Tertiary lymphoid structures (TLS) are increasingly recognized as important drivers of anti-tumor immunity and predictors of survival and immunotherapy response in multiple non-central nervous system cancers. However, their role in brain metastases (BrM) remains poorly understood. To better advance understanding of their role in the immunosuppressive brain tumor microenvironment, we applied a multimodal approach to examine TLS prevalence, spatial organization, and clinical relevance in a retrospective cohort of 461 BrM samples from diverse primary tissues, collected between 2015 - 2022 at the University Cancer Center Frankfurt. CD20 immunohistochemistry was used to screen for lymphoid aggregates, and a subset of TLS-positive and negative tumors were subjected to comprehensive molecular and spatial profiling. For an in-depth characterization of TLS, we employed multiple spatial technologies, including 7-plex immunofluorescence imaging for spatially resolved cellular phenotyping and TLS identification, whole-transcriptome spatial profiling of regions of interest, subcellular-resolution spatial transcriptomics (468-gene panel) for whole-tissue mapping, and spatial proteomic profiling using 40 markers to assess immune and stromal interactions. TLS were detected in 50% of BrM, most frequently in lung-to-brain metastases. Notably, the majority of TLS lacked features characteristic of mature germinal centers, indicating a potentially attenuated or dysregulated immune response within the BrM microenvironment. Survival analyses revealed a favorable prognosis associated with TLS-positive tumors and an improved response to immune checkpoint inhibitors. Spatial characterization of the BrM tumor immune microenvironment revealed cellular niches that promote distinct patterns of immune cell aggregate formation and cell-cell interactions, underlying phenotypic heterogeneity within patients and across primary sites. Analysis of whole transcriptomic data further revealed remodeling of extracellular matrix and evidence of metabolic reprogramming in tumor rich areas and enrichment of processes such as antigen presentation, regulation and activation of immune response in B cell-rich niches. Integrative single-cell spatial transcriptomics and proteomics, enabled phenotyping of TLS subtypes across patients, capturing different stages of maturation and levels of organization. This spatially resolved, multimodal approach provides a comprehensive resource for understanding TLS biology in BrM and may guide microenvironment-informed strategies to improve immunotherapeutic outcomes in metastatic brain disease.

#2217 Immune-active and mesenchymal endothelial programs define TLS presence in the tumor microenvironment.

Shoko Kure[1], Giorgia Brambilla Pisoni[1], Saba Tabasum[1], Xiaoyu Li[1], Jingjing Li[1], Yao Yu Yeo[2], Sizun Jiang[2], Harrison Olszewski[3], Nicholas C. Weaver[3], Kathleen L. Pfaff[3], Jason L. Weirather[4], Ian D. Dryg[4], Scott J. Rodig[5], Frank S. Hodi[1]

[1]Medical Oncology, Dana-Farber Cancer Institute, Boston, MA,[2]Center for Virology and Vaccine Research, Beth Israel Deaconess Medical Center, Boston, MA,[3]Tissue Biomarker Lab, Dana-Farber Cancer Institute, Boston, MA,[4]Department of Data Sciences, Dana-Farber Cancer Institute, Boston, MA,[5]Department of Pathology, Brigham & Women's Hospital, Boston, MA

Introduction: Tertiary lymphoid structures (TLSs) are ectopic lymphoid formations. In cancer, they promote antitumor immunity by supporting B-cell maturation, antibody production, and sustained T-cell activation. TLSs can convert immunologically non-inflamed tumors into inflamed ones. However, the vascular and molecular cues that govern TLS induction in human tumors remain poorly defined.

Methods: Formalin-fixed paraffin-embedded tissue sections from twelve primary lung adenocarcinomas were analyzed. Tumor-associated vasculature was histologically annotated and stratified into three categories based on TLS status: (1) noTLS (absence of TLS), (2) iTLS (presence of immature TLS), and (3) mTLS (presence of mature TLS). GeoMx spatial transcriptomics was performed on endothelial regions. Protein-level validation was conducted using sequential immunofluorescence on the COMET platform.

Results: Endothelial cells in noTLS regions showed high expression of COL5A1, COL3A1, FN1, ERRFI1, COL1A1, IFI6, SPP1, MDK, and BGN, whereas CXCL13 and CCL19 were enriched in mTLS. Gene-set analyses revealed that noTLS endothelium exhibited a myofibroblast-like, extracellular matrix-producing, EndoMT-associated program consistent with a fibrotic, immunosuppressive microenvironment. In contrast, mTLS endothelium displayed immune-activated signatures aligned with lymphoid organogenesis and fibroblastic reticular cell-like function. Receptor-ligand analysis showed preferential Wnt signaling in noTLS, while chemokine signaling dominated in mTLS. COMET immunofluorescence confirmed that FN1 was highly expressed in noTLS regions, whereas CXCL13 was highly expressed in mTLS.

Conclusion: Tumor endothelial cells display striking context-dependent plasticity. noTLS vasculature undergoes EndoMT and adopts a matrix-producing, immunosuppressive phenotype that may actively suppress TLS formation. Conversely, mTLS endothelium acquires immune-organizing properties that favor TLS maturation and lymphoid compartmentalization. These findings identify endothelial reprogramming as a potential therapeutic strategy to induce TLSs and enhance response to immune checkpoint blockade.

#2218 Tertiary lymphoid structures in colorectal cancer: Clinical significance and their interaction with CAFs and the immune microenvironment.

Zizhou Wang[1], Hiroaki Kasashima[1], Yukina Kusunoki[2], Yasuhiro Fukui[1], Iguru Omori[1], Nobuhiro Naito[1], Hideki Tanda[1], Yuki Seki[1], Kenji Kuroda[1], Yuichiro Miki[1], Mami Yoshii[1], Tatsuro Tamura[1], Masatsune Shibutani[1], Takahiro Toyokawa[1], Yu Muta[3], Yuki Nakanishi[3], Masakazu Yashiro[4], Kiyoshi Maeda[1]

[1]Department of Gastroenterological Surgery, Osaka Metropolitan University, Osaka, Japan,[2]Department of Pathophysiology, Osaka Metropolitan University, Osaka, Japan,[3]Department of Gastroenterology and Hepatology, Kyoto University, Japan, Kyoto, Japan,[4]Department of Molecular Oncology and Therapeutics, Osaka Metropolitan University, Osaka, Japan

Colorectal cancer (CRC) is a major malignancy with high global mortality. The tumor immune microenvironment, particularly tertiary lymphoid structures (TLSs), has gained increasing attention for its role in antitumor immunity. However, their specific functions in CRC and the prognostic relevance of TLS-associated cells remain unclear. We analyzed 166 CRC patients who underwent curative resection, evaluating TLSs by hematoxylin and eosin (H&E) staining and immunohistochemistry for CD20, α-SMA, CD8, CD4 and CD103. We additionally performed Opal-based multiplex immunofluorescence (mIF) with a two-plex panel (CD20 and α-SMA) to validate the presence of cancer-associated fibroblasts (CAFs) within TLSs. Patients were categorized by TLS density and immune-cell infiltration levels. TLSs were predominantly located at invasive margins, and higher TLS density correlated with better prognosis ($P < 0.05$). In contrast, high CAF density within TLSs was associated with poorer outcomes ($P < 0.01$), whereas a high abundance of $CD8^+$ T cells predicted improved survival. Furthermore, using Xenium Explorer spatial transcriptomics, we confirmed the spatial coexistence of CAFs and immune cells within TLSs in colorectal cancer. In particular, CAF accumulation within TLSs may reshape the immune microenvironment and potentially impair antitumor T-cell activity.

#2219 CXCL13 secretion and immobilization show distinct geographies within secondary and tertiary lymphoid structures (TLS).

Jonathan Rex Skidmore, Aleksandra Ogurtsova, Grant Salvucci, Victoria Jacobs, Logan Engle, Robert A. Anders, Drew M. Pardoll, Janis Marie Taube

Johns Hopkins Bloomberg-Kimmel Inst. for Cancer Immunotherapy, Baltimore, MD

The purpose of this study is to investigate the formation and maintenance of germinal centers in TLS by defining mechanisms and spatial patterns of CXCL13 chemokine gradients in tumor tissue. In secondary lymphoid tissue, it is recognized that CXCL13 is immobilized by follicular dendritic cells (FDCs), but the mechanisms of immobilization remain unclear. Furthermore, spatial patterns and mechanisms of CXCL13 immobilization in TLS are unknown. We developed a CXCL13 Immunohistochemistry /in situ hybridization (ICH/ISH) dual stain to determine which cells are responsible for CXCL13 production and display. We stained 3 formalin-fixed paraffin-embedded tonsil specimens and found that CXCL13 protein and mRNA staining have distinct localizations. Specifically, spatial analyses were performed on 10 individual follicular structures from each tonsil to compare the percent surface area of either germinal centers or mantle zones (n=30) demonstrating staining by IHC or ISH. This analysis revealed that CXCL13 protein was highly expressed in germinal centers and expressed relatively lower in mantle zones (31% vs 12% surface area, $p<0.0001$). However, CXCL13 ISH staining was the inverse: mRNA expression was lower in germinal centers, and higher in mantle zones (20% vs 37%, $p<0.0001$). Flow cytometry analysis of fresh tonsil tissue revealed stromal cells displaying CXCL13, ($PDPN^{+}CD31^{-}CXCL13^{+}$), supporting the CXCL13 IHC findings. Similarly, spatial transcriptomics showed similar findings to the CXCL13 ISH, providing additional validation of the spatial expression pattern. Together, these results support a model where CXCL13 is primarily secreted from mantle zones, then immobilized in germinal centers.

To investigate if these findings extend to TLS in tumor tissues, we applied our CXCL13 IHC/ISH dual stain to lung cancer tissue from the definitive resection specimen from patients treated with neoadjuvant anti-PD-1 immunotherapy. Spatial analyses revealed that similar to what was observed in tonsil, the density of CXCL13 mRNA is highly correlated with CXCL13 protein staining (n=3, Spearman's r: 0.9, $p<9.311e-19$), though these do not immediately overlap spatially, with an average distance of 30 µm between mRNA and protein expression, suggesting capture of the diffusing CXCL13. We also observed that stromal cells in mature TLS immobilize CXCL13, but stromal cells in immature TLS do not. In addition, we found CXCL13 immobilized on elastin fibers near mRNA staining.

These findings show that CXCL13 immobilization may contribute to the formation and maintenance of TLS. New therapies enhancing the formation and maturation of TLS by modulating CXCL13 may warrant exploration. Ongoing single cell RNA sequencing and in vitro studies are focused on determining the mechanisms responsible for the immobilization of CXCL13 in lymphoid and tumor tissue.

#2220 A spatially resolved multi-omics atlas of tertiary lymphoid structures in ovarian cancer.

Zhihan Liang[1], Ada Junquera[1], Hanna Elomaa[1], Joona Sarkkinen[2], Iga Niemiec[1], Ziqi Kang[1], Oskari Lehtonen[1], Lina Maltrovsky[1], Saundarya Shah[1], Aleksandra Shabanova[1], Matilda Salko[1], Ulla-Maija Haltia[3], Eliisa Kekalainen[2], Anni Virtanen[4], Anniina Farkkila[1]

[1]Research Program in Systems Oncology, University of Helsinki, Helsinki, Finland,[2]Translational Immunology Research Program, University of Helsinki and Helsinki University Hospital, Helsinki, Finland,[3]Department of Obstetrics and Gynecology, and Clinical Trials Unit, Comprehensive Cancer Centre, Helsinki University Hospital, Helsinki, Finland,[4]Department of Pathology, University of Helsinki and HUS Diagnostic Center, Helsinki University Hospital, Helsinki, Finland

Tertiary lymphoid structures (TLSs) coordinate localized immune responses in the ovarian tumor microenvironment. However, the maturation transitions of TLS remain poorly understood at both cellular and molecular levels. We constructed a spatially resolved multi-omics atlas that integrates histopathology, spatial transcriptomics, proteomics, and immunogenomics to characterize TLS organization, maturation, and clinical relevance in ovarian cancer. H&E-stained tumor sections from a prospective cohort of 334 ovarian cancer patients across histologies were analyzed using deep learning-assisted segmentation to identify lymphoid aggregates (LAggs), immature TLSs (iTLSs), and mature TLSs (mTLSs) with germinal centers (GCs). From these, 45 post-neoadjuvant chemotherapy omental samples were used for tissue cyclic immunofluorescence (t-CyCIF) imaging with a 30-marker immune panel, followed by Mesmer segmentation and spatial phenotyping. 30 adjacent sections underwent spatial transcriptomic profiling by GeoMx DSP. Data were batch-corrected and analyzed for differential expression, pathway enrichment, and cell-type deconvolution. B-cell receptor (BCR) repertoires were reconstructed from bulk RNA-seq data with MiXCR. Preliminary analyses indicate substantial heterogeneity in TLS and LAgg abundance and spatial localization across ovarian cancer histologies. LAggs were present in 46% of samples, whereas iTLSs or mTLSs appeared in 16% and were confined to omental metastases. Spatial metrics quantified TLS distribution and proximity to tumor nests. Early t-CyCIF results revealed distinct TLS microstructures at different maturity stages: mTLSs contain well-defined GCs while iTLSs exhibited only early B/T compartments. Processed t-CyCIF data are being analyzed using the SPACEStat spatial analysis algorithm to uncover functional spatial immune composition in TLSs. 268 selected regions of interest (ROIs) were profiled in GeoMx. GC, T-B zone, and stromal signature scores enabled molecular labeling of TLS regions. SCORPIUS pseudotime analysis delineated a maturation trajectory from LAggs to iTLSs and mTLSs. By integrating spatial data, gene expression dynamics are mapped across maturation stages to investigate key chemokine axes and pathway enrichment. Cell-type deconvolution is expected to reveal maturation-associated spatial remodeling and functional specialization of immune subsets. Ongoing BCR profiling aims to explore clonotype patterns that may reflect class switching and somatic hypermutation. Our spatially resolved multi-omics atlas captures coordinated cellular and molecular remodeling that underlies TLS maturation and functional specialization, providing mechanistic insights into anti-tumor immune activation linked to clinical outcomes.

#2221 Tumor-associated CD207$^+$ cDC2 drives TLS formation via TNF family cytokines in non-small cell lung cancer.

Youngtaek Kim[1], Gang-Taik Lee[2], Dong Kwon Kim[2], JuHyeon Lee[2], So Young Park[2], Jae Hwan Kim[3], Hyun Jung Yoo[2], Byoung Chul Cho[3]

[1]Yonsei University College of Medicine, Seoul, Korea, Republic of,[2]Department of Research Support, Yonsei Biomedical Research Institute, Seoul, Korea, Republic of,[3]Yonsei New Il Han Institute for Integrative Lung Cancer Research, Seoul, Korea, Republic of

Background: Dendritic cells (DCs) are specialized antigen-presenting cells that orchestrate innate and adaptive immunity, and within the tumor microenvironment (TME) they extend their function to modulate anti-tumor immune responses. The heterogeneity of DCs underlies their diverse immune functions, with conventional type 2 DCs (cDC2s) showing particularly high phenotypic and functional complexity, which enables context-dependent immune modulation. However, the characteristics and functions of tumor-associated DCs remain incompletely defined. Elucidating how these subsets arise and function could broaden our understanding of tumor immunity and contribute to the development of effective cancer immunotherapies.

Methods: Tumor tissues (n=35) and adjacent normal tissues (n=24) from treatment-naïve, EGFR-wildtype NSCLC patients were enzymatically dissociated and subjected to single-cell RNA sequencing using the 5′ Chromium platform (10x Genomics). Trajectory and SCENIC analyses were performed to delineate cDC2 lineage programs. Functional validation included differentiation of CD207$^+$ DCs from human monocytes, co-culture with HUVECs, and multiplex IHC (mIHC) on FFPE tumor slides from NSCLC patients. Deconvolution analyses of TCGA-LUAD and an in-house immunotherapy bulk RNA-seq cohort were conducted to assess clinical relevance.

Results: We identified 10 transcriptionally distinct DC subtypes and found that CD207$^+$ cDC2s were markedly enriched in tumors. Trajectory analysis defined CD207$^+$ cDC2s as a distinct TME-enriched lineage characterized by reduced NF-κB signaling, chemotaxis, and T cell-regulatory programs, while enhanced TNF superfamily cytokine production and retinoic acid metabolism. SCENIC analysis implicated RARA/RXRA as key regulators of CD207$^+$ cDC2 differentiation. CD207$^+$ cDC2 frequency correlated with higher immune cell infiltration, especially CXCL13$^+$ T cells. Consistently, LTB expression in CD207$^+$ cDC2 correlated with high endothelial venule (HEV) and tertiary lymphoid structure (TLS) gene signatures, suggesting a role in lymphoid organization. Functionally, monocyte-derived CD207$^+$ DCs induced adhesion molecules in endothelial cells *in vitro*, and mIHC confirmed that their co-localization with HEVs and increased TLS density. Higher CD207$^+$ cDC2 abundance was associated with improved survival and immunotherapy response, highlighting their specialized role within TME in supporting lymphoid structuring and favorable outcomes in EGFR-wildtype NSCLC.

Conclusion: CD207$^+$ cDC2s constitute a distinct TME-enriched DC subtype that mediates endothelial activation and drives HEV and TLS formation via LTB. Their enrichment in tumors correlates with improved survival and enhanced immunotherapy response, indicating that CD207$^+$ cDC2s promote lymphoid organization and favorable immune outcomes in EGFR-wildtype NSCLC.

#2222 Mapping lymphoid responses to tumor growth and lymph node metastasis: multiomic spatial analysis of pancreatic ductal adenocarcinoma reveals tertiary lymph node structures.

James P. Agolia[1], Chuner Guo[1], Rosyli F. Reveron-Thornton[1], Xiaomo Li[2], Maria Moozhiyil Korah[1], Angela Tabora[1], Byrne Lee[1], Amanda R. Kirane[1], George Poultsides[1], Brendan Visser[1], Gregory W. Charville[2], Michael T. Longaker[1], Deshka S. Foster[1], Daniel Delitto[1]

[1]Surgery, Stanford University, Stanford, CA,[2]Pathology, Stanford University, Stanford, CA

Introduction**:** Within the next five years, pancreatic ductal adenocarcinoma (PDAC) will become the second-highest cause of cancer death in the United States; even with surgical resection and chemotherapy, median overall survival remains less than three years. Spatial transcriptomic and proteomic analysis is one pathway toward therapeutic target discovery for PDAC. While previous spatial transcriptomic studies have uncovered remarkable intratumoral heterogeneity in primary and metastatic samples, most lack subcellular resolution and multiomic scale.

Methods**:** Using the Singular G4X platform, we performed spatial multiomic analysis of 31 regions of interest in formalin-fixed, paraffin-embedded matched primary tumor and metastatic lymph nodes from eight patients. All patients had a pathological diagnosis of PDAC and received neoadjuvant chemotherapy at a single cancer center, and 7/8 patients showed pathological treatment effect with partial response to therapy. Data were analyzed in python.

Results**:** After quality control, 2.4 million cells were integrated. Major cell types were manually annotated: acinar cells (*CPB1*+ *GATM*+), adipocytes (*ADIPOQ*+ *PLIN1*+), B cells (*MS4A1*+ *HLA-DRA*+), cancer-associated fibroblasts (*COL1A1*+ *LUM*+), plasma cells (*JCHAIN*+ *IGHA1*/*IGHM*+), macrophages (*CD163*+ *CD68*+), mast cells (*KIT*+), neuroendocrine cells (*NRXN1*+ *NCAM1*+), pericytes/endothelial cells (*PECAM1*+ *RGS5*+), smooth muscle cells (*TAGLN*+ *MYH11*+), and T cells (*CD3D*+ *IL7R*+). Tumor cells formed three distinct clusters: *KRT19*+ *MUC1*+ ductal cells, *PIGR*+ *GATM*+ ductal cells, and *STAT1*+ *CD44*+ cells (from one patient with sarcomatoid dedifferentiation). The predominant cell type in the tumor microenvironment, cancer-associated fibroblasts (CAFs) could be subclustered into inflammatory CAF (*CXCL12*-high *IL6*-high), mechanoresponsive CAF (*PDGFRB*-high *ACTA2*-high), and steady-state CAF phenotypes. Although we did not select regions of interest explicitly with tertiary lymphoid structures (TLSs) in mind, we found that 7/8 patients and 9/19 tumor sections contained putative TLSs, with 4 sections containing more than one TLS area. TLS morphology appeared similar to that of lymphoid aggregates in tumor-positive lymph nodes. A predominance of CAFs was also noted in the involved lymph nodes. B cells within TLSs stained positive for CD20 protein and expressed *CXCR5* transcripts; they were surrounded by T cells that stained positive for CD3 and CD4/CD8 proteins. *CXCR5* colocalized closely with its binding partner *CXCL13,* a known trigger of TLS formation.

Conclusion**:** In a cohort of PDAC patients with lymph node metastasis, multiomic spatial analysis revealed TLSs in nearly all patients, suggestive of immune potential within the PDAC stroma. The CXCR5-CXCL13 axis should remain a target of active investigation in TLS formation.

#2226 Novel targeted therapies for malignant ascites in pancreatic cancer.

Kuntal Halder[1], Ruben Munoz[1], Wei Lin[1], Annie Yang[2], Yanghee Woo[2], Erkut Borazanci[3], Haiyong Han[1], Daniel D Von Hoff[1]

[1]TGen (The Translational Genomics Research Institute), Phoenix, AZ,[2]City of Hope National Medical Center, Duarte, CA,[3]Honor Health Research Institute, Scottsdale, AZ

Malignant ascites (MA) remains a severe, untreatable complication in patients with late-stage cancers including pancreatic cancer, contributing to their poor prognosis. Using single-cell RNA sequencing (scRNA-seq), we characterized 12,084 cells isolated in MA samples from patients with pancreatic cancer. We found that immune cells were the dominant (90%) cell population with M2-like macrophages (62.4%) and T cells (23.1%) prevailing, while tumor cells constituted only 7.5% of the total cell population. The M2-like macrophages, marked by high CD163 and low CD80 expression, expressed elevated vascular endothelial growth factor (VEGF) and colony-stimulating factor-1 receptor (CSF1R), potentially promoting tumor proliferation, survival, and ascites formation via increased endothelial permeability. The T cells were mostly CD8-negative, indicating suppressed cytotoxic function, consistent with findings in ovarian cancer ascites. We hypothesize that targeting VEGF, CSF1R, and immune checkpoint proteins (e.g., PD-1 and CTLA-4) can reprogram the MA immune microenvironment, reducing ascites and peritoneal tumor growth. To test this hypothesis, we established an MA model for pancreatic cancer by intraperitoneally implanting murine pancreatic cancer cells derived from the KPC model into C57BL/6 mice. These mice develop ascites 7-10 days after cell injection and succumb to the disease within 4-5 weeks. We then evaluated the activity of anti-PD-1 and anti-CTLA-4 antibodies as a single agent or in combination in the KPC MA model. Both antibodies significantly reduced the formation of MA and extended the survival of the mice. The anti-PD-1 antibody (300 µg/dose for 3 weekly doses) extended the median survival from 25 days in the isotype control antibody group to 55 days, while the median survivals for both the anti-CTLA-4 group (100 µg/dose for 3 weekly doses) and the combination group were not reached 96 days after the initiation of treatment. We are in the process of assessing the efficacy of an anti-VEGFA antibody (2G11-2A05) and a CSF1R inhibitor (PLX3397) in the same model. Results from the studies could establish preclinical evidence supporting the utility of these novel therapeutic regimens for treating MA in pancreatic cancer patients and lead to clinical trials to address this critical unmet need.

#2227 Selectively eliminating senescent cancer-associated fibroblasts via chidamide and chemo-immunotherapy in metastatic pancreatic cancer: phase 2 clinical trial results (PANDA-1706).

Tianxing Zhou[1], Jingrui Yan[2], Jihui Hao[2]

[1]Pancreas Center, Tianjin Medical Univ. Cancer Inst. & Hospital, Tianjin, China,[2]Tianjin Medical Univ. Cancer Inst. & Hospital, Tianjin, China

Lymph node metastasis (LNM) in early-stage pancreatic ductal adenocarcinoma (PDAC) predicts systemic dissemination and poor survival, yet its underlying mechanisms remain elusive. Here, we demonstrate that senescent cancer-associated fibroblasts (senCAFs) drive lymphatic remodeling and LNM in early-stage PDAC and predict distant metastasis. Genetic or pharmacologic elimination of senCAFs suppresses LNM and distant metastasis. Mechanistically, senCAFs promote lymphangiogenesis and LNM by augmenting glucose metabolism and lactate production, which activates lactylation-mediated serine metabolism to protect lymphatic endothelial cells from oxidative stress. Moreover, using advanced multiplex imaging techniques, we have discovered that $CCR4^+$ Tregs from the draining lymph nodes accumulated around lymphatic vessels. This localized accumulation is facilitated by lymphatic endothelia enriched in senCAFs, which established an immunosuppressive peri-lymphatic niche. Furthermore, high throughput drug screening platform determines selective clearance of senCAFs via chidamide, one HDAC inhibitor, attenuates tumor progression and improves chemo-immunotherapeutic efficacy at low concentrations. We subsequently initiated a phase 2 clinical trial in metastatic PDAC patients. Here we report the results of the chidamide arm (chidamide and nab-paclitaxel/gemcitabine plus anti-PD-1/CTLA-4). The pre-specified primary endpoint of this arm was met, with a confirmed objective response rate. Collectively, these findings reveal a closed link between cellular senescence, metabolic reprograming, spatial immusuppressive niche and PDAC metastasis, offering the potential senolytic means to improve chemo-immunotherapy efficacy in PDAC patients. Clinical Trials.gov. identifier: NCT06951997.

#2228 Biofield therapy inhibits pancreatic cancer invasion and metastasis by modulating multiple steps of metastatic cascade.

Peiying Yang[1], Sharmistha Chakraborty[1], Phuong Nguyen[1], Defeng Deng[1], Amanda Eckstrom[1], Andrew Cusimano[1], Daoyan Wei[2], Lorenzo Cohen[1]

[1]Palliative, Rehabilitation and Integrative Medicine, The University of Texas MD Anderson Cancer Center, Houston, TX,[2]Gastroenterology and Hepatology, The University of Texas MD Anderson Cancer Center, Houston, TX

Biofield therapies (BTs) are gaining attention as potential complementary treatments for cancer. Some devices have been developed to mimic the energetic or electromagnetic fields emitted by BT practitioners. We previously reported that BT significantly inhibited growth and invasiveness of pancreatic cancer cells in vitro and in relevant animal models. To identify which steps of the metastatic cascade are affected by BT and to elucidate potential antimetastatic mechanisms in pancreatic ductal adenocarcinoma (PDAC), we conducted in vivo studies using metastatic mouse models. In a KPCY orthotopic model, BT treatment significantly reduced the percentage of visible liver nodules by 61.3% and 54.6% compared with the colony control (CC) and sham control (SC) groups, respectively ($p < 0.05$). Imaging of YFP+ cells in the liver tissues revealed a significant reduction in disseminated tumor cells in the BT group relative to CC and SC groups ($p < 0.05$). In a tail-vein injection model, lung tissues from BT treated mice exhibited a significant 59.6% reduction in YFP+ signal intensity compared with SC mice, supporting the conclusion that BT suppresses metastatic dissemination of PDAC cells. BT treated mice bearing PANC-1 orthotopic tumors had significantly lower levels of tumor cell-free DNA (11.5 ± 4.6 ng/µl) compared with sham control (24.7 ± 7.9 ng/µl; $p < 0.01$), suggesting that BT treatment impairs tumor cell intravasation. This is consistent with our previous findings that BT inhibits EMT in human PDAC PANC-1 cells. Additionally, BT induced anoikis in PANC-1 cells, indicating that BT may also reduce PDAC cell survival in circulation. To investigate whether BT affects metastatic colonization, both PANC-1 and KPCY cells were exposed to BT and subjected to adhesion assay using phalloidin staining and fibronectin quantification, as fibronectin is a key regulator of cell adhesion. PANC-1 cells exposed to BT for 15 mins showed an average of 14 ± 4 adhered cells per field, compared with 96 ± 35 in the SC group ($p < 0.0001$). Similarly, fibronectin-based cell adhesion measurements showed a 58.3% decrease in BT-treated PANC-1 cells relative to SC ($p < 0.001$). BT also significantly reduced F-actin intensity in PANC-1 cells ($p < 0.01$), with similar results observed in KPCY cells after 30 min of treatment. Epigenetic profiling further revealed that BT modulated the expression of genes involved in actin cytoskeleton regulation. Collectively, these results demonstrated that biofield therapy suppressed multiple metastatic steps including cell invasion/migration, intravasation, survival in circulation, and colonization ultimately contributing to its antimetastatic effects in PDAC models. These processes may be mediated in part through alterations in cytoskeleton organization, particularly actin dynamics.

#2229 RIPK2 and CDK2 form a targetable positive feedback loop in prostate cancer cells.

Ahmed Elgehama[1], Jaceline Pires Sanches Sanches[2], Lili Guerra[3], Wei Yang[2]

[1]Stony Brook University, Renaissance School of Medicine, Stony Brook, NY,[2]Stony Brook University, Stony Brook, NY,[3]Stony Brook UNIVERSITY, Stony Brook, NY

Background: Prostate cancer (PC) metastasis is the leading cause of PC-related mortality, yet effective therapies targeting this lethal process remain lacking. We previously identified RIPK2 as a promising drug target in PC metastasis, functioning in part through a noncanonical RIPK2/MKK7/c-Myc phosphorylation pathway (*Nat. Commun.*, 2022). However, additional downstream effectors and upstream regulators of RIPK2 remain poorly characterized. This study aims to address this knowledge gap, which represents a major barrier to developing highly effective and low-toxicity combination therapies.

Methods: Genetic manipulation was performed using CRISPR/Cas9 knockout, siRNA knockdown, and overexpression of wild-type or mutant genes. The metastatic potential of PC cells was assessed by cell proliferation, Matrigel invasion, clonogenicity, and soft-agar assays. RIPK2 activation of CDK2 was evaluated by western blotting and *in vitro* kinase assays. RIPK2-CDK2 interaction was examined using co-immunoprecipitation, GST pulldown, proximity-ligation assay, fluorescence colocalization, and fluorescence resonance energy transfer. Gene transcription and expression were measured by RT-qPCR. Protein stability was determined using cycloheximide chase and ubiquitination assays. Synergistic effects of RIPK2 and CDK2 inhibitors are assessed with a 6x6 matrix. At least two independent cell lines were used for each cell assay.

Results: RIPK2 enhanced the metastatic potential of PC 22Rv1 and PC3 cells primarily through its kinase activity, cytoplasmic localization, and induction of c-Myc expression. RIPK2 bound directly to CDK2 and activated it, leading to phosphorylation of c-Myc at S62. Notably, active CDK2 increased both transcription and protein stability of RIPK2, establishing a positive feedback loop. Co-inhibition of RIPK2 and CDK2 synergistically reduced c-Myc protein levels and suppressed PC cell invasion and colony formation.

Conclusion: RIPK2 and CDK2 form a multi-layered positive feedback loop that sustains c-Myc expression and drives PC metastatic progression. Low-dose co-inhibition of these two kinases using clinically evaluated inhibitors represents a promising therapeutic strategy to overcome c-Myc-dependent PC metastasis with high efficacy and minimal toxicity.

#2230 Combined treatment with agonists for CXCR4 and CB2 receptors reduces prostate cancer growth and metastasis.

Nakea Michelle Pennant[1], Alifiani Bonita Hartono[2], Shiqin Liu[2], Sidharth Paparaju[2], Chung Lee[2], Christopher Massey[2], Tanya Ivanova Stoyanova[2], Cimona V. Hinton[3]

[1]Biological Sciences, Clark Atlanta University, Atlanta, GA,[2]UCLA - University of California Los Angeles, Los Angeles, CA,[3]Microbiology, Biochemistry & Immunology, Morehouse School of Medicine, Atlanta, GA

CXCR4 is a G-protein-coupled receptor (GPCR) widely expressed in tumors, regulates cell migration, survival, and immune responses through activation by stromal cell-derived factor-1α (SDF-1α), contributing critically to metastasis and tumor aggressiveness. Our previous *in vitro* studies demonstrated that CXCR4 forms heterodimers with the cannabinoid receptor 2 (CB2) in human breast and prostate cancer cell lines. Simultaneous stimulation of CXCR4 and CB2 with SDF-1α and the CB2 agonist AM1241 induced the formation of a physical dimer, which markedly suppressed CXCR4-mediated pro-tumorigenic signaling, reduced cell migration, disrupted cytoskeletal organization, and downregulated motility-associated proteins. Given the reported anti-metastatic effects of cannabinoids and the results of our heterodimer, we hypothesized that simultaneous activation of CXCR4 and CB2 could attenuate tumor progression *in vivo*. To test this, we established a spontaneous metastasis model using luciferase-expressing human prostate cancer cells (DU145 RFP/Luc or PC3 GFP/Luc) implanted subcutaneously into male NSG mice. Once tumors reached ~40 mm^3, mice were randomized into four treatment groups: vehicle, SDF-1α, AM1241, or simultaneous SDF-1α+ AM1241. Primary tumors were surgically resected at ~400 mm^3, and treatments continued post-resection to assess metastasis and recurrence. Mice that received the combined agonist treatment exhibited no local tumor recurrence, a significant reduction in tumor volume, and a markedly lower incidence of distant metastases compared to all other groups. These findings demonstrate that concurrent CXCR4 and CB2 activation inhibits tumor growth and dissemination, as we observed *in vitro,* suggesting that targeting the CXCR4-CB2 receptor complex represents a promising alternative to traditional CXCR4 antagonists for managing metastatic prostate cancer.

#2231 Resensitizing therapy-resistant anoxic metastatic melanoma cells.

Gustavo Untiveros[1], Daryl Forney[1], Mariella Andrews[2], Tekaswini Kannan[1], Luigi Strizzi[3]

[1]Midwestern Univ. - Downers Grove Campus, Downers Grove, IL,[2]Loyola University - Chicago, Chicago, IL,[3]Pathology, Midwestern Univ. - Downers Grove Campus, Downers Grove, IL

Introduction: Metastatic melanoma significantly reduces patient survival. Metastatic growth can outpace vascularization creating areas of extreme hypoxia or anoxia. HIF-1α is a master transcriptional regulator of cellular survival response to hypoxia that can facilitate the selection of more stem cell-like, drug-resistant cancer cells. BRAF inhibitors (BRAFi), commonly used to treat melanoma, targets cell signaling involving pERK-dependent melanoma growth. Resistance to BRAFi can lead to melanoma recurrence and poor survival. Dual specificity phosphatases (DUSP), such as DUSP6 can reduce ERK activity; moreover, DUSP6 has been shown to be upregulated by HIF-1α during cellular responses to hypoxia. We hypothesize that HIF-1α levels increase in metastatic melanoma cells as these adapt to the anoxic metastatic niche, which then increases DUSP6 expression, which in turn reduces ERK activity that causes resistance to BRAFi.

Methods: Western blot (WB) was used to compare the expression of HIF-1α, pERK, and DUSP6 in lysates from A375 melanoma cells grown in anoxia or normoxia. An MTT cell proliferation, and a cell apoptosis assay were used to compare the effect of the BRAFi, Dabrafenib between treated normoxic and anoxic A375 cells. Lysates were collected for WB to assess effects on pERK between anoxic A375 treated with the DUSP6 inhibitor, BCI, and untreated control. Finally, to see if BCI can increase drug sensitivity, MTT and cell apoptosis assays were performed on anoxic A375 treated with both BCI and Dabrafenib.

Results: WB results show that anoxic A375 cells express higher levels of HIF-1α, and lower levels of pERK compared to normoxic control cells. Dabrafenib treatment reduced cell proliferation of normoxic but not anoxic A375 cells, presumably due to reduced expression of the pERK target in these cells. Inhibition of DUSP6 with BCI significantly increased pERK expression and when combined with Dabrafenib significantly reduced proliferation and increased cell death of the anoxic A375 cells.

Conclusion: We show that melanoma cells cultured in anoxia express higher levels of HIF-1α. This in turn led to an increase in DUSP6 expression. In these anoxic cells, DUSP6, in turn, reduces pERK level, which is an important component of the signaling cascade targeted by Dabrafenib. Finally, our results from the combination treatment with both BCI and Dabrafenib suggest that by inhibiting DUSP6 it may be possible to re-express pERK in drug-resistant anoxic metastatic melanoma cells and reestablish drug sensitivity.

#2232 Investigating the combined inhibition of RAF, MEK, and FAK in melanoma molecular subtypes.

Jared Almazan

University of Utah Huntsman Cancer Institute, Salt Lake City, UT

Despite promising results from FDA-approved therapies, many patients with advanced melanoma develop resistance to standard-of-care therapy, which includes immunotherapy in all molecular subtypes and targeted therapy for $BRAF^{V600E/K}$ melanoma. Most melanomas harbor alterations in the mitogen-activated protein kinase (MAPK) pathway, including mutations in BRAF, NRAS, and NF1 genes. While $BRAF^{V600E/K}$ melanomas initially respond to mutant BRAF and MEK inhibitors, resistance develops in the majority of cases. Furthermore, there are currently no FDA-approved targeted therapies for patients with tumors harboring NRAS or NF1 alterations following immunotherapy failure. Therefore, novel and effective therapeutic approaches are urgently needed to treat these molecular subtypes of melanoma, both in primary and resistant settings. The PI3K/AKT pathway is often activated in melanoma, contributing to poor clinical outcomes and promoting brain metastases, yet clinical attempts to target this pathway have been hindered by limited efficacy or intolerable toxicity. Proteomic analysis comparing non-metastatic and metastatic primary tumors in mice revealed focal adhesion kinase (FAK) as an AKT1-specific effector and a potential alternative therapeutic target. In mutant BRAF-driven models, the combination of the FAK inhibitor VS-4718 and the RAF/MEK clamp avutometinib, with or without the mutant BRAF inhibitor encorafenib, significantly delayed tumor onset, induced regression of established tumors and brain metastases, and prolonged overall survival. These findings support an ongoing clinical trial evaluating the efficacy of avutometinib and the FAK inhibitor defactinib, with or without encorafenib, in patients with brain metastases from cutaneous melanoma (DETERMINE; NCT06194929). Early observations indicate that the triplet combination is safe and well-tolerated. Additionally, in melanoma models harboring RAS mutations or NF1 loss, the combination of VS-4718 and avutometinib significantly reduced melanoma cell growth and viability in vitro, delayed tumor progression in autochthonous mouse models, and inhibited tumor growth in patient-derived xenografts driven by these alterations. Lastly, we are investigating the non-canonical roles of FAK in modulating the tumor microenvironment to determine whether this treatment strategy alters immune cell composition, chemokine and cytokine production, and enhances the efficacy of immune checkpoint inhibition.

#2233 Novel anticancer mechanisms of melanin: Effects on cancer cell adhesion, survival, and migration.

Dorie Liu, Wei Zhu

SCI research institute, Jericho, NY

Melanoma is the deadliest form of skin cancer, with 330,000 new cases diagnosed and 60,000 deaths globally each year. While early-stage melanoma is often treatable, metastatic melanoma usually has poor prognosis with a high mortality rate.
Melanin, a pigment synthesized through the melanogenesis pathway, has been reported to exert anti-cancer effects. However, the molecular mechanisms underlying its protective role remain poorly understood. We hypothesize that melanin may exert anticancer activity by reducing cancer cell survival and suppressing metastatic potential.
This study uses 3 different cancer cell lines, including U937 (monocytic), HTB-11 (neuronal), and Colo320 (colorectal), and utilizes a combination of methods, including in silico molecular docking, cell attachment assays, and MTT assays, to evaluate the effects of melanin on cancer cell adhesion, proliferation, and survival.
The results revealed that melanin decreased U937 (monocytic) cancer cell adhesion in a dose dependent manner: at a lower concentration, melanin increased cell adhesion by 29.5%, while in a higher concentration, it decreased cell adhesion. In HTB-11 cells, high concentration of melanin decreased cell proliferation by 48.61%, while in Colo320 cells, low concentration of melanin significantly suppressed cell growth by 63%.
Data also showed that melanin has a strong binding affinity to cancer-related target proteins, including MMP2, MMP9, CDH1, and ITGB1, the possible molecular and genetic mechanisms of melanin in working with known cancer target proteins to regulate cancer growth.
In conclusion, these findings suggest novel molecular pathways by which melanin may regulate cancer cell survival, adhesion, and migration. Collectively, this study provides new evidence for melanin as a potential anticancer agent with differential, dose-dependent effects, underscoring its relevance as a therapeutic lead for targeting diverse cancer types.

#2234 Antibodies that bind to primitive human growth factor NME7-AB block interaction with MUC1* growth factor receptor to inhibit cancer growth and metastasis.

Cynthia Carol Bamdad, Benoit J. Smagghe, Mark G. Carter, Kevin R. Yi, Michael J. Nash, Trevor J. Grant, Daniel S. Miller, Natalie K. Miller, Andrew K. Stewart

Minerva Biotechnologies, Woburn, MA

Purpose: Develop therapeutic antibodies that block the tumorigenic action of MUC1* ligands and bacterial mimics thereof.
Methods: Ligand fishing using the MUC1*ecd-45 peptide as bait identified NME1 and NME7-AB as ligands of MUC1*. Dimeric NME1 and monomeric NME7-AB, which has two MUC1* binding domains, dimerize MUC1* extracellular domain (ecd) and activate MAP kinase growth pathway. IF microscopy showed NME7-AB is secreted by all Day 3 cells of a human blastocyst, then only by cells of the Inner Cell Mass by Day 5. NME7-AB is then replaced by adult form, NME1, which only binds MUC1* when a dimer. At higher concentration, NME1 switches from dimer to hexamer, which doesn't bind MUC1* but instead triggers differentiation. NME7 is cytoplasmic until cleavage removes an N-terminal DM10 fragment, which allows secretion, then 'NME7-AB'. Alternative splice variant NME7-X1 is transcribed without the DM10 domain, so is always secreted and active. Cancer cells that have acquired resistance to cancer drugs, increase expression of MUC1*, NME7-AB and NME7-X1. We mapped the MUC1* interaction site on NME7-AB and generated antibodies that block the interaction. We discovered a subset of antibiotic-resistant bacteria that make NME7-AB mimics that function like human NME7-AB. We developed monoclonal antibodies that specifically bind to these bacterial mimics.
Results: Growing cancer cells with recombinant NME7-AB as the only growth factor, enabled anchorage independent cell growth, induced upregulation of metastasis markers and formed tumors as well as metastasis from injection of as few as 10,000 cells within 10-20 days. 50-times as many parent cells did not. A novel antibody, prevented NME7-AB from inducing upregulation of metastatic markers, and prevented anchorage independent growth. In animals, NME7-AB monoclonal antibodies reversed total metastasis in a few days. They also inhibited metastasis of established sub-cu tumors. Similarly, bacterial mimics of NME7-AB induced upregulation of metastatic markers and, in animals, accelerated tumor growth and their metastasis. We developed monoclonals antibodies that bind to the interaction region on bacterial mimics.
Conclusions: MUC1 has long been an elusive target for cancer therapeutics. However, there has been little focus on its onco-embryonic ligand NME7-AB. NME7-AB is turned off early in embryogenesis but is turned on again in all MUC1-positive cancers. Levels of NME7 determine growth rate and metastatic potential of human cancers. Demonstration of NME7-AB antibodies inhibiting cancer and metastasis in animals xenografted with human cancers supports the further clinical development of NME7-AB targeted therapeutics. Discovery of a molecular link between specific bacteria and acceleration of human cancers may be an important area for future research.

#2235 Intercepting metastasis: 8-step CRISPR design via multi-modal foundation models.

Fahad Kiani

CrisPRO.ai, New York, NY

Background: Metastasis accounts for >90% of cancer deaths, yet CRISPR design tools prioritize on-target efficiency alone (CRISPOR, Benchling), ignoring stage-specific biology (EMT, extravasation, colonization). No existing tool integrates essentiality (DepMap), chromatin accessibility (ENCODE), and metastatic cascade relevance into guide selection. We present Interception, a stage-aware CRISPR framework targeting vulnerabilities across the metastatic cascade.
Methods: We compute three orthogonal signals: (i) Functionality (Evo2): predict variant impact on protein function; (ii) Essentiality (DepMap): prioritize genes critical for metastatic survival; (iii) Regulatory (GTEx eQTLs): predict expression changes. Target-Lock score quantifies gene relevance to specific metastatic stages (e.g., EMT vs. extravasation) using literature-derived weights. Guide candidates are generated with PAM constraints, scored for efficacy (Evo2-predicted expression change via sigmoid transformation) and safety (minimap2 genome-wide alignment with exponential mismatch decay), then ranked by Assassin score (0.40×efficacy + 0.30×safety + 0.30×mission fit). Weights were optimized via ablation study on 304 gene-stage pairs. All outputs include full provenance and are reproducible via frozen scripts/environment.
Results: Target-Lock significantly outperformed single-metric baselines: AUROC 0.976 (ours) vs. 0.61 (DepMap alone), 0.58 (Evo2 alone), 0.52 (random); AUPRC 0.948 vs. 0.42 (DepMap), 0.39 (Evo2); Precision@3 = 1.000 (perfect top-3 enrichment) vs. 0.33 (random). All 8 metastatic steps showed significant enrichment (Fisher's exact $p < 0.001$ for 6/8 steps) with large effect sizes (Cohen's $d > 2.0$). Guide validation on 20 designs showed mean efficacy 0.548 ± 0.119, safety 0.771 ± 0.210. Structural validation of 15 guide:DNA complexes via AlphaFold 3 Server achieved 100% pass rate (pLDDT 65.6 ± 1.8, iPTM 0.36 ± 0.01)—the first metastasis-targeted CRISPR framework with structural validation.
Conclusions: Interception delivers reproducible, mission-aware CRISPR design for metastasis, integrating multi-modal signals, genome-wide safety, and structural validation. Future work will (i) integrate Enformer for chromatin predictions, (ii) expand structural validation to 40 guides (complete 8-step coverage), and (iii) validate in metastatic mouse models (PDX/CDX) to assess in vivo efficacy.

#2236 Evaluation of novel medicinal compounds for therapeutic efficacy against liver cancer.

Aarya M. Tripathi[1], Veerababu Nagati[2], Yamile AbuchardAnaya[2], Kaylee Renteria[2], Denise Soto[2], Miguel Salazar[1], Subhash C. Chauhan[2], Debasish Bandyopadhyay[1]

[1]School of Integrative Biological and Chemical Sciences, The University of Texas Rio Grande Valley, Edinburg, TX,[2]Oncology and Medicine ISU, South Texas Center of Excellence in Cancer Research, The University of Texas Rio Grande Valley, McAllen, TX

Hepatocellular carcinoma (HCC), the most common type of liver cancer, makes up over 90% of cases and remains a significant global health issue. Early-stage HCC can be treated with hepatectomy or liver transplant, but advanced disease has a poor outlook due to treatment resistance and widespread drug resistance. Sorafenib, the first-line tyrosine kinase inhibitor for advanced HCC, provides only modest gains in overall survival, highlighting the urgent need for new treatments. This need is especially urgent in the Rio Grande Valley (RGV), where liver cancer rates and mortality are higher than the national average due to high rates of obesity, diabetes, metabolic dysfunction-associated steatotic liver disease (MASLD), hepatitis infections, and limited healthcare access. To address these regional and global disparities, this study evaluates four medicinally privileged molecules: 1. DB5 OTFE, 2. DBMG-5, 3. DBNJ-1, and 4. DB-3-OCAS, for their potential anti-cancer effects. Out of these four compounds, 1 and #4 are natural product mimics with beta-lactam moiety at the core, synthesized by a multi-step procedure. Compound#2 is a macrocycle-fused gamma-lactone and #3 is a pentacyclic triterpene, isolated from plants. Human HCC cell lines SK-HEP1, Hep G2, C3A, and Huh7 will be treated with logarithmic dilutions of each compound (10 mM DMSO stocks) and assessed using the MTT viability assay to determine IC_{50} values. Phase-contrast microscopy will be used to observe morphological changes and confirm cell viability. We hypothesize that these natural compounds will exhibit dose-dependent cytotoxicity against liver cancer cells and that at least one will have significantly lower IC_{50} values compared to Sorafenib. Expected outcomes include decreased confluency, alterations in cell morphology, and the identification of a lead compound with strong cell-killing activity. The most effective compound will then undergo structural optimization of its functional groups, followed by re-evaluation against HCC cell lines and comparison with Sorafenib to assess its therapeutic potential. Long-term goals include conducting mechanistic studies and potentially progressing to *in vivo* models. This research supports developing locally relevant therapies aimed at reducing liver cancer disparities in the RGV and contributes to the broader search for accessible, natural-product-based treatments for HCC.

#2237 Novel MACC1 transcriptional inhibitor act via reduced NFκB signaling pathway to reduce metastasis formation.

Ulrike S. Stein

Translational Oncology of Solid Tumors, Max Delbruck Center for Molecular Medicine, Berlin, Germany

Metastasis Associated in Colon Cancer 1 (MACC1) is a key metastatic molecule, used as a prognostic and predictive biomarker for metastasis formation and therapy outcomes. A high expression predicts poor survival and therapy resistance to common chemotherapeutics. Recently we have identified a novel transcriptional inhibitor of the MACC1 gene. This tetrazolo-pyridazine-based compound (compound 22) was discovered through a high-throughput screen (HTS) using the human MACC1 promoter coupled to a luciferase reporter gene. 1,2,3,4-tetrazolo[1,5-b]pyridazine-based compounds can act as effective MACC1 inhibitors in vitro by reducing MACC1-induced cancer cell motility. This translates in reduced metastasis formation in mice, and thus pose them promising candidates for anti-metastatic therapies particularly for patients with MACC1-overexpressing cancers, that are at high risk to develop metastases. To identify the mode of action, we used RNA-sequencing to reveal the gene expression changes under compound 22 treatment which displayed the TNF-α signaling via NFκB was attenuated. Subsequent gene ontology analysis of the differentially expressed genes showed changes in biological functions such as cell cycle progression and intermediate filament-based processes. These render the cells less proliferative and with more epithelial characteristics. Molecular analysis of the NFκB pathway revealed a reduced p65 and p50 activity with reduced nuclear translocation and activity on the MACC1 promoter. In silico predictions revealed p105 as a possible protein target. Further, the novel compound blocks the TNF-α induced phosphorylation of p105. Although further experimental data is needed to address the potential binding of the identified tetrazolo-pyridazine-based compound to p105, this study revealed that the NFκB signaling pathway is strongly reduced under the treatment with this novel compound. This in turn reduces the MACC1 gene expression and thereby the metastatic potential of cancer cells.

#2238 Anti-metastatic properties of the triterpene diosgenin on lung carcinoma cells.

Laurie Mar Santos[1], Edwin Figueroa[2], Juan Figueroa[2], Yamixa Delgado[3], Daraishka Perez[3], Yancy Ferrer[4]

[1]Universidad Central del Caribe, Bayamon, PR,[2]University of Puerto Rico, Cayey, PR,[3]San Juan Bautista School of Medicine, Caguas, PR,[4]University of Puerto Rico, Medical Science Campus, San Juan, PR

Lung cancer remains the leading cause of cancer-related mortality worldwide, with non-small cell lung carcinoma (NSCLC) accounting for ~85% of all cases. Although chemotherapy is a standard treatment option, its success is limited by dose-dependent toxicity and the development of chemoresistance. These challenges have increased interest in phytochemicals such as triterpenes, natural metabolites with broad pharmacological activities and potential anticancer properties. Diosgenin (Dios), a steroidal triterpene present in numerous medicinal plants, has been reported to modulate pathways central to cancer cell survival and metastasis. This study evaluated the effects of Diosgenin on NSCLC cells to elucidate its mechanism of action. Diosgenin demonstrated strong cytotoxic activity in the micromolar range in a dose-dependent manner within 24 hours. Functional assays showed that Diosgenin significantly inhibited A549 cell migration and induced cell cycle arrest at the S and G2/M phases. Protein analysis revealed reduced expression of proliferative and survival markers, including Ki67, MAPK, and PI3K, accompanied by a notable increase in Caspase 3/7 activation. Metastasis-related gene expression profiling showed that Diosgenin downregulated key pro-metastatic genes such as MMP2, MMP9, and PREX1, all of which contribute to extracellular matrix degradation, cytoskeletal remodeling, and invasive potential. In contrast, Diosgenin upregulated NDRG1, a well-established metastasis suppressor involved in inhibiting epithelial-to-mesenchymal transition and limiting cell motility. Collectively, these findings indicate that Diosgenin exerts multi-targeted anticancer activity by suppressing proliferation, inducing apoptosis, and significantly impairing metastasis-associated pathways. Diosgenin represents a promising natural therapeutic candidate for slowing NSCLC progression and reducing metastatic potential.

#2239 The transcobalamin receptor, CD320, is a therapeutic target for metastatic triple negative breast cancer.

Joanne Tejero, Felicia Lazure, Stanislav Drapela, Eduardo Miranda, Nadir Sarigul, Devesh Raizada, Didem Ilter, Ana Gomes

Moffitt Cancer Center, Tampa, FL

Vitamin B12 is an essential micronutrient that functions as a cofactor for enzymes in the folate and propionate metabolism pathways, placing it at the center of nucleotide metabolism, redox balance, and cell fate decisions. Following dietary intake of vitamin B12, vitamin B12 binds to transcobalamin (TC), which protects it from degradation. Cellular uptake of vitamin B12 is mediated by the TC receptor, CD320, positioning CD320 in a prime position to regulate vitamin B12 availability and govern cell fate decisions. Triple negative breast cancer (TNBC) is a highly aggressive subtype of breast cancer with limited treatment options and poor survival rates once metastasis to distant sites occurs, highlighting the need for novel therapeutic strategies for metastatic TNBC. Using publicly available datasets, we found that CD320 was highly expressed in TNBC cell lines and patient samples compared to hormone receptor-positive and HER2-positive subtypes. High expression of CD320 was associated with poor prognosis specifically in TNBC, unlike in other subtypes. Metastasis accounts for the majority of breast cancer-related deaths, and progression into metastatic disease requires cancer cells to adapt to the different pressures throughout the metastatic cascade. Thus, we hypothesized that upregulation of CD320 represents a metabolic adaptation of TNBC metastasis to meet the steep vitamin B12 demand that drives this aggressive phenotype. Consistent with this hypothesis, we observed that CD320 expression was significantly higher in TNBC metastases compared to the expression in primary tumors. Strikingly, suppression of CD320 induced TNBC cell death while having no cytotoxic effect on mammary epithelial cells and markedly impaired metastatic progression *in vivo*, as demonstrated in orthotopic and experimental models of metastasis. Conversely, overexpression of CD320 in transformed mammary epithelial cells conferred aggressive properties, such as increased proliferation, suggesting that CD320 is not only required for TNBC metastasis but also sufficient to enable TNBC aggressiveness. Together, these findings establish CD320 as a critical regulator of TNBC growth and metastasis and reveal CD320 as a promising therapeutic target to selectively eliminate TNBC cells without eliminating the normal tissue counterpart.

#2240 Inhibition of STAT3 and PARP1 reduces TNBC invasion through cytoskeletal remodeling.

Arielle McGlone[1], Ali Andalibi[2], Pranabananda Dutta[3]

[1]Charles R. Drew University of Medicine & Science, Los Angeles, CA,[2]Office of the Provost, Charles R. Drew University of Medicine & Science, Los Angeles, CA,[3]Division of Cancer Research and Training, Charles R. Drew University of Medicine & Science, Los Angeles, CA

Triple Negative Breast Cancer (TNBC) is an aggressive, treatment-resistant subtype that disproportionately affects African American women, leading to high mortality. TNBCs have significantly higher metastasis rates compared to the receptor-positive Luminal subtype. Although research is ongoing, the biological mechanisms underlying metastasis in TNBC, particularly those related to cytoskeletal organization, remain unclear. Understanding how TNBC cells migrate, particularly through actin cytoskeleton remodeling, is crucial. Here, we demonstrate that combined inhibition of PAPR1 and STAT3 reduces cytoskeletal remodeling, particularly actin filament remodeling, a key factor in TNBC invasiveness. We used TNBC cell lines BT-549 (mesenchymal phenotype) and MDA-MB-468 (Basal-like 1/Immunomodulatory) to test Olaparib (a PARP1 inhibitor), Stattic (a STAT3 inhibitor), or both. Co-immunoprecipitation was used to study the interaction between PAPR1 and STAT3. We assessed cytoskeletal remodeling by western blotting, phalloidin staining, and cell motility using wound-healing and Boyden chamber invasion assays. The results show that PARP1 interacts with STAT3 in TNBC and poly-ADP-ribosylates STAT3. We observed reduced migration with inhibitors, especially with combined treatment, and disruption of actin cytoskeletal organization with the inhibition of STAT3 and PARP1. Combined PARP1 and STAT3 inhibition led to decreased peripheral actin and stress fiber formation, driven by Cofilin phosphorylation. Additionally, we noted downregulation of LIMK2 (Cofilin kinase) and PDXP (Cofilin phosphatase) with Stattic and dual-inhibitor treatment. The inhibitor treatment also downregulated CCL2 and other cytokines in both cell lines, potentially impacting cytoskeletal organization, possibly via the MAP kinase pathway. These findings suggest potential implications for combination therapies and the development of targeted treatments to improve outcomes, particularly by reducing metastasis. Our research enhances understanding of TNBC metastasis by identifying PARP1 and STAT3 as key regulators of actin cytoskeletal remodeling.

#2241 Galectin 1 as a regulator of hormone driven mammary remodeling and early dissemination with therapeutic potential in breast cancer.

Magali Berton[1], Ramiro Perrotta[2], Luis Valencia Salazar[3], Tomas Dalotto Moreno[1], Yamil D. Mahmoud[4], Juan Manuel Perez Saez[1], Sabrina Gatto[1], Rosa Morales[1], Julio Aguirre-Ghiso[3], Gabriel A. Rabinovich[5], Mariana Salatino[6]

[1]IBYME, CONICET, Buenos Aires, Argentina,[2]Department of Genetics, Harvard Medical School, Boston, MA,[3]Montefiore Einstein Comprehensive Cancer Center, New York, NY,[4]Department of Medicine, Weill Cornell Medicine, New York, NY,[5]Institute de Biologia y Medicina Experimental, Ciudad de Buenos Aires, Argentina,[6]Instituto de Biologia y Medicina Experimental, Buenos Aires, Argentina

Galectin-1 (GAL1) is a glycan-binding protein broadly known to shape tumor progression by promoting immune evasion and metastatic dissemination. While GAL1 is well recognized as an immunomodulator in multiple cancer types, its role in hormone-driven mammary gland biology and early tumor evolution remains poorly defined. Using our established MMTV-PyMT model WT or KO for GAL1 (Lgals1-/-), we previously demonstrated that GAL1 deficiency delays tumor onset, reduces metastatic burden, and diminishes mammary branching morphogenesis. Unexpectedly, we also observed a decreased Progesterone Receptor (PR) expression in luminal cells from Lgals1-/- mice in both normal and transformed mammary glands. These findings suggested that GAL1 may act as a critical regulator of hormone-driven mammary gland development. To test this hypothesis, we stimulated C57BL/6 Lgals1+/+ and Lgals1-/- mice with a pellet containing Medroxyprogesterone acetate (MPA), a synthetic progestin, and observed that GAL1-deficient mice exhibited a significantly reduced branching index in response to MPA stimuli. RNA-seq analysis of MPA-treated or control mammary glands further revealed that canonical progesterone-responsive genes such as Tnfsf11 (Rankl) and Wnt4 were attenuated in Lgals1-/- glands. To determine if GAL1 absence perturbs epithelial cell hierarchies, we profiled mammary epithelial cell populations by spectral flow cytometry using EpCAM, CD49f, CD49b and Sca1 markers among CD45neg cells. GAL1-deficient glands exhibited reduced MaSC and ER+ luminal progenitor cell compartments, suggesting that GAL1 helps maintain lineage balance during the development of the mammary gland. This finding is particularly relevant given that this population has been recognized as an early cell of origin in neoplastic transformation. To further interrogate the therapeutic relevance of GAL1 blockade, we used an MMTV-HER2+ model of breast cancer. We developed a GAL1 (clone 3) neutralizing monoclonal antibody and treated MMTV-HER2+ mice (15mg/kg, twice a week) from week 14 of age (preneoplastic stage), through week 19. Therapeutic blockade of GAL1 reduced branching morphogenesis, curtailed the release of early circulating tumor cells (CTCs), decreased the number of transformed ducts, and reduced lung metastasis. Importantly, anti-GAL1 treatment led to reduced PR expression in mammary luminal cells and depleted GAL1 in serum, further confirming the blockade's effectiveness. Together, these findings introduce Galectin-1 as a regulator of progesterone-driven epithelial remodeling and early metastatic spreading. By linking GAL1 to hormone signaling, epithelial hierarchy, and early dissemination, our study positions GAL1 as a promising therapeutic target for treating metastatic breast cancer progression.

#2242 Dual TTK/PLK1 inhibition combined with G-CSF treatment synergistically suppresses metastatic progression in triple-negative breast cancer.

Sunwoong Kim[1], Hanyoung Kim[1], Sung-Dae Cho[2], Jaehan Lee[2], Mi Kyung Park[3], Minkyung Kang[4], Seunghyun Ma[5], Hee-Joo Choi[1], Jeong-Yeon Lee[1]

[1]Department of Pathology, Collegy of Medicine, Hanyang University, Seoul, Korea, Republic of,[2]Department of Oral Pathology, School of Dentistry and Dental Research Institute, Seoul National University, Seoul, Korea, Republic of,[3]Biomedical Science, Hwasung Medi-Science University, Seoul, Korea, Republic of,[4]SillaJen, Inc., Seoul, Korea, Republic of,[5]SillaJen Biotherapeutics, Inc., San Francisco, CA

Threonine tyrosine kinase (TTK) and polo-like kinase 1 (PLK1), critical regulators of the spindle assembly checkpoint (SAC) required for faithful mitotic progression, are frequently overexpressed and dysregulated in human cancers. In recent years, strategies targeting the SAC, including TTK and/or PLK1, have emerged as promising therapeutic approaches in cancer treatment. However, these SAC inhibitors are known to induce adverse effects, including neutropenia. Granulocyte-colony stimulating factor (G-CSF) is widely used to prevent anti-cancer therapy-induced neutropenia, but growing evidence suggests that G-CSF may also promote tumor progression. Here, we demonstrate the broad anti-cancer activity of a novel dual TTK/PLK1 inhibitor, BAL0891, and its functional link to the G-CSF/G-CSF receptor (G-CSFR) axis in metastatic breast cancer. In patients with breast cancer, both TTK and PLK1 were markedly upregulated in triple-negative breast cancer (TNBC), which exhibits aggressive behavior, compared with other subtypes, and their expression levels were positively correlated among TNBC patients. The expression of G-CSFR was upregulated in breast tumors compared with normal tissues and was further elevated in metastatic tumors. In multiple human and murine TNBC cell lines, BAL0891 exerted potent anti-proliferative activity, accompanied by G2/M cell-cycle arrest and apoptosis. BAL0891 showed markedly higher potency in TNBC cells (GI50 ≈ 50—90 nM) than in immortalized MCF10A and ER+ MCF7 cells GI50 > 700 nM). In addition, BAL0891 treatment suppressed the migratory and invasive capacities of metastatic TNBC cells, with a concomitant reduction in vimentin expression, an epithelial-mesenchymal transition (EMT) marker. When comparing the effects of BAL0891 alone and in combination with G-CSF on TNBC progression, G-CSF treatment did not alter the anti-proliferative or apoptotic responses to BAL0891 in TNBC cells harboring moderate to high G-CSFR levels. However, combined BAL0891 and G-CSF treatment further potentiated BAL0891-mediated suppression of migration and invasion in these cells. Taken together, these findings suggest that dual TTK/PLK1 inhibition in combination with G-CSF may represent a valuable therapeutic strategy to suppress metastatic TNBC while potentially reducing the risk of neutropenia.

#2243 Lasofoxifene is a bone protective treatment option for estrogen receptor positive breast cancers.

Emily Kate Zboril[1], David C. Boyd[2], Rachel K. Myrick[2], Nina Dashti-Gibson[3], Faith E. Parker[2], Carson Walker[2], Amy Olex[2], Chuck Harrell[2]

[1]VCU Massey Comprehensive Cancer Center, Richmond, VA,[2]Virginia Commonwealth University, Richmond, VA,[3]Virginia Commonwealth University - VCU, Richmond, VA

Estrogen receptor positive (ER+) breast cancer primarily metastasizes to the bone microenvironment, and patients with ER+ disease are almost twice as likely to develop bone metastasis as those with other subtypes. Treatment with current endocrine therapies frequently results in osteoporosis and subsequent bone turnover which can potentially accelerate metastatic progression. This underscores the need for new treatments which will simultaneously inhibit tumor growth and preserve the bone microenvironment. Standard treatments like aromatase inhibitors and ER-antagonists, like fulvestrant, indiscriminately suppress ER signaling, in both breast and bone. Lasofoxifene, a selective ER modulator, exhibits tissue-selective ER-agonist activity in bone and is currently being evaluated in the ELAINE-III clinical trial [NCT05696626] in combination with abemaciclib for the treatment of ESR1-mutant advanced or metastatic ER+ breast cancer. Here, we investigated the physiological relevance of lasofoxifene's bone-selective ER-agonist activity and its impact on metastatic progression. Animal models of ovariectomy-induced osteoporosis were treated with lasofoxifene or standard endocrine therapies, and femurs were analyzed by histology and micro-CT histomorphometry. In parallel, anti-tumor effects of lasofoxifene were evaluated in vitro and in vivo in clinically relevant endocrine therapy-sensitive and -resistant primary and metastatic Patient-Derived Xenograft models. Additionally, drug synergism studies with lasofoxifene and the NCI NExT Oncology Interrogation Tools Set of 555 drugs were performed which identified pathways that were vulnerable to pharmacological inhibition in lasofoxifene-treated cells. We found that lasofoxifene protected against hormone withdrawal-induced bone loss and maintained a robust anti-tumor response in primary and metastatic models of ER+ breast cancer. Drug synergy screens have defined choices for rational combination with lasofoxifene to further potentiate its anti-tumor activity. Overall, this study supports the use of lasofoxifene-based treatment combinations which will concurrently protect bone architecture while suppressing ER+ metastasis progression in the bone niche.

#2244 Pro-metastatic kinase network inhibition to treat drug-resistant triple-negative breast cancer.

Margarite Matossian[1], Madeline Henn Bungert[1], Kent Schechter[1], Long Chi Nguyen[1], Michael East[2], Denis O. Okumu[2], Rita Nanda[1], Gary L. Johnson[2], Marsha R. Rosner[1]

[1]University of Chicago, Chicago, IL,[2]University of North Carolina, Chapel Hill, NC

Metastatic triple-negative breast cancer (mTNBC) has high mortality rates and limited therapeutic options. Chemotherapy, the basis of standard approved therapy for mTNBC, targets rapidly dividing cells but fails to eliminate the stem-like cells that drive metastasis. While kinases are promising drug targets, single-kinase inhibitors have been largely ineffective in mTNBC due to tumor heterogeneity, drug resistance, and the absence of predictive biomarkers. Our strategy is to identify and target kinase networks in pro-metastatic tumor cells that are upregulated in drug-resistant cells or specifically targeted by physiological regulators of metastasis. We initially utilized this approach to overcome AKT resistance in mTNBC. Employing a kinase activity assay (MIB-MS profiling), we demonstrated upregulation of Src family and ATM/ATR kinase networks following treatment of patient-derived, drug-resistant mTNBC organoids with the AKT inhibitor capivasertib. Sequential administration of capivasertib and dasatinib to target the Src family did not reduce organoid viability but did disrupt organoid formation and self-renewal, suggesting effective inhibition of metastatic potential. Building on our previous work, we then optimized a multi-kinase inhibitor regimen that mimics a physiological metastasis suppressor by targeting key stress-responsive kinase networks (ERK1/2, p38, JNK, and MLK). This low-dose drug combination (4MAPKi) prevented both TNBC metastasis and activation of compensatory pathways. We further refined this to a three-drug regimen (Ralimetinib, JNK-in-8, and Trametinib) that inhibits stress kinase networks, pro-motility gene expression and TNBC cell invasion in organoid assays. Importantly, combining this antimetastatic regimen with standard chemotherapy sensitized both TNBC cells and organoids to treatment. Ongoing studies focus on optimizing treatment efficacy with antibody-drug conjugates, characterizing kinase network targets specific for other metastasis regulators such as transcription factors, and exploring kinase networks as biomarkers for treatment resistance. Our long-term goal is to develop a low-toxicity, multi-kinase inhibitor strategy that reprograms metastatic TNBC cells, enhancing the efficacy and durability of their response to chemotherapy and improving clinical outcomes.

#2245 DNMTi in combination with PARPi inhibits aberrant Wnt/β-catenin signaling and tenasin-C pathways, cancer stemness and metastasis in triple negative breast cancer.

Lora Stojanovic[1], Kaushlendra Tripathi[2], Zahra Gohari[1], Julia L. Rutherford[1], Saranya Rajendran[3], Tara X. Metcalfe[3], Shu Zhang[3], Stephen B. Baylin[4], Michael Topper[5], Kenneth P. Nephew[6], Feyruz V. Rassool[7]

[1]University of Maryland, Baltimore, Baltimore, MD,[2]The National Institutes of Health, Bethesda, MD,[3]Indiana University Bloomington, Bloomington, IN,[4]Johns Hopkins University School of Medicine, Baltimore, MD,[5]Johns Hopkins University, Baltimore, MD,[6]Indiana University School of Medicine, Bloomington, IN,[7]Univ. of Maryland School of Medicine, Baltimore, MD

Triple-negative breast cancer (TNBC) has a higher rate of metastasis; a poor prognosis and survival compared with other breast cancer types. Poly-ADP ribose polymerase inhibitors (PARPis) are used to treat TNBC patients that harbor germline BRCA1/2 mutations, inducing synthetic lethality, but responses are not durable. We previously reported that PARPis in combination with DNA methyltransferase inhibitors (DNMTis) exert synergistic cytotoxicity in TNBC, independent of BRCA mutations, but the effects of these drugs on metastasis and stemness, which are associated with poor survival outcomes, are not known. Aberrant Wnt/β-catenin signaling in TNBC is known to drive cancer stemness, metastasis, and resistance to apoptosis and chemotherapy. Genome-wide transcriptomic analysis in TNBC cell line MDA MB 231 demonstrated that combining DNMTis azacytidine (AZA) and PARPis talazoparib (TAL) down-regulated cancer stemness and metastases pathways, and key leading-edge genes including those involved in Wnt/β-catenin signaling and tenasin-C (TNC), a multimodular glycoprotein that promotes the migration of cancer cells, were decreased. The effects of this drug combination on cell migration were functionally validated using scratch and transwell migration and invasion assays in multiple TNBC cell lines, including MDA MB231 and SUM159, and patient-derived organoids (N=3). Xenograft studies of MDA MB 231 by tail vein and SC injection showed decreased metastasis to the lung with this drug combination. Notably, stem cell assays, including spheroid assays and stem cell markers, SOX2, ALDH1a1 and CD44, were also decreased with AZA and TAL treatment. Notably, we show for the first time in TNBC that Beta-catenin/TCF12 transcriptionally regulates TNC by binding to its promoter region and that inhibition or KD of WNT/Beta catenin or TNC expression decreases the cell migration, metastasis and stemness, mimicking the effects of the drug combination in TNBC cells. Taken together, our results show for the first time that PARPi and DNMTi combination therapy targets WNT/Beta-catenin signaling and TNC regulation in driving aggressive disease, metastasis, stemness and poor survival in TNBC.

#2246 GLUT3 inhibition reduces metastatic potential of triple-negative breast cancer cells by modulating cell mechanics via the TEAD-VASP-Actin axis.

Seeun Oh[1], Wonkyung Lee[2], Song Kim[2], Donghoon Yoon[3], Jun-Yong Choe[4], **Tae-Hyung Kim**[2]

[1]Department of Molecular Genetics & Microbiology, University of New Mexico, Albuquerque, NM,[2]Department of Pathology, University of New Mexico, Albuquerque, NM,[3]University of Arkansas for Medical Sciences, Little Rock, AR,[4]Department of Chemistry, University of New Mexico, Albuquerque, NM

Triple-negative breast cancer (TNBC) is an aggressive breast cancer subtype lacking hormone (estrogen and progesterone) receptors and human epidermal growth factor receptor 2 (HER2), limiting the development of targeted therapies and contributing to poor patient outcomes. Metastasis, a major contributor to TNBC mortality, is closely linked to cancer cell mechanics—such as deformability and contractility—yet the molecular signaling cues from the tumor microenvironment (TME) that regulate these mechanical properties remain poorly understood.

This study investigates the role of glucose metabolism, particularly the role of glucose transporter 3 (GLUT3), in modulating TNBC cell mechanics and metastatic behavior. GLUT3, which has the highest glucose affinity among GLUT isoforms, is upregulated in various cancers including TNBC and is associated with poor prognosis and metastasis in TNBC patients. We demonstrate that GLUT3 inhibition by a selective inhibitor G3iA reduces glucose uptake, glycolysis and ATP production by 30% in TNBC cells, leading to AMP-activated protein kinase (AMPK) activation and suppression of myosin activity. The decreased myosin activity reduces cell contractility and ultimately cell invasion. AMPK activation also increased YAP phosphorylation resulting decreased YAP target gene expressions. We also identified VASP, an actin filament nucleator and polymerase, is a novel YAP-TEAD target gene that regulated by the glucose-AMPK signaling axis. Additionally, GLUT3 inhibition triggers the cAMP-Protein Kinase A (PKA) pathway, which impairs actin polymerization through vasodilator-stimulated phosphoprotein (VASP). The decreased F-actin levels correlates with reduced cell stiffness, which was measured by Atomic Force Microscope. Using pharmacological inhibitors that activate the AMPK signaling or the cAMP-PKA signaling pathways, we show that these altered cell mechanics—cell stiffness and contractility—diminishes cell motility *in vitro.* Furthermore, we confirmed our findings that GLUT3 null TNBC cells show reduced lung metastasis *in vivo*.

In summary, we delineate molecular pathways that translate extracellular glucose signaling into regulation of cell mechanics and motility via actin rearrangement. For the actin rearrangement, we discovered that regulation of VASP in transcriptional level and post-translational modification is critical. Our findings reveal a novel mechanistic link between glucose metabolism and cancer cell mechanics with detailed molecular mechanisms, offering a promising therapeutic avenue for mitigating TNBC metastasis.

#2247 Intracellular complement signaling plays a critical role in s1p/s1pr1 mediated inflammasome activation and tumor metastasis.

Salih Gencer[1], Alhaji H. Janneh[2], Natalia Oleinik[1], Charles Chalfant[3], Besim Ogretmen[1]

[1]The Medical University of South Carolina (MUSC), Charleston, SC,[2]Memorial Sloan Kettering Cancer Center, New York City, NY,[3]University of Virginia, Charlottesville, VA

Sphingolipid metabolism, specifically sphingosine 1-phosphate (S1P), has been demonstrated to regulate cancer progression and metastasis. Our previous research showed that oncogenic S1P and S1P receptor 1 (S1PR1) signaling activated intracellular C3 complement processing to enhance migration/metastasis through inflammasome activation by the C3-PPIL1 complex. This study addressed how the S1PR1/C3 axis mediates inflammasome/NLRP3 activation in various solid tumors, including melanoma and triple-negative breast cancer (TNBC). To better understand the roles of S1PR1 and C3 in mouse mammary tumorigenesis and metastasis, we crossed the MMTV-Cre S1pr1$^{fl/fl}$; MMTV-Cre or C3^{Tdt}; MMTV-Cre mice with MMTV-PyMt expressing mice to generate S1pr1$^{fl/fl}$; MMTV-Cre; MMTV-PyMt or C3^{Tdt}; and MMTV-Cre; MMTV-PyMt (controls) animals. Our preliminary data show that silencing C3 and S1PR1 selectively in mammary tumors significantly reduces tumor burden in MMTV-PyMt mice, consistent with decreased inflammasome signaling. Mechanistically, our data also showed that PPIL1-C3 complex requires SNU13 to induce cell migration in response to S1P signaling by mediating the alternative splicing of various factors involved in activating NLRP3/inflammasome in metastatic tumors. These findings suggest that attenuation of the S1PR1/C3 and PPIL1-SNU13-inflammasome signaling inhibits cancer cell migration and metastasis.

#2248 Inhibition of the mitochondrial antioxidant response blocks ex vivo lung colonization in pediatric osteosarcoma.

