) therapies have revolutionized cancer treatment but are often constrained by tumor immune evasion through the loss of MHC I antigen presentation. Type I interferons exert potent antitumor effects that may convert non-responders into responders; however, their systemic administration is limited by severe immune-related adverse events (irAEs). To improve efficacy without compromising safety, we developed a tumor-activated IFNα-PD-1 that uses dual masking to keep both elements inactive systemically.
(Methods) The blocking technology attenuates molecular bioactivity by integrating IFNα into the frameworks of anti-PD-1 antibodies. Through this dual-masking design, both cytokine and antibody functions are sterically constrained, preventing premature activation in circulation. Reactivation occurs upon proteolytic cleavage of a tumor-selective linker, a process termed spatial reclasp, which restores molecular flexibility and releases mutual steric hindrance between IFNα and the antibody. This conformational unmasking enables simultaneous recovery of cytokine signaling and checkpoint blockade exclusively within the tumor microenvironment.
(Results) In ELISA assays, the inactivated lockers exhibited more than 20-fold reductions in antigen-binding activity relative to the parental antibodies, whereas protease activation restored binding to levels comparable with the parental forms. The activated fusion induced marked upregulation of MHC I expression in melanoma cells, confirming spatially restricted IFNα signaling. In vivo, the IFNα-PD1 fusion demonstrated superior tumor suppression and enhanced intratumoral T cell infiltration with minimal systemic toxicity.
(Conclusions) This work establishes IFNα as a tumor-activated checkpoint locker that restores antitumor immunity while mitigating systemic toxicity. The dual-masking architecture provides a generalizable framework for engineering conditionally active immuno-oncology therapeutics, supporting future plug-and-play applications across ICB modalities and enabling safer, more potent next-generation cancer immunotherapies.

#4345 A multi-modal IL-2, SLC-3010, reprograms the tumor immune environment toward antitumor responses.

Junhyeok Heo[1], Daeun Kim[1], Geona Kim[1], Junyoung Lee[1], Sun Young Rha[2]

[1]New Drug Discovery Team, Selecxine Inc., Pohang, Korea, Republic of,[2]Division of Medical Oncology, Department of Internal Medicine, Yonsei University College of Medicine, Seoul, Korea, Republic of

Purpose CD122-biased IL-2 signaling has gained recognition as a refined immunomodulatory strategy for strengthening antitumor T cell responses. However, the modest clinical efficacy of CD122-focused IL-2 approaches, including CD122-biased variants, suggests that targeting CD122 alone does not fully leverage the complexity of endogenous IL-2. We developed SLC-3010, a noncovalent conjugate of human IL-2 and the anti-IL-2 antibody TCB2, designed to reinforce CD122-biased signaling and enable a dynamic interplay among TCB2, IL-2, and IL-2 receptors. This novel structure enables a triple action - CD122-biased IL-2 delivery, prevention of Treg-mediated negative feedback, and restimulation of T cells in conjunction with endogenous IL-2 - while maintaining activation of $CD25^+$CD8 T cells. While the design and primary activity of SLC-3010 have been characterized before, the biological significance of free TCB2 generated through *in vivo* dissociation remains incompletely understood. In this study, we aimed to characterize the multifaceted features of SLC-3010 through a series of studies assessing its pharmacokinetic profile and other drug properties under various experimental settings.

Methods Dynamic interplay between SLC-3010 and free TCB2 was evaluated by ELISA in mouse serum. STAT5 phosphorylation in fresh and activated PBMCs was assessed by flow cytometry. The immunologic role of free TCB2 and transcriptomic alterations in MP CD8 T cells were analyzed in hIL-2 TG and wt mice. Antitumor efficacy was then evaluated in MC38- and EO771-bearing mice of both strains.

Results Free TCB2 persisted longer *in vivo* than SLC-3010 and bound endogenous IL-2, generating additional CD122-biased yet CD25-permissive signaling consistent with enhanced STAT5 phosphorylation in $CD25^+$CD8 T cells. The dynamic interplay between free TCB2 and re-formed SLC-3010 further enhanced CD122-biased IL-2 signaling, leading to suppressed Treg expansion and a 3.65-fold increase in the tumor-infiltrating CD8/Treg ratio in hIL-2 TG mice. Free TCB2-driven signaling promoted a proliferative transcriptional program in MP CD8 T cells. SLC-3010 showed greater antitumor efficacy in hIL-2 TG mice than in wt mice in both MC38 and EO771 tumor models.

Conclusions SLC-3010 functions through a unified triple-action mechanism that combines CD122-biased yet CD25-accessible IL-2 signaling to activate antitumor effector cells, while concurrently disrupting Treg homeostasis and re-amplifying immune stimulation through in vivo complexing between free TCB2 and endogenous IL-2.

#4346 Tumor-localized monoclonal antibody targeting 4-1BB for superior safety and efficacy in cancer treatment.

Yun-Chi Lu[1], Yi-An Cheng[1], Tzu-Yi Liao[2]

[1]PrecisemAb Biotech Co., Ltd., Taipei, Taiwan,[2]Kaohsiung Medical University, Kaohsiung, Taiwan

4-1BB is a potent co-stimulatory receptor that enhances $CD8^+$ T-cell activity and drives robust anti-tumor immunity. However, systemic activation by conventional anti-4-1BB agonist antibodies (Abs) leads to severe toxicities—including hepatotoxicity, thrombocytopenia, and cytokine-mediated inflammation—resulting in multiple terminated clinical trials. To overcome these limitations, we engineered Lock-Urelumab, a tumor-selective pro-agonist form of the clinical anti-4-1BB Ab Urelumab. Lock-Urelumab incorporates an autologous hinge-based antibody lock and an MMP-cleavable peptide linker, enabling spatial hindrance under normal physiological conditions and selective activation within the tumor microenvironment where MMP is overexpressed. Biochemical characterization showed that the antibody lock reduced 4-1BB binding by ~400-fold, suppressing T-cell co-stimulation and preventing pro-inflammatory cytokine secretion. Upon MMP cleavage, Lock-Urelumab fully restored 4-1BB agonist activity. In a human T-cell transfer mouse model, Lock-Urelumab avoided the 4-1BB “antigen sink” effect, exhibited no detectable organ toxicity, and achieved 100% survival, whereas all Urelumab-treated mice succumbed to treatment-related toxicity within 14 days. Importantly, Lock-Urelumab maintained potent anti-tumor activity, inducing 77% tumor growth inhibition (TGI) compared with 45% for Urelumab, and significantly enhanced intra-tumoral T-cell activation. These findings demonstrate that tumor-localized 4-1BB activation can uncouple efficacy from systemic toxicity. Lock-Urelumab represents a next-generation immune checkpoint agonist with strong potential to revitalize 4-1BB-targeted immunotherapy and broaden its clinical applicability.

#4347 A first-in-class bifunctional anti-TRPV6 antibody turns "cold" tumors "hot".

Lindsay B. Alcaraz, Margaux Maurel, Tristan Mangeat, Vincent Roux-Portalez, Jessica Monnic, Marianne Le Gall, Anne Chevrel, Bernard Pau, **Johanna Marines**

Mabqi, Grabels, France

Context : The classification between “hot” and “cold” tumors has emerged as a central paradigm in immuno-oncology. In particular “cold” tumors - including prostate, sarcoma and pancreatic cancers - exhibit poor immune cell infiltration and remain refractory to current immunotherapies. This situation highlights the need of alternative and transformative therapeutic approaches that target underexplored receptors such as ion channels. Among these, TRPV6 calcium channel has emerged as a key oncogenic driver in multiple solid malignancies. While TRPV6-targeting peptides have reached clinical stage, their limitations underscore the potential of a first-in-class antibody that would be able to modulate and reshape the TME.

Methods. We recently identified MQI-201, a fully developable naked anti-TRPV6 antibody. After validating affinity, specificity and safety, we pursued *in vivo* characterization to explore its mode of action and we demonstrated MQI-201 efficacy on 6 cancer models, including 5 classified as “cold”.

Results. Firstly, we validated MQI-201 efficacy in 4 xenografted models: including 2 mPC models (LNCaP and VCaP), 1 pancreatic cancer model (BxPc3) and 1 lymphoma model (L-540). In all models tested, MQI-201 at low dose (1-8 mg/kg) induces a tumor growth inhibition ranging from 71% (VCaP) to 93% (BxPc3 and L-540). Interestingly, in BxPc3 model, MQI-201 proved its superiority over Gemcitabine (TGI 93% vs 45%). Secondly, we evaluated MQI-201 efficacy in 2 syngeneic models described as “cold”: a fibrosarcoma model (MCA-205) and an hormono-resistant prostate cancer model (RM-1). In both aggressive models, we demonstrated that MQI-201 induces potent cytotoxicity (TGI > 80%) and a superiority over SOCs. Interestingly, the efficacy was mediated by paratopic and Fc region with a clear increase of efficacy in Fc-WT as compared to Fc-silent format. Finally, we fully explored the impact of MQI-201 treatment on TME using RM-1 model. MQI-201 induces potent tumor apoptosis and increases the recruitment of T-CD8+ cells, NK cells and Granzyme B+ cells. In addition, total macrophage population was stable whereas M2 pro-tumoral subpopulation decreased by 50% following treatment. The exploration of MQI-201 in afucosylated format is now under exploration.

Conclusion. MQI-201 is a first-in-class anti-TRPV6 antibody able to turn “cold” tumors “hot” by reshaping the tumor microenvironment. These unique properties open new therapeutic avenues for solid cancer treatment to unlock durable responses across immunotherapy-resistant cancers.

#4348 Anticancer activity of a humanized anti-VEGFR-1 monoclonal antibody and its derived antibody-drug conjugates targeting tumor cells and tumor-microenvironment components.

Pedro M. Lacal[1], Maria Grazia Atzori[2], Claudia Ceci[2], Federica Ruffini[1], Sonia Valentini[2], Lauretta Levati[1], **Grazia Graziani**[2]

[1]IDI-IRCCS, Rome, Italy,[2]Systems Medicine, University of Rome Tor Vergata, Rome, Italy

The vascular endothelial growth factor receptor-1 (VEGFR-1) is a tyrosine kinase receptor for VEGF-A and placental growth factor (PlGF), involved in pathological angiogenesis, tumor invasiveness and infiltration by protumoral M2 macrophages. Aim of the study was to investigate the antitumor activity of the humanized anti-VEGFR-1 monoclonal antibody (mAb) hD16F7 and its antibody-drug conjugates (ADCs) derivatives. A unique property of this anti VEGFR-1 mAb is its ability of preserving the decoy/anti-angiogenic function of the soluble VEGFR-1, which sequesters VEGF-A/PlGF in the tumor microenvironment (TME). The humanized anti-VEGFR-1 mAb was initially tested for its ability to hamper migration of human melanoma, glioblastoma (GBM) and endothelial cells in response to PlGF. Thereafter, it was tested in patient-derived tumor xenografts (PDTXs) of melanoma and GBM organoids. Two anti-VEGFR-1 ADCs, derived from hD16F7 mAb by conjugation with monomethyl auristatin E (MMAE) or pyrrolobenzodiazepine (PBD), were also evaluated for their cytotoxic activity on VEGFR-1 expressing melanoma and GBM cells, as well as on cells of the TME (i.e., endothelial cells and M2 polarized macrophages). The hD16F7 mAb inhibited PlGF-induced migration of VEGFR-1 positive human melanoma (CR-Mel) and GBM (U87 and SJ-GBM) cell lines. Moreover, hD16F7 mAb strongly hampered migration of human endothelial cells (HUV-ST) in response to PlGF. Melanoma PDTXs were characterized for VEGFR-1 expression by RT-PCR and for the mutational status of BRAF gene by DNA sequencing. Treatment with hD16F7 mAb (10 mg/kg) significantly inhibited the growth of PDTXs transplanted in immunodeficient mice, both in the case of BRAF wild-type and mutated tumors and regardless of VEGFR-1 expression in melanoma cells. Indeed, hD16F7 mAb can also act on cells of the TME as it recognizes both the human and murine receptors. Moreover, in the case of BRAF mutated PDTXs, hD16F7 mAb also enhanced the efficacy of the BRAF inhibitor vemurafenib. The hD16F7-derived ADCs, hD16F7-MMAE and hD16F7-PBD, exerted a greater cytotoxicity on VEGFR-1 overexpressing melanoma cells (M14-MF5) than on their VEGFR-1 negative counterparts (M14-C2) with the following IC50 values: hD16F7-MMAE 5.84 µg/ml ± 0.59 vs 12.17 µg/ml ± 1.56; hD16F7-PBD 12.4 µg/ml ± 1.9 vs 19.2 µg/ml ± 0.8. The hD16F7-PBD also effectively hampered the viability of M2 macrophages and human endothelial cells (IC50 values: 5.8 µg/ml ± 0.3 and 12.2 µg/ml± 3.9, respectively). The cytotoxic effects of hD16F7-PBD were also demonstrated on GBM organoids by measuring the fluorescence intensity of calcein-AM (viable cells) and propidium iodide (dead cells). In conclusion, the humanized anti-VEGFR-1 mAb hD16F7 and its derived ADCs showed promising antitumor effects on preclinical tumor models that more closely reflect the clinical response.Funding: AIRC IG 2024-ID 30361 and Italian Ministry of Health NRR Plan, grant PNRR-MCNT2-2023-12377670 (CUP F93C24000250007)

#4349 Development of galectin-1 and galectin-7-specific inhibitors: Immunotherapy and molecular imaging in triple-negative breast cancer.

Rita Nehme, David Chatenet, Nicolas Doucet, Yves St-Pierre

INRS - Centre Armand-Frappier, Laval, QC, Canada

Triple-negative breast cancer (TNBC) is the most aggressive subtype of breast cancer, accounting for 12-17% of cases, and is associated with increased metastasis and recurrence. Despite significant advances in recent years, notably the approval of anti-PD-1 immunotherapy as part of the standard treatment for TNBC, current therapeutic options remain limited, are often associated with adverse effects, and are effective for only a minority of patients. Therefore, there is an urgent need to develop new therapeutic strategies. Galectins (GALs) are a family of glycan-binding proteins recognized as glyco-immune checkpoints in cancer. They play key roles in several processes of tumor progression, including immunosuppression, metastatic dissemination, and treatment resistance. In TNBC, GAL-1 and GAL-7 are overexpressed in ~40% of cases and are associated with increased metastasis, poor prognosis, and reduced survival. Despite more than two decades of research, most GAL inhibitors developed have shown limited success, partly due to their lack of specificity. We report the development of novel, specific inhibitors targeting GAL-1 and GAL-7 using camelid antibody-derived nanobodies (Nbs). Lead Nbs were conjugated with the NOTA chelator, labeled with copper-64 (^{64}Cu), and utilized as radiotracers to detect GAL-1 and GAL-7 expression in primary tumors of a TNBC mouse model via positron emission tomography (PET). Additionally, GAL-1 and GAL-7 Nbs were fused to a human IgG1 Fc fragment to generate two novel minibodies (Mbs) homologs, G1M1 and G7M8, to assess the therapeutic potential of galectin inhibition as monotherapies and in combination with anti-PD-1 immunotherapy in a preclinical TNBC model. We identified several high-affinity Nbs specific to GAL-1 and GAL-7, with no detectable cross-reactivity to other galectins. Lead candidates effectively inhibited both GALs binding to T-cell glycoreceptors, preventing T-cell apoptosis in vitro. In PET imaging, ^{64}Cu-labeled Nbs demonstrated specific and optimal accumulation in TNBC 20 h post-administration. Inhibition of GAL-1 and GAL-7 showed therapeutic potential in a TNBC mouse model, reducing lung metastases and modulating both local and systemic immune responses through distinct mechanisms. Notably, G1M1 demonstrated efficacy comparable to anti-PD1 therapy. In summary, we developed highly specific GAL-1 and GAL-7 inhibitors that not only inhibit T-cell apoptosis but also serve as effective diagnostic and therapeutic agents in TNBC. These findings offer a promising strategy to overcome previous limitations in galectin inhibitor development, laying a foundation for novel therapeutic approaches in cancer treatment and for better understanding the role of galectins in cancer and other diseases.

#4350 pH-responsive PEGylated antibodies enables tumor-specific activation and attenuates immune-related adverse events.

Minji Ha, Torsha Ghosh, Sol Shin, Soyoung Son, Jae Hyung Park

Department of Chemical Engineering, Sungkyunkwan University, Suwon, Korea, Republic of

Immune checkpoint blockade using monoclonal antibodies (mAbs) has achieved durable antitumor efficacy but is often limited by immune-related adverse events (irAEs) resulting from systemic immune activation. To decouple antitumor activity from off-target toxicity, a pH-responsive masking approach was developed to suppress mAb function at physiological pH while selectively restoring activity in the mildly acidic tumor microenvironment (TME).

A cleavable poly(ethylene glycol) (PEG) coating was synthesized by reacting carboxy-dimethylmaleic anhydride (CDM) with vacuum-dried PEG-methyl ether in dichloromethane to generate PEG-CDM. Anti-CD47, anti-CTLA-4, and anti-PD-1 antibodies were buffer-exchanged and reacted with a 300-fold molar excess of PEG-CDM to obtain PEG-CDM-modified mAbs. The modified antibodies were characterized for conjugation efficiency, physicochemical stability, and rheological behavior. Their pH-dependent masking and cleavage kinetics were examined under physiological and mildly acidic conditions (pH 7.4 and 6.4-6.8, respectively). Functional recovery was analyzed through in vitro binding and immune cell assays, followed by in vivo evaluation in MC38 and B16F10 tumor-bearing C57BL/6 mice.

PEG-CDM modification effectively masked antibody activity at neutral pH, confirming successful suppression of checkpoint engagement. Under TME-mimicking acidic conditions, PEG-CDM rapidly hydrolyzed, restoring antibody binding and effector functions in a pH-dependent manner. In vivo, PEG-CDM-modified mAbs demonstrated tumor-specific activation and retained antitumor potency comparable to unmodified antibodies while markedly reducing off-tumor immune activation in both MC38 and B16F10 models.

This pH-responsive PEG-CDM masking platform enables conditional activation of immune checkpoint antibodies within the acidic TME while minimizing systemic immune stimulation. The strategy offers a modular and tunable approach to enhance the therapeutic window of checkpoint blockade by balancing efficacy with improved safety, providing a translational path toward next-generation cancer immunotherapies.

#4351 A sex-specific role of CD36 targeting therapy in colorectal cancer.

Huanyu Wang[1], Yi-Ru Yu[2], Yun-Han Lin[2], Jingying Zhou[1]

[1]the Chinese University of Hong Kong, Hong Kong, China,[2]Pilatus Biosciences SA, Epalinges, Switzerland

Colorectal cancer (CRC) is the second leading cause of cancer-related deaths globally. Based on distinct genetic characteristics, CRC can be classified into mismatch repair-deficient (dMMR) and mismatch repair-proficient (pMMR). Unfortunately, current therapies, including immune checkpoint inhibitors (ICIs) and anti-vascular endothelial growth factor (VEGF) antibodies, showed limited efficacy in pMMR CRC patients. CD36, a fatty acid (FA) transporter and scavenger receptor, is broadly upregulated in cancers, and inhibiting CD36-mediated lipid uptake has shown therapeutic promise. We recently developed PLT012, a humanized IgG4 antibody targeting the lipid-binding pockets of CD36, with cross-species reactivity and a superior safety profile in monkeys. Importantly, PLT012 displayed significant therapeutic efficacy in liver cancers, potentially by shifting immunosuppressive tumor microenvironment. Here, we assess the therapeutic efficacy of PLT012 in pMMR CRC. Using the pMMR CRC mouse cell line SL4, our data showed that PLT012 effectively suppressed orthotopic CRC growth in female, but not male mice. This sex-specific effect correlated with higher CD36 expression in female mice, which we also observed in CRC patient samples. Interestingly, our preliminary data further suggested that CD36 was enriched in cancer-associated fibroblasts (CAFs) in a female-biased manner. Taken together, our findings highlight CD36 as a promising therapeutic target for pMMR CRC, particularly in female patients.

#4352 Therapeutic antibody inhibits target-mediated immune migration in advanced in-vitromodelofanimmune suppressive tumormicroenvironment.

Wouter Strijker[1], Iris Voskamp[1], Brian Duggan[1], **Remko Van Vught**[1], Luuk de Haan[1], Ward Celus[2], Linda Gijzen[1]

[1]MIMETAS B.V, Oegstgeest, Netherlands,[2]Montis Biosciences, Leuven, Belgium

It has become increasingly clear that current immune-oncology treatments are inadequate in generating sufficient targeted treatment effects without damaging the surrounding tissue. Rather than focusing on the tumor as the main target, the immune suppressive tumor microenvironment has recently become a novel therapeutic target as it drives tumor growth, therapy resistance and metastasis. However, current in vitro systems often fail to replicate the tumor microenvironment hindering accurate efficacy evaluation. This study used an advanced in-vitro model of an immune suppressive tumor microenvironment to study treatment effects of therapeutic antibodies. Here we report on the use of an organ-on-a-chip based model to study immune cell migration in the context of a subset of immune suppressive macrophages, known as perivascular macrophages (PVM), and on a target protein released by these cells. The model contains an endothelial vessel (HUVEC), macrophages (PVM or M1) and immune cells (PBMCs or T cells) to study the interaction between these cells and determine the effect of target protein and antibodies. The level of immune cell migration showed to be dependent on the activation state of immune cells and pretreatment of the endothelium. PVMs shown to have an inhibitory effect on immune cells migration, in contrast to M1 macrophages that increased the number of migrated immune cells. The released target protein was found to reduce T cell migration, specifically for stimulated T cells. Finally, novel therapeutic antibodies were assessed after addition of the target protein. For one of the antibodies increased migration of stimulated T cells was observed. These findings highlight the potential of targeting PVMs and their released proteins, as important elements of an immune suppressive microenvironment. Additionally, the study shows the utility of the advanced in-vitro model for evaluating therapeutic antibodies. In the future the system will be used for testing additional therapeutics in the context of an immune suppressive tumor microenvironment.

#4353 PHST001, a humanized anti-CD24 hIgG4 antibody, is effective against metastatic tumors and retains its anti-tumor activity in the presence of competing IgG.

Suzana A. Kahn[1], Joseane Sampaio[1], Douglas V. Faget[1], Rachel E. Brewer[1], Giovanni C. Forcina[1], Blacker Grace[1], Priyanka R. Malusare[1], Alexandria Beans[1], Seth D. Ludwig[1], John S. Burg[1], Jennifer Yinuo Cao[1], Raphael F. Rousseau[1], Amira A. Barkal[2], Ravi Majeti[3], Irving L. Weissman[3], Roy L. Maute[1]

[1]Pheast Therapeutics Inc., Redwood City, CA,[2]Brigham & Women's Hospital, Harvard Medical School, Boston, MA,[3]Stanford University School of Medicine, Stanford, CA

Background: CD24 is a highly glycosylated tumor antigen with a restricted expression profile that acts as macrophage “don’t eat me” signal. CD24 is highly expressed by many human cancers and interacts with the macrophage receptor Siglec-10 to protect cancer cells from phagocytosis. PHST001 is a clinical-stage humanized anti-CD24 monoclonal antibody of IgG4 isotype currently in clinical evaluation. In vivo, PHST001 shows significantly greater efficacy against solid tumors than the anti-CD47 antibody Magrolimab. We assessed PHST001's preclinical efficacy against metastatic tumors and the role of Fc receptor engagement in its anti-tumor activity.

Results and Methods: BT474, a human Her2+ breast tumor cell line, metastasizes to the axillary lymph nodes when engrafted in the mammary fat pad of NSG mice. In contrast to control-treated mice, PHST001 treatment inhibited the formation of lymph node metastases in orthotopic xenograft models of BT474. To generate a disseminated metastatic model, BT474 cells were engrafted intracardially. A metastatic model was also generated in a syngeneic system by expressing human CD24 in MC38 cells (MC38-huCD24) and implanting tumor cells intracardially. PHST001 treatment significantly reduced the number and size of metastatic lesions in both xenograft BT474 and immune competent MC38-huCD24 models. To define PHST001’s mechanism of action, a variant antibody bearing a LALAGANA mutation (Fc-inert) was generated. This variant induced phagocytosis of tumor cells to a lesser extent than PHST001 (human IgG4), demonstrating the contribution of Fc receptor engagement to PHST001 efficacy. When combined with a companion agent, such as the anti-Her2 ADC trastuzumab deruxtecan, the Fc-inert version of PHST001 dramatically increased phagocytosis, demonstrating the contribution of CD24 blockade to PHST001 efficacy in absence of direct Fc receptor engagement. In vitro, PHST001 induced phagocytosis of human neutrophils, however this effect was completely inhibited by the IgG present in serum at physiological concentrations (50%). PHST001 anti-tumor efficacy against BT474 in NSG mice was maintained even when mice were supplemented with polyclonal IgG to match levels found in immunocompetent mice.

Conclusions: PHST001 prevents metastatic spread and demonstrates anti-tumor activity against established metastases. In vitro, peripheral blood cells expressing CD24 are protected from PHST001-mediated phagocytosis due to competition for Fc receptors by high levels of endogenous IgG, predicting protection in treated patients. PHST001 retains anti-tumor effects in vivo despite polyclonal IgG presence, indicating that competition for Fc receptors by endogenous IgG is not a barrier for efficacy in the tumor microenvironment.

#4354 Harnessing VLPs and nanodiscs to unlock antibody discovery for challenging membrane proteins.

Hannah Flaherty Duncan, Shicheng Chen, Jia Cui, Tingxu Chen

KACTUS, Waltham, MA

Multi-pass transmembrane proteins (MP-TMPs), including G protein-coupled receptors (GPCRs), ion channels, and transporters, are vital regulators of cellular communication and signaling. They represent over 60% of current drug targets, yet their structural complexity and dependence on lipid environments make recombinant production and antibody discovery extremely difficult. Traditional soluble formats fail to preserve their conformational integrity, limiting immunogenicity and screening relevance. To address these limitations, KACTUS developed a versatile membrane-protein display platform integrating **virus-like particles (VLPs)** and **nanodiscs** to stabilize full-length MP-TMPs in their native conformations. VLPs, composed of self-assembling structural proteins lacking genetic material, provide a natural lipid envelope that supports proper folding and high-density surface display. Using this system, KACTUS successfully presented the full-length **STEAP1** protein (a prostate-cancer-associated antigen) and demonstrated specific binding to the therapeutic antibody Vandortuzumab with an EC_{50} of 89.8 ng/mL. Complementing this, **SMA-based nanodiscs** produced in mammalian cells offer detergent-free solubilization of membrane proteins within native lipid bilayers. The **A2A adenosine receptor (A2AR)** nanodiscs retained structural integrity and exhibited strong binding to anti-A2AR monoclonal antibodies by ELISA (EC_{50} = 0.15 µg/mL) and SPR (K_D = 0.32 nM). In addition, KACTUS developed **CXCR4 VLP immunogens** that generated functional antisera and monoclonal antibodies capable of ligand-blocking comparable to the commercial CXCR4 antibody Ulocuplumab. Further extending this approach, **biotinylated VLPs and nanodiscs** enabled efficient **phage-display antibody panning**, as validated with GPRC5D constructs (EC_{50} = 7.4 ng/mL for VLPs; 0.28 µg/mL for nanodiscs). KACTUS also established the first **TCR-CD3 complex nanodisc**, preserving all native subunits (TCRα/β, CD3ε/γ/δ/ζ) for accurate CD3 antibody screening and binding analysis (SP34 K_D = 0.1 nM). Together, these results demonstrate that the **KACTUS VLP and nanodisc platforms** deliver native-like, bioactive MP-TMPs suitable for antibody generation, ligand binding, and structural interrogation. This integrated technology provides a powerful solution to overcome long-standing challenges in **membrane-protein immunization and screening**, paving the way for next-generation therapeutic antibody discovery.

#4355 Cryo EM-based structural characterization of IMC-002, a next-generation anti-CD47 antibody with a unique binding site and biomarker candidates, supporting evidence of enhanced safety and efficacy.

Hyesun Lee[1], **Jiyea Choi**[1], HyeHyeon Jang[1], Heewook Shin[1], Jiyoung Yoon[1], Woochan Hwang[2], Sung Ho Kim[1], Heung Tae Kim[1]

[1]ImmuneOncia Therapeutics, Inc., Seoul, Korea, Republic of,[2]Lunit Inc., Seoul, Korea, Republic of

CD47 is a ubiquitously expressed transmembrane glycoprotein that interacts with SIRPα on macrophages to deliver a “don’t eat me” signal, thereby inhibiting phagocytosis. Tumor cells upregulate CD47 to evade immune surveillance, which correlates with poor clinical outcomes. Consequently, the CD47-SIRPα axis has emerged as a promising target for cancer immunotherapy. However, clinical development of CD47 blockade has been hampered by hematologic toxicities and rapid drug clearance due to high CD47 expression on normal cells, particularly red blood cells (RBCs). IMC-002 is a fully human IgG4 monoclonal antibody against CD47, developed to achieve an optimized affinity that balances therapeutic efficacy with safety. IMC-002 shows markedly enhanced tumor-cell selectivity with minimal RBC binding, compared with Hu5F9 and 13H3. Moreover, unlike Hu5F9, IMC-002 did not induce RBC phagocytosis and hemagglutination. The tumor selectivity and lack of RBC binding by IMC-002 appear to result from differences in its binding site. Cryo-electron microscopy (cryo-EM) revealed a unique binding interface near residues containing a predicted O-glycosylation site, which is distinct from the binding modes of competitive antibodies. De-glycosylation study also supported this glycosylation-dependent binding selectivity, as reported at AACR 2025. The results from biochemical and structural studies explaining IMC-002’s reduced hematologic toxicity and enhanced tumor selectivity in its clinical trials. Phase 1a data confirmed a favorable safety profile, and a hepatocellular carcinoma (HCC) cohort in phase 1b has been completed. An ongoing Phase 1b trial is evaluating its efficacy in triple-negative breast cancer (TNBC) and biliary tract cancer (BTC) cohorts in combination with standard of care (SoC). IMC-002 in combination with standard-of-care agents enhanced macrophage-mediated phagocytosis and T-cell activation in vitro and showed potent anti-tumor activity in HCC xenograft model, correlating with tumor CD47 expression. In a Phase 1b (NCT05276310), aptamer-based proteomic and AI-assisted IHC analyses of HCC patient samples identified candidate biomarkers associated with IMC-002 efficacy and macrophage-related signatures, suggesting their use in patient selection. In conclusion, the cancer-selective binding of IMC-002 is characterized by binding sites located proximal to a predicted O-glycosylation region, as supported by biochemical and structural studies. Several factors identified through proteomics and AI-based IHC studies showed potential possibilities as predictive biomarker candidates. IMC-002 demonstrated excellent efficacy and safety in clinical trials through its unique binding mechanism, supporting its continued clinical development as a promising cancer therapy.

#4356 Comprehensive characterization of DT-7012, a highly differentiated anti-CCR8 depleting antibody.

Maria Dolores Garcia Fernandez, Christel Franchet, Luc Baron, Solene Rose, Aurelie Janvier, Malaury Schappler, Lelievre Helene, Melanie Frauli, Orphee Blanchard, Thibaut Brugat, **Stephan Schann**, Nathalie Lenne

Domain Therapeutics, Illkirch, France

Background:CCR8 has recently emerged as a promising target in the treatment of solid tumors. DT-7012 is a novel humanized anti-CCR8 IgG1 monoclonal antibody engineered for optimized binding and enhanced effector functions to preferentially deplete tumor-resident Tregs while maintaining peripheral immune integrity.
Objectives: To complete the preclinical characterization of DT-7012, focusing on its binding properties, effector-function potencies, and selectivity compared with clinical-stage CCR8-targeting antibodies.
Methods:A comprehensive series of in vitro assays were conducted to assess DT-7012's binding properties and functional activities. Data were compared against leading clinical-stage anti-CCR8 competitors to elucidate potential clinical advantages. Assays were conducted under tumor-microenvironment-mimicking conditions to evaluate functional robustness.
Results:DT-7012 displayed a unique binding profile, conferring high-affinity interaction and superior FcγR engagement. In cell-based assays, DT-7012 induced potent selective killing activities, including under tumor-microenvironment-mimicking conditions. Collectively, these findings support DT-7012 as a potential best-in-class CCR8-depleting candidate.
Conclusions: With distinct binding and effector characteristics, DT-7012 emerges as a promising therapeutic for selective modulation of the tumor microenvironment. These results provide the preclinical rationale for clinical evaluation in patients with advanced solid tumors.
Keywords:DT-7012, CCR8, Treg depletion, ADCC, ADCP, tumor microenvironment, immuno-oncology.

#4357 Novel monoclonal antibody kills lymphoma cells via LFA-1/ICAM-1 dependent, antibody-mediated cellular cytotoxicity.

Rui Xue Lee[1], Patrick W. Jaynes[2], Edward Kai-Hua Chow[3], Anand Devaprasath Jeyasekharan[1]

[1]National University of Singapore (NUS), Singapore, Singapore,[2]National University of Singapore, Singapore, Singapore,[3]National University of Singapore, National University of Singapore, Singapore

Background: Diffuse large B-cell lymphoma (DLBCL) is an aggressive form of non-Hodgkin's lymphoma. DLBCL patients undergo a first line immunochemotherapy regimen, termed R-CHOP. Unfortunately, approximately 40% of treated patients eventually relapse, or are non-responsive. Thus, there is an urgent need to devise new treatment options. Recently, a novel monoclonal antibody (Antibody X) has been developed as a potential therapeutic strategy.
Methods: CD16 (Fc receptor)-expressing NK92 cells were used as effector cells against target DLCBL cell lines in co-culture assays. A high-content, high-throughput drug screening tool was developed to test the effects of small molecule drugs in combination with immunotherapies.
Results: We observed that instead of direct cytotoxicity or complement-dependent cytotoxicity, Antibody X exerted its anti-tumour effect primarily through antibody-dependent cellular cytotoxicity (ADCC). To understand the regulators of Antibody X-mediated killing, we utilised a newly developed high-content, high-throughput drug screening tool to evaluate the effects of over 1000 FDA approved compounds on Antibody X-mediated ADCC of DLBCL cells. We noted that BCR-Abl inhibitors differentially regulated Antibody X-mediated ADCC through their effects on Src kinases. Cellular contact between lymphoma cells and immune effector cells was also disrupted through the blockade of LFA-1/ICAM-1 immunological synapse formation. This ultimately led to an absence of death in lymphoma cells.
Conclusion: Overall, findings from this study revealed that Antibody X-mediated ADCC is dependent on Src activity and LFA-1/ICAM-1 immunological synapses. We also demonstrated that the novel high-content, high-throughput ADCC platform can be used for immunotherapy-based combinatorial drug screens and mechanistic evaluation of ADCC.

#4361 Single amino acid residue substitution to improve immunogenicity of HLA peptides targeting p53 neoantigen.

Chi Han Samson Li[1], Hong Wang[1], Kin Tak Chan[1], Genwei Zhang[2], Zhenghui Wang[2], Lipeng Lai[2], Melvin Toh[1]

[1]Sequencio Therapeutics, Hong Kong, Hong Kong,[2]Xtalpi, Inc., Somerville, MA

Background and objective: p53 tumor suppressor gene is frequently mutated in human cancer, which is highly associated with advance malignancy development and poor prognosis. However, there are no effective treatments targeting p53 expressed by mutant p53. Aiming at developing therapeutic vaccines targeting mutant p53, we coupled amino acid residue substitution and HLA peptide prediction using an AI model that we developed. Previously, we reported that modified HLA-A*02:01-specific peptides designed using our approach demonstrated significant immunogenicity in a HLA-A*02:01-humanized mouse model. Here, we further designed modified p53 neo-epitopes specific to HLA-A*03:01 and HLA-A*11:01 using this approach and studied their immunogenicity in HLA-humanized mice.
Methods: The AI model was used to analyze common p53 neoantigens and predict epitopes for HLA-A*03:01 and HLA-A*11:01. The epitopes underwent computer-assisted saturation mutagenesis that simulated single amino acid substitution to obtain the associated presentation score changes. Peptide sequences with improved presentation scores were synthesized. The binding affinity with HLA was determined using surface plasmon resonance (SPR). The immunogenicity was determined by IFNγ ELISpot assay and intracellular cytokine staining (ICS) using splenocytes collected from mice vaccinated with the peptides.
Results: Modified p53 neo-epitopes were analyzed by our AI model after saturation mutagenesis, and twelve of the modified neo-epitopes with at least 5% increase of presentation probability were selected for experimental analyses. Most of these peptides demonstrated high binding affinity with HLA-A*03:01 or HLA-A*11:01 and β2-microglobulin heterodimer as characterized by SPR. Using splenocytes collected from HLA-A*03:01 or HLA-A*11:01-humanized mice vaccinated with pools of these peptides, IFNγ ELISpot assay and IFNγ ICS revealed that all HLA-A*03:01 peptides and 9 out of 10 HLA-A*11:01 peptides effectively induced $CD8^+$ T-cell response. Remarkably, challenging the splenocytes with the respective native neoantigen peptides reactivated the cellular immunity induced by most of AI-designed modified peptides, suggesting that immunization of the AI-designed modified peptides induced $CD8^+$ T-cell response against the native p53 neoantigens.
Conclusion: We have designed multiple peptides derived from common p53 neoantigens and demonstrated that they are strongly immunogenic in HLA-A*02:01, HLA-A*03:01 and HLA-A*11:01 background. These findings further support that the coupling of MHC-I presentation prediction AI model and computer assisted saturation mutagenesis is promising in modifying neo-epitopes to improve anti-tumor immunity via the $CD8^+$ T-cell response.

#4362 Mesenchymal stem cells delivering IL-33 oncolytic vaccinia virus enhance antitumor effects and overcome PD-1 inhibitor resistance in bladder cancerResistance in bladder cancer.

Yong Tang[1], Yingzhao Liu[2], Songlin Li[1], Wenjie Wang[2], Jiahu Wang[3], **Qi Wang**[2]

[1]Department of Urology, Guangxi Medical University Cancer Hospital, Nanning, China,[2]Department of Research, Guangxi Medical University Cancer Hospital, Nanning, China,[3]Genvira Biosciences Inc, Ottawa, ON, Canada

Approximately 80% of patients with advanced bladder cancer (BCa) develop resistance to PD-1 inhibitors, presenting a substantial clinical challenge. This study seeks to develop an innovative therapeutic strategy utilizing mesenchymal stem cells (MSCs) to deliver an oncolytic vaccinia virus engineered to carry interleukin-33 (IL-33), with the objective of overcoming resistance to PD-1 inhibitors and elucidating the associated immune mechanisms. To create the oncolytic vaccinia virus variants OVV-hIL33(GVB-2030)and OVV-mIL33, human or mouse IL-33 cDNA was inserted into the vaccinia virus Copenhagen strain. Integration was confirmed via quantitative PCR and ELISA. The impact on human and mouse bladder cancer cell proliferation was measured using real-time cell analysis. In C57BL/6 mice with the MB49 model, OVV-mIL33's effectiveness with anti-PD-1 therapy was tested. A PD-1 inhibitor-resistant MB49/R cell line was developed, and MSCs were used to deliver OVV-mIL33, forming MSC-OVV-mIL33. Its efficacy with PD-1 inhibitors was evaluated against uncoated OVV-mIL33 by comparing tumor size and survival. Single-cell sequencing, spectral flow cytometry, and multiplex immunofluorescence analyzed cytokines and immune cells in the tumor environment. The findings indicate that OVV-hIL33 (GVB-2030) and OVV-mIL33 demonstrate selective cytotoxicity towards BCa cells in vitro, sparing normal cells. In murine models, intraperitoneal administration of OVV-mIL33 in conjunction with a PD-1 inhibitor effectively inhibited tumor progression and extended survival, although tumor recurrence was observed. Notably, the combination therapy involving MSC-OVV-mIL33 and PD-1 inhibitors demonstrated enhanced efficacy. This regimen not only suppressed both primary and recurrent tumors, achieving a 90% cure rate in mice, but also significantly reduced tumor formation by 60% upon re-challenge with MB49/R, thereby establishing an anti-BCa immune response. The combination therapy effectively remodeled the tumor microenvironment by augmenting the infiltration of cytotoxic CD8+ T cells, memory B cells, and type 2 innate lymphoid cells, while concurrently decreasing the presence of regulatory T cells and terminally exhausted CD8+ T cells. Additionally, the MSC coating conferred protection to the virus against neutralization, thereby ensuring efficient tumor targeting and proliferation. Consequently, we propose that the MSC-mediated delivery of OVV-mIL33, combined with PD-1 blockade therapy, presents significant potential to overcome resistance to PD-1 inhibitors in BCa. This synergistic interaction is principally attributed to the reversal of T cell exhaustion and the enhancement of anti-tumor immune memory formation.

#4363 Viral vector vaccination induces brain resident memory T cells to drive anti-glioblastoma immunity.

Emily Elizabeth Steffke[1], Laila Latifi[1], Taijun Hana[1], Ayaka Hara[1], Morgan Coombs[1], Jo Spurgeon[1], Caitlin Huguely[2], John Hancock[1], Brita Anderson[2], James McAuliffe[3], Vinnycius Pereira-Almeida[3], Amanda Wicki[3], Sara Abdel Malak[3], Laurine Noblecourt[3], Meili Zhang[2], Wei Zhang[2], Dionne Davis[2], Nicole Briceno[2], Hua Song[2], Chen Cam-El Makranz[2], Hideho Okada[4], Mark Gilbert[2], Carol Leung[5], Benoit Van den Eynde[3], Masaki Terabe[1]

[1]LICI, National Cancer Institute, Bethesda, MD,[2]Neuro-Oncology Branch, National Cancer Institute, Bethesda, MD,[3]Ludwig Institute for Cancer Research, University of Oxford, Oxford, United Kingdom,[4]UCSF - University of California San Francisco, Mill Valley, CA,[5]Center for Immuno-Oncology, University of Oxford, Oxford, United Kingdom

Glioblastoma is a lethal brain tumor notable for limited spontaneous induction of $CD8^+$ T cell responses. While viral-vector vaccines can drive particularly high magnitudes of tumor-reactive T cells, they have not been investigated for the treatment of glioblastoma. Here, we demonstrate that heterologous prime-boost vaccination with the simian adenovirus ChAdOx1 and poxvirus modified vaccinia Ankara (MVA) treats the orthotopic, syngeneic, checkpoint-inhibitor refractory SB28 murine model of glioblastoma, both in the context of the murine tumor antigen, P1A, and a newly identified tumor-associated antigen expressed by SB28. Adjuvant anti-PD-1 and anti-CTLA-4 did not further improve outcomes. Vaccination induced immunoediting of tumor antigen expression and tumor-specific recruitment of antigen-specific T cells to challenged brains, the majority of which had a $CD103^+CD69^+CD8^+$ tissue resident memory (TRM)-like phenotype. While induction of TRMs by vaccination has been implicated in superior control of other cancers, their role in mediating anti-glioblastoma immunity was unclear. ChAdOx1/MVA-induced brain TRMs displayed superior polyfunctionality compared to circulating and non-TRM brain antigen-specific $CD8^+$ T cells. Long-term surviving mice maintained consistent levels of antigen-specific TRM cells in their brains at days 70 and 175 post-tumor challenge, despite a three-fold decrease in circulating antigen-specific T cells, indicating durable T cell memory in the brain parenchyma. Furthermore, survivors were protected against a second orthotopic, but not subcutaneous, tumor rechallenge, demonstrating tissue-specific immunological memory. Intracranial adoptive transfer of brain-derived antigen-specific TRMs isolated from vaccinated, tumor-bearing mice was sufficient to prolong the survival of naïve mice challenged with tumors, whereas blood-derived antigen-specific non-TRMs and non-antigen-specific brain-derived $CD8^+$ T cells were not. Despite peripheral administration of the vaccines, antigen-specific $CD8^+$ T cells were induced not only in the brains of tumor-free animals, but in many tissues, including the liver, lung, skin, skull bone marrow, and meninges, with distinct phenotypes observed in different tissues. Overall, we demonstrate that ChAdOx1/MVA vaccination is a potent strategy to induce TRMs to mediate anti-glioblastoma immunity, establishing a basis for further clinical investigation of ChAdOx1/MVA vaccination to treat patients with glioblastoma.

#4364 Next-generation RNA vaccine modalities enable high-fidelity antigen discovery and T-cell immunogenicity screening.

Molly Chilton, Henry Leonard, Elsenoor Klaver, Olivier Reelfs, Lauren Schewitz-Bowers, James Corbett, Rebecca Roberts, Christopher Kirkham, Dan Rocca, **Louise Brackenbury**

Charles River Laboratories, Bristol, United Kingdom

RNA-based cancer vaccines provide exceptional flexibility for encoding tumour-associated antigens (TAAs) or patient-specific neoantigens and recent clinical data show promising efficacy over traditional approaches, yet comparative functional data across RNA formats remain limited. We developed an integrated evaluation workflow to benchmark linear mRNA, circular RNA (circRNA), self-amplifying RNA (saRNA), and 27-mer peptide vaccines for their ability to drive antigen expression and prime functional antigen-specific T-cell responses. Using GFP reporter constructs, expression levels and persistence were assessed across selected RNA formats in primary antigen-presenting cells. Linear mRNA and circRNA robustly produced higher and more durable antigen expression than peptide pulsing, consistent with emerging insights into RNA vaccine potency. Vaccine candidates were subsequently screened using an antigen-specific T-cell expansion workflow, which expands rare tumour-reactive CD8+ T cells via a mature dendritic cell (DC) co-culture system. This platform addresses challenges of low precursor frequency and HLA diversity, enabling de novo priming of T cells against TAAs such as MART-1 or unique neoantigens. In the majority of donors, RNA-encoded antigens elicited stronger T-cell responses than 27-mer peptides, reflected by greater expansion of antigen-specific CD8+ T cells and increased IFNγ release following restimulation. Functional killing was confirmed using peptide-loaded tumour targets and tumour cell lines endogenously expressing relevant-antigen. RNA-encoded antigens produced T cells with higher cytotoxic potential, evidenced by enhanced tumour apoptosis in killing assays. Crucially, the strongest response seen was with a circRNA neoantigen vaccine candidate relative to the same neoantigen encoded in linear mRNA or peptide formats. To support personalised vaccine programs, putative neoantigens were first validated using TAP-deficient MHC-loading assays to confirm direct presentation, then screened in the DC-T-cell co-cultures to generate donor-resolved immunogenicity hierarchies. This enabled rapid identification of high-value epitopes suitable for inclusion in bespoke mRNA or circRNA vaccine constructs. Collectively, these data demonstrate that RNA vaccine modalities can outperform peptide-based vaccination in generating functional tumour-reactive T cells. The integrated platform provides a modality-agnostic, human-relevant workflow spanning antigen selection, RNA vaccine characterisation, and comprehensive functional T-cell assessment, supporting rapid advancement of next-generation cancer vaccine pipelines.

#4365 Pre-existing immunity boosts therapeutic efficacy of oncolytic influenza a virus in the presence and absence of neutralizing antibodies.

Gloria Dawodu, Soner Yildiz, Yonina Bykov, Vicent Tur Planells, Ethan Spodeck, Sara Cuadrado-Castano, Adolfo Garcia-Sastre

Icahn School of Medicine at Mount Sinai, New York, NY

The study of oncolytic viruses that naturally target humans requires models that elucidate the impact of pre-existing immunity on therapeutic efficacy. Recent studies have shown that the presence of anti-viral T cells in the tumor can be associated with potentiation of oncolytic viruses [1,2]. Conversely, the presence of neutralizing antibodies has also been shown to abolish response [1]. Thus, we hypothesized that pre-existing immunity to Influenza A virus (IAV) would lead to abrogation of oncolytic IAV therapy. To study the effect of neutralizing antibodies and IAV-specific T cells on oncolytic virus treatment, we established models of both homosubtypic and heterosubtypic immunity. Mice were infected with either PR8 virus (H1N1) or X-31 virus (H3N2.) 6 weeks post infection, mice were given bilateral CT26 tumors, and one tumor was treated with PR8 deltaNS1. Both tumors were monitored for tumor growth and overall survival. In a single tumor model, flow cytometry was used to define changes in the immune landscape unique to immunized mice. Additionally, anti-viral TILs were analyzed and characterized. Interestingly treated tumors displayed significant delays in tumor growth in PR8 and X-31 mice compared to naïve mice. Additionally, an increased abscopal effect in the contralateral tumor was only observed in X-31 mice. Treatment of X-31 mice resulted in a 20% increase in overall survival compared to PR8 and naïve mice. Rechallenged mice rejected tumor engraftment, indicating a durable anti-tumor memory response.There was an increase in both tumor infiltrating CD8+ and CD4+ T cells in the single tumor model. Amongst CD4s, there was a significant decrease in the presence of T regulatory cells (Treg); corresponding with an increase in CD8:Treg ratio. Immunized tumor bearing mice showed infiltration of anti-viral CD8s prior to treatment with oncolytic virus. X-31 mice had a higher prevalence of anti-IAV CD8s in the tumor and draining lymph node. In both immunization models, CD44+ anti-IAV CD8s were $CD127^{hi}CD69^{hi}$ indicating a central memory phenotype. Further phenotyping TILs in X31-immunized, tumor bearing mice displayed a trends to less T-cell exhaustion and increased cytotoxicity. In models of both homosubtypic and heterosubtypic immunity, therapeutic efficacy is strengthened. This indicates that the presence of neutralizing antibodies does not hinder the therapeutic efficacy of the virus and that the presence of anti-IAV T cells in both models may be responsible for this potentiation. Future studies aim to understand how anti-viral T cells in the TME contribute to anti-tumor response via interaction with anti-tumor T cells and overall myeloid cells.

#4366 Individualized neoantigen vaccine as adjuvant therapy in high-risk esophageal carcinoma: A study with the largest reported cohort and longest follow-up to date.

Ming Wu[1], Hong Shen[1], **Fan Mo**[2], Zixiang Wu[1], Chuanqiang Wu[1], Youping Wang[1], Kailai Wang[1], Shanshan Zhang[2], Ning Han[2], Liqian Wu[2], Wenjin Zhuang[2], Shuqing Chen[3]

[1]The Second Affiliated Hospital of Zhejiang University School of Medicine, Hangzhou, China,[2]Hangzhou Neoantigen Therapeutics Co., Ltd., Hangzhou, China,[3]Zhejiang University, Hangzhou, China

Background: For esophageal carcinoma (EC) patients with residual pathological disease (non-pCR) after neoadjuvant chemoimmunotherapy and surgery, effective adjuvant strategies to reduce recurrence are urgently needed. This study evaluates the safety, efficacy, and immunogenicity of iNeo-Vac-P01, a personalized neoantigen peptide vaccine, in this high-risk setting. To our knowledge, this is the largest and longest-following cohort reported to date for a personalized cancer vaccine in postoperative EC.

Methods: In this single-arm trial (NCT05307835), eligible stage IIA-IIIB EC patients with non-pCR received the vaccine. Tumor and matched normal tissues underwent whole-exome and RNA sequencing. Somatic mutations were identified, and up to 20 individualized long peptides (15-30 aa) encompassing predicted HLA class I and II neoantigens were designed and synthesized for each patient using a proprietary bioinformatics platform (iNeo®). Patients received subcutaneous injections of iNeo-Vac-P01 (300 μg/peptide) co-administered with GM-CSF (40 μg) on Days 1, 4, 8, 15±3, 22±3, 52±7, and 82±7. Primary endpoints were safety and 1-year recurrence-free survival (RFS).

Results: As of November 15, 2025, 26 patients were enrolled, with 23 constituting the efficacy-evaluable population (65.2% were ypT+N+). All patients completed the initial 7-vaccination course. Treatment-related adverse events were primarily Grade 1-2 (fatigue: 39.1%; fever: 30.4%; injection site reactions: 21.7%), with one Grade III acute hypersensitivity event. With a median follow-up of 25.3 months from surgery, the 1-, 2-, and 3-year RFS rates were 91.3%, 85.6%, and 78.5%, respectively. These outcomes compare favorably with the adjuvant nivolumab arm in the CheckMate 577 trial, which reported a 3-year RFS of 43%. The 1-, 2-, and 3-year OS rates were 100%, 95%, and 83.1%, respectively. ELISpot assays confirmed immunogenicity in 100% (23/23) of patients, with 79.5% (233/296) of administered peptides eliciting de novo T-cell responses. TCR sequencing demonstrated durable expansion of neoantigen-specific T-cell clones, detectable during treatment and for six months after the final vaccination.

Conclusion: This study, representing the largest and longest-followed cohort in this context, establishes the individualized neoantigen vaccine iNeo-Vac-P01 as a promising adjuvant strategy for high-risk EC. The compelling survival benefit over historical standards, manageable safety profile, and universal immunogenicity support its potential to change the postoperative management paradigm and warrant further randomized trials.

#4367 Strong therapeutic efficacy of oncolytic virus KLS-3021 in orthotopic head and neck cancer models regardless of PD-L1 expression via tumor microenvironment remodeling.

Sungmin Lee, **Jinwon Seo**, Kiwon Park, Joonsung Kim, Eunjin Lee, Jaeil Shin, Soon-Oh Hong, Sujeong Kim, Sun Jin Kim

Kolon Life Science Inc., Seoul, Korea, Republic of

Treatment of confined or locally advanced head and neck squamous cell carcinoma (HNSCC) remains challenging, even though surgery, radiotherapy, and chemotherapy are standard therapeutic options. High recurrence rates after treatment and limited systemic therapeutic efficacy always meet persistent unmet needs. Recent advances have highlighted the value of neoadjuvant immuno-oncology strategies, which can reduce tumor burden and prime systemic immunity to improve postsurgical outcomes. In recurrent or metastatic HNSCC, first-line therapy is guided by PD-L1 expression, using immune checkpoint inhibitors, chemotherapy, or their combinations; however, clinical benefit remains limited regardless of PD-L1 status. These limitations emphasize the need for new treatment modalities capable of reducing tumor burden and eliciting robust antitumor immunity regardless of PD-L1 levels. KLS-3021 is a genetically engineered oncolytic vaccinia virus encoding PH-20 (hyaluronidase), interleukin-12, and a soluble PD1-Fc. This design enables extracellular matrix (ECM) degradation, intratumoral immune activation, and localized blockade of PD-1/PD-L1 signaling. In this study, the therapeutic activity of KLS-3021 was evaluated in orthotopic HNSCC models. The CAL27 xenograft model was used to investigate antitumor efficacy, viral spread, and apoptotic tumor cell death after a single intratumoral dose of KLS-3021. Syngeneic NOOC1 (PD-L1-high) and MOC2 (PD-L1-low) models were used to study PD-L1-independent tumor control by KLS-3021 and to compare efficacy against standard therapies—anti-PD-1 antibody and cisplatin, respectively—while characterizing TME remodeling and immune activation. In CAL27 model, KLS-3021 produced robust antitumor efficacy, including complete regression with prolonged survival. In NOOC1 model, KLS-3021 outperformed anti-PD-1 therapy in both tumor regression and TME reprogramming. Notably, KLS-3021 markedly degraded the intratumoral ECM, enhancing viral spread and immune cell infiltration, and shifted the TME toward an M1-dominant state with increased CD86 and TNF-α and reduced CD206 levels. This M1-skewed milieu was accompanied by CXCL10 upregulation and increased infiltration of activated T cells. KLS-3021 also induced immunogenic cell death establishing conditions favorable for durable antitumor immunity. In MOC2 model, KLS-3021 provided superior tumor control and survival benefit compared to cisplatin. Collectively, these findings indicate that KLS-3021 elicits potent antitumor immunity and remodels the TME regardless of PD-L1 levels, exceeding current conventional standards. Given its capacity for local tumor debulking and immune activation, KLS-3021 implicates strong translational potential as a next-generation therapeutic, including neoadjuvant applications for HNSCC.

#4368 Vaccine targeting IGF1R induces neutralizing antibody and robust anti-tumor activity in a syngeneic mouse colon cancer model.

Kenneth Nansheng Lin, Melvin Toh, HONG WANG

Sequencio Therapeutics, Hong Kong, Hong Kong

Background Insulin-like growth factors (IGFs) and their receptor (IGF1R) induce important cellular signalling that regulates cell proliferation, survival, and metabolism. Overexpression of IGF1R in cancers is associated with poor prognosis and resistance to conventional therapies, highlighting the need for innovative therapeutic strategy. In this study, we developed IGF1R vaccine candidates and evaluated their anti-tumor activity in a syngeneic mouse colon cancer model.

Methods Recombinant proteins comprising different immune enhancers and computationally-predicted B-cell epitopes in the regions involved in IGF-IGF1R ligand-receptor interaction, intended to induce antibodies to block IGF-IGF1R interaction, were produced. Immunogenicity of the vaccine proteins was assessed in C57BL/6 mice by vaccination 6 times on days 0, 14, 28, 42, 49 and 56 using the proteins adjuvanted with CpG ODN 1826 and AS03. Serum samples were collected at multiple time points for determining anti-IGF1R antibody titers using ELISA as well as *in vitro* neutralization activity via blocking IGF1 binding to IGF1R using competitive ELISA. Anti-tumor efficacy of the vaccines was evaluated in a syngeneic MC38 mouse colon cancer model in C57BL/6 mice, which were vaccinated and inoculated subcutaneously with MC38 cells a week after the last vaccination. Mice administered adjuvant only were used as controls. Tumor growth was recorded twice a week till the end point.

Results IGF1R vaccines induced robust humoral immune response as demonstrated by high titer of anti-IGF1R antibody. Importantly, serum samples collected from vaccinated mice demonstrated strong neutralizing activity, inhibiting IGF1 binding to IGF1R by up to 68% in a competitive ELISA. Two proteins which induced the highest antibody titer (i.e. 1:125,000) were further evaluated for their anti-tumor efficacy. In the anti-tumor study using the MC38 model, these two IGF1R vaccines suppressed the growth of tumors by 62% and 61%, respectively, at the study endpoint compared to controls ($p<0.01$).

Conclusions In summary, these findings establish proof-of-concept that IGF1R-targeting vaccines can elicit neutralizing antibodies that block IGF1 binding to IGF1R, thereby inhibiting the growth of tumors where IGF/IGF1R signalling plays critical roles. This result supports further investigation and optimization to improve these IGF1R vaccines to treat cancers dependent on IGF/IGF1R signalling.

#4369 B7-H3 vaccine induces robust humoral and cellular immunity and inhibits tumor growth in mice.

Kenneth Nansheng Lin, Melvin Toh, HONG WANG

Sequencio Therapeutics, Hong Kong, Hong Kong

Background B7-H3 (CD276) is an immune checkpoint molecule frequently overexpressed in a wide range of cancers, where it plays critical roles in immune evasion, tumor progression, and metastasis, underscoring its potential as a promising target for cancer immunotherapy. Here, we developed a novel protein vaccine to induce humoral and cellular immunity against B7-H3 and evaluated its anti-tumor efficacy in syngeneic mouse colon cancer models.

Methods A recombinant vaccine protein was generated, consisting of tandem repeats of the FG loop fragment of human B7-H3 - a structural motif linking the F and G β-strands of B7 family proteins that is critical for ligand-receptor interactions (though no ligand has yet been identified for B7-H3) - combined with an N-terminal cell-penetrating peptide to enhance immunogenicity. Immunogenicity of this B7-H3 vaccine, adjuvanted with CpG ODN 1826, was studied in BALB/c and C57BL/6 mice vaccinated subcutaneously weekly for 6 weeks. Controls were mice administered adjuvant only. Serum samples was collected at multiple time points to determine anti-B7-H3 antibody titer by ELISA. Splenocytes were harvested to assess cellular immunity using IFNγ ELISPOT assay. Anti-tumor efficacy of vaccine was evaluated in both prophylactic and therapeutic studies using B7-H3-humanized mouse colon cancer cell lines, CT26-hB7-H3 and MC38-hB7-H3, in BABL/c and C57BL/6 mice, respectively. Tumor growth was recorded. Tumor-infiltrating lymphocytes (TILs) were characterized by flow cytometry.

Results The B7-H3 vaccine induced robust humoral and cellular immunity against human B7-H3 in both BALB/c and C57BL/6 mice. In prophylactic studies, the vaccine demonstrated significant anti-tumor activity: 1) in the CT26-hB7-H3 model, tumor growth inhibition (TGI) in vaccinated mice was 99.8%, compared to controls and 90% of vaccinated mice were tumor-free at the endpoint; 2) in the MC38-hB7-H3 model, TGI was 72.4%. Using tumors collected from the MC38-hB7-H3 study, TIL characterization using flow cytometry revealed 1.2-fold and 4.3-fold increases of activated CD4+IFNγ+ and CD8α+IFNγ+ T-cells, respectively. In therapeutic studies, TGI in CT26-hB7-H3 tumor-bearing mice was 91.2%, with 7/12 of mice becoming tumor-free at the end point, and TGI in MC38-hB7-H3 tumor-bearing mice was 85%. In MC38-hB7-H3 tumors, TIL analysis showed a 2.8-fold increase in CD8α+IFNγ+ T cells.

Conclusions Our study demonstrates that the B7-H3 vaccine induces robust humoral and cellular immunity, effectively suppressing the growth of B7-H3-positive tumors in mice. These findings highlight its potential for clinical translation as a therapeutic strategy for B7-H3-overexpressing cancers in humans.

#4370 TROP2-circular RNA vaccine and IL7 synergistically inhibit TROP2+ tumor growth in mouse models.

Zirong He, Yanan Li, Antong Li, Xiaoxuan Liu, Kenneth Nansheng Lin, Fan Yan Meng, Melvin Toh, Hong Wang

Research & Development, Sequencio Therapeutics, Hong Kong, Hong Kong

Human trophoblast cell surface antigen 2 (hTROP2), a transmembrane glycoprotein encoded by the Tumor-Associated Calcium Signal Transducer 2 (TACSTD2) gene, is a promising tumor-associated antigen (TAA) in several types of cancers for targeted immunotherapy. We developed hTROP2 protein and RNA vaccines that effectively suppressed the growth of TROP2-positive tumors in mouse models. However, the efficacy of TAA-targeted vaccines in humans may be limited by self-tolerance and poor tumor infiltration of immune effector cells. Given the critical role of interleukin-7 (IL7) in promoting T-cell proliferation, survival, and repertoire diversity, we hypothesized that IL7 could enhance hTROP2 vaccine efficacy by expanding and diversifying the T-cell pool, thereby improving tumor infiltration and overcoming self-tolerance. To test this, we co-administered an hTROP2-expressing circular RNA-lipid nanoparticle (hTROP2-circRNA-LNP) vaccine with an IL7-expressing circRNA-LNP (IL7-circRNA-LNP) in mouse models. Cellular immune responses were assessed using IFNγ ELISpot assays on splenocytes from vaccinated mice. Co-administration with IL7-circRNA-LNP enhanced the cellular immune response by 2.3- and 2.7-fold for the two predominantly active stimulating peptides compared with the response induced by hTROP2-circRNA-LNP alone. Comparable results were observed when IL7-circRNA-LNP was administered either before or after the hTROP2-circRNA-LNP vaccine. In mice bearing tumors derived from TROP2-humanized cancer cell lines (MC38-hTROP2 and 4T1-hTROP2), co-administration of the hTROP2-circRNA-LNP vaccine with IL7-circRNA-LNP significantly enhanced anti-tumor efficacy compared with hTROP2-circRNA-LNP alone. Tumor growth inhibition increased from 57.4% to 87.0% in the MC38-hTROP2 model and from negligible effect to 63.4% in the 4T1-hTROP2 model. In control mice that received IL7-circRNA-LNP alone, IL7 monotreatment achieved 20% tumor growth inhibition (without statistical significance) in the MC38-hTROP2 model but had no effect in the 4T1-hTROP2 model. Analysis of tumor-infiltrating lymphocytes revealed that co-administration of the hTROP2-circRNA-LNP vaccine with IL7-circRNA-LNP significantly increased the proportions of cytotoxic CD8α+ and helper CD4+ T-cells, as well as their activated subsets (CD8α+IFNγ+ and CD4+IFNγ+ cells). Neither the hTROP2-circRNA-LNP vaccine nor IL7-circRNA-LNP alone significantly altered these T-cell populations. Collectively, our findings demonstrate that IL7 enhances the anti-tumor activity of the hTROP2-circRNA-LNP vaccine by the expansion of cytotoxic and helper T cells. These results suggest that co-administration of IL7-circRNA-LNP with hTROP2-circRNA-LNP represents a promising strategy for human cancer immunotherapy.

#4371 Preclinical potential of γδ T cells in novel virus-like particle vaccines for triple-negative breast cancer.

Arnau Sole Casaramona[1], Anish Ghimire[1], Romano Josi[1], Sanjana Marar[1], Anita Ogriņa-Komarova[2], Simone De Brot[1], Chang Wang[1], David Wiggins[3], Wendao Liu[3], Sarat Kumar Kottarath[3], Martin F. Bachmann[1], Eva M. Sevick[3], Mona O. Mohsen[1]

[1]University of Bern, Bern, Switzerland,[2]Latvian Biomedical Research, Riga, Latvia,[3]University of Texas at Houston, Houston, TX

Triple-negative breast cancer (TNBC) is an aggressive subtype with limited treatment options, high recurrence rates and poor outcomes. The conventional treatment among the standard of care strategies fail to elicit a long-term benefit for these patients. Personalized cancer vaccines using virus-like particles (VLPs), represent a promising strategy with the potential to induce durable immune responses. Recent research has highlighted the innate and adaptive properties of γδ T cells, underscoring their potential in cancer immunotherapy. However, how VLPs interact with γδ T cells, and their clinical efficacy to enhance their antitumor activity remains poorly understood and requires further investigation. We designed and developed novel next-generation VLPs engineered to incorporate cell-adjuvanted innate ligands and present tumor-neoantigens on their surface from a preclinical model of TNBC. We validated them by Cryo-EM and biochemical assays. We evaluated the interaction of VLPs with γδ T cells in wildtype and transgenic mice by transmission imaging techniques. Tumor *in vivo* experimentation was carried out in the 4T1 TNBC model. We compared three subcutaneous (s.c.) administration routes: systemic, targeting tumor-draining lymph nodes (tdLNs), and targeting non-tdLNs. Survival was assessed under different dosing and immune checkpoint inhibitor co-treatment. CD4, CD8, and γδ T cells were depleted to determine their contributions. We performed immunohistochemistry, flow cytometry, and RNA-seq analysis to evaluate the immune response. Our results show that γδ T cells efficiently engulfed VLPs in wild-type mice while this interaction is hindered in transgenic mice lacking key components of innate immune sensing pathways. Our novel VLPs expanded γδ T cells in tdLNs, promoting antitumor subsets and phenotypes. Subtype analysis revealed distinct activation profiles of γδ T cells subsets Vγ-1 and Vγ-4. Evaluation of tdLNs and tumors revealed early expansion of γδ T cells, highlighting innate properties. Depletion of γδ T cells abolished antitumor efficacy of the immunotherapy, suggesting adaptive properties. Furthermore, our personalized vaccine enhanced tumor infiltration of CD4, CD8 and γδ T cells, increased cytotoxic markers, reduced recurrence and metastasis, and improved survival despite low tumor mutational burden. Our findings reveal novel innate and adaptive properties of γδ T cells in response to our next-generation VLPs loaded with diverse innate immune stimuli and presenting tumor-neoantigens from 4T1 cells. These findings have the potential to reshape the field of cancer vaccines by harnessing γδ T cells as key players in anti-tumor immunity.

#4372 Proteolysis-targeting vaccines, or PROTAX, for robust tumor combination immunotherapy.

Qiyan Wang, wenhua li, Shaomeng Wang, **Guizhi Julian Zhu**

University of Michigan, Ann Arbor, MI

Current peptide vaccines elicit limited antitumor T cell responses, leading to suboptimal tumor therapeutic efficacy. Here, we present proteolysis-targeting vaccines (PROTAX) that facilitate antigen proteolytic processing and cross-presentation to potentiate T cell responses for robust tumor immunotherapy in combination with immune checkpoint blockade (ICB). PROTAX are peptide antigens conjugated with a E3 ligase-binding ligand via linkers. In antigen-presenting cells (APCs), PROTAX bind to E3 ligases to rapidly ubiquitinate PROTAX antigens, facilitating antigen proteolytic processing by proteasome, and thereby promoting antigen cross-presentation to T cells. In mice, PROTAX promoted both the quantity and quality of $CD8^+$ T cell responses against antigens, such as multivalent melanoma-associated antigen Trp2-gp100-Trp1 (TgT) and synthetic long peptide human papillomavirus (HPV)-16 E7. In melanoma-bearing mice, PROTAX-TgT + ICB remodeled the tumor immune microenvironment and enhanced tumor complete regression (CR) rates, in a manner dependent on classic type-1 dendritic cells (cDC1) and $CD8^+$ T cells. PROTAX-TgT + ICB eradicated 100% large $Braf^{V600E}$ SM1 melanomas (~300 mm^3), and promoted the CR rates of M3 melanoma and highly immunosuppressive $Braf^{CA+}$ M2 melanoma with low TgT antigen expression. In an autochthonous $Braf^{V600E}$ melanoma in $Braf^{V600E/Pten-/-}$ mice, PROTAX-TgT + ICB reduced the molecular and cellular immunosuppression in the tumor, inhibited tumor progression and metastasis, and extended mouse median survival from 21 days to 66 days post initial tumor treatment. Similarly, PROTAX-E7 + ICB resulted in 43% CR of large TC-1 tumors (~300 mm^3). In human leukocyte antigen (HLA)-A02:01 human PBMCs from healthy donors and HPV-16^+ Head and Neck Squamous Cell Carcinoma (HNSCC) patients, HLA-A02:01-restricted trivalent $PROTAX^{E6-(E7)2}$ promoted tri-specific $CD8^+$ T cell responses, characterized with enhanced antigen-specific T cell expansion and production of human interferon-γ (IFN-γ) and tumor necrosis factor-α (TNF-α). Therefore, PROTAX hold the potential for robust tumor combination immunotherapy.

#4373 Rational design of immune-cell-homing macroporous hydrogels for enhanced dendritic cell recruitment and cancer vaccination.

Wenhao Xu, Hua Wang

University of Illinois at Urbana-Champaign, Champaign, IL

Macroporous biomaterials have emerged as a promising platform for in situ cancer vaccination because they can create localized immune niches that recruit, activate, and program dendritic cells (DCs) more effectively than traditional soluble vaccines. However, the immune-cell homing profile of these materials remains difficult to rationally control because key physical parameters—stiffness, viscosity, and pore size—are often inherently coupled. To overcome this challenge, we engineered an alginate-based macroporous hydrogel in which these properties were independently tunable, enabling a systematic investigation of how each dimension shapes DC recruitment and downstream antitumor immunity. The resulting design space revealed a striking synergy: hydrogels combining high stiffness, high viscosity, and large interconnected pores generated the most favorable immune microenvironment, recruiting 1.6-fold more DCs and markedly enriching the cDC1 subset associated with efficient cross-presentation. Large-pore hydrogels supported deeper cellular infiltration and increased MHC II expression, while high-viscosity formulations enhanced cell retention within the scaffold. Although softer matrices facilitated early migration in vitro, stiffer gels promoted superior DC proliferation, survival, and release, revealing a two-phase mechanism in which initial recruitment and sustained persistence are governed by distinct material properties. When loaded with GM-CSF, OVA, and CpG, the optimized hydrogel induced the strongest SIINFEKL-specific $CD8^+$ T-cell expansion and achieved significantly delayed tumor progression in prophylactic E.G7-OVA challenge, outperforming all other formulations and soluble controls. These findings establish a mechanistic framework for engineering macroporous hydrogels as programmable immune niches and demonstrate that precise decoupling of material mechanics and pore architecture can amplify vaccine potency in vivo. This work advances the rational design of biomaterial-based cancer vaccines and highlights the importance of material-immune cell crosstalk in generating durable antitumor immunity. AI-assisted text generation (ChatGPT) was used solely for language refinement of this abstract.

#4374 A novel RNA-LNP immunotherapy platform to drive anti-tumor efficacy in solid tumors.

Hailey R. Lee[1], Khalid Rashid[1], Tony Luu[1], Amanda Creech[1], Pu-Lin Teng[1], Emma Lieberman[1], Bridget Vause[1], Catherine Xie[1], Britney Trieu[1], Willy Hugo[1], Ting-Ting Wu[1], Norbert Pardi[2], Caius G. Radu[1]

[1]Molecular and Medical Pharmacology, UCLA Health, Los Angeles, CA,[2]Microbiology, University of Pennsylvania, Philadelphia, PA

Nucleoside-modified RNA vaccines complexed in ionizable lipid nanoparticles (RNA-LNPs) constitute a promising immunotherapy platform for T cell-directed cancer vaccine development. A challenge in generating a proper anti-tumor CD8 T cell response with current RNA vaccine iterations remains, however, in providing optimal activation of antigen-presenting cells. Further, the presence of an immunologically cold tumor microenvironment (TME) presents an additional obstacle in designing an immunotherapeutic strategy to overcome such immunosuppression. To address these challenges, we hypothesized that an optimized RNA-LNP platform which couples an antigen-encoding RNA with a novel RNA-LNP innate immune activator will synergistically activate dendritic cells (DCs) by engaging multiple pattern recognition receptor (PRR) pathways to enhance cross-presentation and drive CD8 T cell responses. To this end, we immunized mice with our novel RNA-LNP platform and demonstrated that multiple DC subsets were activated at both local and distal secondary lymphoid organs respective to the injection site. The DCs from the immunized mice also activated and expanded antigen-specific T cells and resulted in memory T cell formation. Abrogation of these T cell responses in genetic knockout models demonstrate that such T cell activation is mediated by multiple PRRs. Systemic delivery of the novel innate immune activators activated DCs at draining lymph nodes local to the tumor site in an orthotopically implanted murine pancreatic cancer model and subsequently conferred tumor growth suppression. Collectively, these studies establish a new paradigm for RNA-LNP immunotherapy that integrates multifaceted PRR engagement to promote antigen-specific vaccination and facilitate T cell priming and reactivation at the tumor.

#4375 Claudin 6 vaccines effectively inhibit tumor growth in a syngeneic mouse colon cancer model.

Na Wang, Lam Chow, Melvin Toh, Hong Wang

Sequencio Therapeutics, Hong Kong SAR, China

Human Claudin 6 (CLDN6) is a member of the Claudin family of proteins, which plays a crucial role in the structure and function of tight junctions. In humans, CLDN6 is primarily expressed in stem cells and embryonic tissues, with minimal mRNA detected in testis, pancreas, and placenta. Elevated expression of CLDN6 has been found in several types of cancers, suggesting that CLDN6 is an ideal tumor-associated antigen for targeted immunotherapy, albeit its precise role in cancer remains to be defined. Here, we generated recombinant proteins consisting of multiple human CLDN6 B- and T-cell epitopes (CLDN6-B+T) or T-cell epitopes only (CLDN6-T), which were selected based on computationally predicted B/T-cell epitope sequences and fused with the transmembrane domain of diphtheria toxin (DTT) as an immune enhancer. The immunogenicity and anti-tumor activity of these two vaccines were evaluated in mouse models. In both wildtype and HLA*02:01-humanized mice, CLDN6-B+T and CLDN6-T with adjuvant CpG induced robust cellular immune response as assessed by IFNγ ELISpot assay using splenocytes collected from mice vaccinated weekly for 6 weeks. In a syngeneic mouse tumor model using CLDN6-humanized MC38 colon cancer cell line (MC38-CLDN6(K)), both vaccines significantly suppressed the growth of tumor cells inoculated one day after the 6th vaccine dose, compared to control mice that received adjuvant only (n=8 in each group). In this study, 7/8 mice vaccinated with CLDN6-B+T and 8/8 mice vaccinated with CLDN6-T were tumor-free at the endpoint. A replicate study using an independently-derived CLDN6-humanized MC38 cell line, MC38-hCLDN6(C), demonstrated 72.6% and 73.2% tumor growth inhibition by CLDN6-B+T and CLDN6-T vaccines, respectively, compared to adjuvant controls(n=10 in each group). In a therapeutic study in which MC38-hCLDN6(C) cells were inoculated subcutaneously one day before weekly vaccination for 5 times, tumor growth was inhibited by 67.0% and 81.0% in mice vaccinated with CLDN6-T (n=11) and CLDN6-B+T (n=12), respectively, compared to mice that received adjuvant only (n=10). Collectively, our findings demonstrate that CLDN6-targeted vaccines significantly suppressed the growth of CLDN6-positive tumors in mice. These results support CLDN6-targeted vaccines as a promising therapeutic strategy for CLDN6-positive cancers in humans, with their potential to be further validated in upcoming studies.

#4376 Harnessing artificial intelligence to optimize neoantigen prediction and mRNA design for personalized cancer vaccine.

Yang Liu, Qingyi Mao, Wu Xinghan, **Qiu Mantang**

Xinyi Pharma (Hangzhou) Co., Ltd., Hangzhou, China

Background:Neoantigen-based mRNA personalized cancer vaccines (PCV) represent a promising frontier in cancer immunotherapy. However, current neoantigen prediction strategies primarily rely on MHC binding affinity, which leads to limited accuracy in immunogenicity and results in a high false-positive rate. The precise identification of neoantigen epitopes that are efficiently presented by MHC and elicit robust immunogenicity remains a central challenge hindering the clinical application of PCV. Here, we developed EchoNeo 1.0, a multimodal deep learning-driven pipeline that innovatively integrates immunogenicity prediction with mRNA sequence design to accelerate the of application of PCV.
MethodsThe core of pipeline is a multimodal deep learning model for immunogenicity prediction. Trained on publicly available databases (IEDB, TSNAdb v2.0, TESLA) and published immunogenicity data, the model integrates peptide/HLA pseudosequence features with multidimensional biological metrics to achieve accurate immunogenicity scoring. Neoantigen mRNA vaccines were synthesized and formulated with lipid nanoparticles (LNP), and evaluated in mouse models for safety (including toxicology and in vivo biodistribution) and therapeutic efficacy.
Results:Approximately 3,700 peptides (8-11 amino acids) with confirmed experimental immunogenicity data were used to train and validate EchoNeo, which demonstrated superior performance in benchmark tasks against established prediction tools (e.g., DeepImmuno, IEDB Class I Immunogenicity tool) and showed excellent immunogenicity prediction accuracy on independent, clinically validated neoantigen datasets. In C57BL/6 mice intramuscularly administered with vaccine (at a maximum dose of 54 μg, approximately 2.7 mg/kg), no significant adverse changes were observed in body weight, body temperature, blood biochemistry (ALT, AST, DBIL, CREA, UREA, TG, TC, LDL, HDL, LDH, CK), or complete blood count (CBC, DIFF, and RET). In a melanoma model, the vaccine significantly inhibited tumor growth, and enhanced therapeutic effect was achieved when combined with anti-PD-1 antibody.
Conclusion:Superior immunogenicity prediction accuracy was confirmed, as well as the favorable safety and potent antitumor efficacy in mouse models. This work represents a paradigm shift from conventional affinity-based prediction to an end-to-end framework that directly assesses the immunogenicity of neoantigen peptides, holding significant promise for accelerating the development of PCV.

#4377 High affinity receptor bio-selected novel oncolytic RNA virus, IVX055, demonstrates potent anti-tumor activity in human NSCLC, hepatocellular carcinoma and bladder cancer with potential for immunotherapeutic combinations.

Min Quah, Christine Lee, Rebecca Ingham, Oksana Zdanska, **Darren Shafren**

ImmVirX, Newcastle, Australia

Background:
Oncolytic viruses represent a promising therapeutic approach through their dual mechanisms of direct tumor cell lysis and stimulation of anti-tumour immunity. IVX055 is a novel, non-enveloped, single-stranded RNA oncolytic virus developed using a proprietary receptor bio-selection platform, which enables preferential targeting of tumor cells by exploiting overexpressed surface receptors. This platform enhances tumor specificity, efficient viral entry, and replication within the tumor microenvironment. Infection with IVX055 induces cell lysis and potential pro-inflammatory signaling, including PD-L1 upregulation, which may increase immune cell infiltration and sensitize tumors to immune checkpoint inhibitors (ICIs). These immunostimulatory effects position IVX055 as a strong candidate for combination with ICIs, T-cell engagers, antibody-drug conjugates (ADCs), and bispecific antibodies to amplify anti-tumor responses.
Methods:
The oncolytic activity of IVX055 was evaluated *in vitro* using multiple human Non-small cell lung cancer (NSCLC), hepatocellular carcinoma (HCC) and bladder cancer cell lines. Monolayer cultures were infected with varying multiplicities of infection (MOIs). Cell viability was measured using the XTT assay as a surrogate for cytolytic activity and metabolic function. For mouse models, immunocompromized mice were seeded with single flank human tumor cell administrations. Following development of palpable tumors, IVX055 was administered via the i.t route. calliper measurements were employed to assess tumor burden.
Results:
IVX055 demonstrated potent, dose-dependent cytolytic activity in NSCLC, HCC and bladder cancer cell lines. Multiple rounds of viral replication were evident, consistent with high level production of progeny virus coupled with sustained oncolytic activity and induction of a potential pro-inflammatory tumour phenotype. Significant reductions in cell viability were detected shortly after infection, confirming rapid and robust tumor cell killing. Intratumoral administration of IVX055 in human tumor xenograft models using immunocompromized mice was well tolerated and displayed potent anti-tumor activity against NSCLC cancers.
Conclusions:
IVX055 exhibits strong preclinical *in vitro* and *in vivo* oncolytic activity and tumor selectivity, supporting its continued development. Future studies will explore combination strategies with ICIs, T-cell engagers, ADCs, and bispecific antibodies to enhance efficacy in advanced solid tumours. A phase 1 basket study of intratumoral IVX055 in combination with systemic anti-PD1 therapy in pts (n=32) bearing visceral disease from checkpoint refractory NSCLC, HCC and Cholangiocarcinoma is planned to commence in 2026.

#4378 Live attenuated MMR vaccines modulate tumor immune cell infiltration and synergize with standard of care to prolong survival in preclinical HCC models.

Mulu Z. Tesfay[1], Aleksandra Cios[2], Khandoker Usran Ferdous[3], Randal S. Shelton[3], Isabelle Miousse[3], Camila C. Simoes[3], Alexei Basnakian[3], Rangaswamy Govindarajan[3], Martin Cannon[3], Mitesh J. Borad[4], Bolni M Nagalo[2]

[1]UAMS Winthrop P. Rockefeller Cancer Institute, Little Rock, AR,[2]Department of Pharmacology and Physiology, University of Maryland School of Medicine, Baltimore, MD,[3]University of Arkansas for Medical Sciences, Little Rock, AR,[4]Director Phase I Drug Dev, Dept. of Hemat./Onco., Mayo Clinic Arizona, Scottsdale, AZ

Hepatocellular carcinoma (HCC) is a leading cause of cancer-related death worldwide, thus, there is an urgent need to develop more effective therapeutic options for this dismal condition. Tumor-infiltrating lymphocytes (TILs) are associated with improved response to immune checkpoint blockade in HCC, but their low abundance in most cases limits their therapeutic efficacy. Here, we demonstrate, in mice, that low-dose intratumoral immunovirotherapy with the trivalent measles, mumps, and rubella vaccine (MMR) induces superior tumor-growth delay and extended host survival compared to individually administered vaccines for measles, mumps, or rubella viruses. Further, our results show that MMR therapy synergizes with PD-1 and CTLA-4 blockade to reprogram the tumor microenvironment, resulting in increased CD8+ TIL infiltration and reduced PD-1 expression on TILs, among other effects. These changes in the immunological landscape translated into greater survival and more durable tumor-specific and memory immune responses for hosts. Comprehensive toxicology analysis revealed no evidence of MMR-induced liver or kidney toxicity after intrahepatic administration. This work reinforces an unrecognized role of MMR plus ICB in reprogramming the immune landscape in HCC through multimodal immune activation, providing a strong rationale for further development of MMR-based therapies for HCC.

#4379 Enhanced cancer immunotherapy via sPD1-based DNA vaccination targeting epitope-focused TWIST1 antigen.

Zhiwu Tan[1], Mei Sum Chiu[1], Helen Xinyue Yu[2], Xiaoxiao Chang[1], Zhiwei Chen[2]

[1]The Hong Kong Polytechnic University, Hong Kong, China,[2]The University of Hong Kong, Hong Kong, China

TWIST1, a basic helix-loop-helix transcription factor, is overexpressed in a variety of tumors such as melanoma, breast, colon cancer and mesothelioma, and associated with tumorigenesis and metastasis. We have previously shown that full-length TWIST1 vaccine elicited cytotoxic T lymphocytes (CTLs) that recognized TWIST1-expressing tumors and conferred protection against tumor challenge in the form of DNA vaccine and adeno-associated viral vector system, highlighting TWIST1 as a promising target for cancer immunotherapy. In this study, we sought to apply optimization approach on the TWIST1-based vaccine platform in order to enhance T cell immunity and reduce potential toxicity.

We developed a novel soluble PD-1 (sPD1)-based DNA vaccine encoding a truncated version of TWIST1 (sPD1-TruncT1) that includes major T cell epitopes found in both human and mouse proteins. The immunogenicity and antitumor efficacy of the vaccine were evaluated and compared in parallel to full-length TWIST1 vaccine in two murine models of TWIST1-expressing tumors. By doing epitope mapping, we identified immunodominant T cell epitopes within the TWIST1 antigen, showing that majority of T cells recognized a C-terminal conserved region. sPD1-based DNA vaccine encoding epitopes of this conserved region, via in vivo electroporation (EP), elicited more robust TWIST1-specific T cell responses compared to full-length TWIST1 vaccine. Furthermore, these TWIST1-specific T cells were polyfunctional because they produced multiple effector cytokines when encountering TWIST1-expressing tumors. In addition, immunotherapy with the sPD1-TruncT1 vaccine showed a notable enhancement in antitumor efficacy in both preventive and therapeutic scenarios. With the widespread expression of TWIST1 in different cancer types, truncated TWIST1 vaccination has high potential for cancer immunotherapy and warrants investigation in human clinical trials to evaluate its applications as a vaccine for patients with WT1-expressing cancers.

#4380 IRZ-01: A self-adjuvanted outer membrane vesicle vaccine targeting CEA and MUC1 for colorectal cancer immunotherapy.

Kevin Chen[1], Caleigh Fletcher[1], John Cowger[1], James E. Galen[2], Mayukh Das[3], Marcio Chedid[1]

[1]Irazu Oncology, LLC, Baltimore, MD,[2]Center for Vaccine Development and Global Health, University of Maryland, Baltimore, Baltimore, MD,[3]Arcus Biosciences, Hayward, CA

Background: Irazu Oncology developed a tumor vaccine platform using a proprietary, attenuated *Salmonella* Typhi strain engineered to express human tumor antigens and shed antigen-decorated outer membrane vesicles (OMVs). This flexible system enables rapid development of mono- or multi-valent vaccines. IRZ-01 is an OMV-based vaccine displaying epitopes from two well-characterized and validated tumor-associated antigens (TAAs): Mucin-1 (MUC1) and CEACAM5 (CEA). Here we show that IRZ-01 administration to immunocompetent mice triggers potent antigen-specific humoral and cellular immunity and confers single-agent antitumor efficacy in models expressing CEA and/or MUC1.

Methods: *Salmonella* Typhi CVD911Δ*fliC* (pPagL-CEA/MUC1) was cultured in animal-free soytone media to produce IRZ-01 OMVs. OMVs were purified by tangential flow filtration and size-exclusion chromatography. Characterization included DLS (size), TRPS (zeta potential), cryo-EM (morphology), immuno-gold EM, and Western blotting for CEA/MUC1 surface display. Toll-like receptor (TLR) activation was tested using HEK-Blue™ cells expressing human TLR2, 3, 4, 5, 7, 8, or 9 (InvivoGen). Immunogenicity was evaluated in C57BL/6 mice given two doses of IRZ-01 (0.25 µg IV or 2 µg IM, days 0 and 7) or 5×10^9 CFU live bacteria; controls received PBS. Serum IgG was quantified by ELISA (days -1, 6, 20); T-cell responses assessed by IFN-γ ELISPOT on day 21 splenocytes. Antitumor efficacy was assessed in MC38-CEA and MC38-MUC1 syngeneic models by monitoring tumor growth post-challenge with IRZ-01.

Results: Purified IRZ-01 OMVs were 90-100 nm, zeta potential -13.9 mV, with confirmed CEA/MUC1 surface expression by Western blot and immuno-gold EM. IRZ-01 selectively activated TLR2 and TLR4, confirming self-adjuvanting properties due to native microbe-associated molecular patterns (MAMPs) naturally present in their outer membrane.Vaccination elicited rapid, high-titer antigen-specific IgG by day 6, strongly boosted after the second dose, with comparable responses via IV or IM routes and similar to the live vector. IFN-γ ELISPOT showed significant ($p<0.05$ vs PBS) CEA- and MUC1-specific T-cell responses that correlated closely with antibody levels.Encouraged by strong humoral and cellular responses, we conducted efficacy studies using a syngeneic C57BL/6 mouse model implanted with MC38-CEA and MC38-MUC1 cells, IRZ-01 induced marked tumor growth inhibition; volumes receded shortly after treatment and remained significantly lower than untreated PBS control groups for all
experimental groups. Survival data demonstrated >90% survival in groups treated with IRZ-01 regardless of tumor line.

Conclusion: IRZ-01 is a potent, self-adjuvanted OMV vaccine that induces robust CEA/MUC1-specific humoral and cellular immunity and delivers strong single-agent efficacy in syngeneic tumor models.

#4381 Combination therapy with a HIF-1α/c-MET peptide vaccine and carboplatin reprograms the tumor microenvironment to overcome platinum resistance in an intraperitoneal metastasis model of high-grade serous ovarian carcinoma.

Soon Young Lim, JinHwa Hong, DongGeRaMi Moon, Hyeyeon Roh, Ju Won Kim, Ji Won Lee, Kyong Hwa Park

Korea University, Seoul, Korea, Republic of

Ovarian cancer is the most lethal gynecologic malignancy, with most patients diagnosed atadvanced stages (III-IV). Although initially responsive to platinum-based chemotherapy, about60% of patients relapse within a few years due to acquired chemoresistance. Tumor hypoxiahas been implicated as a key driver of aggressive phenotypes and treatment resistance. Ourprevious study showed that a HIF-1α/c-MET-derived peptide vaccine combined with platinumcompounds elicited strong antitumor immunity in a mouse model of ovarian cancer. Here, weinvestigated whether type I immune activation could overcome platinum resistance in anaggressive intraperitoneal metastasis model in vivo. An intraperitoneal metastasis model was established in C57BL/6 mice using a murineplatinum-resistant ID8 ovarian cancer cell line. To evaluate antitumor effects, mice wereassigned to four groups: (1) control, (2) carboplatin, (3) HIF-1α/c-MET vaccine, and (4)combination of carboplatin and vaccine. The vaccine was administered subcutaneously threetimes at one-week intervals prior to tumor inoculation, and carboplatin was administered oneweek after tumor inoculation. Tumor progression and metastatic burden were monitored usingan in vivo imaging system (IVIS). Ascites formation was quantified by measuring abdominalcircumference. Immunohistochemistry (IHC) was used to assess HIF-1α and c-METexpression, intratumoral $CD8^+$/ $CD4^+$ T-cell ratios, and M1/M2 macrophage ratios in the peritoneum. Both monotherapies with either carboplatin or vaccine significantly inhibited intraperitonealmetastasis compared with the control. Furthermore, the combination therapy showedsignificantly better suppression of intraperitoneal metastasis than either monotherapy. Ascitesformation was markedly decreased in both monotherapy groups compared with the control,and it was further decreased in the combination group. IHC revealed that carboplatin aloneincreased HIF-1α and c-MET expression, suggesting activation of tumor-promoting signals,while the vaccine—alone or combined—suppressed expression of these markers. Bothtreatments enhanced intratumoral $CD8^+$ T-cell infiltration and improved the $CD8^+$/ $CD4^+$ ratio($p < 0.0001$) as well as the M1/M2 macrophage ratio ($p < 0.0001$), with the combination therapyshowing the significant effect. These results suggest that immunotherapy with a combination of HIF-1α/c-MET peptidevaccine with carboplatin reversed the tumor hypoxia induced by carboplatin alone andreprogramed the tumor microenvironment toward immune activation, offering a promisingimmunotherapeutic strategy to overcome platinum resistance and prevent recurrence in ovariancancer.

#4382 Bridging *in vitro* screening to *in vivo* efficacy for cancer vaccines.

Hongyan Sun, Jialu Fan, Yujing Zhang, Yunlong Jiang, Huixin Yang, Xiang Gao

GemPharmatech Co., Ltd., Nanjing, China

mRNA cancer vaccines represent a next-generation immunotherapy platform with the potential to elicit robust, antigen specific immune responses. Upon in vivo delivery, mRNA vaccines are taken up by antigen-presenting cells (APCs), translated into the tumor associated antigen and presented via MHC molecules to activate adaptive immunity. However, standard mouse models with murine MHC molecules are not suitable for evaluating these MHC-restricted immune responses. GemPharmatech has developed an in vitro and in vivo mRNA vaccine drug evaluation service platform, including the in vitro and in vivo immunogenicity evaluation, in vivo anti-tumor efficacy and safety evaluation. For in vitro immunogenicity, dendritic cells derived from autologous monocytes (moDCs) are matured and loaded with specific antigen peptides using electroporation or administered with LNP-mRNA. The peptide-pulsed moDCs are then co-cultured with T cells from the same donor. The antigen-specific T-cell response is detected by ELISpot or flow cytometry. In vitro immunogenicity evaluation is applicable to early antigen peptide screening, assessing the affinity of antigen peptides for corresponding HLA molecules and their immunostimulatory capacity. For in vivo evaluation of cancer vaccine, GemPharmatech has developed a series of HLA-humanized mouse models across multiple mouse backgrounds including the immunocompetent mice B6, BALB/c, CB6F1 and the immunodeficient NCG derived mice. These models express human HLA molecules, enabling the accurate evaluation of antigen presentation, immunogenicity, and therapeutic efficacy of mRNA vaccines. The HLA-humanized mice exhibit strain-dependent humoral and cellular immune responses, satisfying various evaluation needs. HLA humanized mice exhibited strain specific humoral and cellular immune responses, but are sufficient to satisfy various evaluation needs. CB6F1 exhibited good combination of humoral and cellular immune response to the same immunogen, making them more suitable for assessing vaccine immunogenicity. In NCG-M-hHLA-A2.1 mice engrafted with hematopoietic stem cells, HLA-A2.1-restricted immune responses were observed, reflecting successful reconstitution of human DCs and functional T cells. Therapeutic studies using TA-1 (mRNA vaccine) or anti-PD1 in a patient derived xenograft (PDX) demonstrated that TA-1 or anti-PD-1 inhibited tumor growth, while combination therapy led to greater tumor inhibition. In conclusion, GemPharmatech has established a comprehensive vaccine evaluation platform that integrates in vitro screening with in vivo models to provide more options for preclinical evaluation of tumor vaccines.

#4383 Utilization of HBV-vaccinated immunity to suppress tumor progression via targeted delivery of HBsAg to CEA-positive colorectal cancer.

Chun-Chia Cheng[1], Zong-Lin Sie[1], Yung-Chin Hsiao[1], Ai-Sheng Ho[2], Chih-Liang Wang[3], Cheng-Liang Peng[4], Chun-I Wang[5], Hong-Zen Yeh[6], Jungshan Chang[7], Chun-Chao Chang[8]

[1]Chang Gung University, Taoyuan, Taiwan,[2]Cheng Hsin General Hospital, Taipei, Taiwan,[3]Chang Gung Memorial Hospital, Taoyuan, Taiwan,[4]National Atomic Research Institute, Taoyuan, Taiwan,[5]China Medical University, Taichung, Taiwan,[6]Taichung Metro Harbor Hospital, Taichung, Taiwan,[7]Taipei Medical University, Taipei, Taiwan,[8]Taipei Medical University Hospital, Taipei, Taiwan

Limited antigen recognition hampers the anti-tumor efficacy of $CD8^+$ T cells. We hypothesized that vaccinated immunity against hepatitis B virus (HBV) in individuals could be harnessed to target hepatitis B surface antigen (HBsAg)-expressed tumor cells, thereby suppressing tumor progression. We aimed to validate the proposed concept and to develop a tumor-targeting agent that delivers HBsAg to colorectal tumor cells via carcinoembryonic antigen (CEA)-targeted antibodies. We generated HBsAg-overexpressed CT26 colorectal tumor cells and utilized HBV-vaccinated BALB/c mice to evaluate the proposed concept. A fusion protein comprising a fragment of HBsAg (fHBs, amino acids 103-170) and a single-chain variable fragment (scFv) against CEACAM5 (CEA), linked to a Fc domain (fHBs-T84scFv-Fc), was constructed to deliver HBsAg into tumor cells for immune recognition and tumor suppression. We found that HBV-vaccinated mice exhibited strong anti-HBsAg responses and significantly suppressed HBsAg-overexpressed CT26 tumor growth, accompanied by increased $CD3^+$ and $CD8^+$ T cell infiltration in tumor tissues. CEACAM5 was identified as a colorectal tumor-specific receptor exhibiting internalization. We consequently demonstrated that the created anti-tumor reagent fHBs-T84scFv-Fc effectively bound tumor cells and inhibited growth of CEACAM5-positive MC38 tumors in the HBV-vaccinated mice. Meanwhile, enhanced infiltration of $CD3^+$ and $CD8^+$ T cells was observed in the tumor tissues under fHBs-T84scFv-Fc treatment. We demonstrated a novel strategy by utilizing HBV-vaccinated immunity for colorectal tumor suppression via CEA-targeted HBsAg delivery. This study suggests that the anti-HBV immunity containing anti-HBsAg $CD8^+$ T cells can be utilized to suppress a range of tumors using HBsAg-antibody conjugates by targeting the tumor-specific internalizing receptors.

#4384 Advancing novel vaccines: Preclinical evaluation in HLA-A2.1/HLA-DRB1*1.1 humanized mice.

Dana Emerson, Zhenlan Niu, Shuaiqiang Zhang, Xiaofei Zhou

Biocytogen, Waltham, MA, MA

The human leukocyte antigen (HLA) system plays a central role in orchestrating adaptive immune responses. While existing single-allele humanized models have been valuable, there is a growing need for preclinical platforms that more fully recapitulate human HLA class I and II restricted immunity to evaluate complex immunotherapies. To address this, we developed a novel MHC I/II dual-humanized mouse model, the B-HLA-A2.1/HLA-DRB1*1.1 mouse.The B-HLA-A2.1/HLA-DRB1*1.1 model was generated by co-integrating the human HLA-A02:01 and HLA-DRB1*01:01 genes into the C57BL/6 background. Human HLA-A2.1 and HLA-DRB1 protein expression was confirmed by flow cytometry on spleen, peripheral blood, and bone marrow leukocytes. Comprehensive immune cell profiling was performed to characterize T and B cell populations. The model's functionality was validated in a therapeutic tumor vaccination study using a human epitope-targeting vaccine.Flow cytometric analysis confirmed stable and robust cell surface expression of both HLA-A2.1 and HLA-DRB1 proteins in homozygous mice. The frequency of CD8+ T cells in the spleen, blood, and lymph node was significantly decreased, while the frequency of CD4+ T cells was significantly increased, demonstrating that the introduction of HLA-A02:01 and HLA-DRB1*01:01 affected the development of T cells. Additional analyses, including hematology, serum biochemistry, and histopathological examination (H&E staining) of major organs, indicated no spontaneous pathology, confirming the overall health and physiological stability of the model. In a vaccine efficacy study, immunization with a human antigen-specific vaccine significantly inhibited tumor growth in the dual-humanized mice compared to controls, demonstrating the model's capability to mount a functional HLA-restricted immune response.We have successfully developed and preliminarily validated the novel B-HLA-A2.1/HLA-DRB1*1.1 dual-humanized mouse model. It represents a powerful and physiologically relevant preclinical tool for investigating combination immunotherapies, including vaccines and immune checkpoint inhibitors, and for studying anti-tumor and infectious disease immunity within a more complete human-like context.

#4385 Engineering durable tumor immunity with a virus-tumor hybrid antigen dendritic cell vaccine.

Jin Muk Kang[1], Eun Hyang Han[2], Jin-kyu Choi[3], Seunghee Youm[2], Tej Pareek[3], Seong-Jin Kim[4], John Letterio[1], **Seunghwan Lim**[3]

[1]University Hospitals, Angie Fowler Adolecent and Young Adult Institute, Cleveland, OH,[2]Case Western Reserve University, School of Medicine, Cleveland, OH,[3]Celloram Inc., Cleveland, OH,[4]MedPacto Inc., Seoul, Korea, Republic of

Introduction: Dendritic cell (DC)-based cancer vaccines have shown limited efficacy in clinical trials, a result that has been partly attributed to poorly immunogenic tumor antigens that fail to induce robust MHC class-II directed CD4+ T cell help. CD4+ T cells 'license' DCs to upregulate key costimulatory molecules (e.g. CD80/86) and cytokines (IL-12) that are essential for the generation of effective, long-lived tumor-directed CD8+ T cells. However, therapeutic approaches that effectively harness both T-cell subsets have been constrained by difficulties in identifying $CD4^+$ T-cell-specific cancer neoepitopes. Here, we introduce , a novel DC-based cancer vaccine platform designed to co-present non-tumor-related $CD4^+$ T helper epitopes from the SARS-CoV-2 Spike protein alongside tumor-specific $CD8^+$ T-cell epitopes derived from tumor-associated antigens (TAAs), leveraging widespread Covid-19 immunity in the context of a cancer vaccine.

Methods: In proof-of-concept studies, PROTEXI was generated by simultaneously loading mature bone marrow-derived DCs (BMDCs) with pMHC-II-$OVA^{323-339}$ and pMHC-I-$Trp2^{180-188}$ complexes. To model the prevalence of SARS-CoV-2 Spike-specific $CD4^+$ T-cell memory, mice were either primed with DC-OVA^{323} or received adoptive transfer of OT-II $CD4^+$ T cells prior to tumor challenge, followed by PROTEXI treatment (weekly for 2 weeks) or PROTEXI in combination with immune modulating agents. The therapeutic potential of PROTEXI in a human immune context was evaluated in humanized mice reconstituted with blood from COVID-19-vaccinated donors. The human version, PROTEXI-Spike/TAA, was designed to co-present $CD4^+$ T-cell-restricted Spike epitopes together with $CD8^+$ T-cell-restricted PRAME and MAGE-A3 antigens.

Results: PROTEXI significantly improved survival and reduced tumor growth, correlating with enhanced T-cell infiltration into immune-cold tumors and induction of gene signatures associated with T-cell cytotoxicity, migration, and memory formation. Combination therapy with either anti-PD-1 immune checkpoint blockade or the ALK5 (TGF-β type I receptor) inhibitor Vactosertib further augmented therapeutic efficacy in therapy-resistant tumor models. Importantly, tumor-specific cytotoxic T-cell memory derived from PROTEXI mice was sufficient to mediate complete tumor rejection upon re-challenge. In humanized models, PROTEXI-Spike/TAA markedly expanded antigen-specific $CD8^+$ T-cell populations and reduced tumor burden, demonstrating translational feasibility and potency.

Conclusion: Collectively, these findings highlight the clinical potential of PROTEXI as an innovative DC vaccine platform that leverages the widespread prevalence of Spike-specific $CD4^+$ T-cell immunity to enhance cancer vaccine efficacy—offering a promising therapeutic strategy for patients with advanced, immune-cold tumors.

#4386 Expanding the therapeutic potential of Bvax: A B-cell-based vaccine for solid tumors.

Hanxiao Wan[1], Joshua L. Katz[1], **Yotam D. Hahn**[1], Si Wang[1], Grace V. Jones[1], Alina R. Murphy[1], Rebecca Du[1], Jeffrey Bacha[2], Roger Stupp[3], Catalina Lee-Chang[3]

[1]Department of Neurological Surgery, Northwestern Univ. Feinberg School of Medicine, Chicago, IL,[2]Sera Biopharma Inc, Chicago, IL,[3]Lou and Jean Malnati Brain Tumor Institute, Robert H. Lurie Comprehensive Cancer Center, Northwestern Univ. Feinberg School of Medicine, Chicago, IL

Glioblastoma (GBM) presents a major clinical challenge due to its highly invasive nature and resistance to treatment. We previously developed Bvax, a novel B-cell-based cancer therapy. In preclinical models of GBM, Bvax elicited robust antitumor immunity by enriching a subpopulation of CD8+ T cells characterized by high TCF1 and low PD-1 expression. Additionally, Bvax differentiated into plasma cells that secreted antibodies targeting tumor-associated proteins involved in motility and matrix remodeling, suggesting the disruption of tumor progression and enhanced immune infiltration. A first-in-human (FIH) Phase I clinical trial at Northwestern University evaluates the safety and feasibility of Bvax in patients with newly diagnosed GBM. Given the encouraging preclinical results in GBM, we explored therapeutic potential of Bvax for other solid tumors, namely lung and prostate cancer. This study aims to characterize the effects of Bvax on tumor growth, survival, and the preferential migration of Bvax in these new models. To assess Bvax in a lung cancer model, we utilized an orthotopic KP (Kras/p53 mutated) lung tumor model that recapitulates KRAS-driven non-small cell lung cancer (NSCLC). Bvax treatment resulted in a marked survival extension (median 39 vs. 17 days) in tumor bearing mice compared to controls (Wilcoxon $p = 0.046$). To further assess biodistribution, we used B cell knockout (muMt) mice and observed enriched Bvax infiltration within the tumor, confirming strong tumor tropism within the lung microenvironment. We next evaluated Bvax in a subcutaneous prostate tumor model known for immune exclusion and poor immunotherapy responsiveness. Twenty one days after tumor induction, Bvax was administered and tumor volumes were measured regularly until they reached the defined size endpoint. At peak treatment response, tumor volumes were reduced by 68% relative to controls, accompanied by a higher percentage of MHC-II tumor-infiltrating B cells. These results suggest Bvax retains efficacy across several tumor types with restricted immune infiltration. Ongoing work is now evaluating Bvax in combination with standard-of-care regimens across both tumor models to determine whether its therapeutic activity can be enhanced. In parallel, we are performing immunophenotyping analyses to define how Bvax reshapes the immune landscape within the tumor and surrounding tissue, and better quantify Bvax infiltration across tumor compartments. Additionally, to support translational relevance, we are extending these investigations into patient-derived samples to assess Bvax function in human disease contexts.

#4387 A clinical-adopted vaccine platform and new immunogenic epitopes combined against prostate cancer.

Elisa Marmocchi[1], Rubens Begaj[1], Marta Cantarelli[1], Davide Bressan[1], Nicole Annesi[1], Martina Cortese[1], Mattia Barbareschi[2], Giovanni Bertalot[2], Francesco Giuseppe Carbone[2], Alessandro Alaimo[1], Marianna Kruithof-de Julio[3], Nicola Ternette[4], Ugo Ala[5], Fulvio Chiacchiera[1], Guido Grandi[1], Andrea Lunardi[1]

[1]CIBIO, University of Trento, Trento, Italy,[2]Pathological Anatomy Unit, Santa Chiara Hospital-APSS, Trento, Italy,[3]University Hospital of Bern, Bern, Switzerland,[4]University of Dundee, Dundee, United Kingdom,[5]Department of Veterinary Sciences, University of Turin, Turin, Italy

Introduction: Prostate cancer (PCa) is the archetype of an immunological “cold” tumour, characterised by a very low mutational burden and neoantigen presentation, and minimal immune infiltration. In line with this, immune therapies turn out to be ineffective in PCa. The project aims at transforming PCa into an immunocompetent tumour through the development of *ad hoc* vaccinal strategies.
Methods and Results: Recruiting adaptive immune cells into the prostate gland: The efficacy of a versatile clinical-adopted vaccine platform (X) to attract the immune system into the prostate tumour is under study in mouse model of advanced PCa. Immunohistochemistry on formalin-fixed paraffin-embedded (FFPE) slides of PCa allografts is defining the tumour microenvironment (TME) composition. $Cd8^+$ T-cells infiltrate PCa tumours, while $Cd4^+$ T-cells and $FoxP3^+$ regulatory T-cells preferentially accumulate in the periphery. A dense network of Collagen VI fibrils might be responsible for the different distribution. Intratumoral injection of X adjuvants does not change T cells behaviour, but it stimulates the formation of tumour abscesses surrounded by tightly packed neutrophils. Identifying immunogenic antigens to instruct effector T cells against PCa: Non-canonical human leukocyte antigen (HLA)-restricted PCa antigens are caught among peptides coming from aberrant splicing events, expression of transposable elements and atypical expression of tissue/development-restricted genes thanks to the integration of in-depth RNA Seq transcriptome with mass spectrometry HLA-I epitome analyses.
Conclusions: We expect that the ability to attract the immune system into the prostate combined with the identification of immunogenic epitopes, will pave the way for the development of tailored and affordable vaccine therapies for the effective treatment of advanced PCa.

#4388 Inducing memory humoral responses using multiple vaccines in PBMC humanized mice.

Destanie Rose, Ilian Radichev, Beau Parry, Leandro Salati D'Abronzo, Zahid Delwar, Jiwon Yang, Li-Chin Yao, James G. Keck

The Jackson Laboratory-West, Sacramento, CA

Humanized mouse models, such as those generated by administering human peripheral blood mononuclear cells (PBMC) into immunodeficient mice, hold great potential for studying immunotherapies and the immunogenicity of biologics and vaccines. Humanized mice are known for their quick engraftment of human cells, strong functional T-cell responses and for their capacity to assess donor-specific responses in vivo. However, these models face several limitations, including partial reconstitution of the human immune system, inadequate human cytokine support, and development of graft-versus-host disease (GvHD). To help address these issues we have developed new immunodeficient mouse strains and here show the potential of hPBMC mice to elicit humoral responses against various antigens. We engrafted human PBMC into NSG-SGM3xIL-15xDKO strain (JAX# 037320) followed by vaccination with formulated vaccines (Tdap, COVID-19 mRNA, or H5N1) or with antigen with or without adjuvant. Elevated levels of human IgG specific for tetanus toxoid, diphtheria, SARS-CoV-2 spike, or H5N1 were found in vaccinated animals compared to unvaccinated controls. Moreover, we also see an increase in total numbers of CD19+ B cells, activated B cells (CD38+) and CD138+ human plasma cells. These findings demonstrate that PBMC humanized mice provide a promising platform for evaluating humoral immunity.

#4389 Establishing a CTC-driven workflow for mRNA-transfected moDC production in personalized cancer immunotherapy.

Giovanna Manga Guimaraes[1], Nadia Bayou[1], Mara Serena Serafini[1], Eleonora Nicolo[1], Letizia Pontolillo[1], Brenno Pasto[1], Nassima Messali[1], Kiran Sahu[1], Paraskevi Giannakakou[1], Gabriela Coeli Menezes Evangelista[2], Olivier Elemento[3], Carolina Reduzzi[1], Jose Alexandre Barbuto[2], Massimo Cristofanilli[1]

[1]Department of Medicine, Weill Cornell Medicine, New York, NY,[2]Biomedical Sciences Institute, University of Sao Paulo, Sao Paulo, Brazil,[3]Systems and Computational Biomedicine, Weill Cornell Medicine, New York, NY

Background: After its success during SARS-CoV-2 pandemic, RNA-based vaccines are now being explored for cancer therapy. One of the strategies is the use of monocyte-derived dendritic cells (moDCs) transfected with tumor mRNA, but access to tumor tissue - especially from metastatic sites - is a limitation. Circulating tumor cells (CTCs) offer an alternative source for tumor material. Here, we developed a workflow integrating CTCs and mRNA technology for personalized cancer therapy.
Methods: Our first aim was to compare the recovery rate (RR) of 3 different CTCs isolation platforms (Parsortix [P], RosetteSep [RS], or ScreenCell [SC]) by spiking fluorescently-labeled breast cancer SKBR3 cells (200, 50, 30; triplicate) into healthy donor (HD) blood and counting the number of recovered CTCs using the Incucyte System. In parallel, moDCs were differentiated from HD monocytes and transfected with 500 ng of GFP-mRNA using Lipofectamine™ MessengerMax™ (LMM) to standardize conditions for CTC-mRNA transfection. GFP expression was assessed at 6, 24, 48, 72, and 96h by confocal microscopy, with non-transfected and mock-transfected moDCs as controls.
Results: Spiking tests showed that P and SC had similar performance and higher RR compared to RS, which yielded the lowest RR (Table 1). Regarding moDCs transfection, GFP expression was detectable at 6h, persisted through 24-48h and declined after 72h, with no signal in the controls. These conditions are currently being tested on SKBR3 cells recovered with SC, to assess the possibility to transfect moDCs with CTC-derived mRNA.
Conclusion: SC and P showed similar RR, but SC's simplicity and lower cost make it more suitable for deployment with our collaborators in Brazil. moDCs transfection was effective and LMM successfully delivered the target sequences for moDC processing and expression, supporting this as an immunotherapeutic approach. Future studies will be performed to validate the workflow also in clinical samples.

Recovery rates (RR) of each enrichment platform

#4393 Development of an anti-CD171 (L1CAM) antibody-drug conjugate with high avidity and strong activity in resistant tumor models.

Kyoung-Ho Pyo[1], Hee Su Chae[2], Seong-Hyun Park[1], Younggeun Lee[1], Hojin Yeom[1], Sowon Aum[1], Sun Hee Park[1], Huijo Oh[1], Cheyeon Kim[1], Mi Jin Yoo[2], Min-Jung Shin[2], Hyo Jeong Hong[2], Jong-Soo Kang[2], Ju Hwan Kim[1], Seon-Joo Yoon[2], Taedong Han[1]

[1]AbTis Co., Ltd, Yongin, Korea, Republic of,[2]APITBIO, Inc., Seoul, Korea, Republic of

Background: CD171 (L1CAM) is a cell-adhesion molecule implicated in epithelial-mesenchymal transition (EMT), receptor tyrosine kinase (RTK) activation, and neuroendocrine differentiation across various solid tumors. Spatial transcriptomic profiling of lung and colorectal cancers revealed enrichment of CD171 in EMT- and neuroendocrine-like tumor microenvironments (TMEs), suggesting its involvement in metastasis and therapeutic resistance. Ab612 is a novel anti-CD171 monoclonal antibody developed by APITBIO that demonstrates a favorable developability profile. GLP toxicology studies and GMP manufacturing of Ab612 were completed, providing a robust foundation and enabling accelerated ADC development.
Methods: We characterized Ab612 to evaluate its biochemical stability, binding kinetics, internalization, and antitumor efficacy. Comparative analyses were performed against a benchmarking anti-CD171 antibody. Binding affinity and avidity were measured under both physiological and acidic conditions using surface plasmon resonance (SPR) and flow cytometry, while internalization efficiency was assessed via live-cell imaging. Ab612 was conjugated to MMAE (DAR2) and Exatecan (DAR4) using AbTis's proprietary linker, Abclick® Pro, designed to preserve antibody-FcRn interaction, and thereby support extended half-life. These ADCs were evaluated for *in vivo* efficacy in trastuzumab-resistant breast (JIMT-1) and TKI-resistant lung (Calu-6) xenograft models.
Results: Ab612 maintained strong binding under acidic conditions and demonstrated approximately four-fold higher kinetic affinity relative to internal reference values in SPR assays. In CD171-high ovarian (SNU-840) and breast (JIMT-1) cancer cells, flow cytometry analyses showed 22-23% higher avidity, and live-cell imaging confirmed more than 15% increase in internalization efficiency. Ab612-Abclick® Pro-MMAE and Ab612-Abclick® Pro-Exatecan demonstrated high stability in human plasma. *In vivo*, Ab612-Abclick® Pro-MMAE achieved near-complete tumor regression at ≥3 mpk (minimum effective dose = 3 mpk) and 100% complete responses at 10 mpk in JIMT-1 xenografts without body-weight loss. Ab612-Abclick® Pro-Exatecan induced >100% tumor-growth inhibition in KRAS/TP53-mutant, TKI-resistant Calu-6 models with favorable tolerability.
Conclusion: Ab612-ADCs,generated by conjugation of MMAE or Exatecan to the anti-CD171 monoclonal antibody Ab612 with the high-affinity binding within acidic TMEs using the Abclick® Pro linker, demonstrated highly potent preclinical antitumor efficacy at low effective doses. These findings highlight Ab612-ADCs as a promising therapeutic candidate for CD171-expressing refractory solid tumors characterized by EMT and neuroendocrine phenotypes, offering a potential strategy to overcome resistance in aggressive cancer subtypes.

#4395 A best-in-class HER2xHER2 novel biparatopic antibody-drug conjugate with an efficacious, low-toxicity design that maximizes antibody functionality.

Ge Song, Yushi Chi, Xiansong Xiong, Rui Liu, Xiaoling Yuan, Wan-Jen Yang, Wanli Zhang, Xinwei Wang, Boqi Gu, Qian Zou, Peng Huang, Kuichao Qu, Haixiang Yu, Futang Yang, Qingyu Wang, Chen Hu, Jijun Yuan

Shanghai Henlius Biotech, Inc., Shanghai, China

Introduction: HLX22 is a novel anti-HER2 antibody that binds to a unique site on HER2 subdomain IV, different from trastuzumab. When combined with HLX02 (a trastuzumab biosimilar), HLX22 increases internalization of HER2 homodimers and HER2/EGFR heterodimers, reducing cell proliferation signals. This combination shows stronger antitumor effects than HLX02 plus HLX11 (a pertuzumab biosimilar) both *in vitro* and *in vivo*. Based on the binding sites of HLX22 and HLX02, we developed a biparatopic antibody-drug conjugate (ADC) with an effective, low-toxicity payload, allowing higher dosing and better receptor coverage for improved tumor cell killing.
Methods: Cytotoxicity of HER2xHER2 biparatopic ADC was assessed using the CellTiter-Glo (CTG) assay in tumor cell lines. ADC binding and internalization were evaluated by flow cytometry in cells with varying HER2 expression levels. Pharmacokinetics (PK) of the HER2xHER2 biparatopic ADC were characterized in rats following a single intravenous 5 mg/kg dose. Bystander killing was quantified by co-incubating antigen-positive and -negative (Jurkat) cells, measuring Jurkat viability via the CTG assay. *In vivo* efficacy of HER2xHER2 biparatopic ADC was evaluated in multiple xenograft models (JIMT-1, BT-474 and patient-derive xenografts). Preliminary toxicology in cynomolgus monkeys was assessed at 60 mg/kg, administered every three weeks for three cycles.
Results: The HER2xHER2 biparatopic ADC demonstrated superior internalization efficiency than KN026 (a HER2-targeted bispecific antibody) and trastuzumab deruxtecan in BT474 and NCI-N87 cell lines. The biparatopic ADC showed better anti-tumor efficacy than trastuzumab deruxtecan across multiple cell lines. The ADC induced significant tumor regression at a single 6 mg/kg dose in various xenograft models outperforming trastuzumab deruxtecan head-to-head, including HER2-positive (immunohistochemistry [IHC] 3+, IHC2+ and fluorescence in situ hybridization [FISH]+), HER2-low (IHC2+/FISH- or IHC 1+), and HER2-Ultra low (IHC<1+) models. Preliminary toxicology shows good tolerability in cynomolgus monkeys following 3 doses of the ADC at 60 mg/kg.
Conclusion: We have developed a potential best-in-class HER2xHER2 novel biparatopic ADC that exhibits a superior therapeutic index, antibody-mediated signaling blockade. The preclinical findings support clinical development in breast and gastric cancers, with the hope that the improved therapeutic index of this agent confers survival benefit.

#4396 Selective intratumoral distribution and post-T-DXd activity of K-679, an ultra-high-DAR EGFR-targeted antibody drug-loaded unimicelle conjugate (ADUC).

Hideo Yoshida, Hideyuki Higashi, Masato Mori, Kahori Hosono, Nobuhiro Fujimaki

Kowa Company, Ltd., Tokyo, Japan

Background: K-679 is a compact, 20-nm EGFR-targeted antibody drug-loaded unimicelle (unimer-micelle) conjugate (ADUC) utilizing single-chain polymer nanoparticles that carry DM1 at an ultra-high-drug-to-antibody ratio (DAR, ~50) while maintaining colloidal stability at low antibody mass. This design aims to enhance intratumoral penetration and tumor-selective payload exposure even when antigen density is low and/or heterogeneous. While antibody-drug conjugates (ADCs) have improved cancer therapy, there remains an unmet need for patients progressing after ADC treatment, particularly following trastuzumab deruxtecan (T-DXd). We investigated whether the ADUC design of K-679 enables tumor-selective pharmacokinetics (PK), extensive intratumoral distribution, spatial pharmacodynamics, and activity following prior T-DXd treatment.
Methods: K-679 versus a benchmark ADC (cetuximab-DM1 ADC, cleavable disulfide linker, DAR ~4.5) was evaluated in head-to-head comparisons using EGFR-expressing CDX (HT-29, SK-OV-3, SK-CO-1 [KRAS G13V]) evaluated at DM1-equivalent dosing. Total DM1 (all species, measured after deconjugation) and free DM1 levels in tumor and plasma were quantified by LC-MS/MS. At 48 h, tumor sections were immunostained for human IgG (to map conjugate distribution), CD31 (microvasculature), pHH3 (mitotic arrest), and cleaved PARP (apoptosis). In HT-29 colorectal CDX with HER2-low/EGFR-low expression, animals received T-DXd, then on Day 18 were switched to K-679 or repeat T-DXd for 3 weeks. A parallel arm received K-679 on Day 0 and Day 18. Colorectal PDX harboring KRAS G13D (EGFR IHC score 1+, patchy) were also evaluated.
Results: Across CDX models at DM1-equivalent dosing, K-679 delivered 12.7-13.7-fold higher intratumoral total DM1 and 2.3-3.5-fold higher intratumoral free DM1 while reducing plasma free DM1 by 4.2-8.4-fold versus the benchmark ADC, indicating tumor-selective payload release with reduced systemic deconjugation. At 48 h, K-679's IgG signal exceeded benchmark ADC despite at least an 11-fold lower antibody mass and extended into regions distant from CD31-positive vessels; pHH3 and cleaved PARP increased across the tumor, indicating mitotic arrest/apoptosis. After prior T-DXd in HT-29 xenografts, K-679 induced robust tumor regressions, whereas repeat T-DXd did not. Consistently, two K-679 doses induced complete regressions (6/6) by Day 22, sustained to Day 39. In EGFR-low and heterogeneous colorectal PDX, a single K-679 dose inhibited tumor growth over 3 weeks.
Conclusions: The ultra-high-DAR ADUC design of K-679 confers tumor-selective PK, extensive intratumoral distribution, concordant spatial pharmacodynamics, and activity after prior T-DXd. These data support clinical development for EGFR-expressing solid tumors with low/heterogeneous antigen density and post-T-DXd settings.

#4397 Leveraging patient-derived organoids to investigate bystander effects of antibody-drug conjugates in solid tumor backgrounds.

Oksana Sirenko, **Nikki Carter**

Molecular Devices, LLC (Moldev), San Jose, CA

Background: Antibody-drug conjugates (ADCs) have demonstrated significant clinical benefit, yet their efficacy can be influenced by heterogeneous target expression and bystander killing. Understanding these dynamics in physiologically relevant models is critical for optimizing ADC design and patient selection.
Methods: We established and expanded patient-derived organoids (PDOs) from solid tumor backgrounds using our automated CX.ai platform, enabling high-throughput and standardized culture conditions. Target abundance for HER2 and c-MET was assessed via immunohistochemistry (IHC). Co-culture systems were optimized to include disease and healthy PDOs at defined ratios. Experimental assays incorporated mosaic PDO populations treated with ADCs (trastuzumab deruxtecan, telisotuzumab adizutecan, ADCs) and controls (antibody alone, warhead alone). Readouts included live-cell imaging, fixed-cell labelling, and high-content analysis to quantify PDO shrinkage, cell death, and target expression.
Results: Preliminary data indicate feasibility of generating mosaic PDO systems and detecting differential responses to ADCs. Optimization of co-culture conditions and imaging-based metrics (nuclear count reduction, PDO object shrinkage) are underway to correlate target expression heterogeneity with bystander killing.
Conclusions: PDO-based platforms combined with automated culture and advanced image analysis provide a robust system to study ADC bystander effects in heterogeneous tumor contexts. These findings will inform ADC development strategies and biomarker-driven patient selection.

#4398 Developing 3D cell models for high-throughput antibody-drug conjugate screening in cancer.

Peilin Tian[1], **Morgan Hamon**[2], Sean Porazinski[2], Maria Kavallaris[3], Kristopher A. Kilian[1], Justin Gooding[1]

[1]School of Chemistry, UNSW, Sydney, Australia,[2]Inventia Life Science, Alexandria, Australia,[3]Children's Cancer Institute, Lowy Cancer Research Centre, Sydney, Australia

Antibody-drug conjugates (ADCs) are a rapidly evolving class of biotherapeutics designed to deliver potent cytotoxic agents directly to cancer cells while minimizing systemic toxicity. ADCs offer this highly targeted approach by combining the selectivity of antibodies with the lethality of small-molecule drugs. However, their preclinical development still faces substantial challenges, including species-specific differences in antigen expression and antibody binding that complicate translational studies, often leading to discrepancies between preclinical efficacy and clinical outcomes. As a result, there is growing interest in developing more predictive preclinical models, including those that incorporate extracellular matrix (ECM) components into three-dimensional (3D) culture models which can help dissect how microenvironmental factors influence ADC target engagement. Such models provide a more physiologically relevant environment to assess ADC diffusion and payload delivery.

Using Inventia Life Science's RASTRUM^{TM} Allegro platform, we developed and validated the utility of high-throughput 3D bioprinted patient-derived colorectal cancer (CRC) models for the testing of a CEACAM5-targeted ADC in two CRC subtypes. These engineered hydrogel-based tumoroid models, using the Gibco^{TM} OncoPro^{TM} CRC Tumoroid Cell Lines (ThermoFisher Scientific), were tuned to mimic the stiffness and ECM composition of CRC tumors and maintained subtype-specific molecular and phenotypic features. This allowed comparisons of ADC efficacy versus standard-of-care chemotherapies and here we show clinically-relevant differential drug responses between subtypes, with the ADC demonstrating enhanced cytotoxicity over chemotherapy alone.

We also provide evidence for the ease of assessing target expression in situ by immunofluorescence imaging of models. Furthermore, the ability to test on-target cytotoxicity dependence was demonstrated by blocking target binding with anti-CEACAM5, which reduced ADC cytotoxicity in the sensitive tumoroid models.

This scalable and reproducible workflow is applicable across many cancer types, and bridges the gap between oversimplified in vitro assays and complex in vivo systems, offering more predictive insights into ADC performance by using models that incorporate physical and biochemical features relevant in patient tumors.

#4399 ANT045: A novel format, antibody fragment drug-conjugate (FDC) product for challenging cMET-expressing solid tumors.

Mahendra Deonarain, Bryan Edwards, Gokhan Yahioglu, Isabel Perez-Castro, Sam Ness, Anja Pomowski, Laura Bouche, Soraya Diez-Posada, Lowri Davies, Howard Desmond

Antikor Biopharma Ltd, Stevenage, United Kingdom

Antibody Fragment Drug Conjugates (FDCs), a new product class tailored for solid tumors promise many advantages over conventional ADCs including rapid tumor penetration and faster and safer systemic clearance. However, these formats have been technologically-challenging to apply in oncology. Our novel approach enables high-Drug:Antibody Ratios (DARs) whilst retaining effective binding and other favourable biophysical properties. To achieve this, single-chain Fvs and other recombinant antibody formats must be considered in context with complex linker-payload chemical moieties. In some cases, antibody surface charge needs to be manipulated to achieve high DARs. This platform technology has led to our lead product, ANT-045 is a cMET-targeted FDC addressing a wide range of solid tumors. ANT-045 demonstrates superior tumor cure efficacy in cMET high, moderate and low CDX and PDX gastric cancer xenograft models and better tolerability compared to the leading competitor ADCs, notably telisotuzumab vedotin. In a non-GLP, non-human primate study, ANT-045 was well tolerated with a predicted half-life in humans of around 12-14 hours supporting a viable clinical dosing strategy with a wide therapeutic window. Insights into how FDCs behave *in vivo* through quantitative uptake studies and toxicological parameters will be shared and how these have informed our follow-up products.

#4400 Degrader antibody conjugates (DACs) as a next-generation therapeutic approach for selective and potent targeted protein degradation in EGFR-positive cancers.

Jihye Lee[1], Soohyun Lee[1], Jiyoung Kim[1], Han Wool Kim[1], So Hyuk Kim[1], Onnuri Bae[2], Jeonghwa Han[2], Je Ho Ryu[2], **Song Hee Lee**[1]

[1]Ubix Therapeutics Co., Ltd., Seoul, Korea, Republic of,[2]Ubix Therapeutics Co., Ltd., Incheon, Korea, Republic of

Antibody Drug Conjugates (ADCs) have become an established therapeutic modality in oncology; however, challenges such as payload-associated systemic toxicity and the emergence of resistance to conventional cytotoxic payloads underscore the need for next-generation payload. Degrader Antibody Conjugates (DACs) have recently attracted attention as an alternative strategy that leverages targeted protein degradation rather than traditional toxin-mediated cytotoxicity. In this study, we synthesized a panel of DACs by generating diverse linker-payload (LP) designs engineered for targeted degradation and conjugating them to cetuximab. These DACs were evaluated across multiple cell lines for their degradation potency and anti-proliferative activity. In several EGFR-positive models, specific DAC constructs demonstrated significantly enhanced degradation efficiency relative to the corresponding free payloads, accompanied by improved inhibition of cellular proliferation. *In vivo* pharmacodynamic studies confirmed selective degradation of the target protein in EGFR-positive tissues, whereas no degradation was detected in EGFR-negative tissues, demonstrating the high specificity of the DAC mechanism. Overall, our findings show that our DAC platform exhibits potent on-target antitumor activity in relevant indications while minimizing off-target toxicity in non-expressing tissues. These results establish a proof-of-concept for DACs as a safer and mechanistically differentiated therapeutic approach warranting further development.

#4401 A novel antibody-drug conjugate targeting alkaline phosphatases ALPP and ALPPL2 in solid tumors.

Yujun Huang, Xiao Liang, Yajuan Xue

Hepius Therapeutics, Suzhou, China

Alkaline phosphatase placental (ALPP) and ALP-like 2 (ALPPL2) are highly expressed in a wide set of solid tumors, including ovarian, endometrial, gastric and non-small cell lung cancers. Their expression is highly restricted in normal tissues. ALPP/ALPPL2 are attractive targets for antibody-drug conjugate (ADC) and CAR-T therapies. HP-004 is a novel ADC targeting both ALPP and ALPPL2, with high selectivity and enhanced internalization efficiency. HP-004 specifically binds ALPP/ALPPL2 but not the related isozymes ALPI or ALPL, minimizing potential on-target off-tumor liability. In cellular internalization assays using ALPP/ALPPL2 high- and low-expressing tumor cells, HP-004 demonstrated higher uptake and an improved capacity to deliver cytotoxic payload intracellularly across a range of target expression levels. HP-004 is site-specifically conjugated with monomethyl auristatin E (MMAE) with an average DAR about 4. In vitro, HP-004 induced potent target-dependent cytotoxicity in ALPP/ALPPL2-overexpressing tumor cell lines, with an IC_{50} of approximately 248 pM. In the ALPP/ALPPL2-positive NCI-H1651 xenograft lung cancer model, HP-004 administration achieved near-complete tumor regression at 3 mg/kg (Q2W X4), with complete tumor regression in 6 of 8 mice, demonstrating a robust antitumor activity. HP-004 is further being evaluated in cell line- and patient-derived xenograft models with different expression levels of ALPP and ALPPL2. In parallel, bispecific ADC formats incorporating HP-004 are being explored to further enhance therapeutic index and extend activity to heterogeneous or low-antigen tumors. Collectively, our data support HP-004 as a highly selective ADC candidate with superior internalization, strong preclinical efficacy, and promising potential for translation in solid tumors expressing ALPP/ALPPL2.

#4402 EGFR and LGR5 dual-targeting antibody-drug conjugate-based therapeutic strategies for the improved treatment of colorectal cancer.

Peyton C. High, Zhengdong Liang, Maya Cappellino, Tiffani Blackburn, Cara Guernsey-Biddle, Shraddha Subramanian, Yueh-Ming Shyu, Adela Aldana, Yukimatsu Toh, Kendra S. Carmon

Institute of Molecular Medicine, UT Health Houston, Houston, TX

Colorectal cancer (CRC) remains the second-leading cause of cancer-associated death in the United States, indicating an urgent need for improved therapies. Antibody-drug conjugates (ADCs) are a promising class of therapeutics that function as “biological missiles,” employing the specificity of monoclonal antibodies to direct highly potent drug payloads to cancer cells while sparing normal tissues. We have developed ADCs targeting leucine-rich repeat-containing G-protein coupled receptor 5 (LGR5), a marker of normal adult intestinal stem cells and CRC stem-like cells with roles in CRC tumorigenesis, tumor progression, metastasis, and drug resistance. While LGR5-targeting ADCs incorporating microtubule inhibitors promoted tumor regression in select xenograft models and were well-tolerated, tumors eventually relapse following treatment cessation due to LGR5 downregulation and suboptimal ADC payload selection (Gong et al. 2016, *Molecular Cancer Therapeutics*). Thus, this work aims to investigate multi-targeting therapeutic strategies with improved LGR5-targeting ADCs to improve CRC care and prevent relapse. Our work showed that therapies targeting the epidermal growth factor receptor (EGFR), including cetuximab (CTX) which is approved for $KRAS^{WT}$metastatic CRC, increased LGR5 protein levels in CRC cell lines, tumor organoids, and mouse models independent of *KRAS* mutational status. To evaluate EGFR and LGR5 dual-targeting approaches, we generated a novel LGR5-targeting ADC incorporating a topoisomerase I inhibitor payload via site-specific conjugation that was well-tolerated in immunocompetent mice. Importantly, combination of CTX with LGR5-targeting ADCs significantly enhanced anti-tumor efficacy and extends survival as compared to ADC and CTX monotherapies in RAS^{MUT} CRC patient-derived xenografts (High et al. 2025, *Cell Reports Medicine*). Still, tumors eventually relapsed following combination treatment, warranting investigation into alternative dosing regimens and dual-targeting modalities. We have therefore generated two EGFR:LGR5 bispecific antibodies (bsAbs) that promote lysosome-mediated EGFR degradation. EGFR:LGR5 bsAbs demonstrated minimal cytotoxicity in CRC cells, necessitating drug conjugation to generate highly potent EGFR:LGR5 bispecific ADCs (bsADCs). Importantly, EGFR:LGR5 bsADCs exert 100- to 1000-fold enhanced potency over LGR5 ADCs with identical linker-payloads in LGR5/EGFR-expressing CRC cell lines of varying genetic backgrounds. These promising findings warrant further investigation into the anti-tumor efficacy of EGFR:LGR5 bsADC monotherapy versus combination therapy of CTX and LGR5 ADCs in CRC xenograft models. Taken together, this work strongly rationalizes dual-targeting of EGFR and LGR5 as an effective therapeutic option for CRC and other EGFR- and LGR5-expressing cancers.

#4403 A fast and robust development process providing new highly internalized anti-hHER2 antibody-drug conjugates.

Eric Chabrol, Marie-Claire Phelipot, Cecile Lemoigne, Julie Lichiere, Nadjiba Mares, Alice Aymard, Alexandre Bagnolini, Sophie Mesnard, Caroline Huber, Matthieu Tassa, Ester Morgado, **Jacques Fieschi**

Mimabs, Marseille, France

Purpose: The aim of this study was to establish an accelerated and de-risked workflow for the generation of potent anti-hHER2 antibody-drug conjugates (ADCs), addressing key bottlenecks that currently limit the efficiency, predictability, and overall success rate of ADC discovery.
Methods: We implemented a fully integrated four-step strategy. (1) A multisite immunization protocol was developed to rapidly induce robust anti-hHER2 responses, enabling the isolation of high-titer antibodies in less than two weeks; antibodies generated with this accelerated protocol were benchmarked against a classical schedule. (2) Antibody-secreting plasma cells were isolated and ranked on the Bruker Beacon single-cell platform based on antigen binding and relative affinity prior to sequencing and recombinant expression. (3) A microscale, robotics-assisted production workflow was established to express and purify dozens of antibodies in parallel. Binding affinity was measured by bio-layer interferometry BLI, and internalization kinetics were quantified using a new lanthanide-based pH-sensitive probe. (4) A two-stage ADC synthesis pipeline was created using enzymatic conjugation and click chemistry. A first library of ADCs was generated by coupling 24 antibodies to MMAF at DAR4, followed by cytotoxicity assessment on patient-derived xenograft-derived cells (PDX-DC). The most promising hits were then reformatted into a second ADC library conjugated to multiple linker-payload combinations at diverse DARs with the same conjugation strategy.
Results: The rapid immunization protocol consistently produced highly internalized anti-hHER2 antibodies, some surpassing those from classical schedule and trastuzumab. Beacon-based screening enabled efficient prioritization of clones with superior affinity. In the first ADC library, multiple candidates showed strong cytotoxic activity on PDX-DC models. Subsequent optimization through linker-payload engineering further enhanced potency for selected candidates.
Conclusions: This integrated and optimized workflow accelerates ADC generation from immunization to functional readout while reducing technical risk at each stage. It enabled the rapid identification of novel anti-hHER2 antibodies with enhanced internalization and highly potent ADC derivatives. This approach is broadly applicable to future ADC discovery programs targeting diverse antigens.