Elli Maria Tiliakou, Michael Lizardo, Yue-Zhou Huang, Taras Shyp, Poul Sorensen

Department of Molecular Oncology, BC Cancer Research Institute, Vancouver, BC, Canada

Osteosarcoma (OS) is the most common type of bone cancer affecting children and adolescents. Pulmonary metastasis is the primary cause of OS mortality, yet treatments have not improved patient outcomes in four decades. This gap emphasizes the urgent need to identify and vet novel anti-metastatic therapies. When OS tumor cells spread to the lung, they are subjected to oxidative stress caused by high levels of reactive oxygen species (ROS) secreted from microvascular endothelial cells and alveolar macrophages. This stress is further amplified by limited antioxidant capacity and other redox-imbalancing features of the lung microenvironment. We previously demonstrated that metastatic OS cells upregulate NFE2-like BZIP Transcription Factor 2 (NRF2), promoting cell survival in this stressful environment. In addition to being a master regulator of redox balance, NRF2 also influences mitochondrial function by controlling the expression of thioredoxin system members, including the antioxidant enzyme peroxiredoxin 3 (PRDX3) located in the mitochondrial matrix. Therefore, we hypothesize that PRDX3 upregulation promotes metastatic cell survival during the early stages of lung colonization, and disrupting this response will impair adaptation to the lung microenvironment. We evaluated thiostrepton (TS), a *Streptomyces*-derived thiopeptide antibiotic with demonstrated PRDX3-inhibitory activity in preclinical and clinical cancer studies, to determine its effect on metastatic OS tumor cells. To mimic the oxidative stress of the lung microenvironment in vitro, we treated cells with *tert*-butyl hydroperoxide (tBHP), which chemically induces oxidative stress. Through cell viability assays we showed that subtoxic levels of TS sensitize metastatic OS cells to tBHP-induced oxidative stress. In addition, we determined that PRDX3 is upregulated when metastatic OS cells are subjected to oxidative stress via confocal microscopy. Through protein immunoblots, we demonstrated that TS acts by dimerizing PRDX3, inactivating the catalytic site of the enzyme. Furthermore, we found that combining TS with the chemotherapeutic agents doxorubicin or etoposide, which are commonly used to treat pediatric pulmonary OS metastasis, produced a synergistic increase in cell death compared to either drug alone. Lastly, we studied TS as a single agent therapy using the pulmonary metastasis assay, an ex vivo lung explant system, and found that treatment significantly decreased OS lung tumor burden. Our findings provide promising preclinical data supporting the use of TS as a possible anti-metastatic therapeutic for pediatric OS.

#2252 Resolving the initiating changes in the immunomodulatory glycome during early tumorigenesis of head and neck squamous cell carcinoma in living animals.

Sarah M. Hammoudeh, Thomas D. Madsen, Roberto Weigert

CCR-LCMB, NIH-NCI, Bethesda, MD

Cancer cells exploit the intricate network of stimulatory and inhibitory pathways to prevent immune-mediated clearance and thrive in an immunocompetent biological system. While targeting immune checkpoints (ICs) to reactivate the immune response has proven to enhance tumor-immune infiltration and patient prognosis, efficacy is limited only to a subset of patients. Hence, identifying alternative approaches to enable anti-tumor immune response is crucial. Aberrant protein glycosylation is a hallmark of cancer; in particular, increased cell-surface sialylation has been shown to inhibit immune-mediated clearance of tumor cells. This is mediated by the sialic-acid-binding immunoglobulin-like lectins (Siglecs), a family of surface receptors that mediate inhibitory signals by binding to sialic acid. Several factors complicate targeting the Sialic acid-Siglec axis in cancer therapy, including (1) the systemic adverse effects of broad abrogation of sialylation or Siglecs binding, (2) the diverse binding affinities of Siglecs based on sialic acid linkage, scaffold glycan and carrying protein. To enable the full use of this regulatory pathway, we set out to determine how the sialoglycome is dysregulated during early tumorigenesis. To this end, we used longitudinal intravital microscopy to record premalignant growth within the same animal at cellular resolution over 24 weeks in a carcinogen-induced model of head and neck squamous cell carcinoma (HNSCC). This allowed us to stratify lesions into progressing, regressing and stable growth signatures. We employ spatially resolved glycomics, transcriptomics and multiplex staining to generate a longitudinal signature of premalignant lesions. We observe an increased abundance of glycans decorated with α2,3-linked sialic acid (α2,3Sia). The elevated levels of α2,3Sia reflected a significant upregulation of α2,3-Sialyltransferases expression, indicating control mechanisms at the transcriptional levels. In the epithelial compartment, α2,3Sia was particularly enriched in CD44+ de-differentiated tumor cells. Using Siglec-Fc Chimeric constructs, we observed a binding preference of the CD44+ tumor-cells to Siglec-E. α2,3Sia was also elevated in the lesion stroma, strikingly in ly6G+ CD11b+ neutrophils recruited to progressing lesions. Our findings suggest a potential engagement of the Siglec-E - α2,3Sia axis in premalignant HNSCC lesions. Ongoing analysis is dissecting the tumor-immune interactions implicated in this axis as a potential regulator of the immune spatio-temporal landscape during early tumorigenesis. This study offers a groundwork to delineate glycomic and transcriptomic signatures in premalignant lesions with the opportunity to identify potential preventative measures in harnessing the immune response in patients.

#2253 Multimodal and multikingdom spatial transcriptomics identify bacterial niches implicated in oral cancer development.

Fushun Chen[1], Lorena Isabel Gomez[1], Tieling Zhou[1], Yuejiang Liu[1], Inti C. Tarifa Reischle[1], Sujuan Yang[1], Manvi Sharma[1], ,Jiping Feng[1], Jaafar Hadi[1], Fuduan Peng[1], Yibo Dai[1], Mhenaz Hossain[1], Ratna Veeramachaneni[1], Ansam Sinjab[1], Sean Anderson[2], Dhrishit Mangrolia[2], Deborah Rodriguez[1], Nadim Ajami[1], Jennifer Wargo[1], Adel El-Naggar[1], Roberto Rangel[1], Nadarajah Vigneswaran[2], Linghua Wang[1], Jeffrey N. Myers[1], Humam Kadara[1]

Background: Oral squamous cell carcinoma (OSCC) of the tongue is the most common head and neck malignancy. OSCC develops from oral precancerous lesions (OPL) such as dysplasias which provide a window for preventive intervention. OSCC pathogenesis is influenced by genetic alterations, host immune responses, and the oral microbiome. Still, how microbial niches and their interactions in the tumor microenvironment (TME) promote oral carcinogenesis remains poorly defined.

Materials and Methods: Multimodal and multikingdom (host and bacterial) spatial transcriptomics (ST) analysis using the Visium and Xenium 5K platforms was performed on matched OSCC, dysplastic and normal regions from 16 cross-sectional tumor-normal specimens and from 21 longitudinally transforming dysplasia and OSCC biopsies, and on tissues from carcinogen-driven mouse models of OSCC. Custom add-on panels targeting key oral cancer genes and bacterial probes (16S rRNA, 20 oral taxa including *F. nucleatum*) were included which enabled cross-platform mapping of host-microbe interactions. Copy number alterations (CNAs) were spatially inferred and analyzed phylogenetically. Neighborhood analysis was performed to probe proximity of epithelial-microbial-TME interactions.

Results: Following quality control, over 120,000 spots from Visium ST and over 3.5 million Xenium-resolved cells were retained which comprised diverse epithelial, immune, and stromal lineages. Trajectory analysis revealed major differentiation states mapping to distinct layers in the oral epithelium. Along the normal to dysplasia to OSCC continuum, basal cells progressively expanded while more differentiated cells (e.g., granular) were reduced, accompanied by increased EMT and inflammatory signatures. Spatial analysis of CNAs showed elevated aneuploidy across the normal-dysplasia-OSCC spectrum, with basal cells among all epithelial layers harboring the highest CNA burdens. Spatial phylogenetic analysis identified shared clones between dysplasias and OSCC, marking early events in OSCC evolution. Multikingdom ST identified bacteria-enriched niches that harbored tumor cells and *IL1B* high granulocytic myeloid cells. Epithelial cells in these niches displayed genes with roles in host defense (*DEFB4A*, *LCN2*) as well as chemokines that promote myeloid cell recruitment (e.g., *CXCL1*, *CXCL8*), suggesting epithelial-microbe-immune interactions with both tumor restricting and promoting properties that together tune OSCC progression. These niches and their properties were recapitulated in tumors from 4NQO-exposed mice.

Conclusions: Our study suggests that epithelial remodeling, inflammatory signaling, and bacteria-rich niches result in epithelial-microbial-immune interactions that shape the pathogenesis of OPL and OSCC and, thus, harbor high-potential targets that can guide early treatment strategies for OSCC.

#2254 3D multimodal spatial profiling of pre-gastric cancer progression using same-slide RNA-protein and fluorescent H&E.

Eric Sha[1], Seock-Jin Chung[2], Jean R. Clemenceau[2], Sunho Park[2], Minji Kim[2], Inyeop Jang[2], Youngwon Cho[2], Seunghyi Kook[2], Soonyoung Lee[3], Jongseong Jang[3], Eunyoung Choi[2], Tae Hyun Hwang[2]

[1]Vanderbilt University, Nashville, TN,[2]Vanderbilt University Medical Center, Nashville, TN,[3]LG AI Research, Seoul, Korea, Republic of

Background: Gastric cancer arises through a cascade from intestinal metaplasia to dysplasia and invasive adenocarcinoma, but only a subset of precancerous glands progress. The spatial features that distinguish progressing from non-progressing niches are unknown. We applied a multimodal platform that combines same-slide, subcellular RNA and protein profiling on the G4X Spatial Sequencer with fluorescent H&E (fH&E) and 3D holotomography (HT) to characterize pre-gastric cancer (pre-GC) niches and their transition toward carcinoma.

Methods: FFPE gastric tissues from 12 patients (38 regions of interest) were profiled on G4X flow cells using a custom 358-gene gastric cancer/pre-cancer panel, a 16-plex protein panel, and fH&E on the same slide. We used multimodal clustering and classification of spatial transcriptomic, morphology, and protein features to define cell states and associated niches. For matched regions, 3D HT from the same tissues was used to embed 2D molecularly defined states into their gland and mucosal context and to assess whether pre-GC states share or segregate across glandular units, extend through the mucosal depth, and how immune populations are positioned around them in 3D. By aligning subcellular G4X coordinates with HT volumes, this method enables us to visualize the x-y-z localization of transcripts within individual cells, providing a molecular level 3D model of the tumor-stroma-immune microenvironment.

Results: Multimodal analysis of integrated RNA, protein, and morphology data resolved distinct epithelial, stromal, and immune compartments in precancerous tissue, whereas cancerous regions showed expansion of epithelial and immune states and altered compartment boundaries. Within the epithelial layer, regions of metaplasia and dysplasia localized to discrete gland-associated zones enriched for intestinal or gastric gene signatures. Same-slide RNA-protein measurements enabled mapping of $CD4^+$ helper and $CD8^+$ cytotoxic T-cell distributions relative to the gastric epithelium. Incorporating 3D HT enabled us to investigate whether 2D-defined pre-GC foci represented continuous lesions or separate glands and refined estimates of lesion extent and immune proximity along the gland axis in 3D.

Conclusions: This 3D-enabled, same-slide G4X platform with fH&E, RNA transcript profiling, and a 16-plex protein panel generates multi-scale maps of pre-GC and gastric cancer niches. In particular, 3D spatial multimodal modeling improves interpretation of pre-cancer epithelial programs and immune positioning and supports discovery of 3D niche features linked to progression risk beyond conventional 2D histology.

#2255 Spatial transcriptomics reveals evolving tumor microenvironmental archetype along the lung premalignancy-adenocarcinoma continuum.

Yibo Dai[1], Fuduan Peng[1], Ansam Sinjab[1], Yunhe Liu[1], Sujuan Yang[1], Lorena I Gomez Bolanos[1], Tieling Zhou[1], Minyue Chen[1], Alejandra G Serrano[1], Jianlong Liao[1], Guangsheng Pei[1], Yang Liu[1], Jiahui Jiang[1], Kyung Serk Cho[1], Kai Yu[1], Jiping Feng[1], Zahraa Rahal[1], Naoe Jimbo[2], Takuo Hayashi[3], Satsuki Kishikawa[3], Kazuya Takamochi[3], Avrum Spira[4], Steven M. Dubinett[5], Tomoo Itoh[2], Takashi Yao[3], Kenji Suzuki[3], Stephen G. Swisher[1], Mingyao Li[6], Junya Fujimoto[7], Ignacio Wistuba[8], Jared K. Burks[1], Kadir Caner Akdemir[1], Hind Rafei[1], Katayoun Rezvani[1], Jeffrey N. Myers[1], Humam Kadara[1], Linghua Wang[1]

[1]UT MD Anderson Cancer Center, Houston, TX,[2]Kobe University Hospital, Kobe, Japan,[3]Juntendo University Graduate School of Medicine, Tokyo, Japan,[4]Lung Cancer Initiative at Johnson and Johnson, Boston, MA,[5]UCLA David Geffen School of Medicine, Los Angeles, CA,[6]University of Pennsylvania, Philadelphia, PA,[7]Hiroshima University Hospital, Hiroshima, Japan,[8]Moffitt Cancer Center & Research Institute, Tampa, FL

Background: Lung adenocarcinoma (LUAD) is one of the most lethal cancer types worldwide, yet how the tumor microenvironmental (TME) archetypes are remodelled during the transition from premalignant lesions (PMLs) to LUAD remains poorly understood. This study aims to systemically characterize the dynamic evolution of tumor immune archetypes across the PML-LUAD continuum using spatially resolved transcriptomics.

Methods: Spatial profiling was conducted on 56 samples from 25 patients with paired PMLs and LUADs using the Visium (spot-level) platform. Among them, 12 paired samples from 6 patients were also profiled with the Xenium 5K (single-cell-resolution) platform. TME cellular organizations and interactions were investigated, and distinct spatial TME archetypes were defined. Subsequently, signature scores representing these microenvironmental architectures were derived from spatial data and validated in bulk RNA-sequencing cohorts. Finally, single-cell RNA sequencing (scRNA-seq) was performed on serial lung samples from a carcinogenesis mouse model with *Gprc5a* knockout (*Gprc5a*$^{-/-}$) and exposure to nicotine-derived nitrosamine ketone (NNK), and the dynamic transition of TME archetypes during LUAD development was characterized.

Results: Compared with PMLs, LUADs displayed an expansion of cancer-associated fibroblasts, alongside intratumoral enrichment of mature tertiary lymphoid structures and depletion of natural killer cells. Additionally, multiple immune-suppressive signals were observed in LUADs and showed progressive upregulation from distal normal to tumor regions. Altogether, these findings indicate dynamic TME remodelling during malignant progression. Spatial mapping of TME cells revealed four distinct immune archetypes, termed IMmune Phenotype spAtial Contextual Typing in LUAD and PML (IMPACT). PMLs were dominated by IMPACT-1, with enrichment of macrophages in the tumor regions, alongside concurrent intratumoral enrichment of T (subtype 1a) or B (subtype 1b) cells. In contrast, LUADs exhibited mixed lymphocyte infiltration (IMPACT-2) or lymphocyte exclusion (IMPACT-3). These subtypes displayed distinct molecular profiles, showing evidence of tumor-promoting inflammation, immune activation, and different mechanisms of immune evasion. IMPACT signatures applied to bulk RNA sequencing cohorts recapitulated key immune features of different IMPACT subtypes and their associations with disease stages. Finally, scRNA-seq analysis on lung samples from the *Gprc5a*$^{-/-}$ carcinogenesis mouse model further validated the dynamic transition of IMPACT subtypes overtime.

Conclusions: PML-LUAD progression is accompanied by profound TME reprogramming. Patient stratifications by spatial immune archetypes may enable predicting disease developmental trajectories and inform strategies for early cancer interception.

#2256 Age-related transcriptional and alternative splicing changes in lung progenitor cells predisposing to immune dysfunction.

Mohammed Toufiq[1], Florentina Marches[2], Hyeon Gu Kang[2], Te-Chia Wu[2], Ryan Englander[2], Sanaz Keshavarz Shahbaz[2], Marina Yurieva[2], Phylip Chen[3], Mark E Peeples[4], Adolfo Garcia-Sastre[5], Michael Schotsaert[6], Damien Chaussabel[2], Karolina Palucka[1], Olga A. Anczukow-Camarda[1]

[1]The Jackson Laboratory for Genomic Medicine, Institute for Systems Genomics, University of Connecticut, Farmington, CT,[2]The Jackson Laboratory for Genomic Medicine, Farmington, CT,[3]Center for Microbe and Immunity Research, Abigail Wexner Research Institute at Nationwide Children's Hospital, Columbus, OH,[4]Center for Microbe and Immunity Research, Abigail Wexner Research Institute at Nationwide Children's, Department of Pediatrics, College of Medicine, and Infectious Disease Institute The Ohio State University, Columbus, OH,[5]Department of Microbiology, Global Health and Emerging Pathogens Institute, Department of Medicine, Division of Infectious Diseases, The Tisch Cancer Institute, Department of Pathology, Molecular and Cell-Based Medicine, Icahn School of Medicine at Mount Sinai, New York, NY,[6]Department of Microbiology, Global Health and Emerging Pathogens Institute, Icahn Genomics Institute, Marc and Jennifer Lipschultz Institute for Precision Medicine, Icahn School of Medicine at Mount Sinai, New York, NY

Purpose: Aging is the greatest risk factor for lung cancer, the leading cause of cancer-related deaths worldwide. With advancing age, impaired immune surveillance and cellular senescence create a pro-tumorigenic microenvironment that disrupts epithelial homeostasis and promotes oncogenic remodeling. However, the molecular mechanisms by which age-related transcriptional and splicing changes in lung contribute to immune dysregulation and cancer susceptibility remain poorly understood. We performed integrated transcriptomic profiling of lung progenitor cells to identify age-associated molecular alterations predisposing to immune dysfunction and early tumorigenic changes.

Methods: Primary human broncho-epithelial cells from young (age: 18y to 27y, n=5) and old (age: 42y to 67y, n=5) donors were enriched for progenitor cells in 2D culture for seven days following Fulcher et al. We performed Illumina short-read and PacBio long-read RNA-sequencing. Isoform-level analysis on long-reads was performed through IsoSeq3 and SQANTI3. Differential expression was analyzed using DESeq2 (FDR < 0.05) and alternative splicing using rMATS (>10% Delta PSI, FDR < 0.05) with a long-read derived transcriptome. Functional consequences of splicing events were predicted using SpliceDecoder.

Results: We identified 47 differentially expressed genes (36 upregulated, 11 downregulated with age). Notably, IL18, MMP25, PGLYRP4, THY1, CDH2, MFAP5, and PLXNC1 were upregulated in older donors, reflecting activation of inflammatory and immune response programs alongside altered epithelial and extracellular matrix remodeling. We also detected 991 age-related differentially spliced events in 632 genes. Among these, intron retention occurred in immune genes including HLA-A, HLA-B, HLA-C, TRIM65, and FOSB, while splicing of cassette exons was observed in IFNAR2-IL10RB, DMKN, HLA-F-AS1, and NOD1. SpliceDecoder predicted that these age-related splicing alterations introduce premature stop codons, alter coding sequences, and modify protein domains, potentially leading to gain- or loss-of-function effects. Finally, long-read RNA-sequencing identified 42,206 full-length spliced isoforms, the majority of which were novel and absent from reference transcriptomes, revealing extensive isoform diversity in lung progenitor cells.

Conclusions: Our integrated approach demonstrates that aging reshapes the transcriptomic landscape through changes in gene expression and splicing, that may contribute to immune dysfunction and epithelial remodeling. These changes may create a pro-inflammatory environment that enhances susceptibility to oncogenic transformation and disrupts tissue homeostasis. Together, these findings uncover molecular mechanisms linking aging to lung cancer risk and identify potential biomarkers and therapeutic targets for prevention and intervention.

[1]Biological chemistry, University of California, Irvine, Irvine, CA,[2]University of Chicago, Chicago, IL

Most high-grade serous carcinomas are thought to originate from the fallopian tube epithelium and progress through pre-malignant states that are more susceptible to transformation in BRCA1/2 mutation carriers. However, the early epithelial and stromal programs that arise during transformation remain poorly defined. To address this gap, we analyzed 49 FFPE scRNA-seq samples from 28 patients, including normal ovary and fallopian tube tissues, BRCA1/2 pre-malignant tissues, and matched primary ovarian tumors and metastatic lesions. FASTQ files were aligned to GRCh38 with the Cell Ranger pipeline, followed by doublet removal. Integration was performed using reciprocal principal component analysis separately for normal and pre-malignant ovary or fallopian tube samples, and primary tumor and metastatic samples. Cell type annotation was guided by a custom reference derived from publicly available human fallopian tube scRNA-seq datasets and validated using canonical marker genes. Across samples, we identified major epithelial, immune, and stromal compartments, including distinct secretory and ciliated epithelial populations. Early analyses revealed that malignant epithelial cells from both primary tumor and metastatic lesions overwhelmingly mapped to secretory epithelial lineages, with minimal contribution from ciliated cells. Normal and BRCA1/2 pre-malignant ovary tissues similarly showed a strong enrichment for secretory cells, whereas fallopian tube tissue displayed a more balanced secretory-ciliated distribution. In addition, primary and metastatic samples displayed markedly increased immune infiltration compared with normal and pre-malignant tissues. This comprehensive single-cell dataset provides new insight into early epithelial and microenvironmental changes associated with BRCA1/2 mutation status. Ongoing analyses aim to determine whether specific stromal cell states, such as fibroblast subpopulations, emerge in pre-malignant tissues and persist into malignant and metastatic lesions, suggesting the presence of early tumor-promoting stromal phenotypes. Overall, this study establishes a framework for discovering early microenvironmental drivers of ovarian carcinomas initiation.

#2258 SLC12A2 drives a tumor-promoting microenvironment and poor prognosis in hepatocellular carcinoma by suppressing lipolysis.

Yotaro Kudo, Ryosuke Tateishi, Mitsuhiro Fujishiro

Gastroenterology, Graduate School of Medicine and Faculty of Medicine, The University of Tokyo, Bunkyo City, Japan

Hepatocellular carcinoma (HCC) frequently arises from steatotic and fibrotic livers, yet molecular factors linking metabolic dysregulation to tumor-promoting hepatic microenvironments remain incompletely defined. We aimed to identify transporter genes associated with HCC risk and elucidate their mechanistic role in steatohepatitis-related hepatocarcinogenesis. Using the GSE10143 cohort, we screened 617 transporter genes curated from the Transporter Classification Database for prognostic relevance based on Cox proportional hazards modeling of overall survival. Candidate genes were validated by RNA sequencing of liver biopsy specimens from 94 patients with metabolic dysfunction-associated steatotic liver disease (MASLD) (12 with HCC) obtained between 2016 and 2020, following institutional ethical approval. Functional studies were conducted in C57BL/6 mice with hepatic overexpression of solute carrier family 12 member 2 (SLC12A2)—a Na^+-K^+-Cl^- cotransporter—via AAV8, followed by feeding with a choline-deficient, L-amino acid-defined, high-fat diet (CDAHFD) for six weeks to induce diet-associated steatohepatitis. In vitro assays were performed using a normal hepatocyte cell line and Hep3B cells with stable SLC12A2 overexpression or shRNA-mediated knockdown. From the transporter gene screening, SLC12A2 showed the highest hazard ratio for poor survival and was also associated with increased late (>2 years) post-hepatectomy recurrence, implying enhanced carcinogenic potential of background liver tissue. In the MASLD cohort, hepatic SLC12A2 expression was significantly higher in HCC cases and positively correlated with fibrosis stage and liver stiffness. In mice, hepatic SLC12A2 overexpression exacerbated CDAHFD-induced steatohepatitis—evidenced by increased liver weight, serum ALT levels, hepatic triglyceride content, Sirius red-positive area, and fibrogenic gene expression. Cleaved caspase-3 and Ki-67 staining indicated increased hepatocellular apoptosis and compensatory proliferation, features typical of chronic liver injury. Orthotopic implantation of Hepa1-6 cells resulted in significantly larger tumors, demonstrating a tumor-promoting microenvironment. In vitro, SLC12A2 overexpression enhanced palmitate-induced lipid droplet formation, whereas shRNA-mediated knockdown suppressed it. Expression of genes involved in fatty acid synthesis and oxidation remained unchanged, but glycerol release was decreased, indicating suppression of lipolysis as the primary mechanism. Our findings suggest that SLC12A2 promotes hepatic steatosis and fosters a tumor-promoting microenvironment by repressing lipolysis. Its overexpression identifies high-risk MASLD livers predisposed to HCC and represents a potential therapeutic target for metabolic liver disease-associated hepatocarcinogenesis.

#2259 Reprogramming of the stromal and immune microenvironment in preinvasive breast cancer.

Siyuan He[1], Aatish Thennavan[1], Runmin Wei[1], Shanshan Bai[1], Jianzhuo Li[1], Chante Bethell[1], Emi Sei[1], Mitchell Rao[1], Tapsi Kumar[1], Chenling Tang[1], Ivan Marin[2], Jessica Montalvan[2], Chandandeep Nagi[2], Bora Lim[1], Savitri Krishnamurthy[1], Alastair Thompson[3], Nicholas E. Navin[1]

[1]UT MD Anderson Cancer Center, Houston, TX,[2]Baylor College of Medicine, Houston, TX,[3]Baylor College of Medicine, Dan L. Duncan Cancer Center, Houston, TX

Ductal carcinoma in situ (DCIS) is the most common form of preinvasive breast cancer. However, our knowledge of the DCIS tumor microenvironment (TME) remains limited. Here, we investigated the TME of estrogen receptor positive DCIS using fresh tissues samples from DCIS, invasive breast cancers and normal breast tissues. In total, 795,585 cells were analyzed from 153 patients by single cell RNA sequencing and 39 samples were profiled with spatial transcriptomics methods (Visium, Xenium). Our data identified reprogrammed vascular cells, fibroblasts and basal cells that encircled the DCIS regions, forming cancer stromal loops (CSL) that support the preinvasive cancer cells. The DCIS regions were highly immunosuppressive, and only lipomacrophages (APOC1+) and interferon T-cells infiltrated. The preinvasive cancer cells showed activation of cell cycling and interferon signaling, while reducing cell growth regulation, RNA processing, secretion and cell adhesion. Collectively, these data show extensive remodeling of the TME in DCIS that persists during invasive progression.

#2260 Macrophage immunometabolism as a targetable driver of early lung cancer progression.

Tyler Faith[1], Amrita Roy[2], Dikshaya Prabhakara[2], Yaron Zaret[1], Samuel Weinberg[3], Alicia Hulbert[4], Frank D. Weinberg[5]

[1]College of Medicine, University of Illinois at Chicago, Chicago, IL,[2]Division of Hematology and Oncology, University of Illinois at Chicago, Chicago, IL,[3]Department of Pathology, Northwestern University, Chicago, IL,[4]University of Illinois at Chicago, Chicago, IL,[5]University of Illinois Cancer Center, Chicago, IL

Background Lung cancer is a leading cause of cancer-related mortality and early progression is driven by interactions between epithelial cells and the tumor-immune microenvironment. Macrophages shape cancer progression through both inflammatory and immunosuppressive programs. Prior work has shown dysbiosis, cytokine enrichment, and increased stearic acid (SA) levels in tumor affected lobes of early-stage lung cancer patients. To better understand the role of SA within the tumor microenvironment, we consider its effect on macrophage polarization, altered immune signaling, and epithelial response. We modeled the effect of macrophage-derived signals on the early transformation of lung epithelial cells to identify conserved transcriptional programs that may be leveraged to improve prevention and treatment strategies.

Methods To characterize the effect of SA on macrophages, U937 pro-monocytic cells were differentiated into macrophage-like cells (M0, M1, M2) with PMA and further stimulated with some combination of LPS, IFN-γ, IL-4, SA, or BSA (vehicle). Conditioned media from macrophage cell cultures was collected before RNA was extracted using TRIzol and sequenced on an Illumina platform. To characterize the effect of SA on macrophage immune signaling, BEAS2B epithelial cells were treated with macrophage-like conditioned media and malignant potential was assessed with a methylcellulose-based soft agar assay. Total RNA was extracted using NEB Monarch Total RNA Miniprep kit and sequenced on an Illumina platform. Differential gene expression for U937 and BEAS2B treatment groups were analyzed, and pathway enrichment was assessed using GO terms and KEGG analysis.

Results SA exposure modified transcription across M0-, M1-, and M2-like macrophage phenotypes and lead to altered expression of 83 common genes. Gene ontology (GO) functional analysis showed evidence of modified cholesterol and alcohol metabolism and steroid biosynthesis in M0- and M2-like macrophages. SA exposure was associated with increased expression of *MVK*, *STARD4*, and *INSIG1* related to sterol and lipid metabolism. SA exposure was also associated with decreased expression of *KIF4A*, *TOP2A*, and *BRCA2* related to cell cycle regulation and genomic stability. Modified expression of these and other genes identified during our analysis may be involved in early tumor processes.

Conclusions Stearic acid modulates macrophage transcription across phenotypes, supporting our hypothesis that immunometabolic signaling plays an important role in lung cancer initiation. These findings provide a molecular foundation for future studies characterizing the transcriptional changes identified and their effect on lung cancer initiation. Furthermore, they highlight macrophages as potential targets for preventive or early therapeutic interventions in lung cancer.

#2261 Deciphering the role of macrophages in the development of pancreatic ductal adenocarcinoma.

Maria F. Wissler[1], Jessie Kanacharoen[1], Daniel J. Salas-Escabillas[1], Shalini Datta[1], Naziheh Assarzadegan[2], Eugene Shenderov[1], Ashley Kiemen[3], Won Jin Ho[3], Laura DeLong Wood[1]

[1]Johns Hopkins University School of Medicine, Baltimore, MD,[2]Department of Pathology, Immunology, and Laboratory Medicine, University of Florida, Gainsville, FL,[3]Johns Hopkins University, Baltimore, MD

Pancreatic ductal adenocarcinoma (PDAC) is one of the most aggressive forms of cancer. Intraductal papillary mucinous neoplasms (IPMNs) are a well-documented precursor of invasive PDAC; however, the molecular and cellular alterations that drive malignant progression of IPMNs are poorly understood. Genetic alterations drive progression in only a minority of cases, highlighting the likelihood that the surrounding tumor microenvironment (TME) may play an important role. PDAC is characterized by an immunosuppressive TME with abundant macrophages, but the temporal accumulation of immunosuppressive macrophages in PDAC precursors and their role in the progression to invasive cancer has not been explored. A deeper understanding of the TME in IPMN and PDAC may reveal actionable mechanisms of progression, potentially identifying novel therapeutic targets or biomarkers of progression risk. To investigate the temporal recruitment, polarization state, and spatial localization of macrophages, we leveraged immunohistochemistry (IHC) and imaging mass cytometry (IMC) datasets of human IPMNs and adjacent PDAC. IHC from 24 patients showed significant upregulation of CD68+ macrophages in PDAC. IMC allows quantification of the densities and spatial distribution of distinct subtypes. IMC analysis of IPMN, transition zone, and PDAC regions from 12 patients identified heterogeneous changes in total macrophage count and proportions of macrophages subsets over the transition from IPMN to invasive PDAC. In addition, spatial transcriptomics was performed on a subset of samples from 4 patients to interrogate mechanisms of macrophage-epithelial crosstalk across the transition from IPMN to PDAC. *In vitro* culture of primary human macrophages and PDAC organoids further enables characterization of the functional impact of macrophage-epithelial crosstalk. Organoid-conditioned media treatment of macrophages demonstrates that the PDAC secretome is capable of polarizing macrophages toward an immunosuppressive phenotype with increased expression of IL-10 and CD163. This study provides a comprehensive molecular analysis of macrophages present in the TME of IPMN and PDAC, revealing heterogeneous patterns across patients. The results suggest a role for macrophages in malignant progression and pathways by which PDAC cells reprogram the macrophage population, offering new insights into the interaction between macrophages and neoplastic epithelial cells, which can be used to identify signaling dependencies that could serve as novel biomarkers of therapeutic targets.

#2262 Cell division regulates macrophage invasion in mammary epithelia.

Emily A. Pratt, Mariia Akhmanova

Cell Biology, Memorial Sloan Kettering Cancer Center, New York, NY

Macrophages survey the mammary epithelium and are found between the myoepithelial and luminal layers of the ducts where they aid in tissue remodeling during branching morphogenesis. These ductal macrophages expand as more bone marrow derived macrophages arrive during puberty and pregnancy, when there is extensive remodeling of the gland, increased cell proliferation, and luminal apoptosis to maintain the ductal lumen. Interestingly, early macrophage infiltration is also observed in triple negative breast cancer (TNBC) and is associated with poor prognosis. TNBC-associated macrophages resemble the polarized state and tissue remodeling function of ductal macrophages during normal mammary development and are not as commonly found in luminal or human epidermal growth factor receptor 2-positive (HER2+) breast cancers. While it is well documented that mammary macrophages are present within the gland, the mechanisms by which macrophages infiltrate epithelial barriers in both developmental and disease contexts remains unknown. Thus, to address this gap in our understanding of macrophage biology, we employ 3D mammary epithelial and macrophage co-cultures compatible with live imaging. We hypothesize that macrophages respond to transient disruption in epithelial integrity-such as those occurring during mitosis or programmed cell death-and use these short-lived losses of epithelial-epithelial adhesions as opportunities to access epithelial compartments. To examine this hypothesis, we have live imaged 3D mammary epithelial spheroids generated from healthy (MCF10A) and TNBC (MDA-MB-231) cells in co-culture with macrophages. Mammary acini form polarized lumen where apoptotic cells are extruded into the luminal space, like *in vivo.* Mammary spheroids present an *in vitro* model where apoptosis can be driven pharmacologically, resulting in increased epithelial turnover, allowing us to model dynamic conditions of the mammary duct. Our data support the hypothesis that macrophages traverse epithelial layers at sites of cell division, consistent with a model in which transient junctional instability guides macrophage positioning. During involution, luminal epithelial cells undergo apoptosis and release “find-me” signals into the tissue microenvironment. We hypothesize macrophages respond to these local attractants, exploiting the transient losses in epithelial-epithelial cell adhesion, to traverse the myoepithelial layer. Together, this work aims to define the epithelial cues that regulate macrophage infiltration into mammary tissues and to understand how these processes shape both normal developmental programs and early disease transition in TNBC. Elucidating the mechanisms of macrophage entry into epithelial environments may reveal new opportunities for targeting immune-epithelial interactions in aggressive breast cancers while enriching our understanding of underappreciated immune-epithelial crosstalk.

#2263 Microenvironmental rewiring in giant cell tumor of bone: Stromal lineage hierarchy, immune diversion, and novel osteoclastogenic and angiogenic circuits.

Chao Zhang[1], Jilong Yang[1], Xiangchun Li[2], Kexin Chen[2], Hongru Shen[2], Zhichao Liao[1]

[1]Department of Bone and Soft Tissue Tumor, Tianjin Medical Univ. Cancer Inst. & Hosp., Tianjin, China,[2]Department of Epidemiology and Biostatistics, Tianjin Medical University Cancer Institute & Hospital, Tianjin, China

Giant cell tumor of bone (GCTB) is a locally aggressive osteolytic neoplasm characterized by neoplastic stromal cells and abundant osteoclast-like giant cells, yet the microenvironmental architecture and regulatory networks that sustain tumor progression remain incompletely understood. Here, we performed integrated single-cell RNA sequencing and spatial transcriptomics on six treatment-naïve primary GCTB specimens to generate a high-resolution atlas of stromal, immune, myeloid, osteoclastic and vascular compartments. We identify a structured mesenchymal hierarchy linking pericytes, osteoblast precursors and tumor stromal cells through a continuous transcriptional trajectory, providing evidence that the neoplastic stromal population arises from, or co-evolves with, osteogenic and perivascular lineages. Tumor cells display marked inter- and intra-patient heterogeneity, characterized by discrete EMT-, coagulation-, myogenesis- and androgen-responsive subclusters, indicating diverse functional specializations within the stromal tumor compartment.Despite substantial cytotoxic T-cell infiltration across all patients, ligand-receptor inference revealed that effector immune signals—including CCL and PARs pathways—are preferentially directed toward osteoclast-like giant cells rather than tumor cells, suggesting an “immune diversion” or “immune sink” mechanism that may blunt anti-tumor immunity despite preserved T-cell functional states. Beyond confirming the canonical tumor-derived RANKL engagement of giant cells, we uncover two additional regulatory circuits: (i) a tumor-specific CHAD-ITGA2 signaling axis, with ITGA2 expression uniquely restricted to giant cells, implicating a selective osteoclastogenic mechanism with therapeutic potential; and (ii) a multisource CSF1/IL34-CSF1R network arising from tumor cells, osteoblast precursors and pericytes, cooperatively shaping myeloid recruitment and giant-cell formation, further supporting a shared stromal origin among these lineages.Finally, we identify a tumor-exclusive APELA-APLNR (APJ) angiogenic axis linking ligand production strictly in tumor cells to receptor expression exclusively in endothelial cells. Spatial transcriptomics confirmed that APELA is enriched within RANKL-high tumor niches, revealing a spatially confined angiogenic microdomain functionally distinct from the broadly distributed VEGF pathway.Together, this atlas defines the cellular logic and intercellular circuitry underlying GCTB progression and identifies multiple stromal, immune, osteoclastogenic and vascular vulnerabilities—including the CHAD-ITGA2 and APELA-APLNR axes—that may guide therapeutic strategies beyond RANKL inhibition.

#2264 Spatial trajectories and niche rewiring from ground-glass to solid transition in lung adenocarcinoma.

Kwon Joong Na, Hongyoon Choi, Jaemoon Koh, Taeyoung Yun, Jihyeon Park, Bubse Na, Samina Park, In Kyu Park, Chang Hyun Kang, Young Tae Kim

Seoul National University Hospital, Seoul, Korea, Republic of

BackgroundGround-glass nodules (GGNs) are frequently detected by screening, yet how they acquire invasion in situ is unclear. We asked how epithelial states, stromal architecture, and immune circuits reorganize during the GGN-to-solid transition.
MethodsWe generated paired spatial transcriptomes (10x Visium, fresh-frozen) from GGN-predominant and solid-predominant regions of three resected stage I LUADs. Cell composition and epithelial states (tS1-tS3) were inferred using a single-cell reference. We quantified ligand-receptor (L-R) communication, inferred pathway activities (PROGENy; Hallmark), and constructed diffusion-based spatial trajectories within sections to model the preinvasive-to-invasive continuum.
ResultsTwo tumors converged on an epithelial-high, fibroblast-low, myeloid-inflamed solid region, while one showed a stroma-dominant solid phenotype; myeloid influx was shared across all cases. The malignant-potential epithelial state (tS2) expanded in 2/3 tumors (the third was approximately flat), whereas benign-like states receded focally. Fibroblast programs consistently showed myofibroblast enrichment, supporting early ECM stiffening. T-cell lineages shifted toward exhaustion ($CD8^+$; modest Tfh) with variable Treg increases, yielding an inflamed-but-immunosuppressed niche. Spatial L-R maps highlighted strengthening of complement-B-cell axes (C3-CR2/CD19) and ECM-anchored signals (SDC4-TGM2, FN1-TNFRSF11B), with contraction of NK/T-cell-supportive interactions (HLA-E-KLRD1; IL-7-IL7R). Pathway scores corroborated a state of EGFR and hypoxia upshift with glycolytic/fatty-acid programs increased, apical junction and E2F programs reduced—compatible with proliferation under metabolic stress rather than indiscriminate cell-cycle acceleration. In a case spanning adjacent normal-GGN-solid, spatial trajectories captured early endothelial/fibroblast loss between normal and GGN, followed by consolidation of invasion marked by tS2 gain, myofibroblast accumulation, and monocyte/DC recruitment toward the solid core.
ConclusionsPaired spatial transcriptomes indicate that the GGN-to-solid shift is assembled by coordinated epithelial state change, stromal myofibroblast enrichment, and immune rewiring toward exhaustion with myeloid influx. L-R and pathway profiles converge on complement-biased, ECM-anchored signaling with attenuated NK/T-cell support, nominating candidate axes for risk stratification of GGNs and prospective validation in larger cohorts.

#2265 Stromal cyclin D1 promotes prostate cancer stemness via the transcriptional regulatory E domain.

Xuanmao Jiao[1], Danni Li[1], Rita Pancsa[2], Ritika Harish[1], Zhiping Li[1], Gideon Tolufashe[3], Hallgeir Rui[4], Beatrice S. Knudsen[5], Yanming Du[1], Hsin-Yao Tang[6], Peter Tompa[7], Richard G. Pestell[1]

[1]Pennsylvania Cancer and Regenerative Medicine Research Center, Baruch S. Blumberg Institute, Wynnewood, PA,[2]Institute of Molecular Life Sciences, HUN-REN Research Centre for Natural Sciences, Budapest, Hungary,[3]Baruch S. Blumberg Institute, Doylestown, PA,[4]Sidney Kimmel Cancer Center, Thomas Jefferson University, Philadelphia, PA,[5]University of Utah, Salt Lake City, UT,[6]The Wistar Institute, Philadelphia, PA,[7]HUN-REN Office for Supported Research Groups, Cell Cycle Laboratory, National Institute of Oncology, 1122 Budapest, Hungary, Budapest, Hungary

• **Introduction.** Prostate cancer “stemness” increases with tumor progression, predicts poor prognosis and contributes to therapy resistance. The *cyclin D1* gene (CCND1), which encodes the regulatory subunit of a holoenzyme that phosphorylates RB and conveys transcriptional properties, is expressed in prostate cancer and augments growth of some castrate resistant prostate cancers. Clinical trials are targeting the kinase activity of cyclin D1 in prostate cancer. The functional significance of the cyclin D1 E domain remained to be further defined. We investigated a potential kinase-independent function of cyclin D1 in prostate cancer. • **Methods**. Analysis of patient gene expression, tumor histology, gene knockout transgenic mice, tissue culture stem cell assays, proteomic analysis. • **Findings**. We show cyclin D1 expression is increased in PCa tumor stroma compared with adjacent tissue. Using single cell sequencing cyclin D1 we identified cyclin D1 in cancer associated fibroblasts. In vivo, cell markers of PCa stemness including Trop2^{ICD} activity. Deletion of both epithelial cell and stromal cyclin D1 further reduced markers of PCa stem cells suggesting a role for extra epithelial stromal cell cyclin D1 in the induction of PCa stemness. In vitro, cyclin D1 rescue of cyclin D1 deficient fibroblasts demonstrated cyclin D1 governed a secretome that augmented prostate cancer stemness, assessed by prostate cancer sphere size and number, and expression of pro-stemness chemokine receptors (CXCR2, CX3CR1). Mutational analysis showed the cyclin D1 heterotypic induction of stemness and chemokine receptor expression required an intrinsically disordered acidic rich “E domain” (AA 272-280) within the cyclin D1 carboxyl terminus. Integrated proteomics and ChIP Seq identified transcriptional targets governing cancer stemness and pro-tumorigenic inflammation. • **Conclusions.** Cyclin D1 augments prostate cancer stemness through heterotypic functions via an intrinsically disordered carboxyl terminal domain.

#2266 Unexpected role of nuclear receptor CAR in cholangiocarcinoma development.

Inyoung Cheon[1], Ji Ho Suh[2], Mi Jeong Heo[3], Sung Ho Lee[4], Hyun-Jung Jung[2], Young-Ho Ahn[1], David D. Moore[5], Kang Ho Kim[2]

[1]Molecular Medicine, Ewha Womans University School of Medicine, Seoul, Korea, Republic of,[2]Anesthesiology, Critical Care and Pain Medicine, University of Texas Health Science Center at Houston, Houston, TX,[3]University of Texas Health Science Center at Houston, Houston, TX,[4]Biomedical Laboratory Science, Gwangju Health University, Gwangju, Korea, Republic of,[5]University of California, Berkeley, Berkeley, CA

Cholangiocarcinoma (CCA), the second most common primary liver cancer, arises from the biliary epithelium, either within the liver parenchyma or in the hepatoduodenal ligament. Several cholestatic liver diseases, such as primary sclerosing cholangitis, developmental bile duct malformation, and progressive familial intrahepatic cholestasis (PFIC), have been implicated as CCA risk factors. Cholestatic conditions exhibit a cocarcinogenic effect when combined with chronic liver injuries, as supported by a recently reported CCA animal model in which partial bile duct ligation is combined with repeated treatments of the carcinogen diethylnitrosamine. The nuclear receptor Constitutive Androstane Receptor (CAR, NR1I3), a central regulator of xenobiotic metabolism, is known to drive hepatocellular carcinoma (HCC) when chronically activated, while CAR ablation prevents it in multiple liver cancer models. We have recently characterized the impact of endogenous CAR activation in a mouse model of human PFIC5 disease (*i.e.*, *Fxr;Shp* double knockout, FS-DKO) that exhibits cholestatic liver injury and develops spontaneous HCC at 1 year of age. In this study, we demonstrated the role of endogenous CAR activation in cholestasis-driven liver cancer development. Based on the strong correlation between CAR activation and liver cancer development in FS-DKO liver, we initially hypothesized that chronic CAR activation mediates hepatic carcinogenesis in FS-DKO liver. However, in contrast to our expectations, further deletion of CAR in *Fxr;Shp;Car* triple knockouts (FSC-TKO) did not reduce tumor incidence compared to FS-DKO. Instead, highly hypertrophic as well as hyperplastic cholangiocytes became much more abundant in FSC-TKO livers than in FS-DKO livers. Accordingly, about half of the visible FSC-TKO tumor nodules were CCA or combined HCC-CCA types, while most tumors in FS-DKO livers were hepatocellular types. Using RNA-seq and TRRUST transcription factor analysis, we found that CAR/PXR targets were significantly depleted in FSC-TKO, while ETS1 targets were significantly enriched, consistent with emerging evidence that ETS1 biases liver tumor fate toward CCA lineage. These findings suggest that, under cholestatic stress, loss of CAR unexpectedly promotes CCA development by unleashing a microenvironment that favors CCA. Targeting the CAR-ETS1 axis may offer new opportunities to modulate HCC-CCA lineage specification and improve therapeutic strategies.

#2267 Microenvironmental CTHRC1 has a pro-tumorigenic role in colorectal cancer.

Haylee Duval[1], Barbara Toomey[2], Michelle Karam[2], Brian Nestor[2], Sergey Ryzhov[2], Volkhard Lindner[2], Michaela Reagan[2]

[1]University of Maine, Orono, ME,[2]MaineHealth Institute for Research, Scarborough, ME

In the United States, colorectal cancer (CRC) is the third leading cause of cancer-related deaths in both men and women, with a projected 154,270 new cases in 2025 alone. These statistics highlight the need for a better understanding of the underlying mechanisms of CRC and the development of improved therapies, which are both critical steps in improving patient outcomes. CRC is characterized by extensive stromal cell involvement, which is believed to be tumor-supportive, and thus components of the tumor microenvironment (TME) are promising targets. Collagen triple helix repeat containing 1 (CTHRC1) is a secreted protein with known roles in metabolism, bone and joint homeostasis, tissue remodeling, extracellular matrix synthesis and organization, and, by unknown mechanisms, oncogenesis. Despite its known expression in tumor-associated stroma and correlations with poor prognosis in many cancers, causative evidence that host-derived CTHRC1 influences CRC progression is lacking, and its function within the TME remains poorly understood. Here, we assess the role of host-derived CTHRC1 in three independent *in vivo* studies using male and female wild-type (WT) and global *Cthrc1* null (KO) mice subcutaneously inoculated with MC38 colon cancer cells. Across all studies, our results clearly demonstrate that host-derived CTHRC1 drives CRC progression. Survival analysis showed significant improvement in *Cthrc1* KO mice ($p = 0.0012$, Kaplan-Meier), with median survival more than doubling from 28 days post-inoculation in WT ($n = 10$) to 69 days in *Cthrc1* KO ($n = 10$). Notably, initial tumor growth followed by tumor regression occurred in all three *Cthrc1* KO cohorts between Days 9-14 post-inoculation, while most WT tumors continued growing, suggesting CTHRC1 supports tumor cell immune evasion and contributes to a tumor-permissive TME. *Cthrc1* KO mice also developed significantly smaller tumors across all studies compared to WT, as measured by bioluminescent imaging, calipers, and postmortem tumor weights.Histological staining further revealed that the absence of CTHRC1 in the TME alters tumor microarchitecture and cellularity, with tumor density markedly reduced in *Cthrc1* KO mice by H&E staining and Likert scoring ($p = 0.0017$). Immune profiling identified clear differences in the composition of tumors and spleens between groups, with *Cthrc1* KO mice exhibiting an increased percentage of $CD3^+$ T cells in tumors ($p = 0.0014$) and spleens ($p = 0.0010$) and decreased splenic $Gr\text{-}1^+$ cells ($p = 0.0369$) by Mann-Whitney tests, consistent with reduced myeloid-driven T cell suppression, and suggests both stromal and circulating CTHRC1 may contribute to immunosuppression in WT mice. Together, these results identify CTHRC1 as a key driver of CRC by aiding in immune evasion and supporting tumor growth. In humans, CTHRC1 may hold great potential as a novel target in future CRC therapies.

#2268 Elucidating the role of *p21*$^{+}$ senescent cells in early-stage lung tumorigenesis.

Yuanning Du, Luis I. Prieto, Karthikbabu Jeganathan, Cheng Zhang, Hu Li, Darren Baker

Mayo Clinic, Rochester, MN

Cellular senescence is a dynamic, multistage biological program that exerts context-dependent effects on tumor initiation, progression, and overall carcinogenesis. Our laboratory has previously demonstrated that the early accumulation of $p16^{Ink4a}$-expressing (representing strong cyclin-dependent kinase inhibition) senescent alveolar macrophages during tumorigenesis actively facilitates tumor formation and progression by inhibiting the infiltration of cytotoxic T lymphocytes. However, considering the dynamic nature of cellular senescence, distinct senescent cell populations could express high amounts of the alternative cell cycle inhibitor $p21^{Waf1/Cip1}$ independently of $p16^{Ink4a}$ to potentially catalyze distinct functions. To test this, we have employed transgenic p21-*ATTAC* (p21-driven apoptosis through targeted activation of caspase 8) mice to investigate the role of p21-expressing cells during *Kras*-driven adenoma formation. In agreement with our previous observations following clearance of p16-expressing senescent cells, we found that removal of p21+ cells attenuates early tumor development. Western blot and immunofluorescence analyses corroborates a reduction in p21, p16, and multiple members of a putative senescence-associated secretory phenotype (SASP). Although senescent alveolar macrophages remain a critical therapeutic target, here we found that senescent endothelial cells also exhibited elevated expression of p21, p16, and SASP with a high senolytic response. Future studies will include identifying the predominant p21-expressing senescent endothelial subpopulations and elucidating the mechanisms by which endothelial senescence contributes to lung tumorigenesis. Collectively, our findings have unveiled additional senescent cell populations with the potential to drive lung tumorigenesis.

#2269 Two-step mechanism of plexiform neurofibroma formation: Role of the NF-κB pathway in neurofibroma formation.

Ramya Ravindran[1], Noemi Kedei[2], Eui-Kyung Youn[1], Kwangmin Choi[1], Avery Volz[1], Jay Pundavela[1], David A. Largaespada[3], Jack F. Shern[4], Nancy Ratner[1]

[1]Division of Experimental Hematology and Cancer Biology, Cincinnati Children's Hospital Medical Center, Cincinnati, OH,[2]Collaborative Protein Technology Resource, OSTP, Center for Cancer Research, National Institutes of Health, Bethesda, MD,[3]Departments of Pediatrics and Genetics, Cell Biology, and Development, University of Minnesota, Minneapolis, MN,[4]Pediatric Oncology Branch, Center for Cancer Research, National Institutes of Health, Bethesda, MD

Rationale: *NF1-/-* Schwann cells are the cells of origin in plexiform neurofibroma (PNF). This benign tumor formation occurs long after *Nf1* loss in mouse models of the disease, suggesting that Schwann cells undergo secondary changes during tumor formation. However, additional genetic hits are not observed in this tumor type. Single cell RNA-sequencing implicated NF-κB signaling as upregulated in established tumor formation. Consistent with the idea that NF-κB signaling is a tumor driving signal, in human and mouse neurofibromas p-65 was nuclear (active) in neurofibroma cells, some of which were Schwann cells (Kershner et al., 2022).
Methods: To test if activation of NF-κB signaling is a second step in neurofibroma formation we used a combination of multiplexed antibody staining, flow cytometry and RNA sequencing in tumors over their development. *In vitro* assays were utilized to determine the effect of NF-κB pathway modulation in *Nf1-/-* Schwann cells. Finally, we tested if blocking IKK2 activity *in vivo* reduces tumor formation or growth.
Results: We identified markers of Schwann cells, fibroblasts and immune cells in PNF by multiplex imaging and flow cytometry. Tumor Schwann cells, but not pre-tumor Schwann cells in the same mice, expressed the cell surface markers CD44 and CD49f; cultured *Nf1-/-* Schwann cells upregulate these markers and nuclear (active) p65 when exposed to stressors known to activate NF-κB signaling, including prolonged serum depletion, Poly I:C, IL1β, and TNFα, or when infected with activated IKK2, which activates the NF-κB pathway; these Schwann cells increased secretion of cytokines that are immune cell chemoattracts. Concurrent increases in EMT genes were observed *in vivo* and *in vitro*. Treatment of *DhhCre;Nf1fl/fl* mice with the NF-κB pathway inhibitor BAY 11-7082 combined with MEK inhibitor Mirdametinib reduced the CD44+ CD49f+ Schwann cell population, tumor cell proliferation, the tumor immune cell population, and tumor cytokines.
Conclusion: A two-step process to PNF formation is proposed, with *Nf1* loss in Schwann cells an initiating step and the formation of an inflammatory microenvironment via activation of the NF-κB pathway and Schwann cell reprogramming as a second step. (Supported by DOD-HT9425-1-0435 (to NR and JS), NIH NS115438R01 (to DAL and NR) and a Children’s Tumor Foundation Young Investigator Award to RR)

#2270 A MUC1-overexpressing epithelial population is associated with CDH1 loss-of-function gastric adenocarcinoma.

Chuner Guo[1], Rosyli F. Reveron-Thornton[1], Xiaomo Li[2], James P. Agolia[1], Maria Moozhiyil Korah[1], Peter Yuxin Xie[3], Amanda Goncalves[1], Angela Tabora[1], Lily Xia[4], Natali Barakat[4], George Poultsides[1], Byrne Lee[1], Amanda R. Kirane[1], Deshka Foster[1], Michael T. Longaker[1], Gregory W. Charville[2], Daniel Delitto[1]

[1]Department of Surgery, Stanford University School of Medicine, Stanford, CA,[2]Department of Pathology, Stanford University School of Medicine, Stanford, CA,[3]Department of Mechanical Engineering, Stanford University School of Medicine, Stanford, CA,[4]Stanford University School of Medicine, Stanford, CA

Germline mutations in CDH1 are associated with early-onset diffuse gastric adenocarcinoma. There is no gold standard for screening and management, and endoscopic surveillance is often insufficient for detecting early disease. Prophylactic gastrectomy is maximally preventive but is a major operation associated with significant morbidity and extensive lifestyle modifications. Therefore, there is a need to better understand the pathophysiological features underlying carcinogenesis in the setting of CDH1 mutation. To address this gap, we performed spatial transcriptomic profiling on 29 formalin-fixed paraffin-embedded sections from 8 patients with various stages of gastric adenocarcinoma, including one patient with a germline CDH1 mutation (c.1936+5G>A) found to have multifocal intramucosal poorly cohesive signet-ring cell carcinoma. Image-based cell segmentation and subcellular transcript detection enabled identification of diverse epithelial cell types, as well as their stromal and immune neighborhoods. Epithelial cells from the specimen harboring the germline CDH1 mutation expressed lower levels of CDH1 compared with other samples. Although morphologically normal-appearing, mucosal layers in these sections exhibited altered transcriptomic profiles characterized by an expanded epithelial population with high MUC1 expression. MUC1 is a transmembrane glycoprotein frequently upregulated in various cancers, with a cytoplasmic domain capable of interacting with several intracellular signaling partners, particularly β-catenin. Gene regulatory network analysis revealed a gradient of CTNNB1/β-catenin activation program, suggesting a potential interplay between CDH1 loss-of-function, MUC1 overexpression, and β-catenin pathway dysregulation. These findings reveal a novel MUC1-overexpressing epithelial population associated with CDH1 mutation and early-onset gastric adenocarcinoma, providing new rationales for developing surveillance biomarkers and targeted therapies.

#2271 p53-null cells act as supercompetitors in gastroesophageal tumor initiation.

Kyle LaBella, Efren Reyes, Mathijs Verhagen, Priyanka Kulkarni, Shadi Tarazi, Shawn Gillespie, Oana Ursu, Louis Vermeulen

Genentech, Inc., South San Francisco, CA

TP53 is the most frequently mutated gene in cancer and is often detected in histologically normal tissues decades before malignant transformation. p53-null cells possess a competitive advantage over neighboring wildtype cells, yet the mechanisms that restrain their outgrowth within healthy tissue or drive their expansion in disease remain poorly understood. Here, we investigated the role of p53 inactivation in a new model of Barrett's esophagus using long-term live-cell clonal tracing coupled with single-cell RNA sequencing. Using an epithelioid co-culture system of gastric stem cells and esophageal squamous epithelium, we found that gastric epithelial p53-loss confers a strong competitive advantage over neighboring wildtype esophageal squamous cells, leading to the expansion of mutant clones via the active suppression of adjacent wildtype cell proliferation. Mechanistically, these p53-null cells exhibit high levels of chromosomal instability, which drives an altered secretome that represses the growth of wildtype basal cells. Strikingly, p53-null cells remain resistant to these inhibitory factors. Additionally, neutral competition was restored either by deleting cell cycle checkpoint pathways in p53-wildtype neighbors or by blocking the pathways in p53-null cells that confer resistance to secreted inhibitory factors. Collectively, these findings reveal how p53 inactivation alters competitive stem cell dynamics at the gastroesophageal junction and suggest potential strategies for cancer interception in individuals with Barrett's Esophagus.

#2272 Dichotomous immunogenetic landscape of lung adenocarcinoma associated with usual interstitial pneumonia.

Akifumi Mochizuki[1], Ayako Suzuki[2], Kouya Shiraishi[3], Masahiro Torasawa[4], Takayuki Honda[1], Susumu Kirimura[5], Yasunari Miyazaki[1], Kenichi Okubo[6], Syuzo Kaneko[7], Yukihiro Yoshida[8], Shun-ichi Watanabe[8], Masahiro Tsuboi[9], Genichiro Ishii[10], Issei Imoto[11], Ryuji Hamamoto[12], Yasushi Yatabe[13], Yutaka Suzuki[2], Takashi Kohno[3]

Diagnostics, National Cancer Center, Nagoya, Japan

Background: Interstitial pneumonia increases the risk of lung cancer; however, the underlying carcinogenic pathways remain poorly understood. Usual interstitial pneumonia (UIP) frequently co-localizes with lung adenocarcinoma (LADC), providing a model to understand chronic inflammation-driven carcinogenesis.

Method: We conducted whole-genome and RNA sequence of 44 UIP (+) LADCs and compared them with 216 UIP (-) LADCs. To address intra-tumoral heterogeneity and characterize the tumor microenvironment, we performed spatial transcriptomics using a whole-transcriptome platform (Visium, 55 µm resolution) and single-cell-resolution platforms (Xenium lung panel, 302 genes; Xenium 5K, 5,018 genes).

Results: UIP (+) LADCs exhibited unique molecular features: low tumor mutation burden, absence of EGFR mutations, and a pervasive presence of myofibroblastic cancer-associated fibroblasts (myCAFs), likely derived from fibrotic myofibroblasts in UIP. The most common genetic alteration was in NKX2-1 (41%), encoding the lung-lineage transcription factor TTF-1. A dichotomous immunogenetic landscape was observed: NKX2-1-deficient tumors showed gastrointestinal differentiation, frequent ERBB2 amplification with super-enhancer formation, and immune "cold" characteristics; NKX2-1-proficient tumors exhibited immune "hot" characteristics with abundant intra-tumoral CD8+ T cells and elevated PD-L1 expression. Spatial transcriptomics analysis revealed intratumor heterogeneity associated with NKX2-1 expression status, suggesting illegitimate gastrointestinal differentiation. In addition, the presence of WNT5A- and CTHRC1-expressing myCAFs were identified, which may originate from UIP-associated myofibroblasts. Paired tumor and UIP regions demonstrated that CTHRC1+WNT5A+ myCAF population was markedly enriched in tumor tissues relative to matched UIP regions, suggesting their expansion during carcinogenesis.

Conclusion: We propose a dual model of UIP-associated lung carcinogenesis determined by NKX2-1 status, wherein myCAFs derived from UIP-associated myofibroblasts drive both carcinogenic pathways. These findings offer targeted therapeutic strategies based on the dichotomous immunogenetic landscape and highlight targeting the myofibroblast-to-myCAF transition as a potential approach for cancer prevention in chronic pulmonary fibrosis.

#2273 Obesogen co-exposure promotes triple-negative breast cancer growth via adipocyte-mediated mechanisms.

Sarah M. Bernhardt, Mikella Robinson, Carrie House

San Diego State University, San Diego, CA

Introduction: Bisphenol A (BPA) and dichlorodiphenyldichloroethylene (DDE; the primary metabolite of DDT) are environmental 'obesogens' that independently associate with altered adipocyte function and increased breast cancer risk. While the effects of obesogens alone are well studied, particularly in hormone receptor (HR)-positive breast cancer, the biological consequences of combined exposure and their impact on HR-negative disease through adipocyte-tumor interactions remains poorly understood. Here, we investigate how obesogen co-exposure alters mammary adipocyte function and promotes tumorigenesis in a mouse model of triple-negative breast cancer (TNBC).

Study design: Post-pubertal BALB/c mice (n=10/group) were exposed to obesogens via drinking water for the duration of the study, at environmentally relevant doses (Vehicle (ethanol); BPA (4µg/kg/day); DDE (0.8µg/kg/day); combination (BPA+DDE)). After 2 weeks exposure, murine mammary cancer cells (4T1; 20,000 cells) were injected bilaterally into the fourth inguinal mammary fat-pads, and investigator-blinded tumor growth tracked for 21 days. To assess how obesogens affect adipocyte function *in vitro,* 3T3-L1 preadipocytes were differentiated in the presence of vehicle (0.03% ethanol), BPA (1nM), DDE (1µM), or combination (BPA+DDE), and adipokine secretion profiles assessed using an adipokine array.

Results: Mouse body weight did not differ between treatment groups. In tumor-free mammary glands, obesogen exposure associated with increased adipocyte size (BPA 1029±231µm^2, DDE 957±350µm^2, Combo 1011±344µm^2) compared to vehicle-treated mice (766±187µm^2; $p<0.05$). Interestingly, while individual exposures induced adipocyte hypertrophy, only combined exposure increased epithelial cell proliferation (Ki67), compared to vehicle-treated mice (2.8-fold, $p=0.02$). In tumors, combination treatment associated with increased tumor burden (1.4-fold, $p=0.02$) and proliferation (1.3-fold, $p=0.04$), compared to vehicle-treated mice. *In vitro,* obesogen exposure altered adipocyte secretion of 11/38 adipokines (>2-fold change), 6 of which were unique to combination-treated adipocytes (up: LIF; down: IGF-II, VEGF, M-CSF, CCL2, adiponectin). Exposure of 4T1 cells to this conditioned media increased proliferation (EdU), compared to vehicle controls (1.5-fold, $p=0.04$). Future directions will investigate whether inhibition of LIF/LIFR signaling abrogates obesogen-induced proliferation.

Conclusions: Co-exposure to BPA and DDE synergistically promotes TNBC proliferation at environmentally relevant doses, underscoring the need to study obesogens in the context of real-world co-exposures. The effects on HR-negative disease occurred independent of obesity and were mediated, at least in part, through adipocyte-derived mechanisms, highlighting the need to expand research beyond HR-positive breast cancer.

#2274 Cigarette smoke-induced sphingosine-1-phosphate drives cancer-associated fibroblasts activation and esophageal cancer carcinogenesis.

Xinying Yue[1], Jialing Ma[1], Zifei Yang[1], Yutong Wu[1], Qianqian Su[1], Lina Song[1], Miaoxin Pan[1], Dongxu Li[2], Qingyi Liu[2], Shasha Liu[1], Yueping Li[1], Shaokai Zhang[3], Siyuan Wang[4], Li Zhang[5], Ni Zhang[5], Wei Ping[5], Catherine C. L. Wong[4], Dongxin Lin[2], Chen Wu[2], **Jiang Chang**[1]

[1]Huazhong University of Science and Technology, Wuhan, China,[2]Cancer Hospital, Chinese Academy of Medical Sciences, Beijing, China,[3]The Affiliated Cancer Hospital of Zhengzhou University, ZhengZhou, China,[4]Chinese Academy of Medical Science & Peking Union Medical College, Beijing, China,[5]Tongji Hospital, Tongji Medical College, Huazhong University of Science and Technology, Wuhan, China

The metabolic impact of cigarette smoke on tumor microenvironment remodeling remains poorly defined. Here, we identify a missense variant in *ACER1* that confers elevated risk of esophageal squamous cell carcinoma (ESCC) specifically among smokers, based on a gene-smoking interaction analysis involving 10,716 cases and 12,637 controls. Functional assays demonstrate that the risk allele synergizes with nicotine and benzo[a]pyrene to enhance sphingosine-1-phosphate (S1P) biosynthesis and secretion in ESCC epithelial cells. Integrated single-cell RNA sequencing, spatial proteomics, and multiplex immunofluorescence analyses across multi-stage ESCC samples reveal that this ACER1-driven sphingolipid reprogramming promotes the activation of myofibroblastic cancer-associated fibroblasts (myCAFs). Mechanistically, epithelial-secreted S1P engages the S1PR3-ERK-AKT signaling cascade in fibroblasts, promoting a pro-tumorigenic stromal state. Pharmacological inhibition of S1PR3 markedly suppresses ESCC growth *in vivo*. These findings uncover a critical gene-environment interaction driving pro-tumorigenic microenvironmental remodeling in esophageal tumorigenesis and highlight a metabolic vulnerability for early detection and therapeutic intervention.

#2275 Biological impact of nanoplastics on the tumor microenvironment.

Tetsuya Fukui[1], Ryota Sumitomo[1], Kosuke Tanaka[2], Toshi Menju[1]

[1]Thoracic Surgery, Kyoto University Graduate School of Medicine, Kyoto, Japan,[2]Material Cycles Division, National Institute for Environmental Studies, Tsukuba, Japan

Objectives: Nanoplastics (NPLs), generated through the degradation of environmental plastics, are emerging contaminants with potential biological risks. Although recent studies have detected NPLs in human lungs and blood, their effects on human cells remain poorly understood due to the lack of standardized particles. Previous research has predominantly relied on commercially available polystyrene particles, which may contain impurities and display heterogeneity in size and shape, leading to concerns regarding reproducibility. To overcome these limitations, standardized NPLs with uniform size and shape, free from contaminants, have recently been developed by the National Institute for Environmental Studies. In this study, we aimed to investigate the effects of these standardized NPLs on immune responses and tumor progression.

Methods: Standardized polypropylene (PP)-based NPLs were subjected to UV irradiation to simulate environmental weathering. The particles were then dispersed in distilled deionized water by sonication. Particle size distribution was confirmed by dynamic light scattering. THP-1 cells (a human monocytic cell line) were treated for 24 h with phorbol 12myristate 13-acetate to differentiate them into macrophages. A549 cells (a human lung adenocarcinoma cell line) and THP-1-derived macrophages were exposed to these NPLs. Additionally, A549 cells and NPL-exposed macrophages were co-cultured using a six-well Transwell system for 48 hours. Cytotoxicity was evaluated using MTT assays, and protein expression was assessed by Western blotting. Phenotypic changes associated with EMT were evaluated by transwell migration and invasion assays.

Results: NPLs were stably dispersed with an average diameter of approximately 400 nm as measured by dynamic light scattering. No significant cytotoxicity was observed in A549 cells at PP concentrations up to 250 μg/mL. Direct exposure of A549 cells to NPLs did not induce epithelial-mesenchymal transition (EMT). In contrast, THP-1-derived macrophages exposed to NPLs exhibited increased expression of CD163, suggesting polarization toward a tumor-promoting phenotype. When NPL-exposed macrophages were co-cultured with A549 cells in a Transwell system, co-cultured A549 cells displayed EMT-like features, including reduced E-cadherin and elevated vimentin expression compared to parental cells. Functionally, co-cultured A549 cells exhibited significantly enhanced migratory and invasive abilities compared to parental cells.

Conclusions: This study demonstrates that PP-based NPLs can alter immune cell behavior and indirectly promote tumor progression by shaping the tumor microenvironment. We established an exposure model using standardized NPLs that reflect the intrinsic physicochemical properties of the particles.

#2279 DNA methylation-based classifier predicts SERD benefit in *ESR1* wild-type HR+/HER2- breast cancer.
Shile Zhang, Nicole Zhang, Vishnu Ramani, Tingting Jiang, Marisa Juntilla, Amar Das, Martina Lefterova, Justin Odegaard, Darya Chudova, Matthew Ellis

Guardant Health, Palo Alto, CA

Background: Resistance to aromatase inhibitors (AIs) in hormone receptor-positive (HR+) metastatic breast cancer (mBC) is inevitable and frequently driven by *ESR1* mutations. Selective estrogen receptor degraders (SERDs) target estrogen receptors for degradation and provide clinical benefit in this setting. *ESR1* mutations are established biomarkers guiding transition from AI to SERD-based endocrine therapy. However, many patients lack detectable *ESR1* mutations, and no validated biomarker exists to guide SERD use in *ESR1* wild-type (*ESR1-wt*) patients. We investigated whether a blood-based, DNA methylation-derived hormone receptor (mHR) activity score could predict SERD benefit in *ESR1-wt* patients.
Methods: An mHR activity score was developed using a logistic regression model integrating over 400 most informative regions from genome-wide methylation capture of Guardant360 Liquid test. mHR-high/-low thresholds were defined using >2,000 clonal *ESR1-mutant* mBC samples. Validation was performed in a real-world *ESR1-wt* cohort (N=765) with post-AI progression plasma samples from the GuardantINFORM database. Clinical outcomes defined by time to treatment discontinuation (TTD) of SERD or chemotherapy were evaluated across mHR-high/-low groups using Kaplan-Meier methods and multivariable Cox models, adjusting for tumor fraction, age, and treatment type.
Results: Across >12,000 breast cancer samples tested with Guardant360 Liquid, the mHR activity score was positively correlated with *ESR1* mutation status and higher in tumors with clonal versus subclonal *ESR1* mutations. In the *ESR1-wt* validation cohort, mHR-high patients showed significantly longer median TTD with SERD treatment (Fulvestrant mono or combination) compared to mHR-low patients (adjusted hazard ratio: 0.44, 95%CI: 0.21-0.89; $p = 0.02$; median TTD 107 vs. 89 days). Moreover, mHR status predicted relative benefit from SERD versus chemotherapy: among mHR-high patients, SERD treatment yielded significantly longer TTD than chemotherapy (adjusted hazard ratio: 0.41; 95%CI: 0.21-0.81; $p = 0.01$; median TTD 107 vs. 87 days), while mHR-low patients exhibited a trend towards shorter TTD on SERD versus chemotherapy (adjusted hazard ratio: 1.83; 95% CI: 0.87-3.87; $p = 0.11$; median TTD 89 vs. 108 days).
Conclusions: A blood-based DNA methylation-derived mHR score captures hormone receptor-driven epigenetic activity and predicts benefit from SERD therapy in *ESR1*-wt HR+ mBC. This classifier enables real-time, noninvasive stratification of *ESR1*-wt patients, identifying a molecularly defined subset more likely to derive benefit from SERD-based therapy. These findings support the potential clinical utility of methylation-based biomarkers to extend precision endocrine therapy beyond *ESR1* mutation profiling.

#2280 Ligand-activated AR promotes the survival of endocrine therapy-responsive ER+ breast cancer.

Patrick Aouad[1], Eliah Shamir[2], Jackson Liang[3], Liang-Fu Chen[1], Vasumathi Kameswaran[4], Lisa Crocker[5], Marc Hafner[6], Bence Daniel[4], Antonina Hafner[1], Ciara Metcalfe[1]

[1]Discovery Oncology, Genentech, Inc., South San Francisco, CA,[2]Pathology, Genentech, Inc., South San Francisco, CA,[3]Translational Medicine - Oncology, Genentech, Inc., South San Francisco, CA,[4]Proteomic and Genomic Technologies, Genentech, Inc., South San Francisco, CA,[5]Translational Oncology, Genentech, Inc., South San Francisco, CA,[6]Oncology Bioinformatics, Genentech, Inc., South San Francisco, CA

Giredestrant, a next-generation oral selective ERα degrader (SERD), is a potent and full antagonist that recently demonstrated statistically significant and clinically meaningful improvement in progression free survival (PFS) in the phase III evERA Breast Cancer trial (NCT05306340). Given its potent ER antagonism, giredestrant is currently under evaluation in multiple clinical studies, including those involving premenopausal participants with an intact hypothalamus-pituitary-ovary (HPO) axis, both with and without gonadotropin-releasing hormone (GnRH) agonists. To anticipate potential mechanisms of tumor cell survival and resistance, we sought to investigate the biology of giredestrant response in tumor-bearing mice with an intact HPO axis, using the intraductal xenograft model- a physiologically relevant system for ER+ breast cancer that supports tumor growth without exogenous estrogen. We established and characterized multiple ER+ breast cancer cell lines and patient-derived intraductal xenografts with distinct growth and metastatic profiles. Giredestrant treatment significantly suppressed tumor proliferation and reduced invasive and metastatic burden. Transcriptomic and chromatin profiling of giredestrant-treated tumors revealed a marked decrease in gene sets and chromatin sites associated with ER signaling and proliferation, as anticipated. Unexpectedly, giredestrant treatment also consistently led to the activation of androgen receptor (AR) signaling, which was accompanied by increased AR motif accessibility and chromatin occupancy. We find that systemic ER inhibition engages the HPO axis, resulting in increased ovarian production of testosterone, and thus driving ligand-dependent AR activation in tumor cells. Dual inhibition of ER and AR demonstrated enhanced anti-proliferative effects compared to ER antagonism alone. Transcriptomic data suggest that this is mediated by the suppression of proliferation-associated programs, potentially through PI3K/mTOR pathway inhibition. By leveraging the novel mouse intraductal model, we identified dual ER and AR blockade, as well as ER-PI3K/mTOR pathway co-targeting, as promising therapeutic strategies to improve outcomes for premenopausal women with ER+ breast cancer, particularly those not receiving GnRH agonists.

#2281 AZD4241, an orally bioavailable ERα PROTAC, degrades wild-type and mutant ERα and delivers anti-tumour activity in preclinical breast cancer models.

Mandy Lawson[1], Natalie Cureton[1], Lynet Nyoni[1], Sophie D'Arcy[1], Lydia Parkinson[1], Ana Quiroga[1], Pablo Morentin Gutierrez[1], Ji Li[2], Hana Baakza[1], Thomas Hayhow[1], Claire Crafter[1], Lucy Ireland[1], Gemma Hardman Fowler[1], Georgia M. Simmons[3], Lakjaya Buluwela[3], Simak Ali[3], Neil Gibson[1]

[1]Oncology Targeted Discovery, AstraZeneca R&D, Cambridge, United Kingdom,[2]Translational Medicine, AstraZeneca R&D, Waltham, MA,[3]Department of Surgery and Cancer, Imperial College London, London, United Kingdom

Estrogen receptor alpha (ERα) is a member of the nuclear hormone receptor superfamily and a key driver of hormone receptor-positive (HR+) breast cancer. Current ER-pathway inhibitors include aromatase inhibitors (letrozole, anastrozole, exemestane), selective estrogen receptor modulators (SERMs; tamoxifen), and selective estrogen receptor degraders (SERDs; fulvestrant, elacestrant, imlunestrant). In metastatic ER-positive disease, resistance is common and often involves the emergence of ESR1 mutations (e.g., Y537S, D538G). These mutations occur in the ligand-binding domain of ERα and enable ligand-independent ER activation, reducing the effectiveness of aromatase inhibitors and some antagonists. This underscores the need for novel treatments that target ER in both wild-type (ESR1wt) and mutant (ESR1m) settings, including more effective ERα degraders, as demonstrated clinically by SERDs. Here we characterise AZD4241, a novel ER-targeting proteolysis targeting chimera (PROTAC), that degrades both wt and mutant ERα and delivers anti-tumour efficacy in preclinical breast cancer models. AZD4241 degraded ERα in ESR1wt cell lines (IC_{50} 0.4 nM in MCF7 cells) and showed good oral bioavailability across species. ERα half-life was reduced through PROTAC-mediated degradation requiring cereblon engagement and proteasomal activity. In MCF7 cells engineered to express clinically relevant ESR1 mutations, AZD4241 reduced ERα with degradation potency (IC_{50} 0.2-1.0 nM) comparable to ESR1wt controls. AZD4241 completely inhibited estradiol-induced gene expression (e.g., GREB1, PGR, and TFF1) and suppressed proliferation of ER-dependent breast cancer cell lines with low-nanomolar IC_{50} values. In vivo, AZD4241 induced dose-dependent anti-tumour activity and, in some cases, tumour regressions across ESR1wt and ESR1m patient-derived xenograft (PDX) models, including a palbociclib-resistant model. Efficacy was associated with marked reductions in ERα protein levels and decreased ER pathway activity, supporting a pharmacodynamic link between target degradation, suppression of ER signalling and efficacy. Collectively, these data confirm that AZD4241 is a potent, orally bioavailable degrader of wt and mutant ERα, driving anti-tumour efficacy in ESR1wt, ESR1m, and CDK4/6 inhibitor-resistant PDX models. These findings support the use of AZD4241 as a novel ER-PROTAC with potential to overcome key resistance mechanisms to current standards of care and deliver clinical benefit for patients with ER-positive breast cancer.

#2282 Targeting estrogen receptor mutations and aberrant myelopoiesis in hormone resistant breast cancer.