#4404 Diverse VHH antibodies targeting multiple LGR5 epitopes for cancer therapy.

Chenrui Xu[1], Yifan Li[1], Trang Nguyen[2], Roger Shek[2], Longfei Chong[1], Tek H. Lee[2], Yuxiang Lang[1], Li Yi[2], **Per Greisen**[2]

[1]BioMap Research, BioMap Inc, Beijing, China,[2]BioMap Research, BioMap Inc, Palo Alto, CA

Background: LGR5 is a validated therapeutic target highly expressed in cancer stem cells and solid tumors. Petosemtamab, an EGFR/LGR5 bispecific antibody, confirms its druggability. Single-domain antibodies (VHHs) provide advantages over conventional antibodies through small size, high tissue penetration, and scalable manufacturing. We aimed to create a panel of VHH binders against LGR5 with broad epitope diversity and favorable biophysical traits for therapeutic use.
Methods: VHHs were designed using AI-based structure and sequence-guided modeling targeting recombinant human LGR5 extracellular domain. Chain-of-thought optimization was applied to improve multiple parameters simultaneously, including affinity, thermal stability (Tm), expression yield, and hydrophobic interaction chromatography (HIC) behavior. Top candidates were evaluated for kinetics via surface plasmon resonance, epitope mapping by cryo-EM using N-glycan knockout variants, thermal stability by differential scanning fluorimetry, and expression in mammalian systems. Specificity was tested against related receptors LGR4 and LGR6.
Results: Multiple VHH clones showed high-affinity binding to LGR5, with KD values in the nanomolar range. Cryo-EM mapping revealed distinct, non-overlapping epitopes across the LGR5 extracellular domain, providing full structural coverage of potential binding sites. The panel included both LGR5-selective and pan-LGR binders, offering flexibility in therapeutic design. R-spondin competition assays identified ligand-blocking and non-competing VHHs targeting alternate epitopes. All lead molecules displayed strong stability (Tm >65°C) and robust expression, supporting high manufacturability. These characteristics enable both pathway inhibition and targeted payload delivery approaches to eliminate LGR5+ cancer stem cells.
Conclusions: AI-driven protein engineering produced a diverse, high-quality panel of LGR5-targeted VHHs with multi-epitope coverage, broad affinity range, and strong manufacturability. Chain-of-thought optimization improved multiple parameters in parallel, accelerating VHH development. This library enables rational design of bispecific and multispecific therapeutics for enhanced tumor targeting and represents a foundation for next-generation LGR5-directed ADCs, bispecifics, and CAR-T therapies.

#4405 Real-time, label-free assessment of HER2-targeted antibody-drug conjugate therapies.

Danny Flanigan, BEN STREETER, STACIE CHVATAL, DANIEL MILLARD

Axion BioSystems, Atlanta, GA

Antibody-drug conjugates (ADCs) are made of monoclonal antibodies covalently linked to small molecule drugs that, together, can improve both components' anti-tumor effects. Several ADCs are targeted towards human epidermal growth factor receptor 2 (HER2), a cell surface receptor that is overexpressed in many cancers. Its increased expression in tumor cells makes HER2 an attractive target for cytotoxic therapies, allowing for the specific killing of cancer cells while minimizing off-target effects. Here, we developed an in vitro assay to measure the cytotoxic capacity of ADCs that use the HER2-targeted monoclonal antibody trastuzumab. This assay was performed in a real-time, label-free manner using the Maestro Z platform. The Maestro Z measures electrical impedance via electrodes embedded in the surface of the well to monitor cell growth and proliferation. To assess the cytotoxic effects of one HER2-targeted ADC, trastuzumab-deruxtecan (DS-8201a, branded as ENHERTU®), 5,000 HER2-positive SKOV3 cells were plated in CytoView Z plates and monitored for 24 hours before being dosed with increasing amounts of DS-8201a. SKOV3 cells were killed in a dose-dependent manner, and higher doses of DS-8201a led to larger decreases in SKOV3 impedance, indicative of greater SKOV3 death. SKOV3 cytolysis at the highest dose reached 90.9% at ~ 5 days post dose, and the EC50 value was calculated to be 30.7 µg/mL. We also tested the effects of DS-8201a against other cell types with varying degrees of HER2 expression, including A549 (low HER2 expression) and MDA-MB-231 (no HER2 expression) cells. As expected, impedance data showed that DS-8201a had enhanced cytotoxic effects on the high HER2-expressing SKOV3 cells compared to the other two cell types with lower HER2 expression. Finally, we compared the cytotoxic effects of DS-8201a to another trastuzumab-based ADC, trastuzumab-emtasine (T-DM1, branded as Kadcyla®) on the Maestro Z. Taken together, these results show that the cytotoxic capacity of ADC therapies toward HER2 positive cell types can be screened using the Maestro Z. The assay presented here can be used to further develop ADC therapies aimed at HER2-positive cancers as well as ADCs toward other cancer-specific targets.

#4406 Mouse analog of micvotabart pelidotin, an antibody-drug conjugate targeting extradomain-B of fibronectin, demonstrates anti-tumor efficacy in an immunotherapy-refractory syngeneic head and neck squamous cell carcinoma model.

Anthony B. Rodriguez, Amanda Facklam, Justin Trickett, Sara Lewandowski, Matthew Iovino, Chuan Shen, Frank Wang, Nicolas Severe, Marsha Crochiere

Pyxis Oncology, Boston, MA

Head and neck squamous cell carcinoma (HNSCC) is a difficult-to-treat indication, with current standard of care providing limited long-term survival, underscoring the need for more effective treatment options. Micvotabart pelidotin (MICVO) is a first-in-concept antibody-drug conjugate targeting extradomain-B of fibronectin (EDB+FN), a non-cellular component of the tumor extracellular matrix that is abundantly expressed in the stroma of many malignancies, including HNSCC, but minimally in normal adult tissues, making it an attractive drug-delivery target. In preclinical studies, a murine analog of MICVO (maMICVO) demonstrated pronounced anti-tumor activity, enhanced T cell tumor infiltration, and synergy with anti-PD1, resulting in greater efficacy in syngeneic triple-negative breast cancer models, including one refractory to immunotherapy. MICVO also showed broad anti-tumor activity across multiple patient-derived xenograft models, with particularly strong responses in HNSCC. Consistent with these findings, preliminary results from a Phase 1 Part 1 trial (NCT05720117) showed favorable anti-tumor activity with MICVO monotherapy across several solid tumor types, including HNSCC. This clinical observation is further supported by the present study, in which strong maMICVO activity was observed in the poorly immunogenic, immunotherapy-refractory mouse oral carcinoma 2 (MOC2) syngeneic HNSCC model. *In vitro*, MOC2 cells exhibited minimal EDB+FN expression at baseline. However, tumors established in immunocompetent mice with these cells displayed markedly elevated EDB+FN expression within the extracellular space, suggesting that signals arising during tumor growth drive EDB+FN induction. To evaluate efficacy, mice bearing subcutaneous MOC2 tumors were treated with up to 6 mg/kg maMICVO, with tumor growth and body weight monitored. Treatment was well tolerated at all doses, and a dose-dependent anti-tumor effect was observed, with 6 mg/kg producing the greatest tumor growth inhibition. Notably, image analysis of MOC2 tumors after maMICVO treatment revealed trends of increased CD8 T cell infiltration, reduced regulatory T cell frequencies, and elevated PD-L1 expression, suggesting modulation of the tumor-immune landscape that may enhance susceptibility to anti-PD1 therapy in this model. Ongoing studies aim to determine whether maMICVO synergizes with anti-PD1 to enhance efficacy in this immunotherapy-refractory MOC2 model and to further define the immune changes driving this response at the cellular, molecular, and spatial levels. Collectively, these findings support the continued clinical evaluation of MICVO both as a monotherapy (NCT05720117) and in combination with pembrolizumab (NCT06795412) in difficult-to-treat HNSCC.

#4407 Integrative design of PSM101 Lock-antibody for EGFR-positive tumors through clinical protease profiling and structure-based computer simulation.

Yi-An Cheng[1], Yun-Chi Lu[2], Yu-Chi Lee[1], Chen-Yung Hung[1]

[1]Reseach and development center, PrecisemAb Biotech Co., Ltd., Taipei, Taiwan,[2]President, PrecisemAb Biotech Co., Ltd., Taipei, Taiwan

Objective: On-target toxicity remains a major limitation of anti-EGFR antibodies, as exemplified by a 9.8% discontinuation rate in cetuximab-treated patients due to skin toxicity. Protease-activated pro-antibodies can improve tumor selectivity; however, their performance is limited by heterogenous clinical protease activity and antibody-specific CDR structural constraints. We aimed to develop an optimized EGFR Lock-antibody (PSM101) with improved blocking efficiency, high tumor-specific cleavability, and minimal normal-tissue binding.
Methods: PSM101 was engineered by fusing the Antibody Lock™ masking domain, tumor-associated protease substrates, and optimized linkers to an anti-EGFR antibody. Clinical tumor tissues were profiled to identify highly active protease substrates across multiple cancer types. An automated structure-based simulation platform (MSCS 2.0) was established to predict cover rate and protease cleavability for variant designs. Lead PSM101 molecules were evaluated for (1) binding to human normal cells (flow cytometry), (2) protease activation in clinical tumor tissues (IHZ assay), and (3) antitumor efficacy in EGFR-positive CDX and PDX mouse models.
Results: Clinical protease profiling from head and neck, lung, colon, and gastric tumors identified substrates with high and consistent tumor-associated cleavage activity. MSCS 2.0 successfully predicted variants with optimal masking coverage and cleavability, enabling rational selection of the final PSM101 design. PSM101 demonstrated a 100-200-fold reduction in binding to human normal cells compared with cetuximab, and showed robust activation in head and neck tumor tissues. In vivo, PSM101 achieved significant antitumor activity in both CDX and PDX models.
Conclusion: We developed a protease-activated EGFR Lock-antibody, PSM101, with markedly improved tumor selectivity and strong therapeutic efficacy. MSCS 2.0 provides a predictive framework for early-stage optimization of pro-antibodies, which may accelerate next-generation antibody drug development and reduce clinical toxicity. Ongoing studies include safety evaluation of PSM101 in cynomolgus monkeys.

#4409 Comparing potential bispecific formats comprising of trastuzumab and a humanized OKT3.

Sabrina Mateos, Catherine Bladen, Abbie Hardisty, Emily Blackwood, Holly Guz, Stacey Walker, Stephen Anderson, Michael Fiebig

Vector Laboratories, Inc., Newark, CA

Purpose: This abstract showcases how Absolute Antibody (a Vector Laboratories company) generate bi-specific antibodies based on existing monoclonal antibody therapeutics molecules, compare the constructs and feasibility in order to produce “well-behaved multi-specifics”.
Experimental Procedures: Our recombinant platform converts any antibody into customizable multispecific formats with defined Fc mutations, enabling precise control of effector function. Using trastuzumab and a humanized OKT3 variant as binding arms, we generated and expressed a panel of bispecific constructs, purified them to high quality, and compared their expression profiles, monomer content, and binding. These variants now serve as a reference set for ongoing functional and biophysical characterization studies.
Conclusions: Recent reports list 79 multi-specific antibodies in the clinic, while Absolute Antibody (a Vector Laboratories company) has produced more than 180 engineered formats. In this study, we built and analyzed 17 bispecific designs, revealing that Fc-containing architectures, scFv placement, and interface engineering strongly affect expression and stability. This reference panel highlights how design choices shape bispecific performance and is available for collaborative research.

#4410 The discovery and development of a bispecific T cell engager prodrug targeting ENPP3.

Li Chen[1], Lindi Wang[1], Yingyu Li[1], Xin Wang[1], Yang Xin[1], Mingzhu Shao[1], Jiangtao Ning[1], Ziyu Chen[1], Cheng Luo[1], Jingjing Nie[1], Yue Wu[1], Tingting Yang[1], Hai Huang[1], Miaomiao Song[1], **Yu Liang**[2]

[1]Probio, Inc, Nanjing, China,[2]Probio, Inc, Pennington, NJ

T cell engager (TCE) antibodies have been proven to be effective for a variety of hematological malignancies, with at least 10 marketed drugs to date; however, their efficacy in many solid tumors is still very limited due to a number of challenges. One of the leading challenges is the lack of tumor-specific targets, leading to an increased risk of on-target, off-tumor toxicity. An approach to address this challenge is to build a “prodrug” TCE that is conditionally activated in the tumor microenvironment (TME), taking advantages of various masking technology platforms that block the release of active TCE drug outside of the TME. To develop such a novel TCE molecule with improved tumor selectivity, potency, and safety profile, we first discovered a masking peptide specific to a CD3 VHH antibody that we previously developed, and demonstrated that the masked CD3 VHH can effectively reduce T cell activation several hundred-fold. Next, we fused this masking peptide to the CD3 VHH arm via a proteolytically-labile linker containing sequence motifs sensitive to proteases enriched in the TME, and showed that upon cleavage by proteases, the T cell-activating potency of such a masked CD3 VHH can be effectively recovered. Finally, with such a CD3 VHH armed with cleavable linker and masking peptide, we built a series of prodrug TCE molecules targeting ENPP3 (ectonucleotide pyrophosphatase/phosphodiesterase family member 3), a tumor associated antigen with good tumor selectivity for renal cell carcinoma. Our *in vitro* validation studies demonstrated that the potency of these TCE prodrugs in killing ENPP3+ tumor cells can be restored to a similar level as the unmasked, active TCE molecule upon proteolytic cleavage. Our *in vivo* studies using an ENPP3+ CDX model with transplanted human PBMCs demonstrated two important points: (i) the prodrug/masked ENPP3-targeted TCE can potently inhibit tumor growth to a comparable level as the unmasked version and clinical benchmarks, and (ii) the prodrug TCE can be dosed at least 100-fold higher than the active drugs without any observed toxicity, suggesting a greatly improved safety profile. Further preclinical development of these ENPP3-targeted prodrug TCE molecules, including pharmacokinetics and toxicity studies in non-human primates, is ongoing.

#4411 Discovery of mutation-independent cKit degrading bispecific antibodies that suppress tumor growth in preclinical models of GIST.

Kenneth Ng, Shruti Yadav, Brianna McIntosh, Andy Goodrich, Hai Tran, Josef Gramespacher, Kimberly Hoi, Sara Yan, Brian Hiller, Adison McLaggan, Zhong Huang, Noah Solomon, John Coan, Jon Sitrin, Shyra Gardai, **Ken Flanagan**

Epibiologics, San Mateo, CA

Extracellular targeted protein degradation (eTPD) has emerged as a promising drug modality focused on the selective elimination of extracellular and transmembrane proteins. Unlike intracellular protein degraders, such as proteolysis targeting chimeras (PROTACs) and molecular glues, which rely on ubiquitin-proteasome pathways, extracellular degraders can harness a variety of internalizing receptors that can be tailored to specific targets and tumor types. EpiTACs are a novel type of extracellular targeted protein degrader (eTPD) defined as bispecific antibodies designed to bind a protein of interest (POI) with one arm and a degrading cell-surface receptor with the other. When the receptor is engaged, it carries the POI target into the cell, leading to selective degradation of the POI on receptor-expressing cells. EpiTACs combine favorable pharmacological and manufacturing properties of antibodies with the ability to engineer tissue specificity aiming to enhance efficacy while reducing off-target toxicity. To demonstrate the potential of this platform, we developed EpiTACs to the canonical receptor tyrosine kinase c-KIT. c-KIT is a critical driver of gastrointestinal stromal tumor (GIST) pathogenesis, with activating mutations representing the primary oncogenic event. Current kinase inhibitors are limited by the inevitable emergence of secondary resistance mutations. EpiTACs offer a compelling alternative by eliminating c-KIT itself, rather than merely inhibiting its activity, thereby overcoming mutation-dependent resistance and providing a potentially more durable therapeutic strategy. Importantly, c-KIT is also expressed on healthy cells, including hematopoietic stem cells (HSCs), highlighting the need for approaches that selectively target tumor cells while sparing normal tissue. We generated over 50 c-KIT-targeting EpiTACs spanning 10 degrading receptors expressed on GIST cells but absent from HSCs. These constructs were screened in tumor cell-based assays for c-KIT internalization and degradation. One such construct preserved degrading receptor expression, allowing for sustained catalytic degradation of the POI, which resulted in markedly reduced c-KIT levels and strong efficacy in vitro and in CDX and PDX mouse models. This EpiTAC demonstrates limited toxicity to HSCs, and could be used as a complementary approach as well as a front line combination opportunity with standard of care. In conclusion, eTPD of c-KIT using EpiTACs represents a promising new therapeutic modality and expands the toolbox of extracellular targeted degraders that can be applied in a target-, tissue-, and disease-specific manner.

#4412 Discovery and characterization of GI-128: A PD-L1 x LILRB1/2/4 bispecific antibody as a macrophage engager.

Seong Hun Kim, Eunji Ahn, Min Sang Yoon, Ji Cheol Kim, Hye Jun Park, Wonjae Lee, Hyuckjun Mok, Eun Jin Lee, Jisoo Kim, Young Min Oh, Kook Hwan Kim, Myoung Ho Jang

GI Innovation Inc., Seoul, Korea, Republic of

Immunosuppressive activity of myeloid cells within the tumor microenvironment (TME) contributes significantly to tumor immune evasion. Leukocyte immunoglobulin-like receptor subfamily B (LILRB) members are inhibitory receptors primarily expressed on myeloid cells. LILRB1, LILRB2 and LILRB4 are upregulated on tumor-infiltrating myeloid cells across many cancers. LILRB1 and LILRB2 suppress cytotoxic T cell and NK cell activity through interactions with their ligands such as HLA-G and HLA-G/β2m. LILRB4 interacts with extracellular matrix proteins and subsequently promotes myeloid-mediated immunosuppression, leading to impairment of anti-tumor immunity. Although immune checkpoint inhibitors (ICIs) show broad clinical benefit, many patients are refractory or develop acquired resistance. ICI-resistant tumors often exhibit increased polarization of immunostimulatory M1 to immunosuppressive M2 tumor-associated macrophages. As macrophages are abundant in the TME across many cancer types, reprogramming of tumoricidal macrophages and their engagement with tumor cells could be a promising approach to elicit effective anti-tumor responses. Since high LILRBs expression correlate with poor prognosis and ICI non-responsiveness, and PD-L1 is highly expressed in multiple cancer types or positively correlates with LILRBs expression, we designed GI-128, a macrophage-engaging bispecific antibody composed of an anti-PD-L1 sdAb (single domain antibody) and an anti-LILRBs sdAb. Here, we showed that GI-128 candidates exhibited high affinity for both PD-L1 and LILRB1/2/4 and effectively suppressed their receptor-ligand interactions against each target in cell-based blockade assay or cell-based reporter assay. In functional assays using immune cells, GI-128 candidates enhanced macrophage-mediated phagocytosis of tumor cells. Furthermore, they promoted pro-inflammatory cytokine production in LPS-stimulated PBMC-derived monocytes and induced M1 polarization during macrophage differentiation. In addition, a trans-binding assay showed that GI-128 candidates bound simultaneously to PD-L1-expressing cells and to LILRB1-, LILRB2- or LILRB4-expressing cells, implying their functionality as macrophage-engaging molecules. These findings suggest that GI-128, a bispecific macrophage engager, has a promising potential to reinvigorate tumoricidal macrophage function in immunosuppressed PD-L1-positive tumors. *In vivo* anti-tumor efficacy of GI-128 is being investigated.

#4413 KRAS amplification creates a targetable pMHC antigen for T cell engager therapy to overcome KRAS inhibitor resistance.

Lorenzo Maso, Diamond N. Mensah, Angelina Pizzo, Sergio A. Rodriguez-Aponte, Samantha Sze, Weifeng Liu, Sean T. Toenjes, Paul Da Silva Jardine, Christoph Rader, Lauren E. Stopfer

Aethon Therapeutics, New York, NY

KRAS amplification has emerged as a shared mechanism of resistance to KRAS-targeted therapies, including $KRAS^{G12C}$ and KRAS-multi small molecule inhibitors. Wild-type KRAS allele amplification also defines a subset of aggressive gastroesophageal cancers with poor outcomes. To exploit this alteration, we sought a mutation-agnostic, HLA-A*02:01-restricted KRAS pMHC antigen selectively presented in KRAS-amplified tumors. Using peptide prediction & targeted immunopeptidomics, we identified the amplified antigen “kAMP.A2,” enabling a strategy to selectively target KRAS-amplified tumors with a bispecific pMHC×CD3 T cell engager (TCE). Quantitative immunopeptidomics across multiple models estimated kAMP.A2 at ~10^2-10^3 copies-per-cell (CPC) in KRAS-amplified cell lines (MKN1*, 119 CPC; COR-L23*, 555; HSKTC*, 1432) and undetectable or <10 CPC in non-amplified cell lines (A375, NCI-H661, ND; NCI-H520*, 9). A*02:01-negative lines (*) were A*02:01-engineered. KRAS pathway inhibition further increased antigen levels: treatment of 10 nM RMC-7977 in COR-L23 cells (G12V; KRAS CN=16), produced a 2.5× rise in surface HLA and an 8-fold increase in kAMP.A2, reaching ~4,000 CPC at 48 h. KRAS amplification thereby establishes an exploitable pMHC therapeutic window—analogous to gp100 or PRAME—that is further broadened by KRAS inhibition. Importantly, NRAS & HRAS paralogs of kAMP.A2 were not detected in any model. Consistent with this, stability profiling showed kAMP.A2 to be markedly more stable at 37 °C ($t_{½}$ ≈ 45 min) than NRAS/HRAS peptides ($t_{½}$ < 4 min), supporting kAMP.A2 as a selective TCE target with minimal paralog cross-reactivity. Screening our ultra-large human naïve antibody library with phage/yeast display and stringent counter-selection yielded the TCR-mimicking antibody PK313, exhibiting high affinity (K_D = 5.3 nM) and strict specificity confirmed by SPR as well as by X-scan and healthy-tissue pMHC libraries (>10^2 & ~10^4 peptides) with no high-affinity off-targets. A 2.8-Å cryo-EM structure revealed extensive kAMP.A2-specific contacts. Reformatted as a TCE, PK313 induced potent cytotoxicity in KRAS-amplified models (MKN1*, EC_{50} = 1.1 nM; COR-L23*, 150 pM; HSKTC*, 160 pM) and showed enhanced activity with KRAS inhibitors. Structure-guided maturation is underway to advance PK313 toward development candidate nomination. Our data demonstrate that KRAS amplification—whether intrinsic or emerging under therapeutic pressure—creates a robust, tumor-amplified pMHC antigen with exceptional potential for therapeutic exploitation. PK313 enables selective targeting of KRAS-amplified tumors as a monotherapy or in combination with KRAS small molecule inhibitors to enhance treatment durability and provides a therapeutic strategy for A*02:01 patients (~42% in US population), who are currently excluded from A*03/A*11 KRAS-mutant neoantigen TCR-T/CAR-T/TCE programs.

#4414 A bispecific antibody-drug conjugate targeting protein tyrosine kinase 7 and fibroblast activation protein alpha simultaneously acts on tumor cells and the tumor microenvironment.

Yifan Zhan, Shi Chen, Jingen Xu, Xiaofang Chen, Changping Zheng, Xianfei Pan, Shaojie Wang, Simin Xia, Haijia Yu, Yujie Feng, Guoyuan Peng, Huifeng Jia, Xiaopei Cui, Xiangyang Zhu

Shanghai Huaota Biopharmaceutical, Shanghai, China

Bispecific antibody-drug conjugates (Bs-ADCs) represent a significant advancement over traditional ADCs by addressing key limitations, including tumor selectivity, on-target/off-tumor toxicity, tumor heterogeneity, antigen escape, inefficient internalization, and low payload delivery efficiency. By simultaneously targeting tumor cells and cancer-associated fibroblasts (CAFs), Bs-ADCs not only enrich drug concentration at the tumor site but also disrupt the tumor's supportive stroma, thereby improving drug penetration. We have developed a Bs-ADC, HB0085, which targets tumor cells through protein tyrosine kinase 7 (PTK7) and CAFs through fibroblast activation protein (FAP), delivering a topoisomerase I inhibitor (TOP1i) payload to tumor. HB0085 has demonstrated potent antitumor activities both in vitro and in vivo. In multiple patient-derived xenograft (PDX) experiments, HB0085 achieved a tumor growth inhibition (TGI) rate greater than 70% in 42.9% (3/7) of lung cancer models and 83.3% (5/6) of pancreatic cancer models. Notably, HB0085 exhibited superior efficacy compared to combination therapy with individual monospecific ADCs targeting PTK7 and FAP in PDX models. Furthermore, when combined with the bispecific antibody HB0025 (targeting PD-L1/VEGF), the antitumor activity of HB0085 was significantly enhanced. These results position HB0085 as a promising therapeutic candidate for a range of solid tumors.

#4415 AI-powered analysis of millions of IHC images identifies 19 spatially highly co-expressed protein pairs to enable bispecific antibody development.

Sukjun Kim[1], Hosik Kim[1], Biagio Brattoli[1], Sergio Pereira[1], Siraj Mahamed Ali[2]

[1]Lunit Inc., Seoul, Korea, Republic of,[2]Lunit USA Inc., Cambridge, MA

Background: Developing effective bispecific antibodies requires identifying target protein pairs that are co-expressed within the same spatial context of a given tumor. However, discovering such co-expressed targets is challenging due to the vast combinatorial search space across the human proteome. AI-powered analysis of IHC images enables systematic identification of spatially co-expressed protein pairs, facilitating rational bispecific antibody design.
Methods: We analyzed 6.8M IHC-stained TMA core images from the Human Protein Atlas, where 21144 different antibodies were used to stain 15303 human proteins. Serial section pairs were identified using a feature-matching-based image similarity algorithm. For each pair, positive and negative cells were detected from the IHC images using the Lunit SCOPE uIHC model. The spatial similarity of expression between two proteins was quantified using the intersection over union (IoU) of their positive cell regions.
Result: From all possible image pairs generated by combining every two images from 1.5M positively stained TMA cores, 26730 pairs were identified as serial sections based on image similarity analysis. By selecting pairs in which the positive cell regions overlapped (IoU ≥ 70) and only consisted of plasma membrane proteins, we identified 19 pairs across 10 tumor types with the most pairs in bladder cancer. B7-H3 was co-expressed with NT5E or JAG1 in bladder cancer, and with NT5E in cervical cancer. In thyroid cancer, CLDN3 was co-expressed with ROBO1.
Conclusion: We developed an AI-powered pipeline for spatial analysis of IHC images and applied it to a large publicly available data source, enabling systematic identification of co-expressed protein pairs. This approach can guide the design of tumor type specific bispecific antibodies as demonstrated by the possibility of targeting B7-H3 and simultaneously either the ectonucleotidase NT5E or the Notch ligand JAG1.

List of identified co-expressed target pairs by tumor types.

Tumor type	**Number of pairs**	**List of pairs (A x B)**
Bladder	7	B7-H3 x NT5E, B7-H3 x JAG1, PIEZO2 x GPR142, DDR1 x IL6ST, ITGA3 x BTN3A3, CSF1R x BTN3A3, LSR x SORT1
Cervix	2	B7-H3 x NT5E, DDR1 x ICOSLG
Pancreas	2	SLC4A4 x PKD2L1, DCHS1 x GFRAL
Brain	1	TRPV2 x CSPG4
Head and Neck	1	DCHS1 x GFRAL
Liver	1	CDH8 x KCNE3
Lung	1	SLC4A4 x PKD2L1
Testis	1	PIEZO2 x GPR142
Thyroid	1	CLDN3 x ROBO1
Uterine	1	FZD1 x IGF1R

#4416 Overcoming the limited monospecific target landscape in cancer via discovery of tumor selective AND and OR gate bispecifics.

Daniel Holdbrook, **Katherine Vousden**, Michael Hunter, Roy Pettipher, Mark Edwards

Promatix Biosciences Ltd., London, United Kingdom

The pool of membrane proteins suitable for monospecific antibody-drug conjugates (ADCs) is inherently limited, restricting tumor selectivity and leaving many cancers without actionable antigens. Bispecific ADCs unlock a much larger combinatorial target universe by pairing antigens, enabling AND-gate designs that enforce dual expression for engagement and OR-gate designs that extend coverage where individual markers are insufficient. However, rational construction of such bispecifics depends on identifying antigen pairs that are co-expressed in tumors but absent - or expressed only individually - in normal tissues. To meet this need, we developed a discovery framework that combines quantitative proteomic profiling across more than 14 tumor types, matched normal tissues, and cell lines with computational modeling of cancer-normal specificity. This approach systematically evaluates both AND- and OR-logic potential across all bispecific ADC pairings currently under clinical or preclinical investigation, while also uncovering previously unexplored combinations with favorable selectivity profiles. Our analysis confirms that the universe of high-selectivity monospecific targets is extremely small, whereas the application of AND-logic markedly expands the number of viable tumor-restricted pairings by exploiting cancer-specific co-expression signatures. OR-logic designs provide complementary value by maintaining or improving selectivity while accommodating tumor expression heterogeneity. Among existing clinical bispecific ADC programs, only a limited subset demonstrates true AND-gate behavior, with the EGFR/MET pairing showing the most robust tumor-restricted co-expression profile. Beyond the current landscape, the platform identifies novel AND-gate opportunities with predicted improvements in therapeutic index. Functional evaluation of one such candidate validated the model's prediction of avidity-driven dual engagement and tumor-selective cytotoxicity. Collectively, these findings demonstrate that a proteomics-driven AND/OR bispecific discovery platform can substantially expand the therapeutic target space beyond what is achievable with monospecific ADCs, enabling the development of safer and more selective next-generation cancer therapeutics.

#4417 GS24-B025, a novel CDH17- and CEA-directed bispecific antibody-drug conjugate, for the treatment of colorectal cancer.

Zeng Qi, **Fu Li**, Liping Shao, Yuting Lu, Chong Ding, Nan Li, Huan Wang, Weiming He, Qiangqiang Deng, Peng Qi, Wenqiang Zhai, Yihui Lin, Xiaozhen Wang, Fanglong Yang, Siqin Wang, Lei Jin, John L. Xu

Changchun GeneScience Pharmaceutical Co., Ltd., Shanghai, China

Background: Colorectal cancer (CRC) is the third most common cancer worldwide and the second leading cause of cancer deaths. Often diagnosed at advanced stages with limited treatment options, substantial unmet need remains in the metastatic setting of CRC (mCRC). Both CDH17 and CEA are highly expressed tumor-associated antigens (TAAs) in CRC, representing promising therapeutic targets. GS24-B025, a dual CDH17- and CEA-targeting ADC comprising topoisomerase 1 inhibitor payloads site-specifically conjugated to a CDH17 x CEA bsAb by a proprietary peptide-based cleavable linker with a drug-to-antibody ratio (DAR) of 8, is currently in development as a potential therapy for mCRC.
Methods: Membrane expression of CDH17 and CEA was assessed in CRC tissue microarrays (TMAs) by immunohistochemistry (IHC). Binding affinity and activity of GS24-B025 to CDH17 and CEA were determined by Biacore and flow cytometry, respectively. *In vitro* cytotoxicity and bystander killing effect of GS24-B025 were examined in a Cell Titer-Glo assay in CRC cell lines. *In vivo* anti-tumor efficacy of GS24-B025 was investigated in the CRC xenograft models in mice. Pharmacokinetics was studied in cynomolgus monkeys.
Results: CDH17 and CEA were found to be highly co-expressed in CRC tissues (N=209), and thus, dual targeting of CDH17 and CEA may enable broader patient coverage across and provide benefit to the entire CRC population. GS24-B025 showed single-digit nanomolar affinity to both CDH17 and CEA and potent binding to $CDH17^+$ and CEA^+ tumor cells, resulting in efficient internalization, and displayed robust cytotoxicity and bystander killing activity against CRC cell lines *in vitro* (with an EC50 in the sub-nanomolar range). Furthermore, GS24-B025 effectively induced tumor regression across different levels of CDH17 and/or CEA expression and demonstrated superior *in vivo* efficacy *versus* benchmark ADCs, including in-house generated M9140 and TORL-3-600. Furthermore, GS24-B025 featured a favorable pharmacokinetic profile in cynomolgus monkeys.
Conclusion: These data suggest the potential of GS24-B025 as an effective treatment option for CRC patients and support its further evaluation in IND-enabling studies.

#4418 Preclinical characterization of a potential best-in-class camptothecin-based antibody-drug conjugate targeting ADAM metallopeptidase domain 9.

Rui Liu, Lan Ding, Yushi Chi, Ge Song, Kuichao Qu, Wan-jen Yang, Kun Yan, Jinbo Liu, Huixin Yan, Xiaoling Yuan, Ying Chen, Zhenjian Li, Chen Hu, Jijun Yuan

Shanghai Henlius Biotech, Inc., Shanghai, China

Introduction: ADAM metallopeptidase domain 9 (ADAM9), a member of the disintegrin and metalloproteinase, mediates proteolytic shedding of cytokines and growth factors. ADAM9 dysregulation promotes tumor progression, metastasis, and pathological angiogenesis. ADAM9 is overexpressed in various solid tumors, including pancreatic, lung, gastric, and breast cancers, with low expression in normal adult tissues. Previously, the clinical development of ADAM9-targeted ADC IMGC-936 was terminated due to maytansinoid-related ocular toxicities. Herein, we developed a next-generation ADAM9 ADC using a camptothecin-based linker-payload, which is anticipated to avoid ocular toxicity and possess expanded therapeutic index.

Methods: ADC cytotoxicity was evaluated using the CellTiter-Glo (CTG) assay in Jurkat (ADAM9-negative), Calu-3 (intermediate ADAM9 expression), and NCI-H1693 (high ADAM9 expression) cell lines. Bystander activity was assessed in Jurkat cells co-cultured with CHOK1-hADAM9 cells, with Jurkat viability determined by CTG. ADC stability in human and rat plasma was monitored over 14 days, with payload release quantified by LC-MS. Accelerated stability was examined by incubating ADCs at 25 °C for 7 days, followed by drug antibody ratio (DAR) and size exclusion chromatography monomer fraction analysis. *In vivo* efficacy was investigated in Calu-3 (non-squamous NSCLC, *EGFR* wildtype) and DLD-1 (CRC, MSI-H, *KRAS* G13D) cell line-derived xenograft (CDX) mouse models. A PK study was conducted in Sprague-Dawley rats administered intravenously with ADAM9 ADC 5 mg/kg.

Results: The parental antibody exhibited nanomolar affinity for human and cynomolgus ADAM9, with no cross-reactivity to rodent orthologs or other ADAM family members. Antibody internalization in MKN-45, MiaPaCa-2, and Calu-3 cells were time-dependent and highly efficient (>50% at 4 h), while the ADC showed comparable or enhanced internalization. The ADAM9-ADC demonstrated potent cytotoxicity and bystander killing effects. In Calu-3 CDX models, a single 3 mg/kg dose elicited 109.3% tumor growth inhibition (benchmark ADC, 91.1%). In DLD-1 CDX models, TGIs reached 90.2% and 66.8% at 3 and 8 mg/kg, respectively, significantly outperforming the benchmark (39.2%) at 3mg/kg. The ADC also displayed excellent plasma stability, with minimal DAR reduction and aggregation in accelerated and freeze-thaw stability assays. The ADAM9 ADC also exhibited a favorable pharmacokinetic profile in rats, characterized by minimal free toxin release and antibody-like half-life.

Conclusion: Preclinical studies reveal that the ADAM9-ADC exhibits potent *in vitro* cytotoxicity and superior in vivo antitumor efficacy relative to benchmarks. Pilot toxicology studies in cynomolgus monkeys are ongoing. Further clinical development is warranted.

#4419 Development of a first-in-class camptothecin-based antibody-drug conjugate targeting ALPP/ALPPL2 with potent antitumor activity and excellent tolerability.

Rui Liu, Lingli Zhang, Fan Yang, Junjie Zhang, Wan-Jen Yang, Xiaoling Yuan, Jichen Sha, Yushi Chi, Ge Song, Weiguang Qu, Zhiliang Lv, Qian Zou, Huixin Yan, Chen Hu, Jijun Yuan

Shanghai Henlius Biotech, Inc., Shanghai, China

Introduction: ALPP (alkaline phosphatase, placental) and ALPPL2 (alkaline phosphatase, placental-like 2) emerge as promising targets due to their expression across multiple solid tumors, including ovarian (60%), endometrial (50%), pancreatic (30%), and gastric cancer (15%) along with minimal expression in normal adult tissues. We developed a novel ALPP/ALPPL2-directed antibody-drug conjugate (ADC) incorporated a proprietary camptothecin-derived payload linked through a protease-cleavable linker to a high-affinity monoclonal antibody. Preclinical studies demonstrate robust antitumor activity with favorable safety, supporting its potential to benefit patients with refractory advanced solid tumors.

Methods: Parental antibody binding to ALPP/ALPPL2-positive cells was evaluated by flow cytometry. Selectivity against related phosphatases (hALPL and hALPI) was confirmed via enzyme-linked immunosorbent assay. ALPP/ALPPL2-ADC cytotoxicity was assessed using CellTiter-Glo (CTG) in ALPPL2-positive cells (HEP2, NCI-H1651). Bystander killing was quantified in co-cultures of ALPPL2-positive HEP2 cells and Jurkat controls by measuring Jurkat viability with CTG assay. *In vivo* efficacy was examined in Capan-1 pancreatic adenocarcinoma cell line-derived xenograft (CDX) model and LD1-0017-200702 gastric patient-derived xenograft (PDX) models. Pharmacokinetics and toxicology were characterized in cynomolgus monkeys at 20 and 40 mg/kg, administered every three weeks for three cycles.

Results: The parental ALPP/ALPPL2 antibody demonstrated high specificity for human and cynomolgus ALPP/ALPPL2, with no cross-reactivity to related phosphatases (hALPL and hALPI). The ALPP/ALPPL2-ADC (drug antibody ratio of 8), incorporating a proprietary camptothecin-based linker-payload, exhibited target mediated cytotoxicity in HEP2 (ALPP/ALPPL2^{high}) and NCI-H1651 (ALPP/ALPPL2^{medium}) cells *in vitro*. The ADC also showed a 50-fold greater bystander killing effect compared with a deruxtecan-based ADC. *In vivo*, a single 1 mg/kg dose induced profound tumor regression in the Capan-1 CDX model, while in the gastric adenocarcinoma PDX model refractory to an ADC with an MMAE payload, a single 8 mg/kg dose achieved deep tumor remission. In non-human primates, the ALPP/ALPPL2 showed linear pharmacokinetics and excellent tolerability (highest non severely toxic dose ≥40 mg/kg).

Conclusion: ALPP/ALPPL2-ADC is a promising therapeutic candidate for solid tumors, particularly gynecologic cancers. As a first-in-class camptothecin-based ADC targeting ALPP/ALPPL2, it combines high antibody specificity with robust antitumor efficacy and favorable tolerability, supporting advancement into clinical development.

#4423 Advancing ADC therapeutics with next-generation site-specific glycan conjugation and dual-payload flexibility.

Wei-Chien Tang, Yu-Hung Chen, Chih-Kang Chang, Ting-Wei Liu, Hung-Yi Lin, Wei-Jhen Huang, Chi-Huan Lu, Ren-Yu Hsu, Nan-Hsuan Wang, Ya-Chi Chen, Teng-Yi Huang

OBI Pharma, Inc, Taipei, Taiwan

The unique technology by enabling site-specific glycan-based conjugation via a proprietary dual-function enzyme offers an innovative approach for developing antibody-drug conjugates (ADCs). This advanced technology facilitates the production of homogeneous ADCs at a specific drug-to-antibody ratio (DAR) from DAR2 to DAR16, while maintaining the integrity and function of the native antibody. A key feature of the technology is its proprietary linker, specifically designed to enhance payload stability and enable selective release within the tumor, thereby potentially broadening the therapeutic index.
Expanding upon its core capabilities, the new technologies serve as a dual-payload platform, enabling the development of site-specific ADCs carrying two distinct payloads. This technology allows for flexible DAR construction, including both equal and asymmetric payload ratios, providing versatility to tailor ADCs for optimized therapeutic outcomes. Moreover, the ability to specify distinct conjugation sites further enhances its flexibility for diverse payload combinations, including cytotoxic agents, immunomodulators, anti-tumor inhibitors, and degraders. The platform also accommodates both mono- and multi-specific antibodies, broadening its applicability across therapeutic modalities.
Here we used microtubule inhibitor and Topoisomerase I inhibitor to demonstrate the site-specific dual-payload platform. In preclinical studies, the site-specific dual-payload ADCs exhibited superior cytotoxicity and promising antitumor activity in various tumor models, compared to approved and benchmark single payload ADCs, underscoring their potential for enhanced antitumor efficacy. Importantly, these ADCs maintained structural integrity and
avoided antibody aggregation. These features provide a strong foundation for the future clinical development of biomolecules derived from this site-specific dual-payload technology.
Through the integration of glycan engineering, dual-function enzymatic control, proprietary linker chemistry, and flexible payload conjugation, the site-specific dual-payload technology suite provides a robust and adaptable solution to overcome key limitations in current ADC design. Continued innovation and clinical translation of the site-specific dual-payload platform may unlock new therapeutic possibilities to overcome drug resistance and is applicable across oncology and beyond.

#4424 Preclinical efficacy of a first-in-class anti-Integrin α/β ADC in hard-to-treat solid tumors.

Qinhong Ma, Daizong Li, Kewei Zhao, Mary Q. Xu, **Mason Lu**

MedAbome, Inc., Fremont, CA

Integrin (ITG) α/β is a heterodimeric type I transmembrane glycoprotein composed of one α and one β integrin subunit. It mediates cell-cell and cell-extracellular matrix (ECM) interactions and elicits subsequent signaling cascades that regulate cell adhesion, motility, proliferation, survival, and gene expression. The aberrant overexpression of ITGα/β has been observed across a variety of solid tumors, and it supports cancer progression and metastasis, suggesting that it may serve as a potential therapeutic target. Using our proprietary live-cell immunization (LC-I) and high-throughput screening (LC-HTS) platforms, we generated and developed MAb51-31, an anti-ITGα/β monoclonal antibody (mAb), which selectively recognizes a tumor-restricted conformational epitope of ITGα/β. MAb51-31 exhibited no cross-reactivity with normal cells or tissues. Both the chimeric and humanized versions of MAb51-31 displayed high binding affinity to recombinant ITGα/β ($K_D \approx 1.4$ nM). MAb51-31-cAb, engineered with two point-mutations in each Fc region, was conjugated to MMAE via an MC-Vc-PAB linker to generate MAb51-31-ADC (DAR4). MAb51-31-ADC demonstrated potent antiproliferative effects *in vitro*, with cytotoxicity correlating with its internalization efficiency across various solid tumor cell lines. In cell line-derived xenograft (CDX) models of triple-negative breast cancer (TNBC), non-small cell lung cancer (NSCLC), gastric cancer (GC), and other solid tumors, a single intraperitoneal (*i.p.*) dose of MAb51-31-ADC at 4, 7, or 10 mg/kg effectively inhibited tumor growth, resulting in complete tumor regression within 24~30 days post-treatment. Initial toxicology assessments indicated that MAb51-31-ADC was well tolerated, with no notable safety concerns observed. MAb51-31-ADC is a promising therapeutic candidate for treating solid tumors, with selective recognition of a tumor-specific ITGα/β epitope potentially enabling strong antitumor efficacy and reduced off-target effects. Ongoing studies include evaluation of MAb51-31-ADC in patient-derived xenograft (PDX) models of gastrointestinal (GI) cancers, as well as retrospective analyses of target expression in tumor samples, to further support its clinical development.

#4426 Novel tumor microenvironment (TME)-activated, pan-RASi and Topo1i dual-payload linker enables safe broad RAS inhibition and overcomes Topo1i resistance.

Zhengsong Gu, Cheng Liu, **Yuan Liu**

Affinity Biopharmaceutical Co., Ltd., Shanghai, China

Pan-RAS inhibitors target RAS mutations in tumor cells but also affect wild-type RAS in normal tissues. Consequently, pan-RASi-related skin toxicities such as rash and acneiform dermatitis commonly occur, narrowing their therapeutic window. QHL-P1711 is a potent pan-RAS inhibitor which effectively suppresses the proliferation of wild type NRAS and HRAS tumor cells and tumor cells with $KRAS^{G12C}$, $KRAS^{G12D}$ and $KRAS^{G12V}$ mutations. In cytotoxicity assays, QHL-P1711 demonstrated synergistic effects with DXd (a Topo1 inhibitor) in MIA PaCA-2^{G12C}, AGS^{G12D} and Capan-1^{G12V} tumor cells.

TMEAlinker is a clinically validated, selectively activated linker in the tumor microenvironment (TME) by legumain, an active protease highly overexpressed in the TME while exhibiting negligible expression in skin endothelial cells. By using the dual-payload TMEAlinker, both pan-RASi (QHL-P1711) and DXd can be conjugated to an EGFR-TROP2 bispecific antibody to construct a dual-payload ADC EGFR-TROP2-TMEAlinker-RASi-DXd (IMD2146). The highly hydrophilic dual-payload TMEAlinker effectively addressed CMC challenges and enabled homogeneous formation of dual-payload ADCs with a drug-to-antibody ratio (DAR) of 8+8.

IMD2146 exhibited superior efficacy than single-payload ADCs and pan-RAS inhibitor treatment at equivalent pan-RASi molar doses in the NCL-H1975 tumor model. Notably, IMD2146 retained antitumor activity in the PA-1 Topo1i-resistant tumor model, whereas the single-payload ADC (EGFR-TROP2-TMEAlinker-DXd) showed no efficacy. In human plasma at 37 °C, <1% of free pan-RASi was released after 7 days of incubation of IMD2146, indicating excellent plasma stability. In preclinical toxicology studies in cynomolgus monkeys, IMD2146 was well tolerated after repeated dosing at 50 mg/kg. Pharmacokinetic analysis in cynomolgus monkeys revealed high plasma concentrations of IMD2146 with minimal levels of free pan-RASi and free DXd, further confirming its stability in circulation.

In summary, these results demonstrate that the dual-payload TMEAlinker design provides a novel strategy to achieve systemic safety with broad RAS inhibition while effectively overcoming Topo1i resistance. This approach integrates precise TME activation with dual-mechanism targeting, offering a promising therapeutic platform for RAS-driven tumors while minimizing systemic toxicity.

#4427 Development of CLIO-8221: A HER2-targeted multi-payload ADC to address ADC resistance.

Alyson Smith[1], Ben Ayers[2], Shalini Paliwal[2], Bhushan Dharmadhikari[2], Jerome Boyd-Kirkup[1]

[1]Callio Therapeutics, Seattle, WA,[2]Hummingbird Bio, Singapore, Singapore

Antibody drug conjugates (ADCs) are transforming the treatment landscape for patients across tumor types, particularly HER2 expressing cancers, however they continue to be limited by narrow therapeutic indexes and rapidly emerging resistance. Studies have confirmed that most ADC patients retain target expression post progression, suggesting that treatment resistance emerges in part because of payload insensitivity. Patient samples have highlighted DNA damage response activity as one important cause of reduced efficacy and resistance to Topoisomerase 1 inhibitor (TOP1i) payloads, therefore, blockade of DNA damage repair pathways in conjunction with TOP1i may drive better and more durable efficacy. Dual payload ADCs are a novel modality with the potential for efficient delivery of combination therapies to the same tumor cell at the same time, balancing PK and exposure profiles. We have developed CLIO-8221, a novel anti-HER2 dual payload ADC conjugated to both TOP1i and a potent DNA damage response inhibitor (ATRi), designed for optimal efficacy and tolerability. CLIO-8221 is an Fc-engineered anti-HER2 antibody conjugated site-specifically via MTGase to a hydrophilic branched linker carrying both a Topo1 inhibitor and an ATR inhibitor, with a DAR of 4 for each payload. ELISA, SPR, flow cytometry and live cell imaging were used for ADC characterization. The pharmacologic activity of CLIO-8221 was assessed using proliferation assays, cell line-derived xenograft studies and non-human primate tolerability studies (NHP). CLIO-8221 is rapidly internalized into lysosomes in HER2 expressing tumor cells to release TOP1i and ATRi payloads with strong bystander effect. CLIO-8221 shows *in vitro* cell killing activity across cell lines with a range of HER2 expression levels and Trastuzumab-DXd (T-Dxd) sensitivities, and drives tumor regressions after a single dose in T-DXd-resistant and refractory xenograft models, with strong durable activity seen at 3 mg/kg. The optimized Fc and linker engineering reduces off-target uptake via abrogated FcγR binding and decreased macropinocytosis. Toxicokinetic studies in NHPs demonstrate high tolerability with minimal systemic free payload exposure and no significant CLIO-8221 changes in safety endpoints up to 70mg/kg. CLIO-8221 has dose dependent exposure with comparable PK profiles between the total antibody (mAb) and conjugated mAb and a half-life of 8-12 days. CLIO-8221 is a first-in-class anti-HER2 dual payload ADC that allows targeted delivery of TOP1i and ATRi payloads to HER2 expressing tumors to maximize anti-tumor efficacy, overcome TOP1i resistance, and reduce systemic toxicity. Our findings strongly support the development of CLIO-8221 as a potential therapeutic option for HER2-positive cancers and a phase 1/2 study of CLIO-8221 in patients with advanced solid tumors has been initiated.

#4430 WuXiTecan2: A hydrophilic exatecan linker-payload for dual-payload ADC discovery.

Hu Chen, Qirui Fan, Zili Xu, Xiaomei Li, Ding Wei, Lin Zhang, Chenghu Hu, Cindy Cheng, Marie Zhu

Discovery and development, WuXi XDC, Shanghai, China

Background: Exatecan, a camptothecin-derived topoisomerase inhibitor, demonstrates high potency along with robust bystander activity. Several exatecan-based ADCs against diverse targets have now entered into late-stage clinical trials. In parallel, the need to overcome resistance mechanisms have intensified interest in dual-payload ADC strategies, with exatecan emerging as a compelling payload option in these combination formats. However, its hydrophobic physicochemical properties can lead to ADC aggregation, non-specific uptake, reduced plasma stability, particularly at DAR8, or in dual-payload settings. Therefore, the introduction of hydrophilic moieties via linker design is essential to improve ADC hydrophilicity and physicochemical behavior. Here, we developed a super-hydrophilic linker payload, named WuXiTecan2, that overcomes exatecan's hydrophobicity and shows strong efficacy and good tolerability in vitro and in-vivo, both as DAR8 ADC and in dual-payload ADC formats.

Methods: WuXiTecan2 was conjugated to Trastuzumab at DAR8 or formulated as a trastuzumab-dual payload ADC paired with an MMAE payload using WuXiDARX Technology. The resulting ADCs were fully characterized by HIC-HPLC, SEC-HPLC, and LC-MS. The in-vitro activity was assessed across breast and gastric cancer cell lines with varied HER2 expressions. Plasma stability was evaluated in the mouse, and human plasma. In-vivo efficacy was determined in Her2 expressing CDX models, and the tolerability of trastuzumab-WuXiTecan2 ADC(DAR8) was evaluated in mice and preliminary cynomolgus monkey studies.

Results: WuXitecan2 was conjugated to trastuzumab at DAR8 and incorporated into a dual-payload ADC pairing with MMAE payload. Both formats were successfully generated and demonstrated highly uniform conjugation profiles. Notably, the introduction of WuXiTecan2 showed excellent ADC hydrophilicity, which is very close to naked antibody. In-vitro, both ADC formats displayed sub-nanomolar IC50 across a panel of breast and gastric cancer cell lines spanning HER2 expression levels. Both DAR8 and dual-payload ADCs showed improved plasma stability in mouse and human plasma, consistent with the enhanced hydrophilicity of the linker and its stabilizing effect on the exatecan payload. In Her2-expressing CDX models, the dual-payload ADC achieved superior tumor growth inhibition relative to the single-payload DAR8 ADC at comparable doses. Treatment was well tolerated; the trastuzumab-WuXiTecan2 DAR8 ADC demonstrated acceptable tolerability in mouse studies at a single dose up to 250mg/kg,and tolerated well in preliminary cynomolgus monkey studies at 45mg/kg, Q3Wx3.

Conclusions: WuXitecan2, enabled by the hydrophilic linker moiety design, demonstrated strong efficacy, stability and tolerability, supporting its use as a promising dual-payload ADC component.

#4431 ZW427, a Ly6E-targeting antibody drug conjugate bearing a novel pan-RAS inhibitor payload for the treatment of RAS mutated cancers.

Dunja Urosev[1], Vidhi Khanna[1], Ambroise Wu[1], Jodi Wong[1], Saki Konomura[2], Elizabeth Porter[1], Matthew Bonderud[1], Victoria Harman-McKenna[1], Taixiang Wang[1], Linglan Fu[1], Diego Alonzo[1], Devika Sim[1], Adele Chan[1], Allysha Bissessur[1], Spencer Boisjoli[1], Michael Lee[1], Germanna Righetto[1], Jesse Leblanc[1], Raffaele Colombo[1], Graham Garnett[1], Jamie Rich[1], Stuart Barnscher[1]

[1]Zymeworks Inc., Vancouver, BC, Canada,[2]None, None, BC, Canada

Aberrant RAS signaling is implicated as an oncogenic driver in up to 30% of cancers. Mutant selective RAS inhibitors (RASi) have been clinically approved in select indications, but their durable efficacy is hampered by acquired alterations that render tumors refractory to drug. Pan-RASi are showing broad clinical promise, but their full potential has been limited by toxicities likely arising from on-target inhibition of wild-type RAS in normal tissues, as well as by the emergence of resistance. These challenges may be improved upon by optimizing delivery of a RASi via an antibody drug conjugate mechanism. Lymphocyte antigen 6 family member E (Ly6E) is a GPI anchored cell surface protein with minimal presence in normal tissues that is prevalently overexpressed in many solid tumors including those which commonly feature oncogenic RAS mutations, such as NSCLC, PDAC, and CRC. We sought to leverage the ability of an ADC to increase the delivery of a novel pan-RASi payload to tumors for improved response, and to provide a differentiated safety profile that mitigates the toxicity limitations of current small molecule pan-RASi.

ZW427 comprises a novel Ly6E-targeted humanized IgG1 antibody conjugated to a novel pan-RAS inhibitor via a cleavable linker. The anti-Ly6E antibody was discovered and optimized for ADC application, with a focus on binding, specificity, internalization and payload delivery to tumor cell lines. To study the therapeutic potential of ZW427, *in vitro* ADC cytotoxicity was assessed in spheroids derived from a panel of RAS mutated cancer cell lines. Internalization and spheroid penetration were evaluated, and tumor cell co-culture assays were performed to assess bystander-mediated cell killing potential. Anti-tumor activity of ZW427 was investigated in multiple RAS mutated mouse xenograft models with a range of Ly6E-expression. Pharmacodynamic aspects of RAS inhibition were also assessed.

ZW427 exhibited target specific binding to cancer cells, highly effective internalization and bystander-mediated killing. Importantly, the ADC demonstrated potent and target-specific cytotoxicity in multiple Ly6E-expressing cancer cell spheroids. A single administration of ZW427 resulted in anti-tumor activity across a range of xenograft models. The pan-RASi ADC platform that has been developed shows encouraging tolerability in mice and an imminent toxicology study of ZW427 in non-human primates will further define its safety profile. Overall, the data supports the potential of ZW427 as a novel, highly differentiated therapeutic agent against Ly6E-expressing RAS mutant cancer indications.

#4432 LNF2105, a next-generation nectin-4-targeted ADC with a specially designed linker and a DXD analogue.

Zhongsong Zhu, Shili Wang, Jinhua Xu, Fanliang Cheng, Yuqiang Zhu, Peibiao Zhang, Guimin Zhang, Lili Zhao, **Zhenyu Li**

Lunan Pharmaceutical Group Co., Ltd., Linyi, China

Background: Nectin-4 is an attractive tumor-associated antigen, with over-expression in various solid tumors including UC, TNBC, CC, NSCLC, and HNSCC, while minimal expression in normal tissues. High Nectin-4 expression is closely associated with tumor development and poor prognosis, acting as a crucial biomarker for cancer recurrence and metastasis. Currently, only one Nectin-4 ADC with MMAE as the payload, Enfortumab Vedotin (EV), has been approved for marketing. However,EV has the issue of non-uniform DAR values, which can result in drug heterogeneity. Moreover, there is a black box warning in its instruction for severe and fatal skin adverse reactions. Therefore, we developed a novel Nectin-4-targeted ADC drug with a new mechanism, LNF2105 whose homogenous drug-antibody ratio and novel linker chemistry increase the stability of the conjugate in the systemic circulation, enabling highly efficient drug delivery and avoiding off-target toxicity.

Methods: To measure the bystander killing effect, CHO-GFP and MCF-7 cell lines were used. To assess serum stability, LNF2105 and DS8201 were incubated at 37℃ for up to 25 days in human plasma; free DXD was quantified by LC/MS-MS. For *in vitro* studies, assays for competitive ability and specificity, binding affinity, internalization, ADCC activity, and killing activity were performed. The *in vivo* antitumor efficacy of LNF2105 was evaluated in MDA-MB-468, xPC3, NCI-H322, and SW780 in subcutaneous xenograft models.PK properties were studied in cynomolgus monkeys, and safety studies of the payload and ADC were conducted in rats and cynomolgus monkeys, respectively. In general toxicology studies, cynomolgus monkeys and ICR mice were used.

Results: LNF2105 appeared as a homogeneous ADC composed of a Nectin-4-targeting monoclonal antibody conjugated to a Topo I inhibitor using interchain-disulfide-based site-specific conjugation technology, with DAR 8. A significant bystander killing effect were observed. Compared to DS8201, the payload dropout rate of LNF2105 was much slower and its plasma stability was higher. In various solid tumor xenograft models, LNF2105 demonstrated dose-dependent tumor suppression, with efficacy comparable to or superior to that of EV, which may be attributed to the site-specific conjugation. In addition, LNF2105 demonstrated a favorable safety profile, and the only side effect on the skin of monkeys was reversible. Ocular, pulmonary, and hematologic toxic side effects—common in Nectin-4-targeted therapy—were not observed. The HNSTD in monkey was 6 mg/kg, with milder adverse events compared with those of EV.

Conclusions: Overall, LNF2105 is a Nectin-4-directed ADC drug with a specially designed linker and a DXD analogue payload. Next generation site-specific conjugation technologies endow the drug with excellent homogeneity, remarkable preclinical antitumor activity, and a favorable safety profile.

#4433 Preclinical evaluation of LM-364^{TME}: A next-generation anti-Nectin4 ADC with promising efficacy and reduced toxicity.

Lei Shi, Yun Zhang, Rongrong Huang, Xia Qin, Da Fei, Yuan Li, **Wei Cao**

LaNova Medicines, Shanghai, China

Background: Antibody-drug conjugates (ADCs) has shown significant efficacy across multiple tumor types. Nectin-4, an adhesion molecule with limited expression in normal tissues (restricted to skin and secretory glands), is overexpressed in bladder, triple-negative breast, and other epithelial cancers. The clinical success of enfortumab vedotin valudated Nectin-4 as a therapeutic target; however, dose-limiting skin rash and neuropathy arise from on target, off-tumor toxicity due to low Nectin-4 epxression in nomal tissues. Extracelluar adenine nucleotides (ANP:ATP/ADP/AMP) accumulate to micromolar concentrations within the tumor microenvironment (TME), while remaining at nanomolar levels in heathy tissues. LM-364^{TME} is a novel anti-Nectin-4 ADC designed to exploit this metabolic difference. It comprises a humanized antibody endineered for ANP-dependent binding to Nectin-4, conjugated via a cleavable linker to topoisomerase I inhibitor payload, with a drug-to-antibody ration of 8.

Methods: Binding activity, specificity, and cross-species reactivity of LM-364^{TME} were evaluated by flow cytometry. Internalization was evaluated using a pH-sensitive fluorescent probe. Cytotoxicity was measured via CellTiter-Glo luminescent cell viability assay. *In vivo* anti-tumor activity of LM-364^{TME} was evaluated in Nectin 4-positive cell line-derived xenografts (CDX) and patient-derived xenografts (PDX) models. Repeated-dose toxicity studies were performed in Sprague-Dawley rats and rhesus monkeys.

Results: LM-364^{TME} exhibited strong ANP-dependent binding to Nectin 4, with an EC_{50} of 0.02 nM to huNectin4 protein and 0.187 -1.837 nM in Nectin-4 positive tumor cells under high ANP conditions, butnegligible binding in the absence of ANP, resulting a large selectivity window. LM-364^{TME} also exhibited cross-reactivity with Nectin-4 in rodent and non-human primate models. LM-364^{TME} showed robust ANP-dependent internalization and cytotoxicity in in MDA-MB-468 and huNectin 4 CHOK1 cells. *In vivo*, LM-364^{TME} treatment (3-6 mg/kg) significantly induced tumor growth and regression in multiple models, including MDA-MB-468 (TGI 119.1%), urothelial carcinoma PDX (TGI 107.46%) , esophageal cancer PDX (TGI 86.73%), and cervical cancer PDX (TGI 168.79%). In repeat-dose studies, LM-364^{TME} was well tolerated in both rats and rhesus monkeys.

Conclusion: LM-364^{TME} is an ANP-dependent, conditionally active anti-Nectin-4-ADC that demonstrates potent and selective antitumor activity with favorable safety profile in preclinical models. These data support LM-364^{TME} as a promising next-generation Nectin-4-targeted therapy with the potential to improve the therapeutic index of this class.

Keywords: Nectin-4, antibody-drug conjugate, LM-364^{TME}, solid tumors

#4434 *In vitro* and *in vivo* study of C^2LP-ADC & CLP^2-ADC targeting human breast and gastric cancer.

Xingquan Ma[1], Greg Liang[1], Weihua Shi[1], Bing Li[2], Shuwei Lu[1], **Xinxin Yang**[1], Qikuan Chen[1], Guilan Wang[1], Yao Ma[2]

[1]Shanghai ChemPartner Co., Ltd., Shanghai, China,[2]ChemPartner Co., Ltd., Boston, MA

Antibody-Drug Conjugates are a class of targeted cancer therapeutics that combine the specificity of monoclonal antibodies with the potency of cytotoxic agents. This design enables selective delivery of the agents to cancer cells, while avoiding healthy tissue. Some of the challenges that remain with the development of these treatments is the narrowness of the therapeutic window and significant off target toxicity due to non-specific release of the payload. One of the other major challenges is tumor resistance. Leveraging our experience in linker synthesis, we set out to design next-generation linkers that address the persistent challenges of ADC development. Our strategy centered on creating a cleavage cascade system incorporating two distinct cleavage events, enhancing linker robustness and reducing the risk of non-specific payload release (C^2LP-ADC). As a potential solution to drug resistance, we engineered linkers with the ability to tailor the Drug-to-Antibody Ratio (DAR), enabling incorporation of multiple payloads (CLP^2-ADC). We synthesized and conjugated analogues of known ADCs for Anti-HER cancers using both C^2LP and CLP^2 linkers. The C^2LP was compared *in vitro* and *in vivo* to a reference ADC, demonstrating improved therapeutic index and decreased off-target toxicity, with the test subjects maintaining body mass for longer than those treated with the reference-ADC. In addition, the linker-payload complex was demonstrated to be stable in plasma for much longer than the reference-ADC. *In vitro* treatment of resistant cell lines with CLP^2-ADC demonstrated enhanced therapeutic efficacy with respect to the reference-ADC.These findings highlight the critical role of linker technology in optimizing ADC performance. Incorporation of C^2LP and CLP^2 linkers can substantially improve safety, stability, and therapeutic efficacy in ADCs targeting HER-positive breast and gastric cancers, offering a promising strategy for overcoming resistance and minimizing systemic toxicity.

#4435 Transforming ADC development with novel linker architectures and payload optimization.

Gengcheng Jack Yang, Xudong Wei

Payload-linker Department, WuXi XDC, Cranbury, NJ

Antibody-drug conjugates (ADCs) are an expanding class of targeted cancer therapies, and innovations in linker and payload chemistry are critical to improving therapeutic index and clinical outcomes. We present four complementary strategies designed to enhance ADC performance and manufacturability. First, a novel linker adapter, N-(ortho-hydroxyphenyl)-N-methylcarbamate, enables controlled side-chain modification and rapid payload release, resulting in pronounced tumor regression in colonic cancer xenograft models. Second, a Val-Ala-based double self-immolative linker-payload platform was developed to optimize hydroxyl group-containing payload integration. A trastuzumab-DXd ADC constructed using this platform demonstrated improved stability, cathepsin B sensitivity, potent bystander effect, and a broad therapeutic index in HER2-positive and -negative xenografts, with favorable safety profiles in preclinical toxicology studies. Additionally, we introduce a streamlined two-step synthesis of a disaccharide linker for glycosite-specific conjugation, reducing the traditional >15-step process and enabling cost-effective production of homogeneous ADCs with enhanced quality and consistency. Finally, we report the first ADC incorporating homocamptothecin as a payload, achieving antitumor activity comparable to Enhertu at 3 mg/kg while demonstrating improved tolerability in NCI-N87 xenograft models. Collectively, these innovations establish a versatile platform for next-generation ADCs, combining precision targeting, improved pharmacological properties, and scalable manufacturing to advance clinical oncology.

#4436 Sutro's site-specific dual-payload ADCs combining TOPO1i and DNA damage response inhibitors to enhance efficacy, overcome resistance, and improve safety.

Krishna Bajjuri, Robert Yuan, Daniel Calarese, Rhoneil Pena, Ravi Singh, Young Park, Cuong Tran, Abigail Yu, Xiaofan Li, Guifen Xu, Yihong Zhou, Brian Vuillemenot, Werner Rubas, Genevive Hernandez, Alice Yam, Gang Yin, Hans-Peter Gerber

Sutro Biopharma Inc, South San Francisco, CA

Antibody-drug conjugates (ADCs) have demonstrated transformative potential in oncology, but enhancing efficacy of ADC against low-antigen and heterogeneous tumors while overcoming resistance and maintaining safety remain a major challenge. Resistance to single-payload ADCs, particularly TOPO1i based ADCs, is often driven by payload-specific mechanisms such as enhanced DNA repair or upregulation of drug efflux pumps, limiting sustained clinical responses. Sequential administration of TOPO1i ADCs frequently fails to restore efficacy, underscoring the need for novel, multi mechanistic strategies. Topoisomerase I inhibitors (TOPO1i) induce DNA breaks that collapse replication forks, but their efficacy is constrained by rapid repair via PARP and ATR dependent pathways. DNA damage response inhibitors (DDRi), such as PARPi and ATRi, block these repairs, restoring TOPO1i sensitivity in resistant, SLFN11-deficient, or repair-proficient tumors. This combination enforces checkpoint failure and prevents fork repair, providing a strong rationale for synergistic antitumor activity while limiting the development and progression of acquired resistance. Although combining TOPO1 inhibition with DDRi has a strong mechanistic rationale, clinical application is constrained by overlapping and non-overlapping toxicities. To overcome these challenges, we developed site-specific dual-payload ADCs (dpADCs) to co-deliver TOPO1i and proprietary DDR inhibitors, including PARPi or ATRi that are not substrates for drug efflux pumps. This strategy leverages synthetic lethality by pairing TOPO1i-induced DNA damage with DDR blockade, selectively enhancing cytotoxicity in target-antigen expressing tumor cells. Key challenges in developing TOPO1i × DDRi dpADCs include optimizing DDRi properties suitable for ADC delivery, selecting payload ratios, maintaining conjugate homogeneity, ensuring linker stability, and mitigating systemic toxicity. By leveraging Sutro's cell-free expression platform, precise dual-conjugation technology, and hydrophilic tumor-selective β-glucuronidase cleavable linkers, we engineered homogeneous, site-specific dpADCs with tunable drug-to-antibody ratios (DARs). These design features enhance solubility, stability, and pharmacokinetics while preserving payload synergy. We demonstrate that Sutro's site-specific TOPO1i × DDRi dual-payload ADCs (dpADCs) exhibit superior anti-tumor activity compared to single-payload ADCs, including in models resistant to TOPO1i ADCs. The targeted co-delivery of TOPO1i and DDRi has the potential to minimize off-target toxicity typically associated with systemic DDR inhibition, thereby broadening the therapeutic window and streamlining preclinical and clinical development compared to separate combination regimens.

#4437 Preclinical development of XNW28012, an antibody drug conjugate targeting tissue factor for treatment of solid tumors.

Yonghan Hu[1], Zhe Zhang[2], Yuanbao Li[2], Liang Kong[2], Shihua Wang[2], Zhenwei Wu[2], Xiaocheng Hu[2], Ka Ruan[2], Wengui Wang[2], Guorong Li[1], Qifeng Shi[2], Haiyang Wei[2], Xiaojun Liu[2], Meijie Le[1], Jing Qiang[1]

[1]Evopoint, Shanghai, China,[2]Evopoint, Suzhou, China

Tissue factor (TF) is a transmembrane protein that serves as the primary initiator of physiological hemostasis. TF binds coagulation factor VII (FVII), promotes its activation, and enhances the proteolytic activity of FVIIa to initiate the extrinsic pathway of blood coagulation. To prevent any improper coagulation cascade activation, TF is normally not expressed by cells exposed to flowing blood such as endothelial cells. Elevated TF expression has been reported in multiple solid cancers, such as cervical cancer, esophageal cancer, and pancreatic cancer. TF is well-internalized into lysosomes and given these various features, represents a favorable target for an antibody-drug conjugate (ADC) modality.XNW28012 is a TF-targeting ADC comprised of a humanized IgG1 antibody conjugated with a potent DNA topoisomerase I inhibitor *via* a protease-cleavable linker with a drug-antibody ratio (DAR) of 8. The tripeptide linker is highly stable in blood and cleavable in the tumor microenvironment and in tumor cell lysosomes. In preclinical studies, XNW28012 can bind to TF on cell surface, enter the cell through internalization effect, and then exhibits similar efficacy with toxin, such as inhibition of cell proliferation, cell cycle arrest, DNA damage response and apoptosis. XNW28012 also exhibits significant antitumor efficacy in multiple tumor xenograft models, including cervical cancer (CaSki), ovarian cancer (OVCAR8), pancreatic cancer (HPAF-II), etc. *In vivo* efficacy is dose-dependent and test dosages are well-tolerated, with minimum effective dose at 1 mg/kg/dose weekly. At the well-tolerated 3 or 10 mg/kg dosage, XNW28012 achieves partial tumor regression (PR) and complete tumor regression (CR) in most xenograft models. XNW28012 combined with SOC showed synergistic effect in multiple xenograft models. The antibody has minimal effect on blood coagulation through antibody screening and therefore no bleeding adverse effect (AE) is observed in toxicity studies.In pharmacokinetic studies, the ADME characteristics of XNW28012 confirmed the designed attributes of the ADC that directs toward the target antigen expressed on the cancer cell surface, and has excellent stability in the bloodstream and the exposure of payload was very low, leading to reduced toxicity. In toxicity studies, XNW28012 displays good tolerability with wide therapeutic windows in Cynomolgus monkeys. It is particularly important to note that XNW28012 has no toxic effect on the lungs and eyes, and no bleeding risk was observed in monkeys.Taken together, preclinical data suggest that XNW28012 could be a promising new antitumor agent for further investigation in clinical trials. Clinical activity of XNW28012 is currently under evaluation in a Phase I/II clinical trial (CTR20233056) and a Phase III clinical trial (CTR20252545).

#4438 A novel synergistic dual-payload TROP2 ADC (CTPH-03) delivering enhanced safety by increased MTD.

Myeong Joo Kim, Soyeon Lim, Dahyun Kim, Han ah Kim, Jaebeom Park, Eunseok Choi, Da wo Jeong, Ji Eun Choi, Young Sang Kim, Seung Chan Kim, Hyo Jin Kang, **Chang-Sun Lee**

Celltrion Pharm, Inc., Incheon, Korea, Republic of

Dual-payload antibody drug conjugates (ADCs) have gained increasing attention due to their potential to overcome limitations of single-payload ADCs. Depending on the combination strategy, dual-payload formats have been reported in order to mitigate tumor heterogeneity or to address resistance that may develop with single payload ADCs. Our dual-payload approach is differentiated from these approaches by aiming to identify two distinct payloads that could provide synergistic anti-tumor activities while minimizing overlapping unwanted side effects. Through extensive combination screening campaigns, we have discovered payload pairs that synergize each other by ZIP score experiments. TROP2 is a perfect target antigen to validate our dual-payload ADC format since it is a clinically validated. Although there are two FDA-approved ADCs, Trodelvy and Datroway, anti-tumor efficacy from these TROP2 ADCs have been subpar due to dose-limiting toxicities. We have developed a novel TROP2-targeting dual-payload ADC (AD^2C) by using MMAE-based dual-payload combination to address this unmet need. The presentation highlights advantages of the synergistic dual-payload TROP2 ADC over known single-payload ADCs or other dual-payload ADC formats by demonstrating, (1) *in vitro* cytotoxicity for cancer cells having different TROP2 expression levels (2) *in vivo* efficacy in various CDX(cancer-cell derived xenograft) models (3) *in vivo* ADC stability in rats and monkeys by PK(pharmacokinetics) studies, and (4) preliminary toxicity studies conducted in mice and monkeys.In due course, we are currently in preparation of PDX efficacy studies for further confirming its *in vivo* efficacy over various patient-derived tumor cells, and IND-enabling toxicology studies in order to quickly move forward the dual-payload TROP2 ADC(AD^2C) into clinical study.

#4439 Preclinical assessment of HWK-007, a next-generation, PTK7-targeting ADC with novel bioconjugation and linker-payload technology.

Kathy S. Keegan[1], Shihe Hou[1], Ashwini B. Pai[1], Enrico Bellomo[1], Erik Kratzer[1], Victor Peykov[1], Bryan Ball[1], Xia Wang[2], Qingling Lu[2], Lei Wu[2], Jijie Gu[2], David J. Lennon[1], David Dornan[1]

[1]Whitehawk Therapeutics, Morristown, NJ,[2]WuXi Biologics, Shanghai, China

Protein tyrosine kinase-7 (PTK7) is a catalytically-inactive receptor tyrosine kinase that promotes tumor progression through the Wnt/planar cell polarity (PCP), phosphatidylinositol 3-kinase/protein kinase B (PI3K/AKT), mitogen-activated protein kinase (MAPK), and vascular endothelial growth factor (VEGF) pathways. Overexpression of PTK7 contributes to metastasis, chemoresistance, and poor clinical outcomes in multiple tumor types. PTK7 is overexpressed in up to 70% of solid tumors, including—but not limited to—lung, ovarian, and endometrial cancers, and has low expression in normal cells, making it an attractive target for an antibody-drug conjugate (ADC). Results from early clinical trials of cofetuzumab pelidotin, a PTK7-targeted, auristatin-based ADC, showed promising signs of clinical activity. HWK-007 is a next-generation, PTK7-targeting ADC that comprises an Fc effector-attenuated IgG1 antibody conjugated to the DNA topoisomerase I inhibitor CPT116, with a drug-to-antibody ratio of 6. HWK-007 incorporates novel bioconjugation (carbon bridge cysteine re-pairing) and advanced linker-payload technologies, designed to maximize intracellular delivery while minimizing systemic exposure of free payload. The mechanism of action of HWK-007 was investigated in preclinical models of cancer. Results showed that HWK-007 bound specifically to cells expressing PTK7, was internalized through receptor-mediated endocytosis into lysosomes, and induced DNA damage resulting in loss of cell viability. Potent antitumor activity was demonstrated in multiple xenograft tumor models, with durable tumor regression observed with as low a dosage as 1 mg/kg single dose; this antitumor activity was superior to that of cofetuzumab pelidotin at equivalent doses. HWK-007 showed a notable bystander killing effect *in vitro*, suggesting the ability to elicit activity against heterogeneous tumors. HWK-007 demonstrated a favorable pharmacokinetic profile in non-human primates (NHP), with an extended half-life and very low levels of free payload observed (0.0067% of the AUC). Repeat-dose toxicology studies in NHP determined a highest non-severely toxic dose (HNSTD) of 60 mg/kg. Combined with preclinical efficacy results, these data suggest a therapeutic index that is suitable for testing in humans. In summary, HWK-007 is a highly potent and selective, next-generation, PTK7-targeted ADC. A phase I dose-escalation study is planned to evaluate HWK-007 in patients with advanced solid tumors.

#4440 Preclinical assessment of HWK-206, a next-generation, biparatopic, SEZ6-targeting ADC with novel bioconjugation and linker-payload technology.

Kathy S. Keegan[1], Shihe Hou[1], Ashwini B. Pai[1], Enrico Bellomo[1], Erik Kratzer[1], Victor Peykov[1], Bryan Ball[1], Lei Wu[2], Mengmeng Sun[2], Lu Jiang[2], Jijie Gu[2], David J. Lennon[1], David Dornan[1]

[1]Whitehawk Therapeutics, Morristown, NJ,[2]WuXi Biologics, Shanghai, China

Seizure-related 6 homolog (SEZ6) is a cell-surface transmembrane protein that plays a role in neuronal development. SEZ6 expression is highly elevated in neuroendocrine (NE) tumors, including, but not limited to, small cell lung cancer (SCLC), brain or central nervous system cancers, and NE tumors of prostate and bladder origin, and has limited expression in normal tissues. In SCLC, SEZ6 expression is correlated with worse survival outcomes. Single-epitope, SEZ6-directed antibody-drug conjugates (ADCs), such as ABBV-706, have shown initial promise in SCLC and NE neoplasms, but with some potential challenges attributed to side effects associated with these agents. HWK-206 is a next-generation ADC that utilizes a biparatopic antibody (bpAb) approach to target SEZ6, with an Fc effector-attenuated IgG1 antibody conjugated to the novel DNA topoisomerase I inhibitor, CPT116. HWK-206 was designed using novel bioconjugation (carbon bridge cysteine re-pairing) and advanced linker-payload technologies to maximize intracellular delivery while minimizing systemic exposure of free payload. The mechanism of action of the HWK-206 bpAb was investigated in preclinical SCLC models. Results showed that the HWK-206 bpAb bound to SEZ6 with higher affinity than the parental antibodies or that reported previously for ABBV-706. HWK-206 induced DNA damage and loss of SCLC tumor cell viability. Furthermore, the HWK-206 bpAb demonstrated superior binding, receptor-mediated internalization, and reduction in viability of SCLC tumor cells expressing varying levels of SEZ6, compared with the parental antibodies and historical benchmarks. Potent antitumor activity was observed in various SCLC xenograft tumor models, with tumor regression observed at single doses as low as 2 mg/kg. HWK-206 demonstrated a bystander killing effect *in vitro*, suggesting the ability to elicit activity against heterogeneous tumors. The pharmacokinetic (PK) and safety profiles of HWK-206 were evaluated in nonclinical toxicology studies. HWK-206 demonstrated a favorable PK profile and was well tolerated. In summary, HWK-206 is a highly potent and selective next-generation, biparatopic, SEZ6-targeted ADC that warrants further investigation. A planned phase I dose-escalation study will investigate HWK-206 in patients with advanced solid tumors.

#4441 Preclinical characterization of novel LIV1 antibody drug conjugates.

Fei Teng, Huanhuan Guo, Xinlai Yao, Lizhi Qin, Lei Shi, Xu Lin, **Yi Gu**, Xueming Qian

Transcenta Therapeutics Co., Limited, Suzhou, China

Background: LIV1 is a member of the zinc transporter family. With limited normal tissue expression, LIV1 was found to be overexpressed with high prevalence in breast (93%), prostate (72%) and lung (10%) cancers, and considered as an attractive cell surface target for developing ADC therapeutics. We have generated 48D6, a proprietary novel humanized anti-LIV1 mAb with high affinity, specificity, internalization ability, unique epitope and improved pharmacokinetics (PK) profile in mice. Then we developed 48D6 based ADCs using glycotransferase mediated site-specific conjugation with Topo I inhibitor (ADC-2) or MMAE (ADC-3), and characterized their anti-tumor activities in preclinical PDX/CDX models and exploratory toxicity in mice.
Methods: PK properties were studied with single dose (i.v.) of 3 or 10 mg/kg of both naked antibodies and ADCs in Balb/c mice. To evaluate anti-tumor activities, nude mice were subcutaneously implanted with LIV1-expressing PDX tumor blocks. When tumors reached ~200mm3, mice were treated (i.v.) with isotype control-ADC or LIV1 ADCs. To explore the combination efficacy of LIV1 ADCs and PD-1 antibody, we established LIV1/PDL1 co-expressing NCI-H460-LIV1 CDX model in human PBMC reconstituted mice. For exploratory tox study, mice were i.v. injected with LIV1 ADC or 48D6 at 10, 30, 60 mg/kg every week for 3 times, then recovered for 5 weeks.
Results: The T1/2 of of 48D6 antibody is 13.8~15.6 days relative to 1.7~3.3 days for Ladiratuzumab analog in mice. After conjugation into ADCs, the T1/2 of 48D6 ADC-2 ranged 10.4~11.6 days while that of SGN-LIV1A analog in mice is 3.7~3.9 days. Topo I inhibitor payload based ADC-2 displayed strong anti-tumor activities in LIV1 expressing NSCLC and breast PDX models. However, for LIV1 expressing prostate PDX models, two doses of ADC-2 did not inhibit tumor growth significantly. Thus MMAE-based ADC-3 replaced ADC-2 from the 3rd dose. Interestingly ADC-3 inhibited the growth of the prostate tumor significantly. In a LIV1 high expressing prostate PDX, the tumor growth was suppressed by ADC-3 for over 70 days after the dosing was stopped on Day 28. In the LIV1/PDL1 co-expressing NCI-H460-LIV1 CDX model, combination group inhibited tumor growth significantly better than single agent group. In exploratory tox study, ADC-2 were well tolerated following repeated administrations in mice at all doses tested. Slight lesions were observed in 60 mg/kg group during the treatment period and fully recovered at the end of the recovery period. Based on these results, the maximum tolerated dose (MTD) of ADC-2 in mice was determined at 60 mg/kg.
Conclusions: LIV1 targeting ADC-2 and ADC-3 exhibited strong anti-tumor activities as monotherapy in PDX models and the anti-tumor activity is further enhanced by checkpoint inhibitor. ADC-2 displayed excellent tolerability profile in mice. These results support further investigation of our LIV1 ADCs in LIV1 positive solid tumors.

#4442 Targeting ITGB4 with a topoisomerase I ADC: Preclinical antitumor activity in colorectal and head and neck cancers.

Mi Young Cha, **Hyunuk Kim**, Hyunkyung Yu, Youngeun Ha, Kitae Park, Seungmin Byun, Bu-Nam Jeon, Mira Kim, Gyeongyeon Kim, Sangmoo Park, Wuhwui An, Suah Choi, Yura Kang, Hansoo Park

Genome & Company, Suwon-si, Korea, Republic of

Integrin beta 4 (ITGB4) was identified as a promising tumor-specific antigen through the GNOCLE™ platform, a drug discovery engine that leverages real-world clinical data. ITGB4 is highly expressed in various solid tumors, including head & neck, colorectal, and esophageal cancers, but shows minimal expression in matched normal tissues, as confirmed through immunohistochemistry analysis, supporting a favorable therapeutic window. In cancer progression, ITGB4 promotes epithelial detachment, migration, and invasion. Its high expression is linked to resistance to chemo and targeted therapies and correlates with poor prognosis and aggressive tumor behavior. Based on its tumor-specific profile and functional relevance, ITGB4 was selected as an attractive target for antibody-drug conjugate (ADC) development. Here, we report the preclinical activity and safety of GENA-120, an ITGB4-targeting ADC composed of a humanized anti-ITGB4 antibody (GENA-120B17), a cleavable hydrophilic linker (LinkerE) designed to minimize retro-Michael elimination, and the topoisomerase I inhibitor payload exatecan. GENA-120B17 demonstrated high binding affinity to ITGB4, as well as efficient internalization into ITGB4-expressing cancer cells. Because ITGB4 exclusively dimerizes with integrin α6 to form α6β4 and interacts with its extracellular ligand, the binding and functional role of GENA-120B17 were further investigated in the context of α6β4-ligand interactions. Off-target screening confirmed high specificity to the primary target, with no detectable binding to irrelevant targets. GENA-120 was readily internalized into ITGB4-positive cancer cell lines and showed efficient lysosomal trafficking. In cellular assays, GENA-120 exhibited potent, target-dependent cytotoxic activity against multiple cancer cell lines. GENA-120 also demonstrated strong bystander activity in co-culture systems of ITGB4-positive and negative cancer cells. In addition, treatment with GENA-120 significantly increased ATP and HMGB1 release from ITGB4-positive cancer cells, indicating the induction of immunogenic cell death. In in vivo studies, GENA-120 demonstrated potent antitumor activity in ITGB4-positive cell-derived colorectal and head & neck cancer xenograft models (COLO205, LS174T, and FaDu). GENA-120 exhibited high stability in mouse, cynomolgus monkey, and human serum, as well as a favorable pharmacokinetic profile in mice. It was well tolerated in mice at single doses up to 140 mg/kg, with no maximum tolerated dose reached and no dose-limiting toxicities observed. These robust preclinical data, demonstrating strong efficacy, favorable pharmacokinetics, excellent cross-species serum stability, and a promising safety profile, support the continued development of GENA-120 as a therapeutic candidate for ITGB4-expressing solid tumors, including colorectal and head & neck cancers.

#4443 Preclinical development of GENA-104 ADC, an exatecan-based novel antibody-drug conjugate targeting CNTN4, for solid tumors.

Mi Young Cha, Hyunkyung Yu, Hyunuk Kim, Kitae Park, Youngeun Ha, Seungmin Byun, Jiyeong Lee, Mira Kim, Bu-Nam Jeon, Soojung Moon, Gyeongyeon Kim, Gyeong-Jin Cheon, Hansoo Park

Genome & Company, Suwon-si, Korea, Republic of

Contactin 4 (CNTN4) has emerged as a novel immune checkpoint molecule, previously shown to suppress T cell activity through interaction with amyloid precursor protein on T cells. Immunohistochemical (IHC) analysis revealed elevated CNTN4 expression across multiple tumor types, most notably in melanoma, liver, and endometrial cancers, while its expression remains low in normal tissues, including immune cells. Leveraging this tumor-specific expression profile, we developed an antibody-drug conjugate (ADC) targeting CNTN4, designated GENA-104A16B.LinkerE.Ex (hereafter referred to as GENA-104 ADC). This ADC consists of GENA-104A16.hIgG1, an anti-CNTN4 antibody engineered with reduced effector function, conjugated via cysteine to a hydrophilic, cleavable linker (Linker E) designed to minimize retro-Michael elimination. Linker E is an improved version of Linker D and demonstrated robust serum stability across species. The payload is exatecan, a potent topoisomerase I inhibitor, incorporated at a high drug-to-antibody ratio. GENA-104 ADC demonstrates potent cytotoxicity in CNTN4-positive cancer cells while maintaining low Fcγ receptor-mediated cytotoxicity, an advantageous safety feature for ADCs. Mechanistically, it induces tumor cell death through multiple pathways: direct cytotoxicity via internalization, lysosomal trafficking, and payload release; a bystander effect; and immunogenic cell death. Additionally, it enhances T cell-mediated cytotoxicity through immune checkpoint blockade. *In vivo*, GENA-104 ADC showed robust anti-tumor efficacy in fibrosarcoma (HT1080) and hepatocellular carcinoma (HEPG2) xenograft models. Using IHC analysis, CNTN4 expression was evaluated in 23 patient-derived xenograft (PDX) tissues, including gastric, hepatic, NSCLC, pancreatic, and prostate cancers, as well as sarcoma. High CNTN4 expression (H-score >250) was observed in 11 tissues, notably in 4 of 5 sarcoma models. Moreover, CNTN4 gene expression generally showed a positive correlation with H-scores. Ex vivo and in vivo evaluations of the GENA-104 ADC using PDX models are currently in progress, and updated results will be presented. Non-GLP toxicology in Sprague-Dawley rats and cynomolgus monkeys is in progress, with safety updates to follow. Taken together, these findings support the therapeutic potential of GENA-104 ADC as a targeted treatment strategy for CNTN4-expressing solid tumors. This research represents a meaningful step toward the development of precision oncology therapeutics that may offer improved outcomes for patients with limited treatment options.

#4444 Integrin alpha-2 (ITGA2) is a novel and well-suited antibody-drug conjugate (ADC) target.

Sophie Colombo[1], Vincent Martin[1], Aurelie Courtin[1], Sylvain Roqueviere[1], Lou-Amelia Revellin[1], Benjamin Beaufils[1], Catherine C. L. Wong[2], Pei Han[2], Wei Li[2], Yu Song[2], Qing Zhou[3], Feng He[3], Chuanying Xu[3], Weihong Nian[3], Mary Jane Hinrichs[4], Elisabetta Leo[5]

[1]Ipsen, Paris, France,[2]Foreseen Bio, Shangai, China,[3]Escugen Bio, Shangai, China,[4]Ipsen, Boston, MA,[5]Ipsen, London, United Kingdom

Background: IPN60300 is a novel, potential first-in-class ADC targeting ITGA2, a subunit of the heterodimeric transmembrane receptor integrin α2/β1 involved in cell adhesion and signal transduction. The ADC is designed to deliver exatecan, a potent topoisomerase I inhibitor, to ITGA2-expressing cancer cells. Here, we present a summary of newly generated and publicly available data indicating that the expression pattern of ITGA2 is well-suited for an ADC target. ITGA2 shows low expression in normal tissue and marked overexpression in various solid tumors, in particular gastrointestinal malignancies, where ITGA2 is known to contribute to tumor progression via extracellular matrix signaling and epithelial-mesenchymal transition. Furthermore, we confirm that IPN60300 activity in preclinical models is dependent on ITGA2 expression.
Methods: ITGA2 RNA and protein expression data were extracted from public databases (GEPIA 2, cProSite) and published literature. Additional expression data were generated through immunohistochemical analysis on human tissue microarrays (TMAs). Target-dependent anti-cancer activity was assessed in preclinical models with differential ITGA2 expression.
Results: ITGA2 is expressed ubiquitously at low levels in normal tissue, but is restricted to few cell types, in particular epithelial cells. In contrast, ITGA2 is overexpressed in several cancers, in particular in gastrointestinal tract tumors. Both transcriptomics and proteomics data demonstrate a strong differential expression of ITGA2 between tumor and normal tissue, with high overexpression in cholangiocarcinoma, pancreatic, colorectal, esophageal and stomach cancers, among other indications. Published literature further supports that in many cancer patient samples, ITGA2 is highly expressed in tumor cells. In addition, we confirm this expression pattern on TMAs, and show that overall, >90% of gastrointestinal tumor samples present ITGA2 expression, with a majority displaying medium-to-high expression levels. In preclinical studies, IPN60300 showed potent in vitro ITGA2-dependent cytotoxicity in cells overexpressing ITGA2 compared to the parental cell line. Consistently, in vivo, IPN60300 demonstrated strong anti-tumor activity in mice bearing ITGA2-expressing tumors, whereas no efficacy was observed in mice with ITGA2 knockout tumors.
Conclusion: The ITGA2 expression pattern makes it a well-suited ADC target, and IPN60300 efficacy in preclinical models is dependent on ITGA2 expression. These findings support IPN60300 as a promising first-in-class ADC for individuals harboring ITGA2-expressing tumors. IPN60300 is advancing to a First-in-Human clinical trial (NCT07213817).

#4445 Diverse ADC novel payloads, comprehensive screening and evaluation platform.

Ying Meng, Qian Wang, Min Kang, Xuan Qiao, Chanrui Wang, Yixiao Zhao, Jiangtao Lin, Jiamei Zhao, Li Li, **Tiejun Bing**

ICE Bioscience, Beijing, China

By combining the potency of payload with the specificity of antibody, Antibody-drug conjugate (ADC) is an innovative and promising drug modality for cancer therapy, possessing the advantages of both chemotherapy and immunotherapy. As ADC technology development continues to advance, more novel types of payloads are being actively explored.
ICE Bioscience employed different screening approaches including biochemical, biophysical, cell-based, and LC/MS-based assays for payload screening and evaluation. To be specific, the methods for cytotoxic drug evaluations include microtubule polymerization assay, NMT1/2 FI assay, different biochemical assays for DNA-damage response (DDR) targets, and DNA topoisomerase inhibition assay; For degrader payloads, spectral shifts or HTRF can be applied for measuring binary/ternary complex formation, HiBiT system and WB assay for quantifying target degradation; For STING agonist/antagonist payload, ICE has ready-to-use assays for detecting STING binding, STING activation and cytokine release. Cell panels of different types of cancer cell lines, ADC-related drug-resistant cell lines, immunogenic cell death (ICD) evaluation, in vitro hematotoxicity prediction, as well as ADME evaluation especially permeability and lysosome stability assays are valuable for all different types of payloads.
Based on 15 years of experience in early drug discovery, from target validation to pre-clinical candidate identification, our well-established ADC integrated platform can support comprehensive payload screening and evaluation early-stage drug discovery projects of traditional ADCs and emerging new ADC formats, including different cytotoxic payloads, novel degrader payloads and immune-related payloads, which can greatly accelerate ADC early-stage research.

#4447 Next generation molecular tools for evaluating antibody drug conjugates in 3D systems.

Jayanth Surya Narayanan Shankara Narayanan, Ryan Holly

Thermo Fisher Scientific, Eugene, OR

The development of effective anti-cancer drugs relies on accurately evaluating therapeutic antibodies. Three-dimensional (3D) tumoroids, which closely mimic the tumor microenvironment, help provide a promising platform for these evaluations. Our research focuses on validating therapeutics using antibody degradation trackers and antibody drug conjugates within 3D tumoroids. LysoLight tagged antibodies are fluorogenic in lysosomes, allowing visualization of antibody behavior within tumoroids, enabling insights into antibody degradation. Our studies showed higher Cetuximab uptake and localization to lysosomes in EGFR-overexpressing lung adenocarcinoma tumoroids, while non-specific antibodies or EGFR-null tumoroids showed minimal LysoLight activity. Additionally, we generated MMAE conjugated therapeutic antibodies using the new SiteClick rapid antibody conjugation technique, that allowed rapid screening of candidates from selected monoclonal antibodies to identify candidates with favorable therapeutic potential. High-throughput assays within 3D tumoroids enabled us to evaluate binding affinity, internalization rates, and cytotoxic effects. Our findings indicated that a MMAE conjugated EGFR targeted antibody-drug conjugate, facilitated a targeted cell penetration of drugs in colon cancer tumoroids and induced cell death. Integrating antibody degradation trackers and high-throughput Ab screenings within 3D tumoroids offers a robust platform for evaluating therapeutic efficacy, by providing a more accurate representation of their behavior in vivo.

#4448 3D-tumor organoid, over 2D-cell, is more predictive of *in vivo* anti-cancer pharmacology in assessing ADC candidates.

Tao Yang[1], Jun Zhou[2], Hang Ke[3], Jessie Jingjing Wang[4], Jiawen Gao[5], Qing Li[5], Jinxi Wang[5], Feiyu Peng[3], Cen Chen[1], Lei Zhang[3], Faming Zhang[3], **Henry Li**[1]

[1]Hanx Bio, Wuhan, China,[2]Crown Bioscience, Inc., San Diego, CA,[3]Hanx Biopharmaceuticals, Ltd, Wuhan, China,[4]Crown Bioscience, Inc., Taicang, China,[5]CrownBio, Taicang, China

ADC is a promising anti-cancer modality lately for widened therapeutic window (TW) due to tumor-specific targeting by direct binding to tumor cell-associated antigen (TAA), internalization and payload releasing/cytotoxicity induction. The conventional evaluation of lead ADC candidates usually involves the following steps: 1) ELISA-based binding to recombinant TAA protein; 2) TAA^+-2D-cell culture for assessing binding, internalization and cytotoxicity; 3) anti-tumor pharmacology using TAA^+ xenograft tumor models. This process is largely based on the assumption that 2D cancer cell line culture is predictive of *in vivo* tumor models. However, 2D-assay is frequently not reflective of tumor pharmaology assay from time to time due to distinct architectures of tumor (cell), rendering the process unproductive. Considering 3D tumor organoid being more reflective of tumor than 2D cell culture, we hypothesized that addition of 3D-tumor organoid culture as a new tier of assessment, right before *in vivo* tumor pharmacology, could make the process more productive. In this report, we set out to test this hypothesis by using three antibodies (Ab1, 2 and 3) against three different epitopes of PD-L1 and their corresponding ADCs (ADC1, 2, 3) with the same payload/DAR-value for binding/ internalizations/cytotoxicity in several $PD\text{-}L1^+$ cancer cell lines. Despite similar high-affinity to PD-L1 recombinant protein or $PD\text{-}L1^+$ cells, ADC-1 exhibited the strongest internalization/cytotoxicity in $PD\text{-}L1^+$ tumor cell lines, whereas ADC2 and 3 showed significantly lower activity (up to 1000x folds in differences). In another word, only ADC1 looks promising as an ADC candidate for further development. However, when all three ADCs were tested *in vitro* using 3D-tumor organoids, all ADCs demonstrated potent and comparable activities, sharp contrasting to those seen in 2D-cultures. We then tested them in the same 2D-cell-derived xenograft tumor models (CDXs), the results of which are consistent with those from 3D-tumor organoid cultures, but not those from 2D-cell cultures. These confirmed better transnationality of 3D-organoids over 2D-cells. Together, these findings support a practical workflow in which 2D assays serve as early benchmarks, while 3-D organoids provide a more predictive *in vitro* readout of ADC pharmacology prior to *in vivo* confirmation. We believe that the process of 2-D (benchmark) → 3-D organoids (translational) → in vivo (validate) can more efficiently streamline preclinical ADC triage. Furthermore, if the hypothesis that 2D (monolayer) culture is more representative of normal tissues, while 3D-tumor organoid is more representative of tumor architecture, is true, we could further suggest that 3D tumor and 2D cell culture differentiation assay could help to identify more tumor-specific ADC candidates with widen TW, *e.g.* ADC2 and ADC3 described in this report.

#4449 Functional organoid screening uncovers target dependency and bystander killing in TROP2 ADCs.

Organoid, Crown Bioscience, Inc., San Diego, CA

Introduction: TROP2-targeted antibody-drug conjugates (ADCs) represent a promising therapeutic class for multiple tumor types with elevated TROP2 expression. Membrane-permeable payloads can induce bystander killing, making functional, physiologically relevant testing crucial. We developed an advanced organoid-based ADC evaluation workflow combining large-scale patient-derived (xenograft) organoid (PD(X)O) screening, CRISPR-engineered isogenic models, and 3D high-content imaging (HCI) to assess potency, target dependency, and bystander effects.
Methods: Two TROP2 ADCs - an experimental exatecan-based ADC linked via a hydrophilic, cleavable linker, and datopotamab-deruxtecan (Dato-Dxd; DS-1062) - were evaluated in the organoid screening platform, where models were selected irrespective of TROP2 expression. The exatecan-based ADC was tested in 109 PD(X)Os (101 tumor, 8 normal) across ten cancer types using nine-point dose-response. Dato-Dxd was screened using six-point dose-response assays in 142 PD(X)Os (132 tumor; 10 normal) spanning nine tumor types. Drug incubation ran over five days, and efficacy was determined by ATP-based cell viability assay. Free payloads exatecan and Dxd (both naked and linker-conjugated) served as controls. CRISPR/Cas9-generated TROP2 knockout (KO) organoid pairs were labeled with fluorescent/luminescent reporters for target HCI-based dependency and bystander effect assays.
Results: The exatecan-based ADC demonstrated high overall efficacy (68.6% showed >50% inhibition at the highest dose of 1 μM), with pancreatic models even showing 100% sensitivity, and 32.4% of organoids achieving IC_{50} < 0.1 μM. Payloads alone were strongly cytotoxic in most models (93.3% of models sensitive with IC_{50} < 0.03 μM) with similar potency for exatecan and Dxd, whereas linker-conjugated Dxd was significantly less cytotoxic (average IC_{50} > 0.1μM). Dato-Dxd responses varied across the PD(X)O panel (54% showed >50% inhibition at 0.1μM, 37% IC_{50} < 0.1μM). For both TROP2 ADCs, a correlation between efficacy and TROP2 mRNA abundance was observed. In isogenic KO organoid models, loss of TROP2 abrogated Dato-Dxd responses, confirming target dependency. Mixed-culture assays quantified Dato-Dxd bystander killing, validating membrane-permeable payload action in neighboring cells.
Conclusion: The combined organoid screening and HCI workflow provides a robust, translationally relevant platform for ADC evaluation, integrating efficacy profiling, mechanistic validation, and functional bystander effect modeling. CRISPR-generated isogenic organoids enable precise dissection of target dependency and resistance, supporting the preclinical optimization of TROP2-targeted ADCs.

Poster Session

#4453 Ataxia telangiectasia and Rad3 related kinase inhibitors and gemcitabine induce synergistic killing of uterine leiomyosarcoma cells.

Megan Doherty, Minnie Malik, Montanna Macias-Young, Adora Jacobs, Yuka Otsuka, William H. Catherino

Uniformed Services University, Bethesda, MD

Introduction: Uterine leiomyosarcoma (uLMS) is a rare, lethal gynecological cancer. Therapeutic response to standard-of-care chemotherapy for uLMS is hindered because cancer cells can activate DNA damage response (DDR) pathways. For example, gemcitabine stalls replication forks and halts DNA synthesis. This activates Ataxia telangiectasia and Rad3 related kinase (ATR), which aids DDR by repairing stalled replication forks and delaying cell cycle progression. Therefore, we investigated the potential for ATR inhibitors to enhance the potency and efficacy of chemotherapy for uLMS *in vitro*.

Methods: CellTitre Glo, Bliss Independence analysis, and Multidimensional Synergy of Combinations (MuSyC) assessed synergy between three ATRi (elimusertib, ceralasertib, berzosertib) and SOC chemotherapy (gemcitabine, doxorubicin, docetaxel) in three commercially available (SK-LMS-1, SK-UT-1B, SK-UT-1) and two patient-derived uLMS cell lines (ACI-44A, ACI-44B). Following treatment of gemcitabine alone, elimusertib alone, or gemcitabine + elimusertib, flow cytometry was performed to analyze cell cycle phase distribution using propidium iodine-stained cells, as well as to assess apoptosis and necrosis using annexin V and sytox blue-stained cells. Western blotting investigated protein expression of ATR pathway proteins, DNA damage markers, and apoptosis markers.

Results: ATR inhibitors synergized most strongly with gemcitabine, with elimusertib + gemcitabine emerging as the most synergistic combination across all five cell lines. In contrast, combinations of ATRi with doxorubicin or docetaxel showed minimal to no synergy. ATRi enhanced gemcitabine potency in all cell lines by significantly reducing its EC50. Elimusertib also increased gemcitabine's cytoxicity. In SK-UT-1B cells, the combination increased apoptotic cells by 51.4% (14.7% vs 9.7%, $p < 0.05$) and necrotic cells by 120.2% (24.7% vs 11.2%, $p < 0.001$) compared to gemcitabine alone. Elimusertib did not prevent gemcitabine-induced S phase arrest but increased the sub-G1 population, consistent with enhanced cell death. Western blot analysis confirmed that elimusertib inhibited downstream ATR signaling, including CHK1 S345 phosphorylation blockage, and that the combination produced greater DNA damage and apoptosis - evidenced by increased p-H2AX (S139) and cleaved caspase-3 expression - than either agent alone.

Conclusions: Elimusertib strongly synergizes with gemcitabine *in vitro* across uLMS cell lines by potentiating DNA damage and apoptosis. The lack of synergy with docetaxel or doxorubicin underscores gemcitabine as the most effective combination with ATR inhibitors. These finds support further preclinical and clinical evaluation of elimusertib + gemcitabine as a promising novel therapy for uterine leiomyosarcoma.

#4454 AI-driven discovery of an IRP2-EGFR dual-targeting strategy reveals synergistic antitumor efficacy in colorectal cancer.

Soseul Won[1], Jieon Hwang[2], Sejeong Park[3], Sunkyu Kim[3], Sanghoon Lee[3], Areum Park[4], Hyuk Lee[4], Joong-Bae Ahn[2], Jaewoo Kang[3], Sang Joon Shin[2]

[1]Department of Clinical Drug Discovery and Development, Yonsei University College of Medicine, Seoul, Korea, Republic of,[2]Division of Medical Oncology, Department of Internal Medicine, Yonsei Cancer Center, Seoul, Korea, Republic of,[3]AIGEN Sciences, Seoul, Korea, Republic of,[4]Infectious Diseases Therapeutic Research Center, Korea Research Institute of Chemical Technology, Daejeon, Korea, Republic of

Background: IRP2 is a key regulator of intracellular iron homeostasis and is known to be overexpressed in colorectal cancer (CRC). As a relatively novel therapeutic target, IRP2 has been implicated in tumor progression, and our previous study demonstrated the antitumor effects of IRP2 inhibitors. To broaden the therapeutic potential of IRP2 inhibition and establish effective combination strategies, we applied a multifaceted AI-based predictive approach to identify compounds capable of synergizing with the IRP2 inhibitor.
Methods: We predicted compounds capable of producing a synergistic effect with IRP2 inhibition using an AI-based model on the AIGEN InSight platform. Cell viability was assessed using CCK-8, and synergy scores were calculated using the SynergyFinder 3.0. To investigate the mechanism underlying the combination effect at the RNA level, we performed RNA sequencing (RNA-seq) and identified differentially expressed genes (DEGs) using the DESeq2 R package. Pathway enrichment analysis was conducted, and key findings were validated in CRC cell lines using qRT-PCR and western blotting.
Results: Based on the AI-driven prediction model, Osimertinib was identified as a top-ranked candidate, achieving an AI-score of 0.73, which places it within the top 0.03% of all evaluated compounds. IRP2 inhibitor was subsequently optimized to generate KS-20260 with improved potency. The combination of KS-20260 and Osimertinib exhibited differential synergy scores across seven colorectal cancer cell lines. Notably, LoVo and DLD-1 cells showed the highest synergy scores of 10.845 and 7.843, respectively, and the combination treatment markedly reduced the protein levels of IRP2 and phosphorylated EGFR compared with single-agent treatments. Using RNA-seq data from LoVo cells treated with KS-20260, Osimertinib, or their combination, we analyzed pathways that were more affected by the combination treatment than the additive effect, defined as the average response of individual treatments. The Gene Set Enrichment Analysis (GSEA) revealed a significant downregulation of cell-cycle-related gene sets (e.g., CELL_CYCLE and CELL_CYCLE_PHASE_TRANSITION). Supporting these transcriptomic findings, the mRNA expression of key cell-cycle regulators, including CDK1, AURKB, CENPF, and E2F8, was decreased in the combination-treated cells. Furthermore, in the preliminary in vivo experiment, the combination-treated group (TGI 57.01%) exhibited a greater reduction in both tumor volume and tumor weight compared with the single-agent treatment groups (KS-20260, 38.37%; Osimertinib, 20.57%).
Conclusion: This study demonstrates that KS-20260 and Osimertinib combination therapy disrupts cell-cycle progression and enhances antitumor efficacy in colorectal cancer, supporting dual IRP2-EGFR targeting as a promising therapeutic strategy.

#4455 Efficacy of Tumor Treating Fields (TTFields) together with standard chemotherapy and PD-L1 blockage in preclinical models of small cell lung carcinoma.

Rotem Engelman[1], Lina Somri-Gannam[1], Talya Borkum[1], Roni Blatt[1], Daria Gerasimova[1], Shay Cahal[1], Catherine Tempel Brami[1], Mai Shai[1], **Yiftah Barsheshet**[1], Eyal Dor-On[1], Itai Tzchori[1], Adi Haber[1], Moshe Giladi[1], Uri Weinberg[2], Yoram Palti[1]

[1]Novocure Ltd, Haifa, Israel,[2]Novocure GmbH, Baar, Switzerland

Introduction: SCLC is a highly aggressive cancer treated with platinum-etoposide chemotherapy, immunotherapy, and radiotherapy. Tumor Treating Fields (TTFields), an FDA-approved therapy for several solid tumors, has been shown to enhance chemotherapy and immunotherapy treatment efficacy. Here, we assessed the potential of TTFields to augment the effects of chemotherapy and PD-1 inhibition in preclinical SCLC models.

Methods: Human SCLC cell lines (H196, DMS-53) were exposed to 150 kHz TTFields (1.62 V/cm RMS, 120 h; 1 V/cm RMS, 72 h), alone or with the chemotherapy combination cisplatin and etoposide (0.15 µM and 0.3 µM; 0.25 µM and 0.5 µM). Treatment efficacy was assessed by cell count and colony formation, combined to determine overall response. Protein expression in the Fanconi anemia-BRCA DNA repair pathway was analyzed by western blot, and DNA damage was quantified via γH2AX fluorescence microscopy. Immunogenic cell death (ICD) was evaluated by flow cytometry for ATP depletion (quinacrine staining) and surface calreticulin, and by Homogeneous Time Resolved Fluorescence (HTRF) assay for HMGB1 release. In vivo, mice orthotopically implanted with murine KP3 SCLC cells received TTFields (150 kHz) or sham-heat for 10 days starting seven days post-implantation, with or without cisplatin (2 mg/kg), etoposide (8 mg/kg), and anti-PD-L1 (10 mg/kg) administered intraperitoneally. Tumor burden was monitored by MRI at treatment initiation and completion, and tumor weight measured at endpoint. DNA damage was examined by γH2AX immunohistochemistry and by flow cytometry of tumor single-cell suspensions.

Results: TTFields and the chemotherapy combination each reduced cell counts and increased overall treatment efficacy compared with control, with greater effects observed when applied simultaneously. While TTFields or chemotherapy alone induced minimal DNA damage and ICD, concurrent application markedly enhanced both endpoints relative to control and single treatments. TTFields exposure suppressed expression of Fanconi anemia-BRCA pathway proteins essential for homologous recombination repair. In mice, TTFields reduced tumor growth, with further suppression observed when delivered together with cisplatin, etoposide, and anti-PD-1 therapy. Enhanced DNA damage was likewise detected under concurrent TTFields and immunochemotherapy exposure.

Conclusions: In preclinical SCLC models, TTFields showed antitumor activity and augmented the effects of standard chemoimmunotherapy. By interfering with DNA repair, TTFields intensify the cytotoxic impact of DNA-damaging chemotherapeutics, while their ability to trigger immunogenic cell death may potentiate immune checkpoint blockade. These complementary mechanisms highlight TTFields as a promising modality to reinforce the efficacy of existing therapeutic approaches in SCLC.

#4456 Tumor Treating Fields (TTFields) potentiate antitumor and immune responses to standard immunochemotherapy in non-small cell lung cancer models.

Boris Brant[1], **Yiftah Barsheshet**[1], Tali Voloshin[1], Tal Kan[1], Tharwat Haj Khalil[1], Simona Zisman-Rozen[1], Lilach Koren[1], Avital Vorontsov[1], Bella Koltun[1], Cfir David[1], Anat Klein-Goldberg[1], Efrat Zemer-Tov[1], Adi Haber[1], Moshe Giladi[1], Uri Weinberg[2], Yoram Palti[1]

[1]Novocure Ltd, Haifa, Israel,[2]Novocure GmbH, Baar, Switzerland

Introduction: Tumor Treating Fields (TTFields) are low-intensity alternating electric fields that disrupt mitotic processes in cancer cells, promoting downstream immunogenic cell death (ICD), and leading to activation of antitumor immunity. TTFields are approved for treatment of metastatic non-small cell lung cancer (NSCLC) following progression on platinum-based chemotherapy, together with immune checkpoint inhibitors (ICIs) or docetaxel. The ongoing LUNAR-2 trial (NCT06216301) is evaluating first-line TTFields with the anti-PD-1 pembrolizumab and platinum-based chemotherapy in metastatic NSCLC. The present study assessed the therapeutic efficacy and immunological effects of TTFields administered alongside anti-PD-1, cisplatin, and pemetrexed (PCP) in preclinical NSCLC models.

Methods: Human A549 NSCLC cells were exposed to TTFields (150 kHz, 1.7 V/cm RMS, 72 h) with or without cisplatin and pemetrexed (CP; 1.5 and 6.3 μM, respectively). Cell count, apoptosis (assessed by annexin V/7-AAD staining), and ICD markers surface calreticulin exposure and ATP depletion (quinacrine staining) were evaluated by flow cytometry In vivo, C57Bl/6 mice were orthotopically implanted with LL/2 lung carcinoma cells and allowed seven days for tumor establishment. The mice were then randomized into four groups: control, TTFields, anti-PD-1/cisplatin/pemetrexed (PCP), or TTFields + PCP. Treatment included continuous TTFields (150 kHz) or sham (heat) for 10 days and intraperitoneal injections of anti-PD-1 (10 mg/kg), cisplatin (1 mg/kg), and pemetrexed (6 mg/kg) or vehicle every 72 hours (three doses). Tumor localization was confirmed by MRI at study initiation, and at study end tumors were measured (MRI and weight) and processed to single cell suspensions for flow cytometric analysis of tumor-infiltrating lymphocytes. IFN-γ and granzyme B expression in $CD8^+$ T cells were assessed following PMA/ionomycin stimulation.

Results: Chemotherapy at the tested doses exerted minimal cytotoxic or pro-apoptotic effects on A549 cells and negligibly induced ICD. TTFields exposure reduced cell counts, increased apoptosis, and enhanced ICD markers, including calreticulin exposure and ATP depletion; however to a higher extent in the presence of CP chemotherapy. In vivo, TTFields or PCP each limited tumor growth compared with controls, while the concomitant regimen resulted in the smallest tumor volumes. Both PCP and TTFields + PCP increased tumor infiltration of $CD3^+$ T cells, particularly $CD8^+$. The TTFields + PCP group showed the highest proportion of IFN-γ- and granzyme B-producing $CD8^+$ T cells, indicating an elevated cytotoxic immune response.

Conclusions: TTFields enhanced the antitumor and immunostimulatory effects of standard immunochemotherapy in NSCLC preclinical models, supporting its therapeutic potential as an immune-modulating modality.

#4457 A novel CerS2 activator, DH20931, synergizes with doxorubicin to overcome therapeutic resistance in breast cancer.

Hissah Alatawi[1], Haritha H. Nair[1], Lingbao Ai[2], Abhisheak Sharma[3], Christopher Vulpe[4], Arun K. Sharma[5], Coy D. Heldermon[2], **Satya Narayan**[1]

[1]Physiology and Aging, University of Florida, Gainesville, FL,[2]Medicine, University of Florida, Gainesville, FL,[3]Pharmaceutics, University of Florida, Gainesville, FL,[4]Physiological Sciences, University of Florida, Gainesville, FL,[5]Molecular and Precision Medicine, Penn State Cancer Institute, Hershey, PA

Background: Doxorubicin (DOXO) efficacy in triple-negative breast cancer (TNBC) is severely limited by acquired resistance and dose-limiting cardiotoxicity. We identified ceramide synthase 2 (CerS2), producer of tumor-suppressive very long-chain ceramides (VLCCs), as a prognostic marker and therapeutic target in breast cancer (BC). We previously developed DH20931, a CerS2 activator that inhibits growth across BC subtypes by inducing lipotoxic endoplasmic reticulum (ER) stress. We hypothesized that DH20931 could sensitize BC cells to DOXO and reverse resistance.
Methods: The synergistic efficacy of DH20931 and DOXO was evaluated in parental and DOXO-resistant BC cell lines, e.g., MDA-MB-231, 4T1. Synergy was quantified using the Chou-Talalay method (Combination Index, CI). Mechanisms were assessed via confocal microscopy (DOXO uptake), immunoblotting (ER stress, apoptosis markers) and *in vivo* efficacy.
Results: The DH20931 combination significantly reduced the required IC_{50} of DOXO by 3-8-fold. DH20931 demonstrated strong synergy with DOXO (CI <1) across all tested BC cell lines, including DOXO-resistant models. The synergy was eliminated in CerS2-knockout cells indicating CerS2 target engagement. Mechanistically, the combination therapy resulted in hyper-activation of the UPR, maximized ATF4/CHOP/PUMA expression, and a marked increase in cleaved caspase-3 compared to either agent alone. *In vivo*, the DH20931+DOXO combination significantly inhibited tumor growth compared to DH20931 and DOXO monotherapy.
Conclusion: DH20931 effectively sensitizes BC cells to Doxorubicin and reverses DOXO-resistance, likely by enhancing CerS2-mediated lipotoxic ER-stress. This synergistic approach offers a promising clinical strategy to improve DOXO efficacy, reduce its cardiotoxicity by allowing dose reduction, and improve outcomes for patients with TNBC and other BC subtypes.

#4458 Enhancing the antitumor efficacy using a combination of FGFR4 inhibitor(H3B-6527) and oxaliplatin in gastric cancer.

Nadeem Bhat, Mohammed Soutto, Ahmed Gomaa, Shoumin Zhu, Selma Maacha, Marwah Al-Mathkour, Melanie Genoula, Oliver McDonald, Wael El-Rifai

University of Miami, Miami, FL

Background: Chemotherapy resistance continues to be a major obstacle in treating gastric cancer. This study investigates whether combining the FGFR4 inhibitor (H3B-6527) with Oxaliplatin can enhance treatment effectiveness in preclinical models, with emphasis on their combined impact on tumor growth inhibition and cell-death pathways.
Material and Methods: To assess the effectiveness of the H3B-6527 and oxaliplatin combination, we utilized IC50 assays, colony formation tests, patient-derived xenograft (PDX) models, immunofluorescence, immunohistochemistry, western blotting and caspase-3/7 luminescence assays. These methods allowed us to evaluate how the combined treatment influences tumor cell proliferation, DNA damage, and apoptosis in gastric cancer cell lines (MKN28 and HGC27) as well as in tumor tissues.
Results: IC50 analyses showed that both MKN28 and HGC27 cells were markedly more sensitive to the combination treatment than to either drug alone. Colony formation assays further demonstrated a substantial reduction in colony numbers with the combined therapy, underscoring its stronger anti-proliferative effect. In PDX mouse models, the combination produced significant tumor growth suppression and extended overall survival compared to controls. IF and IHC analyses revealed increased DNA damage, indicated by elevated γH2AX, decreased proliferation (Ki67), and higher apoptosis (cleaved caspase-3). Caspase-3/7 luminescence assays confirmed enhanced apoptotic activity in treated cells. Western blotting also showed increased cleaved PARP and γH2AX levels in both gastric cancer cell lines and PDX samples, supporting the heightened DNA damage and apoptosis triggered by the combined treatment.
Conclusions: This study highlights the strong synergistic effect of H3B-6527 and oxaliplatin in inducing apoptosis, increasing DNA damage, and suppressing tumor growth in gastric cancer models. The results offer strong support for the potential clinical use of this combination as an effective treatment approach, particularly for gastric cancer patients who exhibit chemoresistance.

#4459 Repurposed FDA-approved agents for hepatic artery infusion in colorectal liver metastases.

Manasa Ravi[1], Colin M. Court[2], April Risinger[1]

[1]UT Health Science Center at San Antonio, San Antonio, TX,[2]Division of Surgical Oncology and Endocrine Surgery, UT Health Science Center at San Antonio, San Antonio, TX

Colorectal cancer (CRC) remains a leading cause of cancer-related death, with liver metastases (CRLM) representing the most common cause of mortality. Despite advances in systemic therapy, outcomes for patients with CRLM remain poor, underscoring a critical need for improved, liver-directed treatment strategies. Hepatic artery infusion (HAI) pumps are an effective method to deliver high local concentrations of chemotherapy directly to the liver while limiting systemic toxicity. The currently-standard of care compounds for HAI have limited efficacy and elevated hepatotoxicity, emphasizing the demand for treatment regimens that have better patient outcomes. In this project, we explored a drug repurposing strategy by evaluating FDA-approved chemotherapeutic agents with pharmacokinetic properties compatible with HAI delivery. Drugs were selected using established pharmacokinetic databases and then tested in vitro using CRC cell models and a normal epithelial liver cell line to assess cytotoxicity and dose-response. In addition, we investigated the therapeutic potential of combining a microtubule destabilizer with an FDA-approved fatty acid synthase (FASN) inhibitor. Synergy experiments demonstrated enhanced cytotoxic effects when chemotherapeutics were combined with the FASN inhibitor, suggesting that there is potential for a novel treatment regimen for patients presenting with this disease. These preliminary findings support drug repurposing within the context of HAI delivery as a clinically translatable approach. By utilizing existing FDA-approved compounds of both chemotherapeutic agents and metabolic inhibitors, this strategy may lay the groundwork for novel therapies for patients with CRLM. Further preclinical and translational studies will be necessary to define optimal drug combinations and dosing regimens, with the ultimate goal of expanding therapeutic options and improving outcomes for this high-risk patient population.

#4460 Drug repurposing in Nectin-4-positive epithelial ovarian cancer.

Xiaoyan Zhong[1], Runying Long[2], Ruiqian Zhang[1], Ling Shan Hung[1], Can Cui[1], Chen Bao[1], Kui Liu[1], Cho Wing Li[1], Haonan Lu[1], Kar Loen Chan[1]

[1]Department of Obstetrics and Gynaecology, The University of Hong Kong, Hong Kong SAR, Hong Kong,[2]Materials Innovation Institute for Life Sciences and Energy (MILES), HKU-SIRI, Shenzhen, China

Objectives: Antibody-drug conjugates (ADCs) are promising therapeutic biologics for cancer treatment, and Mirvetuximab soravtansine (MIRV) is currently the only FDA-approved ADC for treating folate receptor alpha (FRα) positive platinum-resistant epithelial ovarian cancer (PROC). Results from the Phase 3 EV-302/KEYNOTE-A39 trial indicate that the combination of Nectin-4-directed ADC Enfortumab Vedotin-ejfv (anti-Nectin-4 ADC) and pembrolizumab yields better treatment outcomes than platinum-based chemotherapy in patients with metastatic urothelial carcinoma. The study aims to investigate the potential of repurposing anti-Nectin-4 ADC as a therapeutic strategy for epithelial ovarian cancer (EOC), and to explore effective combination therapies targeting Nectin-4-positive EOC tumors.
Methodology: Nectin-4 expression in EOC was validated through multiplex immunohistochemistry (MIHC) in our institutional tissue cohort and corroborated in independent public datasets. In vitro efficacy of anti-Nectin-4 ADC was evaluated using cytotoxicity, apoptosis, and clonogenic assays in EOC cell lines. Anti-tumor activity was investigated in patient-derived organoid models and xenograft models.
Result: Nectin-4 expression in EOC is heterogeneous but generally elevated compared to matched normal tissues. The Nectin-4-targeted ADC demonstrated significant cytotoxicity in Nectin-4-positive EOC cell lines. Both in silico and in vitro analyses revealed that Nectin-4-positive tumors are sensitive to two FDA-approved compounds, potentially due to dysregulated fatty acid metabolism. In vivo studies confirmed that anti-Nectin-4 ADC monotherapy effectively suppressed tumor growth, and combination treatments further enhanced survival outcomes.
Conclusion: This study demonstrates the therapeutic potential of Nectin-4-targeted agents in preclinical models of Nectin-4-positive EOC, supporting their advancement toward clinical translation. Additionally, the findings suggest that repurposing Nectin-4-guided combination therapy could expand and enhance treatment options for EOC.

#4461 Nebivolol exhibits cell growth inhibition in drug-resistant HR+/HER2- breast cancer and anti-tumoral synergism with abemaciclib *in vitro*.

Chia-Ling Wu, Meghana Trivedi, Shivaani Suresh Kanna

University of Houston, College of Pharmacy, Houston, TX

Background: We are investigating nebivolol, a third-generation beta-blocker, as a drug-repurposing candidate for breast cancer (BC). While prior studies have focused on triple-negative BC, we evaluated its efficacy and potency in hormone receptor-positive, HER2-negative (HR+/HER2-) BC, which is the most prevalent subtype. Since HR+/HER2- BC is typically treated with endocrine therapy (ET) alone or in combination with CDK4/6 inhibitors (CDK4/6i), we also assessed the effects of nebivolol in ET- and CDK4/6i-resistant models, as well as in combination with ET and CDK4/6i.
Methods: The efficacy and potency (IC50) of nebivolol were evaluated using MCF7 and T47D parental cells and their estrogen deprivation-resistant (EDR), palbociclib-resistant (PalboR), and EDR/PalboR derivatives. Cells were treated with vehicle or nebivolol (0.01 to 30 μM). Efficacy (% inhibition at 30 μM) and IC50 of nebivolol were determined using a three-parameter non-linear regression model using GraphPad Prism v.10. For evaluating drug combinations, concentration ranges of the drugs (nebivolol with palbociclib or abemaciclib) were selected based on their estimated IC50 values in the concentration-response matrices. Growth inhibition was quantified using the EnSight™ Multimode Plate Reader, and drug interaction was analyzed using CompuSyn (combination index, CI) and SynergyFinder (Loewe synergy score). A parallel analysis was performed to determine the statistical significance between combination and single-agent groups using One-way ANOVA, followed by Tukey multiple comparison test.
Results: Nebivolol inhibited growth in parental and ET- and CDK4/6i-resistant MCF7 and T47D cells in a concentration-dependent manner. Efficacy (%) and potency (μM) of nebivolol were as follows: MCF7-P [84.1 and 7.9]; EDR [79.1 and 12.3]; PalboR [73.5 and 13]; EDR/PalboR [68.4 and 20.4]; T47D-P [96.1 and 5.8]; EDR [94.6 and 5.4]; PalboR [86.7 and 5.7]; EDR/PalboR [91.6 and 5.2]. Additionally, nebivolol demonstrated synergism with abemaciclib in Chou-Talalay and Loewe analysis. Effective combinations included 1 or 10 μM and 0.3-10 μM of nebivolol with 30-300 nM of abemaciclib (CI < 1 in Chou-Talalay method) in MCF7P and T47DP, respectively, suggesting synergy. Significant % inhibition in combination compared to single agent alone was observed at 3 μM of nebivolol with 100 or 300 μM abemaciclib in MCF7P and 0.3-3 μM of nebivolol with 30 nM of abemaciclib in T47DP cells. Loewe analysis also revealed nebivolol-abemaciclib synergism, with the most synergistic area score of >10 (12.51 in MCF7P and 41.14 in T47DP).
Conclusion: Nebivolol inhibited the growth of HR+/HER2- BC cell lines sensitive or resistant to ET and/or CDK4/6i and synergized with abemaciclib. Ongoing studies are evaluating nebivolol and abemaciclib in other cell-based assays and combination with ET for enhanced therapeutic potential.

#4462 Nebivolol inhibits cell growth, inhibits autophagic flux, and enhances growth inhibition in combination with bicalutamide in prostate cancer cells.

Swarnil Mandal[1], Chia-Ling Wu[2], Shivaani S. Kanna[1], **Wangjia Cao**[2], Meghana V. Trivedi[3]

[1]Department of Pharmacy Practice and Translational Research, University of Houston, Houston, TX,[2]Department of Pharmacological and Pharmaceutical Sciences, University of Houston, Houston, TX,[3]University of Houston, Houston, TX

Introduction: Nebivolol, a β1-adrenergic receptor blocker, is being explored as a repurposed therapeutic for breast cancer, showing inhibition of cell growth and autophagic flux. This study evaluated nebivolol's anti-tumor effects in prostate cancer (PCa) cells and determined whether it enhances the effect of the androgen receptor antagonist bicalutamide.

Methods: PCa cell lines, LNCap and 22Rv1, were treated with vehicle or nebivolol (0.01-30μM) for 7 days to assess cell growth using the EnSight™ Multimode Plate Reader. Clonogenic growth was measured after 14-15 days of vehicle or nebivolol (0.1-10μM). Autophagy and lysosome formation were evaluated after 24-hour treatment with vehicle, nebivolol (1 or 10μM), or chloroquine (50μM) using Hoechst 33342, Cyto-ID® Green, and Lyso-ID® Red staining followed by confocal imaging. Combination studies with nebivolol and bicalutamide (0-30μM) were performed over 7-day using concentration-response curves to access growth inhibition and interaction effects. IC_{50} values were calculated by non-linear regression curve analysis. LC3B protein expression was measured in 22Rv1 cells by immunoblotting following vehicle or nebivolol (10μM) treatment for 24, 48, and 72 hours. Statistical significance was determined using paired student's t-test or one-way ANOVA followed by Dunnett's multiple comparison test, as appropriate, using GraphPad Prism v.10. Drug synergism of nebivolol and bicalutamide was tested by CompuSyn software using the Chou-Talalay method.

Results: Nebivolol inhibited cell growth (IC_{50}: 37.1μM in LNCap; 9.8μM in 22Rv1) and suppressed clonogenic potential (IC_{50}: 1.1μM in LNCap; 2.5μM in 22Rv1) in a concentration-dependent manner. Nebivolol (10μM) significantly increased autophagosome and lysosome accumulation compared with vehicle ($p<0.05$). Nebivolol significantly upregulated LC3B protein expression in 22Rv1 cells in a time-dependent manner ($p<0.05$), suggesting inhibition of autophagic flux. Chou-Talalay analysis indicated a potential synergism at 1 to 30μM bicalutamide in combination with nebivolol 10 to 30μM, with combination index<1.

Conclusion: Nebivolol inhibited PCa cell growth and clonogenic potential, and inhibited autophagic flux with increased LC3B expression. Furthermore, nebivolol enhanced growth inhibition when combined with bicalutamide. These findings support further investigation of nebivolol, with/without bicalutamide, in PCa.

#4463 Repurposing the anti-dementia drug memantine, (a dualα7-nAChR NMDAR antagonist) as an anti-cancer agent in human squamous cell lung cancer.

Javan Christian[1], Sarah L. Miles[2], Kritsa L. Denning[3], Kushal J. Modi[4], Reagan S. Light[4], Piyali Dasgupta[4], Yi Charlie Chen[5]

Purpose of the study: Memantine is a drug used in clinical practice to combat dementia associated with mild-to-moderate Alzheimer's disease. Traditionally, memantine is an NMDAR receptor antagonist, but published reports show that it has multiple molecular targets apart from NMDAR. Nicotinic acetylcholine receptors (nAChRs) are a class of ion-channel receptors which mediate the bioactivity of nicotine. Published reports reveal that memantine functions as an antagonist to a particular kind of nAChR, namely the alpha-7-nicotinic receptor (α7-nAChR). The binding affinity of memantine for α7-nAChRs is stronger than its affinity for the NMDAR receptor. Squamous cell lung carcinoma (LUSC) is a type of non-small cell lung cancer (NSCLC) that typically develops in one of the air passages (bronchi) of the lungs. The primary objective of our research project was to repurpose the drug memantine as a growth-inhibitory agent in LUSCs.
Experimental procedures. Data from the TCGA atlas show that the α7-nAChR is overexpressed on patient-isolated LUSC tumors relative to matched normal tissue. Our research has shown that the α7-nAChR is upregulated in LUSC tissues and LUSC cell lines relative to normal lung epithelial cells. It is well known that almost 30% of LUSC patients continue to smoke after diagnosis, and many LUSC patients are exposed to nicotine via smoking-cessation devices like patches and gums. Therefore, we decided to evaluate the antiproliferative activity of memantine on nicotine-induced LUSC cells. Proliferating Cell Nuclear Antigen (PCNA) ELISA assays revealed that memantine robustly inhibited nicotine-induced proliferation of LUSCs. The growth-inhibitory activity of memantine was further confirmed in chicken chorioallantoic membrane (CAM) model systems of LUSC. Additionally, the anti-tumor activity of memantine was measured in two independent mice models, namely the cell derived xenograft (CDX) mouse model and the patient derived xenograft (PDX) mouse model. Finally, siRNA methodology was used to delineate the signaling pathways underlying the anti-proliferative activity of memantine in LUSC.
Results: Memantine potently inhibited nicotine-induced proliferation across a panel of human LUSC cell lines. The presence of memantine induced cell cycle arrest (at G1/S phase) in nicotine-treated LUSC cells and the anti-proliferative activity of memantine was also observed in chicken CAM models of LUSC. Finally, the administration of memantine via dietary methods decreased nicotine-induced growth of LUSC tumors in both CDX and PDX tumors in immunodeficient mice models. Depletion of the α7-nAChR expression by siRNA methodology abrogated the anti-proliferative activity of memantine in human LUSC cells.
Conclusions: The drug memantine could be repurposed as a potent anti-cancer drug for the treatment of LUSC.

#4464 Repurposing nebivolol with CPI-613 for triple-negative breast cancer: Linking *in-vitro* synergy to *in-vivo* exposure.

Mikayla Skillman[1], Airong Li[1], Junhyoung Park[2], Amir Mohammad-Gholizadeh[1], Fatima Dagher[1], Meghana Trivedi[3], Benny Kaiparettu[2], Diana S-L Chow[1]

[1]University of Houston, Houston, TX,[2]Baylor College of Medicine, Houston, TX,[3]Department of Pharmacy Practice and Translational Research, University of Houston, Houston, TX

Triple-negative breast cancer (TNBC) is an aggressive subtype lacking ER, PR, and HER2 expressions, making chemotherapy the default standard of care with high relapse and late-onset toxicities. Drug repurposing offers a rapid, cost-effective path to safer, mechanism-based therapies using agents with known safety. Nebivolol (NEB), an FDA-approved third-generation β_1-blocker, shows anti-cancer activity in preclinical models and is believed to act in part by inhibiting oxidative phosphorylation and angiogenesis, although its precise mechanism remains incompletely defined, while CPI-613 (CPI), a lipoate analog that targets pyruvate and α-ketoglutarate dehydrogenases, disrupts mitochondrial metabolism. We hypothesized that dual metabolic targeting would suppress TNBC growth. Murine 4T1 cells were treated with NEB (0.5-16 μM) and CPI (5-250 μM) in fixed ratios. MTT assays (72 h) and Chou-Talalay analysis identified 4-8 μM NEB + 5-50 μM CPI as the optimal synergistic ratio (>90% inhibition, CI < 0.2). *In vivo*, orthotopic 4T1-Luc tumors were established by mammary fat-pad injection in BALB/c mice and treated with vehicle (N=5), NEB (10 mg/kg QD) (N=5), CPI (25 mg/kg BID) (N=5), or NEB + CPI (NC) (N=6), 5 days/week for 3 weeks. All treatments significantly reduced tumor growth versus vehicle on day 28 ($p < 0.01$-0.001). Mean tumor volumes (mm^3 ± SD) were: Vehicle 1484.9 ± 492.4; NEB 595.8 ± 134.6; CPI 634.7 ± 116.9; NEB + CPI 702.5 ± 352.0. Tumor weights showed the same pattern ($p < 0.0001$), with all treated groups significantly lower than vehicle but no difference among NEB, CPI, and combination. LC-MS/MS confirmed intratumoral concentrations of NEB and CPI (NEB 42.2 ± 20.4 ng/g; CPI 22.7 ± 6.6 ng/g; combo NEB 39.3 ± 39.8, CPI 16.8 ± 8.5 ng/g). Systemic PK was similar across groups, though CPI in NC showed reduced volume of distribution vs single CPI ($p = 0.0368$). Tumors collected 23 h post-dose were used to calculate molar concentrations (μM = [ng/g × ρ_tumor (g/mL)] / MW), where density (ρ = weight/volume) was derived from caliper volume. Tumor concentrations in μM were NEB 0.093 ± 0.051, CPI 0.043 ± 0.011; combo NEB 0.067 ± 0.080, CPI 0.031 ± 0.022—below the *in-vitro* synergistic range and not reaching the optimal ratio, which may explain the lack of combination benefit over single agents. PK/PD analyses showed moderate, non-significant trends ($r = 0.26$-0.70). NEB and CPI inhibited TNBC growth, but the combination did not outperform single agents. Sub-synergistic, ratio-mismatched tumor exposure may underlie this outcome; upcoming tumor PK studies will determine whether the synergistic ratio is reached within the dosing interval to guide dose optimization.

#4465 Miconazole induces cell cycle arrest and apoptosis in prostate cancer cells via a p53-mediated pathway: A Drug repurposing strategy.

Eswara Naga Hanuma Kumar Ghali[1], Lindsey Shim[1], Rahul Tiwari[1], Rajasekhar Baru[1], Anupam Dhasmana[1], Chang Ryan Jisoo[2], Sung Yun Jung[2], Vivek Kumar Kashyap[1], Neeraj Chauhan[1], Subhash C. Chauhan[1], Murali M. Yallapu[1]

[1]Medicine and Oncology, University of Texas Rio Grande Valley, McAllen, TX,[2]Baylor College of Medicine, Houston, TX

Purpose of the study: This study explores the repurposing of FDA-approved antifungal drugs as potential therapeutics for prostate cancer.
Background: Prostate cancer remains the second leading cause of cancer-related deaths among men in the United States. The American Cancer Society estimated about 313,780 new cases and 35,770 deaths projected from prostate cancer in 2025. Current treatments, including radiation, chemotherapy, hormone therapy, and other emerging modalities, are often associated with long-term adverse effects, underscoring the need for novel therapeutic strategies.
Procedures: We screened antifungal drugs using CCK-8, colony formation, invasion, and migration assays to identify the most effective compound against prostate cancer cells. The lead hit molecule, miconazole, was further evaluated for its pro-apoptotic and cell cycle regulatory effects using confocal and scanning electron microscopy, flow cytometry, and Western blotting. Proteomic profiling and pathway enrichment analyses were performed to identify key molecular targets. The binding affinities of miconazole were evaluated via molecular docking.
Results: Miconazole significantly inhibited prostate cancer cell proliferation, clonogenic capacity, invasion, and migration properties compared to other antifungal agents. Mechanistic studies revealed G0/G1 cell cycle arrest through downregulation of cyclin D3, CDK2, CDK4, and PCNA, and induction of apoptosis via upregulation of p53, p21, p27, cl-PARP, cl-caspase-3, alongside suppression of PARP-1 and caspase-3. Further, proteomic analysis revealed that miconazole significantly regulated many proteins that are responsible for cell cycle arrest and apoptosis. Molecular docking demonstrated that miconazole exhibited strong binding affinities with PARP1 (-8.97 kcal/mol) and cyclin D3 (-8.50 kcal/mol), moderate binding affinities with CDK4 (-7.19 kcal/mol) and CDK2 (-6.15 kcal/mol), and lower binding affinities with PCNA (-5.14 kcal/mol), TP53 (-4.89 kcal/mol), and CDKN1B (-3.50 kcal/mol). No significant binding was found with caspase-3 (+65.04 kcal/mol).
Conclusions: These findings highlight miconazole as a promising candidate for drug repurposing in prostate cancer therapy, offering a potential foundation for future combination strategies.

#4466 Clinical-grade CK2 inhibitor CX-4945 synergistically enhances venetoclax-mediated antileukemic activity in preclinical acute myeloid leukemia models.

Upendarrao Golla, Muhammad Danial, Rajesh Rajaiah, Marudhu Pandiyan Shanmugam, Koby Duke, Katherine Mercer, Yi Qiu, Sinisa Dovat, Yasin Uzun, Hong Zheng, Suming Huang, Chandrika G. Behura

Penn State College of Medicine, Hershey, PA

Introduction: Dysregulated apoptotic machinery and signaling contribute to acquire resistance to regimens containing venetoclax (VEN), a BCL2 (B-cell lymphoma-2) inhibitor, in acute myeloid leukemia (AML) and pose a clinical challenge. Casein kinase 2 (CK2) is a serine/threonine kinase with 300+ substrates and regulate cell cycle, survival, differentiation, and apoptosis. Its aberrant activity promotes disease progression, poor prognosis, and drug resistance. CX-4945 (CX), a selective CK2 inhibitor, shows potent anticancer activity in leukemia and other solid tumors. Here, we tested combined CK2 and BCL2 targeting with CX and VEN in pre-clinical AML models.

Methods: Cytotoxic and pro-apoptotic effects of the CX+VEN combo were tested in AML cell lines and primary samples by WST and annexin V assays. The ZIP synergy score was determined by SynergyFinder tool. Flow cytometry and immunoblotting assessed cell surface markers, various apoptosis regulators along with CK2 target levels after drug treatment. Dynamic BH3 profiling assessed priming of VEN-resistant (VR) cells to apoptosis after CX treatment. Transcriptome of VR-AML cells with and without drug treatment was analyzed by RNA sequencing. *In vivo* efficacy of CX+VEN combo was tested in cell line and patient-derived xenograft (PDX) mouse models.

Results: CK2α (*CSNK2A1*) expression exhibited negative correlation similar to that of *BCL2* levels with VEN activity in BeatAML cohort and VR-AML cells showed higher CK2 activity. CX+VEN combo showed synergistic cytotoxicity and augmented apoptosis in VEN-sensitive (MOLM13, HL60, THP1), VR-AML (U937, MOLM13/VR, HL60/VR) cell lines, and PDX cells *in vitro*. CX treatment enhanced VR-AML cells priming to BH3 peptides and increased cytochrome c release. Also, CX+VEN combo effectively induced apoptosis and decreased leukemia stem cells (CD34+CD38-) and chemo-resistant (CD47+CD123+) subpopulations in VR-AML cells. AML cells showed downregulation of CK2 activity and other pro-survival BCL2 member family proteins with increased PARP activity after CX+VEN combo treatment. Functional enrichment analysis of transcriptome after CX+VEN combo treatment showed upregulation of cell cycle arrest, TP53 and apoptotic signature genes that were repressed in VR-AML cells. Lastly, CX+VEN combo effectively decreased leukemia burden and prolonged overall median survival of xenograft (CDX/PDX) mice *in vivo*.

Conclusions: CX+VEN combo showed a superior antileukemic activity in different pre-clinical AML models and CK2 inhibition overcome VEN resistance. CX-4945 (Silmitasertib) has favorable pharmacokinetics with good tolerability in human studies and is being evaluated in early phases of clinical trial. Our findings provide a rationale for CK2 and BCL2 co-targeting as an effective approach for AML treatment and to overcome VEN resistance.

#4467 Synergistic antileukemic activity of JAK inhibition combined with cytarabine in acute megakaryoblastic leukemia.

Akira Shimada[1], Shiho Aoki[1], Hiroko Hayakawa[2], Erico Jimbo[3], Narumi Omika[3], Kaito Furuya[3], Hideya Asai[3], Hiroki Yoshinari[3], Hitomi Niijima[3], Yuta Kawahara[3], Kentaro Ushijima[4], Masakazu Mimaki[5], Mitsuteru Hiwatari[5]

[1]Jichi Medical University, Tochigi, Japan,[2]Research Equipment Center, Jichi Medical University, Tochigi, Japan,[3]Pediatrics, Jichi Medical University, Tochigi, Japan,[4]Faculty of Pharmaceutical Sciences, Yamaguchi University of Science, Yamaguchi, Japan,[5]Pediatrics, Teikyo University, Tokyo, Japan

Background: Acute megakaryoblastic leukemia (AMKL) remains a therapeutic challenge, with limited responsiveness to standard cytarabine-based regimens and frequent microenvironment-mediated resistance. Aberrant activation of the JAK-STAT signaling pathway has been implicated in AMKL pathogenesis but has not been fully exploited therapeutically in combination with cytarabine.
Methods: We evaluated the antileukemic efficacy of combining a JAK inhibitor with cytarabine across multiple preclinical models: (i) AMKL cell lines (including CMK, CMY, MKPL1, UT7, MOLM16, Mo7e) assessing viability, apoptosis, and combination index; (ii) three-dimensional (3D) co-culture with mesenchymal cells (MSCs) modelling bone-marrow niche-mediated protection; and (iii) murine xenograft models of AMKL assessing leukemic burden and survival.
Results: In cell-line experiments, the JAK inhibitor plus cytarabine demonstrated marked synergy (combination index < 0.7) with significantly increased apoptosis (Annexin V+) and reduced proliferation compared to either agent alone. In the 3D MSC co-culture model, the microenvironment protected AMKL cells from cytarabine-induced death, but this protective effect was abrogated by JAK inhibition, restoring cytarabine sensitivity especially in MOLM16 and MKPL1 cells. In vivo, combination therapy significantly reduced leukemic burden ($p < 0.05$) and significantly prolonged median survival compared to cytarabine alone. Mechanistically, ruxolitinib suppressed phosphorylation of STAT3 and STAT5 and exerted a synergistic effect in combination with cytarabine; however, this inhibitory effect on phosphorylation was attenuated under the 3D co-culture condition.
Conclusions: Our results provide robust preclinical evidence that combining JAK inhibition with cytarabine yields synergistic antileukemic effects in AMKL, including in a niche-protected context, and significantly improves in vivo outcomes. This data strongly supports the rationale for clinical evaluation of this combination in AMKL patients, especially those with JAK-STAT pathway activation.

#4468 WNK1 inhibition induces AML differentiation via ERK-CEBPβ signaling.

Jordan D. Cress, Emily Katoni, Parameswaran Ramakrishnan

Case Western Reserve University, Cleveland, OH

Impaired differentiation is a key pathological feature of Acute Myeloid Leukemia (AML). AML differentiation-inducing agents such as all-trans retinoic acid (ATRA) have shown great promise to treat AML patients as seen by improved overall survival and relapse rates. However, this success has been limited to a subset of AML patients, namely those with Acute Promyelocytic Leukemia (APL). This highlights the need to identify more differentiation therapy options that could be effective for other AML subtypes. In this study, we identified With-no-Lysine(K) kinase 1 (WNK1) as a novel regulator of AML differentiation arrest. We show evidence of WNK1 dysregulation in AML patients demonstrated by its increased expression and activity compared to healthy controls. Targeting WNK1 through genetic or pharmacologic inhibition induced granulocytic differentiation of AML cell lines in vitro. WNK1 inhibition also caused cell cycle arrest and apoptosis. Furthermore, oral administration of WNK1 inhibitor reduced leukemic burden in AML xenograft models. We observed that knocking down expression of WNK1 substrates SPAK and OSR1 mirrored the effects of WNK1 inhibition suggesting their involvement in mediating pro-leukemic functions of WNK1. Mechanistically, we show that WNK1 inhibition induces differentiation by promoting MEK-ERK activity and increasing C/EBPβ activity and expression, resulting in increased transcription of myeloid differentiation genes. Finally, we illustrate that combining WNK1 inhibition with ATRA further boosts ATRA's efficacy, synergistically increasing differentiation, apoptosis, and cell cycle arrest. C/EBPβ expression was also enhanced by this combination treatment, suggesting a role for C/EBPβ in mediating these anti-leukemic effects. Taken together, our findings suggest that WNK1 negatively regulates ERK phosphorylation and activity, likely through SPAK/OSR1. Inhibiting WNK1 releases ERK suppression, increasing C/EBPβ activity and expression which leads to myeloid differentiation. Overall, our findings reveal a novel role for WNK1 in promoting differentiation arrest and highlight its potential as a new therapeutic target for AML treatment.

#4469 FACT Complex — A gatekeeper of differentiation in AML.

Soumya Sharma[1], Sagarajit Mohanty[2], Stefan R. Sweha[2], Kazuya Fukasawa[2], Jieun Jeong[2], Katerina V. Gurova[3], Hans-Guido Wendel[2]

[1]Department of Physiology and Biophysics, Weill Cornell Medicine, New York, NY;, Cancer Biology and Genetics Program, Memorial Sloan Kettering Cancer Center, New York, NY,[2]Cancer Biology and Genetics Program, Memorial Sloan Kettering Cancer Center, New York, NY,[3]Department of Cell Stress Biology, Roswell Park Cancer Institute, Buffalo, NY

Acute Myeloid Leukemia (AML) is an aggressive hematological malignancy with a dismal 5-year survival rate of ~32%. Given that the treatment of AML remains an unmet clinical need, it is critical to identify novel, therapeutic targets in AML. Differentiation blockade is the key problem in AML. Hallmarks of AML include myeloid progenitors proliferating constantly and failing to terminally differentiate into their mature, functional counterparts such as macrophages. Presently, there are only a few differentiation therapies for AML traversing the regulatory drug development pipeline. Available differentiation therapies are limited to specific subtypes of AML, for example, All-Trans Retinoic Acid (ATRA) for Promyelocytic Leukemia (PML) and Enasidenib for IDH2-mutated AML.To identify genes encoding druggable proteins essential in maintaining the undifferentiated state of AML, we designed a creative CRISPR screen. The screen revealed that FACT (FAcilitates Chromatin Transcription) complex is required for AML to maintain this undifferentiated state. The FACT complex is a key histone chaperone that stabilizes nucleosomes during transcription, DNA replication, and DNA repair. The FACT complex is overexpressed in AML patient samples, and its expression is significantly associated with poor patient prognosis. Little is known about its function in AML. In the present study, our goal is to explore the mechanistic role of FACT complex in AML differentiation. We also intend to exploit the dependency of the FACT complex in AML to develop therapeutic approaches to target AML.

#4470 Combination of NAMPT inhibitors plus pyrimidine analog antimetabolites floxuridine and 5-FU impair rhabdomyosarcoma proliferation and survival.

Jamie Gudyka[1], Choh Yeung[1], Senna Munnikhuysen[1], Christina M. Robinson[2], Amy James[2], Xiaohu Zhang[3], David Holland[3], Michele Ceribelli[3], Simone Difilippantonio[2], Craig J. Thomas[3], Christine M. Heske[1]

[1]Pediatric Oncology Branch, National Cancer Institute, Bethesda, MD,[2]Laboratory Animal Sciences Program, Frederick National Laboratory for Cancer Research, Fredrick, MD,[3]Division of Preclinical Innovation, National Center for Advancing Translational Sciences, Rockville, MD

Pediatric rhabdomyosarcoma (RMS) is a soft tissue sarcoma of high unmet need that requires novel treatment approaches. Nicotinamide phosphoribosyltransferase (NAMPT) catalyzes the rate limiting step of the nicotinamide adenine dinucleotide (NAD^+) salvage pathway. Previously, we showed that RMS is highly sensitive to NAMPT inhibition, with *in vivo* RMS models undergoing tumor regression upon treatment with the NAMPT inhibitor OT-82. However, we observed recurrence after cessation of treatment, suggesting single agent therapy is not durable. The aim of this project is to identify and evaluate drug combinations that synergize with NAMPT inhibitors in RMS in an effort to improve treatments for patients with RMS. To identify synergistic drug combinations, we used a matrix drug screen of 2 RMS cell lines (Rh30 (fusion-positive (FP)) and Rh36 (fusion-negative (FN)) testing 2 NAMPT inhibitors (daporinad and GNE-618) in combination with 62 other anticancer agents. We identified that floxuridine, a pyrimidine analog antimetabolite, was the most highly synergistic agent with both NAMPT inhibitors. Validation of the screen results using longitudinal proliferation assays confirmed synergy between floxuridine and an additional NAMPT inhibitor, OT-82, across additional FP and FN RMS cell lines. Doses of each drug that had minimal effect on proliferation as single agents resulted in durable cell death when combined. Notably, when this combination was tested in proliferating non-cancer cell lines, there was a minimal effect on proliferation, suggesting a therapeutic window exists. Rescue experiments using nicotinamide mononucleotide (NMN), the product of NAMPT, reversed the antiproliferative effect of the combination, indicating that the synergy is NAD^+ dependent. Protein analysis revealed that floxuridine-related ternary complex formation of thymidylate synthase is blocked by NAD^+ loss mediated by NAMPT inhibition. To evaluate this combination for potential translation into the clinic, we extended our testing to include clinical agents, including RPT1G (Remedy Plan Therapeutics), a NAMPT inhibitor currently under early phase evaluation, and 5-FU, a prodrug of floxuridine. Validation studies of these agents using longitudinal proliferation assays again demonstrated that single agent doses had minimal effect on proliferation but when combined, resulted in persistent cell death. Preliminary toxicity testing in Rh30 tumor-bearing NSG mice demonstrated tolerability of OT-82 plus 5-FU up to the highest doses tested (15 mg/kg and 25 mg/kg respectively) and reduced tumor volume. Efficacy experiments are ongoing and will be reported. These findings demonstrate that combining NAMPT inhibitors with floxuridine or 5-FU results in significant synergy and preliminarily suggest that this is a promising and feasible combination regimen for patients with RMS.

#4471 Synergistic metabolic inhibition with 2-DG and metformin loaded electrospun scaffolds disrupts glioblastoma redox balance and glycolytic output.
Bryce William Jewett

Northern Arizona University, Flagstaff, AZ

Glioblastoma (GBM) displays exceptional metabolic plasticity. Beyond the canonical Warburg Effect, which demonstrates preferential reliance on aerobic glycolysis despite sufficient oxygen, GBM can upregulate oxidative phosphorylation to maintain proliferation and redox balance under glycolytic stress. Targeting both pathways simultaneously represents a promising strategy to overcome this resilience. This study evaluates the synergistic effects of 2-deoxy-D-glucose (2-DG), a glycolytic inhibitor, and metformin, a mitochondrial complex I modulator, delivered through electrospun polycaprolactone scaffolds engineered for localized release at the tumor resection margin.Concentration range-finding was conducted by quantifying total metabolic activity via PrestoBlue and normalizing to total DNA content via CyQUANT. Mechanistic assays included mitochondrial membrane potential (ΔΨm) via JC-1 and reactive oxygen species via CellROX. Viability was assessed using Trypan Blue. Scaffolds were electrospun de novo, drug-loaded, and evaluated for structural integrity to determine feasibility for sustained local delivery. Parallel studies are extending this work to primary human astrocytes to assess differential sensitivity in noncancerous glial tissue.Dual treatment produced a synergistic reduction in metabolic index and viability that surpassed monotherapy and exceeded the response to temozolomide. Mechanistically, combined inhibition induced a hyperpolarized ΔΨm consistent with stress-driven proton-gradient accumulation under impaired ATP synthesis rather than improved mitochondrial function. Reactive oxygen species measurements indicated redox imbalance characteristic of mitochondrial stress. Trypan Blue analysis confirmed near-complete loss of viable GBM cells by day five. Electrospun scaffolds incorporated both agents effectively and retained fiber morphology compatible with controlled release.These findings indicate that simultaneous inhibition of glycolysis and mitochondrial respiration precipitates bioenergetic failure in glioblastoma cells through coordinated disruption of ATP production, ΔΨm homeostasis, and redox stability. Integrating this strategy into drug-releasing electrospun scaffolds offers a platform for localized metabolic therapy at resection margins while minimizing systemic exposure. Ongoing studies include astrocyte toxicity profiling, scaffold release kinetics, and application to three-dimensional tumorsphere models.

#4472 Combination of medroxyprogesterone acetate (MPA) and a WEE1 or ATR inhibitor enhances anti-tumor activity of estrogen receptor-positive endometrial cancer cells.

Yuki Takemoto, Yasuto Kinose, Li Han, Mai Koizumi, Yan Wang, Kanako Kasuya, Aasa Shimizu, Erika Nakatsuka, Mahiru Kawano, Kenjiro Sawada, Michiko Kodama

Department of Obstetrics and Gynecology, Graduate School of Medicine, the University of Osaka, Suita-city, Japan

Objectives: Hormonal therapy is an important treatment option for patients with early-stage, low-grade endometrial cancer who desire fertility preservation, as well as for those with advanced or recurrent disease resistant to chemotherapy and immune checkpoint inhibitors. Based on evidence that estrogen signaling regulates cell cycle progression via cyclin D1 transcription, the combination of endocrine therapy with cyclin-dependent kinase 4/6 inhibitors has become a pivotal strategy in the management of estrogen receptor-positive (ER+) recurrent breast cancer in recent years. However, clinical trials investigating similar approaches in ER+ recurrent endometrial cancer have shown only limited responses so far. The aim of this study is to develop a novel therapeutic strategy combining hormonal therapy with targeted therapy for ER+ endometrial cancer.

Methods: The anti-tumor effects of combining hormonal therapies were assessed, using ER+ endometrial cancer cells, ARK1 and MFE280. Tamoxifen, letrozole, fulvestrant, and medroxyprogesterone acetate (MPA, 25 μM for MFE280; 30 μM for ARK1) were used as hormone therapies. As drugs for targeted therapies, either the ATR inhibitor (ATRi) AZD6738 (2.5 μM) or the WEE1 inhibitor (WEE1i) MK1775 (0.1 μM) was employed. The anti-tumor effect of *ESR1* knockdown via siRNA was also examined. The synergistic effects of MPA and ATRi/WEE1i were evaluated by coefficient of drug interaction (CDI) methods.

Results: Among these hormone therapies, only MPA showed a distinct dose-dependent anti-tumor effect, and thus it was selected for combination with molecular-targeted agents. MPA and ATRi synergistically decreased cell viability compared with control in both cell lines, reducing viability to 0.48-, 0.40-, and 0.16-fold in ARK1 and to 0.83-, 0.85-, and 0.56-fold in MFE280 by MPA monotherapy, ATRi monotherapy, and MPA-ATRi combination therapy, respectively. The CDI values of the MPA-ATRi combination were less than 1 (ARK1 = 0.81; MFE280 = 0.79). When *ESR1* was knocked down, the cell viability under MPA-ATRi combination treatment was 0.37-fold in ARK1 and 0.74-fold in MFE280 relative to the control, suggesting that *ESR1* knockdown attenuated the anti-tumor effects of the combination therapy. In contrast, MPA and WEE1i exhibited only additive effects in ARK1 cells, reducing viability to 0.39-, 0.71-, and 0.30-fold following MPA monotherapy, WEE1i monotherapy, and MPA-WEE1i combination therapy, respectively. The CDI value for the combination was approximately 1, consistent with an additive interaction.

Conclusion: We found that the combination of MPA and ATRi markedly enhances anti-tumor activity in ER+ endometrial cancer, in an ERα expression-dependent manner. Future studies are needed to elucidate the mechanism of these synergistic effects.

#4473 Advancing new rational drug combinations to treat mutant KRAS-driven pancreatic adenocarcinoma.

Brajendra K. Tripathi[1], Sophia M. Shahin[1], Elise Van Meter[1], Marian E. Durkin[1], Xiaolan Qian[1], Ross Lake[2], James H. Doroshow[3], Dunrui Wang[1], Douglas R. Lowy[1]

[1]Laboratory of Cellular Oncology, National Cancer Institute, Bethesda, MD,[2]Laboratory of Genitourinary Cancer Pathogenesis, National Cancer Institute, Bethesda, MD,[3]Developmental Therapeutics Branch, National Cancer Institute, Bethesda, MD

Pancreatic ductal adenocarcinoma (PDAC) is a highly aggressive malignancy with a poor prognosis, largely due to late diagnosis and limited response to currently available therapies. Identifying effective drug combinations that harness PDAC-specific vulnerabilities remains a major challenge for molecularly targeted therapy. Oncogenic mutations in the *KRAS* gene, which are found in over 90% of PDAC patients, play a critical role in PDAC. Although KRAS inhibitors may be found to be clinically useful for treating PDAC, it is likely that resistance will develop in most patients when given as single agent treatment. To overcome this anticipated limitation, effective drug combinations that include KRAS inhibitors will be necessary. We have determined in preclinical human and mouse lung cancer models that RAS facilitates the export of nuclear proteins into the cytoplasm via a mechanism independent of canonical RAS signaling (Tripathi et al., 2024, *Nature Cancer*). This observation suggests that new drug combinations that cooperate with the inhibition of the RAS nuclear export function might be suitable for targeted cancer therapy. Our preclinical PDAC studies suggest that the newly identified RAS-dependent nuclear export mechanism is also relevant to PDAC and may have implications for developing new drug combinations for PDAC treatment. In human PDAC models, we have found that the DLC1 tumor suppressor protein is a critical downstream target of KRAS-dependent nuclear protein export. Perinuclear binding of KRAS-GTP to RanGAP1 promotes the hydrolysis of RAN-GTP to RAN-GDP and the consequent release of nuclear protein cargo into the cytoplasm. In human PDAC models, export of the nuclear EZH2 methyltransferase into the cytoplasm leads to methylation of the cytoplasmic DLC1 protein, making it susceptible to ubiquitin-dependent proteasomal degradation. Conversely, KRAS inhibition prevents the nuclear export of EZH2, leading to an increase in DLC1 protein levels. Consistent with these findings, analysis of the Clinical Proteomic Tumor Analysis Consortium (CPTAC) database indicates DLC1 protein levels in PDAC are lower than would be expected from the relatively high *DLC1* mRNA expression in these tumors. Remarkably, the low levels of DLC1 protein in PDAC are inversely correlated with the high levels of the FBXW5 E3 ubiquitin ligase. Our preclinical PDAC studies show that a three-drug combination, comprising a KRAS inhibitor plus AKT and SRC inhibitors, exhibits significantly greater antitumor activity than the KRAS inhibitor alone. The cooperative effect of the three-drug combination arises as the KRAS inhibitor increases DLC1 protein levels, while AKT and SRC kinase inhibitors block phosphorylations that attenuate DLC1 tumor suppressor activity. Mechanistically, this three-drug combination enhances antitumor effects in mutant *KRAS* PDAC by stabilizing and reactivating the DLC1 tumor suppressor protein.

#4474 Cannabidiol enhances etoposide efficacy in non-small cell lung cancer by engaging a p53-mTOR-TFEB lysosomal death program.

Youngsic Jeon[1], Hyukjoon Kwon[1], Young Nyun Park[2], Taejung Kim[1], **Young-Joo Kim**[1]

[1]Korea Institute of Science and Technology (KIST), Gangneung, Korea, Republic of,[2]Yonsei University College of Medicine, Seoul, Korea, Republic of

The search for more effective and safer cancer therapies has intensified interest in combination regimens that repurpose well-established agents. Here, we investigated whether cannabidiol (CBD), a cannabis-derived compound clinically used for pediatric epilepsy, can potentiate the anticancer activity of etoposide in non-small cell lung cancer (NSCLC). Among multiple chemotherapeutics tested, etoposide displayed the most pronounced reduction in NSCLC cell viability when combined with CBD, indicating a robust synergistic interaction. To elucidate the underlying mechanisms, we performed comprehensive transcriptomic and proteomic profiling, revealing that the CBD-etoposide combination up-regulated gene programs associated with autophagic cell death while concomitantly downregulating key oncogenic drivers linked to tumor progression. Mechanistically, this autophagic cell death was associated with PI3K-AKT-mTOR pathway inactivation and required functional p53. Importantly, downstream of mTOR suppression, the combination was associated with reduced TFEB phosphorylation, enhanced TFEB nuclear translocation, and increased transcriptional activation of lysosome-related gene networks, consistent with amplification of lysosomal stress programs that can contribute to lysosome-associated cell death. Notably, the therapeutic synergy was independent of classical cannabinoid receptors and transient receptor potential channels, supporting a noncanonical mode of CBD action. We also performed pharmacological blockade experiments using antagonists of PPARγ and GPR55 to test whether these pathways contribute to the CBD-etoposide response. Collectively, our findings suggest that CBD combined with etoposide represents a promising strategy to enhance treatment efficacy in NSCLC—particularly in tumors retaining p53 function—by concurrently engaging autophagic/lysosomal cell death programs and suppressing oncogenic signaling beyond canonical cannabinoid pathways.

#4475 Neuroendocrine-like dedifferentiation mediates resistance to EGFR inhibitors via the NRG1/HER3 axis.

Alessandra Morselli[1], Chiara Miroglio[1], William Kothalawala[2], Donatella Romaniello, Idan Lahat[3], Paola Cecchi[1], Davide Zilio[1], Michelangelo Fiorentino[4], Andrea Ardizzoni[1], Yosef Yarden[5], Yaara Oren[3], Balazs Gyorffy[6], **Mattia Lauriola**[1]

[1]University of Bologna, Bologna, Italy,[2]Budapest, Hungary, Semmelweis University, Hungary,[3]Tel Aviv University, Tel AViv, Israel,[4]Pathologist, Istituto Oncologico Addarii, University of Bologna, Bologna, Italy,[5]Weizmann Institute of Science, Rehovot, Israel,[6]Semmelweis University, Budapest, Hungary

Non-small cell lung cancer (NSCLC) patients with activating EGFR mutations, such as exon 19 deletions (del746-750) and the L858R point mutation in exon 21, respond well to third-generation tyrosine kinase inhibitors (TKIs) like osimertinib. However, resistance inevitably emerges, limiting the long-term efficacy of these therapies. In this study, we investigated non-genomic mechanisms that enable drug tolerant persister cells to survive and cycle under EGFR inhibition, likely by exploiting alternative signaling routes. One such mechanism involves the upregulation of HER3. However, the precise molecular and cellular basis for HER3 dependency in NSCLC patients who progress on TKI therapy remains poorly understood. We employed a combination of immortalized and patient-derived cell lines, alongside advanced single-cell sequencing technologies, to elucidate the underlying biology. Our findings reveal that EGFR/HER3 axis upregulation dependency represents an early mechanism of response to TKI treatment, specifically enriched in pulmonary alveolar type I and II cancer cells. This dependency is driven and maintained by paracrine signaling involving secreted factors, with neuregulin-1 (NRG1) playing a central role. NRG1 is primarily secreted by the tumor stroma and by cancer cells undergoing neuroendocrine (NE)-like dedifferentiation, contributing to the resistance mechanisms, leading to invasiveness and metastatic progression. Notably, animal studies demonstrated that the combination of an NRG1-neutralizing antibody with a dual EGFR blockade, achieved through a TKI and an anti-EGFR antibody, eradicated tumors *in vivo*. These results highlight the critical role of HER3 signaling and its interplay with EGFR and the tumor microenvironment in mediating TKI resistance, and suggest a compelling therapeutic strategy for overcoming resistance in NSCLC.

#4476 Repurposing PARP inhibitors in molecularly defined subgroups of peritoneal metastatic colorectal cancer (pmCRC): Preclinical analysis of patient-derived xenograft (PDX) models.

Mathias Dahlmann[1], Beate Rau[2], Safak Gul-Klein[2], Bernadette Brzezicha[1], Marlen Keil[1], **Antje Wengner**[1], Jens Hoffmann[1], Sebastian Stintzing[3], Ulrike S. Stein[4], Wolfgang Walther[1], Loredana Vecchione[3]

[1]Experimental Pharmacology & Oncology Berlin-Buch GmbH, Berlin, Germany,[2]Department of Surgery, Charite - University Medicine Berlin, Berlin, Germany,[3]Department of Hematology, Oncology, and Cancer Immunology, (CCM), Charité - University Medicine Berlin, Berlin, Germany,[4]Translational Oncology of Solid Tumors, Experimental and Clinical Research Center, Charite - University Medicine Berlin, and Max-Delbruck-Center for Molecular Medicine in the Helmholtz Association, Berlin, Germany

Peritoneal metastatic colorectal cancer (pmCRC) has the worst outcome compared to metastatic CRC patients with metastases in other organs, such as liver or lung. More importantly, despite of the improvement of both systemic and peritoneal specific treatment, 50% to 90% of patients experience relapse and progression of the disease, leading to premature death. Precision oncology has successfully improved the overall survival of several solid and non-solid malignancies. For CRC, large volumes of information have been acquired regarding the molecular aberrations, characterizing both lung and liver metastases from CRC, thus leading to a more personalized treatment approach. On the contrary, this has not yet been done for pmCRC. In a comprehensive effort to close this gap and to identify new predictive signatures to drug responses in pmCRC, we previously established a novel platform of matched preclinical pmCRC models, including 14 patient-derived xenografts (PDX) of peritoneal metastases from a total of 10 pmCRC patients and showed that tumors intrinsically resistant to 5-Fluorouracil (5-FU) were enriched in alterations of the DNA damage response and repair (DDR) machinery. We therefore hypothesize, that those tumors are responsive to DDR inhibitors such as olaparib. In order to prove our hypothesis, we generated a new cohort of 48 pmCRC PDX, characterized by RNA sequencing. Based on both transcriptomic and mutational profiles, we classified 14 PDX as homologous recombination deficient (HRD) and 34 PDX as proficient. The most common alteration identified in the HRD positive group were loss-of-function frameshift insertions/deletions in BRCA1/2, in addition to other homologous recombination repair genes (HRRmut). Clinical data, in particular treatment response data, were combined with the genomic profiles of the respective PDX models, supporting the prediction of 5-FU resistance. Subsequently, a total of 12 pmCRC models predicted to be resistant to 5-FU-based treatment regimens, but sensitive to PARP due to HRD, were treated with 5-FU or olaparib alone, as well as in combination. Response data will be presented. Our study highlights the importance of molecular profiling for better personalized treatment.

#4477 Resistance interception: Development of novel immune checkpoint inhibitor as dynamic combination with Anti-PD-1 to overcome resistance.

Lynda Chin, Ronan O'Hagan, Magali Pederzoli-Ribeil

Apricity Health, Inc., Houston, TX

Background: Durable benefit from anti-PD1 therapy is limited by adaptive resistance that evolves under therapeutic pressure which is often missed by static pretreatment tumor profiling. We developed Dynamic Precision™ to mine longitudinal plasma proteomic profiling before and on-treatment to identify adaptive immune resistance drivers. With dynamic blood-based biomarkers to detect emerging resistance as early on-treatment, we establish a window before clinical progression to intercept resistance with precision drug and extend anti-PD-1 therapeutic benefit.
Methods: We analyzed serial plasma proteomics from melanoma patients on standard-of-care anti-PD1 therapy to define dynamic non-responder signatures and identify actionable immune targets driving resistance, including AH004, a novel B-cell checkpoint. Mining of public multi-omic datasets defined tumor contexts associated with AH004 biology.
Results: In this study, we conducted Dynamic Precision™ analysis of 2.7 million plasma proteomic data points from 300+ melanoma patients before and on anti-PD1 standard-of-care treatment. AH004 was found to be differentially regulated in ~17% of anti-PD1 non-responders after one treatment cycle. Mechanistically, as a checkpoint on B-cells, AH004 inhibits T and NK effector cell function and promotes an immunosuppressive tumor milieu. Analysis of public multi-omic datasets showed that AH004+ tumors exhibit an inflamed-but-ineffective (“pseudohot”) phenotype and have poor ICI response.
Utilizing Alloy Therapeutics’ antibody discovery platform, we have generated and characterized 24 antibody clones with high affinity binding to cell-surface human AH004 and inhibition of ligand binding. Functional characterization is ongoing.
Conclusions: Resistance Interception represents a paradigm shift from reactive to proactive combination therapy, using blood-based biomarker surveillance to detect emerging immune-mediated resistance and guide targeted intervention before clinical progression.
AH004 is a tractable B-cell checkpoint associated with anti-PD1 resistance and pseudo-hot tumor phenotypes. A biomarker-guided “resistance interception” strategy—adding AH004 blockade as the signal emerges—may extend anti-PD1 efficacy and increase durable response rate.

#4478 Synergistic antitumor activity of tumor-treating fields and multiselect-RAS (ON) inhibitor RMC-6236 in pancreatic ductal adenocarcinoma.

Ishita Saha, Santanu Bhattacharya, Debabrata Mukhopadhyay, Hani M. Babiker

Mayo Clinic Florida, Jacksonville, FL

RMC-6236 (daraxonrasib) is a novel multiselect RAS(ON) inhibitor under investigation for pancreatic ductal adenocarcinoma (PDAC) and other RAS-mutant cancers. This compound shares structural similarities with RMC-7977 and exhibits a conserved binding site and interaction pattern within the tri-complex formed between active RAS (RAS(ON)) proteins and cyclophilin A (CypA). Tumor Treating Fields (TTFields) are low-intensity, alternating electric fields that disrupt mitosis and have shown clinical benefit in solid tumors. The PANOVA-3 trial demonstrated that TTFields combined with gemcitabine plus nab-paclitaxel improved survival, pain control, and quality of life in locally advanced PDAC. Our previous work demonstrated that TTFields abrogate oncogenic KRAS pathway. We thus hypothesize a potential for increase in effectievness with the combination. In this study, the metastatic PDAC cell line AsPC-1 was treated with TTFields (150 kHz, 1.8 V/cm), RMC-6236 (15 nM; sub-IC_{50}), or combination. A sub-IC_{50} concentration (15 nM) of RMC-6236 was selected based on MTS assay results, and subsequent experiments were performed at this dose. The MTS assay revealed that both TTFields and RMC-6236 independently reduced AsPC-1 cell viability, with a more pronounced reduction observed at 72 hours compared to 48 hours. RMC-6236 alone produced minimal effects at either 48 hours (85.82 ± 13.9%) or 72 hours (90.48 ± 15.4%) compared with control (100.0 ± 8.4%, 48 h; 100.0 ± 8.2%, 72 h). TTFields treatment significantly reduced viability to 74.42 ± 21.4% at 48 hours and 50.17 ± 26.5% at 72 hours. The combination treatment (TTFields + RMC-6236) further decreased viability to 63.8 ± 25.2% at 48 hours and 40.93 ± 18.1% at 72 hours, demonstrating synergistic cytotoxicity relative to monotherapy. Clonogenic assays were performed to evaluate cell survival fractions following treatment with RMC-6236, TTFields, and their combination. Cell migration was assessed using scratch assays, revealing that untreated cells exhibited a migration rate of 91.49 ± 0.85%, RMC-6236-treated cells showed 89.48 ± 1.3%, TTFields alone reduced migration to 61.33 ± 16.3%, and combination treatment markedly suppressed migration to 24.6 ± 22.13% . For every case we were compared with 72h cell migration rate with 0 h migration rate. These findings indicate that TTFields alone significantly impair cellular motility, while their combination with RMC-6236 results in a profound anti-migratory effect, substantially inhibiting wound closure. Additionally, western blot analysis was performed to assess changes in KRAS protein expression, a key PDAC biomarker. Overall, our results demonstrate that the combination of TTFields and RMC-6236 significantly inhibits PDAC cell growth, migration, and survival at sub-IC_{50} concentrations, suggesting a promising alternative therapeutic approach for PDAC management.

#4482 Catalytic inhibition of NSD2 demonstrates *in vitro* antitumor activity in head and neck squamous cell carcinoma.

Amr Ismail[1], Iuliia Topchu[2], Tingting Zhang[3], Ahmed Ismail[4], Peter Makhov[5], Jia Xu[6], Kang Le[7], Michael Soth[7], Yanis Boumber[1]

[1]Medicine - Hematology and Oncology, University of Alabama at Birmingham, Birmingham, AL,[2]Institute of Fundamental Medicine and Biology, Kazan Federal University, Kazan, Russian Federation,[3]Department of Oncology, Shengli Oilfield Central Hospital, Dongying, China,[4]Medicine, Eastern Virginia Medical School at Old Dominion University, Norfolk, VA,[5]Fox Chase Cancer Center, Philadelphia, PA,[6]Genetics, University of Alabama at Birmingham, Birmingham, AL,[7]Institute for Applied Cancer Science, MD Anderson Cancer Center, Houston, TX

NSD2 is a histone methyltransferase that catalyzes H3K36 dimethylation and is frequently altered or overexpressed in diverse cancers. Recent work has demonstrated that selective NSD2 catalytic inhibitors suppress tumor growth in preclinical models of pancreatic and lung cancer by reprogramming chromatin and transcriptional states. However, the effect of NSD2 catalytic inhibition in other solid and hematologic malignancies remains undefined. Prior studies from our lab and others demonstrated that NSD2 depletion suppresses HNSCC cell growth. We therefore evaluated the activity of a highly selective NSD2 inhibitor (IACS-17817) and its enantiomer (IACS-17818) as a negative control in head and neck squamous cell carcinoma (HNSCC) JHU-11 and FaDu cell lines, as well as in the RPMI-8402 acute lymphoblastic leukemia (ALL) cell line, which carries an NSD2-activating mutation. Cells were treated with escalating concentrations of the inhibitor for 72 hours, and cells were treated with a fixed concentration of the compounds at serial time points. Then, global H3K36me2 levels were tested via western blotting. IACS-17817 decreased H3K36me2 levels in a time and concentration-dependent manner, with a significant drop at treatment concentrations as low as 10 nM of the active compound after 72 hours in all cell lines tested. IACS-17817 showed an onset of action as early as 24 hours in HNSCC and 48 hours in ALL cells. NSD2 inhibition suppressed the proliferation of HNSCC cells as measured by clonogenic assays in a time- and concentration-dependent manner. ALL RPMI-8402 methylcellulose cell survival is also being evaluated, and results are pending. Combination treatment with IACS-17817 and the PARP inhibitor olaparib demonstrated additive cytotoxicity compared to single agents in HNSCC cells, as shown in clonogenic assays. These findings broaden the known therapeutic scope of NSD2 catalytic inhibition from pancreatic and lung cancers to head and neck squamous cell carcinoma (HNSCC), highlighting NSD2 as a convergent oncogenic driver and supporting further preclinical development of NSD2-targeting agents for clinical translation.

#4483 The KAT6/7 inhibitor IDE574 disrupts tumor lineage identity and drug tolerance to deliver robust antitumor activity in biomarker selected indications.

Manav Gupta, Scott R. Tyler, Nour Ghaddar, Carl Schultz, Pranav Gupta, Steven L. Spivak, Katelyn N. Lukas, Zabrisky Roland, Anjali Bisaria, Mona Khalaj, Mason Appel, Oscar Aubi, Kelly S. Trego, Parker Y. Jameson, Jacob Burch-Konda, Angelica Gonzalez-Sanchez, Brittany Cruzan, Rushika Pandya, Jay Prakash Jain, Michael E. Dalziel, Julie Deichert, Sunjay Sethi, Ivan G. Shabalin, Jonathon S. Ryan, Daniel M. Walden, Muzaffar Alam, Daniel Severance, Amber C. Donahue, Edward Chan, Rebeca Choy, Diana M. Munoz, Richard Zang, Xin Linghu, Peter Teriete, Christian R. Intra-tumoral heterogeneity often limits therapy benefit due to intrinsic and adaptive phenotypic diversification via interactions between somatic variation and epigenetic regulation. Important opportunities to overcome this challenge may lie in new therapies that target obligatory lineage-specific gene regulatory programs and constrain emergence of drug tolerant cell states. Lysine acetyltransferases (KATs) are a promising epigenetic target class due to their roles in the establishment and maintenance of permissive chromatin architecture that supports both tumor lineage identity and adaptive plasticity. In particular, KAT6A, KAT6B and KAT7 collaboratively promote oncogenic transcription programs via acetylation of histone H3 at K9, K14, and K23. Preclinical modeling of dual KAT6/KAT7 inhibition has demonstrated pathway modulation and antitumor activity that is superior to selective inhibition of KAT6, highlighting the essential role of KAT7 in sustaining tumorigenic transcription factor activity. Furthermore, the clinical KAT6 inhibitor monotherapy experience in ER+ mBC indicates an opportunity to augment therapeutic benefit by maximizing pathway modulation and preventing acquired resistance. Here we describe IDE574, a potent dual KAT6/KAT7 inhibitor with high selectivity over related KAT5/KAT8 enzymes. IDE574 demonstrated robust suppression of both H3K23ac and H3K14ac in multiple cancer models. This was concomitant with selective chromatin condensation at locations typically occupied by lineage survival transcription factors including FOXA1 in NSCLC and GATA3/ESR1 in ER+ mBC. RNA-seq analysis of drug response and an unbiased evaluation of affected biological systems with a custom RAG AI method, indicated perturbation of lineage identity and epigenetic remodeling. scRNA-seq and protein profiling of PDX-derived ER+ mBC cells revealed that dual KAT6/7 blockade likely overcomes acquired resistance by inhibiting emergence of drug-tolerant persister cells and renewal of cancer stem-like cells. In contrast to selective inhibition of KAT6, IDE574 reduced ALDH+, CD133+, and CD44+/CD24- cell populations, and inhibited clonogenic capacity. Consistent with this biology, IDE574 delivered deeper and durable antitumor activity in aggressive ER+ mBC PDX models including ESR1 mutant backgrounds reported to be resistant to the clinical KAT6 inhibitor even when combined with palbociclib and fulvestrant. Pan-cancer cell viability assessments and xenograft studies with IDE574 revealed indication opportunities in addition to mBC, including predictive biomarker-associated subsets of NSCLC and bowel cancer. These preclinical findings combined with favorable drug-like properties and non-clinical safety profile support evaluation of IDE574 in the clinic as a treatment option for patients with biomarker positive disease.

#4484 Characterization and pre-clinical development of LG-CBP/p300 inhibitor, a potent and selective bromodomain inhibitor of CBP/p300.

Sinae Lee, Yuna Chang, Ik Sun Kim, Sung Woong Jang, Rira Kim, Gyungah Pak, Bitna Oh, Byung Gyu Kim, Sugyeong Woo

Life Sciences R&D, LG Chem, Ltd., Seoul, Korea, Republic of

[Background] Acute Myeloid Leukemia (AML) is a heterogeneous hematologic malignancy characterized by uncontrolled proliferation and impaired differentiation of myeloid progenitors. Despite advances in targeted and combination therapies, relapse and resistance remain major clinical challenges, underscoring the need for novel therapeutic approaches. Epigenetic dysregulation is a hallmark of AML, with transcriptional co-activators CBP (CREBBP) and p300 (EP300) emerging as key regulators of leukemogenesis. These histone acetyltransferases (HATs) catalyze acetylation of histone H3 lysine 27 (H3K27), promoting open chromatin and transcriptional activation of genes involved in cell proliferation and differentiation. Aberrant CBP/p300 activity sustains oncogenic transcriptional programs driven by factors such as MYC and MYB. Preclinical studies have demonstrated that pharmacologic inhibition of CBP/p300 suppresses leukemic cell growth and reduces leukemia-initiating potential, supporting CBP/p300 as a promising therapeutic target in AML. In this study, we evaluated the antileukemic efficacy and molecular mechanism of a selective CBP/p300 inhibitor in AML models to assess its translational potential.
[Method] The antileukemic activity of the LG-CBP/p300 inhibitor was assessed in AML cell lines and in vivo mouse models. Cell viability was measured using CellTiter-Glo®. H3K27ac levels were analyzed by flow cytometry. The expression of MYC and MYB were quantified by reverse transcription quantitative PCR (RT-qPCR) and western blot. Pharmacodynamic and efficacy studies were conducted in both subcutaneous and disseminated xenograft AML mouse models.
[Result] The LG-CBP/p300 inhibitor exhibited potent anti-proliferative activity in AML cell lines, with IC_{50} values in the nanomolar range. The compound was effective across AML cell lines regardless of the presence or absence of common AML-associated mutations. Target engagement was confirmed by concentration-dependent reductions in H3K27ac levels and downregulation of MYC and MYB mRNA expression. In in vivo studies using AML cell lines resistant to venetoclax, this inhibitor significantly suppressed tumor growth in a dose-dependent manner in a subcutaneous xenograft model. Moreover, in a systemic AML mouse model, it reduced leukemia burden and prolonged survival.
[Conclusions] Selective inhibition of CBP/p300 exerts potent antileukemic effects by regulating multiple oncogenes. The LG-CBP/p300 inhibitor represents a promising epigenetic therapeutic strategy for AML with strong translational potential.

#4485 ASTU-045, a novel METTL3 inhibitor with anti-tumor activity in the MC38 syngeneic mouse model.

Laurence Mevellec[1], Nicolas George[2], Ludovic Waeckel[3], Remi Longuespee[4], Nathalie Weidner[4], Hugues Prevet[1], Celine Ronin[4], Jean-Michel Linget[3], Anna Bonhoure[4], Roland Blanque[3], Sabine Gratzer[4]

[1]NOVALIX, Val de Reuil, France,[2]AQEMIA, Paris, France,[3]NOVALIX, Romainville, France,[4]NOVALIX, Strasbourg, France

N^6-methyladenosine (m^6A) is the most prevalent modification of eukaryotic mRNA and plays a crucial role in gene regulation. Methyltransferase-like 3 (METTL3), the key catalytic component of the m^6A methyltransferase complex, is primarily responsible for depositing m^6A on target RNA. METTL3 is highly expressed in various cancers and is closely associated with tumor development. Previous studies have also shown that METTL3 inhibition activates anti-tumor immunity and reshapes the tumor microenvironment. Using structure-based drug design owing to the generation of multiple high resolution crystal structures of ligands bound to the METTL3-METTL14 complex, we developed novel METTL3 inhibitors. This effort led to the identification of ASTU-045, a selective METTL3 inhibitor that demonstrated cellular target engagement (m^6A inhibition) and, in an *in vitro* co-culture system, showed strong, concentration dependent enhancement of PBMC-mediated killing of cancer cells. In the MC38 colorectal syngeneic model, oral administration of ASTU-045 to immune-competent, tumor-bearing mice resulted in tumor stasis. Combination treatment with ASTU-045 and an anti-PD1 antibody produced significant tumor regression. Strong target engagement was also observed in the spleen under both treatment conditions. In summary, we identified ASTU-045 as a novel, selective METTL3 inhibitor with high efficacy in the MC38 syngeneic model.

#4486 The MTA-cooperative PRMT5 inhibitor CTS3497 alone and in synergy with mechanism-based combination targeted therapies for the treatment of *MTAP*-deleted cancers.

Yilin Liu[1], Xinyue Duan[1], Hui Shi[1], Qiugeng Ouyang[1], Jiaxin Huang[1], Meng Wang[1], Xingnian Fu[1], Yiqin Wang[2], Guoliang Xu[2], Haiping Wu[1]

[1]CytosinLab Therapeutics Co., Ltd., Hangzhou, China,[2]Center for Excellence in Molecular Cell Science, Chinese Academy of Science, Shanghai, China

Homozygous deletion of chr9p21/*CDKN2A*/*MTAP* occurs in approximately 15% of human cancers and represents a high unmet medical need. Protein arginine methyltransferase 5 (PRMT5), a key member of the type-II PRMT family, has emerged as a synthetic-lethal target for $MTAP^{null}$ cancers. The MTA-cooperative PRMT5 inhibitor CTS3497, currently in Phase I/II trials (NCT06971523), exhibited potent cell growth inhibition with a low single-digit nM IC50 and 171-fold high selectivity for $MTAP^{null}$ over isogenic $MTAP^{wt}$ cells. *In vivo*, CTS3497 led to tumor inhibition or deep regression in $MTAP^{null}$ xenograft models of various lineages, notably $MTAP^{null}$ orthotopic glioma. The brain penetration property of CTS3497 underscores its therapeutic potential for both primary brain tumors and brain metastases. Mechanism-based therapeutic combinations were explored to improve response and defeat emergent resistance of standard of care (SOC) targeted agents. Co-targeting type I and type II PRMTs with CTS2190 (currently in Phase II trial, NCT06224387) and CTS3497 demonstrated strong synergy against $MTAP^{null}$ tumors *in vitro* and *in vivo*, especially in intractable pancreatic cancer. Moreover, the synergy of CTS2190 and CTS3497 was also significant in $MTAP^{null}$ cells that were established acquired resistance to PRMT5 inhibitors, suggesting the potential combinational use of the dual PRMT inhibitors post PRMT5 targeted therapy. In addition, combination of CTS3497 and osimertinib (EGFR-TKI) enhanced anti-tumor efficacy and suppressed acquired resistance to osimertinib in $MTAP^{null}EGFR^{mut}$ lung cancer xenografts. Furthermore, CTS3497 effectively reversed resistance to adagrasib ($KRAS^{G12C}$) in an adagrasib-resistant $MTAP^{null}$ model, resulting in profound tumor regression without regrowth even after discontinuation of treatment. CTS3497 also synergized with Bcl-2/xL inhibitors by promoting apoptosis, more prominently in $MTAP^{null}$ $BCL2L1^{amp}$ tumor cells. In summary, CTS3497 exhibits strong antitumor activity alone and in combination with clinically feasible targeted agents including but not limited to type I PRMT, EGFR, KRAS and Bcl-2/xL inhibitors. CTS3497 represents a promising synthetic-lethal precision medicine for patients with MTAP-deficient cancers either as a single agent or in combination with rational combination partners. Particularly, combination of CTS3497 with CTS2190, a type I PRMT inhibitor, may provide a potential solution for patients post PRMT5 targeted therapy.

#4487 CTS2190, a first-in-class PRMT1 inhibitor in phase I/II clinical development, demonstrates robust and broad monotherapy efficacy and provides a rationale for novel combinations based on translational findings.

Hui Shi[1], Qiugeng Ouyang[1], Jiaxin Huang[1], Xingnian Fu[1], Guoliang Xu[2], Haiping Wu[1]

[1]CytosinLab Therapeutics Co., Ltd., Hangzhou, China,[2]Center for Excellence in Molecular Cell Science, Chinese Academy of Sciences, Shanghai, China

Background: Protein arginine methyltransferase 1 (PRMT1) is a master epigenetic regulator implicated in oncogenesis through diverse mechanisms, including signal transduction, DNA damage repair, and immune evasion. CTS2190 was designed as a first-in-class, oral PRMT1 inhibitor to achieve high selectivity and minimize off-target toxicity. This agent is currently being evaluated in a phase I/II clinical trial (NCT06224387) and has shown encouraging efficacy and a favorable safety profile, with no thrombotic events observed, in heavily pretreated patients with advanced solid tumors.

Methods: The potency and selectivity of CTS2190 were characterized through biochemical and cellular assays. Its monotherapy efficacy was evaluated in multiple cell-derived xenograft (CDX) and patient-derived xenograft (PDX) models. Furthermore, the combinatorial potential of CTS2190 was investigated with targeted therapies (Enzalutamide, Osimertinib, Gilteritinib), a radioligand therapy (Lu177-PSMA), and an anti-PD-1 antibody across relevant *in vivo* models. Tumor growth and immune profiling were assessed.

Results: CTS2190 exhibited high selectivity for PRMT1 and potent dose-dependent antitumor activity as a single agent in various CDX and PDX models, leading to significant tumor growth inhibition. This robust monotherapy efficacy provided a strong foundation for exploring combinations. CTS2190 demonstrated robust synergistic antitumor activity with all combination partners. It enhanced the efficacy of targeted agents, sensitized tumors to radiation, and remodeled the tumor immune microenvironment.

Conclusion: The compelling single-agent activity of CTS2190 in preclinical models corroborates its ongoing clinical investigation. The broad and potent synergy observed with targeted, radioligand, and immunotherapeutic agents provides a strong mechanistic rationale for the imminent clinical development of novel CTS2190-based combination regimens, positioning it as a versatile therapeutic strategy for multiple cancers.

#4488 Targeting non-canonical PRC2 functions via small-molecule degradation: A novel therapeutic strategy for prostate cancer and other solid tumors.

Hui Shi[1], Xinyue Duan[1], Jiaxin Huang[1], Qiugeng Ouyang[1], Xingnian Fu[1], Guoliang Xu[2], Haiping Wu[1]

[1]CytosinLab Therapeutics Co., Ltd., Hangzhou, China,[2]Center for Excellence in Molecular Cell Science, Chinese Academy of Sciences, Shanghai, China

Background: The Polycomb Repressive Complex 2 (PRC2) is a key epigenetic regulator responsible for histone H3 lysine 27 methylation (H3K27me3) and is implicated in essential cellular processes. However, its core components, EZH2 and EED, also exert extensive non-conventional functions through protein-protein interactions (PPIs) with other proteins, independent of its methyltransferase activity. Aberrant activation or overexpression of PRC2 components, particularly EZH2, drives oncogenesis and tumor progression in a variety of cancers. While several enzymatic inhibitors targeting PRC2 components (EZH2, EED, and EZH1/2) have been developed, their therapeutic efficacy remains limited, particularly in solid tumors, where clinical responses are often modest and transient. Notably, emerging evidence from KO/KD models, as well as PROTACs underscores the non-canonical, non-enzymatic functions in tumor maintenance, positioning PRC2 as a more effective therapeutic target. PROTAC-based degraders targeting these functions show promise but are hampered by poor permeability and stability. We developed novel small-molecule PRC2 degraders to overcome these limitations.

Methods: Small molecular lead candidates CTS3353 and CTS3952 were evaluated for their -PRC2 degradation efficacy, and *in vitro* antiproliferative effects across multiple cancer cell lines (e.g., mCRPC cell 22Rv1, DLBCL Karpas422). Pharmacokinetic and *in vivo* efficacy were performed in cell-derived xenograft (CDX) models of prostate cancer (especially in mCRPC) and DLBCL.

Results: CTS3353 and CTS3952 achieved potent PRC2 downregulation through complex disruption in 22Rv1 and Karpass422 cells. They exhibited superior cell permeability and metabolic stability compared to conventional PROTAC-based degraders. Both compounds induced sustained suppression of PRC2 components, leading to potent anti-proliferative effects. In mCRPC CDX models, CTS3353 and CTS3952 achieved robust antitumor activity, reducing tumor burden and improving survival without observable systemic toxicity. These effects were attributed to the disruption of PRC2's non-canonical functions rather than its histone methyltransferase activity.

Conclusions: Our findings highlight the therapeutic potential of targeting the non-enzymatic functions of PRC2 through small-molecule degradation. CTS3353 and CTS3952 represent a new class of potent and bioavailable PRC2 degraders with promising preclinical efficacy in solid tumor models such as mCRPC and TNBC. This strategy provides a foundation for next-generation PRC2-directed cancer therapies beyond enzymatic inhibition.

#4489 CAAP1 loss uncovers vulnerability of MTAP-deficient NSCLC to PRMT5 inhibition with AZD3470.

Jelena Urosevic[1], Angelos Papadopoulos[2], Shaun Moore[1], Ted Hong[3], Valentina Quarantotti[2], Harriet Southgate[1], Maximilian Wechsung[2], Lukasz Magiera[1], Daniel Barrell[2], Grainne Gernon[2], Elissavet Kentepozidou[2], Laura Rosenberg[2], Anisha Solanki[1], James T. Lynch[1], Stephen Fawell[4], Ho Man Chan[4], Susan Critchlow[1], Emma Dean[1]

[1]Oncology Targeted Discovery, Oncology R&D, AstraZeneca, Cambridge, United Kingdom,[2]Discovery Sciences, Biopharmaceuticals R&D, AstraZeneca, Cambridge, United Kingdom,[3]Data Science, Oncology R&D, AstraZeneca, Waltham, MA,[4]Oncology Targeted Discovery, Oncology R&D, AstraZeneca, Waltham, MA

Introduction: This study aimed to identify genes that sensitize NSCLC cells to AZD3470, an MTA-cooperative PRMT5 inhibitor that targets MTAP-deficient tumors while sparing normal tissues. Early clinical data for this class of drugs as monotherapy has shown objective response rates (ORRs) of approximately 20% across multiple tumor indications. Encouragingly, the duration of response and disease control rates are substantial, suggesting that PRMT5 inhibitors may play a significant role in disease stabilization. While these findings are promising, they also highlight the need to further improve clinical efficacy. Therefore, we aimed to identify genetic alterations—beyond MTAP deficiency—that contribute to sensitivity to PRMT5 inhibition.
Experimental procedures: To identify genes associated with sensitivity to AZD3470 we performed a genome-wide CRISPR screen across six NSCLC cell lines. Hit validation was conducted using two NSCLC CRISPR/Cas9 generated isogenic pairs. RNAseq, cell cycle analysis, apoptosis assay and γH2AX staining were used to provide mechanistic insight for AZD3470 sensitization. Finally, findings were validated in 29 NSCLC PDX models.
Results: The genome-wide CRISPR screen identified CAAP1 loss as one of the top sensitizers to AZD3470 treatment. The CAAP1 (Caspase activity and apoptosis inhibitor 1) gene is located on chromosome 9p21, in close proximity to MTAP, and was found to be co-deleted with MTAP in approximately 20% of tumors. CRISPR screen results were further validated using HCC15 and NCI-H838 CAAP1 KO/WT isogenic pairs in long term proliferation assays, where CAAP1 null cells showed increased sensitivity to AZD3470 compared to CAAP1 WT cells. In addition, cell cycle analysis of the NCI-H838 and HCC15 CAAP1 KO cells after 96h of treatment with 1μM AZD3470 showed a higher percentage of cells in G2/M phase compared to CAAP1 WT cells. Moreover, CAAP1 deficiency potentiated both DNA damage and apoptosis induced by AZD3470. RNAseq analysis of HCC15 CAAP1 KO/WT isogenic cell line pairs revealed significant number of differentially spliced events in CAAP1 KO versus CAAP1 WT cells that increased with AZD3470 dose. Notably, the most abundant changes were detected in the transcripts with skipped exons that were enriched for pathways such as DNA repair or cell cycle consistent with the increased DNA damage and cell cycle alterations detected in CAAP1 null cells treated with AZD3470. Finally, our findings were confirmed using PDX models, where 71% of NSCLC PDXs in which AZD3470 induced regression were CAAP1 null.
Conclusions: In summary, CAAP1 deletion in MTAP-null tumors increases sensitivity to AZD3470, both in vivo and in vitro, by potentiating AZD3470 induced cell cycle alterations and DNA damage, potentially through the regulation of alternative splicing.

#4490 PRMT5 inhibition alters cellular chromatin landscape and drives vulnerability to BH3 mimetics in mantle cell lymphoma.

Christoph Weigel[1], Claire Hinterschied[1], Shirsha Koirala[1], Mackenzie Long[1], Shelby Sloan[1], Jessica Weist[1], Lynda Villagomez[2], Allesandro La Ferlita[1], Coinne Gao[1], Ian Hout[1], Sydney Leon[1], Fiona Brown-Burke[1], Betsy Pray[1], Maggie Harper[1], Neha Bhagwat[3], Kris Vaddi[3], Peggy A. Scherle[3], Cem Meydan[4], Selina Chen-Kiang[5], Maurizio DiLiberto[5], Olivier Elemento[4], Christopher E. Mason[4], Jihye Paik[5], Lapo Alinari[1], Rosa Lapalombella[1], Lalit Sehgal[1], Robert Baiocchi[1]

[1]The Ohio State University Comprehensive Cancer Center, Columbus, OH,[2]Department of Pediatrics, The Ohio State University and Nationwide Children's Hospital, Columbus, OH,[3]Prelude Therapeutics, Wilmington, DE,[4]Department of Physiology and Biophysics, Institute for Computational Biomedicine, Weill Cornell Medicine, New York, NY,[5]Department of Pathology and Laboratory Medicine, Weill Cornell Medicine, New York, NY

Background: Mantle cell lymphoma (MCL) is a rare and incurable blood cancer, comprising 10% of Non-Hodgkin lymphomas. Especially in relapse settings, there remains a crucial need for novel treatments. The enzyme protein arginine methyltransferase 5 (PRMT5) is an oncogenic driver in MCL which targets both histones and non-histone proteins for posttranslational symmetric arginine dimethylation (me2s). BCL2 family proteins govern apoptosis and their dysregulation is a hallmark of MCL, but treatment with pharmacological inhibitors (BH3 mimetics) has had limited success. We hypothesized that transcriptional and epigenomic perturbations via PRMT5 inhibitors (PRMT5i) will sensitize MCL cells to BH3 mimetics for synergistic drug action.
Methods: Plate- and flow-cytometry-based BH3 profiling was used to read out the apoptotic priming state of n=5 MCL cell lines and n=2 primary patient samples. Effects of the small molecule PRMT5i PRT382 were assessed via BH3 profiling, transcriptomics (RNA sequencing) and genome-wide histone modification profiling (CUT&RUN sequencing for H3K4me3, H3K27me3, H3K27ac and two me2s marks H3R8me2s and H4R3me2s). Drug combination effects of PRT382 and BH3-mimetics (navitoclax, A852/A-1331852, PRT1419) were tested in MCL cell lines (n=5). Efficacy of navitoclax and PRT808, a related PRMT5i, was assessed alone or in combination in a murine patient-derived xenograft (PDX) model of aggressive, relapsed MCL.
Results: Global analysis of histone modifications and RNA expression revealed strong association around transcription start sites (adjusted $p<0.0001$), including for PRMT5-mediated H4R3me2s (adjusted $p<0.0001$), but revealed no pronounced global loss of histone arginine methylation under PRT382. Epigenomic responses to PRT382 were highly distinct in MCL models Z-138 and CCMCL1, with the latter revealing lowered global H3K4me3 ($p<0.0001$) at loci specifically enriched for cell cycle pathways (adjusted $p<0.0001$). BH3 profiling revealed vulnerabilities to mitochondrial insults in cell lines, PDX cells, and patient samples, which was correlated with pro-survival BCL2 family RNA- and protein expression ($p<0.01$). Pronounced sensitization to depolarization with PRT382 in Z-138, but not CCMCL1, was reflective of transcriptomic differences in these models. We observed strong synergistic reduction in cell viability with n=16 distinct PRMT5i/BH3 mimetic combinations ($p<0.01$). In our PDX model, the PRT808/navitoclax combination outperformed single treatment cohorts in survival (median 93 vs. 65/75 days for PRT808/navitoclax alone, $p<0.01$) and circulating disease ($p<0.01$).
Conclusions: Our study showed the broad synergistic potential of combining PRMT5i and BH3 mimetics both in vitro and in vivo. PRMT5i lead to epigenome-wide modulation of chromatin states with potential to create vulnerabilities to targeted agents.

#4491 HDAC inhibitors induce NOX5 expression in human uveal melanoma cells in a Brd4-Sp1/Sp3-dependent manner.

Smitha Antony, Ballachanda N. Devaiah, Mariam M. Konate, Yongzhong Wu, Guojian Jiang, Jennifer L. Meitzler, Jiamo Lu, Becky A. Diebold, David J. Mallick, Krishnendu K. Roy, Dinah S. Singer, James H. Doroshow

National Cancer Institute, NIH/DHHS, Bethesda, MD

Epigenetic reprogramming, particularly histone deacetylation (HDAC), and reactive oxygen species (ROS) play key roles in melanoma progression and the development of drug resistance. While various histone deacetylase inhibitors (HDACi) are already in clinical use for hematological cancers, recent studies indicate their potential effectiveness in melanoma models as well. Given the increasing interest in enhancing the therapeutic efficacy of HDACi, we investigated the molecular mechanisms underlying their association with ROS formation in melanomas. Uveal melanoma (UM), a rare and aggressive eye cancer, has been identified in the TCGA dataset as expressing the highest levels of the superoxide-producing enzyme NADPH oxidase 5 (NOX5) among all human cancers. Our study demonstrates that HDACi treatment increases NOX5 expression in UM cell lines. This upregulation is accompanied by elevated extracellular ROS, which is suppressed when NOX5 is silenced. The use of actinomycin D and cycloheximide significantly reduced HDACi-induced NOX5 expression, suggesting regulation at both transcriptional and translational levels. HDACi treatment also led to accumulation of acetylated histones H3 and H4. Since histone acetylation (particularly H4K5/8/12Ac) recruits BRD4 to facilitate transcription, we evaluated the effect of BRD4 knockdown or exposure to BRD4 inhibitors on NOX5 levels in UM cells. Both approaches reduced NOX5 expression induced by HDACi. Furthermore, dual silencing of the transcription factors Sp1 and Sp3 markedly attenuated both basal and HDACi-induced expression of NOX5. ChIP assays revealed that HDACi treatment increases chromatin-associated acetylated histone H3, phosphorylated RNA polymerase II (p-Ser2), BRD4, Sp1, and Sp3 at the NOX5 promoter region. Collectively, these findings suggest that HDACi-mediated upregulation of NOX5 in UM cells occurs, at least in part, via transcriptional activation of the NOX5 promoter. This process is driven by HDACi-induced histone hyperacetylation, which enhances the recruitment of BRD4, Sp1, and Sp3 to the promoter region, thereby facilitating RNA polymerase II-dependent transcription. Given that HDAC inhibition elevates both NOX5 expression and ROS production, co-targeting HDACs and NOX5 may offer a novel and effective therapeutic strategy in the treatment of UM.

#4492 Linking VHL and SETD2 in a common oncogenic pathway that converges on the mitotic spindle.

Manga Motrapu[1], Pratim Chowdhury[2], Sung Yun Jung[2], Xiaoli Wang[2], Ashley Boice[2], Ruhee Dere[2]

[1]Center for Precision Environmental Health, Baylor College of Medicine, Houston, TX,[2]

Background: Loss of chromosome 3p is a landmark event in clear cell renal cell carcinoma (ccRCC) that results in mono-allelic loss of *VHL* (*von Hippel-Lindau*) and *SETD2* (*Set-domain containing 2*) (and other tumor suppressors co-located on 3p). Second hits in *VHL* inactivate this key tumor suppressor, initiating tumor progression. SETD2, a histone methyltransferase, has been previously shown to have a dual function in methylating both histones and microtubules, thereby contributing to the histone and tubulin codes. Methylation by SETD2 on microtubules occurs at the mitotic spindle and is essential for normal mitosis and cytokinesis; the loss of SETD2 acts as a strong driver of apoptosis. This raises a conundrum of how cancer cells survive the early mono-allelic loss of *SETD2*, escaping cell death.

Methods: Using biochemical kinase assays and mass spectrometry, we have identified SETD2 as a substrate for AURKA. Additionally, we have employed immunoblotting and immunofluorescence assays to investigate the phosphorylation of SETD2 and its effects on both chromatin and cytoskeleton targets.

Results: We have identified the mitotic kinase, Aurora kinase A (AURKA), as a regulator of SETD2. Our data uncover SETD2 as a unique substrate for phosphorylation by AURKA, with mass spectrometry identifying serine 2080 (S2080) as the site of phosphorylation on SETD2. We found that phosphorylation of SETD2 by AURKA at S2080 contributes to its methyltransferase (i.e., enzymatic) activity on microtubules but does not impact chromatin methylation at H3K36, which remains unchanged. We demonstrate that VHL regulates SETD2 through AURKA, and the loss of phosphorylation on SETD2 leads to mitotic defects and genomic instability. Importantly, we demonstrate that inhibition of AURKA is synthetic lethal in the setting of *VHL* and *SETD2* deficiency.

Conclusions: AURKA expression levels are high in *VHL*-null cells, resulting from an inability of VHL to target AURKA for degradation, and our data now highlight a direct link between VHL and SETD2, two tumor suppressors believed to drive RCC pathogenesis independently. In summary, our data reveal a tumor-specific vulnerability linked to mitotic fragility that can be precisely targeted to drive mitotic catastrophe ultimately.

*Presenting and primary author.

#4493 Comprehensive assay approaches for PRMT5 targeted drug discovery.

Jianghong Wu, Charles Schmidt, Jamin Steffen, Joseph J. Ferry, Li Liang, Shawn McGinley, Joshua Rettew, Yong Wan, Haiching Ma

Reaction Biology, Malvern, PA

Protein arginine methyltransferase 5 (PRMT5) is a type II methyltransferase that symmetrically dimethylates arginine residues on histone and non-histone proteins, an essential epigenetic modification that shapes chromatin structure and regulates gene expression. Through these activities, PRMT5 controls key cellular processes, including transcription, RNA splicing, DNA repair, and signal transduction. PRMT5 operates in complex with MEP50, which is required for efficient catalytic activity. Dysregulated PRMT5 is strongly associated with diseases, particularly cancer. PRMT5 is frequently overexpressed in breast, lung, prostate, and hematologic malignancies, where it promotes tumor growth, metastasis, and therapy resistance. Small-molecule PRMT5 inhibitors have emerged as promising agents that block methyltransferase activity, reverse aberrant epigenetic marks, and disrupt oncogenic pathways. Here, we established comprehensive assay platforms for PRMT5-targeted drug discovery and validated them using five known inhibitors (LLY-283, JNJ-64619178, GSK591, EPZ015666, and GSK33326595). Our biochemical FlashPlate assay demonstrated potent inhibition of PRMT5/MEP50 activity, with IC_{50} values in the low nanomolar range (0.6-17 nM). Surface Plasmon Resonance (SPR) revealed distinct binding profiles: substrate-competitive inhibitors (EPZ015666, GSK33326595, GSK591) showed weak affinity for apo PRMT5, enhanced by cofactors (MTA, SAH, SAM), whereas cofactor-competitive LLY-283 bound tightly to apo PRMT5 but exhibited >50-fold reduced affinity with cofactors. JNJ-64619178 displayed reduced signal upon cofactor binding, driven by a slow off-rate consistent with pseudo-irreversible inhibition. NanoBRET target engagement intracellular assay results indicated that the PRMT5 inhibitors engaged with the PRMT5/MEP50 complex within one hour of incubation in live HEK293 cells, and Western blot confirmed inhibition of histone H4R3me2s methylation, a key substrate of PRMT5, in MV4-11, Jeko-1, 22RV1, and PC3 cancer cell lines. Collectively, these platforms enable identification, optimization, and mechanistic characterization of PRMT5 inhibitors, accelerating development of selective and potent therapeutic candidates.

#4494 A highly selective KAT6/7 dual inhibitor with best-in-class potential and favorable pharmacokinetic profile.

Yang Yang, Xin Nie, Zhen Mi, **Yin Guo**, Yinyin Zhang, Yong Peng, Lei Zhang

Beijing Konruns Pharmaceutical Co., Ltd., Beijing, China

A growing body of published studies suggested the important role for epigenetic regulation in promoting tumor heterogeneity. Targeting these epigenetic proteins becomes an exciting and attainable approach for several cancer types with unmet clinical needs.

MYST-family acetyltransferases, KAT6A/B and KAT7 (HBO1), maintain promoter-proximal H3 acetylation (e.g., H3K23ac, H3K14ac) that sustains lineage transcription in multiple cancers. First-generation KAT6-selective agents have shown early clinical activity in $ER^+/HER2^-$ breast cancer but can produce predominantly cytostatic responses. We here report an orally bioavailable dual KAT6/7 inhibitor, KC1086, designed to produce deeper promoter closure, broaden lineage program suppression, and translate into tumor regressions with superior efficacy and a favorable safety window.

KC1086 showed sub-10 nM potency on KAT6A/B and potent KAT7 inhibition (IC_{50} around 16 nM) with wide selectivity over KAT5/8. In addition, KC1086 retained activity under elevated Acetyl-CoA (AcCoA), indicating reduced co-factor competition liability. Unlike PF-07248144, KC1086 did not drive significant Malonyl-CoA accumulation, while maintaining on-target AcCoA modulation, suggesting potentially much less hepatotoxicity. In ER^+ breast cancer cells, KC1086 durably suppressed H3K23ac/H3K14ac, which outperformed PF-07248144 on biomarker depth and duration.

KC1086 monotherapy exhibited strong tumor growth inhibition in various xenograft models. Combinations of KC1086 further demonstrated enhanced efficacy: (i) with Palbociclib (CDK4/6 inhibitor) (TGI 101%) in ZR-75-1 ER^+ breast cancer xenograft model; (ii) with Fulvestrant (Estrogen Receptor Antagonist) (TGI 83%) in xxT47D breast cancer models yielding tumor regressions and survival benefit. Furthermore, KC1086 demonstrated favorable PK profile and significant safety window: linear PK, high oral bioavailability, minimum drug accumulation and clean safety pharmacology (eg. CV, CNS and respiratory).

In conclusion, we demonstrated equipotent dual inhibition of KAT6/7 delivering potentially deeper chromatin closure than KAT6-selective blockade, which translated into robust monotherapy activity and combination synergy across ER^+ breast cancer, ovarian cancer as well as other tumor models, with favorable preclinical safety. These data supported clinical development of KC1086 as a dual KAT6/7 inhibitor with best-in-class potential.

#4495 TACC3 inhibition with KC1101 drives mitotic catastrophe and broad antitumor activity.

Lei Zhang, Xin Nie, Zhen Mi, **Yin Guo**, Xiaona Yang, Yinyin Zhang, Huaying Wang, Bingqian Li, Yong Peng, Yang Yang

Beijing Konruns Pharmaceutical Co., Ltd., Beijing, China

TACC3, an oncogenic member of the transforming acidic coiled-coil domain-containing protein (TACC) family, is a core component of multi-protein complexes regulating microtubule and centrosome-related processes. Aberrant overexpression of TACC3 is found across multiple cancers with centrosome instability and worse prognosis. Emerging evidence further highlights TACC3 as a therapeutic vulnerability, particularly in highly aggressive cancers characterized with centrosome amplification.

We have profiled our selective TACC3 inhibitor -- KC1101 via cell proliferation assays across diverse cancer cell lines. KC1101 demonstrated potent anti-proliferative effects, approximately 2-fold more potent than AO-252, an oral TACC3 inhibitor currently in Phase I. Meanwhile, no cytotoxicity was observed in primary hepatocytes or PBMCs. Further studies indicated KC1101 triggered robust cell-cycle arrest at G2/M phase and markedly increased multipolar spindle formation, consistent with on-target disruption of TACC3-dependent spindle regulation. With once-daily oral dosing, KC1101 demonstrated superior antitumor activity in vivo across TNBC (MDA-MB-231, CAL-51) and colon (HCT116) xenograft models. At 20 mpk, KC1101 achieved 94.4% TGI in CAL-51 and 61.1% TGI in HCT-116, outperforming AO-252 (24.7% and 54.2%, respectively). Encouragingly, KC1101 also produced significant tumor suppression in an intracranial TNBC (MDA-MB-231-Luc) and AML (MOLM-13-Luc) model. All the data highlighted high therapeutic potential of KC1101. A wide safety margin in exploratory toxicology, coupled with low interspecies PK variability in mouse, rat, and dog, supports future clinical investigation.

In conclusion, KC1101 delivers best-in-class potential for TACC3-addicted tumors by coupling strong mitotic-catastrophe biology with consistent, QD oral efficacy—including intracranial and hematologic settings—while avoiding primary-cell cytotoxicity. Collectively with the clinical precedent for TACC3 inhibition (AO-252), these data nominate KC1101 for IND in 2026.

#4496 Imofinostat, a histone deacetylase inhibitor, enhances anti-tumoral activity on colorectal cancer with an immune checkpoint inhibitor.

Chung-Yen Li[1], Chin-Wen Wei[1], Ka-Po Tse[1], Shih-Han Huang[1], Tzu-Hsien Yang[1], Meng-Chieh Lin[2], Chien-Ting Lin[3], Sue-Ming Chang[1], Mark Shiuh-Sheng Horng[1], John Tsu-An Hsu[1], Kien Thiam Tan[1]

[1]AnBogen Therapeutics, Inc., Taipei, Taiwan,[2]Yang Ming Regenerative Therapeutics Co., Taipei, Taiwan,[3]National Taiwan University Cancer Center, Taipei, Taiwan

Background: Histone deacetylase (HDAC) inhibitors have been shown to exert immunomodulatory effects and enhance immune responses elicited by immune checkpoint inhibitors (ICIs). Imofinostat (ABT-301) is an HDAC inhibitor with potent activity against class I HDACs and moderate activity against class IIb HDACs. In this study, we investigated the therapeutic efficacy and underlying immunomodulatory mechanisms of imofinostat combined with ICI-based regimens in colorectal cancer (CRC).

Methods: Imofinostat was evaluated in combination with ICIs (anti-mPD-1 or anti-PD-L1) in both murine syngeneic (CT26) and human microsatellite stable (MSS) CRC cell line-derived xenograft (CDX) models (HT29) with or without antiangiogenic agent aflibercept. Transcriptomic profiling was performed using the NanoString IO360 panel, while immune cell alterations and functional markers were analyzed by flow cytometry and immunohistochemistry (IHC).

Results: In the CT26 syngeneic mouse model, the combination of imofinostat with avelumab (anti-PD-L1) induced complete tumor regression in 7 of 8 animals. Notably, of those achieving complete remission, 6 of 7 remained tumor-free following tumor re-challenge, indicating the establishment of durable anti-tumor immunity. This combination demonstrated superior efficacy compared to the pan-HDAC inhibitor vorinostat and the class I-selective HDAC inhibitor tucidinostat in parallel CT26 models. In the HT29 CRC model co-engrafted with patient-derived PBMCs, an additive anti-tumor effect was observed with the combination of imofinostat and nivolumab (anti-PD-1), which was further enhanced by the addition of aflibercept. Gene Set Enrichment Analysis (GSEA) revealed that imofinostat, alone and in combination, significantly enriched gene signatures associated with central memory T-cells. The combination treatment also increased infiltrated cytotoxic $CD4^+$ and $CD8^+$ T cells ($IFN\text{-}\gamma^+$ or $GzmB^+$) and reduced monocytic-myeloid-derived suppressor cells (M-MDSCs) in PBMCs.

Conclusion: Imofinostat synergizes with ICI by targeting mechanisms of immune suppression, including the reduction of M-MDSCs in PBMCs, while concurrently promoting the development of robust cytotoxic and memory T-cell responses. This provides a strong rationale for the clinical investigation of imofinostat in combination with ICIs for CRC.

#4497 Imofinostat enhances chemotherapy response by targeting HDAC3-NRF2 pathway in KRAS-mutant pancreatic cancer.

Yi-Chen Lin, Ka-Po Tse, Chung-Yen Li, Tzu-Hsien Yang, Shih-Han Huang, Sue-Ming Chang, Mark Shiuh-Sheng Horng, John Tsu-An Hsu, Kien Thiam Tan

Anbogen Therapeutics, Inc., Taipei, Taiwan

Background: Aberrant HDAC3 activation in solid tumors contributes to therapeutic resistance and poor prognosis. Inhibition of HDAC3 has therefore emerged as a potential strategy to overcome resistance to chemo-, radio-, and immunotherapies. Imofinostat (also known as ABT-301), a hydroxamic acid-based HDAC inhibitor, exhibits potent HDAC class I selectivity with preferential inhibition of HDAC3 (IC_{50} = 7 nM). This study evaluated the antitumor efficacy of imofinostat, alone or in combination with standard therapies, in cancers exhibiting high HDAC3 dependency.

Methods: HDAC3 dependency was assessed across cancer types using the DepMap database. The *in vitro* anti-proliferation effects of imofinostat, alone or in combination with gemcitabine, were measured via standard cell viability assays across multiple cancer cell lines. RNA sequencing and Western blot analyses were conducted to examine transcriptomic and protein expression changes following imofinostat treatment. *In vivo* efficacy of imofinostat, alone or in combination with chemotherapies, was evaluated in KRAS-mutant pancreatic ductal adenocarcinoma (PDAC) xenograft models.

Results: DepMap analysis revealed PDAC, bladder cancer, brain tumors, and leukemia as malignancies with pronounced HDAC3 dependency. *In vitro*, imofinostat inhibited cell proliferation in PDAC cell lines (GI_{50} 0.3 - 4.8 μM) and bladder cancer cell lines (GI_{50} 0.2 - 0.5 μM), demonstrating synergistic effects with gemcitabine and pemetrexed, respectively. Mechanistically, transcriptomic profiling in PDAC revealed imofinostat downregulated antioxidant genes (*NQO1*, *GPX4*, *GSS*, *COQ2*) and upregulated ferroptosis-associated genes (*STEAP3*, *FTL*, *SLC39A14*, *CP*). Consistently, Western blot analysis of KRAS-mutant PDAC xenografts confirmed target engagement (increased histone H3 acetylation) and reduced expression of NRF2 and its targets (NQO1, SLC7A11). Together, these findings indicate that imofinostat suppresses NRF2-driven antioxidant programs, enhances ferroptotic susceptibility and exposes metabolic vulnerabilities linked to oncogenic KRAS. *In vivo,* imofinostat alone or in combination with gemcitabine significantly inhibited tumor growth in NRF2-high, KRAS-mutant xenograft models.

Conclusion: Imofinostat exerts potent anti-tumor activity via HDAC3 inhibition, exploiting the HDAC3-NRF2 vulnerability in KRAS-mutant PDAC models. Its combination with gemcitabine further enhanced efficacy, supporting the clinical potential of imofinostat with DNA-damaging or metabolic agents in NRF2-activated cancers.

#4498 Discovery of novel SMARCA2 small molecule inhibitors with best-in-class potency and selectivity for the treatment of SMARCA4-mutant cancers.

Lijs Beke[1], Sandrine Grosse[1], Shaun Martin[2], Godelieve Lammens[1], Pieter Peeters[1], Bart Stoops[1], Sandrine Vendeville[1], Stephane De Cesco[1], Kenneth Goossens[2], Sara Musch[2], David Moreno Delgado[2], Line Oste[2], Pierre Raboisson[1], Francois Gonzalvez[1]

[1]Onco3R Therapeutics, Leuven, Belgium,[2]Former Galapagos employee, Mechelen, Belgium

Patients with homozygous loss-of-function (LOF) mutations in SMARCA4 constitute a molecularly distinct subgroup of non-small-cell lung cancer (NSCLC), encompassing approximately 5% of all patients. This subset is defined by its mutual exclusivity with other oncogenic drivers and demonstrates resistance to standard treatments, including radiotherapy, chemotherapy, and PD-L1 inhibitors. Notably, SMARCA4 LOF can co-occur with KRAS-G12C mutations, leading to resistance against KRAS-targeted therapies.

Mechanistically, the loss of SMARCA4 function creates a synthetic lethal dependency on SMARCA2, a vulnerability that has been validated through both genetic and pharmacological approaches. However, the development of selective SMARCA2 inhibitors remains challenging due to the high sequence homology between SMARCA2 and SMARCA4—yet achieving selectivity is critical for clinical success. Previous clinical trials with a dual SMARCA4/2 inhibitor were discontinued due to safety concerns, highlighting the urgent need for potent and selective SMARCA2 inhibitors. Addressing this therapeutic gap could unlock the full potential of targeting SMARCA2 in SMARCA4-deficient cancers.

At Onco3R Therapeutics, our patient-centric strategy—combining deep translational science with rational, structure-based and AI-augmented drug design—has led to the discovery of a novel series of SMARCA2-selective small molecule inhibitors with a best-in-class potency and selectivity profile. Lead compounds exhibited single digit to sub-nanomolar activity and over 30-fold selectivity for SMARCA2 versus SMARCA4, as demonstrated in a KRT80 qRT-PCR assay using SMARCA2/4 isogenic knockout cell lines.

Notably, these lead compounds combined potent anti-proliferative effects in SMARCA4-deficient cells with favourable in vitro ADME characteristics, a supportive safety profile and pharmacokinetic properties suitable for in vivo evaluation. Following oral administration, the compounds achieved sustained target engagement and elicited pronounced anti-tumor activity in a SMARCA4-deficient RERF-LC-A1 CDX mouse model without evidence of SMARCA4-related body weight loss.

These unique SMARCA2-selective lead compounds are currently further profiled as potential clinical candidate with the ultimate goal of delivering transformative efficacy and enhanced safety for patients with SMARCA4-deficient cancers.

#4499 KAT6i prifetrastat combines with PI3K pathway inhibitors to drive superior efficacy in preclinical models of PIK3CA mutated ER+ BC.

Kamakoti Prakash Bhat, Joan Q. Cao, Christopher Beldon Proffitt, Jelena Petrovic, Xinmeng Jasmine Mu, Kyle Spinler, Colin Ashton Flaveny, Thomas A. Paul, Joal Garrido Mayor, Heather Neumann, Shikhar Sharma

Tumor Biology, Pfizer, Inc. Medical Oncology, San Diego, CA

KAT6A, and its paralog KAT6B, are histone lysine acetyltransferases (HATs) that acetylate histone H3K23 and regulate lineage-specific transcriptional programs. KAT6A/B activity is dysregulated in cancer, resulting in an oncogenic function for KAT6A/B in several tumor types, including in breast cancer. Prifetrastat is a first in class catalytic inhibitor of KAT6A and KAT6B with selectivity over other HAT enzymes. KAT6A/B inhibition results in downregulation of key pathways including estrogen signaling, cell cycle and MYC, resulting in anti-tumor activity in ER+ breast cancer. Here, we evaluate the activity of prifetrastat across a panel of breast cancer cell lines comprising different subtypes. Prifetrastat response was enriched in ER+, luminal subset of breast cancer cell lines with activity observed in both PIK3CA mutant and WT cells. Transcriptomic and chromatin accessibility analyses demonstrate that KAT6i treatment inhibits similar pathways in both PIK3CA WT and mutant cell lines. In vivo PDX studies also confirm the efficacy of prifetrastat in PIK3CA mutated models. Given the potential interplay between the mechanisms of action of KAT6i and PI3Kα inhibition in ER+ BC, we explored the potential of combining prifetrastat with PI3Kα inhibitors. In vitro drug combination studies demonstrate synergy between prifetrastat and several PI3Kα inhibitors including alpelisib and inavolisib as well as mutant selective PI3Kα inhibitors such as tersolisib across cell lines harboring PIK3CA helical or kinase domain mutations. Mechanistically, the combination of prifetrastat with PI3Kα inhibitors leads to further suppression of ER pathway genes and cell cycle pathways as compared to monotherapy activity. Finally, the triple combination of prifetrastat + Fulvesterant with PI3Kα inhibitors drives deeper tumor growth inhibition in PIK3CA mutant ER+ PDX models in vivo. Overall, we find that KAT6A/B inhibitors can effectively be combined with PI3Kα inhibitors and endocrine therapy to further drive efficacy in PIK3CA-mutant ER+BC indicating that the triplet combination could present a promising therapeutic option for this population.

#4500 Embryonic ectoderm development (EED) inhibitor APG-5918 synergizes with topoisomerase I inhibitors in preclinical small-cell lung cancer (SCLC) models through epigenetic priming of chemosensitivity.

Yan Yin[1], Zhiyan Liang[2], Baisong Li[1], Zhou Yu[1], Daojie Liu[1], Dajun Yang[1], Yifan Zhai[2]

[1]Ascentage Pharma (Suzhou) Co., Ltd., Suzhou, China,[2]Ascentage Pharma Group Inc., Rockville, MD

SCLC initially responds to platinum-based chemotherapy but rapidly acquires resistance, resulting in poor prognosis. PRC2-mediated epigenetic silencing represses Schlafen 11 (SLFN11)—a biomarker of sensitivity to DNA-damaging therapies—contributing to resistance. EZH2, the PRC2 catalytic subunit, promotes chemoresistance via SLFN11 repression. EED, another core PRC2 subunit, stabilizes the complex and maintains its methyltransferase activity, making it an attractive target. Topoisomerase I inhibitors, such as topotecan and irinotecan, are used in relapsed SCLC, but efficacy is limited when SLFN11 is epigenetically suppressed. APG-5918, a selective and investigational EED inhibitor, disrupts PRC2 function. This study evaluated antitumor activity of APG-5918 combined with topoisomerase I inhibitors in preclinical SCLC models.

In vitro antiproliferation was assessed using human SCLC cell lines (NCI-H446, NCI-H69, NCI-H889, DMS-114); cell viability via CellTiter-Glo® luminescent assays; apoptosis with Annexin V/PI flow cytometry; molecular mechanisms via western blot; and in vivo antitumor efficacy using a subcutaneous NCI-H446 cell-derived xenograft (CDX) model.

APG-5918 synergized with topoisomerase I inhibitors (topotecan or SN-38, the active metabolite of irinotecan) to suppress proliferation and induce apoptosis in SCLC cell lines. In NCI-H446 CDX, single-agent APG-5918 (100 mg/kg) or irinotecan (5 mg/kg) at 27 days showed limited efficacy (T/C: 115.79% and 61.58%, respectively). The combination significantly enhanced antitumor activity, achieving a T/C value of 38.92% ($p < 0.05$ vs. vehicle) and a synergistic index of 1.83. No significant body-weight changes indicated favorable safety. Mechanistically, APG-5918 reduced H3K27me3 confirming on-target epigenetic modulation, and upregulated SLFN11 and p21 (CDKN1A). This EED inhibition reverses epigenetic silencing of chemosensitivity genes and sensitizes tumor cells to topoisomerase I inhibitors. Notably, topotecan or SN-38 alone increased H3K27me3, indicating that compensatory epigenetic repression was countered by APG-5918. The combination further downregulated PRC2 components (EED, EZH1, EZH2, SUZ12), suppressed cell-cycle regulators (pRb, CDK4, CDK6), and induced DNA damage (γH2A.X) and apoptotic markers (cleaved PARP-1, cleaved caspase-3, BIM, Noxa), supporting a synergistic proapoptotic mechanism.

APG-5918 synergistically enhances antitumor activity of topoisomerase I inhibitors in preclinical SCLC models by reversing PRC2-mediated epigenetic silencing of SLFN11 and amplifying DNA damage, cell-cycle arrest, and apoptosis. These findings support clinical investigation of APG-5918 combined with DNA-damaging agents as a promising strategy for SCLC.

#4501 Targeting the epigenetic adaptor protein menin in multiple myeloma.

Emily Gruber[1], Sree Kumar[1], Rheana Franich[1], Tiffany Khong[2], Daniel Neville[1], Andrew Spencer[2], Omer Gilan[2], Lev Kats[1]

[1]Peter MacCallum Cancer Centre, Melbourne, Australia,[2]Australian Centre for Blood Diseases, Monash University, Melbourne, Australia

The interaction between the epigenetic proteins Menin and MLL1 is critical for sustaining the expression of self-renewal genes in specific subsets of acute leukemias. Disrupting the Menin-MLL1 interaction with Menin inhibitors (iMenin) is showing promising overall response rates in leukemia clinical trials, however, iMenin are not known to be active in other cancers. We analysed DepMap and discovered that many multiple myeloma (MM) cell lines are highly dependent on Menin/MLL1 for proliferation. MM is a common plasma cell malignancy that remains largely incurable, despite the plethora of treatments available. The objectives of our study are to understand the role of the Menin/MLL1 complex in MM, determine the efficacy of iMenin in MM pre-clinical models and identify biomarkers of response to enable the rapid and successful translation of iMenin into the myeloma setting.

To assess the efficacy of iMenin in MM, we performed growth assays across 13 commercially available cell lines and 9 early passage patient-derived MM cells (physiologically relevant model). We found that ~30% were highly sensitive to iMenin with a substantial impact on viability and proliferation, with an additional ~40% showing a significant anti-proliferative response. Sensitivity was significantly correlated with the absence of the MYC t(8;14) translocation. Importantly, iMenin showed *in vivo* efficacy in a xenograft and in the syngeneic Vk*MYC-32052 model of MM.

RNA-, ChIP- and chromatin conformation sequencing found that iMenin sensitivity was characterized by the deposition of Menin/MLL1 at the super-enhancer of IRF4, with iMenin evicting Menin/MLL1 from chromatin and suppressing IRF4 and its target genes. Genome-wide CRISPR screening was performed to identify the molecular determinants of iMenin response in MM. This identified the EP300/CREBBP/NCOR1 axis as a key modulator of iMenin sensitivity. To further advance the translational potential of iMenin, we tested several combination strategies. Among the most effective was the combination of Menin and EP300/CREBBP inhibitors, which demonstrated synergistic activity even in models which were unresponsive to the single-agents, including JJN3 cells *in vitro* and the syngeneic *in vivo* Vk*MYC-14551 model. Molecular analyses uncovered deep suppression of IRF4, via disruption of the canonical IRF4 super-enhancer, as the mechanism underpinning the synergy between Menin and EP300/CREBBP inhibitors.

Taken together, Menin regulates the pan-myeloma essential transcription factor IRF4 and is a promising and clinically actionable target in MM.

#4502 Expanding the PRISM platform: Addition of new hematologic models and a 10-day assay improve drug sensitivity mapping for epigenetic targets.

Colleen T. Harrington, Antonella Masciotti, Ursula Widocki, Laura Doherty, Tenzin Sangpo, Li Wang, Mustafa Kocak, Anthony Fazio, Aydin Golabi, Rachael Barry, Emily Reeves, John Davis, Melissa Ronan, Matthew G. Rees, Jennifer A. Roth

Cancer Program, Broad Institute, Cambridge, MA

Despite major advances in targeted therapies, cancer remains a leading cause of death among pediatric, adolescent, and adult populations, emphasizing the need for continued therapeutic innovation. The PRISM assay enables large-scale evaluation of oncology agents by barcoding and pooling over 900 cancer cell lines with extensive genomic and functional characterization. This platform enables systematic analysis of drug potency, selectivity, and rapid identification of genomic correlates of sensitivity. To broaden the coverage of pediatric, hematologic, and rare tumor types in the PRISM assay and enhance our ability to investigate novel therapeutics for these disease areas, we expanded the PRISM cell line panel in collaboration with the Pediatric Cancer Dependencies Accelerator to include 109 additional lines, including 21 pediatric, 60 hematopoietic, and 14 previously unrepresented subtypes. We re-profiled compounds with predicted activity in new cell models and found that many compounds targeting heme-centric proteins such as BCL6, FLT3, IKZF3, EP300, EZH2, EED had stronger correlations with target dependency. Targeting of epigenetic drivers is an attractive therapeutic strategy for hematopoietic tumors, so we sought to compare clinically relevant epigenetic targeting compounds in PRISM. For example, mevrometostat more selectively targets EZH2-dependent cell lines compared to other EZH2 inhibitors profiled after 5 days of treatment. However, the observed potency of many epigenetic targeting compounds is somewhat limited in a 5-day assay, as the mechanistic nature of these compounds often requires a longer incubation period to enact their cytotoxic effects. We developed a 10-day PRISM assay for our hematopoietic cell collection and re-screened mevrometostat as part of an assay validation screen. We observed greater potency, selectivity, and stronger correlations with EZH2 dependency for mevrometostat in the 10-day assay compared to the 5-day assay. Future assay development will enable higher throughput screening of slow-acting compounds against our hematopoietic cell lines. Taken all together, these advances position PRISM to accelerate hematologic and pediatric cancer research by expanding disease-relevant models and enabling long-duration single-agent screening at scale. All data will be made publicly available on depmap.org, providing a resource for the cancer research community to explore novel therapeutic opportunities.

#4503 RCZY-843: A potential best-in-class, second-generation menin-MLL inhibitor engineered to overcome clinically observed menin-mutation-mediated resistance, with superior preclinical efficacy and safety in acute leukemia models.

Xiaojing (Celia) Chen[1], Zhengyong Wan[1], Xiaohong Liu[1], Qiaoni You[1], Shenjun Li[2], Ling Wang[2], Shanshan Bi[2], Jing Jiang[2], Jianming Bao[1]

[1]Rongchang Pharmaceuticals, Ltd., Yantai, China,[2]RemeGen Co., Ltd., Yantai, China

Menin, encoded by the MEN1 gene, is a ubiquitously expressed scaffold protein that regulates gene transcriptions and key signaling pathways. The menin-MLL1 (KMT2A) complex drives aberrant HOX/MEIS1 expression, promoting leukemogenesis in KMT2A-rearranged or NPM1-mutant acute leukemias. Disrupting this interaction is a validated therapeutic strategy, as evidenced by FDA approvals of Syndax's revumenib (initially for R/R KMT2A-rearranged acute leukemia in November 2024, expanded to R/R NPM1-mutant AML in October 2025) and Kura's ziftomenib (for R/R NPM1-mutant AML in November 2025). However, first-generation menin inhibitors rapidly develop clinical acquired resistance driven by MEN1 somatic mutations—especially loss-of-function alterations eliminating menin dependency—urgently requiring next-generation, mutation-resilient menin inhibitors. Herein, we report RCZY-843, a novel, highly potent, orally bioavailable second-generation menin-MLL inhibitor with superior preclinical efficacy against acute leukemias. Surface plasmon resonance assays show its picomolar binding affinity to wild-type menin—4-fold and 5-fold stronger than SNDX-5613 and KO-539, respectively. Fluorescence polarization assays further confirm its potent disruption of the menin-MLL interaction in the presence of clinically observed resistance mutations (M327I/V, G331R, T349M) with substantially lower IC_{50} values than approved or clinical-stage menin inhibitors (SNDX-5613, KO-539, JNJ-75276617). RCZY-843 exerts potent growth inhibition in KMT2A-rearranged/NPM1-mutant cell lines, with >476-fold selectivity over wild-type MLL HL-60 cells and demonstrates favorable drug-like properties, including robust in vitro ADME characteristics, a clean safety profile (hERG IC_{50} >30 μM), and excellent pharmacokinetics across preclinical species. Notably, it exhibits a longer half-life ($T_{1/2}$) and ~3-fold higher oral bioavailability than SNDX-5613 in rat. In AML xenograft models (MV-4-11, OCI-AML-3), orally administered RCZY-843 achieves tumor growth inhibition comparable to SNDX-5613 at only one-third to one-tenth of the dose, accompanied by higher plasma exposure and preferential tumor distribution. Compared to SNDX-5613, RCZY-843 further demonstrates favorable PK/PD characteristics—including stronger and more durable MEIS1 mRNA suppression—along with good in vivo tolerability, and a wide therapeutic window, as supported by a 14-day rat DRF toxicity study. In conclusion, RCZY-843 is a potential best-in-class, second-generation menin-MLL inhibitor capable of overcoming MEN1 mutation-mediated acquired resistance, with robust preclinical efficacy and a favorable safety profile for the treatment of KMT2A-rearranged/NPM1-mutant acute leukemias.

#4504 Synergistic antitumor activity of the MTA-cooperative PRMT5 inhibitor ABSK131 in combination with multiple therapeutic agents in diverse cancer models.

Bin Shen, Qianqian Chen, Xiao Chen, Jie Wang, Jie Zhang, Manqi Liu, Hongping Yu, **Nannan Zhang**

Abbisko Therapeutics Co., Ltd., Shanghai, China

Background: Homozygous deletion of *MTAP* occurs in ~10-15% of solid tumors and frequently coexists with major oncogenic drivers such as *EGFR* and *KRAS*, providing a strong rationale for combining their inhibitors with MTA-cooperative PRMT5 inhibitor. Moreover, low *MTAP* expression is linked to poorer survival in NSCLC treated with chemoimmunotherapy, underscoring the need for novel, effective therapeutic strategies in *MTAP*-deleted tumors. ABSK131, a highly potent and selective MTA-cooperative PRMT5 inhibitor discovered by Abbisko, is under clinical evaluation. Here, we investigated the potential of ABSK131 combined with multiple therapeutic agents to enhance antitumor efficacy across diverse cancer models preclinically.

Methods: Synergistic activity of ABSK131 with various agents was evaluated using *in vitro* antiproliferative assays across various cancer cell lines, primarily from NSCLC and PDAC origins. Combination partners included chemotherapy agents and the inhibitors targeting KRAS, EGFR, MAT2A, etc. Synergy was quantified by combination index analysis. Prioritized combinations were further tested in xenograft models reflecting clinically relevant biomarker-defined contexts, including in combination with KRAS, EGFR inhibitors, and standard chemotherapy.

Results: ABSK131 demonstrated strong *in vitro* synergy with multiple KRAS inhibitors in anti-proliferation assays. In *KRAS*-mutant and *MTAP*-deleted models, ABSK131 led to robust tumor growth inhibition when combined with KRAS G12C inhibitor AMG510 or KRAS G12D inhibitor ABSK141. In *EGFR*-mutant and *MTAP*-deleted NSCLC, ABSK131 combined with osimertinib produced enhanced anti-proliferative and *in vivo* antitumor efficacy. ABSK131 plus MAT2A inhibitor IDE397 induced consistent synergy across diverse cell types, indicating a broadly applicable mechanistic interaction. Additionally, synergy was observed with carboplatin in multiple NSCLC models *in vitro* and *in vivo*.

Conclusion: ABSK131 synergizes with multiple therapeutic classes across *MTAP*-deleted models, providing compelling preclinical support for developing ABSK131-based combination strategies in genetically defined patient populations in clinic.

#4505 IDE892 is a highly potent and selective PRMT5 inhibitor, with MTA-positive and SAM-negative cooperativity, optimized for development in MTAPdel cancers in combination with the allosteric MAT2A inhibitor IDE397.

Arjun A. Rao, Marcus M. Fischer, Rebeca M. Choy, Angelica M. Gonzalez-Sanchez, Natalie Bresnahan, Zhipeng Fang, Mason J. Appel, Atul Rathore, Oscar Aubi, Shannon Faris, Parker Y. Jameson, Zabrisky Roland, David Trinh, Kelly Trego, John Vivian, Michael E. Dalziel, Christian R. Frey, Yuchen Bai, Jasgit Sachdev, Claire L. Neilan, Jay Prakash Jain, Michael A. White, Paul A. Barsanti, Peter Teriete, Melissa Fleury

Computational Biology, Ideaya Biosciences, South San Francisco, CA

Homozygous deletion of MTAP frequently co-occurs with the adjacent CDKN2A tumor suppressor on chromosome 9p21.3 in human cancers. Loss of MTAP activity creates an acute dependency on MAT2A, the rate-limiting enzyme for SAM synthesis, to produce sufficient SAM to overcome MTA suppression of PRMT5 and to support the folate cycle via 1-carbon metabolism. Proof-of-concept therapeutic targeting of this vulnerability has been achieved by allosteric inhibition of MAT2A or by MTA-cooperative inhibition of PRMT5. However, variability of response highlights the opportunity to continue to improve outcomes with combination therapy strategies. Preclinical profiling has indicated the extent of MTA accumulation in tumor cells and intrinsic or acquired resistance mechanisms are key determinants of antitumor activity. Notably, co-administration of appropriately designed MAT2A and PRMT5 inhibitors can deliver durable tumor regressions and complete responses in multiple MTAPdel PDX models recalcitrant to either monotherapy. Here we describe the biochemical, cell biological, and in vivo efficacy profiles of IDE892, an MTA-cooperative PRMT5 inhibitor purposely designed to exploit the therapeutic opportunity associated with combined inhibition of PRMT5 and MAT2A. Extensive biophysical and biochemical characterization of the IDE397 mode-of-inhibition of MAT2A yielded a mechanistic model that accounts for MTAPdel tumor-specific activity of IDE397 due to allostery-dependent preservation of basal MAT2A activity, maintaining SAM levels above the threshold required to sustain function in normal tissues. In addition, extensive evaluation of the kinetic and equilibrium binding parameters of metabolite and inhibitor exchange on PRMT5 revealed key relationships that specify MTA-cooperativity as well as slow on-rate binding kinetics to the SAM-bound state (negative cooperativity) relative to the apo state. These findings informed the design of IDE892 that optimized efficacy and tolerability in combination with allosteric inhibition of MAT2A. IDE892 demonstrated at least 1,400-fold selective binding to MTA-PRMT5 versus SAM-PRMT5 complexes (by SPR) and robust MTAPdel-specific PRMT5 pathway inhibition in vitro and in vivo. Whole transcriptome, proteome, and mRNA/tRNA methylome analyses indicated both shared and distinct contributions of IDE397 and IDE892 to perturbation of MTAPdel cellular systems which translated to robust combination benefit in MTAPdel CDX and PDX models. These preclinical studies indicate that the combination of IDE892/IDE397 has the potential to deliver durable therapeutic activity for patients harboring MTAPdel tumors; an opportunity that is currently under evaluation in phase 1 clinical trials.

#4506 H11 is a first-in-class bifunctional HDAC and autophagy inhibitor with potent antileukemic activity.

Natalie L. Hakim[1], Claudia M. Espitia[1], Sruthi Sureshkumar[1], Madison Gamble[1], Bi Fangchao[2], Wei Wang[2], Kevin Kelly[3], Jennifer S. Carew[1], Steffan T. Nawrocki[1]

[1]Cancer Center, University of Arizona, Tucson, AZ,[2]Pharmacology Toxicology, University of Arizona, Tucson, AZ,[3]Hematology, University of Southern California, Los Angeles, CA

Acute myeloid leukemia (AML) is a highly aggressive hematologic malignancy characterized by the accumulation of immature myeloid blasts that disrupt hematopoiesis. Although initial remissions can be achieved with standard chemotherapy, relapse is frequent and durable responses remain uncommon. This underscores the need for new therapeutic strategies that can overcome established resistance mechanisms. Disruption of epigenetic homeostasis is a common feature of AML pathogenesis and offers an opportunity for targeted therapy. Histone deacetylase (HDAC) inhibitors are one class of agents that induce epigenetic reprogramming and have previously demonstrated antileukemic activity. However, their efficacy is blunted by the activation of cytoprotective autophagy. Simultaneous blockade of HDAC activity and autophagic flux therefore represents a rational approach to enhance therapeutic benefit. To address this, we developed H11, a first-in-class bifunctional small molecule engineered to concurrently inhibit HDACs and suppress autophagy. H11 potently reduced viability and triggered apoptosis across genetically diverse AML models and primary AML specimens from patients including those with adverse features such as *FLT3-ITD* and loss of p53 function. H11 retained potent activity in models resistant to frontline therapies, indicating its potential to overcome both epigenetic and lysosomal-mediated resistance mechanisms. Importantly, H11 demonstrated strong therapeutic selectivity with very limited effects against normal CD34+ bone marrow progenitors. Mechanistic studies demonstrated robust HDAC inhibition, evidenced by increased global histone acetylation, coupled with impaired autophagic degradation, reflected by p62 accumulation, lysosomal deacidification, and blocked autophagic flux. H11 treatment also decreased the expression of the oncogenic transcription factor c-Myc and increased CDKN1A (p21), consistent with epigenetic reprogramming and disruption of AML survival circuitry. Because epigenetic dysregulation is a hallmark of AML, we next evaluated H11 in combination with the FDA-approved hypomethylating agent azacitidine (AZA). The H11-AZA combination produced strong synergy, markedly enhancing cytotoxicity across multiple AML cell lines and significantly extending overall survival in an orthotopic FLT3-ITD+ mouse xenograft model of AML. Together, these findings establish H11 as a first-in-class dual HDAC-autophagy inhibitor that integrates epigenetic modulation with autophagy suppression to promote apoptosis and disrupt adaptive AML survival pathways. This coordinated mechanism of action highlights H11 as a promising next-generation therapeutic with strong potential to improve clinical outcomes in patients with AML.

#4510 Comprehensive surfaceome proteomics uncovers CD70 as a novel immunotherapeutic target in natural killer/T cell lymphoma (NKTL).

Ern Sen Chew[1], Nurulhuda Mustafa[2], Wai Khang Yong[1], Vartika Khanchandani[1], Rui Xue Lee[1], Anand Jeyasekharan[1], Dennis Kappei[1], Siok Bian Ng[3], Wee Joo Chng[1]

[1]Cancer Science Institute of Singapore, National University of Singapore, Singapore, Singapore,[2]Pharmacology, National University of Singapore, Singapore, Singapore,[3]Department of Pathology, Yong Loo Lin School of Medicine, National University of Singapore, Singapore, Singapore

Natural killer/ T cell lymphoma (NKTL), a subtype of non-Hodgkin lymphoma, is an Epstein-Barr virus (EBV) associated lympho-proliferative disease prevalent in Asia and South America. Current treatments options are inadequate with treatments such as conventional radiotherapy or chemotherapy having limited efficacy. Moreover, efficacy of newer therapies such as targeted therapies or immunotherapies has been less than ideal in clinical trials likely due to heterogeneous nature of disease. Novel treatments which are more efficacious, such as immunotherapy with higher specificity and less cytotoxicity, will have to be formulated. Hence, this project aims to identify new targets and develop novel antibody-based therapies against NKTL. First step in antibody-based therapy development involves identification of suitable targets. Here, we combined aminooxy-biotin labeling followed by streptavidin enrichment with label-free quantitative mass spectrometry analysis to systematically profile the plasma membrane landscape of NKTL. Considering a lack of proper pipeline for plasma membrane annotation, we designed a unique membrane annotation pipeline based off publicly available databases, including UniProt, Gene Ontology and in silico surfaceome database, SURFY. Strategy for prioritization of targets with highest immunotherapeutic potential was employed by looking at target specificity and accessibility. Plasma membrane profiling via this method of analysis was successful with GO terms enrichment of the significant proteins in different cell lines pre-membrane protein annotation revealing molecular functions and biological processes associated with surface membrane proteins such as signalling receptor activity and adhesion. Our method of immunotherapeutic potential analysis revealed CD70, ITGA4 and CD48 as top targets with CD70 having highest potential. CD70 is a tightly regulated immune co-stimulatory ligand which is aberrantly expressed in different malignancies. Expression of CD70 was validated on multiple NKTL cell lines while PBMCs and primary NK cells from healthy donors were CD70 negative. Substantial internalization of CD70 was validated via FACS, immunofluorescence and Fab-ZAP assays, revealing potential as an antibody-drug conjugate (ADC) target for NKTL. Cusatuzumab, anti-CD70 monoclonal antibody currently in clinical trials for other malignancies, elicited strong antibody effector functions such as complement dependent cytotoxicity (CDC) and antibody dependent cellular cytotoxicity (ADCC) in NKTL. Lastly, in-house generated ADC through conjugation of Cusatuzumab with MMAE via VC-PAB linker showed efficacious response in NKTL. As such, our work characterized plasma membrane landscape of NKTL and shed light on targets with potential to become novel treatments for this dreadful disease.

#4511 Dual targeting of IKKβ and NR4A1 for AML therapy.

Chandra Kumar Maharjan[1], Yi Liu[1], Yufeng Xiao[1], Bristy Podder[1], Tyler Montgomery[1], Lei Wang[2], Myung-Chul Kim[3], Zeng Jin[4], Seyedehalaleh Anvar[1], Alexandra Stevens[5], Ryan Kolb[1], Chen Zhao[6], Zhijian Qian[7], Jatinder K. Lamba[1], Guangrong Zheng[1], Weizhou Zhang[1]

[1]University of Florida, Gainesville, FL,[2]Genentech, South San Francisco, CA,[3]Kyungpook National University, Gainesville, Korea, Republic of,[4]University of Florida College of Medicine, Gainesville, FL,[5]Texas Children's Hospital, Houston, TX,[6]Case Western Reserve University, Cleveland, OH,[7]City of Hope Comprehensive Cancer Center, Monrovia, CA

Acute myeloid leukemia (AML) is a common aggressive blood cancer with a lethality rate among the highest of all leukemia subtypes. Cure rates of available therapeutic options are very low, underscoring an urgent need to develop more effective drugs. Here we identify IKKβ and NR4A1 as two closely related, clinically meaningful drivers of AML progression, and develop a proteolysis targeting chimera (PROTAC) drug that degrades both the proteins. IKKβ and the downstream NF-κB signaling are aberrantly activated in around 40% AML patients. However, IKKβ inhibitors exhibit serious side effects such as neutrophilia, limiting their therapeutic development. As opposed to the previously reported AML-suppressive role, we found that NR4A1 can also promote AML pathogenesis in different contexts. Moreover, IKKβ and NR4A1 were found to be highly expressed in AMLs associated with poor clinical outcomes, positively regulate each other's expression, and synergize to maintain AML cell viability. We designed, synthesized, and validated an array of celastrol-based PROTACs as celastrol binds to both IKKβ and NR4A1, and identified one lead PROTAC, A9, that effectively kills several AML cell lines and primary human AML cells. Mechanistically, A9-induced AML cell killing was found to be dependent on CRBN E3 ligase-mediated dual degradation of IKKβ and NR4A1. *In vivo*, A9 attenuated AML disease progression in a clinically relevant KMT2A::MLLT3 mouse model and didn't induce neutrophilia. Our results reveal a potentially novel strategy to treat intractable and aggressive AMLs in the clinic.

#4512 WASP activation by BM011 triggers mitochondrial collapse and aldolase-dependent glycolytic vulnerability in lymphoma.

Filippo Spriano[1], Luciano Cascione[1], Stephen Croke[2], Digvijay Gahtory[2], Maurits van den Nieuwboer[2], Francesco Bertoni[1]

[1]Institute of Oncology Research, Universita della Svizzera italiana, Bellinzona, Switzerland,[2]BIMINI Biotech B.V., Leiden, Netherlands

Background. BM011 is the first-in-class WASP (Wiskott-Aldrich Syndrome Protein) activator (Spriano et al, 2024). WASP regulates cytoskeletal remodeling, immune synapse formation, vesicle trafficking, and mechano-metabolic coupling. Aberrant actin dynamics and rewiring of the WASP pathway contribute to proliferation, metabolic flexibility, and stress resistance in lymphomas and other cancers. Here, we investigated the mechanism of action of BM011 by combining transcriptomics, proteomics, and a genome-wide CRISPR-Cas9 knockout screen in lymphoma cells treated with the compound.

Methods. JEKO1 mantle cell lymphoma cells were treated with BM011 for 8h and analyzed by RNA-Seq and mass spectrometry (MS). A genome-wide CRISPR-Cas9 knockout screen was conducted following 14-day exposure to BM011.

Results. Proteomics revealed a strong downregulation of mitochondrial import and respiratory chain proteins in BM011-treated cells, while many RNAs coding for the same molecules were upregulated, consistent with an attempt to compensate for mitochondrial stress. Similarly, ribosomal proteins decreased, while ribosomal transcripts increased, suggesting a proteotoxic stress response and a translational offset. Stress-response genes (e.g., HSPA family), cytoskeleton, and apoptotic pathways were strongly induced, indicating proteotoxic pressure, cytoskeleton remodeling, and apoptosis induction following cytoskeletal forcing. At the genetic screen, the loss of many mitochondrial respiratory chain genes sensitized cells to BM011, confirming their importance in mitigating BM011-induced mitochondrial collapse. In contrast, the knockout of FUNDC2 and TIMM23, not part of the mitochondrial respiratory chain, conferred resistance, likely due to the interruption of mitochondrial quality control and decreased apoptosis upon BM011 treatment. The genetic screen also revealed a divergent vulnerability to glycolysis. Knockout of genes coding for enzymes of the upper glycolytic process (HK2, PFKM, PFKL, GPI, PFKFB3) conferred resistance, while knockout of genes coding for proteins in the lower part of glycolysis (PGK1, ENO1, PKM, PFKFB4) increased sensitivity. This pointed to aldolase and the fructose-1,6-bisphosphate node as a critical metabolic point. Aldolase can indeed bind to F-actin and WASP, inhibiting actin polymerization. Additionally, an excess of fructose-1,6-bisphosphate (F16bP) inhibits aldolase binding to F-actin. We proved that F16bP supplementation or aldolase inhibition increased the sensitivity of BM011 in otherwise resistant lymphoma cells.

Conclusion. BM011-driven activation of WASP induces cytoskeletal stress, mitochondrial import failure, and a proteotoxic response, with upper-glycolysis and aldolase acting as a metabolic safety valve. These reveal druggable metabolic-cytoskeletal vulnerabilities in lymphoma.

#4513 Structural surface protein targets for AML.

James Dowell, Daniel Benjamin, Patric Sadecki, Jonathan Schmitz, Anjali Nelliat, Anna Ritter, **Neal C. Goodwin**

Immuto Scientific, Inc., Madison, WI

Background: Nearly all current antibody- or CAR-T-directed therapies in AML (e.g., CD33) target antigens that are also expressed (often at lower levels) on healthy hematopoietic stem/progenitor cells (HSPCs), causing dose-limiting myeloablation or prolonged cytopenias. Driven by this critical need for tumor-specific targets, we developed a deep learning approach that combines structural proteomics with multi-modal biological network integration and high-throughput protein complex structure prediction to predict potential targets based on predicted surface localization, changes in protein-protein interactions (PPIs), degree of conformational change, and estimated potential therapeutic relevance.
Methods: Protein tagging reagents were used to quantify changes in amino acid surface accessibility and solvent accessibility (SASA) via quantitative LC-MS/MS. Using this innovative approach, changes in the global structural surfaceome of NOMO-1 AML cells treated with all-trans retinoic acid (atRA) were compared with those of vehicle-treated cells. Peptides with significant SASA changes (FDR: $q < 0.05$; $\log_2$ fold-change > +/-1) were filtered using a surfaceome localization score, and conformational ensembles generated for this protein list were scored by a custom GNN-based structure encoder fine-tuned on surface proteomics data. Further, to identify PPIs with interface SASA changes, an all-by-all list of protein pairs was first fed to a graph attention-based module integrating multiple data modalities to retain high-confidence interactions, which were subsequently passed to AlphaFold-Multimer for complex structure prediction, and final target PPIs were predicted by a scoring function based on interface SASA.
Results: The global structural analysis identified 20,933 modified peptides from 3,540 proteins, of which 2,627 peptides from 1,089 proteins exhibited significant changes in SASA. These proteins and the corresponding 1089×1089 candidate PPIs were analyzed by our AI/ML pipeline to generate a final ranked list of potential structural targets, with the top candidates demonstrating high predicted affinity and specificity against AML. The data set achieved in the current study has successfully identified new surface targets in response to atRA treatment that are independent of atRA-RARA differentiation.
Conclusion: Our structural proteomics platform significantly broadens the potential druggable space in AML by identifying novel structural surface targets. The data set achieved in the current study has successfully identified new surface targets in response to multiple atRA-induced mechanisms. The top-ranked structural targets from this study are being evaluated as potential antibody-drug conjugates (ADCs)-based therapies for AML.

#4514 Development and validation of a CyTOF assay for measuring phosphoproteins in AML blast cell populations in whole blood from AML patients.

Steven R. Pirie-Shepherd[1], Crystal Tarrago[2], Wenxin Zheng[3], **Sen Zhang**[3], Hamish Wright[2]

[1]Schrodinger, San Diego, CA,[2]Schrodinger, New York City, NY,[3]Schrodinger, Cambridge, MA

CDC7 (Cell Division Cycle 7-related protein kinase), also known as DBF4-dependent kinase (DDK), is a critical serine/threonine cell cycle protein kinase indispensable for maintaining DNA replication fork progression and stability, particularly under conditions of replication stress. CDC7 activates fork protection and restart mechanisms, including the phosphorylation and activation of MCM2 (Minichromosome Maintenance protein 2) at Ser40. Inhibition of CDC7 disrupts the capacity of cancer cells to ameliorate replication stress and repair DNA damage, leading to the accumulation of DNA damage, incomplete DNA replication, apoptosis, and cellular demise. Consequently, CDC7 represents a promising therapeutic target in cancer, especially for hematologic malignancies such as acute myeloid leukemia (AML).

Given that pMCM2 (phosphorylated MCM2) serves as a biomarker of CDC7 inhibition, the development of a CyTOF assay to quantify pMCM2 and gH2AX (a downstream marker of dsDNA damage) in cells holds significant utility in clinical trials evaluating CDC7 inhibitors. Precise measurement of these phosphoproteins in whole blood AML blast cells for example is expected to provide insights into a drug's mechanism of action and its efficacy in AML patients.

We present the development and validation of a cytometry by time-of-flight (CyTOF) assay designed to measure pMCM2 and gH2AX in blast cell populations prevalent in AML patients and comparing a one step fixation process and a two-step fixation process. Initial investigations demonstrated the feasibility of characterizing the phenotype of AML blast cells using cell surface markers such as CD34, HLADR, CD33, and CD123, as well as assessing the cellular state with respect to the presence or absence of pMCM2 and gH2AX, and quantifying changes in Median Channel Value (MCV) in response to proliferation stimulators or inhibitors. We further detail the development and validation of the assay, along with an assessment of the comparability between a one-step PROT-1 fixation process versus two-step SLST (Stable Lyse Stable Store) fixation process. The finalized assay utilizing the SLST fixation process could facilitate the monitoring of treatment response and the identification of potential biomarkers in clinical trials, which could have utility in investigating disruptions to the DNA damage response (DDR) in blood cancers.

(AI was used to refine the text of this abstract)

#4515 Clinically relevant AML modeling with *in vitro* bone marrow niche and *in vivo* PDX approaches.

Talita Stessuk, Hanna Vermeer, Afsaneh Golestani, Jolie Flach, Jessie Wang, Qingzhi Liu, Jinping Liu, Gera Goverse, Marrit Putker, Ludovic Bourre

Crown Bioscience, Inc., San Diego, CA

Introduction Acute Myeloid Leukemia (AML) remains therapeutically challenging due to various genetic alterations, drug resistance, and relapse at the clinical stage. Preclinical evaluation is therefore critical to identify effective novel therapeutic strategies. Optimal ex vivo growth and in vivo engraftment of primary AML cells are challenging, and current preclinical screening of oncology drugs is often compromised by the lack of advanced models that mimic therapeutical response in the native human bone marrow niche (BMN). To address this challenge, we present the integration of our 3D BMN in vitro platform composed of hematopoietic cells cultured on the perivascular site to capture response and resistance patterns with in vivo AML Patient Derived Xenograft (PDX) models, giving translational preclinical insights for therapy development. Methods Three AML PDX models were systemically engrafted in immunodeficient mice and exposed to standard of care (SoC) drug panels containing FLT3 and IDH inhibitors, as well as classical chemotherapy. Endpoint readouts included survival, clinical signs, and peripheral leukemic burden by flow cytometry (blood, bone marrow, spleen). In parallel, human CD45+ cells from the same AML PDX models were integrated in 3D mesenchymal-endothelial networks (BMN platform) and exposed to SoC and targeted drug panels for 10 days. Quantitative assessment of the in vitro drug effects was performed using a proprietary automated high content imaging (HCI) analysis platform. Immunofluorescence (IF) staining, NSG, cytogenetics, and flow cytometry were used for in-depth characterization of AML PDX. Results Engraftment of AML PDX (AM9626, AM9627, and AM9628) cells into mice was validated upon evaluation of leukemia signs, immunophenotypic profiling, and histopathology. Tumor burden growth (% of hCD45+) assessment across AML PDX models harboring FLT3 and IDH1 mutations revealed sensitivity and resistance patterns to targeted inhibitors and SoC agents. HCI analysis showed decreased AML PDX cell counts at the highest doses of FLT3 and IDH1 inhibitors in comparison to the control in the BMN platform, identifying different drug sensitivities across the PDX models upon support and protection provided by human mesenchymal and endothelial cells. Conclusion Here, we present a combination of advanced, patient-relevant preclinical platforms that offer valuable information on how a drug performs under divergent conditions. The in vivo AML PDX system recapitulates disease progression and enables systemic pharmacokinetic and pharmacodynamic assessment. In parallel, the in vitro BMN platform provides a quantitative measurement of treatment response in leukemia cells attached to the perivascular site. These findings underscore the utility of integrating in vitro and in vivo preclinical models to support AML therapeutic development and prioritize compounds for clinical translation.

#4517 Triamterene inhibits NRF2^{Mut} as a molecular glue.

Yahui Li[1], Zachary Ladd[2], Haining Wang[3], Candice Bui-Linh[4], Boopathi Subramaniyan[1], Chorlada Paiboonrungruang[4], Huan Li[1], Yan Ma[1], Kiera Chang[1], Katherine Gao[1], Maiya Ang[1], Francis Spitz[1], Zhaohui Xiong[4], Xiaoxin Luke Chen[1]

[1]Cooper University Health Care, Camden, NJ,[2]Cooper Medical School of Rowan University, Camden, NJ,[3]Insilico Medicine Canada Inc, Montreal, QC, Canada,[4]Coriell Institute for Medical Research, Camden, NJ

Background: NFE2-like bZIP transcription factor 2 (NRF2, encoded by *NFE2L2*) is a master regulator of the oxidative stress response. Under normal conditions, NRF2 is ubiquitinated and degraded via the proteasome following its interaction with Kelch-like ECH-associated protein 1 (KEAP1). Persistent activation of NRF2, commonly caused by gain-of-function *NFE2L2* or loss-of-function *KEAP1* mutations, is frequently observed in human esophageal squamous cell carcinoma (ESCC) and contributes to tumor progression and therapeutic resistance, underscoring the urgent need for effective therapeutic strategies against NRF2-addicted ESCC. Despite its importance, targeting NRF2 pharmacologically has proven challenging, as it is considered an 'undruggable' target due to its function as a transcription factor lacking classical enzymatic pockets or well-defined ligand-binding sites. In a previous high-throughput NRF2 reporter screen, we identified triamterene (TRM), an FDA-approved potassium-sparing diuretic, as a potential NRF2 inhibitor. The effects of TRM on NRF2 expression were validated by Western blot in two NRF2^{Mut} ESCC cell lines (KYSE70 and TE14). This study is aimed at understanding its efficacy *in vivo* and its mechanisms of action.

Methods: *In vivo* efficacy of TRM was evaluated using both a genetically engineered mouse model (GEMM) and a cell line-derived xenograft (CDX) model. Mechanistic studies including biochemical assays (ubiquitination and proximity ligation assay [PLA]) and biophysical analyses (isothermal titration calorimetry [ITC], surface plasmon resonance [SPR], hydrogen-deuterium exchange mass spectrometry [HDX-MS], and molecular docking), were conducted to elucidate the mechanism of action of TRM.

Results: TRM significantly suppressed tumor growth and NRF2 signaling in the NRF2^{W24C} ESCC CDX and the NRF2^{D29H} GEMM model. Mechanistically, TRM shortened the half-life of NRF2^{W24C} by promoting KEAP1-dependent ubiquitination and degradation. PLA confirmed enhanced KEAP1-NRF2^{W24C} interaction both *in vitro* and *in vivo* following TRM treatment. ITC demonstrated high-affinity binding between TRM and human recombinant KEAP1 (Kd = 0.975 μM). SPR analysis revealed that TRM enhanced the interaction between the DLG^{W24C} peptide and the Kelch domain, but not between DLG^{WT} and Kelch. HDX-MS identified two TRM-binding sites on KEAP1, including residues 397-417, consistent with molecular docking predictions implicating Arg^{415} as a critical residue for TRM binding.

Conclusion: TRM selectively inhibits NRF2^{Mut} ESCC by restoring KEAP1-mediated NRF2 degradation through direct binding to the Kelch domain of KEAP1. These findings support TRM as a promising therapeutic candidate for NRF2-addicted cancers. Ongoing studies aim to further define the structural basis of TRM-KEAP1 interaction and its role in modulating NRF2 stability and signaling.

#4518 Preclinical assessment of BT5528 anti-tumor activity in patient-derived xenograft (PDX) models of pancreatic ductal adenocarcinoma (PDAC).

Lukas Stanczuk[1], Assunta De Rienzo[2], Gavin Bennett[1]

[1]BicycleTx Ltd, Cambridge, United Kingdom,[2]BicycleTx Ltd, Cambridge, MA

Background: Erythropoietin-producing hepatocellular receptor A2 (EphA2) is a receptor tyrosine kinase critical for cell development; it is highly expressed in a range of solid tumors, and its expression correlates with higher grade, later stage disease, and poor prognosis. There is high unmet need for patients with EphA2-expressing tumors, including pancreatic cancer, which has one of the highest EphA2 expression levels across solid tumors. BT5528 is a Bicycle® Drug Conjugate (BDC®), comprising a highly selective EphA2-targeting bicyclic peptide conjugated to the cytotoxin MMAE via a stable valine-citrulline cleavable linker. BT5528 has low molecular weight (4.4 kDa), enabling rapid and efficient delivery of the BDC® to the tumor and subsequent payload release, with minimal systemic exposure to the conjugate. Here we evaluate EphA2 expression and antitumor activity of BT5528 in murine PDX models of PDAC.
Methods: Cohorts of female NOD SCID gamma (NSG) mice were used to generate 16 PDAC PDX models by subcutaneous implantation of patient-derived PDAC tumors into the left abdominal flank. Flash frozen paraffin embedded tumor samples from vehicle treated mice were used to assess EphA2 expression by immunohistochemistry (IHC); Tumor Proportion Score (TPS) was calculated as the number of membrane EphA2+ cells/total number of viable tumor cells x 100. Tumor-bearing mice were treated once weekly for 4 weeks with either vehicle control or BT5528 (3 mg/kg IV). Tumor growth was monitored by caliper measurements and tumor volume was calculated as $[(\text{width})^2 \times \text{length}]/2$. Tumor growth inhibition (TGI) was estimated for each treatment group per model using the average response across replicates after 4 weeks.Results: Of 16 PDAC PDX models tested, all 16 displayed some degree of EphA2 membrane staining, with 16/16 considered positive (TPS ≥1%), including models JH029 (20%), Panc163 (30%), and Panc421 (90%). Fourteen of 16 PDAC PDX models were assessed for antitumor activity. Six of 14 models showed high sensitivity to BT5528 (TGI ≥100%), including JH029 (157%), Panc163 (114%), and Panc421 (110%), with most models showing some level of sensitivity to BT5528 (only 3/14 had TGI <50%). Anti-tumor activity of BT5528 was not affected by the extent of desmoplasia, with TGI scores roughly equivalent across mature, intermediate, and immature tumor models. No increase in response was seen with increasing membrane EphA2 TPS.
Conclusions: Expression of EphA2 was found in all PDAC PDX models. Most models were sensitive to BT5528 treatment, which was not affected by the degree of desmoplasia or membrane EphA2 TPS. These results may reflect a lack of truly EphA2-negative models in this analysis. These data support the potential for BT5528 to offer a novel option for the treatment of PDAC.

#4519 FS-207: A potential best-in-class WRN helicase inhibitor for treating MSI-H cancers.

Bin Li, Cai Wu, Yaqian Liu, Linsen Li, Yan Ma, Dongbo Li

Foresight Therapeutics Co., Ltd., Hefei, China

Microsatellite instability-high (MSI-H) cancers, characterized by impaired DNA mismatch repair (MMR), are vulnerable to synthetic lethal targeting of Werner Syndrome RecQ helicase (WRN). Although PD-1 inhibitors are the standard treatment for MSI-H tumors, their response rate is around 40%-60%, with many patients eventually developing resistance and relapse. WRN inhibition offers a promising alternative therapeutic strategy, potentially overcoming resistance to PD-1 inhibitors. We discovered FS-207, a potent and selective small-molecule inhibitor of WRN helicase, using Foresight Therapeutics' multimodal drug discovery platform. FS-207 demonstrates low nanomolar potency in inhibiting WRN helicase/ATPase activity and exhibits over 1000-fold selectivity against other RecQ helicases. Inhibition of WRN by FS-207 induces chromosomal structure aberrances, leading to selective killing of MSI-H cancer cells via the DNA damage response pathway. FS-207 is well tolerated, with excellent pharmacokinetic properties. Its potent inhibition of WRN helicase, combined with favorable oral bioavailability, translates into robust and durable efficacy in MSI-H cancer cell line derived (CDX) and patient-derived (PDX) xenograft models. Notably, tumor regression was observed in mice dosed at 5 mg/kg or higher in these models. Study results, including efficacy and pharmacodynamic responses, will be presented. Our findings position FS-207 as a promising, potentially best-in-class WRN helicase inhibitor for the treatment of MSI-H cancers, owing to its superior efficacy, durability, and selectivity. FS-207 is poised to enter clinical trials in 2026.

#4520 Development of terfenadine-derived small-molecule inhibitors of TFE3-O dimerization for translocation renal cell carcinoma.

Christian Migliarese[1], Mohd Abdullaha[1], Ilaria Delle Fontane[2], David E. Heppner[3], Roberto Pili[4]

[1]University at Buffalo SUNY, Buffalo, NY,[2]University of Lausanne, Lausanne, Switzerland,[3]University at Buffalo, Department of Chemistry, Buffalo, NY,[4]University at Buffalo, Buffalo, NY

Translocation renal cell carcinoma (tRCC) is an aggressive kidney cancer subtype with poor clinical outcome and no effective standard therapies. It is characterized by gene fusions involving members of the MiT transcription factor family, most commonly TFE3 fused to various partner genes. Work from our laboratory has previously identified the antihistamine terfenadine as a promising compound capable of inhibiting TFE3 dimerization, highlighting dimerization as a targetable mechanism in tRCC. These findings suggest that disrupting TFE3 fusion protein dimerization may enhance therapeutic response and could be leveraged in combination with existing treatment options, including tyrosine kinase inhibitors (TKIs).

The purpose of this study was to optimize terfenadine-derived tool compounds and identify novel small molecules that enhance its antiproliferative activity while reducing terfenadine well-known long QT associated cardiotoxicity. We aimed to determine whether these derivatives selectively inhibit dimerization of TFE3 fusion proteins and improve activity against tRCC diminishing hERG interaction and cardiotoxicity. Two series of terfenadine analogs based on chemical structure modifications were synthesized to evaluate groups specific functional contribution. All compounds were purified and structurally verified by NMR, LTQ mass spectrometry, and HPLC. Their antiproliferative activity was assessed in tRCC cell lines harboring distinct TFE3 fusions (R07: SPFQ-TFE3; UOK-109: NONO-TFE3; UOK-146: PRCC-TFE3). FRET-based assays are being established to measure inhibition of TFE3/TFE3-O dimerization, and hERG activity monitored.

Several newly synthesized compounds, in particular two leading candidates exhibited improved antiproliferative effects (IC_{50}s ~2 µM) as compared to terfenadine (IC_{50}s ~7 µM). These results provide a foundation for further structural refinement and assessment of pharmacological properties with modifications also aiming to reduce its cardiotoxic effect. Combination studies with TKIs demonstrated that co-treatment with terfenadine significantly reduced IC50 values relative to monotherapy, as confirmed by Combination Index analysis. This supports the hypothesis that inhibiting TFE3 fusion protein dimerization enhances drug response to TKIs, potentially by reducing drug sequestration in the lysosome.

In conclusion, this work identifies terfenadine derivatives with improved antiproliferative potential and reduced predicted cardiotoxicity, and highlights TFE3 dimerization as a therapeutically targetable mechanism that may help overcome drug resistance in tRCC.

#4521 Use of a p120 RasGAP glue to inhibit KRas in NF1-null cells.

Anastasiia Gerasimova[1], Sven Miller[1], Jonathan Chernoff[2]

[1]Fox Chase Cancer Center, Philadelphia, PA,[2]Fox Chase Cancer Center, Jenkintown, PA

Neurofibromatosis type 1 (NF1) is an autosomal dominant genetic disorder that is associated with a spectrum of pathologies including glioma, autism spectrum disorder, Lisch nodules of the iris and neurofibroma. The *NF1* gene encodes neurofibromin, a Ras GTPase-activating protein. Deletion or disabling mutations in *NF1* gene result in an absence of neurofibromin and sustained Ras activation, driving uncontrolled cell proliferation and tumorigenesis. Targeting the Ras protein directly has until recently proved challenging due to the lack of binding cavities on molecular surface and due to its high affinity for GTP/GDP.

Purpose: Our study aims to evaluate the efficacy of novel molecular glues designed to modulate Ras activity by increasing its binding to p120RasGAP, a ubiquitously expressed negative regulator of Ras that, like NF1, augments the GTPase activity of Ras, assisting its conversion from active Ras-GTP to inactive, Ras-GDP. The goal is to use these compounds to enable p120RasGAP to functionally replace neurofibromin in *NF1*-deficient cells, restoring normal Ras signaling.

Methods: We used an artificial intelligence/machine learning (AI/ML) protocol to identify potential molecular glues that should stabilize the p120RasGAP/Ras complex. To assess the impact of these compounds, we used NF1-deficient cell line and employed Western Blot analysis to measure changes in phosphorylated ERK (p-ERK) levels as a downstream marker of Ras activity. In addition, we used shRNA-mediated knockdown of the RASA1 gene, which encodes p120RasGAP protein, to verify whether the observed effects are dependent on the proposed Ras/RasGAP interaction mechanism. To assess direct interaction, purified recombinant KRAS and p120RasGAP were used in AlphaScreen binding assay. Compound binding was further validated by surface plasmon resonance (SPR).

Results: Preliminary data indicate a reduction in p-ERK levels upon treatment with novel compounds, suggesting partial suppression of Ras signaling. Furthermore, in p120RasGAP knockdown cells, the molecular glues had a less potent effect in reducing p-ERK levels, suggesting that our compounds act through the proposed mechanism rather than producing off-target effects. Of the three most perspective candidates, one promoted significant binding of KRAS to p120RasGAP in an AlphaScreen assay. This result was also confirmed by SPR.