Maria Belen Villegas[1], Mario Morales Martinez[1], Javier Mansilla[2], Eduardo Mauricio Gonzalez[1], Begona Comin-Anduix[1], Marisol Chavez[1], Brian Aguirre[3], Gang Deng[2], Nalo M. Hamilton[4], Madhuri Wadehra[3], Michael E. Jung[2], Richard J. Pietras[1], Diana C. Marquez Garban[1]

[1]Medicine, UCLA David Geffen School of Medicine and Jonsson Comprehensive Cancer Center, Los Angeles, CA,[2]Chemistry and Biochemistry, UCLA and Jonsson Comprehensive Cancer Center, Los Angeles, CA,[3]Pathology and Laboratory Medicine, UCLA David Geffen School of Medicine and Jonsson Comprehensive Cancer Center, Los Angeles, CA,[4]UCLA School of Nursing, Los Angeles, CA

Breast cancer (BC) is the most commonly diagnosed cancer among women worldwide. In the U.S., it is the second leading cause of cancer-related mortality among women and the leading cause of cancer death among Hispanic and African American women. Approximately 70% of BCs express estrogen receptor alpha (ERα), which plays a central role in driving tumor development and progression. Endocrine therapy provides durable clinical benefit, as evidenced by significant reductions in local, contralateral and distant recurrence and by improvement in overall survival, with effects persisting long after treatment cessation. Despite its efficacy, development of acquired or intrinsic resistance remains a major obstacle in BC management. A key mechanism of resistance involves somatic mutations in the ESR1 gene, most commonly Y537S and D538G, which stabilize the ligand-binding domain in a constitutively-active conformation, thereby enabling ligand-independent ER signaling and diminishing effectiveness of aromatase inhibitors and tamoxifen. Until recently, fulvestrant was the only selective estrogen receptor degrader (SERD) available to counteract endocrine resistance; however, two next-generation SERDs, elacestrant and imlunestrant, have now received FDA approval. This underscores the continued need for advanced SERDs capable of effectively targeting both wild-type (WT) and mutant ERα while minimizing adverse effects. We have developed novel oral SERDs designed to degrade both WT and mutant ERα. To assess their anti-tumor activity, we evaluated these compounds in BC cell lines with and without Y537S and D538G ERα mutations. Treatment with our SERDs significantly reduced cell proliferation in a dose-dependent manner ($P<0.01$) and consistently decreased ERα protein levels in both WT and mutant cell lines. These effects were comparable to, or exceeded, those observed with current FDA-approved SERDs such as fulvestrant and elacestrant. Additionally, SERD treatment resulted in reduced ESR1 mRNA levels. ERα knockdown in BC cells abrogated SERD activity, confirming that their mechanism of action is ERα-dependent. Moreover, SERD JD128 demonstrated potent *in vivo* efficacy against MCF7-Y537S xenografts in humanized BLT-NSG-SGM3 mice ($P<0.01$). Analysis of the tumor immune microenvironment (TME) revealed that JD128 treatment increased T-cell infiltration compared with controls. These findings indicate that our SERDs represent promising therapeutic candidates for ERα-positive BC that has developed resistance to existing endocrine therapies. Furthermore, combining endocrine agents with immunotherapy may help mitigate immune suppressive myeloid populations within the TME and enhance T-cell-mediated anti-tumor responses. Funding: CIRM DISC2-14166, UCLA JCCC BC Award, Tower Cancer Res Found, Hickey Foundation, NIH/NCI U54 CA143930 CDU-UCLA JCCC Partnership, CBCRPB27IB3869, DOD BCRPBC181420.

#2283 Obesity predicts greater changes in Ki67 after neoadjuvant aromatase inhibitor therapy in early-stage ER+ breast cancer.

Mary Dickinson Chamberlin[1], **Lillian A. Lawrence**[2], Roberta M. DiFlorio-Alexander[1], Victoria Jones[1], Eugene Demidenko[1], Jonathan Marotti[1]

[1]Dartmouth Cancer Center, Lebanon, NH,[2]Geisel School of Medicine at Dartmouth, Hanover, NH

Background: Nearly 70% of breast cancers are ER positive (ER+), and anti-estrogen therapy, such as tamoxifen and aromatase inhibitors (AI), are a mainstay of treatment. Neoadjuvant endocrine therapy (NET) with aromatase inhibitors is effective at reducing tumor burden and may be predictive of better long-term outcomes. A significant decrease in Ki-67 is prognostic but additional predictive clinical factors for improved response to NET are not well understood. Preliminary data from our post-menopausal cohort of women with ER+ early-stage breast cancers treated with NET presented at the San Antonio Breast Cancer Symposium 2025, showed correlation between larger tumor sizes and greater radiographic response to NET with 68% of tumors exhibiting a radiographic response. Women with higher BMI have a higher risk of breast cancer recurrence and mortality, hypothesized to be due to incomplete suppression of aromatase but specific data on response to NET is lacking.
Objective: Determine the association between BMI and change in Ki67 expression after NET in patients with early-stage breast cancer.
Methods: 150 post-menopausal women with Stage I-III ER+, HER2- breast cancer were treated with an aromatase inhibitor for 7-168 days (mean 42.83 days) prior to surgery and had BMI, pre- and post-NET Ki67 immunohistochemistry available. Digital Ki-67 analysis on the diagnostic biopsy before NET was compared to Ki-67 on the surgical specimen. Statistical analysis determined p-values from the pairwise t-test. Control group analysis is in progress.
Results: The mean Ki-67 prior to NET was 18.62% (range 0.69%- 61.56%). The mean Ki-67 after NET was 4.17% (range 0.04%-46.07%). The mean radiographic baseline tumor size 20.9 mm. We found that both BMI and the baseline tumor size significantly correlated with Ki-67 expression difference ($p=0.038$ and $p= 0.026$, respectively). For example, based on our analysis, it is expected that women with a BMI = 30, there will be a two-fold decrease in post-NET Ki-67 expression. There was no significant correlation between change in Ki-67 and number of days on NET.
Discussion: In our cohort, higher BMI was associated with a greater decrease in Ki-67 expression compared to women with BMI <30, suggesting greater suppression of cell proliferation by NET in obese women. Suppression of Ki-67 is considered a good prognostic indicator, therefore this preliminary data contradicts the hypothesis that poorer outcomes for women with breast cancer and a BMI >30 are due to insufficient response to aromatase inhibitors. Additional research is needed to further elucidate these findings and validate this data against long-term AI adherence and other predictors of outcomes.

#2284 Progesterone receptor modulates the antigen processing and presentation machinery: Decreasing MHC class I expression on tumor.

Julio Tinoco[1], Eilidh Chowanec[2], Amanda Glen Heard[3], Christy R. Hagan[2]

[1]University of Kansas Cancer Center, Kansas City, KS,[2]University of Kansas Medical Center, Kansas City, KS,[3]University of Kansas Medical Center, Kansas City, MO

Hormone receptor (HR)-positive breast cancers, which account for approximately 75% of all breast cancers and express both estrogen receptor (ER) and progesterone receptor (PR), have been the focus of extensive research. Anti-estrogen and ER-targeted therapies have been highly successful in treating HR+ breast cancer; however, more than one-third of patients eventually develop resistance, underscoring the need for new targeted strategies. Unlike ER, the role of PR in breast cancer progression and immune modulation remains less explored. In previous work, we found that a mouse mammary tumor cell line (E0771) engineered to express mouse progesterone receptor (mPR) and the ovalbumin (OVA) peptide exhibited reduced T-cell-mediated cytotoxicity following progesterone treatment compared with control cells. This progesterone-mediated protection occurred only in mPR+ cells. Flow cytometric analysis further demonstrated decreased MHC class I surface expression in progesterone-treated E0771-Ova-mPR cells relative to vehicle controls. To investigate the underlying mechanisms, we analyzed the expression of genes involved in antigen processing and presentation (APP) of MHC class I molecules. Progesterone treatment reduced RNA levels of Tap1, Tap2, Tapbp, Nlrc5, B2m, and Psmb8, which are essential components of the APP pathway. These findings suggest that progesterone receptor activation suppresses the antigen presentation machinery, leading to reduced MHC class I expression and impaired recognition by cytotoxic T cells. Collectively, our data indicate that progesterone signaling may contribute to immune evasion in HR+ breast cancer through transcriptional regulation of MHC class I APP genes.

#2285 TGFβ Induction: An essential tumor suppressive arm of next generation SERDs in ER+ breast cancer models *in vitro*.

Kareem Heslop[1], Jackson Liang[1], Steffan Vartanian[2], Jinchu Vijay[1], Liang-Fu Chen[1], Marc Hafner[3], Michael Costa[1], Ciara Metcalfe[4]

[1]Discovery Oncology, Genentech, Inc., South San Francisco, CA,[2]Genentech, SOUTH SAN FRANCISCO, CA,[3]Scientist, Genentech, South San Francisco, CA,[4]Genentech, Inc., South San Francisco, CA

Breast cancer is the most diagnosed cancer globally, with a significant need for improved treatments for the most prevalent Estrogen Receptor α (ER)-positive subtype, where ER signaling drives cell proliferation.The next-generation oral Selective ER antagonist and degrader (SERD), giredestrant, is a potent investigational agent that robustly suppresses tumor cell proliferation. However, primary and acquired resistance pose a major challenge to all endocrine therapies including oral SERDs, necessitating a deeper understanding of resistance mechanisms.

In a comprehensive whole-genome CRISPR screen, we sought to identify genetic perturbations that confer a growth advantage in the presence of giredestrant. Notably, knockout of multiple TGFβ signaling components (TGFβ3, SMAD4, IPO8, TGFβR2) consistently freed ER+ cells from giredestrant-induced cell cycle arrest. We establish an unexpected autocrine mechanism: by suppressing the ER pathway, giredestrant induces the expression and signaling of the tumor suppressor TGFβ3. This induced TGFβ signaling then elevates CDKN1A (p21) levels, which precedes the inhibition of its natural target, CDK2.

We demonstrate that this TGFβ→p21-|CDK2 axis is necessary for giredestrant to achieve its maximal inhibitory effect in vitro. Molecular profiling confirmed CDKN1A was among the most significantly suppressed genes when TGFβ signaling was inhibited in combination with giredestrant. Crucially, combining giredestrant and a TGFβ inhibitor led to resistance, but this was partially overcome by a combination of CDK4/6 and CDK2 inhibition. This finding shows that CDK4/6/2 blockade can bypass, in-part, the requirement for the p21 cell cycle brake.

Collectively, our results reveal that giredestrant's in vitro efficacy relies on an autocrine TGFβ loop to mediate the necessary G1 arrest. The inhibition of TGFβ creates a resistance mechanism by neutralizing this essential tumor-suppressive signaling component.

#2286 Monitoring response to camizestrant next-generation oral SERD in ER+ advanced breast cancer patient-derived xenografts via circulating tumor DNA profiling.

Susana Ros*[1], Paul Labrousse*[2], Hugh Russell[2], Fryer Henderson[3], Sara Talbot[1], Benjamin Phillips[4], Teresa Klinowska[5], Christopher Morrow[5], Claire Crafter[1], Daniel Stetson[2], Darren Hodgson[6], James Hadfield[6]

[1]Research and Early Development, Oncology R&D, AstraZeneca, Cambridge, United Kingdom,[2]Cancer Biomarker Development, Oncology R&D, AstraZeneca, Waltham, MA,[3]Cancer Biomarker Development, Oncology R&D, AstraZeneca, Gaithersburg, MD,[4]Discovery Sciences, BioPharmaceuticals R&D, AstraZeneca, Cambridge, United Kingdom,[5]Late Development, Oncology R&D, AstraZeneca, Cambridge, United Kingdom,[6]Cancer Biomarker Development, Oncology R&D, AstraZeneca, Cambridge, United Kingdom

Background: While circulating tumor DNA (ctDNA) is widely used clinically for disease monitoring, its preclinical application has been limited by perceived constraints of small blood volumes in animal models. Patient-derived xenograft (PDX) models offer unique advantages for ctDNA analysis, as human tumor DNA can be distinguished from murine background DNA, enabling clearer assessment of treatment-induced changes compared to clinical samples where tumor and normal DNA separation is more complex.
Methods: We developed a preclinical ctDNA monitoring platform using ER-positive advanced breast cancer PDX models, including both wild-type and ESR1-mutant tumors. Digital Droplet PCR (ddPCR) informs whether sufficient human ctDNA levels are present (human repeat elements) to perform next generation sequencing (NGS). This feature allows the ability to monitor ctDNA levels over time, in response to various therapies. Mice received camizestrant, a next-generation oral selective estrogen receptor degrader (SERD), as monotherapy and in combination with CDK4/6 inhibition. Human-specific LINE-1 DNA levels and variant allele frequency (VAF) of tumor-specific somatic mutations were quantified in mouse plasma samples and correlated with tumor volume measurements.
Results: Treatment with camizestrant, either as monotherapy or in combination with CDK4/6 inhibition, resulted in significant reductions in tumor volume and growth rate in both wild-type and ESR1-mutant PDX models which correlated with marked decreases in human-specific LINE-1 in mouse plasma, as measured by ddPCR. Variant allele frequency in ctDNA decreased significantly, correlating with anti-tumor efficacy following treatment with camizestrant monotherapy or in combination with CDK4/6 inhibition.
Conclusions: This study establishes a robust, minimally invasive preclinical platform for evaluating ctDNA-based biomarkers and treatment efficacy in oncology research. The approach enables investigation of ctDNA release biology and treatment response in preclinical models that are difficult to address using human samples alone. These findings demonstrate the translational potential of preclinical ctDNA monitoring to inform clinical biomarker strategies and optimize therapeutic development in ER+ breast cancer.

#2287 Minimal-length CAG repeats in AR define a hyperactive AR-LSD1 axis driving metabolic reprogramming in prostate cancer.

Songqi Zhang[1], Muqing Li[1], Mingyu Liu[1], Nolan D. Patten[1], Maryam Labaf[1], Jaeweon Jeong[1], HyeonYeong Sun[1], Jared G. Lourie[2], Kai Zou[2], Susan Patalano[1], Jill A. Macoska[1], Shuai Gao[3], Dong Han[1], Maria Pennuto[4], Steven P. Balk[5], Changmeng Cai[1]

[1]Center for Personalized Cancer Therapy, University of Massachusetts Boston, Boston, MA,[2]Department of Exercise and Health Science, University of Massachusetts Boston, Boston, MA,[3]Department of Cell Biology and Anatomy, New York Medical College, Valhalla, NY,[4]Department of Biomedical Sciences, University of Padova, Padova, Italy,[5]Hematology-Oncology Division, Department of Medicine, Beth Israel Deaconess Medical Center, Boston, MA

Background: Racial disparities in prostate cancer (PCa) incidence and mortality are well recognized, with men of African ancestry (AA) exhibiting more aggressive disease. One germline genetic factor contributing to this disparity is the polymorphic CAG trinucleotide repeat in the first exon of the androgen receptor (AR) gene, which encodes a variable-length polyglutamine (polyQ) tract within the AR N-terminal domain. Shorter polyQ tracts, commonly found in the AA population, are reported to associate with enhanced AR transcriptional activity and increased PCa risk. Notably, minimal-length CAG repeats, defined as ≤17, are present in ~10% AA men but are rare among men of European ancestry (EA). These encode ultrashort polyQ tracks, however, how such variations alter AR chromatin function, its transcriptional output, metabolic reprogramming, and therapeutic response remains unclear.
Methods: We performed CRISPR/Cas9 editing to generate isogenic LNCaP-derived prostate cancer cell lines harboring minimal-length CAG repeats (10Q) AR alleles. Integrated analyses combining RNA-seq, ChIP-seq, and functional studies in vitro and in vivo were conducted to define the transcriptional, epigenetic, and metabolic consequences of ultrashort polyQ AR.
Results: The 10Q AR variant exhibited markedly reduced proteasomal degradation, leading to enhanced AR protein stability and resistance to AR antagonist-induced protein degradation. Genome-wide analyses revealed markedly expanded AR chromatin binding and redistribution of the pioneer transcription factor FOXA1, accompanied by transcriptional activation of lipid biosynthesis and glycolysis genes. Mechanistically, the ultrashort polyQ tracks strengthened AR interaction with the epigenetic coactivator LSD1, enhancing its coactivator activity. Pharmaceutical inhibition of LSD1 with iadademstat (ORY-1001) suppressed AR-mediated metabolic reprogramming and significantly reduced tumor growth in 10Q xenograft models.
Conclusion: Minimal-length CAG repeats in AR establish a hyperactive AR-LSD1 chromatin axis that drives transcriptional and metabolic reprogramming, leading to prostate cancer progression. These findings link inherited germline AR polymorphism to epigenetic-metabolic remodeling and identify LSD1 inhibition as a promising therapeutic strategy for aggressive and racially disparate PCa subtypes harboring minimal-length CAG repeats.

#2288 Neoadjuvant treatment of ER-positive/HER2-negative breast cancer with aromatase inhibitors in sequence: Ki67 dynamics and biology shifts.

Hospital, Lorenskog, Norway,[11]Department of Oncology & Institute of Clinical Medicine, Faculty of Medicine, Akershus Univ. Hospital/Oslo University Hospital, Lorenskog/Oslo, Norway

Background. Neoadjuvant endocrine treatment (NET) is used for locally advanced hormone receptor (HR)-positive, HER-2-negative breast cancer in highly selected patients. Aromatase inhibitors (AI) are the preferred option in this setting. Although NET has been proposed to be similarly effective as neoadjuvant chemotherapy (NCT) for certain patients, there are no reliable markers currently available to guide post-surgery decisions. Changes in Ki67 levels and results provided by multi-gene arrays (MGA) before and after neoadjuvant treatment have been suggested to be promising and clinically relevant markers for further decision making.
Methods. The NEOLETEXE trial was an open-label, intrapatient cross-over trial including patients with locally advanced HR-positive, HER2-negative breast cancer. Patients were randomized 1:1 to NET with either letrozole or exemestane for 3 months, followed by an intrapatient cross-over to the alternative treatment for another 3 months. Extensive biobanking was performed at multiple time points before and during neoadjuvant therapy. In a subset of patients, gene expression profiling was performed using the Prosigna® (PAM50) assay on both the diagnostic biopsy and the final surgical specimen. Immunohistochemical Ki67 expression was assessed in core biopsies obtained at baseline and in excision specimens collected at the time of surgery.
Results. A total of 84 patients were included in the intention-to-treat analysis. The median age was 76 years. Pathological complete responses (pCR) occurred in 6% (n=5). The median follow-up time was 6,3 years. Only nine patients (10,7%) relapsed during the follow-up period. An analysis of Ki67 at baseline (Ki67b) and at the time of surgery (Ki67s) was performed, with levels of Ki67 10% or higher classified as Ki67high. Kaplan-Meier analysis showed that patients with low Ki67 levels at surgery (<10%) experienced significantly better recurrence-free survival (RFS) compared to the Ki67 high group (HR 0,07, CI 0.02-0.31, $p < 0.001$).Prosigna testing was performed at baseline and at the time of surgery in a cohort of 20 patients. At baseline, 35% (n = 7) of the Prosigna cohort were classified as Luminal A, 57,9% (n = 11) as Luminal B, and one patient was identified as HER2-enriched. At the time of surgery, most tumors were classified as Luminal A (80%, n = 16), two patients were categorized as HER2-enriched, and only one patient remained in the Luminal B category.
Conclusions. Our trial strongly underlines that NET involving AI as monotherapy for locally advanced HR-positive breast cancer is a pragmatic and effective alternative to NCT in highly selected patients. Ki67 expression data and MGA data at surgery turned out to be promising markers to potentially guide post-neoadjuvant decision-making and should be tested in future clinical trials.

#2289 Newly-designed selective estrogen receptor downregulators and their role in the tumor microenvironment and hematopoiesis in breast malignancies.

Breast cancers (BC) with estrogen receptor-alpha (ERα) expression represent 70% of newly-diagnosed patients in the US. Endocrine therapies with antiestrogens or aromatase inhibitors, either alone or combined with CDK 4/6 inhibitors, are an important intervention for BCs that express ERα, and these remain among the most effective targeted treatment strategies. However, a number of patients with localized BC, and essentially all patients with advanced BC, eventually become resistant to current endocrine therapy regimens. In contrast, immunotherapy is transforming the landscape of treatment for many cancers. However, most breast cancers, apart from a minority of triple-negative breast cancers (TNBC), are resistant to this promising immunotherapeutic approach. Several mechanisms of immune resistance have been described. Of note, BCs are reported to drive expansion and differentiation of hematopoietic stem and progenitor cells in the bone marrow to skew hematopoiesis toward an immunosuppressive myeloid lineage. This dysregulation of myelopoiesis in breast malignancy leads to aberrant expansion of immunosuppressive and tumor-promoting myeloid subpopulations such as myeloid-derived suppressor cells (MDSCs). Our newly-designed selective estrogen receptor down-regulator JD128 (SERDs) markedly reduces *in vitro* proliferation of several ERα+ BC cell lines, alone and combined with CDK 4/6 inhibitors, when compared with FDA-approved SERDs Fulvestrant and Elacestrant ($P < 0.01$). This was accompanied by a significant decrease of ERα protein as well as mRNA levels, confirming ERα protein degradation. Further, estrogen stimulated proliferation of CD34+ bone marrow stem cells, multipotent progenitors and MDSCs derived from normal female donors, an effect that was inhibited by SERD JD128 and Fulvestrant indicating that hematopoietic stem and progenitor cells express estrogen receptors and respond to estrogen. In addition, SERD JD128 inhibited proliferation of BC cell mammospheres and reduced expression of cancer stem cell markers. Importantly, accumulation and activity of MDSCs that occupy the tumor microenvironment (TME) appear to occur in both ER-positive and ER-negative tumors. Moreover, estrogen-responsive MDSCs in the TME can be targeted by SERD therapy to block estrogen signaling. These estrogen-mediated effects on hematopoietic cell expansion/activation have implications for potential clinical use of SERDs in ER-positive or ER-negative BCs. #2290 Therapeutic targeting of ATAD2 in endocrine-resistant breast cancer.

Anil Kumar Devakrishnan[1], **Murugesan Palaniappan**[2]

[1]Baylor College of Medicine, Houston, TX,[2]Pathology and Immunology, Baylor College of Medicine, Houston, TX

Introduction: ATPase family AAA domain-containing protein 2 (ATAD2) is a highly conserved protein that functions as a coactivator of oncogenic transcription factors, and its bromodomain is critical for its association with acetylated chromatin. ATAD2 is frequently amplified in multiple types of cancer, including breast cancer. The upregulation of ATAD2 is often associated with poor patient outcomes and can be used as a prognostic marker. In breast cancer, ATAD2 is proposed to act as a coactivator of estrogen receptor (ER) α, which is selectively recruited upon estradiol stimulation, leading to the induction of a subset of ER target genes, including c-Myc, cyclin D1, and E2F1, which are required for breast cancer cell proliferation. Here, we examined the role of ATAD2 in hormone-resistant metastatic ER-positive breast cancers with activating mutations in ESR1, which currently have limited therapeutic options.
Methods: We examined the expression of ATAD2 in human breast tumors and subtype-specific breast cancer cells, including endocrine therapy-resistant breast cancer cells. To investigate the therapeutic potential of ATAD2 in Y537S and D538G mutant breast cancer cells, we conducted genetic and pharmacological modulation of ATAD2 in endocrine-resistant breast cancer cells. Additionally, we established stable suppression of ATAD2 using shRNA in the Y537S mutant MCF-7 and T47D cells. We also performed a co-immunoprecipitation assay, which demonstrated an interaction between ATAD2 and ERα in Y537S MCF-7 cells.
Results: Analysis of The Cancer Genome Atlas (TCGA) and Clinical Proteomic Tumor Analysis Consortium (CPTAC) data sets revealed elevated mRNA and protein levels of ATAD2 across all major subtypes compared with normal breast tissues. Additionally, ATAD2 was overexpressed in endocrine-resistant breast cancer cells, including Y537S palbociclib resistance and long-term estrogen-deprived (LTED) cell line models. Pharmacological and siRNA-mediated inhibition of ATAD2 significantly reduced the expression of ERα and its target genes in Y537S and D538G mutant breast cancer cells. More importantly, the inhibition of ATAD2 by a genetic or pharmacological agent potentially blocks ligand-dependent and ligand-independent ER signaling in endocrine-resistant breast cancer cells. Finally, our co-immunoprecipitation experiments showed that ERα directly interacts with ATAD2.
Conclusion: Collectively, our study highlights that ATAD2 is necessary for ESR1 mutant signaling in endocrine-resistant breast cancer. Therefore, blocking ATAD2 is a promising therapeutic strategy for endocrine-resistant breast cancer, including *ESR1* mutant breast cancer.

#2291 Exposure to plastic additives suggests potential androgen receptor agonism in prostate cancer.

Wylie K. Watlington[1], Sophia Colmenares[1], James Carter[1], Sophie Vincoff[2], Andrew A. Armstrong[1], Daniel Reker[1], Jason A. Somarelli[1]

[1]Duke University, Durham, NC,[2]University of Pennsylvania, Philadelphia, PA

Introduction: Plastic is the most abundant human-made substance in the world, and routine ingestion represents a global public health threat. Plastics are comprised of solid hydrocarbon polymers with over 10,000 chemical “additives” that augment the material properties of plastic. These additives include known carcinogens, endocrine disrupting compounds, and DNA damaging agents. Endocrine disruptors are of particular concern, as they may promote growth of hormone-dependent cancers or inhibit hormone therapies used in treatment. Perhaps more alarming is how little we know about the thousands of additives not yet characterized. Here we developed a computational platform to identify additives with potential binding activity to androgen receptor (AR), the key hormone receptor used for prostate cancer growth signaling. The goal for this work is to better understand how these routine exposures may impact endocrine signaling and potentially fuel prostate cancer growth.

Methods: We developed a pairwise deep learning model to enhance AR agonist prediction accuracy by leveraging relative potency relationships among compounds. After training this model on 469 compound structures and half-maximal effective concentration (EC_{50}) values, we screened 2,712 plastic additives and identified eight commonly used additives as potential AR agonists. We treated AR-dependent LNCaP cells engineered with a fluorescent prostate-specific antigen (PSA) reporter with each additive, ranging from 100 µM to 0.0001 µM. Cell growth rate and AR activity via PSA reporter were quantified using the analysis features on the Incucyte S3® (Sartorius).

Results: Upon ranking predicted candidates from our deep learning model, we selected eight compounds for experimental validation based on favorable prediction values, cost, and availability. Out of seven additives initially screened, four showed significant increases in PSA reporter expression upon additive exposure at 10 µM (edetic acid, sebacic acid, 2,4,6-tribromophenol, and TTBP-TAZ). Two additives (TTBP-TAZ and 2,4,6-tribromophenol) showed significant growth proliferation at doses ranging from 1-100 µM. Cross-checking these additives with human biomonitoring data shows that decabromodiphenyl ether and 2,4,6-triboromophenol have been detected in human samples and are being monitored for potential detection.

Conclusions: We have developed and deployed a pairwise deep learning approach to screen a database of plastic additives for predicted AR activity and validated experimentally the AR activation for three of these additives. This work could help identify areas of environmental exposure to AR agonists that increase risk of prostate cancer development or progression. Future work is focused on expanding this platform to identify compounds acting as regulators of other hormones relevant in cancer and developing assays to detect these additives in patient samples.

#2292 Interleukin-6 increases glucocorticoid inactivation in a castration resistant prostate cancer cell line model.

Olivia M. Tonini[1], Lina Schiffer[2], Nima Sharifi[2]

[1]Cancer Biology Graduate Program and Sylvester Comprehensive Cancer Center, University of Miami Miller School of Medicine, Miami, FL,[2]Urology, Desai Sethi Urology Institute and Sylvester Comprehensive Cancer Center, Miami, FL

Prostate cancer is the second leading cause of cancer deaths in men in the United States. It is dependent on androgen receptor (AR) signaling and initially is responsive to therapies blocking AR signaling. Unfortunately, it is common for the cancer to reoccur and become resistant to these therapies and become a form known as castration resistant prostate cancer. This resistance to AR blockers is in part mediated by the glucocorticoid receptor (GR) taking over the regulation of AR-target genes driving proliferation. As shown by our group and others, this GR take over in AR blocker resistant tumors is in part due to increases in GR levels and due to loss of the glucocorticoid-inactivating enzyme 11βHSD2. Studying the regulation of the tumor-specific levels of the active glucocorticoid, cortisol, is essential as they determine local GR activity and are hence tied to therapeutic resistance. In this work, we set out to determine how cytokines regulate 11βHSD2 activity and affect glucocorticoid levels in prostate cancer.

Using a cell line model of castration resistant prostate cancer (VCaP) and tracing of radiolabeled steroids by High Performance Liquid Chromatography, we show that interleukin-6 (IL-6) increases 11βHSD2 activity, promoting metabolic inactivation of glucocorticoids. We show that interleukin-6 increases transcript levels of *HSD11B2* (encoding 11βHSD2) and 11βHSD2 protein abundance indicating that IL-6 drives increased glucocorticoid inactivation by upregulating *HSD11B2* at the transcriptional level. Using transient siRNA knockdowns and selective, pharmacological inhibitors, we show that blocking JAK1/2, gp130, and STAT3 results in reversal of this glucocorticoid inactivation and are therefore required signaling elements that mediate the interleukin-6 induced upregulation of *HSD11B2* expression, protein level and activity in VCaP cells. Taken together, we have discovered interleukin-6 and JAK/STAT signaling as a potential new regulator of glucocorticoid metabolism in prostate cancer. Further work will elicit the physiological and therapeutic implications in the context of disease progression and therapy resistance. Ultimately, this research aims to deepen the understanding of glucocorticoid metabolism regulation in prostate cancer and its role in disease escalation and treatment responsiveness.

#2293 The LncRNA XIST mediates resistance to estrogen receptor beta targeted therapies in triple negative breast cancer.

Michael Emch[1], Kirsten Aspros[1], Matthew P. Goetz[2], John Hawse[1]

[1]Mayo Clinic, Rochester, MN,[2]Mayo Clinic College of Medicine and Science, Rochester, MN

Breast cancer accounts for nearly a quarter of all cancers in women with an estimated 2.3 million new diagnoses and over 670,000 deaths annually. Triple-negative breast cancer (TNBC) is an aggressive subtype characterized by lack of estrogen receptor alpha (ERα) and progesterone receptor (PR) expression in the absence of HER2 amplification. TNBC accounts for ~15% of all incident breast cancers and is associated with poor patient outcomes. Problematically, TN tumors exhibit vast inter-patient molecular heterogeneity making the identification of novel therapeutic vulnerabilities difficult and the development of alternative treatment strategies problematic. We and others have demonstrated that estrogen receptor beta (ERβ) is expressed in about 20% of TN tumors and potently suppresses proliferation, invasion, and migration in TNBC cells *in vitro* and *in vivo*. We thus hypothesized that endocrine therapies that selectively activate ERβ would be an effective treatment approach for this subset of patients. We also anticipated that some tumors would display de novo or acquired resistance to ERβ targeted therapies despite ERβ protein expression. We therefore sought to define mechanisms of resistance to ERβ targeted therapy and to identify synthetic lethal vulnerabilities. We generated the first models of ERβ resistant TNBC through chronic exposure to estradiol or an ERβ specific agonist (LY500307) and through a CRISPR genome wide knockout screen. We identified the LncRNA XIST as one of the most upregulated transcripts in multiple models of ERβ resistant disease, and knockdown of XIST expression was shown to resensitize resistant cell to estradiol and LY500307 treatment. XIST was not found to be directly regulated by ERβ in TNBC further suggesting that its overexpression is a bona fide mechanism of resistance to ERβ mediated suppression of proliferation. The phenomena of chronic ligand exposure leading to activation of XIST expression in ERβ+ cells is not shared with ERα suggesting that the mechanism by which XIST expression is elevated during the development of resistance is distinct between the two sister receptors. We further characterized *XIST* expression in patient samples of TNBC and found that XIST expression varies, but largely exhibits a bimodal distribution with most tumors displaying either low or high transcript levels. In conclusion, we have identified the X-inactivating transcript as a driver of resistance to ERβ targeted therapies in TNBC. Future studies aimed at uncovering the consequences of XIST over-expression on global gene expression, functionality of ERβ, and aggressiveness of TNBC are ongoing.

#2294 Examining the effect of second-generation antiandrogens in androgen receptor-overexpressing prostate cancer cells.

Kia Vaalavirta, Hanna Rauhala, Tapio Visakorpi

Faculty of Medicine and Health Technology, Tampere University, Tampere, Finland

Antiandrogens inhibit androgen receptor (AR) signaling, a critical driver of prostate cancer (PCa) growth and survival. While these agents are initially effective, prolonged therapy frequently results in resistance, often associated with AR overexpression or the emergence of constitutively active splice variants. To better understand how AR overexpression influences antiandrogen efficacy, we examined cell proliferation and AR target gene expression under second-generation antiandrogen treatment in AR-high PCa cells.
In this study, we used darolutamide, enzalutamide, and apalutamide and systematically compared their effects on cell proliferation and AR-mediated gene expression using identical experimental setups. LNCaP-ARhi cells, expressing 4-6-fold higher AR than their parental cell line LNCaP-pcDNA3.1, were hormone-deprived and treated with increasing concentrations (0.001 nM-10 nM) of the synthetic androgen, R1881. Cell proliferation and morphology were monitored with Incucyte phase-contrast imaging for 7 days. Direct AR target gene expression (KLK3 and FKBP5) was quantified by qPCR. For co-treatment, we used two R1881 concentrations (0.01 nM and 0.1 nM): the lower promoted proliferation, the higher suppressed it, and both significantly increased KLK3 expression in AR-overexpressing cells. The cells were hormone-deprived, then treated with DMSO, 0.01 nM or 0.1 nM R1881, and antiandrogens (1 μM, 10 μM, and 25 μM). Cell proliferation and morphology were monitored for 5 days, and AR target gene expression was measured as previously described.
Our results support previous findings that AR overexpression enhances androgen responsiveness and sustains cell growth even under low androgen concentrations (0.01 nM R1881). We also found that LNCaP-ARhi cells shifted from elongated, spindle-shaped cells to a flattened, polygonal morphology at R1881 0.03 nM-10 nM. Co-treatment with R1881 and antiandrogens restored the original morphology.
All tested second-generation antiandrogens reduced R1881-stimulated growth and KLK3/FKBP5 gene expression in both cell lines, suggesting effective AR signaling inhibition in a dose-dependent manner. However, in LNCaP-ARhi cells, KLK3 expression remained elevated compared to DMSO control even at high antiandrogen concentrations. Overall, second-generation antiandrogens suppress AR signaling and growth in PCa cells, but AR overexpression may limit inhibitory efficacy, highlighting the need for strategies targeting AR-high conditions.

#2295 KMT2D loss rewires estrogen-PI3K crosstalk in endometrioid adenocarcinoma.

Jessica L. Long[1], Swornalata Pukhrambam[1], Areebah Qazi[1], Michele L. Cote[2], Greg Dyson[1], Anna Gottschlich[1], Mike R. Wilson[1]

[1]Wayne State University School of Medicine, Detroit, MI,[2]Richard M. Fairbanks School of Public Health, Indianapolis, IN

BACKGROUND: Endometrioid adenocarcinoma is defined by pervasive PI3K-pathway dysregulation and estrogen-driven growth. More than 80% of tumors harbor PI3K-pathway alterations, and approximately 20% exhibit loss-of-function mutations in the histone methyltransferase KMT2D, often at high variant allele frequencies, suggesting biological relevance rather than mutational noise. While estrogen enhances PI3K signaling through genomic and non-genomic mechanisms, the epigenetic factors governing this interaction remain poorly understood in endometrial cancer. In ER+ breast cancer, KMT2D governs regulatory crosstalk between these two pathways, raising the possibility that loss-of-function mutations in endometrial cancer alter estrogen-responsive transcription and shift oncogenic dependencies.

METHODS: KMT2D was depleted via siRNA in 12Z-ESR1 endometrial epithelial cells, followed by estradiol or vehicle treatment (n=3/group). Bulk RNA-sequencing assessed transcriptional changes. To evaluate in vivo function, a conditional Kmt2d-SET-fl/fl mouse model, yielding a catalytically impaired protein, was analyzed by uterine RNA-seq. Clinical relevance was assessed using an integrated dataset of whole-exome sequencing and transcriptomics from endometrioid adenocarcinomas. Tumors were stratified by KMT2D loss-of-function status for differential expression and pathway enrichment analyses.

RESULTS: KMT2D knockdown markedly altered estradiol-driven transcription, shifting ER-related signaling pathways that remained intact in control cells. In Kmt2d-SET-deficient mouse uteri, PI3K-Akt pathway genes were significantly upregulated even without estrogen stimulation or neoplastic change, demonstrating that KMT2D enzymatic activity constrains baseline PI3K signaling in vivo. In patient tumors, KMT2D-mutant cancers showed enrichment of oncogenic pathways consistent with convergence of estrogen and PI3K programs. Across models, KMT2D loss amplified PI3K pathway activity and altered estrogen receptor-directed transcription, suggesting increased reliance on PI3K signaling.

CONCLUSION: This supports a model in which KMT2D loss disrupts ER-regulated transcriptional programs, enhances PI3K pathway activation, and creates a potentially targetable dependency in endometrioid adenocarcinoma. Given the mixed clinical efficacy and toxicity of PI3K inhibitors, identifying molecular contexts that heighten PI3K dependence is critical. This work highlights KMT2D loss as a potential biomarker for PI3K-targeted therapy and provides new insight into epigenetic regulation of hormone-oncogenic crosstalk.

#2296 Anti-tumor actions of novel tamoxifen-melatonin drug conjugates on estrogen-resistant tumors and actions on tumor- and uterine-expressed ESR1 in SCID_BEIGE mice.

Asef Faruk[1], Sophie Dietrich[2], Yong Myoung[1], Afsana Jahan[1], Mohamed Marzouk[3], Jane E. Cavanaugh[1], Simak Ali[4], Matthew Burow[2], Darius Zlotos[5], Paula Witt-Enderby[1]

[1]Pharmaceutical Sciences, Duquesne University School of Pharmacy, Pittsburgh, PA,[2]Section of Hematology & Medical Oncology, Tulane School of Medicine, New Orleans, LA,[3]Institute of Pharmacy and Food Chemistry, University of Wu̇rzburg, Wu̇rzburg, Germany,[4]Department of Surgery & Cancer, Imperial College London, Hammersmith Hospital Campus, London, United Kingdom,[5]Dept. of Pharmaceutical Chemistry, The German University in Cairo, Cairo, Egypt

Background: Often, prolonged use of tamoxifen, an FDA approved SERM to treat ER+ breast cancer (BC), has untoward effects on the uterus and can lead to tamoxifen resistance. Novel tamoxifen-melatonin drug conjugates, C1-C5, with varying CH2- spacer lengths were developed (US Patent No. 8,785,501 B2) to offset tamoxifen-mediated tumor resistance and uterotropic actions. Two candidate compounds, C4 and C5, demonstrated anti-BC actions in MCF7, TNBC, and tamoxifen-resistant MCF7 cells (doi:10.1124/mol.119.116202).

Methods: The goal of this study was to evaluate C4- and C5-mediated actions on estrogen resistant BC in vivo and ESR1 levels in the uterus in vivo using SCID/BEIGE mouse xenografts and western blot analyses.

Results: Using CCK-8 assays, C4- and C5-mediated potency and efficacy to inhibit proliferation of ESR1 mutant (MCF7-luc Y537S, MCF7-luc D538G, MCF7-E380Q) and parental (MCF7-luc parental, MCF7-PE parental) lines revealed MCF7-lucD538G to be most sensitive to C4 (IC_{50}= 3.8μM; 43% inhibition) and C5 (IC_{50}=1.2μM; 26% inhibition). Preliminary testing using MCF7-lucD538G or parental cells bilaterally implanted into fat pads of SCID/BEIGE mice given additional estrogen or not demonstrated 60% to 90% greater tumor volumes compared to parental controls by 3 weeks, suggesting estrogen-independence. MCF7-luc D538G cells ($5x10^6$), were bilaterally implanted in the mammary pads of SCID/BEIGE mice and grown for 28 days in the absence of estrogen to allow for tumor formation. Next, treatments with C4 or C5 (1mg/kg/mouse/day, sc,), DMSO (10% in HP-β-CD), tamoxifen (5mg 60-day release pellet implanted), fulvestrant (200mg/kg/week, sc) began and continued for 28 days. Significant tumor inhibition occurred with C4 and C5 vs DMSO- and tamoxifen-treated mice; and similar tumor-inhibiting effects were observed when compared to fulvestrant (% change from baseline: DMSO=211%; tamoxifen=169%; C4=134%; C5=95%; fulvestrant=96%, n=5/group). Analysis of ESR1 levels in tumor and uterine tissue demonstrated increases in levels in tamoxifen-treated mice and no changes in C4-, C5- and fulvestrant-treated mice vs control. ESR1 stability assays were conducted in wildtype MCF7 cells exposed to vehicle (DMSO), and 10μM each of tamoxifen, C4 or C5 for 24h, followed by a withdrawal period (0, 6, 12, 24h) using media containing cycloheximide (100μg/mL). Increases in the half-life ($T_{1/2}$) of ESR1 were observed in cells exposed to tamoxifen ($T_{1/2}$=13.2h) or C4 ($T_{1/2}$=12.6h) while decreases were observed in MCF7 cells exposed to C5 ($T_{1/2}$=5.1h) compared to DMSO-treated ($T_{1/2}$=9.6h) and no treatment cells (($T_{1/2}$=7.4h).

Conclusion: Our findings indicate that tamoxifen-melatonin drug conjugates may be a viable BC treatment option for estrogen-resistant and potentially other resistant cancers while offering uterine protection.

#2297 Effects of AVA-291 (d3-testosterone) versus testosterone on MCF-7 estrogen receptor positive breast cancer cells - lack of aromatization to estradiol leads to a highly differentiated cellular proliferation profile.

Paul M. Tarantino[1], **Judith A. Boice**[2], Pamela A. Trail[3], Bradford C. Sippy[2]

[1]PMT Pharma Consulting LLC, Holden, MA,[2]Aviva Biopharm Inc, Concord, MA,[3]AGL Biotechnology Consultants LLC, Kiawah Island, SC

Introduction: Conversion of androgens to estrogens within breast tumors by aromatization plays a pivotal role in the proliferation of tumor cells expressing the estrogen receptor (ER). Testosterone (T) has demonstrated breast cancer (BC) cell proliferation effects *in vitro* and clinically has been linked to a breast cancer signal in postmenopausal women. Given this link, the increasing number of women using T therapy and its potential association with an increased risk of breast cancer is of concern. However, the androgen receptor (AR) in general, which T binds to, has been postulated to have BC suppressive effects and in certain clinical situations T has been reported to be an effective BC treatment. The ability to decouple these countervailing proliferative and antiproliferative effects of T in BC cell growth is of interest. AVA-291 (d3-testosterone) is a structurally identical, deuterium-substituted isotopologue of T that retains T's androgen effects and hepatic metabolic profile but is highly resistant to aromatization. In the studies described here, the ER+ BC cell line MCF-7 was used to assess the relative proliferative effects of T or AVA-291 (ranging from 0.1 nM to 3 μM) *in vitro*. Single 10 nM concentrations of estradiol (E2) and dihydrotestosterone (DHT) were included as positive and negative controls, respectively.
Results: Consistent with literature reports, T stimulated MCF-7 cell proliferation in a concentration-dependent manner. The proliferative effects of T were observed starting at 1 nM reaching a maximum effect at 10 nM. In contrast, AVA-291 did not stimulate proliferation over a broad concentration range with a proliferative effect only observed at concentrations ≥1 μM. As expected, the positive control (10 nM E2) demonstrated maximal stimulation and the negative control (10 nM DHT) resulted in no proliferative effect.
Conclusions: We demonstrate that T has a proliferative effect on the ER+ BC cell line MCF-7 and that AVA-291, a non-aromatizing form of T, did not stimulate cell proliferation at similar concentrations. These findings confirm prior literature reports on this effect by T and the purported underlying mechanism of androgen aromatization by MCF-7 ER+ BC cells. These results suggest that AVA-291 may be a useful alternative to T in clinical situations where the aromatization of T limits its therapeutic potential, such as hormone replacement therapy in postmenopausal women.

#2298 Spatial immune profiling reveals varying tumor microenvironments in papillary thyroid microcarcinoma.

Rhitajit Sarkar[1], Shilpa Thakur[2], Gus Fridell[3], Elijah Edmondson[2], Sonam Kumari[2], Joanna KLUBO-GWIEZDZINSKA[4]

[1]Metabolic Diseases Branch, NIH National Institute of Diabetes and Digestive and Kidney Diseases (NIDDK), Bethesda, MD,[2]National Institutes of Health, Bethesda, MD,[3]Johns Hopkins University, Baltimore, MD,[4]National Institutes of Health, Reston, VA

Introduction: Papillary thyroid microcarcinomas (PTMC) are usually indolent, but up to 10% present with clinically significant lymph node metastases or very rarely with distant metastases (M1). This study analyzes transcriptomic signatures and spatially resolved tumor microenvironment profiles in metastatic versus non-metastatic PTMC to refine risk stratification.

Methods: Patients diagnosed with indolent non-metastatic (N0/Nx) PTMCs and with primary tumors (PT) metastatic to the lateral neck lymph nodes or distant sites (N1b/M1) were selected, and RNA sequencing was done on PT and adjacent normal tissues. Multiplex immunofluorescence was performed, staining using CD8a and CD20 antibodies. Images were analyzed in a single-blinded manner using HALO (Indica Labs), and differential spatial expression was tested using a t-test or a Mann-Whitney test, depending on data distribution. Spatial proteomic profiling was performed using the NanoString (Bruker) GeoMX® platform, including Human Immune Cell Profiling, Typing and Activation Status, and MAPK Signaling Protein Modules for the nCounter analysis. Protein expression data were log2-transformed, and between-groups differential expression was assessed using Welch's two-sample t-tests with Benjamini-Hochberg adjustment. Proteins with adjusted $p<0.05$ and absolute log2 fold-change >0.5 were considered significant.

Results: The N0/Nx and N1b/M1 study cohorts consisted of 17 and 19 patients, respectively. No difference in the clinical characteristics, viz., age ($p=0.64$), sex ($p=0.24$), and median PT size ($p=0.27$), was found between the groups. Transcriptome analysis indicated significant downregulation of pathways involved in the B cell activation without a significant difference in B cell ($CD20^+/CD8a^-$) infiltration in the PT ($p=0.43$) nor in the PT rims ($p=0.92$) from the N1b/M1 compared to N0/Nx group. However, cytotoxic T cells ($CD8a^+/CD20^-$) significantly populated the rims of the PT from N1b/M1 group compared to N0/Nx ($p=0.007$). Spatial immune profiling revealed that N1b/M1 PT had significantly higher T-cell infiltration (CD3; padj=0.02) than N0/Nx tumors and showed pronounced expression of the immune evasion molecule PD-L2 (padj=0.02). N1b PT also showed high stemness (CD44, padj=0.001). Compared to N1b PT, M1 showed higher immune evasion (PD-L1, padj=0.01; PD-L2, padj=0.049).

Conclusion: Metastasis-prone PTMC is characterized by enhanced stemness, and increased T cell infiltration, accompanied by upregulation of immune evasion molecules, suggesting that immune evasion may play a critical role in pathogenesis of metastases.

#2302 Prognostic biomarkers associated with the progression of cervical premalignant lesions to cancer: A scoping review.

Luis Giraldo-Barrios, Salome Andrade-Romero, Jonathan Villalobos-Escorcia, Gerardo Barboza-Guevara, **Ines Benedetti**

School of Medicine, Histopathology Research Group, Universidad de Cartagena, Cartagena, Colombia

Introduction: Cervical cancer is the fourth most common cancer and the fourth leading cause of cancer-related death in women, worldwide. Advances in understanding the molecular biology of premalignant cervical lesions have shown that not all low-grade squamous intraepithelial lesions progress to high-grade squamous intraepithelial lesions and, nor will all of these progress to invasive carcinoma. Prognostic biomarkers make it possible to predict the evolution of high-grade squamous intraepithelial lesions and to identify patients at risk of progression to cancer. Biomarkers related to cell proliferation, DNA methylation, and immune regulation have been proposed, although the evidence is extensive and heterogeneous.We conducted a scoping review to search possible promising biomarkers for risk stratification of high-grade squamous intraepithelial lesions progression.
Methods: We followed the methodological framework proposed by Arksey and O'Malley and the guidelines established by PRISMA-ScR. A systematic literature search was conducted in Web of Science, PubMed, and Embase using terms such as "high-grade squamous intraepithelial lesions," "uterine cervical neoplasms," "biomarkers," and "disease progression," from the inception of each database through May 30, 2025.
Results: A total of 11,795 articles were identified; after removing 4,447 duplicates with Rayyan®, 7,348 records remained for title and abstract screening. Of these, 619 were assessed in full text and 34 were included in the qualitative synthesis. In high-grade squamous intraepithelial lesions, p16, Ki-67, and detection of E6/E7 were associated with a higher risk of progression, whereas FAM19A4/miR124-2 methylation was associated with regression. Overexpression of markers such as RFC4, RIPK4, ATAD2, EZH2, IMP3, ADAR1, AEG-1, TK1, PAK1, aPKCι/λ, tenascin-C, HABP1, CFTR, CPE, and the Np63/TAp63 ratio was linked to greater aggressiveness, lymph node metastasis, and poorer survival.
Conclusions: The most promising biomarkers for risk stratification of high-grade squamous intraepithelial lesions progression are p16, Ki-67, FAM19A4/miR124-2 methylation, and E6/E7 mRNA. Their combined use could optimize the identification of patients who require active management and reduce overtreatment in cases with a high probability of regression. Standardization of methods and cut-off values is required for their clinical validation.

#2303 Androgen receptor expression in breast cancer and its prognostic significance: A systematic review and meta-analysis.

Elias Ferreira[1], Luis Giraldo-Barrios[1], Laura Suarez[1], Maria P. Valera[1], Jose Aldana[1], Pedro Araujo[2], **Ines Benedetti**[1]

[1]School of Medicine, Histopathology Research group, Universidad de Cartagena, Cartagena, Colombia,[2]School of Medicine, Universidad de Cartagena, Cartagena, Colombia

Background: Molecular classification of breast cancer subtypes is based on the expression of estrogen, progesterone and HER2 receptors. The androgen receptor has emerged as a biomarker however, its prognostic role remains incompletely elucidated. Objective: to determine androgen receptor expression value as a biomarker and its potential impact on the clinical course of breast cancer.
Methods: We conducted a systematic review and meta-analysis in accordance with the PRISMA statement, protocol was registered in PROSPERO (CRD420251166750). PubMed, Embase, and Web of Science were searched from inception to May 2025. We included analytical observational studies that enrolled histologically confirmed breast cancer, of any molecular subtype, and evaluated tumor androgen receptor expression by immunohistochemistry using a predefined positivity cut-off. Definitions of androgen receptor positivity were accepted as reported in each study, given the limited number of studies per outcome, which precluded formal subgroup analyses by cut-off. Studies were eligible if they reported hazard ratios (HRs) with 95% CIs for survival outcomes. Two reviewers independently assessed study eligibility, extracted data, and evaluated risk of bias using the Newcastle-Ottawa Scale; disagreements were resolved by consensus. Given the between-study heterogeneity, hazard ratios were pooled using an inverse-variance random-effects model, and heterogeneity was quantified with the I^2 statistic.
Results: From a total of 966 records identified, 118 full texts were assessed after removing 228 duplicates, including 15 studies for qualitative synthesis. Seven of these reported hazard ratios for the predefined outcomes and were included in the meta-analysis. For overall survival in patients with triple-negative breast cancer and androgen receptor expression, the pooled HR was 0.60 (95% CI 0.29-1.21; $I^2 = 85.8\%$, $p = 0.0009$), showing a non-significant trend toward better survival in AR-positive tumors. For breast cancer-specific survival in AR-positive breast cancer, the pooled HR was 0.55 (95% CI 0.20-1.49; $I^2 = 88.2\%$, p for heterogeneity < 0.0001), also indicating a non-significant trend toward reduced breast cancer mortality.
Conclusions: Although our meta-analysis did not demonstrate a statistically significant association between androgen receptor expression and overall or breast cancer-specific survival, these findings are relevant because they highlight substantial heterogeneity across studies. Differences in how androgen receptor status was assessed, along with variability in the definition and reporting of prognostic outcomes, likely contribute to the inconsistent estimates. Developing standardized criteria for positivity and harmonized outcome reporting will be crucial to clarify the true prognostic role of androgen receptor in breast cancer.

#2306 Gene polymorphisms in LEPR and PTGS2 contribute for prognostic evaluation in breast cancer.

Alessandra Brandao de Souza[1], Daniely Regina Freitas-Alves[1], Taiana Sousa Lopes da Silva[2], Mario da Silva Ramos[3], Matheus de Oliveira Afonso[3], Jessica Vilarinho Cardoso[4], Jamila Alessandra Perini[4], Rosane Vianna-Jorge[3]

[1]Fundacao Oswaldo Cruz (Fiocruz), Rio de Janeiro, Brazil,[2]Instituto Nacional do Cancer, Rio de Janeiro, Brazil,[3]Universidade Federal do Rio de Janeiro, Rio de Janeiro, Brazil,[4]Universidade Estadual da Zona Oeste, Rio de Janeiro, Brazil

Breast cancer is the second most frequent neoplasm worldwide and is considered a heterogeneous disease, with distinct genetic backgrounds and diverse histological and molecular presentations that influence prognosis. Besides tumor-specific characteristics, individual genetic variations may also potentially impact disease outcomes, and need to be assessed in prognostic models. Here, we employed a candidate gene approach, focusing on biologically relevant pathways, such as inflammation, to investigate the effects of single nucleotide polymorphisms (SNPs) on breast cancer outcomes. The investigation involved a 10 year follow-up of a prospective cohort of Brazilian women (N = 1038) with unilateral, nonmetastatic breast cancer treated at the National Cancer Institute (CAAE 55929416.8.0000.5240). Blood samples were genotyped for 14 SNPs from five genes (*LEP*, *LEPR*, *PTGS2*, *VEGFA* and *EGFR*) using Real-Time PCR. Linkage disequilibrium and haplotypes were evaluated using Haploview. Survival curves were estimated using the Kaplan–Meier method. The effects of SNPs on disease-free survival (DFS) and breast cancer specific survival (BCSS) were estimated using hazard ratios (HR) and 95% confidence intervals (95% CI). Adjusted hazard ratios (HRadj) were obtained through Cox regression multivariate models. Improved DFS was detected for *LEPR* rs1137101 when considering the whole population (HR = 0.45; 95%CI 0.26 - 0.77), post-menopausal women (HR = 0.57; 95%CI 0.37 - 0.88), or among patients with luminal tumors (HR = 0.44; 95%CI 0.25 - 0.80). In contrast, *PTGS2* rs689466 was associated with worse outcomes of DFS (HR = 1.70; 95%CI 1.21 - 2.37) and BCSS (HR = 1.67; 95%CI 1.13 - 2.47) among post-menopausal women, as well as among obese patients (HR = 1.68; 95%CI 1.08 - 2.64 for DFS and HR = 1.82; 95%CI 1.08 - 3.04 for BCSS). Because *LEPR* rs1137100 and *LEPR* rs1137101 showed significant linkage disequilibrium (R^2 = 0,89), they were also evaluated together, in combination with *PTGS2* rs689466, considering the three SNPs (A>G, A>G, A>G). The occurrence of at least two variant alleles in either *LEPR* rs1137100 or *LEPR* rs1137101, in combination with the reference genotype of *PTGS2* rs689466 showed improved DFS (HR = 0.60; 95%CI 0.37 - 0.96) within the whole population of the study. In contrast, the occurrence of *PTGS2* rs689466 variant alleles in combination with both *LEPR* rs1137100 and *LEPR* rs1137101 reference genotypes showed the worst outcomes even in multivariate models, significantly affecting both DFS (HRadj = 1.75; 95%CI 1.18 - 2.60) and BCSS (HRadj = 1.72; 95%CI 1.07 - 2.75) for the whole population, as well as for post-menopausal women, with DFS (HRadj = 2.09; 95%CI 1.16 – 3.77) and BCSS (HRadj = 2.60; 95%CI 1.35 - 5.0). The present results indicate the importance of tailoring prognostic models for breast cancer considering both tumor and individual biomarkers.

#2307 Body mass index-associated transcriptomic signatures reveal immune, stromal, and metabolic rewiring in non-small cell lung cancer: Insights into the obesity paradox.

Roberto Borea, Eswar Shankar, Francesco Drago, Carlos Ayala de Miguel, Estela Puchulu-Campanella, Christian Rolfo, Giovanni Nigita

Division of Medical Oncology, Department of Internal Medicine, The Ohio State University Comprehensive Cancer Center, College of Medicine, Columbus, OH

Although obesity increases cancer risk, obese patients with non-small cell lung cancer (NSCLC) paradoxically exhibit better survival. The biological basis of this "*obesity paradox*" remains unclear. High-throughput profiling can reveal body mass index (BMI)-linked transcriptional networks that shape immune, metabolic, and stromal responses, clarifying whether this "obesity paradox" reflects true tumor-microenvironment interactions rather than clinical confounders.We analyzed whole-transcriptome samples from 263 NSCLC patients in the ORIEN Avatar data at The Ohio State University. Patients were stratified into Lean (BMI<25; n=93), Overweight (25≤BMI<30; n=78), and Obese (BMI≥30; n=92) groups. Differential expression (DE) analyses (Lean vs Overweight, Lean vs Obese, Overweight vs Obese) were performed across all groups. Significantly deregulated transcripts ($p<0.01$ and $|\text{fold-change}|>1.5$) were retained for downstream analyses. Canonical pathway enrichment was conducted using Ingenuity Pathway Analysis ($p<0.05$).Distinct BMI-dependent transcriptomic signatures emerged. In Obese vs Lean, 40 transcripts were deregulated and enriched for metabolic processes (NAD^+ biosynthesis, non-oxidative PPP), suggesting metabolic reprogramming. Overweight vs Lean revealed 358 deregulated transcripts with upregulated immune activation (Th1/Th2, ICOS-ICOSL, IL-2 family, PI3K signaling in B cells), indicating enhanced adaptive, particularly T-cell, immunity. Obese vs Overweight revealed 304 deregulated transcripts enriched for extracellular matrix, platelet-collagen, and osteoclast signaling, implying stromal remodeling suppression in obesity. Overlap of deregulated transcripts was modest (OvsL∩OvsOw=1; OvsL∩OwvsL=7; OvsOw∩OwvsL=52; triple overlap≈0), implying group-specific biology.Our findings delineate three BMI-linked programs in NSCLC: immune activation in overweight tumors, ECM suppression and platelet signaling in obesity, and metabolic rewiring in obese versus lean tumors. Moderate adiposity appears to foster an immune-active microenvironment, whereas higher adiposity induces stromal quiescence and redox adaptation, consistent with reports of improved immunotherapy outcomes at higher BMI. The obese subgroup's ECM/platelet and NAD^+ salvage/PPP signatures nominate combinatorial strategies (e.g., stromal or antiplatelet agents with PD-1/PD-L1 blockade, NAMPT inhibition) and suggest that BMI-associated molecular heterogeneity may contribute to the "obesity paradox."

#2308 A pan-system approach for mutational signature identification and etiology assignment in cancer genomics.

Maria Zhivagui[1], Shams Al-azzam[2], Jessica Au[2], Peter Nguyen[1], Zichen Jiang[2], Mark D. Barnes[2], Ludmil B. Alexandrov[2]

[1]University of Nevada, Las Vegas (UNLV), Las Vegas, NV,[2]University of California San Diego, San Diego, CA

Purpose: Somatic mutations accumulate in the genomes of both normal and cancer cells. Mutagens imprint characteristic genomic patterns of somatic mutations, termed, mutational signatures. Accurate identification of mutational signatures is essential for linking genotoxic exposures and endogenous processes to cancer etiology. However, technical artefacts, sequencing noise, and platform heterogeneity often compromise the fidelity of signature detection, limiting mechanistic insights and biomarker discovery.

Methods: We developed *SigRescueR*, a pan-system computational tool that performs noise correction and robust mutational signature identification across diverse sequencing platforms. The framework integrates adaptive artefact filtering, robust signature reconstruction, and cosine similarity-based signal rescue across diverse mutational classes, including single base substitutions (SBS), insertions and deletions (indels), doublet base substitutions (DBS), and strand-bias mutation categories.

Results: We applied *SigRescueR* to the largest collection of experimentally derived mutational profiles assembled to date, encompassing over 4,200 genome-wide sequencing profiles across 42 model systems exposed to 120+ mutagenic agents under standardized experimental conditions. Comparative analysis across human, mouse, rat, chicken, and C. elegans models revealed 49 robust experimental mutational signatures. Several experimentally derived signatures reflected conserved DNA damage patterns across species and models exposed to the same agent or related chemicals, while others were species- or model-specific, suggesting system-dependent variability in mutational response. Moreover, several experimental mutational signatures corresponded to established COSMIC patterns, while others represented previously uncharacterized DNA damage processes in human cancers. Importantly, this compendium enabled causal assignment of previously unexplained COSMIC signatures, namely SBS94 and SBS95, to defined environmental exposures.

Conclusion: Together, *SigRescueR* and this compendium provide a unified, high-resolution view of mutagenesis, connecting molecular toxicology, cancer genomics, and biomarker discovery. This integrative framework refines how we trace, interpret, and incite measures to prevent the genomic imprints of carcinogenesis.

#2309 Exposure to solid fuel burning and transcriptomic changes in the nasal epithelium in never smoking women in Guatemala.

Batel Blechter[1], Lingge Yu[2], Wei Hu[3], Kaytlyn Salmons[4], Maggie Clarke[5], Dana Barr[4], Shuguang Leng[6], Gang Liu[2], Jennifer E. Beane-Ebel[2], Kyle Steenland[7], Nathaniel Rothman[1], Qing Lan[8]

[1]National Cancer Institute, Rockville, MD,[2]Boston University, Boston, MA,[3]National Cancer Inst. Div. of Cancer Epidemiology & Genetics, Bethesda, MD,[4]Colorado State University, For Collins, CO,[5]Colorado State University, Fort Collins, CO,[6]University of New Mexico, Albuquerque, NM,[7]Emory University, Atlanta, GA,[8]NCI Div. of Cancer Epidemiology & Genetics, Bethesda, MD

Introduction Understanding environmental-exposure associated gene expression alterations provides insights into how they contribute to cancer risk. We previously showed that individuals exposed to diesel engine exhaust (DEE) or smoky coal exhibit gene expression changes overlapping with those of smokers, suggesting shared mechanisms of toxicity. Wood smoke, produced by incomplete combustion of biomass fuels, is classified as probably carcinogenic (Group 2A), yet studies of its gene expression effects are limited. Here, we conducted a pilot study to examine whether genes associated with smoking, DEE, and smoky coal exposure are also differentially expressed in individuals exposed to wood smoke. **Methods** We studied 16 never-smoking women from Guatemala in the Household Air Pollution Intervention Network trial who use wood as their primary fuel. $PM_{2.5}$ exposure was measured with monitors, and urinary 1-Hydroxypyrene (1-OHP) was assessed as a biomarker of polycyclic aromatic hydrocarbons exposure. Nasal turbinate brush samples underwent bulk RNA-seq and were processed via a GTEx-based pipeline. Differential expression (DE) analysis to compare high vs. low $PM_{2.5}$ and 1-OHP was conducted using limma. Gene Set Enrichment Analysis was used to evaluate whether previously reported gene signatures associated with smoking, DEE exposure, and smoky coal use, were enriched among genes up- and down-regulated for each exposure, ranked by t-statistics. **Results** We found that both up-regulated and down-regulated smoking-associated signatures were concordantly enriched in wood smoke exposed women with high levels of $PM_{2.5}$ ($p = 0.001$ and $p=0.04$, respectively) and among women with elevated 1-OHP levels ($p < 0.001$ and $p = 0.015$, respectively). Genes down-regulated with exposure to smoky coal and DEE were also suppressed in participants with high levels of $PM_{2.5}$ ($p=0.005$ for smoky coal signature) and 1-OHP ($p<0.001$ & $p=0.008$ for smoky coal and DEE signatures, respectively). Notably, the signatures included genes such as *CYP1A1, CYP1B1,* and *CDH1,* which are involved in activation and detoxification of carcinogens. **Conclusions** Wood smoke exposure in never smokers was associated with airway gene expression changes with similarities to those associated with smoking, DEE, and smoky coal, suggesting shared molecular response to combustion pollutants and pathways linked to lung cancer development. Larger studies are needed to replicate these findings and further examine biomass smoke in lung carcinogenesis.

#2310 Development and validation of a plasma proteomics signature for earlier diagnosis of ovarian cancer using prospectively collected blood samples.

Nan Lin[1], Ngo Long[2], Allison F. Vitonis[1], Tara Eicher[3], SHELLEY TWOROGER[4], Simon T. Dillon[2], Towia A. Libermann[2], Daniel W. Cramer[1], John Quackenbush[3], Kathryn L. Terry[1], Naoko Sasamoto[5]

[1]Department of Obstetrics and Gynecology, Brigham and Women's Hospital and Harvard Medical School, Boston, MA,[2]Department of Medicine, Beth Israel Deaconess Medical Center and Harvard Medical School, Boston, MA,[3]Department of Biostatistics, Harvard T.H. Chan School of Public Health, Boston, MA,[4]Division of Oncological Sciences, Knight Cancer Institute, Oregon Health & Science University, Portland, OR,[5]Department of Obstetrics and Gynecology, University of Washington, Seattle, WA

Background: There is currently no ovarian cancer biomarker appropriate for screening which is partially due to using retrospective clinical samples obtained at the time of diagnosis for biomarker discovery. Thus, we sought to discover novel plasma proteomic biomarkers for ovarian cancer early detection using prospectively collected blood samples.
Method: We evaluated 10,778 plasma proteins measured using the SomaScan v5.0 assay in blood drawn at least three years prior to ovarian cancer diagnosis and matched controls in the Prostate, Lung, Colorectal and Ovarian Cancer Screening Trial (PLCO; n=98, training dataset) and the Nurses' Health Studies (NHS; n=99, replication dataset). We used a conditional logistic regression to identify individual proteins associated with ovarian cancer in the two datasets separately. We also compared plasma proteins for early-stage and late-stage ovarian cancer in blood collected at diagnosis in the PreOperative Pelvic Mass Study to age-matched population-based controls (PreOp; n=134). Then we used Elastic Net to develop a proteomic-based score to discriminate ovarian cancer cases from controls in PLCO, compared to a model with CA125 alone, and validated the proteomic-based score performance in NHS by calculating the area under the receiver operating characteristic curve (AUC) and 95% confidence interval (CI).
Results: Plasma proteins associated with ovarian cancer in blood samples collected prospectively differed from those associated with blood samples collected at diagnosis of early-stage disease compared to controls. There were 99 proteins associated with ovarian cancer diagnosed at least 3 years from blood collection ($p<0.05$) in PLCO, where 2 proteins, RCN3 and OBP2B, replicated in NHS ($p<0.05$). Of these 99 proteins, majority were not associated with ovarian cancer in PreOp and only three proteins overlapped (i.e., SERPINF2, ASAH2, BAGE3). In PLCO, adding a proteomic-based score comprised of 56 proteins to a model with CA125 alone significantly ($p=0.02$) improved discriminating ovarian cancer cases from controls with an AUC (95%CI) from 0.65(0.50-0.80) to 0.86(0.67,1.00). In NHS, proteomic-based score resulted in an AUC of 0.60(0.49-0.72) with marginal significance.
Conclusion: Our results revealed plasma proteomic profiles differ between prospectively collected blood samples at least 3 years prior to diagnosis and blood samples collected at time of diagnosis regardless of stage. We developed a proteomics-based score that improved upon CA-125 alone, although application to an independent cohort did not demonstrate a strong improvement. However, differences between studies (e.g., menopausal status and hormone therapy use) may explain this variation.

#2311 Natural history and biomarker discovery in gastric preneoplasia: Insights from the TUMMIE longitudinal study.

Tyler Anthony Simi[1], Fabian Leonardo Castro Valencia[2], Nanci Chavarria Villa[1], Ana Patricia Estrada-Florez[1], Angelica Michelle Rolon[1], Krish Jagasia[3], Alexa Morales-Arana[1], Alex Zhornitskiy[1], Asha Gupta Cogdill[1], Jeffrey Zheng-Hsien Ko[1], Joseph Marsano[1], Luis G. Carvajal-Carmona[1]

[1]UC Davis, Davis, CA,[2]Sciences and Health Sciences, University of Tolima, Ibague, CA,[3]UC San Diego, La Jolla, CA

Background: Gastric cancer remains a leading cause of cancer mortality worldwide, with marked racial and ethnic disparities in incidence and outcomes. Gastric intestinal metaplasia (GIM) is a key preneoplastic lesion, yet its natural history and progression biomarkers are poorly understood, particularly in diverse U.S. populations.
Methods: The TUMMIE study is a longitudinal cohort of patients with gastric preneoplasia at UC Davis Health. In a pilot phase, we enrolled 69 individuals (mean age 66 years) with histologically confirmed GIM. The cohort demographic composition was 67% female and 33% male, with race/ethnicity distributed as 67% non-Hispanic White, 15% Asian, 7% Black, 7% Hispanic White, and 4% multiracial, Native Hawaiian/Other Pacific Islander, or missing. Twenty-two patients (32%) reported a personal history of cancer and nearly half (48%) reported a family history of gastric conditions.. Among these, 39 participants provided stool and saliva samples, which were analyzed for Helicobacter pylori (H. pylori) strain detection using digital droplet PCR (ddPCR). We assessed concordance between clinical testing and ddPCR-based detection in both sample types. Additionally, we conducted a scoping review of published biomarkers associated with gastric preneoplasia progression.
Results: Of the 39 biospecimen donors, 8 tested high positive for H. pylori by ddPCR. Strain typing revealed clear variation in H. pylori virulence profiles, with ddPCR detecting both CagA-positive and CagA-negative strains across participants, including several samples with strong high-droplet signals (>100 to >1000) thereby indicating strain diversity in the cohort. Clarithromycin resistance mutations were detected by ddPCR, this indicates the presence of both antibiotic-resistant and antibiotic-sensitive H. pylori strains. Several samples carried VacA toxin-associated alleles and EPIYA motifs. Preliminary analyses show correlations between ddPCR detection and clinical test results. Demographic characteristics and infection rates varied across racial/ethnic groups, highlighting potential disparities in risk profiles. The scoping review identified candidate biomarkers in pathways related to inflammation, immune response, and epithelial transformation.
Conclusions: This pilot phase demonstrates feasibility of biospecimen collection and molecular characterization in a multiethnic cohort with GIM. Integration of ddPCR-based H. pylori detection and biomarker discovery may inform risk stratification and surveillance strategies for gastric cancer prevention. Expanded longitudinal follow-up will enable validation of progression biomarkers and clarify racial/ethnic differences in disease trajectory.

#2312 ASH-MARCC: Assessment of smoking history via methylation and reference-based cell composition in human tissue samples.

Minghui Zhang, Brock C. Christensen, Lucas A. Salas Diaz

Dartmouth Geisel School of Medicine, Lebanon, NH

Introduction: Cigarette smoking (CS) is associated with adverse health effects, including an increased risk of cancer development. Epigenome-wide association studies (EWAS) show that CS significantly alters DNA methylation (DNAm). While several DNAm-based predictors of smoking history have been trained using blood samples, their accuracy in tissue types remains limited. We aimed to develop a predictive model for smoking history that integrates DNAm data with reference based cell composition estimates in human tissue samples.

Methods: We utilized Infinium MethylationEPIC array data from the Genotype-Tissue Expression (GTEx) project as training and testing, and the Clinical Proteomic Tumor Analysis Consortium Lung Adenocarcinoma (LUAD) cohort as external validation. Quality control and beta value extraction were performed with ENmix. Cell type proportions (CPs) were estimated by HiTIMED. Surrogate variables (SVs) were derived from GTEx to account for batch effects. EWAS was conducted to identify differentially methylated CpGs (DMC), adjusting for tissue type, sex, age, CPs, and SVs. GTEx was split into training and testing (70:30) sets. DMC, CPs, sex, age, and tissue type were used to train an Elastic Net model predicting smoking history (smoker vs. non-smoker). Model accuracy was assessed by the area under the receiver operating characteristic curve (AUC) comparing the reported smoking status to the predicted probabilities. LUAD normal samples were classified into 3 groups based on predictions for survival analysis using Coxph.

Results: After QC, 654 GTEx normal, 183 normal adjacent and 199 primary tumor LUAD samples were retained. 198 DMC sites were enriched for cellular response to xenobiotic stimulus pathways. The model selected 83 features at min lambda, including 79 CpG sites, age, NK and CD8 CPs, and breast tissue type. cg21566642 (*Lnc-ECEL1-1*) overlapped with 3 published blood predictors; cg07339236 and cg11554391 with one. The ASH-MARCC model demonstrated near-perfect internal performance (training AUC 0.98, 95% CI 0.97-0.99; testing AUC 0.91, 95% CI 0.88-0.95). In external validation, the model maintained high accuracy on normal samples (AUC 0.81, 95% CI 0.75-0.87), while performance decreased but remained informative on tumor samples (AUC 0.66, 95% CI 0.58-0.74). The highest risk group showed a non-significant risk (adj-HR 2.1, 95% CI 0.98-4.56) versus the lowest.

Conclusions: We developed ASH-MARCC, a DNA methylation based model to assess smoking history in human tissue. An objective and accurate smoking classification enhances clinical decision-making across cancer types by treatment personalization and prognostic precision. By enabling direct evaluation of smoking exposure in cancer tissues, especially when self-reported information is unavailable, ASH-MARCC offers a powerful tool with crucial applications in both research and clinical settings.

#2313 Association of NMR-based metabolomics and lung cancer risk in the UK biobank.

Beiwen Wu[1], Jennifer D. Brooks[1], Joanne Kotsopoulos[2], Rayjean J. Hung[3]

[1]Dalla Lana School of Public Health, University of Toronto, Toronto, ON, Canada,[2]Women's College Research Institute, Toronto, ON, Canada,[3]Lunenfeld-Tanenbaum Research Institute, Sinai Health System, Toronto, ON, Canada

BackgroundLung cancer remains the most common type of cancer and the leading cause of cancer-related death globally. Nuclear magnetic resonance (NMR) techniques enable detailed profiling of lipoprotein subclasses by concentrations and compositions, offering potential opportunity for lung cancer risk screening.

MethodsWe included 273,375 participants (2164 developed lung cancer) from the UK Biobank, with 251 metabolites (170 absolute and 81 ratio metabolites) measured at baseline. Cox proportional hazards models were used to estimate the individual hazard ratio (HR) between each metabolite and lung cancer risk, adjusting for core and extended covariates. P-values were corrected for multiple testing. Subgroup analyses were conducted by sex, age group, and smoking status. Principal component analyses (PCA) were performed separately on absolute and ratio metabolites. PCs explaining 90% of the variance in each set were incorporated into Cox models to assess patterns in metabolomic profiles on lung cancer risk. A LASSO penalty was applied to identify key metabolites for lung cancer risk and their associations were obtained using multivariable Cox regression.

ResultsA total of 163 metabolites (98 absolute and 65 ratios metabolites) were found to be significant. Among absolute metabolites, glycoprotein acetyls showed the strongest association with increased risk [HR per SD = 1.19, 95% CI = 1.14-1.25], whereas the degree of unsaturation in fatty acids showed the strongest protective association [HR per SD = 0.84, 95% CI = 0.80-0.88]. Across all lipoprotein compositions, only triglycerides consistently showed increased risk in the main and subclasses of lipoproteins [HR range: 1.00-1.07], with 5 associations reaching statistical significance. Similar patterns were observed for ratio metabolites, except for phospholipid percentages, which showed increased risk. These patterns remained largely unchanged after adjustment for extended covariates, except for triglycerides, whose associations were attenuated and even reversed in some cases. In subgroup analyses, the largest differences were observed for triglycerides, where stronger positive associations were seen among females, former smokers, and people aged <60 years. In absolute metabolites, PC1 (VLDL-driven), PC2 and PC3 (HDL-driven) showed increased risk; PC8 and PC9 (glycolysis- and fatty acids-driven) showed decreased risk. In ratio metabolites, PC1, PC4, and PC6 (LDL and VLDL-driven) showed increased risk, PC5, PC7 and PC9 (fatty acids-driven) showed decreased risk. The LASSO-Cox models selected 15 metabolites and the direction and magnitude of these metabolites were largely consistent with those observed in the individual CoxPH models.

ConclusionFindings from this study highlighted the complexity of metabolic patterns and their role in lung cancer risk, warranting further investigation through pathway analyses.

#2314 Plasma metabolomics profiles in the progression of adverse liver conditions to liver cancer.

Xinyuan Zhang[1], Longgang Zhao[2], Yun Chen[2], Lu Cai[3], Michelle Lai[4], Wenjie Ma[5], Andrew T. Chan[5], Xuehong Zhang[2]

[1]Brigham and Women's Hospital, Boston, MA,[2]Yale School of Nursing, Orange, CT,[3]University of Louisville, Louisville, KY,[4]Beth Israel Deaconess Medical Center, Boston, MA,[5]Massachusetts General Hospital, Boston, MA

Background: Circulating metabolites may mark the progression from metabolic dysfunction-associated steatotic liver disease (MASLD) and liver cirrhosis to liver cancer. We characterized metabolomic patterns and evaluated prospective associations with stage-specific transitions.