Conclusion: AL/ML methods can be used to design molecular glues that stabilize the interaction of p120RasGAP to Ras, providing a promising avenue for targeted NF1 therapies. Such compounds might be useful in reducing Ras activity in NF1-mutant cells. We aim to further characterize this interaction using STD NMR and initiate crystallization trials to determine the structural basis of binding.

#4522 Advancing protein engineering through AcroAIxTM: AI-driven strategies for enhanced structure and function optimization.

Spencer Chiang[1], Jane Liu[1], **Lisa Chou**[2], An Ouyang[2], Lili Qin[1]

[1]ACROBiosystems Co., Ltd., Beijing, China,[2]ACROBiosystems Inc., Newark, DE

Recombinant proteins are indispensable tools in biomanufacturing, underpinning drug development and manufacturing processes ranging from biologics to cell therapies. Cellular pathways are driven by the modulation of varying signaling pathways comprising of numerous proteins and membrane receptors. However, reproducing certain proteins ex vivo poses a significant challenge, especially when the tertiary and quaternary structure are complex. This results in a protein that suffers from limited stability, short half-life, and inconsistent bioactivity which further restricts reproducibility, production costs, and poses a significant barrier to scalable manufacturing. In many cases, traditional protein engineering strategies, while valuable, are constrained by experimental throughput and limited predictive accuracy. To overcome this challenge, AcroAIxTM is an artificial intelligence-driven protein design platform that integrates structural modeling, machine learning, and sequence-function prediction to systematically generate high-performing protein variants. By optimizing key biophysical parameters, AcroAIxTM enables the rational enhancement of recombinant proteins for improved conformational stability, functional half-life, and binding efficiency. These advances are particularly impactful in cell culture applications, where growth factors such as interleukin-21 (IL-21) and fibroblast growth factor 2 (FGF-basic) are essential. Heat-stable forms of IL-21 and FGF-basic were developed to maintain their bioactivity and half-life in 37ºC media for 3 days. The resulting cytokine remains active for a longer period and improves cell counts significantly under a reduced-feeding protocol compared to wild types. As such, engineering variants with enhanced stability and bioactivity can directly improves culture robustness, reduce factor replenishment requirements, and increase the efficiency of cell-based manufacturing workflows. By bridging computational design with experimental validation, the AcroAIxTM platform establishes a transformative framework for recombinant protein innovation, advancing both general biomanufacturing practices and cell culture-driven therapeutic production.

#4524 LDHA-positive neutrophils drive Treg-mediated immune tolerance to promote resistance to pan-RAS inhibitors in pancreatic cancer.

Xiangyan Jiang[1], Xiaoe He[1], Wen Wei[1], Qichen He[1], Lei Shi[2], **Zuoyi Jiao**[1]

[1]Lanzhou University, Lanzhou, China,[2]Cancer Research UK Manchester Institute, Manchester

KRAS is the most common and critical oncogenic mutation in pancreatic cancer, with a mutation rate exceeding 90%. The pan-RAS inhibitor RMC-6236 (Daraxonrasib) has shown promising progress in clinical trials and has been designated as a breakthrough therapy by the FDA. However, resistance to RAS-targeted drugs is inevitable. Here, we collected tumor tissues from KPC mice treated with the pan-RAS inhibitor RMC-6236, both at the time of tumor shrinkage and after the development of acquired resistance, and performed single-cell sequencing. We found that regulatory T cells (Tregs) decreased after treatment but increased after resistance. Similarly, myeloid immune cells exhibited similar subpopulation changes in both treated and acquired resistant states, with LDHA-positive tumor-associated neutrophils (TANs) significantly reduced after RMC-6236 treatment, but replenished after the development of acquired resistance. Mechanistically, LDHA-positive neutrophils upregulate PD-L1 expression via STAT3 signaling and NETs, and promote the immune suppressive effect of Tregs through PD-L1/PD-1 interactions. Additionally, the ablation of LDHA in neutrophils combined with RMC-6236 significantly inhibited tumor growth in KPC mice and restored pancreatic cancer sensitivity to RMC-6236. In conclusion, this study reveals the tumor microenvironment regulatory mechanisms underlying resistance to pan-RAS inhibitor RMC-6236 and proposes a promising strategy for overcoming RAS inhibitor resistance.

#4525 Potential of Rac and Cdc42 inhibitors as pancreatic cancer therapeutics.

Anamaris Torres-Sanchez, Ailed Cruz-Collazo, Nilmary Grafals, Stephanie Dorta-Estremera, Suranganie Dharmawardhane Flanagan

Biochemistry, University of Puerto Rico Medical Sciences Campus, San Juan, PR

Pancreatic ductal adenocarcinoma (PDAC) remains one of the deadliest forms of cancer, with a distinct extracellular matrix and immunosuppressive tumor microenvironment. Existing chemotherapies are hampered by toxicity and demonstrate poor clinical response. Therapies targeting the KRAS G12D mutation, prevalent in pancreatic cancer, have yet to receive FDA approval. Therefore, there is a critical need for novel targeted therapies for PDAC. These therapies should simultaneously target metastatic cancer cells and immunosuppressive cells such as tumor-associated macrophages (TAMS), since they promote pancreatic cancer progression. Ras-activated related GTPases Rac and Cdc42 are ideal targets for pancreatic cancer therapy because they regulate migration, invasion, polarity, viability, and survival in cancer cells and immune cells. Therefore, we developed Rac and Cdc42 inhibitors for metastatic diseases such as PDAC to target cancer and its immunosuppressive environment. The hypothesis tested in this study is that Rac/Cdc42 inhibitors will simultaneously target the migration and activity of cancer cells and macrophage-like cells in the TME. We assessed the potential of the dual Rac and Cdc42 inhibitors MBQ-167 and MBQ-168, which block guanine nucleotide association with Rac and Cdc42. The effects of vehicle, MBQ-167 or MBQ-168 were tested in human and mouse PDAC cells or macrophages by performing pulldown assays for Rac and Cdc42 activation, MTT assays for cell viability, wound-healing assays for cell migration, phagocytosis, as well as co-culture assays with PDAC cells and macrophages. Results demonstrated that Rac and Cdc42 inhibitors significantly reduced active Rac and Cdc42 in pancreatic and macrophage cells. Both MBQ-167 and MBQ-168 reduced pancreatic cancer cell viability, without affecting macrophage viability, and inhibited cell morphology and migration. In co-culture using Transwells, MBQ-167 and MBQ-168 decreased pancreatic cancer cell migration from the top wells, with macrophages in the bottom wells, and reduced inflammatory mediators such as IL-6, CHI3L1 and S100A8 and S100A9 levels in conditioned media. A preliminary study was also conducted in C57BL6 mice bearing orthotopic KPC (KRas G12D, p53 null, Cre) tumors to test the effect of vehicle or 10mg MBQ-167 administered by IP 5X a week for 21 days. MBQ-167 treatment decreased tumor growth and increased survival compared to vehicle treatments. In conclusion, MBQ-167 and MBQ-168 pose as potential therapeutics for PDAC due to their ability to target both pancreatic and macrophage-like cells.

#4526 Activation of the RXR nuclear receptor improves survival and the therapeutic window of immunotherapy in murine breast cancer.

Ana S. Leal

Division of Hematology and Oncology, Indiana University School of Medicine, Indianapolis, IN

The retinoid X receptor (RXR) is a member of the nuclear receptor superfamily of ligand-dependent transcription factors. Bexarotene, the only approved RXR agonist, is used in refractory cutaneous T cell lymphoma but lacks effect on solid tumors. Based on structure-activity-relationships (SAR) we selected MSU42011, as a more potent and specific RXR agonist.Treatment with the RXR agonist MSU42011 (300 mg/Kg diet) reduced tumor burden and increased survival in a MMTV-Neu murine model of HER2+ breast cancer (p=0.01, 55 days vs 62 days median survival, respectively). HER2 breast cancer patients have not benefited from the approval of immunotherapy. However, HER2 positive stomach cancer patients see benefit when treated with anti-PD1, which is now approved for clinical use. We previously shown that MSU42011 can be combined with immunotherapy in a lung cancer murine model, therefore we tested the combination of MSU42011 with anti-PD1 in MMTV-Neu mice. The combination of MSU42011+anti-PD1 significantly (median survival 69 days) increases survival when compared with mice that receive either only control (p=0.008) or anti-PD1 (p= 0.05, median survival 53 days). No obvious side effects were observed in either anti-PD1 alone or in combination with MSU42011 groups. MMTV-Neu mice were treated as above and euthanized at 40 days after treatment initiation for tumor immunophenotyping. Mice receiving MSU42011 or MSU42011+anti-PD1 showed a significant reduction in the expression of CD206 and PDL-1, two immunosuppressive molecules, in inflammatory (p=0.03) and resident (p=0.05, p=0.005) monocytes. CD11c (p=0.04) and CD11b (p=0.03) tumor associated macrophages (TAMs) had a significant reduction in PDL-1 expression in both MSU42011 and MSU42011+anti-PD1 groups. The reduction in the immunosuppressive CD206 and PDL-1 expression in the myeloid lineage, was associated with a significant increase in the infiltration of CD8 T cells (p=0.01), as well as in the activation markers of CD8 T cells (CD44, p=0.05; CD69, p=0.007).In the highly aggressive MMTV-PyMT murine model of triple negative breast cancer (TNBC), MSU42011 treatment significantly (p= 0.001) prolonged survival (median 39 vs 49 days). Flow cytometry of tumors at 28 days of treatment showed a decreased number of TAMs (36.6% vs 20.2%) and an increased number of CD8 T cells (3.4% vs 5.9%). Moreover at this time point only 1 of 10 mice had visible lung metastasis in the MSU42011 group compared with control where 4 of 10 mice had lung metastasis, additionally, one mouse that had a bone metastasis. In conclusion, MSU42011 increased recruitment and activation of CD8 T cells and a decrease of tumor promoting myeloid cells in both HER2+ and TNBC murine mammary tumors. These data, in combination with our previous work shows that the RXR agonist MSU42011 reduces tumor growth by modulating the tumor microenvironment and can safely be combined with anti-PD1.

#4528 The basal cell-derived matricellular protein SPON2 suppresses luminal cell oxidative phosphorylation and cancer progression by blocking the SLC38A1/mTOR metabolic axis.
Pengfei (Paul) Lu

University of South China, Hengyang, Hunan, China

Tumor resistance, largely driven by cellular heterogeneity and complex interactions within the tumor microenvironment (TME), remains a central challenge in oncology. In breast cancer, the crosstalk between basal-like cancer stem cells (bCSCs) and luminal niche cells is hypothesized to be a critical driver of therapy resistance, yet the underlying molecular mechanisms are poorly defined. Here, we identify and characterize SPON2, a matricellular protein secreted by basal cells, as a master regulator of luminal cell metabolism and function. Mechanistically, SPON2 directly binds to the amino acid transporter SLC38A1 on luminal cells, thereby blocking the glutamine-leucine exchange and consequently suppressing PI3K-AKT-mTOR signaling. This inhibition leads to a profound reduction in oxidative phosphorylation (OXPHOS) and energy metabolism in luminal cells. Phenotypically, *Spon2*-knockout mice exhibit aberrantly increased and accelerated mammary ductal branching. Conversely, SPON2 overexpression in vitro potently inhibits organoid formation, branching morphogenesis, and epithelial proliferation. Crucially, SPON2 exerts potent tumor-suppressive effects across multiple breast cancer subtypes, including Luminal A and triple-negative breast cancer (TNBC). Our findings establish SPON2 as a basal-derived paracrine signal that is essential for maintaining metabolic homeostasis in the mammary gland and the TME. This work unveils the SPON2-SLC38A1-mTOR axis as a fundamental pathway of metabolic communication between cell populations, providing a novel conceptual framework for understanding breast cancer heterogeneity and a promising therapeutic target for overcoming drug resistance.

#4529 Antibody-drug conjugates for the treatment of hematologic malignancies.

Priya Hays

Hays Documentation Specialists LLC, San Mateo, CA

Belantamab mafodotin is composed of a monoclonal antibody targeting BCMA and is conjugated to the cytotoxic payload monomethyl auristatin F (MMAF), a microtubule disrupting agent, and is approved for multiple myeloma. Its efficacy was evaluated in DREAMM-7, an open-label, randomized trial in adults with R/R multiple myeloma with at least one prior therapy. The mPFS was 31.3 months (95% CI: 23.5, NR) in the BVd arm and 10.4 months (95% CI: 7, 13.4) in the DVd arm (HR 0.31, 95% CI: 0.21, 0.47). The mOS was NR and 35.7 months (95% CI: 21.1, NR) in respective arms (HR 0.49, 95% CI: 0.32, 0.76). Gemtuzumab oxogamicin targets the CD33 receptor on myeloid cells and is approved for AML. Its approval in combination with CT for adults was based on ALFA-0701, a multicenter, randomized, open-label phase 3 study of 271 patients with newly-diagnosed, de novo AML. The second trial, MyloFrance-1, a phase 2, single-arm, open-label study, included 57 patients with CD33-positive AML in first relapse. Fifteen (26%; 95% CI: 16% - 40%) patients achieved CR following a single course of gemtuzumab ozogamicin. Inotuzumab ozogamicin targets the CD22 receptor on B-cell precursor leukemic cells and is approved for ALL in pediatric patients with R/R CD22-positive B-cell precursor ALL. Efficacy was evaluated in a multicenter, single-arm, open-label study and the main efficacy outcome measures were complete remission (CR), duration of CR, and the proportion of patients with MRD negative CR. CR was defined as < 5% blasts in the bone marrow and the absence of peripheral blood leukemia blasts, full recovery of peripheral blood counts and resolution of any extramedullary disease. MRD was defined by leukemic cells comprising < 1 × 10-4 (<0.01%) of bone marrow nucleated cells. 22/53 (42%, 95% CI: 28.1, 55.9%) achieved CR and the median duration of CR was 8.2 months (95% CI: 2.6, NE). The MRD negativity rate in patients with CR was 21/22 [95.5% (95% CI: 77.2, 99.9)] based on flow cytometry, and 19/22 [86.4% (95% CI: 65.1, 97.1] based on RQ-PCR. Brentuximab vedotin is composed of a monoclonal antibody targeting the CD20 antigen and conjugated to microtubule disrupting agent monomethyl auristatin, which serves as the payload, for chronic Hodgkin's lymphoma. Approval was based on ECHELON-3, a randomized, double-blind, placebo-controlled trial enrolling 230 adult patients with R/R LBCL who were ineligible to receive an auto-HSCT or CAR T-cell therapy. The major efficacy outcome measure was OS. Additional efficacy outcome measures included PFS and ORR. The trial demonstrated a statistically significant improvement in OS, PFS and ORR. mOS of 13.8 months (95% CI: 10.3, 18.8) in the BV+R2 arm and 8.5 months (95% CI: 5.4, 11.7) in the Pbo+R2 arm (HR 0.63, 95% CI: 0.45, 0.89) were shown. mPFS was 4.2 months (95% CI: 2.9, 7.1) with BV+R2 and 2.6 months (95% CI: 1.4, 3.1) with Pbo+R2 (HR 0.53, 95% CI: 0.38, 0.73). The ORR was 64.3% (95% CI: 54.7, 73.1) and 41.5% (95% CI: 32.5, 51.0), respectively.

#4530 Synergistic targeting of Mediator complex and BCL-2 reveals a novel therapeutic strategy for acute myeloid leukemia.

Camille Aitchedji[1], Celine Moison[1], Deanne Gracias[1], Rodrigo Mendoza-Sanchez[2], Simon Fortier[1], Jean-Francois Spinella[1], Tara Macrae[1], Nadine Mayotte[1], Melanie Frechette[1], Valerie Blouin-Chagnon[1], Koryne Leveille[1], Rejean Ruel[2], Anne Marinier[2], Guy Sauvageau[1], Josee Hebert[3]

[1]Molecular Genetics of Stem Cells Research Unit, Institute for Research in Immunology and Cancer (IRIC), Montreal, QC, Canada,[2]Drug Discovery Unit, Institute for Research in Immunology and Cancer (IRIC), Montreal, QC, Canada,[3]Division of Hematology-Oncology and Leukemia Cell Bank of Quebec, Hopital Maisonneuve-Rosemont, Montreal, QC, Canada

Background: Acute myeloid leukemia (AML) is a heterogeneous and aggressive hematologic malignancy characterized by the uncontrolled proliferation of myeloid stem and progenitor cells. Despite therapeutic advances, the 5-year survival rate remains low, underscoring the urgent need for novel therapeutic strategies.
Methods: To meet this need and identify new anti-leukemic agents, we conducted a high-throughput cell viability screen of 10,000 small molecules using 56 different primary AML specimens of diverse genetic anomalies. Molecules showing highly correlated inhibition profiles were grouped into 21 compound correlation clusters (CCCs). The overall hypothesis was that compounds sharing highly correlated inhibition profiles most likely act on the same biological pathway / molecular target. Among the various CCC identified, CCC163, which include compound AML874, emerged as a potent and selective anti-leukemic hit.
Results: Integrated pharmacological and CRISPR-Cas9 screening revealed the Mediator complex as the molecular target of AML874. Mechanistic studies confirmed that AML874 inhibits Mediator complex function through CDK8/CDK19 kinase inhibition, leading to transcriptional dysregulation and loss of Mediator structural integrity. Kinase-dead CDK8 rescue assays confirmed that AML874 activity depends on CDK8 kinase function. Notably, FLT3-mutated AML primary specimens exhibited increased sensitivity to AML874, indicating a potential subtype-specific therapeutic opportunity. Structure-activity relationship profiling of AML874 analogs further supported the dependency on Mediator complex disruption for anti-leukemic activity. Finally, combination studies demonstrated strong synergy between AML874 and the BCL2 inhibitor venetoclax both in vitro and in vivo, resulting in markedly improved anti-leukemic activity in xenograft models.
Conclusions: This work identifies the Mediator complex as a novel vulnerability in AML and positions CDK8/CDK19 inhibition, alone or in combination with Venetoclax, as a promising strategy for the development of next-generation targeted therapies for this disease.

: Next-Generation Targeted Therapies Directed Against Tumor Surface Antigens
Poster Session

#4533 Discovery and characterization of CARs against novel, highly selective solid tumor targets identified using the Oncolinkage platform.

McKensie Collins, Benjamin Hallisey, Andrew Astley, Murray O. Robinson

Rubik Therapeutics, Cambridge, MA

CAR T cell therapy has demonstrated remarkable efficacy in treating hematologic malignancies. However, these therapies have been largely unsuccessful in solid tumors, which account for approximately 90% of cancer diagnoses. A critical obstacle to developing CAR T cell therapies for solid tumors is the lack of surface-expressed targets that are selectively present on tumors and not healthy tissues. Identification of tumor-restricted targets is essential to avoid on-target, off-tumor toxicity, which has proven therapeutically limiting for several CAR T therapies, including anti-PSMA and MSLN CARs. To address this challenge, we developed Oncolinkage, a computational platform to discover novel, selectively expressed surface targets whose upregulation is linked to an inciting oncogenic event through the non-specific nature of genomic mutation. As these events drive tumor formation, oncolinked targets are under positive selection, resulting in uniform expression and resistance to loss, making them ideal CAR targets. We first selected a set of ten surface targets that exhibited oncolinked properties--restricted expression in normal tissues, but dysregulated expression in tumors-and identified antibodies that bound cells for 9/10 targets examined. Binding was confirmed by CRISPR/Cas9 knockout of the gene of interest and assessed by flow cytometry. Next, 4-1BB/CD3z CARs were generated for each target using the VH/VL regions of the identified antibodies for scFv generation. After lentiviral transduction of CAR constructs into Jurkat E6.1 cells, active CARs were identified for multiple targets by assessing antigen-dependent CD69 upregulation in overnight co-culture experiments with target-expressing cell lines. The most advanced CAR binds a surface protein whose cancer-specific amplification is observed in subsets of multiple solid tumors, including lung and prostate cancers. This CAR was advanced into primary donor T cells for functional validation. Cytotoxicity was assessed against cell lines exhibiting varying antigen densities of the target protein to demonstrate anti-tumor efficacy at expression levels comparable to primary human tumors. Together, this study highlights the potential of the Oncolinkage platform to efficiently identify and validate multiple novel CAR targets and demonstrates pre-clinical efficacy of solid tumor-directed CARs based on this platform.

#4534 FGF19/ FGFR4 Axis: A key driver in tumorigenesis and treatment resistance in colorectal cancer.

Anh Nguyen, **Bruce M. Boman**

Helen F. Graham Cancer Center & Research Institute, Newark, DE

Colorectal cancer (CRC) remains one of the most treatment-resistant malignancies, yet the mechanisms underlying this resistance are not fully understood. Our GOAL is to define these mechanisms and identify new therapeutic targets to improve treatment outcomes. We investigate the role of the Fibroblast Growth Factor (FGF) signaling, particularly the FGF19/FGF Receptor (FGFR) 4 axis, in CRC tumor growth and therapeutic response. This axis is compelling because our preliminary data show that: *(i)* FGF19 and FGFR4 are co-overexpressed in human CRC, based on publicly available single-cell RNA-seq and bulk RNA-seq of our paired patient specimens; *(ii)* FGF19 overexpression correlates with worse relapse-free survival (RFS) in the TCGA-COAD cohort; and *(iii)* both FGF19 and FGFR4 expression correlate with poor overall survival (OS). Importantly, FGF19/FGFR4 signaling is an upstream regulator of the MAPK and WNT/β-catenin pathways, key drivers of tumorigenesis and treatment resistance in CRC. We HYPOTHESIZE that autoactivation of the FGF19/FGFR4 axis promotes tumor growth, survival, and treatment resistance in CRC. To dissect this axis's functional contributions, CRC cell lines underwent selective FGFR4 inhibition or induced FGF19 overexpression. Effects on viability, proliferation, clonogenic growth, invasion, and drug sensitivity were assessed using established in vitro assays, while mechanistic changes were examined by qRT-PCR and Western blotting. Functionally, targeting FGFR4 with the selective inhibitor BLU9931 impacted all critical cancer hallmarks: increased apoptosis, reduced proliferation, suppressed clonogenic capacity, and diminished invasion. Pre-treatment with BLU9931 sensitized cells to 5-fluorouracil (5-FU), a standard chemotherapeutic agent, enhancing cytotoxicity synergistically. Conversely, FGF19 overexpression activated ERK1/2 and β-catenin signaling to promote proliferation, induced resistance to 5-FU by maintaining cells in the G1-protective phase, and facilitated rapid post-chemotherapy recovery. Our findings support the hypothesis that the FGF19-FGFR4 axis is a key driver of CRC progression and therapy resistance, underscoring the rationale for developing targeted therapies against this tumor-specific signaling axis.

#4535 Targeting LPAR1 as a potential therapeutic strategy for glioblastoma.

Satoshi Takagi, Sumie Koike, Ryohei Katayama

Japanese Foundation for Cancer Research, Tokyo, Japan

Glioblastoma (GBM) is the most aggressive primary brain tumor, with a poor prognosis and a 5-year survival rate of 10%, despite multimodal treatment combining surgery, radiotherapy, and chemotherapy. Due to its high invasiveness, complete surgical resection is challenging, making postoperative radiotherapy and chemotherapy indispensable. Temozolomide (TMZ), a DNA alkylating agent, remains the only FDA-approved therapeutic agent for GBM, novel therapeutic agents for GBM are warranted. In this study, to identify potential therapeutic targets in GBM, we conducted an siRNA-based screening of G protein-coupled receptors (GPCRs) and identified lysophosphatidic acid receptor 1 (LPAR1) as a key molecule whose knockdown significantly reduced the GBM cell viability. LPA, a bioactive lipid mediator, signals through six receptors (LPAR1-6), with LPAR1 particularly implicated in cytoskeletal remodeling, migration, proliferation, and differentiation. Analysis of TCGA data revealed that LPAR1 is highly expressed in brain tumors compared to other cancer types. *In vitro*, LPAR1 knockdown significantly suppressed cell proliferation and induced PARP cleavage, a hallmark of apoptosis, in several GBM cell lines expressing LPAR1. LPA treatment enhanced proliferation of LPAR1-positive GBM cell lines in a concentration-dependent manner and this effect was cancelled by both genetic and pharmacological inhibition of LPAR1. These results indicate that the LPA-LPAR1 axis plays a critical role in promoting GBM cell proliferation and survival. Further analysis using phospho-Kinase arrays and pathway-specific inhibitors revealed that the PI3K/Akt signaling pathway downstream of LPAR1 is involved in these pro-survival effects. In an orthotopic GBM xenograft model, oral administration of the LPAR1 antagonist BMS-986020 significantly suppressed tumor growth in brain. Additionally, combinatorial treatment with BMS-986020 and TMZ lowered the IC_{50} value of TMZ *in vitro*, suggesting a potential synergistic cytotoxic effect. We have previously reported the potential of LPAR1 antagonists as therapeutic agents for osteosarcoma (Takagi S *et al. Oncogene* 2021); our current findings suggest that LPAR1 antagonists would be promising therapeutic option for GBM treatment.

#4536 GFS784, a next-generation ADC with a novel panRAS(ON) inhibitor payload.

Feng Yan, Jichen Zhao, Jingyang Zhang, Li Wang, Yumei Li, Siyuan Le, Fusheng Zhou, Jiong Lan, Qiang Lu

Genfleet Therapeutics, Shanghai, China

Background: Antibody drug conjugate (ADC) has proven an effective drug modality and keeps evolving with innovations explored on each of its components. However, the potential coordination between the antibody and the payload of an ADC is usually overlooked efficacy-wise. Here we introduce the development of a novel panRAS (ON) inhibitor payload and more importantly, the Functional Antibody and Synergistic conjugate(FAScon^{TM}), a novel ADC design which employes the antibody-payload synergy to further enhance the therapeutic activity of an ADC beyond precision delivery. The preclinical profile of an exemplified FAScon GFS784, an EGFR-panRASi ADC is presented for concept demonstration.
Methods: GFS784 was established by conjugating Cetuximab with a panRAS(ON) inhibitor GF005095 via a proprietary, cleavable linker at DAR of 8. The anti-growth activity of GFS784 was tested in cell lines with different RAS genotypes. The bystander effect of GFS784 was investigated by comparing its effect on the growth of an EGFR negative cell line when mono-cultured or co-cultured with an EGFR-positive cell line. The plasma stability of GFS784 was studied via incubation in vitro or injection into mice. CDX tumor mouse models were used to explore the in vivo efficacy of GFS784.
Results: The pan-RAS(ON) inhibitor payload GF005095 employes cyclophilin A to target K/H/N-RAS mutants or wild type proteins and demonstrated higher anti-growth activity than DXd in vitro. GFS784 bound to and was internalized into tumor cells in an EGFR-dependent manner. GFS784 showed broad and potent anti-proliferation activity in EGFR-expressed tumor cell lines addicted to mutant or wild type RAS genes with a sub-nanomolar median IC_{50}, which is significantly lower than that of an EGFR-DXd ADC. GFS784 demonstrated significant bystander effect in vitro. GFS784 showed good plasma stability when tested in vitro and in animals. GFS784 at dose levels of 1-5 mg/kg via i.v., q3W showed robust therapeutic efficacy in RAS-mutant CDX models which were either sensitive or resistant to the DXd counterpart. Compared with combination therapy using Cetuximab and RMC-6236 at clinical equivalent doses, GFS784 demonstrated comparable efficacy but better tolerability in CDX mice. GFS784 also induced deep tumor regression in both Osimertinib-sensitive and resistant EGFR-mutant NSCLC CDX models.
Conclusions: GFS784 has a satisfactory preclinical profile as an ADC candidate. GFS784 is effective in CDX models resistant to DXd ADC or Osimertinib, suggesting the potential as a next-generation ADC and an alternative solution for TKI resistance. Therefore, GFS784 provides a promising solution for treating RAS mutant or EGFR-altered tumors and a further clinical investigation is warranted.

#4537 Modified acetate salt form of GHRH-antagonist retains anti-leukemic activity against acute myelogenous leukemia.

Joel Costoya[1], Elizabeth Costoya[2], Medhi Wangpaichitr[3], Wei Sha[4], Joaquin J. Jimenez[5]

[1]Department of Biochemistry and Molecular Biology, University of Miami Miller School of Medicine, Miami, FL,[2]College of Arts, Sciences & Education, Florida International University, Miami, FL,[3]DeWitt Daughtry Family Department of Surgery, Division of Cardiothoracic Surgery, University of Miami Miller School of Medicine, Miami, FL,[4]Bruce W. Carter Veterans Affairs Medical Center, Miami, FL,[5]Phillip Frost Department of Dermatology and Cutaneous Surgery, University of Miami Miller School of Medicine, Miami, FL

Acute myeloid leukemia (AML) is a heterogenous hematological malignancy characterized by an accumulation of immature myelocytic cells resulting from aberrancies to programs underlying the survival, proliferation, and maturation of myeloid progenitor cells during hematopoiesis. Despite continuous improvement in AML therapies, five-year survival rates remain at 31.7%, and standard induction therapy relies on the use of intense chemotherapeutic regimes, followed by HSCT if applicable. This underscores the need for novel therapies, ideally without introducing adverse events as side effects to treatment. GHRH antagonists, represent a new therapeutic modality and pre-clinically have shown robust activity against various cancer types with minimal peripheral toxicity. Previously we demonstrated MIA-602, a GHRH antagonist, to have significant anti-leukemic activity both *in-vitro* and *in-vivo* against APL and an all-trans retinoic acid/arsenic trioxide (RAA) resistant clone, as well as AML and a doxorubicin resistant (DR) clone. When MIA-602 was combined with standard therapy in non-resistant models, the anti-leukemic effect produced was made even more potent. Whilst in resistant models, MIA-602 monotherapy retained its significant anti-leukemic activity, implying a distinct mechanism of action independent from that of traditional therapeutic modalities. Here we tested a more clinically acceptable acetate salt form of MIA-602, MIA-602 Ac, and showed that it retained significant anti-leukemic activity against both APL and AML *in-vitro* as well as versus their RAA and DR analogs, respectively. In order to assess retention of MIA-602Ac's anti-leukemic efficacy, NB4 and NB4-RAA cells, were cultured with increasing doses of MIA-602Ac ranging from 0.05 to 5 µmol/L. K562 and K562-DR cells, were cultured with MIA-602Ac alone or combined with doxorubicin at varying concentrations ranging from 0.05 to 5 µmol/L and 0.005 to 0.05 µg/ml respectively, using doxorubicin as the standard-of-care comparator. Cell viability was measured 24h and 48h post-treatment. Our results show that MIA-602Ac maintained a significant dose- and time-dependent anti-leukemic effect as seen previously with MIA-602. Synergism of GHRH antagonism with standard of care therapies was preserved. MIA-602Ac as a monotherapy could still produce significant anti-leukemic effects in resistant cell lines. In conclusion, further clinical investigation of MIA-602Ac as a monotherapy, or adjuvant therapy for the treatment of acute myeloid leukemia is warranted, given its continued preclinical success and improvements made to toxicity.

#4539 A MUC1-C-targeting ADC exhibits potent antitumor activity against neuroendocrine prostate cancer in both intact and testosterone-depleted preclinical models.

Surender Kharbanda[1], Rehan Ahmad[1], Deepak Raina[1], Changchuin Mao[1], Sourav Choudhary[2], Brian Lawney[3], Nandita Sreenivasalu[1], Govind Panchamoorthy[1], Neeraj Agarwal[4], Ravi Jasuja[1]

[1]R&D, Xyone Therapeutics Inc., Canton, MA,[2]Birla Institute of Technology and Science, Hyderabad, India,[3]Dana Farber Cancer Institute, Boston, MA,[4]Asst. Professor, Div. of Med. Onc., University of Utah Huntsman Cancer Institute, Salt Lake City, UT

Background: Prostate cancer (PC) is one of the most frequently diagnosed malignancies in men and remains the second leading cause of cancer-related mortality. The castration-resistant and neuroendocrine variants (CRPC/NEPC) are especially challenging to treat, as these tumors often lose dependence on androgen receptor signaling and become refractory to androgen-targeted therapies. Although prostate-specific membrane antigen (PSMA) is a valuable surface target in many forms of PC, its absence in PSMA-negative tumors necessitates alternative therapeutic markers. One such marker is MUC1, whose expression becomes markedly upregulated in PSMA-negative disease. Notably, aberrant MUC1 expression is a hallmark of CRPC/NEPC and is strongly associated with aggressive tumor behavior and poor clinical outcomes.
Methods: In-vitro cytotoxic activity of MUC1-C targeting ADC (XYA02-8) was evaluated in a series of prostate cancer cell lines. Preclinical antitumor activity was evaluated in-vivo in both intact and castrated nude mice to model androgen replete and depleted states in PC patients.
Results: We find that the MUC1-C mAb 7B8* binds to ~90% cells compared to isotype control in CRPC/NEPC in-vitro. To develop multiple ADC formulations and to optimize the candidate, Quality by Design (QbD, FDA) approach was utilized, leveraging the Design of Experiments (DOE) statistical framework. XYA02-8-ADC exhibits efficient internalization at 3 hours at 37^{o}C in multiple CRPC/NEPC cell lines and displayed potent cytotoxicity in in-vitro. Both intact and castrated nude mice with established tumor xenografts were treated with 7.5 mg/kg QW x 3 i.v. and monitored for over two-month post treatment. Significant (~70%) tumor growth inhibition was observed with XYA02-8-ADC without an accompanying weight loss and/or tissue toxicity. Interestingly, the antitumor activity persists in both intact and castrated nude mice xenografts demonstrating that targeting MUC1-C present a unique opportunity for tumor abrogation downstream of androgen signaling.
Conclusions: XYA02-8-ADC demonstrates strong antitumor activity with a favorable safety profile in CRPC/NEPC models. Notably, its ability to retain efficacy even under testosterone-replete conditions highlights an important therapeutic opportunity: targeting MUC1-C with XYA02-8-ADC without relying on androgen-deprivation strategies. These findings open a promising avenue for developing effective treatments that avoid the systemic adverse effects associated with hormonal deprivation.* https://patents.google.com/patent/US20230265208A1/en

#4540 BC602: An IND-enabling stage LGR5x EGFR bispecific antibody with superior anti-tumor efficacy in mouse CDX and PDX models.

Zhe Shao, Tao Wang, Wen Chao Jia, Keng Hoe Lok, **Zhong Zong Pan**

Dragon Boat Biopharmaceutical, Shanghai, China

Epidermal growth factor receptor (EGFR) is a key driver oncogene in the tumorigenesis of many cancer types. EGFR targeting antibodies are approved mainly in EGFR overexpression cancers including colorectal cancer (CRC), head and neck squamous carcinoma (HNSCC), and squamous non-small cell lung cancer (NSCLC). These antibodies exert their function by binding to the extracellular domain(s) to block ligand binding and to induce receptor internalization and degradation. To further enhance EGFR internalization and degradation, we developed an asymmetric LGR5*EGFR bispecific antibody (BsAb) BC602, with one arm as VHH targeting leucine-rich repeat-containing G-protein coupled receptor 5 (LGR5), and the other arm as Fab targeting EGFR. To further increase the anti-tumor activity, BC602 Fc is engineered for enhanced FcγRIII binding and ADCC activity. In ELISA and BLI assays, BC602 binds to the LGR5 protein and EGFR protein with high affinity, respectively. In LGR5 and EGFR expressing cell lines,BC602 showed high binding affinity to cell surface receptors at single digit nM, while isotype control antibody showed no binding. In the pH-rodo internalization assay, BC602 induced significantly higher internalization magnitude than EGFR antibody or LGR5 antibody alone in both cell lines. In growth inhibition assay using the patient-derived organoids (PDO), BC602 showed potent inhibitory activity, much stronger than EGFR antibody. The antitumor efficacy of BC602 was studied in several mouse CDX and PDX models. BC602 demonstrated dose-dependent anti-tumor efficacy, with the antitumor efficacy stronger than EGFR antibody, superior or comparable to its competitor in clinical development stage. In AGS mouse xenograft tumor model, BC602 at 5 mg/kg showed a TGI of 72% while EGFR antibody had a TGI of 50%. In A431-LGR5 mouse xenograft tumor model, BC602 at 1/3/10 mg/kg showed TGI of 42%, 67%, and 83% respectively. BC602 showed no effect on mouse body weight or showed any other safety concerns in these mouse models. BC602 demonstrated good physicochemical properties for CMC, with a high production yield. Non-clinical GLP PK and toxicity studies of BC602 and 200L scale clinical batch production are ongoing. IND filing is expected in 2026 Q3, and the planned indications include cancer types that overexpress both EGFR and LGR5 including HNSCC and CRC.

#4541 DR319-DP: A Nectin-4/Trop-2 bispecific ADC with an avidity-driven VHH design and dual-MOA payloads.

Xiaofang Wen[1], Wenwen Duan[1], Gaofeng Yao[1], Shaoqi Liu[1], Yonglu Chen[1], Teng Li[1], Xiaoyu Qian[1], Zhenxing Zhou[1], Jingjin Fang[1], Jie Zhao[1], Ke Chen[1], Yi Yang[2], Yanshan Huang[1]

[1]Zhejiang Doer Biologics Co., Ltd, Hangzhou, China,[2]Glyco-therapy Biotechnology Co. Ltd., Hangzhou, China

Trop-2 and Nectin-4 have emerged as attractive targets for the development of next-generation antibody-drug conjugates (ADCs). However, the emergence of drug resistance remains a critical challenge in ADC therapy. Combination strategies represent a promising approach to enhance therapeutic efficacy and mitigate resistance. Notably, Trop-2 and Nectin-4 exhibit high and frequent co-expression across multiple solid tumors, while showing limited or moderate expression in normal tissues. In clinical attempts, the combination of sacituzumab govitecan (SG) and enfortumab vedotin (EV) has demonstrated substantially improved efficacy in early-phase trials for metastatic urothelial carcinoma. However, toxicities arising from both “off-target, off-tumor” and “on-target, off-tumor” effects remain a major concern. To maximize antitumor efficacy while minimizing systemic toxicity, we developed an avidity-driven bispecific antibody, DR319, featuring a “1+1” bispecific format that incorporates a low-affinity but high-avidity anti-Trop-2 VHH arm. We demonstrated that DR319 enables potent, high-avidity binding to Nectin-4/Trop-2 dual-positive tumor cells in our diverse cell line panel, while minimizing binding to Trop-2 single-positive cells, thereby mechanistically reducing on-target toxicities. We then conjugated DR319 to a novel Topoisomerase I inhibitor (TopoI) linker-payload (CPD3) featuring improved plasma stability, generating DR319-CPD3 (DAR 6). Our results showed that DR319-CPD3 exhibited superior antitumor efficacy in CDX models compared with benchmark mono-targeting ADCs with TopoI payloads, even those using the same CPD3. Furthermore, we generated a dual-payloads ADC, DR319-DP, with a DAR of 4 TopoI + 2 microtubule inhibitor (MTI), through a one-step glyco-conjugation strategy. This construct is designed to deliver synergistic, orthogonal mechanisms of action (MOA) to address tumor heterogeneity and therapeutic resistance. In our studies, DR319-DP demonstrated excellent target and bystander killing and achieved more potent and durable tumor suppression than mono-targeting ADCs (with either TopoI or MTI payloads) and DR319-CPD3, across multiple CDX and PDX models. Additionally, our characterization confirmed that DR319-DP displayed excellent thermal and plasma stability, along with a favorable pharmacokinetic (PK) profile in mice and cynomolgus monkeys. DR319 is precision-engineered with an avidity-driven backbone to minimize the on-target toxicities that limit current Nectin-4 and Trop-2 therapies. The incorporation of synergistic dual-MOA payloads (DP) into DR319 provides a comprehensive strategy to maximize efficacy and overcome resistance. These preclinical data strongly support the clinical development of DR319 ADCs as a potential best-in-class therapeutic for solid tumors.

#4542 Zanidatamab modulates multiple pathways involved in tumor growth and survival and is efficacious post T-DXd.

Ankur Karmokar[1], Emanuele Loro[2], Al Hassan Kyakulaga[3], Desmond Lau[4], Nina Weisser[4], Genevieve Desjardins[4], Prajwal Raghunatha[4], Edwin Clark[1], Robin Humphreys[1], **Kedar S. Vaidya[1]**

[1]Oncology Research, Jazz Pharmaceuticals, Palo Alto, CA,[2]Bioinformatics, Jazz Pharmaceuticals, Palo Alto, CA,[3]DMPK, Jazz Pharmaceuticals, Palo Alto, CA,[4]Zymeworks, Vancouver, BC, Canada

Zanidatamab (Ziihera), a biparatopic antibody against the human epidermal growth factor receptor-2 (HER2), is currently approved in previously treated advanced HER2+ biliary tract cancer. To understand the specificity of binding, affinity of zanidatamab and the one-armed antibodies (OAAs) that comprise the Fab and scFv of zanidatamab, to WT HER2 extracellular domain (ECD) and mutein HER2 ECD domains were determined by surface plasmon resonance. The anti-HER2 Fab bound HER2 ECD II, and the anti-HER2 scFv bound HER2 ECD IV generated a Kd of 0.25 and 0.48 nM, respectively. Zanidatamab bound HER2 ECD with a lower Kd (0.047 nM) when compared to HER2 ECD II (0.31 nM) or HER2 ECD IV muteins (0.26 nM), demonstrating the avidity of Fab and scFv paratopes. To further understand MoA of zanidatamab, a multi-omics analysis including whole transcriptomics, proteomics and phospho-proteomics was performed on BT-474 HER2-amplified breast cancer xenograft tumors exposed to zanidatamab. A combination of unbiased analyses showed that zanidatamab significantly altered key pathways associated with DNA damage/repair, cell cycle, and MAPK signaling in a dose- and time-dependent manner. Expanded analysis of in vivo response demonstrated that zanidatamab is efficacious post T-DXd (trastuzumab deruxtecan) therapy. Mice bearing BT-474 HER2-amplified tumors were treated with T-DXd to regression and regrowth to baseline followed by treatment with zanidatamab. Zanidatamab was efficacious on these progressed tumors with 100% regressions following the first dose. These data demonstrate HER2 domain specific binding affinity, zanidatamab impacting key cellular pathways in driving *in vivo* efficacy, and potential utility in a post-T-DXd population.

#4543 A novel CDH17-targeted radioligand therapy overcomes resistance to microtubule and topoisomerase I inhibitor ADCs and achieves potent efficacy in GI-tract tumors.

Abdul Mondal[1], Garima Kaushik[1], Marina Bell[1], Maxwell Hilbert[1], Arnab Mukharjee[1], Dennis Beckford[2], Paul Heverly[2], Michael Ritchie[1], Kakajan Komurov[1]

[1]Corellia AI, Rockville, MD,[2]Champions Oncology, Rockville, MD

CDH17 (Cadherin 17) is a single-pass transmembrane protein that is highly and widely expressed in adenocarcinomas of the colon, stomach, and pancreas, as well as in subsets of ovarian and lung cancers. Here, we describe the development of a CDH17-targeted antibody-drug and a radioligand conjugate, their in vivo efficacy across a large panel of GI-tract PDX tumors, and the pharmacokinetic and safety profiles in non-human primates. A fully human monoclonal antibody against CDH17 was generated and conjugated to Deruxtecan at a DAR of 8 (CO-ADC-010). CO-ADC-010 demonstrated rapid internalization and potent CDH17-dependent cytotoxicity, along with favorable plasma stability, pharmacokinetics, and manufacturability. In a large-scale in vivo efficacy study, CO-ADC-010 achieved >90% tumor growth inhibition (TGI) in 80% of tested PDX models. This performance significantly surpassed a comparator ADC carrying MMAE at DAR 4, which showed a similar TGI in only 33% of models, suggesting better suitability of topoisomerase-based payloads for CDH17-directed delivery. In non-human primates, a single-dose exploratory toxicology study of CO-ADC-010 at 10, 30, and 45 mg/kg revealed no target-related toxicities at any dose, with all clinical and pathological findings deemed mild and reversible.Despite strong initial responses to CO-ADC-010, many tumors relapsed over prolonged treatment due to acquired resistance to the payload, while CDH17 expression was not altered. To overcome the limitations of the *de novo* and acquired resistance to the ADC treatments, we also developed a CDH17-targeted radioligand therapy (RLT) using the same antibody scaffold. We demonstrate that CDH17-targeted RLT shows broad and durable responses across the PDX panel, including full activity in models refractory to Deruxtecan-based ADCs, demonstrating the superiority of RLT in these indications in overcoming drug resistance and achieving durable responses. These data collectively support CDH17-targeted RLT as a promising therapeutic approach for CDH17-positive gastrointestinal malignancies.

#4544 Predictive biomarkers and combination strategies to overcome resistance to HER2- and TROP2-directed antibody drug conjugates with topoisomerase I inhibitor payloads in SCLC.

Kavya Ramkumar, C. Allison Stewart, Shui-Ping So, Runsheng Wang, Azusa Tanimoto, Alberto Duarte Jr., Jenna H. Gray, Li Shen, Lixia Diao, Yuanxin Xi, Qi Wang, Alejandra G. Serrano, Luisa M. Solis Soto, Jing Wang, Bingnan Zhang, Carl M. Gay, Lauren A. Byers

UT MD Anderson Cancer Center, Houston, TX

Treatment-naïve small cell lung cancer (SCLC) is highly sensitive to frontline chemotherapy; however relapsed SCLC acquires broad chemoresistance that renders conventional second line agents like topotecan, a topoisomerase inhibitor (TOP1i), largely ineffective. Recent clinical trials with surface targeting strategies such as antibody drug conjugates (ADCs) with TOP1i-based payloads have demonstrated strong responses in relapsed small SCLC. Identifying biomarkers of response and resistance to these agents will be important to optimize the effectiveness of this new therapeutic class. We previously showed that non-neuroendocrine SCLC tumors express low levels of *DLL3* and *SEZ6*, but high levels of *TACSTD2* (TROP2) and *ERBB2* (HER2). In this study, we examined the activities of different HER2- and TROP2-directed ADCs with TOP1i- and non-TOP1i-based payloads in SCLC cell lines. While target expression did not correlate with ADC sensitivity, SCLC cell lines with high SLFN11 levels showed greater sensitivity to TOP1i-based HER2- and TROP2-ADCs and their payloads. SLFN11 knockdown confirmed that SLFN11 loss reduces ADC sensitivity. Notably, combination with an ATR inhibitor sensitized resistant SLFN11-low SCLC cell lines to TOP1i-based ADCs. In contrast, sensitivity to a non-TOP1i-based HER2 ADC was not associated with SLFN11 expression. High cMYC and *ABCB1* (P-glycoprotein) levels were also associated with resistance to TOP1i-based ADC, but not to non-TOP1i ADCs. Mechanistically, TOP1i-based HER2- and TROP2-ADCs induced significant DNA damage and apoptosis. Increases in PDL-1 expression, STING-chemokine *CCL5,* along with extracellular ATP were also detected, indicating induction of immunogenic responses and supporting combinations with immunotherapy. Overall, these results identify SLFN11 as a clinical biomarker for patient selection and provide preclinical support for combinations with ATR inhibitor or using alternate non-TOP1i-based ADCs to overcome resistance to TOP1i-based HER2- and TROP2-ADCs.

#4545 Targeting heparan sulfate proteoglycans in pancreatic cancer with *Salmonella* expressing bacterial heparinase III.

Nancy Danielle Ebelt, Suvithanandhini Loganathan, Lara C. Avsharian, Edwin R. Manuel

Immuno-oncology, Beckman Research Institute of The City of Hope, Duarte, CA

Heparan sulfate proteoglycans (HSPG) regulate processes that drive tumor progression and promote treatment resistance in pancreatic ductal adenocarcinoma (PDAC), including increased fatty acid metabolism, sustained survival signaling, high fibrosis, and increased macropinocytosis. HSPG are regulated in a pro-tumor manner by site-specific cleavage of their heparan sulfate chains by mammalian heparanase; however, alternative cleavage by bacterial heparinase III (HepIII) has been shown to deactivate these proteins and prevent downstream pro-tumor signaling. To broadly target HSPG on tumor cells surfaces, we have expressed a highly active bacterial HepIII from *Bacteroides* on a clinically evaluated, attenuated strain of *Salmonella typhimurium*, YS1646 (YS-HepIII). This tumor-targeting YS both continuously expresses active HepIII enzyme and limits its expression to tumor tissue using an inducible system to circumvent toxicities that might arise from systemic HepIII treatment. Analysis of human PDAC cell lines treated with YS-HepIII *in vitro* as well as of human PDAC xenograft tumors treated *in vivo* shows evidence of decreased macropinocytosis, reduced survival signaling, lipid storage depletion, and decreased expression of translation machinery. These vulnerabilities sensitize tumors to FDA approved cancer therapies. This translatable therapeutic has the potential to improve PDAC patient survival, an unmet medical need.

#4546 HER2- and TROP2-antibody-drug conjugates in small cell lung cancer cell lines and 3D culture: Efficacy and role of target expression.

Jenna Gray, Kavya Ramkumar, C. Allison Stewart, Runsheng Wang, Alberto Duarte, Azusa Tanimoto, Robert J. Cardnell, Lauren Averett Byers, Carl M. Gay

UT MD Anderson Cancer Center, Houston, TX

Small cell lung cancer (SCLC) is an aggressive neuroendocrine cancer characterized by robust responsiveness to frontline chemotherapy and immunotherapy followed by rapid resistance and poor survival. Recently, cell-surface targeting drugs, such as T-cell engagers (tarlatamab) and antibody-drug conjugates (ADCs), have demonstrated significant responses in relapsed SCLC patients. Paradoxically, the efficacy of TROP2-ADCs and HER2-ADCs both have failed to correlate with the level of target expression in both SCLC and breast cancer patients, yielding difficulty in predicting the patient population which would receive benefit from these treatments. Treatment efficacy across a range of expression may be due to tumor heterogeneity and the delivery of the payload to a cell presenting the target resulting in a bystander effect on cells with low or no expression. SCLC cell lines and dissociated PDX tumors were evaluated for development of spheroids, which better mimic a solid tumor than 2D cell culture. The growth of these spheroids and PDX organoids were evaluated following treatment with HER2-ADC (trastuzumab deruxtecan), TROP2-ADC (sacituzumab govitecan), tarlatamab, activated T-cells, and combinations of these. Effect of complete siRNA knockdown of the surface target on the efficacy of targeted ADCs was also determined. HER2- and TROP2-ADCs slowed growth of the spheroids as compared to the control. Additionally, the combination of TROP2-ADC, tarlatamab, and T-cells caused contraction of the spheroids. Notably, the tarlatamab and T-cells arm demonstrated what is likely a pseudo-progression sometimes seen in patients as T-cells infiltrate and begin to kill tumor cells. Knockdown of ERBB2 and TACSTD2 demonstrated no demonstrable difference in ADC sensitivity. In conclusion, HER2- and TROP2-ADCs demonstrated efficacy in these models and may be used in combinatorial approaches in the future. Additionally, co-cultured cell line spheroids could provide a better model of tumor heterogeneity. Lastly, HER2- and TROP2- levels are not predictive biomarkers for ADC sensitivity, suggesting that other biomarkers should be explored to identify responsive patient populations.

#4547 TRO-02, a conditionally activated EGFR-targeting ADC incorporating TROCAD^{TM} and TROSIG^{TM} platforms, shows enhanced tumor selectivity and potent efficacy.

Young Hun Lee, Do Hyeon Kim, Eun Young Shim, Eunhyun Choi, Jong Un Cho, Myoungki Baek, Sung Ho Woo

TriOar Inc., Daejeon, Korea, Republic of

Epidermal growth factor receptor (EGFR) represents a validated therapeutic target across multiple solid tumor indications, including non-small cell lung cancer, head and neck squamous cell carcinoma, and colorectal cancer. However, EGFR expression in normal epithelial tissues, particularly skin, has limited the therapeutic window of EGFR-targeted therapies, often causing dose-limiting toxicities that impair clinical efficacy. To overcome this challenge, we developed TRO-02, a novel conditionally activated EGFR-targeting antibody-drug conjugate (ADC) that selectively activates in the tumor microenvironment while remaining masked in healthy tissues. TRO-02 is a DAR8-type ADC generated by conjugating a potent topoisomerase I inhibitor to panitumumab via a cleavable, stable, and hydrophilic TROSIG^{TM} linker. Furthermore, it incorporates our proprietary TROCAD^{TM} platform, which provides dual functions: (1) masking the panitumumab to prevent EGFR binding until proteolytic cleavage by tumor-associated proteases, and (2) guiding the ADC to the tumors by targeting annexin A1, which is highly expressed on tumor vasculature and facilitates transcytosis. This dual mechanism allows TRO-02 achieve both specific activation within the tumor microenvironment and selective tumor delivery. In vitro, the masked TRO-02 exhibited approximately 100-fold weaker binding to EGFR than the activated ADC, confirming effective suppression of target engagement. The unmasked TRO-02 displayed sub-nanomolar cytotoxicity against EGFR-expressing tumor cells, whereas the masked form showed markedly reduced cytotoxicity, with 30- to 100-fold lower potency depending on the cell type compared with the unmasked form. In MDA-MB-231 xenograft model, a single dose of 0.3 and 1 mg/kg achieved 65% and 98 % tumor growth inhibition, respectively. Rat plasma stability studies showed high stability, with >85% of intact ADC remaining after 7 days of incubation. Furthermore, pharmacokinetic analysis in rats demonstrated favorable PK properties ($t_{1/2}$ = 4.47 days, AUC = 163.52 day·μg/mL, CL = 25.05 mL/day/kg, Vd = 0.08 L/kg at 4 mg/kg), indicating high in vivo stability and low clearance. Collectively, these findings demonstrate that TRO-02 is a conditionally activated EGFR-targeting ADC with improved therapeutic index, achieving potent antitumor efficacy while minimizing on-target/off-tumor toxicity.

#4548 Therapeutically targeting B7-H6 with antibody-drug conjugates for diffuse large B-cell lymphoma.

Qiaoling Ye, Ye Lu, Chulin Sha, Peng Guo

Hangzhou Institute of Medicine, Chinese Academy of Sciences, Hangzhou, China

Background: Diffuse large B-cell lymphoma (DLBCL) remains fatal in ~40% of patients who relapse after first-line R-CHOP chemoimmunotherapy. Although CD19- and CD79b-targeted ADCs offer additional therapeutic options, their benefit is limited by on-target depletion of normal B cells, restricting the therapeutic window. To identify tumor-selective antigens with minimal normal-tissue expression, we performed multi-omics analyses across lymphoma datasets and identified B7-H6 (NCR3LG1) as a cancer-enriched surface protein. B7-H6 is undetectable in healthy tissues, consistently elevated in DLBCL, and further inducible by cellular stress, suggesting a therapeutically exploitable vulnerability.
Methods: Monoclonal antibodies against B7-H6 were conjugated to monomethyl auristatin E (MMAE) or DXd to generate B7-H6-targeted ADCs. Antigen-dependent cytotoxicity and selectivity were evaluated across B7-H6-high DLBCL cell lines and normal epithelial or hematopoietic cells. Tumor targeting and biodistribution were assessed by IVIS imaging using fluorescently labeled antibodies. Antitumor efficacy was evaluated in subcutaneous DLBCL xenograft models by tumor growth inhibition and treatment durability. Mechanistic studies assessed NKp30 engagement, immune-evasion pathways, and Fc-dependent effector activity.
Results: B7-H6 ADCs induced strong antigen-dependent cytotoxicity, eliminating B7-H6-high DLBCL cells while sparing normal cells. IVIS imaging demonstrated highly selective tumor accumulation with minimal off-tumor uptake in major organs, indicating a favorable biodistribution profile. In multiple DLBCL xenograft models, both MMAE- and DXd-based B7-H6 ADCs produced significant and sustained tumor regression, outperforming the unconjugated antibody and standard chemotherapy. Mechanistically, B7-H6 acted as an immune-modulatory ligand that engaged NKp30, enabling DLBCL cells to diminish NK-cell activity. B7-H6 ADCs counteracted this immune-evasion mechanism by directly delivering cytotoxic payloads to antigen-expressing cells. The intact Fc domain further promoted Fcγ-receptor-mediated NK- and macrophage-dependent effector functions, complementing payload-mediated killing.
Conclusions: B7-H6 is a tumor-selective, immune-regulatory, and mechanistically validated target for next-generation ADC development in DLBCL. B7-H6 ADCs demonstrate potent tumor-selective activity, favorable biodistribution, and dual mechanisms of antitumor action, providing a promising strategy to overcome the limitations of existing DLBCL therapies.

#4549 Discovery of HMPL-A580, a first-in-class antibody-targeted therapy conjugate (ATTC) of a novel PI3K/PIKK inhibitor payload linked to an anti-EGFR antibody.

Yu Cai, Xiangling Chen, Shishuang Chen, Na Yang, Yan Xu, Huijing Yu, Shiming Fan, Haibin Yang, Min Cheng, Nelson Ng, Jianlin He, Shaohui Shen, Weigang He, wei shao, xiaoming dai, Yajing Bai, Yizhen Yang, linfang wang, Jian Wang, Weihan Zhang, Yongxin Ren, Guangxiu Dai, Michael Shi, Weiguo Su

HUTCHMED Ltd., Shanghai, China

Background: EGFR is highly expressed in multiple types of solid tumors and well recognized as a driving force in tumorigenesis and disease progression. Modulation of the PI3K/AKT/mTOR (PAM) pathway is required for EGFR-mediated tumorigenesis or conferred resistance to EGFR-targeted therapy. Importantly, PAM pathway inhibition synergizes anti-EGFR therapy to enhance anti-tumor activity. Consequently, an Antibody-Targeted Therapy Conjugate ("ATTC") with a PI3K/PIKK small molecule inhibitor conjugated to an EGFR antibody is developed and expected to enhance anti-tumor efficacy of anti-EGFR therapy while reducing off-tumor toxicities of PAM inhibitors. HMPL-A580 is a first-in-class ATTC comprising of a highly selective and potent PI3K/PIKK inhibitor payload linked to an anti-EGFR IgG1 antibody, via a cleavable linker.
Methods: EGFR binding and internalization were evaluated by FACS. Confocal microscopic imaging was used to monitor endocytosis. Cell viability was measured by CCK-8 or luminescence in 3D cell viability assays. Multiple human xenograft tumors were applied in immune-deficient mice to investigate the anti-tumor activity of HMPL-A580.
Results: The payload of HMPL-A580 potently inhibited PI3K and PIKK family kinases, with IC_{50} ranging around 1 to 10 nM. Eurofins profiling across 418 kinases revealed the payload has excellent selectivity. By conjugating this potent payload with an anti-EGFR antibody via a cleavable linker, the ATTC compound HMPL-A580 demonstrated robust anti-tumor effect. Upon binding to EGFR-expression cancer cell line, HMPL-A580 underwent rapid internalization, lysosomal trafficking, payload release, and PAM and PIKK signaling inhibition to induce tumor cell apoptosis. In a 38-human solid tumor cell line panel, HMPL-A580 potently inhibited EGFR-expression tumor cell proliferation. The tumor cells harboring EGFR high expression, EGFR mut or PAM alterations were more sensitive to HMPL-A580. HMPL-A580 showed a strong bystander effect when EGFR-negative cells co-cultured with EGFR-expression cells. In human tumor xenograft models in mice, HMPL-A580, administered intravenously at 1~10 mg/kg once weekly for two weeks, demonstrated a dose / exposure-dependent anti-tumor activity in multiple EGFR-expression models, which is associated with much stronger target inhibition and suppression of downstream functions than antibody and payload alone treatment. The preliminary results demonstrated that HMPL-A580 was stable in human, monkey, rat and mouse plasma, and showed favorable PK property in cynomolgus monkeys.
Conclusion: HMPL-A580 demonstrates strong anti-tumor activity in preclinical models and good PK characteristics, supporting further clinical evaluation.

#4550 Tumor cell surface targeting of high-grade neuroendocrine carcinomas.

C. Allison Stewart, Kavya Ramkumar, Azusa Tanimoto, Runsheng Wang, Alberto Duarte, Angelo Chen, Alejandra Serrano, Yuanxin Xi, Lixia Diao, Qi Wang, Li Shen, Alexa Halliday, Shui Ping So, Luisa Solis Soto, Jing Wang, Bingnan Zhang, Lauren A. Byers, Carl M. Gay

UT MD Anderson Cancer Center, Houston, TX

High-grade neuroendocrine carcinomas (hgNECs) are aggressive malignancies that arise, most commonly, from the aerodigestive tracts, though, more rarely from other sites. Frustratingly, hgNECs are, initially, exquisitely sensitive to chemotherapy and/or radiation, but these responses are short-lived and inevitable relapses occur. Recent therapeutic developments have focused on hgNEC-associated cell surface antigens which, when targeted with an antibody, can serve as beacons for delivery of cytotoxic or immunologic payloads. T-cell engagers (TCEs) and/or antibody-drug conjugates (ADCs) against hgNEC antigens, including DLL3 and SEZ6, have demonstrated unprecedented responses in relapsed hgNECs. In some cases, such as small cell lung cancer (SCLC), the expression of these antigens is nearly ubiquitous and sensitivity to surface-targeting therapies is contingent primarily on payload. However, in other hgNECs, neuroendocrine (NE) features, including DLL3 and SEZ6 expression, are bimodal, which necessitates strategies for patient selection and alternative antigens for NE-low hgNECs. DLL3 levels have been evaluated by CLIA-validated immunohistochemistry in >340 patients at MDACC, including those diagnosed with rare extrapulmonary hgNECs (i.e., Merkel cell carcinoma, small cell of the breast, thyroid, etc.) for off-label use of tarlatamab (DLL3-targeting TCE). We utilized expression data from public hgNEC cohorts, as well as our own patient and preclinical model cohorts to characterize the relationship between known cell surface target expression (i.e., DLL3, etc.), various established biomarkers, including NE status and SLFN11, and sensitivity to surface targeting therapies. NE status defined two major subsets of hgNECs. NE-high specimens expressed high DLL3 and SEZ6 and were responsive to therapies targeting these antigens. In contrast, the NE-low subsets expressed high TROP2 and HER2. Surprisingly, target expression was not the dominant predictive biomarker for ADCs targeting these antigens as, instead, biomarkers of payload sensitivity (e.g. SLFN11 for topoisomerase I inhibitor payloads, P=0.01) offered superior insight into efficacy. Surface-targeting therapies represent a new paradigm for hgNEC therapeutics and while DLL3- and SEZ6-targeting therapies are showing promise across all hgNECs, their impact will be limited outside SCLC without patient selection. Utilizing biomarkers, including those for target expression, inflammatory potential, and payload sensitivity, will be critical to optimize drug selection for patients with these malignancies.

#4551 Nano-protomers targeted at tumor metastasis.

Rebecca Benhaghnazar[1], Dutsin Sirvinas[1], Joseph Aceves[1], Ryan Cho[1], Felix Alonso-Valenteen[2], Nelyda Gonzalez[2], Ravinder Abrol[3], Robin Shaw[4], Lali Medina-Kauwe[1]

[1]Biomedical Sciences, Cedars Sinai Medical Center, Los Angeles, CA,[2]Cedars Sinai Medical Center, Los Angeles, CA,[3]cal state university Northridge, Northridge, CA,[4]University of Utah, Salt Lake City, UT

Therapeutic failure in many highly aggressive cancers is often driven by early metastatic spread and poor delivery of effective treatments. Protein-based therapeutics represent an attractive alternative to small-molecule drugs due to their strong biological activity, target selectivity, and generally limited off-target effects. In this work, we investigated whether a HER3-directed fusion construct, HPK, can function as a carrier to transport three different protein payloads—GFP, Gelonin, and GJA1-20k—into HER3-positive tumor cells. By incorporating a simple tagging motif onto each cargo, we assessed HPK's capacity to load the proteins, recognize HER3 on the tumor cell surface, and promote internal uptake. Our findings show that HPK engages HER3 with high specificity, mediates efficient entry into cancer cells, and delivers intact, functional protein therapeutics. In vivo studies using melanoma and triple-negative breast cancer (TNBC) models further demonstrate that HPK enables payload activity within tumors. Collectively, these results identify HPK as a promising vehicle for successful protein delivery and highlight its potential utility in treating HER3-expressing cancers.

#4552 BSI-730, a first-in-class HER2xPD-L1 bi-specific ADC, demonstrates potent anti-tumor activity in HER2-low models via selective tumor cell killing and immune modulation.

Hui-Han Hu[1], Xiaoyao Hao[1], Yue Gao[1], Hongyan Li[1], Jinyu Liu[1], Jinge Zhao[1], Yi Lu[1], Liezhou Ji[1], Zhigang Ma[1], Mingjiu Chen[1], Kedan Lin[2]

[1]Biosion Inc., Nanjing, China,[2]Biosion USA Inc., Delaware, DE

Background: HER2-targeting ADCs approved worldwide benefit patients with HER2-positive/overexpression, yet the efficacy in HER2-low/null setting is limited. HER2-positive cancers often display adaptive resistance to HER2-targeted therapies, driven in part by PD-L1-mediated immunosuppression. Current clinical readouts on HER2-targeting ADCs combined with immune checkpoint modulators and PD-L1-targeting ADCs support the dual targeting design. Engaging HER2 and PD-L1 simultaneously enables enhanced internalization, selective tumor cell killing, and promoted anti-tumor immune response via payload-induced immunogenic cell death, subsequently improving efficacy in HER2-low/null patients.

Methods: The HER2xPD-L1 bi-specific antibody was composed of trastuzumab and the humanized anti-PD-L1 antibody identified from A/J mice immunized with PD-L1-ECD-Fc. The *in vitro* characterization of the bi-specific construct, including simultaneous dual target binding, internalization, and PD-1/PD-L1 signal blocking, has been reported previously. The bi-specific antibody was conjugated to exatecan via a glyco-site-specific conjugation technology in a DAR of 4. The *in vitro* cytotoxicity of BSI-730 was evaluated across cancer cell lines with various expression levels of HER2 and PD-L1. The anti-tumor activity of BSI-730 was investigated in animal models with low/null HER2 expression. The CMC developability as well as the stability of BSI-730 in mouse and human plasma were also assessed.

Results: BSI-730 simultaneously bound to HER2 and PD-L1 with high affinity and showed strong PD-1/PD-L1 signal blocking activity as well as efficient internalization regardless target expression. BSI-730 exhibited potent *in vitro* cytotoxic activity across cell lines with various expression levels of HER2 and PD-L1. The potency of BSI-730 was higher than and comparable to T-Dxd in HER2-low and high expressing cell lines, respectively. In a HER2-null breast cancer CDX model (MDA-MB-231), a single administration of BSI-730 resulted in a significant anti-tumor activity, which was higher than T-Dxd at the same dose level. BSI-730 possesses favorable CMC developability profile.

Conclusion: BSI-730 is a first-in-class HER2xPD-L1 bi-specific ADC tailored for HER2-low/null patients leveraging dual function of selective cell killing and immune modulation. The current pre-clinical data highlight the potential of BSI-730 in HER2-low setting and further pharmacokinetics, toxicity, and IND-enabling studies are underway.

#4553 BSI-128 (AK2024) enhances trastuzumab function and potentiates trastuzumab-deruxtecan activity across HER2-positive preclinical models.

Hui-Han Hu[1], Yinghui Dou[2], Hongyan Li[1], Liansheng Cheng[2], Jinyu Liu[1], Li Wei[2], Wenwen Dai[1], Daoqin Liu[2], Hui Wang[1], Ting Xu[2], Xiaoyao Hao[1], Yue Gao[1], Jinge Zhao[1], Yi Lu[1], Mingjiu Chen[1], Kedan Lin[3]

[1]Biosion Inc., Nanjing, China,[2]Anhui Anke Biotechnology (Group) Co., Ltd., Hefei, China,[3]Biosion USA Inc., Delaware, DE

Background: HER2-targeted therapy continues to evolve with the development of synergistic antibody combinations and novel payload-coupled modalities. Pertuzumab, the first approved trastuzumab-efficacy booster, demonstrates clinical benefit when combined with trastuzumab or trastuzumab-deruxtecan (T-Dxd) in HER2-positive breast cancer. BSI-128 (AK2024), a HER2-targeting monoclonal antibody identified through trastuzumab-synergy-based functional screening, has been characterized as a differentiated trastuzumab efficacy enhancer. Here, we further evaluate the synergistic cytotoxicity and anti-tumor activity of BSI-128 in combination with T-Dxd across HER2-positive *in vitro* and *in vivo* models.

Methods: The binding epitope of BSI-128 was compared with trastuzumab, pertuzumab, and a competing antibody of similar epitope class HLX22 analog (synthetic antibody generated from published Henlius sequence). Trastuzumab-mediated cell binding, HER2 internalization, and antibody-dependent cell-mediated cytotoxicity (ADCC) in the presence of BSI-128 were assessed by flow cytometry, pH-sensitive internalization probes, and ADCC reporter assay. *In vitro* cytotoxicity assays for BSI-128 ± T-Dxd were performed using a 1:1 antibody ratio. *In vivo* synergy studies evaluated BSI-128 with sub-efficacious doses of T-Dxd in HER2-positive xenograft models. The efficacy comparisons were performed against pertuzumab and HLX22 analog.

Results: BSI-128 engaged a HER2 epitope distinct from trastuzumab and pertuzumab and partially overlapping with the HLX22 analog. Despite epitope proximity, BSI-128 did not block trastuzumab binding, unlike the HLX22 analog. When combined at equal molar ratios, BSI-128 plus trastuzumab induced an approximate 2-fold increase in HER2 internalization compared with trastuzumab alone, and this enhancement exceeded that observed with pertuzumab or HLX22 analog combinations. Trastuzumab-mediated ADCC activity was maintained despite a 50% reduction in trastuzumab concentration when BSI-128 was added. Superior synergy of BSI-128 with trastuzumab relative to pertuzumab and HLX22 analog was confirmed in multiple HER2-positive *in vitro* and *in vivo* models. The presence of BSI-128 enhanced T-Dxd *in vitro* cytotoxicity by 2-fold in HER2-positive cells, whereas pertuzumab did not augment T-Dxd activity. BSI-128 also significantly potentiated the anti-tumor activity of T-Dxd in HER2-positive animal models.

Conclusion: These data robustly support BSI-128 as a differentiated trastuzumab-synergy antibody with improved performance relative to pertuzumab and the competing synergy antibody when combined with T-Dxd. These findings support the clinical development of BSI-128 plus T-Dxd for HER2-positive gastric cancer and other T-Dxd-approved indications. BSI-128 is currently being evaluated in a Phase 1 clinical trial.

#4554 Correlation of GI cancer antigens expression or association with patient survival outcomes using TCGA data.

Catherine Wu[1], Salique Hassan Shaham[2], Manish Tripathi[2]

[1]School of Medicine, University of Texas Rio Grande Valley, Edinburg, TX,[2]Oncology and Medicine ISU, South Texas Center of Excellence in Cancer Research, School of Medicine, The University of Texas Rio Grande Valley, McAllen, TX

Background: Cancers of the GI system, including the esophagus, stomach, colon, rectum, pancreas, liver, and biliary tract, comprise a significant portion of the global cancer burden. Recently, tumor-associated antigens (TAAs) have been shown to be useful in targeted cancer therapies and as markers. Although many GI cancer-related TAAs have been identified, treatments could be improved if they could target multiple antigen profiles simultaneously. This study first examines the expression of eight well-known GI cancer-specific TAAs: MMP7, TACSTD2, FOLR1, EPCAM, AADAT, MSLN, CLDN18, and CEACAM5; then it investigates their relationships with each other and with patient survival.

Methods: The Cancer Genome Atlas (TCGA) database; UALCAN was used to analyze the expression profile of TAA in normal and tumor samples, along with their significance. The effects of each TAA on survivability (Kaplan-Meier) and their significance were also analyzed. Survival plots and significance were calculated using log-rank tests. Lastly, Pearson correlations between the eight antigens across all seven cancers were obtained from the Gene Expression Profiling Interactive Analysis (GEPIA) portal.

Results: Across GI cancers show that TAA expression varies from that in normal tissue. MMP7 and MSLN are the most commonly upregulated. Most cancers exhibit three or more antigens that are increased, except for LIHC, where MMP7, EPCAM, and AADAT are downregulated. Only five of eight TAAs correlate with survival: EPCAM and MMP7 in STAD, FOLR1 and CLDN18 in LIHC, EPCAM in ESCA, and MSLN in PAAD. Correlations are mostly weak to moderate, except TACSTD2, which is negatively correlated with all ESCA antigens.

Conclusion: Since MMP7 and MSLN are broadly upregulated in GI cancers, these TAAs could be studied further as potential targets for pan-GI therapies. Cancers with multiple high-impact upregulations associated with survival may be suitable for treatment with multi-antigen antibody or CAR-T therapies, such as EPCAM and MMP7 for STAD. Additionally, the weak correlations among the TAAs suggest that somewhat independent mechanisms might regulate their expression. Therefore, this implies that therapies targeting a single antigen may not be fully effective.

Poster Session

#4558 First disclosure of a highly potent and selective oral KRAS G12V inhibitor PSTA-6208.

Wenxi Li, Lihong Hu, zhenzhen Zhu, Yingchun Liu, Tao Yu, Qianwei Jiang, **Chi-Chung Chan**, Jian Li, Shuhui Chen

Prospect Therapeutics, Nanjing, China

Introduction:
The KRAS G12V mutation is a major oncogenic driver in numerous cancers, promoting tumorigenesis and metastasis via constitutive activation of the MAPK pathway. Although the advent of KRAS-targeted therapy has yielded approved G12C inhibitors and clinical candidates for G12D and pan-KRAS inhibition, a significant unmet need remains for KRAS G12V-driven cancers. Here, we present PSTA-6208, a novel, orally bioavailable KRAS G12V inhibitor with sub-nanomolar cellular potency, marked efficacy in preclinical models, and high selectivity over wild-type KRAS, positioning it as a promising therapeutic candidate for KRAS G12V-positive tumors.
Methods and Results:
PSTA-6208 demonstrated potent and selective anti-proliferative activity in a panel of KRAS G12V-mutant cell lines, with IC_{50} values around 0.1 nM in most cells. In head-to-head comparisons, PSTA-6208 was 17-fold more potent than RMC-5127. This activity was mechanistically linked to MAPK pathway suppression, as evidenced by inhibition of phospho-ERK in KRAS G12V-mutant CAPAN-1 cells (IC_{50} = 1 nM). PSTA-6208 showed >500 folds selectivity over wild-type KRAS cells.
PSTA-6208 exhibited favorable oral pharmacokinetics across multiple species, with low systemic clearance, a prolonged half-life (~10 hours), and high plasma exposure. These properties supported once-daily dosing, which achieved tumor regression in mice at doses as low as 3 mg/kg.
PSTA-6208 induced profound, dose-dependent tumor growth inhibition and regression in multiple KRAS G12V xenograft models. In the NCI-H727 model, daily oral administration of PSTA-6208 at 1, 3, and 10 mg/kg for 21 days resulted in tumor growth inhibition (TGI) of 82%, 108%, and 112%, respectively. Notably, treatment with PSTA-6208 at 10 mg/kg led to near-complete tumor regression (complete response) by Day 21. All treatment groups were well-tolerated, with no significant adverse effects reported.
Conclusions:
PSTA-6208 is a potent, highly selective, and orally bioavailable KRAS G12V inhibitor. Its compelling preclinical profile—including sub-nanomolar cellular potency, exceptional selectivity, favorable pharmacokinetics, and robust *in vivo* efficacy culminating in tumor regression at low doses—strongly supports its further development as a clinical candidate for KRAS G12V-driven cancers.

#4559 PLM-103: A dual-mechanism YES1/YAP pathway inhibitor exhibiting broad antitumor efficacy and immuno-oncology synergy.

Soo Jin Kim[1], Kyoung Mee Kim[1], Jaehyeon Kim[1], Soo Yeon Jang[1], **Yong-Chul Kim**[2]

[1]PeLeMed, Co. Ltd., Seoul, Korea, Republic of,[2]Gwangju Institute of Science & Technology, Gwangju, Korea, Republic of

The Hippo-YAP pathway is a key regulator of tumor progression, metastasis, and immune evasion. Aberrant activation of YAP promotes epithelial-mesenchymal transition (EMT), suppresses immune cell infiltration, and contributes to poor immune responsiveness in various cancers. YES1, a Src family kinase, functions as a critical upstream activator of YAP nuclear signaling, and its oncogenic amplification has been reported in multiple YAP-driven malignancies. Therefore, pharmacologic inhibition of YES1 represents a promising approach to suppress YAP (Yes-Associated Protein) activity and identify new therapeutic strategies targeting YAP-dependent tumors. PLM-103 is a novel small-molecule inhibitor that potently inhibits YES1 kinase and concurrently suppresses TEAD-mediated transcription, leading to robust inactivation of YAP signaling. Through this dual mechanism, PLM-103 achieves TEAD inhibition comparable to classical TEAD inhibitors but exhibits superior suppression of cell proliferation and downstream oncogenic signaling, translating into potent in vivo antitumor efficacy. Unlike conventional TEAD inhibitors whose activity is largely restricted to mesothelioma, PLM-103 demonstrates broad spectrum antitumor activity across YAP-driven cancers including esophageal squamous cell carcinoma (ESCC), renal cell carcinoma (RCC), pancreatic ductal adenocarcinoma (PDAC), and mesothelioma. In the KYSE70 ESCC xenograft model, PLM-103 monotherapy exhibited a remarkable antitumor effect, achieving complete tumor regression (CR) in 4 out of 7 mice. In this in vivo model, PLM-103 treatment significantly reduced the expression of CYR61 and CTGF, YAP target genes, confirming effective suppression of YAP transcriptional activity in tumors. Mouse PK study demonstrated that PLM-103 is orally available and provides sufficient systemic exposure to exert its pharmacologic effects. Additional ADME and safety profiling, including metabolic stability, plasma protein binding, and hERG assay, confirmed that PLM-103 possesses favorable drug-like properties suitable for further development. When combined with the immune checkpoint inhibitor anti-PD-1 antibody, PLM-103 exhibited remarkable synergistic efficacy characterized by enhanced infiltration of $CD8^+$ effector T cells and reduced regulatory T (Treg) cells within the tumor microenvironment. The combination of PLM-103 with anti-PD-1 therapy resulted in durable complete responses, underscoring the potent immunomodulatory and immune-potentiating capacity of PLM-103. Collectively, these findings establish PLM-103 as a highly promising next-generation anticancer agent that integrates targeted YES1/YAP pathway inhibition with robust immunomodulatory activity, providing dual and complementary mechanisms capable of addressing a broad range of YAP-driven malignancies.

#4560 CTPS1 as a metabolic vulnerability and novel therapeutic target in breast and ovarian cancer.

Xiyin Wang[1], Michael Emch[1], Lauren Voll[1], Rebecca Epp[2], Esther Rodman[3], Noa Odell[1], Hannah Smith[1], Nicole Pearson[1], Xiaonan Hou[4], Matthew Goetz[4], Scott Kaufmann[4], S. John Weroha[4], Phillip Beer[5], John Hawse[1]

[1]Department of Biochemistry and Molecular Biology, Mayo Clinic, Rochester, MN,[2]Case Western Reserve University, Cleveland, OH,[3]Vincent Center for Reproductive Biology, Mass General Brigham, Boston, MA,[4]Department of Oncology, Mayo Clinic, Rochester, MN,[5]Step Pharma, Saint-Genis-Pouilly, France

Breast and ovarian cancers are major causes of cancer mortality in women with frequent relapse after curative intent treatment, underscoring the need for novel therapeutics. To this end, we identified CTPS1 as an essential gene in multiple breast and ovarian cancer models, including those resistant to chemotherapy and PARP inhibitors.

CTPS1 and CTPS2 are responsible for *de novo* synthesis of cytidine triphosphate (CTP) which is required for DNA/RNA polymerization, phospholipid synthesis and protein glycosylation. We found CTPS1 to be the predominant isoform expressed in cancer cells, with significantly higher levels in advanced and resistant disease models compared to normal tissue, benign lesions and treatment naïve cancers. Using CTPS1 siRNAs and CTPS1-dTAG (degradation tag) cell lines, we discovered that depletion of CTPS1 induces S-phase cell cycle arrest followed by apoptosis.

Leveraging a first-in-class, highly selective, and orally bioavailable CTPS1 inhibitor (STP938) developed by Step Pharma, we identified nanomolar IC50 values across a panel of cell lines, both in 2D and 3D culture systems, and potent anti-neoplastic activity *ex vivo* and *in vivo* using patient-derived xenograft (PDX) models. STP938 also synergized with standard-of-care chemotherapy agents and PARP inhibitors, including in therapy-resistant models.

Given the essentiality of CTP for biosynthetic processes, we performed bulk and single cell RNA-seq, total and phospho-proteomics, metabolomics, and lipidomic strategies to examine changes induced by acute and chronic STP938 exposure. This revealed that cancer cells are able to overcome pharmacologic CTPS1 inhibition by rewiring of pyrimidine and purine synthesis pathways, upregulation of the pentose phosphate pathway, and extensive remodeling of lipid synthesis pathways including shifts in PC/PE content, increased lysophospholipid production, and altered mitochondrial lipid composition (decreased cardiolipin and increased PG).

To identify genetic drivers of STP938 resistance and synthetic lethal vulnerabilities, we performed a genome-wide CRISPR knockout screen together with a PRISM drug sensitivity screen. Genes regulating dNTP biosynthesis, S-phase progression, and RNA processing were identified as primary escape mechanisms, while DHODH inhibitors, purine and nucleoside analogs, and mitosis modifiers were implicated as synthetic lethal opportunities.

Notably, we discovered that 25% of ovarian tumors lack CTPS2 protein expression, suggesting near complete reliance on CTPS1 for survival. Thus, a Phase 1a/b clinical trial of STP938 (NCT06297525) has been initiated, including an expansion cohort for patients with CTPS2-null ovarian tumors. These laboratory discoveries and ongoing clinical efforts aim to enable broader uptake of this novel therapeutic approach to improve long-term outcomes in patients with CTPS1-dependent disease.

#4561 Cbl-b inhibition with ISM3830 restores innate and adaptive immunity and demonstrates antitumor activity against solid tumors *in vitro* and *in vivo*.

Zhongying Cao[1], Fanye Meng[1], Jinxin Liu[1], Zhilin Ning[1], Jiaojiao Yu[1], David Gennert[2], **Suguna Rachakonda**[2], Man Zhang[1], Xin Cai[1], Xiao Ding[1], Alex Zhavoronkov[2]

[1]Insilico Medicine, Shanghai, China,[2]Insilico Medicine, Cambridge, MA

Therapeutic inhibition of immune checkpoints, such as CTLA-4 and PD-1/PD-L1, has dramatically improved outcomes for cancer patients, yet there remains a critical need for the majority of patients who relapse or insufficiently respond to current checkpoint inhibitor treatments. Cbl-b is an intracellular immune checkpoint downstream of both CD28 and CTLA-4 signaling that negatively regulates activation of T cells, NK cells, dendritic cells, and mast cells, representing a promising, distinct target for cancer immunotherapy. Here, we describe a novel Cbl-b inhibitor, ISM3830, which demonstrated strong Cbl-b inhibition *in vitro* and *in vivo*, leading to enhanced activation of primary human T cells and NK cells.

Comprehensive metabolic and pharmacokinetic profiling showed that ISM3830 has low drug-drug interaction potential, minimal off-target risk, and low in vitro clearance across multiple species. ISM3830 treatment led to increased IL-2 and IFN-γ release in primary human T and NK cells upon anti-CD3 stimulation, with minimal cytotoxicity up to 10 μM. ISM3830 treatment also restored T cell function in the immunosuppressive tumor microenvironment in the presence of PGE2 or adenosine and significantly recovered the function of exhausted T cells. Oral administration of ISM3830 suppressed tumor growth in CT26 and MC38 syngeneic mouse models, with a significant synergistic effect when combined at a dose of 10 mpk with anti-PD-1, achieving a 96% tumor growth inhibition (TGI) rate and complete tumor regression (CR) in 6 out of 8 animals. Notably, ISM3830 also conferred protection against CT26 tumor rechallenge in cured mice by increasing effector memory T cells and NK cells, indicating ISM3830 induced long-term tumor immunity. In vivo pharmacokinetic studies also demonstrated low clearance (CL < 30% Qh) and an average oral bioavailability of 71% across preclinical species, including mice, rats, dogs, and monkeys. Toxicology studies in mice and dogs indicated a favorable safety profile compared to other small-molecule Cbl-b inhibitors. Human dose projection suggested lower effective doses with sustained target coverage. These data together demonstrate ISM3830 potently activates the innate and adaptive immune responses, sustains antitumor efficacy in animal models, and synergizes with other immune checkpoint inhibitors while maintaining favorable pharmacokinetic and safety profile suitable for clinical development. This work supports the further development of ISM3830 as an immune checkpoint inhibitor to treat various solid tumors.

#4562 ISM6210, a potent and selective CDK4 inhibitor for the treatment of HR+/HER2- breast cancer.

Yilin Yang[1], Zhongying Cao[1], Zhisen Zhang[1], Fanye Meng[1], Jinxin Liu[1], Jiamin Zheng[1], Zuoxiao Shi[1], Ling Wang[1], David Gennert[2], **Suguna Rachakonda**[2], Xiao Ding[1], Xin Cai[1], Man Zhang[1], Feng Ren[1], Alex Zhavoronkov[2]

[1]Insilico Medicine, Shanghai, China,[2]Insilico Medicine, Cambridge, MA

CDK4/6 kinases drive the G1-S cell cycle transition, and overactive cyclin-CDK4/6 complexes are common across cancer types. While clinically approved CDK4/6 inhibitors have benefited patients with HR+/HER2- breast cancer, their efficacy is constrained by dose-limiting hematological toxicities, particularly CDK6-driven myelosuppression. Hematopoietic stem cell activation relies primarily on CDK6, but breast cancer cells are more dependent on CDK4, suggesting a potential therapeutic window for a CDK4-selective inhibitor. Here, we report the development and preclinical characterization of ISM6210, an orally bioavailable CDK4 inhibitor with high selectivity over CDK6.

ISM6210 demonstrated potent inhibition of the CDK4/Cyclin D1 complex in enzymatic assays with nanomolar IC50 values and good selectivity over CDK6 and other CDKs. Kinome profiling revealed minimal off-target activity, confirming its high selectivity. In cellular assays, ISM6210 selectively targeted CDK4-dependent breast cancer cells over CDK6-dependent cells. Notably, in human hematopoietic stem cell assays, ISM6210 exhibited an IC50 value about 30-fold higher than the dual CDK4/6 inhibitor Palbociclib against human hematopoietic stem cells, suggesting reduced myelosuppressive potential. Mechanistically, ISM6210 effectively blocked Rb phosphorylation and the G1/S cell cycle transition, resulting in growth arrest in HR+ breast cancer cell lines. In vivo, ISM6210 achieved robust anti-tumor activity at 30 mg/kg BID across multiple HR+ breast cancer xenograft models with notable tumor enrichment.

In addition to its robust biological potency and high selectivity, ISM6210 exhibited favorable drug-like properties, including desirable in vitro ADMET profiles, excellent in vivo exposure and clearance, and good oral bioavailability across multiple preclinical species. Collectively, these findings establish ISM6210 as a potent and selective CDK4 inhibitor that delivers strong efficacy and a promising hematologic safety margin for HR+/HER2- breast cancer treatment.

#4563 Small molecules inhibited dysregulated STAT3-proinflammatory axis and induced antitumor responses in pancreatic and breast cancer.

Rasaq Akinsola[1], Monday Ogaba Ogese[1], Lihong Huo[2], Yue Chen[1], Francisco Lopez-Tapia[1], Richard T. Waldron[3], Aurelia Lugea[3], Stephen J. Pandol[4], James Turkson[1]

[1]Department of Medicine, Division of Medical Oncology and Cancer Biology Program, Cedars-Sinai Medical Center, Los Angeles, CA,[2]Department of Medicine, Division of Gastroenterology, Cedars-Sinai Medical Center, Los Angeles, CA,[3]Department of Medicine, Division of Gastroenterology and Cancer Biology Program, Cedars-Sinai Medical Center, Los Angeles, CA,[4]Department of Medicine, Division of Gastroenterology, and Cancer Therapeutics Program, Cedars-Sinai Medical Center, Los Angeles, CA

Signal transducer and activator of transcription 3 (STAT3) is a promising anti-cancer therapeutic target that promotes tumor development and progression. To study the STAT3-specific mechanisms underpinning tumor formation and that underlie the responses to its targeting, we used the validated mutant *Kras*^{G12D} (KC) mice that under high-fat diet (HFD) has a high pancreatic adenocarcinoma (PDAC) incidence and progression, human cancer-associated fibroblasts (CAFs), PDAC and triple-negative breast cancer (TNBC) cells and xenograft models and interrogated STAT3 activity with two small molecule inhibitors, H182 and H279. Human CAFs, PDAC and TNBC cells harboring aberrantly-active STAT3 responded to growth factor and cytokine stimulation by further enhancing phospho-tyrosine-STAT3 (pYSTAT3) levels. Likewise, upon feeding KC mice the HFD, pYSTAT3 was strongly increased in cells that tracked along a path of altered phenotype, including acinar-ductal-metaplasia (ADM) elements, neoplastic ducts, stromal and immune cells, but was not present in normal acinar cells, in parallel with the development of pancreatic intraepithelial neoplasia (PanIN) lesions. To define the contexts of the pYSTAT3 and the phenotype changes, we probed the cells and mouse models with the inhibitors. The pYSTAT3 levels in the cells were suppressed early by H182 and H279 treatment. In PDAC cells, prolonged treatments with H182 severely shifted the secretome, including decreased IL-6-stimulated production of IL-8, SERPINE1, CXCL1, CXCL12, CCL2 and MIF, repressed the expression of genes involved in immune evasion, angiogenesis, cell proliferation, migration, oxidative stress and tumor progression, and upregulated tumor suppressor genes. In PDAC or TNBC cells, similar prolonged treatments with H182 or H279 also suppressed the expression of anti-apoptotic Mcl-1, Bcl-xL and c-Myc, pro-invasive matrix metalloproteinase 9, and the epithelial-mesenchymal transition proteins, SNAIL, Twist, Snug and ZEB, while inducing E-cadherin and pro-apoptotic Bax, Bad, PUMA and BIM. Treatments of PDAC and TNBC cells with the inhibitors also led to DNA damage, γH2AX, ATM and Chk2 induction, mitochondrial oxygen consumption rate impairment, cell cycle arrest at the G2/M phase, decreased viability, migration and invasiveness *in vitro*, and apoptosis. H182 treatment prevented acinar cell de-differentiation into ADM/PanINs, in parallel with decreased pro-fibroinflammatory gene expression in the pancreas, such as CXCL12, CCL2, and CCL5 in HFD-fed KC mice, and inhibited growth of PDAC subcutaneous xenografts in mice. Together, the findings support a hyperactivated STAT3-pro-fibroinflammatory cytokines and chemokines axis in diverse cell types within tumors that is critical in tumor initiation and progression. Inhibiting STAT3 functions may be a preventative and therapeutic approach against cancer.

#4564 Dual mechanisms of PARP7 inhibition driving potent antitumor activity.

Iksoo Jang, Dajeong Kim, Daehyeon Seong, Jeong Yoon Shin, Kyu Hwan Kim, SeungHyun Song, Joon Yonug Hwang, Hong Sik Han, Kyung Seok Lee, Jongho Cho, Ki Moon Ryu, Mi-Kyung Kim

Dong-A ST, Yongin-si, Korea, Republic of

PARP7 is a mono-ADP-ribosyltransferase that transfers a single ADP-ribose moiety to its substrates, thereby modulating protein function and contributing to the regulation of type I interferon (IFN) signaling and cellular homeostasis. In cancer models, PARP7 inhibition exhibits strong antitumor activity through a dual mechanism involving activation of the type I IFN pathway and direct tumor-intrinsic effects within cancer cells. We have developed a couple of series of novel PARP7 inhibitors, and in this study, we focused on characterizing the molecular features associated with responsiveness to PARP7 inhibitors in parallel with mechanistic studies using the clinical-stage benchmark, RBN-2397. First, in the context of antitumor immune activation, we hypothesized that interferon-stimulated gene (ISG) induction upon PARP7 inhibition is positively correlated with antitumor activity. In mouse syngeneic models, cancer cells showing strong ISG induction upon PARP7 inhibition exhibited greater antitumor responses. Combination with chemotherapeutic agents that increase cytosolic double-stranded DNA (dsDNA) further enhanced ISG induction and antitumor activity. To define ISG induction responsiveness, we screened more than 40 human cancer cell lines and categorized them as ISG responders or non-responders. Responders exhibited gene expression patterns characterized by elevated innate immune signaling and reduced genome stability. In addition to its immuno-oncological activity, PARP7 inhibition exerts an intrinsic, cell-autonomous antitumor effect, suggesting a dual mechanism of action for PARP7-targeted therapy. This intrinsic cytotoxic effect acts independently of the catalytic inhibition responsible for immune activation. While multiple mechanisms have been proposed, our data support that a PARP7 inhibitor-induced chromatin-associated trapping process represents a critical event leading to nuclear accumulation of PARP7 and subsequent DNA damage. Additionally, we confirmed that intracellular PARP7 expression is essential for PARP7 inhibitor-induced cytotoxicity. Furthermore, using the CRISPR-Cas9 system, we validated an additional key factor involved in this intrinsic cytotoxicity. Collectively, our findings demonstrate that PARP7 inhibition elicits a dual mechanism involving ISG induction and intrinsic cytotoxicity, resulting in robust antitumor activity. The key regulatory factors underlying this dual mechanism may serve as potential biomarkers for patient selection in future clinical trials and help identify individuals most likely to benefit from PARP7-targeted therapy.

#4565 Preclinical evaluation of GFH276 monotherapy and combination therapy for RAS-mutant tumors.

Feng Yan, Jichen Zhao, Jingyang Zhang, Siyuan Le, Fusheng Zhou, Jiong Lan, Qiang Lu

Genfleet Therapeutics, Shanghai, China

Background: RAS mutations are found in 90% PDAC, 50% CRC, 30% NSCLC, 27% cholangiocarcinomas, 20% uterine corpus endometrial carcinomas and some other types of tumors. KRAS G12C was the first RAS mutant clinically conquered, yet targeting other isoforms remains unresolved. GFH276, an investigational molecular-glue panRAS(ON) inhibitor currently being evaluated in a Phase 1 trial (NCT07198321), has previously shown potent activity across RAS-mutant models and demonstrated MOA-derived superiority to SIIP-based KRAS inhibitors and dose-level advantage over the competitor compound. Here we present a further pre-clinical assessment of GFH276 monotherapy and its rational combination with distinct therapeutic agents.
Methods: BULB/c nude mice bearing CDX tumors harboring different KRAS mutations were used to determine the anti-tumor efficacy of GFH276 monotherapy or its combination with Cetuximab. BULB/c mice bearing CT-26 tumors engineered to harbor KRAS G12C mutation were used to compare GFH276 monotherapy with its combination with an anti-mouse PD-1 mAb.
Results: Across a serial of NSCLC, CRC and PDAC CDX models, daily oral administration of 3 mg/kg of GFH276 drove significant anti-tumor efficacy. In a cholangiocarcinoma and an endometrial tumor models, GFH276 also inhibited tumor growth in a dose-dependent manner. Considering the validated synergism between KRAS G12C inhibitors and EGFR mAbs in clinic, combination therapy of GFH276 plus Cetuximab was also investigated and the result showed that co-administration with Cetuximab enhanced the efficacy of GFH276 significantly. Coordination between GFH276 and immunotherapy was also explored in the syngeneic CT26-KRAS^{G12C} mouse model. In this model, 21-day treatment with 0.3-3 mg/kg of GFH276 elicited significant anti-tumor effect and all animals from the 3 mg/kg group were tumor free. Co-treatment with an anti-mouse PD-1 antibody not only synergized with GFH276 dosing , but also helped maintain the tumor free status after GFH276 dosing was stopped for another 79 days.
Conclusions: GFH276 monotherapy was effective in mouse models harboring tumors originating from most common RAS-mutant cancers. GFH276 also showed synergistic effects with anti-EGFR mAb and immunotherapy. These results depict the promising therapeutic potential of GFH276 in broad indications via different application strategies.

#4566 Discovery and characterization of CKD-9001, a novel PARP1-selective inhibitor and DNA trapper with enhanced efficacy and an improved toxicity profile in HRD cancers.

Yuji Kim, Moosung Ko, Gun-Woo Park, Yoo-Kyung Song, Hye-Jin Hong, Keesoo Nam, Junho Cho, Younghue Han, Jaeyoung Lee, Dahae Lee, Jiyeon Back, Seong-Ho Hong, Ju Young Song, Jinsol Park, Hyunmo Yang, Nina Ha, Se-Mi Kim, In-Chang Hwang, Changsik Lee, Sung Jun Kang

CKD Pharmaceutical Corp., Seoul, Korea, Republic of

Poly(ADP-ribose) polymerase (PARP) inhibitors have been established as therapeutic agents for patients with homologous recombination repair (HRR) deficiencies, such as BRCA1/2 mutations, in ovarian, breast, prostate, and pancreatic cancers. Currently, pan-PARP inhibitors that have received approval target both PARP1 and PARP2, demonstrating potent antitumor activity. However, PARP2 inhibition has been identified as a major contributor to hematologic toxicity, resulting in dose limitations and treatment discontinuation. Given PARP1's role as the primary enzyme in sensing single-strand breaks and regulating DNA repair processes, the development of PARP1-selective inhibitors has emerged as a promising strategy to achieve potent antitumor efficacy while minimizing toxicity compared with conventional pan-PARP inhibitors. In this study, we present the preclinical development of CKD-9001, a novel PARP1-selective inhibitor and potent DNA trapper.We developed CKD-9001, a next-generation PARP1-selective inhibitor, and evaluated its preclinical efficacy and toxicity profile against the leading agents, olaparib and saruparib. Our findings demonstrated excellent selectivity for PARP1, as evidenced by its high levels of enzymatic inhibition and DNA-trapping potency.*In vitro* studies demonstrated that CKD-9001 exhibited potent antiproliferative effects, with IC_{50} values ≤10 nM in HRR-deficient and BRCA2-knockout cancer cell lines. *In vivo* studies showed remarkable antitumor efficacy of CKD-9001, even at low doses, in HRR-deficient animal models. Furthermore, pharmacokinetic and safety analyses confirmed that CKD-9001 markedly reduced hematologic toxicity and significantly improved the safety margin compared with conventional pan-PARP inhibitors. In addition, we found that CKD-9001 was capable of penetrating the blood-brain barrier (BBB).In conclusion, CKD-9001 is a next-generation PARP1-selective inhibitor that successfully combines enhanced efficacy with remarkably low toxicity, demonstrating outstanding therapeutic potential in HRD cancers.

#4567 A novel PARP7 inhibitor exhibits dual antitumor activity through immune activation and tumor-intrinsic growth inhibition.

Dajeong Kim, Iksoo Jang, Daehyeon Seong, Jeongyoon Shin, Kyu Hwan Kim, SeungHyun Song, Joon Yonug Hwang, Hong Sik Han, Kyung Seok Lee, Boram Lee, Soo-Jung Choi, Song-Yi Lee, Dae Young Lee, Jinhoon Jeong, Hojeong Hong, Haneol Kim, Jongho Cho, Ki Moon Ryu, Mi-Kyung Kim

Dong-A ST, Yongin-si, Korea, Republic of

PARP7 (TIPARP, TCDD-induced poly[ADP-ribose] polymerase) is a stress-inducible mono-ADP-ribosyltransferase frequently overexpressed across multiple cancer types. Elevated PARP7 expression has been implicated in tumor progression, immune evasion, and the establishment of an immunosuppressive tumor microenvironment (TME). Mechanistically, in cancer cells, PARP7 negatively regulates type I interferon (IFN) signaling by mono-ADP-ribosylating TBK1, thereby suppressing nucleic acid sensing and dampening antitumor immune activation within the TME. Pharmacological inhibition of PARP7 restores IFN signaling and potentiates immune-mediated antitumor responses. In addition to immune activation, PARP7 inhibition exerts tumor-intrinsic antitumor effects through multiple cellular mechanisms, culminating in direct tumor cell growth inhibition. Collectively, these findings suggest that targeting PARP7 may offer superior therapeutic potential compared with current immuno-oncology (IO) approaches by coupling immune activation with tumor-intrinsic control. In this study, we identified a novel small-molecule PARP7 inhibitor, referred to as compound 1, which exerts dual anticancer mechanisms. Compound 1 demonstrated potent inhibition of PARP7 enzymatic activity in biochemical assays and markedly reduced global mono-ADP-ribosylation (MARylation) in PARP7-inducible SK-MES-1 cells, thereby confirming its activity at the cellular level. From an IO perspective, compound 1 robustly induced interferon-stimulated gene (ISG) expression in RAW-Lucia ISG cells and various cancer cell lines. It also enhanced the activation of multiple immune cell subsets, showing pronounced effects particularly under TME-mimicking conditions. Compound 1 exhibited strong monotherapy activity in syngeneic tumor models and achieved complete responses (CR) when combined with anti-PD-1 or standard chemotherapies. Beyond immune modulation, PARP7 inhibition also mediates tumor-intrinsic growth inhibition. We identified a chromatin-associated trapping mechanism as a primary driver of these intrinsic effects. Correspondingly, compound 1 produced potent growth inhibition across multiple cancer cell lines, including NCI-H1373, and significantly suppressed tumor growth in xenograft models. Notably, across both mechanisms, compound 1 demonstrated comparable or superior activity to RBN2397, a PARP7 inhibitor under clinical evaluation. In summary, our findings highlight PARP7 inhibition as a promising therapeutic strategy that integrates immune activation with tumor-intrinsic growth inhibition. The novel PARP7 inhibitor, compound 1, consistently demonstrated this dual mechanism across diverse preclinical models, supporting its potential as a next-generation therapeutic candidate with both immune-mediated and tumor-intrinsic antitumor activity.

#4568 Inhibition of nicotinamide phosphoribosyltransferase (NAMPT) impairs cellular viability, affects energy metabolism, induces DNA damage, and drives tumor regression in preclinical models of neuroblastoma.

Amy Yu[1], Sophia Varriano[1], Victor J. Collins[1], Ariana E. Nelson[1], Abantika Chakraborty[1], Unsun Lee[1], Amy James[2], Kristine Isanogle[2], Nimit Patel[3], Joong Kim[3], Ming Sun[1], Ye Yang[4], Ying Wu[5], Krithika Bhuvaneshwar[5], Bhushan L. Thakur[6], Arnulfo Mendoza[1], Sameer H. Issaq[7], Mirit I. Aladjem[6], John F. Shern[1], Parthav Jailwala[5], Joseph D. Kalen[3], Simone Difilippantonio[2], Craig J. Thomas[8], Daniel R. Crooks[4], Rosa Nguyen[1], Carol J. Thiele[1], Christine M. Heske[1]

[1]Pediatric Oncology Branch, National Cancer Institute, Bethesda, MD,[2]Animal Research Technical Support, Laboratory Animal Sciences Program, Frederick National Laboratory for Cancer Research, Frederick, MD,[3]Small Animal Imaging Program, Laboratory Animal Sciences Program, Frederick National Laboratory for Cancer Research, Frederick, MD, [4]Clinical Cancer Metabolism Facility, Urologic Oncology Branch, National Cancer Institute, Bethesda, MD,[5]Advanced Biomedical Computational Science, Frederick National Laboratory for Cancer Research, Frederick, MD,[6]Developmental Therapeutics Branch, National Cancer Institute, Bethesda, MD,[7]Urologic Oncology Branch, National Cancer Institute, Bethesda, MD,[8]Division of Preclinical Innovation, National Center for Advancing Translational Sciences, Rockville, MD

Cancer cell metabolism is altered to meet increased metabolic demands of proliferating cancer cells. Reprogrammed metabolic pathways represent cell type and context specific therapeutic opportunities. Targeting NAD^+ production via inhibition of the NAD^+ salvage pathway presents one potential opportunity, as NAD^+ is essential for energy metabolism and other downstream processes. Presently, NAMPT is the only clinically targetable enzyme in this pathway. We conducted a high-throughput cancer cell line screen and identified that neuroblastoma (NB) cells are significantly more sensitive to NAMPT inhibitors (NAMPTis) than most other solid tumors, with IC50 values >20-fold less than the cell line panel average. NB is the most common extracranial solid tumor in children, accounting for 15% of pediatric cancer deaths. We used 2 clinical NAMPTis under early phase study (OT-82 and KPT-9274) to validate our drug screen results in 10 molecularly diverse NB cell lines including 2 NB PDX-derived cell lines. We investigated the mechanistic effects of NAMPT inhibition on NAD^+-dependent pathways and analyzed the *in vivo* effects of OT-82 in 3 orthotopic NB models. Treatment of NB cell lines with NAMPTis results in failure of cells to proliferate following replacement with drug-free media at 48h, suggesting irreversible cell death. Furthermore, NAMPTi treatment results in neither apoptotic nor necroptotic cell death but induces autophagy. NAMPTis reduce intracellular NAD^+ levels and co-treatment with NMN, the product of NAMPT, fully rescues cell viability, verifying NAD^+-dependence and on-target activity of each NAMPTi. Moreover, we observed reductions in ATP of 50% and >90% after 24h and 72h of treatment, respectively. Examination of drug effects on glucose metabolism using extracellular flux and metabolomics analyses demonstrated cell line-specific effects, including reduction in oxidative phosphorylation and/or glycolysis with depletion of metabolites produced via NAD^+-consuming enzymes. Investigation of the effects of NAMPTis on other key NAD^+ consuming enzymes including sirtuin 1 (SIRT1) and poly (ADP-ribose) polymerase (PARP), demonstrated significant loss of activity of both enzymes in a time-dependent manner. As loss of PARP and SIRT1 activity can compromise DNA repair, comet assays were used to assess the extent of DNA damage, revealing increased DNA damage upon NAMPTi treatment in all models. *In vivo* studies of OT-82 in orthotopic xenografts demonstrated significant tumor shrinkage. Across models, 23/26 mouse tumors had average volume reductions of 67% (range 10%-99%). Together, these data demonstrate that in NB, multiple critical pathways are impacted by the loss of NAD^+ mediated by NAMPT inhibition and suggest NAMPTis may have translational potential as a novel agent against NB.

#4569 D3S-003, an orally bioavailable potent and selective dual-state inhibitor targeting both GDP- and GTP-bound KRAS G12D.

Jing Zhang[1], Tienan Wang[1], Robert A. Mook Jr.[2], Haibo Xie[1], Shaonan Wang[1], Zhiqiang Zheng[1], Xin Xiong[1], Hui Wang[1], Zhi Jian Chen[1]

[1]D3 Bio, Inc., Shanghai, China,[2]Department of Medicine, Duke University Medical Center, Durham, NC

KRAS G12D is the most prevalent KRAS mutation in human cancers and represents a highly attractive yet challenging oncogenic target. Compared with KRAS G12C, the intrinsic hydrolysis rate of KRAS G12D is significantly slower, resulting in a more persistent active (GTP-bound) state that limits the efficacy of GDP-state inhibitors. To address this challenge, we identified D3S-003, a potent and selective small-molecule inhibitor that targets both the GDP-bound (OFF) and GTP-bound (ON) forms of KRAS G12D through intensive optimization guided by molecular dynamics and co-crystal-based SAR interrogation. In SPR binding assays, D3S-003 sub-nanomolar affinity for both GDP-bound and GTP-bound KRAS G12D, with a target residence half-life exceeding 13 hours on the GDP-bound form, a key feature enabling a covalent-like inhibition. In biochemical assays, D3S-003 inhibited GDP-bound KRAS G12D nucleotide exchange and disrupted GTP-bound KRAS G12D-cRAF interaction with single-digit nanomolar IC_{50} values, validating its dual-state molecular mechanism of action. In cellular assays, D3S-003 demonstrated nanomolar IC_{50} inhibition in both p-ERK inhibition and proliferation across a panel of KRAS G12D-mutant cell lines, while maintaining high selectivity over KRAS non-G12D lines. Notably, D3S-003 showed improved potency and selectivity compared with RMC-9805, an investigational KRAS G12D (ON) inhibitor currently in clinical trials. D3S-003 exhibits desirable drug-like properties, oral bioavailability across multiple preclinical species, and a robust GLP safety profile. In i*n vivo* studies, it demonstrated robust antitumor activity in KRAS G12D-driven HPAC pancreatic cancer xenografts, requiring only 17.5 nM·h and 56 nM·h free drug AUC to achieve 30% tumor regression (PR) and 100% complete remission (CR), respectively. Across a broad panel of PDX and CDX models of NSCLC and pancreatic cancer with KRAS G12D mutations and diverse genetic backgrounds, D3S-003 achieved a 70% overall response rate (ORR), indicating broad efficacy across these tumor types. Together, these findings highlight D3S-003 as a potent and selective KRAS G12D dual-state inhibitor with strong translational potential. A Phase 1 first-in-human (FIH) study is currently being planned.

#4570 HEC228032, an orally bioavailable molecular glue pan-RAS (ON) inhibitor with highly potent anti-tumor efficacy.

Haiwang Liu, Lingling Chen, Yangyang Meng, Hong Huang, Ming Li, Ning Kang, Yahui Feng, Ziting Liu, Jing Li, Kai Lin, Yingjun Zhang

HEC Pharma Co. Ltd, Shenzhen, China

Background: The RAS oncogene, one of the most frequently mutated drivers in human cancer, is pathogenic in approximately 25% of malignancies, with particularly high prevalence in pancreatic ductal adenocarcinoma, colorectal carcinoma, and non-small cell lung cancer. Approved RAS inhibitors are predominantly limited to the KRAS G12C mutation, leaving a substantial patient population with other KRAS mutations (e.g., G12D, G12V, G13D, Q61R, etc.) or NRAS/HRAS mutations underserved. The emergence of resistance to these agents further underscores the critical need for broad-spectrum pan-RAS inhibitors.

Methods: The affinity of HEC228032 for Cyclophilin A (CypA) and KRAS mutants (G12C/D/V, etc.), as well as its disruption of RAS-RAF interactions, was evaluated using HTRF binding assays. Its anti-proliferative activity was assessed via CTG assays in tumor cell lines. Pharmacodynamic and anti-tumor efficacy were investigated in multiple KRAS-dependent xenograft models *in vivo*.

Results: HEC228032 exhibited high binding affinity for CypA and KRAS mutants (G12C, G12V, G12D, etc) and potently disrupted KRAS-RAF interactions. It demonstrated superior *in vitro* potency compared to RMC-6236, inhibiting proliferation across multiple RAS-mutant cell lines with sub-nanomolar IC50 values. In KRAS-mutant xenograft models (including PK59 (G12D), HPAC (G12D), and LU99 (G12C)), HEC228032 administered orally once daily at 3-10 mg/kg induced dose-dependent tumor regression, with good tolerability over 21 days. Furthermore, HEC228032 achieved higher oral exposure than RMC-6236 in mice, rats, and beagle dogs.

Conclusions: HEC228032 is a promising pan-RAS(ON) inhibitor, characterized by potent antitumor activity against diverse RAS mutants, favorable pharmacokinetic properties, and an excellent tolerability profile, supporting its strong potential for clinical development.

#4571 Discovery and characterization of RGT-490, a mutant selective PI3Kα inhibitor.

Jing Han[1], Kailiang Wang[1], Feng Zhao[1], Xinjuan Wang[1], Xiaoming Ren[1], Xiuliang Huang[1], Xiumei Chen[1], Teng Feng[1], Xin Hua[1], Zhuanzhuan Zhang[1], Lili Yao[1], Jing Lin[1], Wenge Zhong[2], Julie Xie[2]

[1]Qilu Regor Therapeutics Inc., Shanghai, China,[2]Regor Pharmaceuticals Inc., Boston, MA

PI3Kα is frequently mutated and overactivated in a variety of human cancers including breast, gynecological, head and neck, and colorectal cancers. Clinical use and efficacy of the approved PI3Kα inhibitors alpelisib and inavolisib are limited by the side effects associated with wild-type (WT) PI3Kα inhibition, prominently hyperglycemia, rash, stomatitis and GI toxicities. RGT-490 is a potent and mutant selective PI3Kα inhibitor discovered by deploying Computer Accelerated Rational Design (CARD) technology platform. It demonstrated potent anti-proliferation activity in PIK3CA mutated cancer cells. In ER+ breast cancer T47D xenograft model, RGT-490 robustly suppressed Akt phosphorylation and induced significant apoptosis without increasing insulin or glucose levels. In addition, RGT-490 caused near-complete tumor regressions in T47D models without any apparent toxicity. As an allosteric PI3Kα inhibitor, RGT-490 overcame the resistance to orthosteric inhibitors alpelisib and inavolisib resulted from the secondary mutations in the ATP binding pocket. In HER2+ breast cancer HCC1954 cells, RGT-490 suppressed the resistance to HER2 inhibition caused by PI3Kα mutation. With potent activity and excellent selectivity, RGT-490 provides opportunity to reduce WT PI3Kα-associated toxicities, enable deeper target coverage and achieve further improved clinical efficacy in PI3Kα mutant patients. RGT-490 phase 1 study is planned 1H2026.

#4572 Discovery of SY-14556, a highly potent and selective small molecule reactivator of p53 Y220C mutant with differentiated preclinical profile.

Hongjuan Li, Zhenbang Lou, Xiaopeng Li, Chang Lu, Shikang Cheng, Bo Li, Xianxing Shang, Xiaofeng Zhai, Yan Zhu, Hong Luo, **Yinghui Sun**

Shouyao Holding (Beijing) Co., Ltd., Beijing, China

As a key tumor suppressor, p53 binds to DNA and transcriptionally activates target genes to regulate cell-cycle arrest, DNA damage repair, apoptosis, and multiple other antiproliferative processes. *TP53* is the most frequently mutated gene in human cancer, and Y220C is one hot-spot mutation occurring in approximately 1% of solid tumors. Pharmacologic stabilization and reactivation of the Y220C mutant to a wild-type-like conformation is a validated therapeutic strategy, as demonstrated by the clinical activity of PC14586 (rezatapopt). Here, we characterize SY-14556 as a highly potent and selective p53 Y220C reactivator. In biochemical assay, SY-14556 induced p53 Y220C DNA binding with an EC_{50} < 5 nM. In luciferase reporter assay, SY-14556 activated wild-type p53 transcriptional activity with an EC_{50} < 50 nM. Across a panel of p53 Y220C-mutant cancer cell lines, SY-14556 inhibited proliferation (IC_{50} 20-100 nM) with >100-fold selectivity over p53-WT cells. Consistent with high-fidelity p53 pathway reactivation, SY-14556 also dose-dependently activated p53 target genes expression including p21 and MDM2, inducing cell cycle arrest and apoptosis. *In vivo,* SY-14556 demonstrated robust anti-tumor activity in several p53 Y220C-mutant cell line-derived xenograft (CDX) models. Furthermore, SY-14556 displayed favorable PK properties and tolerability in preclinical studies. In conclusion, SY-14556 is a best-in class p53-Y220C reactivator with robust preclinical efficacy and safety. These data support its advancement into clinical trials for p53 Y220C-mutant solid tumors.

#4573 JMKX007129 is a next generation of androgen receptor inhibitor targeting N-terminal domain for the treatment of metastatic castration-resistant prostate cancers.

Shengjian Huang, Gang Deng, Liyan Yue, Xiaodong Zhang, Aishen Gong, Xiumei Li, Nan Liu, Shurong Yang, Amin Wang, Jiayu Zhao, Jianbiao Peng

Shanghai Jeyou Pharmaceutical Co., Ltd., Shanghai, China

Background: Androgen receptor ligand binding domain (AR LBD) mutations are one of the key factors leading to resistance to AR inhibitors or degraders in castration-resistant prostate cancer (CRPC). As a result, inhibitors targeting other domains of AR, such as the NTD, have become a major focus in current drug development efforts to overcome this resistance. However, the clinical development of Anitens-based AR-NTD inhibitors has encountered setbacks due to insufficient activity and selectivity. Therefore, there is an urgent need to develop AR-NTD inhibitors with higher potency, improved selectivity, and enhanced safety profiles.

Methods: Based on the core structure of Anitens, we conducted rational design and obtained the lead compound JMKX007129. A comprehensive suite of in vitro and in vivo characterizations was subsequently performed. These evaluations included assessments of its target binding affinity, mechanism of action, in vitro and in vivo efficacy, pharmacokinetic and toxicological profiles, as well as its combination effects with existing AR inhibitors and degraders.

Results: Compound JMKX007129 demonstrated excellent in vitro and in vivo activity and selectivity. Cellular Thermal Shift Assay (CETSA) confirmed that JMKX007129 simultaneously engages both full-length AR (in LnCap cells) and the splice variant AR-V7 (in 22RV1 cells). Reporter gene and qPCR assays demonstrated that JMKX007129 effectively (EC50≈20 nM) modulates the transcription of downstream genes of both AR and AR-V7. It potently inhibited the proliferation of AR-positive prostate cancer cells, exhibiting a selectivity window of approximately 20-fold over AR-negative cells. JMKX007129 displayed favorable pharmacokinetic properties in mice, rats, and dogs, which translated into robust in vivo antitumor efficacy. Significant activity was observed in models sensitive to AR inhibitors (LnCap) as well as in those with acquired resistance (VCap, 22RV1), accompanied by a favorable tolerability profile. Finally, JMKX007129 exhibited a synergistic anti-proliferative effect in combination with AR inhibitors or degraders in 22RV1 cells.

Conclusions: In summary, we have successfully developed JMKX007129, a novel small-molecule compound targeting the AR-NTD. Preclinical studies demonstrate that JMKX007129, both as a monotherapy and in combination with AR inhibitors or degraders, exhibits promising in vitro and in vivo efficacy and a favorable safety profile, indicating its potential to overcome resistance mediated by AR LBD mutations. IND-enabling studies for JMKX007129 are currently underway.

#4574 Highly potent inhibitors of RAD51, with first-in-class potential, targeting HR-proficient cancers.

Alessandro Galbiati, Daniela Asa, Pietro Picconi, Annamaria Marra, Claudia Stellato, Patrizia Banfi, Liviana Cozzi, Fabio Gasparri, Frank Narjes, Claudia Perrera, **Alessia Montagnoli**

Nerviano Medical Sciences, Nerviano, Italy

BACKGROUND: Targeting DNA repair pathways to selectively eliminate cancer cells has seen a huge success with multiple PARP1 inhibitors (PARPi) approved in different solid tumor indications. RAD51 is a key DNA repair gene with an important role in maintaining genomic stability by mediating homologous recombination repair (HRR) and promoting replication fork protection. Impairment of HRR reduces cell fitness in genetic backgrounds with high replication stress and sensitizes cancer cells to DNA-damaging agents and DNA Damage Response (DDR) inhibitors.
METHODS: A drug discovery campaign was conducted to identify novel small-molecule inhibitors of BRCA2-RAD51 protein-protein interaction (PPI). Structure-based drug design was employed to develop multiple compound series. Biochemical potency was assessed using a Fluorescence Polarization (FP) assay and an ATPase assay to measure the DNA-induced activity of RAD51, which is reliant on RAD51 self-oligomerization. A cellular reporter assay to measure HRR proficiency and a high content imaging assay to measure RAD51 foci formation were developed to assess compounds target engagement.
RESULTS: We have identified proprietary RAD51 PPI inhibitors, orally bioavailable, demonstrating single-digit nanomolar biochemical potency on RAD51 and anti-proliferative activity in a subset of cancer cell lines. These include cell lines resistant to cisplatin or PARP1 inhibitors with a sensitivity profile distinct from RAD51 genetic depletion (based on the analysis of DepMap dataset). The anti-proliferative potency correlates with biochemical potency, cellular target engagement and activation of DNA damage response, confirming the expected on-target mechanism of action.
CONCLUSIONS: The novel mechanism of action, with potential for combination with DNA damaging agents and DDR inhibitors, positions Nerviano Medical Sciences' RAD51 inhibitors as promising first-in-class candidates for further development across multiple cancer types resistant to standard of care.

#4575 Non-clinical characterization of Mocertatug Rezetecan (GSK5733584), a novel B7-H4-directed antibody-drug conjugate.

Jeremy Waight[1], Yuanfeng Zhou[2], Danni Sun[2], Lu Zhang[3], Jon Chung[4], Michael Adam[1], Wenjin Zhou[3], Pengchao Qiu[3], Jifa Fan[3], Anna Strobl[5], Jaegil Kim[4], Aishwarya Bhaskar[1], Srujana Neelam[1], Geeta Sharma[4], Shannon McKearnan[1], Huifeng Niu[2], Takahiro Sato[1], Derek Poore[1], Alexander Cocks[5], Prajna Behera[4], Chris Hopson[1], Ken Hance[1], Richard Davidson[5]

[1]GSK, Collegeville, PA,[2]Hansoh Pharmaceutical Group Co., Ltd, Shanghai, China,[3]Hansoh Pharmaceutical Group Co., Ltd., Shanghai, China,[4]GSK, Waltham, MA,[5]GSK, London, United Kingdom

B7-H4 (B7 homolog 4 protein), also known as B7S1 (B7 superfamily member 1) or VTCN1 (V-set domain-containing T cell activation inhibitor 1), is an important immunoregulatory ligand in the B7-CD28 family. B7-H4 is overexpressed in various tumor tissues such as breast, ovarian, uterine, and lung cancers. B7-H4 has been described to both attenuate T cell function (e.g., proliferation, cytokine secretion and cell cycle) as well as promote tumor cell proliferation, invasion, and metastasis. Consistent with its described immunoregulatory and tumor promoting role, B7-H4 is associated with poor prognosis and negative clinicopathological features in patients with advanced tumors. Due to its overexpression in tumors and tumor-promoting functions, B7-H4 represents an attractive target for tumor-selective therapies like antibody-drug conjugates (ADCs). Mocertatug Rezetecan (Mo-Rez) is a novel ADC that combines a humanized anti-B7-H4 immunoglobulin G1 monoclonal antibody with an exatecan-derived topoisomerase I (TOPO1) inhibitor (SHR-9265, GSK5757810A, average DAR of 6).

Here we describe various non-clinical characteristics of Mo-Rez, including biophysical, functional, and mechanistic attributes of the ADC. In vitro, Mo-Rez demonstrated concentration-dependent binding to B7-H4-expressing tumor cells, which resulted in time-dependent B7-H4 internalization and subsequent cellular cytotoxicity. Consistent with its TOPO1i payload characteristics, Mo-Rez also exhibited cell cycle arrest (S-phase) and bystander killing capability. In vivo, Mo-Rez exhibited significant and dose-dependent tumor growth inhibition (TGI) towards MX-1 (breast) and RL95-2 (endometrial) CDX models. Similar anti-tumor activity was observed across human PDX models of breast cancer, cholangiocarcinoma, cervical cancer, and ovarian cancer. Notably, Mo-Rez antitumor responses were observed in both homologous recombination deficient and proficient (HRD and HRP, respectively) ovarian cancer PDX models.

Importantly, the strong antitumor activity in ovarian models align with recent clinical data for Mo-Rez in heavily pretreated platinum-resistant ovarian cancer (PROC, 48.5% ORR). Collectively, these findings support Mo-Rez as a promising cancer therapy and its rapidly progressing global clinical development (BEHOLD trials).

#4576 2X-121/ stenoparib - a novel, dual inhibitor of PARP and tankyrase in phase 2 clinical trials in advanced ovarian cancer- blocks the WNT signaling pathway and inhibits growth of human colorectal cancer cell lines at clinically relevant drug concentrations.

Louis F. Stancato[1], Sydney Leohr[1], Mustapha Moussaif[1], Mogens Winkel Madsen[2], Steen Knudsen[2], Annette Nielsen[2], Mette Jacobsen[2], Peter Gimsing[2], Thomas Jensen[2], **Jeremy R. Graff**[2]

[1]Indiana Biosciences Research Institute, Indianapolis, IN,[2]Allarity Therapeutics, Inc., Tarpon Springs, FL

2X-121 (stenoparib/ E7499) is a novel inhibitor of PARP1/2 (1nM ~IC50) and Tankyrase 1/2 (IC50 ~50nm). As such, 2X-121 impairs DNA repair while simultaneously inhibiting the WNT/ß-catenin oncogenic signaling pathway. 2X-121 has shown durable clinical benefit in a phase 2 study in patients with advanced, platinum resistant and refractory ovarian cancer as a single agent dosed twice daily, regardless of BRCA status. A new protocol is currently enrolling platinum resistant or ineligible ovarian cancer patients to further deepen the clinical understanding of 2X-121 mediated clinical benefit.

The clinical experience in ovarian cancer patients has shown benefit in $BRCA^{wt}$ patients- patients who typically do not show durable clinical benefit from first generation PARP inhibitors. These data may suggest that, in addition to PARP 1/2 inhibition, the added activity of 2X-121 inhibiting tankyrase and the WNT pathway may contribute to the therapeutic mechanism of action for 2X-121. Accordingly, 2X-121 may be therapeutically useful as an inhibitor of the WNT pathway for cancers not typically sensitive to PARP 1/2 inhibition. Colorectal cancers are not typically sensitive to PARP1/2 inhibition. However, approximately 80% of colorectal cancers (CRCs) do show mutational activation of the canonical WNT pathway, which may impart resistance to standard chemotherapy. Moreover, WNT pathway activation may also enable a cancer initiating cell/ cancer stem cell-like phenotype enabling the cellular plasticity that often characterizes advanced malignancies.

We therefore sought to explore the therapeutic activity of 2X-121 in a panel of CRC cell lines chosen for a spectrum of WNT pathway activating mutations. We show that 2X-121 inhibits growth of multiple colorectal cancer cell lines in monolayer and 3D culture conditions. 2X-121 also inhibits the WNT pathway, stabilizing Axin, reducing activated beta-catenin, and generally blocking WNT pathway activation in CRC cell lines harboring TCF-LEF reporters. The reduction in cell number following 2X-121 treatment may reflect both cytostasis and direct cell killing. Importantly, these effects are evident at clinically relevant drug concentrations for 2X-121. Collectively, these data provide the foundation to explore the clinical potential of 2X-121 in colorectal cancers as well as other cancers where WNT pathway activation is prevalent.

#4577 Targeting midkine-driven oncogenic signaling with HBS-101: A novel therapeutic strategy for lung cancer.

Roberto Borea[1], Francesco Drago[1], Malaak Sammour[2], Nigita Giovanni[2], Serena Li Zhao[3], Blake R. Peterson[4], Hareesh B. Nair[5], Christian Rolfo[2], Eswar Shankar[2]

[1]Department of Internal Medicine, Division of Medical Oncology, The Ohio State University Comprehensive Cancer Center, College of Medicine, Columbus, OH,[2]Division of Medical Oncology, Department of Internal Medicine, The Ohio State University Comprehensive Cancer Center, College of Medicine, Columbus, OH,[3]The Ohio State University College of Pharmacy, Columbus, OH,[4]Division of Medicinal Chemistry & Pharmacognosy, The Ohio State University, Columbus, OH,[5]Department of Molecular and Translational Medicine, Texas Tech University Health Science Center El Paso, El Paso, TX

Midkine (MDK), a heparin-binding growth factor, is aberrantly overexpressed in non-small cell lung cancer (NSCLC) and small cell lung cancer (SCLC), where it drives tumor progression, angiogenesis, EMT, and therapy resistance via PI3K/Akt, MAPK/ERK, and Notch pathways. Despite progress with low-dose computed tomography (LDCT) screening for lung cancer, high false-positive rates, cumulative radiation exposure, and suboptimal sensitivity are still major concerns. These limitations underscore the need for novel, noninvasive biomarkers to enhance early detection and guide the development of targeted therapies. Circulating MDK in serum and urine is a promising biomarker, and HBS-101, a first-in-class small-molecule inhibitor, selectively blocks MDK-receptor interactions and downstream oncogenic signaling, offering a biomarker-guided therapy.MDK expression was analyzed across tumor and normal tissues using The Cancer Genome Atlas Program (TCGA) and the Genotype-Tissue Expression (GTEx) data. Anti-tumor efficacy of HBS-101 was evaluated in vivo using an SW1573 NSCLC xenograft model treated intraperitoneally with HBS-101 (5 or 10 mg/kg) for 56 days and in vitro using a 3D SCLC organoid model (SB-17-54) across 0-200 µM to determine IC_{50} values. Tumor growth, body weight, systemic toxicity, and gene expression were monitored.RNA analyses revealed broad MDK overexpression in both NSCLC and SCLC, with significantly elevated levels in lung adenocarcinoma and squamous cell carcinoma compared to matched normal tissues. HBS-101 treatment led to a statistically significant dose-dependent tumor growth inhibition in NSCLC xenografts, reducing tumor volume by 55-60% compared to control ($p<0.01$) without systemic toxicity. In SCLC organoids, HBS-101 demonstrated potent growth inhibition with an IC_{50} of 5.09 µM.Ongoing works include synthesizing fluorescent MDK derivatives and HBS-101 analogues to elucidate receptor interactions and enable high-throughput screening, and profiling MDK in *EGFR*-mutated NSCLC cell lines (PC-9, H1975) and their Osimertinib-resistant derivatives aim to define the MDK axis and its role in therapeutic resistance. Taken together, our findings validate MDK as both a circulating biomarker and a druggable target, and position HBS-101 as a promising candidate for precision lung cancer therapy. If validated, MDK inhibition could overcome EGFR-TKI resistance and enable MDK-based patient stratification, guiding next-generation inhibitors and early detection strategies.

#4578 Discovery of a Best-in-Class small molecule p53 Y220C reactivator: Breaking through the potency ceiling.

Ruben Boon[1], Jo Alen[1], Nihed Draoui[2], Koen Vandyck[2], Elke Behaeghel[1], Godelieve Lammens[1], Sandrine Vendeville[1], Lijs Beke[1], Pieter Peeters[1], Stephane De Cesco[1], Bart Stoops[1], Pierre Raboisson[1], **Francois Gonzalvez**[1], Carla De Legher[3]

[1]Onco3R Therapeutics, Leuven, Belgium,[2]Former Galapagos employee, Mechelen, Belgium,[3]Onco3R Therapeutics, Heverlee, Belgium

The tumor suppressor p53 is inactivated in approximately 50% of human cancers. In about 1% of solid tumors, a specific Y220C point mutation induces p53 misfolding, leading to its inactivation. This mutation also creates a unique, druggable pocket on the protein's surface, making it a promising target for cancer therapy. The first-generation small molecule reactivator (PC14586, Rezatapopt), designed to bind to this pocket, to refold p53 and to restore its tumor-suppressive functions, has shown clinical efficacy in patients harboring the Y220C mutations.
However, this first-generation compound is limited by modest potency, necessitating high dosing in patients. This high-dose requirement increases the risk of adverse events and narrows the therapeutic window, as monotherapy and even more so in combination regimens. As a result, this compound fails to deliver the drug pressure needed to reach full reactivation of this critical tumor suppressor. Thus, there is a clear need to discover and develop a highly potent p53 small molecule reactivator to fully unlock the therapeutic potential of this promising target.
At Onco3R Therapeutics, our patient centric approach, integrating deep translational science with rational, structure-based and AI-augmented drug design, has led to the identification of best-in-class series of p53 Y220C reactivators. Our lead series exhibits more than 200-fold superior potency compared to the clinical compound PC14586 (Rezatapopt) across diverse preclinical assays, including biochemical p53 refolding, cellular p53 refolding, and cellular p21 induction.
Importantly, our lead series, characterized by strong potency and long residence times in vitro, significantly sustains target engagement and P53 reactivation in cells. This profile enables robust activation of the pro-apoptotic protein PUMA and induces potent, selective cytotoxicity in p53 Y220C mutant cells and in an isogenic cell model. In line with their superior cellular activity and in combination with optimized key ADME, safety parameters, and favorable in vivo PK profiles across species, our leads reach similar efficacy in vivo as PC145586 at much lower exposure.
In conclusion, we have identified unique p53 Y220C small molecule reactivators with clear best-in-class cellular potency and favorable drug-like properties. We are currently further profiling these leads as potential drug candidates to achieve superior efficacy at substantially lower doses, maximizing the safety window to ultimately deliver better outcomes to cancer patients with p53 Y220C mutations.

#4579 Preclinical evaluation of a novel hyperbolic NAMPT inhibitor in combination with pan-RAS targeted therapies in pancreatic ductal adenocarcinoma.

Husain Yar Khan[1], Mohammed Najeeb Al Hallak[1], Sahar F. Bannoura[1], Md. Hafiz Uddin[1], Bin Bao[1], Mohamad Walid Sukkari[1], Adeeb Aboukameel[1], Khalil Choucair[1], Hugo Jimenez[1], Grayson Barker[1], Callum McGrath[1], Ganji Purnachandra Nagaraju[2], Rafic Beydoun[1], Yang Shi[1], Philip A. Philip[3], Azeddine Atfi[1], Bassel El-Rayes[2], Ramzi M. Mohammad[1], Min Wu[4], Michael Schelle[4], Boris C. Pasche[1], Asfar S. Azmi[1]

[1]Wayne State University School of Medicine, Karmanos Cancer Institute, Detroit, MI,[2]University of Alabama at Birmingham, O'Neill Comprehensive Cancer Center, Birmingham, AL,[3]Henry Ford Cancer Institute - Henry Ford Health System, Detroit, MI,[4]Remedy Plan Therapeutics, Gaithersburg, MD

Background: Pancreatic ductal adenocarcinoma (PDAC) remains highly lethal, driven by near-universal KRAS mutations and profound metabolic dependence on nicotinamide adenine dinucleotide (NAD). NAMPT, the rate-limiting enzyme of the NAD salvage pathway, is frequently upregulated in KRAS-driven tumors, suggesting metabolic co-dependence. We evaluated whether simultaneous blockade of NAMPT and KRAS signaling enhances antitumor efficacy in PDAC.
Methods: KRAS-NAMPT expression correlations were analyzed in TCGA PDAC samples (n=179). Multiple KRAS-mutant PDAC cellular models, including KRASG12C inhibitor, KRASG12D inhibitor, and pan-RAS inhibitor (RMC6236)-resistant lines were treated with the hyperbolic NAMPT inhibitor RPT-E-037, RMC6236, or both. Antitumor activity was assessed in 2D viability assays, 3D spheroid cultures, and patient-derived 2D/3D co-culture systems. Drug interactions were calculated using combination index (CI) analysis.
Results: TCGA analysis revealed a fairly strong positive correlation between KRAS and NAMPT expression (Spearman ρ=0.59). RMC6236-resistant PDAC cells displayed increased NAMPT expression and heightened sensitivity to RPT-E-037 compared to parental cells. Similar NAMPT upregulation and enhanced NAMPT inhibitor sensitivity were observed in KRASG12C and KRASG12D inhibitor-resistant models. Across KRAS-mutant PDAC lines, RPT-E-037 combined with RMC6236 produced robust synergy (CI<1) in both 2D and 3D cultures. In patient-derived PDAC co-culture systems, the combination significantly reduced tumor mass, dismantled compact spheroid architecture, and disrupted tumor-stroma interactions more effectively than either agent alone. KRASG12D-mutant metastatic patient rapid autopsy tissue-derived and KPC mice tumor-derived subcutaneous and orthotopic xenograft studies with the combination are ongoing.
Conclusion: Dual inhibition of NAMPT-mediated NAD biosynthesis and KRAS signaling yields synergistic antitumor activity in PDAC, including models resistant to KRAS-targeted therapies. These findings support NAMPT-KRAS co-dependency as a therapeutically actionable vulnerability and justify further translational and in vivo studies to guide clinical development and biomarker-based patient selection."Generative AI was used for improving the language of the abstract".

#4580 Novel PCNA inhibitor AOH1996 synergizes with KRAS-targeted therapies in pancreatic ductal adenocarcinoma.

Sahar F. Bannoura[1], **Husain Y. Khan**[1], Md Hafiz Uddin[1], Amro Aboukameel[1], Yin Wan[1], Bin Bao[1], Adeeb Aboukameel[1], Rafic Beydoun[2], Pouya Haratipour[3], Long Gu[3], Muhammad Wasif Saif[1], Robert J. Hickey[3], Linda H. Malkas[3], Yang Shi[1], Mohammed Najeeb Al Hallak[1], Ramzi M. Mohammad[1], Boris C. Pasche[1], Asfar S. Azmi[1]

[1]Barbara Ann Karmanos Cancer Institute, Wayne State University School of Medicine, Detroit, MI,[2]Department of Pathology, Barbara Ann Karmanos Cancer Institute, Wayne State University School of Medicine, Detroit, MI,[3]Beckman Research Institute of The City of Hope, Duarte, CA

Background: Pancreatic ductal adenocarcinoma (PDAC) is a highly lethal malignancy driven predominantly by oncogenic KRAS mutations. Proliferating cell nuclear antigen (PCNA) is a ring-shaped clamp protein that encircles DNA and regulates replication, repair, and resolution of transcription-replication conflicts; processes hyperactivated in PDAC. AOH1996 is a first-in-class, selective PCNA inhibitor currently in Phase I clinical trials. PCNA has predicted synthetic lethal interactions with KRAS, suggesting combination potential with emerging KRAS inhibitors. This study evaluated AOH1996 alone and in combination with KRAS-targeted agents in PDAC models.

Methods: In this study, we investigated the use of AOH1996 in preclinical models of KRAS-mutant PDAC. We determined cell viability and growth inhibition by MTT, colony formation and spheroid assays. Apoptosis and the cell cycle were analyzed by flow cytometry. RNA-seq, RT-qPCR and western blot were performed for mechanistic evaluations. Drug combination synergy modeling was performed using SynergyFinder. In vivo efficacy was assessed in PDAC xenograft models treated with AOH1996, KRAS inhibitors (MRTX1133, sotorasib, and RMC-6236), or combinations. Residual tumors were analyzed for pERK and pAKT signaling changes.

Results: AOH1996 showed potent, dose-dependent cytotoxicity in multiple PDAC cell lines and 3D spheroids (IC_{50}: 0.5-1.5 μM). RNA-seq revealed broad transcriptional alterations, with enrichment of MAPK, PI3K-Akt and Hippo signaling pathways. Across KRAS G12C and G12D models, AOH1996 exhibited strong synergy with KRAS inhibitors, including MRTX1133, sotorasib, adagrasib, and RMC-6236. Combination therapy caused marked G1 and G2/M phase arrest, increased Annexin V-positive apoptosis, and dual suppression of pERK and pAKT. In patient-derived tumoroids, AOH1996 plus RMC-6236 significantly reduced viability compared to single agents. In vivo, AOH1996 combined with MRTX1133 or with sotorasib produced robust tumor regressions with no significant weight loss, supporting tolerability.

Conclusions: AOH1996 is a promising therapeutic candidate for PDAC, demonstrating potent single-agent activity and strong synergy with clinically relevant KRAS inhibitors across in vitro, ex vivo, and in vivo models. The combination induces profound apoptotic and cell-cycle effects and disrupts key KRAS effector pathways. These results support further translational development of AOH1996-based combination regimens for patients with KRAS-mutant PDAC.

#4581 Small molecule restoring mutant p53R273H DNA binding and activity.

Anne Kingsland[1], Kyle P. Kisor[1], Emil Alexov[2], **Diane L. Barber**[1]

[1]University of California San Francisco, San Francisco, CA,[2]Clemson University, Clemson, SC

Although mutations in TP53 are the most frequent genetic alteration in human cancers, approaches that target mutant p53 to restore p53-wild type (WT) tumor suppressor functions have had limited success and there are currently no FDA-approved therapeutics targeting mutant p53. We report a membrane-permeant small molecule, Compound K, that selectively increases tumor suppressor functions of p53-R273H, one of the two most common p53 mutants in cancers. Key to understanding the loss of tumor suppressor functions of p53-R273H is deprotonation of His273 at the higher intracellular pH (pHi) of cancer cells, which attenuates binding to the negatively charged phosphate backbone of DNA. We identified Compound K in a computational screen of 3.5 million small molecules for targeting deprotonated His273 and imparting a positive charge to restore electrostatic binding to DNA, like positively charged WT p53-Arg273. We find that Compound K selectively increases DNA binding by p53-R273H at the higher pH of cancer cells with no effect on DNA binding by p53-R273H at the lower pH of untransformed cells, or by p53-WT, p53-R175H, and other pH-regulated transcription factors at lower and higher pH values. Compound K also restores p53-WT functions in human PANC-1 pancreatic cancer cells that are homozygous for p53-R273H, with limited effects in human HPDE untransformed pancreatic epithelial cells, including >4200 DEGs in PANC-1 and <200 DEGs in HPDE, as determined by RNA-seq. In PANC-1 cells Compound K increases expression of loss-of-function, anti-tumorigenic genes, including GADD45A, KLF6, and IFIT2, and decreases expression of gain-of-function pro-tumorigenic genes, including CDC20, PLK1, AURKA, and for TGF-β signaling, as determined by RNA-seq and immunoblotting cell lysates. Compound K also selectively decreases viability of PANC-1 cells with no effect on HPDE cells, and tumorigenicity, determined by 80% reduced colony formation in soft agar. Our findings are an important step toward the unmet need of developing therapeutics targeting mutant p53 to limit cancer progression. Additionally, beyond p53-R273H, Arg>His mutations are enriched in many cancers, most notably medulloblastoma, acute myeloid leukemia, and pancreatic and prostate cancers, which makes our approach of targeting an Arg>His substitution to restore a positive charge have broad cancer therapeutic promise.

#4582 Targeting MEIS2 in platinum resistant ovarian cancer.

Yinu Wang[1], Natalia Obrochta[2], Jennifer Heo[1], Junzui Li[1], Natalia Maria Masnica[3], Daniela E. Matei[1]

[1]OB/GYN, Northwestern University, Chicago, IL,[2]Department of Neurobiology, Northwestern University, Evanston, IL,[3]Weinberg School of Arts and Sciences, Northwestern University, Evanston, IL

Background: Recurrent ovarian cancer (OC) develops chemoresistance, which is fatal. Cancer stem cells (CSCs) have been hypothesized to be responsible for driving chemoresistance and tumor relapse. Myeloid Ecotropic Insertion Site 2 (MEIS) is a homeobox transcription factor (TF) that is deregulated in various cancers, playing critical roles in regulating stem cell identity and cell fate decisions. Here, I examined the role of MEIS2 in regulating stemness features that promote chemoresistance of OC, and the impact of a MEIS2 blockade on OC initiation and progression.
Methods: Paired isogenic OC cell lines (platinum sensitive (Pt-S) and resistant (Pt-R)) were used. MEIS2 expression level in these cells was assessed by q-RT-PCR and Western Blotting. The effects of MEIS2 inhibition (by using a pharmacological inhibitor MEISi and biological knockdown (KD)) and overexpression (OE) on OC cell survival and chemosensitivity were assessed using colony formation and cell viability assay, and on stemness features by flow cytometry for analysis of ALDH+ CSC population and measurement of stemness-related gene expression. MEIS2 direct binding targets in OC cells were examined using ChIP-seq and validated using q-PCR. The anti-tumor effects of MEIS2 inhibition on Pt-R OC cells and tumor initiation were tested in vivo.
Results: MEIS2 expression levels were increased in Pt-R vs. Pt-S OC cells at mRNA and protein levels. Treatment with MEIS2i (500nM-1μM) reduced the number of colonies in OC cells by at least 2-fold and resensitized Pt-R OC cells to cisplatin ($p<0.05$). Treatment with MEIS2i (250nM-1uM, 48 hours) decreased ALDH+ CSCs population by at least ~2-fold ($p<0.05$) and inhibited the expression of stemness-associated genes ALDH1 isoforms and Sox2 ($p<0.05$), compared to vehicle control. MEIS2 KD decreased the CSC population by two-fold ($p<0.05$) and inhibited stemness gene expression ($p<0.05$). By integrating ChIP-seq and RNA-seq, we identified that stemness-associated gene ALDH1A2 is a direct binding target of MEIS2 in OC cells, contributing to the maintenance of stemness and chemoresistant features. We further validated the MEIS2 binding region on the enhancer region of the ALDH1A2 genes using ChIP-qPCR, which is highly conserved across multiple species. In vivo, OC xenografts derived from MEIS2 KD OVCAR5 cells were more responsive to carboplatin ($p<0.05$) compared with control xenografts, and MEIS2 KD inhibited tumor-initiating capacity. Importantly, MEISi treatment alone (25μM/100μL, 5 days, 2 weeks) or in combination with carboplatin (25mg/kg, once/week, 2 weeks) suppressed OVCAR5 Pt-R xenograft tumor growth and inhibited ALDH+ CSC population in the tumor residuals.
Conclusions: Altogether, blocking MEIS2 in OC cells inhibits stemness traits that contribute to chemoresistance and tumor relapse, suggesting that MEIS2 is a potential new treatment target in OC therapy.

#4583 Multitarget kinase inhibitor olverembatinib (HQP1351) is efficacious and synergizes with chemotherapy in preclinical models of endometrial carcinoma (EC).

Yan Xiong[1], Zhiyan Liang[2], Huidan Yu[1], Bingxing Wu[1], Guoqin Zhai[1], Zhou Yu[1], Dajun Yang[1], Yifan Zhai[2]

[1]Ascentage Pharma (Suzhou) Co., Ltd., Suzhou, China,[2]Ascentage Pharma Group Inc., Rockville, MD

Background: EC is the most common uterine cancer. Treatments for certain subtypes or advanced disease are limited. Olverembatinib is an investigational multikinase inhibitor targeting factors such as VEGFR1-3, FGFRs, SRC, PDGFRs, and RET. Drug sensitivity screening of 883 human cancer cell lines showed that EC is the second-most sensitive tumor type to olverembatinib, prompting us to explore antitumor effects of olverembatinib alone or combined with standard-of-care chemotherapy in preclinical EC models.

Methods: PRISM (Profiling Relative Inhibition Simultaneously in Mixtures) was used to screen olverembatinib activity in multiple cancer cell lines. Cell viability was assessed using CellTiter-Glo® assays, and apoptosis was measured by flow cytometry. Western blotting was used to illustrate mechanisms of action. Subcutaneous MFE296 and AN3CA cell line-derived xenograft (CDX) models were established to evaluate antitumor effects *in vivo*.

Results: Olverembatinib inhibited proliferation of 31 EC cell lines across different histological types, with IC_{50} values ranging from subnanomolar to ~4 μM. Olverembatinib was significantly more potent (IC_{50} up to 100-fold lower) than lenvatinib in cell growth inhibition in AN3CA, HEC-1B, RL95-2, and Ishikawa cells. Combinations of olverembatinib and paclitaxel or carboplatin were evaluated in AN3CA, HEC-1B, MFE296, and Ishikawa cells. All were resistant to carboplatin. Olverembatinib synergized with paclitaxel to inhibit cell proliferation and promote apoptosis. In the MFE296 CDX model, olverembatinib showed dose-dependent antitumor activity at day 29 with respective T/C values of 61.72% and 39.04% at 5 and 10 mg/kg. Combining paclitaxel (10 mg/kg) and carboplatin (50 mg/kg) with olverembatinib (10 mg/kg) significantly enhanced the latter's antitumor activity, with a T/C value of 9.08% and synergistic index of 1.37. Antitumor effects of olverembatinib and synergy with chemotherapy were recapitulated in AN3CA CDX models. No significant body weight loss was observed. Mechanistically, olverembatinib suppressed phosphorylation of oncogenic FGFR2, SRC, and PI3K-AKT (the most frequently altered pathway in EC) and downstream factors STAT3 and ERK. When olverembatinib was combined with chemotherapy, synergistic downregulation of the above pathways, cell cycle proteins (pRB, CDK4, and CDK6), and augmentation of apoptotic markers (cleaved caspase3 and PARP) and DNA damage marker (γH2AX) were observed, as well as modulation of epithelial-mesenchymal transition (tumor metastasis) markers.

Conclusions: In a broad range of preclinical *in vitro* and *in vivo* EC models, olverembatinib is efficacious and synergizes with chemotherapy to promote antitumor effects. The findings support future clinical evaluation of olverembatinib and its combination with other approved treatment options in EC.

#4584 Effects of ergosterol peroxide on proteostasis disruption in triple negative breast cancer cells.

Michelle Martinez-Montemayor[1], Aliyah Bocachica-Adorno[2], Adriana Aponte-Ramos[3], Taotao Ling[4], Fatima Rivas[4]

[1]Universidad Central del Caribe, Bayamon, PR,[2]University of Puerto Rico, Bayamon, PR,[3]Universidad Interamericana, Bayamon, PR,[4]Louisiana State University, Baton Rouge, LA

Triple-negative breast cancer (TNBC) is a highly aggressive and heterogeneous subtype of breast cancer characterized by the absence of estrogen receptor, progesterone receptor, and HER2 expression, known for its high malignancy, invasiveness, and propensity for metastasis. Due to the lack of targeted therapies, TNBC patients typically undergo multimodality chemotherapy with cytotoxic agents like taxanes, anthracyclines, and cyclophosphamide. Therefore, there is an urgent need for selective therapies for TNBC. Natural products have gained significant attention for their potential in cancer therapy, as around 60% of clinically approved anticancer drugs were inspired by secondary metabolites found in nature. In our laboratory, we work with Ergosterol Peroxide (EP), a bioactive compound extracted from the *Ganoderma lucidum* mushroom. We discovered that the natural product EP exhibits selective cytotoxicity against TNBC models, demonstrating activity in the low micromolar range while sparing normal cells. Our studies indicate that EP exerts its anticancer effects by disrupting critical cellular processes including proteostasis, protein synthesis, and protein degradation pathways. We hypothesize that EP compromises TNBC cell viability by disrupting proteostatic balance. Mechanistically, we propose that EP inhibits protein synthesis and induces mitochondrial dysfunction, which collectively impair the ability of TNBC cells to restore protein homeostasis, ultimately resulting in cell death**.** To validate our hypothesis, we performed protein synthesis assays in two TNBC cell models, SUM149 and MDA-MB-231. Veh (0.2% DMSO), EP (20μM), or cyclophosphamide (1μM, positive control) were administered for 6 or 24h. EP effects on protein aggregation, under Veh, EP, or MG132 (positive control) in SUM149 or MDA-MB-231 TNBC cells and MCF10A non-cancerous cells, we used an aggresome assay. Finally, to assess protein degradation we performed western blots probing for ubiquitin. We previously established that EP increases ROS levels in TNBC cells. EP affects protein synthesis, compared to negative vehicle control treated cells, and in reduced capacity when compared to cyclophosphamide. Moreover, EP significantly increases protein aggregation, although the signal detected for MG132 was greater. Finally, EP decreases cancer cell degradation, as seen by decreased levels of ubiquitin when treated after 24h. In summary, EP demonstrates the capacity to modulate proteostasis in TNBC cells. Further investigation is warranted to comprehensively characterize the intricate mechanistic pathways by which EP exerts its anticancer effects in this malignancy.

#4585 A novel thioxanthenone activates p47phox to exploit redox vulnerabilities in acute myeloid leukemia.

Madison Gamble[1], Claudia M. Espitia[1], Sruthi Sureshkumar[1], Natalie Hakim[1], Kevin R. Kelly[2], Wei Wang[3], Steffan T. Nawrocki[1], Jennifer S. Carew[1]

[1]Cancer Center, University of Arizona, Tucson, AZ,[2]Hematology, University of Southern California, Los Angeles, CA,[3]Pharmacology and Toxicology, University of Arizona, Tucson, AZ

Acute myeloid leukemia (AML) is an aggressive hematologic malignancy with poor outcomes, particularly among older adults and patients harboring adverse-risk features such as FLT3-ITD and p53 mutations. Relapsed or refractory (R/R) AML remains largely incurable, underscoring the urgent need for new therapies that selectively target leukemia-specific survival pathways while sparing normal hematopoiesis. Through a focused medicinal chemistry campaign, we optimized an understudied thioxanthenone chemotype and identified 06-30 as a potent lead compound with broad anti-AML activity. 06-30 induces robust and selective cytotoxicity across genetically diverse AML cell lines including models resistant to standard of care agents (cytarabine, azacitidine), and demonstrates strong activity in primary AML blasts with adverse molecular profiles. Unbiased integrative proteomic and transcriptomic analyses revealed p47phox (NCF1), a cytosolic organizer subunit of the NADPH oxidase complex, as the top common drug-induced target following 06-30 treatment with >9-fold increases in protein abundance and >50-fold increases in mRNA levels. Although p47phox is well established in host defense and inflammatory reactive oxygen species (ROS) generation, its role in AML pathogenesis and therapeutic sensitivity remains undefined. We hypothesize that p47phox functions as a pharmacodynamically regulated effector of 06-30 that drives ROS-mediated DNA damage and apoptosis in AML by exploiting leukemia-specific redox dysregulation. Supporting this hypothesis, shRNA-mediated silencing of p47phox significantly diminished 06-30-induced ROS generation and apoptosis and antioxidant co-treatment similarly blunted cell death. Importantly, 06-30 demonstrated selective toxicity toward AML cells while sparing normal CD34+ bone marrow progenitors, consistent with the enhanced antioxidant capacity of normal hematopoietic cells and establishing a clear therapeutic window. *In vivo*, 06-30 significantly extended overall survival and was very well tolerated. *Ex vivo* analyses demonstrated that its antileukemic efficacy was associated with increased p47phox expression and oxidative DNA damage as quantified by 8-oxoguanine levels. To our knowledge, no anticancer pharmacologic activators of p47phox have been previously described. Thus, thioxanthenone 06-30 represents both a first-in-class mechanistic probe and a promising therapeutic lead for redox-based targeting in AML. Together, these findings provide strong rationale for the further preclinical development and eventually clinical investigation of 06-30 as a strategy to exploit redox vulnerabilities in leukemia and improve outcomes for patients with limited therapeutic options.

#4586 p97/VCP inhibition with CB-5339 induces REDD1-dependent antitumor activity in renal cell carcinoma.

Sruthi Sureshkumar[1], Claudia M. Espitia[1], Maria Janina Carrera Espinoza[1], Madison Gamble[1], Natalie Hakim[1], Kevin Kelly[2], Jennifer S. Carew[1], Steffan T. Nawrocki[1]

[1]Cancer Center, University of Arizona, Tucson, AZ,[2]Hematology, University of Southern California, Los Angeles, CA

Renal cell carcinoma (RCC) is the tenth most common cancer in the United States and disproportionately affects Hispanic and Native American populations, who experience higher incidence and mortality. Although current therapies targeting tyrosine kinases and immune checkpoints have extended survival, most patients ultimately develop resistance. This emphasizes the need for novel treatment strategies that disrupt essential survival pathways. The AAA+ ATPase p97/valosin-containing protein (VCP) is a central regulator of protein quality control that extracts misfolded or unfolded proteins from the endoplasmic reticulum (ER) for degradation, thereby preventing proteotoxic stress. We demonstrated that genetic knockdown of p97 significantly reduced RCC cell viability, supporting p97 as an essential survival factor and a promising therapeutic target. Consistent with this, the orally bioavailable, clinically relevant p97 inhibitor CB-5339 potently induced ER stress and apoptosis across human RCC cell lines and in Hispanic and Native American patient-derived xenograft (PDX) models. Transcriptomic profiling identified REDD1 as the most strongly upregulated gene following CB-5339 treatment. CRISPR-mediated knockout studies showed that REDD1 was required for maximal induction of ER stress and apoptosis, indicating that CB-5339 triggers a REDD1-dependent stress response. Because REDD1 is a negative regulator of mTORC1, we further assessed downstream effects on nutrient-sensing pathways. CB-5339 treatment inhibited mTORC1 activity and activated autophagy, as confirmed by autophagic flux assays using the lysosomal inhibitor bafilomycin-A1. Therefore, we hypothesized that combining p97 inhibition with autophagy blockade would enhance cytotoxicity by preventing the compensatory autophagic response. Consistent with this, co-treatment with CB-5339 and the lysosomal autophagy inhibitor ROC-325 produced strong synergy, significantly increasing apoptosis and reducing viability compared with either agent alone. In RCC xenograft models, the combination achieved marked tumor suppression, robust induction of apoptotic signaling, and excellent tolerability. Together, these results identify p97 as a novel therapeutic vulnerability in RCC and demonstrate that CB-5339's anticancer effects are driven by REDD1-mediated ER stress and cell death. The synergistic efficacy of CB-5339 and ROC-325 highlights the therapeutic potential of combining proteostasis disruption with autophagy inhibition. Moreover, the use of multiple RCC PDX models enhances the translational relevance of this approach and provides a strong rationale for clinical investigation of p97 inhibition alone and in combination with autophagy-targeting agents in RCC.

#4587 USP10 inhibition with GL-320 enhances chemo-immunotherapy efficacy and overcomes resistance in NSCLC.

Sadaf Dorandish[1], Komal Bhayekar[1], Prahlad Parajuli[1], Amirreza Samarbakhsh[1], Babita Kushwaha[2], Yubin Ge[3], Navnath Gavande[1]

[1]Pharmaceutical Sciences, Wayne State University-Eugene Applebaum College of Pharmacy and Health Sciences, Detroit, MI,[2]Pharmaceutical Sciences, Wayne State University, Detroit, MI,[3]Pharmaceutical Sciences, Wayne State University-School of Medicine, Detroit, MI

Platinum-based chemotherapy combined with immunotherapy remains the frontline regimen for advanced non-small cell lung cancer (NSCLC), yet most patients ultimately relapse due to acquired resistance. A major contributor to this resistance is hyperactivation of the DNA damage response (DDR), which enables tumor cells to repair chemotherapy-induced lesions, evade cytotoxicity, and suppress immunogenic signaling. The deubiquitinating enzyme USP10 stabilizes multiple DDR and pro-survival proteins, making it an attractive target for re-sensitizing resistant tumors. Inhibiting USP10 may attenuate DNA repair, disrupt oncogenic pathways, and enhance anti-tumor immune activation. GL-320, a potent and selective small-molecule USP10 inhibitor developed in our laboratory, was evaluated across NSCLC models using integrated biochemical, cellular, and molecular assays. MTT and colony formation studies demonstrated robust, dose-dependent suppression of proliferation and clonogenic survival, while CellTiter-Glo and combination colony assays showed that GL-320 effectively re-sensitized cisplatin-resistant cells. CETSA confirmed direct intracellular USP10 engagement. Comet assays and immunofluorescence imaging revealed increased DNA fragmentation and elevated γH2AX, PARP1, and 53BP1 foci, indicating impaired DNA repair capacity. Flow cytometry demonstrated early G_0/G_1 arrest accompanied by ATM/ATR activation and increased pChk1 and γH2AX. Co-treatment with ATM and pan-caspase inhibitors confirmed the involvement of DDR signaling and caspase-dependent apoptosis. Broader mechanistic profiling showed modulation of DDR and checkpoint proteins (MSH2, p21, MDM2, p53), destabilization of survival factors (HDAC6, CD36), and induction of autophagy (p62, Beclin-1, LC3-II). Importantly, GL-320 induced strong immunogenic stress, marked by increased GRP78/BiP, caspase-8 activation, calreticulin exposure, and reduced CD47 expression, hallmarks of endoplasmic reticulum stress and immunogenic cell death. Collectively, GL-320 mediated USP10 inhibition disrupts DDR signaling, activates autophagy and caspase-dependent apoptosis, and triggers immunogenic cell death, thereby restoring cisplatin sensitivity and potentially enhancing response to immunotherapy. These multifaceted effects position USP10 as a promising therapeutic target for overcoming treatment resistance and stimulating anti-tumor immunity in NSCLC.

#4591 SC3613 (IN-207387), a mutant-selective EGFR degrader, exhibits potent anti-tumor activity and improved safety profile in EGFR TKI-resistant NSCLC.

Jun Gyu Kim[1], Jihoon Choi[1], Ok Young Lee[1], Young Jun Park[1], Young Min Jeong[1], Choongsil Lee[1], Seo Yoon Jeong[1], Hye Yeon Lee[1], Yu Jin Lee[1], Hyesun Lee[1], Dae Young Lee[1], Ah Yeon Park[1], Hyoeun Jo[1], Sun Ho Choi[1], Sun Ho Jeon[1], Ji-Young An[2], Jong Hyun Lee[2], Yang Hun Tae[2], Mirae An[2], Keunho Lee[2], Jong Ryoul Choi[2], Bong Tae Kim[2], Mi-Kyung Kim[1]

[1]Dong-A ST, Youngin-si, Korea, Republic of,[2]Innovative Drug Discovery R&D Institute, HK inno.N Corp., Gyeonggi-do, Korea, Republic of

Non-small cell lung cancer (NSCLC) accounts for approximately 85% of all lung cancers, with activating mutations in the epidermal growth factor receptor (EGFR) strongly associated with tumor progression and poor clinical outcomes. Among these mutations, the L858R mutation in *exon 21* serves as a major oncogenic driver that confers initial sensitivity to EGFR tyrosine kinase inhibitors (TKIs). However, patients with L858R-driven tumors exhibit a poorer prognosis and shorter progression-free survival even with third-generation EGFR TKIs, such as osimertinib, compared with those harboring *exon 19* deletions, underscoring a substantial unmet clinical need in this molecular subgroup. In addition, the emergence of secondary resistance mutations, including C797S, further limits the long-term efficacy of current TKIs. To address these challenges, targeted protein degradation has emerged as a promising strategy to eliminate both activating and resistance-associated mutant EGFR. We developed SC3613 (IN-207387), a novel heterobifunctional degrader designed to selectively bind an allosteric pocket of mutant EGFR while sparing the wild-type receptor, thereby minimizing off-target toxicities. SC3613 efficiently induced ubiquitin-proteasome-mediated degradation across L858R-containing EGFR variants, including L858R/C797S, and exhibited potent anti-proliferative activity in patient-derived cells harboring resistant EGFR mutations. A potent antitumor effect was also observed in NCI-H1975 (L858R/T790M) cells. Consistent with effective target engagement, SC3613 treatment resulted in marked suppression of downstream EGFR signaling pathways. Importantly, SC3613 demonstrated a superior safety profile. In BALB/c nude mice, SC3613 produced substantially lower levels of skin keratosis on the face, neck, and abdomen compared with osimertinib, indicating a reduced incidence of cutaneous adverse effects and a broader therapeutic window. Furthermore, orally administrated SC3613 induced potent, dose-dependent anti-tumor activity in multiple EGFR TKI-resistant xenograft model. Treatment led to a high incidence of durable complete tumor regressions without associated body-weight loss, highlighting its favorable tolerability. Collectively, these findings identify SC3613 as a potent, highly mutant-selective, and orally active EGFR degrader with robust anti-tumor efficacy and improved safety. SC3613 represents a promising next-generation therapeutic candidate for NSCLC patients harboring activating and resistance mutations such as L858R, T790M, and C797S.

#4592 The highly selective and potent reversible-covalent FGFR4 inhibitor, BB102, induces targeted-protein degradation through lysosomal autophagy.

Min Li, Qi Wang, Gongping Duan, Xiaoyi Ma, Junheng Wang, Lijie Wei, **Xingmin Zhang**

BroadenBio Co., Ltd., Beijing, China

Introduction: Fibroblast growth factor 19 (FGF19) overexpression contributes to the tumorigenesis of certain forms of hepatocellular carcinoma (HCC) and fibroblast growth factor receptor 4 (FGFR4) mutations have been found in rhabdomyosarcoma, breast, colorectal, and gastric cancer. Thus, FGFR4 is considered as a novel target to treat cancer with hyperactivated FGF19/FGFR4 signaling. We previously reported BB102 was a highly selective and potent reversible-covalent FGFR4 inhibitor. Here we demonstrated for the first time that BB102 not only inhibited FGFR4 kinase activity but also induced FGFR4 degradation through lysosomal autophagy.

Methods: BB102 was developed through structure-based drug design, and optimized by SAR analysis and medicinal chemistry iteration. Biochemical and cell-based assays were applied in evaluation of BB102 inhibitory activity. Parallel artificial membrane permeability assay (PAMPA) and permeability in MDCK-MDR1 cell line were conducted. The degradation of FGFR4 protein induced by BB102 was demonstrated in both tumor cell lines and tumors from xenograft models in mice.

Results: BB102 inhibited FGFR4 kinase activity with IC_{50} of 2.5 nM and displayed >400-fold selectivity against the other 206 kinases tested. BB102 blocked the phosphorylation of the downstream protein ERK with IC_{50} of 2.4 nM. BB102 exhibited strong inhibitory effects on the cell proliferation with the high expression of both FGF19 and FGFR4, or FGFR4-mutated tumor cells and suppressed tumor growth in mouse models. PAMPA and permeability in MDCK-MDR1 cell line had shown BB102 was permeable to blood-brain barrier (BBB) and BB102 was found in the rat brain tissues. BB102 clearly induced FGFR4 protein degradation in FGFR4 over-expressed HuH-7, Hep3B, and SJCRH30 cancer cell lines, which was blocked by Bafilomycin A1, an inhibitor of lysosomal autophagy. BB102 induced degradation of FGFR4 only in the tumors but not in the normal lungs and livers from xenograft mouse models.

Conclusion: BB102 is a degrader of FGFR4 with highly selective and potent reversible-covalent FGFR4 kinase inhibition. BB102 has remarkable antitumor activity in mice bearing HCC tumor xenografts. It is permeable to BBB. It has shown safe profiles in the phase Ia study and preliminary promising efficacy in the phase Ib study.

#4593 PBI-381, a development candidate PROTAC for KRasG12D solid tumors.

Bing Zhang[1], Yuxin Liu[1], Yufeng Chen[1], Danqiu Lin[1], Jinhua Chai[1], Yang Meng[1], Mixue Tong[1], Ganng Yang[1], Michael Xiang[2], Liping Zhao[1], Rui Yang[1], **Lan Xu**[2], He Zhou[1], Jason Xiang[1]

[1]Polymed Biopharmaceuticals, Hangzhou, China,[2]Polymed Biopharmaceuticals, Cambridge, MA

Kras gain-of-function mutations are prominent cancer drivers in pancreatic, colorectal, lung and other solid tumors. While several small molecule inhibitors against KRasG12C have been approved to treat non-small cell lung and colorectal cancers, either as single agent or in combination, there is still a great unmet need for other more prevalent Kras mutations such as KrasG12D. Furthermore, given the complexity of KRasG12D molecular mode of action and its downstream signaling branches, whether complete elimination of the KRasG12D protein or functional inhibition of its signaling activity has a bigger impact on cancer cells remains an open question. Therefore, Proteolysis Targeting Chimera (PROTAC)-based Kras degraders may bring differentiated clinical benefits to patients with Kras-mutant solid tumors. At present, ASP3082 (Astellas Pharma) and PT0253 (PAQ Therapeutics) are the only two KRasG12D PROTAC degraders that have entered clinical trials.Polymed Biopharmaceuticals has generated a series of potent and selective PROTAC molecules targeting the KRasG12D mutant protein. *In vitro*, these PROTAC molecules exhibited DC_{50} (degradation IC_{50}) < 1 nM and D_{max} (maximal % of degradation) > 98% against KRasG12D in cancer cell lines harboring this mutation. Moreover, as measured by cancer cell growth inhibition, the Polymed PROTAC molecules are highly selective against cells with the KRasG12D mutation while sparing cells harboring KRasG12V, KRasG12C or cells with amplified wild type KRas. More importantly, in KRasG12D pancreatic cancer xenograft model PK59, treatment with the lead molecule PBI-381 resulted in robust tumor regression without impact on body weight and any other noticeable adverse effects on the mice after 4 weeks of treatment. A good PK/PD/efficacy relationship was also observed with PBI-381. Preliminary ADME, *in vitro* safety and drug-drug interaction assessments further supported PBI-381 as a development candidate for advancing into the clinic.Compared to the most clinically advanced KRasG12D PROTAC ASP3082, PBI-381 has superior potency and more favorable tissue distribution for a drug designed to treat solid tumors. In head-to-head comparison studies using xenograft models, PBI-381 also exhibited significantly higher anti-tumor activity than ASP3082. IND-enabling activities on PBI-381 are underway to progress the compound further towards the clinic.

#4594 LY4584180, a novel BCL6 molecular glue, demonstrates antitumor efficacy in preclinical models of B Cell NHL.

Candace Langan[1], Nicholas E. Brown[1], Bryan G. Perria[1], Petia Gatzeva-Topalova[1], Bonita D. Jones[1], Lisa J. Kindler[1], Wayne D. Blosser[1], Rebecca J. Metivier[2], Eric S. Fischer[2], Xueqian Gong[1], Nathan A. Brooks[1]

[1]Eli Lilly and Company, Indianapolis, IN,[2]Department of Cancer Biology, Dana-Farber Cancer Institute, MA, and Department of Biological Chemistry and Molecular Pharmacology, Harvard Medical School, Boston, MA

B-cell lymphoma 6 (BCL6) is a protooncogene and key molecular driver of DLBCL, FL, and other B-cell malignancies. BCL6 gene alterations such as chromosomal translocations or somatic mutations, lead to deregulation of BCL6 expression, contributing to poorly prognostic double- and triple-hit lymphomas.[1] Given its role in repressing genes involved in DNA damage response, cell cycle checkpoints, and differentiation,[2] BCL6 is a promising drug target for the treatment of non-Hodgkin Lymphomas (NHL). Small molecule inhibitors have been ineffective in disrupting BCL6-mediated oncogenic activity; emerging evidence suggests that degradation of BCL6 is essential for antitumor activity.[3] Here, we describe the characterization of LY4584180, an oral, highly selective, small molecule BCL6 molecular glue. LY4584180 induces BCL6 homodimerization at the BTB/POZ domain, resulting in BCL6 polymers sequestered into cellular aggregates, leading to polyubiquitination of the BCL6 aggregates by E3 ligases, and subsequent degradation by the proteasome. The unique non-cereblon dependent degradation mechanism allows combination with IMiDs and may also reduce a key mechanism for on-target drug resistance, in comparison to other ligand directed cereblon degraders. LY4584180 has demonstrated rapid, potent, and concentration-dependent degradation of BCL6 protein in both transcriptionally defined DLBCL subtypes, activated B-cell (ABC; OCI-Ly10) and germinal center B-cell (GCB; Farage and SU-DHL-4). DC_{50} (concentration of LY4584180 resulting in 50% degradation of BCL6) values ranged from 1 to 22 nM at 24 hrs with maximal degradation (~96-97%) observed within 2 hrs, as quantified by Mesoscale Diagnostics ELISA. Furthermore, LY4584180 demonstrated anti-proliferative activity across a panel of human NHL cell lines with mid- to high-BCL6 expression, including ABC and GCB DLBCL subtypes. Additionally, in a mass spectrometry-based proteomics study using SU-DHL-4 cells, the compound selectively reduced BCL6 relative to its effects on the global proteome. In DLBCL cell line-derived xenograft models, LY4584180 demonstrated robust dose-dependent BCL6 degradation and antitumor activity ($p<0.001$), including tumor regression at multiple dose levels, with no significant body weight loss. These results demonstrate the ability of LY4584180 to selectively degrade BCL6, exert antiproliferative effects across a panel of malignant human B-cell lines, and exhibit antitumor activity *in vivo*. These findings suggest that LY4584180 has the potential to be effective in patients with hematologic malignancies. NOVA-BCL6-1, a phase 1 clinical trial evaluating LY4584180 in patients with NHL is currently enrolling (NCT07226843). [1]Xu J, et al. *Cancer Res* 2024, 84: Abstract 6062 [2]Liongue C, et al. *Int J Mol Sci* 2024, 25:10968 [3]Groocock L, et al. *Blood* 2024; 144 (Supplement 1): 957

#4595 A first-in-class potent EZH2 degrader, AXT-1003, exhibits robust anti-tumor activity across multiple lymphomas and solid tumors.

Yong Yang, Huiya Huang, Enxing Zhou, Yan Lin, Qian Gao, Alex Xu

Axter Therapeutics, Beijing, China

Enhancer of Zeste Homolog 2 (EZH2) acts as the core enzymatic component of the Polycomb Repressive Complex 2 (PRC2), which mediates trimethylation of histone H3 lysine 27 (H3K27Me3) to maintain the epigenetic repression of target genes. Mutated and/or dysregulated EZH2 expression is a hallmark of various cancers and is frequently correlated with poor patient prognosis. Several S-adenosylmethionine (SAM)-competitive EZH2 inhibitors, which suppress methyltransferase activity of EZH2, have clinically shown promising results in treating sarcoma and lymphoma, including the FDA-approved tazemetostat (EPZ-6438). However, monotherapy with these EZH2 inhibitors has limited efficacy in most solid tumors, even though they effectively reduce the H3K27Me3. Growing evidence suggests that EZH2 commonly functions noncanonically, in a methyltransferase-independent manner, as a transcriptional coactivator through associating with oncogenic transcription factors in solid tumors. Therefore, targeting EZH2 with degradation can be advantageous for the treatment of EZH2-dependent cancers. Herein, we reported the development of a first-in-class, oral, and potent EZH2 degrader, AXT-1003. Across multiple *in vitro* and *in vivo* tumor models, this degrader promoted a dose- and time-dependent reduction of EZH2 protein, which led to significant inhibition of H3K27Me3. Meanwhile, AXT-1003 had no significant effect on EZH2 at transcriptional levels, and its protein expression was restored by MG-132 (proteasome inhibitor). Our ubiquitinomics and proteomics studies demonstrated that AXT-1003 simultaneously triggered ubiquitination and degradation of EZH2 protein, suggesting AXT-1003 serves as an EZH2-targeting degrader via the ubiquitin-proteasome pathway. Additionally, AXT-1003 effectively inhibited enzymatic activity of wild-type EZH2 and its mutants at nanomolar concentrations in a non-SAM-competitive manner and exhibited greater selectivity for EZH2 inhibition than EPZ-6438. AXT-1003 exhibited broader and stronger anti-proliferative activities against various lymphoma cell lines with wild-type or mutated EZH2 as well as solid tumor cell lines. Notably, in the patient-derived organoid (PDO) models from ovarian clear cell carcinoma (OCCC) samples, AXT-1003 displayed superior efficacy compared with cisplatin or mevrometostat (PF-06821497), regardless of ARID1A status. AXT-1003 suppressed tumor growth more effectively than EPZ-6438 in several cancer cell-derived xenograft (CDX) mice models. Furthermore, the *in vivo* combination treatment of AXT-1003 with enzalutamide showed synergistic efficacy in a prostate cancer (LNCaP) CDX mice model. In conclusion, our preclinical data highlight the therapeutic potential of AXT-1003 and support its ongoing clinical evaluation in patients with EZH2-driven cancers.

#4596 The combination of the AR PROTAC AZD9750 and AKT inhibitor capivasertib delivers improved efficacy over monotherapy in prostate cancer.

Antonio Ramos-Montoya[1], Chrysiis Michaloglou[1], Nuria Galeano-Dalmau[1], Ana Quiroga[1], Michael Niedbala[2], Claire Crafter[1]

[1]Oncology R&D, AstraZeneca, Cambridge, United Kingdom,[2]Oncology R&D, AstraZeneca, Waltham, MA

The PI3K-AKT pathway is frequently activated in prostate cancer through *PTEN* genetic alterations—primarily homozygous deletion in tumor cells—and is associated with poor clinical outcomes. Capivasertib, a potent, oral, selective inhibitor of AKT1/2/3, inhibits proliferation in prostate cancer cell lines with PTEN alterations. Preclinical evidence demonstrates reciprocal feedback between AR and PI3K-AKT signaling, providing a strong rationale for combined pathway blockade. Consistent with this, in the Phase III CAPItello-281 trial (NCT04493853), capivasertib plus abiraterone and ADT achieved a statistically significant improvement in radiographic progression-free survival versus abiraterone and ADT in patients with *PTEN*-deficient *de novo* metastatic hormone-sensitive prostate cancer (mHSPC). Abiraterone, an androgen receptor pathway inhibitor (ARPI), is a key standard-of-care treatment in mHSPC, yet resistance inevitably emerges via mechanisms such as AR amplification and ligand-binding domain mutations. AZD9750 is a novel AR-directed proteolysis targeting chimera (AR-PROTAC) that co-engages AR and the E3 ligase CRBN to promote AR ubiquitination and degradation, achieving deeper suppression of AR signaling and activity against both wild-type and mutant AR, with the potential to overcome resistance to current standards of care. Given the robust preclinical and clinical evidence supporting combinations of AKT inhibitors with AR pathway suppression, we evaluated whether AZD9750 could combine effectively with capivasertib in preclinical prostate cancer models. *In vitro*, combining AZD9750 and capivasertib in LNCaP (PTEN null) and VCaP (PTEN wt) cell lines enhanced antiproliferative activity and induced apoptosis, accompanied by inhibition of AKT pathway signaling (reduced pS6 and pPRAS40) and AR signaling (decreased PSA expression). In PTEN-null patient-derived xenograft prostate tumor models (both HSPC and CRPC), the combination consistently delivered significantly greater efficacy than either monotherapy, including 73% tumor growth inhibition (TGI) in TM00298 (vs AZD9750 52% TGI and capivasertib 14% TGI) and >100% TGI with 25% regression in MR041 (vs AZD9750 90% TGI and capivasertib 61% TGI), with similar benefits observed in other models. These findings indicate that in PTEN-null prostate cancer AZD9750 mediated AR degradation synergizes with AKT inhibition by capivasertib to enhance antitumor efficacy and support clinical evaluation of the AR-PROTAC-AKT inhibitor combination in PTEN-deficient prostate cancer.

#4598 An orally bioavailable, specific PLK1 bifunctional degrader for the treatment of small cell lung cancer and other cancers.

Keum Young Kang[1], Im Suk Min[1], Seong Hye Ahn[1], Gi Bbeum Lee[1], Sol Hee Noh[1], Yeon Jung Song[1], Hyun Lim[1], Boas Nam[1], Hanbit Lee[1], Su Gwon Lee[1], Woojeung Song[2], Kyungsik Ha[1], Junyang Jung[2], Jihoon Ryu[1], Soo Hee Ryu[1], Na Young Lee[1], Seong Hoon Kim[1], **Hwajin Lee**[2]

[1]UPPThera, inc., Incheon, Korea, Republic of,[2]College of Medicine, Kyung Hee University, Seoul, Korea, Republic of

Polo-like kinase 1 (PLK1) is a G2/M phase checkpoint protein that regulates signaling pathways critical for cell cycle progression, making it a key contributor to cancer cell proliferation and tumorigenesis. Due to its essential role across diverse cell types, PLK1 has emerged as an attractive therapeutic target for various cancers. Although several PLK1 inhibitors have reached clinical evaluation, most have failed to demonstrate efficacy at doses that show tolerable toxicity, highlighting the need for novel therapeutic approaches to effectively target PLK1. UP1002 is an orally administered, selective bifunctional PLK1 degrader which has been designed to potentially overcome such limitations. UP1002 promotes the proximity between PLK1 and cereblon (CRBN), leading to selective PLK1 degradation through a proteasome-dependent mechanism. Unlike traditional PLK1 inhibitors, UP1002 prevents PLK1 accumulation during G2/M arrest and induces robust cell cycle arrest and apoptosis. In preclinical models, UP1002 monotherapy demonstrated significant antitumor efficacy in multiple cancer types, which achieved near-complete tumor regression in a subset of dosing groups while reducing toxicity compared to canonical PLK1 inhibitors. Moreover, combinations of UP1002 with multiple approved therapies showed synergistic or additive antitumor activity, highlighting its potential to enhance current treatment regimens. Together, these findings suggest that UP1002 has therapeutic potential in small-cell lung cancer and may extend its efficacy to additional cancer types.

#4599 Rationally designed allosteric EGFR degrader SC3499 (IN-207375) selectively eliminates mutant EGFR and overcomes osimertinib resistance in non-small cell lung cancer.

Jihoon Choi[1], Jun Gyu Kim[1], Yu Jin Lee[1], Young Jun Park[1], Ok Young Lee[1], Young Min Jeong[1], Choongsil Lee[1], Seo Yoon Jeong [1], Hye Yeon Lee[1], Hye Sun Lee[1], Moon Jung Goo[1], Hyun Woo Park[1], Ah Yeon Park[1], Hyoeun Jo[1], Sun Ho Choi[1], Soo jung Choi[1], Dae Young Lee[1], Sun Ho Jeon[1], Jong Ryoul Choi[2], Jong Hyun Lee[2], Mirae An[2], Keunho Lee[2], Yanghun Tae[2], Ji-Young An[2], Bong Tae Kim[2], Mi-Kyung Kim[1]

[1]Dong-A ST Co. Ltd, Seoul, Korea, Republic of,[2]HK inno.N Corp, Seongnam, Korea, Republic of

Epidermal growth factor receptor (EGFR) tyrosine kinase inhibitors (TKIs) have demonstrated remarkable therapeutic efficacy in patients with non-small cell lung cancer (NSCLC) harboring activating EGFR mutations. However, acquired resistance often driven by secondary EGFR mutations remains a major clinical challenge. Although the third-generation covalent inhibitor osimertinib effectively overcomes T790M-mediated resistance and is widely used as first-line therapy. Nevertheless, resistance to osimertinib eventually develops, and patients with the EGFR L858R mutation often experience less durable responses than those with *exon 19* deletions. Therapeutic options for patients who progress after osimertinib remain limited. Targeted protein degraders act through a catalytic, event-driven mechanism that can reduce on-target resistance relative to occupancy-driven inhibitors. SC3499 is an orally active, allosteric bifunctional degrader rationally designed to selectively target mutant EGFR containing the oncogenic L858R mutation. In preclinical studies, SC3499 demonstrated potent and durable antitumor activity in both in vitro and in vivo L858R-driven NSCLC models. Importantly, SC3499 maintained full activity against multiple resistance mutations, including L858R/C797S, L858R/T790M, and L858R/T790M/C797S, which confer resistance to approved EGFR TKIs such as osimertinib. In in vivo studies, SC3499 exhibited favorable pharmacokinetic properties, excellent oral bioavailability, and induced marked tumor regression with once-daily oral dosing. Broad kinase profiling showed exceptional kinase selectivity, and global proteomic analysis confirmed selective degradation of mutant EGFR without affecting unrelated proteins or other cereblon (CRBN) substrates. These results support SC3499 as a promising, orally active, allosteric EGFR degrader capable of overcoming resistance to current EGFR-targeted therapies, including osimertinib, and providing durable antitumor responses in EGFR-mutant NSCLC.

#4600 Discovery of PLX-66140, a first-in-class, potent and selective CDK2 molecular glue degrader for CCNE1-amplified tumors.

Leenus Martin, Jean-Francois Brazeau, Nasrin Rastgoo, Quinn Spalding, Gabrielle Blanco, Kyohei Hayashi, Susan Song, Jianguo Ma, Shu You, Campos Alex, Jay Chung, Farhana Barmare, Kevin Freeman-Cook, Peggy A. Thompson

Plexium, San Diego, CA

Introduction: Dysregulation of the cell cycle is a hallmark of many cancers. The Cyclin-Dependent Kinases (CDKs) with their cyclin binding partners are associated with cell cycle progression and transcriptional regulation. Targeting CDK2 is a key therapeutic strategy in oncology, especially in Cyclin E1 (CCNE1) amplified/overexpressed and ER+ breast cancers. CCNE1 amplification/overexpression and activation of its canonical binding partner CDK2 is a major resistance mechanism in CDK4/6i breast cancer therapy. In addition, elevated CCNE1 expression and complexation with CDK2 promotes aberrant cell cycling which is associated with poor prognosis in ovarian, breast and uterine cancers. Targeting CDK2 using small molecule active site inhibitor-based approaches have advanced into the clinic; however, maintaining selective CDK2 inhibition at efficacious exposures is challenging due to the high sequence homology across other CDKs. Molecular glue degraders have the potential to selectively target CDK2 and provide improved clinical benefit while minimizing off-target toxicities.

Results: Here we report the discovery of our development candidate, PLX-66140, a novel, potent and selective cereblon (CRBN) based CDK2 molecular glue degrader for the treatment of CCNE1 amplified cancers. Plexium's ultra-high throughput screening platform and medicinal chemistry optimization efforts identified our lead molecular glue degrader that induces CRBN-CDK2 ternary complex formation and demonstrates proteasomal dependent, CRBN-mediated degradation of CDK2 in cell-based assays. Global proteomics confirms that PLX-66140 degrades CDK2 selectively without modulating known cereblon neosubstrates and exhibits dose dependent modulation of E2F target genes. Potent, deep and selective degradation of CDK2 with PLX-66140 treatment, results in robust inhibition of RB phosphorylation, cell cycle arrest and antiproliferative activity in a panel of CCNE1 amplified cancer cell lines. In contrast to ATP-competitive small molecule inhibitors, PLX-66140 demonstrates selective inhibition of cell cycle arrest and proliferation in CCNE1 amplified cells, and minimal activity in non-CCNE1 amplified cells, highlighting the selectivity and potential superior safety profile over inhibitors. Oral administration of PLX-66140 in tumor bearing mice demonstrates robust target degradation and enhanced anti-tumor activity over ATP-competitive inhibitors in multiple CCNE1 amplified xenograft models at well tolerated doses.

Conclusion: Our development candidate, PLX-66140 provides compelling preclinical evidence and scientific rationale for clinical development in CDK4/6 inhibitor-naïve and -resistant $HR^+/HER2^-$ breast cancer along with CCNE1 amplified solid tumors.

#4601 Rational design of potent androgen receptor degraders via AI-assisted molecular modeling and validation of anti-tumor efficacy in prostate cancer.

Chih-Chang Chou, You-Sheng Lin, Cheng-Li Chou, Kuan-Hung Chen, Shu-Jen Chen, Chu-Chiang Lin

AnHorn Medicines Co., Ltd., Taipei, Taiwan

The androgen receptor (AR) plays a central role in the progression of prostate cancer, and its sustained signaling remains a major challenge in castration-resistant prostate cancer (CRPC). Targeted protein degradation of the AR offers a promising therapeutic strategy to overcome therapeutic resistance that limits the efficacy of current AR antagonists. To rationally design novel AR degraders, we employed AnHorn's proprietary AIMCADD (Artificial Intelligence-bio-Informatic-MedChem-Computer-Aided Drug Design) platform to predict the three-dimensional binding conformations between the AR ligand-binding domain (AR-LBD) and CRBN E3 ligase. Molecular dynamics (MD) simulations were used to calculate binding free energies and identify the most stable AR-CRBN ternary complex. Based on this complex, the binding conformations of AR-LBD and CRBN warheads were obtained via molecular docking, followed by AI-assisted linker generation using AIMLinker, a deep neural network-based algorithm, to construct a virtual library of degrader candidates. Molecular docking and dynamic simulations were further applied to evaluate ternary complex stability and binding affinity, from which a subset of top-ranked candidates were selected for experimental validation. Lead candidates effectively induced AR degradation in LNCaP, 22Rv1, and VCaP cells. Notably, these degraders also retained activity against clinically relevant AR mutants frequently observed in CRPC patients, including L702H, T878A, H875Y, W742C, and F877L. The degradation was abolished by co-treatment with the proteasome inhibitor MG132, confirming a ubiquitin-proteasome-dependent mechanism. Direct binding of the lead compound to AR was further verified by drug affinity responsive target stability (DARTS) assay. Quantitative RT-PCR analysis revealed a marked downregulation of AR downstream targets, *KLK3* (PSA), suggesting the loss of AR transcriptional activity. In cell viability assays, the most potent compound selectively suppressed proliferation of AR-positive prostate cancer cells, with minimal cytotoxicity in normal cells. In xenograft animal models, once daily administration significantly reduced tumor volume and prostate specific antigen (PSA) level in plasma without observable systemic toxicity. In summary, through AI-assisted molecular design and computational screening, we developed a potent AR degrader that efficiently induces proteasome-dependent AR degradation, suppresses AR transcriptional activity, and exhibits robust anti-tumor efficacy *in vivo*. These results highlight a promising therapeutic approach for advanced prostate cancer through targeted AR degradation.

#4602 Dual HDAC3/8 PROTAC degraders exert anti-tumor and immunomodulating effects in diffuse large B-cell lymphoma.

Michael Y. He[1], Yufeng Xiao[2], Mehran Bakhtiari[1], Ting Liu[1], Wenxi Xu[1], David G. Brooks[1], Housheng Hansen He[1], Guangrong Zheng[2], Robert Kridel[1]

[1]UHN Princess Margaret Cancer Centre, Toronto, ON, Canada,[2]University of Florida, Gainesville, FL

Critical challenges remain in the clinical management of diffuse large B-cell lymphoma (DLBCL), as up to 40% of patients experience disease relapse or refractoriness. Despite the use of novel therapies, relapsed/refractory DLBCL results in a high risk of mortality, especially in the activated B-cell-like (ABC) subtype. Developing new therapeutic options for those patients becomes a pressing and clinically unmet need. Here, we explore the combined targeting of histone deacetylase (HDAC) 3 and 8 by targeted protein degradation to combat epigenetic deregulation in DLBCL. Through a comprehensive screen using single or dual HDAC3/8-targeting compounds in 12 DLBCL cell lines, we discovered that a highly selective, potent, first-in-class dual HDAC3/8 proteolysis-targeting chimera (PROTAC) degrader YX968 potently suppressed cell survival and proliferation. This effect was particularly more prominent and significantly stronger than single HDAC3 or 8 PROTACs in the ABC-DLBCL cell lines. Further functional evaluations revealed that YX968 specifically induced caspase-3-mediated apoptosis and caused cell cycle arrest. Mechanistically, YX968 profoundly upregulated H3K27 acetylation (H3K27ac), a key epigenetic mark for enhancer regulation, and generated a unique transcriptomic profile with downregulated genes associated with cell cycle regulation and upregulated genes implicated in immune activation. Moreover, we validated the gene expression results using flow cytometry for upregulated surface protein expression of the antigen presentation markers MHC-I and II, and detected enhanced $CD8^+$ T-cell-induced cytotoxicity by YX968 in an in vitro T-cell co-culture assay, indicating its immunomodulating activities to potentiate anti-tumor immunity. Although YX968 showed in vitro efficacy, we found that it had poor metabolic stability, which precluded its potential in vivo application. To enhance the translation value of our approach, we developed a second-generation dual HDAC3/8 PROTAC (YX226) with improved metabolic stability while maintaining potent degradation, cell-killing, and immunomodulating activities. Using global proteomics, we confirmed the on-target activity of YX226 to selectively degrade HDAC3 and 8 but not the other HDAC isoforms. Importantly, we observed significant in vivo HDAC3/8 protein degradation and tumor growth inhibition by YX226 in a xenograft lymphoma model without adverse reduction of body weight, providing proof-of-principle evidence for in vivo efficacy and safety of a dual HDAC3/8 PROTAC. In conclusion, our findings demonstrate that dual HDAC3/8 PROTAC degraders induce significant anti-tumor and immunomodulating effects in our preclinical DLBCL models, supporting further development and evaluation of our second-generation bioavailable compound YX226 as a novel treatment option for DLBCL.

#4603 Favorable DMPK properties enable development of a novel arylsulfonamide RBM39 molecular glue degrader, PPI-101, for the treatment of neuroblastoma.

Jian Wu, Lei Zhou, Yongzhi Gao, Shanshan Wang, Qi Zhang, Jingping Mei, Fang Bai, Song Feng, **James X. Rong**

Peak Perform Innova, Shanghai, China

Background: E7820 and related arylsulfonamides have recently been recognized as molecular glues that recruit the splicing factor RBM39 to the CRL4-DCAF15 E3 ligase complex, triggering RBM39 ubiquitination and degradation. Despite clinical evaluation, these degraders have shown limited efficacy and dose-limiting hematotoxicity. The underlying in vivo pharmacology of RBM39 degraders remains poorly defined, hindering optimization.
Methods: We characterized the pharmacokinetic (PK), pharmacodynamic (PD), and efficacy relationships of E7820 and analogs (PPI-101, R134, R111, R011) in an IMR32 neuroblastoma xenograft model. Compounds were administered orally once daily for 28 days. Tumor growth inhibition (TGI), plasma/tumor exposures, and RBM39 protein levels were quantified to establish PK/PD relationships and identify next-generation RBM39 degraders with improved therapeutic index (TI).
Results: E7820, PPI-101, R134, and R011 achieved complete tumor growth inhibition at 30 mg/kg. TGI correlated with unbound exposure normalized by cellular DC50 values, exhibiting a sigmoidal relationship between efficacy and exposure multiples. Following 3-day dosing, tumor RBM39 remained ≥75% depleted for up to 30 hours after the last dose, even when unbound plasma and tumor concentrations had fallen >300-fold below DC50, indicating slow RBM39 recovery kinetics and sustained pharmacodynamic effect. PPI-101 showed the most favorable DMPK profile, with the lowest human plasma protein binding, the highest volume of distribution (Vss = 0.77 L/kg)—an indicator of drug distribution between plasma and peripheral tissues—and superior tumor penetration (tumor/plasma ratio = 1.0, ~50% higher than E7820). Consequently, lower plasma exposure was required for equivalent tumor coverage, reducing systemic exposure and the risk of hematologic toxicity. Preliminary toxicology studies revealed a markedly improved TI (14 for PPI-101 vs <2.7 for E7820), consistent with reduced reticulocyte and lymphocyte suppression.
Conclusions: This study defines, for the first time, the in vivo PK/PD relationships governing RBM39 degradation and demonstrates that favorable distribution properties can markedly enhance therapeutic index. PPI-101 emerges as a potent and safer RBM39 degrader candidate for neuroblastoma therapy, warranting GLP toxicology and IND-enabling development.

#4604 Preclinical efficacy of a PROTAC pan-KRAS degrader in a KRAS G12D syngeneic mouse model and concurrent immune tumor microenvironment changes.

Jason M. Berk, Andrea Lopez-Arroyo, Dana M. Klug, John P. Caldwell, Peter Hegan, Samantha Andella, Jessica Kraus, Amanda Chapman, Jennifer Pizzano, Mark Bookbinder, Gregory Cadelina, Debbie Gordon, Kim Davenport, Wendy Wu, Madeline A. Dorso, Morena Scopel, Rebecca Conrad, William Corwin, Goutham Pattabiraman, Keith R. Hornberger, Angela Cacace, Ignacio J. Juncadella, Kathryn D. Smith

Arvinas Operations, Inc., New Haven, CT

Missense mutations in *KRAS* occur in ~20% of cancers. Although 2 KRAS inhibitors have been approved for patients with *KRAS* G12C-mutated disease, resistance quickly develops; moreover, no approved agents target other KRAS mutants. We developed a tool PROteolysis TArgeting Chimera (PROTAC) pan-KRAS degrader that induces the ubiquitination and subsequent proteasomal degradation of KRAS; it potently and selectively degrades active and inactive KRAS forms. Selective KRAS degradation that spares HRAS and NRAS may yield a higher therapeutic index than current investigational RAS inhibitors targeting all RAS isoforms. Additionally, the iterative activity of the PROTAC pan-KRAS degrader may overcome resistance driven by *KRAS* upregulation, a common RAS inhibitor resistance mechanism. Mutant KRAS is an established intrinsic driver of an immunosuppressive tumor microenvironment (TME), which can be alleviated by KRAS inhibition, suggesting potential synergy with immune checkpoint blockade (ICB). We compared the antitumor activity of PROTAC-driven KRAS degradation vs RAS inhibition (± ICB with an anti-programmed death-1 antibody) and the effects on TME in a KRAS G12D murine colorectal cancer model, CT-26. Our PROTAC potently degraded mutant KRAS and exhibited antiproliferative effects in spheroids that were comparable to a clinical RAS(ON) inhibitor. Oral administration of the PROTAC pan-KRAS degrader as a single agent in the CT-26 model led to substantial KRAS degradation (>85%), robust and durable suppression of mitogen-activated protein kinase pathway activity, and substantial tumor growth inhibition, including complete responses (CRs). The PROTAC pan-KRAS degrader combined with ICB led to deeper and more rapid tumor regressions, resulting in a higher rate of CRs and longer post-treatment survival, compared with the RAS(ON) inhibitor plus ICB. To characterize TME changes, tumors treated with the PROTAC pan-KRAS degrader or RAS(ON) inhibitor (± ICB) were compared by bulk RNA sequencing (RNAseq) and tumor-infiltration leukocyte (TIL) analysis. RNAseq revealed strong RAS pathway suppression by both agents, leading to altered gene expression in tumor-intrinsic and extrinsic molecular pathways. KRAS degradation demonstrated a differential positive enrichment for key immune-related pathways associated with antitumor immunity and immune activation, suggesting PROTAC-specific immune TME changes may contribute to its antitumor effects. TIL analysis demonstrated statistically significant changes in immune populations, including cytotoxic T cells and myeloid cells, after PROTAC treatment. The observed rapid tumor regressions, paired with deeper immune response and longer survival, suggest that the PROTAC pan-KRAS degrader is more efficacious and permissive to ICB combination than a RAS(ON) inhibitor in an immunocompetent tumor model system.

#4605 Brigatinib based degraders as a therapeutic strategy for triple negative breast cancer.

Manu Khosla[1], Suresh Alahari[1], Guangdi Wang[2]

[1]Biochemistry and Molecular Biology, Louisiana State University Health Sciences Center, New Orleans, LA,[2]Xavier University of Louisiana, New Orleans, LA

Background: Treatment of patients with triple-negative breast cancer (TNBC) has been challenging due to the absence of well-defined molecular targets and high invasive and proliferative capabilities of these cells. Therefore, new therapeutic strategies for treatment of TNBC are urgently needed. Protease-targeted chimeras (PROTACs) are a class of emerging therapeutic inhibitors that recruit the ubiquitin E3 ligase to selectively degrade proteins. PROTAC degrader technology has shown robust results in inhibiting TNBC progression.
Methods: RNA sequencing and analysis were done. Samples were submitted to PamGene for kinome profiling and analysis. Western blotting was performed to visualize protein expression. MTT assays were carried out to evaluate cell viability. Colony formation assays assessed changes in clonogenicity. Data were analyzed using Graph Pad Prism Software 8 using one-way ANOVA and the unpaired two-tailed Students t-test. All data were evaluated in triplicate against control cells.
Results: Analysis of RNA sequencing in LM2-4175 TNBC cells treated with our target degrader showed increased genes associated with apoptosis and a decrease in genes associated with cell cycle checkpoint, DNA replication, and regulation of P53 signal transduction pathways. Kinase activity profiling of MDAMB231-LM2-4175 TNBC cells treated with our degrader showed a significant reduction in serine/threonine kinases (STKs) associated with Mitogen-activated protein kinase (MAPK) and cyclin-dependent kinase (CDK) families. In addition, we noticed a significant decrease in protein tyrosine kinases (PTK) associated with ephrin receptor proteins. Western blot analysis confirmed targeted degradation of Focal Adhesion Kinase in multiple TNBC cell lines (MDAMB-231-LM2-4175, MDAMB-468, and 4QXTB). MTT analysis of cell proliferation showed our degrader selectively targeted
MDAMB231, MDAMB231-LM2-4175, MDAMB-468, and 4QXTB (Primary)TNBC cells over our non-neoplastic cell line, MCF10A, in a nanomolar range. Colony formation assays also showed our degrader was able to reduce clonogenicity in TNBC cell lines MDAMB231-LM2-4175, MDAMB-468, and 4QXTB.
Conclusions:Breast cancer is a diverse and intricate disease which is known to have unique inter- and intra-tumoral characteristics. We have identified a candidate PROTAC which can selectively target TNBC cells while minimally affecting normal bystander cells at nanomolar ranges in vitro. The further development of this degrader can serve as the fundamental basis for a novel therapeutic treatment in TNBC.

#4606 Rational development of novel DCAF16-mediated SMARCA2 selective Targeted Glues™ for the treatment of SMARCA4 deficient tumors.

James T. Lynch, Martin Ambler, Nicole Zordan, Claudia De Fusco, Laura Casares Perez, Kathryn Bosson, Alexander Fawcett, Paula MacGregor, Tarun Narwani, Colin T. R. Davies, Mahad Gatti Lou, Edward Hooper-Greenhill, Liliana Greger, Giles A. Brown, Martin Pass, Louise K. Modis

Amphista Therapeutics, Cambridge, United Kingdom

SMARCA2 and SMARCA4 are mutually exclusive catalytic subunits of the SWI/SNF chromatin remodelling complex. In non-small cell lung cancer (NSCLC), SMARCA4 mutations are observed in >5% patients and are associated with poor prognosis and advanced disease. Selective degradation of SMARCA2 exploits paralogue dependency in SMARCA4-deficient tumors to impact disease burden with minimal toxicity in normal tissues.

Here, we report the rational design and optimisation of a novel class of SMARCA2 degraders that exploit a Targeted Glue™ mechanism to induce DCAF16-dependent proteasomal degradation. Amphista's degraders potently drive >95% SMARCA2 degradation within 4 hours, resulting in deep suppression of biomarkers KRT80 and PLAU *in vitro*. Further, we observe exceptional degradation specificity for SMARCA2, as revealed by global proteomics and, critical for a best-in-class molecule, achieve near complete selectivity over SMARCA4 in a SMARCA4 WT model.

Comprehensive mode of action studies, including E3-ligase knock-out and cysteine mutant rescue experiments demonstrate that our SMARCA2 Targeted Glues™ induce degradation via selective recruitment of DCAF16 and covalent interaction with a single DCAF16 cysteine residue. Structural studies, including generation of multiple high resolution (sub-3Å) cryo EM ternary complex structures have enabled informed structure-activity relationship optimisations of degradation potency, kinetics and selectivity. Consequently, optimised compounds can deliver fast, deep degradation of SMARCA2 as demonstrated *in-vivo* in a disease-relevant SMARCA4 mutant model.

We have achieved compound profiles that uniquely position Amphista to deliver class-leading SMARCA2 degraders for the treatment of SMARCA4-mutant NSCLC.

#4607 Preclinical evaluation of a cardiosafe first-in-class MCL-1 degrader for the treatment of hematological malignancies.

Tomasz Tomczyk, Anna Maria Serwotka-Suszczak, Robert Dyjas, Jose Arencibia, Monika Milewicz, Klaudia Poniatowska, Jolanta Skalska, Andrzej Tracz, Diana Trębicka, Karolina Wojcik, Sylvain Cottens, Piotr Kowalczyk, Paweł Dobrzański, Michał Biśta, Katarzyna Brach, Toshimitsu Takagi, Martyna Pastok, Justyna Adamczyk, Iwona Mames, Michał Walczak

Captor Therapeutics S.A., Wrocław, Poland

MCL-1, a member of the Bcl-2 family of apoptosis regulators, is a critical pro-survival factor implicated in tumor maintenance and therapeutic resistance across a wide range of cancers. Although several MCL-1 inhibitors have entered clinical development, many were discontinued due to dose-limiting cardiac toxicity. Targeted protein degradation offers an alternative strategy with potential advantages, including improved selectivity, prolonged pharmacodynamic effects, and reduced risk of adverse cardiac events.

Here, we describe the discovery and preclinical characterization of a novel bifunctional compound designed to selectively degrade MCL-1 for the treatment of hematological malignancies. Biophysical assays confirmed ternary complex formation between the degrader, MCL-1, and an E3 ligase. The compound induces proteasome-dependent degradation of MCL-1, leading to apoptosis and cell death in a broad panel of human cancer cell lines, with low nanomolar potency (pIC_{50} ~9 for MV4-11, OPM-2, and DMS114). Cytotoxic effects were observed across leukemia, lung cancer, and multiple myeloma models, while sparing normal and primary cells. In human iPSC-derived cardiomyocytes, the degrader caused only transient reduction of MCL-1 levels, in contrast to MCL-1 inhibitors that induced 6-15-fold MCL-1 upregulation persisting after washout, a mechanism linked to elevated cardiac troponin in clinical trials.

In vivo, the compound demonstrated strong antitumor activity in AML xenograft models, inducing MCL-1 degradation and tumor growth inhibition. Combination with low-dose venetoclax (7.5 mpk) promoted tumor regression at 5 mpk using an intermittent dosing regimen (2 days on/5 days off). In non-human primates, the compound exhibited a favorable pharmacokinetic/pharmacodynamic profile with effective MCL-1 degradation and no evidence of cardiac toxicity at exposures exceeding predicted human efficacious levels.

In conclusion, we have developed a highly potent and selective bifunctional MCL-1 degrader that shows robust activity *in vitro* and *in vivo*, complete target coverage, and a favorable safety margin compared with MCL-1 inhibitors. These findings support MCL-1 degradation as a promising therapeutic approach for hematologic malignancies. The compound is advancing through IND/CTA-enabling studies, with a first-in-human Phase 1 trial planned for 2026.

#4608 GSK5471713: A novel, selective oral androgen receptor degrader with best-in-class potential for the treatment of prostate cancer.

Christine Thompson[1], Yang Lee[2], Melissa C. Musso[1], Kwok-Ho Chan[3], Kamelia Behnia[1], Edward Hooper-Greenhill[3], Christian S. Sherk[1], Nanhua Deng[2], Nadeesha Rajapaksha[1], Mansi Babbar[1], Sarah Gerhart[1], Julie Bullock[1], Kenneth W. Hance[1], Benjamin Schwartz[2], Laure Rittie[1], Christopher P. Tinworth[3], **Anastasia Wyce**[1]

[1]GSK, Collegeville, PA,[2]GSK, Cambridge, MA,[3]GSK, Stevenage, United Kingdom

The androgen receptor (AR) is a ligand-dependent transcription factor that controls expression of genes involved in normal prostate development and is a critical driver of prostate cancer growth and survival. Patients with locally advanced or metastatic disease are frequently treated with AR pathway inhibitors (ARPIs) targeting AR (e.g., enzalutamide) and/or androgen synthesis (e.g., abiraterone), and while these therapies offer survival benefit, patients frequently develop resistance via reactivation of AR signaling. AR pathway re-activation is often mediated by direct alterations to AR, including gene amplification, structural rearrangements, point mutations in the ligand binding domain (LBD), and co-expression of constitutively active splice variants. In total, AR alterations are observed in >60% of metastatic castration resistant prostate cancer (mCRPC) patients and are associated with resistance to ARPIs.

Heterobifunctional degraders recruit proteins of interest to the ubiquitin-proteasome system for targeted degradation. As these molecules degrade their target protein, they offer an opportunity to overcome or avoid resistance mechanisms impacting inhibitors of functional activity. We disclose herein GSK5471713 as a potent and selective oral AR degrader, comprised of an AR LBD ligand linked to a binder of the E3 ubiquitin ligase CRBN. GSK5471713 potently degrades all clinically relevant forms of full-length AR, including wild type, LBD mutants, and in amplified settings. Similar to other AR degraders currently in clinical development, it functions as a dual AR degrader and antagonist. GSK5471713 potently degrades full-length AR in prostate cancer cell lines *in vitro*, resulting in transcriptional down-regulation of AR-dependent genes and gene signatures and inhibition of cell growth. Increased potency is observed for GSK5471713 in prostate cancer cell lines *in vitro* compared to both enzalutamide and other AR degraders. *In vivo*, GSK5471713 induces time- and dose-dependent AR degradation in prostate cancer xenografts. Daily oral administration induces dose-dependent tumor growth inhibition and tumor regressions, with commensurate decreases in plasma PSA levels. Comparison of the *in vivo* activity of GSK5471713 to enzalutamide and other AR degraders dosed at clinical exposure equivalents suggest an opportunity for differentiated efficacy. In total, these data demonstrate GSK5471713 as a potential best-in-class AR degrader offering benefit to patients with prostate cancer. GSK5471713 is expected to advance into Phase 1 clinical studies in early 2026.

#4609 Discovery and development of PRMT5/MEP50 degraders for the selective targeting of MTAP-null cancers.

Yue Zhong, Qian Chao, Yan Xiong, Husnu Kaniskan, Jian Jin

Departments of Pharmacological Sciences and Oncological Sciences, Icahn School of Medicine at Mount Sinai, New York, NY

Protein arginine methyltransferase 5 (PRMT5) is an important regulator of various biological processes through the mono- and symmetric dimethylation of protein substrates. PRMT5 is overexpressed in multiple human cancers, and its overexpression is often associated with poor prognosis. We recently reported MS115, a best-in-class PRMT5 degrader that potently and selectively degraded PRMT5 and its coactivator, MEP50, in concentration-, time-, and ubiquitin-proteasome system-dependent manners. MS115 displayed markedly improved PRMT5/MEP50 degradation potency over published PRMT5 degraders, which translated to superior antiproliferative effect in both breast and prostate cancer cells. More importantly, MS115 exhibited safer cytotoxicity profile compared to existing PRMT5 degraders and inhibitors in normal cells. Nonetheless, residual antiproliferative activity in MTAP-proficient cells highlights the need for improved therapeutic selectivity. To address this limitation, we tackled the synthetic lethality between PRMT5 and MTAP loss. MTAP homozygous deletions, present in approximately 15% of human cancers, lead to accumulation of methylthioadenosine (MTA), an endogenous PRMT5 inhibitor. By leveraging MTA-cooperative PRMT5 inhibitors, we generated a series of PRMT5/MEP50 degraders that selectively degraded PRMT5 and MEP50 and suppressed proliferation in MTAP-null cancer cells, while sparing MTAP-wild-type counterparts across breast cancer and cholangiocarcinoma models. This targeted selectivity enables the study of both catalytic and non-catalytic functions of PRMT5 with substantially improved tolerability. Collectively, we have discovered MS115 and multiple MTA-cooperative PRMT5/MEP50 degraders with enhanced potency and safety, providing valuable chemical probes and promising candidates for the treatment of cancers driven by PRMT5 dysregulation.

#4610 The B-hCRBN mice model facilitates PROTACs studies based on CRBN ligands.

Jay Zhang, Yue Zhang, Chonghui Liu, Ying Zhao, Xiao Liu, Jiansu Zhang

Biocytogen, Waltham, MA

In recent years, CRBN ligands have gradually become popular E3 ligase ligands. They can be used to design and synthesize PROTACs and molecular glue degraders, playing an important role in these fields. CRBN, together with DDB1 (damaged DNA binding protein 1), Cul4A (Cullin 4A), and ROC1, forms the E3 ubiquitin ligase complex (CRL4). As a substrate receptor, CRBN binds certain proteins, promoting their ubiquitination and proteasome-dependent degradation. Through its E3 ligase function, CRBN regulates the degradation of various proteins, which is crucial for cell growth, differentiation, and apoptosis. CRBN is expressed not only in tumor cells but also in normal cells. In the treatment of multiple myeloma (MM), immunomodulatory drugs targeting CRBN (such as thalidomide and lenalidomide) show significant efficacy. These drugs alter the substrate specificity of CRBN, inducing degradation of tumor-associated proteins and thereby inhibiting cancer cell growth. Additionally, CRBN-based PROTACs (Proteolysis Targeting Chimeras) are currently being developed as a novel cancer treatment strategy. CRBN-based PROTACs recruit the CRBN complex to the target protein, leading to its polyubiquitination and subsequent proteasome degradation.Biocytogen has developed the B-hCRBN mouse model. The CDS of the human CRBN gene that encodes the full-length protein was inserted into the mouse *Crbn* exons 2-3. The B-hCRBN mice will express the human CRBN protein, while mouse *Crbn* will no longer be expressed. Heart, liver, spleen, lung, kidney, stomach, small intestine, colon, and cortex were collected from homozygous B-hCRBN mice. Human *CRBN* mRNA was only detectable in homozygous B-hCRBN mice. The cortex, liver, lung, kidney, and spleen were collected from homozygous B-hCRBN mice, and then analyzed by western blot with anti-CRBN antibody. CRBN was detectable in homozygous B-hCRBN mice. Naïve CD4+ T cells from B-hCRBN mice have increased production of IL-2 when treated with Lenalidomide. CC-885 exhibits marked toxicity exclusively in B-hCRBN mice, with no detectable toxicity observed in wild-type mice. The body weight, complete blood count, and blood biochemistry of male and female B-hCRBN mice were analyzed. The main organs were dissected, weighed, and analyzed by H&E staining. No obvious abnormalities were found in all the organs detected (brain, heart, lung, liver, spleen, stomach, small intestine, colon, kidney, uterus, ovary, and testis). In summary, the development of the B-hCRBN mouse model has been successful, as it successfully expresses the human CRBN protein and can be used functionally. Tumor cell lines inoculated in B-hCRBN mice can be used to study the *in vivo* efficacy and safety evaluation of CRBN small molecule drugs, molecular glue drugs based on CRBN, or PROTAC drugs based on CRBN.

#4611 Small-molecule stabilization of non-native c-Myc multimer drives degradation using an IDP-targeting discovery platform.

Markus K. Muellner[1], Christian Kuehne[2], Michael Ahrweiler[2], Antony Crisp[1], Florian Kellner[1], Katharina Strasser[1], Paulina Pacak[1], Bechir Zitouni[1], Joonsun Lee[1], Milanka Gavrilovic[1], Lisa Wurm[1], Bernadette Winter[1], Manuela Richter[1], Fiona Liebig[1], Noel Riedl[1], Christoph Berger[1], Stefan Seidl[1], David Fischer[1], Christine Triska[1]

[1]RDP Pharma AG, Romanshorn, Switzerland,[2]RDP Pharma AG

Intrinsically disordered proteins (IDPs) such as c-Myc remain largely undrugged despite their central role in cancer. We developed Prompt Degrader™, a computational platform that predicts transient ordered conformations in IDPs and identifies drug-like, orally bioavailable, non-covalent small molecules that stabilize degradation-prone states. Using in silico modeling of a c-Myc homodimer pocket, we identified compounds predicted to stabilize dimerization and to promote targeted protein degradation of c-Myc via a mechanism distinct from conventional PROTACs or molecular glues. Our hit RDP-02004 induced rapid, dose-dependent loss of c-Myc protein (DC_{50} ~5-10 µM) and apoptosis across diverse MYC-dependent cancer cell lines, including multiple myeloma, lung and triple-negative breast cancer, with selectivity over non-transformed cells. RDP-02004 showed high microsomal stability and broad in vivo activity, suppressing tumor growth in three xenograft models after oral dosing. Minimal weight loss and only mild hepatic and renal findings were observed. Mechanistic studies indicated engagement of multiple protein quality-control pathways, consistent with clearance of misfolded c-Myc species. The proteasome inhibitor MG-132, the ubiquitin-activating enzyme inhibitor TAK-243, and the autophagy inhibitor Autophinib each rescued c-Myc levels after compound treatment, implicating both ubiquitin-proteasome and aggrephagy-like mechanisms. Based on these findings, we screened scaffold-divergent analogues and identified RDP-09024, which likewise showed potent c-Myc degradation and cytotoxicity with an improved off-target profile. Direct target engagement of recombinant c-Myc protein was confirmed by ligand-observed STD and WaterLOGSY NMR experiments, in which RDP-09024 showed no binding to a negative-control protein. We confirmed the predicted binding mode and pocket of RDP-09024 via hydrogen-deuterium exchange mass spectrometry (HDX-MS) with or without compound, revealing a flexible loop on c-Myc directly involved in RDP-09024 binding. Prompt Degrader™ compounds were active ex vivo in $CD138^+$ multiple myeloma patient cells as well as in xenograft models and showed a significantly improved selectivity profile versus non-cancer cells. Structure-activity and pharmacophore analyses, together with structure-based design, yielded additional series with improved properties and activity (DC_{50} < 1 µM). These data provide proof of concept that exploiting IDP conformational ensembles to stabilize degradable c-Myc assemblies can generate small-molecule c-Myc degraders and support further optimization of this platform toward safer, more selective anti-MYC therapeutics.

#4612 Application of mechanistic preclinical PK/PD/efficacy modeling to support combination strategy for AZD9750, a novel oral androgen receptor degrader (PROTAC).

Ana Quiroga[1], Pablo Morentin Gutierrez[1], Antonio Ramos-Montoya[1], Chrysiis Michaloglou[1], Nuria Galeano-Dalmau[1], Claire Crafter[1], Aaron Smith[1], Jamie Scott[1], Michael Niedbala[2]

[1]AstraZeneca, Cambridge, United Kingdom,[2]AstraZeneca, Waltham, MA

The androgen receptor (AR) is highly expressed in prostate cancers and is a clinically validated target in oncology. AZD9750 is a novel potent oral selective AR Proteolysis-targeting chimera (PROTAC) with a suitable pharmacological profile to be used in combination with a variety of other therapeutics such as capivasertib, a potent pan-AKT kinase inhibitor with anti-tumor activity in tumors with PIK3CA and PTEN mutations, and saruparib, a PARP1-selective inhibitor especially effective against tumors with mutations in genes like BRCA1 and BRCA2. We present here the preclinical PK/PD/Efficacy modeling work used to understand the anti-tumor mechanism of AZD9750 in combination with AKT and PARP inhibitors. We developed a novel mechanistic mathematical model applied to in vivo preclinical hormone sensitive, ARwt prostate PDX models C901 and MR041. C901 has homologous deletion of BRCA2 and MR041 is PTEN null, making them appropriate candidates for combination with PARP and AKT inhibitors, respectively. The PK module of the model describes the compound exposure in monotherapy and combination. The PD module describes the AR, AKT, GSK3β and S6 total and phosphorylated levels measured by Western Blotting and PARylation levels measured by ELISA. In the efficacy module, the levels of AR, pS6 and PARylation were linked to tumor growth inhibition while pGSK3β and PARylation levels were linked to induction of apoptosis; subsequently, these parameters determine the tumor size. All model parameters were derived from internal studies; some were estimated using Non-Linear Mixed Effect modeling of individual longitudinal PK, PD biomarkers and tumor size data taken from several studies. The model describes well the relationship between plasma concentration of the different compounds and PD biomarkers modulation both in monotherapy and in combination. Furthermore, the mathematical model is capable of explaining the enhanced anti-tumor efficacy in combination as a function of the different biomarkers' modulation. This study provides quantitative mechanistic insights into the AZD9750 combination with AKT and PARP inhibitors. The study enriches our understanding of biomarkers relevant to AR-PROTACs, PARP inhibitors, and AKT inhibitors, informing the selection of biomarkers for monitoring in clinical trials. Additionally, it quantifies the extent of biomarker modulation required to achieve maximal antitumor activity and supports rational combination strategies, as well as dose and schedule optimization for clinical development.

#4613 ZMS-4426, an oral degrader of SMARCA2 shows potent anti-tumor activity, but variant selectivity against SMARCA4 across species.

Lu Liu, Fanxun Zeng, Ruonan Chen, Mengnan Hu, Yao Guo, Wenjing Li, Mei Lan, Liting Xue, Zhengtao Li, Renheng Tang

State Key Laboratory of Neurology and Oncology Drug Development, Simcere Zaiming Pharmaceutical Co., Ltd., Shanghai, China

Mammalian SWI/SNF complexes always contain one of two mutually exclusive and structurally highly related ATPases: SMARCA2/BRM or SMARCA4/BRG1, as its catalytic subunit. It is reported that SMARCA4 is absent in a serial of cancers, and these SMARCA4 deficient cancer cells are highly dependent on its paralog SMARCA2 for survival. Therefore, it holds great therapeutic promise to treat SMARCA4 deficient cancers with selective SMARCA2 degraders. Here, we reported ZMS-4426, a highly selective SMARCA2 degrader. In HiBiT knock-in HeLa cells, it potently degraded SMARCA2 with a >10,000-fold selectivity over SMARCA4. The global proteome data also indicated that ZMS-4426 was highly specific in degrading the expected target proteins SMARCA2. Furthermore, ZMS-4426 demonstrated high degradation selectivity of SMARCA2 over SMARCA4 in a variety of human cancer cell lines and PBMCs of multiple species. However, in dog PBMCs, the degradation selectivity between SMARCA2 and SMARCA4 varies among individuals.Due to the high selectivity over SMARCA4, ZMS-4426 effectively inhibited the proliferation of SMARCA4 deficient cells, and inhibited the proliferation of neither SMARCA2/4-WT cells nor SMARCA2/4-DEL cells. Furthermore, the *in vitro* synergistic effects were observed when SMARCA4-loss NSCLC cells were treated with ZMS-4426 in combination with docetaxel.ZMS-4426 exhibited good oral availability in mice, rats, and dog. In the NSCLC NCI-H838 CDX model, ZMS-4426 effectively inhibited tumor growth, and the tumor growth inhibition (TGI) correlated well with SMARCA2 degradation in tumors. Further, the combination treatment of ZMS-4426 and nab-paclitaxel effectively suppressed tumor growth to a greater extent than either agent alone.

However, ZMS-4426 was not tolerated in dog for 7-day treatment at 2 mpk. Strong degradation of SMARCA4 in lung was detected, suggesting poor *in vivo* degradation selectivity in dog. Further, in monkey, the treatment of ZMS-4426 for 7-day at 1.5 mpk resulted in body weight loss and deep degradation of SMARCA4 in PBMCs, indicating that *in vitro* degradation selectivity in monkey PBMCs did not maintained *in vivo*.Similar findings were also observed in rats. In a head-to-head comparison with compound A (a reference molecule from WO2025194405, Prelude Therapeutics), treatment of ZMS-4426 and compound A for 4-day at 5 mpk intravenous injection in rats both induced complete degradation of SMARCA4 at 24 hours post-dose, indicating that neither compound preserved its selectivity profile *in vivo*.In conclusion, our potent and selective SMARCA2 degrader, ZMS-4426 induces strong synthetic lethality in SMARCA4 deficient cells both *in vitro* and *in vivo*. However, more studies are needed to elucidate discrepancy in degradation selectivity between *in vitro* and *in vivo* results.

#4614 Evaluation of targeted protein degraders using high-throughput ubiquitination assays for mechanistic and SAR analysis.

Yuzhou Xu, Jichuan Zhang, Yanfei Hu, Ye Tian, Min Lyu, Yinfei Yin

Shanghai ChemPartner Co., Ltd., Shanghai, China

Targeted Protein Degraders (TPDs) represent a paradigm shift from traditional occupancy-driven inhibition to event-driven pharmacology by harnessing the ubiquitin-proteasome system for selective protein elimination. Despite their therapeutic potential, the rational design of effective degraders, particularly Molecular Glues, remains a significant challenge due to the complex interplay between binding cooperativity, ubiquitination efficiency, and degradation kinetics. To better understand these mechanisms, we established a suite of preclinical assays to systematically evaluate TPD activity across key mechanistic steps, including ternary complex formation, ubiquitination induction, cellular uptake, and target protein degradation in cellular and *in vivo* models. During the early screening of degrader libraries, medicinal chemists require efficient methods to assess structure-activity relationships (SARs). Comparative studies revealed that the ubiquitination assay provides a more predictive measure of cellular degradation efficiency than ternary complex formation assays. While ternary complex assays characterize binding affinity, cooperativity, and complex stability among the target, degrader, and E3 ligase, they fail to capture conformational changes necessary for productive ubiquitination. Our data demonstrate that ubiquitination assays offer deeper mechanistic insights with high throughput and scalability, enabling rapid generation of robust datasets for data-driven SAR development. This approach effectively bridges the gap between structural optimization and functional outcomes, accelerating the rational design of next-generation degraders with improved potency and selectivity for therapeutic applications.

#4615 Preclinical characterization and evaluation of JSB462 (Luxdegalutamide), a novel AR degrader, and its combinations in prostate cancer.

Stephane Ferretti[1], Daniel A. Guthy[1], Marco Taddio[1], Marc Hattenberger[1], Marion Dourdoigne[1], Ramona Stump[1], Sabina Ciaghi[1], Mylene Lanter[1], Alessandra Amadori[1], Laurent Laborde[1], Asif Khan[2], Rafael Caparica[1], James Warburton[3], **Marta Cortes Cros**[1]

[1]Novartis Pharma AG, Basel, Switzerland,[2]Novartis Pharmaceuticals UK, London, United Kingdom,[3]Novartis Pharmaceuticals Corporation, East Hanover, NJ

The androgen receptor (AR) is a key therapeutic target in prostate cancer, being an important tumor driver in patients with metastatic hormone-sensitive prostate cancer (mHSPC), and AR alterations are a key mechanism of acquired resistance to androgen deprivation therapy (ADT) and androgen receptor pathway inhibitors (ARPIs) in those with metastatic castration resistant prostate cancer (mCRPC). JSB462 (Luxdegalutamide, formerly ARV-766) is an orally bioavailable proteolysis targeting chimera (PROTAC®) that induces a protein-protein interaction between AR and the Cereblon (CRBN) E3 substrate receptor, resulting in the ubiquitination of AR and its subsequent degradation via the proteasome. JSB462 is efficacious against wild type AR as well as clinically relevant AR ligand binding domain (LBD) mutants that confer resistance to ADT and ARPIs, including AR L702H, H875Y, and T878A mutations. AR degradation overcomes limitations of conventional AR antagonists that only inhibit AR activity and cannot compensate for the feedback loop leading to AR upregulation. JSB462 demonstrates potent AR degradation at sub-nanomolar concentrations *in vitro* and dose-dependent tumor growth inhibition in mouse xenograft models, including those resistant to enzalutamide and with high levels of AR. In addition to degrading the androgen receptor, JSB462 also exhibits direct antagonistic activity against AR signaling, inhibiting AR-driven transcriptional programs independent of receptor abundance. Beyond single agent activity, we have also explored biology-guided combination opportunities to maximize JSB462 efficacy. Abiraterone inhibits AR activity by targeting CYP17A1 and reducing synthesis of androgen receptor ligands, and combination with JSB462 leads to sustained AR pathway inhibition and improved *in vivo* efficacy. JSB462 treatment leads to sustained upregulation of PSMA in multiple prostate cancer cell lines, and pre-treatment of prostate tumor xenografts with JSB462 in combination with a sub-efficacious single dose of the PSMA-targeting radioligand therapy (RLT) Lutetium (^{177}Lu) Vipivotide Tetraxetan (Pluvicto®) led to sustained tumor growth inhibition. In a phase I/II trial, JSB462 was well tolerated and showed encouraging antitumor activity in pretreated patients with mCRPC. Here, we show preclinical combination data of JSB462 with abiraterone and Pluvicto® that support further investigation of these regimens. Towards that end, two phase 2 trials of JSB462 in combination with abiraterone in patients with high-volume mHSPC (NCT06991556) as well as in combination with Pluvicto® in patients with mCRPC (NCT07047118) are ongoing.

#4616 Integrated organoid screening approaches enable preclinical assessment of protein degrader efficacy and target engagement.

Marten Hornsveld[1], Dennis van der Grinten[1], Dorrith Verstegen[1], Shannon Kouters[1], Esther Kingma[1], Tomas Veenendaal[1], Mariusz Madej[1], Aaron Hua[2], Jinxi Wang[2], Lenno Krenning[1], Jessie Wang[2], **Marrit Putker**[1], Ludovic Bourre[3]

[1]Crown Bioscience Netherlands B.V., Leiden, Netherlands,[2]Crown Bioscience Taicang, Taicang, China,[3]Crown Bioscience, Inc., San Diego, CA

Introduction Proteolysis-targeting chimeras (PROTACs) and molecular glues are novel therapeutics designed for selective protein degradation, offering new avenues for targeted cancer treatment. Two cereblon (CRBN)-mediated protein degrader candidates, CC-885 (GSPT1 degrader; molecular glue) and ARV-471 (estrogen receptor (ER) degrader; PROTAC), were evaluated using patient-derived organoids to address the unmet need for physiologically relevant platforms in preclinical protein degrader development.

Methods: CC-885 was screened using the OrganoidXplore™ CellTiterGlo assay at 6 doses across 98 NGS characterized organoids derived from six tissue types (colorectal, cervical, gastric, head and neck, lung, and pancreatic cancer), including non-diseased models. ARV-471 efficacy was assessed in ten organoid models of ER-sensitive indications (breast, ovarian) in high content imaging (HCI) assays. CC-885 sensitivity was validated in HCI assay for a selection of models, and GSPT1 and ER degradation were assessed in immuno-fluorescent (IF) assays. CC-885-sensitive models were selected to generate CRISPR/Cas9-mediated CRBN knockout organoid models. (Patient-matched) PDX models were subcutaneously engrafted in immunodeficient mice, and in vivo efficacy was evaluated by tumor growth inhibition (TGI) measurement.

Results: Large panel organoid screening of CC-885 revealed heterogeneous tumor responses (IC50s ranging from ~0.1nM to 50nM) that did not correlate to GSPT1 or CRBN mRNA expression levels. In isogenic KO organoid models, loss of CRBN abrogated CC-885 responses, confirming E3-ligase dependency. HCI studies validated CC-885 responses and quantified target engagement and degradation through IF staining. ARV-471 efficacy testing in ER positive organoids by HCI demonstrated both robust activity and ER degradation. The integration of efficacy and target engagement through HCI provided a mechanistic link between observed responses and molecular mode-of-action. Lastly, findings from organoid screens were compared to responses in matched patient-derived xenograft (PDX) models.

Conclusion: Organoids offer genomically stable, patient-derived models that capture patient diversity and tumor heterogeneity, enabling clinically translatable insights for precision medicine. Our results establish organoid-based screening platforms (OrganoidXploreTM), combining CTG and HCI modalities, as robust tools for preclinical protein degrader evaluation. These platforms uniquely enable identification of tumor subtypes likely to respond to targeted degradation and will potentially facilitate translational biomarker discovery through simultaneous efficacy and mechanistic readouts. PDXO to PDX follow-up opportunities further underscore the utility of these platforms for guiding early therapeutic development and target selection in oncology.

#4617 NRX-0305, an orally bioavailable, CNS penetrant pan-mutant BRAF degrader demonstrates robust efficacy in intracranial models of melanoma brain metastasis and primary glioma.

Alexandra Borodovsky, Ya-Wen Lu, Ge Peng, Karthik Arumugam, Paul L. Auger, Delia Bradford, Lilly G. Carlson, Scott K. Kimura, Daniel Medina-Cleghorn, Mariah J. Mesner, Davorka Messmer, Madeleine P. Nemchek, Ryan B. Rountree, Rusha M. Sardhara, Sangita Sridharan, Jennifer M. Stokes, Leslie Tong, Alexandra M. S. Trotier, Jennifer S. Tung, Ge Wei, Jeffrey Wu, Jordan Ye, Gwenn M. Hansen

Nurix Therapeutics, Inc., Brisbane, CA

Mutations in *BRAF*, a key component of the MAPK pathway, drive constitutive pathway activation and oncogenic transformation across multiple tumor types. *BRAF* V600 mutations occur in approximately 40–50% of cutaneous melanomas, of which 30–50% develop brain metastases during disease. CNS progression is common following acquired resistance to BRAF inhibitor and MEK inhibitor combination therapy, with 40–60% of patients experiencing intracranial relapse despite initial systemic response. *BRAF* mutations are also detected in ~5–8% of primary gliomas, predominantly in pediatric and epithelioid subtypes. Although approved BRAF inhibitors provide meaningful benefit to patients with Class 1 mutations, there is a high unmet need for patients with brain involvement due to limited CNS activity of existing therapies.We developed NRX-0305, a CNS-penetrant, pan-mutant BRAF degrader designed to selectively degrade mutant BRAF across Class 1/2/3 mutant tumors while sparing wildtype BRAF. Pharmacokinetic and pharmacodynamic studies following oral dosing confirmed brain exposure, robust BRAF degradation, and pathway inhibition. Daily oral administration of NRX-0305 demonstrated potent single-agent efficacy in multiple intracranial models of BRAF-mutant melanoma and glioma. In a BRAF inhibitor-resistant melanoma brain metastasis PDX model, NRX-0305 achieved dose-dependent efficacy and significantly improved survival relative to vehicle and dabrafenib treatment, demonstrating superiority to clinically approved BRAF inhibitors.These findings establish pan-mutant BRAF degradation as a promising therapeutic strategy for BRAF-mutant CNS malignancies and highlight NRX-0305's potential to overcome the limited CNS activity and treatment-emergent resistance associated with BRAF targeted therapies.

#4618 TRI-611, a development stage molecular glue degrader of ALK for the treatment of ALK-positive NSCLC including central nervous system metastases.

Andrew R. Conery, Daniel S. La, Artyom A. Alekseyenko, David Marcoux, Aaron G. Bart, Matt L. Harlow, Patrick R. Arsenault, Nico R. Cantone, Rebecca L. Casaubon, Hari B. Kamadurai, Aravind Prasad Medikonda, Duncan E. Nunes, Tim J. Wigle, Maolin Yu, Aleksandra Zagulyaeva, Christine Zarate, Kathleen I. Seyb, Patrick Trojer, Vito J. Palombella

Triana Biomedicines, Lexington, MA

Therapeutic inhibition of Anaplastic Lymphoma Kinase (ALK) has transformed the treatment of ALK fusion-positive non-small cell lung carcinoma (NSCLC), but ALK tyrosine kinase inhibitors (TKIs) suffer from liabilities common to all orthosteric inhibitors, such as off-target kinase inhibition and resistance alleles in and around the TKI binding site. Molecular glue degraders (MGDs) that engage the $CRL4^{CRBN}$ E3 ligase to promote neosubstrate degradation offer an alternative therapeutic approach. Here we describe TRI-611, a potent, brain-penetrant MGD that promotes the proximity of ALK and CRBN via a unique, non-G loop degron interface that is distal from the kinase active site. TRI-611 functions by engaging CRBN to create a neosurface that interacts with the C-lobe of the ALK kinase domain. This ALK:TRI-611:CRBN ternary complex promotes ALK polyubiquitination and CRBN-dependent degradation of ALK proteins, including ALK fusions such as EML4-ALK, and oncogenic, transmembrane ALK. Cellular degradation of EML4-ALK is rapid (occurring within 1-2 hours), robust (>90% maximum degradation), and durable (recovery half-life of more than 15 hours after compound withdrawal). Cellular proteomics profiling demonstrates the profound selectivity of TRI-611 across CRBN neosubstrates and the kinome (including key off-target kinase families such as NTRK), consistent with the unique degron interface located in a less conserved region of ALK. TRI-611 treatment leads to inhibition of downstream signaling and subsequent selective anti-proliferation of ALK-positive cell lines. TRI-611 is orally bioavailable and brain penetrant, with daily oral dosing leading to deep and durable degradation of endogenous EML4-ALK and tumor regression in both subcutaneous and intracranial xenograft models of ALK-positive NSCLC. TRI-611 represents the first example of a development stage degrader targeting an oncogenic gene fusion and has the potential to expand the arsenal of meaningful therapeutic options for ALK-positive NSCLC patients. The discovery of TRI-611 additionally broadens the reach of CRBN-modulating MGDs by exploiting a previously undescribed degron.

#4619 Disabling oncogenic signaling with Apertor Interceptors - Proximity inducing bisteric molecules.

Andrew Robertson, Shinji Kasahara, Jennifer Schmidt, Bo Pang, Nage Yarravarapu, Diego Garrido Ruiz, Rose Citron, Arash Samadi, Denisse Martinez, Nefeli Chanoutsi, Colleen Mulvihill, Arushi Singhai, Vinh Thai, Raissa Estrela Curado, Ericka Mendez, Edmund Graziani, **Lawrence Lum**

Apertor Pharmaceuticals, South San Francisco, CA

All proteins including those encoded by corrupted DNA in diseased tissues, convey cellular instructions in partnership with other physically interacting proteins. Disrupting these protein-protein interactions (PPIs) to achieve therapeutic goals face a number of daunting chemistry challenges, including the shallow chemical-target interfaces to achieve selective PPI disruption typically found in cell membrane penetrant small molecules. Here we introduce bisteric molecules (AP Interceptors) that are able to traverse the cell membrane and recruit abundantly expressed members of the intracellular FKBP protein family to achieve selective disruption of PPIs essential to the function of several oncogenic driver proteins. We demonstrate the durable effects of AP Interceptors in blocking the growth of cancerous cells harboring alterations in KRAS and present a mechanistic account of their anti-cancer activity.

#4620 RCZY-698: An orally bioavailable, highly potent, and selective reversible KRAS^{G12V} (ON)-state inhibitor with robust antitumor activity in preclinical models of KRAS^{G12V}-driven solid tumors.

Xiaojing (Celia) Chen, Lin Wang, Xiaohong Liu, Zhengyong Wan, Qiaoni You, Jianming Bao

Rongchang Pharmaceuticals, Ltd., Yantai, China

The KRAS^{G12V} mutation is the second most common oncogenic RAS alteration, particularly as a driver mutation in pancreatic (~34%), colorectal (~21%), and non-small cell lung cancers (~5%). It is associated with poor prognosis in affected cancer patients. Due to its very low GTPase activity, which impairs hydrolysis of RAS-bound GTP to RAS-bound GDP, the mutant protein spends most of its time in the active (GTP-bound) state with limited cycling. As a result, an off-state KRAS^{G12V} inhibitor targeting the conformation of GDP-bound (inactive) state would theoretically be ineffective at blocking downstream signaling pathways such as MAPK and PI3K-AKT, as the mutant protein rarely accesses its GDP-bound state. The lack of a nucleophilic side chain at position 12 (valine) of KRAS^{G12V} precludes development of covalent inhibitors targeting the mutation site directly. Currently, no direct inhibitors targeting KRAS^{G12V} have been approved, representing a significant unmet medical need. RCZY-698, developed by Rongchang Pharmaceuticals, is a novel, highly potent, orally bioavailable, and mutant-selective non-covalent tri-complex inhibitor that specifically targets the GTP-bound (ON) conformation of KRAS^{G12V}. It potently disrupts the interaction between KRAS^{G12V} and downstream effector proteins, thereby robustly suppressing key signaling cascades, including the MAPK pathway mechanistically, RCZY-698 engages cyclophilin A (CypA) specifically to form a stable ternary complex with KRAS^{G12V}, conferring exceptional selectivity over wild-type KRAS. In a panel of KRAS^{G12V}-mutant tumor cell lines, RCZY-698 elicits potent antiproliferative effects, demonstrating superior in vitro growth inhibition compared with RMC-5127. This compound exhibits favorable in vitro absorption, distribution, metabolism, and excretion (ADME) characteristics, alongside distinctive oral pharmacokinetic profiles across multiple species. In human KRAS^{G12V}-mutant xenograft models, RCZY-698 induces dose-dependent tumor regression at well-tolerated doses, achieving comparable tumor growth inhibition (TGI) to RMC-5127 at substantially lower exposures. Collectively, these data delineate the discovery and preclinical profiling of RCZY-698 as a novel oral non-covalent KRAS^{G12V}(ON)-selective tri-complex inhibitor with compelling in vitro potency and in vivo efficacy. Further efforts and characterization work are being implemented to complete the preclinical candidate (PCC) data package for RCZY-698.

#3329 Targeting DNA Damage Response Dependencies for Radiosensitization in Li-Fraumeni Syndrome.

Madeleine Driscoll[1], Paula R. Quaglietta[1], David Malkin[2]

[1]Genetics and Genome Biology, The Hospital for Sick Children, Toronto, ON, Canada,[2]The Hospital for Sick Children, Toronto, ON, Canada

Li-Fraumeni Syndrome (LFS) is a hereditary cancer predisposition syndrome associated with germline *TP53* mutations, leading to a significantly increased lifetime cancer risk. Individuals with LFS display striking clinical heterogeneity, including variation in tumour onset, aggressiveness, and metastasis, highlighting the need to better understand genetic modifiers and their influence on cancer susceptibility.

Recent work from our lab suggests that variation in Wnt signalling may be contributing to this clinical diversity. The Wnt pathway regulates many cellular processes, including proliferation, differentiation, and stemness. When hyperactivated, it can promote oncogenesis by stabilizing β-catenin levels, activating transcriptional programs that support tumour initiation and progression. Whole-genome sequencing on a large, multi-institutional cohort of LFS patients has identified Wnt-pathway variants that appear to decrease cancer risk and are associated with improved survival. These variants are predicted to dampen β-catenin signalling, pointing toward a novel mechanism that may act to counterbalance TP53-driven oncogenesis.

To further investigate the differences contributing to heterogeneity in LFS, we are developing a proteomic atlas of patient-derived dermal fibroblasts, representing a range of clinical presentations: wild-type (n=5), clinically unaffected LFS carriers (n=7), and LFS individuals with known malignancies (n=6). Baseline protein expression was quantified using mass spectrometry, and Wnt-related proteins were identified for further testing. To explore the functional mechanisms of these variants, siRNA-mediated knockdowns will be used to examine how short-term reductions in Wnt expression affect cancer-associated cell phenotypes.

Preliminary analyses have identified that LFS fibroblasts demonstrate increased expression of Wnt receptors compared to wild-type, suggesting a baseline priming towards Wnt activation. Gene set enrichment analysis demonstrated an enrichment of β-catenin, Lef1, and Myc transcriptional programs in LFS cells, consistent with a strongly activated Wnt signalling state. Together, these findings support hyperactive Wnt signalling as a defining feature of the LFS cellular environment and a contributing factor to TP53-driven oncogenesis.

By integrating proteomic profiling with functional variant validation, this work examines how Wnt-modifying variants contribute to the tumorigenic environment in LFS. The results of this study will help us to better understand the biological heterogeneity seen among LFS patients and lay the groundwork for future research into Wnt modifiers as therapeutic interventions. Beyond the scope of this project, the LFS fibroblast proteomic atlas may act as a novel resource for the LFS and *TP53* research communities, providing unbiased quantification of proteins across different clinical outcomes.

#4624 Investigation of the efficacy of reduced coenzyme Q10 (CoQ10) for alleviating acute intestinal toxicity associated with pelvic radiotherapy: A randomized, placebo-controlled, double-blind comparative study.

Satoshi Seno[1], Akifumi Kajiwara[1], Yasuyuki Shimizu[1], Kazuma Iwashita[1], Kana Kobayashi[1], Qin Qin[2], Qu Zhang[3], Hatamei Takabayashi[1], Kanako Suda[1], Hiroki Kawaguchi[1], Takeaki Ishihara[1], Daisuke Miyawaki[1], Sae Murakami[4], Yoshito Terai[5], Ryohei Sasaki[1]

[1]Radiation Oncology, Kobe University Graduate School of Medicine, Kobe, Japan,[2]Radiation Oncology, Nanjing Medical University First Affiliated Hospital, Jiangsu Province Hospital, Nanjing, China,[3]Radiation Oncology, Tongji Medical College, Hubei Cancer Hospital, Huazhong University of Science and Technology, Wuhan, China,[4]Clinical & Translational Research Center, Kobe University Graduate School of Medicine, Kobe, Japan,[5]Obstetrics and Gynecology, Kobe University Graduate School of Medicine, Kobe, Japan

Background: Diarrhea is one of the major acute adverse effects in patients undergoing pelvic radiotherapy, often impairing treatment continuity and quality of life. Despite its clinical importance, the pathogenesis of radiation-induced diarrhea (RID) remains inadequately understood, and effective prophylactic strategies have yet to be established. Reduced coenzyme Q10 (rCoQ10) possesses antioxidant properties capable of neutralizing activated reactive oxygen species generated during irradiation. This study aimed to evaluate whether oral administration of rCoQ10 could mitigate intestinal mucosal damage and reduce the severity of diarrhea in patients receiving curative pelvic radiotherapy.

Materials and Methods: This randomized, placebo-controlled clinical study included patients with cervical, endometrial, or vaginal cancer (FIGO 2018 Stage IB-IVA) treated with radiotherapy at Kobe University Hospital between June 2021 and November 2023. Eligible patients were ≥20 years old, had ECOG Performance Status 0-2, and provided written informed consent. A total of 47 patients were randomized into rCoQ10 and placebo groups. Participants received three 200 mg soft capsules of rCoQ10 or placebo orally once daily starting 5-7 days before radiotherapy. From the first day of radiotherapy, capsules were taken once daily approximately one hour before each irradiation session. Thirty patients (63.8%) underwent IMRT, and 33 patients (70.2%) received concurrent chemotherapy with weekly cisplatin (40 mg/m²). Adverse events, including diarrhea, were graded according to CTCAE version 5.0. The primary endpoint was the maximum increase in the number of daily bowel movements during the radiotherapy period. Analyses were adjusted for chemotherapy use and radiotherapy modality.

Results: Among the 47 enrolled patients, 44 were evaluable for analysis (two withdrew consent and one discontinued due to cognitive decline). The median maximum increase in bowel movements was 5.3 in the rCoQ10 group and 5.8 in the placebo group, showing no significant difference ($p = 0.937$). While the overall incidence and severity distribution of diarrhea did not significantly differ, a trend toward reduced occurrence of Grade 2 diarrhea was observed in the rCoQ10 group. The 2-year progression-free survival was 80.4% in the rCoQ10 group and 84.0% in the placebo group ($p = 0.491$), indicating no negative influence on oncologic treatment efficacy. No serious adverse events related to rCoQ10 were reported.

Conclusions: Although the primary endpoint was not met, rCoQ10 showed a potential benefit in reducing moderate diarrhea in patients undergoing pelvic radiotherapy, without compromising cancer treatment outcomes. Further large-scale studies are warranted to clarify its clinical utility as a supportive therapy.

#4625 Mechanistic insights into the radioprotective action of GM-0111 via CCL5 inhibition and endothelial-immune modulation.

Kholod A. Elhasany[1], Shukran Alizada[2], Sushanto Kumar Saha[3], Thomas A. Zangle[2], Abigail Pulsipher[1], Hamid Ghandehari[1]

[1]Molecular Pharmaceutics, College of Pharmacy, University of Utah, Salt Lake City, UT,[2]Department of Chemical Engineering, University of Utah, Salt Lake City, UT,[3]Department of Biomedical Engineering, University of Utah, Salt Lake City, UT

Radiation-induced proctitis (RIP) is a painful inflammatory condition of the rectum affecting up to 20% of cancer patients undergoing pelvic radiation. RIP manifests as a broad spectrum of side effects, which may lead to discontinuation of cancer treatment, and surgical intervention. Current therapeutics are merely symptomatic, highlighting the need for new effective prophylactics. We have demonstrated that synthetic glycosaminoglycan, GM-0111, has promising activity in mitigating the tissue-damaging effects of ionizing radiation when administered prophylactically in a murine model of RIP. We found that immune cell infiltration, and rectal tissue expression of CCL5, a potent chemotactic agent for mast cells and other immune cells, and its associated signaling pathways were significantly reduced with GM-0111 compared to irradiated controls. The mechanisms by which GM-0111 interacts with CCL5 and exerts its prophylactic effects against RIP have yet to be elucidated. We therefore performed a series of *in vitro* studies using immune and endothelial cells implicated in different stages of RIP. As mast cells hyperplasia and activation have been implicated in RIP development, we hypothesized that GM-0111 inhibits mast cell chemotaxis and degranulation, thereby reducing the immunological response resulting from radiation, including immune cell chemotaxis, activation, and viability and reactive oxygen species (ROS) generation. To test our hypothesis, the effect of GM-0111 treatment on CCL5 secretion and mediated responses was assessed in endothelial cells (HUVECs) and mast cells (P-815 and RBL-2H3). Due to the significant crosstalk between mast cells and macrophages, we also evaluated mast cell degranulation, ROS production, and cell viability using a colorimetric assay, flow cytometry, and quantitative phase imaging. We found that GM-0111 inhibited CCL5-induced chemotaxis with the IC_{50} of 82 nM. GM-0111 showed strong binding to CCL5 with K_d 3.34 ± 1.21 nM which may play a significant role in inhibiting its chemotactic effect. We also investigated the effect of GM-0111 on CCL5 released from TNF-α- and IFN-ɣ-activated HUVECs, whereby 10 µM GM-0111 caused an 8-fold reduction in CCL5 secretion, suggesting that GM-0111 also interferes with CCL5 production. GM-0111 (10 µM) was found to exert cytoprotective effects on RAW 264.7 cells irradiated with 2.5 Gy and 5 Gy, which may be attributed to decreased ROS production. Collectively, these data demonstrate that GM-0111 exerts coordinated radioprotective effects by attenuating oxidative stress, inhibiting endothelial CCL5 production, and blocking mast cell recruitment. This integrated mechanism positions GM-0111 as a promising prophylactic candidate against radiation-induced injury for supportive cancer care. We would like to acknowledge NIH (5R01CA227225-05) (HG) and NIH (R01CA276653) (TAZ) for funding this project.

#4626 Radioprotective fullerene derivative as a potential systemic therapeutic to alleviate radiation-induced cardiovascular disease.

Khadijeh Koushki[1], Prapannajeet Biswal[1], Joseph B K Kim[2], Ngoc Tuyet Tra[1], Prudhvi C. Mallepaddi[1], Naren Gundapaneni[1], Sai Kumar Samala[1], Lydia WT Cheung[1], Geraldine Vijay[1], Sivareddy Kotla[3], Yuri Mackeyev[1], Sunil Krishnan[1]

[1]Neurosurgery, UT Health Houston, Houston, TX,[2]Department of Radiation Oncology, MD Anderson Cancer Center, Houston, TX,[3]Department of Cardiology, MD Anderson Cancer Center, Houston, TX

Despite advances in radiation therapy (RT), radiation-induced cardiovascular disease remains a major cause of long-term morbidity and mortality in cancer survivors, increasing cardiovascular risk by 10-30% within 5-10 years after treatment. Excess reactive oxygen species (ROS) are major drivers of RT-induced endothelial injury and cardiovascular dysfunction, causing direct oxidative damage to DNA, lipids, and proteins and activating inflammatory pathways that sustain endothelial dysfunction. Targeting ROS-mediated injury, therefore, represents a promising strategy to mitigate the cardiovascular toxicity of radiation therapy. Fullerenes (C60) and their derivatives are potent antioxidants and are referred to as "free radical scavengers" because of their ability to readily interact with and neutralize free radicals. Despite promising reports of the antioxidant and anti-inflammatory activity of C60 fullerenes in recent years, translating C60 into clinic application is challenging due to their inherent lipophilicity and insolubility in aqueous media. To address this challenge, we have developed a novel chemistry for the custom synthesis of C60 derivatized with serinol (C60-ser). This derivative is neutral, amphiphilic and exquisitely soluble in water. Our data demonstrated that C60-ser is non-toxic and can protect non-malignant normal endothelial cells, but not cancer cells, from RT-mediated damage. Mechanistically, C60-ser radioprotection is exerted by both neutralizing RT-induced free radicals and inducing antioxidant response pathway and activity of antioxidant enzymes to neutralize RT-induced free radicals. The resultant radioprotective effects include preservation of mitochondrial respiratory capacity and reduction in DNA damage, senescence, and inflammatory responses of endothelial cells, which together enhance the long-term cell survival after RT. Remarkably, C60-ser treatment upregulates the expression of the transcription factor Nrf2 and promotes its nuclear translocation, thereby activating the Nrf2-antioxidant response element (ARE) signaling axis for the expression of downstream antioxidant enzymes (catalase, SOD2, HO-1, NQO1, and TRX1) in normal cells but not in cancer cells. Collectively, these results highlight a critical role of the Nrf2-ARE pathway in mediating the effects of C60-ser against oxidative stress. This study advances the realization of the clinical translation of C60-ser for reducing RT-induced toxicity in cardiovascular tissues of cancer patients.

#4627 Receptor-targeted gold nanospheres strengthen radiation efficacy and reprogram tumor immunity.

Bhoomika Muruvekere Lakshmisha[1], Prudhvi Chand Mallepaddi[1], Prapannajeet Biswal[1], Ngoc Tuyet Tra[1], Aria Sabbagh[1], Ayobami Fidelix[2], Sai Kumar Samala[1], Gabrielle Krouse[1], P M Quan Mai[1], Khadijeh Koushki[1], Lydia WT Cheung[1], Geraldine V Vijay[1], Yuri Mackeyev[1], Sunil Krishnan[1]

[1]Vivian L. Smith Department of Neurosurgery, University of Texas Health Science Center at Houston, Houston, TX,[2]Baylor College of Medicine, Houston, TX

Radiation therapy is an essential component of colorectal cancer management. However, it is limited by anatomical constraints, toxicity, and modest immune activation. When tumors are laden with high atomic number (Z) elements and exposed to ionizing radiation, a higher radiation dose is deposited within the tumor. This radiosensitization, achieved here using gold nanospheres (GNS), is boosted by a greater degree of free radical formation resulting in greater DNA damage with GNS + radiation. Recent evidence shows that unrepaired DNA damage can lead to chromosome missegregation and the formation of immature nuclei called micronuclei. The poorly formed nuclear envelope around these micronuclei exposes DNA to cytoplasmic sensors, triggering a type I interferon response and innate immune activation. Based on this, we hypothesized that GNS amplifies X-ray therapy and elicits unique immune responses. To improve receptor-mediated internalization into colorectal cancer cells overexpressing epidermal growth factor receptor (EGFR), we employed our prototype, cetuximab-conjugated gold nanospheres (cGNS). Cetuximab (monoclonal antibody targeting EGFR) was attached to 30 nm gold nanospheres using thiol polyethylene glycol (PEG) for improved biocompatibility. Two murine colorectal cancer cell lines engineered to overexpress human EGFR, CT26-EGFR and MC38-EGFR, were used to test cGNS and a pegylated control (pGNS). Cellular uptake of the GNSs was shown by Inductively Coupled Plasma Mass Spectrometry and dark-field microscopy. Clonogenic survival assays assessed radiosensitization, while immune activation was examined using flow cytometry, immunoblotting, cytokine arrays, and macrophage polarization assays. Following radiosensitization, we observed upregulation of the cGAS-STING pathway and pro-inflammatory cytokines. Conditioned media applied to RAW 264.7 macrophages increased the M1/M2 macrophage ratio, indicating enhanced innate immune activation. We next used the CT26 syngeneic mouse model to assess GNS biodistribution, the extent of radiosensitization, immune cell infiltration, and potential abscopal effects. Efficacy studies demonstrated that cGNS outperformed pGNS in combination with radiation. Immune studies incorporating immune checkpoint inhibitors are currently underway. By integrating nanotechnology with radiation oncology and immunotherapy, this project lays the groundwork for advancing nanomaterial-based radio-immunotherapy toward clinical translation.

#4628 Mitochondrial serine/threonine phosphatase, phosphoglycerate mutase 5 (PGAM5) is a novel target to promote abdominal radiotherapy.

Shujah Hamid Rehman, Rishi Man Chugh, Payel Bhanja, Stacey Krepel, Subhrajit Saha

University of Kansas Medical Center, Kansas City, KS

Pancreatic cancer patients frequently undergo radiotherapy, which carries a significant risk of toxicity to the small bowel and gastrointestinal tissues. Therapeutic outcomes in pancreatic cancer often depend on delivering higher radiation doses, and thus strategies that minimize gastrointestinal toxicity without compromising tumor radiosensitivity would be profoundly beneficial to patients. Radiation induced oxidative stress plays a significant role in radiation induced toxicity in intestinal epithelial cells. However, mitigation of gastrointestinal toxicity requires reduction of oxidative stress and stimulation of epithelial regeneration through activation of WNT/β-catenin signaling. Mitochondrial serine/threonine phosphatase, phosphoglycerate mutase 5 (PGAM5), is involved in activation of oxidative stress along with inhibition of WNT/β-catenin signaling. PGAM5, located in the mitochondrial membrane, inhibits nuclear translocation of NRF2 and thereby represses NRF2-dependent antioxidant gene expression. Moreover, PGAM5 induces β-catenin degradation by dephosphorylating DVL2, a β-catenin destruction complex**.** We have observed PGAM5 expression significantly increased in intestinal epithelium in response to irradiation. Pharmacological inhibition of PGAM5 using a novel small molecule-based modulator LFHP-1c (3 mg/kg BW, subcutaneous) at 24 hours post irradiation mitigates gastrointestinal toxicity. Mice exposed to partial body irradiation (PBI) with 2.5% bone marrow shielding (LD100/15) followed by LFHP-1c treatment demonstrated significant improvement of mice survival (90% mice survived beyond 30 day) ($p< 0.00002$) compared to irradiated control where all the mice died within 14 days. Histopathological analyses demonstrated preservation of crypt-villus structures in the jejunum sections of LFHP-1c-treated mice compared to untreated irradiated mice. LFHP-1c treatment significantly ($p<0.005$) induced stabilization and nuclear translocation of NRF2, along with increased nuclear localization of β-catenin, indicating activation of the WNT/β-catenin signaling pathway in the irradiated intestinal epithelium. LFHP-1c treatment in irradiated organoids from Lgr5/eGFP-IRES-Cre-ERT2; R26-ACTB-tdTomato-EGFP mice intestine demonstrated mitigation of radiation induced toxicity and significant improvement in Lgr5+ve intestinal stem cell survival. In mice model of Pancreatic tumors, LFHP-1c treatment did not compromise the radiosensitivity of Kras positive KPC cells. In conclusion, our studies using mice model of radiation induced genotoxic stress and ex vivo organoid model demonstrated that PGAM5 can be a potential target to promote therapeutic ratio for abdominal radiotherapy.

#4629 Modeling pharmacokinetics and efficacy of the ATM inhibitor WSD0628 in GBM and melanoma metastasis PDX models.

Ann Catherine Mladek[1], Juhee Oh[2], Sneha Rathi[2], Lily Liu[3], Danielle M. Burgenske[1], Brett L. Carlson[1], Katrina K. Bakken[1], Lauren L. Ott[1], Zeng Hu[1], Wei Zhong[3], William F. Elmquist[2], Jann N. Sarkaria[1]

[1]Radiation Oncology, Mayo Clinic, Rochester, MN,[2]Department of Pharmaceutics- College of Pharmacy, University of Minnesota, Minneapolis, MN,[3]Wayshine Biopharm, Corona, CA

Radiation is a cornerstone of glioblastoma (GBM) treatment, however, the majority of tumors progress within the radiation field due to inherent radiotherapy (RT) resistance. The integration of highly potent radiosensitizers, such as the ATM inhibitors AZD1390 or WSD0628, could reverse resistance and significantly improve local control of these tumors. However, the achievable brain tumor exposure of these inhibitors may be limited by drug exposure in skin and mucosa, leading to enhanced radiation toxicity. To support the clinical development of WSD0628, we developed pharmacokinetic (PK)-efficacy models to help interpret ongoing PK analyses. A model based on in vitro cell studies was based on the in vitro observations that 30 nM WSD0628 provided maximum ATM inhibition and the extent of radiosensitization was directly related to the duration of drug incubation after irradiation, up to a maximum of 24 hours. The unbound WSD0628 concentration, measured by rapid equilibrium dialysis, was 66% of the total concentration in cell culture media, and was used to define an optimal radiosensitizing target of 20 nM free WSD0628 for 4 to 24 hours. Previous PK analyses showed that the free, unbound fraction (fu) of WSD0628 in plasma and brain tumor tissue are 0.02 and 0.054, respectively, and the brain tumor-to-plasma ratio is 0.32 in GBM43 patient-derived xenografts (PDXs). From these data, a total drug level of 1160 nM in plasma is predicted to achieve unbound drug levels above the 20 nM WSD0628 target unbound concentration. To validate this prediction, parallel in vivo dose-ranging studies were performed in orthotopic PDXs. Mice with orthotopic GBM43 were randomized to treatment with RT (8 Gy x1) alone or in combination with a range of WSD0628 doses. RT combined with 0.25 mg/kg and 1 mg/kg WSD0628 had no impact on survival, compared to RT alone, while median survival increased by 1.3-fold for RT combined with 2.5 mg/kg, 1.7-fold with 5 mg/kg, and 3.2-fold with 10 mg/kg WSD0628. A similar dose-response was observed in an M12 melanoma brain metastasis PDX. Based on PK modeling of these drug doses, 2.5 mg/kg dosing will maintain total WSD0628 plasma levels above 1160 nM for 11.9 hours, 5 mg/kg for 23.6 hours, and 10 mg/kg for 40 hours. Taken together, we have developed a model to predict efficacious dosing of a brain tumor based on the free drug hypothesis, which allows integration of multiple aspects of in vitro modeling with measured drug levels in animal models to predict total plasma levels associated with robust sensitizing effects. Assuming similar tissue to plasma partitioning in human GBM, this model could be directly applied to interpret the ongoing Phase 1 PK analysis of WSD0628 in recurrent GBM.

#4630 CD46-targeted dual-modality alpha-particle and cytotoxic payload-loaded antibody for enhanced treatment of metastatic castration-resistant prostate cancer.

Anil Bidkar[1], Scott Bidlingmaier[2], Anju Wadhwa[3], Kondapa Naidu Bobba[3], Shubhankar Naik[4], Cheng Xue[3], Athira Raveendran[3], Megha Basak[3], Jonathan Chou[3], Rahul Aggarwal[3], Henry VanBrocklin[3], Youngho Seo[3], Bin Liu[3], Robert Flavell[3]

[1]Radiology and Biomedical Imaging, University of California San Francisco, San Francisco, CA,[2]Department of Anesthesia, University of California San Francisco, San Francisco, CA,[3]University of California San Francisco, San Francisco, CA,[4]University of California Berkeley, Berkeley, CA

Background: CD46 is a validated therapeutic target broadly expressed in prostate cancer, including metastatic castration-resistant and PSMA-low or neuroendocrine subtypes. The CD46-targeting YS5 antibody supports two complementary therapeutic platforms: a CD46-directed antibody-drug conjugate (YS5-MMAE) and a radioimmunoconjugate delivering the alpha-emitter actinium-225 (^{225}Ac-YS5). Each monotherapy induces tumor regression, yet dose escalation increases systemic toxicity, underscoring the need for a combined approach.

Methods: Two combination strategies were evaluated: (1) co-administration of YS5-MMAE with ^{225}Ac-Macropa-PEG4-YS5, and (2) a dual-labeled construct, ^{225}Ac-Macropa-PEG4-YS5-MMAE, integrating both payloads on a single scaffold. The dual construct was synthesized by conjugating MMAE to YS5, attaching the Macropa-PEG4 chelator, and radiolabeling with ^{225}Ac. Radiochemical purity, antigen binding, and in vitro stability were confirmed. In vitro cytotoxicity was assessed in 22Rv1 prostate cancer cells, and in vivo efficacy was tested in 22Rv1 tumor-bearing mice (n = 9 per group) receiving saline, YS5-MMAE (1.8 mg/kg), ^{225}Ac-YS5 (0.125 μCi), their combination, or the dual-labeled construct.

Results: In vitro, combination therapy induced greater cytotoxicity than either monotherapy, indicating synergistic interaction. In vivo, median survival was 24 days for saline, 30 for YS5-MMAE, and 66 for ^{225}Ac-YS5. Co-administration of YS5-MMAE and ^{225}Ac-Macropa-PEG4-YS5 extended survival beyond 80 days, with delayed tumor progression. In contrast, the dual-labeled construct achieved survival exceeding 90 days, accompanied by durable tumor regression and minimal renal or hematologic toxicity. Both combination and dual-modality therapies exhibited enhanced therapeutic efficacy compared to single-agent treatments.

Conclusion: Simultaneous alpha-particle and cytotoxic targeting of CD46 produces synergistic effects, improving tumor control while reducing dose-limiting toxicity. The dual-labeled construct represents a next-generation radiotheranostic platform combining targeted alpha therapy and cytotoxic payload delivery, offering enhanced potency, safety, and translational potential for advanced prostate cancer therapy.

#4631 Utilizing a dual action agent for targeted neuroendocrine tumor therapy.

Tyler M. Bateman[1], Sukhen C. Ghosh[2], Solmaz AghaAmiri[2], Majid Momeny[2], Servando Hernandez Vargas[1], Jack T. Adams[1], Vahid Khalaj[2], Ali Azhdarinia[2]

[1]Experimental Therapeutics, UT Health Houston, Houston, TX,[2]Experimental Therapeutics, Institute of Molecular Medicine, Houston, TX

Neuroendocrine tumors (NETs) are rare, heterogeneous neoplasms with an incidence of 8 per 100,000 individuals, a rate that has increased significantly over the past four decades. These tumors frequently overexpress somatostatin receptor subtype 2 (SSTR2), enabling a form of NET-targeted radiotherapy called peptide-receptor radionuclide therapy (PRRT). Although PRRT improves progression-free survival (PFS), over half of patients in the NETTER-2 trial did not respond, and recurrence often occurs after the four FDA-approved therapy cycles. Strategies to improve outcomes for patients on PRRT have been explored, such as combining PRRT with the DNA alkylating agent temozolomide (TMZ). This combination has improved objective response rates but has not significantly extended overall or progression-free survival.

To overcome these limitations, our lab developed tumor-targeted TMZ (ttTMZ), a drug conjugate that selectively delivers its chemotherapeutic payload directly to SSTR2-positive tumors and can chelate radioisotopes for imaging and therapy. Chelation of gallium-67 (^{67}Ga) by ttTMZ yields ^{67}Ga-ttTMZ, a dual-action agent that combines radiotherapy and chemotherapy in a single targeted construct. The Auger emitter ^{67}Ga has high linear energy transfer (4–4500 keV/μm) and a small radius of emission (2.4 μm), properties that lead to increased damage from emissions and decreased off-target effects, respectively.

Radiolabeling ttTMZ with ^{67}Ga yields ^{67}Ga-ttTMZ with >95% efficiency. We evaluated ^{67}Ga-ttTMZ in IMR-32 cells using Western blotting for cleaved PARP and γ-H2AX to assess apoptosis and DNA damage, respectively. Optimal dosing was identified as 0.5 MBq/mL ^{67}Ga and 100 μM ttTMZ. γ-H2AX immunofluorescence confirmed a dose-dependent increase in DNA damage. *In vivo* PET imaging with ^{68}Ga-ttTMZ demonstrated selective localization to SSTR2-positive tumors and rapid clearance in dual-implant mouse models 1 h post-injection.

These findings demonstrate that ^{67}Ga-ttTMZ induces significant DNA damage and apoptosis. Western blotting and γ-H2AX immunofluorescence microscopy results both indicate that DNA damage is a primary mechanism of action for ^{67}Ga-ttTMZ. The selective tumor targeting and dual-action mechanism of ^{67}Ga-ttTMZ highlight its potential as a next-generation combination therapeutic for NETs, addressing key limitations of current PRRT and TMZ combination therapy.

#4632 LSD1 inhibition enhances radiotherapy efficacy in OSCC by attenuating SUMOylation and activating NK cells.

Chumki Choudhury[1], Amit Kumar Chakraborty[1], Rajnikant Raut[1], Marilia Takada[2], Bikash Sahay[2], Minh-Tam Truong[3], Daniel L. Gustafson[4], Jenna Burton[4], Manish V. Bais[1]

[1]BU School of Medicine, Boston, MA,[2]College of Veterinary Medicine, University of Florida, Gainesville, FL,[3]Boston Medical College, Boston, MA,[4]Associate Professor, Clinical Sciences, Colorado State University, Fort Collins, CO

Background: Oral squamous cell carcinoma (OSCC) is a prevalent and deadly cancer, with limited treatment success using radiation therapy (RT) alone. This study investigated the role of lysine-specific demethylase 1 (LSD1) in promoting oncogenic signaling, resistance to RT, and immunosuppression in OSCC. We hypothesized that targeting LSD1-specific mechanisms, in combination with RT, could inhibit OSCC growth and immune evasion.

Methods: We employed a 4NQO-treated progressive mouse OSCC model to identify the molecular and cellular changes during radiotherapy and LSD1 inhibition (with SP2509) in combination with radiation. To identify these changes, we used RNA-seq for pathway-related changes, flow cytometry for immune regulation, and *in vitro* cell culture techniques for ChIP, qRT-PCR, and pathway validation. Finally, we treated feline spontaneous OSCC with a combination of SP2509 and radiation to test its efficacy.

Results: RT combined with the LSD1 inhibitor SP2509 promoted the infiltration of natural killer (NK) cells and dendritic cell (DC)-mediated antitumor immunity in mouse OSCC preneoplasia. Feline OSCC treated with an LSD1 inhibitor and RT showed reduced tumor growth. In vitro studies have demonstrated that combination therapy induces the activation of IFNγ+ CD8+ T cells and NK cells. RNA sequencing showed that the combination therapy attenuated the cell cycle and CDK-related pathways. Clinical OSCC samples treated with RT exhibited inhibition of CD8+ T cells, while the combination of an LSD1 inhibitor and RT recovered CD8+ T cell proliferation with a significant increase in NK cell population in mouse OSCC and peripheral blood mononuclear cells co-cultured with human OSCC cells (HSC3). It was also observed that LSD1 inhibition in OSCC, both in vivo and *in vitro,* attenuated SUMOylation pathways and downregulated the SUMO1 gene while upregulating NKG2DL-related genes such as MICB in humans and their mouse analog RAEγ. Using ChIP-qPCR, we observed that LSD1 inhibition increased H3K9me2 methylation at the SUMO1 gene locus and decreased H3K4me2 methylation. LSD1 inhibition in combination with radiotherapy in feline OSCC attenuates cancer growth.

Conclusion: SP2509 treatment enhances the efficacy of radiation therapy by inhibiting SUMOylation pathways, which increases NK cells by NKG2DL-NKG2D axis activation, thereby inducing anti-tumor immunity.

#4633 Theranostic evaluation of ^{68}Ga-PMSA, ^{177}Lu PSMA therapy, and biomarker guided immunotherapy and DDR inhibitor combinations in LNCaP prostate cancer xenografts.

Juliana Maynard, Anita Liu, Benedetta Arno, Tracy Hall, William Drewe, Kerry Shea, Andrzej Rutkowski, Grace Haydon, Tiffany-Jane Allen, Fiona Yau, Liviu Lucaciu, Mikaela Griffiths, Gayle Marshall

Medicines Discovery Catapult, Ltd., Alderley Park, United Kingdom

Background and Rationale. PSMA-targeted radioligand therapy with ^{177}Lu-PMSA is a promising treatment for metastatic castration-resistant prostate cancer. To optimise its clinical translation, preclinical models are required to link to diagnostic imaging with dosimetry, assess biomarkers or response, and evaluate sensitising combination. We conducted an in vivo study using LNCaP xenograft model comparing ^{177}Lu-PSMA monotherapy with immunotherapy, DDR inhibition and combinations, integrating multimodal imaging, pharmacokinetics, toxicity, and ex vivo biomarker analyses.

Methods. Male immunodeficient mice bearing LNCaP tumours (100-150mm^3) underwent baseline ^{18}F-PSMA PET/CT to confirm uptake and lesion dosimetry, then were randomised into 6 cohorts (n 8-10). 1. Vehicle; 2. ^{177}Lu-PSMA monotherapy (minimal effective dose); 3. anti-PD-1; 4. ^{177}Lu plus anti-PD-1; 5. ^{177}Lu plus PARP inhibitor, 6. Triple combination. Longitudinal ^{18}F-PSMA at 7, 14, and 28 days monitored early metabolic response, alongside tumour volume and body weight. Blood samples post ^{177}Lu (1-96 h) informed PK and clearance, with concurrent CBC and serum chemistry to assess systemic toxicity. At endpoint, tumours were harvested for immunostaining and molecular analysis for markers of proliferation, immune response and DDR inhibition. In addition, exploratory γH2AX in PBMCs and ctDNA profiling were assessed as translational biomarkers.

Results. ^{18}F-PSMA-PET early uptake and diagnostic assessment correlated with ^{177}Lu efficacy. Minimal dose ^{177}Lu maintained significant anti-tumour activity and reduced haematologic toxicity. Combination with anti-PD-1 enhanced efficacy via radio sensitisation. Triple therapy produced maximal tumour suppression with manageable toxicity. Ex vivo biomarkers provided mechanistic insight and predictive correlates across cohorts.

Conclusions. This integrated preclinical study demonstrates that ^{177}Lu-PSMA efficiency is enhanced by immunotherapy and DDR inhibition. Multimodal imaging, PK, toxicity, and biomarker analyses inform rational dosing, combination design, and translational strategies for future clinical trials in prostate cancer.

#4634 Pretreatment with pan-integrin inhibitor GLPG-0187 sensitizes GBM cells to radiation.

Maryam Ghandali[1], Ianlan Zhou[2], Wafik S. El-Deiry[3]

[1]Brown university, Providence, RI,[2]Brown University, Providence, RI,[3]Legorreta Cancer Center at Brown University, Providence, RI

Glioblastoma multiforme (GBM) is the most common primary CNS tumor in adults. Treatment of GBM involves a combination of radiation, chemotherapy, and surgery. Despite significant advancements in radiotherapy, treatment response in GBM remains limited due to challenges such as radioresistance and tumor recurrence. Multiple biological factors contribute to this resistance, including hypoxia, tumor microenvironment interactions, and DNA damage response and repair mechanisms. Previous studies have highlighted the role of integrins in promoting tumor radio resistance under both normoxic and hypoxic conditions. Based on this, we hypothesized that pretreatment of GBM cells with a pan-integrin inhibitor could enhance radiation sensitivity by blocking integrin-mediated pro-survival signaling before radiation-induced stress. In our study, U251 and SNB19 GBM cell lines were treated with GLPG-0187 24 hours before irradiation under both normoxic and hypoxic conditions. CellTiter-Glo (CTG) assays were performed 48 hours post-irradiation, and the combination effects were analyzed using Combenefit software. Under normoxic conditions, pretreatment with GLPG-0187 increased radiation sensitivity in both cell lines. Under hypoxic conditions, pretreatment still enhanced sensitivity, although the effect was attenuated compared to normoxic conditions. Our ongoing studies are expanding these findings to include additional GBM and diffuse intrinsic pontine glioma (DIPG) cell lines and are exploring the molecular pathways affected by this combination treatment. Overall, our results indicate that pan-integrin inhibition prior to radiotherapy could be a promising strategy to improve treatment outcomes in GBM patients.

#4635 Mapping PSMA-617 sensitivity in prostate cancer PDX models to enable combination therapy and resistance studies.