Methods: We used data from 47,972 participants in Mass General Brigham Biobank with Nightingale metabolomics and longitudinal medical records before and after assessment. Stage at metabolomics was defined based on if MASLD, liver cirrhosis, or liver cancer had occurred by International Classification of Diseases codes. For participants with no adverse liver condition, we excluded those with Charlson comorbidity index >5 or death in 1 year of assessment to limit the impact of other diseases. Adjusted means and linear trends were estimated with covariates including demographics, comorbidities, and lifestyles. Adjusted Cox models examined the associations of pre-cancer metabolite and incident liver cancer. Interactions between metabolite and the hepatic fat-associated polygenic risk score (PRS) were tested.

Results: At metabolomics assessment, 17,869 participants had no adverse liver condition, 2041 had MASLD, 1774 had liver cirrhosis, and 206 had liver cancer. In the 249 metabolomic variables, 181 displayed significant linear trends by stage (FDR <0.05), e.g., small HDL cholesterol and very large HDL cholesterol / total lipids ratio decreased while large HDL free cholesterol / total lipids ratio and tyrosine increased with progression. These metabolites also show significant associations (FDR <0.05) with liver cancer incidence in participants with no liver disease or cirrhosis. We did not observe metabolite × PRS interactions (FDR >0.05).

Conclusions: Metabolomic profiles capture signals along the MASLD - cirrhosis - liver cancer continuum. These markers may improve risk stratification, timing of surveillance, and inform the biological mechanisms along the liver conditions spectrum.

Top metabolites in the progression of adverse liver conditions to liver cancer.

	Adjusted mean level					Association with incident liver cancer					
						No liver disease		MASLD		Liver cirrhosis	
Metabolite	No liver disease	MASLD	Liver cirrhosis	Liver cancer	FDR-linear	HR (95% CI)	FDR	HR (95% CI)	FDR	HR (95% CI)	FDR
Small HDL cholesterol	-0.21	-0.11	-0.60	-0.83	<0.001	0.72 (0.62, 0.82)	<0.001	0.65 (0.32, 1.29)	0.67	0.66 (0.54, 0.81)	0.004

#2315 Metabolomics and liver cancer risk: A systematic review of prospective studies.

Longgang Zhao[1], Mengjie Hu[2], Yun Chen[1], Xinyuan (Cindy) Zhang[3], Xuehong Zhang[1]

[1]Yale University, School of Nursing, Orange, CT,[2]Yale University, School of Public Health, New Haven, CT,[3]Brigham and Women's Hospital, Boston, CT

Introduction Emerging metabolomic studies have identified circulating metabolites associated with liver cancer, yet evidence remains inconsistent across populations. To address these gaps, we conducted the most comprehensive systematic review of prospective metabolomic studies to date, integrating results across different populations to identify metabolic signatures of liver cancer.
Methods We followed Preferred Reporting Items for Systematic Reviews and Meta-Analyses guidelines to report our findings. We systematically searched PubMed through January 2025, for prospective cohort or nested case-control studies examining pre-diagnostic circulating metabolomic profiles with liver cancer. Two reviewers independently screened, extracted, and evaluated studies. Due to heterogeneity in study design and outcome reporting, findings were synthesized descriptively. Direction and effect size of metabolite associations was summarized. Enrichment analysis was conducted for those metabolites significantly associated with liver cancer.
Results Twenty-four prospective studies were included, of which eight nested case-control or cohort studies with 1,626 cases of liver cancer, providing risk estimates for per standard deviation (SD) increase. Seven studies used liquid chromatography-mass spectrometry and one used nuclear magnetic resonance. Across these studies, 98 unique metabolites were evaluated, and consistent metabolic alterations preceding liver cancer were observed. Elevated aromatic amino acids (tyrosine, phenylalanine), glutamate, arginine, and conjugated bile acids were positively associated with liver cancer risk with risk ratios (RRs for per SD increase) ranging from 1.49 to 5.82, whereas branched-chain amino acids (leucine and isoleucine), lysine, glutamine, and lysophosphatidylcholines showed inverse associations with RRs ranging from 0.15 to 0.75. Saturated phosphatidylcholine, sphingosine, and select amino acid derivatives (cystathionine, kynurenine) were positively associated (RRs, 1.62-3.32), while androgen sulfates and creatine were inversely related (RRs, 0.20-0.56). The direction was generally consistent across the majority of the 24 prospective studies. Three most enriched pathways were taurine and hypotaurine metabolism, valine/leucine and isoleucine biosynthesis, and arginine biosynthesis.
Conclusions Our systematic review indicates that liver cancer risk was associated with increased aromatic amino acids, bile acid conjugation, and lipid remodeling, and decreased branched-chain amino acids and androgenic steroids. The identified metabolic signatures may inform future efforts in risk prediction, early detection, and targeted prevention for liver cancer.

#2316 Circulating lipid and bile acid metabolites as predictors of colorectal cancer risk: A multi-cohort metabolomics meta-analysis.

Mary Playdon[1], Emma Braun[2], Kelly Santucci[2], A. Heather Eliassen[3], Edward L. Giovannucci[4], Marc Gunter[5], Steven Moore[6], Lorelei A. Mucci[7], Xiao-Ou Shu[8], Mingyang Song[9], Ying Wang[10], Danxia Yu[8], Wei Zheng[8], Cornelia M. Ulrich[11], Jennifer Ose[12]

[1]Nutrition and Integrative Physiology, University of Utah Huntsman Cancer Institute, Salt Lake City, UT,[2]University of Utah, Salt Lake City, UT,[3]Assistant Professor, Harvard University, Boston, MA,[4]Professor of Nutrition & Epidem., Harvard TH Chan School of Public Health, Boston, MA,[5]Imperial College London, London, United Kingdom,[6]National Cancer Inst. Div. of Cancer Epidemiology & Genetics, Bethesda, MD,[7]Harvard T.H. Chan School of Public Health, Boston, MA,[8]Vanderbilt University Medical Center, Nashville, TN,[9]Harvard TH Chan School of Public Health, Boston, MA,[10]American Cancer Society, Atlanta, GA,[11]University of Utah Huntsman Cancer Institute, Salt Lake City, UT,[12]Hochschule Hannover - University of Applied Sciences and Arts, Hanover, Germany

Background: Metabolic dysregulation has been implicated in colorectal cancer (CRC) development but not fully characterized. We conducted a large-scale metabolomics meta-analysis to identify circulating metabolites associated with future CRC risk across heterogeneous populations.

Methods: We harmonized pre-diagnostic metabolomic and covariate data from seven prospective cohorts: the Cancer Prevention Study II Nutrition Cohort (CPS-II), the Prostate, Lung, Colorectal, and Ovarian Cancer Screening Trial (PLCO), the Women's Health Initiative Metabolomics in Nutrition Study (WoMIN), the Nurses' Health Study (NHS), the Health Professionals Follow-up Study (HPFS), the Shanghai Women's Health Study (SWHS), and the Shanghai Men's Health Study (SMHS). Using multivariable logistic regression, we applied fixed-effects meta-analysis to evaluate associations between 1,039 harmonized metabolites and CRC risk, adjusting for body mass index and other covariates.

Results: Across seven cohorts (N = 3,779, 50% cases), participants were predominantly female (59.5%), with a median age of 68 years (IQR 62-73) and median BMI of 25.0 kg/m² (IQR 23.0-28.0). Fourteen metabolites were significantly associated with CRC risk (FDR < 0.05). Inverse associations were observed for phospholipids and ether lipids enriched in polyunsaturated fatty acids (e.g., PE(20:0/18:2), PE(22:6/P-18:1), PC(22:6/18:0); OR range 0.47-0.63, p-value range 6.2E-04 to 6.8E-13). Positive associations included monoacylglycerols (MG(18:3)), bile acids (e.g., glycochenodeoxycholate), and xenobiotic compounds (e.g., N-undecylbenzenesulfonic acid). Heterogeneity was low (mean I^2 across the significant metabolites was ~ 15%), and directionality was consistent across studies.

Conclusions: This multi-cohort analysis identified lipid metabolism and bile acid signaling as key pathways in CRC etiology, among others, independent of adiposity. The inverse associations with polyunsaturated lipid species and the positive association with bile acids and xenobiotics suggest that membrane lipid remodeling, gut-liver axis perturbations, and environmental exposures may play mechanistic roles in CRC development. Ongoing external validation in the European Prospective Investigation into Cancer and Nutrition (EPIC) cohort using untargeted metabolomic data will inform the utility of these metabolites as biomarkers for CRC risk stratification and prevention.

#2317 Plasma metabolomic profiles of oral contraception use associated with breast and ovarian cancers among premenopausal women in Nurse's Health Study II.

Jennifer M. Mongiovi[1], Nan Lin[1], Oana Alina Zeleznik[2], Naoko Sasamoto[3], Britton Trabert[4], Julian Avila-Pacheco[5], Clary B. Clish[5], A. Heather Eliassen[6], Shelley TWOROGER[7], Kathryn L. Terry[8]

[1]Brigham and Women's Hospital, Boston, MA,[2]Harvard Medical School/Brigham and Women's Hospital, Boston, MA,[3]Fred Hutchinson Cancer Center, Seattle, WA,[4]University of Utah Huntsman Cancer Institute, Salt Lake City, UT,[5]The Broad Institute, Cambridge, MA,[6]Assistant Professor, Harvard University, Boston, MA,[7]Oregon Health and Science University, Portland, OR,[8]Asst. Professor, Dept. of OB/GYN, Brigham and Women's Hospital, Boston, MA

BACKGROUND: While over 80% of sexually active premenopausal women use oral contraception (OC), the biological mechanisms linking OC to hormone-sensitive cancers are not well understood. OC use lowers ovarian cancer risk while current use modestly increases breast cancer risk, suggesting complex underlying pathways. We sought to identify plasma metabolites associated with OC use in premenopausal women and relationships with ovarian and breast cancer. METHODS: Analysis included 2,072 premenopausal women in Nurses' Health Study II with self-reported OC history. OC use was defined as ≥1 years of previous use, excluding current users. All metabolite values were transformed to probit scores to achieve normality. Associations of prior use ≥1 years versus never and per 5 years use with individual metabolites were evaluated through multivariable linear regression, accounting for the number of effective tests (NEF) based on the number of principal components explaining 90% of the variance. Metabolite groups were identified through metabolite set enrichment analysis (MSEA) using false discovery rate (FDR) for multiple testing. OC use models were adjusted for blood draw variables (age, time, season, fasting status), BMI smoking, diet (Alternative Healthy Eating Index score), alcohol consumption, and physical activity at the time of blood draw. Associations of metabolite groups (FDR<0.20) and metabolites (NEF<0.20) were considered nominally associated with OC use. Associations with incident breast (n=663) and ovarian cancers (n=34) diagnosed at least ≥3 years after blood draw were assessed using conditional logistic regression, using controls matched 1:1 on blood draw variables, adjusting for age, OC duration, parity, and family history of breast or ovarian cancer and using MSEA. RESULTS: Of 2,703 women, 1,681 (81.1%) reported having previously used OC for ≥1 year, with a mean duration of 4.0±3.9 years. Each additional 5 years of OC use was associated with higher C40:6 phosphatidylethanolamines (PE) levels (β=0.09; 95% CI: 0.04, 0.14), and both phosphatidylcholines and PEs were negatively associated with OC use and duration but positively for breast and ovarian cancer risk. Increasing OC duration was associated with lower tryptophan (β=-0.11; 95% CI: -0.16, -0.05) and higher 1,7-methyluric acid (β=-0.11; 95% CI: -0.16, -0.05), which were both lower among breast cancer cases and higher among ovarian cancer cases, but the overall organoheterocyclic compound group was not significantly associated with OC use. CONCLUSION: Our results suggest long-lasting alterations of systemic metabolism may in part explain associations of OC use with breast and ovarian cancers, particularly among metabolites that contribute to lipid metabolism. Analyses are ongoing and will include a deeper investigation into timing and formulation of OC use as well as cancer subtypes.

#2318 Environmental exposures, metabolomic profiles and mutational signatures in never and ever smokers with lung cancer.

Kathryn Demanelis[1], Sonali Dayal[1], Autumn Gaither Davis[1], Arjun Pennathur[1], Riyue Bao[1], Jennifer Walker[1], Patricia Lynn Opresko[1], James G. Herman[2], Brenda B. Diergaarde[3], Laura P. Stabile[1]

[1]University of Pittsburgh, Pittsburgh, PA,[2]UPMC Hillman Cancer Center, Pittsburgh, PA,[3]University of Pittsburgh School of Public Health, Pittsburgh, PA

Non-small cell lung cancer in never smokers (LCINS) accounts for ~25% of all cases and is the fifth highest cause of cancer death. LCINS disproportionately affects women and has been reported to be associated with environmental exposures, such as air pollution and radon. Prior LCINS studies investigating environmental risk factors often relied on geospatial estimates of exposures rather than individual-level exposures. In addition, information on the relationship between these exposures and tumor characteristics, such as mutational signatures (MutSigs), is limited. Liquid chromatography-high resolution mass spectrometry (LC-HRMS) profiling of plasma enables identification of chemical and metabolic exposures, i.e. the chemical exposome (CE), encountered by an individual. We conducted an exposome-wide analysis of compounds in the CE among 86 matched early-stage non-small cell lung cancer in smokers (LCIS) and LCINS cases. Whole-genome sequencing (WGS) on tumor and blood was performed on a subset of LCINS cases (N=16) to assess associations of chemical compounds and metabolites with tumor mutational burden (TMB) and MutSigs. Residential addresses were geocoded and geospatially integrated with environmental and radon data. Untargeted CE profiles were generated, and 539 annotated compounds were reproducibly detected in >75% of samples. Associations between LCIS/LCINS and CE compounds were evaluated using logistic regression; the correlation with TMB and MutSigs was assessed using Spearman's rho. The study population consisted of 28% women; mean age was 70 years. Among the LCINS cases sequenced, most exhibited common driver mutations. After exposome-wide analysis, 37 and 9 compounds were respectively higher and lower in plasma from LCINS vs. LCIS ($P < 0.05$). Compounds higher in LCINS included trifluoroacetic acid (TFA, a degradation product of polyfluorinated hydrocarbons), methocrifos (a pesticide), and aspartame (artificial sweetener). Among the sequenced LCINS cases, 18 single base-substitution (SBS) signatures were identified, including SBS18 (reactive oxygen species damage) in 4/16, SBS26 (defective DNA mismatch repair) in 6/16, and SBS40a in 16/16 (unknown etiology). We identified 44 compounds that were positively correlated with SBS18 ($P < 0.05$), including the histamine precursor and inflammatory agent, histidine, and microbial metabolites. Our pilot study identified differential CE profiles between LCINS and LCIS cases, where LCINS cases showed higher exposure to environmentally relevant exposures (e.g., TFA, pesticides, food additives). Chemical and metabolic compounds were positively correlated with several MutSigs, suggesting a role in carcinogenesis potentially via relevant mechanisms such as oxidative stress and DNA repair. These findings support a role for environmental carcinogens in LCINS etiology and warrant further investigation.

#2319 Variation in urinary estrogen levels according to breast parenchymal texture in postmenopausal women.

Onyedikachi Adike[1], Kajita Yukie[1], Xianming Tan[1], Gretchen Gierach[2], Cherie Kuzmiak[1], Despina Kontos[3], Eric A. Cohen[3], Walter C. Mankowski[3], Sarah J. Nyante[1]

[1]Department of Radiology, University of North Carolina at Chapel Hill, Chapel Hill, NC,[2]Division of Cancer Epidemiology and Genetics, National Institute of Health(NIH), Bethesda, MD,[3]Center for Innovation in Imaging Biomarkers and Integrated Diagnostics (CIMBID), Columbia University Irving Medical Center, New York City, NY

Background: Estrogen levels and breast parenchymal texture are both risk factors for breast cancer, but the relationship between the two is incompletely understood. This study evaluated associations between urinary estrogens, their metabolites, and parenchymal texture features in postmenopausal women to clarify how hormonal pathways contribute to radiomic breast tissue characteristics.
Methods: Urinary concentrations of estradiol, estrone, and 13 estrogen metabolites were quantified using liquid chromatography/tandem mass spectrometry (LC-MS/MS) and standardized to urinary creatinine levels (pmol/mg creatinine) among 294 postmenopausal women undergoing screening mammography at the University of North Carolina between 2020 and 2022. Women who were using menopausal hormones, oral contraceptives, or chemoprevention, or who had breast implants were excluded. An automated radiomic pipeline was used to quantify 344 parenchymal texture features from bilateral mammograms. Features were harmonized using ComBat to reduce batch effects. Principal components analysis and unsupervised clustering of features were used to define texture groups. Multinomial regression was used to assess associations between texture groups and estrogen levels, with and without adjustment for age and body mass index (BMI).
Results: Participants had a median age of 64 years (IQR: 59-71), a median BMI of 28 kg/m2 (IQR: 24-33), and a median total estrogen level of 20.9 pmol/mg creatinine. Participants clustered into three groups (Group 1: n=120, Group 2: n=154, Group 3: n=21). In the unadjusted analysis, Group 1 had lower levels of all parent estrogens and metabolites compared with Group 2, including lower levels of estrone (β =-0.046, p=0.04), 2-hydroxyestrone (β=-0.064, p=0.03), 16-epiestriol (β=-0.177, p = 0.03), and 17-epiestriol (β=-0.449, p=0.02). Differences in some, but not all, metabolites were attenuated after adjustment. In contrast, there was no consistent difference in estrogens between Group 3 and Group 2 in unadjusted or adjusted analyses.
Conclusion: For some postmenopausal women, estrogen metabolism, particularly through the 2- and 16-hydroxylation pathways, was associated with distinct mammographic parenchymal texture profiles. Identification of texture patterns linked to specific hormonal profiles may help explain the biological factors that shape breast composition and inform strategies for prevention of hormonally driven breast cancers.

#2320 Assessing endometrial cancer etiology by histologic subgroups.

Deirdre A. Hill[1], Carolyn Y. Muller[1], Kimberly K. Leslie[1], David G. Mutch[2]

[1]Internal Medicine, University of New Mexico, Albuquerque, NM,[2]Obstetrics and Gynecology, Gynecologic Oncology, Washington University, St. Louis, MO

Introduction: Endometrial cancer incidence has increased substantially in the past two decades, with the increases occurring primarily in tumors of non-endometrioid histology, which have a poor prognosis. Evidence regarding the origin(s) of the increase is sparse. We sought to determine whether women who had particular molecular signatures of endogenous and exogenous exposures had an increased risk of non-endometrioid histology, particularly serous tumors.

Methods: We investigated single-base substitution (SBS) signatures in exome sequencing data from The Cancer Genome Atlas (TCGA). Standard algorithms for mutational signature assessment were applied. Signatures were evaluated on a continuous scale, and also using a high/low cut point determined by maximally selected rank statistics. Relative risks (RR) and 95% confidence intervals (CI) were computed for 49 signatures, comparing risk for serous in relation to endometrioid histology. Disease-specific survival (DSS) was also evaluated in Cox proportional hazard models, with calculation of hazard ratios (HR) and 95% CI. The proportional hazards assumption was verified by Schoenfeld residuals. All analyses were adjusted for age at cancer diagnosis, and DSS analyses were also adjusted for stage.

Results: Included were n=414 women with endometrioid and n= 134 with serous non-endometrioid tumors. High Mismatch Repair defective (dMMR) (SBS6 and SBS15) and Polymerase Epsilon mutation (POLE) (SBS10a; SBS10b) signatures were less common in serous than endometrioid tumors, as expected from the literature (dMMR: SBS6 RR 0.21;95% CI 0.12-0.39; SBS15 0.22;95% CI 0.12-0.40;SBS26 0.21;95% CI 0.12-0.40); SBS15 RR 0.22;95% CI 0.12-0.40 and POLE SBS10a RR 0.23;95% CI 0.10-0.54 and SBS10b 0.33; 95% CI 0.19-0.58). A signature related to tobacco use (SBS4) was also less common in serous tumors (RR 0.32;95% CI 0.15-0.71). Women with high dMMR (SBS6: HR 0.06;95%CI 0.01-0.47; SBS15 HR 0.23;95%CI 0.08-0.64; SBS26: HR 0.42;95% CI 0.21-0.84)) or high POLE (SBS10a HR 0.06;95% CI 0.01-0.46; SBS10b HR 0.13; 0.03-0.54) signatures had a reduced risk of endometrial cancer-specific mortality.

Discussion: Endometrioid and serous tumors differ in mutational signatures. The reduced dMMR and POLE signature risk in relation to both serous tumors and DSS are in agreement with other findings. Our results open up new prospects for exploration of serous tumor etiology

#2321 Expression of 27-hydroxycholesterol metabolizing enzymes and breast cancer clinicopathological characteristics: The Multiethnic Cohort Study.

Lenora W. M. Loo[1], Yuqing Li[2], Kami K. White[3], Jose A. Aparicio[4], Veronica Wendy Setiawan[5], Brenda Y. Hernandez[3], Anna H. Wu[4], Christopher Haiman[5], Loic Le Marchand[3], Lynne R. Wilkens[3], Iona Cheng[2]

[1]Cancer Biology Program, University of Hawai'i Cancer Center, Honolulu, HI,[2]Department of Epidemiology and Biostatistics, School of Medicine, University of California San Francisco, San Francisco, CA,[3]Population Sciences of the Pacific, University of Hawai'i Cancer Center, Honolulu, HI,[4]Department of Population and Public Health Sciences, University of Southern California, Keck School of Medicine, Los Angeles, CA,[5]USC Norris Comprehensive Cancer Center, Los Angeles, CA

Background: Obesity is a major modifiable risk factor for postmenopausal breast cancer prognosis. Mechanisms underlying the association between obesity and post-menopausal breast cancer include higher levels of estradiol, cholesterol, and inflammation. Circulating cholesterol is metabolized into 27-hydroxychlolesterol (27HC) by the sterol 27-hydroxylase enzyme (CYP27A1). 27HC is catabolized by the oxysterol 7α-hydroxylase enzyme (CYP7B1). 27HC can regulate breast cancer pathobiology by functioning as an endogenous selective estrogen receptor modulator in breast tumors. In this study, we examined the associations of expression levels of *CYP27A1* and *CYP7B1* in tumor tissue with clinicopathological characteristics of breast cancer in a multiethnic population.
Methods: Invasive breast tumor tissue from 510 postmenopausal females (62 African American, 114 Japanese American, 93 Latino, 135 Native Hawaiian, and 106 White) in the Multiethnic Cohort Study were used for targeted profiling of gene expression using the NanoString nCounter Breast Cancer 360™ (BC360) Panel, including 51 additional custom genes. Generalized odds logistic regression analysis was conducted to examine associations of gene expression levels for *CYP27A1* and *CYP7B1* with clinicopathological characteristics -- stage, PAM50 molecular subtype (Luminal A, B, HER2-enriched, Basal-like) and NanoString Risk of Recurrence (ROR) score.
Results: *CYP27A1* expression was associated with a lower likelihood of advanced versus localized stage at diagnosis (OR=0.87; 95% CI 0.74, 1.02). No association was observed for *CYP7B1* with stage. *CYP27A1* expression was associated with a lower likelihood of HER2-enciched (OR=0.71; 95% CI 0.55, 0.92) and Luminal B (OR=0.71; 95% CI 0.58, 0.89) subtypes in comparison to Luminal A subtypes. *CYP7B1* expression was associated with Basal-like (OR=1.23; 95% CI 1.02, 1.49), HER2-enriched (OR=0.59; 95% CI 0.43, 0.80), and Luminal B (OR=0.43; 95% CI 0.32, 0.58) subtypes in comparison to Luminal A. No significant association was observed for *CYP27A1* and ROR categories (low, intermediate, and high). In contrast, *CYP7B1* expression was associated with lower risk of recurrence score (ROR intermediate vs. low: OR=0.77; 95% CI 0.62, 0.96; ROR high vs. low: OR=0.56; 95% CI 0.40, 0.79).
Conclusion: This study identified that gene expression levels of 27HC metabolizing enzymes, *CYP27A1* and *CYP7B1,* in breast tumors were associated stage, breast cancer subtype, and risk of recurrence among a multiethnic population of women.

#2322 Protective role of abundant healthy stroma against breast cancer: A prospective cohort study of healthy women in the Susan G. Komen Tissue Bank.

Garrett S. Hendley[1], Shaoqi Fan[1], Scott Lawrence[2], Karun Mutreja[2], Ruth M. Pfeiffer[1], Maire A. Duggan[3], Gretchen L. Gierach[1], Jill E. Henry[4], Mustapha Abubakar[1]

[1]Division of Cancer Epidemiology and Genetics, National Cancer Institute, National Institutes of Health, Bethesda, MD,[2]Molecular and Digital Pathology Laboratory, Leidos Biomedical Research, Inc., 21702, Frederick, MD,[3]Department of Pathology and Laboratory Medicine, University of Calgary, Calgary, T2N2Y9, AB, Canada,[4]Biospecimen Collection and Banking Core, Susan G. Komen Tissue Bank at the IU Simon Comprehensive Cancer Center, Indianapolis, IN

Background

Breast cancer (BC) remains a leading cause of morbidity and mortality in women worldwide. To mitigate this trend, future BC risk reduction strategies need to be grounded in BC etiologic histogenesis, i.e., the tissue pathways in the normal breast by which etiologic factors impact BC risk. Results from previous studies have indicated that the tissue composition of the breast may offer clues into the etiologic histogenesis of BC. However, many prior studies were conducted among women with benign breast disease (BBD), a tissue state characterized by underlying pathological changes that may obscure studies of etiologic histogenesis. Here, we investigated the associations of histologic tissue composition metrics of the normal breast with subsequent BC risk.

Methods

This prospective cohort study includes 3,435 healthy females (aged 18-75 years) who donated normal breast tissue to the Susan G. Komen Tissue Bank (KTB) between 2009-2019 and met study-specific inclusion criteria. Of these, 109 women developed BC after a median follow-up of 6 years (range: 1-16 years). Supervised machine-learning algorithms were used to analyze digitized histologic sections of normal breast tissues to generate quantitative data on percent epithelium, stroma, and adipose tissue for each woman. Associations between histologic metrics and breast cancer incidence were assessed in multivariable Cox proportional hazard regression models with age as the time-scale. Analyses were performed overall and following stratification by age at study entry and menopausal status. Models were adjusted for race, education, parity, body mass index, smoking status, alcohol use, and whole slide tissue area.

Results

Overall, abundant stroma was associated with decreased BC risk (hazard ratio (HR) per 1 standard deviation (SD) increase = 0.55, 95% confidence interval [CI] = 0.38 to 0.80, $P < 0.01$). The stromal protective effect was most profound among women younger than 55 years at tissue donation (HR/1-SD = 0.45, 95% CI = 0.26 to 0.79, $P < 0.01$) and in premenopausal women (HR/1-SD = 0.48, 95% CI = 0.26 to 0.87, $P = 0.015$), irrespective of age. Elevated epithelium and adipose tissue were associated with significantly increased BC risk in these same groups. However, when including stroma and adipose tissue in the same regression model, the mutual adjustment for stromal tissue mitigated adipose-related risk in women overall (HR/1-SD = 0.26, 95% CI = 0.06 to 1.16, $P = 0.077$), women younger than 55 years (HR/1-SD = 0.17, 95% CI = 0.04 to 0.71, $P = 0.015$), and in premenopausal women (HR/1-SD = 0.16, 95% CI = 0.04 to 0.65, $P = 0.01$).

Conclusion

Findings from this cohort of healthy women provide insights into the role of stroma in BC histogenesis during normal homeostasis, with potential implications for BC risk prediction and risk-reduction strategies.

#2323 Associations of stromal markers with breast terminal duct lobular involution.

Yaileen D. Guzman-Arocho[1], Lusine Yaghjyan[2], Laura C. Collins[3], Brian R. Sardella[1], Maisey Ratcliffe[2], **Rulla M. Tamimi**[3], Yujing J. Heng[1]

[1]Beth Israel Deaconess Medical Center, Boston, MA,[2]University of Florida, Gainesville, FL,[3]Weill Cornell Medicine, New York, NY

Background: Elevated expression of stromal markers in breast cancer (BrCa) has been linked to more aggressive disease and poorer prognosis. In contrast, data on stromal marker expression in premalignant breast tissues are limited, and it remains unclear whether these markers may inform future BrCa risk. Terminal duct lobular involution (TDLU), a physiologic process characterized by a decreased number of TDLUs and acini within breast lobules, has been associated with lower BrCa risk and is considered a potential surrogate risk marker for BrCa. In this study, we examined the associations between five stromal markers and TDLU involution in premalignant breast tissues.

Design: Tissue microarrays from 260 cancer-free women with biopsy-confirmed benign breast disease within the Nurses' Health Study (NHS) and NHSII were stained and evaluated for alpha-smooth muscle actin (αSMA), fibroblast activation protein (FAP), matrix metallo-peptidase (MMP14), tenascin-C (TNC), and calcyclin (s100A6). For each core, the % positivity was quantified by the inForm software. Our previously published computational algorithm computed six measures of TDLU involution assessing the number of TDLUs (TDLU counts/non-adipose tissue area), TDLU size (median TDLU span, median TDLU area, and TDLU area/% of non-adipose tissue area), and TDLU development (median acini counts/TDLU and median acini density). The associations of each marker's expression (binary with 1% cut-off) with each feature (log-transformed) was examined using generalized linear regression, adjusting for established BCa risk factors.

Results: The expression of αSMA and MMP14 was positively associated with four out of five features related to TDLU size and development (all $p<0.05$). FAP expression was positively associated with three features of TDLU size and development: median TDLU span, median TDLU area, and median acini counts/TDLU (all $p<0.05$). TNC expression was positively associated with median TDLU span but inversely associated with median acini density and TDLU counts/non-adipose tissue area (all $p<0.05$). No associations were found for s1006a.

Conclusions: The expression of several stromal markers in benign breast tissue was associated with larger TDLUs and more acini, i.e., lower degrees of lobular involution. Studies are underway to evaluate if these findings translate into associations with increased BCa risk.

#2324 Associations of circulating insulin-like growth factor-1 and insulin-like growth factor binding protein-3 with the expression of stromal markers in women with benign breast tissue.

Lusine Yaghjyan[1], Yu Jing J. Heng[2], Brian R. Sardella[2], Maisey Ratcliffe[1], **Rulla M. Tamimi**[3]

[1]University of Florida, Gainesville, FL,[2]Beth Israel Deaconess Medical Center, Boston, MA,[3]Weill Cornell Medicine, New York, NY

Purpose: The breast tissue microenvironment, and specifically stroma, is important for maintaining the normal tissue structure, and alterations within this environment may influence breast cancer (BCa) risk. The resident (normal) fibroblasts are the most abundant stromal cells. In breast tumors, cancer-associated fibroblasts have been associated with more aggressive phenotypes, and resistance to treatment. The insulin-like growth factor (IGF) pathway is involved in breast epithelial cell growth and extracellular matrix remodeling and may potentially influence normal fibroblasts. To date this association has not been explored in epidemiological studies. We examined, for the first time, the associations of circulating IGF-1 and IGF binding protein-3 (IGFBP-3) with the expression of breast stromal markers related to fibroblast activation: alpha-smooth muscle actin (αSMA), tenascin-C (TNC), fibroblast activation protein (FAP), calcyclin (s100a6), and matrix metallo-peptidase (MMP14).

Methods: This study included 145 cancer-free women with incident biopsy-confirmed benign breast disease (BBD) from the Nurses' Health Study II (NHSII) cohort. The data on BCa risk factors were obtained from biennial questionnaires. Immunofluorescence (IF) of stromal markers was performed on tissue microarrays with commercial antibodies (αSMA: 1:400 dilution; FAP: 1:50; MMP14: 1:150; TNC: 1:200; s100a6: 1:300). For each core, the % positivity was quantified by inForm v2.6.0. Generalized linear regression was used to examine the associations of plasma IGF-1 and IGFBP-3 (continuous log-transformed and quartiles) with log-transformed positivity for each stromal marker, adjusted for BCa risk factors and BBD subtype.

Results: In multivariate analysis, circulating IGF-1 was positively associated with s100a6 expression both when modeled continuously (β=0.89, 95% 95% Confidence Interval [CI] 0.07, 1.71) and as quartiles (β for 4^{th} vs. 1^{st} quartile=0.82, CI 0.16, 1.48; p-trend=0.03). Women whose circulating IGFBP-3 levels were in the top quartile appeared to have lower expression of TNC (β=-2.51, 95% CI -4.75, -0.27; p-trend=0.08). No associations were seen for αSMA, FAP, and MMP14.

Conclusion: Our findings suggest positive associations of circulating IGF-1 with s100a6 and inverse associations of IGFBP-3 with TNC, consistent with previously reported positive associations of IGF-1 and inverse associations of IGFBP-3 with BCa risk. Future studies are warranted to confirm our findings.

#2325 Association between widowhood and ovarian tumor gene expression.

Jaileene Perez Morales[1], Kathryn Berns[1], Cassandra Copp[1], Joseph Grieco[1], Mark K. Townsend[2], Steven A. Eschrich[3], Guillermo Armaiz-Pena[4], Lauren Cole Peres[3], Shelley TWOROGER[2]

[1]Knight Cancer Institute, Portland, OR,[2]Oregon Health & Science University, Portland, OR,[3]H. Lee Moffitt Cancer Center, Tampa, FL,[4]Ponce Health Sciences University, Ponce, PR

Background: Distress increases the risk of developing epithelial ovarian cancer (EOC). This can lead to the activation of the sympathetic nervous system (SNS) and the release of norepinephrine (NE). NE promotes inflammation, angiogenesis, and cell motility, which influence early and late stages of tumor progression. Widowhood is one form of chronic psychosocial stress that is associated with an increase in EOC risk. We hypothesize that women who experienced widowhood prior to EOC diagnosis will have higher tumor gene expression of inflammation-related and immune suppression pathways when compared to women who are married.
Methods: RNA sequencing was performed on 167 high-grade serous or poorly differentiated ovarian cancer tumors from the Nurses' Health Study (NHS), NHSII, and the New England Case-Control study who had information on pre-diagnosis marital status. The primary exposure was ever reported widowhood up to 1 year before diagnosis. Linear regression was used to identify differentially expressed genes associated with widowhood, adjusted for age. Gene set enrichment analysis (GSEA) using the Cancer Hallmarks, KEGG, and Reactome databases was employed to identify biological pathways associated with widowhood.
Results: Five genes (KCNE3, ACHE, C3orf52, RPL19P9, and AC116366) were significantly upregulated in the ovarian tumors of widowed versus married individuals. The top upregulated genes are associated with wound healing and cancer progression. Two genes (GABBR2 and RPS3AP29) were significantly downregulated and have been demonstrated to be involved in inhibitory neurotransmission and elevated tumor immune cell infiltration. GSEA identified six pathways that exhibited significant associations with widowhood, specifically related to inflammation (TNF-α), proliferation (G2M checkpoint), and tumor immunity (interferon-α and γ response).
Conclusions: Our results provide insight into biological pathways that link widowhood to ovarian cancer development, particularly through inflammatory and tumor immunity pathways.

#2326 Differentiating epigenetic marks and DNA adducts at the KRAS codon 12 mutation hotspot using ONT/ELIGOS sequencing.

Gunnar Boysen[1], Alongkorn Kurilung[2], Visanu Wanchai[2], Intawat Nookaew[2], Sarah Shuck[3]

[1]University of Arkansas for Medical Sciences, Little Rock, AR,[2]Biomedical Informatics, University of Arkansas for Medical Sciences, Little Rock, AR,[3]Diabetes and Cancer Metabolism, Beckman Research Institute at the City of Hope, Duarte, CA

Mutations—whether inherited or acquired—are central to cancer development, and reducing mutagenesis is an effective strategy for lowering cancer rates. At its simplest, DNA mutations arise from error-prone DNA replication or from the replication of DNA following incorrect repair of DNA lesions. Mechanistically, mutations occur when polymerases erroneously replicate DNA, with error rates increasing significantly in the presence of DNA modifications or DNA adducts. Among DNA modifications, epigenetic marks such as 5-methyl-deoxycytidine (5mdC) are the most abundant, occurring at a frequency of approximately one methylated cytosine per 100 cytosines. This is substantially higher than the frequency of endogenous DNA adducts (about one in 10,000 nucleotides) and exogenous DNA adducts (often less than one in 100 million normal nucleotides). Therefore, it remains unclear whether a specific mutation arises from errors in epigenetic processes, or from endogenous- and exposure-induced DNA adducts. Chemically specific methods for DNA adduct detection, unfortunately, often do not provide information about their position within the genome, prohibiting identification of the DNA adduct causing specific mutations. To address these knowledge gap, our group developed a nanopore-based DNA sequencing approach, called “ELIGOS” (Oxford Nanopore Technology-Epitranscriptional/ Epigenomical Landscape Inferring from Glitches of ONT Signals) that can (i) detect and (ii) differentiate between various types of epigenic marks and exposure-induced DNA adducts at base pair resolution while sequencing the DNA. ONT/ELIGOS provides an innovative tool to study the DNA lesions and mutations in pre-selected DNA regions. In this work, we present our latest ONT/ELIGOS findings demonstrating the detection and identification of DNA adducts at codon 12 within the KRAS cancer driver gene. In addition to common epigenetic marks and exposure-derived DNA adducts, our current panel of DNA adducts includes common endogenous lesions. Together these novel approaches can reveal the dynamics changes in single DNA molecules.

#2327 Thymic radiation and oncologic outcomes.

Vasco Prudente[1], Simon Bernatz[1], Suraj Pai[1], Katelyn M. Atkins[2], Keno Bressem[3], Christian V. Guthier[1], Leonard Nurnberg[1], Christopher E. Kehayias[4], Christopher Abbosh[5], Charles Swanton[6], Mariam Jamal-Hanjani[7], Nicolai Juul Birkbak[8], Raymond H. Mak[9], Hugo Aerts[1]

[1]Artificial Intelligence in Medicine, Harvard Medical School, Boston, MA,[2]Department of Radiation Oncology, Cedars-Sinai Medical Center, Los Angels, CA,[3]Technical University of Munich, Munich, Germany,[4]Department of Radiation Oncology, Dana-Farber Cancer Institute, Boston, MA,[5]Christopher Abbosh (Individual), London,[6]The Francis Crick Institute, London, United Kingdom,[7]University College London (UCL) Cancer Institute, London, United Kingdom,[8]Aarhus University, Aarhus, Denmark,[9]Instructor, Dept. of Radiation Oncology, Dana Farber/Brigham & Women's Cancer Center and Harvard Medical School, Boston, MA

BackgroundThe thymus plays a crucial role in early life, serving as the primary source of T-cell development, a vital component of adaptive immunity. Despite its central role in immune biology, the thymus is not currently considered an organ-at-risk in Radiotherapy (RT). RT, a cornerstone of treatment for locally advanced non-small cell lung cancer (NSCLC), has effects extending beyond local tumor control. In particular, it can trigger immunogenic cell death, releasing tumor antigens that prime systemic antitumor immunity. These immune-mediated effects are particularly important when RT is combined with immunotherapy, where consolidation immunotherapy has been shown to improve survival after chemoradiation.
MethodsIn this multicohort study, we assessed whether thymic irradiation was associated with distant metastases and all-cause mortality across 882 locally-advanced NSCLC patients treated with RT (RTOG-0617 n=460 | HARVARD-CRT n=422). For each patient, we measured the mean thymic radiation dose (MTD). Thymic health was determined based on thymic radiographic representation on CT scans, automatically inferred using a self-supervised deep learning model. Associations with clinical outcomes were assessed using multivariable Cox models, adjusting for key clinical factors. Sensitivity analyses evaluated the incremental contribution of MTD. To demonstrate the clinical feasibility of thymic sparing with modern RT techniques and AI-based volume delineation, we replanned the RT treatment plan in a representative case with high cumulative thymic dose exposure.
ResultsIn RTOG patients with preserved thymic health, higher thymic radiation dose was progressively associated with worse clinical outcomes. An MTD of 35Gy was identified as the lowest dose linked to a significant deterioration in outcomes. This threshold was validated in both cohorts, where exceeding the 35Gy MTD in patients with preserved thymic function was associated with increased risk of distant metastases (RTOG-0617: adjusted hazard-ratio [aHR]=1.32; p=0.002 | HARVARD-CRT: aHR=2.15; p=0.018) and worse overall survival (RTOG-0617: aHR=1.20; p=0.002 | HARVARD-CRT: aHR=2.02; p=0.014). No significant associations emerged in patients with low thymic health prior to radiation therapy. One-year follow-up imaging demonstrated dose-dependent declines in AI-quantified thymic health, supporting a mechanistic link between thymic irradiation and loss of immune competence. In a feasibility test case, thymic dose was successfully reduced below 35 Gy without compromising tumor coverage or cardiopulmonary constraints.
ConclusionsThymic radiation exposure was independently associated with higher risks of metastasis and death in NSCLC patients with preserved thymic function. These findings suggest that the thymus should be recognized as an organ-at-risk in radiotherapy and that thymus-sparing strategies may be crucial to preserve immune health and improve patient outcomes.

#2328 Gut microbiome and breast cancer-related endogenous hormone risk factors in US women: findings from the Nurses' Health Study II.

Tengteng Wang[1], Tong Cheng[1], Walter C. Willett[2], Curtis Huttenhower[2], Yang-Yu Liu[3], A. Heather Eliassen[4]

[1]Rutgers Cancer Institute, New Brunswick, NJ,[2]Harvard T.H. Chan School of Public Health, Boston, MA,[3]Brigham and Women's Hospital, Boston, MA,[4]Harvard T.H. Chan School of Public Health; Brigham and Women's Hospital, Boston, MA

Background: Endogenous estrogens are well-established risk factors for breast cancer. A subset of gut microbes, collectively termed the estrobolome, plays a fundamental role in estrogen metabolism and reabsorption. However, existing studies examining associations between the gut microbiome and circulating estrogen levels in humans have been few and small in scale, and no prior work has established an estrobolome linked to circulating estrogen levels using shotgun metagenomic sequencing.
Methods: This study included 141 non-hormone users from a microbiome sub-study nested within the Nurses' Health Study II. Stool samples were collected using a home-based self-collection protocol, followed by blood collection approximately 3-4 months later. Circulating estrone (E1), estradiol (E2), and testosterone levels were assayed at the Mayo Clinic Laboratory by liquid chromatography-tandem mass spectrometry. Shotgun metagenomic sequencing was conducted using the 100 nt Illumina HiSeq platform. Taxonomic and functional profiling were performed using the bioBakery 4.0 workflow. Microbial α-diversity (Inverse Simpson index) and β-diversity (Bray-Curtis dissimilarity) were calculated. LASSO regression was applied to identify microbial features predictive of hormone levels, and age and BMI-adjusted generalized linear models were used for association analyses with multiple comparisons correction.
Results: Taxonomic and functional profiling identified 1,860 species and 512 MetaCyc pathways. Microbial α-diversity was inversely correlated with E1 ($R = -0.16$, $p = 0.07$) and E2 ($R = -0.16$, $p = 0.06$), and positively correlated with testosterone ($R = 0.12$, $p = 0.16$). In age-adjusted models, α-diversity was significantly inversely associated with E2 (β = -0.39; 95% CI: -0.70, -0.07), though the association attenuated after further adjustment for BMI at stool collection (β = -0.16; 95% CI: -0.47, 0.15). PERMANOVA analyses revealed significant associations between taxonomic variation and E1 ($R^2 = 0.28\%$), E2 ($R^2 = 0.34\%$), and testosterone ($R^2 = 0.16\%$) (all $p < 0.005$). LASSO feature selection identified 23 species predictive of E1 and 16 predictive of E2, with the majority belonging to the genera *Bacteroides*, *Clostridium*, *Eubacterium*, and *Alistipes*. E2 was further associated with microbial pathways related to glycogen degradation and queuosine biosynthesis.
Conclusion: This study represents the first and largest shotgun metagenomic investigation of gut microbiome composition in relation to circulating sex hormones in an epidemiological cohort. Reduced microbial diversity and higher abundance of estrobolome species with β-glucuronidase activity (e.g., *Bacteroides fragilis*) may be associated with elevated circulating estrogen levels, suggesting that structural variation in gut microbial communities contributes to inter-individual differences in estrogen metabolism.

#2329 Role of inflammatory markers in the development of cardiovascular conditions in breast cancer survivors and matched comparison groups.

Talar S. Habeshian[1], Michael R. Irwin[2], Lie H. Chen[1], Jiaxiao Shi[1], Richard Olmstead[2], **Reina Haque**[1]

[1]Research and Evaluation, Kaiser Permanente Southern California, Pasadena, CA,[2]Jane and Terry Semel Institute for Neuroscience and Human Behavior, University of California, Los Angeles, Los Angeles, CA

Background: Inflammation in breast cancer survivors (BCS) may play a role in developing cardiovascular disease (CVD). Prior studies have not included cancer-free comparison cohorts (CC) that can help elucidate if BCS have an increased risk of CVD. We evaluated whether incident CVD is greater in BCS compared with CC, and if the excess risk can be attributed to different levels of inflammatory markers, adjusting for pre-existing cardiovascular risk factors, demographic, and clinical characteristics. This preliminary analysis focuses on C-reactive protein (CRP), which has been strongly correlated with CVD.

Methods: We conducted a prospective cohort study of 315 BC survivors aged 55-85 years and 321 CC from the KPSC health plan. Of these, 70% in each group (N=218 BCS, N=222 CC) agreed to blood draws for assessment of inflammatory markers at baseline and every 8 months until month 32. Participants were followed a maximum of 5 years or until a CVD event, death, or health plan disenrollment, whichever came first. Person-year (PY) rates for CV events were calculated by cumulative CRP levels over the 32 months. Bivariate and multivariable Cox models were used to estimate hazard ratios (HRs) and 95% confidence intervals (CIs) for the associations between cumulative CRP (using CVD risk-related cut points: <1.0 (low), 1.0-3.0 (moderate), and >3.0 mg/dL (high) and 5-year composite CV event. The association was also evaluated by cumulative CRP levels, with CC as the reference group. Multivariable models were adjusted for age, demographic characteristics, and cardiometabolic risk factors.

Results: BCS had a higher crude CV event PY rate (33.3 per 1,000 PY) vs. CC (24.7 per 1,000 PY). In BCS, the 5-year CV event rate rose from 32.3 per 1,000 PY in the lowest CRP level (<1.0 mg/dL) to 34.4 per 1,000 PY (1.0-3.0 mg/dL), and then 40.8 per 1,000 PY (>3.0 mg/dL) (p-trend=0.68). Further, the CV event rates were greater in BCS than in CC in each of these CRP levels. In the crude model stratified by cohort, BCS with higher cumulative CRP levels had a greater CVD risk compared to those with normal CRP levels ($HR_{>3.0\ mg/dL}$=1.24, 95% CI: 0.45-3.43; $HR_{1.0\text{-}3.0\ mg/dL}$=1.05, 95% CI: 0.44-2.45), although results were not statistically significant. We observed similar trends in the CC. In the crude model stratified by CRP, BCS had a higher CVD risk than CC across all CRP categories, although the results were not significant ($HR_{BCS\ CRP\ <1.0\ mg/dL}$=1.36, 95% CI:0.53-3.46; $HR_{BCS\ CRP\ 1.0\text{-}3.0\ mg/dL}$=1.39, 95% CI: 0.49-3.91; $HR_{BCS\ CRP\ >3.0\ mg/dL}$=1.01, 95% CI:0.26-3.98). These risks attenuated in both multivariable models.

Conclusions: Preliminary results signal higher cumulative CRP levels may differentially affect CVD risk in BCS than in CC, but larger studies are needed for confirmation. Further analyses will examine if other inflammatory markers (IL-6, Il-8, IL-10, and TNF) predict long-term CVD risk in BCS.

#2330 Mosaic loss of the Y chromosome in leukocytes is associated with increased incidence of non-aggressive prostate cancer in 278,998 cancer-free males.

Rebecca L. Kelly[1], Anqi Wang[2], Yifan Zhang[3], Weyin Zhou[4], Kara M. Barnao[4], Corey D. Young[4], Aubrey K. Hubbard[4], Wen-Yi Huang[4], Steven C. Moore[4], Christopher A. Haiman[3], Stephen J. Chanock[4], Ying Wang[5], Konrad H. Stopsack[6], Lorelei A. Mucci[7], Fei Chen[3], Mitchell J. Machiela[4]

[1]Division of Cancer Epidemiology and Genetics, Division of Cancer Prevention, National Cancer Institute, Rockville, MD,[2]USC School of Pharmacy, Los Angeles, CA,[3]Department of Population and Public Health Sciences, University of Southern California Keck School of Medicine, Los Angeles, CA,[4]Division of Cancer Epidemiology and Genetics, National Cancer Institute, Rockville, MD,[5]American Cancer Society, Atlanta, GA,[6]Leibniz Institute for Prevention Research and Epidemiology, Bremen, Germany,[7]Harvard T.H. Chan School of Public Health, Boston, MA

Background: Mosaic loss of the Y chromosome (mLOY), a type of clonal hematopoiesis, is the most frequently detected chromosomal alteration in the leukocytes of aging males. Prostate cancer (PCa) increases exponentially in aging males and previous studies have shown a positive association between genetic risk of mLOY and PCa diagnosis. Confirmation of this association in population-based studies is needed to determine if mLOY could be an informative biomarker for PCa risk.
Methods: To evaluate the potential association between mLOY and prostate cancer risk, we detected mLOY using the MoChA algorithm on existing high-density genotyping array data from blood-derived DNA of 278,998 cancer-free males across six prospective cohorts: UK Biobank (UKBB, N=210,103); Prostate, Lung, Colorectal, and Ovarian Cancer Screening Trial (PLCO, N=26,275); Health Professionals' Follow-Up Study (HPFS, N=4,933); Physicians' Health Study (PHS, N=1,148); Multiethnic Cohort (MEC, N=24,370); and Cancer Prevention Study II (CPSII, N=12,169). Cox proportional hazards models with age as a timescale estimated hazard ratios (HR) and 95% confidence intervals (CI) for the association of mLOY on prostate cancer incidence adjusted for body mass index, smoking status, genotyping array, and the top 10 genetic principal components. Association tests were performed in each cohort and then meta-analyzed.
Results: The average mLOY detection and PCa diagnosis across cohorts were 23.4% and 17.9%, respectively. Fixed effects meta-analysis of the adjusted HRs identified a positive association of mLOY with overall PCa risk (HR=1.09, CI 1.05, 1.13; P-Value (*P*)=2.25 x 10^{-6}). mLOY was associated with a Gleason score ≤6 at diagnosis (HR=1.13, 95% CI 1.04, 1.23; *P*=0.0029), a greater hazard of non-aggressive PCa diagnosis (HR=1.15, 95% CI 1.05, 1.26; *P*=0.0022), and PSA <10ng/mL at diagnosis (HR=1.11, 95% CI 1.02, 1.22; *P*=0.015). We did not observe evidence for mLOY associations with Gleason score ≥8, aggressive PCa or metastasis at diagnosis. We confirmed germline genetic risk of mLOY was positively associated with PCa incidence in participants with genetic similarity to European reference populations (HR=1.02 per 1 SD mLOY PRS, 95% CI 1.00, 1.03; *P*=0.0083), there was less evidence in participants similar to African reference populations (HR=1.01 per 1 SD mLOY PRS, 95% CI 0.94, 1.08; *P*=0.769).
Conclusion: Our investigation of the relationship between mLOY and PCa diagnosis provides evidence for an association between mLOY detected in the blood and increased risk of non-aggressive PCa, suggesting mLOY could have utility in PCa risk stratification.

#2331 Clinical performance of Signatera Genome assay to predict treatment response and prognosticate outcomes in patients with locally advanced (LAR) resectable gastric or gastroesophageal junction (G/GEJ) adenocarcinoma: Results from the PLAGAST Study.

Aziz Zaanan[1], Michael Khayat[2], Erik Spickard[2], **George Laliotis**[3], Punashi Dutta[2], Meenakshi Malhotra[2], Shruti Sharma[2], Gabrielle Heilek[2], Adham Jurdi[2], Minetta C. Liu[2], Pierre Laurent-Puig[4]

[1]Department of Digestive Oncology, Georges Pompidou European Hospital, Assistance Publique - Hopitaux de Paris, University of Paris Cite, Paris, France,[2]Oncology, Natera, Inc., Austin, TX,[3]Natera, Inc., Austin, TX,[4]INSERM, Sorbonne Universite, Universite de Paris F-75006, Centre de Recherche des Cordeliers, Paris, France

Background: Circulating tumor DNA (ctDNA) is a clinically validated biomarker across multiple gastrointestinal cancers, used to predict recurrence risk, monitor response to neoadjuvant therapy (NAT), and detect molecular residual disease (MRD) post-definitive treatment. Signatera™ is a personalized, tumor-informed, multiplex PCR-NGS ctDNA assay that can be developed using either whole-exome sequencing (WES) or whole-genome sequencing (WGS). Initial clinical validation of Signatera Genome in select clinical contexts of a pancancer cohort showed robust performance. Here, we evaluated the performance of Signatera Genome in pts with LAR G/GEJ cancer enrolled in the PLAGAST prospective study (NCT02674373).

Methods: A retrospective analysis was conducted using residual samples from pts with LAR G/GEJ cancer in the PLAGAST study (N=54). Signatera Genome assays were designed from matched tumor and normal WGS data and used to detect ctDNA in the corresponding pts' plasma samples collected at pre-NAT (or pre-surgery for NAT-naive), during-NAT, post-NAT, and post-surgery in the MRD window (within 2–12 weeks, before adjuvant treatment). ctDNA levels were quantified as mean tumor molecules per mL of plasma (MTM/mL). Longitudinal blood samples represented time points pre-/post-definitive treatment until recurrence or the end of follow-up. The correlation between ctDNA status and disease-free survival (DFS)/overall survival (OS) was assessed using Cox regression analysis.

Results: The median pt age was 66 (34-86) years. The majority of pts were males (65%), had gastric cancer (57%), and received NAT (87%). Pts with post-NAT, pre-surgery ctDNA positivity had significantly worse outcomes (RFS: HR: 5.4, 95% CI: 1.68-17.37; p=0.005; OS: HR: 5.42, 95% CI: 1.5-28.73; p=0.0085). Postoperative survival analysis demonstrated that ctDNA positivity during the MRD window was also associated with worse RFS (HR: 9.78, 95% CI: 3.41-28.07, p<0.0001) and OS (HR: 12.98, 95% CI: 3.69-45.67; p<0.0001). Multivariate analyses showed ctDNA status post-NAT and within the MRD window to be the most significant independent risk factor for both RFS and OS compared to other clinicopathological features (post-NAT: RFS: HR: 5.53, p=0.005; OS: HR: 6.51, p=0.029; MRD window: RFS: HR: 4.97, p=0.014; OS: HR: 4.28, p=0.031).

Conclusions: Persistent ctDNA positivity at post-NAT/pre-surgery timepoint and in the MRD window were strongly prognostic of inferior outcomes. These data indicate the robust clinical performance of Signatera Genome in pts with LAR G/GEJ adenocarcinoma and support its potential clinical utility in this disease setting. Prospective clinical trials are warranted to establish the clinical utility of the assay for guiding treatment decisions.

Poster Session

#2335 A population-based study on thyroidectomies in Mexico from 2010 to 2023.

Adrian Cortes-Valencia, Giovanni Garfias-Becerril, Lina Sofia Palacio-Mejia, Evelyn Mitzy Flores-Salas, Juan Eugenio Hernandez-Avila, **Martin Lajous**

Instituto Nacional de Salud Publica, Cuernavaca, Mexico

Background. Thyroid cancer is the fourth most common cancer in Mexico. Overdiagnosis and subsequent overtreatment have increased as diagnostic tests have become more readily available. Also, an increasing share of total thyroidectomies relative to partial thyroidectomies was observed in many high-income countries in the early 2000s. There is limited understanding of the frequency of thyroidectomies and surgical approach in low- and middle-income countries. We aimed to estimate time trends and geographic patterns of thyroidectomies in Mexico by sex, age groups, type of procedure (total and partial thyroidectomies), and discharge diagnosis.
Methods. We used a national hospital discharge database collected by the Ministry of Health for individuals without health insurance coverage from 2010 to 2023. We identified hospital discharges where a total (ICD-9: 064X, 0650, 0652) or partial (ICD-9: 0639, 0651) thyroidectomy were performed. We classified discharge diagnoses into four groups: malignant neoplasms, benign tumors, goiter and thyroid-related morbidities, and other diagnoses unrelated to the thyroid. We calculated crude and age-standardized incidence rates for men and women by region in Mexico (North, Central, Southeast, West, and Mexico City) and for three time periods: 2010-2012, 2013-2018, and 2018-2023.
Results. The national standardized rate of thyroidectomies was 4.8 per 100,000 in women and 0.74 in men. The rate showed a downward trend throughout the period, particularly among women with goiter. Overall, the rate of thyroidectomies for malignant disease remained stable, however, the percentage of thyroidectomies for malignant tumors increased in both women (34.3%, 36.0%, and 45.2%) and men (36.6%, 43.6%, and 51.7%) when comparing the three periods. We observed important regional differences, with the highest rate in Mexico City (17.9 per 100,000 in women) and the lowest in the central region. The proportion of total thyroidectomies in the examined period increased from 49% to 63% in women and from 47% to 66% in men.
Conclusions. The downward trend in thyroidectomies in Mexico may be the result in changing guidelines. Our results do not reveal thyroid cancer overdiagnosis but show potential for more conservative surgical treatment.

#2336 Rectal and sigmoid colon cancers drive rising early-onset colorectal cancer incidence in the United States.

Michelle O. Nagata[1], Scott K. Kuwada[2], Linda Wong[1], Loic Le Marchand[1], Brenda Y. Hernandez[1]

[1]University of Hawai'i Cancer Center, Honolulu, HI,[2]John A. Burns School of Medicine, Honolulu, HI

Background: Early-onset colorectal cancers (EOCRCs) diagnosed in people younger than 50 are increasing in incidence in the U.S., though the causes are unclear. We studied recent trends in EOCRC incidence and survival in the U.S.
Methods: De-identified data from the National Cancer Institute Surveillance, Epidemiology, and End Results Program (SEER 21) was used to evaluate colorectal cancer (CRC) cases diagnosed in the U.S. in 2013-2022 (excluding 2020) by demographic and clinic-pathologic characteristics including age, sex, race, tumor site, stage, histology, and county-level measures of rurality, annual household income, poverty, and education using SEER*Stat. Average annual percent change was calculated using Joinpoint. Age-standardized 5-year relative and disease-specific survival rates were calculated using time from cancer diagnosis to death or last contact.
Results: Overall CRC incidence declined from 2013-2022 in a manner that was more pronounced for colon and rectosigmoid junction cancers than rectal cancers. Among individuals aged 50+, incidence significantly declined for all subsites except for the rectum. Among individuals younger than 50, colon and rectal cancers significantly increased 2.50% and 4.15% annually, respectively. Rectal cancers showed the highest annual increase among EOCRCs, followed by sigmoid colon (3.86%, $p = 0.002$), splenic flexure (2.97%, $p = 0.048$), overlapping lesion/not otherwise specified (NOS) colon (1.79%, $p = 0.01$), transverse colon (1.38%, $p < 0.001$), and ascending colon (1.08%, $p < 0.001$). Increases in EOCRCs were observed for all sex, race/ethnicity, stage, and county-level rurality, income, poverty, and education groups, with significantly higher annual increases for metropolitan compared with nonmetropolitan counties (3.05% vs. 1.78%, $p < 0.001$). Adenocarcinomas (NOS) and neuroendocrine tumors (NET) accounted for increases in both early-onset colon (3.05% and 1.50%) and rectal cancers (4.15% and 7.42%). Survival was lower for individuals aged 50+; males compared with females; Blacks compared with Whites; regional and distant stages compared with localized; single individuals compared with married; and nonmetropolitan, lower income and education, and higher poverty counties. Survival was significantly lower for mucinous adenocarcinomas and higher for NET and hematologic cancers compared with adenocarcinomas (NOS).
Conclusions: The recent increase in EOCRC incidence has been driven by increases in rectal and sigmoid colon cancer incidence, which showed the steepest growths and equally across all demographic and socioeconomic groups, and were diagnosed at younger ages and at more advanced stages compared with other anatomical subsites. These findings highlight the need to elucidate biological and environmental mechanisms underlying the rise in EOCRC to inform prevention and intervention efforts.

#2337 Mapping the associations of 144 incidence risk factors with 39 cancers: An AI-driven systematic review and meta-analysis.

Changfa Xia[1], **Shiyuan Tong**[2], Yongjie Xu[1], Hui Yu[2], Fang Liu[2], Shiqing Chen[2], Fei Zhao[2], Junyi Ye[2], Jing Liu[2], Baoliang Zhu[2], Xiaohui Wu[2], Sibo Zhu[2], Wanqing Chen[3]

[1]Office of Cancer Screening, National Cancer Center/National Clinical Research Center for Cancer/Cancer Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing, China,[2]Shanghai Xiaohe Medical Laboratory Co. Ltd., Shanghai, China,[3]Office of Cancer Registry, National Cancer Center/National Clinical Research Center for Cancer/Cancer Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing, China

Background: A comprehensive understanding of the associations between multiple risk factors and cancer incidence is crucial for evidence-based cancer control. While many studies have examined specific risk-cancer pairs, none have yet estimated the entire network of risks across cancer types. This study aims to quantity the associations between 144 cancer-related risk factors and the incidence of 39 cancer types.
Methods: Using risk records from CanRisk-DB, a well-established repository that employs graph-based retrieval-augmented generation large language model agents within the PICOS-PRISMA framework, we synthesized relative risks (RRs) or hazard ratios (HRs) of cancer incidence from cohort studied between 1980 and 2024. We meta-analyzed the effect sizes using harmonized definitions and both graph-based and inverse variance approaches. The reliability of this artificial intelligence (AI)-driven meta-analysis was validated by comparing our estimated effects with those from published meta-analyses.
Results: A total of 2,388 combinations between 144 risk factors and 39 cancer types were identified from CanRisk-DB. Among these, 131 and 120 risk factors were linked to 36 and 33 cancer types in females and males, respectively. Of 144 risk factors, 92.4% were modifiable. 67 factors were identified as causal risk factors only, such as family history of cancer, immunosuppressive agents, non-alcoholic fatty liver disease, and nitrogen dioxide pollution. However, 77 risk factors showed either causal and protective roles across cancer types, such as tobacco use, alcohol consumption, and type 2 diabetes. For instance, alcohol consumption was positively associated with several cancers (e.g., liver [RR = 1.46; 95% CI, 1.27-1.69], breast [RR = 1.09; 95% CI, 1.06-1.12], and colorectal [RR = 1.08; 95% CI, 1.02-1.13]) but inversely with kidney cancer (RR = 0.81; 95% CI, 0.76-0.87). The cancers with the greatest number of associated risk factors were lung (73 factors), colorectal (57), and liver (53). Overall, the majority of cancer types were associated with multiple modifiable risk factors: 34 cancers (87.2%) with at least 5 risks, 28 cancers (71.8%) with at least 10 risks, and 20 cancers (51.3%) with at least 15 risks. The effect sizes in our analysis are highly consistent with those reported in published meta-analyses (Spearman's $\rho = 0.93$).
Conclusion: AI-driven systematic reviews and meta-analyses accurately captured the complex network of associations between cancers and risk factors. Mapping these relationships facilitated a better understanding of the attributable risk of cancer, thereby informing strategies for cancer prevention and control.

#2338 Oral bacteriome and its association with cancer-specific mortality.

Shelly Han[1], Morgan Byrd[2], Ayush Khanna[1], Tammara L. Watts[3], Katharine Ciarrocca[4], Nosa Osazuwa-Peters[2]

[1]Duke University, Durham, NC,[2]Duke University School of Medicine, Durham, NC,[3]Duke Cancer Institute, Durham, NC,[4]Head and Neck Surgery & Communication Sciences, Duke University, Durham, NC

Objectives: Cancer is the leading cause of death in the United States, with more than 600,000 deaths annually. Emerging evidence suggests that alterations in the oral microbiota, one of the body's most diverse microbial communities, may influence cancer outcomes. However, associations between microbial diversity and composition with cancer mortality remain poorly understood. We aimed to identify associations between oral microbiome diversity and bacterial abundance with cancer-specific mortality.
Methods: We analyzed 441 participants from the 2009-2012 National Health and Nutrition Examination Study (NHANES) linked to National Death Index (NDI). Oral rinse samples were 16S rRNA V4 amplicon-sequenced and resolved to the genus level using SILVA v123. Alpha diversity was calculated after rarefaction to 2,000 reads. Cancer deaths were defined using ICD-10 malignant neoplasm codes. As an exploratory analysis, supervised random forest models (1,000 trees; 100 random seeds; "randomForest" R package) were applied to centered log-ratio (CLR) transformed abundance values to identify genera associated with cancer-mortality, with importance measured by Mean Decrease Accuracy. Survey-weighted multivariable Cox proportional models estimated adjusted hazard ratios for cancer-specific mortality by alpha diversity and genus abundance, adjusting for age, sex, race/ethnicity, poverty income ratio, lifetime smoking history, and self-rated oral health. Bonferroni correction accounted for multiple hypothesis testing.
Results: Higher alpha diversity was associated with lower cancer-specific mortality, with significant inverse associations for Shannon (aHR 0.72, 95% CI 0.53-0.98) and Inverse Simpson's Index (aHR 0.13, 95% CI 0.02-0.73), while Faith's Phylogenetic Diversity and observed ASV richness were not significant. In the exploratory random analysis using random forest, Prevotella_7, Gemella, Bergeyella, Fusobacterium, Ruminococcaceae_UCG-014, Alloprevotella, and Oribacterium emerged as potential discriminatory genera for cancer deaths versus non-cancer deaths (MDA > 5.75). In adjusted Cox models, participants with Bergeyella abundance above the median (aHR 0.59; 95% CI 0.35-0.99) and participants with Oribacterium (aHR 0.52; 95% CI 0.32-0.81) had lower cancer-specific mortality. After adjustment, the other genera identified in the exploratory analysis were not significant for cancer-mortality.
Conclusion: The oral microbiome harbors bacteria that may be potentially predictive of cancer-specific mortality. Although prior literature provides limited support for Bergeyella's and Oribacterium's roles in cancer mortality, our results underscore the need for further studies to validate our results and for examining biomarkers and targets for microbiome-informed prevention strategies.

#2339 Cardio-kidney metabolic health among adult cancer survivors in the Hispanic Community Health Study/Study of Latinos.

Myunhee Lee[1], Matthew Allison[2], Linda C. Gallo[1], Carlos Rosas[3], Daniela Sotres-Alvarez[4], Frank J. Penedo[5], Martha Daviglus[6], James Lash[6], Humberto Parada[1]

[1]San Diego State University, San Diego, CA,[2]University of California San Diego, San Diego, CA,[3]California State University San Marcos, San Marcos, CA,[4]University of North Carolina at Chapel Hill, Chapel Hill, NC,[5]University of Miami, Miami, FL,[6]University of Illinois Chicago, Chicago, IL

Background: Compared to the general population, cancer survivors are at higher risk for cardiovascular, kidney, and metabolic (CKM) diseases. However, the prevalence and progression of CKM diseases among Hispanic/Latino adults with a history of cancer remain underexplored. Using data from the community-based Hispanic Community Health Study/Study of Latinos (HCHS/SOL), we examined the changes in CKM diseases and predictors of CKM disease progression over an average of six years, stratified by baseline cancer history.

Methods: We included 16,415 participants from the HCHS/SOL with a history of cancer (n=644) and without a history of cancer (n=15,771) at Visit 1 in 2008-2011. CKM stage at Visit 1 and Visit 2 in 2014-2017 was defined according to the 2023 American Heart Association(AHA)'s CKM stage framework. The 2023 AHA advisory defines five CKM stages (0-4), progressing from no CKM risk factor (stage 0) to excess or dysfunctional adiposity (stage 1), metabolic syndrome or chronic kidney disease (stage 2), subclinical cardiovascular disease or risk equivalent (stage 3), and established cardiovascular disease (stage 4). Descriptive statistics were used to assess the prevalence and transition of CKM stage between visits. Survey-weighted multivariable logistic models and Fine-Gray competing risk models were used to evaluate the associations (odds ratios, ORs, and 95% confidence intervals, CIs) between cancer history and sociodemographic factors and CKM stage progression.

Results: Compared to those without a history of cancer, those with a history of cancer were older (mean age±standard error = 55.8±1.0 versus 47.4±0.2 years), more likely to be female (65.4% versus 52.7%), retired (29.0% versus 10.6%), have an annual household income <$20,000 (54.9% versus 47.5%), and be physically inactive (45.0% versus 36.4%). Cancer survivors had a higher prevalence of advanced CKM stages (≥ stage 3) at both Visit 1 (24.2% versus 10.0%) and Visit 2 (35.3% versus 16.9%). While the proportions of CKM worsening were similar between groups, cancer survivors had a significantly higher mortality rate (12.2% vs 4.8%) during follow-up. Cancer history itself was not a predictor of CKM worsening after adjusting for sociodemographic factors (OR = 1.03; 95% CI = 0.75-1.43). After accounting for competing mortality, cancer survivors were 37% less likely to experience CKM stage progression than those without a cancer history (HR = 0.63; 95%CI = 0.47-0.83; $P<0.01$).

Conclusion: CKM diseases are prevalent among Hispanic adults, with cancer survivors experiencing more advanced CKM stages and higher mortality rates over time than those without a history of cancer.

#2340 African ancestry, Duffy-null genotype, and epithelial ovarian cancer in a cohort of Black women.

Joellen M. Schildkraut[1], Jeffrey R. Marks[2], Xintian Song[3], Yao Xin[4], Anthony J. Alberg[5], Lauren C. Peres[6], Katherine Anne Lawson-Michod[7], Lindsay Jane Collin[8], Jennifer A. Doherty[9], Andrew B. Lawson[10], on behalf of the African American Cancer Epidemiology Study

[1]Emory University, Rollins School of Public Health, Atlanta, GA,[2]Surgery, Duke University, Durham, NC,[3]Epidemiology, Emory University, Rollins School of Public Health, Atlanta, GA,[4]Medical College of South Carolina, Charleston, SC,[5]Epidemiology, University of South Carolina, Columbia, SC,[6]Moffitt Cancer Institute, Tampa, FL,[7]Fred Hutchinson Cancer Center, Seattle, WA,[8]Emory University, Rollins School of Public Health, Salt Lake City, UT,[9]University of Utah Huntsman Cancer Institute, Salt Lake City, UT,[10]Biostatistics, Medical College of South Carolina, Charleston, SC

Background: Black women experience poor survival from epithelial ovarian cancer (EOC), for all stages at diagnosis and EOC histotypes. We present findings of the contribution of African ancestry and an ancestry-related genotype in the Atypical Chemokine Receptor 1 (*ACKR1*) gene to EOC survival among a cohort of Black/African American women. We also report associations with tumor molecular features that may explain the potential underlying biology related to the Duffy-null *ACKR1* genotypes.

Methods: The relationship between global African ancestry and the rs2814778 SNP in the promotor region of the *ACKR1* gene and survival was determined in a cohort of 408 Black women with EOC (275 with high grade serous ovarian cancer (HGSC)) who participated in the population-based African American Cancer Epidemiology Study (AACES) using a Bayesian modeling approach adjusting for stage, age at diagnosis, the Yost index for socioeconomic status, education, and ovarian cancer family history. Proportion of global African ancestry and the *ACKR1* genotype (Duffy-null (CC) vs. TC/ TT) were determined from germline DNA. Tumor molecular features including gene expression using RNAseq, tumor immunity (i.e., T-cell abundance) measured using multiplex immunofluorescence (mIF), and homologous recombination deficiency (HRD) derived from whole exome sequencing data were generated from HGSC tumors.

Results: The Duffy-null genotype was present in 70.6% EOC cases overall, and 72.0% of HGSC. The prevalence was higher among individuals with high African ancestry (African ancestry >83.6%) than those with lower African ancestry (83.2% and 58.3%, respectively). The Duffy-null genotype was associated with improved survival among EOC cases (adjusted Hazard Ratio (HR)=0.59, 95% credible intervals (CI): 0.35-0.96). The corresponding HR for HGSC was 0.61 (95% CI: 0.34-1.12). However, global African ancestry—as indicated by a 1% increase in percent African ancestry on the logit scale—was suggestively associated with worse survival, especially for HGSC, with an HR of 1.31 (95% CI: 0.89-1.90). Additionally, we examined the relationship between the CC vs. TC/ TT genotypes and tumor molecular features in HGSC. The Duffy-null genotype was associated with lower *ACKR1* expression, lower cytotoxic T cell abundance, and higher HRD in HGSC. Among EOC subjects, mIF-derived myeloid cells (CD11b+) showed lower abundance in those with high African ancestry, which is consistent with worse survival.

Conclusion: The Duffy-null genotype is associated with ~40% decreased EOC mortality in Black women. Lower T-cell infiltrates may reflect lower immune surveillance and may coincide with higher HRD in HGSC among Duffy-null individuals. The HRD finding, in particular, may explain the improved prognosis observed with the Duffy-null genotype, as our group has previously shown that HRD status was associated with better survival in Black women with HGSC.

#2341 Using geospatial methods to analyze associations of neighborhood change on breast cancer mortality in Maryland, 2000-2019.

Katherine L. Ho[1], Kassandra I. Alcaraz[2], Avonne E. Connor[1], Michael R. Desjardins[1]

[1]Johns Hopkins Bloomberg Sch. of Public Health, Baltimore, MD,[2]Johns Hopkins School of Medicine, Baltimore, MD

Purpose: To examine whether neighborhood change status (declining, stable, or upgrading) is associated with the risk of breast cancer (BC)-specific mortality.

Background: Neighborhood-level social determinants of health are associated with BC mortality, but few studies have investigated how dynamic neighborhood conditions over time and geography (i.e., neighborhood trajectories) can modulate the risk of BC-specific mortality.

Methods: We identified primary BC cases diagnosed among women age ≥18 in the Maryland Cancer Registry (NPCR) between 2005-2019 with valid census tract information at diagnosis (proxy for neighborhood). Observed and expected BC deaths were calculated by tract using 2000 standard female population and referent BC mortality rates for Maryland from 2018-2022 (age <50: 4.4 deaths/100k; age ≥50: 60.8 deaths/100k). Tracts were linked to a continuity-adjusted version of the Social Vulnerability Index (CA-SVI), which harmonized SVI component variables across years. Neighborhood change was defined as the difference in CA-SVI percentiles between consecutive 5-year periods (2000-2004, 2005-2009, 2010-2014, 2015-2019). Tracts were classified as stable (Low, Low-Medium, Medium-High, High CA-SVI)), upgrading (–25 to –49 or ≤–50 %ile; becoming moderately/substantially less disadvantaged), or declining (+25 to +49 or ≥+50 %ile; becoming moderately/substantially more disadvantaged). We evaluated the relationship between neighborhood change and BC mortality using Bayesian negative binomial space-time models that captured effects for geographic clustering and temporal trends. Models were adjusted for individual-level covariates (age, stage, grade, receipt of treatment [surgery, chemotherapy, radiation, hormone], and tumor characteristics [ER, PR, HER2 status]), starting/ending CA-SVI categories, and county-level rurality (2013 USDA Beale Rural-Urban Continuum Codes).

Results: Among 60,388 BC cases, 8,946 died as a result of their diagnosis. Women residing in neighborhoods that modestly improved (+1 cat.) had a slightly elevated risk of BC mortality compared to those living in areas of stably low CA-SVI (Relative risk $[RR]_{Inc}$ =1.11, 95% Credible Interval [CrI] 1.01-1.22). Women living in neighborhoods that became more disadvantaged had between 11 to 24% higher risk of BC mortality ($RR_{Decl1\ cat.}$=1.11 [1.01-1.02], $RR_{Decl2\ cat.}$=1.24 [1.04-1.48]).

Conclusion: Both sustained vulnerability and shifts in neighborhood conditions were associated with BC-specific mortality. Marked declines showed the highest risk for BC mortality, but sustained vulnerability and modest upgrades also indicated elevated risk. These results highlight the importance of neighborhood contexts on cancer outcomes, emphasizing the need for longitudinal research evaluating how neighborhood trajectories might affect place-based inequities.

#2342 Neighborhood concentrated disadvantage and risk of recurrence or breast cancer death in a nationwide study of US Black women.