Rocio Matesanz Sanchez[1], Karg Margarete[1], Nikoline Nielsen[1], Marina Simon Martin[1], Kira Ropke Jorgensen[1], Mette Munk Wessek[1], Rasmussen Patricia[1], Anne Hessellund Langhave[1], Louise Juul Nielsen[1], Jacobsen Helle Jane[1], Neal D. Shore[2], Sebastian Gnosa[1], Michael Wick[3], **Carsten Haagen Nielsen**[1]

[1]Minerva Imaging ApS, Olstykke, Denmark,[2]The START Center for Cancer Research - Carolinas, Myrtle Beach, SC,[3]The START Center for Cancer Research-XenoSTART, San Antonio, TX

Prostate cancer represents the second most frequently diagnosed malignancy and ranks fifth in cancer-related mortality worldwide among men. Therapeutic strategies include the FDA-approved radioligand therapy (RLT) [^{177}Lu]Lu-vipivotide tetraxetan ([^{177}Lu]Lu-PSMA-617, Pluvicto), indicated for PSMA-positive metastatic castration-resistant prostate cancer (mCRPC) following progression on hormone therapy and/or chemotherapy. Given the favourable toxicity profile of [^{177}Lu]Lu-PSMA-617, clinical investigations are exploring its application earlier in the therapeutic sequence. Nevertheless, a substantial proportion of patients exhibit only transient responses or fail to respond due to intrinsic or acquired resistance mechanisms, underscoring the need for combination regimens incorporating chemotherapeutics, radiosensitizers, targeted agents, and/or immunotherapies. Robust preclinical models are essential for evaluating such combination strategies, as they enable controlled assessment of treatment efficacy within biologically relevant systems. Patient-derived xenografts (PDXs) retain the genomic, histopathologic, and pharmacologic characteristics of the original tumors, providing reliable predictive power for clinical outcomes. Consequently, well-validated PDX models are critical for elucidating synergistic interactions and guiding translational application of novel combinatorial approaches. We utilized a panel of prostate cancer PDX models selected based on PSMA expression, quantified by immunohistochemistry and AI-driven image analysis (Visiopharm). PSMA-expressing tumors validated by IHC before the treatment were treated with ~1 mCi (30-37 MBq) of [^{177}Lu]Lu-PSMA-617 and tumor uptake of was evaluated using SPECT/CT. Tumor growth was monitored longitudinally, and therapeutic efficacy was assessed using tumor growth inhibition (TGI) and time to progression (TTP). To model acquired resistance, a [^{177}Lu]Lu-PSMA-617-resistant PDX (ST1273/RTR; XenoSTART) was derived from an initially sensitive tumor (ST1273; XenoSTART). This model tolerated up to 30 MBq of [^{177}Lu]Lu-PSMA-617, while PSMA expression and radioligand uptake remained comparable between parental and resistant tumors. As proof-of-concept, PARP inhibition with olaparib was evaluated as a radiosensitizer in ST1273/RTR. Tumor relapse occurred 29 days post-[^{177}Lu]Lu-PSMA-617 monotherapy, whereas combination treatment extended relapse to 49 days, demonstrating enhanced antitumor efficacy. Collectively, these fully characterized prostate PDX models-validated for PSMA expression and [^{177}Lu]Lu-PSMA-617 responsiveness-integrated with comprehensive clinical data, establish a robust, translationally relevant platform for preclinical evaluation of innovative combinatorial strategies in RLT.

#4636 Deciphering radiation sensitivity identifies MDM2 as a targetable driver of synergistic radiosensitization in TP53 wild-type lung adenocarcinoma.

Chan Hoon Maeng[1], Jieon Hwang[2], Joong Bae Ahn[2], Sang Joon Shin[2]

[1]Department of Medicine, Yonsei University College of Medicine, Seoul, Korea, Republic of,[2]Division of Medical Oncology, Department of Internal Medicine, Yonsei Cancer Center, Seoul, Korea, Republic of

Background: Resistance to ionizing radiation (IR) remains a major obstacle to effective radiotherapy. Beyond its classical role as a negative regulator of p53, MDM2's broader contribution to radioresistance remains insufficiently understood. Given that lung adenocarcinoma (LUAD) exhibits heterogeneous responses to radiotherapy, defining molecular determinants of radiation sensitivity may reveal actionable targets. In this context, we sought to identify such determinants and to determine whether MDM2 represents a critical and therapeutically targetable regulator capable of enhancing radiotherapy efficacy in LUAD.

Methods: LUAD cell lines (A549, NCI-H460, NCI-H650, NCI-H1573) were stratified into IR-sensitive and IR-insensitive groups using clonogenic survival following irradiation. Transcriptomic profiles and DepMap CRISPR dependency datasets were integrated to uncover potential molecular determinants of radiation sensitivity. Pharmacologic MDM2 inhibition (idasanutlin) was tested alone or in combination with IR across LUAD cell lines with distinct TP53 backgrounds. Clonogenic assays, 3D spheroid cultures, and xenografts were used to assess treatment responses in 2D, 3D, and *in vivo* settings.

Results: Clonogenic survival analysis revealed distinct IR-sensitive and IR-insensitive subsets among LUAD cell lines. Integrated analyses demonstrated that MDM2 dependency was markedly higher in TP53 wild-type IR-insensitive cells, suggesting a p53-proficient context for MDM2-driven radioresistance. In line with this prediction, MDM2 inhibition alone (idasanutlin monotherapy) induced more pronounced growth inhibition in p53 wild-type compared with p53-mutant cells. The IR-idasanutlin combination produced robust synergistic cytotoxicity, profoundly reducing clonogenic survival and causing spheroid shrinkage accompanied by markedly elevated EthD-1 fluorescence intensity, indicating increased cell death. In an NCI-H460 xenograft model, idasanutlin (15 mpk, p.o. daily) combined with IR (4 Gy) yielded the highest tumor growth inhibition (TGI = 77.1%, $p < 0.001$) without body-weight loss, demonstrating strong *in vivo* synergistic efficacy and tolerability. These findings underscore the translational potential of MDM2 blockade as a radiosensitizing strategy in p53-proficient tumors.

Conclusions: Our findings demonstrate that MDM2 dependency, revealed through integrative omics analyses, represents a therapeutic vulnerability underlying IR-resistance in p53-proficient LUAD. Combining idasanutlin with radiotherapy effectively overcomes this resistance, highlighting MDM2 as a robust and actionable target for enhancing radiation response in cancers driven by high MDM2 activity.

#4637 Alpha-particle radiotherapy combined with anti-CTLA-4 synergistically overcomes radioresistance and induces local and systemic antitumor immunity in PDAC.

Marco Reis[1], Poliana C. Marinello[2], Walison Augusto da Silva Brito[2], Scott Bright[2], Mark Wasley[2], Alexandre Rubinstein[2], Ronen Sega[3], Vered Bachar[3], Gabriel O. Sawakuchi[2]

[1]Radiation Physics & BioSciences, UT MD Anderson Cancer Center & Rice University, Houston, TX,[2]Radiation Physics, UT MD Anderson Cancer Center, Houston, TX,[3]Alpha Tau Medical Ltd, Jerusalem, Israel

Pancreatic ductal adenocarcinoma (PDAC) is the third leading cause of cancer death in the U.S., with over 90% of patients presenting mutant KRAS (mtKRAS). Increased radioresistance and elevated CTLA-4 expression are hallmarks driven by mtKRAS. Radiation has only shown meaningful efficacy in PDAC at very high doses that are not achievable with conventional radiotherapy due to toxicity to adjacent organs. Additionally, although CTLA-4 upregulation suggests a therapeutic target, PDAC shows limited response to immune checkpoint blockade because of its highly immunosuppressive tumor microenvironment. We propose to sensitize a cold mtKRAS murine PDAC model (KPC) to anti-CTLA-4 (aCTLA-4) by overcoming radioresistance using Diffusing Alpha-emitters Radiation Therapy (Alpha DaRT), an intratumoral source of alpha particles with >1,000-fold greater ionization density than photons. This enables delivery of very high doses directly to the tumor while sparing healthy tissue. To further enhance this effect, an ATR inhibitor will impair DNA repair, increasing susceptibility to treatment. To assess local tumor response, mice received 5×10^5 cells in the left leg, and after 7 days (day 0) one DaRT source (inert or active) was implanted. ATRi (75 mg/kg) or DMSO was administered orally on days 0, 1, 2, 7, 8, and 9, and aCTLA-4 or IgG was injected intraperitoneally every 3 days starting on day 3 (4 doses). Animals with complete regression (>100 days tumor-free) were rechallenged on day 130. To assess systemic immunity, mice received 5×10^5 KPC cells in the left leg and 1×10^5 in the right leg, and after 10 days (day 0) one DaRT source was implanted in the left leg. The drug schedule was identical, except mice received six doses of aCTLA-4. The triple therapy (Alpha DaRT + ATRi + aCTLA-4) induced significantly ($p<0.05$) greater tumor growth delay compared to control, monotherapies, and duotherapies, excluding Alpha DaRT + aCTLA-4, from day 25 onward. By day 41, all control and monotherapy mice reached euthanasia criteria, whereas 60% and 70% of the Alpha DaRT + aCTLA-4 and triple therapy groups remained alive. Complete tumor regression >100 days was sustained in 40% and 50% of mice, respectively. Upon rechallenge, no tumors regrew in the Alpha DaRT + aCTLA-4 group, and only 1 of 5 in the triple therapy group showed regrowth. A significant ($p<0.0001$) synergistic effect was observed between Alpha DaRT and aCTLA-4. For systemic immunity, Alpha DaRT + aCTLA-4 and the triple therapy induced greater tumor growth delay in both the irradiated and unirradiated tumors compared to all other treatments. In conclusion, Alpha DaRT combined with aCTLA-4 generates durable local and systemic antitumor responses in mtKRAS PDAC, offering a strategy to overcome KRAS-mediated radioresistance and immune evasion.

#4638 Oncolytic herpes simplex virus, M002, increases the antitumor radiation response by decreasing the G2/M arrest in murine rhabdomyosarcoma orthotopic allograft cells.

Maryam G. Shaikh[1], Nazia Nazam[1], Morgan L. Brown[1], Pranava Nande[1], Ali M. Eakes[1], Shamza Manzoor[2], Joel C. Opara[1], James M. Markert[3], Jamie M. Aye[4], Elizabeth A. Beierle[1]

[1]Surgery, University of Alabama at Birmingham, Birmingham, AL,[2]Department of Neurosurgery, University of Alabama at Birmingham, Birmingham, AL,[3]Neurosurgery, University of Alabama at Birmingham (UAB), Birmingham, AL,[4]Pediatrics, University of Alabama at Birmingham (UAB), Birmingham, AL

Introduction: Rhabdomyosarcoma (RMS) represents the predominant soft tissue sarcoma in children. For most RMS patients, multimodality therapy is employed to achieve optimal outcomes, incorporating chemotherapy, radiotherapy (RT) and surgery. RT, although an integral component of local control, often results in significant long-term sequelae. Further, children with RMS who relapse after RT continue to experience the poorest outcomes. These issues underscore the need to develop strategies to minimize late toxicities and improve therapeutic index. Investigations have indicated that RT-induced antigen release amplifies the immune response triggered by oncolytic viruses (OVs), and viral infection of tumor cells impedes the repair of RT-induced DNA damage, both enhancing RT efficacy. We previously showed that treatment of murine orthotopic allograft (OA)-RMS cells with an oncolytic Herpes Simplex Virus (oHSV), M002, enhanced the response to RT. These findings led us to investigate the mechanism by which M002 enhances the antitumor response to RT in OA-RMS cells.
Methods: Murine OA-RMS cells were treated with M002 (0 or 5 plaque forming units (PFU)/cell) for 24 hours and whole cell RNA sequencing was performed. RT doses were delivered as X-rays at 275 kV and 10.0 mA. Viability was measured using almarBlue. Cell cycle distribution was assessed by flow cytometry.
Summary of results: OA-RMS cells demonstrated resistance to RT as measured by no significant change in viability between control cells and RT treated cells on post-treatment day 6. RNA sequence data and pathway analysis of M002 (5 PFU/cell) treated OA-RMS cells showed significant downregulation of genes involved in the G2/M pathway. Combined treatment with 2 Gy RT and M002 abrogated G2/M phase arrest caused by RT alone. The percentage of OA-RMS cells arrested at the G2/M phase increased after 2 Gy RT to 24.4% compared to 8.3% in the control cells. Combined treatment with M002 and RT decreased the percentage of OA-RMS cells arrested at G2/M phase to 2.5%. Combining M002 with RT significantly increased the sub-G1 population compared to the control group, indicating dying and apoptotic cells.
Conclusion: We demonstrate that the oHSV, M002, significantly suppresses the genes regulating the G2/M phase of the cell cycle in OA-RMS cells. Combining RT with M002 reduced the G2/M phase arrest caused by RT. The loss of G2/M arrest was accompanied by an increase in cell death. These results indicate that M002 is a promising strategy to disrupt the G2/M checkpoint, a mechanism through which RT-resistant RMS tumors function.

#4639 Redox modulation by gold nanorods enhances radiosensitivity in MOLT 4 cells.

Paras Jawaid[1], Mati Ur Rehman[2], Azhar Hussain Rajabali[3], Ather Enam[4]

[1]Biological and Biomedical Sciences, Centre of oncological research in surgery, Aga Khan University Hospital - Karachi, Pakistan, Karachi, Pakistan,[2]Biological and Biomedical Sciences, Aga Khan University hospital, Karachi, Pakistan,[3]Biological and Biomedical Sciences, Aga Khan University Hospital - Karachi, Pakistan, Karachi, Pakistan,[4]Neurosurgery, Centre for regenerative medicine and stem cell research, Aga Khan University Hospital - Karachi, Pakistan, Karachi, Pakistan

Gold nanoparticles have gained increasing interest because of their unique optical properties. Among different shapes of nanoparticles, gold nanoparticles (Au-NPs) with non-spherical shape, such as gold nanorods (Au-NR), are gaining particular attention for various applications because of their facile synthesis and modification. They can be conjugated with different molecules for biomedical applications, such as tumor imaging and therapy. Previously, we have shown that small sized Au-NPs possess distinct effects depending on the treatment modality; they protect against x-ray induced apoptosis while enhancing apoptosis induced by ultrasound and helium based cold atmospheric plasma. Therefore, this study is intended to investigate the effects of Au-NR, on x-ray (2.5 Gy) induced apoptosis as well as mediating molecular pathways in MOLT 4 cells *in-vitro*. The effect of Au-NR on x-ray induced apoptosis was determined by observing the changes in intracellular reactive oxygen species (ROS) formation and apoptotic signalling pathways. The results indicate that cells pre-treated with 10 nm size of Au-NR at a dose of 0.1 and 0.5 µg significantly enhanced apoptosis. Typical morphological changes were observed by using Giemsa staining which shows the enhanced apoptotic cell death in combination treatment. Loss of mitochondrial membrane potential, glutathione and intracellular calcium ion level was significantly enhanced; observed by using flow cytometry. Furthermore, western blot analysis was employed to determine the expression of caspase-3, and Bcl-2 family proteins. In this study we have shown for the first time that in combination treatment, Au-NR significantly enhanced the low dose of x-ray-induced apoptotic cell death. Our finding indicates that the combination treatment of cancer will be emerged as a critical approach to achieve remarkable anticancer effects.

#4640 Benefit of combining DLL3 targeted alpha therapy with standard of care in preclinical small cell lung cancer models.

Hanan Babeker[1], Emma Cummins[1], Alex Mandel[1], Lily Li[1], Etienne Melese[1], Rachael Brake[2], Iva Kulić[1]

[1]Abdera Therapeutics Inc., Vancouver, BC, Canada,[2]Abdera Therapeutics Inc., San Francisco, CA

ABD147 is a human delta-like ligand 3 (DLL3) engineered antibody designed with optimized pharmacokinetics and biodistribution to preferentially deliver actinium-225 (^{225}Ac) to DLL3 expressing tumor cells resulting in potent antitumor activity in preclinical models. ^{225}Ac-ABD147 is built using Abdera's Radio Optimized Vector Engineering (ROVEr™) platform and is currently in phase I clinical trials for small cell lung cancer (SCLC) and large cell neuroendocrine carcinoma (LCNEC). SCLC is an aggressive neuroendocrine malignancy characterized by rapid progression and high relapse rates despite initial response to standard-of-care (SOC) treatment, including platinum-based chemotherapy and immune checkpoint inhibitors, underscoring the unmet need for therapies that improve tumor control and prolong survival. SCLCs are intrinsically radiosensitive and along with other neuroendocrine cancers commonly express DLL3 on the cell surface. Targeted alpha therapy induces difficult to repair DNA double-strand breaks and can promote immunogenic cell death enhancing SOC tumor-directed cytotoxicity by overwhelming DNA repair pathways and overcoming resistance. A single administration of ^{225}Ac-ABD147 or a murine DLL3 ROVEr™ was assessed in combination with SOC in DLL3-expressing chemo-resistant SCLC cell line derived xenograft models or a syngeneic model. The combination treatment was tolerated and outperformed SOC alone for anti-tumor efficacy, sustained tumor responses and prolonged survival across models. In conclusion, DLL3-targeted alpha therapy demonstrates potent anti-tumor activity in combination with SOC across multiple SCLC models. These findings suggest ^{225}Ac-ABD147 has a combinatorial benefit that could support an add-on to a SOC therapeutic approach in the clinic.

#4641 Highly soluble prodrug boronophenylalanine (L-BPA) dipeptide, exhibits notable tumor suppression whilst inducing cancer vaccine effect post neutron irradiation treatment.

Samkeliso Dlamini[1], Michael Torgov[1], Arthur Raitano[1], Jason Quintana[1], Tioga Martin[1], Chunying Zhang[1], Maria Christina Malinao[1], Maki Ikeura[1], Linnette Capo[1], Karen Morrison[1], Robert Dorn[1], Kotaro Matsumoto[2], Aoi Komatsu[2], Yuya Higashi[2], Takushi Takata[3], Yoshinori Sakurai[4], Minoru Suzuki[4], Fuyuhiko Tamanoi[2], Kendall Morrison[1]

[1]Medicinal Chemistry, TAE Life Sciences, Santa Monica, CA,[2]Institute for Advanced Study, Institute for Integrated Cell-Material Science, Kyoto University, Japan,[3]Institute for Advanced Study, Institute for Integrated Radiation and Nuclear Science, Kyoto University, Japan,[4]Institute for Integrated Radiation and Nuclear Science, Kyoto University, Japan

Boron Neutron Capture Therapy (BNCT) is an emerging cancer treatment modality that has seen a resurgence due to its efficacy and the advent of compact neutron beam devices. BNCT is a binary cancer treatment that combines selective boron delivery with epithermal neutron irradiation. When ^{10}B-enriched compounds accumulate in tumor cells and capture low-energy neutrons, the reaction generates high-linear energy transfer (LET) α-particles and ^{7}Li nuclei that deposit their energy within a few microns, producing irreparable DNA double-strand breaks and tumor cell death while sparing normal tissues. The clinical success of BNCT critically depends on the selective delivery of sufficient boron to tumors. Currently, 4- l-boronophenylalanine (l-BPA) is the leading BNCT agent, as it exploits LAT-1 (SLC7A5), a transporter highly expressed in many solid tumors. However, l-BPA suffers from poor solubility, severely limiting the maximum intravenous dose that can be administered and thereby constraining therapeutic efficacy. Here we report the synthesis and evaluation of highly soluble ^{10}B-enriched l-BPA-based dipeptides as next-generation boron delivery agents. These dipeptides, incorporating hydrophilic peptide linkages, enabled substantially higher intravenous bolus doses in mice compared to l-BPA while maintaining favorable biodistribution. In vivo, the dipeptides were rapidly cleaved by endogenous proteases, releasing l-BPA de novo within tumors. Neutron irradiation of syngeneic CT26 tumors in dipeptide-treated mice produced complete and durable tumor regressions, accompanied by immunological effects including a vaccine response and abscopal tumor suppression. By contrast, l-BPA administered at its solubility-limited maximal dose and using the same irradiation produced only transient growth delay without durable regression or immune activation. These findings establish dipeptides as a promising strategy to overcome the solubility limitations of l-BPA, enabling higher boron delivery, improved tumor control, and immune-mediated benefits. This approach could significantly expand the therapeutic potential of BNCT.

#4642 Defining radiosensitivity indicators to predict prognosis using patient-derived organoids in oral cancer.

Sumin Kang[1], Mi Rim Lee[1], Jonghyun Lee[1], Dongkwan Shin[1], Jong-Ho Lee[1], Ikjae Kwon[2], Jiyoung Lee[1], Yu-Sun Lee[1], Sun-il Choi[1], Hye Won Shon[1], Gyeongmin Kang[1], Sung Woen Choi[3], Yun-Hee Kim[1]

[1]National Cancer Center, Goyang-si, Korea, Republic of,[2]School of Dentistry, Seoul National University, Seoul, Korea, Republic of,[3]National Cancer Center, Goyaing-si, Korea, Republic of

Over 60% of patients with oral cancer are diagnosed at advanced stages, and the standard treatment was surgery followed by adjuvant radiotherapy. Nevertheless, 30-50% of patients experience recurrence within two years, whereas patients with radiosensitive tumors may be exposed to unnecessarily high radiation doses. Therefore, predicting radiotherapy response and stratifying patients is essential for personalized treatment approaches and improving clinical outcomes. Patient-derived organoids (PDOs) are robust preclinical models that recapitulate the characteristics of patients' tumors. In this study, we defined radiation sensitivity indicators using an oral cancer PDO library comprising 102 patient-derived organoids. Dose-dependent radiation responses were evaluated for 68 PDOs and correlated with clinical data. When organoids were classified based on the mean survival fraction at 2 Gy (SF2), patients in the high-SF2 group exhibited a significantly shorter recurrence-free survival. It suggests that PDO-based assessment of radiation response may serve as a useful predictor of clinical outcomes. In addition, a radiation sensitivity-related pathway score was generated from differentially expressed genes (DEGs) identified in radiosensitive PDOs and applied to The Cancer Genome Atlas (TCGA) oral cancer cohort. Patients were classified into low- and high-score groups according to the sensitivity score. The high-score group had a significantly more favorable survival prognosis. Furthermore, to identify a tissue-detectable radiation sensitivity marker (RSM), we selected the gene associated with the most enriched pathway in the low-SF2 organoid group, resulting in the identification of a candidate marker, RSM-1. Subsequent immunohistochemical (IHC) analysis demonstrated that RSM-1 was expressed at higher levels in tumors from patients without recurrence. Overall, this study utilized patient-derived organoids to evaluate radiation responses, derive a radiosensitivity score, and identify a clinically relevant biomarker. By integrating molecular and phenotypic tumor characteristics, this approach provides reliable prognostic indicators, enabling prediction of patients' radiation responses and supporting personalized therapeutic strategies to improve prognosis in oral cancer.

#4643 Microsatellite instability as a determinant of chemoradiotherapy sensitivity in colorectal cancer: Integrated clinical, radiomic, and 3D organoid-based analyses.

Hyowon Hong[1], Shin Kim[2], Sang Jun Byun[3], Seong Kyu Baek[3], hyewon lee[2], sung wook bae[3]

[1]Research Affairs, Keimyung University Dongsan Medical Center, Daegu, Korea, Republic of,[2]Keimyung University School of Medicine, Daegu, Korea, Republic of,[3]Keimyung University Dongsan Medical Center, Daegu, Korea, Republic of

Background: Microsatellite instability (MSI) is an established biomarker affecting immunotherapy outcomes and may influence DNA damage responses following chemoradiotherapy (CRT). While clinical studies have reported favorable CRT outcomes in MSI-high (MSI-H) colorectal tumors, the biological basis for differential radiosensitivity remains incompletely understood. To address this gap, we integrated clinical-radiomic analyses with functional assays using 3D organoid models derived from MSI-H and microsatellite-stable (MSS) colorectal cancer (CRC) cell lines.
Methods: Clinical data from 87 rectal cancer patients receiving neoadjuvant CRT were analyzed. MSI status was determined by PCR and immunohistochemistry for MLH1, MSH2, MSH6, and PMS2. Radiomic features were extracted from pre-CRT CT images, and a machine learning model was trained to classify MSI status. For biological validation, 4 MSI-H (HCT116, HCT15, RKO, DLD-1) and 5 MSS cell lines (HT29, CACO2, SW480, COLO205, COLO320DM) were subjected to graded irradiation. Cells were embedded in 70% Matrigel or BME to generate 3D organoids. Radiation responses were evaluated using Calcein-AM-based viability area analysis, ATP-based 3D CellTiter-Glo assays, and area-under-curve (AUC) quantification across 0-8 Gy.
Results: MSI tumors were exclusively found in the responder group (18.52%) and absent in non-responders ($P<0.05$). Pathological downstaging (T0-T2) was significantly higher in responders (88.89% vs. 38.33%, $P<0.001$), with increased nodal clearance (N0; 92.59% vs. 61.67%, $P=0.003$). In 3D organoid models, MSI-H cell lines displayed markedly greater radiosensitivity than MSS lines. MSI-H organoids showed stronger growth inhibition and lower viability in both Calcein-AM and ATP 3D assays, resulting in reduced radiation-response AUC values. In contrast, MSS organoids maintained higher viability and metabolic activity after irradiation, indicating relative radioresistance.
Conclusion: MSI-H colorectal cancer demonstrated consistently higher chemoradiotherapy sensitivity across clinical outcomes, radiomic signatures, and 3D organoid-based functional assays. The enhanced radiosensitivity observed in MSI-H organoids suggests that deficiencies in DNA mismatch repair may contribute to increased susceptibility to radiation-induced damage, although the precise molecular pathways have not yet been fully defined. These integrated findings support the potential value of combining MSI testing with organoid-based functional profiling to refine patient stratification and guide personalized CRT approaches in colorectal cancer. Validation in larger and ethnically diverse cohorts will be necessary to confirm generalizability.

#4644 Protein kinase D1 modulates LET- and dose-dependent radiosensitivity in prostate cancer cells.

Joseph McGrath[1], Sanjeev Shukla[1], Mohammad Saki[2], Hardev Grewal[2], Jiyeon Park[2], Mark Artz[2], K.C. Balaji[1]

[1]Urology, University of Florida Health, Jacksonville, FL,[2]University of Florida Health Proton Therapy Institute, Jacksonville, FL

Protein kinase D1 (PrKD1) participates in DNA damage response signaling, but its role in modulating dose- and linear energy transfer (LET)-dependent radiosensitivity in prostate cancer remains poorly defined. We evaluated the effect of PrKD1 loss on clonogenic survival following photon and proton irradiation to determine whether PrKD1 influences radiosensitivity across clinically relevant dose ranges. LNCaP and their PrKD1-knockdown derivative (shPrKD1) prostate cancer cells were exposed to 0-4 Gy X-rays or proton irradiation delivered at increasing dose-averaged LET (PL2-PL4 = 2-4 keV/µm). Clonogenic survival was normalized to unirradiated controls, and linear-quadratic modeling was used to derive D10, D37, and relative biological effectiveness (RBE) values. Both cell lines showed a dose-dependent decline in survival, but their response profiles diverged with dose and LET. LNCaP cells were more radioresistant at 1 Gy and demonstrated a steep loss of viability from 2-4 Gy with LET-associated sensitization that was most evident at PL4 and at higher doses. In contrast, shPrKD1 cells exhibited greater sensitivity at low-to-intermediate doses (≤2 Gy), a more linear survival curve, and reduced LET dependence. The survival curves crossed at higher doses, with shPrKD1 more sensitive at clinically relevant doses yet relatively more resistant at high, near-ablative doses. D10 values ranged from 5.2-5.7 Gy in shPrKD1 versus 4.2-5.1 Gy in LNCaP, with both cell lines showing greatest sensitization at PL4. RBE values remained modest (~1.0-1.2) but increased slightly with LET in shPrKD1, indicating enhanced sensitivity at intermediate doses. These findings demonstrate that PrKD1 loss enhances radiosensitivity in the fractionated dose range and attenuates LET-dependent effects, identifying protein kinase D1 as a modulator of radiation response and a potential biomarker for optimizing proton and photon therapy strategies in prostate cancer.

#4645 Integrative transcriptomic and CRISPRi screening identifies determinants of intrinsic radiosensitivity in breast cancer.

Breanna Nicole McBean[1], Priyanka S. Rana[2], Reine Abou Zeidane[3], Alexander Davis[2], Vesna Mercer[2], Benjamin Hauk[3], Anna Michmerhuizen[1], Samuel Lichtman-Mikol[3], Camila Diedrich[2], Kari Wilder-Romans[1], Mingfang Tao[3], Alan P. Boyle[1], Corey Speers[2]

[1]University of Michigan, Ann Arbor, MI,[2]University of Alabama Birmingham, Birmingham, AL,[3]Case Western Reserve University School of Medicine, Cleveland, OH

Background: Breast cancer (BC) remains a leading cause of cancer-related mortality among women, and radiation therapy (RT) is a cornerstone of its management. Despite its efficacy, more than 15% of patients experience locoregional recurrence following RT, highlighting a critical need to define the molecular determinants of RT response and resistance. We hypothesized that transcriptomic changes that occur after ionizing radiation in intrinsically radiosensitive and radioresistant BC models would offer mechanistic insight into mediators of this differential response. To investigate this, we performed *in vitro* RNA-sequencing across a panel of BC cell lines spanning a spectrum of intrinsic radiosensitivity to characterize radiation-induced transcriptional programs. Recognizing that key mediators of radioresistance may not exhibit differential expression, we complemented this approach with a genome-wide CRISPR interference (CRISPRi) screen to identify additional functional targets that modulate radiosensitivity. Together, these studies aim to elucidate novel molecular pathways underlying RT resistance and inform future therapeutic strategies
Methods: Eight BC cell lines were treated with 4 Gy RT and RNA was collected 24 hours after treatment for RNA-seq. Differential gene expression analysis with DESeq2 was performed, followed by pathway analysis with Advaita Bioinformatics' iPathwayGuide. For the CRISPRi experiments, dCas9-KRAB-expressing BT-549 cells were transfected with the Dolcetto library and treated with 3 fractions of 3 Gy RT. DNA was isolated for sequencing to determine sgRNA abundance 7 days after the last dose of radiation and analyzed with MAGeCK.
Results: Radiation induced significant transcriptional changes across both radiosensitive and radioresistant models, with highly enriched pathways including cell cycle regulation, DNA replication, and the Fanconi anemia pathway. The CRISPRi screen identified canonical regulators of the DNA damage response as modulators of radiosensitivity, as well as less-characterized candidates such as the potassium channel modifier *KCNG3* and the spliceosome component *U2AF1*, with mechanistic studies now underway.
Conclusions: Ionizing radiation activates transcriptomic programs predominantly involving expression changes in DNA damage response-replated pathways, consistent with top hits identified in the CRISPRi functional screen. Importantly, the screen also reveals previously underexplored mechanisms of radiosensitization, including perturbations in alternative splicing and potassium channel signaling. Together, these findings highlight biologic vulnerabilities that may underlie intrinsic radioresistance and nominate potential targets for therapeutic intervention in women at high risk of local BC recurrence.

#4646 Validation of a panel of fibroblast activation protein expressing cell line derived xenograft models as a platform for the development of targeted radioligand therapeutics.

Michael Batey, James Suchy, Taylor Hotz, Michael Milhollen, Kayla Duval, Jackson Chan, Karen Gelinas, Michael Bruce, Michelle Petrozzi, William Maccuaig, Neil Rollins, Jennifer Tavares, Erin Snay, Kyeara Mack-Henry, Soumya Ullas

Perceptive Discovery, Needham, MA

Targeted radioligand therapy (RLT) has emerged as a promising strategy for precision oncology, enabling selective tumor targeting while reducing collateral damage to healthy tissue. A major challenge in advancing novel RLT agents, however, is the limited availability of well-validated preclinical models for assessing target-specific efficacy. Fibroblast Activation Protein (FAP), a membrane-bound protein with minimal expression in normal tissues but high prevalence in cancer-associated fibroblasts and glioblastoma (GBM) cells, represents an attractive therapeutic target. FAP-2286, a FAP-binding peptide radiolabeled with lutetium-177 (^{177}Lu), offers potential as both an imaging and therapeutic agent. In this study, we evaluate target expression and compare the anti-tumor efficacy of ^{177}Lu-FAP-2286 across multiple immunocompromised mouse models bearing subcutaneous, cell line-derived tumors. Our findings underscore the critical role of model selection in preclinical development and highlight its importance for rational decision-making in RLT programs.

#4647 Development and validation of a panel of cell line derived xenograft models representing multiple tumor indications for the evaluation of targeted radioligand therapeutics.

Michael Batey, James Suchy, Taylor Hotz, Michael Bruce, Jennifer Tavares, Erin Snay, Neil Rollins, Jackson Chan, Karen Gelinas, Kayla Duval, William Maccuaig, Michael Milhollen, Michelle Petrozzi, Kyeara Mack-Henry, Soumya Ullas

Perceptive Discovery, Boston, MA

Targeted radioligand therapy (RLT) represents a significant advancement in precision oncology, enabling selective tumor targeting while minimizing damage to healthy tissue. However, the development of innovative RLT agents is often hindered by the limited availability of robust, well-validated preclinical models needed to evaluate target-specific efficacy. Here, we demonstrate the development and validation of a comprehensive panel of in vitro screening assays and in vivo cell line-derived xenografts, including models such as Colo205, MiaPaca2, SHP-77, HT29, A549, LNCaP, and 22Rv1, which express key targets relevant to radioligand therapy. These models provide an ideal pathway for evaluating novel agents in this rapidly growing field, covering targets such as TROP2, CAIX, DLL3, FAP, and PSMA across a range of indications including glioblastoma, colorectal, lung, pancreatic, and prostate cancers. We also discuss the use of *in vivo* and *ex vivo* imaging techniques such as single photon emission computed tomography (SPECT) and cryo fluorescence tomography (CFT) . These studies highlight the utility of these platforms for the preclinical development of a wide range of target-based therapies, with potential applications spanning multiple therapeutic modalities including RLT, antibody-drug conjugates (ADCs), and small molecules.

#4648 Targeting alternative end-joining overcomes *miR-21-5p*-mediated radioresistance in oral squamous cell carcinoma.

Lin Ma[1], Nilupaier Tayier[2], Weitao Hu[3], Junyang Chen[2], Yanhe Li[2], Lu Wen[2], Yonghui Luo[2], Xinghan Li[3], **Qi Liu**[4]

[1]Department of Stomatology, Shenzhen University General Hospital, Institute of Stomatological Research, Shenzhen University, Shenzhen, China,[2]Shenzhen University, Shenzhen, China,[3]Department of Stomatology, Shenzhen University General Hospital, Institute of Stomatological Research, Shenzhen University, Shenzhen, China,[4]International Cancer Center, Shenzhen University, Shenzhen, China

Radiation resistance remains a major barrier to effective radiotherapy in oral squamous cell carcinoma (OSCC), yet its molecular basis is incompletely defined. Here, we uncover activation of the alternative end-joining (alt-EJ) DNA repair pathway as a key driver of miR-21-5p-mediated radioresistance in OSCC. Comprehensive miRNA profiling of radioresistant OSCC clones revealed distinct expression signatures marked by robust upregulation of miR-21-5p and miR-486-5p, coupled with reduced miR-320b and miR-1248. Functional assays, including clonogenic survival and syngeneic mouse tumor models, demonstrated that enforced expression of miR-21-5p markedly enhanced radioresistance, accompanied by sustained DNA damage response signaling and improved double-strand break (DSB) repair capacity. Transcriptomic and genomic analyses of the TCGA-HNSC cohort revealed that high miR-21-5p expression correlates with suppression of canonical DNA repair targets, poor radiotherapy outcomes, elevated tumor mutational burden (TMB), and an increased frequency of microhomology-mediated insertions/deletions, consistent with heightened alt-EJ activity. Cross-validation in independent OSCC datasets and local tumor panels confirmed that miR-21-5p-overexpressing tumors exhibit strong activation of alt-EJ gene programs, including upregulation of PARP1, POLQ, and associated accessory factors. Analysis of diverse cancer cell line databases further established that miR-21-5p activity positively correlates with alt-EJ gene expression independent of microenvironmental influence. Mechanistically, miR-21-5p overexpression shifted DSB repair dependence from homologous recombination and classical non-homologous end-joining toward alt-EJ. Pharmacologic or genetic suppression of alt-EJ components (PARP1 or POLQ) disrupted DSB resolution and effectively restored radiosensitivity in miR-21-5p-high OSCC cells. Notably, radiosensitization by PARP inhibition was abrogated in POLQ-deficient cells, confirming a POLQ-dependent mechanism. In vivo, miR-21-5p-driven OSCC tumors exhibited enhanced expression of alt-EJ signatures, increased radioresistance, and high TMB. Combination treatment with irradiation and PARP blockade suppressed tumor growth, diminished alt-EJ gene expression, and prolonged survival in a syngeneic mouse model. Collectively, these findings establish a novel miR-21-5p/alt-EJ signaling axis as a central determinant of radioresistance in OSCC. Targeting alt-EJ represents a promising therapeutic strategy to overcome miR-21-5p-mediated treatment failure and improve radiotherapy efficacy in head and neck cancers.

: Cell Death Regulation and Therapeutic Resistance in Cancer

#4652 Deciphering neutrophil heterogeneity to enhance therapeutic efficacy of TRAIL (Tumor necrosis factor-related apoptosis-inducing ligand) in triple negative breast cancers.

Manjari Kundu Sil[1], Wenqi Wu[2], Lichun Ma[2], Stan Lipkowitz[1]

[1]Women's Malignancies Branch, National Institute of Health, CCR, NCI, Bethesda, MD,[2]Cancer Data Science Laboratory, National Institute of Health, CCR, NCI, Bethesda, MD

TRAIL induces apoptosis in many preclinical cancer models including breast cancer models and has been extensively studied as a potential cancer therapeutic target. However, the clinical efficacy of TRAIL agonists is limited, suggesting that there are unknown modulatory mechanisms responsible for the lack of activity in patients. Our prior work demonstrated that TRAIL induces various cytokines (CXCL1, CXCL2, CXCL3, CXCL8, CXCL11, IL6) via NFKB2-dependent pathway in triple negative breast cancers (TNBC), promoting the recruitment of immunosuppressive neutrophils, suggesting that neutrophil-mediated regulation of the tumor immune microenvironment modulates TRAIL activity in TNBC. Thus, this study aims 1) to characterize the neutrophil heterogeneity induced by TRAIL as well as derived factors from TRAIL treated TNBC, and 2) to identify targetable pathways that could reprogram neutrophils towards an anti-tumor phenotype, thus enhancing TRAIL efficacy. To address this, neutrophils isolated from a healthy donor were incubated with 4 different conditions: serum-free media (SFM), SFM supplemented with TRAIL (SFM-T), conditioned media from TNBC (CM), or conditioned media from TRAIL-treated TNBC (T-CM). Single cell RNA sequencing (scRNA-seq) of neutrophils (43,420 cells) across the 4 conditions indicated that there are 10 transcriptionally distinct clusters. These findings were further validated with scRNA-seq of pooled neutrophils from 5 different healthy individuals (35,500 cells). *t*-SNE analysis identified similar transcriptionally distinct states encompassing inflammation, antigen presentation, and ribosome biogenesis programs, demonstrating remarkable neutrophil heterogeneity. Based on literature and functional relevance, we focused on 2 key clusters that were increased upon treatment of the neutrophils with T-CM identified in both experiments. One is enriched for antigen-presentation genes and immunosuppressive markers such as *CCL4*, *CD274*, *IL1A*, and *IL1B*, and a second enriched for ribosome biogenesis-related genes including *DDX21*, *UTP18*, *LAGE3*, and *NPM1*. These clusters also exhibited low expression of IFN-gamma/alpha-responsive genes, further suggesting the immunosuppressive role of T-CM. In contrast, SFM-T treatment resulted in a population with markers regulating neutrophil-specific function (e.g. NETosis, degranulation). The Sc-RNA-seq findings are currently being confirmed by gene expression analysis and surface staining methods. Collectively, our study delineates a potential mechanistic role of supernatants from TRAIL treated TNBC cells and neutrophil plasticity. These findings imply that targeting the innate immune system may modulate the effects of TRAIL on TNBC tumors enhancing the therapeutic outcomes.

#4653 TC-PTP-mediated regulation of p38 MAPK signaling induces epidermal apoptosis in response to UVB irradiation.

Rodrigo Vidales, Lindsey Shim, Subhash Chauhan, Dae Joon Kim

University of Texas Rio Grande Valley, McAllen, TX

T-cell protein tyrosine phosphatase (TC-PTP) is a non-receptor PTP that has been shown to have various roles in signaling pathways. Our previous studies have demonstrated that the TC-PTP deficiency in the epidermis can exacerbate hyperplastic response by inducing epidermal cell proliferation in response to tumor promoter TPA or UVB exposure. This implies that TC-PTP plays a tumor-suppressive role in the epidermis and provides protection against UVB radiation, which is well known to contribute to skin cancer development. In the present study, we aim to elucidate the molecular mechanisms by which TC-PTP influences the p38 MAPK pathway and its subsequent effects on cellular responses to UVB exposure. We utilized transgenic mice that specifically overexpress TC-PTP in the epidermis (*K5HA.Ptpn2*) and immortalized primary keratinocytes (IPKs) derived from both FVB mice (TC-PTP/WT) and *K5HA.Ptpn2* mice (TC-PTP/OVER). Upon UVB irradiation, the overexpression of TC-PTP in keratinocytes leads to an increase in apoptosis, which plays a protective role by removing damaged cells. Consistent with *in vitro* results, epidermal thickness induced by UVB was significantly decreased in *K5HA.Ptpn2* mice. The phosphorylation of p38 MAPK was increased progressively over time, reaching its peak expression at 12 hours post-UVB exposure in both TC-PTP/OVER IPKs and *K5HA.Ptpn2* mice. This effect was not observed in similarly treated control IPKs and FVB mice. Western blot analysis revealed a significant increase in the levels of cleaved Caspase-3 and PARP in TC-PTP/OVER IPKs following UVB treatment. FACS analysis confirmed that higher levels of apoptotic cells were observed in TC-PTP/OVER IPKs compared to TC-PTP/WT IPKs following UVB treatment. Similarly, annexin V staining was particularly more pronounced in TC-PTP overexpressing keratinocytes compared to control keratinocytes. Pretreatment with SB203580, p38 MAPK inhibitor, before UVB exposure led to an increase in cell viability in TC-PTP/OVER IPKs with decreased apoptotic response, suggesting that UVB-induced apoptotic response is mediated via the TC-PTP/p38 MAPK axis. Our findings reveal insights into the protective role of TC-PTP against UVB-induced skin damage via the regulation of p38 MAPK signaling pathway. Understanding the interaction between TC-PTP and the p38 MAPK signaling pathway is essential, as these underlying molecular mechanisms could be a potential therapeutic target for skin cancer prevention and treatment.

#4654 *Leptospermum petersonii* methanol and ethyl acetate crude extracts as antimetastatic and apoptotic effects against pancreatic and prostate cancer cells.

Lesetja Motadi[1], Maria Matlou[2]

[1]University of Johannesburg, Johannesburg, South Africa,[2]Biochemistry, University of Johannesburg, Johannesburg, South Africa

Cancer remains number one health care challenge worldwide with an estimation of 1 in 9 people developing cancer in their lifetime. As cancer becomes increasingly prevalent, research focuses on finding palliative care and natural treatments that could transform cancer therapeutics. The aim of the project was to investigate the anti-cancer and anti-metastatic effects of medicinal plant *Leptospermum petersonii*'s active compounds against pancreatic and prostate cancer cells. The following techniques were employed: TLC, Column and NMR chromatography, alamarblue assay, ATP assay, wound healing assay, Hoechst Staining, caspase assay, Agarose gel (DNA fragmentation analysis) and RT-PCR. Through cell viability assay and IC_{50} of approximately 100 µg/mL for the methanolic crude extract was identified with greater cytotoxic effect on MIA PaCa-2 than PC3 cells. The EtOAc extract showed cytotoxicity indices IC_{50} > 100 µg/mL signifying 60% of the cells were viable even at a dose of 100 µg/mL and thus led to the termination of additional testing because of its ineffective potency. Caspase 3/7 assay and DNA fragmentation had shown some positive result in support of apoptosis. Wound healing demonstrated untreated cells healed the gap in 24 hours, whereas treated cells took longer to do so. Gene expression showed upregulation of RB1 and checkpoint 1 which are necessary for DNA damage and apoptosis induction. In conclusion, the results suggest that there might be compounds within *L. petersonii* extracts that can be exploited for anticancer agent.

#4655 Carnosic acid inhibits proliferation and induces apoptosis of breast cancer cells.

Amanda L. Kornel, Evangelia Tsiani

Brock University, St. Catharines, ON, Canada

Breast cancer remains a major cause of cancer-related mortality among women worldwide, contributing to an estimated 670,000 deaths in 2022. Although advances in early detection and systemic therapy have improved outcomes, incidence rates continue to rise, and therapeutic resistance—particularly in aggressive subtypes such as triple-negative breast cancer (TNBC)—remains a critical challenge. Plant-derived chemicals have historically served as a source of anticancer agents, exemplified by the clinical success of paclitaxel, highlighting the continued potential of plant-derived compounds.In this study, we examined the anticancer effects of carnosic acid (CA), a polyphenolic diterpene abundant in rosemary, sage, and oregano, across multiple breast cancer subtypes. CA significantly suppressed proliferation of TNBC cell lines (MDA-MB-231, HCC70, HCC1143) and Luminal A cell lines (MCF7, T47D) in a dose-dependent manner with IC_{50} values in the range of 30 to 78 μM, (MDA-MB-231: 77.92 μM; HCC70: 63.51μM; HCC1143: 38.56 μM; T47D: 30.29μM).CA induced apoptotic cell death, confirmed by increased Annexin V/PI staining and elevated levels of cleaved PARP in MDA-MB-231, MCF7, and T47D cells. Additionally, CA promoted autophagy, demonstrated by enhanced LC3A/B-II accumulation and increased Beclin-1 expression.These anti-proliferative and pro-apoptotic effects of CA were associated with robust activation of AMP-activated protein kinase (AMPK) signaling, as evidenced by increased phosphorylation of AMPK and its downstream target, acetyl-CoA carboxylase (ACC).Collectively, these data indicate that carnosic acid suppresses breast cancer cell proliferation, induces apoptosis and autophagy with a concomitant AMPK activation. These findings support CA as a promising plant-derived therapeutic candidate and justify further evaluation in in vivo breast cancer models.

#4656 A Novel FOLR1 and TRAIL-R2 targeting bispecific antibody to treat ovarian cancer.

Shiva Bhowmik[1], William Brady[2]

[1]Purdue University, West Lafayette, IN,[2]University of Washington, Seattle, WA

We report a first-in-class tumor antigen dependent apoptotic inducing bispecific antibody, TRAILBody™, that co-targets FOLR1 and TRAIL-R2, selectively inducing TRAIL-R2 mediated apoptotic cell death with superior selectivity and efficacy. In a head-to-head comparison with the recently approved ADC drug, Elahere, FOLR1 TRAILBody showed superior activity. Extensive in vitro and in vivo analyses across ovarian cancer cell lines, patient-derived xenografts (PDX), and murine models demonstrate that FOLR1 TRAILBody drive high-level tumor-specific apoptosis independent of ADCC, significantly overcoming limitations of FcγR-mediated TRAIL-R2 clustering. Mechanistically, FOLR1 functions as a clustering anchor for TRAIL-R2, yielding enhanced receptor oligomerization, rapid caspase-3 activation, and robust cell death in FOLR1+ ovarian cancer models. Preclinical models confirm optimal stability, avidity, and selective tumor localization with minimized off-target toxicity. Notably, FOLR1 TRAILBody show superior regression of cisplatin-resistant PDX tumors and improved safety profile compared to clinically tested monospecific TRAIL-R2 antibody agonists, including minimized liver accumulation and hepatotoxicity with reduced levels of AST/ALT in blood. This study reveals a previously unappreciated mechanism in antibody therapeutics: the use of a tumor-enriched anchor (FOLR1) to optimize death receptor clustering and activation, enabling a quantum leap in apoptotic signaling and therapeutic index for ovarian cancer. The TRAILBody platform thus offers a foundation for next-generation immuno-oncology agents and revives hope for the clinical translation of death receptor agonism, particularly in solid tumors marked by immune exclusion and therapeutic resistance.

#4657 Antigenic cancer persister cells survive direct T cell attack.

Brandon E. Mauch[1], Michael Wang[2], August (Gus) Finley Williams[2], Tania Barazande-Pour[1], Filipe Araujo-Hoffman[3], Sophie Harris[4], Cooper Lathrop[1], Matthew Hangauer[5]

[1]UCSD Moores Cancer Center, La Jolla, CA,[2]University of California San Diego - UCSD, La Jolla, CA,[3]Stanford University, Stanford, CA,[4]The University of Miami Miller School of Medicine, Miami, FL,[5]UC San Diego Health, San Diego, CA

Cancer persister cells survive cytotoxic drug stress through nongenetic mechanisms, but it is unclear whether cancer cells enter a similar survival state during immunotherapy. Using a long-term coculture model of human melanoma cells with antigen-specific CTLs, we found that antigenic cancer cells can enter a persister state in response to CTL attack and survive despite delivery of granzyme B, mitochondrial outer membrane permeabilization, and apoptotic caspase activation. Although both CTL- and drug-tolerant persister cells undergo sublethal apoptosis, they differ markedly in their transcriptomes, pro- and anti-apoptotic factors, and vulnerabilities, including opposite ferroptosis sensitivities. CTL-tolerant persister cells occupy a caspase-inhibited state partially dependent on inhibitor of apoptosis proteins, yet exhibit multiple stress-dependent features including DNA damage and mutagenesis, and are growth-arrested as a result of IFNγ-IDO1-mediated tryptophan starvation. Apoptotic caspase activity protects CTL-tolerant persister cells from potent caspase-independent death and suppresses type I IFN production. Persister cell features are enriched in inflamed tumors that regressed during immunotherapy in vivo and in surgically resected human melanoma ex vivo. These findings reveal a sublethal apoptotic persister state that allows cancer cells to survive CTL attack and identify a targetable barrier to durable immunotherapy responses.

#4658 Novel Bcl-2/Bcl-xL inhibitor, LP-118, enhances apoptosis induction by the CDK2/9 inhibitor, fadraciclib, in BRAF(V600E) human colorectal cancer cells.

Md Mohiuddin[1], Vanda Povoa[2], Beatriz Sebo[2], Rita Fior[2], Frank A. Sinicrope[1]

[1]Department of Medicine, Gastrointestinal Research Unit, Mayo Clinic Alix School of Medicine, Rochester, MN,[2]Champalimaud Centre for the Unknown, Champalimaud Research, Champalimaud Foundation, Lisbon, Portugal

Background: The *BRAF(V600E)* mutation in colorectal cancer (CRC) is associated with treatment resistance and a poor prognosis. CDK2/9 is frequently activated in human cancers, and we have previously shown that $BRAF^{V600E}$ can upregulate MCL-1, which can be suppressed by the selective CDK2/9 inhibitor fadraciclib. Herein, we determined whether targeting CDK2/9 by fadraciclib can be enhanced by concurrent Bcl-2/Bcl-xL inhibition using LP-118, which minimizes platelet toxicity in patients, compared to the Bcl-2 inhibitor venetoclax. Effects of the drugs on apoptosis, colony formation and tumor growth were studied in a zebrafish model.

Methods: We utilized isogenic human RKO ($BRAF^{V600E/V600E/WT}$) and T29 ($BRAF^{WT/-/-}$) CRC cell lines in addition to HCT-116 ($BRAF^{WT}$) and *Bax* knockout (HCT-$116^{Bax-/-}$) CRC cells. Cells were treated for 24h with fadraciclib (500nM) plus encorafenib (500nM) in the presence or absence of LP-118 (1μM) or venetoclax (1μM). Apoptosis and cell growth inhibition were assessed using annexin V/PI staining and colony formation assays, respectively. Expression of MCL-1, Bcl-xL, Bcl-2, PARP, and cleaved caspase-3 (Asp175) proteins was analyzed. In a zebrafish tumor xenograft model, the effects of the drugs on caspase-3 cleavage and tumor growth were then evaluated.

Results: Fadraciclib suppressed MCL-1 expression, induced apoptosis and significantly inhibited colony formation in all CRC cell lines. However, this effect was enhanced by encorafenib only in RKO ($BRAF^{V600E/V600E/WT}$) cells. The addition of LP-118 to fadraciclib plus encorafenib potently enhanced apoptosis induction, shown by annexin V and cleavage of PARP, caspase-3, in RKO and HCT-116 cell lines, which was synergistic and *Bax* dependent. Treatment with LP-118 combined with fadraciclib and encorafenib suppressed both Bcl-xL and MCL-1 expression in RKO cells. The addition of LP-118 to fadraciclib plus encorafenib enhanced apoptosis (annexin V) to a greater extent than did venetoclax. In a zebrafish tumor xenograft model, the addition of LP-118 to fadraciclib plus encorafenib significantly enhanced caspase-3 activation and reduced the tumor xenograft size.

Conclusion: LP-118 synergistically enhanced the antitumor activity of fadraciclib plus encorafenib in $BRAF^{V600E}$ human CRC cells, and to a greater extent than did venetoclax. Mechanistically, targeting Bcl-2/Bcl-xL concurrent with inhibition of MCL-1 and CDK2/9 by fadraciclib potently induced apoptosis and suppressed tumor cell growth. These findings suggest a novel and effective therapeutic strategy for $BRAF^{V600E}$ human CRCs.

#4660 Mcl-1 inhibitors and antidepressants as enhancers of chemotherapy response in pleural mesothelioma.

Francisco A. Molina-Pelayo[1], Cristian G. Medina[1], Jaylon C. Aggison[1], Naren Li[1], Siqi Wu[1], Hainin Yang[2], Michele Carbone[2], Yuan Xu[1], Robert T. Ripley[1]

[1]Surgery, Baylor College of Medicine, Houston, TX,[2]University of Hawaii Cancer Center, Honolulu, HI

Background: Pleural mesothelioma (PM) remains a highly lethal malignancy with limited therapeutic options. Chemotherapy with cisplatin (CDDP) and pemetrexed provides modest benefit which is limited by primary resistance mechanisms involving dysregulated apoptotic signaling. Myeloid Cell Leukemia (MCL)-1 is a Bcl-2 family member that blocks apoptosis by targeting the mitochondria which works synergistically with activation of autophagy to promote chemoresistance. Targeting MCL-1 lowers the apoptotic threshold and may suppress autophagy to enhance chemosensitivity and improve therapeutic response. This study aimed to determine whether combining MCL-1 inhibition with the antidepressant, desmethyl-clomipramine (DCMI), will enhance chemosensitivity via autophagy in PM cells.

Methods: IC_{50} calculations of CDDP, the MCL-1 inhibitor (AZD-5991), DCMI and the combinations were performed in PM cell lines H28 and H2452. Synergistic interactions were quantified using the Highest Single Agent (HSA) model. To explore autophagy, cells were treated with the autophagy inhibitor, chloroquine (CQ, 10 μM), as a positive control and analyzed for known markers, LC3 and p62, by Western blot. In addition, MCL-1 expression after DCMI combination treatments was evaluated. Cell death and apoptosis were evaluated by flow cytometry (Anexin V and PI) following treatment. Mitochondrial and glycolytic metabolic parameters were quantified by Seahorse XF.

Results: CDDP + AZD-5991 exhibited robust synergy (HSA = 10.51, $p < 0.0001$ in H2452; HSA = 9.06, $p < 0.0001$ in H28). In contrast, CDDP and DCMI produced limited interaction in H2452 cells (HSA = 2.48, $p = 0.0015$) and a near-additive effect in H28 cells (HSA = 0.76, $p = 0.175$). However, the combination of CDDP, AZD-5991, and DCMI revealed synergistic activity at lower AZD-5991 concentrations, suggesting enhanced potency. DCMI promoted accumulation of p62 and delayed LC3-II processing, consistent with inhibition of autophagy. Furthermore, DCMI + AZD-5991 increased apoptotic cells relative to CDDP alone. These findings suggest enhancement of apoptotic signaling via combined inhibition of autophagy and MCL-1 activity. Seahorse analysis revealed that DCMI decreased basal respiration in H2452, with no effect on H28 bioenergetics. MCL-1 decreases under CDDP + DCMI versus CDDP alone, indicating that DCMI enhances apoptotic priming via MCL-1 suppression and mitochondrial dysfunction.

Conclusion: These findings support that complementary mechanisms of DCMI blocking autophagy and MCL-1 promoted apoptosis will enhance the response to cisplatin. This cooperative mechanism reveals metabolic and anti-apoptotic vulnerabilities that could be exploited to overcome chemoresistance in mesothelioma. Further investigation is warranted to assess whether blocking autophagy will increase patient's response to chemotherapy.

#4661 Expression of the ferroptosis suppressor FSP1 but not GPX4 shows significant adverse prognostic effect in diffuse large B-cell lymphoma with wild-type *TP53*.

Beibei Lyu[1], Zijun Xu-Monette[1], Xiaoxian X. Zhao[2], Eric D. Hsi[3], Ming Chen[4], Carlo Visco[5], Alexandar Tzankov[6], Karen Dybkaer[7], Mu-En Wang[4], Chang Wang[1], Qingyan Au[8], Harry Nunns[8], Zenggang Pan[9], Benjamin Parsons[10], Santiago Montes-Moreno[11], Fenghuang Zhan[12], Michael B. [1]Department of Pathology, Duke University Medical Center, Durham, NC,[2]Wake Forest University School of Medicine, Winston-Salem, NC,[3]Mayo Clinic, Rochester, MN,[4]Duke University School of Medicine, Durham, NC,[5]University of Verona, Verona, Italy,[6]University Hospital Basel, Basel, Switzerland,[7]Aalborg University Hospital, Aalborg, Denmark,[8]NeoGenomics Laboratories, Aliso Viejo, CA,[9]University of Colorado School of Medicine, Aurora, CO,[10]Gundersen Lutheran Health System, La Crosse, WI,[11]Hospital Universitario Marques de Valdecilla/IDIVAL, Santander, Spain,[12]University of Arkansas, Little Rock, AR,[13]Odense University Hospital, Odense, Denmark,[14]Assoc. Professor of Pathology, The Methodist Hospital-Cornell University, Houston, TX,[15]Duke University Medical Center, Omaha, NE,[16]University of Texas Southwestern Medical Center, Durham, NC,[17]Columbia University Irving Medical Center, New York, NY,[18]Baylor College of Medicine, Houston, TX

Introduction: Diffuse large B-cell lymphoma (DLBCL) is the most common type of malignant lymphoma. Previous studies have shown that DLBCL cells are susceptible to GPX4 (Glutathione peroxidase 4)-regulated ferroptosis, an iron-dependent type of programmed cell death characterized by increased reactive oxygen species and excessive lipid peroxidation. In addition to GPX4, FSP1 (Ferroptosis suppressor protein 1, previously known as AIFM2) is a glutathione-independent repressor of ferroptosis that has shown prognostic significance in solid tumors. In this study, we aimed to reveal the significance of GPX4 and FSP1 in DLBCL.

Patients and Methods: We performed immunohistochemistry (IHC) for GPX4 and FSP1 in a large cohorts of patients with de novo DLBCL, and evaluated their cytoplasmic and nuclear expression. Prognostic analysis was performed for FSP1 and GPX4 expression in patients treated with rituximab (R)-CHOP or CHOP chemotherapy, respective of TP53 mutation status, as p53 regulates ferroptosis and TP53 mutation is associated with poorer prognosis in DLBCL.

Results: FSP1 expression with a ≥10% cutoff was positive in 42.3% of DLBCL cases. Patients with TP53 mutations had a non-significant trend of higher mean FSP1 expression than those with wild-type (Wt) TP53 (P=0.11). Prognostic analysis revealed that cytoplasmic FSP1$^+$ expression was associated with significantly poorer overall survival and progression-free survival in Wt-TP53 DLBCLs treated with R-CHOP (P=0.016 and P=0.003, respectively), and only showed non-significant unfavorable trends in TP53 mutated DLBCLs and patients treated with CHOP. In contrast, GPX4 expression did not show a significant unfavorable prognostic effect in DLBCL, and in fact, was associated with a non-significant trend of better survival. Previously we have quantified immune cell abundance and PD-1/PD-L1 expression in the tumor microenvironment of the study cohort using multiplex fluorescent IHC. Correlative analysis found that FSP1$^+$ patients had significantly higher mean and median abundance of CD68$^+$ cells (both M1 and M2 macrophages) and CD11c$^+$ cells than FSP1- patients. Further analysis in Wt-TP53 and mutated TP53 subcohorts found that only in the TP53 mutated DLBCL subcohort, FSP1 expression was associated with significantly higher mean and median CD163$^-$CD68$^+$ (M1) and overall CD68$^+$ macrophages, whereas in the Wt-TP53 DLBCL subcohort, FSP1 expression was associated with significantly higher median (but not mean) CD163$^+$CD68$^+$ (M2) macrophages and CD11c$^+$ cells.

Summary: Cytoplasmic FSP1 expression but not GPX4 had significantly adverse prognostic effect in patients with Wt-TP53 DLBCL treated with standard immunochemotherapy. Our results also suggest that in addition to ferroptosis regulation, macrophage abundance was relevant for the prognostic effects of FSP1 expression.

#4662 The mitochondrial antioxidant mitoquinone alters cancer cell death outcomes in response to therapy.

Christopher W. Clark[1], Xingping Qin[1], Cameron Fraser[2], Jessalyn Ubellacker[2], Kristopher A. Sarosiek[1]

[1]Environmental Health, Harvard T.H. Chan School of Public Health, Boston, MA,[2]Molecular Metabolism, Harvard T.H. Chan School of Public Health, Boston, MA

Background: Cell death resistant cancer cells are challenging to treat with existing therapies and are major drivers of recurrence, morbidity, and mortality. Novel cell death-modulating drugs show promise for enhancing the therapeutic efficacy of first-line chemotherapeutic agents and may potentially improve patient outcomes. Both apoptosis and ferroptosis sensitivities are known to be modulated by changes in the redox environment from excessive oxidative stress, however, the mechanisms that determine cell commitment to each form of cell death are unclear. Therefore, to investigate how cell death outcomes might be adapted by changes to the cellular redox environment we used the mitochondrial antioxidant Mitoquinone (MitoQ) as a tool compound to dissect differences between apoptosis and ferroptosis outcomes in response to chemotherapeutic agents.

Methods: Wild-type and $BAX^{-/-}BAK^{-/-}$ HeLa (human cervical cancer) cells, as well as B16-F10 (metastatic murine melanoma) wild-type cells were treated with MitoQ (0.1-1 μM) alone or in combination with either an apoptosis-inducing cocktail of BH3 mimetics (1 μM ABT-263 + 1 μM S63845) or a ferroptosis-inducing cocktail (1 μM RSL3 + 1 μM Erastin2). Inhibitors of apoptosis (Q-VD-OPh) and ferroptosis (Ferrostatin-1) were used as controls to confirm the cell death modality. After 48 hours, cell viability and stage of cell death were assessed by flow cytometry using TMRE staining, CellEvent Green Caspase 3/7 Reporter, Annexin V, and DAPI to detect mitochondrial outer membrane permeabilization, caspase activation, phosphatidylserine externalization and plasma membrane permeabilization, respectively.

Results: In wild-type cancer cell lines, increasing MitoQ concentrations (doses up to 0.3 μM) enhanced the induction of apoptosis in response to BH3 mimetics but suppressed ferroptosis induction in response to GPX4/System xc^- inhibition. Across all three cell lines, treatment with high doses of single-agent MitoQ (1 μM and above) induced a significant increase in cell death, even in BAX/BAK-deficient cells.

Conclusion: These findings suggest that modulation of mitochondrial oxidative stress via MitoQ modulates cancer cell death outcomes, promoting apoptosis while suppressing ferroptosis at low doses. Further work is needed to elucidate the molecular mechanisms underlying these effects and their implications for modulating cancer cell death modalities to improve cancer therapy outcomes.

#4663 BGB-21447, a next-generation Bcl-2 inhibitor, demonstrates superior potency and overcomes Venetoclax resistance in preclinical models of hematologic malignancies.

Shuran Li[1], Shasha Yang[1], Xiaolong Yang[1], Yanwen Ma[1], Shining Nie[1], Longbo Yin[1], Qin Wang[1], Haimei Xing[1], Zhu Mei[1], Ali Wang[1], Xiaolin Liu[1], Ying Guo[1], Haitao Wang[1], Weiwei Song[1], Lin Li[1], Lu Lyu[1], Yiwen Wang[1], Jin Wei[1], Chuanxiu Wang[1], Ye Liu[1], Xi Yuan[1], Yunhang Guo[1], Yu Shen[2], Lai Wang[2], Xiaomin Song[1]

[1]BeOne Medicines (Beijing) I GmbH, Beijing, China,[2]BeOne Medicines (Shanghai) Research & Development I GmbH, Beijing, China

Bcl-2 is a key anti-apoptotic gatekeeper that controls intrinsic apoptosis pathway. Its overexpression or aberrant activation is frequently observed in hematologic malignancies, where it promotes tumorigenesis and confers resistance to chemotherapy. Venetoclax (VEN), the first-in-class Bcl-2 inhibitor approved for R/R CLL and AML, shows modest efficacy in non-Hodgkin lymphoma and is compromised by acquired BCL2 mutations (e.g., G101V, D103Y).

Herein, we report the preclinical characterization of BGB-21447, a highly potent and selective next-generation Bcl-2 inhibitor that demonstrates remarkably better potency than VEN across multiple hematologic cancer cell lines and effectively targets a broad spectrum of VEN-resistant Bcl-2 mutations. BGB-21447 displays ≥121-fold higher selectivity for Bcl-2 over Bcl-xL, Bcl-W, Mcl-1 and Bcl2A1. Across a panel of 9 hematologic lines, it consistently achieved lower IC_{50} values than VEN (0.18-6.6 nM vs 4.8-238 nM for Ven). In RS4;11 cells overexpressing Bcl2 mutants, BGB-21447 achieved IC_{50} values of 11-44 nM IC_{50}s, including G101V (15 nM vs 3854 nM for VEN) and D103Y (44 nM vs 4731 nM for VEN). Its anti-proliferative effects were accompanied by hallmark features of intrinsic apoptosis, including caspase-3/7 activation, phosphatidylserine externalization (Annexin V positivity), and sub-G0/G1 DNA accumulation.

In PK/PD studies, oral administration of BGB-21447 demonstrated a clear exposure-response relationship in both RS4;11 wild-type and Bcl-2-G101V knock-in xenograft models, with cleaved caspase-3 levels correlating with intratumoral drug concentration. At 1.5 mg/kg, BGB-21447 showed superior antitumor efficacy compared to VEN at 15 mg/kg and ABBV-453 (AbbVie's selective Bcl-2 inhibitor) at 1.5 mg/mL. in the RS4;11 WT model. Notably, BGB-21447 showed robust antitumor effects in VEN-insensitive models, including the Toledo (DLBCL), RS4;11 Bcl2-G101V, and RS4;11 Bcl2-D103Y xenografts. No significant weight loss or laboratory toxicities were observed.

In conclusion, BGB-21447 surpasses VEN in potency and mutant coverage, and durably inhibits VEN-resistant tumors at well-tolerated doses in preclinical models. These findings support the ongoing Phase 1 clinical trials (NCT05828589, NCT06756932) evaluating BGB-21447 in B-cell malignancies and metastatic breast cancer.

#4664 Impacts of endothelial cell autophagy inhibition on tumorigenesis.

Nancy Esmeralda Leon-Rivera, Brayden Chin, Teresa Monkkonen

Biology, San Diego State University, San Diego, CA

Metastasis is the leading cause of cancer related mortality, and this burden is particularly severe in breast cancers lacking hormone receptor expression. These patients have limited treatment options and poorer outcomes. Endothelial cells are important regulators of metastasis, as they control vascular integrity and migration of circulating tumor cells into other tissues. Inhibition of autophagy, a conserved degradative process which promotes metabolic adaptation in tumor cells, is being tested as a targeted therapy for breast and other cancers. However, the impact of autophagy inhibition on the tumor vasculature and metastasis is poorly understood. To determine how endothelial autophagy influences breast tumor progression, we generated endothelial cell specific *Atg12* and *Atg5* knockout (ECKO) mice driven by the Cdh5CreER vascular endothelial cadherin promoter. In orthotopic transplantation of *MMTV-PyMT* tumor organoids and genetic crosses to *PyMT* mice, *Atg12* ECKO mice displayed delayed primary tumor growth compared to controls. Mid- stage *Atg12* ECKO tumors exhibited increased apoptosis, whereas proliferation and necrosis were unchanged at endpoint, indicating that endothelial cell autophagy promotes efficient tumor cell survival during mid-stage cancer progression. Despite increased $CD31^+$ vascular density, *Atg12* ECKO tumors demonstrated elevated HIF1-α, consistent with impaired vascular function and hypoxia. Following surgical resection of primary tumors, *Atg12* ECKO mice demonstrated higher rates of tumor recurrence and lung metastasis, and tail vein injection of *PyMT* cells into tumor naïve mice confirmed enhanced metastatic outgrowth. To test whether these effects were tumor type specific, we used the Rat insulin promoter-SV40 Large T antigen (RIP-Tag) model of pancreatic neuroendocrine tumors, which are highly vascular and sensitive to anti-angiogenic therapy. Neither early nor late endothelial deletion of *Atg12* altered primary tumor burden or survival, in contrast to the *PyMT* findings. However, *Atg12* ECKO mice displayed increased liver micrometastasis, indicating that the effects of endothelial autophagy loss are highly context specific. These results highlight the context dependent roles of endothelial autophagy in shaping tumor growth and metastasis, underscoring the need to consider strategies to limit changes to metastasis with autophagy inhibition strategies in cancer therapy.

#4665 Programmable multivalent siRNA nanostructure rewires apoptosis by co-silencing MCL-1 and BCL-XL in glioblastoma.

Qianhui Feng, Henry Lin, Yichen Yan, Rong Zheng, Yang Xu, Hao Yan

Arizona State University, Tempe, AZ

Background: Glioblastoma is one of the most aggressive and treatment-resistant brain cancers. Many standard treatments fail because glioblastoma cells rely on powerful survival proteins, especially MCL-1 and BCL-XL, to block cell death, which stabilizes mitochondrial integrity, suppresses caspase activation, and maintains the survival of glioblastoma. Pharmacologic inhibitors of these proteins face dose-limiting toxicities and incomplete target suppression. To overcome these barriers, we engineered a multivalent siRNA nanostructure that enhances functional activation of RNAi modules within tumor cells.

Methods:A branched multivalent siRNA nanostructure was first engineered using GFP-targeting siRNAs to validate multivalent RNAi performance in U251-GFP glioblastoma cells. This model enabled assessment of cooperative gene silencing, spatial organization-dependent activity, and prolonged knockdown efficiency. Upon confirming the effectiveness of multivalent RNAi silencing, the nanostructure was redesigned to present siRNAs targeting MCL-1 and BCL-XL, thereby overcoming anti-apoptotic signaling and engaging the intrinsic apoptosis pathways. Functional testing, including qPCR, confocal microscopy, western blotting, mitochondria-dependent apoptosis assays, and long-term knockdown stability, was conducted to evaluate dual-gene silencing and apoptotic activation in U251 glioblastoma cells.

Results: The GFP-targeting multivalent siRNA nanostructure exhibited strong cooperative silencing in U251-GFP cells, achieving a sustained reduction in GFP fluorescence of over 90% for up to 7 days, demonstrating enhanced potency, improved intracellular stability, and superior durability compared to a single siRNA. The therapeutic multivalent siRNA nanostructure targets MCL-1 and BCL-XL, achieving robust dual-gene suppression at both mRNA and protein levels. Co-silencing of these anti-apoptotic nodes triggered mitochondrial activation of caspase-9/3 signaling, confirming reactivation of the apoptotic pathway. Cells exhibited a pronounced loss of viability and reduced colony-forming capacity.

Conclusions: This study established a programmable multivalent siRNA nanostructure capable of both validating multivalent RNAi using GFP and achieving therapeutic co-targeting of MCL-1 and BCL-XL to overcome apoptotic resistance in glioblastoma. The observed strong apoptotic activation supports the potential of this modular RNAi nanotechnology for treating refractory and malignancies. This approach offers a clinically translatable, programmable strategy for next-generation multi-target RNA interference therapies.

#4666 CAPZB suppresses disulfidptosis through SQOR interaction to drive intrahepatic cholangiocarcinoma progression and therapeutic vulnerability.

Jiangqiao Yao[1], Tong Chen[1], Ziyan Chen[1], Gang Chen[2], **Chongming Zheng**[3], Yi Wang[1]

[1]Department of Epidemiology and Biostatistics, Wenzhou Medical University, Wenzhou, China,[2]The First Affiliated Hospital of Wenzhou Medical University, Wenzhou Medical University, Wenzhou, China,[3]The First Affiliated Hospital of Wenzhou Medical University, Wenzhou, China

Background: Intrahepatic cholangiocarcinoma (ICC) is an aggressive malignancy with limited therapeutic options. Disulfidptosis, a novel cell death modality triggered by disulfide stress, represents a promising therapeutic target. While CAPZB has been implicated in disulfidptosis, its role in ICC remains undefined. This study investigates whether CAPZB regulates disulfidptosis via SQOR to promote ICC progression.

Methods: Transcriptomic analysis of three ICC cohorts (n=98) and single-cell RNA-seq (n=4) evaluated CAPZB expression and prognostic significance. CAPZB was genetically modulated in ICC cell lines using shRNA/overexpression constructs. Disulfidptosis was induced by glucose deprivation and assessed via cell viability, F-actin staining, and NADP+/NADPH/GSH/GSSG ratios. Protein interactions were identified by IP-MS and validated by co-immunoprecipitation. AKT/NICD mouse models evaluated in vivo tumor progression. Patient-derived organoids were treated with GLUT1 inhibitor BAY-876.

Results: CAPZB was significantly overexpressed in ICC tissues and correlated with poor overall survival ($p<0.01$). Single-cell analysis revealed elevated CAPZB in malignant cholangiocytes. CAPZB knockdown suppressed proliferation, migration, and invasion, while overexpression enhanced malignant phenotypes. IP-MS identified SQOR as a CAPZB-interacting protein, with strong expression correlation ($p<0.001$). CAPZB knockdown promoted disulfidptosis under glucose deprivation, increasing cell death ($p<0.001$), F-actin contraction, and NADP+/NADPH ratio. SQOR overexpression partially rescued these effects. In vivo, CAPZB knockdown reduced tumor burden ($p<0.01$). Patient-derived organoids showed BAY-876 sensitivity (IC_{50}=0.315 μM). Combination therapy with CAPZB knockdown and BAY-876 demonstrated synergistic anti-tumor efficacy ($p<0.001$). Conclusions: CAPZB is a disulfidptosis-related oncogene that drives ICC progression by interacting with SQOR to maintain redox homeostasis and suppress disulfidptosis. Targeting CAPZB alone or with GLUT1 inhibitors induces synthetic lethality via disulfidptosis, offering a promising therapeutic strategy.

Clinical Significance: This study identifies the CAPZB-SQOR axis as a novel disulfidptosis regulator in ICC and demonstrates synergistic anti-tumor effects of dual targeting CAPZB and glucose metabolism, providing a translational framework for disulfidptosis-based therapies.

#4667 Targeting ULK1 overcomes autophagy-mediated chemoresistance in cancer cell.

Eun-Jung Kim, Youngjun Park

Jeju National University, Jeju-si, Korea, Republic of

Autophagy is a tightly regulated, lysosomedependent recycling process that preserves energy balance and proteostasis during stress, thereby promoting cell survival. Although chemotherapy aims to eliminate malignant cells, many tumors acquire resistance by engaging prosurvival autophagy. To disable this escape, we targeted Unc51like kinase 1 (ULK1), the initiator of autophagosome biogenesis. We generated a library by modifying reported ULK1 inhibitor scaffolds and screened for blockade of autophagic flux using an LC3GFPmCherry tandem reporter. Western blotting verified ontarget suppression, including phosphorylated ATG13 reduction and p62 accumulation, which nominated a novel lead compound. By treating this compound with standard chemotherapeutics in multiple cancer cell lines, cell death was increased concomitant with the blunted autophagic flux. These data support ULK1 as a tractable node to overcome autophagymediated chemoresistance and rationalize ULK1 inhibition as a combination strategy to deepen chemotherapy responses. Future study will evaluate antitumor efficacy and tolerability in vivo to advance a novel ULK1 inhibitor toward preclinical development.

#4668 Targeting the histone acetyltransferase GCN5 sensitizes cancer cells to ferroptosis.

Ling-Chu Chang[1], Shih-Kai Chiang[2], Shuen-Ei Chen[2]

[1]China Medical University Hospital, Taichung, Taiwan,[2]National Chung Hsing University, Taichung, Taiwan

Ferroptosis is an iron-dependent form of regulated cell death with emerging significance in cancer. However, its full regulatory network, particularly epigenetic regulation, remains poorly understood. Here, we identify the histone acetyltransferase GCN5 as a critical novel mediator of ferroptosis. We demonstrate that the ferroptosis inducers Erastin and RSL3 trigger reactive oxygen species (ROS) production, lipid peroxidation, and labile iron accumulation in a GCN5-dependent manner. Genetic knockdown or pharmacological inhibition of GCN5 ameliorated Erastin/RSL3-induced mitochondrial dysfunction (including ROS, lipid peroxidation, and impaired dynamics), restored endoplasmic reticulum (ER) homeostasis, and normalized autophagic flux. Furthermore, Erastin/RSL3 upregulated several transcription factors in a GCN5-dependent manner. Notably, HDAC inhibitor-induced cell death was synergistically enhanced by Erastin or RSL3, suggesting a compelling combination therapy strategy.In conclusion, our work establishes GCN5 as a central regulator of ferroptosis, governing its execution through mitochondrial, autophagic, and nuclear pathways. These findings nominate GCN5 as a therapeutic target to sensitize cancers to ferroptosis.

#4669 Label free identification of cancer cell death pathways via holotomography and deep learning as an early pharmacodynamic biomarker.

Minwook Kim[1], Park Weisun[1], Geon Kim[1], Sanggeun Oh[2], **Juyeon Park**[1], Jihwan Yu[1], Hyun-Suk Min[2], Sumin Lee[3], Won Do Heo[1], YongKeun Park[1]

[1]KAIST, Daejeon, Korea, Republic of,[2]Tomocube, Inc., Daejeon Metropolitan, Korea, Republic of,[3]Sumin Lee (Individual)

Accurate measurement of regulated cell death (RCD)—including apoptosis, necroptosis, and necrosis—is critical for oncology drug development and mechanism-of-action studies. Conventional fluorescence assays introduce phototoxicity, labeling bias, and incompatibility with long-term or high-frequency pharmacodynamic monitoring. We developed a fully label-free platform that integrates 3D holotomography (HT) and deep learning to classify RCD phenotypes directly from intrinsic refractive-index (RI) signatures, enabling non-perturbative, mechanism-aware drug-response biomarkers.HeLa cells were induced into apoptosis, necroptosis, or necrosis using canonical biochemical triggers, with fluorescence markers (Annexin V, PI, Hoechst) used solely for ground truth. 3D RI tomograms acquired by HT-X1 Plus were converted to 2D maximum-intensity-projection (MIP) patches to train an ImageNet-pretrained CNN to classify five states (live-control, live-treated, apoptosis, necroptosis, necrosis) using a sliding-window/majority-vote strategy. Temporal concordance was evaluated through synchronized HT–fluorescence time-lapse imaging and flow cytometry. For subtle drug-induced phenotypes (doxorubicin, cisplatin), performance of full 3D volumetric models was compared with 2-D projections to assess the necessity of depth information. Cross-cell-line robustness was tested on A549 cells with minimal fine-tuning.The five-state classifier achieved 99.3% accuracy on held-out HeLa datasets, with misclassifications limited to the apoptosis–necroptosis boundary. HT-based predictions identified early necroptotic transitions 2–4 hours before Annexin V/PI fluorescence, and population-level dynamics closely matched flow cytometry, establishing an earlier, dye-free pharmacodynamic window. In drug-response experiments, 3D volumetric models outperformed all 2D approaches, capturing spatially heterogeneous, mechanism-rich morphological signatures (76–88% accuracy in 3D vs. 50–55% in 2D MIP and 0% in SUM projections). The HeLa-trained model generalized poorly to A549 cells initially (50.4% accuracy), but small-data fine-tuning restored near-perfect performance, demonstrating practical assay portability across cancer cell types.Holotomography-based AI provides a fully label-free, segmentation-free, real-time biomarker for distinguishing RCD pathways and quantifying early drug responses with high accuracy. The platform detects necroptosis hours earlier than biochemical assays, resolves subtle drug-induced morphologies, and adapts rapidly to new cell types. These capabilities position HT-AI as a scalable pharmacodynamic tool for mechanism-of-action profiling, cytotoxicity testing, and high-content oncology drug discovery, enabling longitudinal, non-destructive phenotyping beyond fluorescence-based methods.

#4670 Multimodal mechanistic control of autophagy by the CtBP1/KAISO/TRIM28 Complex in breast cancer cells.

Young-Ho Lee[1], Kevin L. Gardner[2]

[1]Columbia university, New York, NY,[2]Vagelos College of Physicians & Surgeons, New York, NY

Autophagy plays a context-dependent role in breast cancer progression, alternately promoting or suppressing tumor survival. However, the transcriptional and metabolic mechanisms for autophagy remain poorly understood. Here, we identify a CtBP1/Kaiso/Trim28 transcriptional regulatory complex as a key metabolic sensor that coordinates both transcriptional control of autophagy genes in the nucleus and structural regulation of autophagic machinery in the cytoplasm. We demonstrate that this CtBP1/Kaiso/Trim28 complex mediates multimodal control of autophagy in response to glucose availability. Genome-wide chromatin occupancy (CNR-seq) and transcriptomic profiling (RNA-seq) across luminal (MCF7) and triple-negative (MDA-MB-231) breast cancer cells reveal that CtBP1 directs complex assembly at promoters of key autophagy-related genes, including *ULK1*, *MTOR*, *VPS34*, and *TFEB*. Loss of CtBP1 or Kaiso leads to de-regulation of these targets, underscoring their cooperative role in maintaining autophagic balance. Proximity ligation assays detect CtBP1/Kaiso/Trim28 complexes in both nucleus and cytoplasm, highlighting their “moonlighting” function together with autophagic components such as LC3 in regulating autophagosome formation and stability. Several of these complexes display glucose-dependent dynamics, directly linking metabolic flux to autophagic regulation. Together, these findings uncover a previously unrecognized CtBP1-linked multimodal mechanism that integrates metabolic signals with both transcriptional and structural control of autophagy. The defined coordination between CtBP1, Kaiso, and Trim28 establishes a critical metabolic-autophagy axis in breast cancer and suggests new therapeutic strategies targeting CtBP1-mediated metabolic adaptation in therapy-resistant tumors.

#4671 Autophagy alterations in KRAS-mutant colorectal cancer following PRMT5 inhibition.

Komalpreet Kaur[1], Danbee Chae[1], Daniel Aguaiza[1], Netanel Louloueian[1], Shloimie Lowy[1], SANJAY GOEL[2], Radhashree Maitra[1]

[1]Biology, Yeshiva University, New York, NY,[2]Oncology, Rutgers Cancer Institute, New Brunswick, NJ

Introduction: The KRAS mutation is found in 45% of Colorectal Cancer (CRC) patients. Evidence indicates upregulation of Protein Arginine Methyltransferase 5 (PRMT5) expression in 75% of KRAS-mutated CRC patient tumor samples and suggesting PRMT5 as a surrogate therapeutic target for KRAS Mutant CRC treatment. The exact mechanism of crosstalk between PRMT5 and mutant KRAS is poorly understood. This study evaluates the mechanism of autophagy induction under PRMT5 inhibition and the possible apoptotic transition.
Methodology: Four CRC cell lines, HCT116, SW640 (KRAS mutant), HKE3, and LIM2405 (KRAS wild type), were treated with three inhibitors, EPZ015666 (EPZ), GSK3326595 (GSK), and AMG-193 (AMG), each at 0.5 μM, 1 μM, and 10 μM, and assessed at 24 h and 48 h. Western blot analysis was conducted for ATG5, BECLIN1, BRG1, LC3B, ULK1, and ACTIN (housekeeping) to quantify autophagy regulation. Fold-change values and p-values were used to determine significance, and comparisons were made across drug, dose, time point, and KRAS mutation status.
Results: All three PRMT5 inhibitors elicited the autophagy pathway, with varying temporal and dose-dependent effects. EPZ showed autophagy induction at most doses at 24 h, yet regulation fluctuated over further timepoints, suggesting induction without any clear shift toward either sustained flux or apoptosis. GSK demonstrated mild early induction at 24 h, which was followed by marked reductions. Notably, at 0.5 μM concentration, ULK1 ($p=0.002$) and BECLIN1 ($p=0.023$) were significantly downregulated at 48 h, suggesting that an initial trigger of the pathway is followed by autophagy collapse. AMG caused the highest activation with strong induction (Fold Change>2.5, $p=0.045$), observed at 48 h at concentrations of 1 and 10 μM; however, the absence of significant increases to LC3B suggests impaired flux and a transition toward apoptosis. EPZ and GSK both also demonstrated BECLIN1-independent initiation of autophagy across early doses and timepoints.
Conclusion: Across four CRC lines, PRMT5 inhibition enhanced autophagy signaling, significantly in KRAS-mutant backgrounds. AMG consistently caused the strongest activation across early and late autophagy markers, indicating potent disruption of PRMT5-regulated stress-response circuits. We are currently investigating the onset of apoptosis under these treatment conditions by western blotting and gene expression by transcriptomics. This work aims to identify therapeutic targets within the autophagy-apoptosis axis to improve PRMT5 inhibitor-mediated cancer cell killing.

#4672 Neuropeptide Y Y1 receptor inhibition induces autophagy to limit colorectal cancer progression.

Sooraj Kakkat, Prabhat Suman, Aris Richter, Steven B McClellan, Debanjan Chakroborty, Chandrani Sarkar

University of South Alabama, Mobile, AL

Introduction: Deregulation of autophagy in colorectal cancer (CRC) increases cell proliferation, disrupts intestinal epithelial cell homeostasis, and contributes to therapeutic resistance. Therefore, determining the mechanisms by which CRC cells evade autophagy is important for developing new therapeutic strategies. The present study aimed to investigate the role of neuropeptide Y (NPY), a neurohormone that is overexpressed in CRC, and its receptors in regulating CRC cell growth and survival.
Methods: The status of NPY and Y1 receptor (Y1R) expressions in CT26 (ATCC) and MC38 (Kerafast) mouse CRC cells was determined by western blot analysis. NPY and Y1R expressions in human colon adenocarcinomas and mouse colon cancer tissues were determined by immunohistochemistry. In vitro cell proliferation assays and flow cytometry were performed to determine the effects of blocking Y1R by antagonist (BIBO3304 trifluoroacetate) or by siRNA-mediated silencing of Y1R in CT26 and MC38 cells. Western blot and qRT-PCR were also performed to determine the changes related to autophagy upon blocking/silencing Y1R. To elucidate the underlying mechanism of Y1R inhibition-induced autophagy, the signaling pathway was analyzed. The impact of the Y1R inhibition on tumor growth and progression was assessed in vivo.
Results and Conclusion: Our analysis revealed a significant increase in NPY and Y1R expressions in human colon adenocarcinoma and mouse orthotopic CRC tissues. NPY is primarily secreted by CRC cells that express Y1R on their surfaces. Suppression of Y1R with both an antagonist and siRNA resulted in significant inhibition of proliferation and increased autophagy in CRC cells. Also, the levels of autophagy markers (ATG3, ATG12, ATG16L, LC3A, ATG5, LC3B and BECN1) were significantly enhanced with the inhibition of Y1R. Further analysis revealed that autophagy was induced in CRC cells via AMPK activation, leading to mTOR inhibition. Our results, therefore, indicate that targeting Y1R with clinically safe antagonists may represent a promising therapeutic strategy to suppress tumor growth and restore autophagy-mediated tumor suppression in CRC. These findings suggest a decisive role for the NPY/Y1R axis in regulating CRC cell behavior and indicate the potential of targeting Y1R with clinically safe Y1R inhibitors to improve therapeutic outcomes in CRC.

#4673 Targeting BCL2 pathway to enhance immunogenicity in *ALK+* NSCLC.

Batkhishig Munkhjargal[1], Sudha Mudumana Sadasivan[2], Shirish M. Gadgeel[3], Amanda Pilling[4]

[1]Henry Ford Health System, Detroit, MI,[2]Henry Ford Health System, Troy, MI,[3]Henry Ford Hospital, Detroit, MI,[4]Hematology/Oncology, Henry Ford Health System, Detroit, MI

Background: Translocations of the Anaplastic Lymphoma Kinase (ALK) gene occur in 3-5% of Non-Small Cell Lung Cancer (NSCLC) patients and are treated with ALK tyrosine kinase inhibitors (TKIs). However, resistance to ALK TKIs develop through on-target mutations and bypass signaling. Treatment response to ALK TKIs also relies on apoptosis, a complex mechanism regulated by BCL2 family proteins. Therefore, dysregulation of this pathway promotes tumor progression and therapy resistance. It has been reported that cancer cells depend on anti-apoptotic proteins of BCL-2 family (e.g. BCL-2, MCL-1, BCL-xL) for their survival. This has led to the development of BH3 mimetics, which are inhibitors of anti-apoptotic proteins. ALK+ NSCLC is considered an immune “cold” tumor with low immunogenicity, demonstrated by fewer neoantigens and lack of cytotoxic tumor-infiltrating lymphocytes (TILs), leading to limited efficacy of immune checkpoint-targeting therapies in these patients. Some TKIs have been reported to elicit durable antitumor immunity by inducing immunogenic cell death (ICD) through the release of damage-associated molecular patterns (DAMPs). However, this has not been studied in the context of ALK+ NSCLC.We hypothesized that ALK-directed therapy in combination with BH3 mimetics would initiate ICD through the release of DAMPs and increase sensitivity to ALK TKIs.

Methods: We evaluated the efficacy of ALK TKIs (Lorlatinib, Alectinib) alone and in combination with the BH3 mimetics navitoclax (BCL-2/BCL-xL inhibitor), venetoclax (BCL-2 inhibitor) and s63845 (MCL-1 inhibitor) to induce damage-associated molecular patterns (DAMPs) in ALK+ NSCLC cell lines.

Results: ALK+ cancer cell lines exhibited high expression of MCL-1 and BCL-xL proteins, indicating their dependency on BCL-2 family proteins for survival. The addition of BH3 mimetics enhanced apoptosis induction, as evidenced by increased PARP cleavage, and further reduced colony formation efficiency compared to ALK TKI single-agent treatment. Both ALK TKI single agent and combination treatment with BH3 mimetics induced key DAMPs essential for ICD, including: (1) increased type I interferon signaling via IFN-β (3-7-fold) and CXCL10 (2-3-fold); (2) peak release of extracellular ATP at 7 hours of treatment; and (3) enhanced phosphorylation of eIF2α compared to the control.

Conclusions: ALK-directed therapy has the potential to induce immunogenic cell death (ICD) and elicit antitumor immune responses. Combining BH3 mimetics with ALK TKIs can be a promising therapeutic strategy to enhance anti-tumor immunity and overcome ALK TKI resistance in ALK+ NSCLC

#4674 Activation of a STAT3/LATS1 signaling axis by folate receptor alpha enables breast cancer cells to resist ferroptosis.

Prajakta Prasad Ambegaokar[1], Hira Goel[2], Arthur M. Mercurio[3]

[1]Molecular, Cell and Cancer Biology, UMass Chan Medical School, Worcester, MA,[2]Research Assistant Professor, Cancer Bio. Dept., Univ. of Massachusetts Medical School, Worcester, MA,[3]Interim Chair & Professor, Dept. of Cancer Bio., University of Massachusetts Medical School, Worcester, MA

Dynamic changes occurring in the tumor microenvironment that carcinoma cells encounter during their progression can trigger ferroptosis, a form of cell death characterized by the iron-dependent lipid peroxidation of cell membranes. This phenomenon is exacerbated during metastasis as tumor cells in circulation are exposed to conditions of matrix-detachment, oxidative stress and high iron concentration. Many tumor cells withstand these conditions to survive, which suggests they have acquired mechanisms to resist ferroptotic stimuli. Our goal in this study was to identify specific cell surface proteins expressed on breast cancer cells that promote ferroptosis resistance since such proteins can serve as therapeutic targets. To achieve this goal, we used an unbiased approach that involved analysis of single-cell RNA sequencing data (scRNA-seq) that we obtained from an organoid derived from a breast cancer patient that was exposed to a ferroptosis-inducing drug, imidazole ketone erastin (IKE). Differential gene expression analysis of this scRNA seq revealed that folate receptor α (FRα) is significantly expressed in ferroptosis non-responder populations. Subsequently, we demonstrated a causal role for FRα in promoting resistance to ferroptosis induced by both IKE and matrix detachment in breast cancer cell lines (CAL51 and T47D). We verified the ability of FRα to activate STAT3 and observed that STAT3 drives ferroptosis resistance in our model. To understand how STAT3 promotes ferroptosis resistance, we identified LATS1, a key regulator of Hippo signaling that phosphorylates and inactivates YAP and TAZ. Using chromatin immunoprecipitation, we observed that STAT3 binds to the LATS1 promoter region and that inhibition of STAT3 reduces LATS1 gene and protein expression. We also found that STAT3-mediated regulation of LATS1 inhibits YAP, which is known to promote ferroptosis sensitivity. To investigate a mechanism for how inhibition of YAP by STAT3/LATS1 contributes to ferroptosis resistance, we focused on the ability of YAP to regulate Acyl-CoA synthetase long-chain family member 4 (ACSL4), an enzyme that triggers ferroptosis by remodeling lipid membranes in cells. Our data revealed that STAT3 and LATS1 have a causal role in inhibiting YAP-mediated induction of ASCL4 expression. Together, these data highlight a novel role for FRα in promoting ferroptosis resistance by a mechanism that is dependent on LATS1. Ongoing studies are aimed at investigating the ability of FRα and LATS1 to enhance metastasis by promoting ferroptosis resistance. This work also suggests that FRα could be an effective therapeutic target for mitigating metastatic breast cancer.

#4675 Integrated real-time impedance and fluorescence imaging to characterize NETosis.

Tian Wang[1], **Xiaoyu Zhang**[2], Grace Yang[1], Peifang Ye[1], Nancy Li[2]

[1]Agilent Technologies, Hangzhou, China,[2]Agilent Technologies, La Jolla, CA

NETosis is a specialized form of neutrophil cell death characterized by the release of web-like DNA structures and associated proteins, known as neutrophil extracellular traps (NETs). Two main pathways mediate NETosis[1,2]: (1) classical “suicidal” NETosis, which involves cell lysis following NET release, typically occurs within 3-4 hours and depends on reactive oxygen species (ROS) generation via NADPH oxidase; and (2) “vital” NETosis, where NETs are extruded through vesicles within 1-2 hours while the cell remains intact. NETosis plays a dual role in host defense and disease, contributing to antimicrobial immunity as well as pathological inflammation, thrombosis, and autoimmunity[3]. In this study, differentiated neutrophil-like HL-60 (dHL-60) and primary human neutrophils were treated with a small set of compounds: PMA, which triggers suicidal NETosis; A23187, a pharmacological agent that induces rapid, vital NETosis; and camptothecin, an apoptotic compound. To visualize NET formation, the cells were cultured in media containing eTox Green, a membrane-impermeable DNA-binding dye. The morphological and physiological changes were continuously monitored via both impedance readout, reported as Cell Index, and live-cell imaging simultaneously on an xCELLigence RTCA eSight system. Our results show that: (1) the extent of DNA-binding dye staining distinguished apoptosis from NETosis, with NETosis inducers PMA and A23187 producing larger green fluorescence areas than the apoptotic agent camptothecin, reflecting that extruded NETs are substantially larger than nuclei; (2) suicidal NETosis induced by PMA was differentiated from vital NETosis triggered by A23187 based on ROS dependency—NET release was completely inhibited by DPI, an NADPH oxidase blocker, after PMA treatment but not after A23187 exposure. Additional distinctions included earlier onset of NET extrusion with A23187 and neutrophil death following PMA stimulation but not A23187 treatment; and (3) PMA-induced NETosis was associated with a transition from suspension to adherent states, which was monitored and quantified by impedance measurements. In conclusion, this real-time, noninvasive impedance-imaging approach enables visualization of NETosis, quantification of NET release kinetics via fluorescence imaging, and monitoring of neutrophil transitions between suspension and adherent states through impedance measurements. This integrated method provides a robust and versatile platform for mechanistic NETosis studies, drug-screening applications, and broader investigations into neutrophil-driven pathologies.

#4676 Therapeutic exploitation of AUTAC in hematologic malignancies with cardiac protection.

Ahmed M. Elshazly, Nayyerehalsadat Hosseini, Senthil K. Radhakrishnan

Virginia Commonwealth University, Richmond, VA

Background: Myeloid cell leukemia-1 (Mcl1) is a critical member of the Bcl_2 family that plays an essential role in regulating apoptosis and maintaining mitochondrial integrity, particularly within cardiac tissue. While Mcl1 overexpression is a major driver of resistance to multiple anticancer therapies, its pharmacologic inhibition has been hampered by dose-limiting cardiotoxicity, representing a significant and unresolved challenge in cardio-oncology. The development of safer therapeutic strategies that selectively target Mcl1 in cancer cells while sparing cardiac cells remains a high-priority goal. In this study, our group investigated a novel autophagy-targeting chimera (AUTAC) designed to selectively degrade Mcl1 via the autophagy-lysosomal pathway. We aimed to determine whether AUTAC could induce selective cytotoxicity in multiple myeloma cells while preserving cardiac cell viability and mitochondrial function.
Methods: Multiple myeloma cell lines (U266B1, RPMI-8226) and cardiac cell lines (AC16, H9c2) were used as tumor and cardiac models, respectively. Cell viability was assessed using the CellTiter-Glo assay and IncuCyte live-cell imaging. Mitochondrial membrane potential was measured by TMRE fluorescence. Effects of AUTAC on Mcl1 and autophagy dynamics were evaluated by Western blotting, confocal microscopy, and inhibition studies with 3-methyladenine (3-MA) and chloroquine (CQ). To confirm autophagy dependence, ATG5 was knocked down using shRNA.
Results: Treatment with AUTAC selectively induced lysosomal degradation of Mcl1, without detectable effects on other anti-apoptotic Bcl_2 family members, including Bcl_2 and Bcl_{xL}. Pharmacological inhibition of autophagy with 3-MA (early-stage inhibitor) or CQ (late-stage inhibitor) effectively blocked AUTAC-mediated Mcl1 degradation, confirming that the process required an intact autophagy-lysosomal pathway. Furthermore, knockdown of ATG5 abolished Mcl1 reduction, reinforcing the autophagy dependence of this degradation mechanism. Functionally, AUTAC treatment led to a greater than 50% reduction in cell viability in U266B1 and RPMI-8226 multiple myeloma cells, accompanied by increased apoptotic signaling. In contrast, AUTAC caused minimal cytotoxicity in AC16 and H9c2 cells, maintaining mitochondrial function and morphology. Compared with conventional Mcl1 inhibitors, AUTAC exhibited substantially reduced cardiotoxicity, underscoring its favorable safety profile.
Conclusions: Targeted lysosomal degradation of Mcl1 via AUTAC represents a promising therapeutic strategy that repurposes autophagy for selective oncogenic protein removal. AUTAC effectively degraded Mcl1 in malignant cells while sparing cardiac cells from apoptosis and mitochondrial injury, highlighting its potential as a next-generation, cardio-safe alternative to conventional Mcl1 inhibitors.

#4677 Estrogen induces cell death in non- reproductive cancer cells through disrupting mitotic spindle assembly.

Pu Liang[1], Song Zeng[2], Wei Chen[3], Dong Li[3], Wei Feng[4], Xiaopeng Hu[2], Wensheng Wei[5], Xin Liang[3], Xi Wang[1]

[1]Beijing Ditan Hospital, Capital Medical University, Beijing, China,[2]Beijing Chaoyang Hospital, Capital Medical University, Beijing, China,[3]School of Life Sciences, Tsinghua University, Beijing, China,[4]Institute of Biophysics, Chinese Academy of Sciences, Beijing, China,[5]School of Life Sciences, Peking University, Beijing, China

Cancer epidemiology shows consistent sex dimorphism across many non reproductive cancers: males typically have earlier onset, higher incidence, and worse outcomes. While these differences have been partly attributed to differential exposure to risk factors, they persist after adjustment, implicating intrinsic biological contributors. Changes in cancer behavior around the menopausal transition further implicate estrogenic environments in modulating core processes such as cell division and tumor survival. Here, we examine effects of high concentrations of estrogen on proliferation in multiple non reproductive cancer types, including bladder cancer. We find that estrogen induces tumor cell death through a mechanism independent of classical estrogen receptors (ERα, ERβ, and GPER). To identify mediators of this cytotoxicity, we conducted an unbiased whole genome CRISPR knockout screen. Notably, the ten most significant genes—KIFC1, TPX2, LIN37, KIF4A, KIF18B, KIF2C, WDR62, CLASP1, CLIP1, and VPS37C—are all required for spindle assembly and function. These results implicate spindle assembly as a key determinant of cellular sensitivity to estrogen. Kinetic studies showed that estrogen inhibits both microtubule polymerization and depolymerization. Biochemical analysis identifies estrogen binds αβ-tubulin dimers and acts as a negative catalyst of microtubule dynamics, impairing spindle assembly, disrupting mitosis, and triggering cell cycle-associated death pathways. Consistent with this model, overexpression of the microtubule polymerase Ch-TOG attenuates estrogen's effects. Together, these data suggest that elevated estrogen levels can compromise spindle assembly and promote tumor cell death, providing a potential mechanism by which reproductive age females may be relatively protected from many non reproductive cancers and offering insight into the sex disparities observed in epidemiological studies.

Poster Session

#4681 Probing the RecQL4 homolog Hrq1: A genetic suppressor screen identifies critical functional features.

Robert H. Simmons, Matthew Bochman

Molecular and Cellular Biochemistry, Indiana University, Bloomington, IN

The DNA repair helicase RECQL4 is a potent oncogene whose dysregulation is a hallmark of multiple cancers and diseases of genomic instability. Overexpression of RECQL4 is observed in human breast, ovarian, and liver cancers, where its expression is a biomarker for poor prognosis. Conversely, germline loss-of-function perturbations in the ATPase domain of the protein are linked to genetic diseases like Rothmund-Thomson syndrome that are characterized by high risk of developing osteosarcoma and lymphoma. This bifurcated role highlights that RECQL4 dosage and activity must be precisely tuned. Additionally, RECQL4 has a highly conserved function in the repair of DNA interstrand crosslink (ICL) damaging agents such as platinum-based chemotherapeutics, making this an important protein to understand for overcoming chemoresistance. However, mechanistic studies of RECQL4 are difficult to study *in vivo* as well as overexpress and purify because its N terminus contains an essential replication-initiation domain equivalent to *Saccharomyces cerevisiae's* Sld2. Therefore, we study the *S. cerevisiae* homologue of RECQL4, Hrq1. We use this model to discover more details about this protein's functions that can then be linked back to the human system. The ATPase-dead mutant of Hrq1 (*hrq1-K318A*) is profoundly hypersensitive to the ICL agent diepoxy butane (DEB), exhibiting a lethality far greater than the complete deletion strain (*hrq1Δ*). This defines a dominant-negative "protein-trapping" or "roadblock" phenotype. To identify how this toxic protein-DNA complex is resolved, we generated spontaneous suppressor colonies by plating *hrq1-K318A* strains on DEB. Whole-genome sequencing revealed that over 90% of screened colonies in the *hrq1-K318A* strain had a secondary mutation within the *hrq1* gene itself. Crucially, spot dilution assays confirmed that these intragenic suppressors rescue the K318A hypersensitivity back to the level of the *hrq1Δ* deletion. This provides powerful genetic evidence for the "roadblock" hypothesis, demonstrating the suppressors function by "defusing" the toxic K318A protein, reverting its phenotype to a simple loss-of-function. Further analysis of those results has revealed that many of the mutations are at highly conserved residues amongst RECQL4 and its homologues, suggesting important functional properties at those sites. Finally, we compared these genetic suppressors to a rationally-designed, DNA-binding-deficient mutant (*hrq1-R739A*). While *in vitro* assays confirmed reduced DNA binding, this mutation *in vivo* provided only a slight rescue of the K318A toxicity. This finding suggests the dominant-negative "trap" is a complex intermediate stabilized by more than DNA-binding alone—likely including key protein-protein interactions—and reveals critical mechanistic nuances for the design of future RECQL4-targeting therapeutics.

#4682 Metabolic enzymes as protective modulator of BRCA2 haploinsufficiency and genome instability.

Xiao Zi Huang[1], Tuan Zea Tan[2], C. Pawan K. Patro[2], Li Ren Kong[3], Ashok R. Venkitaraman[2]

[1]NUS Centre for Cancer Research, Yong Loo Lin School of Medicine, National University of Singapore (NUS), Singapore, Singapore,[2]Cancer Science Institute of Singapore, Singapore, Singapore,[3]Lee Kong Chian School of Medicine, Nanyang Technological University, Singapore, Singapore

Germline mutations in the BRCA2 tumor suppressor gene predispose individuals to various cancers. Our lab previously discovered that endogenous reactive metabolites selectively degrade BRCA2 below the protective threshold and transiently induced BRCA2 haploinsufficiency. This functional insufficiency promotes genome instability and drives cancer evolution, establishing a direct mechanistic link between metabolic stress and carcinogenesis. My project aims to uncover the cellular mechanisms that counteract metabolic stress and prevent BRCA2 depletion. I hypothesise that specific metabolic enzymes act as protective buffers by detoxifying reactive metabolites and maintaining BRCA2 stability. To investigate this, I employed isogenic cells modeling two distinct classes of BRCA2 mutations - truncating (+/3036del4) and missense (+/D2723H) mutations. These mutations differ in protein expression, subcellular localisation and some of the biochemical properties, making them ideal to examine how different subtypes of BRCA2 mutations influence cellular metabolic requirements.Using a dual-readout targeted metabolic CRISPR-Cas9 knockout screening, I identified metabolic genes essential for cell survival and maintenance of genome stability. The primary screen revealed subtype-specific dependencies, with truncating mutants showing heightened sensitivity to perturbations in energy metabolism, whereas missense mutants relied on DNA damage response-linked metabolic pathways. Focused analysis of the top hits identified distinct metabolic responses associated with energy balance, reactive oxygen species accumulation and ER homeostasis. Ongoing work focuses on mechanistic validation of high-priority candidate genes to elucidate how specific metabolic pathways safeguard BRCA2 function under stress. These findings reveal mutation-specific metabolic vulnerabilities and provide a foundation for identifying potential metabolic interventions to preserved genome stability in BRCA2 mutation carriers.

#4683 Loss of nuclear integrity at persistent DNA bridges ties PARP inhibitors to cGAS/STING signaling.

Ece Kocak[1], Kerry A. Larkin[1], Nicholas R. Ader[2], Yiduo Hu[3], Kevin Li[1], C. Patrick Lusk[1], Anna Dominika Staniszewska[4], Mark R. Albertella[4], Megan C. King[1]

[1]Cell Biology, Yale School of Medicine, New Haven, CT,[2]Biology, UNC Greensboro, Greensboro, NC,[3]Medical Oncology, University of Kansas Medical Center, Westwood, KS,[4]Oncology Targeted Discovery, AstraZeneca, Cambridge, United Kingdom

BRCA mutant tumors, deficient in homologous recombination DNA repair (HRR), exhibit some of the highest levels of tumor cell-intrinsic interferon (IFN)-stimulated gene (ISG) expression among The Cancer Genome Atlas primary tumors, consistent with preclinical studies tying DNA repair deficiency to increased ISG expression through an as yet poorly understood mechanism. The goal of our ongoing studies is to examine the contribution of mitotic errors to IFN signaling in BRCA-deficient cancer. We find that DNA bridges that persist beyond the abscission checkpoint into the following interphase occur more frequently with *BRCA1* deficiency. Treatment with PARP inhibitors (PARPi) including olaparib, saruparib, and AZD9574, which cause targeted tumor cell death of BRCA-deficient cells, further increases the frequency of persistent bridges. Similarly, PARPi induce an elevated number of persistent bridges in BRCA2-deficient prostate tumor xenografts but not in those that are competent for HRR. Our findings show that the majority of persistent bridges recruit the cytosolic DNA sensor cGAS *in vitro*, suggesting a loss of nuclear integrity that exposes the bridging DNA to the cytoplasm. Indeed, performing the first correlative light and electron microscopy (CLEM) of persistent DNA bridges, we find nuclear envelope (NE) ruptures at PARPi-induced bridges. cGAS is maximally activated by non-nucleosomal DNA, and we find the bridging DNA to be highly accessible as assessed by Tn5 transposition (ATAC-see). Surprisingly, our CLEM data reveals efficient NE repair at persistent bridges, which we tie to the robust recruitment of the NE repair factors BAF, LEM2 and CHMP7. This NE repair network may influence cGAS activation by the bridging DNA thereby influencing ISG expression. Consistent with this, knockdown of the most upstream NE repair factor, BAF, increases ISG expression and synergizes with PARPi. Taken together, our results demonstrate that PARPi treatment increases the frequency of persistent DNA bridges that are over-stretched, non-nucleosomal, and defective in nuclear integrity, leading to activation of cGAS-dependent IFN signaling. We are additionally investigating the prevalence of persistent bridges in patient samples and xenograft models to explore their potential use as a biomarker for PARPi sensitivity. Further elucidating the mechanisms contributing to ISG expression in BRCA-deficient cancers will provide novel insights into strategies for maximizing the therapeutic potential of PARPi treatment.

#4684 A RHNO1-ATR/Chk1 positive feedback loop sustains the cellular DNA replication stress response.

Niphat Jirapongwattana, Carley M. Conover, Catalina Trujillo Jaramillo, Adam R. Karpf

Eppley Institute, University of Nebraska Medical Center, Omaha, NE

Cancer cells are continually challenged by both intrinsic and extrinsic stresses that interfere with DNA replication, causing DNA replication stress (DRS). DRS can fuel cancer progression by increasing genomic instability, but if left unregulated, it can also cause widespread DNA damage and cell death. Consequently, cancer cells are highly dependent on the ATR/Chk1 signaling pathway to regulate DRS and ensure survival. Rad9-Hus1-Rad1 interacting nuclear orphan 1 (RHNO1) is a novel component of the ATR/Chk1 pathway and is often overexpressed in cancer cells with high DRS, where it contributes to chemotherapy resistance. However, the precise function of RHNO1 in the DRS response is still largely unknown. Here, we investigated the roles of RHNO1 in cancer progression and DRS response using an ovarian cancer cell (OVC) model in both in vitro and in vivo systems. Furthermore, we generated an endogenously HiBiT-tagged and degron-tagged RHNO1 cell line to precisely track RHNO1 levels and temporally deplete RHNO1 during different phases of the DRS response in HEK293T cells. Depletion of RHNO1 significantly reduces OVC proliferation rate, clonogenicity, and in vivo tumor growth, while extending host mouse survival. RHNO1 knockdown sensitized cells to hydroxyurea (HU), increasing cell death and micronuclei formation. Mechanistically, RHNO1 was upregulated and stabilized following DRS. Notably, we show that RHNO1 stabilization is mediated by ATR/Chk1 phosphorylation, which is also required for RHNO1 translocation to stressed replication forks. Interestingly, chromatin recruitment of RHNO1 appears to be independent of 9-1-1, a DNA clamp complex previously known to bind RHNO1. Furthermore, cells with stable RHNO1 knockdown demonstrated normal initial ATR/Chk1 signaling activation in response to HU treatment, however, at later time points, the absence of RHNO1 caused premature termination of ATR/Chk1 signaling despite the persistence of DRS. These findings are consistent with a dispensable role of RHNO1 in the initial activation of the ATR/Chk1 pathway but a key role in sustaining the ATR/Chk1 response. In summary, we demonstrated the RHNO1 promote critical OVC phenotypes and uncovered a novel positive feedback loop between RHNO1 and ATR/Chk1 signaling. This work identifies RHNO1 as a key component in maintaining the DRS response, highlighting its potential as a therapeutic target for cancers reliant on ATR/Chk1 signaling.

#4685 Intestinal inflammation triggers *POLE*^{P286R}-driven ultramutated colorectal cancer.

Md Kawsar Mustofa, He Zhang, Diego H. Castrillon, Hasan Zaki

UT Southwestern Medical Center, Dallas, TX

Pathogenic variants of DNA polymerase ε (POLE), such as P286R, result in high tumor mutational burden (TMB), particularly in endometrium and colorectal cancer (CRC). Here, we investigated the role of *POLE* mutations in CRC using a conditional mouse model expressing the *Pole*^{P286R} mutation in intestinal epithelial cells. We generated *LSL-Pole*^{P286R} knock-in mice and crossed them with *Vilin-Cre* mice to obtain intestinal epithelial cell-specific *Pole*^{P286R} mutant mice (PVC). Spontaneous tumor development in the small intestine and colon of PVC mice was monitored. *Additionally, effect of inflammation on POLE-driven colorectal tumorigenesis was monitored following induction of colitis with 2.5% dextran sulfate sodium (DSS).* PVC developed invasive adenocarcinoma in the small intestine (SI) with partial penetrance but did not develop any tumor in colon spontaneously. Surprisingly, induction of chronic colitis with DSS resulted in colorectal tumor development with 100% penetrance in PVC mice but not control wild-type mice. Tumors of PVC mice were pathologically diverse, with low-grade and high-grade dysplasia and invasive adenocarcinoma. Whole genome sequencing demonstrated that colorectal tumors of PVC mice bear high TMB, including recurring mutations in *Apc* and *Ctnnb1*. Consistently, there was increased expression of proliferative genes, including *cMyc, Ccnd1, Ki67,* and *Lgr5* and higher activation of Wnt/β-catenin, NF-κB, and ERK pathways. Notably, mice expressing intestinal *Pole*^{P286R} recovered faster from acute DSS-induced mucosal injury, prior to the development of tumors. In vitro organoid culture further confirmed that *Pole*^{P286R} mutant intestinal organoids grow faster and larger than those from control mice. These findings demonstrate that POLE plays a crucial role in the maintenance of intestinal genomic stability, and inflammation plays an essential role in driving ultra-mutated CRC in the presence of pathogenic *POLE* variants.

#4686 Lymphatic niches shield stem cells from malignant fate.

Ananya Goyal, Madison Conte, Shiri Gur-Cohen

UC San Diego, La Jolla, CA

Oncogenic mutations arise frequently in young tissues, yet most remain clinically silent, suggesting that non-genetic variables may act as major drivers of cancer initiation. With age, this landscape of tolerance gradually diminishes, allowing mutated cells to bypass restraint and initiate tumorigenesis. Although cancer has long been considered as a hallmark disease of aging, recent evidence shows its incidence is now rising sharply in younger individuals, particularly of squamous cell carcinomas (SCCs). Understanding how mutated cells tolerate oncogenic stress in youth, and why this tolerance collapses over time, may provide opportunities for preventive intervention. These considerations are particularly important in the context of stem cells (SCs) which serve as the cells of origin for many cancers and whose fate and fitness are tightly orchestrated by their microenvironment, or “niches.” Yet, the niche-derived signals that precede and direct tumor formation remain poorly understood. The lymphatic vasculature, recently identified as a SC niche, is consistently remodeled in tumors and associated with heightened risk of metastasis and death among cancer patients. To investigate the impact of the lymphatic niches on early-stage tumorigenesis, we used skin SCC as a model, and examined SC tolerance to oncogenic stress under lymphatic loss-of-function conditions. Deep volumetric imaging revealed that lymphatic dysfunction predisposes stem cells to genomic instability, marked by accumulation of DNA damage indicators such as γH2AX in non-dividing cells, even in the absence of carcinogen exposure. These findings suggest that intact lymphatic niches protect SCs from genomic instability and preserve tissue homeostasis. Using a novel stem cell-lymphatic organotypic model, we found that SCs co-cultured with lymphatic vessels exhibited reduced DNA damage compared to those cultured with stromal cells following exposure to suboptimal carcinogenic insults. To directly test whether lymphatic dysfunction accelerates tumorigenesis, we induced *Kras* activation and *p53* loss in *Sox9+* hair follicle SCs. Pharmacological perturbation of lymphatics in this model led expansion of mutant clones in the epidermis within three weeks post-induction and significantly earlier tumor onset. Together, these findings uncover a previously unrecognized role for the lymphatic vasculature in reprogramming stem cell vulnerability to oncogenic stress. By linking lymphatic integrity to genomic stability, this work highlights lymphatic-driven regulation as a potential target for early detection and prevention of SC-derived cancers, including age related metastatic disease.

#4687 The BRCT domain is a modular platform for signal transduction in the DNA damage response.

Nicholas Woods[1], **Thales Nepomuceno**[2], Rebekah Baskin[3], Rafael Mesquita[4], Volha Golubeva[5], Xueli Li[2], Nicholas Palermo[6], John M. Koomen[2], Alvaro N. Monteiro[2]

[1]UNMC Eppley Institute, F&P Buffett Cancer Center, Omaha, NE,[2]Moffitt Cancer Center, Tampa, FL,[3]Graduate Student, St. Jude Children's Research Hospital, Memphis, TN,[4]Federal University of Rio de Janeiro, Rio de Janeiro, Brazil,[5]Ohio State University, Columbus, OH,[6]University of Nebraska, Omaha, NE

Protein modular domains are critical for the cellular response to intra- and extracellular signaling, facilitating the assembly of dynamic multi-protein complexes in response to specific stimuli. The BRCA1 C-Terminal (BRCT) domain is present in 23 proteins in the human proteome, containing 46 individual BRCT modules organized as 14 singletons, 16 tandems, and one quartet of BRCT functional units. The BRCT singleton consists of a central core of four parallel beta sheets flanked by two alpha helices on one side and one alpha helix on the opposite side. The BRCT domain is a versatile protein-modular domain that has emerged as an integrator of signals in maintaining genomic integrity. We previously charted the protein-protein interaction network of seven tandem BRCT domains (tBRCT), revealing previously unknown components in DNA damage signaling. Here, we present a comprehensive BRCT-centered human protein-protein interaction network (PPN) comprising 46 BRCT domains organized into various domain architectures, building on our previous work. This network was determined by integrating data from literature curation, yeast two-hybrid (Y2H) screens, and tandem affinity purification coupled to mass spectrometry (TAP-MS) and comprises 3,162 highly curated BRCT-dependent interactions and 1,672 unique human proteins. The BRCT-containing protein PAXIP1 (also known as PTIP) is critical for DNA double-strand break repair by non-homologous end joining. PAXIP1 has a distinctive structural organization, containing three tBRCT domains, which present a unique set of PPN. Interestingly, the last four BRCT domains form a unique quartet (qBRCT) in the human proteome, binding to a set of proteins not observed in either of the tBRCTs alone. These data indicate that distinct interacting partners may be recruited by different combinations of higher-order BRCT domain organization to assemble inter- or intramolecular complexes, accommodating combinatorial interactions in response to genotoxic stimuli. Moreover, we mapped 62 unique phosphorylation sites at 19 BRCT domains. We identified that PAXIP1 qBRCT phosphorylation alters its binding to gH2AX, providing an additional layer of regulation by modulating BRCT-mediated ligand recognition. The BRCT PPN resource charted here provides a comprehensive analysis of these modular protein domains in the human proteome, contributing to an understanding of cancer and its response to genotoxic clinical therapies.

#4688 The nuclease EXO1 promotes genomic instability by degrading nascent DNA in BRCA-proficient cells.

Alexandra Nusawardhana, Claudia M. Nicolae, George-Lucian Moldovan

Molecular and Precision Medicine, Penn State College of Medicine, Hershey, PA

Genomic instability promotes carcinogenesis. DNA repair genes are generally considered tumor suppressors, as their inactivation is observed in tumors and is associated with carcinogenesis. Mutations in BRCA1 and BRCA2 genes are observed in breast, ovarian, and other cancers. BRCA pathway inactivation results in defective homologous recombination DNA repair, as well as in degradation of nascent DNA during replication stress. This degradation is catalyzed by nucleases including MRE11 and EXO1, and occurs at two types of DNA structures which are formed upon replication stress, namely single stranded DNA (ssDNA) gaps and reversed replication forks, eventually causing double strand DNA break (DSB) formation. However, most tumors are BRCA pathway-proficient. Here, we show that EXO1 is overexpressed in a significant proportion of tumors. EXO1 overexpression causes the degradation of nascent DNA at both ssDNA gaps and reversed forks, through its exonuclease catalytic activity. Importantly, EXO1-mediated nascent strand degradation occurs efficiently in BRCA-proficient cells, through its cooperation with MRE11. This results in increased DSB formation and hypersensitivity to genotoxic agents. We thus identify increased EXO1 activity as a mechanism of genomic instability similar to BRCA pathway inactivation, but occurring more frequently in tumors compared to BRCA inactivation.

#4689 Dynamic and defective repair of extrachromosomal DNA drives genome instability in cancer.

Shu Zhang[1], Yanbo Wang[2], Thomas B. K. Watkins[1], Xiaowei Yan[3], Aditi Gnanasekar[3], Jun Tang[3], Ivy T. Wong[3], Howard Y. Chang[4], Paul S. Mischel[2]

[1]Pathology, Stanford University, Stanford, CA,[2]Stanford University School of Medicine, Stanford, CA,[3]Stanford University, Stanford, CA,[4]Amgen, Stanford, CA

Extrachromosomal DNA (ecDNA) is megabase-sized circular DNA amplified exclusively in tumor cells, driving poor outcomes and therapeutic resistance. EcDNA represents a distinct form of genome instability associated with heightened replication stress and DNA damage. However, how ecDNA manages these elevated damage levels remains unclear. Here, we used long-read sequencing and live-cell imaging to investigate DNA damage repair dynamics and genomic patterns in isogenic cell lines harboring either ecDNA or homogeneously staining region (HSR). We found that damaged ecDNAs are preferentially sequestered into micronuclei following induction of double-strand breaks. This process triggers additional DNA damage beyond the initial lesions and impairs homologous recombination (HR) during knock-in by CRISPR-Cas9. Structural variant analyses further revealed that although ecDNA damage initiates HR repair, the process is frequently incomplete or aberrant. Analysis of whole-genome sequencing data from 14,778 tumors across 39 cancer types in the Genomics England cohort confirmed that ecDNA-positive cancers exhibit enriched HR deficiency (HRD) mutational signatures, even after excluding cases with canonical HRD driver mutations. Together, these findings delineate the dynamic and error-prone repair of ecDNA, linking it to HRD-associated genomic alterations. Our study exposes vulnerabilities of ecDNA-positive cancers that may be therapeutically exploited through synthetic lethality related to HRD.

#4691 Assessing prognostic and therapeutic associations across EMAST, MSI, and MSS among African Americans colorectal cancer subtypes.

Hassan Brim[1], Mudasir Rashid[1], Ahmed Imran[1], Somtochukwu Abazu[1], yumna siddiqui[1], Shweta Dixit[1], Anas Brim[1], Wardah Bajwa[1], Mrinalini Deverapal[1], Rumaisa Rashid[1], Aurmin Amirmokri[1], Chibuzor Nwachukwu[1], Neda Dezfuli,[1], Rabia Zafar[1], Gholamreza Oskrochi[2], Zaki Sherif[1], Adeyinka O Laiyemo[1], John Carethers[3], Babak Shokrani[1], **Hassan Ashktorab**[1]

[1]Howard University, DC, DC,[2]American University of the Middle East, Egaila, Kuwait,[3]UC San Diego, San Diego, CA

Background: Elevated Microsatellite Alterations at Selected Tetranucleotide Repeats (EMAST), microsatellite instability-high (MSI), and microsatellite stability (MSS) represent distinct forms of genomic instability and characterize colorectal cancer (CRC) genotypes related to DNA mismatch repair (MMR) deficiency and proficiency. EMAST is reported with a higher prevalence among African American (AA) vs White rectal cancers. The full clinical significance and phenotype of EMAST and its relationship with tumor characteristics, treatment factors, and patient outcomes remain unclear.

Aim: We compared clinical characteristics, treatment patterns, and survival outcomes across EMAST, MSI, and MSS genotypes among AA CRC patients, and evaluated whether these genotypes have distinct prognostic or therapeutic associations.

Methods: We retrospectively analyzed 304 CRC patients at Howard University, the majority being from AAs. Patients' CRCs were assessed for EMAST, MSI, and MSS via fragment analysis. Clinical variables, including demographics, survival, tumor location, and treatment history, were compared across groups. Remission and recurrence outcomes were assessed. Statistical significance was determined using p-values provided in the dataset.

Results: Patients with EMAST CRCs demonstrated higher overall[JC1] mortality when compared with patients with MSI and MSS CRCs (32% vs 18% vs 14%, respectively). The higher mortality between patients with MSI versus MSS CRCs may reflect a greater proportion of stage III tumors in the MSI vs MSS subgroup (n=14, 48.3% vs n=91, 39%) as advanced stage is strongly associated with poor survival. Patients with MSI CRCs demonstrated more right-sided tumors (46%) than patients with MSS (13%) or EMAST (15%) CRCs. Symptom-wise, gastrointestinal bleeding was the most frequent occurring in 25%, 19% and 12% of patients with MSS, EMAST, and MSI CRCs, respectively. Treatment-wise, chemotherapy was administered to 57%, 63% and 57% of patients with EMAST, MSI, and MSS CRCs, and 84%, 100%, 76%, respectively, were treated with radiotherapy. However, patient benefit was not equal based on the higher mortality of patients with EMAST CRCs. Demographic and clinical variables showed no significant differences ($p>0.05$) between patients with EMAST, MSS, and MSI CRCs. Similarly, we identified no differences among the 3 groups in overall survival or remission and recurrence rates ($p>0.05$).

Conclusions: Patients with EMAST CRCs have the highest mortality despite similar treatment exposures and comparable demographic and clinical characteristics amongst our three groups. As expected, patients with MSI CRCs demonstrate a predominance of right-sided cancers. Overall, the EMAST genotype aligns with being a biological modifier that associates with poorer patient outcomes.

#4692 Environmental toxin-induced m6A RNA modification promotes R-loop accumulation and chromosomal instability.

Rebekah Gridley[1], Palakshi Bandapalli[1], Sharmila Govindaraj[1], Siddhant Meshram[2], Suvo Chatterjee[2], Gurdeep Singh[1], **Arunkumar Ganesan**[1]

[1]Cell Biology & Physiology, University of New Mexico Health Sciences Center, Albuquerque, NM,[2]Department of Epidemiology and Biostatistics, Indiana University, Bloomington, IN

Chromosome instability (CIN) is a defining feature of cancer and a driver of tumor evolution. While genetic and epigenetic mechanisms underlying CIN are well characterized, the role of environmental carcinogens remains underexplored. Hexavalent chromium [Cr(VI)], a widespread groundwater contaminant in the United States, particularly in New Mexico, has been epidemiologically linked to increased cancer risk. Our study investigates the molecular consequences of Cr(VI) exposure in normal human colon epithelial cells, revealing a novel RNA-mediated pathway contributing to CIN. We demonstrate that Cr(VI) exposure induces epigenetic reprogramming, including the loss of repressive histone marks and disruption of heterochromatin. Notably, Cr(VI) downregulates METTL3, a key RNA N6-methyladenosine (m6A) methyltransferase, leading to reduced m6A modification and accumulation of genome-wide R-loops. Since m6A methylation is critical for R-loop resolution, its loss impairs RNA processing and genome stability. These findings suggest that Cr(VI)-induced m6A deficiency promotes R-loop persistence, thereby compromising genome integrity and facilitating CIN. Our investigation reveals a novel mechanism by which an environmental toxin induces genomic instability through RNA epigenetic dysregulation. It highlights the role of RNA modifications in genome stability and underscores the need to consider environmental exposures in cancer risk.

#4693 The cancer testis antigen, HORMAD1, promotes genomic stability in lung adenocarcinoma.

Ronnesha Johnson[1], Angelique Whitehurst[2], Anthony J. Davis[1], Luis Reza Herrera[1]

[1]UTSW, Dallas, TX,[2]Asst. Prof., Dept. of Pharmacology, UT Southwestern Simmons Comp. Cancer Ctr., Dallas, TX

Cancer-testis antigens (CTAs) are proteins whose expressions are typically restricted to the testes but are aberrantly expressed in cancer. There are over 200 known CTAs, most of which have no known function in cancer. In the testis, HORMA Domain Containing Protein 1 (HORMAD1) is expressed in meiotic cells, and recruits proteins to sister chromosomes for the exchange of genetic information during crossing over. HORMAD1 is necessary for crossing over, and mice lacking HORMAD1 are healthy, yet infertile. HORMAD1 is aberrantly expressed in approximately 50% of lung adenocarcinoma patient samples. Patient tumor expression data reveal that high HORMAD1 expression correlates with poor overall patient survival and increased mutational burden. HORMAD1-positive tumors are enriched for genes essential for the DNA replication stress response and DNA repair, including MRE11 and RAD51. HORMAD1 promotes the formation of RAD51 filaments, which accumulate in response to replication stress. Cancer cells undergo chronic replication stress and are able to proliferate while evading catastrophic DNA damage. To determine if HORMAD1 is directly associated with proteins involved in DNA metabolism, we conducted immunoprecipitation mass spectrometry and found that endogenous HORMAD1 associates with a subset of proteins involved in the replication stress response. We found that cells lacking HORMAD1 undergo nascent DNA strand degradation, which is mediated by the MRE11-DNA2-BLM pathway. Moreover, we found that HORMAD1 protects stalled replication forks that are remolded by F-Box DNA Helicase 1 (FBH1) to maintain fork stability. FBH1 negatively regulates the activity of RAD51 via displacement from DNA and/or through ubiquitination for degradation. We found that loss of HORMAD1 leads to single strand DNA gaps during replication. Moreover, we found that HORMAD1 protects FBH1-mediated gaps during replication, but the mechanism as to how HORMAD1 protects these gaps is unknown. We hypothesize that HORMAD1 recruits RAD51 to FBH1-mediated single strand gaps during replication to protect these gaps from degradation and promote genomic stability. Our data suggest that aberrant HORMAD1 expression reduces replication stress-induced DNA damage accumulation to prevent genomic instability. This research gives insight into the mechanism by which HORMAD1 promotes genomic stability and how this process can be targeted for lung adenocarcinoma treatment.

#4694 Oxidative base damage to telomeres sensitizes cancer cells to ATR inhibition.

Alex Garbouchian[1], Natalia Cestari Moreno[1], Aninda Dey[1], Patricia Lynn Opresko[2], **Ryan Barnes**[1]

[1]University of Kansas Medical Center, Kansas City, KS,[2]University of Pittsburgh, Pittsburgh, PA

Targeted inhibition of DNA damage response proteins has received significant clinical attention owing to the success of PARP inhibitors. Due to the loss of G1/S checkpoint proteins like p16 and p53, cancer cells are reliant on the G2/M checkpoint to cope with elevated DNA replication stress, making them vulnerable to ATR and Chk1 inhibition. Cancer cells also experience elevated levels of oxidative stress, and targeting this is another therapeutic strategy, especially in photodynamic therapy. Our group has developed a chemoptogenetic tool (FAP-TRF1) which allows for targeted induction of singlet oxygen mediated 8-oxo-guianine (8oxoG) at telomeres. We previously demonstrated a single induction of 8oxoG at telomeres in cancer cells was sufficient to induce replication stress but was well tolerated at the cellular level. This led us to hypothesize that oxidative base damage to telomeres may sensitize cancer cells to low dose ATR inhibition. In this study we found inhibition of ATR, Chk1, or Wee1 after induction of telomeric 8oxoG significantly induced genome instability and reduced viability of cancer cells. This occurred at doses markedly less than those required to increase instability in non-cancer cells, and at levels in the cancer cells which the drug alone had no effect. We found p53 was critically protective of the non-cancerous cells in our model. We determined genome instability after 8oxoG induction and ATR inhibition was enhanced when cells were damaged in S-phase and when Mre11 was inhibited, while CDC7 inhibition restored stability. This phenotype resulted in an increased amount of time required to complete mitosis suggesting cells entered mitosis with unresolved replication intermediates. Indeed, pharmacologic prevention of mitotic entry during ATR inhibition rescued the genome instability caused by telomere oxidation. Together our findings indicate that manipulating the levels of reactive oxygen species in cancer cells may be an effective therapeutic alongside ATR inhibitors, allowing for tumor destruction while mitigating off-target effects to non-diseased tissue.

#4695 Distinct genomic remodeling in Li Fraumeni Syndrome breast cancer.

Nabamita Boruah[1], Renyta Moses[1], Ryan Hausler[1], Heena Desai[1], Maliha Tayab[2], Ahn Le[1], Gregory Kelly[1], Anupama Nayak[1], Kara Maxwell[1]

[1]University of Pennsylvania, Philadelphia, PA,[2]Jefferson University, Philadelphia, PA

Background: Pathogenic germline variants (PGVs) in *TP53* cause Li-Fraumeni Syndrome (LFS), a hereditary multicancer predisposition syndrome. Among females with LFS, breast cancer (BC) is the most prevalent malignancy, affecting 80-90% of carriers, typically at a much earlier age than sporadic cases and frequently exhibiting HER2 positivity. Interestingly, LFS-BC displays a high burden of short- amplified segments of aneuploidy (SAAS), suggesting that germline *TP53* loss may drive tumorigenesis through distinct genomic mechanisms that remain poorly understood.
Methods: To elucidate genotype-phenotype correlations underlying these unique genomic features, we performed whole-genome sequencing (WGS) and targeted sequencing on invasive ductal carcinoma (IDC), ductal carcinoma in situ (DCIS), and matched adjacent and contralateral normal breast tissues from individuals with LFS. Data were compared to early-onset nonLFS-BC and to The Cancer Genome Atlas (TCGA) tumors harboring either wild-type or somatic *TP53* mutations.
Results: Across hormone receptor (HR) subtypes, expected increases in genomic instability were observed in triple-negative versus ER+ nonLFS-BC. However, overall instability measures were similar or lower in LFS-BC. Specifically, in ER+ tumors, microsatellite instability (MSI) and aneuploidy scores were significantly lower in LFS-BC compared to nonLFS-BC. In contrast, LFS-BC exhibited a notable increase in segmental allelic imbalance (AI) with high-level amplifications-particularly within HER2+ subtypes. These amplified regions were significantly shorter than those in nonLFS-BC and often encompassed oncogenes such as *ERBB2*, defining a distinct SAAS phenotype. Unlike sporadic *TP53*-mutant breast cancers in TCGA, which showed globally elevated aneuploidy and HRD, LFS-BC uniquely accumulated focal, short amplifications. WGS of LFS DCIS and invasive tumors revealed predominant chromosomal instability (CN9) and chromothripsis (CN5) copy number signatures, with minimal whole-genome doubling. Amplicon Architect analysis identified ecDNA structures in 14 of 19 tumors, including *ERBB2*-containing ecDNA in 3/6 DCIS and 5/9 HER2+ IDCs with 4 and 8 number of ecDNA structure in each category respevtively. Our work is consistent with prior reports of ecDNA in ~23% of breast cancers and up to 46% of HER2+ cases.
Conclusion: LFS-associated breast cancers are defined by a unique genomic remodeling pattern characterized by focal, high-level amplifications within short aneuploid amplified segments (SAAS) and frequent ecDNA formation. These features distinguish LFS-BC from sporadic *TP53*-mutant tumors and highlight a germline *TP53*-driven mechanism of oncogene amplification and structural genome evolution.

#4696 Oncogenic transcriptional rewiring in micronuclei.

Duaa Hassan Al-Rawi[1], Danguole Norkunaite[1], Kaden Southard[1], Mercedes Duran[1], Xuelan Chen[1], Andrew William McPherson[1], Scott W. Lowe[1], Sohrab Shah[1], Samuel F. Bakhoum[2]

[1]Memorial Sloan Kettering Cancer Center, New York, NY,[2]Memorial Sloan Kettering Cancer Center, Rye, NY

Chromosomal instability (CIN) is a well-known feature of aggressive tumors, yet the distinct oncogenic mechanisms associated with CIN remain an area of active discovery. We previously demonstrated that in addition to driving karyotypic heterogeneity, chromosomal localization into micronuclei (MN)—the extranuclear bodies formed from missegregated chromosomes— causes epigenetic dysregulation. Moreover, we and others had previously demonstrated that micronuclei were largely silenced. Here we took a multimodal approach to examine the transcriptional behavior of micronuclei, using imaging-based approaches as well as purification of nascent RNA from micronuclei. We show that despite global dampening, micronuclei are transcriptionally active. Across epithelial and cancer cell models, micronuclei display robust nascent RNA synthesis. GSEA of differentially expressed micronuclear genes reveals an enrichment of MYC programs as well as preferential transcription of short genes with fewer introns. This is consistent with constrained RNA processing within the micronuclear environment. Overexpression of a panel of transcription factors reveals that MYC upregulates micronuclear transcription. A chromosome-specific missegregation system confirms that these transcriptional effects occur on the missegregated chromosome itself, linking mitotic errors to locus-directed transcriptional change. Analyses of TCGA and SPECTRUM ovarian cancer datasets connect regions of copy number alteration with micronuclear transcriptional signatures, underscoring clinical relevance. Together, these findings establish a direct and novel relationship between chromosomal missegregation and oncogenic transcription. Chromosomal localization to micronuclei endows cancer cells with locus-specific transcriptional programs and reveals new oncogenic mechanisms in CIN-high disease.

#4698 Quantifying ongoing chromosomal instability using single-cell whole-genome sequencing.

Barbara Hernando[1], Blas Chaves-Urbano[1], Maria Escobar-Rey[1], Alice Cadiz[1], Angel Fernandez-Sanroman[1], Marina Torres[1], Sara Barrambana[1], Carmen G. Lechuga[1], Carmen Guerra[1], Mariano Barbacid[1], Maria Garcia-Perez[2], Patricia G. Santamaria[1], **Geoff Macintyre**[1]

[1]Spanish National Cancer Research Ctr. (CNIO), Madrid, Spain,[2]Institute for Biomedical Research Sols-Morreale (IIBM), Spanish National Research Council-Universidad Autonoma de Madrid (CSIC-UAM), Madrid, Spain

Chromosomal instability (CIN) describes the set of processes that generate numerical and structural DNA changes that typically operate during tumourigenesis. High-resolution readouts of DNA changes can be achieved using whole-genome sequencing (WGS) and the distinct patterns of copy number aberrations seen in these data can then be used to infer which type of CIN operated on the genome[1-3]. However, this static readout only provides evidence of historical or past CIN, as bulk WGS lacks the resolution needed to identify ongoing CIN that is actively shaping genome evolution.