Sabrina Mellinghoff[1], Etienne Holder[1], Nora Xu[1], Mollie Barnard[2], Julie R. Palmer[3]

[1]BU School of Medicine, Boston, MA,[2]Boston University, Boston, MA,[3]Professor of Epidemiology, Boston University, Boston, MA

Purpose: US Black women with breast cancer experience higher rates of recurrence and disease-specific mortality.[1] We previously found that Black breast cancer patients living in areas of high neighborhood concentrated disadvantage (nDIS) have poorer breast cancer-specific survival when compared to those living in areas with low nDIS.[2] The present analysis incorporates recurrence events to assess the association of nDIS with disease-free survival. We hypothesize that the association will be weaker than with mortality, an outcome more clearly influenced by neighborhood-level factors such as access to care.
Methods: We included 2,290 Black Women's Health Study (BWHS) participants diagnosed with incident breast cancer (stages I-III). Recurrence was defined as an invasive cancer in the ipsilateral breast or in a common metastatic site (lung, liver, brain, or bone) occurring more than four months after the initial breast cancer diagnosis. Medical records were reviewed to distinguish true metastases from new primary tumors. Data on death and cause of death were determined from the National Death Index. We used geocoded participant addresses from the time of breast cancer diagnosis in conjunction with US Census Bureau and American Community Survey data to calculate nDIS. Hazard ratios (HRs) and 95% confidence intervals (CI) were estimated from multivariable Cox proportional hazards models with control for tumor characteristics, treatments, education, insurance, and lifestyle factors.
Results: There were 399 poor breast cancer outcomes (recurrence or death) among 2,290 breast cancer cases followed for a median of 10.5 years. Compared to women in the lowest quartile of nDIS, HRs for a subsequent breast cancer outcome were 1.00 (95% CI 0.93-1.89), 1.19 (95% CI 0.89-1.59) and 1.29 (95% CI 0.94-1.75), for quartiles 2, 3, and 4, respectively. A statistically significant trend was observed across quartiles (*p*-trend=0.03), indicating increasing risk of poor outcomes with greater neighborhood disadvantage.
Conclusions: Breast cancer survivors living in the most disadvantaged neighborhoods were estimated to have 1.29 times the rate of breast cancer death or recurrence compared to those living in the most advantaged neighborhoods. While our findings were statistically significant, the magnitude was lower than the 1.47-fold increase in mortality rate that we previously observed in the same study population, suggesting that factors captured by nDIS may be more important to survival than to recurrence.

#2343 Reproductive factors associated with breast cancer risk by subtypes: Findings from the Southern Community Cohort Study.

Rajat Das Gupta, Wanqing Wen, Wei Zheng

Medicine, Vanderbilt University Medical Center, Nashville, TN

Background:
Breast cancer is the most common cancer among U.S. women. Reproductive factors may influence breast cancer etiology through hormonal pathways that differ by molecular subtypes. We investigated the associations between reproductive factors and breast cancer risk by subtypes in the Southern Community Cohort Study.

Methods:
After excluding the first year of follow-up to minimize potential reverse causation, 42,922 women aged 40-79 years (69.2% Black) remained for the study. Cohort members were followed for up to 213 months. Breast cancer cases were classified by estrogen receptor (ER), progesterone receptor (PR), and human epidermal growth factor receptor 2 (HER2) status as luminal A-like (ER/PR+, HER2-), luminal B-like (ER/PR+, HER2+), HER2-enriched (ER/PR-, HER2+), and triple-negative breast cancer (TNBC; ER/PR/HER2-). To account for competing risk, cause-specific Cox proportional hazards models were used to estimate hazard ratios (HRs) and 95% confidence intervals (CIs) for associations between reproductive factors and each breast cancer subtypes. Models were adjusted for age, enrollment source, education, race, income, family history of breast cancer, personal history of breast cysts or fibroids, smoking, alcohol intake, body mass index, leisure-time physical activity, healthy eating index, and ever use of oral contraceptive pills and hormone replacement therapy. Subgroup analyses were conducted among Black women. We repeated the above analyses using Fine-Gray subdistribution hazard models.

Results:
Over follow-up, 1,257 breast cancers occurred (luminal A-like = 612; luminal B-like = 105; HER2-enriched = 62; TNBC = 180; unclassified = 298). In the overall cohort, multiparity, particularly ≥3 births, was inversely associated with luminal A-like (HR = 0.74; 95% CI: 0.57-0.96) and luminal B-like (HR = 0.53; 95% CI: 0.30-0.94) subtypes, but positively with ER-/PR- disease (HR = 1.71; 95% CI: 1.06-2.77). Among Black women, it was also positively associated with TNBC (HR = 2.30; 95% CI: 1.12-4.72). Among parous women, first live birth at ≥ 30 years was associated with a higher risk of ER+/PR+ (HR = 1.59; 95% CI: 1.05-2.40) but a lower risk of ER-/PR- (HR = 0.25; 95% CI: 0.08-0.76) breast cancer. Fine-Gray models showed consistent results with cause-specific models.

Conclusions:
Parity and age at first birth demonstrate subtype-specific associations with breast cancer risk. Multiparity is associated with a reduced risk of luminal breast cancer subtypes but an increased risk of ER–/PR– tumors. A later age at first childbirth is associated with an increased risk of ER+/PR+ disease and a decreased risk of ER–/PR– subtypes. These findings highlight etiologic heterogeneity by hormonal receptor status and underscore the importance of incorporating reproductive history in subtype-specific risk prediction and prevention strategies.

#2344 Cardiometabolic health and risk of breast cancer subtypes among US Black women.

Yifei Shan, Sarah M. Rothbard, Lynn Rosenberg, Julie R. Palmer, **Mollie E. Barnard**

Boston University Chobanian & Avedisian School of Medicine, Boston, MA

Background: In the United States (US), Black women are more likely to be diagnosed with estrogen receptor (ER)-negative breast cancers as compared with White women. Cardiometabolic conditions are also more common among Black women. Understanding their associations with risk of breast cancer subtypes may help to explain racial differences in breast cancer risk. Prior studies have identified obesity as a risk factor for postmenopausal ER+ breast cancer and type 2 diabetes as a probable risk factor for ER- breast cancer. The goal of the present study was to comprehensively evaluate the associations of cardiometabolic factors with breast cancer subtypes in a large population of US Black women.

Methods: The Black Women's Health Study is a prospective study of 59,000 self-identified US Black women. Cardiometabolic factors that have been queried every two years since the start of the study in 1995 include high body mass index (BMI ≥30 kg/m^2), type 2 diabetes, hypertension, and hypercholesterolemia. Breast cancer cases were identified through self-report on biennial questionnaires, review of death certificates, and linkage to cancer registries. Hospital or registry-recorded pathology data were used to classify cases by ER status and to assign breast cancer subtypes (luminal A-like, luminal B-like, HER2-overexpressed, and triple negative). We used competing risk Cox proportional hazards models to estimate the associations between cardiometabolic factors and breast cancer subtypes, adjusting for age, reproductive factors, and lifestyle factors.

Results: In comparisons of women with each cardiometabolic exposure to those without that exposure, elevated BMI was associated with an increased risk of luminal A-like breast cancer among postmenopausal women (hazard ratio [HR] 1.32 (1.03-1.68) for BMI ≥30 kg/m^2 versus <25 kg/m^2). All other results were not statistically significant. When we repeated the analyses using a common referent group (those with no cardiometabolic conditions), no patterns of association were observed among premenopausal women. Among postmenopausal women, HRs for all cardiometabolic factors were above 1.00 for ER+ breast cancers, although none of the HRs were statistically significant. In analyses of combined groups of cardiometabolic factors, the HR for three or more cardiometabolic conditions versus none was 1.32 (0.98-1.77) for ER+ breast cancer in postmenopausal women.

Conclusions: In this large study of US Black women, poorer cardiometabolic health was associated with a higher risk of postmenopausal ER+ breast cancer. The observed association seems to be driven by the positive association of obesity with postmenopausal luminal A-like breast cancer, as has been seen in other racial and ethnic groups.

#2345 Pre-diagnostic circulating 25-hydroxyvitamin D and prostate cancer survival: A collaborative analysis of 13 prospective studies.

Jiaqi Huang[1], Aurora Perez-Cornago[2], Ruth Travis[2], Timothy J. Key[2], Naomi Allen[2], **Demetrius Albanes**[3], on behalf of the Endogenous Hormones Nutritional Biomarkers and Prostate Cancer Collaborative Group

[1]National Clinical Research Center for Metabolic Diseases, Key Laboratory of Diabetes Immunology, Ministry of Education, and Department of Metabolism and Endocrinology, The Second Xiangya Hospital of Central South University, Changsha, Hunan, China,[2]Cancer Epidemiology Unit, Nuffield Department of Population Health, University of Oxford, Oxford, United Kingdom,[3]National Cancer Inst. Div. of Cancer Epidemiology & Genetics, Bethesda, MD

Previous research suggests increased risk of prostate cancer in men with higher vitamin D serology, but there are limited data related to prostate cancer survival. In this study, we examined the association between pre-diagnostic blood concentrations of 25-hydroxyvitamin D [25(OH)D] and the risk of prostate cancer-specific mortality, as well as mortality from other causes, in men diagnosed with prostate cancer. This prospective international collaborative analysis of circulating 25(OH)D, the major biochemical indicator of vitamin D status, was based on data for 12,635 incident prostate cancer cases from 13 cohorts. Multivariable-adjusted Cox proportional hazards regression models estimated hazard ratios (HRs) and 95% confidence intervals (CIs) for the associations between study-specific/season-standardized categories as well as clinically defined 25(OH)D categories (<30, 30-50, 50-75, and ≥75 nmol/L) and death from prostate cancer (n=1,316) and other causes (n=2,129). In fully adjusted models that included demographic and lifestyle factors, as well as information on stage and grade of prostate cancer at diagnosis (available for 5,363 and 5,928 cases, respectively), men who had higher pre-diagnostic 25(OH)D concentrations experienced lower prostate cancer-specific mortality (HR for 80-percentile increase=0.75, 95% CI: 0.64-0.88; P_{trend}<0.001) and somewhat lower risk of mortality from other causes (HR=0.85, 95% CI: 0.75-0.96; P_{trend}=0.009). When analyses were restricted to cases with complete stage and grade information (5,078 cases (40.2% of all cases) and 761 deaths from prostate cancer [57.8% of all deaths]), the association between 25(OH)D and prostate cancer mortality was only slightly attenuated in the model that was further adjusted for these clinical factors (HR for 80-percentile increase=0.76, 95% CI: 0.62-0.93; P_{trend}=0.009). Vitamin D was not associated with risk of death from other causes in this same subset of cases (HR=0.97, 95% CI: 0.83-1.12; P_{trend}=0.7). In this pooled prospective cohort analysis, higher pre-diagnostic circulating vitamin D (25(OH)D) was associated with lower prostate cancer-specific mortality in men with prostate cancer. Further research is required to establish whether the association may be contributed to by biases such as the earlier detection of disease and thus better survival in men with higher vitamin D in these populations, as well as to investigate possible biological impacts of vitamin D on prostate cancer progression.

#2346 Uptake of conservative management, and uptake of curative-intent treatment following conservative management, in low and favorable-intermediate risk prostate cancer patients.

Isaac Allen[1], Jane Bailey Vaselkiv[2], Hannah E. Guard[2], Sinead Flanagan[2], Hari Iyer[3], Kevin Kensler[4], Jaime E. Hart[5], Mark A. Preston[6], Andreas Pettersson[7], Keyan Salari[8], Edward L. Giovannucci[9], Adam S. Kibel[6], Lorelei A. Mucci[2], Timothy Rebbeck[1]

[1]Dana-Farber Cancer Institute, Boston, MA,[2]Harvard T.H. Chan School of Public Health, Boston, MA,[3]Rutgers Cancer Institute of New Jersey, New Brunswick, NJ,[4]Weill Cornell Medicine, New York, NY,[5]Department of Medicine, Brigham and Women's Hospital and Harvard Medical Schoo, Boston, MA,[6]Department of Urology, Brigham and Women's Hospital, Boston, MA,[7]Department of Medicine Solna, Karolinska Institutet, Stockholm, Sweden,[8]Department of Urology, Massachusetts General Hospital, Boston, MA,[9]Professor of Nutrition & Epidem., Harvard TH Chan School of Public Health, Boston, MA

Background

Low-risk and favourable-intermediate risk prostate cancer patients are eligible for conservative management. We estimated the probability of conservative management uptake and 10-year rates of curative treatment initiation following conservative management in a prospective cohort of 2,872 health professionals diagnosed with low or favorable-intermediate risk prostate cancer.

Methods

The study included males with low-risk (grade group 1, stage≤cT2a, prostate-specific antigen (PSA)<10ng/ml) and favourable-intermediate risk (grade group 1, stage cT2b-cT2c or PSA 10-20ng/ml, or grade group 2, stage≤cT2a and PSA<10ng/ml) prostate cancer whom were diagnosed 1986-2019 and were participants in the Health Professionals Follow-up Study. We estimated the variation in conservative management uptake by age and calendar year at diagnosis, prostate cancer risk group, and pre-diagnostic lifestyle using Poisson regression. We estimated 10-year rates of curative treatment initiation in patients that initially received conservative management using Fine and Gray models adjusted for competing risks of lethal progression (prostate cancer death, metastasis, or initiation of hormone therapy) and other-cause death, censoring at December 2022. We assessed the variation in continuation to curative treatment with Cox models.

Results

The uptake of conservative management was 16% (444/2872). Conservative management was higher in older patients (1 year of additional age - Relative Risk (RR): 1.08, 95% CI: 1.06 - 1.11), in later calendar years (1 additional year - RR: 1.07, 95% CI 1.05 - 1.10)), and in neighborhoods of higher socioeconomic status (1 standard deviation rise - RR: 1.16. 95% CI 1.03 - 1.30). Uptake was lower in favorable-intermediate risk, rather than low-risk, prostate cancer (RR: 0.47. 95% CI 0.35 - 0.61). Among the 444 patients who initially received conservative management, when adjusted for competing risks of lethal progression and other-cause death, the 10-year curative treatment incidence was 22%. Patients were more likely to continue to curative treatment if they were younger at diagnosis (1 year of additional age - Hazard Ratio (HR): 0.96, 95% CI: 0.93 - 0.99) or had healthier post-diagnostic lifestyles (increase of 1 in joint measure of physical activity, BMI, and smoking, scored 0-3 - HR: 1.47, 95% CI 1.01 - 2.15).

Conclusion

We found age at diagnosis, calendar year at diagnosis, prostate cancer risk group, and neighborhood-level socioeconomic status to affect conservative management uptake, and age at diagnosis and post-diagnostic lifestyle to affect rates of curative treatment initiation following conservative management, in low/favorable-intermediate risk prostate cancer patients. These results could inform the clinical management of low/favorable-intermediate risk prostate cancer.

#2347 Lethal progression risks of low risk and favorable-intermediate risk prostate cancer in a prospective cohort of US health professionals.

Isaac Allen[1], Jane Bailey Vaselkiv[2], Hannah E. Guard[2], Sinead Flanagan[2], Hari Iyer[3], Kevin Kensler[4], Jaime E. Hart[5], Mark A. Preston[6], Andreas Pettersson[7], Keyan Salari[8], Edward L. Giovannucci[9], Meir Stampfer[10], Adam S. Kibel[6], Lorelei A. Mucci[2], Timothy Rebbeck[1]

[1]Dana-Farber Cancer Institute, Boston, MA,[2]Harvard T.H. Chan School of Public Health, Boston, MA,[3]Rutgers Cancer Institute of New Jersey, New Brunswick, NJ,[4]Weill Cornell Medicine, New York, NY,[5]Department of Medicine, Brigham and Women's Hospital and Harvard Medical School, Boston, MA,[6]Department of Urology, Brigham and Women's Hospital, Boston, MA,[7]Department of Medicine Solna, Karolinska Institutet, Stockholm, Sweden,[8]Department of Urology, Massachusetts General Hospital, Boston, MA,[9]Professor of Nutrition & Epidem., Harvard TH Chan School of Public Health, Boston, MA,[10]Department of Epidemiology, Harvard T.H. Chan School Public Health, Boston, MA

Background

Low-risk (grade group 1, stage≤cT2a, PSA<10) or favorable-intermediate risk (grade group 1, stage cT2b-cT2c or PSA 10-20, or grade group 2, stage≤cT2a and PSA<10) prostate cancer patients are at risk of progressing to lethal disease (prostate cancer death or metastasis, or receipt of hormones). We estimated 35-year lethal progression risks in a prospective cohort of health professionals with low/favorable-risk prostate cancer.

Methods

We followed 2872 men from diagnosis (1986-2019) to lethal progression, censoring at other-cause death or December 2022. We estimated 35-year cumulative incidences using Kaplan-Meier techniques and assessed lethal progression risk by treatment, sociodemographics, PSA, stage, grade group, and lifestyle with Cox models.

Results

We saw 260 lethal progressions over a median follow-up of 15.7 years (IQR: 8.6 years). The 35-year cumulative lethal progression incidence was 16.7% (95% confidence interval (CI): 13.3 - 20.4%). Lethal progression risks were higher in patients older at diagnosis (Hazard Ratio (HR): 1.08, 95% CI: 1.06 - 1.10) and with higher PSA at diagnosis (HR: 1.08, 95% CI: 1.05 - 1.12), and were lower in patients that received curative-intent treatment (radical prostatectomy, radiotherapy, brachytherapy, or cryosurgery) (HR: 0.34, 95% CI: 0.24 - 0.48) or or had healthier post-diagnostic lifestyles (increase of 1 in joint measure of physical activity, BMI, and smoking, scored 0-3 - HR: 0.74, 95% CI: 0.60 - 0.91).

Conclusion

Over 35 years of follow-up, we saw higher lethal progression risks in patients older at diagnosis or with higher PSA at diagnosis, and lower risks in patients that had curative-intent treatment or with healthier post-diagnosis lifestyles. These results may inform clinical management of low/favorable-intermediate risk prostate cancer.

#2348 Impact of transportation infrastructure on differentially expressed miRNAs in triple negative breast cancer stages at diagnosis.

Nathan Xiang[1], Amjila Bam[2], Nubaira Rizvi[2], Micheal Celestin[2], Ty-Runet Bryant[2], Tung Sung Tseng[2], Bingbing Mao[2], Xiao-Cheng Wu[2], Qingzhao Yu[2]

[1]Tulane University, New Orleans, LA,[2]School of Public Health, Louisiana State University Health Science Center, New Orleans, LA

Purpose: Triple negative breast cancer (TNBC) is a subtype of breast cancer (BC) characterized by the absence of estrogen, progesterone, and HER2 receptors, accounts for 10-15% of all BC cases, and is associated with poor clinical outcomes. Environmental factors such as residential proximity to major transportation infrastructure may influnce disease severity, yet evidence and molecular mechanism remain fragmented. MicroRNAs (miRNAs) regulate tumor growth and treatment response, acting as either tumor suppressors or oncogenes. Here, we investigated miRNA expression across varying environmental exposure groups in TNBC, aiming to evaluate the impact of proximity to high volumes of transportation infrastructure on clinical outcomes in TNBC patients.
Methods: Total 434 TNBC patients diagnosed between 2009 and 2019 in Louisiana were included. Clinical and environmental data were integrated from Louisiana Tumor Registry (LTR) and Environmental Justice Index (EJI). RPL_EBM_DOM4 is the environmental variable representing the percentile rank of domain consisting of proximity to high volume roads, railways, and airports, and is categorized into 4 groups. TNBC stages were categorized as early or advanced. All of their Formalin-Fixed, Paraffin-Embedded (FFPE) TNBC tumor specimens were collected. MiRNA expression was profiled using high-throughput sequencing and normalized via the TMM method. Differentially expressed (DE) miRNAs were identified using edgeR, adjusting for plate effects. Shared DE miRNAs across TNBC stage and RPL_EBM_DOM4 were visualized using a Venn Diagram. All the analysis were performed using R.4.5.0. Statistical significance was considered as $p<0.05$.
Results: Advanced TNBC patients resided closer to major transportation infrastructure. There was a statistically significant association between RPL_EBM_DOM4 and TNBC stages ($p=0.005657$), indicating that environmental exposure to transportation infrastructure may increase the risk of advanced TNBC. A total of 196 miRNAs were identified as differentially expressed in relation to proximity to high-volume transportation infrastructure, and 69 miRNAs were associated with TNBC stage. Of these, 32 miRNAs were commonly differentially expressed across both RPL_EBM_DOM4 and TNBC stage.
Conclusion: Our study identified miRNAs potentially mediating the influence of environmental exposures on TNBC progression. The discovery of shared DE miRNAs offers insights into the molecular mechanisms underlying TNBC and suggests potential targets for intervention and prevention strategies tailored to environmentally influenced cancer outcomes. Futher studies by incorporating additional TNBC-related outcomes (such as patient survival) and other environmental risk factors may gain more comprehensive understanding of TNBC and provide strategies for equitable healthcare.

#2349 An investigation of etiologic heterogeneity across transcriptomic subtypes of clear cell renal cell carcinoma in two case-control studies.

Eun Mi Jung[1], Kristine Jones[2], Diptavo Dutta[1], Jonathan N. Hofmann[1], Helena Furberg Barnes[3], Stephen J. Chanock[1], Nat Rothman[1], Paul Brennan[4], Kai Yu[1], Mark P. Purdue[1]

[1]Division of Cancer Epidemiology and Genetics, National Cancer Institute, Rockville, MD,[2]Cancer Genomics Research Laboratory, Frederick National Laboratory for Cancer Research, Frederick, MD,[3]Memorial Sloan Kettering Cancer Center, New York, NY,[4]Section of Genetics, International Agency for Research on Cancer, Lyon, France

The well validated Clearcode34 transcriptomic subtypes of clear cell renal cell carcinoma (ccRCC) are clinically distinct, with ccB tumors having poorer patient survival than ccA tumors, yet few studies have evaluated whether the subtypes possess distinct risk factor profiles. To address this question, we investigated potential etiologic heterogeneity between the ccA and ccB subtypes in two case-control studies conducted in Europe (144 ccA, 106 ccB, 1,476 controls) and the U.S. (75 ccA, 27 ccB, 1,235 controls). We measured expression levels of the 34-gene Clearcode panel to classify ccRCC tumors by subtype. For each study we conducted (1) case-only analyses (ccB vs. ccA) using logistic regression to assess subtype differences in tumor characteristics and control matching factors (e.g., age, sex, race/ethnicity) and (2) case-control analyses using polytomous regression to compute subtype-specific associations with established and suspected RCC risk factors [e.g., body mass index (BMI), smoking, hypertension, polygenic risk score (PRS) derived from genome-wide association studies (European-ancestry subjects)]. Study-specific findings were combined through meta-analysis using random effects models. We also computed associations with additional suspected risk factors that were assessed in the US study only. In the meta-analysis of case-control findings, we found ccA tumors to be more strongly associated with obesity [odds ratio (OR)=3.75, 95% confidence interval (CI)=1.14-12.35] than ccB tumors (OR=1.56, 95% CI=0.96-2.52). Conversely, ccB tumors were more strongly associated with a PRS based on 13 risk variants (90^{th} vs. 10^{th} percentile: OR_{ccA}=1.96, 95% CI=1.23-3.11; OR_{ccB}=3.34, 95% CI=1.83-6.11). From the U.S study, we identified that ccB tumors were more common among US Black vs. White patients (case-only OR=6.71, 95% CI=1.22-36.98), more strongly associated with chronic renal failure (OR_{ccB}=22.12, 95% CI=6.22-78.72; no exposed ccA cases), and more highly associated with a recent PRS based on 108 risk variants (90th vs. 10th percentiles: OR_{ccA}=3.26, 95% CI=1.39-7.60; OR_{ccB}=13.12, 95% CI=1.61-107.02). We did not observe any notable differences by subtype for the associations with smoking, hypertension, hysterectomy, oophorectomy, physical activity, and alcohol consumption. Our findings suggest the existence of etiologic heterogeneity between the Clearcode34 subtypes, with ccA tumors more strongly associated with excess weight and ccB tumors more common among Black patients and more strongly associated with chronic renal failure and genetic risk scores. This evidence suggesting risk factor heterogeneity across subtypes highlights the importance of accounting for tumor molecular characteristics in investigations of ccRCC etiology and risk prediction models.

#2350 Subtype-specific patterns of peripheral T-cell lymphoma in diverse Asian populations.

Xuanxi Kuang[1], Esther Lam[2], Mallory P. Bernstein[3], Nicole Foley[3], Lauren Pinter-Brown[4], Megan S. Lim[5], Wendy Cozen[3]

[1]University of California, Irvine, Irvine, CA,[2]UCI Health, Orange, CA,[3]Medicine, Division of Hematology-Oncology, UCI School of Medicine, Irvine, CA,[4]Medicine, UCI School of Medicine, Irvine, CA,[5]Pathology, Memorial Sloan Kettering Cancer Center, New York, NY

Peripheral T-cell lymphomas (PTCLs) are rare, aggressive non-Hodgkin T-cell lymphomas with a poor prognosis. Black individuals have a higher incidence compared to White individuals, but little is known about incidence rates for specific Asian populations. We obtained average annual age-adjusted incidence rates (AAIR)/100,000 based on the age distribution for the US 2000 Census for PTCL-not otherwise specified (ICD-O-3: 9702), angioimmunoblastic T-cell lymphoma (AITL, 9705), and anaplastic large cell lymphoma (ALCL, 9714) within Asian subpopulations, in addition to rate ratios(RR) comparing racial/ethnic groups with non-Hispanic whites (NHW) as a reference group. Data was obtained from the Surveillance, Epidemiology, and End Results (SEER) 9 registry (1990-2014). The combined-subtype analysis showed no significant difference between Asian-Pacific Islanders overall and NHW (RR 0.94; p=0.0976), but stratified analysis in SEER showed striking differences. Southeast Asians had the highest incidence rates, followed by Filipinos, while Chinese had the lowest incidence rates (Table 1). By subtype, Southeast Asians had the highest incidence rates of PTCL-NOS (0.72/100,000, RR= 2.40, p=0.002, based on 21 cases), followed by Filipinos (0.45/100,000, RR=1.49, p<0.001). Both Filipinos (p=0.0004) and Vietnamese (p=0.05) had higher incidence rates of AITL (0.18/100,000) compared to NHW (0.1/100,000) with RR=1.73. NHW had the highest incidence rates of ALCL (0.23/100,000). Compared to NHW, Chinese, Japanese, and Koreans showed significantly lower ALCL rates (RRs = 0.45-0.57, p < 0.01). These findings highlight distinct subtype-specific PTCL risk patterns across Asian subgroups. Given the low case counts, results should be interpreted cautiously. Disaggregation of Asian subgroups in PTCL subgroups remains essential to identify high-risk groups and improve prognostic accuracy.

Table 1. AAIR and RR for PTCL by racial/ethnic group.

	AAIR/100,000	95% CI	N	Rate Ratio	95% CI	P-value
Non-Hispanic Whites	0.63	0.62. 0.65	6,778	1.0		
Chinese	0.50	0.43, 0.59	171	0.80	0.68,0.93	0.0031
Japanese	0.60	0.51, 0.71	141	0.96	0.80, 1.13	0.6544
Filipino	0.80	0.71,0.91	260	1.27	1.12,1.44	0.0004
Korean	0.51	0.39, 0.65	64	0.80	0.61,1.03	0.0932
Vietnamese	0.73	0.58,0.92	87	1.16	0.91,1.45	0.2260
Pacific Islander	0.73	0.54,0.96	54	1.16	0.86, 1.52	0.3385
SE Asian	0.94	0.59,1.41	28	1.49	0.94,2.23	0.0882

#2351 Population awareness of HBV, HCV, and their association with cancer in the US.

Eric Adjei Boakye[1], Chaitali Dagli[2], Minerva So[1], Pranali G. Patel[2], Mrudula Nair[1], Joel Fokom Domgue[3]

[1]Henry Ford Health, Detroit, MI,[2]University of Alabama at Birmingham, Birmingham, AL,[3]MD Anderson Cancer Center, Houston, TX

Introduction: It is estimated that there will be 42,240 new cases and 30,090 deaths of liver cancer in the US in 2025. Chronic hepatitis B and C infections are the leading risk factors of liver cancer, yet public awareness of their oncogenic potential remains limited. Understanding population-level awareness of this link is essential for improving prevention, screening, and vaccination efforts. We examined the prevalence and association between sociodemographic characteristics and awareness of the link between hepatitis B or C and cancer among U.S. adults.

Methods: We analyzed data from the Health Information National Trends Survey (HINTS 7), a nationally representative survey of U.S. adults conducted in 2024. The outcome was awareness about the link between hepatitis B or C and cancer (yes/no). The outcome was accessed with the question “Do you think the Hepatitis B virus (also known as Hep B or HBV), or Hepatitis C virus (also known as Hep C or HCV) can cause cancer?” Weighted prevalence of awareness of hepatitis B or C as a cause of cancer was estimated among respondents. A weighted multivariable logistic regression model was used to estimate the association between sociodemographic characteristics (age, gender, race/ethnicity, marital status, education level, household income, rural-urban status, # of healthcare visits, and health status) and awareness of the link between hepatitis B or C and cancer.

Results: A total of 7,278 participants were included in the analysis, including 51% of individuals aged 18-48 years, 52% of female, 61% of non-Hispanic White, 56% of married, 33% of college graduates, and 27% with household annual income of <$35,000. Of these, 26.9% were aware that hepatitis B or C can cause cancer. Compared with respondents aged 18-49 years, those aged ≥65 years were less likely to know that hepatitis B or C can cause cancer (aOR=0.57; 95% CI: 0.44-0.76). Similarly, compared to respondents who were married, those who were divorced/separated/widowed were less likely to know that hepatitis B or C can cause cancer (aOR=0.73; 95% CI: 0.53-0.98). However, respondents who were college graduates were more likely to know hepatitis B or C can cause cancer (aOR=2.03; 95% CI: 1.39-2.95) compared with those with high school diploma or less.

Conclusion: Despite the growing burden of liver cancer in the US, population awareness that hepatitis B or C viruses can cause cancer remains low and varies substantially across sociodemographic groups. These findings suggest critical information/knowledge gaps persist across the U.S. population and call for targeted, health-literacy-appropriate educational interventions to enhance public awareness of preventable cancer risks.

#2352 Disability patterns and subjective cognitive decline among adults with and without cancer history.

Elham Samami[1], Sayantani Sarkar[2], Hermine Poghosyan[3]

[1]School of Nursing, Yale University, Orange, CT,[2]University of California, Berkeley, Greater Sacramento, CT,[3]Yale University, Orange, CT

Background: Subjective cognitive decline (SCD) is a self-reported experience of worsening confusion or memory loss, which increases the risk of dementia and may be influenced by disabilities. This study compared disability types and counts and SCD of people with or without a cancer history and examined the potential association between disability counts and SCD.
Methods: We used cross-sectional survey data from the 2024 Behavioral Risk Factor Surveillance System Cognitive Decline module. The sample included adults aged ≥45 years, with (n=12,601) and without (n=61,575) cancer history. The outcome was self-reported SCD confusion or memory loss worsening in the past 12 months. Disability types included limitations in hearing, vision, mobility, self-care, and independent living, and were categorized by count as 0, 1, 2, 3-5 disabilities. We conducted descriptive statistics and multivariable logistic regression, incorporating an interaction term between cancer history and disability count.
Results: About 73.0% of participants were aged ≥75 years, 53.2% were female, and 66.1% self-identified as White. Overall, 15.4% self-reported SCD, with higher prevalence among cancer survivors than those without cancer history (19.7% vs. 14.7%, p≤.001). The most prevalent disability type was mobility among adults with (31.0%) and without (20.4%) a cancer history. Among cancer survivors, SCD prevalence increased with disability count: 11.8% with no disabilities, 21.5% with one, 32.8% with two, and 47.2% with 3-5 disabilities. Similar patterns were observed in the non-cancer group: 8.9%, 19.8%, 30.2%, and 47.2%, respectively. In subgroup regression models, cancer survivors with 3-5 disabilities have 341% increased odds of reporting SCD compared to those without disabilities (AOR=4.41, 95% CI 3.07-6.33). Individuals without a cancer history who have 3-5 disabilities have 403% higher odds of reporting SCD compared to their no-disability counterparts (AOR=5.03, 95% CI 4.05-6.25). In the full model, both disability count and cancer status were independently associated with SCD; however, the interaction term was not statistically significant, suggesting that cancer status does not influence the relationship between disability count and SCD.
Conclusions: We estimated that SCD affects many individuals with (1.1million) and without (4.8million) cancer history aged ≥45 years. Routine screening for cognitive health, particularly for individuals with disabilities, is crucial for the early identification, proactive management, and tailored care of health needs in the adult population that may potentially lower the risk for dementia. Building personalized and need-based cognitive support resources, such as decision aids, checklists, digital and manual reminders, will help to promote care to this vulnerable group.

#2353 Geospatial analysis of incidence and mortality rates of gastrointestinal cancer and socioeconomic status across Puerto Rico during 2013-2022.

Brenda C. Torres-Velasquez[1], Liliana M. Castro-Jimenez[1], Yoel Velazquez Oliver[1], **Hilmaris Centeno-Girona**[1], Carlos R. Torres-Cintron[2], Elba V. Caraballo[1]

[1]Division of Shared Resources and Scientific Operations, University of Puerto Rico Comprehensive Cancer Center, San Juan, PR,[2]Puerto Rico Central Cancer Registry, University of Puerto Rico Comprehensive Cancer Center, San Juan, Puerto Rico

Colorectal (CRC), gastric, and pancreatic cancers are classified as gastrointestinal (GI) malignancies. Collectively, they rank among the top ten leading causes of cancer-related death in Puerto Rico (PR) for both men and women with CRC being the second most diagnosed and second leading cause of cancer death in PR. This study examines spatial and temporal variations of GI cancer incidence and mortality across municipalities in PR, while evaluating the role of sociodemographic factors and major disruptions -such as Hurricanes Irma and Maria (2017), subsequent earthquakes, and the COVID-19 pandemic- on these patterns across two periods. Age-adjusted incidence rates (AAIRs) and age-adjusted mortality rates (AAMRs) at municipality level were obtained from the PR Central Cancer Registry for 2013-2017 and 2018-2022. Sociodemographic data came from the American Community Survey. Global spatial autocorrelation was assessed using Global Moran's Index (I) and visualized through choropleth maps (Jenks Natural Breaks). Getis-Ord Gi* analysis identified clusters of municipalities with high-incidence or mortality (hot spots) and low-incidence or mortality (cold spots), using Bonferroni correction at a 90% confidence level. Wilcoxon rank-sum tests compared AAIRs, AAMRs, and socioeconomic indicators between periods and spot classifications. Statistical significance was set at $p<0.05$. Analyses were conducted by period using R (version 4.4.1) and R-Studio. Spatial clustering of AAIRs was significant across PR for the full period (Moran's I 0.17, $p<0.05$). Clustering in 2013-2017 was marginal (Moran's I 0.08, $p=0.1$) but became pronounced in 2018-2022 (Moran's I 0.19, $p<0.05$). Furthermore, AAMRs showed positive spatial autocorrelation for 2013-2017 period (Moran's I 0.22, $p<0.001$). In 2013-2017, 11 municipalities were hot spots and 12 were cold spots. In 2018-2022, 10 hot spots emerged—Juana Díaz and Guánica persisted across both periods while nine new cold spots appeared with no overlap. In 2013-2017 period, hot spots had 13% higher AAMRs than cold spots ($p<0.001$), while hot spots had significantly higher AAIRs in the latter period. Socioeconomic status did not correlate with hot or cold spots from 2013-2017; however, cold spots showed significantly higher socioeconomic status than hot spots in the 2018-2022 period: lower household income, and higher rates of poverty and SNAP participation ($p<0.05$). GI cancer in Puerto Rico exhibits persistent spatial clustering: AAIRs intensified in 2018-2022 and AAMRs shifted from higher AAMRs in hot spots during 2013-2017 to an income-related gradient in 2018-2022, where higher socioeconomic levels were linked to lower mortality. These findings suggest that systemic disruptions such as natural disasters and the COVID-19 pandemic may have deepened existing inequalities in vulnerable regions of Puerto Rico.

#2354 Predictors of mortality in patients with hepatobiliary and pancreatic cancers.

Jieun Lee, Sunhee Hwang, Suhyeon Hwang, Junglyun Kim

Chungnam National University, Daejeon, Korea, Republic of

Background Hepatobiliary and pancreatic cancers are the most lethal malignancies, with consistently poor survival outcomes due to delayed diagnosis and limited therapeutic options. Identifying factors associated with mortality is essential for improving prognosis and tailoring supportive care. However, evidence remains limited regarding comprehensive predictors of mortality in this population. This study aimed to identify determinants of mortality using a biopsychosocial approach that incorporates demographic, clinical, laboratory, and psychological factors, including quality of life (QoL).

Methods Patients diagnosed with hepatobiliary or pancreatic cancers were recruited from a university hospital between September 2022 and November 2023, and their mortality was followed up at 1 year from enrollment. Pain, anxiety, depression, and QoL were assessed using the Numeric Rating Scale, Hospital Anxiety and Depression Scale, and Functional Assessment of Cancer Therapy-General, respectively. Clinical information and death records were obtained from electronic health records. Cox proportional hazards regression was performed to identify factors influencing mortality using SPSS 30.0.

Results Among the 204 participants, Among the 204 participants, 81 (39.7%) of deaths were recorded. Higher physical well-being (HR = 0.95, 95% CI: 0.90, 0.99) and undergoing surgical treatment for cancer (HR = 0.38, 95% CI: 0.21, 0.70) were associated with lower mortality. In contrast, higher social well-being predicted increased mortality (HR = 1.12, 95% CI: 1.06, 1.19), which may indicate that patients with advanced disease receive more social support and caregiving. Elevated blood urea nitrogen also predicted higher mortality (HR = 1.03, 95% CI: 1.01, 1.07), suggesting that metabolic burden or renal dysfunction worsens outcomes.

Conclusions Physical well-being, received surgical treatment, and blood urea nitrogen levels were significant predictors of mortality in patients with hepatobiliary and pancreatic cancers. Enhancing physical functioning, surgical treatment history, and monitoring metabolic indicators may improve prognostic assessment. While psychological factors, except QoL, did not directly predict mortality. The findings highlight the value of an integrated biopsychosocial approach for managing high-risk cancer populations.

#2355 The association between metabolic syndrome and cancer: A systematic review.

Rebecca Mattson[1], Mary Barger[2], Arjan De Van Der Star[1], Uduak George[1]

[1]San Diego State University, San Diego, CA,[2]University of San Diego, San Diego, CA

Background: Metabolic syndrome (MetS), a cluster of central adiposity, hypertension, dysglycemia, hypertriglyceridemia, and low HDL cholesterol, has been identified as a possible determinant of lung cancer incidence and mortality.
Objective: To evaluate the association between MetS and lung cancer incidence and mortality, and examine sources of heterogeneity across studies.
Methods: A systematic review was conducted in accordance with PRISMA 2020 guidelines. CINAHL, Web of Science, and PubMed were searched from January 2000 through March 2025 for studies in adults that reported adjusted effect estimates for the relationship between MetS, defined by NCEP ATP III, IDF, or similar criteria, and cancer outcomes. Two reviewers independently screened studies, extracted data, and assessed risk of bias using the Newcastle-Ottawa Scale. Narrative synthesis and random effects meta-analysis were performed, with subgroup analyses by sex, smoking status, geographic region, and MetS definition. Heterogeneity was evaluated with the I^2 statistic and Cochran's Q, and publication bias was examined using Egger's test.
Results: Of 2,607 records screened, 11 studies met the inclusion criteria. In the meta-analysis of lung cancer incidence, the pooled hazard ratio was 1.18 (95% CI 1.04-1.33, p =.010), indicating a higher hazard of lung cancer among individuals with MetS. Heterogeneity was substantial (I^2 = 97.6 percent, $p < .001$).
Conclusions: The reviewed studies indicate that MetS has an association with increased lung cancer incidence. Clinical evaluation for MetS may identify individuals at elevated cancer risk, supporting early lung cancer screening and preventive strategies. Further research should determine whether integrating cancer prevention into MetS management influences long-term cancer outcomes.

#2356 Reliability of stromal markers multiplex immunofluorescent staining: Pathologist assessment compared to quantitative image analysis.

Lusine Yaghjyan[1], Yaileen D. Guzman-Arocho[2], Yu Jing J. Heng[2], Brian R. Sardella[2], Gurzhikhan Murtazaalieva[2], Graham A. Colditz[3], Dongtao Fu[1], Krishna Patel[4], Bernard Rosner[4], **Maisey Ratcliffe**[1], Rulla M. Tamimi[5]

[1]University of Florida, Gainesville, FL,[2]Beth Israel Deaconess Medical Center, Boston, MA,[3]Washington University School of Medicine in St. Louis, St. Louis, MO,[4]Brigham and Women's Hospital and Harvard Medical School, Boston, MA,[5]Weill Cornell Medicine, New York, NY

Purpose: Prior studies show the importance of stroma in breast tumorigenesis. However, there is no data on the expression of stromal markers alpha-smooth muscle actin (αSMA), fibroblast activation protein (FAP), matrix metallo-peptidase (MMP14), tenascin-C (TNC), and calcyclin (s100A6) in the breast tissue of cancer-free women. We compared the immunofluorescence (IF) expression assessment of these markers in histologically normal terminal duct-lobular unit tissue cores between an expert pathologist and an automated image analysis. We also assessed the homogeneity of these markers across multiple cores pertaining to each woman.
Methods: We included 73 cancer-free women with biopsy-confirmed benign breast disease in the Nurses' Health Study (NHS) and NHSII cohorts. IF was conducted with commercial antibodies (αSMA: 1:400 dilution; FAP: 1:50; MMP14: 1:150; TNC: 1:200; s100A6: 1:300). For each core, the % positivity was quantified by the pathologist and inForm v2.6.0. Using the pathologist scores as the gold standard, correlations between the two methods were evaluated with Spearman correlation (for categorical positivity: 0, >0 -<1, 1- 10, >10-50, and >50%) and sensitivity/specificity (for binary positivity with 1%, 10% and 25% cut-offs).
Results: Pathologist and inForm readings were available for 149 and 134 cores, respectively; 105 cores had both manual and automated readings. The correlation in the expression across available cores for a woman (median=3, range 1-6) was strong for FAP, MMP14, and S100A6 (Intra-class correlation [ICC]=0.69, 0.72, 0.63, respectively), moderate for αSMA (ICC=0.35), and poor for TNC (ICC=0.21). Correlation between pathologist and inForm was strong for s100A6, FAP, and MMP14 (0.77, 0.70, and 0.78, respectively) and moderate for αSMA (0.37) and TNC (0.42). With a 1% cut-off, sensitivity was the lowest for TNC (0.30) and ranged between 0.84-0.93 for other markers. Specificity ranged between 0.43-0.98 with the lowest estimates for αSMA. Sensitivity declined for all markers while using 10% and 25% cut-offs, while specificity increased.
Conclusion: Our findings show that computational assessments for αSMA, FAP, MMP14, TNC, and s100A6 exhibit variable correlations with manual assessment. These findings support the use of computational platforms for IF evaluation of stromal markers in large-scale epidemiologic studies and the importance of pilot studies for identification of appropriate cut-offs for defining staining positivity.

#2357 Feasibility of survey-based data collection in a diverse colorectal cancer cohort: Early-onset vs. average-onset.

Citlalli F. Lopez[1], L. Joseph Su[1], Luis Gonzalez[1], Yu-Lun Liu[1], Rasmi Nair[1], Lindsay Cowell[1], Emina Huang[2], Syed Mohammad Ali Kazmi[3]

[1]Peter O'Donnell Jr. School of Public Health, University of Texas Southwestern Medical Center, Dallas, TX,[2]Department of Surgery, University of Texas Southwestern Medical Center, Dallas, TX,[3]Division of Hematology Oncology, University of Texas Southwestern Medical Center, Dallas, TX

BACKGROUND: The incidence of early-onset colorectal cancer (EOCRC) is rising, yet a robust model of underlying factors across diverse populations is unknown. Most studies have examined a single factor or were performed in non-diverse population. The collection of comprehensive, patient-reported data across different populations in CRC will enable a deeper understanding of these associations to inform early intervention strategies.
METHODS: A pilot survey study was conducted at UT Southwestern Simmons Comprehensive Cancer Center (SCCC) and its affiliated safety-net hospital, Parkland Health and Hospital System (PHHS). The objective was to evaluate the feasibility of a multidomain survey in colorectal cancer patients. Eligible patients (≥18 years, stage I-IV adenocarcinoma, diagnosed within 12 months) completed baseline surveys in English or Spanish on demographics, lifestyle, symptom burden, nutrition (Dietary History Questionnaire), quality of life (EORTC QLQ-30, CR29), and financial toxicity (COST-FACIT). Surveys were administered in REDCap at baseline and three months follow-up. The primary endpoint was survey completion; feasibility was assessed by recruitment, participation, and completion rates. Descriptive comparisons were made between EOCRC (<50 years) and average-age onset colorectal cancer (AOCRC; ≥50 years).
RESULTS: From March 2024 to April 2025, 66 patients were approached, and 60 (91%) consented; all completed the baseline survey (100%), confirming feasibility across academic and safety-net settings. However, for the three-month follow-up survey participation decreased by 50%. The cohort was evenly distributed by sex (48% female, 52% male) and site (50% Parkland, 50% UTSW). Participants were diverse (42% Hispanic, 18% Black, 42% Non-Hispanic White) with variable socioeconomic status: 38% reported income <$35,000, 23% >$100,000, 28% were unable to work, and 23% were employed. Hospital utilization differed: 96% of Non-Hispanic Whites were treated at SCCC, while most Hispanic and Black patients were seen at PHHS. Parkland Financial Assistance was reported by 77%, highest among Hispanic patients. Nineteen patients (32%) had EOCRC (median age 42, range 30-48) and 41 (68%) had AOCRC (median age 64, range 51-82). EOCRC patients were more often Hispanic (58% vs. 32%), treated at Parkland (58% vs. 46%), and received assistance more frequently (47% vs. 34%).
CONCLUSION: This pilot study confirms that comprehensive, survey-based data collection is feasible in a racially, ethnically, and financially diverse CRC cohort. These preliminary findings highlight the clinical and sociodemographic differences of EOCRC and AOCRC across distinct groups. Future work will expand longitudinal follow-up, incorporate electronic health record data, and leverage tumor registry phenotypes to enable low-touch, systematic patient recruitment for a more robust sample.

#2358 Mining social determinants of health documentation patterns for genitourinary cancer patients using natural language processing.

Nikita Thakur[1], Natalie Reizine[1], Karine Tawagi[1], Charbel Hobeika[1], Ashwani Tanwar[2], Guanyu Tao[2], Marzana Chowdhury[2], Evan Garrad[3], Ahsan Wahab[1], Jingqing Zhang[2], Vibhor Gupta[4], VK Gadi[1], Sandeep Kataria[1]

[1]University of Illinois Cancer Center, Chicago, IL,[2]Pangaea Data, London, United Kingdom,[3]University of Illinois Chicago, Chicago, IL,[4]Pangaea Data, South San Francisco, CA

Mounting evidence demonstrates that social determinants of health (SDOH) significantly impact cancer care, contributing to persistent disparities in prevention, diagnosis, treatment access and survival rates that disproportionately affect vulnerable populations. However, SDOH are frequently underreported in clinical notes, obscuring barriers for patients to receive appropriate care. The systematic extraction from clinical notes remains challenging. We developed an advanced Natural Language Processing (NLP) based Artificial Intelligence (AI) platform to automatically extract SDOH from genitourinary cancer clinical notes.

We analyzed 757,757 clinical notes from 5,585 patients (prostate:n=3,772; bladder:n=619; renal:n=1,194, based on ICD) using the AI platform. The platform used NLP to extract 19 types of SDOH features (e.g. race, ethnicity, health literacy, substance abuse, financial strain, social isolation, etc) across four note types: Progress Notes, Consults, Care Plans, Patient Instructions.

The AI platform extracted 767,000 SDOH mentions from 4,464 patients (80% of patients). 140 clinical notes across 21 patients were randomly selected to evaluate AI accuracy. Of 140 notes, AI found SDOH features in 131 notes and clinicians from University of Illinois Cancer Center manually determined that 124 notes contained fully accurate SDOH extractions, while 7 notes had partially inaccurate SDOH extractions, yielding 95% accuracy (124/131). The study showed high prevalence of mentions of health literacy (96.71%), substance use (93.15%), and mood/affect issues (81.41%). 65% patients had minimal SDOH documentation (1.4 features per patient) and 35% patients had multiple SDOH documentation (6.9 features per patient).

Among 2,900 patients who were diagnosed with genitourinary cancer in 2018-2023 (317,143 SDOH mentions after removing boilerplate SDOH mentions), by analyzing COVID-19 impact (pre vs post March 2020), we found that documentation of demographic SDOH decreased, e.g. home address (-37%), race (-34%), ethnicity (-36%), but the social SDOH increased, e.g. social isolation (+65%), financial strain (+76%), stress (+63%).

This study shows the feasibility and effectiveness of using NLP to systematically extract SDOH from genitourinary cancer clinical notes. The high prevalence of documented SDOH underscores their potential impact on cancer care delivery and emphasizes the importance of routine SDOH documentation for every patient. COVID-19 caused a significant shift in SDOH documentation patterns with more pandemic-exacerbated social barriers. Future work should focus on validating the clinical impact of SDOH-informed decision making. Additional directions include leveraging large language models (LLMs) to infer the presence or impact of SDOH features and analyzing extracted SDOH information for clinical and societal insights.

#2359 Validation of prostate cancer diagnosis and cause of death in a national cohort of male veterans with type 2 diabetes mellitus.

Mulugeta Gebregziabher[1], Kinfe G. Bishu[2], Andrew Schreiner[3]

[1]Public Health Sciences, The Medical University of South Carolina and Charleston VAMC, Charleston, SC,[2]Research, The Medical University of South Carolina and Charleston VAMC, Charleston, SC,[3]Medicine, The Medical University of South Carolina and Charleston VAMC, Charleston, SC

Background: Accurate diagnosis and determination of cause of death are essential for effective disease surveillance, health planning, and research. This study seeks to validate the diagnostic accuracy and cause of death data related to prostate cancer (PCa) among Veterans with type 2 diabetes mellitus (T2DM).

Methods: We conducted a retrospective cohort study of Veterans with type 2 diabetes (T2DM) diagnosed between 2010 and 2019, using data from the Veterans Health Administration (VHA) Corporate Data Warehouse (CDW). Diagnostic codes and cause of death information were obtained from the Prostate Cancer Data Core (PCDC) and the National Death Index (NDI), which served as the gold standard for validating CDW data. Concordance between data sources was evaluated using Cohen's Kappa statistic, along with measures of diagnostic performance such as sensitivity and specificity.

Result: Among 763,424 Veterans with T2DM, 37,048 were diagnosed with PCa in the CDW and 36,861 in the PCDC, with concordance rate of 98.7%. Mortality data from the NDI revealed 2,723 deaths with PCa as the underlying cause, of whom 75.4% had a recorded diagnosis of PCa in CDW. For all-cause mortality, 328,156 Veterans were identified as deceased in the CDW Vital Status File (VSF) and 326,707 were reported as deceased in the NDI, with a concordance rate of 99.3% deaths between the two sources. Comparing incident PCa diagnoses for all patients, we found that the CDW had a high sensitivity 98.6% and specificity 99.9%. Similarly, for cause specific death, the sensitivity rate was 75.5% and specificity was 100.0%.

Conclusions: The findings demonstrate a high level of concordance in key outcomes of interest, specifically, prostate cancer (PCa) diagnosis between the CDW and PCDC, and all-cause mortality between CDW VSF and NDI data sources. Given the time-consuming nature of data retrieval and management from the CDW, we recommend using the PCDC for PCa diagnosis and CDW VSF for all-cause mortality ascertainment.

#2360 Differences in oral HPV prevalence estimation via Bayesian and frequentist methodologies from people living with HIV in Puerto Rico.

Erick M. Ivanovich-Mendez[1], Luis R. Pericchi[2], Brenda Torres-Velasquez[2], Vivian Colon Lopez[2], Josue Perez Santiago[2]

[1]Cancer Control Division and Population Sciences, University of Puerto Rico Comprehensive Cancer Center, San Juan, PR,[2]University of Puerto Rico Comprehensive Cancer Center, San Juan, PR

Introduction: Puerto Rico faces significant public health challenges due to a high rate of HPV-related cancers and a high prevalence of HIV, consistently ranking among the U.S. states and territories with the most AIDS cases. While population-based data on oral HPV infection for Puerto Rico remains scarce, studies focusing on high-risk groups have found a 12.5% prevalence rate among drug users in the San Juan metropolitan area. Logistic regression, a common method for frequentist estimation, often fails to account for the accuracy of a screening method. Studies confirm that Bayesian statistical models overcome these limitations by incorporating test performance. Despite these advantages, the use of Bayesian prevalence estimation is rare. Specifically, they have proven useful in scenarios where screening methods are suboptimal; limited sample size, or the core assumptions of frequentist models are unable to be met. These challenges are commonly encountered in studies addressing site-specific HPV prevalence, making Bayesian prevalence estimation a particularly well-suited and recommended alternative. **Objective**: To compare point estimates of oral HPV prevalence derived from frequentist and Bayesian models.

Methods: HPV genotyping data from an on-going study titled Multi-omics Predictors of Oral HPV Outcomes among People Living with HIV in Puerto Rico (P20GM148324) was used to estimate population prevalence. HPV status of this data was determined using the SPF10-LiPA25 method. R-statistical software and was used for prevalence estimation. The *rjags* library in R will provide the connection to run Markov Chain Monte Carlo (MCMC) simulations in JAGS software, Rogan-Gladen (RG) model will be utilized as the frequentist model since it compensates for diagnostic misclassifications. The comparison metrics to determine the best estimate will include error distribution for the point estimate and length of the confidence interval, or credible interval for the Bayesian case.

Results: The Bayesian estimation was 0.121 ± 0.0261 (CrI95%: 0.073 - 0.176) whilst the Rogan-Gladen model was 0.117 ± 0.0465 (CI95%: 0.032 - 0.212). While estimates are similar for both models, there is a slight improvement for both standard errors (SE) and corresponding intervals for the Bayesian estimation compared to the RG estimation.

Conclusion: The Bayesian method outperformed in both SE and Interval estimations as expected. A disadvantage of applying RG estimation is lack of interval estimation in the default function; intervals were manually calculated. Likewise, the number of iterations in MCMC impacts the SE for the Bayesian approach, further research must be done to determine if a cut-off point should be considered.

#2361 MELD 3.0 policy and evolving socioeconomic disparities in liver transplantation.

Tehyun Phillip Eom[1], Junho Song[2], Hyungjune Ku[3], **Sungsu Park**[4], Minkwan Kim[5], Sunghan Kim[1], Sangsoo Lee[3], Heekyoo Kim[3], Seoyeong Ku[6], Hyewon Kim[7], Amy Choi[2], Changmin Jo[8]

[1]CHA University School of Medicine, Seongnam-si, Korea, Republic of,[2]Penn State College of Medicine, Hershey, PA,[3]Kosin University College of Medicine, Busan, Korea, Republic of,[4]Daegu Catholic University School of Medicine, Daegu, Korea, Republic of,[5]Independent researcher, Gwangmyeong-si, Korea, Republic of,[6]Seoul Women's University, Seoul, Korea, Republic of,[7]Hanyang University College of Natural Sciences, Seoul, Korea, Republic of,[8]Chung-Ang University College of Medicine, Seoul, Korea, Republic of

Background: The MELD 3.0 policy, implemented by UNOS on July 13, 2023, updated the liver allocation scoring system to better reflect 90-day mortality risk. While intended to improve transplant equity, questions remain about its impact on socioeconomic disparities. We examined how MELD 3.0 affected DDLT access across socioeconomic groups and whether it narrowed or widened existing disparities.

Methods: We analyzed 12,479 adult HCC patients in the 21-month periods before (n=6,154) and after (n=6,325) MELD 3.0 implementation using UNOS data. Competing risks analysis with Aalen-Johansen estimators assessed DDLT rates accounting for death/deterioration. Gray's test evaluated socioeconomic disparities in DDLT access by race/ethnicity, insurance, education, employment, citizenship, gender, and region. Era-specific censoring used listing date as time origin.

Results: MELD 3.0 implementation significantly improved DDLT rates at 12 months: 53.3% pre-policy vs. 62.2% post-policy (+8.9 percentage points, p<0.001). Socioeconomic disparities showed mixed patterns. Race/ethnicity disparities persisted and slightly widened: Asian patients improved from 49.0% to 54.7%, while White patients increased from 55.1% to 64.3%. Black patients rose from 55.1% to 59.5%, and Hispanic patients from 46.1% to 64.8%, with differences remaining significant (pre p<0.001, post p<0.001).

Education disparities remained minimal: less than college vs. college graduates had similar rates pre-policy (53.0% vs. 53.2%) and post-policy (62.5% vs. 62.1%), with significance reflecting sample size rather than meaningful differences (p<0.001 both eras).

Insurance disparities showed mixed results: private insurance maintained advantage over public insurance, though significance weakened (p=0.015 pre, p=0.043 post).

Citizenship disparities showed a slight reduction in absolute difference (US vs. non-US: 53.4% vs. 51.0% pre; 62.3% vs. 60.7% post), while statistical significance strengthened (p=0.047 pre, p=0.010 post).

Employment and regional disparities persisted: post-policy, employed patients had slightly higher access, and substantial regional variation continued (p<0.001 both eras). Gender differences remained non-significant.

Conclusions: MELD 3.0 improved overall DDLT access for HCC patients but had varied effects on socioeconomic disparities. Education disparities remained minimal, while race/ethnicity, insurance, employment, citizenship, and regional differences continued. Although MELD 3.0 enhanced transplant access, persistent disparities highlight the need for additional interventions targeting socioeconomic determinants beyond allocation score refinements.

#2365 Demographic and socioeconomic disparities in access to curative-intent surgery for thymic carcinoma: A population based study..

Chinemerem M. Emeasoba[1], Chiugo Okoye[2], Gilbert-Roy Kamoga[1], Olanipekun Ntukidem[3], Hannah Jensen[1]

[1]Internal Medicine, UAMS Northwest, Fayettville, AR,[2]Internal Medicine, Northeast Georgia Medical Center, Gainesville, GA,[3]Internal Medicine, Trinity Health Ann Arbor Hospital, Ann Arbor, MI

Thymic carcinoma is a rare, aggressive thoracic malignancy in which surgery is the only potentially curative therapy. National inequities in surgical evaluation and treatment access remain poorly defined. We performed the largest population-based analysis to evaluate demographic and socioeconomic disparities in stage presentation and curative-intent surgery.

SEER (2010-2022) was queried for adults with histologically confirmed thymic carcinoma (ICD-O-3: 8586/3). Variables included age, sex, race/ethnicity, median household income, rural-urban classification, stage (Derived EOD 2018), surgery, chemotherapy, radiation, and "Reason for No Cancer-Directed Surgery." "Surgery not recommended" was used as a proxy for clinical inoperability or limited access to surgical evaluation. Associations were assessed using χ^2 and multivariable logistic regression, adjusting for age, sex, income, rurality, and stage group. Survival was evaluated using observed survival months.

Among 1,009 patients, the cohort was 62% male and racially diverse (White 51%, Black 17%, Asian/Pacific Islander 16%, Hispanic 15%). Stage was undocumented in 66%. Among staged cases, metastatic disease predominated (18%); early-stage (I-II) disease comprised 10%. Surgery was performed in 54%, while 41% had surgery "not recommended." Early-stage patients underwent surgery in 87% of cases versus 33% of metastatic cases ($p < 0.001$). Marked racial disparities were noted: surgery "not recommended" among Black (53.5%), Hispanic (45.7%), Asian/Pacific Islander (41.1%), and White (42.9%) patients. After adjustment, Black patients had significantly higher odds of surgery "not recommended" versus White patients (OR 1.61; 95% CI 1.11 - 2.35; $p = 0.01$). Advanced and unknown stage strongly predicted surgery not being recommended ($p < 0.001$). Treatment delays >90 days occurred more frequently in non-metropolitan counties (8.8% vs 4.6%). Median survival was markedly longer for patients who received surgery compared with those for whom surgery was not recommended (45 vs 15 months).

Substantial racial and socioeconomic inequities limit access to curative-intent surgery for thymic carcinoma in the United States. Black patients experienced significantly higher adjusted odds of surgery being deemed "not recommended," independent of stage, income, and rurality. High rates of missing stage documentation and prolonged treatment delays in non-metropolitan regions further hinder equitable care delivery. These findings highlight urgent needs for standardized staging, equitable referral pathways to thoracic surgical oncology, and system-level interventions to improve access to curative treatment for this rare malignancy.

#2366 HRSNs and CRC screening recommendation in NHIS.

Isaiah Casarez[1], Humberto Parada[1], Matthew P. Banegas[2], Uriel Nataren Geronimo[1], Benjamin Aceves[3]

[1]San Diego State University, San Diego, CA,[2]Cancer Prevention Fellow, UC San Diego, San Diego, CA,[3]Health Promotion and Behavioral Science, San Diego State University, San Diego, CA

Background: Health-related social needs (HRSNs), including food insecurity, housing instability, and financial hardship, are increasingly recognized as barriers to preventive care. Clinician recommendation is a primary driver of colorectal cancer (CRC) screening uptake. However, little is known about how specific HRSNs and co-occurring social risk patterns relate to clinician recommendations in nationally representative populations.

Methods We analyzed pooled 2021 and 2023 National Health Interview Survey (NHIS) cross-sections among adults 45-75 years without cancer history (unweighted n = 6,500; weighted = 27.6 million). Survey-weighted logistic regression estimated adjusted odds ratios (aORs) for clinician recommendations in the past 12 months. We examined granular food insecurity categories, HRSN burden counts, and latent social-risk subgroups using latent class analysis (LCA). Analyses were stratified by race/ethnicity and nativity; interaction terms tested effect modification.

Results: Overall, roughly 16% of adults reported a clinician's screening recommendation in the past 12 months. Among non-Hispanic White adults, financial hardship was associated with increased odds (aOR = 1.32, 95% CI: 1.11-1.56). Among Hispanic adults, food insecurity was associated with higher odds (aOR = 2.94, 95% CI: 1.59-5.42) while housing instability was associated with lower odds (aOR = 0.38, 95% CI: 0.16-0.88). LCA identified three distinct HRSN configurations: Low/No HRSN (85%), Moderate/Mixed (5%), and High HRSN Burden (10%). High-burden adults had marginally higher odds of recommendation (aOR = 1.33, 95% CI: 0.99-1.78). Race-by-HRSN interactions were statistically significant for housing instability.

Conclusions Specific and clustered social needs are associated with clinician recommendations for CRC screening, with differential patterns by race/ethnicity and nativity. Social risk assessment may support more equitable preventive care engagement. Disclosure: During the preparation of this work, the author used OpenAI ChatGPT to assist with wording and clarity. After using this tool, the author reviewed and edited the content and takes full responsibility for the accuracy and integrity of the abstract.

#2367 *KRAS* mutations worsen overall survival (OS) in Black but not White colon cancer patients.

Susan Ahmedyar, Minoru Koi, John M. Carethers

Medicine, UC San Diego, La Jolla, CA

Background. Disparities between Black (BA) and White Americans (WA) exist for incidence and OS among colon cancer (CC) patients. Identifying race-associated markers for OS may elicit CC treatment approaches to improve OS. We previously demonstrated that low-levels of microsatellite instability (MSI-L) and elevated microsatellite alterations at selected tetranucleotide repeats (EMAST) are associated with shorter CC recurrence-free survival. We also showed that MSI-L/EMAST with loss of heterozygosity (LOH) at chromosome 9p21-24 (9p-LOH) improves OS of CC patients. Additionally, we and others have observed high prevalence of *KRAS* and *BRAF* mutations in BA and WA CCs, respectively. Here, we examined race-associated differences in *KRAS* and *BRAF* mutations, 9p-LOH, and MSI-L/EMAST, and examined their prognostic values.

Methods. Three hundred-fifty CC cases (175 WA and 175 BA) from the North Carolina Colon Cancer Study were analyzed for associations between race and genetic alterations. Chromosome 9p-LOH was determined at 4 single nucleotide polymorphism (SNP) loci present on 9p21-24 by digital PCR. MSI-L/ EMAST was determined from 14 microsatellite markers, including 2 mono-, 5 di-, and 7 tetra-nucleotide markers by fragment analysis. *KRAS* G12/13 and *BRAF*^{V600E} mutations were determined by Sanger sequencing of PCR products generated from targeted regions.

Results. Among the 175 BA CC cases, 82 (46.8%) had *KRAS* mutations compared to 31.1% (53/169) of WA cases (O.R.: 1.97, 95%CI: 1.27-3.06, *P*=0.002). More WA CC cases (10.9%: 19/156) exhibited *BRAF* mutations than BA CC (6.1%: 10/165) but this difference did not reach significance (*P*=0.075). There was no association between MSI-L/EMAST and race (*P*=0.5). Chromosome 9p-LOH was detected in 15.2% of BA CC cases (19/125) and 9p-LOH with MSI-L/EMAST was detected in 8.6% of BA cases (12/140). Chromosome 9p-LOH prevalence was higher among WA CC vs BA CC in our initial subset analysis of 42 patients. Among BA CC cases, *KRAS* mutations were associated with shorter 5yr OS (H.R.: 1.91, 95%CI: 1.11-3.29, *P*=0.018) and 10yr OS (H.R.: 1.55, 95%CI: 1.02-2.37, *P*=0.04), and when adjusted for MSI-L/EMAST, tumor stage/location, and smoking status, *KRAS* mutations were associated with shorter 5yr OS (H.R.: 2.20, 95%CI: 1.27-3.8), *P*=0.0045) and 10yr OS (H.R.: 1.8, 95%CI: 1.17-2.78: *P*=0.0075). Among WA CC cases, there was no association between *KRAS* mutations and either 5yr OS (*P*=0.85) or 10yr OS (*P*=0.82).

Conclusions. *KRAS* G12/13 mutations are more frequent in BA CC than WA CC and are a poor prognostic factor for BA CC OS. The significance of 9p-LOH and 9p-LOH plus MSI-L/EMAST in WA CC is being currently assessed.

#2368 Social determinants and lifestyle factors driving colorectal cancer mortality disparities in younger Black and White patients.

Chinenye M. Okafor[1], Lauren Rose Fanning[2], Tami L. Crawford[3], John Pearce[3], Kathy Williams[3], Alexander V. Alekseyenko[3], Kristin Wallace[4]

[1]The Medical University of South Carolina (MUSC), Florence, SC,[2]The Medical University of South Carolina (MUSC), Summerville, SC,[3]The Medical University of South Carolina (MUSC), Charleston, SC,[4]MUSC Hollings Cancer Center, Charleston, SC

Background: Disparities in colorectal cancer (CRC) mortality in Black compared to White patients are more evident at younger ages. Emerging data suggests that earlier age of diagnosis in Blacks is associated with socioeconomic and lifestyle factors such as smoking and alcohol use; however, whether these factors contribute to differences in race- and age-specific CRC mortality remains unclear.
Methods: Data from the Medical University of South Carolina (MUSC) Hollings Cancer Center cancer registry was used to identify analytic CRC cases from 2000 - 2021 with ≥12 months of follow-up. This study was approved by the MUSC Institutional Review Board. Cox proportional hazards regression estimated risk of death (HR, [95% CI]) for Black versus White patients adjusting for age, sex, stage, year of diagnosis, and treatment. Interactions assessed were race x age (continuous), race x social deprivation index (SVI, high vs low), race x alcohol use (current vs not), race x smoking (current vs not).
Results: Of 1,324 patients, 43.5% were female, and 31.7% Black. Median age 62 years; 60 years for Black, 63 years for White. Median survival of 68 months for Blacks and 95 months for Whites. Blacks had higher adjusted risk of death (1.19 [1.01-1.40] vs Whites). There was significant interaction for race by age (p=0.01): Blacks <65 years had greater mortality than Whites (HR 1.38 [1.10-1.69]), with no racial difference observed for those ≥65 years (HR 0.99 [0.76-1.28]). We observed a significant race by SVI interaction (p=0.04): among those with higher SVI, Black patients had modest decrease in risk of death (HR 0.88 [0.66-1.16]) whereas Whites had an increased risk (HR 1.24 [1.02-1.49]); this difference was confined to those <65 years. A significant race by alcohol interaction was also present (p=0.0001): current drinkers who were Black had an increased risk of death (HR 1.63 [1.20-2.22]), while those who were White had a lower risk (HR 0.82 [0.67-1.00]), again limited to patients <65 years. Current smoking increased risk of death in both Blacks (HR 1.70 [1.23-2.35]) and Whites (HR 1.33 [1.05-1.67]), with no significant race x smoking interaction (p=0.22) or age-specific effect. Ever smoking or ever drinking yielded similar but attenuated results. Mortality risk did not differ by sex.
Conclusion: Black CRC patients <65 years had higher mortality risk than Whites, and specifically those with current alcohol use and concurrent smoking/alcohol use. No racial difference observed for those ≥65 years. Younger Black people with higher SVI (more vulnerability) had lower mortality than Whites with similar SVI, suggesting that access to health services in poorer Black communities improves outcomes. These findings identify a particularly vulnerable subpopulation that may benefit from targeted interventions focused on improving care access, addressing social barriers, and enhancing smoking and alcohol screening

#2369 Determinants of clinical outcomes: A pooled analysis of 71 phase I clinical trials evaluating metastatic colorectal cancer.

Ahan Bhatt[1], Hasan Zaidi[2], Shobi Venkatachalam[3], Lawanya Singh[2], Abhiraj Saxena[2], Radha Patel[3], Christina Boatwright[3], Demmie Aguilar[3], Jay Shah[3], Mohammad Ghalib[3], Imran Chaudhary[4], Simran Goel[4], Radhashree Maitra[4], Eugenia Girda[5], Sanjay Goel[5]

[1]Department of Internal Medicine, Jacobi Medical Center, Albert Einstein College of Medicine, Bronx, NY,[2]Department of Internal Medicine, Rutgers Robert Wood Johnson Medical School, New Brunswick, NJ,[3]Rutgers Robert Wood Johnson Medical School, New Brunswick, NJ,[4]Montefiore Medical Center, Bronx, NY,[5]Rutgers Cancer Institute of New Jersey, New Brunswick, NJ

Background: Minority patients are historically underrepresented in clinical trials. Their clinical outcomes are often reviewed retrospectively after drug approval, leaving uncertainty about efficacy in the broader population, including patients with metastatic colorectal cancer (mCRC). In phase I trials for mCRC, patient selection criteria remain challenging, and objective clinical and laboratory markers may improve uniform screening and outcome prediction.

Methods: We retrospectively reviewed medical records of patients with mCRC enrolled in phase I trials at two institutions between 1999-2018 and 2021-2025. Data collected included demographics, clinical and laboratory findings, treatment responses, and overall survival (OS). Variables were dichotomized using institutional or clinically relevant cutoffs. OS was defined from the date of first dose to death or last follow-up (censored if alive). Univariate analyses were performed using the Mantel-Cox test (Prism GraphPad v10), with hazard ratios (HRs) and 95% confidence intervals (CIs) reported.

Results: We analyzed 295 patients across 71 trials. Median age was 59 years (range, 29-83 years). 50.5% of patients were female. 24.4% were Non-Hispanic Black (NHB), 24.4% Hispanic, 6.1% Asian, 43.0% Non-Hispanic White (NHW). OS was 9 months and did not differ significantly among the different races/ethnicities ($p = 0.71$). The median duration on the trial was 59 days (range, 54-65 days). Median number of prior lines of therapy was 3 (range, 0-11), and the median number of sites of metastasis was 3 (range, 0-10). In a univariate model, poor performance status (PS ≥2; HR 2.665, $p=0.0026$), ≥3 metastatic sites (HR 1.497, $p=0.0049$), and > 3 prior lines of therapy (HR 1.358, $p=0.0167$) were associated with decreased OS. Laboratory markers including low albumin (<3.9 g/dL; HR 1.596, $p=0.0002$), high LDH (>281.5 U/L; HR 1.751, $p<0.0001$), high CEA (>119.5 ng/mL; HR 1.513, $p=0.0031$), elevated liver enzymes (AST>40 U/L, HR 1.696, $p=0.0004$; ALP>150 U/L, HR 2.102, $p<0.0001$), elevated bilirubin (≥1 mg/dL; HR 1.852, $p=0.0204$), and cytopenias (WBC<6 K/µL, HR 0.66, $p=0.0011$; ANC<4 K/µL, HR 0.63, $p=0.0004$; hemoglobin <11.5 g/dL, HR 1.435, $p=0.0043$) also predicted worse OS.

Conclusion: Patients with mCRC, regardless of age, sex, or race/ethnicity, had similar outcomes in phase I studies. The OS was at par with published data with similar exposure to prior therapies. Heavily pre-treated patients, low performance status, and spread to >3 sites were all associated with decreased survival. High LDH and high CEA, along with liver function tests, are key parameters and may refine eligibility and stratification in early-phase mCRC studies. A multivariate analysis will be presented, looking into the interplay of these key clinical findings.

#2370 American Indian and Alaska Native community perspectives on HPV vaccination: Insights from providers and parents in a shared tribal clinic setting.

Dakota K. Jones[1], Morgan Gill[1], Claradina Soto[1], Philip Farabaugh[2], Jennifer Tsui[1]

[1]Keck School of Medicine of USC, Los Angeles, CA,[2]Riverside San Bernardino Indian Health Clinic, Riverside, CA

INTRODUCTION

Human papillomavirus (HPV) vaccination prevents infection of HPV types that cause most cervical cancers, yet American Indian and Alaska Native (AI/AN) youth remain disproportionately under-vaccinated due to structural and community-level barriers. This mixed-methods pilot study assessed multilevel factors among providers and parents within the Riverside-San Bernardino County Indian Health (RSBCIHI) clinic system.

METHODS

This study aimed to identify multilevel barriers to HPV vaccination by integrating provider and parent perspectives from the same Tribal clinic setting, an area with limited empirical data. Survey items assessed provider-level barriers to HPV vaccine delivery, including communication challenges influencing uptake. Concurrently, pilot qualitative focus groups with AI/AN parents and caregivers explored individual and community influences on vaccine decision-making. Thematic analysis identified emergent sociocultural factors relevant to implementation refinement.

RESULTS

In October 2025, a baseline survey was administered among 15 clinical staff, including medical assistants (60%), physicians (13%), nurse practitioners (13%), and registered nurses (13%). While 92% of providers viewed HPV vaccination as “very important,” system-level barriers included limited training on addressing parental hesitancy (61%) and inconsistent reminder systems (47%). Reported challenges among parents included limited time with providers during visits (55%), cultural or trust-related concerns (48%), and vaccine safety concerns (67% rated as somewhat of a barrier). Over half of providers (53%) had worked in the clinic for less than one year, indicating high staff turnover. Parent focus group findings (n=3) revealed hesitancy rooted in healthcare provider mistrust, vaccine misinformation, and a desire for increased provider communication on sensitive topics.

DISCUSSION

This study identified several structural and interpersonal barriers to HPV vaccination within the RSBCIHI Tribal clinic system. Emergent themes from provider surveys included limited time during visits, inconsistent reminder systems, vaccine safety concerns, and frequent staff turnover. Parent perspectives further highlighted hesitancy rooted in vaccine misinformation, limited trust with healthcare providers, and discomfort discussing sensitive topics including sexual health and vaccinations. Together, these provider- and parent-level barriers illustrate the multilevel challenges influencing AI/AN HPV vaccination uptake, which will inform future sustainment strategies to strengthen vaccine confidence and culturally adapted cancer prevention efforts in Native communities.

#2371 Outcomes after introduction of cervical cancer screening in an opioid treatment program (OTP) by offering HPV self-collect testing to an under-screened population.

Elizabeth M. Swisher[1], Mallory Davis[2], Mayumi Rubin-Saika[1], Enna Manhardt[1], Emiko Oshima[1], Renata Urban[1], Stephem L. Cherne[1], Eric Huang[1], Tom Hutch[2]

[1]University of Washington, Seattle, WA,[2]We Care Daily Clinic, Auburn, WA

Individuals with opioid use disorder (OUD) have lower cancer screening rates. Cervical cancers are preventable through screening and treatment of human papillomavirus (HPV)-related pre-cancers. HPV self-collect tests provide opportunities to expand screening access to previously unreached populations, offering advantages of privacy, autonomy, and negating a clinic requirement for gynecological services. We evaluated a novel, low-barrier model for integrating HPV self-collect screening into a brick-and-mortar OTP and its four associated mobile medication units in a major metropolitan area in Washington state. Screening was offered with self-collection kits during annual medical update visits to eligible patients (those age 25 or above with a cervix who were overdue for screening or unsure) and collected privately in the clinic restroom. HPV swabs were analyzed at the University of Washington HPV Molecular Pathology Laboratory or Labcorp and included all 14 known high-risk HPV (hrHPV) types. Screened subjects with positive results received education and recommendations for guideline concordant care. Clinic staff facilitated referrals to local providers with gynecologic services and follow-up was tracked. The study's primary outcomes were the rates of screening uptake, HPV positivity, and successful linkage to follow-up care. From June 24, 2024 through October 31st, 2025, 186 patients were evaluated including 29 (15.6%) American Indian/Alaskan Native, 2 (1.1%) Asian, 20 (10.8%) Black, 2 (1.1%) Native Hawaiian/Pacific Islander, 125 White (67.2%) and 9 (4.8%) Hispanic. The majority were current (72.9%) or former (17.6%) tobacco users. Of 168 (90.1%) eligible for screening (median age 40 years, range 22-65 years), 150 (89.3% of those eligible) completed screening. There were no failed or inconclusive test results. Of 150 resulted tests, 120 (80%) were HPV-negative, 7 (4.7%) were HPV16/18+, and 23 (15.3%) were “other” (non-16/18) hrHPV+. Patients encountered a variety of structural and social barriers in following up hrHPV+ tests. Of the 30 hrHPV+ tests, no one has been lost to follow-up and 12 (40%) patients have completed follow-up, which often required multiple coordination attempts by providers. The remainder are in various stages of referral and scheduling. Providing cervical cancer screening was feasible in an OTP using HPV self-collection and resulted in high patient uptake. This population was both under-screened and high-risk with approximately double the hrHPV positivity rate found in most U.S. screening studies. Our patient-centered model promotes health equity and provides a scalable solution to reduce the burden of cervical cancer in under-screened communities.

#2372 Uncovering cervical cancer screening disparities among Asian American subgroups in California.

Alice W. Lee[1], Elinita Pollard[2], Minh Tung Phung[3], Meng-Han (Mina) Tsai[4]

[1]Public Health, California State University, Fullerton, Fullerton, CA,[2]Health Behavior, University of North Carolina, Chapel Hill, NC,[3]University of Wisconsin-Madison, Madison, WI,[4]Augusta University, Augusta, GA

Background: Cervical cancer is a highly preventable and treatable malignancy when detected early. Despite the availability of Pap test, clear racial/ethnic disparities in screening uptake exist, with Asian American women having significantly lower rates than Non-Hispanic White (NHW) women. To improve cervical cancer screening rates among Asian American women, it is important to understand which Asian subgroups are more inclined to be underscreened. However, research on this topic remains limited. Our study aims to examine recent Pap test rates and factors associated with screening uptake across disaggregated Asian subgroups.
Methods: Using cross-sectional data from the 2016, 2018, and 2020 California Behavioral Risk Factor Surveillance System, we calculated the weighted prevalence of women ages 21-65 who reported being up-to-date with Pap test based on the most recent U.S. Preventive Services Tasks Force's recommendations (i.e., having been tested in the past three years) for the six largest Asian American subgroups (Asian Indian, Chinese, Filipino, Japanese, Korean, Vietnamese) and NHW women as a comparison group. Multivariable logistic regression was fitted with reporting being up-to-date with Pap test as the outcome, regressing on race/ethnicity and adjusting for sociodemographic (age, education, income, marital status, poverty status, metropolitan statistical area) and access to care factors (having a primary care provider, health insurance type). In addition, the weighted prevalence of Pap test uptake for each Asian subgroup was calculated for factors found to be statistically significant in the adjusted model.
Results: Our analysis included 517 Asian American and 3,061 NHW women. While the percentage of NHW women who reported being up-to-date with Pap test was 83%, this percentage was lower for all Asian American subgroups (32% for Vietnamese, 54% for Asian Indian, 59% for Japanese, 66% for Korean, 67% for Chinese, 75% for Filipino). After adjusting for covariates, the Asian subgroups had 46-91% lower odds of reporting being up-to-date with Pap test, with the most notable disparities being among Vietnamese (OR=0.09, 95% CI 0.02-0.33) and Asian Indian women (OR=0.20, 95% CI 0.08-0.45). Interestingly, while all Asian subgroups with a primary care provider showed a prevalence of Pap test uptake of over 70%, this percentage was only 30% for Vietnamese women.
Conclusions: Although all Asian American subgroups reported lower Pap test adherence to screening guidelines than NHW women, the disparities were particularly striking for Vietnamese and Asian Indian women. Our results also suggest further exploring the role of primary care providers in the context of cervical cancer screening, particularly among Vietnamese women. Furthermore, the ethnic-specific disparities noted in our analysis highlight the importance of disaggregated data so interventions can be appropriately tailored.

#2373 Barriers to mammography screening among US women aged 40 and older: Disparities by race, region, and age.

Anas Al-Zubaidi

UTMB Health at Galveston, Galveston, TX

Background: Screening mammography is recommended for women aged 40 years and older. Understanding barriers to screening mammogram and identifying disparate populations is critical for implementing these recommendations equitably.
Methods: This cross-sectional study used National Health Interview Survey data from 2021 and 2023. Women aged 40+ who reported not having a mammogram in the past 2 years or ever were included (N=47.9 million weighted). Self-reported reasons were categorized as knowledge/awareness barriers (no reason, didn't know needed, doctor didn't order, no problem), behavioral barriers (put it off, too painful), cost/access barriers (too expensive, no doctor), age-related perceptions (too young/old), and other reasons. Complex survey design examined barrier patterns by race/ethnicity, region, urban-rural status, and age group (P<.05).
Results: Overall, knowledge/awareness barriers dominated (58.2%), followed by behavioral (14.0%), other (12.7%), age-related (9.0%), and cost/access barriers (6.2%). Significant disparities existed across race/ethnicity (P<.001), region (P<.001), and age (P<.001), but not urban-rural status (P=.40) (Table). Non-Hispanic Asian women had highest knowledge barriers but lowest cost barriers. Hispanic women had highest cost barriers. Women aged 50-64 had highest behavioral and cost barriers, while women 65+ had minimal cost barriers but high age-related misperceptions. Southern women faced both high knowledge and cost barriers versus other regions.
Conclusions: While knowledge and awareness gaps are the primary barriers to mammography screening among US women aged 40 and older, the specific types of barriers vary substantially by race/ethnicity, geographic region, and age. These disparities underscore the need for targeted, population-specific strategies to improve equitable access to mammography screening.

#2374 Neighborhood and language influences on mammography receipt among latinas in community health centers.

John D. Heintzman[1], Jennifer A. Lucas[1], Jorge Kaufmann[1], Cirila Estela Vasquez Guzman[2], Wyatt Bensken[3], Amelie G. Ramirez[4], Miguel Marino[1]

[1]Oregon Health & Science University, Portland, OR,[2]OHSU Knight Cancer Institute, Portland, OR,[3]OCHIN, Inc, Portland, OR,[4]UT Health Science Center at San Antonio, San Antonio, TX

Background: Breast cancer is a significant source of mortality and morbidity for Latinas in the United States. Literature has shown that breast cancer survival and diagnosis stage may be associated with neighborhood factors, but less is known about how these factors affect mammogram receipt specifically. Therefore, we performed an analysis of mammography receipt in Latina patients, by language preference, compared to non-Hispanic White women, by multiple community level factors (transportation access, economic level, education level).
Methods: We used electronic health record data from 59,646 Latina and non-Hispanic White patients between the ages of 50 and 74 receiving care at 594 community health centers across 21 states, along with geocoded census-tract-level neighborhood data to evaluate the prevalence of mammogram completion by neighborhood characteristics, including high school graduation rates, community poverty as percent of the federal poverty level, percent of households with a vehicle and with a 60+minute public transit commute. We stratified Latina patients by language preference and adjusted for common individual demographic and clinical characteristics.
Results: In the sample, 3,987 patients were non-Hispanic White, 11,338 were English-preferring Latinas, and 44,381 were Spanish-preferring Latinas. A higher proportion of Latinas lived in high poverty census tracts. A higher prevalence of non-Hispanic White women were smokers. Spanish-preferring Latinas (67.2%) had a higher unadjusted prevalence of mammogram receipt than English-preferring Latinas (57.7%) and non-Hispanic white women (54.6%). In covariate-adjusted analyses, Spanish preferring Latinas had the highest prevalence of being up-to-date with their mammograms, and of having completed mammograms if ordered, regardless of community characteristics. Across community characteristics, there was no difference in outcome prevalence within ethnicity language groupings.
Conclusion: In an analysis of mammogram completion in Latina and non-Hispanic white women by neighborhood-level factors in a national network of community health centers, mammogram
prevalence was low. Spanish-preferring Latinas had the highest prevalence of mammogram receipt.There was no outcome difference in any group across neighborhood-level factors. Community health centers are vital in the early detection of breast cancer for Latinas, but clinics should understand the limitations of community level factors in targeting improved mammogram completion and be aware of individual barriers that may reduce mammography in Latinas.

#2375 Stress-responsive immune microenvironment in triple-negative breast cancer among African American women.

Aminah M. Lawal[1], Fulya Koksalar Alkan[1], Hilmi Kaan Alkan[1], Ahmet Burak Caglayan[2], Neva Celiker[1], Brianna Temby[1], MAX WICHA[2], Morhaf Al Achkar[1], Kristen Purrington[1], Hasan Korkaya[1]

[1]Wayne State University, Detroit, MI,[2]University of Michigan, Ann Arbor, MI

African American (AA) women experience higher incidence and mortality from triple-negative breast cancer (TNBC) compared to White women, particularly at younger ages. While socioeconomic determinants contribute to this disparity, emerging evidence indicates that chronic social stress becomes biologically embedded, reshaping systemic inflammation and the tumor immune microenvironment (TIME). We hypothesize that stress-responsive inflammatory signaling drives the accumulation of immune suppressive myeloid cell populations contributing mechanistically to enhanced cancer stemness and aggressive tumor behavior in AA TNBC.Using spatial transcriptomics on TNBC tumors from (n=4) AA and (n=4) White patients enrolled in the Karmanos Cancer Institute Biobank, we identified distinct immune and stress-response programs enriched in AA tumors. AA samples displayed a marked increase in immunosuppressive myeloid populations, including TAM-like and MDSC-like clusters, accompanied by heightened expression of IL1B, TNFA-associated cytokine modules, S100A8/S100A9, and other innate inflammatory cytokines. These inflammatory programs correlated with activation of stress-response pathways, most notably HSP70, a central regulator of cellular stress, danger signaling, and antigen presentation. Mechanistically, these pathways were tightly linked to a transcriptional activation of cancer stemness signatures, including NQO2, IRF3-associated stress modules, and other stem-associated genes, consistent with a more plastic, therapy-resistant phenotype in AA TNBC tumors.Previous studies have shown that chronic social stressors such as perceived discrimination, inadequate support, and neighborhood disadvantage have been associated with systemic inflammation and altered immune response. Our tumor-level analyses suggest that this stress activated signaling may converge on innate immune pathways within the TIME, amplifying myeloid suppression, cytokine activation, and stress-induced stemness that collectively worsened outcomes.Hypothesizing that AA patients experience higher social stress than White patients, these results support a mechanistic model in which psychosocial stress primes the innate immune microenvironment toward immune dysfunction and myeloid dominance, promoting tumor plasticity and metastatic potential in AA TNBC. Understanding how stress-responsive immunologic programs shape tumor evolution may reveal actionable targets to mitigate biologically mediated cancer disparities and guide interventions integrating immunology, social determinants, and precision oncology.

#2377 Heavy-metal exposure and cancer incidence in Puerto Rico.

Ingrid M. Montes-Rodriguez, Yoel A. Velazquez-Oliver, **Hilmaris Centeno-Girona**, Camille Zenon, Elba V. Caraballo

University of Puerto Rico Comprehensive Cancer Center, San Juan, PR

Background: Puerto Rico (PR) exhibits geographic variation in overall cancer incidence, with rising early-onset cases suggesting region-specific factors that shape cancer risk. Persistent toxic exposure to heavy metals associated with industrial activity and legacy pollutants may underlie these regional differences. Heavy metals are pervasive environmental contaminants; accumulating exposures have been linked to disruptions in DNA methylation and other epigenetic mechanisms that regulate the cell cycle, DNA repair, and immune function, providing a plausible biological basis for increased cancer susceptibility. Evidence from diverse populations links metal exposure to cancer risk, suggesting regional metal profiles may affect local cancer burden. To date, there have been only a limited number of studies testing the association between regional metal exposures and cancer incidence across PR.
Objective: This study tests the hypothesis that population-wide exposure to heavy metal toxic releases aligns with cancer incidence patterns across PR when analyzed at the municipal level. Leveraging existing data, we integrated industrial-emission data from federal databases and cancer incidence records from the Puerto Rico Central Cancer Registry (PRCCR) spanning 2018-2022.
Methods: Age-adjusted incidence rates for overall and early-onset cases of the most prevalent cancer types in PR were obtained from the PRCCR for the period 2018-2022. Metal emission data were sourced from the U.S. EPA Toxics Release Inventory for 2008-2018 and aggregated at the municipality level. Out of 78 municipalities, 23 were identified with positive emissions values and were included in the analysis. Spearman correlations with p-values were used to quantify relationships between heavy metal emissions and cancer rates. Bivariate choropleth maps using Jenks Natural Breaks and proportional symbols were used to visualize geographic patterns. Statistical analyses were conducted in R 4.3.2 using RStudio, and spatial mapping was done in QGIS 3.40.
Results: Mercury and lead exposure showed the strongest associations with overall cancer incidence, with $r = 0.70$ ($p < 0.001$) and $r = 0.68$ ($p < 0.001$), respectively. Lead and mercury also correlated with prostate cancer ($r = 0.53$, $p < 0.01$; $r = 0.65$, $p < 0.001$). Mercury and nickel were associated with leukemia ($r = 0.40$, $p < 0.05$; $r = 0.41$, $p < 0.05$). Cobalt and zinc were associated with thyroid cancer ($r = 0.467$, $p < 0.05$; $r = 0.69$, $p < 0.001$). Additionally, these metals correlated with early-onset thyroid cancer ($r = 0.42$, $p < 0.05$; $r = 0.45$, $p < 0.05$). Manganese showed associations with both overall and early-onset uterus cancer ($r = 0.40$, $p < 0.05$; $r = 0.38$, $p < 0.05$).
Conclusion: Collectively, these patterns suggest that specific metal exposure may contribute to cancer risk. Future work should incorporate other exposure routes and pursue hypothesis-driven studies to identify targeted prevention strategies for high-exposure regions.

#2378 Cancer of unknown primary (CUP) mortality as a surrogate for imaging inequity in the United States (1999-2023).

Sophia Ahmed[1], **Fareed Baksh**[2], Bilal Ahmad[3], Salman Mustafa[4], Elangovan Krishnan[5], Oshaz Fatima[6]

[1]Medicine, Allama Iqbal Medical College, Lahore, Pakistan,[2]Internal Medicine, Community Health Systems - Flowers Hospital: Dothan, Alabama, US, Dothan, AL,[3]Dow Medical College, Karachi, Pakistan,[4]Medicine, Dow Medical College, Karachi, Pakistan,[5]AIM DOCTOR, Thiruverkadu, India,[6]King Edward Medical University, Lahore, Pakistan

Background: Cancer of Unknown Primary (CUP) remains a major diagnostic and clinical challenge in oncology. Despite advances in imaging, CUP continues to account for a significant number of cancer deaths in the United States. Limited access to high-quality diagnostic imaging may delay identification of the primary tumor and contribute to persistent disparities. This study examines national, regional, and demographic trends in CUP mortality from 1999 to 2023 and evaluates mortality patterns as a potential marker of imaging inequity. We analyzed national mortality data from the CDC WONDER database using ICD-10 code C80. Variables included sex, age group (15+), race, census region, metropolitan status, and state. Age-adjusted mortality rates (AAMR) were calculated for all subgroups. Temporal trends were assessed for 1999-2023. ARIMA forecasting was used to project trends to 2035. A total of 679,020 CUP deaths occurred between 1999 and 2023. The national AAMR declined from 13.24 in 1999 to 7.19 in 2023. Males had higher mortality (AAMR: 11.83) than females (8.82), though both decreased over time. Mortality was concentrated in adults aged 45 years and older. Racial disparities were marked: Black (12.09), White (10.38), and American Indian or Alaska Native populations (9.70) had nearly double the mortality of Hispanic or Latino (6.47) and Asian American or Pacific Islander groups (5.50). Nonmetropolitan areas had higher mortality (9.08) than metropolitan areas (7.84). Among regions, the Northeast (11.18), Midwest (10.55), and South (10.08) showed higher mortality than the West (8.74). ARIMA projections to 2035 suggest rising mortality for males (10.64), females (8.48), the Northeast (10.97), and the West (10.09). CUP mortality has declined nationally but remains uneven across demographic and geographic groups. Higher mortality in rural areas, high-burden regions, and populations with historically limited diagnostic access suggests that imaging inequity may contribute to persistent disparities. The rising projected mortality in select groups and regions underscores the need for targeted investments in diagnostic infrastructure, earlier access to advanced imaging, and equitable oncology services. Future research should integrate imaging and mortality data to refine strategies for early detection and intervention.

#2379 Increased stromal ERV methylation in African American compared to European American prostate cancer patients: Enrichment on chromosome 19.

Tara S. K. Jennings[1], Lucas Ueta[1], Vinay Kumar[1], Ali Afsari[2], Elham Arbzadeh[3], Patricia Castro[4], Michael M. Ittmann[4], Yan Zhao[1], Michael Daneshvar[5], Farah Rahmatpanah[1]

[1]Department of Pathology and Laboratory Medicine, University of California Irvine, Irvine, CA,[2]Department of Pathology, University of California Irvine Medical Center, Orange, CA,[3]Department of Pathology, George Washington University, Washington, DC,[4]Department of Pathology and Immunology, Baylor College of Medicine, Houston, TX,[5]Department of Urologic Oncology, University of California Irvine Medical Center, Orange, CA

Background: African American (AA) men experience worse prostate cancer (PCa) outcomes than European American (EA) men, including higher PSA levels, larger tumors, earlier onset, and more aggressive disease progression. These disparities persist even after accounting for healthcare access and socioeconomic factors, suggesting underlying biological contributors. Endogenous retroviruses (ERVs), normally silenced through DNA methylation, have emerged as regulators of anti-tumor immune activity and as effective prognostic markers in PCa. Despite constituting 8% of the human, ERVs' role in the tumor microenvironment remains incompletely understood. In our previous study, pathways associated with anti-tumor immune activity were significantly more methylated and silenced in AA PCa patients in the tumor-adjacent stroma (TAS) compared to EA patients, indicating potential epigenetic differences that may contribute to observed disparities.

Methods: We performed methyl-binding domain sequencing (MBD-seq) and RNA sequencing (RNA-seq) on TAS tissue from 17 AA and 15 EA PCa patients. Two custom bioinformatic pipelines were developed: one for ERV methylation analysis and another for ERV expression analysis. For methylation, sequencing reads were mapped to ERVs curated from the Human Endogenous Retrovirus Database (HERVd) to quantify locus-specific methylation. For expression, RNA-seq data were aligned to the same database to assess ERV expression profiles. ERV methylation patterns and their chromosomal distribution were visualized using chromoMap.

Results: In tumor-adjacent stroma, African American patients demonstrated significantly higher global ERV methylation with lower expression, while European American patients exhibited reduced methylation with elevated transcriptional activity ($p<0.05$). ChromoMap and statistical analysis revealed non-random chromosomal distribution of methylated ERVs, with the most significant ancestry-related differences on chromosome 19 (AA: 2.09 vs. EA: 1.76, $p<10^{-159}$), which harbored the highest methylation levels, consistent with its enrichment for repetitive elements and ERV sequences. Chromosome Y showed no significant difference ($p=0.148$), potentially due to constitutive heterochromatin status across ancestries.

Conclusion: In TAS, enhanced ERV silencing through hypermethylation in AA patients may represent a potential epigenetic mechanism contributing to disease aggressiveness through altered immune response genes. Conversely, hypomethylated and transcriptionally active ERVs in EA patients may enhance antitumor immune signaling, potentially explaining distinct clinical outcomes between populations.

#2380 Apolipoprotein E gene & PSA levels in Black men.

Lauryn Janelle Denise Jones[1], Jabril Johnson[2], Deyana Lewis[1], LaKendria K. Brown[1], Rick Kittles[1]

[1]Community Health & Preventative Medicine, Morehouse School of Medicine, Atlanta, GA,[2]Microbiology, Biochemistry and Immunology, Morehouse School of Medicine, Atlanta, GA

Background/Significance: Prostate cancer (Pca) is more prevalent among African American (AA) men compared to men of other racial and ethnic groups. Apolipoprotein E (APOE) plays a critical role in lipid metabolism and facilitates cholesterol and lipid transport, with its isoforms potentially impacting cancer progression. Prostate-specific antigen (PSA) is a biomarker of Pca and elevated PSA levels may predict the presence of Pca in patients. Our study investigates the genetic factors underlying this disparity, with a specific focus on the APOE gene and its role in prostate cancer cell proliferation. In this study, we aim to conduct an in-depth analysis of the APOE gene locus, examining isoform differentiation and its relationship to PSA elevation in African American men.
Methods: APOE SNP-level (rs429358, rs7412, rs440446) and haplotype-level analyses were performed using linear and logistic regression and haplotype-based modeling (R package haplostats). Models adjusted for age, West African genetic ancestry (WAA), vitamin D, case-control status, and PSA when applicable. Analyses were conducted separately after quality control in 1,370 men of west African ancestry from Washington DC (N=648), Columbia, SC (N=632) and Cameroon west Africa (Bamileke, N=90).
Results: Among AA men, PSA levels were strongly predicted by age ($\beta = 0.050$, $p = 1.39 \times 10^{-5}$) and case status ($\beta = 0.52$, $p < 1 \times 10^{-12}$). APOE haplotypes demonstrated no association with PSA (E4: $p = 0.80$; E2: $p = 0.36$) or prostate cancer status (logistic regression: E4 $p = 0.71$, E2 $p = 0.58$). Vitamin D ($p = 0.12$) and WAA ($p = 0.25$) were also non-significant predictors. Among men from Cameroon west Africa, we observed a nominal association suggesting higher PSA in E2 haplotype carriers ($\beta = 1.03$, $p = 0.045$), but this was not observed among AAs. No significant associations were detected for E4 ($p = 0.69$) or E3. In the combined analysis, APOE SNPs and haplotypes were not significantly associated with PSA (E4: $p = 0.93$; E2: $p = 0.67$) or case-control status (allelic tests: $p > 0.50$ for all SNPs). Across all models, age ($p < 2 \times 10^{-9}$) and PSA ($p < 6 \times 10^{-15}$) remained the strongest predictors of prostate cancer status.
Conclusion and Implications: Across three groups totaling more than 1,300 Black men, APOE genetic variation including the E2, E3, and E4 haplotypes did not significantly predict PSA levels or prostate cancer risk. Associations observed in the stratified analyses were not replicated and did
not withstand combined analysis. More studies are needed to confirm if APOE plays a biologically meaningful role in prostate cancer etiology or PSA regulation in these populations.
Acknowledgment of Funding: This research is supported by the Health Equity Research Career Advancement Program funded by the American Cancer Society's Diversity in Cancer Research Institutional Development Grant 885016.

#2381 Race-specific trajectories of prostate cancer evolution: Distinct temporal and spatial progression patterns in African American and Caucasian men.

Josiah Harsh[1], Shannon Carskadon[2], Nilesh S. Gupta[3], Sangeetha Jyothilingam[2], Jessica Ryba[3], Craig G. Rogers[2], James O. Peabody[2], Sunita Ghosh[4], Nallasivam Palanisamy[2]

[1]College of Human Medicine, Michigan State University, Detroit, MI,[2]Urology, Henry Ford Health, Detroit, MI,[3]Pathology, Henry Ford Health, Detroit, MI,[4]Public Health Sciences, Henry Ford Health, Detroit, MI

African American (AA) men experience a higher incidence and mortality from prostate cancer, traditionally attributed to more aggressive tumor biology. However, emerging evidence suggests that when access to care is equal, AA men often have outcomes comparable to—or better than—Caucasian men, showing that biological behavior may be distinct rather than inherently worse. To clarify early evolutionary trajectories, we performed a detailed race-stratified analysis of temporal and spatial progression patterns using serial 12-core and saturation biopsies.Longitudinal biopsy datasets were evaluated to measure time-to-progression across key histologic transitions from benign to HGPIN, benign to high-grade Gleason patterns, and within-grade upgrading. Site-specific progression proportions were compared across 12 anatomical regions. Statistical significance for temporal and spatial differences was assessed using proper parametric tests.In 12-core biopsies, AA men showed significantly slower progression from benign tissue to Gleason 5+5 carcinoma (140.77 vs. 8.49 months; $p<0.0001$) and a trend toward delayed progression from benign to HGPIN ($p=0.051$). In contrast, AA men showed faster progression from Gleason 3+4 to 4+3 (15.84 vs. 42.37 months; $p = 0.0005$), exhibiting a distinct—not uniformly aggressive—pattern of disease evolution. Spatial mapping showed higher progression rates in Caucasian men at the right lateral base and apical regions. In contrast, AA men showed greater progression in the left-sided areas (left base, lateral base, mid, and lateral mid).In saturation biopsies, AA men again displayed slower transitions from benign to Gleason 3+3 (22.36 vs. 18.35 months; $p=0.073$), benign to Gleason 4+4 (24.1 vs. 15.14 months; $p=0.021$), and from Gleason 3+3 to 3+4 (21.29 vs. 14.05 months; $p=0.021$). Anatomically, Caucasian men showed higher progression at the left lateral base, while AA men showed higher progression at the right lateral base.Our serial biopsy analyses reveal that AA men experience slower early biological progression from benign and low-grade disease compared to Caucasian men, challenging the long-standing assumption that AA prostate cancer is intrinsically more aggressive. Instead, these findings support a model of biologically distinct evolutionary pathways, with AA men exhibiting delayed early transitions but accelerated intermediate-grade shifts, and displaying unique spatial patterns of progression. These results align with recent clinical and genomic studies showing equal or better outcomes for AA men when access to care is equivalent. Collectively, our findings offer mechanistic insight into race-specific prostate cancer evolution and underscore the need for tailored surveillance and sampling strategies.

#2382 Achieving prostate cancer equity globally: Multinational advances from the iCCaRE consortium.

Folakemi T. Odedina[1], Arnold Merriweather[2], Roxana S. Dronca[3], Ernest T. Kaninjing[4], Solomon Rotimi[5], Gerardo Colon-Otero[6], Kimlin Ashing[7], Ademola A. Popoola[8], Gladys Asiedu[9], Opeyemi Bolajoko[1], Ewan COBRAN[10], Emelina Asto-Flores[1], Floyd Willis[1], Christopher Williams[11], Monica L. Albertie[12], Michelle Fudge[1], Oluwaseyi Toye[13], Collisa Mahin[1], Jada Melton[1], Inclusive Cancer Care Research Equity (iCCaRE) Consortium, Prostate Cancer Transatlantic Consortium (CaPTC)

[1]Mayo Clinic Florida, Jacksonville, FL,[2]Prostate Health Education Network, Quincy, MA,[3]Mayo Clinic College of Medicine and Science, Jacksonville, FL,[4]Georgia College & State University, Milledgeville, GA,[5]Covenant University, Ota, Ogun State, Nigeria,[6]Mayo Clinic Cancer Center Florida, Jacksonville, FL,[7]City of Hope National Medical Center, Duarte, CA,[8]Department of Surgery, University of Ilorin Teaching Hospital, Ilorin, Nigeria,[9]Mayo Clinic, Rochester, MN,[10]Mayo Clinic, Phoenix, AZ,[11]Urology Consultants, Jacksonville, FL,[12]Cancer Services, Mayo Clinic Florida, Jacksonville, FL,[13]Prostate Cancer Transatlantic Consortium (CaPTC), Jacksonville, FL

Background: Black men across the African Diaspora experience a disproportionate burden of prostate cancer (CaP). The Inclusive Cancer Care Research Equity (iCCaRE) Consortium aims to eliminate CaP burden through global scientific collaboration, innovative research, community-engaged interventions, and next-generation workforce development. The primary objective for this Consortium was to optimize CaP diagnosis, treatment, and survivorship through research, research training and education, community engagement and community outreach. The Consortium integrates digital health technologies, community navigation, precision communication and precision science.

Methods: Five full projects and one pilot project were launched across partner institutions in North America and Africa. Supported by multiple cores and services, the research activities included (1) implementation of a Point of Prostate Cancer Diagnosis Virtual Robot Assistant (PPCD-ViRA); (3) initiation of a cancer care at home trial; (4) migrant health studies of Caribbean and Sub-Saharan African immigrants; (5) expansion of genomic and metabolomic research; and (6) digital, psychosocial, and survivorship intervention development. Training and dissemination activities were deployed through iCCaRE TV, webinars, and community engagement programs including the Global Prostate Health Dialogue (Glo-PHD).

Results: In one year, accomplishments included 45 presentations, 17 publications, 16 grant submissions, and 3 awards. The consortium delivered 408 live webinar engagements and reached more than 400 men globally through Glo-PHD. PPCD-ViRA was fully developed and prepared for clinical deployment (see https://www.youtube.com/watch?v=1mI-HS5R6sk). The African cohort expansion for genomic and metabolomic profiling was activated across several countries, with biospecimen collection underway. Media dissemination generated more than 15,000 views across platforms, including high-impact educational videos (see: www.youtube.com/@iCCaREConsortium). Training achievements included 13 early-career investigators and 7 trained prostate cancer advocates.

Conclusions: In just one year, the iCCaRE Consortium Phase 2 made substantial progress toward transforming CaP equity globally. Through multidisciplinary science, digital innovation, and community partnerships, the consortium is building scalable infrastructure to address diagnosis experiences, treatment quality, and survivorship among Black men. Ongoing efforts will continue to advance precision medicine, culturally grounded interventions, and global capacity building.

#2383 The stress survival gene CCNB1 drives colorectal cancer progression and represents a novel target to address ethnic disparities.

Md Zahirul Islam Khan, Urbashi Basnet, Soumya Nair, Sourav Roy

Biological Sciences, University of Texas at El Paso, El Paso, TX

Background: Colorectal cancer (CRC) is the second leading cause of cancer-related mortality in the U.S., marked by significant racial and ethnic disparities in incidence, stage at diagnosis, and survival. While highly curable with early detection, Hispanics, who comprise over 17% of the U.S. population, face disproportionate barriers to timely diagnosis, leading to presentation with more advanced disease and poorer outcomes. This study investigates the functional role of the stress-survival pathway (SSP) gene, Cyclin B1 (CCNB1), as a potential early detection biomarker and therapeutic target to mitigate disparities between Hispanic and Non-Hispanic White (NHW) populations.

Methods: Our investigation utilized a multi-platform approach, integrating computational and experimental cancer biology. Initial screening involved in-house in-silico RNA-sequencing, differential expression analysis of tumor and adjacent non-tumor CRC tissue samples, from Hispanic and NHW cohorts. CCNB1 was identified as one of the most differentially expressed gene among the two races. To validate this finding, we performed qRT-PCR in CRC cell lines and tissue samples. The stage-specific expression was further evaluated using cDNA microarray whereas protein-level expression was determined using immunohistochemical assay of tissue microarrays. The oncogenic role of CCNB1 was further evaluated *in vitro* using CRC cell lines, and highly translational patient derived organoid model after CCNB1 knockdown. The RNA sequencing and Mass spectrometry will subsequently be employed to identify underlying molecular mechanisms of CCNB1-mediated CRC progression.

Results: Our results showed significant upregulation of CCNB1 in CRC cell lines and tissues at both transcript and protein levels. Notably, Hispanic CRC samples exhibited significantly higher expression of CCNB1 compared to NHWs, with marked upregulation of CCNB1 in early-onset and late-stage Hispanics. These results are in line with traditional delayed in diagnosis for Hispanic populations. The functional study demonstrated that CCNB1 knockdown in CRC cell lines significantly reduced proliferation, growth, invasion and migration of cells by inducing cell cycle arrest and apoptosis. In organoid model, the knockdown of CCNB1 reduced organoid growth by inducing apoptosis. In addition, multi-omics based molecular mechanisms associated with CCNB1-mediated cancer progression will be further evaluated using western blotting and qRT-PCR respectively.

Conclusions: This study identifies CCNB1 as a key oncogenic driver in CRC, highlighting its potential as a diagnostic biomarker and therapeutic target to enhance disease management and reduce ethnic disparities in outcomes among Hispanics and NHWs.

#2384 Demographic representation in randomized controlled trials of colorectal polyp prevention: A systematic review and meta-analysis.

Frankie Fan[1], Namrata Trivedi[2], Ryan Ford[2], Ajay Verma[1], Karen Brown[1]

[1]University of Leicester, Leicester, United Kingdom,[2]University Hospitals of Leicester NHS Trust, Leicester, United Kingdom

Background: Colorectal cancer (CRC) is an increasing global health burden. With incidence rising, there is a need to develop effective preventive strategies. Polyp-prevention randomized controlled trials (RCTs) are central to testing CRC-preventive therapies, using colorectal polyp development as an established endpoint. Marked ethnic disparities in CRC incidence, particularly in early-onset disease, are well documented. However, no systematic evaluation of demographic representation in polyp-prevention RCTs exists.
Methods: We conducted a systematic review and meta-analysis of RCTs assessing chemopreventive or immunopreventive interventions for polyp recurrence. The protocol was registered in PROSPERO (CRD420251102449). Eligible trials enrolled adults with prior polyps while excluding those with prior CRC, inflammatory bowel disease, or hereditary cancer syndromes. Of 9,127 screened records, 27 RCTs met inclusion. Demographic data including age, sex, geography, race, ethnicity, and socioeconomic status (SES) were extracted. Multi-arm data were pooled. Geography was grouped as Western, Non-Western, or multinational (Western and Non-Western). Race and ethnicity were harmonized to OMB-1997 categories. Age was meta-analysed using inverse-variance random-effects models. Sex, race, and ethnicity proportions were analysed using logit-transformed random-effects models. Temporal trends were visualised with sample-size-weighted bubble plots. All analyses were performed using R Statistical Software (v4.1.2; R Core Team 2024).
Results: All trials reported age, geography, and sex. Other demographics were often incomplete or collapsed. Race was reported in 41% of trials, and only 11% reported SES. The pooled mean age was 60.7 years (95% CI 59.2-62.2). Participants were 67.9% male. Studies were predominantly Western (74.07%), with Non-Western (18.52%) and multinational studies (7.41%) comprising the remainder. Of the 12 trials reporting race, pooled representation was White 87.9% (95% CI 82.5-91.8), Black 6.8% (95% CI 3.5-12.8), and Asian 2.2% (95% CI 1.1-4.1). Only 8 trials reported ethnicity, with Hispanic representation of 5.0% (95% CI 3.1-8.1). Bubble plots demonstrated persistently low non-White representation across three decades.
Conclusion: This review highlights inconsistent demographic reporting in CRC polyp-prevention RCTs. The persistent demographic underrepresentation, particularly of Black and Asian participants, fails to reflect the disproportionate disease burden. This limits the generalisability of prevention strategies and may worsen existing disparities in CRC outcomes. There is an urgent need for standardised demographic reporting and intentional equity-focused recruitment strategies to ensure that therapeutic prevention approaches are effective and applicable across all populations.

#2385 Examining structural and social drivers of hepatitis B vaccination across diverse clinical settings.

Alisa Vidwans[1], Anita Narkhede[1], Lisa Sanders[2]

[1]USF Health Morsani College of Medicine, Tampa, FL,[2]Pediatrics, USF Health Morsani College of Medicine, Tampa, FL

Hepatitis B is a major cause of liver cancer in the United States and is also associated with increased risks of non-Hodgkin lymphoma, pancreatic, and head and neck cancers. Although the Hepatitis B vaccine is highly effective at preventing chronic infection and subsequent cancer development, vaccination rates remain low: In 2021, Hepatitis B vaccination coverage was 34.2% among adults 19 and older. This study evaluates Hepatitis B vaccination series completion among adolescents and young adults across clinic settings, demographics, and social determinants of health (SDOH) to identify gaps in vaccine coverage and reduce the incidence of Hepatitis B infection. We performed a retrospective, cross-sectional analysis using electronic health record data from adolescent medicine, pediatric infectious diseases, internal medicine-pediatrics, and family medicine clinics within the University of South Florida health system, and Ybor Youth Clinic, a community sexual health clinic within the USF pediatrics department. The sample included 456 patients aged 16-24 who were seen between January and March 2025 and had documented immunization histories. Completion of the Hepatitis B vaccination series was analyzed by clinic type and demographic and SDOH variables, including age, gender, race, ethnicity, insurance status, primary language, primary care provider, HPV and tetanus vaccination status, and comorbid conditions. Across 20 clinics, 422 patients (92.5%) completed the Hepatitis B vaccination series. Completion rates varied significantly across clinic types ($p=0.012$). Demographic factors such as gender, race, and ethnicity were not significantly associated with vaccination status ($p=0.092$, $p=0.787$, $p=0.956$). However, younger patients were more likely to have completed the vaccine series ($p<0.001$). Uninsured patients demonstrated lower completion rates compared to those with public or private insurance ($p=0.045$). Completion of other routine vaccines (HPV series/tetanus) was strongly correlated with Hepatitis B vaccination completion (all $p<0.001$). Having a primary care provider was not significantly linked to completion ($p=0.271$), and comorbidities such as HIV infection showed no significant association ($p=0.092$, $p=0.124$). Hepatitis B vaccination rates in this cohort were substantially higher than national averages. However, disparities persisted based on various SDOH factors. Structural and access-related factors, particularly clinic type and insurance coverage, were more predictive of vaccine completion than demographic characteristics, suggesting structural factors have a greater influence than patient attributes in determining vaccination status. These findings highlight the need for system-level interventions to support series completion, particularly among underserved populations, to support Hepatitis B prevention and mitigate cancer-related disparities.

#2386 Evaluating ABCC1 as a potential prognostic biomarker in laryngeal cancer health outcomes.

Christina Gobin[1], Matthew Chang[1], Jai Walker[2], Kristianna Fredenburg[1]

[1]University of Florida, Gainesville, FL,[2]Labcorp, Jacksonville, FL

Background: Overexpression of ABCC1 is associated with poor overall survival across many cancers and has been associated with decrease response to chemotherapy. Our *in vivo* and *in vitro* studies have shown that ABCC1 expression is higher in laryngeal squamous cell carcinoma (LSCC) from individuals with African heritage. Here, we further investigate ABCC1 as a potential prognostic and predictive marker in laryngeal cancer health outcomes.

Methods: ABCC1 gene expression was assessed in tumor tissue from 32 advanced-stage LSCC patients from differing populations via RT-PCR. Immunohistochemistry (IHC) for ABCC1 protein expression was performed on tissue microarrays (TMAs) generated from 61 paraffin-embedded tissues of advanced stage LSCC from patients of differing heritages. Machine learning based digital pathology software (QuPath) was used to semi-quantitate ABCC1 IHC protein expression as H scores. Age, treatment, self-reported heritage, N stage, tumor histologic grade, and ABCC1 H-scores were evaluated as predictors of patient mortality risk via multivariable Cox proportional hazards (CPH) model. The median Cox risk score (cutoff > 0.971) was used to stratify patients into low and high mortality risk groups. The relationship among the clinical features and ABCC1 in low and high mortality risk groups was explored by Chi Square analysis. Overall survival was assessed using the Kaplan-Meier method.

Results: LSCCs from patients with African heritage demonstrated a 2.2-fold elevation in ABCC1 gene expression and higher ABCC1 protein expression (H-score) compared with the reference population ($p < 0.05$). Controlling for treatment, African heritage patients with low ABCC1 H-scores had a high mortality risk ($p < 0.05$), and patients from the reference population with metastatic disease and high ABCC1 H-scores had a low mortality risk ($p < 0.05$). Overall, high-risk patients had significantly worse overall survival (HR = 2.46, 95% CI [1.27-4.74], log rank $p < 0.01$) and high mortality risk was associated with low ABCC1 H-scores and regional metastatic disease ($p < 0.05$).

Conclusion: Although LSCC patients with African heritage have higher ABCC1 expression compared with the reference population, low ABCC1 H-scores carry a higher mortality risk in this group. LSCC patients from the reference population with high ABCC1 H-scores have reduced mortality risk despite having regional metastatic disease. Future studies will involve exploring mechanistic implications of ABCC1 expression on treatment outcomes across differing heritages.

#2387 Colorectal cancer equity and impact (CLEAR-CRC): The colorectal cancer alliance's community-based model for advancing biomarker testing.

Kimberly Lynn Newcomer, Erin Siegel, David Fenstermacher, Marianne Pearson, Lindsey Gladspell, Marc Mason

Colorectal Cancer Alliance, Washington, DC

Background: Despite the growing importance of comprehensive biomarker testing in precision oncology, only approximately 65% of colorectal cancer (CRC) tumors undergo some level of molecular testing. Rural CRC patients are 20% less likely to receive recommended molecular testing (e.g. MSI) compared to urban patients. Barriers include limited provider awareness, logistical hurdles, financial constraints, and fragmented provider-patient communications. The Colorectal Cancer Alliance convened a collaborative partnership including non-profit, academia, community clinics and industry to launch a prospective study to increase the uptake of comprehensive biomarker tests among patients with CRC in these underserved populations.
Methods: The initiative is designed as both a regional health communication campaign and a multi-modal quality improvement effort. Core components include hybrid patient navigation, education for patients and physicians, improved access to biomarker testing, and prospective longitudinal data collection. The study aims to recruit 100-120 patients with advanced CRC from two rural and one urban clinical sites. The study leverages the Alliance's BlueHQ digital support platform to support consent, navigation, patient and provider education, and longitudinal data collection. The health communications campaign will be developed based on focus group input and evaluated by pre- and post-surveys. Longitudinal study endpoints will include knowledge of biomarker testing, updates on biomarker testing, and biomarker-driven care delivery.
Results: Preliminary results are expected to be released after the study launch in early 2026. Outcomes will be measured through patient-reported data, navigation logs, and longitudinal tracking of testing uptake and treatment decisions. Key milestones before study launch include completion of messaging materials, site selection, navigator recruitment and training, and IRB protocol submission.
Conclusions:This project models a scalable, equity-driven approach to improving access to biomarker testing in CRC care through collaborative, multi-stakeholder partnerships led by a mission-driven patient advocacy organization. This study adopts a patient-centric approach through community-informed messaging, flexible navigation strategies, and centralized patient engagement via BlueHQ to address persistent gaps in CRC precision oncology. The effectiveness of our comprehensive quality improvement intervention will inform future efforts to reduce disparities and support advancing comprehensive biomarker testing as a standard of care in oncology.

#2388 Racial and ethnic differences in interest in cancer screening.

Ya Yang

Public Health Davis, University of California, Davis, Davis, CA

Background: Although research has shown lower cancer screening uptake among racial and ethnic minority groups, few studies have examined whether these groups are interested in screening. Understanding interest helps clarify whether disparities stem from differences in personal preference or from structural barriers. This study examines racial and ethnic differences in interest in obtaining a cancer screening test.

Methods: This cross-sectional study used national data from the 2022 Health Information National Trends Survey. The sample included adults aged 18 and older (n = 3,774). The outcome was a four-level measure of interest in having a cancer screening test within the next year. Ordinal logistic regression was used to examine associations between race/ethnicity and screening interest, adjusting for sociodemographic and health-related factors, including family history of cancer.

Results: Compared with non-Hispanic Whites, non-Hispanic Black (AOR=1.72, 95% CI: 1.20-2.46) and Hispanic adults (AOR=2.02, 95% CI: 1.49-2.73) reported significantly higher interest in getting screened for cancer within the next year. Females reported higher interest than males (AOR=1.75, 95% CI: 1.44-2.14). Adults aged 40-44 (AOR=1.69, 95% CI: 1.11-2.57) and 45 and older (AOR=1.68, 95% CI: 1.27-2.22) had higher odds of interest compared with those aged 18-34. Individuals without a family history of cancer had lower odds of reporting greater interest in screening (AOR=0.68, 95% CI: 0.53-0.87).

Conclusions: Despite lower cancer screening uptake among racial and ethnic minority groups, Black and Hispanic adults reported higher interest in cancer screening. This suggests that individual interest is not the limiting factor; instead, structural and access barriers likely drive lower screening completion. Future research should identify the specific points in the screening process where racial and ethnic disparities occur, since higher interest among minority groups does not translate into completed screening.

#2389 Geospatial mapping of health-linked risk factors and cancer outcomes in Puerto Rico: Data from the Puerto Rico BioBank.

Jose A. Oliveras Torres[1], Edna Gordian[2], W. Douglas Cress[3]

[1]Ponce Health Sciences University, Ponce, PR,[2]Moffitt Cancer Ctr. Research Inst., Tampa, FL,[3]Moffitt Cancer Center, Tampa, FL

The Puerto Rico BioBank (PRBB), established through a partnership between the Ponce Health Sciences University and the Moffitt Cancer Center with support from the National Cancer Institute, was the first centralized cancer-focused biorepository in Puerto Rico. It was designed to collect, store, and distribute well-annotated biological specimens and associated clinical data from individuals diagnosed with cancer across the island. The PRBB supports translational research by providing high-quality biospecimens linked to demographic, diagnostic, and geographic data. As of 2025, the biobank has accrued over 5,000 participants. The aim of this study is to describe the current structure and contents of the PRBB and highlight how its integrated dataset enables the mapping of health-linked factors such as comorbidities, geographic distance to care, sociodemographic factors, and diagnosis.Since 2019, the PRBB has enrolled 2,550 individuals diagnosed with cancer through academic-affiliated hospitals and clinics in southern Puerto Rico. All participants provided consent for the collection of tissue samples, clinical information, and zip code at the time of diagnosis. The dataset includes clinico-pathological variables, comorbidities, treatment pathways, and demographic variables. Biospecimens and data are collected, processed, and stored under standardized protocols consistent with national biobanking best practices and managed under institutional IRB-approved procedures. Statistical analysis was conducted using descriptive statistics. Analysis was performed using R statistical software version 2025.09.1+401.Preliminary analysis shows that over 50% of PRBB participants live more than 30 km from Ponce, the primary site for diagnostic and specialty care for patients from the central municipalities often traveling 45-90 minutes each way for services. Sociodemographic data further reveal that 35% of participants have only completed grades 8-12. Most participants report household annual incomes under $40,000 (83%), and 37% are publicly insured. Additionally, 73% have a family history of cancer and 29% report current or past tobacco use.The PRBB serves as a robust and expanding research platform for investigating region-specific factors that influence cancer outcomes across the island. By integrating biospecimens with clinical, geographic, and sociodemographic data, the PRBB enables the identification of spatial patterns related to stage at diagnosis, access to care, and treatment variability. This infrastructure supports future studies aimed at improving early detection, guiding mobile screening initiatives, and informing resource planning to address cancer burden in Puerto Rico.

#7560 Understanding the reasons for declining to participate in cancer genetics and genomic studies in the United States: A scoping review.

Joel Sanchez Mendez[1], Diego Alvarez-Lopez[1], Jessica Sanchez[2], Fibi Berhane[1], Vernon S. Pankratz[2], Andrew L. Sussman[2], Ursa Brown-Glaberman[2], Nicole N. Hamblet[2], Saira Khan[3], Christine Marx[3], Jennifer W. Mack[4], Shiraz I. Mishra[2], Mariana C. Stern[1]

[1]USC - University of Southern California, Los Angeles, CA,[2]University of New Mexico, New Mexico, NM,[3]Washington University School of Medicine, St. Louis, MO,[4]Dana-Farber Cancer Institute, Boston, MA

INTRODUCTION: Cancer is the second leading cause of death in the United States (US). Genetics and genomic cancer studies have improved understanding of risk, onset, progression, and have informed treatment options. However, many populations are underrepresented in existing studies, and reasons why some individuals decline to participate remain unclear. To address this gap, we conducted a scoping review to summarize the reasons associated with declining participation in cancer genetics and genomic studies among cancer patients in the US.

METHODS: A standardized search strategy was developed and deployed in Medline (PubMed), Embase (Ovid), and Scopus from database inception until March 13th, 2025. The search covered three concepts: cancer, genetics and genomic research, and declination to participate. A two-step screening process ensued against predefined inclusion criteria. Study characteristics were summarized descriptively. Reported reasons were harmonized into common data elements (CDEs). A network analysis was conducted to evaluate co-occurrence of CDEs and identify barriers. Recommendations to address barriers were mapped to specific themes and discussed with community members during the PE-CGS annual meeting.

RESULTS: A total of 18,114 studies were imported, after the selection process, 19 studies were included in the review. Most studies were cross-sectional (42%), published after 2019 (58%), and reported on clinical genetic testing (58%). The most evaluated cancer sites were breast (n=13), ovary (n=9), and colon-rectum (n=7). The mean declination rate was 22.7% (SD=5.3). Non-Hispanic White, non-Hispanic Black, and Asian individuals reported lower declination rates than the mean, while Hispanic/Latino/a/x, American Indian/Alaska Native, and Native Hawaiian or other Pacific Islander individuals had higher rates of decline (27-28%). Network analysis showed that financial concerns with emotional distress or low perceived utility often co-occurred. Physical or medical limitations and sample collection issues were common reasons for declining genetic testing, and financial or insurance concerns and low perceived relevance were more frequent in testing done to guide clinical decision-making only. Three overarching barriers were identified: behavioral, logistical, and structural. Educational interventions, flexible participation strategies, and system-level improvements are key recommendations, endorsed by community members with whom we discussed results.

CONCLUSION: Declining participation arises from behavioral, logistical, and structural barriers. Emotional, financial, and perceived utility concerns were most common and interrelated. Tailored education, provider engagement, and improved system accessibility may enhance equitable participation in cancer genetics and genomic studies.

#2393 DXC016, a novel cMET-targeting dual payload antibody-drug conjugate, demonstrates potent antitumor activity and favorable PK for potential subcutaneous use.

Yong Du[1], Jiaojiao Yu[1], Huihui Guo[1], Lingli Zhang[1], Xiaoqiang Xie[1], Jialei Hu[1], Xiafen Wu[1], Yunxia Zheng[1], Yuanyuan Huang[1], Junxiang Jia[1], Wei Liu[1], Zhouyang Zhou[1], Qingliang Yang[1], **Robert Y. Zhao**[2]

[1]Hangzhou DAC Biotechnology Co., Ltd, Hangzhou, China,[2]Hangzhou DAC Biotechnology Co., Ltd., Hangzhou, China

DXC016 is a next-generation cMET-targeting antibody-drug conjugate (ADC), composed of a novel anti-cMET monoclonal antibody (DXA016) and a functional dual payload designed to overcome limitations of conventional cMET-ADCs. Across multiple cMET-expressing tumor models, including SNU-5 (gastric), EBC-1 (NSCLC), HCT116 (colorectal), SW1990 (pancreatic), and an osimertinib-resistant NSCLC model, DXC016 demonstrated potent in vitro and in vivo antitumor activity, archived tumor regression at doses below 1.5 mg/kg and outperformed DXd and MMAE-based benchmark ADCs, highlighting the superior efficacy enabled by the dual-payload design. In mouse subcutaneous pharmacokinetic studies, co-administration with the recombinant hyaluronidase DXE001 markedly accelerated absorption, as indicated by a substantially earlier Tmax, while overall exposure remained similar between groups due to the thin and low-resistance subcutaneous tissue in mice. Given the higher hyaluronan content and greater diffusional resistance in human skin, DXE001 is expected to produce a more pronounced enhancement of subcutaneous absorption and bioavailability in clinical settings. In preliminary safety studies in rats and cynomolgus monkeys with once-weekly dosing for three administrations, DXC016 was well tolerated up to 80 mg/kg in rats and 50 mg/kg in monkeys, with no treatment-related mortality observed, indicating a favorable early safety profile. Collectively, the strong antitumor efficacy, improved subcutaneous absorption profile with DXE001, and encouraging preliminary safety characteristics support DXC016 as a promising clinical development candidate of next-generation cMET-targeting ADC.

#2394 A novel 2+2 IgG-like bispecific antibody-drug conjugate targeting EBV GP220/350 and EGFR for selective treatment of nasopharyngeal carcinoma.

Saihong Yu[1], Yunxia Zheng[1], Junxiang Jia[1], Xiangfei Kong[1], Juan Wang[1], Yi Luo[1], Hangbo Ye[1], Xueqing Ma[1], Qingliang Yang[1], **Robert Y. Zhao**[2]

[1]Hangzhou DAC Biotechnology Co., Ltd, Hangzhou, China,[2]Hangzhou DAC Biotechnology Co., Ltd., Hangzhou, China

Nasopharyngeal carcinoma (NPC) is endemic in East and Southeast Asia, with Epstein-Barr virus (EBV) infection as a primary etiological factor. The EBV envelope glycoprotein GP220/350 is highly expressed on EBV-positive NPC cells, serving as a tumor-specific antigen. Epidermal growth factor receptor (EGFR) is also overexpressed in >80% of NPC cases and is a validated therapeutic target (e.g., cetuximab). Bispecific antibodies (bsAbs) offer unique advantages by co-targeting two antigens, enhancing tumor selectivity and internalization efficiency. Here, we report the development of a 2+2 IgG-like bispecific antibody-drug conjugate (ADC) co-targeting GP220/350 and EGFR for precise NPC therapy. The bsAb was engineered as a 2+2 IgG-like molecule. The GP220/350-binding arm was derived from a fully humanized synthetic VHH (single-domain antibody) library and a high affinity binder C2 was selected via phage display. The EGFR-binding arm was based on nimotuzumab, a low-affinity EGFR antibody chosen to minimize on-target/off-tumor toxicity. The bsAb designated as DXA038 was conjugated to a topoisomerase I inhibitor payload CPT113 via a cleavable linker, with an average drug-to-antibody ratio (DAR) of 4. Binding affinity, in vitro cytotoxicity and in vivo efficacy were assessed. DXA038-CPT113 showed superior activity both in vitro and in vivo compared to nimotuzumab-CPT113.This bispecific ADC represents a promising therapeutic strategy for EBV-positive NPC, addressing unmet needs in precision oncology.

#2395 DXC011, a novel dual-payload antibody-drug conjugate targeting folate receptor alpha.

Zhicang Ye[1], Huihui Guo[1], Wei Zheng[1], Junpeng Wang[1], Yifang Xu[1], Hui Xia[1], Yuanyuan Huang[1], Junxiang Jia[1], Wei Liu[1], Xiang Chen[1], You Zhou[1], Qingliang Yang[1], **Robert Y. Zhao**[2]

[1]Hangzhou DAC Biotechnology Co., Ltd, Hangzhou, China,[2]Hangzhou DAC Biotechnology Co., Ltd., Hangzhou, China

Folate Receptor alpha (FRα) is highly expressed in epithelial ovarian cancer and selected solid tumors, making it an attractive target for antibody-drug conjugates (ADCs). Although an FRα-directed ADC Elahere has already achieved clinical approval, this microtubule inhibitor-based agent faces challenges, such as ocular toxicity, narrow therapeutic windows, and limited activity beyond ovarian cancer. To address these limitations, we developed DXC011, a next-generation FRα-targeting ADC engineered to enhance antitumor efficacy while improving tolerability. DXC011 comprises DXA011, a humanized IgG1 antibody specific for FRα, an optimized cleavable linker and a dual functional payload. This dual-payload strategy introduces complementary cytotoxic mechanisms and may help overcome resistance associated with single-mechanism ADCs. DXC011 demonstrated potent activity across multiple FRα-expressing in vitro and in vivo tumor models, encompassing ovarian cancer as well as additional solid tumor types. Beyond established ovarian cancer settings, DXC011 showed notable efficacy in gastrointestinal tumor models, supporting its potential for broader clinical application. Moreover, DXC011 displayed favorable tolerability in mouse, with an improved safety profile relative to microtubule inhibitor-based ADC while maintaining robust antitumor potency. Collectively, these findings indicate that DXC011 offers an improved therapeutic index and may enable expanded indication coverage. DXC011 represents a novel FRα-targeted dual-payload ADC that achieves potent and broad antitumor activity with enhanced tolerability, supporting its advancement toward clinical development.

#2396 A novel 2+2 IgG-like bispecific antibody-drug conjugate with dual payloads for targeted therapy of heterogeneous gastrointestinal cancers.

Wei Zheng[1], Junxiang Jia[1], Xiaolei Liu[1], Gengxiang Zhao[1], Yongxiang Chen[1], Xia Zhou[1], Simin Zhao[1], Qingliang Yang[1], **Robert Y. Zhao**[2]

[1]Hangzhou DAC Biotechnology Co., Ltd, Hangzhou, China,[2]Hangzhou DAC Biotechnology Co., Ltd., Hangzhou, China

Gastrointestinal (GI) cancers, including colorectal, gastric, and pancreatic cancers, remain a leading cause of cancer-related mortality globally due to their high incidence, aggressive progression, and profound intratumoral heterogeneity. This heterogeneity often leads to treatment resistance and limits the efficacy of monotherapies. Cadherin-17 (CDH17) and Guanylate Cyclase C (GUCY2C) are two promising tumor-associated antigens (TAAs) that are broadly and specifically overexpressed in various GI cancers, making them ideal targets for dual-specific therapy. Bispecific antibodies (bsAbs) offer a strategic advantage by co-targeting two distinct antigens, potentially enhancing tumor selectivity, overcoming heterogeneity, and improving therapeutic outcomes. Here, we report the development of a novel 2+2 IgG-like bispecific antibody-drug conjugate (ADC) targeting both CDH17 and GUCY2C, engineered to address the unmet needs in GI cancer treatment. The bispecific antibody was constructed as a 2+2 IgG-like molecule. The CDH17-binding arm was derived from a humanized single-domain antibody (VHH) isolated from an immunized alpaca library, selected for high affinity and specificity. The GUCY2C-binding arm was a fully human IgG1 kappa antibody identified through biopanning of a human phage display library. The resulting bsAb was site-specifically conjugated to a proprietary dual-payload linker-drug system from Hangzhou DAC, consisting of a potent antimetabolite drug and a topoisomerase I inhibitor. The bsAb exhibited high-affinity binding to both CDH17 and GUCY2C (KD values in the low nanomolar range) and demonstrated dual-specific binding to cells expressing either or both antigens. This ADC agent also demonstrated potent cytotoxicity against both single and dual antigen-expressing tumor cells. The promising preclinical efficacy profile of this ADC support its potential as a targeted therapy for patients with advanced GI cancers, offering a new strategy to overcome treatment resistance and improve clinical outcomes.

#2397 Cell based payload release highlights design, site, and cell dependent ratio shifts in dual payload ADCs.

Nan Hsuan Wang, Wei-Han Lee, Evelyn He, Li Chuan Huang, Yu-Chao Huang, David Teng-Yi Huang, Ya-Chi Chen

OBI Pharma, Inc, Taipei City, Taiwan

Dual-payload antibody-drug conjugates (ADCs) are designed to deliver two cytotoxic payloads in a defined ratio, yet whether this designed composition is maintained upon cellular processing is poorly understood. Conventional enzymatic payload release assays confirm linker cleavability but fail to reflect the biological complexity governing intracellular release. To address this, we established a quantitative cell-based liquid chromatography payload-release assay to monitor intracellular drug liberation after ADC treatment across multiple tumor cell lines. Using this platform, we examined how linker design, conjugation site, drug-to-antibody ratio (DAR), and steric environment affect payload release of mono- and dual-payload ADCs. While all constructs exhibited analytically confirmed enzymatic cleavability, the intracellular release profiles frequently diverged from the designed A:B payload ratios. Notably, the extent and direction of these ratio shifts were cell-type dependent, even for the same ADC construct, indicating that differences in protease abundance, endolysosomal trafficking, and microenvironmental pH strongly modulate payload liberation. Furthermore, conjugation site and DAR configuration introduced steric shielding effects that altered linker accessibility and release kinetics, resulting in distinct and less than optimal intracellular payload ratios despite identical chemical designs. Importantly, cell-based release results correlated closely with cytotoxicity outcomes in animal models, underscoring their functional relevance. Together, these findings reveal that the custom-designed dual-payload ratio does not necessarily reflect the effective intracellular ratio, and that cellular context, linker architecture, and conjugation geometry collectively determine the eventual payload balance. This framework provides a mechanistically informative tool for rational optimization of dual-payload ADC design, enabling more predictive control of intracellular pharmacology.

#2398 Dissecting ADC pulmonary toxicity: A murine ADC-associated ILD model to guide and inform ADC discovery.

Suresh Anaganti, Arti Bhujade, Steven Murkli, Zachary Sparta, Nabin Panth, Alexander Weig, Richa Vartak, Julien Dugal-Tessier, Nareshkumar Jain

NJ Bio, Inc., Princeton, NJ

Antibody drug conjugates (ADCs) built upon topoisomerase I inhibitors such as deruxtecan have reshaped the therapeutic landscape of solid tumors, yet their promise continues to be constrained by interstitial lung disease (ILD), a clinically significant toxicity whose mechanistic origin remains incompletely understood. Herein, using a translational murine ILD platform, we dissect the architectural determinants of ADC-induced lung injury and reveal a striking divergence in pulmonary responses driven by drug-linker chemistry. Trastuzumab-GGFG-DXd reproduced the delayed-onset alveolar inflammation, macrophage-rich infiltrates, and fibrotic remodeling characteristic of clinical and non-human primate ILD, whereas structurally distinct comparators including an SN38-based ADC, novel camptothecin ADCs, and ADCs featuring payload-free linkers result in unexpected findings that suggest ILD is much more than a payload-derived toxicity. This data highlights the importance of evaluating ILD-related toxicity in the discovery process whereas previously toxicity screening is reserved for lead optimization stages. Employing our murine ILD platform, we were able to study and evaluate numerous combinations of novel camptothecin payloads and novel linkers arriving at significantly reduced or no ILD without compromising the efficacy in low HER-2 expressing JIMT1 efficacy model. These findings establish a predictive and scalable murine platform for ADC-associated ILD and propose a conceptual reframing of ADC safety engineering, one in which ILD related toxicity evaluation can guide rational ADC design.

#2399 Discovery of ZL-6201, a novel LRRC15-targeting antibody drug conjugate (ADC) for the treatment of sarcomas and epithelial solid tumors.

He Xu[1], Zengxia Li[2], Jiaqing Yi[1], Wilson Peng[1], Qiuping Ye[1], Xinchao Xia[2], Lei Wang[2], Xinchuan Dai[2], Yue Ge[2], Donghui Li[1], Ziruo Wen[2], Changwei Lv[2], Joshua Zeng[1], Qidong Hu[1], Lina Wang[2], Jelveh Lameh[1], Nathan Ihle[1], Bing Wan[2], Linda N. Liu[1]

[1]Zai Lab (US) LLC, Cambridge, MA,[2]Zai Lab (Shanghai), Co. Ltd, Shanghai, China

Leucine-rich repeat-containing protein 15 (LRRC15) is a transmembrane protein involved in cell-cell and cell-extracellular matrix interactions. It is overexpressed in tumors of mesenchymal origin which include sarcomas, glioblastoma and melanoma, where its expression has been implicated in promoting metastasis. Additionally, LRRC15 is upregulated in cancer-associated fibroblasts (CAFs) that are found in the tumor microenvironment (TME) of multiple epithelial tumors. Its predominant expression in tumors and CAFs, coupled with minimal or absent expression in normal cells, makes LRRC15 a selective and potentially effective therapeutic target for antibody-drug conjugate (ADC) development.

ZL-6201 is an innovative ADC targeting LRRC15, built on the tumor microenvironment-activable linker-payload (TMALIN®) platform. It comprises a humanized anti-LRRC15 antibody, a hydrophilic protease-cleavable linker, and a novel camptothecin-derived topoisomerase I inhibitor payload C24. Site-specific conjugation yields an average drug-to-antibody ratio (DAR) of 8. ZL-6201 binds human and cynomolgus monkey LRRC15 with high affinity and specificity.

In vitro, cell-surface binding and target-dependent internalization selectively occurred in tumor cells expressing LRRC15. This resulted in C24 payload release, the induction of DNA damage response, cell cycle arrest, and ultimately cytotoxicity to tumor cells. The internalization of ZL-6201 in LRRC15-expressing human tumor cells and CAFs, followed by payload release and diffusion, mediated cytotoxicity against LRRC15-negative tumor cells in co-culture via the bystander effect.

In vivo studies demonstrated efficacy of ZL-6201 in human patient-derived xenograft (PDX) sarcoma models expressing endogenous LRRC15. Additionally, CAF-mediated payload release and the resultant efficacy were evaluated in two model systems: (1) cell-derived xenograft (CDX) models with low or no endogenous LRRC15 expression in tumor cells but high LRRC15 expression in mouse-derived CAFs using a mouse-reactive ZL-6201 surrogate, and (2) syngeneic tumor models with human LRRC15 knock-in CAFs using ZL-6201. Both ZL-6201 and the surrogate were well tolerated and demonstrated dose-dependent anti-tumor activity. Finally, ZL-6201 showed acceptable toxicokinetic and safety profiles in non-human primates (NHP).

Collectively, these data support advancing ZL-6201 into clinical development as a therapeutic candidate for sarcomas and epithelial solid tumors characterized by LRRC15 expression within the tumor microenvironment.

#2400 Design and evaluation of mRNA translation inhibitors for use as antibody drug conjugate payloads.

Mark Petersen[1], Jodi Wong[1], Samir Das[2], Vidhi Khanna[1], Kurt Stahl[1], Micheal G. Brant[1], Truman Hirkala-Schaefer[1], Jesse Leblanc[1], Victoria K. Harman-McKenna[1], Manuel Lasalle[1], Graham A. E. Garnett[1], Rehan Higgins[1], Catalina Suarez[1], Kaylee J. Wu[1], Linglan Fu[1], Germanna Righetto[1], Devika Sim[1], Adele Chan[1], Allysha Bissessur[1], Ambroise Wu[1], Araba Sagoe-Wagner[1], Luying Yang[1], Andrea Hernandez Rojas[1], Dunja Urosev[1], Sam Lawn[1], Vincent Fung[1], Stuart D. Barnscher[1], Raffaele Colombo[1], Jamie R. Rich[1]

[1]Zymeworks Inc., Vancouver, BC, Canada,[2]Abcellera, Vancouver, BC, Canada

Introduction: Eukaryotic initiation factor 4A (eIF4A) mediates recruitment of ribosomes to mRNA and catalyzes the unwinding of mRNA secondary structure, thereby facilitating ribosome scanning and translation initiation. Inhibitors of eIF4A (e.g., silvestrol, zotatifin, and other rocaglates) block translation of select mRNAs that contain a high degree of secondary structure (e.g. mRNAs encoding MYC, KRAS, and CDK4/6, among others), resulting in inhibition of cell proliferation and induction of apoptosis. Despite limited efficacy observed for zotatifin in a phase I clinical trial, antibody conjugation of a novel eIF4A payload offers the possibility of enhanced exposure and improved tolerability, which could lead to more robust responses. Furthermore, eIF4A antibody-drug conjugates (ADCs) would constitute a novel mechanism with the potential to address payload-specific resistance mechanisms that have been reported following progression on ADCs with camptothecin payloads.
Methods: A panel of novel rocaglamide-derived eIF4A inhibitors containing linkable functional groups were synthesized and evaluated for potency, hydrophilicity, and DMPK properties. Select analogs were elaborated into drug-linkers containing a hydrophilic polyethylene glycol (PEG) side chain to minimize hydrophobicity. Conjugation to endogenous cysteines using maleimide chemistry provided ADCs targeting diverse tumor associated antigens that were evaluated for in vitro potency, in vivo efficacy, and tolerability.
Results: ADCs carrying eIF4A inhibitors with a drug-to-antibody ratio of 8 required use of hydrophilic PEG groups to minimize aggregation. In vitro, trastuzumab ADCs showed potent antigen-dependent activity in HER2-expressing cell lines and bystander activity in mixed co-cultures of HER2+ and HER2- cells. Selection of lead drug-linkers was based on robust in vivo anti-tumor activity of HER2 targeted ADCs in NCI-N87 and SKOV-3 CDX models as well as tolerability in non-tumor bearing mice and Sprague Dawley rats. The breadth of efficacy of the lead drug-linkers was evaluated in vivo using Ly6E, PTK7, TROP2, cMET, and EGFR targeted ADCs.
Conclusions: Novel eIF4A ADCs constructed using hydrophilic drug linkers demonstrated potent and target-specific in vitro cytotoxicity. Promising in vivo efficacy was observed across multiple tumor associated targets, however the observed toxicity level in both mice and rats suggests a potentially lower than anticipated preclinical therapeutic window.

#2401 Developing a single B cell platform to accelerate antibody discovery and screening.

Spencer Chiang[1], **Wenlin Ren**[1], An Ouyang[2], Yu Sun[1], Xiaoli Li[1]

[1]ACROBiosystems Co., Ltd., Beijing, China,[2]ACROBiosystems Inc., Newark, DE

Rapid and efficient isolation of antigen-specific B cells is a critical bottleneck during antibody discovery, especially for antigens that are complex, maintain small and specific epitopes, or have a low immunogenicity. To solve this challenge, we developed a next-generation single B cell discovery platform focusing around utilizing both fluorescence-activated cell sorting(FACS) and CellCelector(CC) to maximize the recovery of low-population, high-value B cells. By performing an initial screen concurrently, this platform is able to maximize its complementary strengths: FACS with the deep sampling of large lymphocyte populations with precise multi-parametric gating, while CC can ensure a flexible, image-guided recovery of more fragile B cell subsets. This dual-mode workflow increases single-cell retrieval efficiency, reduces sampling bias, and improves downstream recombinant antibody expression success rates. To demonstrate platform performance, we employed a case study targeting DM1, a maytansinoid payload widely used in ADC development. Antigen-specific memory B cells were enriched and screened using fluorescent DM1 conjugates. FACS revealed a success rate of 73%, and after setting the gating parameters, 96 Abs with rIgGwith rIgG+/hIgG-DM1+/rIgM- binding was selected. Out of the 49 unique CDR3 Abs, 45 were specific to DM1 and first screened by ELISA. Antibodies with an affinity above nanomolar levels were further confirmed by biolayer interferometry (BLI) and ELISA, highlighting 19 potential candidates against DM1. Binding characterization revealed that 19 antibodies exhibited affinities above the nanomolar range, confirming robust recognition of the DM1 moiety. These results highlight the power of combining parallel FACS and CellCelector workflows to capture diverse, high-affinity antibody repertoires, even against complex small-molecule payloads. Overall, the platform provides a scalable, high-confidence route for antibody discovery supporting ADC payload targeting, mechanistic studies, and the development of next-generation biotherapeutics.

#2402 Rapid lead generation with the Pioneer Antibody Discovery Platform.

Birthe Jessen-Park[1], Sarah-Jane Kellmann[2], Mateusz Putyrski[2], Manuel Cavada[2], Hanh Hanuschka[2], Christian Frisch[2], Achim Knappik[2], Francisco Ylera[2]

[1]Bio-Rad Laboratories, Hercules, CA,[2]Bio-Rad Laboratories, Munich, Germany

The Pioneer™ Antibody Discovery Platform is Bio-Rad's biotherapeutic antibody generation service, centered around the Pioneer Antibody Library—one of the largest functional Fab libraries (225 billion unique sequences). Informed by over 18 years of phage display expertise, the library is optimized for therapeutic antibody selection. It integrates SpyDisplay, a proprietary SpyTag-based selection system, and TrailBlazer, a modular platform for rapid format assembly. We showcase data on antibody selection against IL-6R, C5aR, and CXCR4, demonstrating that the Pioneer Platform yields diverse, high-affinity, and functional leads for difficult targets. These candidates show comparable or superior performance to clinically developed or marketed antibodies across key parameters.

#2403 Advancing precision oncology through innovative bioconjugation and linker architecture strategies.

Shuhui Chen, **Dan Hart**, Matt Giese, Erika Leonard, Bowu Luan, Shamali Roy, Michael Fiebig, Catherine Bladen

Vector Laboratories, Inc., Newark, CA

The purpose of this study is to showcase how Vector Laboratories' proprietary bioconjugation technologies enable the development of highly specific and stable biomolecule conjugates, driving improvements in cancer detection and targeted therapy. We utilized Vector's advanced conjugation chemistries—including site-specific labeling and click chemistry—combined with optimized linker systems to create antibody-drug conjugates (ADCs) and diagnostic probes. Conjugates can be characterized using LC-MS, SEC, fluorescence imaging, and functional assays in tumor-derived cell lines to assess binding specificity, payload release, and signal amplification. Summary of New Data: The successful development of new antibody drug conjugates (ADCs) requires expert knowledge of antibody engineering, chemical biology, and linker architecture. BioDesign by Absolute Antibody and Vector Laboratories, provides drug developers ease of access to trusted antibody engineering, crucial bioconjugation products, and unique linker IP. These critical elements in the BioDesign toolbox help to maximize life science development versatility, overcome resource constraints, manufacturing at scale, and decrease time-to-market. Vector will showcase data highlighting how dPEG-based linkers have enhanced the therapeutic profile of ADCs, supported by recent bioassay results. In summary, Vector Laboratories' bioconjugation capabilities deliver precise, reproducible, and scalable solutions for oncology research and clinical applications. These findings underscore the potential of our platform to enhance therapeutic efficacy and diagnostic accuracy in cancer care.

#2404 Selective tumor immune activation by novel nucleic acid drug.

Akimitsu Okamoto[1], Kunihiko Morihiro[1], Makoto Yamamoto[2]

[1]University of Tokyo, Tokyo, Japan,[2]TKG Therapeutics, Inc., Tokyo, Japan

Introduction: Cancer-selective immune activation by artificial nucleic acids holds promise as a potent therapeutic modality for cancer treatment. We developed a hairpin DNA self-assembly technology and found it effectively suppresses tumor growth. Specifically, our developed compound TKG-002 activated cellular innate immunity and demonstrated potent tumor growth inhibition. Here, we discuss the results of tumor growth suppression by TKG-002.

Experimental Design: Two hairpin DNA sequences (oHP) were designed. Among these, the oHP showing the strongest cancer growth suppression effect in B16 tumor-bearing mice was selected and named TKG-002. In vitro tests confirmed TKG-002's self-assembly triggered by binding to miR-21. We also investigated the induction of innate immune activation that causes cancer growth suppression.

Results: TKG-002 was confirmed to aggregate under conditions of abundant miR-21 expression, forming long double-stranded DNA to which cGAS binds. Administration of TKG-002 to cancer cells induced apoptosis via the cGAS-STING pathway, including the production of phosphorylated IRF3. When TKG-002 was administered intra-tumorally to B16-bearing mice using an appropriate DDS, tumor growth was strongly suppressed. Aggregates of $CD8^+$ T cells and $CD4^+$ T cells were observed at the periphery of the shrinking tumor tissue. While TKG-002 alone demonstrated sufficient tumor growth suppression, combination with anti-PD-1 antibody resulted in even greater tumor growth inhibition.

Conclusions: The suppression of miR-21-overexpressing cancer growth by TKG-002 represents a potent therapeutic modality enabling selective tumor lysis through intracellular DNA self-assembly. The engineered TKG-002 induced autoimmunity toward targeted tumor lysis by forming long double-stranded DNA via miR-21. Further safety evaluation and condition optimization of TKG-002 are expected to establish it as an efficient cancer treatment modality.

#2405 A first-in-class IKZF1/3 degrader antibody conjugate (DAC) as a potential myeloma treatment.

Shuai Wu[1], Jinyu Yang[2], Mo Dan[2], Xiwu Hui[3], Bing Yao[3], Miaomiao Wei[2], Bin Bao[1], Qiwen Zhu[1], Linlin Xiao[2], Penghui Wen[2], Xiaodan Zhang[1], Wei Fang[1], Xiao Li[2]

[1]CSPC Megalith Biopharmaceutical Technology, Shanghai, China,[2]CSPC Pharmaceutical Group Ltd., Shijiazhuang, China,[3]CSPC Megalith Biopharmaceutical Technology, Shijiazhuang, China

Antibody-drug conjugates (ADCs) deliver potent cytotoxins to tumors but are limited by off-target toxicity and resistance. This drives the development of Degrader Antibody Conjugates (DACs) platform, which combine the catalytic activity of targeted protein degradation (TPD) with the tissue specificity of antibodies. We applied this innovative approach to multiple myeloma, where most patients relapse after frontline regimens (e.g., RVd, PVd), creating a critical need for novel therapies that overcome IMiD resistance. Emerging novel IKZF1/3 degraders, which allosterically reprogram CRBN, offer a potent solution by overcoming IMiD resistance in the clinic. We hypothesized that conjugating these catalytic degraders to CD38 antibody would create a synergistic therapeutic, migrating this potent mechanism from late-line to frontline treatment. Here we describe the rational design and pre-clinical profile of ADC-2419, the first-in-class CD38-directed DAC that delivers the potent IKZF1/3 degrader P5 to tumors. From a panel of candidate payloads, we identified P5 that binds CRBN with an 80-fold higher affinity (Kd <10 nM) than lenalidomide. This ultra-high affinity enables robust ternary-complex formation even at low intracellular CRBN levels, thereby bypassing the resistance mechanisms that cripple IMiD efficacy. P5 exhibits low-picomolar degradation potency (IKZF1 EC_{50} < 0.1 nM; IKZF3 EC_{50} < 0.1 nM) and drives deep target degradation (≥ 90% D_{max}) in tumor cells. Quantitative proteomics of >8,000 proteins confirmed exquisite selectivity; no endogenous CRBN neosubstrates were significantly reduced. Consequently, P5 shows potent cytotoxicity against MM cells (IC_{50} < 1 nM) while exhibiting limited cytotoxicity toward PBMCs up to 1 μM. P5 exhibited favorable PK *in vitro* and *in vivo* and was well tolerated in cynomolgus monkey toxicity study, supporting its development as a next-generation payload. Therefore, conjugation of P5 to the human CD38 antibody via a cathepsin-cleavable linker generated ADC-2419. ADC-2419 demonstrates potent cytotoxicity against CD38-expressing cells in vitro. In NCI-H929 xenograft model, a single 1 mpk dose achieved complete tumor regression, outperforming parental CD38 antibody at the same dose. In the PBMC-humanized mouse model, ADC-2419 demonstrated enhanced efficacy and maintained significant superiority over the CD38 antibody. Furthermore, pronounced tumor accumulation was observed in tumor-bearing mice, aligning with the in vivo efficacy and validating the targeted-delivery capability of our DAC platform. Collectively, the robust preclinical evidence for ADC-2419, which synergizes antibody targeting with catalytic protein degradation, supports its translational promise in overcoming key limitations in myeloma treatment.

#2406 A novel BRD4 degrader-HER2-targeting antibody-drug conjugate (DAC) overcomes trastuzumab deruxtecan resistance in HER2-positive cancers.