To address this limitation, we have developed a computational framework that leverages single-cell whole-genome sequencing (scWGS) to identify and quantify ongoing CIN by detecting cell-unique copy number alterations and probabilistically mapping them to known CIN signatures[2]. We assessed performance by generating in vitro models with 4 types of induced CIN via CRISPR knockout of DNA repair genes or drug perturbation, and correctly identifying the induced-CIN type in each case.

Applied to near-diploid *BRCA1/2*-deficient hTERT-RPE1 models, we show that only single-cell, and not bulk, WGS can reveal ongoing homologous recombination deficiency (HRD) scars, enabling accurate identification of sensitivity to PARP inhibitors. In 4 pancreatic cancer organoids treated with platinum-based chemotherapy, ongoing HRD scars correctly identified the most sensitive organoid, which was misclassified as resistant using bulk WGS. Analysis of scWGS from 8 triple-negative breast cancers further reveal that impaired non-homologous end joining (NHEJ) is associated with subclonal diversification. Consistent with this observation, activity levels of CX10 (a CIN signature linked to NHEJ impairment[1]) was significantly higher in 119 metastatic TNBCs compared with 60 primary tumours (p-value=0.0085, Wilcoxon test), suggesting a link between defective NHEJ, subclonal evolution and increased metastatic potential.

Together, these results show that our framework reveals treatment-relevant, recent CIN processes undetected by bulk sequencing, and it offers a robust tool for dissecting tumour evolution. Our study supports expanding biomarker-guided therapies by targeting active CIN rather than historical genomic scars.

#4699 CK2α is a novel phosphoinositide effector of PIPKIIα and PIPKIIβ in DNA damage repair.

Gavril Limet Ibaan, Suyong Choi

University of Nebraska Medical Center, Omaha, NE

Phosphoinositides (PIs) are a class of lipid second messengers that coordinate signaling events at the membrane interface. This canonical role belies the presence of rich PI metabolism within the nucleus, where emerging functions reveal pivotal contributions to oncogenesis. Despite this, effectors that transduce this lipid network are largely obscure. In particular, dysregulation of nuclear phosphatidylinositol 4,5-bisphosphate ($PI4,5P_2$) and its generative kinases PIPKIIα and PIPKIIβ are salient in breast cancer progression and prognosis, yet the mechanistic basis for how they drive oncogenesis remains enigmatic. Identification of the underlying pathways, therefore, remains a critical question that could inform novel therapeutic strategies. To investigate their nuclear function, we examined $PI4,5P_2$ dynamics by immunofluorescence (IF) and observed accumulation at γH2A.X-positive DNA lesions. Consistent with this, DNA damage response (DDR) assays quantifying caspase activation, growth and genomic integrity revealed that PIPKIIα/β double-knockout breast cancer cells exhibited genotoxic hypersensitivity and exacerbated genomic fragmentation. These observations implicated PIPKIIα/β in DDR signaling. Through mass spectrometric profiling of nuclear extracts, we identified CK2α as an interactor of PIPKIIα and PIPKIIβ. This interaction was validated by endogenous co-immunoprecipitation and further supported by *in vitro* binding assays between purified recombinant proteins and proximity ligation immunofluorescence, which together revealed direct and nuclear-restricted engagement. Cells lacking PIPKIIα/β selectively compromised CK2α activity elicited in response to DNA damage, but not mitogenic stimulation. Interrogation of CK2α-dependent DDR substrates further demonstrated impaired downstream signaling, substantiating PIPKIIα/β control over CK2α in the DDR. To probe lipid signaling transduction, we performed structural, biochemical, and *in silico* assays that uncovered a PI-binding polybasic motif (PBM) in CK2α (residues 71-80) adjacent to the binding interface of its regulatory subunit CK2β; further mutation of this PBM diminished $PI4,5P_2$ binding. This motivated the hypothesis that $PI4,5P_2$ supplants CK2β, releasing monomeric CK2α, thereby redirecting its substrate specificity. Accordingly, PIPKIIα/β depletion enhanced endogenous CK2α-CK2β association while concurrently diminishing its interaction with the DDR-substrate XRCC1. Our findings support a model in which PIPKIIα/PIPKIIβ synthesizes $PI4,5P_2$ following DNA damage to liberate nuclear CK2α from CK2β and potentiate the DDR. Late-stage breast cancers may upregulate this pathway to mitigate otherwise lethal genetic insults and promote survival against their intrinsic genomic instability, defining a previously unrecognized nuclear $PI4,5P_2$ signaling axis that promotes tumor progression.

Poster Session

#4703 Sex-specific metabolic features in pre-cancerous polyps identified in Puerto Rican stool samples: A pilot study.

Melissa Gabriela Soto-Santiago[1], Gabriel Borges Velez[1], Leslie A. Casiano Agosto[1], Luis R. Llanos[1], Ibis R. Vera-Urbina[2], Josue Perez-Santiago[1], Maria Gonzalez-Pons[1]

[1]University of Puerto Rico Comprehensive Cancer Center, San Juan, PR,[2]University of Puerto Rico, San Juan, PR

Background: Colorectal cancer (CRC) is the leading cause of cancer deaths in Puerto Rico when combining men and women, with notable differences in presentation according to sex. Men have a higher incidence of CRC, with a higher overall mortality, while women are more often diagnosed with proximal tumors that respond less effectively to conventional therapies. This pattern suggests the existence of underlying sex-specific pathways that influence CRC development. Metabolite abundance analysis offers a comprehensive approach to identifying biochemical alterations associated with disease mechanisms and progression. This study aimed to characterize metabolite differences in stool between pre-cancerous polyps and healthy samples, and to explore sex-specific metabolic differences in a Hispanic cohort.
Methods: A case-control design was used to analyze stool samples from ninety-seven Puerto Rican participants (68 females, 29 males) with and without colorectal adenomas. Gas chromatography-mass spectrometry was used for metabolite identification; afterwards spectral peak data was normalized and analyzed using MetaboAnalyst 6.0 and RStudio. Significance was assessed using paired t-test for pairwise comparisons and 2-way ANOVA for multivariate analysis.
Results: Fifty-nine metabolites were detected across samples, with significant abundance differences between polyps and controls observed in females: β-alanine (adjusted $p=0.0014$) and N-acetyl-L-aspartic acid (adjusted $p=0.0017$). We observed different top metabolites in males: Thapsic acid (nominal $p= 0.019$) and cholesterol (nominal $p = 0.035$). In a multivariate analysis, seven metabolites were identified in polyps vs controls, adjusting for sex (nominal $p<0.05$): Nicotinic acid, β-alanine, 3,4-Dihydroxyhydrocinnamic acid, Isoleucine, Callitrisic acid, Palmitoleic acid, and Thapsic acid.
Conclusion: The different metabolite profiles observed in males versus females provide evidence supporting different carcinogenic mechanisms according to sex, which may contribute to the CRC differences in presentation and outcomes reported. The metabolites detected could be potential biomarker candidates and we will be examining microbiome integration analyses with additional samples and even matching across groups. Together, these efforts will enable a more precise delineation of sex-dependent metabolic pathways that can ultimately inform tailored CRC risk stratification and prevention strategies.

#4704 Disruption in cholesterol homeostasis by free fatty acid promote colon cancer by modulating CCL20.

Janani Muralidharan[1], Ankit Bhatt[1], Jaliya M. Mims[2], Gene Hughes[3], Paige Marcelline[1], Sejong Bae[4], Shailesh Singh[1], **Hina Mir**[1]

[1]Morehouse School of Medicine, Atlanta, GA,[2]Spelman College, Atlanta, GA,[3]Morehouse College, Atlanta, GA,[4]Auguta University School of Public Health, Augusta, GA

Background: Colorectal cancer (CRC) displays metabolically flexible but dysregulated lipid homeostasis, involving increased lipid synthesis, altered fatty acid uptake, enhanced storage, and remodeling of membranes and cholesterol pools. These processes interact with inflammatory signaling networks and may support cancer progression. CCL20, a chemokine elevated in lipid-rich and inflammatory CRC microenvironments, has been implicated in tumor progression, but its relationship with lipid metabolic regulation remains unclear. This study examines possible interactions between lipid metabolism and CCL20 signaling, and specifically its effects on lipid accumulation, membrane biophysics, and cholesterol metabolic programs in CRC models.
Methods: CRC cell lines (Caco2, DLD1, HCT116) were exposed to free fatty acids (FFAs) differing in chain length (C12, C16) and saturation (C16:0, C18:1(9)). CCL20 production was quantified by ELISA. FFA uptake was assessed using Lauric acid (C12) and palmitic acid (C16). Lipid accumulation was assessed by BODIPY mean fluorescence intensity normalized to cell size. Membrane fluidity was measured using Laurdan generalized polarization (GP) and fluorescence imaging. Total, cellular and secreted cholesterol, as well as ratio of esterified and free cholesterol ratios were measured alongside expression of cholesterol-associated enzymes, including HMGCR, SOAT2, and SREBP2. CCL20-overexpressing HCT116 cells were included to validate effects of CCL20.
Results: Data indicate that FFAs of differing lengths may variably modulate CCL20 expression. Distinct patterns of FFA internalization and accumulation, and membrane fluidity shifts were observed in CRC cell line with differential CCL20 signaling. Levels of cholesterol and expression of key metabolic enzymes were found to be associated with CCL20 modulation.
Conclusions: These findings establish a clear link between lipid metabolism and CCL20 expression and function in CRC cells. Ongoing studies aim to validate these observations and develop a unified model of CCL20-driven metabolic regulation in colorectal cancer.

#4705 A clearer picture of cachexia: Leveraging body composition imaging in C26 tumored mice.

Cheryl Davis[1], Liz Bailey[2], Mollie McArthur[3], Melissa Tran[3], Ben Hoerner[4], Victoria Caruso[4], Helen Ketteringham[3], Corrine Silvio[4], Shannan Paul[4], Delaney McCormick[5], Jocelyn Saurbaugh[5], Chris Holding[6], Aliccia Koznecki[6], Dawn Lusk[4], Shorena Nadaraia-Hoke[4], Kathleen Hutchinson[4]

[1]Reaction Biology Europe GmbH, Freiburg im Breisgau, Germany,[2]Reaction Biology Corp, Boston, MA,[3]Reaction Biology Corp, Malvern, PA,[4]Reaction Biology Corp, Hummelstown, PA,[5]Reaction Biology Corp, Lancaster, PA,[6]Reaction Biology Corp, Hershey, PA

Cancer cachexia remains a major unmet need in oncology, characterized by progressive loss of skeletal muscle and adipose tissue that negatively impacts treatment tolerance and survival. Anamorelin (AML), a ghrelin receptor agonist, is currently the only approved therapeutic for cancer cachexia; however, its clinical benefits remain modest, highlighting the need for improved preclinical models and more informative physiological endpoints. Here, we established and characterized a C26 colorectal carcinoma cachexia model using both traditional metrics and non-invasive body composition imaging performed on a Bruker MiniSpec. This platform enabled longitudinal quantification of lean and fat mass changes with high sensitivity, providing a refined assessment of cachexia progression and therapeutic response.In vitro and in vivo studies confirmed the robust cachexia-inducing phenotype of the C26 model. Consistent with published literature, AML treatment increased food intake in tumor-bearing mice but did not reduce circulating pro-inflammatory cytokines. Combination therapy, evaluated based on the mechanistic rationale that AML-mediated appetite stimulation may complement the anti-inflammatory activity of CYA, demonstrated enhanced preservation of body mass and adipose tissue compared with either monotherapy. Our findings support the utility of integrating body composition imaging with standard physiological and biochemical measures to generate a comprehensive efficacy profile. These results highlight the value of this refined platform for evaluating emerging cachexia therapeutics and suggest that multi-modal combinations such as CYA+AML may provide superior benefit over current single-agent approaches.

#4706 Mechanoplasmonics: Integrating nanoplasmonic materials and stiffness tunable hydrogels for real-time, label-free cellular analysis.

Cason M. Hancock[1], Harlie Rios[2], Alexander McGhee[3], Swarna Ganesh[3]

[1]UA Comprehensive Cancer Center, University of Arizona, Tucson, AZ,[2]Biomedical Engineering, University of Arizona Cancer Center, Tucson, AZ,[3]UA Comprehensive Cancer Center, Biomedical Engineering, University of Arizona, Tucson, AZ

Understanding how cellular biochemical states respond to mechanical stimuli requires analytical approaches capable of probing molecular signatures. We present a multifunctionalplatform that integrates Surface-Enhanced Raman spectroscopy (SERS),silver nanoparticles,and stiffness-tunable hydrogels to investigate mechanochemical interactions at single-cell and, insome instances, single-molecule resolutions. Silver nanoparticles were synthesized via controlled reduction process to optimize size morphology for strong localized surface plasmon resonance.Characterization confirmed the monodisperse nanoparticles with pronounced optical resonances in the visible range, enabling substantial electromagnetic field enhancement and highly sensitive detection of biomolecular vibrations.Hydrogels with tunable stiffness were fabricated by modulating cross linking density while keeping chemical composition and surface functionalization constant. This design provided a controlled range of elastic moduli to emulate diverse physiological and pathological tissue conditions. Healthy and cancerous colorectal cells were cultured on hydrogels with dispersed SERS nanoparticles, creating a mechanically defined and optically accessible interface for molecular imaging and analysis.Raman spectra acquired from cells on soft versus stiff hydrogels revealed reproducible differences in vibrational modes corresponding to lipids, proteins, and nucleic acids. The high enhancement factors produced by the silver nanoparticles enabled these spectral changes to be detected with exceptional sensitivity, offering insight into how extracellular stiffness modulates intracellular chemical composition. These results suggest that mechanical cues lead to measurable biochemical remodeling at the molecular level, detectable through the enhancedRaman scattering signatures of key cellular components. Combining nanoplasmonics and tunable mechanical substrates, our mechanoplasmonic platform captures real-time, label-free molecular responses of living cells to their physical environment. The ability to detect single-molecule spectral features within biologically relevant contexts demonstrates the analytical strength and versatility of this hybrid system. More broadly, the approach bridges the disciplines of mechanobiology, materials science, and nanophotonics, providing a foundation for future studies on stiffness-mediated cell signaling and potential diagnostic tools that exploit mechanical-biochemical coupling for early detection of disease progression or therapeutic response.

#4707 Repurposing statins activates compensatory glutathione metabolism as synergistic vulnerability in colorectal cancer.

Jieqing FENG[1], Jianming LI[2], Hong YAN[2], Zongwei CAI[1]

[1]Department of Chemistry, Hong Kong Baptist University, Kowloon, Hong Kong,[2]Department of Biology, Hong Kong Baptist University, Kowloon, Hong Kong

Metabolic adaptations upon intrinsic and environmental stressors enable cancer cells to resist treatment and sustain proliferation. Understanding of adaptive rewiring and compensatory mechanisms is a pivotal strategy to develop effective treatment options. Statins are receiving increasing attention in the prevention of colorectal cancer (CRC), but the biological mechanism is elusive. Here, we demonstrate that six statins show effective tumor repression capacity in a dose-dependent manner. We next observe that administration of statin alone is not sufficient to induce programmed cell death because inhibitors of ferroptosis, apoptosis, necroptosis, and autophagy fail to rescue the cell viability. To further understand the therapeutic vulnerability, untargeted metabolic analysis is employed to detect the reprogramming metabolites. Pathway analysis shows glutathione metabolism is significantly perturbed. Meanwhile, dramatic increases of cysteine and gamma-glutamylcysteine are widely observed while the reduced glutathione (GSH) and oxidized glutathione (GSSG) levels are decreased, linked to redox imbalance and ferroptosis. Western blotting shows statins have similar effects as RSL3 on increasing the expression of glutamate-cysteine ligase catalytic subunit (GCLC), which catalyzes the rate-limiting step of GSH synthesis, and its inhibition is associated with ferroptosis induction. In contrast, CRC cells show increasing reliance on glutathione peroxidase 4 (GPX4) upon statins treatment when compare to RSL3. Collectively, compensatory upregulation of GCLC indicates combinations of statins and GCLC inhibitors may enhance antiproliferative efficacy of targeting GSH metabolism.

#4708 Metabolomics signatures with multidrug-resistant colorectal cancer cells.

Christopher Farrell

Clemson University, Clemson, SC

Colorectal cancer is one of the deadliest cancers with almost 50,000 deaths each year in the US. Many of the deaths are due to a serious issue of multidrug resistance (MDR) where the cancer cells are unaffected by chemotherapy resistance. The use of metabolic profiling in MDR cancer cells may be useful for identifying weaknesses in the cells. This study analyzes the metabolomic profiles of colorectal cancer cell lines that were treated for a long-term with chemotherapy medication and a non-chemotherapy drug. We treated the colorectal cancer cell lines with medications for approximately 3-4 months and monitored drug resistant markers through expression analysis using qPCR. Once the markers were confirmed using RNASeq and western blots, the cells analyzed for Biolog Phenotype Mammalian Microarray 1 (PM-M1) to assess the metabolic profile of the drug-resistant colon cancer cells. The PM-M1 assay allowed us to evaluate the production of NADH in the presence of different carbon-based energy sources, providing functional information on the major energy pathways of the cells. Other PM-M assays helped to identify and validate possible trends pathways such as glycolysis and major energy sources. Exposing the cells to atorvastatin (10 and 40 μM), the chemotherapeutic drug doxorubicin (positive control), or untreated/DMSO (negative control) resulted in the overexpression of *ABCB1* by the 5th month of the study with bi-weekly treatments of the medication. The protein analysis with western blots and RNASeq analysis confirmed the expression of the transporter. Comparison of the NADH levels from the cells exposed to DMSO (negative control) to the ones from the cells exposed to doxorubicin (positive controls), we noted 21 compounds showing differences. The cells exposed to atorvastatin showed dose-dependent trends: the NADH levels observed with the 10 μM dose showed very few differences when compared to both DMSO- and doxorubicin-treated cells, while the ones with the 40 μM dose were significantly decreased, with lower NADH levels than both DMSO- and doxorubicin-treated cells in about one third of the PM-M1 wells. Overall, our experiments confirmed that the MDR cancer cells in the doxorubicin and 10 μM atorvastatin, showed very little difference from the negative control in metabolic profiling, while the 40 μM atorvastatin-treated cells caused a drastic reduction of energy production, with deleterious effects on compounds encompassing various metabolic pathways. In conclusion, this study provides a promising approach, both alone and in combination with molecular tools by exploring potential biomarkers and molecular targets for treatment development. These results provide insight into how selective pressures through medication can cause the cells to still be able to slowly develop back to the original metabolic levels once they are resistant to the drug.

#4709 Metabolic reprogramming through SREBP2-driven cholesterol synthesis in CAFs of CMS4 colorectal cancer.

Iguru Omori[1], hiroaki kasashima[1], Yukina Kusunoki[2], Nobuhiro Naito[1], Zizhou Wang[1], Yuki Seki[1], Kenji Kuroda[1], Yuichiro Miki[1], Mami Yoshii[1], Tatsuro Tamura[1], Masatsune Shibutani[1], Takahiro Toyokawa[1], Masakazu Yashiro[3], Yu Muta[4], Yuki Nakanishi[4], Kiyoshi Maeda[1]

[1]Department of Gastroenterological Surgery, Osaka Metropolitan University Graduate School of Med., Osaka, Japan,[2]Pathophysiology, Osaka Metropolitan University Graduate School of Medicine, Osaka, Japan,[3]Molecular Oncology and Therapeutics, Osaka Metropolitan University Graduate School of Medicine, Osaka, Japan,[4]Gastroenterology and Hepatology, Kyoto University, Kyoto, Japan

Colorectal cancer has been stratified based on gene expression profiles into consensus molecular subtypes (CMS). Among these, the mesenchymal subtype (CMS4), which accounts for approximately 23% of cases, is associated with a particularly poor prognosis compared with the other subtypes. It has been increasingly recognized that the high malignancy of CMS4 colorectal cancer is driven by activation of the tumor stroma, predominantly composed of CAFs, and by its interactions with cancer cells within the tumor microenvironment (TME). However, the mechanisms remain to be unclear. Cholesterol is essential for cancer, particularly through its roles in membrane integrity and intracellular signaling. Dysregulation of cholesterol homeostasis has been implicated in cancer progression. Recent studies have shown that activation of SREBP2, a key transcription factor for cholesterol biosynthesis, contributes to the development of aggressive serrated colorectal tumors characterized by desmoplasia. However, the metabolic state of cancer-associated fibroblasts (CAFs), particularly regarding cholesterol metabolism, remains unclear. We analyzed bulk RNA sequencing data from 10 colorectal cancer samples. Gene set enrichment analysis (GSEA) was performed to compare CAFs from CMS4 tumors with those from other CMS subtypes. Subsequently, we established CAF lines derived from CMS4 and the other subtype tumors and examined the impact of CAF cholesterol metabolism on tumor progression. We revealed that CMS4-CAFs exhibited significant enrichment of gene sets related to cholesterol homeostasis. In particular expression levels of SREBP2 and its downstream genes were markedly upregulated in CMS4-CAFs. Furthermore our *in vitro* results showed that inhibition of cholesterol biosynthesis or SREBF2 knocking down reduced the proliferative capacity of CMS4-CAFs and suppressed tumor migration. These findings highlight a potential metabolic feature of CAFs in CMS4 colorectal cancer that may contribute to tumor aggressiveness.

#4710 Comprehensive metabolomic profiling of FFPE human tissues reveals key metabolic reprogramming in colorectal cancer and associated pathways.

Tom Cohen[1], Ashima Mehta[1], Adam Richardson[1], Monil Gandhi[1], Douglas Guzior[1], Kevin Cho[2], Ethan Stancliffe[1], Gary Patti[2]

[1]Panome Bio, St. Louis, MO,[2]Washington University in St. Louis, St. Louis, MO

Introduction: Formalin-fixed paraffin-embedded (FFPE) tissues are invaluable for retrospective clinical studies due to superior morphological preservation and easy storage, but their use in metabolomics is limited by a lack of established sample preparation protocols and concerns over metabolite stability. Here we optimized a novel FFPE metabolomic workflow and validated findings with matched fresh-frozen (FF) samples to identify metabolic signatures altered in human colorectal cancer (CRC).

Methods: We analyzed 12 FFPE human tissue samples, comprising 6 paired tumor and Nearby Adjacent Tissue (NAT) specimens from adenocarcinoma patients, alongside matched FF samples for validation. Global metabolomics assays were performed on both polar and lipid fractions using a next-generation mass spectrometry platform.

Results: Metabolic profiling detected 2,564 unique metabolites across 200+ classes from FFPE tissues with low technical variation (median CV < 5%). Unsupervised analyses showed clear tumor-NAT distinctions. Statistical analysis identified 200 differential metabolites ($|\log2(fc)| > 1$, $p < 0.05$). Pathway analysis revealed 39 altered pathways ($p<0.05$), with upregulated diacylglycerophosphoinositols and downregulated triacylglycerols in tumors being the most significant findings. Consistent upregulation of central carbon metabolites and amino acids indicated metabolic reprogramming for biosynthesis and oxidative stress buffering. FF sample validation showed concordance across the most significant hits and pathways identified, confirming the robustness and biological relevance of FFPE-derived signatures.

Conclusion: Our study confirms FFPE metabolomic profiling reliably identifies significant metabolic perturbations in human cancer, consistent with FF findings. The identified shifts in lipid, central carbon, and amino acid metabolism highlight extensive metabolic reprogramming in CRC. FFPE archives are a valuable resource for large-scale retrospective clinical metabolomics studies, offering a powerful avenue for discovery research in human genetics and disease, and for identifying novel biomarkers.

#4711 Investigating synergistic impact of diet-induced hyperinsulinemia and mutant *Kras* on colorectal cancer metastasis.

Anindita Mahanty[1], Cara Wallingford[2], Alexa Magstadt[3], Revan Hammontree[2], Jennifer Davis[4]

[1]Cancer Biology, University of Kansas Medical Center, Kansas City, KS,[2]Cancer Biology, Kansas University Medical Center, Kansas City, KS,[3]Kansas University Lawrence, Lawrence, KS,[4]University of Kansas Cancer Center, Kansas City, KS

Purpose: This study examines how chronic high-fat-sugar (HFS) diet-induced metabolic dysfunction affects cancer metastasis in an in vivo, genetically engineered iKAP model (inducible Kras, Apc, and p53) (Boutin et al., Genes & Development, *2017, 31:370).*

Methods: 8-10 weeks old mice are randomized to either a 10% low-fat-sugar/LFS (healthy diet) or a 45% high-fat-sugar/HFS (western-style diet) to induce hyperinsulinemia and metabolic dysfunction before tumor initiation. The development of metabolic dysfunction is monitored using Echo-MRI for alterations in body composition, a glucose tolerance test (GTT), and endpoint steatosis. Upon tumor induction, tumor growth rates are measured to compare tumor burden in relation to diet and Kras mutation status. Micro- and macro-metastases are being recorded and compared using micro-CT imaging and endpoint tissue histopathology. In parallel, a complementary *in vitro* study using a panel of isogenic colorectal cancer cell lines is underway to evaluate the effect of insulin-mediated cell migration and invasion through scratch and trans-well assays, as well as downstream signaling analyses by Western blot.

Result: Our preliminary *in vivo* findings demonstrate signals of metabolic dysfunctions, including higher body fat percentage, lower glucose tolerance, and the development of hepatic steatosis in HFS-fed iKAP mice. Mice on the 45% high-fat diet showed higher liver disease scores compared to those on the 10% fat diet. Inclusions of hepatocyte ballooning and inflammation were noticeably increased in the high-fat group. Current findings indicate a diet-dependent increase in liver steatosis in 45% HFS mice relative to the 10% control group.

Conclusion: Based on preliminary findings, an HFS diet effectively induces metabolic dysfunction in the iKAP *in vivo* model. This context may support investigating hyperinsulinemia-oncogenic *Kras* crosstalk in CRC progression and metastasis. Additional mice and sex-based analyses will further validate and strengthen these findings. Moving forward, chronic hyperinsulinemia reprograms metabolism and intracellular signaling in the presence of mutant *Kras* to expand tumor metastatic spread, is an open question.

#4712 Targeting NRF2-regulated polyamine and glutathione metabolism enhances chemotherapy efficacy in colorectal cancer based on KRAS status.

Jiamin Li[1], Jieqing Feng[1], Fuyue Wang[1], Yingjie Zhang[2], Hong Yan[1], Zongwei Cai[3]

[1]Hong Kong Baptist University, Hong Kong, China,[2]The University of Hong Kong, Hong Kong, China,[3]Eastern Institute of Technology, Zhejiang, China

Metabolic reprogramming is a hallmark of colorectal cancer and is strongly influenced by oncogenic KRAS mutations, which contributes to reduced drug responsiveness and poor clinical outcomes. Inducing ferroptosis—a form of iron-dependent, lipid peroxidation-driven cell death—has emerged as a promising strategy to augment chemotherapy response by disrupting this adaptive metabolic state. However, the interplay between KRAS-specific metabolism and ferroptosis-induced drug sensitivity remains incompletely understood and could enable precision therapeutic interventions. In our study, we integrated public datasets and in vitro experiments to investigate the drug combination effect and how the metabolism will be altered. We first utilized drug sensitivity data from CRC cell lines, and we found that drug response varied by KRAS status and engaged distinct ferroptotic dependencies: KRAS-mutant cells showed increased reliance on iron-handling genes (*FTH1, FTL, SLC11A2*), whereas KRAS wild-type cells were more vulnerable to disruption of GPX4-mediated antioxidant defense. Given that NRF2 coordinates ferroptosis through both iron homeostasis and antioxidant responses, pharmacologic inhibition of NRF2 using Brusatol across four CRC cell lines (representing wild type, KRAS G12D, and KRAS G13D) markedly enhanced chemotherapy efficacy, with the strongest effect observed in KRAS G12D lines, followed by wild-type cells. Regarding non-targeted metabolomics analysis, co-treatment with Brusatol and Oxaliplatin or 5-Fluorouracil rendered dysregulated pathways that fuel cancer growth and progression, including methionine cycle, nucleotide synthesis as well as energy metabolism only in wild-type cells and $KRAS^{G12D}$ mutant which accounted for improved inhibitory effect. Moreover, distinctive alterations depending on KRAS mutation were observed under this combination therapy, manifesting KRAS mutants (comprising $KRAS^{G12D}$ and $KRAS^{G13D}$) demonstrated an blockage of polyamine catabolism with extremely decreased acetylspermine, whereas wild-type cells suffered elevated oxidative stress with severe GSH exhaustion and GSH/GSSG ratio reduction. In light of clinical unavailability of Brusatol, we successfully repositioned several clinically viable antineoplastic drugs and a panel of therapeutic agents under preclinical status for emerging tumor combat utilizing a transcriptional-based silico drug repurposing approach. Our findings highlighted NRF2 deprivation-mediated polyamine metabolism as a potential target for chemosensitivity and provided a clinically-approved therapeutic option in $KRAS^{G12D}$ CRC, brightening the path for targeted therapy and translation medicine.

#4713 Targeting glycogen metabolism in cancer-associated fibroblasts alleviates immunosuppression and inhibits colorectal cancer malignancy.

Xudong Zhu, Yuning Zhou, Haoxiang Zhang, Yinping Jiang, Jinpeng Liu, Chi Wang, **B. Mark Evers**, Qingding Wang

UK Markey Cancer Center, Lexington, KY

Background: Cancer-associated fibroblasts (CAFs) are the major sources of secreted cytokines and chemokines contributing to the shaping of immunosuppressive tumor microenvironment (TME). Dysregulation of glycogen metabolism is integral to cancer cell proliferation and metastasis. The purpose of this study was to identify whether targeting glycogen metabolism in CAFs could alleviate immunosuppression and inhibit colorectal cancer (CRC) growth.

Methods: Human CAFs (hCAFs) were isolated from CRC patient samples. $APC^{f/f}$; CDX2-Cre/ERT2 mice were injected with tamoxifen to induce adenoma formation. Mouse CAFs (mCAFs) were isolated and cultured. The expression of glycogen phosphorylase liver form (PYGL), phospho-PYGL, hexokinase 2 (HK2), GLUT1, IL6, CLCF1, LIF, and CXCL6 was determined by either real time (RT)-PCR or western blot. Glycogen levels were determined using a Glycogen Analysis Kit. Cell proliferation was determined using WST-1. Extracellular acidification rate (ECAR) was determined utilizing an Agilent Seahorse XFe96 extracellular flux analyzer. To determine whether targeting PYGL would inhibit tumor growth, $APC^{f/f}$; CDX2-Cre/ERT2 and MC38 mouse tumor models were used.

Results: (**i**) Elevated glucose metabolism in CAFs was found compared to normal fibroblasts. (**ii**) Treatment of hCAFs with either conditioned medium (CM) derived from HCT116 CRC cells or TGFβ resulted in activated glycogen metabolism as noted by increased expression of p-PYGL/PYGL and the reduced level of glycogen in hCAFs. Moreover, CM increased the expression of IL6 family cytokines such as IL6, CLCF1, LIF and CXCL6 in hCAFs. (**iii**) Inhibition of glycogen metabolism by knockdown of PYGL or treatment with the PYG inhibitor, CP-91149, significantly repressed hCAFs proliferation and reduced the expression of these cytokines in hCAFs. Knockdown of PYGL decreased glycolytic activity as noted by decreased ECAR. (**iv**) Treatment with CP-91149 significantly inhibited tumor growth. In addition, mCAF cells co-implanted with MC38 cells increased MC38 tumor growth; this increase was attenuated by knockdown of PYGL in mCAFs.

Conclusion: Our results demonstrate that glycogen metabolism is crucial for promoting CAF immunosuppressive functions. Importantly, our findings suggest that targeting glycogen metabolism in CAFs alleviates immunosuppression and inhibits CRC malignancy.

#4714 Tumor-associated macrophage creatine metabolic reprogramming enhances hnRNPA1 phase separation and promotes colorectal cancer stemness and recurrence.

Zhengran Zhou, Xuanhui Liu, Yifan Zheng, Zhengyu Wei, Zerong Cai, Yufeng Chen, Peishan Hu, Xiaojian Wu

The Sixth Affiliated Hospital of Sun Yat-sen University, Guangzhou, China

BACKGROUND: Creatine, a common nutritional supplement, has gained increasing attention in tumorigenesis and development. Our previous study found that creatine is a key metabolic biomarker for colorectal cancer (CRC) recurrence. Further studies are urgently needed to reveal the mechanism by which creatine metabolic reprogramming induces CRC relapse.
METHODS: Targeted metabolomics analysis of creatine was dynamically performed on plasma samples of 160 CRC patients including 30 relapse cases. Creatine metabolism-related genes were investigated in TCGA, ICGC-ARGO database (a large multi-omics study of CRC in China), and CRC single-cell transcriptome datasets. Single-cell RNA sequencing and spatial transcriptomics sequencing were carried out on locally recurrent CRC tissues. Creatine metabolic reprogramming and its effect on CRC stemness were investigated in tumor-associated macrophages (TAMs) and CRC cell lines, patient-derived organoids, and murine models. Limited proteolysis-mass spectrometry (LiP-MS) and RNA-sequencing were performed to illustrate creatine-protein interaction and the regulation of relative signal pathways.
RESULTS: In recurrent CRC cases, creatine level gradually increased over time after the first radical surgery until recurrence. GATM, the key enzyme for creatine synthesis, was found to be enriched in TAMs, while creatine transporter SLC6A8 was highly expressed by malignant cells. Their expression levels were found significantly higher in patients who were going to relapse and they were positively correlated with that of LDHA, the acidic micronment marker. Creatine synthesis in TAMs was found upregulated, especially in acidic condition or after the addition of lactate, and the lactylation level of H3 histone was found elevated. Isotope tracking assays indicated that creatine can be taken up by CRC cells through SLC6A8. The addition of creatine significantly enhanced the self-renewal ability of CRC cells and activated tumor stemness pathways, which could be reversed by SLC6A8 inhibitors. LiP-MS and CETSA assay revealed that creatine directly interacted with hnRNPA1 and enhancement of hnRNPA1 phase separation was observed after the addition of creatine. Function of creatine-hnRNPA1-stemness axis was verified in vivo and in vitro subsequently.
CONCLUSIONS: Creatine has been identified as a biomarker for the dynamic monitoring of post-surgery CRC recurrence. Macrophages in the tumor microenvironment have undergone metabolic reprogramming of creatine, and TAMs-derived creatine contributed to CRC recurrence. Creatine promotes tumor stemness and malignancy via directly interacting with hnRNPA1 and enhancing its phase separation. Therapeutic strategies targeting creatine metabolism and hnRNPA1 have the potential to reduce CRC recurrence.

#4715 Detection of mitochondria-targeting anticancer agents in tumor organoids.

Yoonseok Kam, Lisa Winer, Natalia Romero

Agilent Technologies, Inc., Lexington, MA

Mitochondrial reprogramming is a hallmark of cancer, enabling tumor cells to adapt to hostile microenvironments and resist therapy. While some cancers suppress oxidative phosphorylation, others remain highly dependent on mitochondrial respiration, making mitochondria an attractive therapeutic target. This study presents a robust workflow for evaluating mitochondrial function and drug-induced mitochondrial toxicity in cancer organoids using the Agilent Seahorse XF Flex Analyzer and XF Flex Organoid Microplate. Colon cancer cell line-derived organoids embedded in Matrigel were used to evaluate the mitochondrial inhibitory effects of metformin, a well-characterized metabolic modulator. The Seahorse XF 3D Mito Stress Test and XF Mito Tox Assay enabled real-time measurement of oxygen consumption rate (OCR) and quantification of mitochondrial toxicity via the Mito Tox Index (MTI) - a unitless metric that differentiates between inhibition and uncoupling. The workflow incorporates optimized organoid seeding, image-based normalization, and reproducible metabolic profiling using the XF Flex Organoid Microplate. Results demonstrated dose-dependent mitochondrial inhibition by metformin and revealed differential susceptibility between 2D monolayer and 3D organoid cultures. These findings validate the compatibility of XF technology for organoid-based metabolic profiling in preclinical cancer research and underscore the utility of the MTI for cross-model potency comparisons of mitochondrial-targeting agents. This approach supports the development of new approach methodologies (NAMs) aligned with FDA initiatives to reduce animal testing and improve clinical translatability. The workflow is readily adaptable to patient-derived organoid (PDO) models, offering a scalable platform for screening mitochondrial-targeting therapies in oncology.

#4716 Disruption of mitochondrial dynamics alters DNA repair capacity in colon cancer.

Marion D. Creech[1], Erin M. Wolf Horrell[2], Tianyan Gao[3]

[1]Molecular and Cellular Biochemistry, Univ. of Kentucky College of Medicine, Lexington, KY,[2]Department of Surgery, Univ. of Kentucky College of Medicine, Lexington, KY,[3]Markey Cancer Center, Univ. of Kentucky College of Medicine, Lexington, KY

Mitochondrial dynamics refers to a collection of mitochondrial movements, including fission, fusion, and transport. Cancer cells are known to adjust mitochondrial dynamics to provide the metabolic plasticity needed for cell growth, proliferation and migration. We have shown previously that Drp1, a key regulator of mitochondrial fission, plays an important role in mediating fatty acid-induced activation of Wnt/β-catenin signaling in colon cancer. In this study, we determined the functional interaction between mitochondrial dynamics and DNA damage response in colon cancer cells. To disrupt mitochondrial fission, inducible Drp1 knockdown colon cancer cell lines were generated using lentivirus-mediated RNAi. Control and Drp1 knockdown cells were treated with radiation or chemotherapy drug irinotecan to induce DNA damage response. The extent of DNA damage as well as the activation of DNA repair signaling were analyzed by western blot and RT-qPCR. We found that Drp1 was activated upon irinotecan or radiation treatment as shown by increased phosphorylation at S616 site. Interestingly, the expression of γH2AX, a DNA damage marker, induced by irinotecan or radiation treatment was increased in Drp1 knockdown cells, whereas the expression and activation of DNA damage sensing proteins (e.g., ATM and ATR) remained unchanged. To determine if increased fatty acid uptake alters DNA damage, we showed that the presence of exogenous fatty acids attenuated γH2AX expression induced by radiation in control cells whereas knockdown of Drp1 blunted this response. Functionally, the addition of fatty acids increased, while silencing Drp1 decreased, cell survival post radiation as measured by colony formation assays. However, the pro-survival effect of fatty acids was largely abolished in Drp1 knockdown cells. Taken together, our results suggest that fatty acid uptake may enhance DNA repair via a mitochondrial fission-dependent mechanism. This study establishes a functional link between fatty acid metabolism, mitochondrial dynamics, and DNA damage response in colon cancer cells.

#4717 TBK1/IKKβ-mediated CAD phosphorylation links pyrimidine synthesis blockade and chemosensitization to innate immune activation.

Taolin Xie, Chi Liang, Hansong Xia, Anjie Lu, Chao Qin, Xinchi Xie, Wayne Yeh, Pinghui Feng

Herman Ostrow School of Dentistry, University of Southern California, Los Angeles, CA

Metabolic reprogramming is a hallmark of cancer. Aberrantly-activated metabolic enzymes fuel tumor progression through multiple mechanisms, including tumor cell proliferation, metastasis and drug resistance. Elucidating the regulatory mechanism of metabolic enzymes in cancer is thus of vital importance, which will pave a way to novel anti-tumor therapies. The first three steps of *de novo* pyrimidine synthesis are mediated by a multi-functional enzyme known as carbamoyl-phosphate synthetase 2, aspartate transcarbamylase, and dihydroorotase (CAD). Our lab have identified CAD as a protein deamidase that deamidates the NF-κB transcriptional factor RelA, shunting RelA from mediating the transcription of inflammatory cytokines to glycolytic enzymes. CAD thereby acts as a cellular metabolic node that fuels cancer cell proliferation by mediating pyrimidine synthesis and aerobic glycolysis. Indeed, CAD has been characterized as a critical oncogenic factor in a variety of malignancies. However, whether and how CAD is regulated by innate immune response remain unexplored. In this study, we report that innate immune activation dramatically impairs CAD enzymatic activity in colon cancer cells. Mechanistically, CAD is phosphorylated at multiple residues by two key innate immune protein kinases, TANK-binding kinase-1 (TBK1) and inhibitor of NF-κB kinase-β (IKKβ). TBK1 / IKKβ-mediated phosphorylation significantly attenuates both pyrimidine synthetase and protein deamidase activity of CAD, subsequently suppressing colon cancer cell metabolic reprogramming and proliferation. Furthermore, TBK1 / IKKβ-mediated CAD phoshorylation results in pyrimidine depletion and an imbalance in cellular nucleotide pool, which sensitizes colon cancer cells to DNA damage agents. Pharmacological activation of innate immune signaling by stimulator of interferon gene (STING) agonist can thereby inhibit intratumoral CAD activity and boost chemotherapy agents-induced DNA damage, highlighting a novel combination therapy. Besides, in a panel of cancer cell lines in which TBK1 acts as an oncogene, TBK1 is switched to activate CAD via growth factor signaling pathway, implicating context-dependent roles of TBK1 in regulating CAD. In summary, our study reveals an unprecedented crosstalk that places pyrimidine synthesis as a downstream ramification of innate immune activation. These findings provide fresh insights into how innate immune signaling reshapes tumor metabolic landscape, and offer a mechanistic rationale for combining STING agonists with chemotherapy as a highly potent approach to improve cancer treatment.

#4718 Redox reprogramming protects colon cancer cells from disulfidptosis under glucose deprivation.

Elimelech Nesher, Subha Ranjan Das, Igor Koman

Ariel University, Ariel, Israel

Cancer cells thrive in the tumor microenvironment by reprogramming their metabolism and adapting to severe nutritional stress. Although some cancer cells can withstand prolonged glucose deprivation, the molecular mechanisms underlying this resilience remain poorly understood. In this study, we investigated how glucose deprivation-resistant (GDR) colon cancer cells survive sustained glucose starvation, focusing on their ability to counteract oxidative stress and disulfidptosis, a recently described form of cell death driven by disulfide stress.We established long-term glucose-deprived cultures of colon cancer cells and compared quiescent populations with GDR cells that had resumed proliferation. Metabolic rewiring was assessed using Seahorse XF metabolic flux analysis and LC-MS-based metabolomics to map energy production pathways and metabolite changes. RNA sequencing was performed to identify transcriptional alterations, including those associated with disulfidptosis. Cytoskeletal integrity was evaluated by phalloidin staining, and cell viability was measured using the resazurin assay. To test whether redox support could restore survival, we conducted rescue experiments with antioxidants such as N-acetylcysteine and S-adenosylmethionine, as well as thiol-reducing agents including 2-mercaptoethanol and dithiothreitol, under both glucose-deprived and docetaxel-induced stress conditions.We found that upon glucose depletion, a subpopulation of colon cancer cells enters a dormant state characterized by elevated ROS, loss of mitochondrial membrane potential, extensive DNA damage, and cytoskeletal collapse. In contrast, the surviving GDR cells adapt by shifting from glycolysis to oxidative phosphorylation (OXPHOS). Metabolomic profiling revealed increased levels of TCA cycle intermediates and a pronounced enrichment of redox-active metabolites, including cystine, glutamate, glutamine, γ-glutamylcysteine, reduced GSH, and oxidized GSSG. Transcriptomic analyses further supported this metabolic transition, showing marked upregulation of disulfidptosis-associated genes. Functionally, these adaptations enhanced redox buffering capacity and reduced sensitivity to disulfide-induced cytotoxicity. Notably, supplementation with antioxidants and thiol-reducing agents preserved cytoskeletal integrity and improved overall cell viability, indicating that strengthening redox homeostasis is sufficient to counteract disulfidptosis, even under the combined stresses of chemotherapy and glucose deprivation.In conclusion, GDR colon cancer cells evade disulfidptosis by reprogramming metabolism toward OXPHOS and enhancing redox defense mechanisms that maintain cytoskeletal integrity. Targeting these adaptive redox pathways may provide a promising strategy to eliminate cells that survive glucose deprivation through metabolic plasticity.

#4719 Dissecting metabolism-driven transcriptional reprogramming in human colon and liver cancer cells.

Subhamoy Datta[1], Emilia Kotinurmi[1], Konsta Karttunen[1], Biswajyoti Sahu[2], **Paivi Pihlajamaa**[1]

[1]Applied Tumor Genomics Research Program, Faculty of Medicine, University of Helsinki, Helsinki, Finland,[2]Norwegian Centre for Molecular Biomedicine and Medicine and Applied Tumor Genomics Research Program, University of Helsinki, Finland; University of Oslo, Oslo, Norway

Cellular metabolism is a dynamic process that supports tissue homeostasis, growth, and environmental adaptation. Cancer cells exploit this by rewiring metabolic pathways in response to oncogenic cues and microenvironmental pressures. While oncogene-driven metabolic reprogramming is an established cancer hallmark, the extent to which specific metabolic enzymes shape the chromatin and transcriptional landscape of cancer cells remains incompletely understood. Here, we systematically interrogate how loss of individual metabolic enzymes rewires gene expression programs through chromatin-based mechanisms. We performed a CROP-seq screen targeting key metabolic enzymes across major pathways, including the tricarboxylic acid cycle, glycolysis, nucleotide synthesis, amino acid metabolism, fatty acid biosynthesis, and glutaminolysis, combined with single-cell RNA-seq in HCT116 colon cancer cells. Differential expression analysis relative to non-targeting controls revealed substantial transcriptional changes upon loss of several enzymes, indicating strong metabolic control over gene regulatory states. Interestingly, silencing of ACSS2 (acyl-CoA synthetase short-chain family member 2; acetate-to-acetyl-CoA pathway) elicited one of the most pronounced transcriptional effects, and similarly a broad gene expression shift was observed upon shRNA-mediated ACSS2 silencing followed by bulk RNA-seq in HepG2 liver cancer cells. ACSS2 converts acetate into acetyl-CoA in both the cytosol and nucleus, positioning it as a direct metabolic regulator of histone acetylation and chromatin accessibility. Notably, loss of metabolic enzymes upstream of acetyl-CoA production, including fumarate hydratase (FH; tricarboxylic acid cycle) and pyruvate dehydrogenase beta subunit (PDHB; pyruvate-to-acetyl-CoA conversion), induced compensatory upregulation of ACSS2, suggesting a feedback mechanism that maintains nuclear acetyl-CoA availability. Ongoing work couples these transcriptional profiles with ChIP-seq profiling of histone acetylation and other chromatin marks, enabling direct linkage between metabolic perturbation, chromatin remodeling, and transcriptional outcomes. Together, this study reveals how metabolic dependencies converge on chromatin-mediated transcriptional control and contributes to a broader understanding of how metabolic state influences gene regulation in cancer. Full results and mechanistic insights will be presented at the meeting.

#4720 Glutamine transporter ASCT2 as a therapeutic target in HPV positive organoid models of HNSCC.

Shu-Yun Cheng, Ella Jackert, Liyang Tang, Daniel Kwon, Niels Kokot, Uttam Sinha, Yang Chai, Albert Y. Han

University of Southern California, Los Angeles, CA

Background: Head and neck squamous cell carcinoma (HNSCC) is the sixth most common cancer worldwide, with Human Papillomavirus (HPV) - 16 infections being a cause. Previous studies have shown that glutamine is a crucial amino acid that provides carbon and nitrogen for proliferating cells. In particular, some cancer cells increase the uptake of glutamine through metabolic reprogramming. However, our understanding of glutamine metabolism and transport remains limited in HNSCC. In this study, we will be investigating glutamine transport, specifically ASCT2, in patient-derived normal tonsil organoid and HPV16-positive tonsil organoids.

Methods: Tonsil tissue is obtained from tonsillectomy and process for organoid generation. Through mechanical and enzymatic dissociation, tonsil tissue is dissociated into single cell suspension and plated in extracellular matrices. HPV16 lentivirus is used to infect tonsil organoids and used as premalignant HPV16-positive HNSCC model. RNA of the normal tonsil and HPV+ organoids were extracted for qPCR analysis. V-9302, an ASCT2 competitive antagonist, was treated to the organoids for IC_{50}.

Results: In this study, the glutamine transporter, ASCT2, was investigated in patient-derived normal tonsil organoid and HPV16-positive tonsil organoids. Both organoid models exhibit ASCT2 through qPCR analysis, with HPV16-positive tonsil organoids exhibiting less ASCT2 (FC 0.64 $p<0.00$) than normal tonsil organoids. To see if ASCT2 can be a therapeutic target, V-9302 was treated to normal tonsil organoids and HPV16-positive tonsil organoids. V-9302 IC_{50} of the organoids were obtained, with HPV16-positive organoids being more sensitive (IC_{50}: 15.37 μM) than normal tonsil organoids (IC_{50}: 20.50 μM).

Conclusion: Glutamine is an essential amino acid for cell growth and proliferation, especially in fast growing tumors. With V-9302 being more sensitive to HPV16-positive organoids, V-9302 shows the potential to be used as a therapeutic drug for HNSCC treatment. Future studies will focus on V-9302 sensitivity in patient-derived HNSCC tumor organoids.

#4721 Cross-species multi-omics mapping of APC/KRAS-driven metabolic networks.

Mahima Bharti[1], Swagata Maity[1], Marcos Calderon[1], Peng Zhang[1], Augustine Takyi[2], Marco Marchetti[3], Paul Stewart[2], Bruce A. Edgar[1]

[1]Department of Oncological Sciences, Huntsman Cancer Institute, University of Utah, Salt Lake City, UT,[2]Department of Nutrition & Integrative Physiology, Huntsman Cancer Institute, University of Utah, Salt Lake City, UT,[3]Eccles Institute of Human Genetics, University of Utah, Salt Lake City, UT

Colorectal cancer (CRC) is the third most diagnosed malignancy and the second leading cause of cancer-related deaths worldwide. Over 70% of CRCs harbor activating mutations in the EGFR/KRAS and WNT/APC pathway genes, which regulate intestinal stem cells (ISCs) proliferation and differentiation. While these oncogenic pathways are well depicted for their transcriptional effects, their metabolic interactions and cooperative roles in tumor progression remain unclear. Our preliminary data reveal that EGFR signaling promotes ISC self-renewal through an anabolic program that redirects carbohydrates to biosynthetic pathways while using fatty acid oxidation (FAO) to sustain ATP production. Published evidence also suggests that WNT/APC signaling induces similar metabolic changes. Here we show that co-activation of WNT/APC and EGFR/KRAS signaling reprograms cellular metabolism, generating cancer-specific vulnerabilities distinct from those induced by either mutation alone. To test this, we employ an integrated multimodal and multi-omics strategy that combines transcriptomics, metabolomics, lipidomics, and proteomics across *Drosophila* models and patient-derived organoids (PDOs). This approach maps metabolic changes under normal and oncogenic conditions involving EGFR/RAS and WNT/APC pathways. In *Drosophila*, ISC-derived cell clones carrying Apc^{Δ}, Ras^{G12V}, or dual $Apc^{\Delta}; Ras^{G12V}$ mutations reveal that dual-hit clones show enhanced proliferation, altered morphology, and cancer-like phenotypes, unlike single hits. Transcriptomic and metabolomic analyses identified distinct differentially expressed genes (DEGs) and metabolic profiles in the dual-hit state, particularly in mitochondrial, lipid, and nucleotide biosynthetic pathways. Integrated multi-omic analyses further identified unique metabolic modules reflecting synergistic reprogramming. Parallel studies in patient-derived cancerous (CRC) organoids show similar patterns: compared to normal control gut organoids, CRC organoids displayed altered morphology, transcription, and metabolism, including reprogrammed lipid and amino acid metabolism and enhanced glycolytic and mitochondrial activity. Following prioritization by evolutionary conservation and multi-omic integration, ~40 candidate genes (e.g., *r, mt:ND4L, eloF, Ak1*) will be functionally tested via RNAi or inhibitors in Apc^{Δ} Ras^{G12V} *Drosophila* ISC clones and *APC/KRAS* colon organoids to assess tumor-suppressive effects. Validated effectors will be evaluated in mouse and xenograft models to identify targetable metabolic dependencies. Together, these findings demonstrate that concurrent APC and KRAS mutations establish a unique synergistic metabolic program driving aggressive CRC. By integrating multi-omics and cross-species models, this study is finding conserved, cancer-specific metabolic effectors as promising therapeutic targets in colorectal cancer.

#4722 Genetic background shapes mitochondrial metabolic adaptations underlying thyroid cancer progression.

Vincenzo Davide Pantina[1], Chiara Modica[1], Francesco Verona[2], Giulia Bozzari[1], Roberta Drago[1], Caterina D'accardo[1], Gaetana Porcelli[2], Sebastiano Di Bella[1], Rosario Brancato[2], Pierre Sonveaux[3], Matilde Todaro[2], Giorgio Stassi[1]

[1]Department of Precision Medicine in the Medical, Surgical and Critical Care Areas, University of Pa, University of Palermo, Palermo, Italy,[2]Department of Health Promotion, Mother and Child Care, Internal Medicine and Medical Specialties (P, University of Palermo, Palermo, Italy,[3]Catholic University of Louvain School of Medicine, Brussels, Belgium

Introduction: Anaplastic Thyroid Cancer (ATC) is characterized by rapid progression and unclear dissemination mechanisms. Tumor evolution is not solely defined by the selective pressure acting on pre-existing subclones, but is intricately intertwined with the rapid, environmentally mediated acquisition of adaptive phenotypes. Metabolic plasticity is a critical process that lies at the intersection of these complementary evolutionary paradigms, actively fueling malignant progression and conferring metastatic competence. Elucidating how metabolic rewiring contributes to the emergence and expansion of highly invasive ATC clones is critical to counteract TC progression

Experimental procedures: We established a TC tumorigenesis model by leveraging human embryonic stem cells and CRISPR/Cas9 genome engineering to generate distinct TC progenitor cells, harbouring specific mutations. We developed highly invasive in vitro TC cells to identify the metabolic signatures linked to cellular aggressiveness. The data were corroborated in orthotopic TC mouse models, which recapitulated the disease progression. The metabolic profile was characterized by measuring oxygen consumption rate (OCR), extracellular acidification rate (ECAR). RNA-seq data were analyzed to obtain transcriptomic and metabolism-related signatures associated with specific genetic background. Cells were treated with MitoQ, Treatment effects were assessed on primary tumor growth and metastatic dissemination.

New, unpublished data: We observed that BRAF V600E single/double-mutated cells cluster based on their metabolic profile and undergo a similar metabolic shift during the selection of super-invasive subpopulations. BRAFV600E-mutated ATC-derived aggressive clones experience a reprogramming toward oxidative phosphorylation (OXPHOS). ATC superoxide clones exhibit heightened mitochondrial respiration, increased mitochondrial membrane potential, and accumulation of mitochondrial reactive oxygen species, in line with their enhanced invasive capacity. Leveraging this metabolic dependency uncovered a therapeutic opportunity: treatment with the mitochondria-targeted antioxidant MitoQ significantly reduced cellular invasiveness in vitro and suppressed lung metastasis formation in vivo in mouse models. This defined metabolic vulnerability provides a distinct signature that may aid in stratifying relevant thyroid cancer patient subsets.

Conclusions: Our study demonstrates that mitochondrial metabolic rewiring is not a universal feature of ATC but is instead tightly dictated by the tumor's genetic background. These findings underscore the critical interplay between genetic context and metabolic adaptation, providing a refined framework for developing targeted therapeutic strategies aimed at pharmacologically restraining the metastatic progression of BRAFV600E-mutated ATC

#4723 Dysregulated lipid metabolism accompanies chromosomal instability in obesity-associated oesophageal adenocarcinoma.

Yun Suen Kho[1], Aiswarya Nair[2], Daryl Kai Ann Chia[3], Supriya Srivastava[4], Jimmy Bok Yan So[3], Asim Shabbir[3], Li Ren Kong[5], Ashok R. Venkitaraman[2]

[1]School of Medicine, NUS Centre for Cancer Research, Cancer Science Institute of Singapore, National University of Singapore, Singapore, Singapore,[2]Cancer Science Institute of Singapore, Singapore, Singapore,[3]Department of Surgery, National University Hospital, National University Health System, Singapore, Singapore,[4]Department of Medicine, National University of Singapore, Singapore, Singapore,[5]Lee Kong Chian School of Medicine, Nanyang Technological University, Singapore, Singapore

Background - The global rise in obesity has been paralleled with increasing incidence of obesity-associated cancers, including OAC. While epidemiological studies have shown a strong link between obesity and increased risk of OAC, the underlying mechanism remains poorly understood. We hypothesized that toxic metabolites associated with obesity can induce chromosomal instability, thereby provoking carcinogenesis in OAC.

Method - To investigate obesity-associated metabolic and genomic alterations in OAC, we performed metabolomics, immunohistochemistry (IHC) and whole-genome sequencing on paired malignant and non-malignant gastroesophageal junction (GEJ) tissues from individuals with varying body mass index (BMI). To model early events during obesity-associated tumorigenesis, we have developed long-term organoid cultures from normal simple columnar epithelial biopsies obtained during bariatric surgeries, to test the effects of long-term growth in a high lipid environment.

Results - Our preliminary results suggested an association between obesity and dysregulated lipid metabolism in both non-malignant and OAC tissues. Obese non-malignant tissues showed an elevation in toxic lipid metabolite, 4-hydroxy-2-nonenal (4-HNE) and higher oxidative stress with elevated oxidative DNA damage markers. Obese tumour tissues exhibited a higher tumour mutational burden and genomic instability score, suggesting that obesity may result in a distinct, genomically unstable OAC subtype. To recapitulate these obesity-associated alterations, organoids were grown in a high lipid environment. Prolonged culture induced morphological changes, with reduced differentiation markers and increased stemness. Notably, lipid withdrawal restored the organoid morphology, demonstrating that lipid-rich conditions can transiently alter epithelial cell states and may contribute to tumour initiation.

Conclusion - Our preliminary results suggest the existence of an obesity-associated OAC subtype driven by lipid-mediated metabolic and genomic dysregulation. The organoid model serves as an *in vitro* platform for dissecting early events in obesity-associated tumorigenesis and highlights the potential role of toxic lipid metabolites in cancer initiation.

#4724 Elevated plasma trimethylamine-N-oxide (TMAO) levels correlate with better clinical and molecular responses in immunotherapy-treated resectable gastroesophageal cancer and pleural mesothelioma.

Rachel J. Keogh[1], Paul K. Lee[1], N.V. Rajeshkumar[1], Blair V. Landon[1], Joshua E. Reuss[2], Jaime Wehr[1], Gavin Pereira[1], Amna Jamali[1], Noushin Niknafs[1], Ronan J. Kelly[3], Ali H. Zaidi[4], Josephine L. Feliciano[1], Julie R. Brahmer[1], Vincent K. Lam[1], Patrick M. Forde[1], Chi V. Dang[1], Valsamo Anagnostou[1]

[1]Johns Hopkins University School of Medicine, Baltimore, MD,[2]Georgetown Univ. School of Medicine, Washington, WA,[3]Charles A. Sammons Cancer Center Baylor University Medical Center, Dallas, TX,[4]Allegheny Health Network Cancer Institute, Pittsburgh, PA

Background: Microbiome-derived metabolites have demonstrated significant impact on immunotherapy response, particularly in the context of immune checkpoint blockade (ICB). Trimethylamine-N-oxide (TMAO), an amine oxide generated when gut bacteria metabolize dietary choline, has been identified in preclinical studies to enhance anti-tumor immune responses. Here, we evaluated circulating choline metabolites with respect to clinical outcomes and circulating tumor DNA (ctDNA) residual disease in patients with resectable cancers receiving neoadjuvant ICB.
Methods: Pre-treatment choline, trimethylamine (TMA) and TMAO plasma concentrations from 51 patients with stage I-III diffuse pleural mesothelioma (DPM; n = 25 patients; NCT03918252) or stage II/III esophageal/gastro-esophageal junction cancer (E/GEJ; n = 26 patients; NCT03044613) on neoadjuvant ICB, were quantified via liquid chromatography-mass spectrometry (SCIEX Triple Quad 6500+). Clinical outcomes were compared across metabolite thresholds, as were ctDNA residual disease through tumor-informed cell-free DNA (cfDNA) whole-genome sequencing (WGS). ctDNA residual disease in the DPM cohort was measured by intersecting tumor (n = 28), white blood cell (n = 28), and plasma (n = 97) WGS.
Results: In the DPM cohort, median baseline choline, TMA and TMAO concentrations were 3970, 2840 and 256 ng/mL, respectively. Higher baseline TMAO levels were associated with lower ctDNA residual disease at C2D1 (Fisher's exact, p = 0.028), C3D1 (Fisher's exact, p = 0.057) and pre-surgery (Fisher's exact, p = 0.01). Further, patients with higher TMAO had either undetectable ctDNA throughout the neoadjuvant window or ≥95% reduction in cfDNA tumor fraction from baseline to pre-surgery (Fisher's exact, p = 0.028). In this cohort, ctDNA residual disease strongly correlated with progression-free and overall survival (log-rank, p < 0.05). In the E/GEJ cohort, median baseline choline, TMA and TMAO concentrations were 279, 2945 and 4175 ng/mL, respectively. Patients who attained a major pathologic response had numerically higher TMAO levels (Fisher's exact, p = 0.078). In line with the findings in the DPM cohort, patients in the E/GEJ cohort with lower TMAO (lowest quintile; <197 ng/mL) had shorter overall survival (log-rank, p = 0.034) compared to those with higher TMAO concentration (≥197 ng/mL), an association that remained significant after adjusting for clinicopathological variables (Cox multivariable, p = 0.04).
Conclusion: Our findings indicate that higher plasma TMAO levels may be linked to molecular ctDNA response and better clinical outcomes with neoadjuvant ICB, further supporting a potential immunomodulatory role of choline metabolites in enhancing immunotherapy response.

#4728 Loss of LKB1 promotes lactate utiliaztion in *KRAS*-mutant lung adenocarcinoma.

Yu Qian[1], David Molkentine[1], Yifan Kong[1], Amirali Karimi[1], Qian Huang[1], Chendong Yang[2], Ralph J. DeBerardinis[2], John V. Heymach[1]

[1]UT MD Anderson Cancer Center, Houston, TX,[2]Children's Medical Center Research Institute, University of Texas Southwestern Medical Center, Dallas, TX

Loss of function of the tumor suppressor LKB1, which is encoded by the gene *STK11*, represents about 20% in non-small cell lung cancer (NSCLC). LKB1 is frequently co-mutated with *KRAS*, and LKB1-deficiency is associated with resistance to anti-PD1 therapy but remain partial response to anti-PD1/CTLA4 dual checkpoint blockade. We previously found that LKB1 loss led to increased lactate levels in the tumor microenvironment and suppressed anti-tumor immunity. However, whether LKB1-deficient tumor cells directly benefit from the lactate rich environment remains unclear. We hypothesized that LKB1 deficiency enhances lactate utilization and promotes a malignant phenotype. We performed metabolic profiling on Kras mutant LKB1-proficient (K) and -deficient (KL) cells treated with lactate. Seahorse assay was performed in K and KL cells to measure lactate utilization in vitro, and isotope tracing was conducted in vitro and in vivo. Single-cell RNAseq (scRNAseq) data from murine syngeneic tumors and clinical samples were used to assess the lactate metabolism score in KRAS mutant tumors with or without LKB1/*STK11* alterations. We treated K and KL cells with lactate as the carbon source and performed metabolic profiling. The data showed that altered metabolites were enriched in several pathways including TCA cycle. We observed that KL cells showed increased oxidative phosphorylation (OXPHOS) and GSH and NADPH levels when cultured with lactate, suggesting that LKB1-deficient cells had an enhanced ability to utilize OXPHOS and maintain redox homeostasis when using lactate as an energy source. Moreover, [U-13C]lactate tracing revealed that isotopologues were significantly enriched in pyruvate and TCA components such as citrate, glutamate and malate in KL cells, indicating the enhanced lactate incorporation into the TCA cycle, which was consistent with the observed elevated OXPHOS. Next, we injected K and KL murine cells into mice to establish syngeneic tumor models. Animals were infused with [U-13C]lactate to detect the isotopologues distribution in vivo. KL tumors showed significantly enhanced lactate incorporation as compared to K tumors. Genetically engineered mouse models of K and KL lung cancer similarly showed that increased amounts of lactate transformed into citrate, succinate and malate. Finally, we analyzed data from clinical samples infused with [U-13C]lactate, although the sample size was limited, patients with *KRAS*/*STK11* co-mutation showed a trend towards increased labeling of TCA cycle metabolites as compared to patients with *KRAS* or *KRAS*/*TP53* co-mutation. Additionally, scRNAseq data from murine tumors and clinical samples showed significantly elevated lactate metabolic score in KL tumors. Collectively, our data indicates that LKB1-deficient tumors increase lactate incorporation and utilization, suggesting that targeting lactate metabolism as a novel therapeutic approach for this recalcitrant subgroup.

#4729 LINE-1 retrotransposition drives lipid metabolic reprogramming and immune suppression in lung squamous cell carcinoma via cPLA2/5-LOX axis.

Rui Zhang, Wenjing Tian, Pengpeng Liu, Jinpu Yu

Tianjin Medical Univ. Cancer Inst. & Hospital, Tianjin, China

Background: Long interspersed nuclear element-1 (LINE-1; L1) retrotransposition is frequent in lung squamous cell carcinoma (LUSC), yet its functional impact remains largely unelucidated. We previously identified recurrent L1-ATP8B1 (L1 insertion in ATP8B1) associated with poor prognosis. Given ATP8B1's role in lipid homeostasis, we hypothesize L1-ATP8B1 drives lipid metabolic reprogramming to promote LUSC progression.
Methods: We integrated transcriptomic analyses of The Cancer Genome Atlas (TCGA) and validation cohorts with targeted metabolomics, functional assays, and tumor-immune cell co-culture systems. Mechanistic studies were conducted via genetic perturbation, pharmacologic inhibition, and rescue experiments in both in vitro and in vivo models.
Results: Gene Ontology and KEGG enrichment analysis revealed L1-ATP8B1 correlated with deregulated lipid metabolism, particularly arachidonic acid (AA) metabolism. Metabolomic profiling results confirmed elevated AA-derived 5-HETE and 5-oxo-ETE (the oxidation metabolite of 5-HETE) in L1-ATP8B1-over-expressing cells. Mechanistically, L1-ATP8B1 up-regulated the transcriptional levels of PLA2G4 and ALOX5 to enhance AA release and 5-HETE generation. Pharmacologic inhibition of the activity of their metabolic enzymes cytosolic phospholipase A_2 ($cPLA_2$) and 5-lipoxygenase (5-LOX) abrogated tumor progression, whereas exogenous 5-oxo-ETE rescued the effects. Further, we found L1-ATP8B1 induced immune suppression by recruiting myeloid-derived suppressor cells (MDSCs). Co-culture experiments demonstrated 5-oxo-ETE enhanced the immunosuppressive function of MDSCs by activating non-canonical NF-κB signaling, thereby inhibiting T cell proliferation and IFN-γ production-an effect reversed by 5-LOX inhibition.
Conclusions: Our findings uncover a previously unrecognized L1/cPLA2/5-LOX/NF-κB axis linking lipid metabolic reprogramming to LUSC immune evasion. L1-ATP8B1 drives tumor aggressiveness and immune suppression via lipid mediators. Targeting this pathway is a promising therapeutic strategy to overcome immune resistance in LUSC.

#4730 Construction of a prognostic model for small-cell lung cancer based on lipid metabolism related proteins.

Haohua Zhu[1], **Aijuan Yu**[2], Huiyang Shi[3], Jingyu Lu[3], Kai Zhu[3], Miaohan Wang[3], Yi Liu[2], Naizhong Zheng[2], Xingsheng Hu[3]

[1]Cancer Center, Aerospace Center Hospital, Beijing, China,[2]DeepKinase Biotechnologies Ltd., Beijing, China,[3]Department of Medical Oncology, National Cancer Center/National Clinical Research Center for Cancer/Cancer Hospital, Chinese Academy of Medical Sciences & Peking Union Medical College, Beijing, China

Small cell lung cancer (SCLC) is a highly invasive tumor with poor prognosis. There is an urgent need to develop novel biomarkers to identify patients with high-risk SCLC and optimize individual treatment strategies. We conducted a comprehensive, mass spectrometry-based proteomic analysis of 120 tumors (90 primary, 15 lymph node, 15 brain) from 105 SCLC patients. Metabolic transformation has become a hallmark of cancer. Additionally, we have found a correlation between lipid metabolism and the recurrence and metastasis of SCLC in our previous study, based on this deep, unbiased proteomic profiling. This analysis aimed to construct a prognostic risk score for SCLC using lipid metabolism related proteins and explore the underlying molecular biological mechanisms. We first identified 940 proteins related to lipid metabolism, of which 51 were associated with the prognosis of patients. The unsupervised consensus clustering results showed two different lipid metabolism patterns for SCLC, which was associated with patient prognosis and immune cell infiltration. Eight survival related lipid metabolism proteins were further identified through LASSO regression to construct a prognostic risk score, which is an independent prognostic factor for SCLC patients and validated in an independent cohort. The correlation of risk score with neuronal characteristics and anti-tumor immune response was revealed through pathway enrichment analysis of differentially expressed proteins between low-risk and high-risk groups. Finally, low-risk group showed significantly higher sensitivity to almost all chemotherapy and targeted therapy drugs compared to the high-risk group.

#4731 Cysteine oxidation is required for brain metastasis in lung cancer.

Maolin Ge

Mass General Cancer Center, Boston, MA

Most cysteine residues are believed to require a reduced state for activity and their oxidation by reactive oxygen species (ROS) is traditionally viewed as damaging to proteins. However, it stands that some cysteines that must be oxidized for protein function, yet their identity remains largely unknown. To answer this question, we lowered ROS levels in 55 lung cancer cell lines and analyzed the cellular consequences using cysteine-focused chemical proteomics paired with functional CRISPR screens. This integrated approach revealed hundreds of impacted cysteines required for proliferation. We focused on NDUFA10•C253 in mitochondrial complex I, which we find exists in a more oxidized state in some human brain metastases. This cysteine is dynamically regulated by antioxidant pathways and its oxidation is required for complex I stability and supports metastasis to the brain. Collectively, we demarcate oxidized cysteines essential for cell fitness and disease states including metastasis.

#4732 Anaplastic lymphoma kinase harnesses the SLC4A7 bicarbonate transporter to intensify de novo nucleotide synthesis in neuroblastoma and lung cancer..

Ruth Palmer[1], Wei-Yun Lai[1], Tzu-Po Chuang[1], Joel Johansson[1], Emre Can Tuysuz[1], Dan E. Lind[1], Alexander Schmidt[2], Michael N. Hall[3], Bengt Hallberg[1]

[1]Institute of Biomedicine, University of Gothenburg, Gothenburg, Sweden,[2]Biozentrum, University of Basel, Basel, Switzerland,[3]University of Basel, Basel, Switzerland

There is growing recognition of how metabolic dependencies influence sensitivity or resistance to neuroblastoma (NB) therapies. In this regard, the impact of Anaplastic Lymphoma Kinase (ALK), a receptor tyrosine kinase which is mutated in approximately 10% of primary NB cases, and a clinical target in NB on cellular metabolism is unclear. In this study, we combined phosphoproteomics and BioID-mediated proximity interaction screening in neuroblastoma cell lines, identifying the sodium bicarbonate transporter SLC4A7, a member of the Solute Carrier (SLC) family, and the multifunctional protein Carbamoyl Phosphate Synthetase 2-Aspartate Transcarbamylase-Dihydroorotase (CAD) downstream of ALK signaling in NB cells. SLC4A7 and CAD are both important molecular components in the metabolism of pyrimidine nucleotides. ALK activation leads to phosphorylation of both SLC4A7 and CAD, resulting in increased sodium bicarbonate transport and pyrimidine biosynthesis that is blocked by the addition of ALK tyrosine kinase inhibitors (TKIs). Combined targeting of both ALK signaling and nucleotide synthesis leads to a more effective inhibition of NB tumor growth in both cell and genetically modified mouse NB models. Finally, we show that SLC4A7 and CAD are also targets in ALK-driven non-small cell lung cancer (NSCLC), revealing a novel therapeutic strategy that leverages metabolomic dependencies to target ALK-driven malignancies such as NB and NSCLC.

#4734 Metabolomic profiling among non-small cell lung cancer and non-cancer populations: A case-control study.

Yoo-Min Koh[1], Jae Jeong Yang[2], Mi-Jeong Yoo[3], Qiuyin Cai[4], Feifei Xiao[2], Hiren Mehta[2], Lizi Wu[2], Hyung-Suk Yoon[2]

[1]Yale University, New Haven, CT,[2]University of Florida, Gainesville, FL,[3]Clarkson University, Potsdam, NY,[4]Vanderbilt University Medical Center, Nashville, TN

Lung cancer is the second most common cancer in the United States, with an estimated 124,730 deaths projected in 2025. Non-small cell lung cancer (NSCLC) accounts for 80-85% of all lung cancer cases, making it the predominant form of the disease. 27.4-28.1% of NSCLC cases are diagnosed at early stages, indicating the need for biomarker testing, which enhances detection accuracy beyond imaging-based approaches alone. Metabolomics enables the comprehensive identification of NSCLC-specific metabolites, revealing distinct biochemical alterations that inform the discovery of novel diagnostic biomarkers and could be utilized to further investigate outcomes and therapeutic targets. Therefore, we conducted a pilot metabolomics study using a case-control design to identify differentially abundant metabolites between NSCLC patients and non-cancer controls, with the goal of discovering potential metabolomic biomarkers associated with NSCLC. A total of 80 NSCLC patients (45.6% male; mean age=65.4) and 40 non-cancer control individuals (24.3% male; mean age=40.2) were included in this study. Global metabolomic profiling from serum samples of the study population utilizing the Orbitrap Fusion and the TSQ Altis QqQ mass spectrometry interfaced with the Vanquish Horizon UHPLC system at the UF ICBR Proteomics & Mass Spectrometry. Differentially abundant metabolites were determined using Mann-Whitney U-tests with Benjamini-Hochberg FDR correction and fold-change threshold. Global metabolomic profiling identified 5,307 metabolites, of which 626 (11.8%) were differentially abundant between NSCLC patients and non-cancer controls using stringent criteria (FDR<0.01, FC≥4). 455 metabolites were less abundant, and 171 were more abundant in NSCLC. The results from PCA demonstrated a separation between NSCLC patients and non-cancer controls, with PC1 and PC2 accounting for 25% of the total variance. OPLS-DA confirmed the discrimination of metabolic profiles between NSCLC patients and non-cancer controls. Network analysis revealed dysregulation in metabolic pathways, including the urea cycle, TCA cycle, amino acid metabolism, and polyamine biosynthesis. Key metabolites, including hypoxanthine, adipic acid, and betaine, were significantly less abundant in NSCLC. Pathway enrichment analysis identified enrichment in purine and pyrimidine metabolism, suggesting altered nucleotide metabolism associated with NSCLC. Larger prospective studies are warranted to validate these metabolomic biomarkers for clinical application in NSCLC. Future investigations will evaluate their utility in predicting prognosis, treatment response, and survival. The implementation of these NSCLC-specific metabolomic signatures in clinical practice could enhance prognostic accuracy and inform personalized treatment strategies, ultimately improving outcomes and survival.

#4735 Designing a novel 3D co-culture model incorporating patient T-cells to study lipid metabolism as a metabolic vulnerability in KRAS driven non-small cell lung cancer.

Saoirse Flanagan[1], Robyn Stanley[2], Sze Ying Tan[2], Beatrice Malacrida[3], Noemie Petit[4], David O'Reilly[5], Jarushka Naidoo[5], Shane Browne[4], Paul Murray[1], Catriona M. Dowling[2]

[1]School of Medicine, University of Limerick, Limerick, Ireland,[2]Department of Medicine, Royal College of Surgeons in Ireland, Dublin, Ireland,[3]Centre for Tumour Microenvironment, Barts Cancer Institute, Queen Mary University of London, London, United Kingdom,[4]Tissue Engineering Research Group, Department of Anatomy & Regenerative Medicine, Royal College of Surgeons in Ireland, Dublin, Ireland,[5]Beaumont Hospital, Dublin, Ireland

Non-small cell lung cancer (NSCLC) accounts for 80-85% of all lung cancers worldwide, with KRAS-driven NSCLC representing 30% of these cases. Although immunotherapy has improved outcomes in lung cancer, only 27-46% of patients respond initially to immune checkpoint inhibitors (ICIs). One cohort of patients that do not respond to such treatment include those with KRAS-driven NSCLC harbouring a co-mutation in the LKB1 gene (KL), who have significantly poorer responses to immunotherapy compared to those with a KRAS and TP53 co-mutation (KP). However, the reason for this difference in response to immunotherapy is largely unknown. Recent studies demonstrate that metabolic vulnerabilities in KL genotypes can influence therapeutic response. We aim to identify and target these vulnerabilities in KL NSCLC, with the aim to enhance response to immunotherapy. Using the cBioPortal mRNA database and publicly available patient protein data, we completed a bioinformatic analysis of key genes, proteins, and metabolites involved in major metabolic pathways. Lipid metabolism displayed significant differences between KP and KL genotypes, specifically β-oxidation and fatty acid synthesis. Following this, we conducted a drug screen using inhibitors targeting lipid metabolism. Fatty acid synthase (FASN) inhibitor, TVB-2640, showed the greatest efficacy in KL cells. Moreover, functional assays demonstrated reduced colony formation and migration following FASN inhibition in KL cells. Separately, we have successfully established novel 3D co-culture models of NSCLC cell lines and T-cells. This was achieved by embedding A549 NSCLC cells in a collagen gel matrix, with peripheral blood mononuclear cells (PBMCs) from patients with NSCLC enrolled on PLAN clinical trial (Trial ID: NCT05542485) added to the surrounding media. PBMCs were isolated, activated and expanded for 7 days using CD3, CD28 and IL-2. Following expansion, the T-cells were added to the A549 co-culture model for a further 4 days. These co-cultures were then paraffin embedded and stained using immunohistochemistry (IHC). Results demonstrated positive Ki67 staining and low cleaved caspase-3, indicating cell proliferation and minimal cell death. Moreover, IHC and flow cytometry analysis revealed 12% and 19% CD3 positive staining respectively, confirming successful T-cell infiltration in our co-culture model. In conclusion, we have identified fatty acid synthesis as a metabolic vulnerability in KL NSCLC. Targeting this pathway could be a potential therapeutic option for patients with this genotype of NSCLC. Moreover, we have developed a novel 3D co-culture model using NSCLC cells and patient T-cells. Further analysis, supported by our 3D co-culture model, aims to analyse the consequences of targeting fatty acid synthesis in combination with immunotherapy in the KL genotype of NSCLC.

#4736 Trace metal signatures in non-small cell lung cancer: A pilot study of patients attended at Mount Sinai Hospital in New York City.

Diddier Prada[1], Manish Arora[1], Julio landero[1], Jamshid Abdul Ghafar[1], Rachel Brody[2], Oscar Arrieta[3], Fred R. Hirsch[2]

[1]Icahn School of Medicine at Mount Sinai, New York, NY,[2]Mt. Sinai Medical Center Tisch Cancer Institute, New York, NY,[3]Instituto Nacional de Cancerologia (INCan), Mexico City, Mexico

Abstract Background: Non-small cell lung cancer (NSCLC) is increasing worldwide, yet the environmental and mechanistic contributors driving tumor development and aggressiveness remain poorly defined. Metals and trace elements—ubiquitously present in air pollution—can induce oxidative stress, potentially generating DNA damage that remodels tumor metabolism and promotes malignancy. We evaluated the feasibility of integrating metal profiling in malignant and normal NSCLC tissues and identified preliminary correlations between trace elements and malignancy status.
Methods: Ten OCT-embedded lung adenocarcinoma cases from an urban cohort of patients attended and biobanked at the Mount Sinai Biorepository underwent laser-capture microdissection to isolate paired tumor and adjacent normal tissue. Twenty-three metals and trace elements were quantified using Inductively Coupled Plasma Mass Spectrometry (ICP-MS) following nitric acid digestion. Logistic regression models (unadjusted due to sample size) were used to evaluate associations with tumor status. Linear regressions were used for tumor size.
Results: Tumor tissue demonstrated distinct metal signatures. Magnesium (Mg) and selenium (Se) were significantly enriched in tumors (Mg: Odds ratio [OR]=4.79, 95% Confidence Interval [95% CI]: 1.10-20.82; Se: OR=18.93, 95% CI: 1.48-242.44), while nickel (Ni) and zinc (Zn) showed positive trends toward tumor accumulation. Iron (Fe) was markedly higher in normal tissue. Additional analyses revealed inverse associations between tumor size and chromium (Cr; β = -1.34, 95%CI: -2.41, -0.27, p = 0.02*), manganese (Mn; β = -1.06, 95%CI: -2.32, 0.199, p = 0.09*), and cesium (Cs; β = -1.10, 95%CI: -2.16, -0.04, p = 0.04*).
Conclusions: Preliminary data demonstrate the feasibility of multiple metal and trace element quantification in NSCLC tissues, revealing potential specific perturbations associated with tumor presence and aggressiveness. The observed enrichment of Mg, Se, and Ni in tumors supports a potential mechanistic link between metal exposure, trace element imbalance, and malignant phenotypes, which may contribute to NSCLC tumorigenesis in urban populations. Ongoing analyses will integrate mitochondrial mtDNA heteroplasmy variants from these NSCLC samples to elucidate metal-mitochondrial interactions driving tumor biology.

#4737 Utilizing patient-derived organoid tumor models to combat chemo-immunotherapy resistance in NSCLC.

Manojavan Nagarajan[1], Chunjing Wu[2], Dao M. Nguyen[3], Estelamari Rodriguez[1], Emily Kim[4], Diane Lim[5], George Theodore[2], Irving Vidaurre[2], Wei Sha[2], Adeline Murphy[2], Jose Gomez[2], Durga Prasad Gannamedi Hinder[1], David Lombard[1], Lynn G. Feun[6], Niramol Savaraj[5], Medhi Wangpaichitr[5]

[1]Univ. of Miami/Sylvester Comprehensive Cancer Center, Miami, FL,[2]VA Medical Ctr., Miami, FL,[3]Associate Professor & Chief, Thoracic Onc., University of Miami, Miami, FL,[4]Wistar Institute, Miami, FL,[5]Univ. of Miami/VA Medical Ctr., Miami, FL,[6]Univ. of Miami Sylvester Comprehensive Cancer Ctr., Miami, FL

Immune checkpoint inhibitors (ICIs) have transformed the treatment landscape for non-small cell lung cancer (NSCLC), yet only a subset of patients achieves durable benefit due to primary and acquired resistance. We previously reported elevated kynurenine (KYN) in cisplatin-resistant NSCLC. KYN, produced by indoleamine 2,3-dioxygenase 1 (IDO1) and tryptophan 2,3-dioxygenase (TDO2), promotes immune evasion by diminishing $CD8^+$ T-cell responses and expanding regulatory T cells (Tregs). Clinical failure of selective IDO1 inhibition in cancer suggests compensatory TDO2 upregulation as one of the resistance mechanisms. To target redundant KYN production, we evaluated the efficacy of a dual IDO1/TDO2 inhibitor (AT-0174; Antido Therapeutics) in preclinical models of cisplatin-resistant NSCLC. Efficacy and mechanism were assessed in vivo via a syngeneic orthotopic mouse model. Dual inhibition significantly reduced tumor volume ($n=10$, $p<0.01$) and prolonged survival in the mouse model. These effects correlated with increased activity of $CD8^+$ T cells and natural killer (NK) cells, as well as reduced frequencies of immunosuppressive Tregs and myeloid-derived suppressor cells (MDSCs). Combining AT-0174 with anti-PD-1 therapy produced a synergistic effect, further suppressing tumor growth and significantly improving survival in mice (log-rank, $p=0.0001$). We then developed a patient-derived organoid tumor (PDOT) platform that closely recapitulates the molecular and metabolic features of each patient's NSCLC. Single-cell RNA sequencing demonstrated ~70% transcriptional similarity to original tumors, and metabolomic profiling confirmed comparable pathway activity. IDO1 protein was detected in all PDOTs. Co-culture with patient-matched PBMCs revealed that PDOTs with high baseline PD-L1 and kynurenine (KYN) expression were highly sensitive to dual IDO/TDO inhibition combined with pembrolizumab, resulting in increased immune cell infiltration ($n = 10$, $p < 0.005$). This microfluidic PDOT system enables functional, patient-specific assessment of KYN pathway reliance, supporting timely stratification of NSCLC patients and rational design of combination regimens integrating metabolic targeting with immune checkpoint inhibitors. These findings provide a strong rationale for clinical evaluation of dual IDO/TDO inhibitors alongside checkpoint blockade.

#4738 Pharmacological activation of PI3Kα triggers cancer cell death under metabolic stress.

Cancer cells maintain oncogenic signalling within a survival “fitness zone”. While conventional targetœed therapies suppress this signalling below a critical threshold, excessive activation of the same pathways can also be lethal to cell, an observation currently being explored as a novel therapeutic approach in cancer. In this study, we report that hyperactivation of PI3Kα, one of the most frequently oncogenically activated PI3K isoforms, using the small-molecule PI3Kα activator UCL-TRO-1938 (further referred to as 1938) induces cytotoxicity in cancer cell lines while sparing non-transformed cells. This PI3K activation-induced cell death (PI3K-AICD) depends on AKT/mTORC1 activity, only occurs under serum starvation and is enhanced by low O_2 levels. This hyperactivation lethality is mechanistically linked to an irreconcilable metabolic conflict by simultaneously activating anabolic PI3K/mTORC1 signalling in a catabolic (hypoxic) state, resulting in an unresolvable energy crisis and ultimately cell death. In serum-deprived lung cancer cell lines, 1938 induces a magnified endoplasmic reticulum stress response which, along with PI3K-AICD, can be mitigated by supplementation with unsaturated fatty acids, suggesting a critical metabolic dependency on lipid metabolism for driving this cell death response. Consequently, co-treatment with 1938 and inhibitors of stearoyl-CoA desaturase-1 (SCD1), an O_2-dependent enzyme essential for fatty acid desaturation, amplifies the PI3K-AICD response. In summary, these findings demonstrate that enhancing an oncogenic pathway central to metabolic control can selectively kill cancer cells.

#4739 Targeting PGK1 enhances enzalutamide efficacy in resistant prostate cancer.

Min Zhang, Ruixin Wang, Xiaoqi Liu

Toxicology and Cancer Biology, Univ. of Kentucky College of Medicine, Lexington, KY

Enzalutamide is a standard AR-targeting therapy for advanced prostate cancer (PCa), yet intrinsic and acquired resistance remain major barriers to durable response. To identify regulators of enzalutamide sensitivity, we performed a kinome-wide CRISPR-Cas9 knockout screen in the intrinsically resistant 22Rv1 cell line. Phosphoglycerate kinase 1 (PGK1), a key glycolytic enzyme, emerged as a top negatively selected gene, indicating that its loss increases enzalutamide susceptibility. PGK1 inhibition or genetic deletion reduced viability, colony formation, migration, and invasion in 22Rv1 cells, validating its role in maintaining the aggressive phenotype of resistant PCa. Bulk RNA-seq analysis of PGK1 knockdown cells revealed increased AR signaling pathway activity, suggesting compensatory AR reactivation following metabolic disruption. Combination MTT assays showed synergistic efficacy between PGK1 inhibition and enzalutamide, supporting a metabolic-hormonal interaction that enhances AR-directed therapy response. Mechanistically, Seahorse analysis demonstrated that PGK1 inhibition decreases glycolytic rate in resistant PCa cells, indicating impaired metabolic compensation as a potential mechanism of sensitization. Future work includes xenograft studies using 22Rv1 and LNCaP PDX models, ATP flux assays, mitochondrial stress test, lipid metabolism, and pathway-level analysis. These findings identify PGK1 as a metabolic vulnerability and highlight its therapeutic potential to overcome enzalutamide resistance in advanced prostate cancer.

#4740 Exploiting ketone body metabolism as a therapeutic vulnerability in prostate cancer.

Pablo Sanchis[1], Agustina Ayelen Sabater[2], Jiabin Dong[3], Peter Shepherd[3], Nicolas Anselmino[4], Paul G. Corn[3], Elba Vazquez[5], Christopher J. Logothetis[6], Daniel Frigo[3], Geraldine Gueron[5], Estefania Labanca[7]

[1]UT MD Anderson Cancer Center, Houston, TX, USA; CONICET-Universidad de Buenos Aires, Instituto de Quimica Biologica (IQUIBICEN), Argentina; Universidad Argentina de la Empresa (UADE), Instituto de Tecnologia (INTEC), Buenos Aires, Argentina,[2]UT MD Anderson Cancer Center; CONICET-Universidad de Buenos Aires, Instituto de Quimica Biologica (IQUIBICEN), Argentina; Universidad Argentina de la Empresa (UADE), Instituto de Tecnologia (INTEC), Buenos Aires, Argentina, Houston, TX,[3]UT MD Anderson Cancer Center, Houston, TX,[4]University of Buenos Aires, CABA, Argentina,[5]University of Buenos Aires, Buenos Aires, Argentina,[6]Chairman/Professor, Gu Med. Onc., UT MD Anderson Cancer Center, Houston, TX,[7]UT MD Anderson Cancer Ctr., Houston, TX

Prostate cancer (PCa) progression remains a major clinical challenge with limited therapeutic options, and the complexity of metabolic pathways fueling advanced PCa rests poorly understood. We have identified a shift from glycolysis to ketone body (KB) metabolism in castration-resistant PCa (CRPC), with an upregulation of ketolytic/ketogenic enzymes. From these, ACAT1 is a potential therapeutic candidate, as its expression is elevated in aggressive PCa and associates with unfavorable clinical outcomes. Here, we investigated the contribution of the bone niche -the dominant PCa metastatic site- to KB metabolism during PCa progression and evaluated ACAT1 inhibition as a treatment strategy for advanced disease. Co-culture experiments between PCa cells and bone progenitors (MC3T3, Raw264.7) were used to evaluate bone-driven metabolic adaptations. To validate *in vivo* the effect of the bone niche, we implanted MDA PCa patient-derived xenograft (PDX) 183 either intrafemorally (*i.f.*) or subcutaneously (*s.c.*) in sham or castrated CB17 SCID mice. We assessed cell viability in PCa cells lines and in PDX-derived organoids (PDX.DO), treated with increasing concentrations of ACAT1 inhibitor, arecoline hydrobromide (AH). ACAT1 and phospho-ACAT1 levels were measured by Western blot and immunofluorescence. Intracellular KB and ATP content were quantified by luciferase-based assays. Lipid uptake and accumulation were quantified by flow cytometry using Bodipy probes. *In vivo*, mice bearing MDA PCa PDXs 183, 203 and 173 were treated with AH (50 mg/kg/day i.p., 21 days). Tumor volume, KB content, and ACAT1 modulation were evaluated. We observed transcriptional activation of lipid and KB metabolism in PC3 cells from PCa-bone co-cultures, and consistently, in *i.f.* PDXs compared to matched *s.c.* tumors, alongside a significant increase in ACAT1 expression levels. Castration dynamically modulated ACAT1 levels in MDA PCa 183 tumors growing *i.f.*, with initial downregulation followed by restoration over time, underscoring KB metabolism as a mechanism of resistance within the bone niche. Functional studies showed that AH treatment reduced cell viability in PC3, C42B, and 22Rv1 cells, as well as PDX.DO, decreased ACAT1 and phospho-ACAT1 expression, lowered KB levels, and altered lipid dynamics by increasing lipid accumulation, uptake, and decreasing ATP content ($P<0.05$). *In vivo*, AH treatment in MDA PCa 183 tumors led to a significant reduction in tumor volume and intratumoral KB content ($P<0.05$). Moreover, in the CRPC model MDA PCa 203 -derived from a longitudinal sample of the same patient as 183-, and in the aggressive hormone-naïve model MDA PCa 173, AH treatment significantly reduced both tumor volume and KB content ($P<0.05$). In conclusion, our findings reveal KB metabolism as a critical vulnerability in PCa progression, with ACAT1 emerging as a druggable target whose inhibition disrupts tumor growth and metabolic fitness.

#4741 Loss of SIRT3 promotes metabolic and epigenetic dysregulation in aggressive prostate cancer.

Xiaochen Yu[1], Alphonse Nicholas Dimeck[1], Eriko Katsuta[1], Spencer Rosario[2], Mark Long[3], Song Liu[3], Kent Nastiuk[4], Hai Wang[5], Subhamoy Dasgupta[1]

[1]Department of Cell Stress Biology, Roswell Park Comprehensive Cancer Center, Buffalo, NY,[2]Department of Medicine, Roswell Park Comprehensive Cancer Center, Buffalo, NY,[3]Department of Biostatistics and Bioinformatics, Roswell Park Comprehensive Cancer Center, Buffalo, NY,[4]Department of Cancer Genetics & Genomics, Roswell Park Comprehensive Cancer Center, Buffalo, NY,[5]Department of Molecular & Cellular Biology, Roswell Park Comprehensive Cancer Center, Buffalo, NY

Prostate cancer is one of the leading causes of cancer-related deaths among men worldwide. Localized prostate tumors in certain patients relapse after surgery, radiation therapy or androgen deprivation therapy (ADT), leading to an aggressive metastatic recurrent disease. We recently found that in prostate cancer patients, SIRT3 (sirtuin 3) expression is significantly decreased in advanced metastatic disease compared to localized tumors. SIRT3 is a mitochondrial deacetylase that modulates the biochemical functions of its substrates by regulating their acetylation status. Restoration of SIRT3 levels in human and mouse prostate tumors reduced prostate cancer progression in both immune-deficient and immune competent animals. Transcriptomic profiling and targeted metabolomics analysis of bulk tumors revealed that SIRT3 regulates one-carbon metabolism pathway by controlling the levels of s-adenosyl methionine (SAM) pools. Mechanistic studies indicated that SIRT3 interacts with the rate limiting enzymes MAT1A and MAT2A that catalyze the conversion of methionine to SAM. Biochemical experiments indicated that SIRT3 deacetylates MAT1A/MAT2A which may contribute towards increased SAM synthesis. Additionally, we found that restoration of SIRT3 levels in prostate tumors increased macrophage reprogramming in the tumor microenvironment of the syngeneic mouse models. These findings provide rationale for our working hypothesis that SIRT3 may modulate prostate tumor-immune microenvironment by regulating one-carbon metabolism, and its loss accelerates lethal prostate cancer progression. Supported by NCI grants: R01CA285707 and R01CA252092 to S.D.

#4742 Investigating the crosstalk between metabolic reprogramming and epigenetic modifications in bone metastatic prostate cancer.

Madison Aust, Abbas Jawadwala, Ephraim Jeremiah Gardner, Surendra Gulla, Tej K. Sharma, Remi M. Adelaiye-Ogala

University at Buffalo, State University of New York, Buffalo, NY

Prostate cancer (PCa) is the second leading cause of cancer-related deaths in the United States. PCa is heavily influenced by the androgen receptor (AR). Throughout disease progression, AR overrides treatment efforts to promote proliferation and survival, often leading to metastatic disease, at which point the management of the disease becomes challenging. Approximately 80% of metastatic disease occurs in the bone, which is the most common site of PCa metastasis. Studies have shown that metabolic activity in the bone microenvironment is crucial, and metabolic reprogramming is required to support the functional requirements of cancer cells, such as continued proliferation. In PCa, increased lipid metabolism plasticity, dysregulation of glycolysis, and OXPHOS dysfunction are linked to worse prognosis. We have also learnt that reprogramming can influence, and be influenced by, epigenetic modification. We performed global proteomic and transcriptomic analyses across five patient-derived xenograft models established from patients with metastatic disease, revealing significant concordance in metabolic processes. Validation studies using Western blot confirmed our results from the mass spectrometry proteomic data. FASN and LDHA protein expression were consistent with gene expression. Next, we determined the implications of FASN inhibition on cell proliferation (live-cell imaging, Incucyte) and metabolism (Cell Titre Glo, which measures cell metabolism by quantifying adenosine triphosphate (ATP) present in all metabolically active cells) in the bone metastatic C4-2B cell line. We observed decreased proliferation. At the molecular level, we observed decreased expression of AR, ZEB1, LDHA, and EZH2. These observations were not observed in the LNCaP (non-bone metastatic model) cell line. Ongoing studies will provide more insight into the cross-talk between AR signaling, EZH2, and metabolic reprogramming in bone metastasis of prostate cancer.

#4743 Dual inhibition of PIKfyve and FASN reveals therapeutic potential in neuroendocrine prostate cancer.

Yang Zheng[1], Caleb Cheng[1], Yizhi Cao[1], Gabriel Cruz[1], Yuping Zhang[1], Radha Paturu[1], Somnath Mahapatra[1], Jing Hu[1], Rahul Mannan[1], Huseyin Karaburk[1], Rupam Bhattacharyya[1], Yitong Yin[1], Xuhong Cao[1], Hui Xue[2], Chungen Li[3], Zhen Wang[3], Stephanie Miner[1], Ulka N. Vaishampayan[1], Vaibhav Sahai[1], Lois S. Weisman[1], Ke Ding[3], Costas Andreas Lyssiotis[1], Yuzhuo Wang[2], Yuanyuan Qiao[1], Arul M. Chinnaiyan[1]

[1]University of Michigan, Ann Arbor, MI,[2]The University of British Columbia, Vancouver, BC, Canada,[3]Shanghai Institute of Organic Chemistry, Chinese Academy of Sciences, Shanghai, China

Background: Neuroendocrine prostate cancer (NEPC) is emerging rapidly as a resistance phenotype to androgen receptor pathway inhibitors in castration-resistant prostate cancer. NEPC persists in a profoundly hypoxic microenvironment, yet the mechanisms enabling tumor adaptation to this hostile niche remain largely undefined. We hypothesized that NEPC depends on stress-adaptive lysosomal programs mediated by the lipid kinase PIKfyve that can be targeted therapeutically.
Methods: PIKfyve expression was assessed by immunohistochemistry and RNA-ISH in clinical NEPC specimens. Functional studies used newly derived NEPC cell lines and established cell line (NCI-H660), and multiple NEPC PDX/CDX models. Pharmacologic and genetic perturbations of PIKfyve were evaluated *in vitro* and *in vivo*. Global transcriptomic, proteomic and lysosome-focused profiling were used to assess downstream responses. Combination studies explored the therapeutic impact of concurrently inhibiting PIKfyve and the lipogenic enzyme FASN. Cell death and pharmacodynamic endpoints included apoptotic markers and TUNEL staining.
Results: PIKfyve was consistently elevated in primary and metastatic NEPC and was required for tumor cell survival. Pharmacologic inhibition of PIKfyve led to robust antitumor activity across multiple NEPC models, producing marked apoptosis and sustained tumor regressions. Multi-omic analyses indicated that PIKfyve inhibition activated compensatory lipid metabolic programs, including increased reliance on FASN. Notably, concurrent inhibition of PIKfyve and FASN resulted in enhanced tumor cell death and superior antitumor efficacy *in vivo* compared with single agents.
Conclusions: NEPC exhibits a stress-associated metabolic dependency involving PIKfyve and adaptive lipogenic pathways. Co-targeting PIKfyve and FASN induces a potent therapeutic response in preclinical models, supporting further investigation of this combinatorial strategy as a promising approach for treating NEPC.

#4744 Metabolomic profiling of fresh and formalin-fixed paraffin-embedded samples reveals metabolome alterations in penile cancer.

Andres Enrique Hernandez-Gonzalez[1], Maria Sanchez-Vazquez[2], Luis Torres-Pena[3], Keren Valentin-Lopez[4], Carlos A. Rivera-Lopez[5], Brandon Torres-Rivera[6], Maria Marcos-Martinez[6], Antonio Puras-Baez[5], Nataliya Chorna[4], Magaly Martinez-Ferrer[2]

[1]Department of Pharmaceutical Sciences, University of Puerto Rico, Medical Sciences Campus, School of Pharmacy, San Juan, PR,[2]Division of Cancer Clinical & Translational Research, University of Puerto Rico, Comprehensive Cancer Center, San Juan, PR,[3]Department of Biology, University of Puerto Rico, Rio Piedras Campus, San Juan, PR,[4]Department of Biochemistry, University of Puerto Rico, Medical Sciences Campus, School of Medicine, San Juan, PR,[5]Department of Surgery, Urology Section, University of Puerto Rico, Medical Sciences Campus, School of Medicine, San Juan, Puerto Rico,[6]Department of Pathology, University of Puerto Rico, Medical Sciences Campus, School of Medicine, San Juan, PR

Penile squamous cell carcinoma represents a significant source of morbidity and mortality in Puerto Rico, with HPV-associated cases comprising 56% of cases. The link between clinical variables and metabolomic alterations has not been studied in penile cancer. This study aimed to characterize the non-targeted metabolomic profiles of fresh and formalin-fixed paraffin-embedded (FFPE) penile cancer samples to identify correlations with patient clinical variables: HPV infection status, tumor stage and tumor grade. In this study, 14 fresh and 37 FFPE penile cancer samples were processed for metabolomic analysis. HPV infection status was determined using INNO-Lipa HPV Genotyping and RHA kit HPV SPF10-LiPA25 kits. Sample aliquots were analyzed using GCMS/MS-TQ8050 equipment. Clinical variables were provided by the Departments of Pathology and Surgery. Filtering of raw data was conducted using AMDIS 32 and the NIST MS Spectrum database. Statistical analysis (T-test and Mann-Whitney test) of metabolomic profiles was done using MetaboAnalyst 6.0. Our study identified 52 metabolites in the fresh penile cancer sample cohort and 18 metabolites in the FFPE penile cancer sample cohort. The fresh sample cohort yielded eight metabolite classes: amino acids, sugar alcohols, fatty acids, carboxylic acids, nucleic acids, sterols, cofactor and vitamins, and others. The FFPE cohort yielded five metabolite classes: amino acids, sugar alcohols, fatty acids, carboxylic acids, and others. Statistical findings suggest that HPV infection status and tumor stage are significantly correlated with alterations in expression of several metabolites in both sample cohorts: isoleucine (p value = 0.011), homoserine (p-value = 0.0001), cysteine (p-value = 0.0385), glycolic acid (p-value = 0.0215), methylmalonic acid (p-value = 0.0475), malic acid (p-value = 0.0483) and heptanoic acid (p-value = 0.0461). Statistical findings found no significant correlation between tumor grade and metabolomic alterations. Our findings suggest that HPV infection status and tumor stage are associated with altered metabolomic pathways in penile cancer. Further understanding is needed to establish the clinical relevance of these altered metabolites and their potential role as novel metabolomic biomarkers or therapeutic targets to improve treatment outcomes for this disease.

#4745 Tumor-intrinsic Warburg effect as the driver and therapeutic target for cancer-associated cachexia in mouse models.

Shaozi Fu, **Vincent Pham**, Victoria Sanchez, Yaxing Nie, Kasie Liu, Chenhui He, Yu Luan, Lingtao Jin, Gang Huang

UT Health San Antonio, San Antonio, TX

Cancer-associated cachexia (CAC) is a multifactorial metabolic syndrome affecting 50-80% of patients with advanced malignancies and still lacks FDA-approved interventions. It manifests as progressive loss of body weight, depletion of adipose and skeletal muscle tissues, metabolic inflexibility, and anemia, collectively worsening prognosis and compromising responses to systemic therapy. Accumulating evidence indicates that tumor-intrinsic metabolic reprogramming can sustain aggressive tumor growth and drive systemic energy imbalance, yet the specific molecular events linking oncogenic programs to host peripheral wasting remain incompletely defined. To dissect this tumor-intrinsic axis, we established subcutaneous tumor models in C57BL/6 mice using isogenic KP lung cancer cells ($Kras^{G12D/+}$; $p53^{-/-}$), KPL cells carrying additional Lkb1 loss ($Kras^{G12D/+}$; $p53^{-/-}$; $Lkb1^{-/-}$), and B16F10 melanoma. KPL and B16F10 tumors induced a more severe cachectic phenotype than KP tumors, characterized by greater body weight decline, pronounced loss of adipose tissue and skeletal muscle, and more severe anemia. Thus, this KP/KPL isogenic tumor models provide us an opportunity to dissect the underlying mechanisms for CAC. First, we found that KPL tumors grew faster and relied more heavily on glycolytic metabolism than KP controls. Integrated proteomic and metabolomic profiling confirmed a shift toward aerobic glycolysis in KPL tumors, consistent with a strengthened Warburg effect. Follow-up experiments indicated that this metabolic shift was linked to LKB1 loss and heightened HIF activity. To test therapeutic relevance, we treated KPL- and B16F10-bearing mice with an FDA-approved HIF-2α inhibitor Belzutifan. Belzutifan reduced adipose and muscle loss, suggesting that dampening HIF signaling can lessen cancer-associated wasting, although anemia did not improve under this treatment, likely because systemic HIF-2α blockade reduces erythropoietin (EPO) production in these CAC mouse models. Collectively, our data identifies HIF-driven tumor-intrinsic Warburg effect as a central contributor to CAC in mouse models. Targeting HIF signaling can attenuate tumor-induced wasting and provides mechanistic proof-of-concept for metabolic reprogramming-directed CAC therapy although anemia issues remain. Moreover, our data indicated that rational combination regimens, such as co-administration of EPO, will be required to deliver full muscular, adipose, and hematologic rescue in CAC. These preclinical data warrant further investigation in patient-derived model systems, and eventually in clinical trials.

#4746 Downregulation of PDLIM2 promotes tumor growth through regulation of oncometabolites and HIF-1α pathway.

Tsung-Hsien Chuang[1], Jing-Xing Yang[2], Yu-Chen Chuang[2], Jen-Chih Tseng[2], Yi-Ling Liu[2], Chao-Yang Lai[3]

[1]Buddhist Tzu Chi Medical Foundation, Hualien Tzu Chi Hospital, Hualien, Taiwan,[2]National Health Research Institutes, Miaoli, Taiwan,[3]Asia University, Taichung, Taiwan

Cancer is increasingly recognized as a disease driven by dysregulated cellular metabolism, and elucidating the molecular mechanisms behind these metabolic alterations is essential for developing effective targeted therapies. In present study, we investigated the pro-tumorigenic role of PDLIM2 (PDZ and LIM domain 2) downregulation in lung cancer progression, with a particular focus on its impact on mitochondrial metabolism and hypoxia-inducible factor-1α (HIF-1α) signaling. Our analysis revealed that PDLIM2 expression is significantly downregulated in lung cancer tissues, and this reduction correlates with unfavorable patient prognosis. Transcriptomic profiling indicated that PDLIM2 regulates a network of genes associated with mitochondrial function. Mechanistically, PDLIM2 downregulation impaired the expression of tricarboxylic acid (TCA) cycle genes, notably those encoding succinate dehydrogenase (SDH) subunits. This disruption led to mitochondrial dysfunction, accumulation of succinate and other oncometabolites. These metabolic disturbances contributed to the stabilization and activation of HIF-1α, a transcription factor known to drive tumor progression under hypoxic conditions. Further studies indicated that HIF-1α expression is elevated across all stages of lung cancer, and its levels are inversely correlated with PDLIM2 expression in patient samples. To further validate this axis, we performed an in vivo study with cancer animal model using PX-478, an orally bioavailable HIF-1α inhibitor. Treatment with PX-478 significantly attenuated the tumor growth promoted by PDLIM2 knockdown, supporting the functional relevance of HIF-1α activation in mediating the oncogenic consequences of PDLIM2 loss. Collectively, these findings highlight a novel regulatory link between PDLIM2, mitochondrial metabolism, and HIF-1α signaling in lung cancer. They emphasize the tumor-promoting effects of PDLIM2 downregulation and suggest that therapeutic inhibition of HIF-1α may represent a promising precision strategy for patients with PDLIM2-deficient tumors.

#4747 Chronic E-cigarette aerosol exposure induces metabolic, translational, and immune reprogramming in mice: A serum proteomics analysis.

Rizwana Begum, Ganesan Muthusamy, Shreya Pokharel, Biplov Sapkota, Poorna Sai Vaddi, Shang SU, Abhishek Pandit, Naveen Chintala Ramulu, Joseph Francis

Louisiana State University, Baton Rouge, LA

Background: E-cigarette aerosol exposure has been associated with inflammation and oxidative stress; however, its systemic metabolic effects remain poorly understood. Because circulating serum proteins capture early physiological perturbations, we examined how chronic e-cigarette exposure alters metabolic, translational, and immune pathways using a controlled mouse model.
Methods: We subjected C57BL/6 mice to chronic exposure to e-cigarette aerosols for 10 weeks, with filtered-air controls. Serum samples were collected and analyzed through untargeted LC-MS/MS proteomics. Gene Set Enrichment Analysis (GSEA) was performed using GO, KEGG, Hallmark, and MSigDB immune signatures to identify pathway-level alterations in metabolism, redox biology, translational control, and immune signaling.
Results: Our findings reveal that chronic exposure to e-cigarette aerosols triggers metabolic reprogramming, marked by significant enrichment of pathways related to oxidative phosphorylation, fatty acid metabolism, pyruvate metabolism, vesicle trafficking, and detoxification of reactive oxygen species (ROS). We observed increased levels of redox-adaptive and glycolytic proteins (PKM, IDH1/2, NQO1, GSTM1/2, GSS), indicating a shift toward NADPH-driven antioxidant metabolism and mitochondrial remodeling, consistent with systemic metabolic stress. This metabolic shift was accompanied by strong translational reprogramming, including enrichment of ribonucleoprotein complex assembly and mRNA processing pathways. Increased expression of translation-associated factors, such as eIF4A2, further supported activation of an stress-responsive translational program. Immune analyses revealed selective enrichment of natural killer (NK) cell-associated pathways, indicating altered NK cell functional signatures following chronic e-cigarette exposure. This targeted shift in innate immunity is consistent with the observed metabolic and translational remodeling, as NK cell activity relies heavily on glycolytic and stress-adaptive translational programs.
Conclusion: Chronic e-cigarette exposure leads to interconnected changes in metabolic, translational, and immune processes in mice. The resultant shifts towards antioxidant and glycolytic pathways, stress-responsive translation, and altered immune signaling suggest that metabolic-immune crosstalk serves as an early systemic mechanism of vaping toxicity, warranting targeted validation through metabolic, translational, and immune profiling.

#4751 SOX4 upregulation contributes to ovarian cancer initiation through a stress-adaptation program.

Jayaprakash Mandal[1], Brielle Hayward Piatkovskyi[1], Md Masud Rana[2], Tu-Yung Chang[1], Tian-Li Wang[2], Ie-Ming Shih[1]

[1]Gynecology and Obstetrics, Johns Hopkins University School of Medicine, Baltimore, MD,[2]Pathology, Johns Hopkins University School of Medicine, Baltimore, MD

High-grade serous carcinoma (HGSC) is a clinically aggressive subtype of ovarian epithelial cancer, mainly because of late diagnosis and the development of therapy resistance. Our Ovarian Precancer Atlas study provides a molecular map of HGSC development, and one of our most exciting findings is the identification of a transcription factor, SOX4. SOX4 is a developmentally regulated transcription factor belonging to the SRY-related HMG-box family. It regulates cell fate, lineage determination, and differentiation. Our spatial transcriptomic and immunohistochemical analyses show an upregulation of SOX4 in HGSC and its precancerous lesion, STIC. However, the biological significance of this finding remains unclear. Spatial transcriptomics and Immunohistochemical analyses confirmed progressive SOX4 upregulation in STIC and HGSC tissues. siRNA-mediated SOX4 knockdown in fallopian tube epithelial (FT241, FT2821) and HGSC (UWB1.289 ± BRCA1) models reduced proliferation and colony formation, indicating that endogenous SOX4 is required for cell growth and survival. Conversely, acute SOX4 induction in doxycycline-inducible OVCAR8 models decreased proliferation, clonogenicity, and wound healing, while elevating ROS and ProteoStat-measured proteotoxic stress—indicating a SOX4-induced cellular stress environment. RNAseq analyses also revealed expression of genes involved in reprogramming and redox homeostasis. When the inducible cells were cultured continuously under doxycycline for approximately two months, they underwent stable phenotypic remodeling and regained proliferative fitness, paralleling the enhanced tumorigenicity observed in vivo. This suggests that chronic SOX4 activation drives a transition from an initial stress-induced to a stress-adapted proliferative state that enables malignant progression. Before this adaptive remodeling is complete, SOX4-high cells exhibited heightened vulnerability to ER stress and proteasome inhibition—revealing a stress-sensitized therapeutic window selectively targetable in SOX4-high tumors. SOX4-induced cells showed synergistic reduction in cell proliferation and apoptosis when combined with MG132 or Tunicamycin. This study reveals a new mechanism by which transformed cells exploit SOX4-induced proteomic stress and turn it to their advantage in tumor progression after overcoming a selection pressure. SOX4 induces an oxidative/proteotoxic stress state that temporarily hinders growth in vitro but promotes tumorigenicity in vivo through adaptive remodeling. This process highlights a time-limited, stress-sensitive therapeutic window—before full adaptation, during which ER and proteasome challenges are especially effective. These findings position SOX4 as both a mechanistic driver of stress adaptation in HGSC carcinogenesis and a biomarker to select HGSC patients for targeted stress-modulating therapies.

#4752 HMGA1: An epigenetic driver of colon carcinogenesis by inducing FGF19 signals which can be targeted with FGFR4 receptor blockade.

Yuze Du[1], Li Luo[2], Jung-Hyun Kim[3], Bailey West[4], Tatianna Larman[5], Leslie Cope[6], Eric R. Fearon[7], Cynthia Sears[8], Linda Resar[9]

[1]Molecular Microbiology and Immunology, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD,[2]Johns Hopkins University School of Medicine, Baltimore, MD,[3]Research Institute, National Cancer Center, Goyang-si, Gyeonggido, Korea, Republic of,[4]Pathobiology Graduate Program, Johns Hopkins University School of Medicine, Baltimore, MD,[5]Pat Gastrointestinal Liver Pathology, Johns Hopkins University School of Medicine, Baltimore, MD,[6]Onc Bioinformatics, Johns Hopkins University School of Medicine, Baltimore, MD,[7]Oncology, University of Michigan, Ann Arbor, MI,[8]DOM Infectious Disease, Johns Hopkins University School of Medicine, Baltimore, MD,[9]Hematology, Johns Hopkins University School of Medicine, Baltimore, MD

Advanced colorectal cancer (CRC) continues to be a significant healthcare burden with increasing incidence in younger patients, necessitating the development of novel targeted therapies. The gene encoding the High Mobility Group A1 (HMGA1) chromatin regulator is enriched in adult stem cells, including colon stem cells, and diverse tumors where high levels portend adverse clinical outcomes. Indeed, *HMGA1* is among the genes most highly overexpressed in CRC compared to nonmalignant colon epithelium. To define targetable mechanisms underlying HMGA1 in colon carcinogenesis, we performed gene expression studies (bulk, single cell RNA sequencing) and chromatin accessibility assays (ATACseq) in preclinical models and human tumors which unveiled the FGF19 growth factor as a downstream effector of HMGA1 in CRC. We had previously discovered that disrupting FGF19 signaling with the clinical inhibitor to the FGFR4 receptor (BLU9931) in KPC mouse models of pancreatic cancer and human orthotopic xenografts decreases pancreatic tumor and stroma formation while prolonging survival. In mice with intestinal epithelial cells harboring *Adenomatous polyposis coli* (Apc^{Min}) inactivation, we found that *Hmga1* is induced following inoculation with enterotoxigenic *Bacteroides fragilis* (ETBF), a common oncogenic bacterium in humans with CRC. In this model, ETBF inoculation results in robust distal colon tumorigenesis and HMGA1-dependent amplification of Wnt signaling. HMGA1 also activates murine *FGF19* (*Fgf15*) expression. Strikingly, in human CRC tumors, *HMGA1* and *FGF19* are also up-regulated and positively correlated (r=0.71, $P<0.00001$; TCGA). Further, silencing *HMGA1* in human CRC cell lines (SW620) represses *FGF19* expression. By ATACseq in mouse colon crypt cells with *Apc* inactivation, HMGA1 enhances chromatin accessibility at the murine *Fgf15* locus ($P<0.001$), suggesting that HMGA1 opens chromatin to activate *Fgf15* expression. We therefore tested whether FGFR4 inhibition has anti-tumor efficacy in CRC by treating human CRC cells (SW620) with BLU9931. FGFR4 blockade disrupts clonogenicity in a dose-dependent fashion, recapitulating effects of *HMGA1* silencing. Together, these data illuminate the HMGA1-FGF19 axis as a novel epigenetic pathway driving colon carcinogenesis and a promising therapeutic target.

#4753 The SOX2-RUNX2/TEAD4 signaling axis drives ESCC progression and exposes therapeutic vulnerabilities via Hippo/MAPK pathways.

Shangwei Sun[1], Yixiao Li[1], Yating Xu[1], **Jin Zhou**[1], Adam Bass[2], ZHONG WU[1]

[1]West China Hospital of Sichuan University, Chengdu City, China,[2]Gastrointestinal Oncology Service, Department of Medicine, Memorial Sloan Kettering Cancer Center, New York, NY

SOX2 has been identified as a frequent genomic amplification and potent oncogenic driver in esophageal squamous cell carcinoma (ESCC). We previously generated an ESCC organoid model based on *Trp53*/*Cdkn2a* knockout and *Sox2* overexpression, and subsequently demonstrated the critical epigenetic and transcriptional functions of SOX2 during ESCC development. However, effectively targeting *SOX2*-driven ESCC remains challenging. To define the transcriptional and epigenomic mechanisms downstream of SOX2 and identify targetable vulnerabilities, we profiled our ESCC organoid model and human ESCC cell lines with SOX2 overexpression via RNA-seq, ATAC-seq, SOX2 ChIP-seq, and H3K27ac ChIP-seq. Our findings show that SOX2 upregulates RUNX2 by forming super-enhancers at its cis-regulatory elements. This RUNX2 protein then functions as a cofactor, binding directly to SOX2. By integrating RUNX2 ChIP-seq data with the above multi-omic profiles, we revealed that SOX2 and RUNX2 co-regulate a broad spectrum of oncogenic pathways, among which the Hippo pathway was prominently enriched. Multi-omic analyses revealed that SOX2 and RUNX2 are significantly enriched at the cis-regulatory elements of key Hippo pathway genes—such as *YAP1*, *TEAD4*, *CTGF*, and *CYR61*—and cooperatively regulate their expression. We found that TEAD4, a key Hippo pathway transcription factor, also interacts directly with SOX2. It notably co-occupied SOX2-established super-enhancers, leading to the upregulation of the downstream MAPK pathway. Furthermore, in human ESCC cell lines, SOX2 knockdown downregulated RUNX2, TEAD4, and their downstream targets. Consistently, silencing RUNX2 or TEAD4 suppressed the corresponding Hippo and MAPK signaling pathways. Collectively, these findings uncover a critical role for the SOX2-RUNX2/TEAD4-Hippo/MAPK signaling axis in SOX2-driven ESCC development. Therefore, we evaluated the therapeutic efficacy of the MEK inhibitor trametinib, the TEAD4 inhibitor IAG933, and the BRD4 inhibitor JQ1 using both organoid and cell line models. These agents significantly suppressed ESCC proliferation in vitro and in vivo. Notably, combinatorial treatment strategies demonstrated synergistic effects, resulting in enhanced cytotoxicity. In conclusion, our study uncovers a novel epigenetic mechanism driving *SOX2*-amplified ESCC and identifies the SOX2-RUNX2/TEAD4 axis as a promising therapeutic target. These findings provide a strong preclinical rationale for evaluating therapeutic strategies targeting this axis in clinical trials for patients with this aggressive malignancy.

#4754 ADT-induced stress elevates CDKN2AIP to promote neuroendocrine prostate cancer.

Benjamin Chen[1], Pranabananda Dutta[2], Jerry Salinas[3], Ali Andalibi[4], Kamrul Hasan[5]

[1]Cornell University, Ithaca, NY,[2]Charles R. Drew University of Medicine & Science, Los Angeles, CA,[3]California State University, Dominguez Hills, Dominguez Hills, CA,[4]Office of the Provost, Charles R. Drew University of Medicine & Science, Los Angeles, CA,[5]Internal Medicine, Charles R. Drew University of Medicine & Science, Los Angeles, CA

Approximately 80-90% of prostate cancers (PC) initially depend on androgen signaling for growth, making androgen deprivation therapy (ADT) the standard first-line treatment. However, chronic ADT imposes metabolic and oxidative stress that drives therapeutic resistance and progression to castration-resistant prostate cancer (CRPC). A subset of CRPC tumors further acquires a neuroendocrine (NE) phenotype, leading to the development of neuroendocrine prostate cancer (NEPC), an aggressive, therapy-refractory disease with no effective treatment options. Understanding the molecular mechanisms and identifying key drivers of this phenotypic transition are therefore critical. Analysis of NEPC patient datasets revealed elevated expression of CARF (CDKN2AIP), a stress-responsive RNA regulatory factor whose role in lineage plasticity is unknown. Using an ADT-conditioned LNCaP model, we observed upregulation of CARF together with NEPC-associated regulators SIRT1, CHGA, SYP, and c-MYC, as shown by immunostaining, immunoblotting, and RT-qPCR. Silencing CARF via shRNA significantly reduced the expression of these NE markers, indicating that CARF is required to sustain their induction under ADT. Mechanistically, exposure to H_2O_2-induced oxidative stress increased CARF and SIRT1 expression, suggesting that ADT-associated oxidative stress upregulates CARF and contributes to NEPC development. We further found that ADT increased the expression of the splicing regulator SRSF3, while CARF knockdown suppressed SRSF3, implicating CARF in an alternative splicing pathway that facilitates NE lineage reprogramming.Overall, these findings identify a CARF-SRSF3 signaling axis that integrates oxidative stress and RNA regulation to promote neuroendocrine differentiation in prostate cancer. This pathway represents a potential therapeutic target for preventing or reversing NE transdifferentiation and treatment resistance in advanced disease.

#4755 Novel SOX2-targeting bioPROTACs as multi-faceted anti-tumor agents overcoming resistance to standard therapies in lung cancers.

Yeryoung Yong, Saeyi Lim, Hyerin Song, Yuna Jeon, Kiyoung Choi, Seunghyun Lee, **Jaehyun Choi**

Genexine, Inc., Seoul, Korea, Republic of

SOX2 is one of the pluripotency transcription factors and has been well-known for its crucial role in tumor development through promoting cancer cell survival, metastasis, stemness, and drug resistance. Numerous studies have reported the overexpression of SOX2 in various tumor tissues, such as ovarian, esophageal, and head and neck cancers, and demonstrated an associated poor prognosis. Thus, SOX2 has emerged as a therapeutic target for anti-tumor agents, but directly targeting SOX2 has been proven to be difficult since SOX2 is an “undruggable” transcription factor. Here, we show the versatile anti-tumor efficacy of our SOX2 bioPROTACs as first-in-class SOX2 degraders. Our SOX2 bioPROTACs are composed of a nanobody against SOX2 with high affinity and modified E3 ligases with deletion of natural substrate binding domain, which in turn achieve highly selective degradation of SOX2 protein. First, we validated the potent SOX2 protein degradation and therapeutic efficacy of SOX2 bioPROTACs in lung squamous cell carcinoma (LUSC) cells, which present difficulties for targeted therapy due to the lack of common oncogenic driver mutations. Given that SOX2 is amplified in about 40% of LUSC patients, our SOX2 bioPROTACs offer a promising alternative for patients currently lacking effective therapeutic options. In addition, we confirmed SOX2 overexpression in several chemo-resistant cell lines, and subsequently demonstrated that SOX2 bioPROTACs exhibit synergistic efficacy in combination with chemotherapy via SOX2 degradation. We also verified remarkable tumor growth inhibition in chemo-resistant patient-derived xenograft models upon co-treatment with SOX2 bioPROTACs and chemotherapy, thereby firmly establishing their potential to bypass existing drug resistance. Notably, diverse EGFR-TKIs induced elevated SOX2 levels in EGFR-mutant lung cancer cells and we found that the combination of SOX2 bioPROTACs and EGFR-TKIs resulted in a significant improvement in therapeutic efficacy compared to EGFR-TKI alone. Furthermore, the induction level of SOX2 by EGFR-TKIs was much higher than that of ADC targets, such as TROP2, HER2, or MET, which are actively being developed for combination therapy to overcome EGFR-TKI resistance. This suggests the potential superiority of our SOX2 bioPROTACs as a combination partner for EGFR-TKIs. Finally, we developed the clinically applicable drug product by utilizing a lung-targeted lipid nanoparticle (LNP), and confirmed its potent anti-tumor efficacy upon intravenous injection into an orthotopic lung cancer model. Taken together, our novel SOX2 bioPROTACs exert superior anti-tumor efficacy through multi-faceted mechanisms, positioning them as optimal therapeutic candidates for patients who face challenges in treatment due to the limitations of existing therapies.

#4756 Evaluation of strategies to target the Myc oncogene.

Maria Ahn, Aimee Blair, Juan Bueren-Calabuig, Barbara Farkas, Charlotte Hodson, John Lyons, Stanislava Panova, **Mark Wade**, George Ward, Alison Woolford

Astex Pharmaceuticals, Cambridge, United Kingdom

Aim: Myc overexpression or dysregulation is a hallmark of most malignancies, yet targeting of Myc-driven cancers remains a clinically unmet need[1]. Both indirect and direct modalities of Myc inhibition have been evaluated. Indirect Myc targeting via inhibition of its binding to partner proteins is challenging due to issues around redundancy and patient selection. Furthermore, antisense and other epigenetic approaches have so far failed. While direct targeting is challenging due to the intrinsically disordered nature of Myc[2], peptides/miniproteins, such as OmoMYC[3] (which essentially prevent the interaction of Myc with its obligate heterodimeric binding partner, Max) are being tested in the clinic. It is currently unclear whether a small molecule approach for Myc inhibition will be feasible. Here, we used biophysical, biochemical and functional assays to test published tool compounds that are reported to target Myc. Based on publicly available data, we also present strategies for selection of patients with Myc-driven cancer.
Methods: Commercially available Myc targeting compounds were tested in direct Myc:Max binding assays using NMR. OmoMYC was synthesized and purified by Peak Proteins. An HTRF DNA binding assay was developed to investigate functional binding of recombinant Myc:Max complexes to DNA using consensus E-Box or control oligonucleotides. Myc and Max have been overexpressed in HEK293T cell lines to generate cell lysates for biochemical testing.
Results: Compounds reported to directly inhibit Myc did not bind to the MYC/MAX heterodimer in our assays. We confirmed the ability of OmoMYC to displace Myc binding to the canonical E-box sequence in biochemical assays and in cell lysates. We also identified biomarkers that are predictive of increased sensitivity to genetic inhibition of Myc, which may facilitate patient selection strategies.
Conclusion: Early data from clinical trials with OmoMYC suggest that direct targeting of Myc is feasible. Small molecule inhibition of Myc would offer distinct pharmacological advantages and is, therefore, a first-in-class opportunity. A significant improvement in the affinity of Myc-targeting small molecules will be required to fully validate its potential as an oncology target.

#4757 *CREBBP* drives tumorigenicity via aberrant IL-1α signaling in *EP300* altered bladder cancer.

James August Rodrigues[1], Hikmat A. Al-Ahmadie[1], Sizhi P. Gao[1], Jiaqian Luo[1], Jacob Tallman[1], Fengshen Kuo[1], Merve Basar[1], Cansu Yol[1], Jordan Eichholz[1], Alejandra Lopez Rojas[1], Ecenur Turkay[1], Jonathan E. Rosenberg[1], Gopa Iyer[2], Eugene J. Pietzak[1], Dan Li[1], Dana Schoeps[1], Shipra Shukla[1], Zoe Jacobs[1], Chen Khuan Wong[1], Woo Hyun Cho[1], Ping Chi[1], David B. Solit[1], Yu Chen[1]

[1]Memorial Sloan Kettering Cancer Center, New York, NY,[2]Clinical Instructor, Medical Oncology, Memorial Sloan Kettering Cancer Center, New York, NY

EP300 and *CREBBP* encode p300 and CBP respectively, which are H3K27 acetylases. Both *EP300* and *CREBBP* mutated in a subset of urothelial cancers (~15% for *EP300* or *CREBBP*). The *EP300* and *CREBBP* genes have ~60% sequence similarity and thus have been presumed to have largely overlapping functional roles in cell homeostasis and cancer pathogenesis. To characterize the role of *EP300* mutations in urothelial cancer pathogenesis and to identify non-redundant roles of these paralogues, we generated *EP300* and *CREBBP* isogenic knockout urothelial cancer cell lines and characterized low passage mutant and wild type for *EP300* and *CREBBP* urothelial cancer-derived patient derived organoids. *EP300* KO and loss-of-function mutation was associated with enhanced cell growth in soft agar, increased invasive potential *in vitro* and altered cellular metabolism. These gain-of-function phenotypes were mediated by enhanced JAK-STAT3 activation resulting from IL-6 trans-signaling, the proximal driver of which was increased transcription and production of IL-1á. Notably, isogenic BLCA cells with *CREBBP* knockout did not confer IL-1á hypersecretion or hyperactivation of the IL-6/JAK1/STAT3 signaling axis indicating that this is a phenomenon was specific to *EP300* loss-of-function. Transcriptomic analysis of Parental, EP300 KO, and CREBBP KO RT112 clones revealed that *CREBBP* KO significantly depressed *IL1A* transcript levels which *EP300* KO significantly elevated. Additionally, *CREBBP* inactivated BLCA lines could not upregulate *IL1A* expression following genotoxic stress in contrast to parental and *EP300* null cell lines. Using an inducible short hairpin RNA construct targeting *CREBBP*, we also find that *CREBBP* knockdown rescued *IL1A* upregulation in *EP300* ko clones that coincided with a significant growth defect. Pharmacologic inhibition via the p300/CBP specific inhibitor A485 also abolished *IL1A* upregulation and caused significant growth defect in *EP300* KO cells. *EP300* null clones were also significantly more sensitive to A485 treatment than either *CREBBP* null urothelial cell or parental cell lines. In sum, our results identify regulation of IL-1á-JAK-STAT3 signaling as a novel non-redundancy between *EP300* and *CREBBP* that could be exploited therapeutically in patient with *EP300* loss-of-function mutations.

#4758 MYC-BCL6 state transition drives metabolomic cycling and leukemia-initiating capacity in B-ALL.

Zhangliang Cheng[1], Ruoyi Shi[1], Kohei Kume[1], Mark Robinson[1], Richard Kim[1], Kadriye Nehir Cosgun[1], Yujin Bao[2], Siyi Chen[3], Mina Xu[4], Joerg Bewersdorf[5], Markus Muschen[1]

[1]Center of Molecular and Cellular Oncology and Department of Immunobiology, Yale School of Medicine, New Haven, CT,[2]Department of Physics and Department of Cell Biology, Yale School of Medicine, New Haven, CT,[3]Department of Immunobiology, Yale School of Medicine, New Haven, CT,[4]Department of Pathology, Yale School of Medicine, New Haven, CT,[5]Department of Cell Biology, Yale School of Medicine, New Haven, CT

Background and significance: Stemness in AML is defined by a rare leukemia-initiating cell (LIC) population, but analogous LICs in B-ALL have remained elusive (Kelly 2007, Le Viseur 2008, Rehe 2013). Given that LICs in AML are drug-resistant and initiate relapses, identifying an LIC population in B-ALL would be consequential.
Results: Time-lapse studies of patient-derived B-ALL cells revealed that most B-ALL cells were continuously proliferating, while subpopulations underwent periodic transitions between quiescent and proliferative states. Gene expression studies identified MYC as the top-ranking gene in 'proliferative' and BCL6 in 'quiescent' B-ALL cells. To dissect MYC-BCL6 dynamics, we knocked in dual reporters with mNeonGreen fused to MYC and mScarlet fused to BCL6 in patient-derived B-ALL (PDX). Time-lapse imaging revealed proliferative cells expressed MYC with no detectable BCL6, whereas PDX also included 'alternating' cells that underwent repeated transitions between MYC+ BCL6– and MYC– BCL6+ states. Approximately 30% of BCR-ABL1 B-ALL and >50% of RAS-pathway B-ALL consisted of 'alternating' cells. Transitions occurred independently of the ~36-hour cell-division cycle, with ~3-hour MYC phases and ~6-hour BCL6 phases. Integrated ChIP-seq, RNA-seq, and metabolomics showed that MYC-high cells are much larger and activate glycolysis and protein-synthesis programs, whereas BCL6-high cells are small and enriched for phosphatidylethanolamine (PtdEtn) synthesis, essential for autophagosome formation. To directly link MYC-BCL6 dynamics with growth, we combined quantitative phase microscopy and time-lapse fluorescence to measure single-cell dry mass. MYC-high cells accumulated biomass at twice the rate of BCL6-high cells (0.018 vs 0.009 pg/min), producing stepwise trajectories aligned with each MYC/BCL6 state transition. To experimentally induce transitions, we engineered PDX with MYC-dTAG knock-in alleles and employed the BCL6 PROTAC ARV-393. Acute MYC degradation caused rapid shrinkage and reduced dry mass, whereas BCL6 degradation decreased autophagy and increased biomass, confirming opposing MYC-driven anabolic and BCL6-driven catabolic programs. To functionally study 'steady' (MYC-only) and 'alternating' (MYC/BCL6) B-ALL populations, we developed a cell-sorting strategy that enriched each of the two populations to a purity of 85% as confirmed by subsequent time-lapse imaging. Extreme limiting dilution and series transplantation experiments revealed MYC-BCL6 alternating B-ALL cells significantly enriched for LIC (1 in 124) compared to MYC-only population (1 in 574) and initiated fatal leukemia after short latency.
Conclusion: These findings reveal a MYC-BCL6 state-transition program in B-ALL that coordinates quiescence-proliferation cycling, anabolic-catabolic metabolism, and leukemia-initiating potential.

#4759 NELFE and SMARCB1 cooperate to regulate chromatin accessibility and allow MYC-driven gene activation in hepatocellular carcinoma.

Alvaro Lucci, Anna E. Barry, Laura M. Reynolds, Brittany N. Ruiz, Trish Nguyen, Pongsakorn Choochuen, Kai Zhang, Hien T. Dang

Department of Surgery, Thomas Jefferson University, Philadelphia, PA

Liver cancer is a serious and growing problem in the United States, with cases having more than tripled since 1980. Although there have been some advances in diagnosis and treatment, the five-year survival rate remains below 20%. Hepatocellular carcinoma (HCC), the most common type of liver cancer, often involves aberrant activation of the MYC gene, which helps cancer cells grow and survive. Unfortunately, MYC is very difficult to target directly with drugs. As such, researchers are interested in understanding proteins that control or support MYC's activity. One such protein is NELFE, which regulates gene expression by regulating how genes are turned on and off. We believe NELFE is important because it helps MYC access and activate its target genes, promoting cancer growth. To study this, we used CRISPR/Cas9 to remove NELFE from liver cancer cells and performed ATAC-seq and ChIP-seq experiments to see how this affected MYC and the structure of DNA. We found that without NELFE, the DNA became less accessible, and MYC was less able to bind near important genes. However, NELFE does not directly bind to these MYC sites, suggesting it works together with another protein. Mass spectrometry of NELFE identified SMARCB1, a component of the SWI/SNF chromatin remodeling complex, as a major interacting partner that links NELFE to MYC. Although SMARCB1 is widely known as a tumor suppressor in many cancers, in our liver cancer system, it appears to act as an oncogene, promoting cancer growth. We also showed that NELFE and SMARCB1 form special phase-separated structures in cells that help organize DNA, influencing both paused and non-paused genes. These structures keep the chromatin open, allowing MYC to be more active and interact with its target genes. Moreover, when NELFE is missing, SMARCB1 and MYC cannot interact properly, leading to reduced gene activation by MYC. In summary, NELFE helps MYC promote liver cancer by working with SMARCB1 to change how DNA is organized. Understanding this relationship could lead to new treatments for liver cancers that depend on MYC.

#4760 Uncovering a highly transforming, Myc-stabilizing isoform of dipeptidase-1 in colorectal cancer.