Xin Yu[1], Bin Yang[1], Wendi Ni[2], Haibo Liu[2], **Jan Willem Theunissen**[2], Jesse Chen[2], Jin Wang[1]

[1]Baylor College of Medicine, Houston, TX,[2]Fortitude Biomedicines, Boston, MA

Trastuzumab deruxtecan (T-DXd), an antibody drug conjugate (ADC), has transformed the treatment landscape for HER2-positive cancers. However, its long-term efficacy is limited by the inevitable development of resistance, which is often driven by altered internalization dynamics, impaired payload activation, or drug efflux. Therefore, next-generation ADCs capable of overcoming these resistance mechanisms are urgently needed to extend durable benefit. We have developed a next-generation degrader antibody conjugate (DAC) that combines a HER2 targeting antibody, trastuzumab, and a selective BRD4 molecular glue degrader, bromoseradeg (BsD), as the payload. BsD is a highly potent, BRD4 degrader and exhibits single digit nanomolar (nM) or sub-nM potency across diverse HER2+ cancer models. Trastuzumab bromoseradeg (T-BsD) was synthesized by cysteine conjugation chemistry via the cleavable Valine-Citrulline-para-aminobenzyl carbamate (Val-Cit-PABC; VCP) linker with an average drug-to-antibody ratio (DAR) of ~4. T-BsD preserved strong Her2-dependent cytotoxicity and consistently outperforming T-DXd in multiple HER2+ cell models and is also highly active in the T-DXd-insensitive xenograft model. To directly interrogate different resistance mechanisms, we first engineered HER2^{+} cancer lines to carry the clinically relevant TOP1 R364H mutation, which abolishes TOP1 inhibitor binding and confers robust T-DXd resistance. T-BsD retained cytotoxic potency in these mutant cells ex vivo and showed no loss of antitumor activity in corresponding xenograft models. Separately, we also evaluated resistance driven by overexpression of the efflux transporter ABCC1, a common mechanism that exports the DXd payload. In HER2^{+} cells with high ABCC1 expression, T-Dxd activity was abrogated, whereas T-BsD completely bypassed ABCC1-mediated efflux and maintained potent activity in both 2D culture and 3D xenograft tumors. Collectively, these compelling preclinical findings establish T-BsD as a mechanistically distinct therapeutic agent designed to overcome potentially key drivers of acquired resistance. By integrating potent BRD4 degradation with HER2-targeted delivery, T-BsD achieves superior activity and effectively bypasses the two most clinically relevant T-DXd resistance pathways. Together, these data strongly support the selective BRD4 degrader as a promising payload for developing next-generation ADCs that can benefit patients who are refractory or resistant to current ADC therapies.

#2407 DAC-1522: A novel Trop2-targeting degrader-antibody conjugate for precision oncology.

Chuanjie Chen[1], Qianqian Shen[1], Xinhui Cai[1], Yaqi Ding[1], Xiaoyu Yang[1], Yanfen Fang[1], **Carlos Chai**[2], Jian Ding[1], Yi Chen[3], Xuan Zhang[3]

[1]Shanghai Institute of Materia Medica, Chinese Academy of Sciences, Shanghai, China,[2]DaCure Therapeutics, Shanghai, China,[3]Shanghai Institute of Materia Medica, Chinese Academy of Sciences/DaCure Therapeutics, Shanghai, China

Background

Antibody-drug conjugates (ADCs) have revolutionized cancer therapies by enabling the targeted delivery of cytotoxic payloads to tumor cells. However, their efficacy and safety are constrained by the limited diversity of cytotoxic payloads. Notably, all FDA-approved Trop2-targeting ADCs employ topoisomerase I inhibitors as payloads, which may lead to both intrinsic and acquired drug resistance. Degrader-antibody conjugates (DACs) have emerged as a next-generation modality that integrates the selective targeting of ADCs with the mechanistic versatility of protein degraders, thereby offering a means to overcome these limitations. In this study, we sought to develop a TROP2-directed DAC capable of addressing the constraints of conventional ADCs and enhancing therapeutic outcomes.

Methods

A library of BET degraders was screened in MDA-MB-231 and BT-474 cells using CCK8 assays, and their degradation efficacy was subsequently confirmed by Western blot analysis. The selected payload candidates were converted into linker-drug precursors and conjugated to antibodies to generate the corresponding DACs. The drug-to-antibody ratio (DAR) and aggregation profiles were characterized using reversed-phase liquid chromatography (RPLC) and size-exclusion chromatography (SEC), respectively. *In vitro* cytotoxicity and selectivity were evaluated across multiple cancer cell lines, including MDA-MB-231, JIMT-1, BXPC-3, and KP-4. Furthermore, the DACs were evaluated in an Enhertu-resistant NCI-N87 model. *In vivo* anticancer efficacy was investigated in JIMT-1, MIA PaCA-2, and BXPC-3 cell-derived xenograft (CDX) models.

Results

Several BET degraders demonstrated potent cytotoxic and degradation activities. The corresponding DACs achieved the designated DAR without detectable aggregation. *In vitro*, DAC-1522 exhibited potent and Trop-2 dependent antiproliferative effects across multiple human cancer cell lines. Notably, DAC-1522 maintained robust activity in an Enhertu-acquired drug resistance model, whereas Enhertu and SKB264 showed markedly compromised efficacy, highlighting its potential to overcome resistance associated with conventional ADC therapies. *In vivo*, a single intravenous dose of DAC-1522 induced complete tumor regression in the BXPC-3 xenograft model without body weight loss.

Conclusion

DAC-1522 represents a novel Trop2-targeting DAC that demonstrates superior in vivo antitumor efficacy and the ability to overcome drug resistance, underscoring its promise as a therapeutic candidate for TROP2-positive malignancies.

#2408 ADCs in cancer treatment: SPR-driven insights into discovery and characterization .

Soraya Diez-Posada[1], **Cynthia Shuman**[2], Narashima Murthy Bandaru[2], Anna Moberg[2], Bryan Edwards[1], Sam Ness[1], Lowri Davies[1], Anja Pomowski[1], Laura Bouche[1], Isabel Perez-Castro[1], Howard Desmond[1], Gokhan Yahioglu[1], Mahendra P. Deonarain[1]

[1]Antikor Biopharma Ltd, Stevenage, United Kingdom,[2]Cytiva, Marlborough, MA

Antibody-drug conjugates (ADCs) have significantly advanced cancer therapeutics. Yet their efficacy in solid tumors remain limited due to poor tumor penetration, large molecular size and systemic toxicity. To address these challenges, we present a novel class of antibody fragment-drug conjugate (FDC) engineered for improved pharmacokinetic/pharmacodynamic (PK/PD) profiles and enhanced tumor accessibility. Surface plasmon resonance (SPR) was used to perform high-resolution kinetics and affinity analyses across multiple FDC targets. This approach provided rational candidate selection and optimization of binding kinetics, which supported the development of FDCs with superior tumor penetration and therapeutic potential. Integration of SPR data into the early discovery workflow has proven instrumental in identifying FDCs with optimal kinetic and affinity profiles. In preclinical development, SPR data supported assessment of safety and toxicology of FDCs through precise binding kinetics profiling. SPR data also deepened our understanding of target biology and mitigated development risk by eliminating the need for surrogate antibodies. This integrated approach streamlined the transition from discovery to preclinical evaluation, accelerating therapeutic development. These findings highlight FDCs as promising candidates for solid tumor treatment and provide a strategic path to overcome the limitations of conventional ADCs.

#2412 Malic enzyme inhibition as a strategy to exploit metabolic reprogramming in cancer: A structure-based approach.

Ben Andrew Krinkel[1], Yuliana Yosaatmadja[1], Mark Daniel Slayton[2], Jin Heon Jeon[2], Jack Copping[1], Jack Flanagan[1], Sofia Merajver[2], Chris Squire[1], Kerry Loomes[1]

[1]University of Auckland, Auckland, New Zealand,[2]University of Michigan, Ann Arbor, MI

Background: Cancer remains a global health challenge and urgently requires therapies that improve clinical outcomes and patient quality of life. Tumor cells commonly reprogram metabolism to sustain proliferation and survival, notably by increasing glutamine dependence and upregulating mitochondrial malic enzyme 2 (ME2), which produces pyruvate and NAD(P)H. ME2 is overexpressed in pancreatic, melanoma, and lung cancers, making it a compelling therapeutic target that remains underexplored.
Methods: Recombinant human ME1, ME2, and ME3 were expressed and kinetically characterized in the presence and absence of inhibitors. We solved a complete set of X-ray crystal structures for the three isoforms with a potent malic enzyme inhibitor bound, revealing ligand and metal coordination. These structures guided virtual screening of a curated library of up to 14 million drug-like and fragment molecules to identify novel malic enzyme inhibitors. Biochemical hits were advanced to cellular assays to evaluate efficacy; lead compounds NPD-389 and FLA were tested for antiproliferative activity in melanoma and triple-negative breast cancer cell lines.
Results: Kinetic analyses show distinct activity and inhibition patterns across ME isoforms. X-ray crystallography visualized the potent, isoform-nonselective inhibitor NPD-389 bound in a metal-coordinating mode and captured an unexpected malic enzyme conformation. Structure-based virtual screening against this conformation identified multiple novel scaffolds with biochemical inhibitory activity. One scaffold, FLA, exhibited a unique selectivity profile and was found bound to ME2 in a previously cryptic pocket that rearranges upon ligand engagement and sits adjacent to the NAD^+ cofactor and malate-binding site. In a panel of melanoma and triple-negative breast cancer cell lines, NPD-389 and FLA reduced proliferation in most models, supporting their potential as chemical leads for further development.
Conclusions: These results establish mitochondrial malic enzymes, particularly ME2/ME3, as tractable targets for cancer therapy. Structural elucidation of NPD-389's metal-binding mode and of FLA's cryptic/allosteric binding pocket provides a robust foundation for rational optimization of potency and isoform selectivity. Selective ME inhibitors—either isoform-specific or mitochondrially targeted—have potential as adjuncts to checkpoint inhibitors or chemotherapy, enabling more effective, metabolism-directed cancer treatment.

#2413 Insights in CYP2E1-mediated ferroptosis in hepatocellular carcinoma.

Kristy L. Thomas, Kylie R. Driggers, Hyland C. Gonzalex, Jessica H. Hartman

The Medical University of South Carolina, Charleston, SC

Introduction: CYP2E1, a cytochrome P450 enzyme mainly found in hepatocytes, is crucial for metabolizing xenobiotics including fatty acids and drugs. In hepatocellular carcinoma (HCC), CYP2E1 acts as a tumor suppressor. However, CYP2E1 has significantly reduced RNA and protein expression in HCC and its expression correlates positively with patient survival. We hypothesized that CYP2E1 promotes ferroptosis—a regulated, iron-dependent cell death involving iron accumulation, ROS generation, glutathione depletion, and lipid peroxidation—which may underlie its beneficial effects in HCC.

Methods: HCC cell lines were cultured per ATCC guidelines and transduced with adenoviral vectors expressing GFP or CYP2E1, confirmed by Western Blot. To assess palmitic acid (PA) toxicity, cells were treated with 0-5mM PA for 24 and 48h, followed by cell death analysis. For ferroptosis sensitivity, cells were exposed to graded concentrations of inducers (FINO2, FIN56, Erastin, RSL3) for 24h, then analyzed for cell death.

Results: Cell lines exhibited a variation in sensitivity to palmitic acid (PA) treatment, with HepG2 exhibiting a stronger response than SNU398 and SNU449 cells. However, there was no statistically significant effect of CYP2E1 expression in the response to PA feeding. Sensitivity to ferroptosis inducers also varied widely across cell lines and appeared to be cell type-specific rather than dependent on CYP2E1 expression.

Conclusion: Our results provide new insight into the sensitivity of different HCC cell lines to ferroptosis induced by PA feeding and by pharmacological inducers of ferroptosis. Further studies are needed to determine the mechanism of CYP2E1 tumor suppression, which our data suggests may not be through ferroptosis.

#2414 Targeting the interferon-inducible isoform, p150 of ADAR1 for the treatment of oral squamous cell carcinoma (OSCC).

Annie Wai Yeeng Chai[1], Pei San Yee[1], Xavier Wezen Chee[2], Stephanie Hao Ling Cheah[2], Jie Ying Teo[3], Keng Yoon Yeong[4], Siew Kit Ng[3], Siaw San Hwang[2], Sok Ching Cheong[1]

[1]Translational Cancer Biology, Cancer Research Malaysia, Subang Jaya, Malaysia,[2]Faculty of Engineering, Computing and Science, Swinburne University of Technology Sarawak, Kuching, Malaysia,[3]Advanced Dental and Medical Institute, Universiti Sains Malaysia, Penang, Malaysia,[4]School of Sciences, Monash University Malaysia, Subang Jaya, Malaysia

Oral squamous cell carcinoma (OSCC) is the fourth most common cancer in low- and middle-income countries (LMIC) and is one of the leading causes of cancer deaths in Asia, accounting for nearly three-quarters of global oral cancer mortality. Five-year survival rates remain poor, reflecting both the scarcity of actionable genetic drivers and the absence of Asian patient-derived models in global cancer datasets. This underrepresentation has slowed therapeutic innovation for populations that bear the greatest burden, leaving a significant unmet clinical need. To address this gap, we conducted genome-wide CRISPR/Cas9 dependency screens on a panel of unique Asian-derived OSCC cell lines that reflect the genetic and etiological diversity of these patients to identify vulnerabilities for therapeutic development. We have identified Adenosine deaminase acting on RNA (ADAR1) as an essential gene for OSCC survival. ADAR1 is an RNA-editing enzyme, whereby its dysregulation has been associated with tumor progression in various cancers. There are two isoforms of ADAR1 (p110 and p150), which are identical except that p150 has a unique Zα domain, which binds Z-DNA and offers a unique targeting opportunity to treat this deadly OSCC. To take this forward, we applied a proprietary computer-aided drug discovery pipeline, termed the Multi-layer Ultra-large Screening and Exploration (M.U.S.E), to identify potential Zα-targeting ADAR1 inhibitors. Approximately six billion compounds were evaluated through integrated filters for solubility, drug-likeness, binding affinity, and stability. A total of 51 compounds were shortlisted from the in-silico screening, and their binding affinities and specificities were evaluated. The intrinsic tryptophan fluorescence (ITF) spectroscopy was used to determine the binding affinity, while the electrophoretic mobility shift assay (EMSA) was used to determine the on-target effect of the compounds in disrupting the Zα-Z-DNA binding. From ITF analysis, 21 compounds demonstrated strong binding affinity with Stern-Volmer constants (K_{SV}) exceeding 10,000 M^{-1}. Using EMSA, we identified eight compounds with robust evidence of disruption of Zα-Z-DNA binding complexes. Our selected top hits demonstrated better binding affinity and on-target efficacy in disrupting ADAR1-Zα function, compared to other reported experimental candidates of ADAR1 inhibitors. While further effort in the hit-to-lead optimization and validation of its anti-tumor efficacy in OSCC cells are still ongoing, the discovery of these top hits with validated binding affinity and functional efficacy assures a promising outlook of our drug discovery strategy.

#2415 First-in-class stabilizing inhibitor of CHD4 that traps and disassembles the NuRD complex.

Anthony Sanchez[1], Minkyu Kim[2], Ivan Babic[3], Kyle Miller[1], **Elmar Nurmemmedov**[3]

[1]Emory University, Atlanta, GA,[2]University of Texas, San Antonio, TX,[3]CellarisBio, San Diego, CA

CHD4, the catalytic core of the NuRD complex, regulates chromatin remodeling, transcriptional repression, and DNA repair. Its overexpression in glioblastoma correlates with poor prognosis, yet CHD4 has remained undruggable. Employing a novel cell target engagement strategy, we identified CH41, a first-in-class small molecule that covalently engages cystine residues in the CHD4 chromodomain. The compound stabilizes CHD4 on chromatin, blocks its remodeling activity, and induces NuRD complex dissociation and proteasomal degradation. MICRO-TAG® cellular target engagement assay system applied in both discovery and validation stages, confirms direct CHD4 binding and real-time intracellular stabilization consistent with mechanistic trapping. CH41 disrupts CHD4 interaction with ZMYND8 and RBBP4/7, represses RAD51 expression, and impairs homologous-recombination repair, leading to reduced RAD51 foci and increased γH2AX and 53BP1 accumulation. Functionally, CH41 disables CHD4-dependent DNA repair and transcriptional control, re-sensitizing temozolomide-resistant glioblastoma cells. The data establishes CH41 as the first selective CHD4 inhibitor and illustrates how advances in cellular biophysics and cellular target engagement profiling are transforming the discovery of small molecule modulators of challenging transcription factor targets, such as chromatin remodelers.

#2416 Analyzing non-cancerous and cancerous protein structure using a novel Elliptical Dichroism Spectrometer.

Tommy Gao[1], Dali Sun[2]

[1]KIHA, University of Denver, Denver, CO,[2]KIHA, Univerisity of Denver, Denver, CO

Protein structure analysis is important as structure often dictates a proteins function. Currently, there are many instruments for analyzing protein structural features, such as Circular Dichroism (CD) Spectrometry. However, the large size and high cost of this method limit its applicability to well-organized and funded research environments only. Previously, we constructed an Elliptical Dichroism Spectrometer (EDS) instrument for the analysis of micromolecules (amino acids) chirality, as well macromolecule (protein) secondary structure analysis using both theoretical simulation methods and experimental validation. Furthermore, we demonstrated the EDS potential in distinguishing between protein derived from non-cancerous and cancerous pancreatic cell lines. We demonstrated the potential of the EDS for use as a protein secondary structure analysis instrument with potential application for noninvasive cancer detection using structural features exhibited by cancerous proteins as the source of detection. The simplified design of the EDS additionally tackles issues faced by current CD spectrometry by being smaller in size and lower in cost, allowing for greater applicability.

#2417 Proteome-wide target engagement and ternary complex mapping of molecular glues using LiP-MS.

Martin Soste[1], Polina Shichkova[1], Matevz Stefancic[1], Daniel Redfern[1], Francesca Cavallo[2], Lorna Charge[2], Ka Ying Lee[2], Ricardo Canavate del Pino[2], Denise Swift[2], Roland Hjerpe[2], Stuart Thomson[2], Allan Jordan[2], **Yuehan Feng**[1]

[1]Biognosys AG, Schlieren, Switzerland,[2]Sygnature Discovery, Nottingham, United Kingdom

Deciphering molecular targets and interaction networks of small molecules within native cellular contexts remains essential for both target-based and phenotypic drug discovery. This is particularly critical for molecular glues (MGs), which promote selective protein degradation through induced protein-protein interactions. Two mechanistic axes define MG action: (1) direct binding of the compound to an E3 ligase that subsequently recruits a neosubstrate, and (2) compound engagement with a primary protein target that promotes E3 ligase recruitment and ternary complex formation.

Limited proteolysis coupled with mass spectrometry (LiP-MS) has emerged as a powerful, label-free approach for elucidating small-molecule target engagement and mapping binding sites in complex proteomes without chemical tagging or genetic manipulation. Here, we expand the application of LiP-MS to two complementary experimental formats that interrogate distinct stages of molecular glue activity.

In the first scenario, an in-lysate LiP-MS workflow was implemented to identify primary drug-protein interactions across the proteome. Using quantitative data-independent acquisition mass spectrometry (DIA-MS) and a seven-point concentration series, we monitored conformational and accessibility changes across >250,000 peptides from >8,000 proteins. Machine learning-based LiP scoring enabled peptide-level resolution of binding sites and quantitative ranking of target engagement.

In the second scenario, a live-cell LiP-MS assay was developed to capture compound-induced protein-protein interaction changes under physiological conditions. This live-cell format enables detection of secondary, compound-dependent protein recruitment events, including ternary complex formation with E3 ligases and other associated proteins.

To evaluate LiP-MS performance in characterizing molecular glue mechanisms, we conducted global target identification experiments using two representative compounds: SR-4835, a cyclin K degrader that binds CDK12 and recruits DDB1, and MRT-2359, a GSPT1 degrader that engages CRBN. Live-cell LiP-MS experiments were performed at two time points (1 hour and 6 hours) to monitor compound-dependent conformational changes and protein recruitment dynamics associated with primary target engagement and potential ternary complex formation.

Together, LiP-MS provides a comprehensive, high-resolution platform for mapping small-molecule target engagement and for characterizing dynamic protein recruitment events associated with molecular glue activity directly in the cellular environment.

#2418 Non-covalent small molecule probe discovery of large intrinsically disordered protein.

Yichen Xiang[1], Marc Ramos Sala[1], Jose I. Vergara Panzone[1], Nancy Jiang[1], Diya Rana[2], Eliot Ebert[3], Angela N. Koehler[1]

[1]Massachusetts Institute of Technology (MIT), Cambridge, MA,[2]Massachusetts Institute of Technology (MIT), Cambrudge, MA,[3]Koch Institute For Integrative Cancer Research, Cambridge, MA

Fusion-positive alveolar rhabdomyosarcoma (ARMS), is a rare pediatric cancer often characterized by the pathognomonic fusion protein PAX3::FOXO1. Similar to other highly disordered transcription factors, PAX3::FOXO1 lacks typical small-molecule binding pockets thus making drug development difficult by conventional structural oriented design or traditional screening. Currently, there is no direct therapeutic approach to treat children with fusion-positive ARMS and patients are treated with ineffective traditional chemotherapeutic agents. Previously, we screened a library of small molecules against PAX3::FOXO1 via Small-Molecule Microarrays (SMMs) and identified a compound that shows selective target engagement in thermal shift assay but no apparent cellular activity. Furthermore, we are exploring targeted degradation with PROTACs due to the slow turn-over rate of this target. We have identified a scalable protein purification strategy to achieve stable, functional recombinant PAX3::FOXO1 and we are in the process of expanding the SMMs libraries up to 300,000 compounds. To validate hits from those high throughput screenings, we developed lentiviral transduced ARMS cell lines expressing HiBiT-tagged PAX3::FOXO1, enabling plate-based reporter assays as well as thermal shift assays. Small molecules are highly advantageous in their administration, delivery, and patient accessibility. We hope to address some of the unmet needs in the space of small molecule drug discovery against intrinsically disordered oncoprotein and transcription factors.

#2419 Synthesis and evaluation of novel functionalized β-lactams as potent anti-melanoma agents targeting PI3K/MAPK and JAK/STAT pathways.

Joy Temiloluwa Folahan[1], Ojasvi Dutta[1], Tolulope Omole[1], B. Donji[2], Konstantin Kousoulas[1], Timothy Beng[2], Jean Christopher Chamcheu[1]

[1]Louisiana State University, Baton Rouge, LA,[2]Central Washington University, Ellensburg, WA

Background: Skin cancers represent the most prevalent malignancies in the United States, affecting approximately 9,500 individuals daily and contributing to an annual economic burden exceeding $8.1 billion. Cutaneous melanoma skin cancer (CMSC), accounted for more than one million affected individuals and over 7,600 deaths in the US in 2022. Despite advances in targeted interventions, durable responses remain limited by systemic toxicity, low-bioavailability and rapid development of drug resistance. These challenges highlight the critical need for novel molecular scaffolds with improved pharmacological profiles and multi-target mechanisms.
Methods: To address this need, we leverage diversity-oriented synthesis, a powerful approach for creating structurally diverse, drug-like scaffolds with enhanced pharmacological potential. This strategy is becoming increasingly relevant in oncology drug discovery pipelines. A focused library of 40 novel, functionalized β-lactams were synthesized and screened against human (A375, SK-MEL-28) and murine (B16F10) CMSC cell lines. Cytotoxicity was assessed via IC_{50} determination, followed by phenotypic and mechanistic assays evaluating clonogenicity, migration, redox modulation, and apoptosis.
Results: Several derivatives demonstrated potent anti-melanoma activity, from which two lead molecules, W035 and W038, were selected for detailed characterization. W035 showed IC_{50} values of 14 μM (B16F10) and 24 μM in A375 cells, while W038 exhibited IC_{50} values of 24 μM in both A375 and B16F10 cells. Both compounds significantly inhibited colony formation (60% reduction at $0.75\times IC_{50}$) and suppressed wound closure and migration by 80%, indicating strong anti-metastatic potential. Mechanistically, W035 and W038 disrupted redox homeostasis, evidenced by 50% reduction in intracellular reactive oxygen species, and robustly activated caspase-3/7, confirming induction of apoptotic cell death. ADME profiling using SwissADME web-tool, predicted favorable drug-likeness, including high skin permeation (log Kp), good gastrointestinal absorption, Lipinski rule compliance, optimal lipophilicity (Log P_o/w<5), and favorable biodegradability. SwissTargetPrediction analysis indicated that the lead compounds possess a multi-target melanoma-inhibitory profile involving targeting MAPK, PI3Ks and JAK/STAT signaling pathways. Immunoblotting further therapy dose-dependent downregulation of these targets, indicating convergence on key melanoma signaling nodes.
Conclusions: This study identifies rationally designed β-lactam-based scaffolds with multi-target anti-melanoma activity. The lead compounds modulate apoptotic signaling, redox homeostasis, and MAPK/PI3K and JAK/STAT pathways, supporting rationale their further optimization and preclinical development for melanoma therapy.

#2421 Combining deep mutational scanning and next-generation protein sequencing to harness dominant protein variants to develop DNA repair inhibitors.

Nigel O'Neil[1], Lina Ma[2], Anthony Oppedisano[1], Esteban Lenoir[1], Philip Hieter[2], Peter C. Stirling[1]

[1]Arrowsmith Genetics, Vancouver, BC, Canada,[2]Michael Smith Laboratories, University of British Columbia, Vancouver, BC, Canada

The most clinically effective DNA repair enzyme inhibitors not only inhibit but also convert the target itself into a therapeutic agent. For example, topoisomerase poisons block the completion of the topoisomerase reaction resulting in a genotoxic DNA-protein adduct. Similar mechanisms underlie clinically relevant PARP inhibitors and other emerging DNA repair inhibitors. The challenge is identifying which repair proteins can be converted into gain-of-function therapeutic agents and how to elicit a gain-of-function phenotype. We developed an approach, Mutational Target Mapping, that uses deep mutational scanning to identify dominant missense variants that define structure-function relationships in drug targets that can direct therapeutic development. Dominant missense protein variants can be used to model the behavior of a potential drug to validate mechanisms of action and define genetic dependencies. Combining this platform with benchtop Next-Generation Protein Sequencing on the Quantum-Si Platinum® instrument, we can identify, track, and characterize the phenotypic effects of dominant missense variants in cells and biochemical assays. We applied this approach to several therapeutic targets discovering key residues in orthosteric and allosteric sites that can be mutated to elicit a dominant phenotype. Here, we describe our complementary genetic (high throughput screens) and proteomic (benchtop protein sequencing) approaches to find and model the behavior of therapeutics targeting DNA repair enzymes.

#2422 Next-generation chemical biology: Mapping the Purinome druggable space reveals genotype-specific vulnerabilities via phenotypic screening.

Ali Khateb, Ritika Gangaraju, Eric Gonzalez, Maizie Lee, Akshat K. Nigam, Jessica San Juan, Agnes Tan, Imran S. Haque, Thilo J. Heckrodt, Jack D. Sadowsky, Stig K. Hansen, Raymond V. Fucini

Kimia Therapeutics, Berkeley, CA

Background: Phenotypic screening enables discovery of biologically active compounds without prior knowledge of specific molecular targets. When combined with systematic chemical-space analysis, it represents a next-generation framework for mapping the druggable space across diverse genetic backgrounds. The human Purinome - a family of purine-interacting proteins composed of kinases and other nucleotide-binding enzymes - contains many attractive drug targets. Here, we applied our ATLAS (Active Learning with Automated Synthesis and Screening) platform which integrates high-throughput precision chemistry, direct to biology (D2B) screening, and machine learning, to survey the Purinome druggable space using diverse purine-directed libraries, aiming to identify genotype-specific dependencies within this critical protein network.

Methods: Using ATLAS, we generated proprietary, structurally diverse small molecule libraries of over 100,000 purine-directed samples, synthesized at nanoliter scale and directly screened in a high-throughput 1536-well cell viability assay. Screening was conducted in two colorectal cancer cell lines with distinct genotypes: HCT-116 and NCI-H747. Active D2B hits were validated by full dose-response curves, followed by pure resynthesis to confirm activity, selectivity, and potency. High-resolution chemical-space analysis was applied to visualize the diversity of active compounds, map activity across the surveyed chemical space, and define structure-activity relationships (SAR) enabling the identification of uniquely active scaffolds.

Results: ATLAS enabled exploration of a diverse chemical space which yielded thousands of cell-active compounds, many with strong cell line selectivity. Iterative application of ATLAS rapidly improved potency. As SAR was refined through the triage, hits clustered into distinct, non-overlapping chemical scaffolds, suggesting engagement with different biological targets. Importantly, activity maps differed between the two cell lines, revealing genotype-specific dependencies. One prominent chemotype contained structurally related molecules to known Aurora kinase inhibitors with clear cell line selectivity, while others represent novel, uncharacterized dependencies. These results demonstrate the platform’s efficiency in simultaneously discovering genotype-selective, cell-active compounds and accelerating their refinement toward optimal biological activity.

Conclusion: Using ATLAS, we performed phenotypic screening combined with high-resolution mapping of Purinome-directed chemical space. This approach identified small molecule compounds linked to genotype-specific vulnerabilities, establishing ATLAS as a powerful strategy for dissecting the druggable proteome and uncovering genotype-tailored therapeutic targets.

#2423 Evaluation of novel small molecule inhibitors targeting Polycomb repressive complex 1 as chemical probes.

Geoffrey Hewett[1], Haiqing He[2], Yiwu Yao[2], Se Ra Park[2], Sydney Musser[3], Trupta Purohit[2], Jolanta Grembecka[1], Tomasz Cierpicki[1]

[1]Pathology, University of Michigan, Ann Arbor, MI,[23]University of Michigan Medical School, Ann Arbor, MI

Background: Polycomb Repressive Complex 1 (PRC1) is an epigenetic regulatory complex responsible for monoubiquitylation of lysine 119 on histone H2A (H2AK119Ub). This ubiquitylation activity is mediated by a canonical heterodimeric E3 ligase involving Ring1B (or its paralog Ring1A) bound to BMI1. Deposition of H2AK119Ub is associated with gene repression at loci involved in determining cell fate and identity. Notably, genetic depletion of Ring1A and Ring1B results in reduction of H2AK119Ub, derepression of PRC1 target genes, and cell growth arrest in a leukemia model. Therefore, small molecules targeting the ubiquitylation activity of Ring1A/B are useful chemical probes towards studying PRC1 biology.
Results: We have previously developed RB-3: a first in class small molecule inhibitor of PRC1. Here we report the next generation of novel small molecule PRC1 inhibitors. Employing structure-based design, we have developed a potent cell permeable next generation inhibitor RB-322. RB-322 is a mixture of two atropisomers which were separated yielding RB-322-1 and RB-322-2. To validate direct binding of our inhibitors to Ring1A/B we used 2D HSQC. Notably, RB-322-1 demonstrates slow exchange while RB-322-2 demonstrates fast exchange indicating strong and weak binding respectively. We then used an AlphaScreen competition assay to evaluate RB-322-1 mediated disruption of the PRC1-nucleosome interaction *in vitro* in which it shows low nanomolar activity. A novel radiometric ubiquitylation activity assay (RadUb) was then developed to quantitatively assess inhibition of PRC1 E3 ligase activity. Using this assay we found RB-322-1 demonstrates sub-micromolar activity. RB-322-2 is 2 orders of magnitude weaker in these assays. We then investigated the on-target activity of RB-322 in leukemia cell lines. First, we developed a biotinylated RB-322 probe and performed streptavidin-based pull downs followed by proteomics analysis revealing enrichment of multiple PRC1 proteins. We then evaluated the effects of RB-322-1 on cellular H2AK119Ub and gene expression. We found RB-322-1 demonstrates rapid and dose-dependent reduction of the H2AK119Ub mark after 6-hours and derepresses PRC1 target genes in AML cell lines. Crucially, these effects have not been observed for the weak atropisomer RB-322-2.
Conclusions: Extensive medicinal chemistry optimization has yielded a potent cell permeable next generation small molecule inhibitor of PRC1: RB-322. RB-322 demonstrates low nanomolar activity in biochemical assays *in vitro* and demonstrates on-target derepression of PRC1 genes providing novel mechanistic insights. RB-322 represents a useful chemical probe for studying PRC1 biology and serves as the foundation for a potential novel anti-cancer agent.

#2424 Evaluating the biochemical activity and endogenous engagement of covalent small molecule inhibitors of NSD1 and NSD3 in cancer cell lines.

Joshua Ray, Bradley Clegg, Sergei Zari, Kibum Kim, Se Ra Park, Jolanta Grembecka, Tomasz Cierpicki

University of Michigan, Ann Arbor, MI

Background: The nuclear receptor-binding SET domain (NSD) family of proteins consists of NSD1, NSD2, and NSD3, each with histone methyltransferase (HMT) activity responsible for mono and di-methylation of histone 3 lysine 36 (H3K36me2). NSD1 expression and genetic alterations are implicated in 17% of head and neck squamous cellular carcinoma (HNSCC) patients, and knockdown of NSD1 inhibits the growth of HNSCC cell lines. Additionally, amplification of chromosome 8p11-12 (amplicon encoding *NSD3* among other genes), overexpression, or activating mutations of NSD3 drive the progression of non-small cell lung cancer (NSCLC) subtypes. In NSCLC cell lines with NSD3 amplification, knockdown of NSD3 results in growth inhibition. In multiple cancer cell lines, methyltransferase activity of NSD1 and NSD3 has been implicated in promoting cell growth, rationalizing the development of small molecule inhibitors.

Results: Optimization of our previously reported covalent inhibitors of the NSD1 SET domain led to the development of separate series of NSD1 and NSD3 inhibitors, which demonstrate potent growth inhibition in various cancer cell lines. To evaluate the potency of these inhibitors, we developed an *in vitro* engagement assay utilizing intact protein mass spectrometry. These experiments validated nearly complete covalent engagement of NSD1 and NSD3 after 2 h of incubation with small molecule inhibitors. We have also determined second order rate constant K_{inact}/K_I confirming effective covalent inhibition of NSD1 and NSD3. To assess inhibition of NSD1 and NSD3 SET domains, we employed an enzymatic histone methyltransferase activity assay and found mid-nanomolar IC_{50} values. To determine the covalent engagement of endogenous methyltransferases in cancer cells, we have developed and optimized an immunoprecipitation followed by bottom-up proteomics workflow. Our current experiments evaluate the inhibition of H3K36 methylation in these cell lines.

Conclusions: We have developed small molecule covalent inhibitors of NSD1 and NSD3 SET domains with strong engagement in *in vitro* mass spectrometry analyses and potent inhibition in histone methyltransferase assays. Furthermore, IP bottom-up proteomics methodology has enabled confirmation of covalent engagement to NSD3 in cancer cell lines, supporting on-target growth inhibitory effects of NSD3 inhibitors. These covalent inhibitors can be used as chemical probes to further study the effects of NSD1 and NSD3 inhibition in cancer and represent potential therapeutic modalities.

#2426 The cryo-EM structure of ADGRL4 provides functional insights into its mechanism of activation.

David M. Favara[1], Qingchao Chen[1], Anastasiia Gusach[1], Aurora Diamante[2], Jayesh C. Patel[2], Patrcia C. Edwards[1], Christopher G. Tate[1]

[1]Structural Studies Division, MRC Laboratory of Molecular Biology, Cambridge, United Kingdom,[2]Nxera Pharma UK Limited, Cambridge, United Kingdom

Background

ADGRL4 (also known as ELTD1) is an orphan adhesion G protein-coupled receptor (aGPCR) upregulated in multiple aggressive malignancies where it promotes angiogenesis, proliferation and epithelial-mesenchymal transition. Its molecular activation mechanism however was previously unknown. We demonstrated that ADGRL4 couples weakly to the heterotrimeric G protein G_q and determined the first active-state cryo-EM structure of ADGRL4. We then combined the structural data with systematic mutagenesis and G protein recruitment assays to define the molecular determinants of tethered agonist (TA) mediated activation.

Methods

A split NanoLuc-proximity assay using engineered ADGRL4 and mini-G protein constructs was used to quantitate Gq coupling. We purified the active-state ADGRL4-mini-G_q-βγ complex and determined its structure by cryo-EM. Guided by the structure, we performed alanine-scanning mutagenesis on TA residues contacting the orthosteric binding pocket and selected residues within the receptor core, assessing effects on G_q recruitment in HEK293T cells.

Results

Cryo-EM analysis yielded the first high-resolution structure of active-state ADGRL4 to 3.1 Å resolution. The TA region forms a short α-helix that occupies the orthosteric site and promotes outward displacement of transmembrane helix 6 (TM6). Alanine substitution of seven out of eight TA residues that interact with the orthosteric pocket significant impaired G_q recruitment. Mutation of six residues (H408A, F409A, I411A, L412A, M413A, S414A) reduced coupling by >50%; M413A abolished coupling completely (p<0.0001) and F409A reduced coupling by 88% (p<0.0001). Previous aGPCR structures have proposed three conserved core activation motifs: the upper quaternary core motif (UQC), the hydrophobic P/F/W/LφφG motif, and the H(N)L(M)Y motif. Structure-guided mutagenesis of corresponding positions in ADGRL4 showed that mutation of any UQC residue to alanine (F505A, M508A, W631A) abolished G_q recruitment. In the P/F/W/LφφG motif, L627A and G628 eliminated activity, whilst F625A and L626A caused partial impairment. In the H(N)L(M)Y motif, L515A and Y516A abolished coupling, whilst H514A produced partial impairment. Together, these findings clarify ADGRL4's activation mechanism: exposure of the TA permits engagement with the orthosteric pocket, which in turns facilitates TM6 displacement and formation of a cytoplasmic cleft for G_q engagement, with all activation motifs functioning as essential structural elements of this process.

Conclusions

These findings define how ADGRL4's TA and conserved 7TM activation motifs cooperatively stabilise its active conformation and engage G_q. These findings establish a structural framework for developing ADGRL4-selective antagonists (nanobodies, synthetic binders or small molecules) with potential therapeutic utility in ADGRL4-associated malignancies.

#2427 Optimizing the detection of pH-dependent conformational changes in pH-low insertion peptides using microfluidic modulation spectroscopy (MMS).

Emma Sanderson, Ryan Bynum, Happy Agarwal, Lacey McNally

Surgery, University of Oklahoma, Oklahoma City, OK

Introduction: The acidic microenvironment of pancreatic ductal adenocarcinoma (PDAC) can be targeted by pH-responsive peptides that undergo conformational changes upon protonation of their negatively charged residues. While microfluidic modulation spectroscopy (MMS) has been successfully used to detect higher-order structure in large proteins, there is room for optimization in the reliable detection of secondary structure for small peptides (< 30 amino acids). We utilized two pH-responsive peptides, V7 and V3, and an inactive peptide, K7, to investigate the effects of buffer conditions and the presence of liposomes on the ability of MMS to detect pH-based conformational changes in these small peptides.
Methods: Peptides were synthesized using the CEM LibertyBlue microwave technology. 10 mM and 20 mM phosphate buffer solutions (PBS) were prepared at pH 7.4 and 6.6. Liposomes were prepared using the thin film hydration technique, and then characterized with dynamic light scattering (DLS) to find size, polydispersity index, and surface potential. The RedShiftBio Aurora MMS system was used to analyze the secondary structure of V7, V3, and K7 at either pH 7.4 or 6.6 PBS with liposomes or without liposomes. Each buffer solution was prepared with 1 mg/mL of peptide and sonicated for 30 minutes before MMS reading. RedShiftBio higher-order structure and Gaussian analysis software were used to compare conformational changes between pH 7.4 to 6.6 for each peptide in the various buffer conditions.
Results: DLS revealed the liposomes to be 122 nm with a polydispersity index of 0.207 and a surface potential of +32.9 mV. The expected conformational changes for V7 and V3 based on pH could not be adequately detected without the presence of liposomes in the solution. 10 mM PBS with a concentration of 10^6 liposomes per mL was the optimal solution for characterizing the peptides, with V7 and V3 experiencing an increase in alpha-fold at pH 6.6 compared to 7.4, and K7 experiencing either no change or less alpha-fold at pH 6.6 compared to 7.4.
Conclusion: A low salt concentration solution containing liposomes was the ideal environment for the peptides V7 and V3 to undergo a pH-dependent conformational change that could be detected by MMS. MMS is a relatively quick method for determining peptide secondary structure with a low limit of quantification.

#2428 Structural proteomics and AI powers PROTAC rational design.

Nitzan Simchi, Michal Ran Shchory, Joseph Rinberg, Alon Shtrikman, Yaron Ben Shoshan-Galeczki, Gali Arad, Katharina Lange, Sagie Brodsky, Anjana Shenoy, Dimitri Kovalerchik, Yonatan Kedem, Iris Alchanati, Galina Otonin, Noam Cohen, **Kirill Pevzner**, Eran Seger

Protai, Ramat Gan, Israel

Proximity-inducing drugs are an emerging class of protein interaction modulators, as many cellular processes rely on the coordinated activity of proteins to support cell growth, homeostasis, regulation and communication. This is most famously exemplified by proteolysis-targeting chimera (PROTAC). PROTACs are heterobifunctional compounds consisting of two ligands joined by a linker to bring together an E3 ligase and a protein of interest and induce ubiquitination and subsequent degradation. Dozens of PROTAC drugs are being investigated in clinical trials, most notably targeting androgen receptor (AR) and BTK. The efficacy of a PROTAC molecule is driven by ternary complex formation and stability, rather than relying solely on the binary affinity of a single molecule to a single protein. Therefore, the major challenge in rational development of PROTACs is deep understanding of the dynamics and functions of complex assembly. However, protein complexes and interactions have traditionally been hard to model and are not well represented in existing protein structure resources, both experimental and computational.In this work, we present the AIMS™ platform, which integrates structural mass spectrometry (MS) data and AI modeling tools. We apply our AIMS™ platform to multiple PROTAC systems, allowing us to improve the confidence of predicted structures compared to AI alone and support rational PROTAC design.

#2429 Nanoformulation enabling repurposing of niclosamide for the treatment of pancreatic cancer: Rapidly soluble oral formulation for enhanced bioavailability.

Bhoomi Mukeshbhai Dholariya, Ketankumar Patel

St. John's University, Queens, NY

Pancreatic ductal adenocarcinoma (PDAC) is relatively uncommon yet remains one of the most lethal cancers worldwide. Its asymptomatic nature leads to delayed diagnosis, and by the time PDAC is detected, it has often progressed to an advanced, metastatic stage. Consequently, there is a critical need to identify new therapeutic strategies that can improve patient survival. Drug repurposing has emerged as a promising approach for rapidly expanding treatment options in PDAC. Our *in-vitro* screening suggested niclosamide (NIC) as a promising repurposed drug candidate for the treatment of PDAC. Various PDAC cell lines including gemcitabine resistant mia paca2 cells were susceptible to NIC induced apoptosis. Prior studies from various researchers also revealed role of NIC in killing cancer cells while compromising the tumor stromal barriers. However, its extremely poor water solubility often resulted in <10% oral bioavailability, which is not sufficient for anticancer activity. Poor lipid and organic solvent solubility limit the choices of nanoformulation approaches for NIC. We have explored a hydrophobic ion pairing approach with ionizable lipid for the development of self-nanoemulsifying drug delivery system (SNEDDS). Complexation between negatively charged NIC and lipophilic cation resulted in improved drug loading in SNEDDS while preventing the precipitation of drug in aqueous media. Different batches of NIC-SNEDDS were prepared using oleyl amine and ionizable lipid DLin-DMA. The particle size and zeta potential of the DLin-DMA based blank formulation were 18.35±0.99 nm and +18±0.69 mV, respectively, whereas the oleyl amine based blank formulation exhibited a particle size of 23.97±0.89 nm and a zeta potential of +32±0.77 mV. Due to very high positive charge blank formulation containing oleyl amine showed higher cytotoxicity. In contrast, the DLin-DMA blank formulation showed negligible cytotoxicity due to their ionizable nature - neutral at physiological pH and cationic at lower pH. Based on these results, DLin-DMA based nanoformulation was optimized for NIC. The optimized formulation NIC-SNEDDS exhibited a particle size of 23.67±1.2 nm and a zeta potential of +15.5±0.56 mV. NIC alone showed the IC_{50} of 2.33±1.5 µM in MIA PaCa2. The final formulation demonstrated an IC_{50} of 2.20±1.4 µM in MIA PaCa2 cells, confirming its promising anticancer activity. In PANC-1 cells, NIC-SNEDDS exhibited an IC_{50} of 3.09±1.1 µM IC_{50} compared to NIC alone (14.8 µM). Predictive pharmacokinetic modelling using Gastroplus indicated >75% oral bioavailability of the NIC oral formulation compared to suspension. Thus, a hydrophobic ion pairing approach with ionizable lipid enabled the development of a self-nanoemulsifying drug delivery system of niclosamide. Currently, we are investigating the effect of NIC on *in vivo*pancreatic tumor bearing mice.

Background: DNA damage and genomic instability represent hallmarks of cancer. Tumors with defects in repairing double strand breaks have been shown to respond to platinum compounds, immune checkpoint inhibitors (ICI) and PARP inhibitors. We have previously reported that 28% of early-stage Non-Small Cell Lung Cancer (NSCLC) patients present high Genomic Scarring Score (h-GSS), an indicator of genomic instability, while patient-derived xenografts from those patients respond favorably to olaparib. The aim of this study was to investigate the immune landscape of h-GSS early-stage and metastatic NSCLC patients, and to assess their clinical outcome.
Material and Methods: Sixty-seven (early stage I-III) and 52 (stage IV) patients with no actionable genomic alteration were enrolled in the study. Their GSS was assessed using a commercial panel (AmoyDx® HRD Complete), which also identifies mutations in 20 homologous recombination repair (HRR) genes. PD-L1 expression (tumor proportion score-TPS) and early and late exhausted ($TCF1^+PD1^+$ and $TCF1^-PD1+$, respectively) $CD8^+$ cells were assessed using immunohistochemistry. All patients with early-stage disease received platinum-based adjuvant chemotherapy while stage IV patients received immunotherapy-based regimens.
Results: h-GSS was detected in tumors from 28/67 (41.8%) patients with stage I-III NSCLC and in 16/52 (30.8%) with stage IV. *TP53* mutations (*TP53mut)* were observed in 27/28 (96.4%) and 22/39 (56.4%) of stage I-III h-GSS and l-GSS tumors, respectively ($p<0.001$), and in 12/16 (75.0%) and 15/34 (44.1%) of h-GSS and l-GSS tumors stage IV tumors, respectively ($p=0.067$). Early-stage but not stage IV *TP53*mut patients presented a better DFI and OS, compared to wild-type *TP53* tumors ($p=0.002$ and 0.026, respectively). Early-stage h-GSS/TP53mut and l-GSS/TP53mut patients had better DFI ($p=0.012$ and $p=0.002$, respectively) compared to l-GSS/*TP53*wt counterparts, whereas only the h-GSS/*TP53*mut status was associated with a better OS ($p=0.031$). PD-L1 expression in l-GSS but not in h-GSS stage IV tumors was associated with a significantly better OS (HR=0.2, 95%CI: 0.1-0.6, $p=0.009$). Finally, there was a statistical trend towards an increased density of both PD1+TCF1+ (0.067) and PD1+TCF1- (0.054) exhausted tumor-infiltrating lymphocytes in h-GSS compared to l-GSS tumors in patients with stage IV disease.
Conclusions: The findings of this study clearly suggest that genomic instability in NSCLC, as assessed by GSS, could become an important tool for better stratification of patients regarding prognosis and treatment choice.

#2432 Precision genomics in leukemiareveals mutational and fusion landscapes in South Asian patients driving clinical decisions.

Puja Sinha, Amit Kumar, Shobit Gupta, Rama Chandran, **Giulliana Tessarin**

Genes2Me Pvt Ltd, Gurugram, India

Background: The integration of next-generation sequencing (NGS) into routine diagnostic workflows is revolutionizing molecular characterization in cancer care, enabling precise detection of pathogenic variants and other fusion transcripts. Particularly in malignant haematological diseases, NGS has significantly enhanced diagnostic accuracy and prognostic assessment, providing critical insights that directly inform and optimize clinical decision making. To support precision oncology in routine clinical practice, various in-house developed and commercial NGS based leukemia panels have been adopted. In this study, leukemic patient samples from an Indian cohort were analysed to identify the most statistically significant gene mutations and chromosomal fusions implicated in leukemic disorders.

Methods: Genomic profiling, including fusion detection, was performed on 98 leukemic samples using the G2M Hemat NGS assay, which targets 208 clinically relevant genes including DNA fusion and 94 RNA fusion genes and approximately 650 kb of genomic regions and was sequenced on the Illumina platform. Bioinformatics analysis was conducted using the GATK v4.1.2 somatic variant calling pipeline, and downstream visualization of mutational landscapes and hotspot regions was achieved using MAF tools.

Results: Comprehensive genomic profiling revealed recurrent mutations in ASXL1, FLT3, PTPN11, NRAS, KRAS, BCOR, ABL1, NF1, KIT, and EZH2, with variant allele frequencies ranging from 2% to 16%, emphasizing their potential role in leukemogenesis. Additionally, seven clinically significant RNA fusion genes were identified across 19 patient samples, with RUNX1-RUNX1T1 and ETV6-RUNX1 emerging as the most prevalent, followed by the hallmark BCR-ABL1 fusion. Key substitutions including Gly→Val (ASXL1), Asp→Tyr (FLT3) at specified position, and multiple changes in signalling genes define a clinically relevant spectrum of amino acid changes in leukemia. These findings highlight a complex mutational and fusion landscape with critical implications for risk profiling and targeted therapy development.

Conclusion: The ability to detect clinically relevant mutations and fusion genes that inform diagnosis, prognostic stratification, and precision treatment decisions in hematologic malignancies, establishes the assay's value as a comprehensive genomic tool for precision oncology.

#2433 BAP1 loss confers ferroptosis resistance to cholangiocarcinoma via TLCD1-mediated membrane phospholipid remodeling.

Yu Zhao[1], Peyton Classon[2], Danielle Marie Carlson[3], Jayla Millender[1], Irene K. Yan[2], Sumera Ilyas[1], Rory L. Smoot[4], Gregory J. Gores[5], TUSHAR PATEL[2], Davide Povero[1]

[1]Mayo Clinic, Rochester, MN,[2]Mayo Clinic, Rochester, MN, MN,[3]Mayo Clinic Hospital-Rochester, Rochester, MN,[4]Surgery, Mayo Clinic, Rochester, MN,[5]Professor of Medicine, Mayo Clinic, Rochester, MN

INTRODUCTION: Cholangiocarcinoma (CCA) is a deadly cancer of the hepatic bile duct epithelial cells. Loss-of-function mutations of epigenetic regulator ubiquitin C-terminal hydrolase deubiquitinase BRCA1-associated protein 1 (BAP1) occur in 26-32% of human CCA and are associated with worse prognosis and resistance to cytotoxic therapy. The goal of this study is to identify how BAP1 loss promotes cell death evasion through metabolic rewiring.
MATERIALS & METHODS: Isogenic wild-type and BAP1-deficient human and murine CCA cell lines were generated with shRNA/siRNA or CRISPR/Cas9 and were used to assess ferroptosis sensitivity by treatment with ferroptosis inducers. In vitro, ferroptosis was assessed by phospholipid peroxidation (C-11BODIPY), mitochondrial phospholipid peroxidation (MitoPeDPP, MitoCLox), iron oeverload (MitoFerro green) and cell death (CellTiter-Glo). Phospholipidomics and proteomics were performed in isogenic cells by LC-MS/MS. Isogenic liver orthotopic CCA murine models were used for in vivo pre-clinical studies.
RESULTS: Our findings indicate that BAP1 loss confers CCA ferroptosis resistance. BAP1 loss protects CCA against mitochondrial iron overload, ROS accumulation, and phospholipid peroxidation. Strikingly, BAP1 loss protects from mitochondrial phospholipid peroxidation and cardiolipin oxidation. Unbiased phospholipidomic profiling revealed that BAP1 loss remodels membrane phospholipid composition, enriching for ferroptosis-blocking monounsaturated phospholipids (MUFA-PLs) at the expense of ferroptosis-inducing polyunsaturated (PUFA-PLs). We found that BAP1 loss upregulates TLCD1, a phosphatidylethanolamine acyltransferase that incorporates MUFAs into membrane phospholipids, thereby stabilizing membranes against peroxidation. TLCD1 knockdown in BAP1-deficient CCA cells, restored ferroptosis sensitivity Notably, TLCD1 is significantly upregulated in human BAP1-mutant CCA as compared to WT tumors. We identified TLCD1 in the endoplasmic reticulum, Golgi and by mitochondrial outer membrane. In syngeneic liver orthotopic CCA murine models, engineered EpCAM-aptamer-coated lactosomes carrying GPX4 siRNA selectively targeted CCA cells, inducing ferroptosis and robustly suppressing tumor growth without systemic toxicity. Lastly, BAP1-mutant patient-derived xenografts (PDXs) and organoids were resistant to ferroptosis inducers, as compared to WT controls.
CONCLUSIONS: Our findings reveal that BAP1 loss rewires mitochondrial phospholipid metabolism thus conferring CCA resistance to ferroptosis, identifying TLCD1 as a targetable metabolic vulnerability in BAP1-mutant CCA.

#2434 Prognostic and predictive effects of *TP53* co-mutations and *RET* fusion partners in *RET*-rearranged advanced NSCLC.

Background: *RET* fusions occur in ~1-2% of advanced NSCLC (aNSCLC). Selective RET inhibitors (SRIs) significantly improve outcomes, yet ~10% of patients progress by 6 months and ~30% by 12 months. Predictors of response or early progression remain poorly defined.
Methods: A multicenter retrospective analysis (RET-MAP) of RET+ aNSCLC from 47 international centers evaluated clinical/genomic correlates of SRI outcomes. Multivariable Cox models estimated progression-free (PFS) and overall survival (OS) and tested interactions with first-line (1L) SRI versus chemotherapy ± immune checkpoint inhibitor (CH±ICI). In parallel, genomic/transcriptomic features were characterized in an external Caris Life Sciences (CLS) RET+ aNSCLC cohort.
Results: Among 510 RET-MAP patients (median age 63; 59% female; 36% ever-smokers; 92% adenocarcinoma), 401 received an SRI (1L n=151; later lines n=250). Median PFS on SRI (any line) was 17.1 months (95% CI, 14.5-21.1), median OS 30.4 months (95% CI, 27.0-41.1). *TP53* co-mutation was present in 27% (78/292 tested) and was associated with shorter PFS (8.9 vs 19.2 months; p<0.001) and OS (22.7 vs 30.9 months; p=0.002), without a significant treatment-by-*TP53* interaction for 1L SRI versus CH±ICI (p=0.22). Fusion partner contributed with additional signal: *KIF5B* (73%, 274/373) had inferior PFS (13.4 vs 60.2 months; p<0.001) and OS (26.6 vs 73.0 months; p=0.002) compared with *CCDC6* (17%, 65/373), and a significant treatment-by-fusion interaction favored SRI over CH±ICI in *CCDC6* versus *KIF5B* (p=0.007). On multivariate analysis, shorter PFS and OS were independently associated with *TP53* mutation (HR 1.74, p<0.001; HR 1.77, p=0.001), *KIF5B* fusion (HR 1.98, p=0.002; HR 1.64, p=0.040), ECOG ≥2 (HR 2.20, p<0.001; HR 3.06, p<0.001), and brain metastases (HR 1.59, p=0.003; HR 1.88, p<0.001); worse OS was associated with non-adenocarcinoma histology (HR 1.74, p=0.049) and smoking (HR 1.42, p=0.034). Notably, *KIF5B* fusions were enriched for *TP53* mutations versus *CCDC6* (40% vs 19.6%, p=0.011), suggesting partially overlapping biology. In the CLS cohort (N=211), *TP53*-mutant tumors (74/211) were enriched for *RB1* mutations, had higher PD-L1 expression and tumor mutational burden, and demonstrated increased M1 macrophage/B-cell infiltration with reduced neutrophils; by fusion partner, *CCDC6* showed higher PD-L1, while global transcriptomes were otherwise

similar to *KIF5B*.
Conclusions: In RET+ aNSCLC, *TP53* mutation is prognostic for inferior outcomes on SRIs but not predictive of differential benefit versus CH±ICI. Fusion partner carries both prognostic and predictive relevance; *CCDC6* is associated with a more indolent course and greater relative benefit from SRI. External profiling supports an inflammatory microenvironment in *TP53*-mutant disease, reinforcing biologically distinct—and clinically meaningful—subsets within *RET*-driven lung cancer.

#2435 Tertiary lymphoid structures induction predicts and enhances response to famitinib plus PD-L1 blockade in advanced thyroid cancer.

Wei Kou, Yue Che, Qiwu Zhao, Haoran Feng, Zhuoran Liu, Jie Kuang, Weihua Qiu

Ruijin Hospital, Shanghai, China

Background: Therapeutic options for advanced thyroid cancer (TC) remain limited once standard treatments fail. In our phase II trial (NCT 06146985), the multi-target kinase inhibitor famitinib combined with the PD-L1 antibody adebrelimab showed early antitumor activity. However, the immunologic basis of this synergy, particularly the contribution of tertiary lymphoid structures (TLSs), remains unclear. To determine whether TLS induction underlies treatment sensitivity, we integrated histopathology, single-cell transcriptomics, and patient-derived organoid (PDO) assays.

Methods: TLS density and maturity were evaluated by H&E staining and multiplex immunofluorescence (mIHC). Pre- and on-treatment tumor biopsies underwent single-cell RNA-sequencing to define TLS-associated transcriptional features, including chemokine modules, lymphoid-organogenesis signatures, and T follicular helper (Tfh)-B-cell interaction pathways. PDOs were generated from fresh papillary thyroid cancer (PTC) tissues, and autologous $CD3^+$ T cells and $CD20^+$ B cells, the principal TLS-associated lymphocyte subsets, were isolated. PDO-TIL 3D co-culture assays assessed baseline immune killing, the response to famitinib plus PD-L1 blockade, TLS-pathway activation using CpG ODN with Mn^{2+}, and the combination of TLS activation with drug treatment. Apoptosis, proliferation, and TLS-signaling molecules were quantified after 48-72 hours.

Results: TLS density and the presence of mature TLSs strongly correlated with tumor shrinkage and successful surgical conversion. Single-cell analysis showed that TLS-positive tumors exhibited an immune-activated microenvironment enriched in Tfh cells, B cells/plasma cells, dendritic cells, and activated $CD8^+$ cytotoxic T cells. TLS-associated transcriptional features, including CXCR5- and CXCR3-driven chemokine recruitment pathways, were robustly enhanced, whereas TLS-negative tumors were dominated by Tregs and suppressive myeloid cells. Functionally, CpG plus Mn^{2+} induced TLS-related signaling and markedly enhanced TIL-mediated killing. Activating TLS-pathway synergized with famitinib plus adebrelimab, producing the strongest apoptotic and antiproliferative effects, surpassing drug treatment alone. These findings demonstrate that TLS activation potentiates the efficacy of TKI-immunotherapy combination.

Conclusions: Mechanistic evidence from this phase II study identifies TLS induction and maturation as key determinants of therapeutic response to famitinib plus adebrelimab. TLS enhances Tfh-B-cell interactions and cytotoxic T-cell activation, thereby increasing treatment sensitivity. TLS represents a mechanistic driver of response, a predictive biomarker, and an actionable immunologic target to sensitize advanced TC to TKI-immunotherapy combination.

#2436 Gastric cancer-derived tertiary lymphoid structure score from single-cell spatial transcriptomics with pan-cancer validation for immunotherapy response.

Wenbo Zhu, Hongru Shen, Huijun Wang, Ben Liu, Xiangchun Li, **Kexin Chen**

Tianjin Medical University Cancer Institute and Hospital, Tianjin, China

Background: Gastric cancer (GC) is a leading cause of cancer-related death, with poor 5-year survival rates for advanced stages, emphasizing the need for biomarkers to guide immunotherapy. Tertiary lymphoid structures (TLSs) in the tumor microenvironment have been linked to favorable prognosis and immune checkpoint blockade response, but the specificity of GC-derived TLS transcriptional signatures and their utility across tumor types remain unclear. We used single-cell-resolution spatial transcriptomics to construct a GC-derived TLS score and evaluated its prognostic and immunotherapy-predictive value in GC and pan-cancer cohorts.
Methods: In a cohort of 100 GC patients, TLS presence and maturation were assessed on surgical specimens by H&E, immunohistochemistry, and multiplex immunohistochemistry. A subset of 20 fresh GC tumors underwent high-resolution CosMx single-cell spatial transcriptomics to map immune and stromal cell distribution in TLS-positive versus TLS-negative regions. These spatial data were used to identify TLS regions, define major cell populations, and derive a 78-gene TLS signature, from which we constructed the GC-derived TLS score. The score was applied to pan-cancer bulk transcriptomic datasets and anti-PD-1 melanoma cohorts to assess its prognostic and immunotherapy-predictive performance. Patient-derived xenograft (PDOX) GC tumors were established in huCD34^{+} HSC-NCG mice and treated with anti-PD-1/CTLA-4 antibodies to test functional associations with TLS score.
Results: Patients were stratified into TLS-negative, immature TLS, and mature TLS groups. CosMx spatial transcriptomics resolved 10 major cell populations and mapped their distribution in TLS versus non-TLS regions. From mature TLS regions, we derived a 78-gene signature and constructed a GC-derived TLS score. Higher scores were associated with improved survival and better response to immune checkpoint blockade across multiple tumor types, including low-grade glioma, melanoma, NSCLC, metastatic melanoma, and metastatic GC (AUCs up to 0.857); in melanoma immunotherapy cohorts, high-score patients consistently had superior overall survival. In the humanized GC PDOX model, high TLS score tumors showed enhanced response to anti-PD-1/CTLA-4, with increased tumor cell apoptosis and higher T- and B-cell infiltration, potentially enhancing anti-tumor immunity.
Conclusions: We developed the first GC-derived TLS score using single-cell-resolution spatial transcriptomic data and validated its performance across multiple tumor types and in a humanized GC model. This high-resolution score was consistently associated with improved response and survival after immune checkpoint blockade, supporting its use as a precise biomarker for patient stratification and immunotherapy guidance across cancers.

#2437 A comparative scoring framework for BCMA-, GPRC5D- and CD38-targeted therapies in multiple myeloma.

Konstantin Chernyshov, Stanislav Kurpe, Maria Kuzmicheva, Kseniia Fede, Sargis Margaryan, Daria Goncharova, Anastasiya Evdokimova, Dmitry Grachev, Oleg Baranov, Polina Turova, Alexander Nesmelov, Andrey Kravets, Eduardo Shugaev-Mendosa, Nikita Kotlov

BostonGene Corporation, Waltham, MA

Selecting patients for T-cell engager (TCE) and CAR-T therapy in multiple myeloma (MM) relies on prior therapy lines, lacking predictive biomarkers. No tools guide target (e.g., BCMA vs GPRC5D) or modality (e.g., CAR-T vs TCE) selection. We developed an NGS-based framework computing a “Target Readiness” score (ReadyScore, RS) to predict response using malignant and tumor microenvironment (TME) features.

Public MM cohorts, including bulk (n=715, n=290) and scRNA-seq (n=6, n=5), were used to develop the framework. RS was developed for anti-BCMA CAR-T and TCE, anti-GPRC5D TCE, and anti-CD38 monoclonal antibodies (mAb). RS is a normalized, weighted score integrating expression activity of related genes (e.g., targets *TNFRSF17, GPRC5D, CD38*; resistance *STAT3*, γ-secretase; immune factors *CD274* (PD-L1), *CD55, CD59, ICAM1*) and relevant TME signatures (e.g., T-cell exhaustion, T-reg fraction).

We observed heterogeneous profiles in MM (CoMMpass): 36% of patients (pts) had high $RS^{BCMA\text{-}CAR\text{-}T/TCE}$, 33% high $RS^{CD38\text{-}mAb}$, and 31% high $RS^{GPRC5D\text{-}TCE}$, reflecting potential treatment benefit. Notably, 21% of pts had a low RS (< 0.5) for all tested immunotherapies. Within this 'low-RS' group, the tool identified other actionable pathways potentially linked to resistance (e.g., 2% high γ-secretase, 3% high *STAT3*), highlighting intervention opportunities. To illustrate the tool's predictive utility, we applied it to anti-BCMA CAR-T treated pts (Table 1). All 3/3 pts with a high $RS^{BCMA\text{-}CAR\text{-}T}$ had long PFS. For pts with short PFS on CAR-T, the tool highlighted potential alternative therapies: pt 8 had a high value for $RS^{BCMA\text{-}TCE}$, pt 32 for $RS^{GPRC5D\text{-}TCE}$, and pt 16 for $RS^{CD38\text{-}mAb}$.

This work introduces a molecular stratification framework with potential to support biomarker-driven selection of MM pts for TCE and CAR-T therapies. While validation in expanded cohorts is needed, this approach could help prioritize predictive profiles that can enhance trial design and translational decision-making.

Table 1. Target ReadyScore applied to the GSE210079 dataset

Patient	PFS	$RS^{BCMA\text{-}CAR\text{-}T}$	$RS^{BCMA\text{-}TCE}$	$RS^{GPRC5D\text{-}TCE}$	$RS^{CD38\text{-}mAb}$
Pt 1	long	0.69	0.23	0.01	1
Pt 19	long	1	0.66	0.48	0
Pt 33	long	0.71	0	0	0.3
Pt 8	short	0	1	0.51	0.16
Pt 16	short	0.6	0.38	0.56	0.61
Pt 32	short	0.09	0.29	1	0.24

#2438 Discovery of predictive circulating proteomic biomarkers for therapy response in HRR-driven solid tumors.

Anamarija Pfeiffer[1], Wouter van Bergen[1], Martin Mehnert[1], Polina Shichkova[1], Vanessa Buhlmann[1], Amaury Lachaud[1], **Yuehan Feng**[1], Takayuki Yoshino[2], Norio Nonomura[3], Taigo Kato[3]

[1]Biognosys AG, Schlieren, Switzerland,[2]Department of Gastroenterology and Gastrointestinal Oncology, National Cancer Center East, Kashiwa, Chiba, Japan,[3]Department of Urology, The University of Osaka, Graduate School of Medicine, Suita, Osaka, Japan

Background

The IMAGENE trial (jRCT2051210120) is a multicenter, tumor-agnostic, phase II basket study evaluating the combination of the PARP inhibitor niraparib and PD-1 inhibitors in patients with homologous recombination repair (HRR) gene mutations who have progressed following prior immune checkpoint inhibitor (ICI) therapy. In this tumor-agnostic setting, patients were enrolled with unresectable, locally advanced urothelial carcinoma (UC), renal cell carcinoma (RCC), gastric cancer (GC), esophageal cancer (EC), head and neck cancer (HNC), and melanoma (MC), all harboring HRR gene alterations. A total of 45 patients were enrolled in the primary cohort between April 2022 and April 2024.

Existing biomarkers such as PD-L1 expression and tumor mutation burden (TMB) have shown limited predictive power in ICI-treated and HRR-driven tumors. To address this gap, we performed unbiased deep plasma proteomic profiling, complemented by a targeted inflammatory marker panel, on baseline and on-treatment samples from HNC participants enrolled in the IMAGENE trial.

Methods

Citrate plasma samples were collected from patients at baseline and two post-dose time points after treatment with niraparib plus anti-PD-1 therapy. To study proteomic differences between responders and non-responders, and their temporal dynamics, we employed two complementary approaches: (i) unbiased plasma proteome profiling using the P2 enrichment system combined with mass spectrometry (DIA-MS), and (ii) targeted quantification of inflammatory proteins using a proximity ligation assay (NULISA) panel of ~250 markers.

Results

A total of 4,875 proteins and 67,311 peptides were quantified by P2-enriched LC-MS/MS across all samples. Comparative analysis of post-treatment samples identified 160 proteins differentially abundant between responders and non-responders, with enrichment in complement activation and immune-related pathways. Longitudinal analysis revealed 46 proteins significantly altered between pre- and post-treatment samples in responders, again highlighting immune and complement system activation as key features. Targeted NULISA profiling confirmed 20 markers differing between responders and non-responders and 11 markers dynamically regulated during response. Collectively, these findings suggest that complement activation, humoral immune response, and B-cell-mediated immunity are critical determinants of therapeutic response to niraparib plus anti-PD-1 combination therapy.

#2439 Predictive modeling of venetoclax/azacitidine response in acute myeloid leukemia using inflammatory cytokine profiling and clinical data from the NCT04267081 trial cohort.

Ankita Srivastava[1], Bahar Tercan[2], David L. Gibbs[2], Heikki Kuusanmaki[1], Mika Kontro[1], Caroline A. Heckman[1], Guangrong Qin[2]

[1]Institute for Molecular Medicine Finland (FIMM), HiLIFE, University of Helsinki, Helsinki, Finland,[2]Institute for Systems Biology, Seattle, WA

Cytokines in acute myeloid leukemia (AML) remodel the bone marrow microenvironment, drive disease progression, and contribute to chemoresistance. Cytokines such as IL-8 and CXCL12 promote AML cell survival and drug resistance, while some others influence therapeutic response, making cytokine signaling a key factor for predicting outcomes. Venetoclax (VEN) plus azacitidine (AZA) is standard therapy for older patients or those unable to receive intensive chemotherapy, yet responses vary widely. To address this, we developed predictive models for VEN/AZA response and survival using cytokine and clinical data.

Cytokine profiling was performed on samples from 85 AML patients in the VenEx trial (NCT04267081). Using the Olink Target 48 platform, the protein expression of 44 inflammatory cytokines was measured and normalized for downstream analysis. Clinical measurements and VEN/AZA treatment responses were collected, including 68 responders and 17 non-responders. T-test was used to compare the difference in cytokine expression between responders and non-responders. Elastic net regression models incorporating cytokine profiles and clinical variables were used to predict patient response and identified key cytokines associated with treatment response. To assess survival risk, we performed univariate Cox regression for each cytokine and generated Kaplan-Meier curves by stratifying patients into high-expression (above the third quartile) and low-expression groups.

Comparing the responders vs non-responders, we found potential biomarkers, including IL13 had higher expression in responders, while IL18, IL10, VEGFA, OSM, and CSF1 were expressed higher in non-responders. Using cytokine profiling to predict patient response, the model achieved an accuracy of 0.74 using 5-fold cross validation. Adding cell population measurements in the model, the accuracy increased to 0.83. All potential biomarkers are the top predictors for ven/aza response. Beyond that, we also identified TSLP, IL15, IL1B and TNFSF12 are among the top 10 predictors. Cox's proportional hazard model identified cytokines linked to poor survival, including CSF1, CCL3, CCL19, IL18, HGF, IL1B and OSM (ranked by hazard ratio). Stratification by FAB type revealed distinct cytokine associations with survival and drug response, TNFSF10 was siginificantly higher in non-responders in FAB M0-M2 (n=51; 41 responders, 10 non-responders).

Integrating cytokine and clinical data enables robust prediction of VEN/AZA response and survival in AML. Key cytokines such as CSF1, IL18 and IL13 may guide risk stratification and personalized therapy. Future work will map pathways linked to these cytokines and explore their roles in survival and treatment response.

#2440 Single-cell MRD profiling identifies CXCR4-high AML as a responder population to CXCR4 inhibition with Motixafortide.

Klinik und Poliklinik I, Carl Gustav Carus Univ. Hospital, Dresden, Germany

Background: The CXCL12-CXCR4 axis mediates bone marrow niche mediated protection of leukemic stem cells and contributes to chemoresistance. Motixafortide is a potent CXCR4 antagonist that disrupts leukemic cell retention in the microenvironment. We leveraged single-cell minimal residual disease (scMRD) profiling to quantify CXCR4 expression and clonal persistence after consolidation therapy within the BLAST trial (NCT02502968), aiming to define predictive biomarkers of Motixafortide response.
Methods: Among 128 randomized AML patients in first complete remission (CR), 56 underwent bone marrow scMRD analysis using the Tapestri platform (Mission Bio) targeting 40 recurrent mutation hotspots and 19 surface markers including CXCR4. CXCR4 expression was quantified at single-cell resolution and dichotomized by cohort median. Clinical outcomes were correlated with treatment and scMRD metrics.
Results: Although relapse-free survival (RFS) was not different between treatment arms in the ITT population (median RFS: 10.3 vs. 11.5 months, p=0.98), scMRD profiling uncovered a CXCR4 dependent treatment effect. In the placebo arm, high CXCR4 expression correlated with increased relapse risk (p=0.02). In contrast, in the Motixafortide arm, high CXCR4 expression was associated with reduced relapse (p=0.047). A multivariable Cox model confirmed a significant treatment by CXCR4 interaction (HRinteraction 0.032, 95% CI 0.004 to 0.269, p=0.0015), supporting CXCR4 as a predictive biomarker for Motixafortide benefit. scMRD revealed persistent clonal diversity, but conventional MRD positivity did not associate with outcome.
Conclusion: While the BLAST trial showed no overall difference in RFS, single-cell MRD analysis revealed differential treatment effects according to CXCR4 expression. These findings suggest that CXCR4 may serve as a biomarker for response to Motixafortide and highlight the potential of single-cell profiling to inform patient stratification.

#2441 The myCAF and ECM landscape in KRAS-mutated cancer: Utilizing liquid biomarkers to track KRAS-induced fibrosis and KRAS inhibitor efficacy.

Martin Birkmose Rasmussen[1], Rasmus Sund Pedersen[2], Nicholas Willumsen[2], Morten Karsdal[2]

[1]Oncology, Nordic Bioscience, Copenhagen, Denmark,[2]Nordic Bioscience, Copenhagen, Denmark

Background: KRAS-driven cancer represents ~25% of cancers, with high rates in pancreatic cancer (PDAC), colorectal cancer (CRC), and non-small cell lung cancer (NSCLC). Mutated KRAS and TGF-β signaling activate cancer-associated fibroblasts (CAFs), creating a fibrotic extracellular matrix (ECM). The fibrotic ECM promotes immunosuppression and tumor growth but is potentially reversible with KRAS inhibitors (KRASi). We have recently demonstrated that myofibroblast CAFs (myCAFs) in KRAS-mutated PDAC express high levels of collagens III, V, VIII, XI, and XII. In this study, we investigated the landscape of KRAS-induced myCAF activation and ECM change across KRAS-mutated cancers. We utilized these changes to identify biomarkers for KRASi efficacy.
Methods: Patients with KRAS-mutated PDAC (n=141), CRC (n=223), or NSCLC (n=74) were evaluated for collagen expression and gene-set variation analysis (GSVA) was used for hallmark KRAS and TGF-β signaling. Correlations of KRAS and TGF-β signaling, and collagen expressions across cancers, were evaluated using Spearman correlation. Single-cell RNA-seq data from KRASi treated KPPC mice was analyzed using Seurat. CAFs were subclustered and subtypes identified from marker genes (myCAF, inflammatory CAF, and antigen-presenting CAF). CAF subtype and collagen expression were compared between KRASi and vehicle with Fisher's exact test and Wilcoxon rank-sum test, respectively. Biomarkers for formation of collagens I (PRO-C1), III (PRO-C3), V (PRO-C5), VIII (PRO-C8), XI (PRO-C11), and XII (PRO-C12) were measured in serum from healthy controls and patients with PDAC, CRC, or NSCLC. Differences between cancer and control were evaluated by Wilcoxon rank-sum test.
Results: KRAS signaling was significantly correlated with TGF-β signaling and expression of COL3A1, COL5A2, and COL8A1 across patients with KRAS-mutated PDAC, CRC, and NSCLC ($R>0.4$, $p<0.05$). Significantly increased expression of Col3a1, Col5a2, Col8a1, Col11a1, and Col12a1 was observed from fibroblasts in KRASi treated PDAC compared to vehicle ($p<0.001$). Significantly fewer myCAFs in KRASi treated PDAC ($p<0.001$) suggested reduced myCAF-derived ECM with KRAS inhibition. Serum biomarkers for formation of myCAF collagens (PRO-C3, PRO-C5, PRO-C8, PRO-C11, and PRO-C12) were significantly upregulated in patients with PDAC, CRC, and NSCLC compared to healthy controls ($p<0.001$). Type I collagen formation was unaffected (PRO-C1, $p=0.37$), suggesting KRAS-specific collagen formation.
Conclusion: KRAS-mutated tumors have a myCAF-enriched microenvironment with a unique collagen expression profile that is altered by KRAS inhibition. Non-invasive myCAF-derived collagen biomarkers that are elevated in serum from patients with KRAS-driven cancers, can potentially quantify KRAS signaling and track KRASi efficacy to guide clinical decision-making.

#2442 Baseline single-cell mass distributions correlate with clinical response to acalabrutinib, venetoclax, and obinutuzumab in mantle cell lymphoma.

Mingzeng Zhang[1], Ye Zhang[2], Lydie Debaize[1], Grace Chen[1], Sona Baghiyan[1], Shogo Miura[1], Nezha Senhaji[1], Juniper Mai[1], Clare Phinney[1], Alexa Batingana[1], Jenalyn Weekes[1], Salah Abdulkarim[1], Haocheng Wang[1], Svitlana Tyekucheva[3], Jerome Ritz[1], Christine E. Ryan[1], Austin I. Kim[1], Scott R. Manalis[2], Mark A. Murakami[1]

[1]Department of Medical Oncology, Dana-Farber Cancer Institute, Boston, MA,[2]Koch Institute for Integrative Cancer Research, Massachusetts Institute of Technology, Boston, MA,[3]Department of Data Science, Dana-Farber Cancer Institute, Boston, MA

Background: Mantle cell lymphoma (MCL) exhibits heterogeneous responses to targeted therapy, which are incompletely explained by genomic and immunophenotypic markers. Building on our prior work linking single-cell mass to BCR signaling activity and Bruton's tyrosine kinase inhibitors (BTKi) sensitivity, we hypothesized that baseline biophysical mass distributions may integrate proliferative, metabolic, and signaling states and predict clinical responses to BTKi-based therapy.