Elizabeth Grace Fisher[1], Sarah E. Glass[2], Chelsie K. Sievers[2], Zheng Cao[2], Matthew E. Bechard[3], Samuel T. Ellis[3], Radhika Aramnadla[3], Ping Zhao[2], Ryan T. Smith[2], Yu Wang[4], James N. Higginbotham[3], Frank Revetta[5], M. Kay Washington[5], Martha J. Shrubsole[6], Qi Liu[7], Ken S. Lau[8], Bruce Aronow[9], Robert J. Coffey[2]

[1]Cancer Biology Program, Vanderbilt University School of Medicine, Nashville, TN,[2]Department of Medicine, Vanderbilt University Medical Center, Nashville, TN,[3]Epithelial Biology Center, Vanderbilt University Medical Center, Nashville, TN,[4]Department of Biostatistics, Vanderbilt University Medical Center, Nashville, TN,[5]Department of Pathology, Microbiology, and Immunology, Vanderbilt University Medical Center, Nashville, TN,[6]Division of Epidemiology, Vanderbilt Epidemiology Center, Nashville, TN,[7]Center for Quantitative Sciences, Vanderbilt University Medical Center, Nashville, TN,[8]Center for Computational Systems Biology, Vanderbilt University, Nashville, TN,[9]Department of Biomedical Informatics, University of Cincinnati, Cincinnati, OH

Protein isoforms play significant roles in cancer progression as they can impact localization, binding partners, and functions, especially when it comes to pro-tumorigenic properties. One protein in particular, dipeptidase-1 (DPEP1), was identified 25 years ago as a cell-surface protein upregulated in adenomas and colorectal cancers (CRCs) in comparison to normal colonic tissue. We have found that a diffuse staining pattern of DPEP1, not a cell-surface localization, leads to worse overall and progression-free survival for CRC patients. Spurred by the inconsistency of an intracellular DPEP1 staining pattern for a cell surface protein, we discovered two isoforms of DPEP1 that differ in their C-terminal sequence. This difference reflects an absence of a glycosylphosphatidylinositol anchorage signal sequence in a novel, undescribed isoform of DPEP1, that we have termed DPEP1 Isoform B. We found expression of DPEP1 Isoform B in CRC patient tissue samples which, upon immunohistochemical staining, revealed an intracellular localization of DPEP1 in cells. DPEP1 Isoform B expression transforms a non-tumorigenic cell line to form large, invasive tumors in nude mice and upregulates pro-tumorigenic gene programs including Myc targets, epithelial-to-mesenchymal transition, and angiogenesis as identified by RNA-seq. Surprisingly, in a CRC cell line, we find that DPEP1 Isoform B binds to Myc, increasing its half-life 2-fold. Utilizing TCGA data sets, we deployed a strategy to examine long transcripts and found that DPEP1 Isoform B was present in 91% of CRC patients, with 28% of patients having high expression of DPEP1 Isoform B. To contrast, DPEP1 Isoform A was present in 68% of CRC patients, having high expression in 26% of patients. Overall, our work demonstrates the discovery of a novel isoform of DPEP1, which given its high incidence in CRC, warrants further investigation as a predicative biomarker as well as a novel therapeutic target.

#4761 Investigation of the role of N-MYC in lung neuroendocrine carcinoma.

Hiroki Yamamoto[1], Takashi Sato[1], Yuri Yagami[1], Ryosuke Inoue[1], Hiromi Matsuo[1], Hideo Watanabe[2], Naoki Katsuhiko[1]

[1]Kitasato University School of Medicine, Sagamihara, Japan,[2]Division of Pulmonary, Critical Care and Sleep Medicine, Department of Medicine, Icahn School of Medicine at Mount Sinai, New York, NY

Small cell lung cancer and large cell neuroendocrine carcinoma are classified as high-grade neuroendocrine tumors of the lung, representing extremely aggressive, life-threatening cancers with limited treatment options among various lung cancers. In these cancers, amplification of MYC family transcription factors: c-MYC, L-MYC and N-MYC is found to be mutually exclusive and overall account for ~20%. In addition, recent studies have reported that L-MYC and c-MYC control lineage plasticity across molecular subtypes of small cell lung cancer defined by lineage-specific transcription factors such as ASCL-1 and NEUROD-1. Compared with L-MYC and c-MYC, the role of N-MYC, a lineage factor highly expressed in several tumors derived from neural cell lineages and a subset of neuroendocrine lung cancers, have not been described clearly. In this study, we aimed to investigate the role of N-MYC as a lineage-specific factors in neuroendocrine lung cancers. First, we investigated N-MYC binding profiles in N-MYC-high neuroendocrine lung cancer cell lines and found that genes related to neural cell differentiation were enriched in genes near N-MYC bound regions. Next, examination of genome-wide Myc-accessible regions in neuroendocrine lung cancer cell lines revealed that a fraction of peaks that overlapped between N-MYC- and c-MYC-classified cells, suggesting common functional binding of N-MYC and c-MYC. When we overexpressed N-MYC in L-MYC- or c-MYC-classified cells, expression profiles of the neuroendocrine lineage factors did not change, which was different from the previous findings on the relationships between L-MYC and c-MYC. Our findings suggest that N-MYC regulates distinct transcriptional program among the MYC family members although N-MYC and c-MYC share common binding profile.

#4762 KIF11 regulates EWS-FLI1 and EWS-ATF1 target gene expression in Ewing and clear cell sarcomas.

Hannah Louise Walker-Mimms, Nicole Londono, Neelkamal Chaudhary, David Bean, Yi Liao, Lancia N.F. Darville, Jose Serrano-Velez, Yalin Liao, Jiqiang Yao, Andrew Smith, Fumi Kinose, Xueli Li, Joseph O. Johnson, Smitha R. Pillai, Eric B. Haura, Mingxiang Teng, Uwe Rix, Derek R. Duckett

Moffitt Cancer Center, Tampa, FL

Clear Cell Sarcoma (CCS) and Ewing Sarcoma (ES) have a poor 5-year survival rate and lack targeted therapies. The cancers are driven by aberrant fusion proteins generated through chromosomal translocations, EWS-FLI1 (ES) and EWS-ATF1 (CCS). These fusion proteins activate and repress target genes by targeting enhancers located on the distal intergenic sites, thereby driving the survival and proliferation of ES and CCS. Direct pharmacological targeting of these fusion proteins has been difficult due to their highly disordered structure. Therefore, we sought to identify alternative targets essential to EWS-FLI1 and EWS-ATF1 driven tumor cells. Using a small molecule library screen, we identified that KIF11 inhibitors selectively reduce the viability of ES and CCS cells. Investigating the underlying mechanism of action revealed that the KIF11 inhibitor, filanesib, induces G2/M arrest in ES and CCS cells. This result was translatable in CCS *in vivo* and in relapse-resistant metastatic ES PDXs *in vivo*. Interestingly, we observed that KIF11 interacted with the fusion proteins specifically during mitosis in both ES and CCS. Furthermore, knockdown of KIF11 results in the loss of the EWS-ATF1 fusion protein globally and visually during mitosis. KIF11 knockdown leads to a significant reduction in chromatin accessibility at many of the fusion proteins' target distal intergenic sites as measured with ATAC-Seq. While the relationship between KIF11 and the fusion proteins remains to be fully explored, our data suggest that KIF11 is essential in maintaining the fusion proteins' ability to target their downstream genes during mitosis. We aim to further elucidate why the fusion proteins in ES and CCS remain bound to target genes during mitosis. Furthermore, based on these findings, we are focused on developing KIF11 degraders to further improve the efficacy of targeting KIF11 in ES and CCS. This work has been supported in part by the Flow Cytometry, Analytical Microscopy, Biostatistics and Bioinformatics, Proteomics and Metabolomics, and Molecular Genomics Cores as well as the Nikon Center for Excellence at the H. Lee Moffitt Cancer Center & Research Institute, a comprehensive cancer center designated by the National Cancer Institute and funded in part by Moffitt's Cancer Center Support Grant (P30-CA076292)

#4763 Alternative splicing of ABI1 by enzalutamide treatment drives tumor plasticity in prostate cancer.

Kevin M. Lin[1], Anna Seidl[1], Tanner Waldman[1], Xiang Li[1], Eva Corey[2], Adam G. Sowalsky[3], Leszek Kotula[1]

[1]Urology; Biochemistry and Molecular Biology, SUNY Upstate Medical University, Syracuse, NY,[2]University of Washington, Seattle, WA,[3]National Cancer Institute, Bethesda, MD

Prostate cancer affects nearly 1.4 million new patients each year and is the second leading cause of cancer-related deaths. While initial stages of disease are driven by androgen receptor (AR) signaling and treatable with androgen-depravation therapies (ADT) and androgen receptor pathway inhibitors (ARPIs), tumors frequently recur with resistance to these therapies. The development of resistance is driven by tumor plasticity in which mutations, epigenetic changes, and alternative splicing generate phenotypic alterations that allow for adaptations to circumvent AR inhibition.Recent studies have shown that treatment with second generation ARPIs such as enzalutamide may be the very driver of the plasticity leading to its resistance. Enzalutamide treatment has been shown to induce global splicing changes, and promote a high-grade, treatment-resistant, neuroendocrine phenotype. One potential link between the changes in RNA-splicing and the development of a neuroendocrine phenotype is Abelson Interactor 1 (ABI1), a multi-isoform scaffolding protein known to be a regulator of prostate cancer progression. In this study, we aimed to identify how ARPI treatment induces isoform-specific changes in ABI1, and how these changes drive prostate cancer progression. Using a combination of cell line, patient-derived and animal models of prostate cancer, we were able to determine that ARPI treatment deregulates inclusion of ABI1-exon 4, which is critical to ABI1's DNA-binding ability. This dysregulation in turn alters the expression of many genes involved in pathways of transcriptional regulation and stress response during enzalutamide treatment. Taken together, these findings shed new light on the mechanisms behind the development of enzalutamide resistance and provide a novel target in treatment-resistant prostate cancer.

#4764 Exploring the anti-proliferative impact of PBX1 perturbation in enzalutamide-resistant CRPC.

Ephraim J. Gardner[1], Surendra Gulla[1], Sasikumar Ponnusamy[1], Abbas Jawadwala[1], Madison Aust[1], Remi M. Adelaiye-Ogala[2]

[1]University at Buffalo, State University of New York, Buffalo, NY,[2]University at Buffalo, Buffalo, NY

Advanced prostate cancer (PCa) is often driven by upregulated activity of the androgen receptor (AR) and is clinically targeted by second-generation AR-antagonists such as Enzalutamide. Though patients initially respond to treatment, many develop resistance, leading to disease advancement and poor prognosis. We have focused on a mechanism involving an AR cistrome switch from a canonical to a noncanonical cistrome as PCa becomes Enzalutamide-resistant. As collaborating protein partners drive transcriptional activity, we employed core regulatory circuitry analysis in Enzalutamide-resistant PCa cell line models to identify novel TF candidates that may mediate non-canonical AR cistrome reprogramming, including Pre-B-cell leukemia homeobox 1 (PBX1), a TALE homeodomain TF. We previously showed that PBX1 is highly expressed in castrate-resistant and Enzalutamide-resistant (EnzaR-CRPC) cell line models compared with sensitive models. We have also demonstrated that PBX1 inhibition has an anti-proliferative effect in a high-PBX1-expressing EnzaR-CRPC cell line, with synergism observed with continuous Enzalutamide treatment. In the current study, we perturbed PBX1 expression in an EnzaR-CRPC cell line by shRNA (PBX1 KD) and CRISPR-Cas9 (PBX1 KO). Western blotting, RT-qPCR, and genomic DNA analysis validated a significant reduction in PBX1 protein and gene levels. Similar to previous observations with PBX1 inhibitors, PBX1 KD and PBX1 KO cells showed an initial, prominent decrease in proliferation compared to their respective controls. Interestingly, PBX1 KO clones after several passages regained increased proliferation. On the contrary, the PBX1 KD cells continue to demonstrate anti-proliferation. Ongoing transcriptomic and genome-wide DNA analysis will provide a clear understanding of the biological pathways affected by PBX1 perturbation and, most importantly, of changes in the AR and PBX1 cistrome, promoter, and enhancer landscape at low levels of PBX1 (PBX1 KD) vs. complete elimination of PBX1 (PBX1 KO). This would provide a better insight into (i) AR-PBX1 transcriptional axis and PBX1's role in promoting treatment-resistant, advanced PCa, (ii) the long-term implications for PBX1 suppression, and (iii) the best treatment strategy for targeting both PBX1 and AR for a durable positive outcome in advanced treatment-resistant CRPC.

#4765 Induction of epidermal like differentiation irreversibly limits the invasive and metastatic potential of basal like breast cancer cells.

Justin Hui[1], Andrea E. Doak[1], Nicole Rhoads[1], Ruijin Yang[1], Jimin Park[1], Cory L. Simpson[2], Manu Setty[1], Kevin J. Cheung[1]

[1]Fred Hutchinson Cancer Center, Seattle, WA,[2]University of Washington, Seattle, WA

Triple-negative breast cancer (TNBC) exhibits the worst overall survival compared to other breast cancer subtypes and has the most limited treatment options. Molecularly, most TNBCs are classified as basal-like and are associated with aggressive metastasis and drug resistance.A major hurdle in the development of effective therapeutics is tumor cell state and phenotypic plasticity that confer fitness advantages for growth, therapeutic resistance, and invasion. In this study, we sought to identify transcription factors that regulate basal-like plasticity for collective invasion. Using mouse mammary tumor organoids and time course single-cell RNA sequencing, we show that transcription factor KLF4 is a potent suppressor of basal-like invasion plasticity.Unexpectedly, we observed that KLF4 overexpression potently induced a molecular program recapitulating the classical differentiation of basal epidermal cells processively toward a biologically dead cornified outer skin layer. Overexpression of KLF4 induced hallmark markers of epidermal differentiation such as keratin 10, desmosomal cadherins, loricrin, and multicellular features of maturing epidermis, including cell piling, keratinization, and increased desmosomes, all putative anti-invasive features. Induction of epidermal differentiation, specifically in basal but not mesenchymal or luminal breast tumor cells, resulted in terminal differentiation in vitro and irreversible loss of colony-forming potential, indicative of tumor subtype-specific vulnerability. In vivo, KLF4 potently suppressed metastatic outgrowth of human basal TNBC in an intracardiac metastasis assay. In human breast tumors, we observed 50% of tumors expressed KLF4 RNA yet lacked KLF4 protein. Mechanistically, we show that basal-like TNBCs actively degrade KLF4protein to limit epidermal differentiation, which was overcome by proteasome inhibitors. In sum, these data uncover epidermal differentiation as a latent plasticity switch of highly metastatic basal-like breast cancer cells, making them irreversibly more cohesive, and point to KLF4protein stabilization as a therapeutic strategy.

#4767 Targeted antagonism of the activator protein 1 transcription factor complex results in potent anti-tumor activity in HNSCC models.

Karen Mendelson, Zachary F. Mattes, Siok Leong, Ricardo Ramirez, Mark Koester, Claudio Scuoppo, Julia Diehl, Erin Gallagher, Binh Lee, Franco Abbate, Lila Ghamsari, Gene Merutka, Barry J. Kappel, Abi Vainstein-Haras, Jim A. Rotolo

Sapience Therapeutics, Tarrytown, NY

The AP-1 transcription factor complex, comprised of Fos and Jun family heterodimers, plays a pivotal role in tumor progression and metastasis of head and neck squamous cell carcinoma (HNSCC), where expression of AP-1 component Fra1 positively correlates with poor prognosis. As dimerization is required for AP-1 complex DNA binding and transcriptional activity, we designed Fra1 antagonizing peptide (FraAP) to disrupt complex formation and prevent associated activity. Low nanomolar FraAP binding affinity to Fra1 and Jun and selectivity towards AP-1 family members was demonstrated by bio-layer interferometry (BLI), fluorescence polarization, and DNA ELISA assays. Immunofluorescence imaging reveals rapid FraAP cell entry into both the cytoplasmic and nuclear compartments of HNSCC cells, while proximity ligation assays (PLA) and co-immunoprecipitation experiments demonstrate FraAP antagonism of cJun and Fra1 protein-protein interactions and reporter assays confirm inhibition of AP-1 transcriptional activity in vitro. To investigate the impact of FraAP on tumor cell transcriptomics, RNAseq and pathway enrichment analysis identified a significant impact of FraAP on AP-1-regulated pathways including tumor cell apoptosis, invasion and proliferation. Corresponding functional in vitro assays support transcriptomic observations, as FraAP induces dose-dependent Annexin V+ apoptosis by flow cytometry; promotes a phenotypic mesenchymal to epithelial transition characterized by decreased mesenchymal marker N-cadherin and increased epithelial marker E-cadherin, leading to an inhibitory effect on invasion in Boyden chamber assays; and induces G1 arrest characterized by upregulation of CDKN1A, reduction of CDK4, CDK6, and CCND1 expression, and hypophosphorylation of Rb. The impact of FraAP on CDK4 and CDK6 expression prompted investigation of the combination activity of FraAP with the CDK4/6 inhibitor abemaciclib. Data identifies synergistic anti-tumor activity in vitro in assays of cytotoxicity, clonogenic formation, orosphere formation, and cell signaling. Further, while FraAP results in significant anti-tumor activity as a monotherapy in HNSCC subcutaneous xenograft models, combination of subpharmacologic FraAP and abemaciclib results in enhanced tumor growth inhibition. In summary, these data support FraAP as a potent peptide antagonist of the AP-1 transcription factor family that warrants further development as a novel therapeutic option for AP-1 driven tumors such as HNSCC.

#4768 From peptide screens to biological insights, FOXO4 and the PBAF complex.

Dieu An Hoang Nguyen[1], Andrea Cochran[2], Shalini Gupta[1], E Megan Flynn[1]

[1]Genentech, Inc., South San Francisco, CA,[2]Early Discovery Biochemistry, Genentech, Inc., South San Francisco, CA

Bromodomains are ubiquitous among chromatin regulators, and while they are potentially exciting therapeutic targets for cancer, the specific functions of many of them remain unknown. In a high-throughput peptide screen for potential bromodomain binding partners, acetylated peptides of transcription factors FOXO1/3/4 emerged as significant binders to the polybromo protein PBRM1, a subunit of the SWI/SNF chromatin remodeler PBAF. FOXOs are of particular interest because they are well-conserved mediators of stress adaptation in cells and are regulated by several PTMs. Under oxidative stress, FOXOs are acetylated and translocate to the nucleus, where PBRM1, within PBAF, resides. We sought to characterize the interaction between acetylated FOXOs and PBRM1 and their potential cooperation in stress responses. (1) We validated the interaction by Isothermal titration calorimetry (ITC) and found acetylated FOXO peptides bind to PBRM1 bromodomains with affinities comparable to peptides including the preferred histone modification, H3K14ac. (2) Using purified, site-specifically acetylated FOXO4 proteins as bait, we purified interactors for mass spec analysis, finding that FOXO4 acetylated at K189 interacts with PBAF components. (3) We employed genomic profiling assays ATAC-seq, CUT&RUN-seq, and Bru-Seq to dissect the role of FOXO4 under endogenous conditions versus oxidative stress, with select studies also performed in FOXO4 CRISPR knockout cells. We identified peaks where FOXO4 and PBRM1 co-localize and exhibit changes in peak intensity under acute stress. We also established a transcriptional profile of cellular response to oxidative stress and compared affected genes to the genes bound by FOXO4 and PBRM1. While our findings suggest that the FOXO4-PBRM1 interaction may not be the key driver of transcription in the oxidative stress response, this framework allows us to systematically assess other potential functions of the interaction. Together, by combining biophysical, biochemical, cell growth assays, and functional genomics assays, we have defined a likely aspect of the biology of the tumor suppressor PBRM1, namely regulation of FOXO transcription factor genomic localization.

#4769 Unravelling the transcriptome in mantle cell lymphoma.

Chioniso Patience Masamha[1], Mahesh Gupta[1], Demiah Lockett[1], Caiden Lukan[1], Lael Pasipamire[1], Jie Li[2]

[1]Pharmaceutical Sciences, Butler University, Indianapolis, IN,[2]UC Davis, Davis, CA

Many studies in the incurable B-cell hematological malignancy, mantle cell lymphoma (MCL), have focused on identifying mutations in oncogenes and tumor suppressor genes. Next-generation sequencing technologies have opened the potential to discover other global changes that contribute to the malignancy. In particular, sequencing the RNA can help us uncover transcriptome diversity resulting from alternative splicing, alternative polyadenylation (resulting in different 3'UTRs), generation of fusion transcripts as well as non-coding RNAs. The goal of this study was to characterize the transcriptome of MCL. We performed long-read Iso Sequencing and short-read RNA Sequencing on RNA samples from three MCL cell lines. The data was analyzed to identify novel transcripts as well as alternative splicing and alternative polyadenylation patterns. Select transcripts were validated using different types of PCR, Sanger Sequencing and other molecular biology techniques. Our heatmap showed that while there was always overlap between highly upregulated and downregulated transcripts in two cell lines, each cell line had its own unique gene signature. We were able to identify different variants arising from alternative splicing and alternative promoter usage in several genes including glutaminase (GLS1) by overlaying our long-read sequencing and short-read sequencing data. Our qRT-PCR and Western blot results confirmed the presence of the two most prevalent GLS1 alternatively spliced variants GAC and KGA. At the protein level, all the MCL cell lines expressed higher levels of the GAC isoform than B-cells. The GAC isoform is the form most commonly associated with cancer since the mRNA lacks a target site for miR-23 and an AU rich element (ARE) which are both potent modulators of the KGA isoform. When we looked at alternative polyadenylation, we found that the ATM gene, which is a major contributor to MCL pathogenesis, undergoes shortening of the 3'UTR in MCL cell lines. Using SQANTI3 on our long-read sequencing data, we found that transcripts were in 9 different structural categories and only ~30% of our transcripts mapped to annotated genes. We also identified fusion transcripts from our long-read sequencing data. As a proof of concept, we validated the ubiquitous fusion transcript, CTBS::GNG5, in our MCL cell lines using PCR and Sanger Sequencing. We also detected it in MCL patient samples using PCR. So far, we have identified heterogeneity as well as overlaps in levels of the differentially expressed genes in MCL. Use of both short-read and long-read sequencing technology has uncovered transcripts in MCL cell lines arising from alternative splicing, alternative polyadenylation as well as fusion transcripts. This comprehensive analysis of the MCL transcriptome can provide potential biomarkers and therapeutic targets. Our analysis is currently ongoing.

#4770 Molecular features of patient-derived triple-negative breast cancer models based on super-enhancer-associated transcriptional regulators and biomarkers.

Kuniko Horie[1], Kazuhiro Ikeda[1], Satoshi Inoue[2]

[1]Saitama Medical University, Saitama, Japan,[2]Professor, Dept. of Anti-Aging Med., TMIG - Tokyo Metropolitan Institute of Gerontology, Tokyo, Japan

Super-enhancers (SEs) have been defined as particular genomic regions with clusters of consecutive enhancers, which provide cell- or stage-specific context. SEs are often determined by high-level enrichment for genomic binding of transcriptional coactivators and active chromatin marks such as histone H3 with acetylated K27. In this study, we aim to characterize similarity and specificity of SE-associated gene profiles of patient-derived models of triple-negative breast cancer (TNBC) obtained from distinct advanced cases. We identified SE-associated genes for these models based on the integrated study of RNA-sequencing and chromatin immunoprecipitation (ChIP) sequencing for H3K27ac binding. Since these patient-derived cancer models were generated through a spheroid culture technique, stemness markers such as *CD44* and *MYC* were identified as predominant SE-associated genes in the majority of cases. We further identified MYBL1 as a critical SE-associated transcription factor among basal-like cancer cases. Silencing of MYBL1 in TNBC patient-derived and cell line models showed that this transcription factor contributes to cell proliferation and the regulation of mitosis-associated gene expression. Immunohistochemical study for MYBL1 in our TNBC cohort showed that MYBL1 immunoreactivity is a potential poor prognostic factor for TNBC patients. The present findings suggest that the characterization of SE-associated transcriptional regulators and biomarkers will facilitate the understanding of molecular features of TNBC subtypes and the development of alternative potential therapeutic targets for the advanced disease.

#4771 DEL data-driven discovery of Brachyury (TBXT) ligands toward chordoma therapeutics.

Zhen Chen[1], Rebecca Swett[1], Miklos Feher[2], AJ Baghaie[1], Jeffrey Santandrea[2], Philippe McGee[2], Massaba Keita[2], Jenny Liu[1], **Ying Zhang**[1], Jithender Vakiti[2], Natalia Sannikova[2], Julien Pomarole[2], Timothy Morgan[2], Jean-Christophe Grenier-Petel[2], Aurelien Coelho[2], Ryan Walsh[1], Dylan Hale[2], Faraz Hussain[2], Arnaud Clerc[2]

[1]X-Chem Pharmaceuticals, Waltham, MA,[2]X-Chem Pharmaceuticals, Montreal, QC, Canada

Aberrant expression of the transcription factor Brachyury (also known as TBXT) drives the growth of chordoma, a rare bone cancer with limited treatment options. While transcription factors are traditionally considered undruggable by small molecules, advances in DNA-encoded library (DEL) screening and data-driven drug discovery technologies are challenging this conventional wisdom. To discover noncovalent small molecule ligands for Brachyury, we screened X-Chem's DEL deck comprising >150 billion diverse compounds against the Brachyury DNA-binding domain. The screen produced a rich dataset where ~73k compounds, representing >500 distinct chemical families, showed positive enrichment signal. Using X-Chem's Chemomics platform, we translated this dataset into actionable chemical matter from three avenues: (1) off-DNA resynthesis of exact DEL-encoded structures (library compounds) that are prioritized by our DEL-to-pharmacophore (Del2Ph4) analysis workflow, (2) compounds in commercial catalogs that score highly in Machine Learning (ML) models built from the DEL data and Del2Ph4 analysis, and (3) rapid parallel synthesis of analogs of enriched library compounds using multicomponent reactions. SPR assays using full-length Brachyury protein, independently run by the Chordoma Foundation, have confirmed target-binding activity for several chemically distinct compounds. These results highlight the power of X-Chem's drug discovery platform and offer a path forward for Brachyury-targeted chordoma therapeutics.

#4772 snoRNA-guided ribosome heterogeneity in a model of NSCLC collective invasion.

Sarah F. Webster[1], Yi-Ru Li[1], Virginie Marchand[2], Tala O. Khatib[3], Ryan M. Nottingham[4], Lutfur Rahman[1], Janna K. Mouw[3], Alan M. Lambowitz[4], Blerta Xhemalce[1], Yuri Motorin[5], Adam I. Marcus[3], Homa Ghalei[1]

[1]Biochemistry, Emory University, Atlanta, GA,[2]UMS2008 IBSLor, Universite de Lorraine, Vandoeuvre-les-Nancy, France,[3]Hematology and Medical Oncology, Emory University, Atlanta, GA,[4]Molecular Biosciences and Oncology, University of Texas at Austin, Austin, TX,[5]UMR7365 IMoPA, Universite de Lorraine, Vandoeuvre-les-Nancy, France

The processing, folding, and chemical modification of ribosomal RNAs (rRNAs) are critical for proper ribosome assembly and function and are tightly coordinated by a complex network of proteins and non-coding RNAs (ncRNAs). Among these, an abundant group of ncRNAs, small nucleolar RNAs (snoRNAs), guide the folding and site-specific modification of over 200 nucleotides in human rRNAs. Emerging evidence has linked changes in rRNA modification pattern to distinct tumor stages, but how rRNA modification heterogeneity manifests and contributes to cancer progression remains unknown. One mechanism driving cancer progression to metastasis is collective invasion, which is defined by the presence of cooperative subpopulations within a tumor. Previous work by the Marcus lab isolated two cell subpopulations, leaders and followers, from the H1299 cell line based on their distinct phenotypes. To assess the role of snoRNA-guided modification heterogeneity in invasion, we applied an unbiased genome-wide sequencing approach to leader and follower subpopulations to map rRNA modifications and snoRNAs. We identified 418 snoRNAs in leaders and followers. Of the differentially expressed snoRNAs, 60% are predicted to be ribosome targeting. Analysis of the snoRNA-guided rRNA modifications, revealed differential modification status at specific sites on the rRNA between leaders and followers. The majority of the top differentially modified sites are among the known dynamically modified sites across different cancers and tissues. While the sites of modification heterogeneity are not localized to a distinct site on the ribosome, they fall within key functional regions near the decoding center, subunit bridges, within the L1 stalk, and near the binding site of key ribosomal proteins. Overall, a weakly positive Spearman correlation of <0.3 between snoRNA abundance and rRNA modification status suggests snoRNA abundance alone does not inform the global rRNA modification pattern. To uncouple the roles of snoRNA expression and rRNA modification, we apply a set of biochemical tools and demonstrate that leaders and followers have differential growth and translation capacities that can be changed by altering snoRNA expression. Collectively, our data reveal novel modulators of growth and translation in NSCLC and shed light on the molecular principles underlying ribosomal modification heterogeneity in invasive cancer cells.

#4773 MYC associated transcriptional heterogeneity at the single cell level.

Saravana Gowtham Baskaran[1], Min-Zhi Jiang[2], Ada Tam[1], Hongkai Ji[2], Chi Van Dang[1]

[1]Johns Hopkins University School of Medicine, Baltimore, MD,[2]Johns Hopkins University Bloomberg School of Public Health, Baltimore, MD

Background: Tumor heterogeneity allows cancer cells to adapt to microenvironmental stress and resist therapies. MYC is commonly amplified in human cancers and its expression can be heterogeneous due to variations in extrachromosomal DNA (ecDNA) and the pulsatile nature of MYC expression. However, the heterogeneity of the MYC responsive transcriptome among single cells is unknown. Here, we evaluate the heterogeneity of MYC transcriptional response in vitro in an inducible MYC cancer cell line.
Methods: We used the P493-6 human B cell line model of Epstein-Barr Virus associated Burkitt's lymphoma (BL) with tetracycline-repressible (Tet-OFF) ectopic MYC expression. We modulated MYC expression by addition of tetracycline and performed paired bulk and single-cell RNA-sequencing (scRNA-seq). To further characterize the transcriptional response of these cells with different MYC levels, we turned off MYC in these cells and then turned it back on to capture cells with increasing levels of MYC over time and performed paired bulk and single-cell RNA sequencing.
Results: We observed heterogeneous expression of MYC and strikingly diverse expression of MYC responsive genes at the single cell level. After MYC induction with the removal of tetracycline, we observe a time-dependent decrease in STAT1 and other immune-related gene expression and movement of single cell transcriptomic clusters in high dimensional space visualized with tSNE plotting. Intriguingly, we observed a small cluster of CD58+ cells whose position in the tSNE space is unaltered by MYC status. We surmise that this cluster behaves like 'stem' cells capable of repopulating the entire population of P493 cells. Interestingly, we also see this small cluster of cells in some patient-derived BL cell lines.
Conclusions: Overall, we provide detailed evidence of MYC driven transcriptional heterogeneity at the single cell level. Our preliminary evidence of this unique 'stem-cell' like population of cells in BL warrants further study.

#4774 Targeting Beta-catenin in colorectal cancer: Novel molecular glue drug candidates by Coltac's BOND+ platform.

Yaron Sfadyah[1], Orli Even-Or[1], Michael Mullokandov[1], Hana Boocholez-Vardi[1], Valeria Arkadash[1], Alexandra Brodezki[1], Daniel Feder[1], **Liraz Harel**[1], Elon Yariv[2], Gali Prag[2]

[1]Coltac Therapeutics, Yavne, Israel,[2]School of Biochemistry Neurobiology Biophysics, Tel Aviv University, Tel Aviv, Israel

β-Catenin is a central oncogenic driver through its regulation of the Wnt signaling pathway, controlling cell proliferation, metastasis, drug resistance, across multiple cancer types. Its critical role is well-established in colorectal cancer (CRC), hepatocellular carcinoma, endometrial cancer, desmoid tumors, and subsets of ovarian cancer. In over 90% of colorectal cancers, Wnt/β-catenin pathway mutations elevate β-catenin levels, promoting tumorigenesis and poor prognosis. Restoring control of aberrant Wnt signaling in β-catenin–driven cancers hold significant potential to suppress tumor growth and improve clinical outcomes. Targeted protein degradation (TPD) by molecular glues offers a promising therapeutic strategy for modulating oncogenic drivers such as β-catenin proteins, historically considered challenging for conventional small-molecule inhibition. Discovery of selective glues remains limited by low throughput screening methods, weak detection sensitivity, and the complexity of E3-substrate biology. Coltac Therapeutics developed BOND+ a proprietary bacterial ubiquitin-dependent positive-selection screening system designed to identify molecular glues that enhance E3 ligase-target engagement. This synthetic platform converts functional ubiquitination events into bacterial growth, by leveraging the bacterial environment, which lacks deubiquitinases, proteasomal and lysosomal degradation systems, redundant E3 ligases, and any ubiquitylation-dependent degradation machinery, thus enabling direct, low-signal to noise readouts of functional target engagement. Identified hits are further validated in mammalian cell assays, followed by mechanistic studies and continuous optimization through medicinal chemistry and in silico refinement. Using BOND+ platform we identified selective molecular glue candidates that promote proteasome-dependent degradation of β-catenin and modulate downstream associated signaling. Lead compounds demonstrated up to 100-fold inhibition potency relative to initial hits, with preferential anti-tumor activity effects in various CRC Wnt-dependent cancer cell models. Early mechanistic studies confirmed target selectivity and E3-ligase dependence. Structure activity relationship (SAR) optimization and in vivo pharmacology studies refined potency and translational potential. Despite β-catenin central role in CRC there are no approved therapies directly target β-catenin, highlighting a significant unmet need. Coltac's BOND+ platform enabled rapid discovery and validation supporting therapeutic drugs for β-catenin. We demonstrated potent antitumor activity highlighting Coltac's molecular glue as a new drug candidate in β-catenin-driven cancers.

#4775 Reflux-induced NEK2 activates cap-dependent mRNA translation program in esophageal adenocarcinoma.

Lei Chen[1], Chloe Xiao[1], Tianling Hu[1], Oliver Gene McDonald[2], Steven Xi Chen[3], Heng Lu[1], Zheng Chen[1], Alexander Zaika[1], Wael El-Rifai[1], Dunfa Peng[1]

[1]Surgery, University of Miami Miller School of Medicine, Miami, FL,[2]Pathology, University of Miami Miller School of Medicine, Miami, FL,[3]Public Health Sciences, University of Miami Miller School of Medicine, Miami, FL

Background: The incidence of esophageal adenocarcinoma (EAC) has increased more than sevenfold in the United States and Western countries over the past four decades; however, patient prognosis remains poor, with a five-year survival rate of less than 20%. Dysregulation of mRNA translation, especially the cap-dependent mechanism mediated by eIF4F complex, was found in many human cancers. Aberrant expression and phosphorylation of eIF4E, the rate-limiting component of eIF4F complex, has been evidenced to promote oncogenic translation programs in human cancers. Constitutive overexpression of NEK2, a serine/threonine kinase of the NEK protein kinase family, has been reported to mediate tumor progression and drug resistance in cancer cells. Our study aims to investigate the role of NEK2 in regulating cap-dependent mRNA translation and translational significance of NEK2/eIF4E signaling in EAC.
Methods and Results: We first confirmed activation of the cap-dependent translation using a luciferase reporter assay and increased protein levels of its key factors, such as p-eIF4E, eIF4E, p-4EBP1, and 4EBP1, by western blotting, in the scenarios with either transient or repeated ABS exposure. However, the levels of p-mTOR, mTOR, eIF4A, and eIF4G remained unchanged. Meanwhile, intrinsic overexpression of NEK2 protein was observed in EAC patients, esophageal cell lines of dysplasia/EAC, and ABS-exposure-induced cell models. Overexpression and silence of NEK2 underlined its role in mediating activation of cap-dependent translation under reflux conditions. The co-overexpression of NEK2 and eIF4E was identified by immunofluorescent staining in EAC cells and immunohistochemistry staining in human TMA, indicating their potential interaction. Mechanically, we discovered that NEK2 contributes to cap-dependent translation by stabilizing eIF4E protein and regulated its phosphorylation in an MNK-dependent manner. Exotic overexpression of NEK2 significantly promoted colony formation capacities of tumor cells, while NEK2 silencing greatly suppressed tumor growth and expansion in cells/3D tumor spheres. Moreover, activation of NEK2/eIF4E signaling was proved to facilitate tumor cell survival in the presence of oxaliplatin. NEK2 silencing re-sensitized resistant EAC cells to chemotherapeutic drugs by magnifying apoptosis. Remarkably, the combination therapy of oxaliplatin and pharmacological inhibitor of NEK2, T-1101, synergized in inducing cell death, with minimized interruption on non-neoplastic cells. This finding was further confirmed in EAC-cell-line-derived xenograft models.
Conclusion: Our data elucidates novel functions of NEK2/eIF4E signaling axis in promoting cancer progression and drug resistance. Combination therapy of chemotherapeutic drugs with NEK2 inhibitor provides a promising strategy for treatment of EAC patients.

#4776 Lurbinectedin alters EWS::FLI1 binding to chromatin to poison transcription.

Zachary P. Tolstyka[1], Raphael D. Lopez[2], Sridhar M. Veluvolu[2], Emma Hiscock[1], Andrew Fuller[1], Mia Lollo[1], Emily Seiden[1], Rachael Hinshaw[1], Lauren Gaetano[2], Elizabeth Wilson[2], Gretchen Lam[1], Rebecca Kaufman[2], Elissa Boguslawski[1], Michelle Paulsen[1], Ishwarya Narayanan[1], Jenna Gedminas[2], Mats Ljungman[1], Patrick J. Grohar[1]

[1]University of Michigan Medical School, Ann Arbor, MI,[2]Children's Hospital of Philadelphia, Philadelphia, PA

Relapsed Ewing sarcoma has dismal outcomes and has had minimal treatment advancements in the last 30 years - there is a critical need for the development of new treatments. The tumor is uniquely dependent on the oncogenic EWS::FLI1 fusion transcription factor to develop and maintain malignancy. Lurbinectedin is a small molecule analog of the natural product trabectedin that has shown efficacy in multiple cancers including Ewing sarcoma. The mechanism of toxicity of lurbinectedin in Ewing sarcoma is under investigation.

Lurbinectedin exposure alters EWS::FLI1 trafficking into the nucleolus as measured by confocal microscopy. The subsequent impact of drug exposure on EWS::FLI1 binding to chromatin was determined by CUT&Tag and confirmed by chromatin fractionation. Transcription was assessed by qPCR and RNAseq, and BRUseq was utilized to determine the impact on nascent transcription. Further mechanistic clarification was determined by proximity ligation mass spectrometry. Ultimately, the integration of CUT&Tag of EWS::FLI1 with Bru-seq (CUT, Tag, and Bru) following treatment with lurbinectedin elucidated the effects of the drug on EWS::FLI1 binding and alteration of downstream transcription.

Exposure of Ewing sarcoma cells to lurbinectedin alters EWS::FLI1 distribution in the nucleus to the nucleolus. The relocalized EWS::FLI1 can be trapped in the nucleolus by use of potentiators that inhibit HSP70. The relocalization is driven by altered MAPK signaling and can be rescued by siRNA silencing of MAPK pathway members. The effect is rooted in wild-type function of the FET family of proteins and is associated with altered EWS::FLI1 binding at response elements leading to alteration of the transcriptome. Both transcription initiation and elongation are altered. Importantly, these effects on EWS::FLI1 are both dose and time dependent and can be further amplified with MAPK perturbants.

Treatment with lurbinectedin induces relocalization of the oncogenic transcription factor EWS::FLI1 to the nucleolus leading to transcriptional suppression of EWS::FLI1 target genes and a striking decrease in cell viability. This modulation of EWS::FLI1 binding to chromatin occurs in both a concentration and time dependent manner. Intriguingly, the impact appears to be dependent on gene length: there is greater transcription alteration in longer genes compared to shorter genes.

#4777 Core tension and control: Fxr1 mediates mechanoregulation via ahnak in head and neck cancer.

Anitha Vijayakumar[1], Samuel John[1], Tae-Hyung Kim[2], Breege V. Howley[3], Viswanathan Palanisamy[1]

[1]Department of Internal Medicine, UNM Comprehensive Cancer Center, University of New Mexico, Albuquerque, NM,[2]Department of Pathology, UNM Comprehensive Cancer Center, University of New Mexico, Albuquerque, NM,[3]Department of Biochemistry and Molecular Biology, Medical University of South Carolina, South Carolina, SC

Background: Head and neck squamous cell carcinoma (HNSCC) is the sixth most prevalent cancer globally and is marked by aggressive invasion, high metastatic potential, and a persistently low 5-year survival rate (~50%). Emerging evidence highlights the roles of cytoskeletal remodeling and altered cellular biomechanics, including stiffness, viscoelasticity, and deformability, in promoting cancer cell migration and invasion. However, the molecular regulators of these biomechanical properties in HNSCC remain poorly defined.
Methods: We investigated the role of Fragile X-Related Protein 1 (FXR1), an RNA-binding protein, in modulating tumor biomechanics and invasion in cancer cells. FXR1 knockdown (KD) was performed in HNSCC cell lines, followed by transcriptomic, cytoskeletal, and biomechanical analyses. Functional assays, including cell motility, stiffness, and tumor growth in vitro and in syngeneic mouse models, were performed to define the tumorigenic role of FXR1 in oral cancer.
Results: FXR1 silencing significantly upregulated AHNAK, a large scaffolding protein implicated in cytoskeletal organization. This upregulation was associated with reduced F-actin polymerization, impaired lamellipodia formation, decreased cellular stiffness, and diminished invasive and migratory properties of oral cancer cells. Dual knockdown of FXR1 and AHNAK partially restored F-actin architecture, lamellipodia formation, and cell stiffness, suggesting a functional interplay between the FXR1-associated protein network. Mechanistically, further evidence demonstrated that FXR1 KD activated the Hippo signaling pathway via LATS2, leading to the cytosolic accumulation of phosphorylated YAP (P-YAP), implicating FXR1's role in mechanotransduction. In vivo, WT and FXR1 KD-derived xenografts exhibited significantly reduced tumor volume in syngeneic mouse models with immune cell activation.
Conclusions: FXR1 promotes HNSCC progression by repressing AHNAK and enhancing F-actin dynamics, thereby increasing cellular stiffness, invasion, and migration. Our findings reveal a novel FXR1-AHNAK-F-actin axis that regulates tumor biomechanics and invasiveness of oral tumors, offering new mechanistic insights and identifying FXR1 as a promising therapeutic target in HNSCC.

#4778 FOXR2 reverses MDM2-mediated but not MDM4-mediated p53 repression.

Wei-Hsiung Yang[1], Anmol P. Patel[2], William H. Yang[3]

[1]Biomedical SCiences, Mercer University School of Medicine, Savannah, GA,[2]Mercer University School of Medicine, Savannah, GA,[3]Medical College of Georgia at Augusta University, Augusta, GA

Despite advances in therapy, cancer remains a major health challenge in the 21st century, with mortality rate ranging from approximately 11% to 25%. The tumor suppressor p53, a protein critical for cancer development and prevention, is regulated by numerous interacting partners. In our previous unpublished findings, we identified that FOXR2 (an epigenetically regulated pan-cancer oncogene) is able to module p53 activity. Consequently, in the present investigation, we broaden our exploration to examine how FOXR2 regulates p53 transactivation. We first found that FOXR2 enhances p53 transactivation in a dose-dependent manner in H1299 (p53 NULL) cells. Given that MDM2 and MDM4 (MDMX) are major p53 negative regulators, we then tested whether FOXR2 could counteract MDM2- and MDM4-mediated p53 repression. We found that FOXR2 dose-dependently reverses MDM2-mediated p53 transactivation. However, FOXR2 has minimal or no effect on MDM4-mediated p53 repression. Moreover, our data suggests that FOXR2 is capable of binding to p53. Finally, we found that FOXR2 increases wild-type (WT) p53, but not G245S (hotspot mutation) p53, transactivation. Taken together, our preliminary results demonstrate that FOXR2 is a novel protein to regulate p53 activity likely involving MDM2 competition due to possible p53-FOXR2 interaction. This data is presented to substantiate the concept that p53's activity is governed by a complex and still-expanding network of interactions.

#4779 IL-6/STAT3 signaling mediates MYB dysregulation in prostate cancer: Implications for aggressive disease progression and racial disparities.

Vinayaraj Ellu Valappil[1], Shashi Anand[1], Kunwar Somesh Vikramdeo[1], Ranjana Mitra[2], Seema Singh[1], Ajay P. Singh[1]

[1]Department of Cell and Molecular Biology, Cancer Center and Research Institute, University of Mississippi Medical Center, Jackson, MS,[2]College of Medicine, Roseman University of Health Sciences, Las Vegas, NV

We have previously reported a role for MYB in the progression, aggressiveness, and therapy resistance of prostate cancer. Notably, we also observed racially disparate MYB expression, with higher levels being present in prostate cancer from Black patients, correlating with advanced tumor grade and shorter time to biochemical recurrence. In this study, we investigated the molecular mechanisms underlying MYB dysregulation in prostate cancer that could potentially be linked to its higher levels in Black patients. We found that serum levels of IL-6 were significantly elevated in Black patients with prostate cancer, and treatment of prostate cancer cell lines with IL-6 resulted in a dose- and time-dependent upregulation of MYB expression. IL-6-induced MYB upregulation was abolished when cells were pre-treated with either an IL-6 neutralizing antibody (Tocilizumab) or a STAT3 inhibitor (Stattic). Notably, AR-negative cell lines exhibited high basal MYB expression, which was slightly reduced by Tocilizumab treatment but drastically reduced upon STAT3 inhibition, suggesting that it is a significant regulator of MYB overexpression in prostate cancer. Chromatin immunoprecipitation (ChIP) analysis revealed increased STAT3 binding to the MYB in the first intronic region, following IL-6 treatment, which was reduced upon pre-treatment with Tocilizumab or Stattic. Additionally, in this region, we observed enhanced recruitment of CDK9, a key component of the P-TEFb complex, which is shown to facilitate the release of the MYB transcriptional pause through Ser2 phosphorylation in the c-terminal domain of RNA polymerase II. Pre-treatment of prostate cancer cells with a CDK9 inhibitor also attenuated IL-6-induced MYB expression. Finally, silencing MYB or treating cells with a CDK9 inhibitor significantly impaired IL-6-mediated proliferation, migration, and invasion of prostate cancer cells. These findings establish IL-6/STAT3 signaling as a critical regulator of MYB expression in prostate cancer, highlighting its potential role in prostate cancer pathogenesis and racial disparities.

Poster Session

#4783 An mRNA vaccine targeting angiogenesis elicits a robust immune response and inhibits tumor growth and angiogenesis in two mouse melanoma models.

Srdan Tadic, Laura Ochoa-Callejero, Judit Narro Iniguez, Josune Garcia-Sanmartin, Alfredo Martinez

Angiogenesis Study Group, Center for Biomedical Research of La Rioja (CIBIR), Logrono, Spain

Background: Angiogenesis is essential for tumor growth, metastasis, and the establishment of an immunosuppressive microenvironment. By supporting nutrient delivery and modulating immune cell infiltration, tumor-driven angiogenesis promotes both malignant progression and immune evasion. Among its key regulators, adrenomedullin (AM) is a potent pro-angiogenic factor frequently overexpressed in solid tumors. To explore its therapeutic potential, we developed an mRNA vaccine encoding a fusion antigen composed of a small keyhole limpet hemocyanin (KLH) peptide, as a hapten, linked to mouse AM.
Methods: The in vitro transcribed mRNA was encapsulated in lipid nanoparticles (LNPs) and administered to C57BL/6 mice, with empty LNPs serving as controls. The vaccine was evaluated in two distinct melanoma models: an experimental lung metastasis model induced by intravenous injection of B16-F10 melanoma cells, and a subcutaneous melanoma model. After four immunizations, melanoma cells were injected, followed by a fifth immunization. Mice were sacrificed once tumors reached humane endpoints and blood and organs were analyzed.
Results: Vaccinated mice exhibited significant increases in anti-AM IgG titers ($p= 0.040$) and CD8+ T cell numbers ($p=0.033$) compared to controls. In the lung metastasis model, immunization resulted in a significant reduction in both the number ($p=0.028$) and size of lung metastases ($p=0.020$) as well as a decrease in the number of tumor-associated blood vessels ($p=0.046$), without disrupting normal vasculature as assessed in SMAA-GFP transgenic mice. In the subcutaneous model, vaccination delayed tumor initiation ($p=0.005$) and reduced tumor volume ($p=0.004$), accompanied by decreased tumor angiogenesis ($p=0.045$). Importantly, no systemic toxicity or significant changes in weight were observed.
Conclusion: By targeting angiogenesis, the KLH-AM mRNA vaccine effectively impaired tumor growth in melanoma models. These results highlight AM as an important pro-angiogenic factor driving tumor vascularization and support further development of AM-directed mRNA therapeutic vaccination as a strategy to disrupt angiogenesis-dependent tumor progression.This study was funded by Agencia Estatal de Investigacion (AEI, Spain)'s project PID2022-136735OB-I00.

#4784 Galectin-1 as a central regulator of angiogenesis and metabolic reprogramming in glioblastoma.

Luisina B. Ripari[1], Joaquin P. Merlo[2], Mariana B. Vera[3], Olivia Morris-Hanon[3], Monica B. Mezmezian[4], Marcos Hermida[5], Gustavo E. Sevlever[3], Diego O. Croci[6], Guillermo A. Videla-Richardson*[1], Gabriel A. Rabinovich*[7]

[1]Laboratorio de Investigacion Aplicada a las Neurociencias (LIAN-INEU-Fleni), Fundacion para la Lucha de las Enfermedades Neurologicas de la Infancia (Fleni); Laboratorio de Glicomedicina, Instituto de Biologia y Medicina Experimental (IBYME-CONICET), Buenos Aires, Argentina,[2]Laboratorio de Glicomedicina, Instituto de Biologia y Medicina Experimental (IBYME-CONICET); UADE - INTEC, Buenos Aires, Argentina,[3]Laboratorio de Investigacion Aplicada a las Neurociencias (LIAN-INEU-Fleni), Fundacion para la Lucha de las Enfermedades Neurologicas de la Infancia (Fleni), Buenos Aires, Argentina,[4]Laboratorio de Neuropatologia y Biologia Molecular, Fundacion para la Lucha de las Enfermedades Neurologicas de la Infancia (Fleni), Buenos Aires, Argentina,[5]Departamento perinatal, Hospital Nacional Prof. Alejandro Posadas, Buenos Aires, Argentina,[6]Instituto de Histologia y Embriologia de Mendoza (IHEM-CONICET), Buenos Aires, Argentina,[7]Laboratorio de Glicomedicina, Instituto de Biologia y Medicina Experimental (IBYME-CONICET), Buenos Aires, Argentina

Glioblastoma (GB) is the most aggressive tumor of the central nervous system characterized by rapid growth and remarkable resistance to current therapies. Its biology is shaped by profound inter- and intra-tumoral heterogeneity, a highly immunosuppressive microenvironment, and a strong dependence on metabolic and vascular adaptations that allow tumor cells to thrive under hypoxic and nutrient-poor conditions. A subpopulation enriched in glioma stem-like cells (GSCs) plays a central role in these adaptations, sustaining tumor expansion through flexible metabolic and angiogenic programs. Galectin-1 (GAL1), a glycan-binding lectin with multiple roles in the tumor microenvironment, is considerably elevated in gliomas. This led us to investigate whether GAL1 could act as a common regulator of both metabolism and angiogenesis in GB. We established patient-derived GSC lines (G02, G03, G08, G09), a model that preserves the clinical heterogeneity typical of this disease. RNA-seq and functional assays revealed clear differences among cell lines. G02 showed an endothelial-like signature and promoted endothelial cell migration, while G03 was enriched in angiogenesis-related pathways and formed robust tube-like structures in vitro, in line with higher VEGF secretion ($p<0.01$). Biopsies from the corresponding patients (G02 and G03) recapitulated this biology, displaying broad areas of microvascular proliferation. Inhibition of GAL1 with antibodies or siRNA reduced tube formation mainly in G03, suggesting that not all angiogenic profiles are likely dependent on GAL1. Metabolic analysis further supported this idea. Seahorse analysis showed that G02 and G03 respond to GAL1 depletion by shifting toward opposite metabolic programs, and complementary assays (TMRE, MitoSOX) revealed high mitochondrial activity in G02 (FC=2), while G09 displayed impaired OXPHOS (FC=0.5). Together, our data indicate that both secreted and intracellular GAL1 contribute to the metabolic and angiogenic adaptations that sustain GB growth. These results emphasize that GSCs rely on distinct yet coordinated strategies to obtain resources, and position GAL1 as a central regulator of these processes. Defining the cellular and functional profiles that determine sensitivity to GAL1 inhibition may help guide the development of more precise anti-angiogenic or metabolic therapies for glioblastoma.

#4785 Thermal regulation of dysbiotic tumor vasculature.

Amie A. Brint, Hailey Kristian, Samir Jenkins, Robert Griffin, **Ruud Petrus Dings**

University of Arkansas for Medical Sciences, Little Rock, AR

Antibiotic use has substantially increased over the years. Although oral antibiotics treat infections, they also drastically change the gut microbiota, disturbing commensal bacteria that are essential for maintaining a number of homeostatic processes. Our recent published and unpublished work have shown that GI-tract dysbiosis causes drastic changes to the stroma of distal tumors, resulting in accelerated cancer progression of various solid tumors. We discovered that dysbiosis induces a significant suppression of adhesion molecules on tumor endothelial cells. Conversely, localized hyperthermia has been increasingly recognized to elicit various cellular responses, yet the effects of hyperthermia on the tumor vasculature during ABX-induced dysbiosis are unknown. We found that hyperthermia (60 min of either 41.5 °C or 43 °C, as compared to 37 °C) influenced various adhesion molecules to different degrees. Especially hyperthermic exposure of 43 °C for 1 hr was able to overcome the adhesion-molecule suppression found on the tumor vasculature during dysbiosis. Functional studies with splenocytes and T cells demonstrated that the induced increase in vasculature adhesion molecules caused increased tethering of leukocytes. Although further studies are warranted, these results demonstrate that hyperthermia exerts immune modulating effects and is capable of overcoming the dysbiosis-induced phenotype. Since current systemic anti-cancer treatments are often limited by their toxicities, localized hyperthermia may become a viable alternative in the future.

#4786 AI-powered deep phenotyping: Vision transformers quantify vessel normalization and immune efficacy in a 3D vascularized tumor-on-a-chip.

Delaney K. Donnelly, Byungjun Lee, Junfeng Wang, Sabrina Figueroa Buezo, Hyeon-geun Park, Bushra Rajput, Yeongmin Choi, Jiho Kim, Jihye Baek, Eunjeong Kim, Joseph Harris, Kyusuk Baek, Branka Mitrovic, Tsung-Li Liu, Aneesh Sathe, Sanghee Yoo

Qureator, Inc., San Diego, CA

Introduction: Dysfunctional, chaotic tumor vasculature creates a hostile physical barrier to immune infiltration, severely limiting the efficacy of immunotherapies. Conventional models fail to replicate this structural complexity or the dynamic interplay between vessels and immune cells. To address this, we validated a high-throughput, AI-driven vascularized tumor microenvironment (TME) platform designed not only to model this barrier but to rigorously quantify tumor-induced angiogenesis, vessel normalization, and downstream immune cell behaviors.
Methods: Using the Qureator's microphysiological system (MPS), we generated a patient-derived gastric cancer model with perfusable vasculature. To validate predictive utility, models were treated with FDA-approved anti-angiogenic agents (e.g., Ramucirumab, a second-line therapy for gastric cancer) and a panel of vessel normalization reagents. We developed a customized, machine learning-powered Vision Transformer (ViT) pipeline to analyze immunofluorescence images. Unlike traditional morphological tools, our ViT approach utilizes self-attention mechanisms to capture global dependencies, allowing for the rigorous quantification of high-dimensional deep phenotyping features.
Results: The platform established a clinically relevant TME where Ramucirumab treatment significantly reduced peritumoral vessel density, accurately recapitulating clinical anti-angiogenic effects. Beyond simple density metrics, our ViT-based deep phenotyping identified distinct phenotypic clusters among different normalization reagents based on complex, non-linear features such as vessel tortuosity, branch density, and pericyte coverage. Crucially, this high-dimensional AI analysis revealed a direct functional correlation: reagents that induced a specific "normalized" vascular signature were strongly associated with a measurable increase in T cell-mediated killing efficiency, linking restored vascular morphology to improved therapeutic outcomes.
Conclusion: This AI-enabled TME platform represents a powerful New Approach Methodologies (NAMs), integrating deep learning with complex biology to perform "deep phenotyping" of the tumor microenvironment. By precisely linking vascular morphology to functional immune outcomes, it accelerates the discovery of therapies that restore the TME to a treatment-responsive state.

#4787 Glutaminolysis promotes cancer-associated angiogenesis via the GLS1-TNC signaling pathway.

Jianqiang Yang, Zhenzhen Fu, Soumya Vijaya Kuma, Fanghui Chen, **Yong Teng**

Emory University, Atlanta, GA

Glutaminolysis, a metabolic pathway in which glutamine is converted into glutamate and subsequently into α-ketoglutarate, supports cancer progression by supplying energy and biosynthetic precursors that sustain tumor cell growth, survival, and metabolic flexibility. While its metabolic functions have been extensively studied, its contribution to tumor angiogenesis is not well defined. In this study, we demonstrate that knockdown of glutaminase 1 (GLS1), a key regulator of glutaminolysis, in head and neck cancer (HNC) xenografts markedly reduced intratumoral CD31⁺ endothelial cells, consistent with impaired angiogenesis. In vitro, HUVECs exposed to exosomes from GLS1-deficient HNC cells exhibited diminished migratory capacity and reduced tube formation compared with those treated with control-derived exosomes. Proteomic analysis by LC-MS revealed that exosomes lacking GLS1 were deficient in tenascin-C (TNC), a matricellular protein with established pro-angiogenic activity. Mechanistic studies showed that GLS1 loss triggered USP1-dependent proteasomal degradation of caveolin-1 (CAV1), a critical regulator of exosome biogenesis. Because CAV1 promotes the incorporation of TNC into exosomes, GLS1 deficiency disrupted the CAV1-TNC signaling axis, resulting in exosomes lacking pro-angiogenic cargo. Consequently, these defective exosomes failed to activate extracellular matrix remodeling and adhesion pathways in HUVECs, thereby limiting endothelial migration and angiogenic capacity. Together, these findings uncover a previously unrecognized role for GLS1 in promoting tumor angiogenesis and further suggest that targeting GLS1 could not only suppress tumor metabolism but also inhibit angiogenesis in HNC.

#4788 PSMA-expressing tumor vasculature in renal cell carcinoma: spatial, functional, and therapeutic implications.

Ryuta Watanabe[1], Keito Kagimoto[1], Mami Chosei[2], Tomohisa Sakaue[3], Mie Kurata[4], Noriyoshi Miura[1], Riko Kitazawa[5], Tadahiko Kikugawa[1], Shigeki Higashiyama[6], Takashi Saika[1]

[1]Department of Urology, Ehime University Graduate School of Medicine, Toon, Japan,[2]Department of Biochemistry and Molecular Genetics, Ehime University Graduate School of Medicine, Toon, Japan,[3]Department of Cardiovascular and Thoracic Surgery, Ehime University Graduate School of Medicine, Toon, Japan,[4]Department of Analytical Pathology, Ehime University Graduate School of Medicine, Toon, Japan,[5]Division of Diagnostic Pathology, Ehime University Hospital, Toon, Japan,[6]Department of Oncogenesis and Growth Regulation, Osaka International Cancer Institute, Osaka, Japan

Background

Prostate-specific membrane antigen (PSMA) is an established diagnostic and therapeutic target in prostate cancer, widely utilized in PSMA-PET imaging and PSMA-directed radioligand therapy. Beyond prostate cancer, PSMA has also been reported in the tumor-associated vasculature of several solid tumors, suggesting its potential as a vascular marker and therapeutic target. In renal cell carcinoma (RCC), PSMA-positive vessels have been described, yet their spatial distribution, mechanisms of induction, contribution to angiogenesis, and therapeutic relevance remain insufficiently defined.

Methods

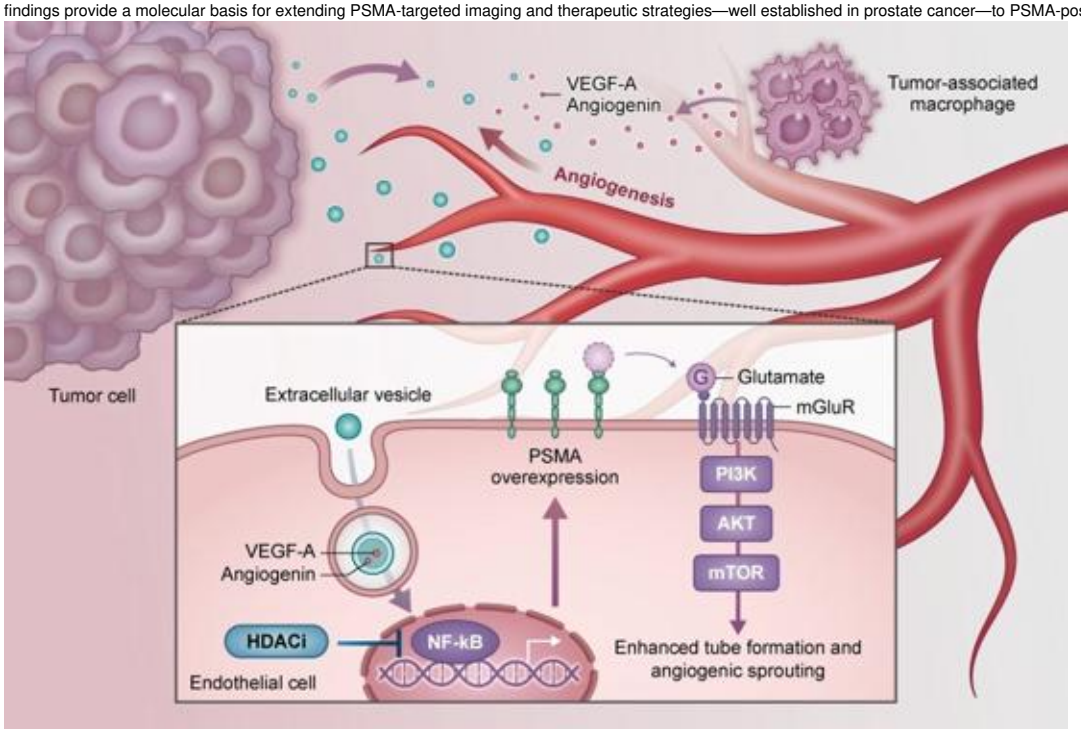
Spatial transcriptomic analysis (10x Genomics Visium) was performed to characterize the spatial localization of FOLH1 (PSMA) expression and associated transcriptional changes within RCC tissues. Immunohistochemistry for PSMA and CD31 was conducted on 45 RCC cases to evaluate associations with recurrence and venous invasion. Endothelial cells were exposed to RCC-derived conditioned medium and differential centrifugation fractions to assess PSMA induction, angiogenic activity, and transcriptional alterations. A Caki1 xenograft model was used to investigate the therapeutic effect of the PSMA inhibitor 2-PMPA.

Results

Spatial analysis showed that FOLH1 expression was concentrated within peritumoral vascular regions and overlapped with areas exhibiting increased expression of angiogenesis-related genes. Immunohistochemistry confirmed that PSMA expression was restricted to tumor-associated vessels, and strong PSMA expression was significantly associated with recurrence and venous invasion. Among RCC-derived fractions, only the 10,000 g pellet robustly induced endothelial PSMA expression, enhanced tube formation, and activated angiogenesis-related transcriptional programs. In vivo, treatment with 2-PMPA significantly reduced tumor growth and microvessel density.

Conclusions

PSMA-positive vasculature in RCC represents an endothelial phenotype induced by tumor-derived vesicles and functionally contributes to angiogenesis. The association between strong PSMA expression and aggressive clinicopathologic features, together with the anti-angiogenic effect of PSMA inhibition, highlights PSMA-positive vessels as a promising therapeutic target in RCC. These findings provide a molecular basis for extending PSMA-targeted imaging and therapeutic strategies—well established in prostate cancer—to PSMA-positive RCC.



#4789 Apelin is a candidate driver for neuromuscular junction recovery from cancer cachexia.

Alice Wang, Tobias Janowitz

Cold Spring Harbor Laboratory, Cold Spring Harbor, NY

Cancer cachexia is a systemic wasting condition that affects multiple organs and failure to recover from the condition ultimately leads to death. It is estimated to affect as many as 80% of patients with cancer and accounts for up to 20% of cancer deaths. Cancer cachexia is characterized by negative energy balance leading to weight loss and organ atrophy. Cancer cachexia results in decreased physical ability, reduced therapy efficacy, and increased mortality and morbidity. There is emerging evidence that hormone signaling drives inter-organ changes in cancer cachexia development, including changes in the brain, liver and muscle. I have developed a cancer cachexia mouse model in which both cancer cachexia development and recovery can be studied in the same animal. Using this model, I observed decreased muscle mass during cancer cachexia development and increased muscle mass during cancer cachexia recovery. By performing unbiased analyses on quadriceps RNA sequencing data from cachectic and recovering mouse, I identified a cluster of genes indicating alterations in the neuromuscular junctions. This suggests that neuromuscular junctions (NMJ) may play a role in muscle atrophy and regeneration in cancer cachexia. By focusing my analyses on circulating hormones, I identified apelin as the most upregulated hormone in the skeletal muscle during cancer cachexia recovery. Apelin has been associated with age-related muscle atrophy, muscle function and the neuromuscular junction. I have modulated apelin level systemically and demonstrated that systemic apelin administration decreased intramuscular E3 ligase (protein degradation) and increased Pax7 (regeneration) marker in the lower leg muscle. These findings have been corroborated by detailed histopathology analyses. My work establishes a novel mouse model that enables studying cachexia development and recovery in the same mice. This model may lead to the discovery of new treatment options that can prevent or treat cancer cachexia. In addition, my work suggests that there may be potential targetable mechanisms for accelerating muscle recovery from cancer cachexia.

#4790 Cancer reprograms the remote vascular microenvironment to promote atherosclerosis.

Lingfeng Luo[1], Changhao Fu[1], Kai-Uwe Jarr[2], Richard Baylis[3], Virginia Sun[3], Julius Heemelaar[3], Moritz von Scheidt[4], Daniela Ramirez[4], Johannes Krefting[4], Nadja Sachs[5], Justus Wettich[5], Hanna Winter[5], Hua Gao[1], Fudi Wang[1], Allen M. Haas[6], Kevin T. Nead[7], Lars Magdefessel[5], Heribert Schunkert[4], Tomas Neilan[3], Nicholas J. Leeper[1]

[1]Surgery, Stanford University, Stanford, CA,[2]Cardiology, Angiology, and Pneumology, Heidelberg University Hospital, Stanford, Germany,[3]Medicine, Massachusetts General Hospital, Boston, MA,[4]Surgery, Technische Universitat Munchen, Munich, Germany,[5]Vascular and Endovascular Surgery, Technical University Munich, Munich, Germany,[6]University of Texas MD Anderson Cancer Center, Houston, TX,[7]Radiation Oncology, University of Texas MD Anderson Cancer Center, Houston, TX

Cancer releases a broad repertoire of circulating cytokines and angiogenic factors that remodel distant tissues. However, the remote vascular consequences of tumor-derived inflammatory signaling remain incompletely understood. Our preliminary data suggest that cancer activates a TNF-driven, LRG1-dependent endothelial pro-angiogenic pathway implicated in remote vascular remodeling. We profiled vascular responses to colorectal tumors using bulk and single-cell RNA sequencing of aortic tissues from tumor-bearing versus control mice across diverse backgrounds, endothelial assays stimulated with tumor-conditioned media, O-link proteomics to define tumor-induced circulating mediators, and in vivo perturbation of the TNF-LRG1 axis using a TNF-neutralizing antibody or endothelial-targeted AAV-LRG1 knockdown. Across independent human datasets, we further observed that large cohort studies from both Europe and the United States demonstrate an increased risk of atherosclerotic CVD in cancer survivors, tumor resection is associated with a reduced risk of atherosclerotic events, and biobank tissues from cancer patients display elevated vascular TNF-LRG1 signaling, supporting clinical relevance. In conclusion, cancer upregulates TNF to activate an LRG1-dependent endothelial pathway, driving angiogenesis and vascular remodeling. These findings uncover a previously unrecognized tumor-CVD interaction and identify the TNF-LRG1 axis as a potential therapeutic target to mitigate cancer-induced vascular dysfunction.

#4791 The role of endothelial cell remodeling in driving immunotherapy resistance of hepatocellular carcinoma.

Baoyi YIN[1], Shufen CHEN[1], Zhewen XIONG[1], Patrick WONG[1], Zhuo Yu[2], Stephan CHAN[1], Alfred Sze Lok CHENG[1]

[1]The Chinese University of Hong Kong, Hong Kong, Hong Kong,[2]Shuguang Hospital Affiliated to Shanghai University of Traditional Chinese Medicine, Shanghai, China

Background: Hepatocellular carcinoma (HCC) has shown limited durable responses to immune checkpoint blockade (ICB) therapies due to tumor microenvironment (TME)heterogeneity. Combining anti-vascular endothelial growth factor (VEGF) with ICB has enhanced therapeutic efficacy, but the limited benefits suggest that understanding endothelial cell (EC) remodeling beyond angiogenesis is essential for enhancing ICB effectiveness. Integrated analyses identified a novel transcription factor(TF) transcriptional program, coupled with elevated bromodomain and extra terminal domain (BET) protein BRD4 expression, that was associated with EC remodeling in ICB-resistant HCC. Emerging studies have shown that this TF functions depend on BRD4 through its recruitment to a specific enhancer region, and inhibiting BRD4 with BET inhibitors can reduce its expression. Hence, we aim to delineate the microenvironmental cue that direct EC remodeling for tumor immunosuppression and their role in promoting ICB resistance.
Methods: Single-cell transcriptomic profiling was performed on samples from a Phase II clinical trial of pembrolizumab in HCC patients (NCT03419481). An ICB-resistant HCC mouse model generated via iterative selection was utilized for validation. BET inhibitor AZD5153, administered in nanoparticle formulations, was used to suppress BRD4 and TF expression selectively in ECs. Quantitative immunofluorescence and flow cytometry was employed for EC assessment and intratumoral immune microenvironment.
Results: scRNA-seq analysis revealed that tumor vessels in ICB non-responders were enriched with disorganized macrovascular-like endothelial cells (MaVEC), which likely originate from liver sinusoidal endothelial cells (LEC). Suggesting a dynamic trans-differentiation process from LEC to MaVEC during the development of ICB resistance. Notably, we identified a novel TF as the top regulon in MaVEC, exhibiting increased transcription factor activity along the LEC-to-MaVEC trajectory, and closely associated with BRD4 in MaVEC. Treatment with the EC-targeted nanoparticle-delivered AZD5153 can suppress this TF expression, caused remarkable intratumoral MaVEC-to-LEC reversion and reshaped the intratumoral immune microenvironment, leading to an augmented anti-PD-L1 efficacy.
Conclusions: Our study reveals that the dynamic trans-differentiation from LEC to MaVEC is related with ICB resistance in HCC. Blocking this EC transformation shifts the TME from immunosuppressive to stimulatory, re-sensitizing tumors to anti-PD-L1 therapy. This project may yield new strategies to counter adaptive immune resistance in HCC.
Keywords: Hepatocellular carcinoma, Immune-checkpoint blockade, Endothelial cells remodeling.

#4792 Krüppel-like factor 8 promotes triple negative breast cancer angiogenesis and metastasis through matrix metalloproteinases.

Ebaa Y. Ababneh, Heng Lu, Chunjiang He, Chao Shen, Lin Yu, Satadru K. Lahiri, Debarati Mukherjee, Xianhui Wang, Jihe Zhao

Burnett School of Biomedical Sciences, College of Medicine, University of Central Florida, Orlando, FL

Krüppel-like factor 8 (KLF8) is a transcription factor known to promote breast cancer. KLF8 upregulates matrix metalloproteinases (MMPs) that degrade the extracellular matrix (ECM) and are associated with enhanced angiogenesis. However, KLF8's role in BC angiogenesis through MMPs has not been elucidated. We hypothesize that KLF8's upregulation of MMPs promotes an angiogenic switch in triple-negative breast cancer (TNBC), the most aggressive breast cancer subtype, by degrading the ECM to create physical space and increase the bioavailability of pro-angiogenic factors. Inducible KLF8 overexpression (MCF10A-Ras) and knockdown (MDA-MB-231) cell models were used to study the function of KLF8 *in vitro*. We employed the broad-spectrum matrix metalloproteinase (MMP) inhibitor GM6001 to confirm dependency, endothelial tube formation and HUVEC recruitment assays to evaluate angiogenesis potential, Quantitative real-time PCR (qRT-PCR) and Vascular Endothelial Growth Factor (VEGF)-A ELISA to measure growth factor expression and active factor release. Findings were then validated using the *in vivo* xenograft tumor growth and tail vein lung metastasis assays, angiogenesis in excised tumors was quantitatively evaluated using microvessel density staining (cluster of differentiation 31 (CD31)), with MMP rescue experiments used to establish molecular pathway. Our results show that KLF8 overexpression promotes endothelial cell migration and tube formation in an MMP-dependent manner. The KLF8-MMP-VEGF axis is established using VEGFA ELISA that shows KLF8-dependent accumulation of active VEGF in conditioned medium. This effect was eliminated by MMP inhibition, Notably, KLF8 does affect VEGF mRNA expression. *In vivo* experiments validate these results showing that KLF8 overexpression markedly increases angiogenesis, xenograft tumor growth, and lung metastasis. On the other hand, MMP-9 or MMP-14 rescue in the knockdown cells restores the effects of KLF8 knockdown. Poor distant metastasis-free survival and elevated angiogenic markers are associated with high KLF8 expression in human breast cancer cohorts. In conclusion, our work demonstrates KLF8's role in promoting TNBC metastasis by activating MMP9 and MMP14, which in turn enhances the angiogenic microenvironment through the release of soluble VEGF. This work advances our understanding of KLF8's carcinogenic function and suggests that KLF8-MMP signaling could be a promising antiangiogenic therapeutic target for TNBC.

#4793 Tumor-intrinsic CD80 mediates cancer stemness and vascular mimicry in aggressive oral squamous cell carcinoma.

Yu-Lin Chen[1], Shih Sheng Jiang[1], Shih-Han Huang[1], Ssu-Han Wang[1], Fang-Yu Tsai[1], Yen-Chung Chiu[1], Kai-Ping Chang[2], Daw-Yang Hwang[3], Ko-Jiunn Liu[3], Yu-Wen Su[1], Ya-Wen Chen[1]

[1]National Health Research Institute, Miaoli County, Taiwan,[2]Chang Gung University, Taoyuan, Taiwan,[3]National Health Research Institute, Tainan, Taiwan

Background Intratumoral heterogeneity drives oral squamous cell carcinoma (OSCC) progression by fostering tumor cell plasticity. This plasticity poses a major therapeutic challenge. We identified the immune molecule CD80 as a potential driver of this process and dissected its non-canonical, tumor-intrinsic functions.

Methods Syngeneic OSCC sublines were established through *in vivo* selection. Gene profiling and single-cell RNA sequencing (scRNA-seq) of mouse tumors, integrated with human datasets, identified candidate drivers. CD80 function was interrogated using shRNA knockdown, cell sorting, and assays of tumorigenesis, cancer stemness, and vascular mimicry (VM) in mouse models and human OSCC cells. SOX2 rescue experiments assessed mechanistic dependency.

Results Gene expression profiling and scRNA-seq identified the co-stimulatory molecule CD80 as highly expressed in the aggressive sublines, and its expression correlated with poor patient prognosis in OSCC. Crucially, CD80 knockdown reduced tumor burden in immunocompetent and immunodeficient mice, demonstrating a tumor cell-intrinsic oncogenic role independent of its canonical function in adaptive immunity. Mechanistically, CD80 enhanced cancer stemness, as evidenced by increased sphere formation and SOX2 expression. *In vivo* scRNA-seq data indicated that $CD80^+$ tumor cells were associated with EMT-active, metabolic, and angiogenesis pathways. Moreover, CD80 knockdown impaired vessel-like formation *in vitro*, while CD80-high tumors displayed prominent VM *in vivo*. Ectopic SOX2 expression rescued both sphere and vessel-like formation in CD80 knockdown cells, suggesting that CD80-mediated oncogenic effects are partly SOX2-dependent.

Conclusions Our findings reveal a novel, non-immunological role for CD80 in driving OSCC progression. By promoting cancer stemness and VM via a CD80-SOX2 axis positions CD80 as a promising therapeutic target.

#4794 Prognostic relevance of angiogenesis-associated genes in gliomas: Influence of idh/1p19q status and opportunities for antiangiogenic immunotherapy strategies.

Pijush Das[1], Kevin A. Camphausen[2], Uma Shankavaram[2]

[1]National Cancer Institute, National Institutes of Health (NIH), Bethesda, MD,[2]National Cancer Institute, Bethesda, MD

Background: Angiogenesis, the formation of new blood vessels, is central to glioma progression and supports tumor growth and invasion. Early identification of aggressive biology in lower-grade gliomas (LGG) is essential for guiding treatment decisions. We developed an immune-oriented angiogenesis gene signature that characterizes aggressive tumor phenotypes in LGG and glioblastoma (GBM). The study also evaluates its association with key glioma biomarkers, including IDH mutations and 1p/19q co-deletions, and assesses its prognostic relevance across both tumor types.
Objective: To develop and validate an immune-oriented angiogenesis gene signature that identifies aggressive glioma biology, predicts patient prognosis in LGG and GBM, and evaluates its relationship with IDH mutation and 1p/19q co-deletion status.
Methods: We analyzed LGG and GBM samples from The Cancer Genome Atlas (TCGA). Immune infiltration levels were estimated using EPIC, and samples were classified into high and low infiltration groups. Differentially expressed genes between these groups were identified, followed by Weighted Gene Co-expression Network Analysis (WGCNA) to cluster co-expressed genes into modules. Fisher's exact test was used to assess enrichment of WGCNA module genes within the Hallmark Angiogenesis gene set, prioritizing overlapping genes. Associations with IDH status, 1p/19q co-deletion, and patient survival were evaluated using Cox regression, Kaplan-Meier analysis, and time-dependent ROC curves. Validation was performed in the Chinese Glioma Genome Atlas (CGGA) and two single-cell datasets (pLGG: GSE222850; GBM: GSE138794).
Results: The derived immune-oriented angiogenesis signature was significantly associated with IDH mutation and 1p/19q subtypes (Adj. $p \leq 0.05$) and strongly predicted patient outcomes. Higher signature expression correlated with poorer survival and remained independently prognostic in multivariate analyses (e.g., TCGA LGG $p = 3.28\times10^{-7}$; CGGA LGG $p = 1.08\times10^{-8}$). The signature showed strong predictive accuracy in time-dependent ROC analyses (TCGA LGG AUCs: 1-year 0.959, 3-year 0.873, 5-year 0.812). Gene expression patterns observed in LGG showed a progressive trend consistent with certain GBM subgroups. In single-cell datasets, most genes showed significant differential expression between high and low immune infiltration groups (Adj. $p \leq 0.05$).
Conclusion: We identified and validated an immune-oriented angiogenesis gene signature that integrates genetic, molecular, and clinical features across gliomas. The signature demonstrates strong prognostic value in both LGG and GBM and reflects increasing angiogenic activity along glioma progression. This gene set may serve as a practical tool for patient risk stratification and offers potential targets for future therapeutic strategies.

#4796 CXCL17 Drives angiogenesis to promote progression in cutaneous squamous cell carcinoma.

Alok R. Khandelwal, Cherie-Ann O. Nathan, Keerthan Jaganmohan

Otolaryngology, Head and Neck Surgery, LSU Health Shreveport, Shreveport, LA

Cutaneous squamous cell carcinoma (cSCC) represents a growing public health challenge, with 200,000 Americans diagnosed annually and limited therapeutic interventions. Despite widespread awareness of ultraviolet B (UVB) radiation as a primary etiologic factor, current prevention strategies remain inadequate, underscoring the urgent need for mechanism-based approaches to interrupt cSCC development and progression. Our investigation unveils a critical molecular mechanism by which CXCL17 drives pro-angiogenic signaling in human microvascular endothelial cells. Comprehensive molecular analysis revealed a profound activation of key oncogenic and angiogenic pathways upon CXCL17 treatment, with significant phosphorylation of endothelial nitric oxide synthase (eNOS), protein kinase B (pAKT), nuclear factor kappa B (NFκB), and hypoxia-inducible factor-1α (HIF-1α). The coordinated activation of these signaling molecules suggests a robust angiogenic reprogramming mechanism. Notably, eNOS phosphorylation indicates enhanced nitric oxide production, a critical mediator of endothelial proliferation and vessel formation. Concurrent AKT activation promotes endothelial cell survival, while NFκB and HIF-1α upregulation demonstrates metabolic and inflammatory adaptations that support aggressive vascular remodeling. Syngeneic Tumor-Cell Xenograft model corroborated these molecular findings, demonstrating significantly reduced CD31 staining in CXCL17-knockout tumors, directly linking CXCL17 to tumor angiogenesis. Clinical correlation studies further substantiated CXCL17's role in metastatic potential, with elevated expression associated with increased perineural invasion and tumor aggressiveness. Our comprehensive analysis establishes CXCL17 as a pivotal molecular orchestrator of angiogenic processes in cutaneous squamous cell carcinoma, offering novel insights into tumor progression mechanisms.

#4797 Antagonistic SMAD2/3 control of TIMP-1, VEGF-A, and hypoxia signaling in myofibroblasts shapes histotype-specific angiogenesis in lung cancer.

Jordi Alcaraz[1], Natalia Isabel Diaz Valdivia[1], Paula Duch[1], Marselina Arshakyan[1], Amelia Parker[2], Alejandro Bernardo Suarez[1], Danielle Park[3], Erik Sahai[3], Noemi Reguart[4], Derek C. Radisky[5], Oriol Casanovas[6]

[1]Universitat de Barcelona, Barcelona, Spain,[2]Garvan Institute of Medical Research, Darlinghurst, Australia,[3]The Francis Crick Institute, London, United Kingdom,[4]Medical Oncology Department, Hospital Clinic i Provincial de Barcelona, Barcelona, Spain,[5]Mayo Clinic Florida, Jacksonville, FL,[6]Catalan Institute of Oncology, Barcelona, Spain

Non-small cell lung cancer (NSCLC) exhibits strikingly different responses to antiangiogenic therapies between its two major histologic subtypes, lung adenocarcinoma (LUAD) and squamous cell carcinoma (LUSC), suggesting an histotype-specific regulation of angiogenesis. Cancer-associated fibroblasts (CAFs) commonly exhibit an activated/myofibroblast-like phenotype in NSCLC, and are emerging as key modulators of tumor progression; however, their contribution to angiogenic control remains undefined. Here, we investigated angiogenesis and hypoxia signatures in NSCLC and integrated bulk RNA-seq, scRNA-seq, CAF secretome profiling, genetic perturbations, and functional in vitro and in vivo assays to dissect the histotype-dependent production of pro-angiogenic factors by CAFs. We observed greater angiogenesis and reduced necrosis/hypoxia in LUAD compared to LUSC across multiple patient cohorts. The LUAD-CAF secretome was primed for angiogenesis through SMAD3-dependent overproduction of key regulators, most notably TIMP-1 and VEGF-A. We also uncovered a previously unrecognized role for TIMP-1 in promoting endothelial hyper-branching. In contrast, LUSC-CAFs displayed attenuated angiogenic activity despite robust HIF-1α upregulation and an hypoxia-associated transcriptional program, due to their epigenetic repression of SMAD3 and compensatory increase in SMAD2. Collectively, these results reveal that CAFs critically shape the distinct angiogenic landscapes of LUAD and LUSC through opposing SMAD2/3 regulation of TIMP-1, VEGF-A, and hypoxia signaling. These results further highlight the therapeutic potential of targeting stromal SMAD3/TIMP-1 in LUAD or microenvironmental stressors such as hypoxia and acidosis in LUSC. In addition, these findings provide a biological framework for understanding histotype-specific patterns of dissemination, immune evasion, and response to antiangiogenic therapies in NSCLC.

#4798 Comparison of three vascular endothelial markers in the evaluation of microvessel density in cutaneous melanoma.

Nolwabo Moyakhe[1], Benny Mosoane[1], Tebogo Marutha[2], Rahaba Marima[2], **Zodwa Dlamini**[2], Meshack Bida[1]

[1]Department of Anatomical Pathology, University of Pretoria, Pretoria, South Africa,[2]Pan African Cancer Research Institute (PACRI), University of Pretoria, Pretoria, South Africa

Background

Angiogenesis underpins tumor growth, survival, and metastasis in many solid cancers, including malignant melanoma. One way to quantify tumor angiogenesis is to assess microvessel density (MVD) using endothelial immunohistochemical markers. In routine practice, anti-factor VIII-related antigen, anti-CD31, and anti-CD34 are all used for this purpose, but how they stack up against each other in cutaneous melanoma is still not very clear. We compared these three markers to determine which is the most useful for MVD evaluation in this specific context.

Methods

We conducted an analytical comparative study using archival cutaneous melanoma samples collected between 2015 and 2021 at the University of Pretoria. Immunohistochemistry with anti-factor VIII, anti-CD31, and anti-CD34 antibodies was performed on 102 tissue sections from 34 cases. Three pathologists independently counted the microvessels in 10 high-power fields (200× magnification) for each marker. Data were analyzed using repeated-measures ANOVA with post-hoc testing ($p<0.05$).

Results

The mean MVDs were 77.33 (±29.57) for anti-CD34, 61.67 (±34.85) for anti-CD31, and 58.67 (±23.51) for anti-factor VIII. Anti-CD34 highlighted significantly more microvessels than anti-CD31 or anti-factor VIII ($p=0.003$). Post-hoc analysis confirmed significant differences between CD31 and CD34, and between CD34 and factor VIII ($p=0.001$). In contrast, anti-CD31 and anti-factor VIII did not show a meaningful difference in sensitivity or specificity for microvessel detection.

Conclusion

In this series, anti-CD34 performed better than anti-CD31 and anti-factor VIII in highlighting MVD in cutaneous melanoma. This is in line with reports from other solid tumors, suggesting that CD34 tends to pick up more vessels. While our sample size is modest and drawn from a single center, the data support the use of anti-CD34 as the preferred marker for intratumoral MVD assessment in surgical pathology, ideally alongside clinicopathological correlation and, where needed, complementary markers.

#4799 Lymphangiogenesis in the uterine horns: Implication of the Netrin-1 and UNC5B signaling pathway in physiology and cancer.

Lia Barcons, Nicolas Rama, Patrick Mehlen

Cancer Research Center of Lyon (CRCL), Lyon, France

The lymphatic system consists of an open, unidirectional network of lymphatic vessels maintaining tissue homeostasis, intestinal absorption, immunosurveillance and immunomodulation. These vessels are lined by lymphatic endothelial cells (LECs). Lymphangiogenesis, defined as sprouting of new lymphatic vessels from pre-existing vessels or embryonic veins, is the main mechanism driving the formation and expansion of lymphatic networks during embryogenesis and in adults under physiological conditions.
This process involves numerous molecules, most notably VEGF-C, but also axon-guidance cues such as Netrins (Hu et al., 2024). Lymphangiogenesis shares many features with angiogenesis, which depends mainly on VEGF-A, but also Netrin-1. Netrin-1, acting through its receptor UNC5B, regulates vascular endothelial migration and branching, thereby stabilizing the vascular network (Lu et al., 2004).
In our laboratory, scRNAseq analysis of murine uterine horns revealed that Netrin-1 and UNC5B are specifically expressed by LECs. The lymphatic network of uterine horns has never been investigated, nor has the role of the Netrin-1 and UNC5B in lymphangiogenesis in general. We hypothesize that Netrin-1 and UNC5B contributes to lymphatic network development by regulating LEC migration and tubulogenesis. Our preliminary in vivo data describe the expression patterns of Netrin-1 and UNC5B during lymphatic development in murine uterine horns. UNC5B and Netrin-1 knockout models are being generated to define their functional roles. In vitro studies on human dermal LECs are assessing Netrin-1 effects on migration and tubulogenesis.
The lymphatic system is a key route for metastatic dissemination, notably in endometrial cancer (Donoghue et al., 2007). Uterine horns are continuously lined by the endometrium, suggesting that lymphatic vessels within uterine horns may provide a pathway for endometrial cancer cell dissemination. Although Netrin-1 is normally absent in adult tissues, it is re-expressed in tumors, where it promotes tumor progression. If Netrin-1 contributes to lymphangiogenesis in uterine horns, it may similarly modulate lymphatic vessel formation and thereby facilitate metastasis in endometrial cancer.
Consistent with this, preliminary results showed that the neutralizing antibody anti-Netrin-1 in mice grafted with endometrial cancer cells significantly reduces lung metastases. The knockout models will help define how Netrin-1 and UNC5B could regulate lymphatic-dependent metastatic spread.
This project aims to characterize lymphangiogenesis in uterine horns and to define the roles of Netrin-1 and UNC5B in physiological and tumor contexts. Ultimately, this work may support new therapeutic applications for the anti-Netrin-1 antibody developed in our laboratory, currently in phase II clinical trial.

#4800 Targeting CD160 as an immunotherapy approach to modulate tumor angiogenesis and improve outcomes in triple-negative breast cancer.

Abdel-Ilah Aziz[1], Maxence Mocquery-Corre[2], Chloe Jean[2], Jessica Thevenard-Devy[2], Alexandre Berquand[2], Sabrina Haddou[2], Cathy Hachet[2], Andre F. Martins[3], Rachid El fatimy[1], Laurent Duca[2], Armand Bensussan[1], Sanae Ben Mkaddem*[1], Jerome Devy*[2]

[1]Faculty of Medical Sciences, UM6P Hospitals, Mohammed VI Polytechnic University, Ben Guerir, Morocco,[2]Universite de Reims-Champagne-Ardennes, UMR CNRS/URCA 7369, MEDyC, Reims, France,[3]Werner Siemens Imaging Center, Department of Preclinical Imaging and Radiopharmacy, Eberhard Karls University,, Tubingen, Germany, Germany

Triple-negative breast cancer (TNBC) is an aggressive subtype with limited treatment options and poor clinical outcomes. While immune checkpoint inhibitors (ICIs) have shown promise in TNBC, many patients remain unresponsive, highlighting the urgent need for new immunotherapeutic targets and mechanisms. CD160, a GPI-anchored receptor expressed on cytotoxic immune and endothelial cells, we have recently been proposed CD160 as a novel immune checkpoint inhibitor in solid tumors (Scheffges, Devy, *et al.* 2024). In this study, we investigated CD160 as a dual therapeutic target in TNBC, combining immunoregulatory and anti-angiogenic potential. Using a novel high-affinity monoclonal antibody against CD160, we demonstrate that targeting this receptor significantly inhibits pathological angiogenesis and promotes vascular normalization *in vitro* and *ex vivo*, without inducing cytotoxicity. These effects may contribute to enhanced immune infiltration and improved tumor perfusion, ultimately improving patient survival. To better understand CD160's mechanism of action, we explored its molecular interactions in human endothelial cells. Super-resolution microscopy and functional assays revealed that CD160 physically associates with LRP1, identifying it as a potential co-receptor involved in its vascular effects. These findings support the development of CD160-targeted immunotherapy as a promising strategy for TNBC, acting both as an immune checkpoint inhibitor and a modulator of the tumor vasculature.

#4801 DDR2 positive endothelial cells promote angiogenesis and metastasis in breast tumors.

Alessandra DiMauro[1], Audrey Brenot[1], Julien Lesage[1], Jade Weber[1], Vasilios Morikis[1], Jason D. Weber[2], Gregory D. Longmore[3]

[1]Washington University in St. Louis, St. Louis, MO,[2]Assoc. Professor, Dept. of Internal Medicine, Washington University, Saint Louis, MO,[3]Washington University School of Medicine, St. Louis, MO

The collagen receptor DDR2, a receptor tyrosine kinase, contributes to breast cancer progression through actions in both invasive tumor cells and tumor stromal cells. In the tumor stroma, DDR2 is predominantly expressed by cancer associated fibroblasts (CAFs) and therein contributes to the formation of a tumor permissive ECM which facilitates metastasis. Through an analysis of human breast tumor scRNAseq data and multiplex immunohistochemistry, we noted that DDR2 is also expressed by a subset of tumor $CD31^+$ endothelial and $LYVE1^+/CD31^+$ lymphatic cells. To determine whether this endothelial cell $DDR2^+$ population contributes to breast cancer progression, and if so how, we genetically depleted $Ddr2^{fl/fl}$ from endothelial cells using inducible $Cdh5\text{-}Cre^{ERT2}$ in the context of MMTV-PyMT mouse breast tumor model. In endothelial $Ddr2^{-/-}$ breast tumors there was no significant difference in primary tumor burden or total number of $CD31^+$ endothelial cells within the tumor; however, there was a significant reduction in lung metastases. Closer analyses revealed a decrease in $CD31^+$ vessel length and area in primary tumors from these mice and an associated increase in hypoxia. When VEGF-containing Matrigel plugs were implanted subcutaneously in ubiquitous DDR2 null mice, $CD31^+$ vessel growth into the plug was reduced. Vessel outgrowth from aortic rings from global DDR2 null mice was decreased. These data suggested some migratory defect in $Ddr2^{-/-}$ endothelial cells. To test this possibility directly, we developed, characterized, and utilized a microfluidic device wherein ECs are subjected to mechanical fluid flow within a 3D fibrin matrix. Genetic depletion of *Ddr2* and antibody inhibition of DDR2 both resulted in reduced EC migration. In summary, we find that DDR2 is present in a subset of ECs, possibly tip cells, and impacts tumoral and non-tumoral angiogenesis *in vivo* and *in vitro.*

#4802 Evaluation of the circulating angiome in cancer: Translational assessment of a 44-plex angiogenesis biomarker panel.

Hans Layman[1], Mai Abdel-Ghani[1], Grace Galen[1], Rony Garcia-Vivas[1], Jenna Slezak[1], Anu Mathew[1], Mingyue Wang[1], Catherine Demos[1], Pankaj Oberoi[1], Andrew B. Nixon[2], Jacob N. Wohlstadter[1]

[1]Meso Scale Diagnostics, LLC, Gaithersburg, MD,[2]Duke Univ. Medical Ctr., Durham, NC

Angiogenesis, the formation of new blood vessels from existing vasculature, is a hallmark of tumor progression, enabling malignant growth, invasion, and metastasis. Tumor-associated angiogenesis leads to the formation of leaky, poorly perfused vessels and localized hypoxia, fostering metabolic stress, immune evasion, and resistance to therapies. Vascular normalization through targeting of VEGF, Ang-2, and PDGF pathways can restore perfusion, enhance immune infiltration, and improve response. Although anti-angiogenic agents are widely used, no predictive biomarker identifies individuals that are likely to benefit. Previously, biomarker development for anti-angiogenic therapies focused on few vascular factors and did not capture the complexity of angiogenic signaling. To address this, we developed a 44-marker angiogenesis panel enabling high-throughput profiling of pro- and anti-angiogenic mediators relevant to oncology and vascular biology. Forty-four biomarkers encompassing established pro- and anti-angiogenic mediators (e.g., VEGF-A, Ang-2, Tie-2, IL-6) were literature-curated. Antibody pairs for each assay were optimized for the electrochemiluminescence detection-based MESO SCALE DISCOVERY (MSD) U-PLEX® platform. Double-spun platelet-poor EDTA plasma samples from Duke University was tested to identify a common diluent. Analytical characterization included LLOD/LLOQ, precision, spike recovery, and dilution linearity/parallelism determinations. The interclass correlation coefficient (ICC) and biological variance were evaluated using longitudinally collected plasma from 28 participants (27-79 y.o.), incorporating diurnal (morning and afternoon) draws over two months. Pharmacodynamic biomarker modulation was explored using retrospective plasma samples from two NCI studies —Cabozantinib + Panitumumab (NCT02008383) and Bevacizumab (NCT00416637). All assays met the predefined criteria, with >90% of assays achieving intra-/inter-assay precision of <15% CV. A single diluent supported multiplex compatibility. Dynamic ranges spanned 3-5 orders of magnitude, with analytical sensitivity for low and high abundance markers ranging from 0.06 pg/mL (IL-6) to 67.4 pg/mL (vWF), demonstrating sub-pg/mL detection. ICC analyses revealed good to excellent variable marker stability across the panel over two months. Retrospective analysis of both sets of NCI study samples demonstrated an association between (a) baseline markers and outcomes (OS, PFS) and (b) pharmacodynamic responses and expected treatment-induced changes, highlighting the value of the biomarker panel. This 44-plex panel demonstrates robust analytical performance, sensitivity, and reproducibility on the MSD® U-PLEX platform. The assay supports harmonized angiogenesis profiling, enabling standardized angiogenesis biomarker assessment in oncology research.

#4803 Ascites protects against ferroptosis and enables the peritoneal spread of ovarian cancer.

Yasaman Setayeshpour[1], Ssu-Yu Chen[1], Divya L. Dayanidhi[1], Yunji Lee[1], Shao-Chin Wu[1], Juan J. Aristizabal-Henao[2], Jianli Wu[1], Chao Chieh (Jerry) Lin[1], Nazanin Setayeshpour[1], Chiara Federico[1], Alexander A. Mestre[1], Michael A. Kiebish[2], Andrew Berchuck[1], David S. Hsu[1], Zhiqing Huang[1], Susan K. Murphy[1], Jen-Tsan Ashley Chi[1]

[1]Duke University, Durham, NC,[2]BPGbio, Waltham, MA

One of the most common sites of metastasis in ovarian cancer (OVCA) is the peritoneum. Often, this spread is accompanied by the accumulation of a fluid called ascites in the peritoneal cavity. Despite its common occurrence in metastatic OVCA patients, ascites and its influence on the peritoneal spread of OVCA are poorly understood. Interestingly, OVCA cells are vulnerable to ferroptosis, a type of cell death caused by lipid hydroperoxides. Hence, how these ferroptosis-sensitive OVCA cells persist in their spread to the peritoneum remains unknown. Here, we show that ascites robustly protects OVCA cell lines, patient-derived tumor cells and organoids against ferroptosis and enhances the peritoneal spread of OVCA cells in mice. Mechanistically, ascites downregulates the mitochondrial enzyme, 3-hydroxy-3-methylglutaryl-CoA synthase 2 (*HMGCS2*), which contributes to an increase in lipid droplets. Additionally, upon ferroptosis induction, ascites represses the upregulation of the transferrin receptor, *TFRC*, thereby decreasing cellular labile iron levels. Furthermore, we show that lipid-lowering fibrates reverse cellular changes induced by ascites, and they attenuate the peritoneal spread of OVCA cells in mice. Our findings implicate the importance of ascites in ferroptosis protection and the peritoneal spread of OVCA, and they suggest that targeting the ferroptosis protection by ascites may present a novel therapeutic approach to limit OVCA metastasis.

#4804 Synchronously implanted cold tumor abrogates anti-PD-1 response of hot tumor in a syngeneic mouse model.

Hao Sun, Ying Zheng, Luke Tsai, Xia Ding, Cassandra Rosemond

HD Biosciences, Inc. A WuXi AppTec company, San Diego, CA

Background and Objective: Synchronous cancer describes a new or second primary cancer that develops at the same time as the first primary cancer, either in the same organ or in a different organ with the same molecular basis. Synchronous cancer is not considered metastatic relapse. The prevalence of synchronous cancer varies depending on the cancer type, but overall, it is a rare event occurring in 4.5% to 11.7% of patients with multiple primary malignancies. The impact of a second primary tumor on the progression and treatment response of the first tumor remains poorly understood. This study investigates the interaction between two distinct primary tumors- MC38 colorectal cancer and LL/2 lung cancer- in a synchronous syngeneic mouse model. Specifically, we evaluated how the presence of LL/2 tumor influences the efficacy of anti-PD-1 immunotherapy against MC38 tumor. Changes in immune cell population and cytokine profiles in circulation and within the MC38 tumor microenvironment were also examined. These findings shed light on how inter-tumoral communication affects therapeutic efficacy in the presence of synchronous malignancies.

Method and Result: C57BL/6 mice were inoculated subcutaneously with 5 x 10^5 MC38 cells on the right flank. Mice in group 1 and 3 received an additional MC38 inoculation on the left flank, while group 2 and 4 received 5 x 10^5 LL/2 cells at the left flank. When MC38 tumor reached approximately 100 mm^3, mice were treated with 10 mg/kg of anti-PD-1 antibody intraperitoneally every 4 days. Tumor growth, body weights, immune cell populations, and cytokine levels in blood and tumor tissues were assessed after 10 days of treatment. The body weights of the mice remained no significant differences between groups. Interestingly, although the tumor volumes in group 2 were only slightly higher than in group 2, the tumor volumes in group 4 were significantly higher than in group 3, indicating the presence of LL/2 tumor greatly impaired the efficacy of anti-PD-1 immunotherapy against MC38 tumor. FACS analysis and cytokine analysis confirmed the changes of immune profiling that led to the insensitive of MC38 tumor to the immunotherapy.

Conclusion: The presence of a second primary cancer can profoundly affect the immune checkpoint inhibitor therapeutic response of the first primary tumor through inter-tumoral immune modulation. These findings emphasize the importance of evaluating tumor-tumor communication when designing treatment strategies for patients with synchronous cancer. WuXi AppTec Biology-IVPU offers bilateral tumors models and comprehensive in vivo capability for preclinical oncology drug efficacy studies.

#4805 Investigating the interaction between GBM and perivascular niche using an engineered brain microenvironment model.

Sheridan Ke-Wing Fok[1], Hanrong Ye[2], Ahmad Khalil[2], Brendan Harley[1]

[1]University of Illinois at Urbana-Champaign, Urbana, IL,[2]Biomedical Engineering, Boston University, Boston, MA

Introduction: Glioblastoma (GBM) is the largest histological group among brain tumors, accounting for 47.8% of malignant brain tumors in the adult population; its high infiltrative nature and incidence of tumor recurrence make GBM lethal and untreatable. Vessel co-option occurs when GBM invades the vasculature; tumor cells hijack pre-existing vessels and utilize it to move inside the brain. To understand GBM mechanisms and facilitate therapeutic developments against tumor recurrence, a tumor microenvironment model for vessel co-option is required. Our lab has previously developed a gelatin hydrogel platform using a photopolymerizable methacrylamide-functionalized gelatin (GelMA). This platform was coupled with the synthetic zinc finger gene regulator (SynZiFTR) to overexpress pro- and anti- angiogenic factors to control vascular formation. We aim to use this model to study the interaction between GBM and the perivascular niche.
Materials: Sequences of human PDGFR-β and ANG-2 were obtained from the NCBI database, which were later inserted into the vector backbone using a Gibson assembly cloning kit. The gelatin hydrogel model is generated by encapsulating a mixture of brain microvascular endothelial cells, normal human astrocyte, and pericytes (3:1: 1, 3 x 10^6 BMVECs/mL); PVN cells were resuspended with GBM spheroid in the GelMA-LAP solution and then polymerized by exposure to UV light.
Results: SynZiFTR containing human PDGFR-β was transduced into human brain vascular pericytes (HBVPs). Immunostaining showed a significant increase in PDGFR-β expression and vessel formation when encapsulated in the GelMA hydrogel with NHAs and BMVECs. Conditioned media collected from this pro-angiogenic microenvironment significantly increased tumor cell migration. We further validated the effect of this vessel network on GBM behavior by encapsulating GBM spheroid into the hydrogel model. We observed a similar increase in cellular outgrowth, and a reduced effect of TMZ on GBM spheroids. Ongoing efforts are expanding the study to consider maturation processes, where we observe overexpression of ANG-2 reduces the overall density of vessel formation, yet conditioned media from more mature vessel networks promotes GBM invasion into the surrounding hydrogel environment.
Conclusion: Our data demonstrate that the cytokines and growth factors released from pro- and anti-angiogenic brain microenvironments significantly affect tumor behaviors. Ongoing efforts seek to co-encapsulate GBM spheroids in engineered vascular hydrogels (overexpressed ANG-2) to more deeply investigate reciprocal interactions between GBM and perivascular cell compartments that shape vessel co-option and GBM invasion. We believe this model would greatly facilitate the development of new therapeutics against GBM recurrence and understanding of vessel co-option.

#4809 The role of estradiol and estrogen receptors in lung cancer: A focus on sex differences.

Omar A. Borges-Sosa, Maksat Babayev, Carolyn D. Ekpruke, Dustin Rousselle, Patricia Silveyra

Environmental and Occupational Health, Indiana University, Bloomington, IN

Background: Lung cancer (LC) is the first and second most diagnosed cancer in males and females, respectively. Despite advancements, LC remains the leading cause of cancer-related mortality worldwide. Recent discoveries have reopened the discussion about the potential influence of hormonal factors on sex differences in LC outcomes. Among these factors, the role of 17β-estradiol (E2) in LC tumor progression is still unclear. This study aims to understand the influence of E2 and its possible role in cell proliferation and tumor growth in LC.
Methods: To study the contribution of E2 to metabolic activity in vitro, we exposed male and female human bronchial epithelial (HBE) cell lines (BEAS-2B, 16HBEC14o-, and HBEC3-KT), and human and murine LC cell lines (NCI-H441, NCI-1650, NCI-1975, A549, LL/2-Luc2) to seven different concentrations of E2 (from 1pM to 1uM), or vehicle (control) in E2-free medium. MTT assay was conducted after 24, 48, and 72hrs of exposure. We then studied specific E2 pathway mechanisms of cell proliferation in selected conditions. To study sex differences in tumor growth in vivo, we orthotopically injected LL/2-Luc2 murine cells into the left lung of 6-9-week-old C57BL/6J male and female mice. The mice were euthanized at 21 days post-injection or before if they reached humane endpoint.
Results: HBE cell lines did not show increased metabolic activity in response to physiological E2 concentrations; however, some cell lines showed a significant increase at the highest concentration (1uM) compared with the control. On the other hand, NCI-H441, NCI-1650, and LL/2-Luc2 showed a significant increase at earlier time points and at lower concentrations of E2. A549 and NCI-1975 did not show increased activity at any E2 concentration compared with control. Additionally, we found that LC cell lines with increased metabolic activity showed a significant increase in expression of genes related to angiogenesis (VEGFA), estrogen metabolism (CYP1B1), and ER pathway co-activation (GREB1) compared with their vehicle-treated cells. In contrast, HBE cell lines did not exhibit these changes, even at the highest E2 concentration, although some showed increased metabolic activity. In vivo, our preliminary results have shown an increased survival in female mice compared with male mice at 21 days post-orthotopic injection with LL/2-Luc2.
Conclusion: The preliminary data suggests that estrogen signaling stimulates metabolic activity and gene pathways associated with tumor progression in some LC cell lines. These effects may be related to the individual cell lines' ER expression or mutations. Unveiling these and other mechanisms by which E2 increases cell metabolic activity and induces gene expression highlights the translational potential of targeting the ER pathway or its downstream effectors in LC. Our preliminary in vivo mouse model results with LL/2-Luc2 show increased survival in male C57BL6/J mice compared to females.

#4810 Cisplatin-oral microbiota synergistic role in HNSCC aggressiveness and its clinical relevance.

Partha Jyoti Saikia[1], Lekhika Pathak[1], Bidisha Pal[2], Upasha Sarmah[1], Tulika Sarma[3], Chayanika Das[3], Debduti Datta[1], Rupam Das[4], Bikul Das[5]

[1]Department of Cancer and stem cell biology, KaviKrishna Laboratory, Guwahati, India,[2]Department of Experimental Therapeutics, Thoreau Laboratory for Global Health, M2D2, University of Massachusetts, Lowell, Massachusetts, Massachusetts, MA,[3]KaviKrishna Telemedicine Care, Sualkuchi, Assam, India,[4]KaviKrishna Laboratory, Guwahati, India,[5]Department of Cancer and Stem Cell Biology, KaviKrishna Laboratory, Guwahati, India

Background: Cisplatin-based chemotherapy remains a cornerstone for treating Head and NeckSquamous Cell Carcinoma (HNSCC). However, its therapeutic success is often limited inpatients with advanced-stage disease (Stage III-IIIb). Emerging evidence indicates thatchemotherapy itself may induce or select for aggressive, therapy-resistant tumor phenotypes.Meanwhile, dysbiosis of the oral microbiota—particularly involving Fusobacterium nucleatumand Porphyromonas gingivalis—has been implicated in HNSCC progression and immuneevasion. Yet, the synergistic interplay between cisplatin treatment and oral microbial ecologyremains poorly understood. Here, we investigate whether oral microbiota enhance cisplatin-induced aggressiveness via reprogramming of cancer stem cell (CSC) phenotypes, particularlythe Tumor Stemness Defense (TSD) state, which represents an adaptive altruistic response totherapy-induced stress.
Methods: Saliva samples were prospectively collected from 15 HNSCC patients prior toinitiation of cisplatin-based chemotherapy. The microbiome composition was analyzed using16S rRNA gene sequencing and targeted qPCR for F. nucleatum and P. gingivalis. In vitro,these isolates were co-cultured with SAS HNSCC cells (MOI 50:1) and treated with cisplatin(1-5 μM) for three days. Post-treatment recovery was monitored up to 14 days, withassessments of colony formation, migration, and expression of TSD-associated stemnessmarkers (EpCAM, ABCG2, HIF-2α, Myc, SOX2, OCT4, NANOG). Clinically, post-therapysalivary microbiota was correlated with patient outcomes and tumor hypoxia profiles.
Results: Co-exposure of SAS cells to cisplatin and F. nucleatum or P. gingivalis led to theemergence of a TSD-like phenotype, characterized by elevated expression of HIF-2α, ABCG2,and Myc, increased clonogenic survival, and enhanced migration capacity. Thisreprogramming effect was attenuated by TLR4 inhibition. Patient saliva analysis revealed thatelevated microbial LPS load and enrichment of F. nucleatum correlated with poorchemotherapy response and higher CTC count during treatment.
Conclusion: Our findings reveal that the oral microbiota synergizes with cisplatin to promotetherapy-induced adaptive stemness in HNSCC. This mechanism, involving microbialLPS/TLR4 signaling and HIF-2α activation, suggests that oral microbial dysbiosis may act asa co-driver of tumor evolution under chemotherapeutic stress. Targeting microbiota-chemotherapy interactions may offer a new avenue to reduce post-therapy relapse.

#4811 Surgical resection versus non-surgical treatment for hepatocellular carcinoma with portal vein tumor thrombosis: A comprehensive systematic review and meta-analysis.

Seok-Hwan Kim[1], Sang Hoon Kim[2]

[1]Surgery, Chungnam National University Hospital, Daejeon, Korea, Republic of,[2]Surgery, Asan Medical Center, Seoul, Korea, Republic of

Background: The role of surgical resection (SR) as a primary treatment for hepatocellular carcinoma (HCC) with portal vein tumor thrombosis (PVTT) remains uncertain.
Methods: A comprehensive search of electronic databases from January 2000 to April 2024 identified studies comparing SR with transarterial chemoembolization (TACE), combined TACE and radiation therapy (TACE-RT), or sorafenib. Meta-analyses were conducted for comparison groups with at least three eligible studies. Hazard ratios (HRs) with 95 percent confidence intervals (CIs) for overall survival (OS) were extracted or reconstructed from Kaplan-Meier curves.
Results: Twelve retrospective cohort studies involving 4,498 patients were included. SR demonstrated superior long-term OS compared with TACE in Vp1-2 (5-year OS: HR 0.53, 95% CI 0.35-0.79) and Vp3 (5-year OS: HR 0.68, 95% CI 0.61-0.75), with comparable outcomes in Vp4. SR and TACE-RT showed similar 1- and 3-year OS, although SR demonstrated a clear 5-year OS advantage in Vp1-3 PVTT (HR 0.48, 95% CI 0.31-0.74). Compared with sorafenib, SR provided superior OS in Vp1-2 (3-year OS: HR 0.26, 95% CI 0.18-0.38) and comparable OS in Vp3. Sensitivity analyses supported the robustness of these findings, and no substantial publication bias was detected.
Conclusion: Based on current evidence, SR is not inferior to non-surgical treatments including TACE, TACE-RT, and sorafenib in patients with HCC and PVTT and provides meaningful long-term survival benefits, particularly in those with segmental PVTT (Vp1-Vp2). Further comparative studies incorporating immunotherapy are needed in future research.
Key words: Hepatocellular carcinoma; tumor thrombosis; resection; transarterial chemoembolization; meta-analysis.

#4812 Ontario Tumour Bank: Accelerating commercial oncology research and development with quality samples and data.

Riley Cox[1], Katarina Maksimovic[1], Larry Phouthavongsy[1], Anumta Amir[1], Ilinca Lungu[1], Terry Hawrysh[2], Dianne Chadwick[1], Lincoln Stein[1]

[1]Ontario Tumour Bank, Ontario Institute for Cancer Research, Toronto, ON, Canada,[2]Patient and Family Advisory Council, Ontario Institute for Cancer Research, Toronto, ON, Canada

The Ontario Tumour Bank (OTB) is a core research resource at the Ontario Institute for Cancer Research, a collaborative research institute that conducts and enables research to find cancer earlier and treat it more effectively. With 20+ years of expertise in biobanking, OTB has collected 150,000+ samples and 15,000+ whole slide images (WSIs) from 22,500+ participants across 30+ solid tumor sites. Each oncology case is comprehensively annotated with diagnostic, treatment and health data for up to 5 years. OTB has a strong record of supporting research, with acknowledgements in 200+ publications and 70,000+ citations. Recently, OTB has experienced an increased demand from commercial research clients. OTB's samples and data can be used for many commercial applications, including fresh tumor tissue for rapid drug screening; frozen tumor and normal adjacent tissue for metabolomics; formalin-fixed paraffin-embedded tumor tissue for diagnostic assay development; plasma for predictive blood tests for cancer detection and monitoring; and WSIs combined with longitudinal health record data for prognostic AI model development. Academic biobanks such as OTB have several challenges when working with commercial research clients. These include ensuring its resources are visible and accessible to the commercial research community, as well as obtaining appropriate participant consent, ethics and contractual approvals. OTB has mitigated these challenges by asking participants to agree to a broad informed consent that includes use of their samples and data in commercial research and creating a researcher-focused website (ontariotumourbank.ca) that allows clients to submit inquiries and start the sample and data request process online. Each request is received by OTB's dedicated senior client coordinator, who is the central point-of-contact for each client and facilitates each project from start to finish. To meet evolving research needs, commercial clients are provided access is to OTB's deep "research ready" inventory as well as custom fresh tumor and blood collections shipped overnight immediately after collection. The number and proportion of projects, samples and data provided to commercial clients - including venture capital-supported biotechnology startups in Canada, the US and globally - has steadily increased over the past 5 years and now represents 1/3 of OTB's business. By streamlining the request process for commercial clients, OTB has demonstrated its ability to meet the unmet demands of this sector, including emerging predictive AI model development in research and medicine. Supporting commercial research projects ensures that access to OTB's deep inventory of quality samples and data is consistent with the wishes of our generous patient participants to support diverse academic and industry research, all while contributing to OTB's long-term financial sustainability.

#4813 Diabetes mellitus related fibroblast activation as a premetastatic niche enhances lung metastasis.

Lingfeng Fu, Takatsugu Ishimoto

The Cancer Institute JFCR, Tokyo, Japan

Distant metastasis is a major determinant of poor prognosis in cancer. Epidemiological data indicate that diabetes markedly increases lung metastasis (LM) in patients with gastric cancer (GC); however, the underlying mechanisms remain unclear. Here, we report that high glucose stimulates GC cells to secrete extracellular vesicles (EVs) that activate FAP+ fibroblasts in the lung to establish a premetastatic niche and enhance metastasis. Transcriptomic and proteomic analyses revealed that high glucose activates FOXM1, promoting CEP55 transcription and its incorporation into EVs. Circulating CEP55-EVs trigger CEP55-pFAK-FAP signaling in lung fibroblasts, driving their activation. This results in extracellular matrix remodeling by tenascin-C secretion and scaffold formation to facilitate GC cell colonization. Finally, we demonstrate that the antidiabetic drug glimepiride suppresses fibroblast activation and significantly reduces LM. These findings reveal a diabetes-driven mechanism of LM mediated by CEP55-EVs and suggest a potent therapeutic strategy to inhibit LM using conventional antidiabetic drugs

#4815 Temporal control of EMT via the miR-200c/Zeb1 regulatory circuit to uncover the drivers of stemness in pancreatic cancer.

Andrew Karam, Divya Murthy, Petra den Hollander, Joseph Zhu, Sendurai A. Mani

Legorreta Cancer Center, Brown University, Providence, RI

Pancreatic cancer is poised to become the second leading cause of cancer-related deaths by 2030, with most fatalities resulting from metastasis. During metastatic progression, tumor cells undergo epithelial-to-mesenchymal transition (EMT), a developmental program that enhances motility, stemness, and resistance to stressors such as chemotherapy. Targeting EMT-induced cancer cells is therefore an urgent therapeutic priority. To investigate the EMT spectrum, we developed a doxycycline-inducible system that enables controlled induction of epithelial or mesenchymal states through the miR-200c/Zeb1 axis. Induction of miR-200c suppresses Zeb1 and promotes epithelial identity, whereas Zeb1 induction drives mesenchymal features. Although this regulatory circuit is well studied in other cancers, its role in pancreatic cancer remains poorly understood. Across human and mouse pancreatic cancer cell lines (PANC-1, CFPAC, FC1242, FC1199), miR-200c induction upregulates E-cadherin, while Zeb1 induction decreases E-cadherin and increases vimentin. In stemness assays, Zeb1 induction exerts minimal or even negative effects on sphere formation, whereas carcinoma cells expressing mesenchymal markers consistently display high stem-like capacity. Overexpression of miR-200c markedly suppresses the cancer stem cell phenotype, highlighting its role as a potent regulator of epithelial identity. Overall, our findings establish miR-200c as a central driver of the epithelial, less invasive state in pancreatic cancer and suggest that developing therapeutic strategies that upregulate miR-200c hold strong potential to prevent metastasis and improve overall survival for pancreatic cancer patients.

#4816 Single-cell transcriptomic analysis reveals KRT17 as a prognostic tumor-initiating cell marker in ovarian cancer.

Jie Wu, Tat San Lau, Kit Ying Loucia Chan, Chi Chiu Wang

Department of Obstetrics and Gynaecology, The Chinese University of Hong Kong, Hong Kong, China

Background: Ovarian cancer (OV) is characterized by high rates of recurrence and chemoresistance, which are largely attributed to a subpopulation of cancer cells known as tumor-initiating cells (TICs). The identification of specific biomarkers for TICs is crucial for developing novel prognostic tools and targeted therapies. This study aimed to identify and validate potential TIC markers in OV using a comprehensive bioinformatics approach at the single-cell level.
Methods: We performed an integrated analysis of publicly available single-cell RNA sequencing datasets from ovarian cancer patients. Malignant epithelial cells were first identified by inferring copy number variations (CNVs). To characterize the heterogeneity within these malignant cells, we quantified cellular stemness using CytoTRACE, reconstructed the differentiation trajectory with Monocle3, and analyzed the cell cycle to assess proliferative states. By integrating these multi-dimensional analyses, we identified a distinct cell subpopulation exhibiting high stemness, an undifferentiated state, and a unique gene expression signature, which we designated as the TIC-like cluster. Candidate markers were defined as the genes specifically upregulated within this functionally characterized cluster. The prognostic significance of the top candidate was then evaluated using bulk RNA-seq and clinical data from an independent cohort from our institution.
Results: Our analysis successfully identified a distinct subcluster of malignant cells exhibiting significant TIC properties. Differential gene expression analysis of this subcluster pinpointed Keratin 17 (KRT17) as a top-ranking, specifically expressed gene. Crucially, survival analysis demonstrated that high expression of KRT17 was significantly associated with worse overall survival and progression-free survival.
Conclusion: Through a multi-faceted bioinformatic pipeline, our study identifies KRT17 as a robust candidate marker for TICs in ovarian cancer. The strong correlation between high KRT17 expression and poor patient prognosis underscores its potential as a valuable prognostic biomarker. These findings provide a strong rationale for future experimental studies to validate the functional role of KRT17 in OV tumorigenesis and its utility as a therapeutic target.

#4817 The role of cancer cell-derived TWEAK in promoting a cancer stem-like phenotype in ovarian cancer cells.

Steffy Mathew, Luisjesus S. Cruz, Mikella Robinson, Sofia Howe, Greg J. Jordan, Dishant Vandra, Harshada Sapre, Carrie Danielle House

San Diego State University, San Diego, CA

Ovarian cancer is the most lethal gynecological cancer in the United States, with over 80% of patients relapsing after chemotherapy. Recurrent ovarian cancer may be due to cancer stem-like cells (CSCs) that are drug resistant and capable of long-term self-renewal and reestablishment of tumors. Previous studies in our lab suggest that TWEAK, a cytokine enriched in ovarian tumors, enhances CSC development and survival. Additionally, inhibiting TWEAK in combination with chemotherapy was shown to significantly prolong survival and remission in mouse models. The source of TWEAK in ovarian cancer remains unidentified, but in normal tissues it is primarily produced by myeloid cells. A recent pancreatic cancer study identified cancer cells as a novel source of TWEAK and preliminary data from our lab suggests that TWEAK protein expression in ovarian cancer cells is significantly increased (2-fold) following chemotherapy treatment. Therefore, we hypothesize that cancer cell-derived TWEAK is a unique driver of CSC phenotypes in ovarian cancer cells. To explore this hypothesis, we generated and validated shRNA knockdown of TWEAK in OVCAR8 and CAOV4 ovarian cancer cell lines at the gene and protein level. To assess TWEAK-mediated tumor formation, we sorted for CSCs and non-CSCs in shNeg and shTWEAK cells and intraperitoneally injected cells into a xenograft mouse model. We found significantly decreased tumor formation in non-CSC shTWEAK tumors compared to non-CSC shNeg tumors ($p<0.05$). Moreover, the calculated stem cell frequency was significantly reduced in the shTWEAK non-CSCs compared to the shNeg non-CSCs and shTWEAK CSCs ($p=0.0144$ and $p=0.0086$, respectively). This data suggests that stem cell frequency is dependent on TWEAK expression. Experiments are underway to assess spheroid formation ability, chemoresistance, and expression of stemness genes in the CSC and non-CSC shNeg and shTWEAK cells. By targeting factors like TWEAK that promote a CSC phenotype, we hope to identify alternative therapeutic strategies to inhibit CSC development and prevent relapse in ovarian cancer.

#4818 Establishing novel, representative prostate cancer cell lines from fresh prostatectomy tissues via an optimized protocol.

Tuong Vi V. Nguyen[1], Steven C. Smith[2], Lance J. Hampton[3], Victoria J. Findlay[4], David P. Turner[4]

[1]VCU Massey Comprehensive Cancer Center, Richmond, VA,[2]Pathology, VCU Massey Comprehensive Cancer Center, Richmond, VA,[3]Urology, VCU Massey Comprehensive Cancer Center, Richmond, VA,[4]Surgery, VCU Massey Comprehensive Cancer Center, Richmond, VA

Background: The existing panel of prostate cancer (PCa) cell lines, often established from metastatic sites or after extensive passaging, frequently fails to fully recapitulate the genetic heterogeneity and tumor microenvironment dependence of primary prostate tumors. Additionally, there is a crucial need for diverse, population-specific cell lines to investigate the biological factors underlying disparities in patient outcomes and therapeutic response. To address this critical resource gap, we optimized and validated a highly efficient protocol for the de novo establishment of patient-derived, primary PCa cell lines from fresh surgical specimens.
Methods: Patients were consented in accordance with VCU IRB protocol #20210623, and their self-reported race was recorded as either White (W) or African American (AA). Fresh tissues were obtained as punched biopsies from 36 radical prostatectomy specimens. Each specimen yielded 1-3 biopsy samples. H&E slides were graded by a licensed pathologist. Optimized from Maitland et al. 2016 protocol, tissue samples digested enzymatically were separated into distinct populations through differential centrifugation, and propagated in optimal media for epithelial and fibroblastic cell lines. The cellular origin of patient-matched lines were confirmed using cytochemistry and further characterized through proliferation assays, Western blot, and short tandem repeat (STR) profiling.
Results: The optimized protocol, carried out in the latter quarter of the trial, demonstrated high efficacy with an 86% success rate (13 out of 15 samples), bringing the total to 30 novel, matched PCa epithelial and fibroblast cell lines successfully established from 18 patients. Among the 30 samples, 18 were benign (11 W and 7 AA) and 10 were cancerous (6 W and 4 AA). Additionally, 3 patient prostatic specimens yielded matched cell lines from both the tumor and the contralateral non-malignant tissue. Critically, these cell lines retained the expression of androgen receptor (AR) and prostate-specific antigen (PSA). Furthermore, the lines exhibited heterogeneous growth patterns reflecting the diversity of the source tumors.
Conclusion: We have established a robust, highly effective protocol for generating patient-derived, primary PCa cell lines directly from prostatectomy tissues. These novel, characterized models significantly enrich the translational research toolkit, providing invaluable resources for several critical applications, including biomarker identification, understanding tumor initiation and progression, resistance mechanism studies, drug discovery and validation, and, most importantly, for studying population-specific differences to guide the development of truly equitable and personalized treatment strategies.

#4819 Gene knockout or selective inhibition of AKT-3, but not AKT-1 or AKT-2 isoform, enhances apoptosis in CD133+ melanoma cancer stem cells treated with the MEK inhibitor trametinib.

Cynthia M. Simbulan-Rosenthal, **Nusrat Islam**, Dhyana Yan, Ingrid Mandala Kol, Noah Smith, Dean S. Rosenthal

Biochemistry and Molecular & Cellular Biology, Georgetown University School of Medicine, Washington, DC

CD133-expressing melanoma-initiating stem cells are associated with tumorigenesis, metastasis, and drug resistance in malignant human melanoma. CD133 knockout (KO) or doxycycline (Dox)-inducible expression shows that CD133 activates an alternate survival pathway, PI3K/AKT, bypassing the MAPK pathway, resulting in apoptosis inhibition, increased melanoma cell survival, and resistance to the MEK-inhibitor trametinib. Combinational inhibition of the MAPK and PI3K/AKT pathways with trametinib and the pan-AKT inhibitor capivasertib synergistically induces melanoma cell apoptosis *in vitro* and inhibits tumor growth *in vivo*. To determine the relative contributions of each of three AKT isoforms, AKT-1, -2, and -3, to apoptosis inhibition, we used CRISPR-Cas9 KO or pharmacological inhibitors of each isoform, in combination with trametinib in a Dox-inducible NRAS-mutant melanoma cell line BAKP. Immunoblot analysis with anti-AKT-1, -2, or -3 and DNA sequence analysis confirmed gene knockout. BAKP control cells and cells with single or triple KO of each or all of the AKT isoforms were then exposed to trametinib, alone or in combination with capivasertib, and subjected to Annexin V apoptosis assays and immunoblot analysis with antibodies to apoptosis markers. Single KO of AKT-2 or -3, but not AKT-1, sensitized BAKP cells exposed to trametinib alone, partially obviating the requirement for inhibition of AKT by capivasertib. Triple KO of all three isoforms further sensitized cells to trametinib alone. We next investigated apoptosis induction by selective inhibitors of each of the AKT isoforms; afuresertib for AKT-1, CCT128930 for AKT-2, or uprosertib for AKT-3, as a monotherapy or in combination with trametinib. The combination of uprosertib and trametinib proved to be the most effective in synergistically inducing apoptosis in melanoma cells, even targeting the CD133-expressing melanoma stem cells. Together, this indicates that AKT-3 plays an essential role in apoptosis inhibition, consistent with reports that implicate AKT-3 in drug resistance in melanoma and glioblastoma. Cells treated with trametinib, alone or combined with capivasertib or uprosertib, exhibited loss of mitochondrial membrane potential, suggesting a mitochondrial pathway of apoptosis. Future studies will focus on optimizing the effect of selective inhibitors of AKT-3 in dose response experiments, and test its effects in *in vivo* mouse xenograft studies. Simultaneously targeting the AKT and MAPK survival pathways with trametinib and uprosertib underscores the importance of combination therapies to eliminate recalcitrant melanoma stem cells.

#4820 TIM-3 as a prospective target to eliminate pancreatic cancer stem cells.

Prapannajeet Biswal, Prudhvi Chand Mallepaddi, Bhoomika Murvekere Lakshmisha, Tuyet Ngoc Tra, Sai Kumar Samala, Khadijeh Koushki, P.M. Quan Mai, Arjun Vasan, Gabrielle Krouse, Yuri Mackeyev, Lydia WT Cheung, Sunil Krishnan, Geraldine Vidhya Vijay

Neurosurgery, UT Health Houston, Houston, TX

Background : Pancreatic cancer (PDAC) is nonresponsive to conventional therapies and poor survival is the norm. A small percentage of malignant cells undergo epithelial-mesenchymal transition to evolve into pancreatic cancer cells stem cells (PCSCs) that evade therapy and subsequently give rise to residual/recurrent tumors and also drive therapy resistance. While radiotherapy (RT), is a cornerstone of PDAC management, it promotes EMT via activation of TGF-β, NF-kB and Akt/GSK-3β pathways. TIM-3 (HAVCR-2) a cell surface marker traditionally designates exhausted T-cells. However TIM-3 overexpression is being increasingly reported in solid tumors. We report RT induced TIM-3 overexpression in PDAC and propose that RT triggered TIM-3, on pancreatic cancer cells could serve as a novel target in selectively eliminating PCSCs.

Methods : GEO datasets were analyzed with the Seurat package in R to evaluate TIM-3 expression across tissue types (benign pancreatic tissue, non metastatic primary PDAC/Pm0, primary of metastatic PDAC/Pm1 and matched liver metastases/Lm). TIM-3 expression between treatment naive and chemo-RT treated tumors was also compared. In vitro, murine (Panc02-ova, KPC) and human (PANC-1, MIA PaCa-2) pancreatic cancer cells were treated with increasing doses of RT alone or in combination with NRF-2 / ATM inhibitor to either simulate a high oxidative stress environment or inhibit DNA repair pathways. Following treatments, TIM-3 expression in these samples were evaluated using RT-qPCR, western blotting, flow cytometry and immunofluorescence. In vivo, Panc-02 xenografts in C57BL/6 mice were irradiated (10Gy RT at 320Kv & 13.2 mA). Tumors were collected, 24 hrs post RT, and dissociated. Single cells thus obtained were assessed for the expression of TIM-3, using flow cytometry.

Results : Advanced stages of cancer (Pm1 and Lm tumors) demonstrated greater TIM-3 expression compared to Pm0 tumors. Further, increased TIM-3 expression was noted in chemo-RT treated tumors compared to untreated tumors. In vitro, RT dose dependent increase in TIM-3 mRNA and protein levels was recorded and cells subjected to 10Gy RT showcase maximal TIM-3 expression (Control < 3Gy < 6Gy < 10Gy). Addition of NRF2 inhibitor or ATM inhibitor before exposing cells to RT further increased TIM-3 levels.The TIM-3+ cells exhibited higher CD24+ and CD44+ positivity, indicating its association with PCSC phenotype.

Conclusion : Our results indicate that TIM-3 can be employed as a specific marker to designate PCSCs in addition to the classical stem cell phenotype (ESA+ CD24+ CD44+). Increased mRNA, total protein and TIM-3 levels post RT are possibly driven by elevated oxidative stress in addition to RT induced ds-DNA breaks. The novel role of TIM-3 as a PCSC marker, establishes it as an ideal candidate for targeting both immune-suppressive T cells and therapy resistant PCSCs.

#4821 Investigating FOXC2-dependent mechanisms regulating stem cell Identity in breast cancer.

Joanna Joyce Maddela[1], Petra den Hollander[1], Nick Allen Kuburich[2], Maria Castaneda[3], Mika Pietila[3], Mercy Adewumi[4], Sendurai A. Mani[2]

Stem cells maintain tissue homeostasis by balancing self-renewal and differentiation, a process shaped by how fate determinants are stabilized and partitioned during mitosis. Disruption of these mechanisms can either generate cancer stem cells (CSCs) that drive tumor progression or deplete CSCs that lead to the elimination of the tumor. In triple-negative breast cancer (TNBC), the embryonic transcription factor FOXC2 is aberrantly reactivated, leading to induction of EMT, the gain of CSC properties, and poor patient outcomes. Although our lab has shown that FOXC2 levels fluctuate across the cell cycle, the cues governing this regulation remain unclear. Since PLK1 is a key mitotic kinase and a targetable vulnerability in aggressive TNBC, we investigated whether FOXC2 is regulated by PLK1-mediated phosphorylation. Pharmacologic PLK1 inhibition (Volasertib) reduces FOXC2 protein levels, and this loss is reversed by the proteasome inhibitor MG132, suggesting that PLK1-dependent phosphorylation stabilizes FOXC2. Using SUM159 cells expressing phospho-ablated (S125A, T465A) and phospho-mimetic (S125E, T465E) FOXC2 mutants, we evaluated its CSC-related function, including mammosphere assays, and found that phosphorylation influences FOXC2's role in maintaining CSC traits. Biochemical pulldown, immunoblotting, and imaging assays support a potential interaction and role for FOXC2 and PLK1. Promoter analysis of the PLK1 promoter identified FOXC2 binding sites near the transcription start site, suggesting possible reciprocal control. Live-cell imaging further indicates that FOXC2 is spatially regulated during mitosis and that phosphorylation may affect its chromatin association and inheritance. Collectively, our findings suggest PLK1-dependent phosphorylation of FOXC2 may stabilize the FOXC2 protein and influence its function during mitosis and regulate stem cell identity in daughter cells during cell division.

#4822 Investigating the role of miR-27a-3p in the WNT signaling pathway in colorectal cancer stem cells.

Cancer stem cell (CSC) overpopulation drives colorectal cancer (CRC) development and growth, but molecular mechanisms are unclear. CSCs functional phenotypic characteristics include signaling pathway dysregulation. CRC CSCs, in particular, are defined by their high WNT signaling activity, particularly those defined by the stem cell maker leucine-rich-repeat containing G protein-coupled receptor 5 (LGR5). A growing body of scientific evidence indicates that miRNAs, involved in post-transcriptional gene expression, play an important role in maintaining the CSC phenotype. However, the exact mechanism is still unknown. Our goal is to investigate how miRNAs contribute to the SC origin of CRC. My preliminary experiments used HT-29 CRC cells and NanoString profiling to identify miRNAs enriched in FACS-isolated CSCs. I discovered that miR-27a-3p is differentially upregulated in LGR5+ CSCs versus LGR5- cells. Analysis of available deep sequencing data also shows that the canonical miR-27a-3p is the highest expressed isoform in human CRC and is significantly upregulated during the colonic adenoma-carcinoma progression. *miR-27a-3p* has been shown to: i) be enriched in human CSCs in CRC utilizing other CSCs markers and methods; ii) activate or repress WNT signaling activity in various cancers; iii) increase chemoresistance in various cancers. The exact mechanism by which *miR-27a-3p* functions in CRC to regulate WNT signaling has not been elucidated. *Hypothesis*: miR-27a-3p is enriched in CRC and the LGR5+ SC subpopulation; miR-27a-3p promotes WNT signaling expression through repression of WNT antagonist targets. A significant increase in cellular proliferation was seen in the HT-29 stable lentiviral overexpressing cell line, and an increase in the WNT target genes mRNA of LGR, cMYC, cyclin D1, MET, and CD44. Decreases in LGR5, cMYC, cyclin D1, and MET were seen in the HCT116 stable lentiviral knockdown CRC cell line. My findings show that miR-27a-3p modulates WNT signaling in CRC cell lines by targeting WNT antagonistic targets that affect the stability and expression of β-catenin.

#4823 Development of a multi-institutional integrated resource platform linking primary and secondary biospecimens in gynecologic cancers.

Yoon Joo Kim, Jue Young Kim, Ha-Yeon Shin, Yookyung Lee, Jae-Hoon Kim

Department of Obstetrics and Gynecology, Gangnam Severance Hospital, Yonsei University College of Medicine, Seoul, Korea, Republic of

Background:
Gynecologic cancers exhibit substantial molecular and histopathologic heterogeneity, highlighting the need for infrastructures that integrate high-quality biospecimens with multi-omics and functional resources. To address this need, we established a seven-center framework that collects standardized primary biospecimens and generates secondary resources for gynecologic cancers, supported by integrated clinical and pathological datasets.
Methods:
Primary biospecimens—including serum, plasma, buffy coat, urine, ascites, frozen tumor tissues, and formalin-fixed paraffin-embedded (FFPE) blocks—were collected under Standard Operating Procedures (SOPs), with pre-analytical variables recorded using the Standard PRE analytical Code (SPREC). Frozen tissues supported high-depth whole-genome sequencing (WGS) and the development of patient-derived xenograft (PDX) and organoid models. FFPE blocks were used to construct tissue microarrays (TMAs). Human ovarian surface epithelial (HOSE) cells were subjected to standard immortalization procedures to establish stable cell lines.
Results:
As of November 5, 2025, 372 patients (161 endometrial, 101 ovarian, 104 cervical cancers, and 6 rare tumors) had been enrolled, yielding more than 6,000 primary biospecimens. WGS was performed using tumor-normal paired samples when available, generating 403 datasets: 215 tumor genomes (60×/90×) and 188 normal genomes (30×), representing 191 endometrial, 35 ovarian, and 177 cervical cancer cases. TMAs were constructed with 373 endometrial, 260 cervical, 490 ovarian cores. In addition, 17 PDX models were established (7 endometrial, 8 cervical, 2 ovarian), along with two organoid models and five IHOSE cell lines. Importantly, the primary biospecimens, WGS datasets, and PDX models were all generated from the same patients, creating a patient-matched resource that enables direct integration of genomic, pathologic, and functional data at the individual-patient level.
Conclusions:
This multi-institutional platform integrates standardized primary biospecimens with a broad set of secondary resources, providing a rare patient-linked structure in gynecologic cancers. The combined availability of WGS datasets, TMAs, PDX and organoid models, and IHOSE cell lines supports genomic-pathologic correlation, biomarker development, and functional studies of therapeutic response. Its scalable design offers a durable infrastructure for advancing gynecologic cancer research.