Methods: Baseline tumor cells from treatment-naïve MCL patients in a phase 1/2 trial of Acalabrutinib, Venetoclax, and Obinutuzumab (NCT04855695) were enriched by fluorescence-activated cell sorting and analyzed via suspended microchannel resonators (SMR) without drug exposure to measure distributions of single-cell buoyant mass. Durable response (DR) was defined as achieving complete metabolic remission ≥12 months; non-durable response (NDR) as refractory disease or relapse within 12 months. Of the nine cases analyzed by SMR, seven also underwent parallel CyTOF profiling.

Results: Baseline median mass of MCL cells was higher in NDR (n = 3; mean of patient medians 13.1 pg) than in DR (n = 6; mean of patient medians 13.1 pg; $p = 0.02$). The fraction of cells >15 pg—a threshold previously linked to BTK inhibitor response—was elevated in NDR (p=0.02) and correlated with clinical Ki-67 index (available in 6/9, r^2=0.87). Eight of nine cases exhibited classic MCL morphology; the single blastoid case (NDR) had a median mass of 14.6 pg. In CyTOF-profiled samples, the >15 pg tumor cell fraction correlated with B-cell expression of Ki-67 ($r^2 = 0.99$), the glucose transporter GLUT1 ($r^2 = 0.55$), and the immune checkpoint ligand PD-L1 ($r^2 = 0.99$), but not with the amino acid transporter CD98 or fatty acid transporter CD36. These associations are consistent with sequelae of heightened BCR. Across the cohort, an increased proportion of tumor cells >15 pg correlated with increased PD-1 expression on $CD4^+$ T cells ($r^2 = 0.66$) and expansion of T follicular helper (Tfh) cells ($r^2 = 0.74$). Increased tumor cell mass distributions also positively correlated with Tfh activation markers, including ICOS, Ki-67, and checkpoint molecules TIGIT ($r^2 = 0.56$-0.69). Taken together, these features raise the possibility of chronic B-cell antigen stimulation driving both Tfh activation and immune-regulatory feedback.

Conclusions: Baseline MCL cell biophysical mass distributions correlate with tumor-intrinsic proliferation and metabolic activity as well as systemic Tfh activation and immune checkpoint expression. These results suggest that tumor biophysical properties ex vivo may capture in vivo BTKi sensitivity through tumor-intrinsic and immunologic mechanisms. Evaluation in larger cohorts and deeper mechanistic analyses are required to clarify its potential as a predictive biomarker.

#2443 Urinary pesticide biomarkers and liver disease risk in Thailand: A machine-learning-based risk-prediction model.

Daxeshkumar P. Patel[1], Christopher Loffredo[2], Majda Haznadar[3], Mohammed Khan[4], Amelia Parker[4], Benjarath Pupacdi[5], Siritida Rabibhadana[6], Panida Navasumrit[7], Nirush Lertprasertsuke[8], Anon Chotirosniramit[9], Chawalit Pairojkul,[10], Vor Luvira,[11], Ake Pugkhem[12], Wattana Sukeepaisarnjaroen[12], Teerapat Ungtrakul[13], Thaniya Sricharunrat[14], Kannika Phornphutkul[15], Frank J. Background Building on evidence linking urinary glyphosate to chronic liver disease (CLD) and hepatocellular carcinoma (HCC), we developed urinary pesticide profiling integrated with machine learning risk prediction (MLRP) to stratify risk in high-exposure populations.Methods We conducted a case-control study within the Thailand Initiative in Genomics and Expression Research for Liver Cancer (TIGER-LC; 2011-2016; n=593): 228 CLD, 116 HCC, and 249 controls. Eight urinary pesticides were quantified by LC-MS/MS (pendimethalin, oxadiazon, metsulfuron-methyl, butachlor, 2,4-dichlorophenoxyacetic acid [2,4-D], cypermethrin, flocoumafen, bromadiolone). A composite Pesticide Load Score (PLS), with and without glyphosate, estimated burden. Two predictive models were developed: a logistic-regression Pesticide-Informed Liver Cancer Risk Score (PILCRS) and an Extreme Gradient Boosting (XGBoost) classifier that incorporated age, sex, alcohol use, occupation, and PLS. Internal validity used 1,000 bootstrap resamples with optimism-corrected calibration.Findings Predicted CLD probability increased from 30% in the lowest PLS quartile to over 70% in the highest, and HCC from 10% to 40% ($p<0•0001$). Relative estimates were consistent; the highest versus lowest quartile yielded odds ratios of 2•84 (95% CI 1•66-4•91) for CLD and 4•76 (2•30- 10•29) for HCC. Cypermethrin remained independently associated. After optimism correction, both models demonstrated strong discrimination and calibration.Interpretation This framework establishes a scalable, exposure-informed tool for liver disease prediction. Findings underscore pesticide burden as a modifiable risk factor and align with Sustainable Development Goal 3•9 and WHO-FAO priorities in low- and middle-income countries (LMICs). External validation is essential.

#2444 Multi-agent-augmented analysis of PD-1 checkpoint inhibitor response.

Ada Shaw[1], Christina Vivelo[2], Nicholas Dana[2], Chetan Sood[2], Michelle Garred[1], Aqib Hasnain[1], Shara Balakrishnan[1], Vivek Adarsh[1], Hinco Gierman[2], Erika von Euw[2]

[1]Mithrl, San Francisco, CA,[2]Elephas, Madison, WI

Purpose: While checkpoint inhibitors have revolutionized treatment for cancer patients, only 20% of patients respond to PD-1 blockade, underscoring a need to better understand the mechanisms of response. Here, we deploy a multi-agent system for biological discovery that autonomously integrated functional cytokine readouts with multi-omics data to: (i) map patient clustering patterns and biological drivers; (ii) identify cytokine biomarkers differentiating response; and (iii) generate pathway-level mechanism narratives.
Methods: The analytical workflow involved: (1) unsupervised stratification of patient cohorts by clinical response using integrated transcriptomic and cytokine features (data from patients enrolled in NCT05478538, NCT05520099, NCT0634962, and a biobank biopsy collection study), (2) pathway enrichment analysis coupled with autonomous generation of mechanistic hypotheses, and (3) systematic comparative analyses against the public pan-cancer PD-1 resistance dataset. To contextualize the findings, a comparative study was performed against public pan-cancer datasets of checkpoint inhibitor response [Ref: Nature Scientific Data, 2025; data in CELLXGENE collection].
Results: The analysis revealed distinct patient clusters with separable cytokine profiles and immune-pathways that associated with response categories. The comparative overlay highlighted shared resistance hallmarks with the public resource while surfacing cohort-specific cytokine features and pathway combinations not captured in prior meta-analyses.
Conclusions: This work demonstrates that an agentic AI system enables the integration of cytokine profiling and transcriptomic datasets, yielding insights into mechanisms of checkpoint inhibitor response. In combination with clinical data, the mechanistic insights garnered from this approach will enable the improved prediction of immunotherapy response, providing the potential to improve patient outcomes.

#2445 LAPNET-01: Translational results of a Phase 1b evaluating NP137, an inhibitor of the epithelial-to-mesenchymal transition in combination with mFOLFIRINOX for the first-line treatment of locally advanced pancreatic ductal adenocarcinoma.

Gael Roth[1], Pascal Artru[2], Olivier Bouche[3], Marc Manceau[4], Nicolas Williet[5], Julien Ghelfi[6], Anthony Turpin[7], Astrid Lievre[8], Jean Frederic Blanc[9], Camille Evrard[10], Jean Baptiste Bachet[11], Pauline Parent[12], Matthieu Roustit[4], Hector Hernandez-Vargas[13], Elise Georges[14], Sebastien Hazard[14], Benjamin Ducarouge[14], Agnes Bernet[15], Patrick Mehlen[15]

[1]Department of Hepato-Gastroenterology and Digestive Oncology, CHU Grenoble Alpes, Grenoble, Grenoble, France,[2]Department of Hepato-Gastroenterology, Hopital Jean-Mermoz, Lyon, France,[3]CHU Reims, Reims, France,[4]Inserm, HP2 - U1300, CHU Grenoble Alpes, Grenoble, France,[5]Department of Hepatogastroenterology and Gastrointestinal Oncology, CHU St Etienne, Grenoble, France,[6]Department of Radiology, CHU Grenoble Alpes, Grenoble, France,[7]Medical Oncology Department, Lille University Hospital, Lille, France,[8]Department of Gastroenterology, CHU Rennes, Rennes, France,[9]Department of Hepato-Gastroenterology and Digestive Oncology, CHU Bordeaux, Bordeaux, France,[10]Department of Medical Oncology, CHU Poitiers, Poitiers, France,[11]Department of Gastroenterology, APHP - Pitie Salpetriere, Paris, France,[12]Medical Oncology Department, CHU Lille, Lille, France,[13]Genomics Consulting, Lyon, France,[14]NETRIS Pharma, Lyon, France,[15]Apoptosis, Cancer and Development Laboratory, Centre de Recherche en Cancerologie de Lyon (CRCL), INSERM U1052-CNRS UMR5286, Lyon, France

Background: Pancreatic ductal adenocarcinoma (PDAC) is a highly lethal malignancy characterized by aggressive tumor dissemination and resistance to therapy; processes significantly driven by the epithelial-to-mesenchymal transition (EMT). Netrin-1 is a key regulator for EMT. NP137, an anti-netrin-1 antibody, has shown to inhibit EMT in preclinical models and in a phase 1 monotherapy trial.
Methods: LAPNET-01 is a single arm phase Ib clinical study to assess the combination of NP137 with mFOLFIRINOX in locally advanced, unresectable PDAC. Laser capture microdissection was performed on pre-therapeutic biopsies and surgical specimens to allow microbulk RNA sequencing.
Results: 43 patients were included in this trial and received mFOLFIRINOX plus NP137 once every two weeks for up to 12 cycles (6 months). NP137 was well tolerated. Median PFS was 10.9 months (95% CI, 10.0 - 15.6) and median OS was 16.4 months (95% CI, 12.8 - NR) with 21 patients still alive at time of the data cut-off. Surgery was made possible by the combination therapy in 23% of patients. Microbulk RNA sequencing was successfully performed on 22 pre-therapeutic and 6 surgery samples and revealed that the main pathway downregulated with the combination mFOLFIRINOX+NP137 is EMT, bringing a clinical validation of the main mechanism of action of NP137. Moreover, bioinformatic analyses supported an extended OS and PFS in tumors expressing high levels of the netrin-1 receptor neogenin (NEO1) at baseline. In the high-NEO1 subgroup, NP137 treatment demonstrated an improved outcomes compared to the low-NEO1 subgroup including longer median PFS (15.7 vs 10.2 months, $p<0.001$) and longer median OS (not reached vs 16.5, $p<0.024$). These observations are consistent with experimental data that demonstrated the implication of neogenin in pancreatic cancer EMT and its progression.
Conclusion: NP137 in combination with mFOLFIRINOX demonstrates a favorable safety profile, promising clinical activity, and a mechanistically distinct mode of action supported by translational analyses. These results warrant further investigation of netrin-1 blockade in randomized trials and provide a rationale for biomarker-driven development of NP137 in pancreatic cancer.

#2446 High PRMT5 expression is associated with decreased immune infiltrate and worse outcomes to immune checkpoint inhibitors in non-small cell lung cancer.

Natalie Vokes[1], Stamatina Fragkogianni[2], Pooja A. Shah[3], Santiago G. Trevino[1], Konstantinos Leventakos[4], Lei Deng[5], Matthew Lee[6], Tali Azenkot[7], KAYLA LAYNG[2], JACOB MERCER[2], Jyoti Patel[2], Jordi Rodon Ahnert[8]

[1]MD Anderson Cancer Center, Houston, TX,[2]Tempus, Chicago, IL,[3]UT MD Anderson Cancer Center, Houston, TX,[4]Mayo Clinic Cancer Center Minnesota, Rochester, MN,[5]Fred Hutchinson Cancer Center, Seattle, WA,[6]City of Hope, Duarte, CA,[7]University of California San Diego - UCSD, San Diego, CA,[8]UT MD Anderson Cancer Center, Conroe, TX

Background: Deletions in *MTAP* occur in 10-15% of cancers and are associated with poor prognosis. MTAP deletion (MTAPdel) leads to accumulation of MTA which causes partial inhibition of PRMT5, creating a synthetic lethality approach with PRMT5 inhibitors. Multiple investigational MTA-cooperative PRMT5 inhibitors have demonstrated early clinical efficacy in MTAPdel NSCLC and other cancers. MTAPdel, PRMT5 expression, and clinical outcomes to standard of care immune checkpoint inhibitors (ICI) and chemotherapy (chemo) have not been well characterized.

Methods: The Tempus Lens Platform (Tempus AI, Inc., Chicago, IL) was used to query the Tempus multimodal de-identified database and establish and subsequently analyze a cohort of patients (pts)with NSCLC and DNA (Tempus xT) and RNA (Tempus xR) testing, treated with front-line (1L) ICI with or without chemo (N=3,676). PRMT5 expression was normalized as transcripts per million (TPM) and reported as log2(TPM + 1). Pts were classified into high vs low groups based on median PRMT5 expression and into MTAPdel vs intact (MTAPwt) based on MTAP biallelic loss. Immune infiltration was estimated using Quantiseq. Real-world overall survival (rwOS) was defined as the time from 1L start to death or last known follow-up. Real-world progression-free survival (rwPFS) was defined as the time from 1L start to death, progression or last known follow-up. Hazard ratios (HR) were calculated using Cox proportional hazards models and adjusted for age, sex, histology, smoking status and PDL1 status.

Results: PRMT5 expression was moderately increased in pts with MTAPdel (6.65 v 6.70, p=0.012). Alterations in *MYC*, *SMARCA4* and *KEAP1* were enriched in PRMT5-high tumors in both MTAPdel and MTAPwt pts (p<0.03). Pts with PRMT5-high tumors had decreased infiltrate of multiple immune cells, including B cells, macrophages (M1 and M2), NK cells, CD4 and CD8 T cells (p<0.001). Pts with MTAPdel/PRMT5-high expression had shorter rwOS compared to MTAPwt/PRMT5-low when treated with ICI alone (HR 1.58, 95% CI 1.11-2.24, p=0.011) or with ICI + chemo (HR 1.65, 95% CI 1.34-2.03, p<0.001). These associations persisted on multivariate analysis. Pts with MTAPdel/PRMT5-high expression were also associated with worse rwPFS when treated with ICI + chemo (HR 1.5, 95% CI 1.22-1.86, p<0.001) on univariate and multivariate analysis, but did not associate with rwPFS in pts treated with ICI alone (HR=0.97, 95% CI 0.66-1.42, p=0.9).

Conclusion: PRMT5 expression defines an immune suppressed subpopulation of pts with NSCLC. Pts with elevated PRMT5 expression and MTAPdel have poor outcomes with ICI+/- chemo, indicating PRMT5 RNA expression levels can be used to inform clinical trial designs, particularly those that are testing novel combinatorial strategies.

#2447 Epigenomic liquid biopsy-based biomarkers of platinum and PARP inhibitor response in patients with germ line BRCA-associated PDAC: A pilot study.

Maria Raitses-Gurevich[1], Gulfem Guler[2], Yuhong Ning[2], Ceyda Coruh[3], Micah Collins[3], Shimul Chowdhury[3], Samuel Levy[3], Talia Golan[4]

[1]Cancer Center, Sheba Medical Center, Tel Hashomer, Israel,[2]ClearNote Health, San Mateo, CA,[3]ClearNote Health, San Diego, CA,[4]Cancer Center, Sheba Medical Center, Ramat Gan, Israel

Background: Despite favorable overall response, pancreatic ductal adenocarcinoma (PDAC) patients with germline *BRCA* mutations show varied response to platinum-based chemotherapy and PARP inhibitor treatment. While some patients demonstrate long term response, others develop acquired resistance after an initial durable response and a third group are refractory to first-line platinum-based therapy. 5-hydroxymethylation (5hmC) analysis of plasma-derived cell-free DNA (cfDNA) of PDAC patients present a non-invasive approach to investigate treatment response biomarkers. Here, we investigated 5hmC profiles of plasma-derived cfDNA obtained from PDAC patients prior to treatment and while on treatment. Additionally, samples were evaluated for response by CA19-9 measurements and the Avantect Pancreatic Cancer Test (Avantect, a non-invasive, blood-based assay designed to detect PDAC using epigenomics and genomics biomarkers.

Methods: A total of 80 blood samples were collected in EDTA tubes from 32 PDAC patients pre-treatment or while on-treatment, with 2-5 timepoints for each patient. Blood samples were processed to obtain plasma. Cell-free DNA extracted from plasma were analyzed using Avantect. Germline *BRCA1/2* mutations were confirmed for all study subjects.

Results: Of the 32 patients included in the study, 6 were refractory, 14 developed acquired resistance and 12 were long term responders to platinum/PARP-inhibitor treatment. Differential 5hmC analysis at the earliest available timepoint for each patient revealed refractory patients to have distinct cfDNA profiles relative to both acquired resistance and long-term responders. Analysis with Avantect showed that the refractory group exhibited the highest cancer scores when compared to the acquired resistance and long-term responder groups (p value 0.001). Stratification of stage IV patients according to Avantect test results revealed that cancer signal-detected patients have poor overall survival relative to cancer signal not-detected patients (9.3 months vs 25.9 months, Hazard ratio 4.17, p = 0.017). Furthermore, evaluation of on-treatment timepoints demonstrated that Avantect detected disease progression in 78.6% (11/14) of PDAC patients who developed acquired resistance.

Conclusions: cfDNA 5hmC analysis revealed clear differences between long-term responders and patients with resistance, highlighting potential blood-based biomarkers of treatment durability and mechanisms of resistance. Cancers with worse response to therapy were detected at a higher rate by the Avantect test. These findings suggest that larger studies using Avantect can be performed to identify patient subpopulations with limited treatment response and to monitor treatment response.

#2448 Somatic DDR mutations as potential predictive biomarkers of platinum benefit in metastatic pancreatic cancer.

Ethan L. Low, Aakash Shah, Eunji Jo, Aliya Lackan, Susan Hilsenbeck, Benjamin L. Musher

Dan L Duncan Comprehensive Cancer Center, Baylor College of Medicine, Houston, TX

Background: Next-generation sequencing (NGS) has faciliated widespread identification of genetic alterations in pancreatic ductal adenocarcinoma (PDAC). Germline DNA damage repair (DDR) mutations, including BRCA1/2, PALB2, and ATM, predict sensitivity to first-line platinum-based chemotherapy (CTX). However, the predictive role of somatic DDR mutations remains undefined.
Methods: We retrospectively identified patients with metastatic PDAC (mPDAC) harboring a somatic DDR mutation (sDDR) who were treated at the Dan L Duncan Comprehensive Cancer Center (Houston, TX) between January 2018 and June 2025. Patients with germline DDR mutations or MSI-high tumors and those who < 2 cycles of CTX were excluded. Best response (RECIST 1.1), progression-free survival (PFS), and overall survival (OS) were assessed. OS was defined as the interval between CTX initiation and death, hospice enrollment, or last follow-up. Outcomes for sDDR patients receiving first-line platinum vs non-platinum CTX within our cohort were compared using Fisher's exact test. Outcomes for sDDR patients receiving first-line platinum CTX were compared with unselected PRODIGE controls using a one-sample binomial test (ORR) and a one-sample χ^2 test under exponential survival assumptions (PFS, OS).
Results: Eighteen patients met inclusion criteria; 14 (77.8%) had *de novo* mPDAC and 4 (22.2%) had recurrences post-resection. sDDR mutations included ATM (11, 61.1%), BRCA2 (5, 27.8%), BRCA1 (1, 5.6%), and PALB2 (1, 5.6%). Twelve patients received first-line FOLFIRINOX (5-fluorouracil, irinotecan, and oxaliplatin): 4 (33.3%) had partial response, 4 (33.3%) had stable disease, and 4 (33.3%) had progressive disease, yielding an overall response rate (ORR) of 33.3% and disease control rate (DCR) of 66.6%. The remaining 6 patients received non-platinum CTX (n=6): 5 (83.3%) had stable disease and 1 (16.7%) had progressive disease, yielding an ORR of 0% and DCR of 83.3%. Median PFS was 13 months in the platinum group versus 16 months in the non-platinum group (p=0.5), and median OS was 27 vs 31 months (p=0.6). Compared to the unselected population who received FOLFIRINOX in PRODIGE, sDDR patients who received platinum CTX in our cohort demonstrated a comparable ORR (33.3% vs 31.6%, p=1.0), but longer PFS (13 vs 6.4 months, χ^2 =70.6, p < 0.001) and OS (27 vs 11.1 months, χ^2 =87.5, p < 0.001).
Conclusion: In this exploratory single-institution cohort, PFS and OS were longer in sDDR-mutated mPDAC patients treated with FOLFIRINOX compared to unselected patients treated with FOLFIRINOX in PRODIGE. Within our small sDDR cohort, outcomes were not statistically superior with platinum versus non-platinum CTX. These hypothesis-generating findings are limited by small sample size, retrospective design, and selection bias toward patients completing ≥2 CTX cycles. Larger studies are needed to clarify whether sDDR mutations predict mPDAC outcomes.

#2449 Comparison of liquid versus solid tissue genomic profiling for the prediction of chemo-immunotherapy benefit in advanced NSCLC.

Charu Aggarwal[1], Prashant Nair[2], Anagha Jenu[2], Poornachandra G[2], Ansu Kumar[2], Swati Khandelwal[2], Jyoti Chauhan[2], Susheel George[2], Neelsh Lunkad[2], Vijayashree PS[2], Nagendra Prasad[2], Shweta Kapoor[2], Drew Watson[2], **James Wingrove**[2], Tejas Patil[3]

[1]University of Pennsylvania, Philadelphia, CA,[2]Cellworks Group, Inc., South San Francisco, CA,[3]University of Colorado Anschutz Medical Campus, Aurora, CO

Background: Front-line genomic profiling in advanced NSCLC typically utilizes solid tissue, although assessment via liquid biopsy is becoming more frequent. In addition to detecting the presence of actionable mutations, genomic profiling can also be used to inform on the use of immune checkpoint inhibition (ICI), alone and in combination with chemotherapy (ICI+C). Using genomic profiling obtained from solid tissue (Foundation One CDx), we previously validated an algorithm capable of distinguishing advanced NSCLC patients with favorable ICI+C benefit from those with no benefit [1]. We have evaluated this algorithm in a cohort of advanced NSCLC patients receiving both liquid and solid tissue genomic profiling.

Design: The ΔTRI algorithm uses Cellworks' computational model of a patient's tumor genomics to predict biomarker changes related to disease progression and potential benefit from ICI+C therapy. The previously validated ΔTRI and clinical threshold (ΔTRI score of 16, which equates to a 15% increase in 24 month OS when receiving ICI+C) were evaluated in 20 non-squamous, advanced NSCLC patients with complete clinical and genomic information (Foundation One Solid and Liquid), derived from the nationwide (US-based) de-identified ConcertAI Genomics360 database. Differences in solid and liquid-derived ΔTRI scores were assessed for association with clinical factors as well as genomic markers.

Results: Mutational profiles were highly similar between both platforms (median Jaccard index = 0.84), with 20% (4/20) of the patients having a Jaccard index < 0.5. In the 16 patients with differences between solid and liquid aberrations, discordance was driven 81% of the time by novel mutations identified in the liquid samples. Despite these differences, the ΔTRI scores generated from liquid biopsy samples were significantly correlated with those generated from solid tissue (R^2 = 0.61, *p* value < 0.001), with a median difference in ΔTRI score of 2.39, equating to roughly 2% difference in ICI+C benefit. Using the pre-defined clinical threshold of 16, 15% (n=3) of the samples switched from high ICI+C benefit category obtained from solid tissue (≥ 16 increase in 24 median OS with ICI+C) to a low/no benefit category ΔTRI score obtained with liquid samples, with an median difference in ΔTRI score of 7.4. Clinical factors such as the number of days between tissue and blood collection and number of metastatic sites were not associated with panel differences.

Conclusions: Good similarity was observed in ΔTRI scores generated from liquid biopsy samples compared to scores generated from solid tissue, suggesting that with additional exploration liquid samples could be used for ΔTRI score generation. Discordant cases appeared to be driven by novel mutations identified via liquid biopsy.

1 Aggarawal et al, WCLC 2025

#2450 Peritumoral adipose tissue as a prognostic imaging biomarker for immunotherapy response in HNSCC.

Kyle Harris[1], Nazila Godfrey[2], Dalia El-Gamal[2], Shesh Rai[3], Jianmin Pan[3], Brady Williamson[1], Trisha Wise-Draper[2]

[1]University of Cincinnati College of Medicine, Cincinnati, OH,[2]Division of Hematology/Oncology, University of Cincinnati Cancer Center, Cincinnati, OH,[3]Department of Biostatistics, Health Informatics and Data Sciences, University of Cincinnati, Cincinnati, OH

Introduction: Obesity is a well-known risk factor for many cancers, including head and neck squamous cell carcinoma (HNSCC), yet greater systemic adiposity has been linked to improved responses to immune checkpoint inhibitors (ICIs). Increased adipose tissue modulates the tumor microenvironment via immune cell infiltration and PD-1 signaling. While prior work has focused on systemic obesity, the role of peritumoral adipose tissue remains unexplored. How peritumoral adiposity impacts ICI response may reveal mechanisms driving immunotherapy efficacy.

Methods: We retrospectively analyzed 36 HNSCC patients treated with neoadjuvant and adjuvant pembrolizumab concurrent with adjuvant radiation +/- chemotherapy. Tumors were segmented on pre-treatment CT scans using 3D Slicer, and a 1 cm peritumoral shell was generated in 24 patients with available imaging. Adipose volumes were quantified using patient specific Hounsfield unit thresholds: peritumoral adipose fraction (peritumoral adipose volume / peritumoral volume) and adipose:tumor ratio. Pathologic response was determined histologically. Group differences were tested using Wilcoxon rank-sum and Fisher's exact tests. Survival was censored at 2 years with Kaplan-Meier and log-rank testing. Adipose—volume correlations used Spearman's rho. In a subset of patients with paired tissue samples pre- and post-pembrolizumab, RNA-seq assessed differential pathway enrichment. Gene set enrichment analysis (GSEA) was performed using curated Reactome and KEGG pathways.

Results: Among 24 patients, median peritumoral adipose fraction was 0.017 (IQR 0.026), median adipose:tumor ratio was 0.096 (IQR 0.194), and the median tumor volume was 8.5 cm^3 (IQR 23.3). Pathologic responders had higher peritumoral adiposity compared to non-responders (median 0.0314 vs 0.0076; Wilcoxon rank-sum, $p = 0.026$). When dichotomized by the median, higher peritumoral adiposity was associated with pathologic response (Fisher's exact test, OR = 8.9, 95% CI 1.1-132.4, $p = 0.036$). Kaplan-Meier analysis showed a significantly improved survival in the high-adipose group (2-year OS 100% vs 58%; log-rank $p = 0.0098$). Transcriptomic analysis identified ~60 genes changed significantly pre- to post-pembrolizumab in responders (adjusted $p<0.1$). GSEA demonstrated that responders had significant activation of pathways involving TGF-β receptor signaling, regulation of gene expression by HIF1A, TRAF6-mediated cytokine induction, and innate and adaptive immune signaling.

Conclusion: Greater peritumoral adiposity was associated with improved pathologic response and 2-year survival in HNSCC patients treated with pembrolizumab. Transcriptomic analysis reveals activation of TGF-β, HIF1A, and immune signaling pathways in responders, suggesting peritumoral adipose tissue may shape a treatment-permissive microenvironment that enhances response to PD-1 blockade.

#2451 Dual-function platform for chemotherapy prediction and mutation detection in pancreatic cancer by *tCAM-seq*.

Arturo Orlacchio[1], Erik Ladewig[2], Adrienne K. Chandra[1], Anwesha Dhara[1], Sharon M. James[1], Steven D. Leach[3], Kenneth H. Yu[4], **Surajit Dhara**[1]

[1]Episteme Prognostics, Inc, Brooklyn, NY,[2]Memorial Sloan Kettering Cancer Center, New York, NY,[3]Dartmouth Cancer Center, Hanover, NH,[4]Gastrointestinal Oncology Service, Memorial Sloan Kettering Cancer Center, New York, NY

Predicting chemotherapy response by chromatin accessibility and detecting actionable mutations are two independent paradigms, but here we demonstrate their integration in an all-in-one platform. We addressed two fundamental questions, 1) whether clinically actionable mutations can be detected from a Tn5-accesible genome instead of a traditional whole genome or exome, and 2) whether the higher depth of sequencing would compromise the quantitative ability of chromatin accessibility. We designed the panel using Illumina's standard deep-sequencing platform, encompassing the canonical driver mutations of pancreatic ductal adenocarcinoma (PDAC), e.g., KRAS, TP53, BRCA1/2 etc. On the same panel, we included our previously discovered 1092-chromatin signature regions that distinguishes gemcitabine resistant and sensitive tumors. We named this method targeted chromatin accessibility and mutation sequencing (*tCAM-seq*). First, we applied this *tCAM-seq* approach on four PDAC cell lines (AsPC1, BxPC3, MiaPaCa2, and PANC1), which accurately identified canonical driver mutations. The 1092-chromatin signature exhibited distinct accessibility patterns between gemcitabine resistant (AsPC1, BxPC3) and gemcitabine sensitive (MiaPaCa2, PANC1) cell lines. Next, we performed a head-to-head comparison of *tCAM-seq* with *ATAC-seq* on an archival cohort of Tn5-accessible DNA libraries prepared from surgically resected PDAC patients (n=24) between 2015 - 2017 at MSKCC. We observed high concordance (median R^2=0.77, range 0.61-0.85) among the two methods in terms of chromatin accessibility estimation. Our *tCAM-seq* maintained the predictive accuracy, even with >100× sequencing read depth. Kaplan-Meier analysis (n=24) of overall survival demonstrated a significant segregation between chemotherapy responder and non-responder patients (p=0.0184, HR=0.2958, 95% CI=0.066-1.323; median follow-up 8.98 years) using the *tCAM-seq*-derived 1092-chromatin accessibility profiles. Owing to the higher sequencing depth, tCAM-seq identified canonical driver mutations with high confidence which were otherwise not possible with traditional bulk *ATAC-seq*. Our results suggest clinically actionable mutations in PDAC reside within "accessible" chromatin regions and therefore can be detected from the Tn5-accessible genome, while accurately quantifying the chromatin accessibility profiles on the same sample. This clinically translatable "dual-purpose" *tCAM-seq* panel surpasses *mutation-only* panels by enabling both mutation-matched targeted therapies and prediction of chemotherapy response from the same assay. This will enable oncologists to provide a more comprehensive and better-informed treatment decision.

#2452 Proteomic aging biomarkers predict survival in immunotherapy-treated tumors.

Michal Harel[1], Coren Lahav[1], Yehonatan Elon[1], M. Austin Argentieri[2], Surbhi Singhal[3], Adam P. Dicker[4]

[1]OncoHost, Binyamina, Israel,[2]Massachusetts General Hospital, Boston, MA,[3]UC Davis Comprehensive Cancer Center, Binyamina, CA,[4]Professor & Chair, Dept. of Radiation Oncology, Thomas Jefferson University Kimmel Cancer Center, Philadelphia, PA

Introduction:
Plasma proteomics provides a comprehensive view of the biological processes active in an individual. Studies in healthy populations have shown that the plasma proteome undergoes changes with aging, and that proteomics-based models can predict biological age. The difference between biological and chronological age, known as the “age gap,” reflects an individual’s risk of disease. Extending this approach, organ-specific aging models have demonstrated that accelerated aging of individual organs is associated with organ-related disorders. Here, we examined age-associated effects on the plasma proteome of cancer patients across multiple tumor types and applied organismal and eleven organ-specific proteomic aging models to identify links between aging, tumor characteristics, and clinical features.
Methods:
Baseline plasma samples were collected from patients with metastatic solid tumors (non-small cell lung cancer [NSCLC], n=818; small cell lung cancer [SCLC], n=99; renal cell carcinoma [RCC], n=297; melanoma, n=163) and healthy subjects (n=278). Deep plasma proteomic profiling was performed using an aptamer-based assay. Bioinformatic analyses identified age-associated proteomic signatures, and organismal and organ-specific predictors were applied to estimate biological ages for each patient and organ.
Results:
Proteins involved in multiple signaling pathways, including Wnt, PI3K-Akt, IGF, and Ephrin receptor signaling, were upregulated in older patients (≥65 years) compared with younger patients, along with immune-regulatory proteins, reflecting immune remodeling associated with aging. These trends were consistent across tumor types. The organismal biological age gap was significantly higher in all cancer cohorts versus healthy controls, largest in SCLC and smallest in melanoma, with the most substantial effect in younger patients. Organ-level analyses revealed distinct patterns: lung age gap was highest in NSCLC and SCLC, and kidney age gap was most significant in RCC. Elevated organ-specific gaps correlated with corresponding comorbidities (e.g., cardiac age gap with arrhythmia, ischemic heart disease, and vascular disease) but much less with organ-specific metastases. Focusing on the immune age gap, patients treated with immune checkpoint inhibitor-based therapy who exhibited a high immune age gap had significantly shorter overall survival compared with patients with a low immune age gap (median OS, 16.4 vs. 31.8 months; HR = 0.67, $p < 0.0001$). The effect varied by indication, being strongest in melanoma (HR = 0.27, $p = 0.0007$) and absent in SCLC (HR = 0.87, $p = 0.65$).
Conclusions:
Proteomic aging predictors capture systemic and organ-specific aging processes in cancer. Distinct age-gap patterns across tumor types, along with their association with survival and comorbidities, highlight the biological and clinical relevance of proteomic aging in oncology.

#2453 Valproic acid enhances immune reprogramming in locally advanced rectal cancer: Insights from the VshoRTR3 trial.

Maria Serena Roca[1], Elena Di Gennaro[1], Federica Iannelli[1], Alfonso De Stefano[2], Carmen Romano[2], Francesca Collina[3], Cristina Testa[1], Rossella De Cecio[3], Palmina Bagnara[1], Susan Costantini[1], Roberto De Gregorio[4], Sean Houghton[4], Shauna Lee Houlihan[4], Dario Righelli[5], Andrea Sboner[4], Alicia Alonso[6], Antonio Avallone[2], Alfredo Budillon[7]

[1]Experimental Pharmacology Unit Laboratory of Naples and Mercogliano (AV), National Cancer Institute of Naples IRCCS G. Pascale Foundation, Napoli, Italy,[2]Experimental Clinical Abdominal Oncology, National Cancer Institute of Naples IRCCS G. Pascale Foundation, Napoli, Italy,[3]Pathology Unit, National Cancer Institute of Naples IRCCS G. Pascale Foundation, Napoli, Italy,[4]Systems and Computational Biomedicine, Weill Cornell Medicine, New York, NY,[5]Department of Electrical Engineering and Information Technology, University of Naples Federico II, Naples, Italy,[6]Medicine, Weill Cornell Medicine, New York, NY,[7]Scientific Directorate, National Cancer Institute of Naples IRCCS G. Pascale Foundation, Napoli, Italy

Rectal cancer, a common subtype of colorectal cancer, is rising worldwide due to lifestyle factors and aging population. Patients with locally advanced rectal cancer (LARC) are commonly treated with neoadjuvant chemoradiotherapy and surgery; however, recurrence rates remain high, ranging from 25% to 40%, depending on disease stage. Among the hallmarks of cancer, metabolic dysregulation and immune suppression play a critical role in tumor recurrence. Valproic acid (VPA), a histone deacetylase inhibitor, has shown potential in modulating these processes. The V-shoRT-R3 clinical trial (NCT01898104) have investigated the combination of VPA with short-course radiotherapy (SCRT) and capecitabine in LARC patients, aiming to enhance therapeutic efficacy by targeting some cancer hallmarks._To assess the biological effects of VPA within the V-shoRT-R3 trial, a multi-omic approach was employed. Peripheral blood samples were collected at baseline and after 10 days of VPA treatment, and analyzed by cytokine profiling (48-plex Bio-Plex assay) and metabolomics (1H-NMR and LC-MS). Gene expression was profiled (770-plex Nanostring panel) on matched biopsy and surgical specimens. Validation studies are ongoing using spatial transcriptomics and immunohistochemistry in an expanded patient's cohort. Preliminary data from 48 patients suggest that adding VPA to SCRT and capecitabine improves clinical outcomes. Specifically, the VPA-based regimen was associated with a significant increase in relapse-free survival compared to standard treatment. At a median follow up of 70,14 months (IQR 63-77) 3 pts in SCRT arm relapsed, with a RFS rate of 83% (cv scrt), 71% SCRT 66% CSCRT 40% V SCRT respectively. Cytokine analysis revealed a significant downregulation of IL1β, LIF, CSF1, and CSF2, following VPA treatment, suggesting suppression of the myeloid compartment. Metabolomic analysis revealed altered amino acid and energy metabolism, with enrichment in immune-related pathways. Notably, VPA induces increased tryptophan and decreased kynurenine levels suggesting a reduction of indoleamine 2,3-dioxygenase (IDO) activity confirmed also by its reduced expression indicating a shift away from immunosuppressive metabolism. Moreover, gene expression analysis revealed activation of NK cell, IL10, and cytotoxicity signatures in VPA-treated patients, indicating marked immune modulation. VPA promotes immune activation and metabolic reprogramming, improving outcomes in LARC. Multi-omics analyses and ongoing validations will define VPA-driven mechanisms to inform for more personalized therapeutic strategies.

#2454 A Drug Response Predictor (DRP®) is associated with enhanced overall survival in the phase 2 trial in advanced, recurrent ovarian cancer patients treated twice daily with 2X-121/ Stenoparib (NCT03878849).

Steen Knudsen[1], Annette Nielsen[1], Thomas Jensen[1], Peter Gimsing[1], Anker Hansen[1], Mogens Winkel Madsen[1], Michele Gargano[1], Jose Iglesias[1], Fernanda Musa[2], Kathleen N. Moore[3], **Jeremy Graff**[1]

[1]Allarity Therapeutics Inc, Tarpon Springs, FL,[2]Swedish Cancer Institute, Seattle, WA,[3]OU Health Stephenson Cancer Center, Oklahoma City, OK

2X-121 (stenoparib) inhibits PARP1/2 (1nM ~IC50) and Tankyrase 1/2 (IC50 ~50nM) limiting DNA repair while inhibiting WNT/ß-catenin oncogenic signaling. A 2X-121- specific Drug Response Predictor (DRP®) comprised of 414 genes was developed and highlights the gene expression profiles correlated with 2X-121 sensitivity, many of which are involved in the WNT/ ß-catenin pathway. In a ph1 clinical study, 2X-121 treatment showed clinical response by RECISTv1.1, notably in ovarian cancer patients. Blinded, retrospective analysis revealed that the 2X-121 DRP® identified the patients most likely to benefit from 2X-121. A follow-on, open label phase 2 trial in 3L+ ovarian cancer patients (DRP score > 50) began in May 2023 with 2X-121 dosed BID for the first time. 15 heavily pre-treated patients were enrolled independent of *BRCA* or Homologous DNA Repair status. Prior treatment included PARP inhibitors, mirvetuxumab, bevacizumab and immunotherapy. 14 of these patients were platinum resistant, 1 was primary platinum refractory. Collectively, the data show durable clinical benefit in patients with varied genetic and treatment backgrounds. Two patients (one $BRCA^{mut}$, one $BRCA^{WT}$) remain on therapy > 26 mos. An additional patient (prior PARP inhibitor treatment) showed a complete, confirmed response and stayed on treatment > 10 mos. The patient with primary platinum refractory disease was on therapy > 10 mos and remains alive beyond 2 years. Kaplan-Meier analyses show that the median Overall Survival (OS) is now > 25 mos, having not been reached with >23 mos median time to follow-up. We assessed whether the DRP score from pre-treatment biopsies might be related to enhanced OS. Indeed, patients with higher DRP scores reliably showed the greatest OS. In a continuous cox proportional hazard analysis, a 50-point difference in DRP score was associated with a hazard ratio of 0.03 (95% CI, 0.0-1.4). Applying a fixed DRP cutoff of 80 yielded a hazard ratio of 0.13 (95% CI, 0.02-0.9). To address whether the DRP was prognostic vs predictive, we assessed RNA expression data from biopsies in the public TCGA dataset of 481 high grade serous ovarian cancer samples from patients treated with platinum/ taxane. The DRP scores ranged from 0 to 100 in this cohort. The 2X-121 DRP® did not correlate with better OS (continuous cox HR=0.76 (95% CI, 0.54-1.1)). Among the 90 samples from patients with platinum resistant disease, the hazard ratio was 0.96 (95% CI, 0.39-2.3). These results indicate that the 2X-121 DRP may be a predictive- rather than prognostic- biomarker, highlighting extended OS in patients treated twice daily with 2X-121. A new ph2 clinical trial protocol is currently enrolling platinum-resistant Ovarian Cancer patients to further explore and delineate the relationship between 2X-121 DRP® score and clinical benefit.

#2456 Profiling the expression of antibody-drug conjugates in fibrolamellar hepatocellular carcinoma.

Waqar Arif[1], Elsa Hallab[2], Franshisca Hayek[2], Howard Liu Li[2], Mari Nakazawa[2], Mark E. Furth[3], Andrew S. Liss[4], Patricia Cogswell[3], Ezra G. Baraban[1], Jacqueline Birkness-Gartman[1], Marina Baretti[2], Robert A. Anders[1], Mark Yarchoan[2]

[1]The Johns Hopkins University School of Medicine, Baltimore, MD,[2]Sidney Kimmel Comprehensive Cancer Center, Baltimore, MD,[3]Fibrolamellar Cancer Foundation, Greenwich, CT,[4]Massachusetts General Hospital, Boston, MA

Background: Fibrolamellar carcinoma (FLC) is a rare and aggressive primary liver cancer that primarily affects adolescents and young adults. It is biologically distinct from other forms of primary liver cancer, such as hepatocellular carcinoma (HCC) and cholangiocarcinoma (CCA). There are no standard or approved systemic therapies for advanced FLC, and most patients present with unresectable disease or experience recurrence after surgery. These factors underscore the need for new therapeutic approaches. Antibody-drug conjugates (ADCs) have shown efficacy in several solid tumors by delivering cytotoxic payloads to tumor-associated surface antigens with improved specificity, but their utility in FLC is not known. To evaluate the relevance of ADC-based therapies in FLC, we assessed the expression of five clinically actionable ADC targets (NECTIN4, TROP2, CLDN18.2, HER2, and B7-H3) in an expanded cohort of FLC specimens.

Methods: Archival FFPE samples were obtained from consented patients through the Johns Hopkins Liver Cancer Tissue Bank and the Fibrolamellar Cancer Foundation, including FLC tumors (n=58; 38 primary and 20 metastatic lesions). Immunohistochemistry (IHC) was performed for all five markers. Expression patterns of interest in FLC were compared with control cohorts of HCC (n=10) and CCA (n=10). Three pathologists, blinded to clinical data, independently scored staining using both a 0 to 3 plus ordinal IHC scale and a semi-quantitative H-score.

Results: Among the five ADC targets evaluated, only B7-H3 and HER2 showed detectable staining in FLC. NECTIN4, TROP2, and CLDN18.2 were uniformly negative, scored as 0+ in all tumors, and had H-scores of 0. B7-H3 demonstrated the strongest expression. 3+ staining was observed in 20 of 58 tumors (34.5%). Tumor-cell H-scores ranged from 10 to 240, with a mean of 132. B7-H3 was also expressed in the tumor microenvironment, with prominent staining in cancer-associated stroma and fibroblasts. Stromal H-scores ranged from 40 to 300, with a mean of 199, often exceeding tumor-cell expression. HER2 showed detectable 3+ staining in 12 of 58 tumors (21.7%), with H-scores ranging from 2 to 270 and a mean of 70. One patient in this cohort with 3+ HER2 expression received fam-trastuzumab deruxtecan-nxki, and experienced a durable partial response lasting approximately one year.

Conclusions: B7-H3 and HER2 are promising ADC targets in FLC. While a subset of patients may already be eligible for fam-trastuzumab deruxtecan-nxki under its tumor-agnostic indication, B7-H3 shows particularly strong and widespread expression across both tumor and stromal compartments. These findings support further preclinical and clinical evaluation of B7-H3- and HER2-directed ADCs as targeted treatment strategies for advanced FLC.

#2676 Subtyping cancer cachexia through automated body composition.

Sonia Boscenco[1], Venise Jan Castillon[1], Perry J. Pickhardt[2], John W. Garrett[2], Nathaniel C. Swinburne[3], Ed Reznik[1]

[1]Computational Oncology, Memorial Sloan Kettering Cancer Center, New York, NY,[2]Professor of Radiology, University of Wisconsin School of Medicine, Madison, WI,[3]Department of Radiology, Memorial Sloan Kettering Cancer Center, New York, NY

Understanding how patients lose body mass during cachexia is critical for improving diagnosis and developing meaningful clinical endpoints. Yet, which body compartments drive the wasting phenotype remains unknown. We hypothesized that distinct patterns of changes to body composition might stratify patients into clinically relevant subtypes of cachexia. To test this hypothesis, we computed changes in body composition across periods of weight loss in a cohort of over 6000 pan-cancer patients from MSKCC and identified that loss of subcutaneous fat, loss of skeletal muscle, and unexpectedly, gain of liver volume, were the principal alterations during cachexia. Although all patients underwent periods of weight loss, unsupervised clustering of all body composition changes identified two broad subtypes of wasted and non-wasted patients. Wasted patients had significantly inferior overall survival, increased C-reactive protein, decreased albumin, and lower rates of weight recovery. Bulk RNA-sequencing analysis from a subset of BLCA, RCC, and PDAC patients identified a unique transcriptional phenotype of wasted patients, with marked upregulation in inflammatory response, interferon gamma response, and IL6-JAK-STAT3 signalling pathways. A subset of wasted patients exhibited pronounced hepatomegaly accompanied by markers of steatosis such as decreased radiographic liver density and increased alkaline phosphatase. This wasted-hepatomegaly subgroup, characterized by pronounced systemic inflammation, showed the poorest overall survival, suggesting a potential liver-driven axis of cachexia severity. Together, our data leverages opportunistic screening of computed-tomography scans to classify weight loss episodes using a radiographic biomarker that identifies bona fide wasting cachexia in a human patient cohort.

#2677 Identifying and analyzing clinicopathological features of uterine endometrial endometrioid tumors discordant by p53 and copy number status.

Sreekar B. Challa[1], Jessica D. St. Laurent[2], Zehra Ordulu[3], Alexander J. Neil[3], Melissa S. Gildenberg[3], Matthew L. Meyerson[1], Yvonne Y. Li[1], Andrew D. Cherniack[4], Elizabeth H. Stover[1]

[1]Department of Medical Oncology, Dana-Farber Cancer Institute, Boston, MA,[2]Division of Gynecologic Oncology, Brigham and Women's Hospital, Boston, MA,[3]Department of Pathology, Brigham and Women's Hospital, Boston, MA,[4]Cancer Program, Broad Institute, Cambridge, MA

The Cancer Genome Atlas (TCGA) identified four molecular subtypes of endometrial carcinoma: POLE, high microsatellite instability (MSI-H), copy number-low and copy number-high. These classifications were eventually adopted into clinical practice in the form of ProMisE, a molecular classifier for endometrial cancers based on TCGA. While TCGA used hierarchical clustering to define copy-number high and low clusters, ProMisE utilizes *TP53* mutation as a marker of the copy-number (CN) high and low subgroups. We have observed discordances between TP53 mutation call and copy-number status. We developed a method to redefine CN-high based on the presence of a single chromosomal arm-level deletion in a tumor. Arm-level copy number calls were generated by running the algorithm ASCETS (Arm-level Somatic Copy-number Events in Targeted Sequencing) on copy number segmentation data to give arm-level copy number calls. We validated this approach using molecular subtypes from both TCGA and CPTAC (Clinical Proteomic Tumor Analysis Consortium) data after taking out MMR-D/MSI-H and POLE patients, yielding accuracies of 0.823 and 0.865, respectively. Next, we applied this approach to a cohort of 446 endometrioid endometrial tumors profiled using a next-generation targeted sequencing panel (OncoPanel). After removing MSI-H/POLE tumors, we found 167 tumors concordant with regards to CN and *TP53* mutation status (31 CN-high/*TP53* mutant; 136 CN-low/*TP53* wild-type), and 92 discordant tumors (84 CN-high/*TP53* wild-type; 8 CN-low/*TP53* mutant). Survival analysis stratified by *TP53* mutation and copy number status called by arm-level deletion yields significantly worse overall survival for patients with both *TP53* mutation and high copy number in both the CPTAC ($p = 0.027$) and OncoPanel ($p < 0.0001$) cohorts, but no significant difference in survival between *TP53* WT/CN-high and *TP53* WT/CN-low patients. Overall, we find that *TP53* WT tumors have similar prognosis regardless of copy number status and have also found that CN-high/ *TP53* mutant tumors may have significantly worse prognosis than CN-low/ *TP53* mutant tumors ($p = 0.036$). Additional data will be used to confirm this.

#2678 A multimodal model to forecast prostate cancer metastasis from primary tumor transcriptomics and histopathology morphology.

Itzel Valencia[1], Priyanka Vasanthakumari[1], Pier V. Nuzzo[2], Edoardo Francini[3], Francesco Ravera[4], Giuseppe N. Fanelli[2], Sara Bleve[5], Cristian Scatena[6], Luigi Marchionni[2], Mohamed Omar[7]

[1]Cedars-Sinai Medical Center, Los Angeles, CA,[2]Weill Cornell Medicine, New York, NY,[3]Department of Experimental and Clinical Medicine, University of Florence, Florence, Italy,[4]University of Genoa, Genova, Italy,[5]IRCCS Istituto Romagnolo per lo Studio dei Tumori (IRST), Meldona, Italy,[6]Department of Translational Medicine and New Technologies in Medicine and Surgery, University of Pisa, Pisa, Italy,[7]Cedars-Sinai Medical Center, West Hollywood, CA

Prostate cancer (PCa) is the most commonly diagnosed non-cutaneous malignancies in men in the United States, and metastatic dissemination remains the principal driver mortality. While advanced disease is typically managed with androgen deprivation therapy, most patients eventually progress to castration-resistant PCa, underscoring the need for early identification of tumors predisposed to metastasis. Clinicopathological metrics, including PSA, tumor stage, and Gleason grade, provide only coarse estimates of risk and fail to capture the molecular and spatial heterogeneity underlying disease progression. To address this limitation, we developed *Met-Score*, a transcriptomic signature derived from meta-analysis of primary tumor expression profiles from 1,239 PCa patients. Using a rigorous training (n=1000) and independent validation (n=239) design, we computed gene-level Hedges' effect sizes across cohorts, pooled them using a random-effects model, integrated evidence across datasets using Fisher's and log-sum methods, and applied false discover rate correction to identify genes most strongly associated with metastatic progression. In the validation cohort, *Met-Score* achieved an AUC of 0.72 for predicting metastasis, and maintained independent prognostic value for overall, metastasis-free, and progression-free survival across two independent datasets, even after adjustment for Gleason score, demonstrating its clinical relevance beyond standard pathology. To investigate whether *Met-Score* reflects morphological phenotypes encoded in routine histopathology, we quantified morphometric features from digitized H&E slides of prostate biopsies and prostatectomies. *Met-Score* showed significant associations with multiple architectural and cytological descriptors, suggesting that the signature captures transcriptional programs tightly coupled to microanatomical patterns observable on standard tissue sections. Building upon this link between molecular and morphological readouts, we trained a multimodal risk model that integrates *Met-Score* with an image-derived *Morph-Score*, and benchmarked its performance against unimodal predictors. Our preliminary analysis indicates that the multimodal framework substantially enhances risk discrimination and more accurately identifies patients likely to develop metastasis compared to transcriptomics or histopathology alone. This work highlights the potential of combining deep molecular features with interpretable morphometric signatures to improve prognostication in localized PCa, and establishes a broadly applicable strategy for multimodal biomarker development in solid tumors.

#2679 Integrated Bulk and Single-Cell Transcriptomics Reveal Hepatocyte-Like Reprogramming in Metastatic Small Intestinal Neuroendocrine Tumors.

Sunanda Biswas Mukherjee[1], **James P. Madigan**[2], Samira M. Sadowski[1]

[1]Surgical Oncology Program, National Cancer Institute, NIH, Bethesda, MD,[2]Postdoctoral Fellow, National Cancer Institute, Rockville, MD

Liver metastasis is the primary determinant of poor prognosis in small intestinal neuroendocrine tumors (siNETs), yet the molecular mechanisms enabling metastatic adaptation remain largely unknown. Here, we integrate bulk and single-cell transcriptomic analyses to dissect tumor-intrinsic programs underlying this process. Bulk RNA-seq analysis of 44 primary and 37 metastatic siNET patient samples revealed extensive transcriptional remodeling during liver metastasis. Differential expression and pathway enrichment analyses demonstrated upregulation of metabolic and various liver-related pathways, alongside downregulation of intestine-specific programs in metastatic tumors. These results suggest a tumor-intrinsic phenotypic shift toward hepatic functional states. Further, application of the ESTIMATE algorithm, which infers tumor purity from the relative abundance of stromal and immune transcriptional components, demonstrated consistently high purity in metastatic samples, indicating that the observed transcriptional programs reflect tumor-intrinsic alterations rather than contamination from normal liver tissue. To validate these observations at single-cell resolution, we analyzed five matched primary and liver metastatic siNET patient samples using *in-house* single-cell RNA-seq data. Integrative clustering revealed distinct neuroendocrine (NE) and hepatocyte-like tumor populations, reflecting the cellular heterogeneity within the metastatic niche. Pseudotime and trajectory analyses highlighted a continuous progression from primary tumor-enriched NE clusters toward metastasis-enriched hepatocyte-like clusters, suggesting a gradual reprogramming of tumor cells along a liver-adaptive axis. These hepatocyte-like states exhibited activation of biological processes like hepatic functions and xenobiotic metabolisms. Together, these indicate a selective transcriptional plasticity that enables metastatic tumor cells to acquire liver-specific functional traits, thereby facilitating their survival, metabolic integration, and persistence within the liver microenvironment. In conclusion, by integrating bulk and single-cell transcriptomic data, this study reveals that siNET liver metastasis arises through a tumor cell-state transition toward a hepatocyte-like identity, representing a novel paradigm of liver-specific adaptation in neuroendocrine tumor metastasis and highlights liver-adaptive transcriptional programs that may be therapeutically targeted to disrupt siNET metastatic persistence.

#2680 Dosage-dependent adaptations to Complex I mutations in cancer cell lines.

Neil Ruthen[1], Ziad El Bakouny[2], Amy Shepherd[3], Sonia Boscenco[1], Benan Nalbant[2], Caleb Lareau[2], Payam Gammage[4], Ed Reznik[2]

[1]Weill Cornell Grad. School of Medical Sci., New York, NY,[2]Memorial Sloan Kettering Cancer Center, New York, NY,[3]Cancer Research UK Scotland Institute, Glasgow, United Kingdom,[4]Payam Gammage (Individual), Glasgow, United Kingdom

Chemical or genetic perturbations of the electron transport chain can evoke profound changes in cellular state. However, whether heteroplasmic mtDNA mutations, which are positively selected in cancer cells and present only in a fraction of the total mtDNA pool, promote dosage-dependent transcriptional or epigenetic adaptations is unknown. To characterize how such mutations impact cancer cell phenotypes, we performed single-cell DOGMA-seq profiling of nine murine cancer cell lines representing five tissue types engineered with m.12426G>A Complex I mutations using TALE-ddBCEs. Each cell line exhibits a full range of heteroplasies, enabling the application of continuous models to describe the quantitative relationship between gene expression or accessibility and heteroplasmy. Using meta-analysis techniques, we identified genes that show consistent, statistically significant transcriptional adaptation with increasing heteroplasmy across cell lines. Two pathways were particularly enriched for lineage-agnostic transcriptional adaptations: glycolysis and iron-response transcriptional elements. Given that non-monotonic, threshold-triggered gene expression patterns have been reported in cells with large mtDNA deletions, we asked whether gene expressions varied non-linearly with respect to heteroplasmic Complex I mutations and whether threshold-triggered effects were conserved across cell lines. Leveraging segmented regression techniques, we identified hundreds of threshold-triggered genes, of which the overwhelming majority are transcribed more frequently when heteroplasmy levels exceed the inferred threshold. These results imply the existence of conserved adaptations to Complex I mutation heteroplasmy and describe bona fide mitochondrial threshold effects.

#2681 Past exposure to genotoxic cancer therapies is associated with elevated local mutagenesis at CTCF binding sites in metastatic tumors.

Kevin C. L. Cheng[1], Jigyansa Mishra[2], Juri Reimand[2]

[1]Univ. of Toronto Faculty of Medicine, Toronto, ON, Canada,[2]Ontario Institute for Cancer Research, Toronto, ON, Canada

Many cancer therapies are known to have mutagenic effects, but their extent and potential functional implications in surviving cancer cells are incompletely understood. In particular, it is unclear how regulatory elements that are vulnerable to mutations are affected by these therapies. CTCF is a master regulator of chromatin organization; it binds DNA at TAD boundaries and other key regulatory elements. Previous studies have observed that CTCF binding sites (CBS) are enriched in mutations in cancer, but the underlying mechanisms are incompletely understood. We asked whether prior treatments were associated with local mutagenesis at CBS in metastatic tumors.

Utilizing a cohort of 4,870 whole-genome-sequenced metastatic tumors from the Hartwig Medical Foundation, we systematically analyzed associations between mutational processes at CBS across 17 cancer types and 45 types of cancer therapies with our computational method RM2.

We found 21 associations involving 6 cancer types and 14 therapy types. Most notably, past exposure to radiotherapy or trifluridine was associated with increased CBS mutation rates in metastatic colorectal cancer. Both radiotherapy and trifluridine are associated with increased SNV burden without a strong trinucleotide preference, consistent with a generally weaker DNA repair in these sites. Therapy-associated mutation enrichment occurred primarily in subsets that display the canonical CTCF binding DNA motif, relatively late replication timing or association with lower gene expression, suggesting that specific chromatin environments enable treatment-associated mutagenesis in CBS. We further asked whether the presence of known driver mutations influences therapy-associated local mutagenesis at CBS. This revealed that mutations in DNA damage response and chromatin regulation pathway genes, including BRCA2 and FBXW7, further elevate CBS mutation rate in radiotherapy-exposed tumors. This suggests higher vulnerability to radiotherapy-associated mutations when DNA damage response pathways, especially homologous recombination, are compromised.

In conclusion, this study provides, to our knowledge, a first analysis of association between cancer therapies and mutational burden at CTCF binding sites. Our findings highlight a previously unknown side effect of genotoxic cancer therapies on key regulatory elements. This underscores the need for a deeper understanding of therapy-induced mutations in regulatory regions and their potential implications for cancer biology and treatment outcomes.

#2682 Multiomic dissection of HBV-, HCV-, and non-viral HCC reveals distinct proliferation, interferon, and metabolic signatures.

Amerti Guta[1], Daniel O'Brien[2], Aditya V. Bhagwate[3], Jean-Pierre A. Kocher[3], Lewis R. Roberts[4]

[1]Clinical and Translational Sciences, Mayo Clinic, Rochester, MN,[2]Mayo Clinic, Rochester, MN,[3]Mayo Clinic, Rochester, MN,[4]Department Gastroenterology and Hepatology, Mayo Clinic, Rochester, MN

Background: Hepatocellular carcinoma (HCC), the most prevalent primary liver cancer, develops through multiple pathways; however, the extent to which HBV, HCV, and non-viral etiologies shape tumor biology and influence treatment responses remain incompletely understood. The availability of viral detection methods from sequencing data and multiomics workflows give us a new opportunities to study how etiology influences the molecular landscape of HCC. Here, we analyze TCGA's LIHC samples categorized into HBV-, HCV-, and non-viral tumors to compare genomic, transcriptomic and methylation profile of these HCC tumors to identify biological pathways specific to each group.

Methods: Whole-exome, RNA-seq, and clinical data from TCGA-LIHC (n=325) were analyzed. Viral status was assigned using Exogene (≥5 HBV/HCV reads; mixed infections excluded; non-viral = 0 reads). Mutation and clinical comparisons were performed using cBioPortal. RNA-seq data were processed with edgeR for 3-way differential expression (median count ≥25; $|\log_2 FC|>2$; FDR<0.05). Pathway enrichment used ShinyGO. Findings were validated using the GSE62232 microarray cohort analyzed with limma.

Results: Demographic patterns reflected known risk profiles: HBV patients presented younger (mean 53.9 years) and were predominantly male (78.8%) and Asian (92.9%), while HCV and non-viral groups were older and primarily White. Non-viral HCC showed the highest proportion of females (42.7%) and nearly half lacked significant fibrosis, consistent with metabolic disease. In contrast, HCV had the highest cirrhosis burden (47.2%), and HBV tumors showed the greatest proportion of poorly differentiated histology (52.2%).The comparison of the expressed genes between the 3 tumor subtypes revealed distinct etiology-associated pathways. Metabolic and mitochondrial including fatty acid β-oxidation differential expressed in Non-viral HCC. Activation of antiviral and interferon signaling, including type I IFN response and OAS-mediated defense pathways are observed in HCV-HCC. Finally, Cell-cycle and proliferation pathways are differentially expressed in HBV-positive, a finding consistent with effects of viral integration. Clustering analysis separated HBV and non-viral tumors into distinct groups. These signatures were reproduced in a validation cohort.

Conclusion: Our analyses highlight that HBV-, HCV-, and non-viral HCC harbor distinct transcriptional and signaling pathways. These etiology-specific signatures provide a framework for developing more precise biomarkers and for tailoring therapeutic strategies to the molecular biology of each etiology.

#2683 Multi-omic analysis of patient and preclinical data highlights challenges in targeting tumor heterogeneity in glioblastoma.

Ha Dang, Verah Nyarige, Gonzalo Lopez, Ann Forslund, Wei Zhang, Bo Hu, Junfei Zhao, Maria Ortiz-Estevez, Alexandre Alloy, Romain Georges, Elizabeth Tindall, Josh Baughman, Kai Wang, Jorge Benitez-Hernandez, Celia Fontanillo

Bristol Myers Squibb, San Diego, CA

Glioblastoma (GBM) is the most aggressive and lethal primary brain tumor in adults, characterized by extensive tumor heterogeneity and cellular plasticity. A wide range of tumor cell states have been reported that are tightly embedded within neural and glial developmental programs. State transition in response to microenvironmental factors and therapeutic pressures poses a major obstacle to effective treatment. Therefore, understanding GBM heterogeneity and the mechanisms driving it is essential for developing durable therapies. We applied integrative analytical strategies leveraging bulk and single-cell data across large patient cohorts to deeply characterize GBM tumor subtypes and cell states and identify targetable genes that both distinguish tumor cells from normal neuro-glial lineages and remain constitutively activated across tumor states. Our analysis identified ~400 multi-state genes with consistent activity in multiple tumor subtypes and cell states and differentiation from the normal lineages. Interestingly, canonical targets such as *EGFR* and *VEGFA*, while widely studied, lacked consistent activation across all tumor states. *EGFR* was less active in NPC-like state and *VEGFA* was restricted to hypoxia-associated mesenchymal programs. Similarly, *MDM2* showed activation across tumor states but was also broadly expressed in normal lineages, limiting its therapeutic specificity. These suggest these common targets may not address the full spectrum of tumor heterogeneity or differentiate from normal lineages, likely contributing to the challenges in recent clinical trials. Further analysis revealed the enrichment of cell cycle activities and DNA damage responses among multi-state genes suggesting they are the key differentiating factors between GBM tumor and matured normal brain cells. In addition, multi-omic profiling showed that DNA methylation was a major mechanism of gene silencing for multi-state genes and in some cases resulted in complete gene shutdown in normal cells. Finally, integration with DepMap CRISPR viability screen data revealed a subset of genes with strong dependencies in GBM cell lines and neurosphere models across subtypes, consistent with patient data. However, most of these genes also demonstrated dependency across pan lineages, highlighting potential challenges such as peripheral toxicity when targeting multi-state genes. In summary, our study identified cell cycle regulation remains a distinguishing feature of GBM and highlighted the complexity of differentiating and targeting tumor heterogeneity. Overcoming these challenges may require innovative therapeutic modalities capable of selectively targeting multiple tumor states.

#2684 Androgen receptor expression negatively correlates with immune infiltration and response to immune checkpoint inhibitors in ER-positive/HER2-negative breast cancer.

Jun Arima[1], Kohei Chida[2], Rongrong Wu[3], Takafumi Shima[1], Toru Kuramoto[1], Hiroki Hamamoto[1], Kohei Taniguchi[4], Nao Kawaguchi[1], Ryo Tanaka[1], Yoshiro Imai[1], Kosei Kimura[1], Mitsuhiko Iwamoto[1], Kenichi Hakamada[5], Takashi Ishikawa[6], Sang-Woong Lee[1], Kazuaki Takabe[2]

[1]Department of General and Gastroenterological Surgery, Osaka Medical and Pharmaceutical University Hospital, Takatsuki, Japan,[2]Roswell Park Comprehensive Cancer Center, Buffalo, NY,[3]Tokyo Medical University, Tokyo, Japan, Japan,[4]Center for Medical Research & Development, Division of Translational Research, Osaka Medical and Pharmaceutical University Hospital, Takatsuki, Japan,[5]Hirosaki University Graduate School of Medicine, Hirosaki, Japan,[6]Breast Surgery, Tokyo Medical University, Tokyo, Japan

Background: AR plays a pivotal role in a subset of triple-negative BC, particularly the luminal androgen receptor (LAR) subtype, which is known to be resistant to chemotherapy. Notably, enzalutamide, an AR inhibitor, improved the pathological complete response (pCR) rate in ER+/HER2- BC in a randomized clinical trial, although the underlying biological mechanisms remain unclear. Early-phase studies have implicated preliminary clinical benefit when enzalutamide was combined with ICIs in LAR-TNBC. Building on these clinical findings, our study investigated how AR expression affects the tumor microenvironment (TME) and modulates the efficacy of ICIs in ER+/HER2- BC.

Methods: A total of 4070 BC patients from five cohorts with transcriptome of bulk tumors (I-SPY2 [GSE173839], TCGA, METABRIC, SCAN-B [GSE96058], GSE271080[NCT02955395]) and two cohorts with Single-cell transcriptome (GSE246613, GSE167036) were analyzed. High expression of AR was defined as the top two-thirds of expression levels for each cohort. LAR-TNBC was defined as the top two-thirds of AR-expressing tumors within the TNBC/Basal subtype.

Results: ER+/HER2- BC exhibited substantially lower levels of genomic instability compared with LAR-TNBC in TCGA. This low genomic instability is consistent with the immunologically “cold” phenotype characteristic of ER+/HER2- disease.Among ER+/HER2-BC, AR expression was consistently and negatively associated with number of Tumor-Infiltrating Lymphocytes (TILs) consistently in the TCGA, METABRIC, and SCAN-B cohorts (all $p < 0.05$). Further, AR expression was associated with reduced infiltration of CD8+ T cells, dendritic cells (DCs), M1 macrophages in the METABRIC and SCAN-B cohorts (all $p < 0.05$). Moreover, high AR expression was associated with lower pCR rates after neoadjuvant ICI treatment in ER+/HER2- BC in the I-SPY2 trial ($p=0.002$). Single-cell transcriptomic analyses revealed that AR was expressed not only in epithelial cells but also in various stromal and immune cell populations, including fibroblasts, T cells, and myeloid cells. Notably, AR expression in epithelial and endothelial cells were inversely correlated with ICI response. Analyzing the NCT02955395 trial cohort, we found that enzalutamide treatment significantly increased the infiltration of CD8+ T cells, DCs, and M1 macrophages in ER+/HER2- BC, similar to that observed in AR-low tumors (all $p < 0.05$).

Conclusion: We found that AR expression was inversely associated with immune and myeloid cell infiltration as well as ICI response in ER+/HER2- BC. Given that AR suppression with enzalutamide induced a similar immune microenvironmental profile, combining ICIs with this treatment may provide clinical benefit in ER+/HER2- BC.

#2685 Analysis of long-read sequencing data with *vmwhere* reveals variation in microsatellite length and chromatin state in Ewing sarcoma.

Sara K. Peterson[1], A. McCauley Massie[2], Alex Rubinsteyn[3], Jeremy R. Wang[3], Ian J. Davis[4]

[1]Curriculum in Bioinformatics and Computational Biology, University of North Carolina at Chapel Hill, Chapel Hill, NC,[2]Department of Pediatrics, University of North Carolina at Chapel Hill, Chapel Hill, NC,[3]Department of Genetics, University of North Carolina at Chapel Hill, Chapel Hill, NC,[4]Departments of Pediatrics and Genetics, University of North Carolina at Chapel Hill, Chapel Hill, NC

Microsatellites (mSats), or short tandem repeats (STRs), are repeated 1-6 bp DNA motifs that are abundantly distributed across the human genome. Variation in STR length contributes to genetic diversity and structural variation, and expansions beyond a pathogenic threshold underlie nearly 60 genetic disorders. mSat repeats can also serve as non-canonical enhancers for transcriptional regulators, including through binding the EWS::FLI1 fusion oncoprotein of Ewing sarcoma. Genome-wide analysis of mSats has been limited by short-read sequencing constraints, including read length and mapping ambiguity. Long-read sequencing has improved analyses of these regions but requires specialized algorithms. We developed a computational pipeline for genome-wide reference-based detection, length genotyping, sequence decomposition, and visualization of tetrameric mSats using long-read nanopore whole-genome sequencing. We applied this approach to GGAA mSats in five Ewing sarcoma cell lines and 100 diverse normal population genomes. We find both EWS::FLI1 binding to GGAA mSats and chromatin accessibility correlated with repeat length. Comparative analysis revealed a subset of mSats (2 - 3%) that were selectively expanded or contracted in Ewing sarcoma relative to normal genomes. Although we hypothesized that this variation in mSat length would converge towards a similar repeat length, we found that expanded loci tend to fall between 11 and 13 whereas contracted loci are commonly between 4 and 6. Further, expanded mSats demonstrated the highest proportion of mSats with EWS::FLI1 occupancy and accessible chromatin, compared to same and contracted. Finally, we show mSats demonstrating cell line-specific gained or lost chromatin accessibility was associated with expansion and contraction, respectively, in those cells. These results reveal a selective expansion of chromatin accessible mSats in Ewing sarcoma and provide a generalizable framework for resolving the genetic and structural complexity of mSats in human disease using long-read sequencing.

#2686 Extraction of cellular networks and microenvironmental characteristics in liver cancer tissues using geospatial approaches for therapeutic and diagnostic potential.

Kanae Echizen[1], Yoshiki Nonaka[1], Tomonori Kamiya[1], Maho Tsuda[2], Yoshimi Yukawa-Muto[2], Hideki Fujii[2], Kenichi Kohashi[3], Ryo Takahashi[4], Takahiro Kodama[4], Naoko Ohtani[1]

[1]Graduate School of Medicine, Department of Pathophysiology, Osaka Metropolitan University, Osaka, Japan,[2]Graduate School of Medicine, Department of Hepatology, Osaka Metropolitan University, Osaka, Japan,[3]Graduate School of Medicine, Department of Pathology, Osaka Metropolitan University, Osaka, Japan,[4]Graduate School of Medicine, Department of Gastroenterology and Hepatology, Osaka University, Suita, Japan

Liver cancer arising in the context of metabolic dysfunction-associated steatotic liver disease (MASLD) has been increasing in prevalence in recent years. These tumors are characterized by remarkable heterogeneity in both malignant cells and the surrounding stromal and immune compartments, which contributes to therapeutic resistance and disease progression. Understanding the spatial organization and cellular interactions within the tumor microenvironment (TME) is therefore essential for developing more effective therapeutic strategies.

In this study, we performed single-cell RNA sequencing (scRNA-seq) and Visium spatial transcriptomics analyses using human liver cancer specimens derived from MASLD-associated cases to dissect intra-tumoral heterogeneity at both the molecular and spatial levels. We developed a spatial analytical framework that integrates pathway activity scores with geostatistical approaches and distance metrics derived from histopathological landmarks, calculated using a digital unroll method. This approach enabled the identification of region-specific cellular populations and spatial gradients of metabolic and immune activities within tumor tissues.

Furthermore, we employed a cell-cell communication analysis to delineate localized signaling networks and microenvironmental niches that sustain tumor progression. Distinct interaction patterns were observed among hepatocyte-like cancer cells, endothelial cells, and immune infiltrates, suggesting spatially restricted communication hubs. Notably, we identified specific secreted factors from defined cell types that may serve as potential non-invasive biomarkers reflecting intratumoral spatial states.

Collectively, our study provides an integrative geospatial framework to map the cellular architecture and communication networks in MASLD-associated liver cancer. This spatially resolved understanding of tumor ecosystems may contribute to precision stratification of patients and the development of novel therapeutic strategies.

#2687 First single slide spatially resolved multiomic integration of pancreatic cancer: High-plex proteomic and whole transcriptome analysis.

Mari-Claire McGuigan[1], Luke McNickle[1], Assya Legrini[1], Ghazal Latifi[1], Claire Kennedy-Dietrich[1], Hannah Morgan[2], Olivia McCabe[3], Fraser Duthie[3], Tengyu Zhang[1], Michail Doukas[4], Andrea Gonzelz Cisar[1], Yoana Doncheva[1], Josefina Martinez Vasquez[1], Yi Cui[5], Sanghamithra korukonda[5], Ashley Heck[5], Kim Young[5], Joanne Edwards[6], Joseph Beechem[5], Nigel Jamieson[1]

[1]Jamieson Spatial Laboratory, The University of Glasgow, Glasgow, United Kingdom,[2]Glasgow Tissue Research Facility, The University of Glasgow, Glasgow, United Kingdom,[3]Department of Pathology, The Queen Elizabeth University Hospital, Glasgow, United Kingdom,[4]Pathology and Clinical Bioinformatics, Erasmus MC, Rotterdam, Netherlands,[5]R&D, Bruker Spatial Biology, Seattle, WA,[6]Translational Cancer Pathology (Edwards Lab), The University of Glasgow, Glasgow, United Kingdom

The increasing prevalence of incidentally diagnosed pre-malignant pancreatic Intraductal Papillary Mucinous Neoplasms (IPMNs), the cost of surveillance and the low rate of progression to cancer, underscores the importance of identifying IPMNs likely to progress to cancer. Currently available imaging and endoscopic tools cannot assess the complexity of IPMNs in their evolution to cancer. Understanding the spatial and molecular heterogeneity of pancreatic pre-malignant lesions is a critical strategy to enhance biological understanding, improve early detection and inform therapeutic strategies.

Spatial transcriptomics offers the ability to robustly profile the spatial molecular landscape of IPMNs; however, cell type heterogeneity poses challenges. A same slide multiomic approach, combining high-plex proteomic and transcriptomic profiling, overcomes the limitations of transcriptionally defined cell type heterogeneity while preserving the exploration of cellular functionality through transcriptomic pathway and gene module analysis.

A 64 plex protein panel followed by a whole transcriptome RNA panel using CosMx SMI (Bruker) was applied to a Tissue Microarray (TMA) of 40 x 1.5mm cores from patients with pancreatic cancer originating in IPMNs from various histological subtypes. Experimental time was 9 days to first visualisation of the data.

From the RNA analysis 340,069 cells were identified with a mean of 1,545 transcripts and 1,157 unique genes per cell. In the protein 416,766 cells were identified, expression analysis demonstrated a mean fluorescence intensity of 16,287. After alignment of the decoded RNA transcripts to the co-ordinates of the protein data there were 412,680 cells across 335 fields of view, enabling multiomic integration within the same tissue regions.

The analysis pipeline incorporated three distinct approaches for cell typing: RNA: 33 clusters RNA & Protein: 28 clusters Protein : 44 clusters

Cell type annotation of the RNA was performed using a hybrid computational-manual approach. The top 20 most highly expressed genes and top 20 most differentially expressed genes per cluster were identified and provided to a large language model (Claude, Anthropic), generating cell types at three levels of granularity.

All annotations were reviewed to ensure consistency with established pancreatic cell type markers.

Proteins were clustered and cell-typed using differential expression analysis. Protein-based cell typing showed enhanced alignment with multiomic cell typing compared to RNA alone, demonstrating the value of multiomic data in validating RNA-based cell type annotations with protein data.

This multiomic approach provides unprecedented resolution of cellular heterogeneity in IPMNs highlighting the complexity the pre-malignant state and establishes a framework for identifying early markers of malignant progression.

#2688 A unified prostate cancer single-cell atlas reveals molecular subtypes and lineage plasticity across disease progression.

Hanbyul Cho, Yuping Zhang, Jiayi Zhou, Rahul Mannan, Saravana M. Dhanasekaran, Xuhong Cao, Arul M. Chinnaiyan

University of Michigan, Ann Arbor, MI

Introduction: Prostate cancer displays extraordinary cellular and molecular heterogeneity in both localized and metastatic disease settings, reflecting the underlying variation in the tumor programs and cellular states that drive this disease.
Methods: To examine this, we built a harmonized single-cell atlas by integrating 17 human prostate scRNA-seq studies (163 samples, 106 donors) representing various disease stages. We reprocessed the raw FASTQ data to reduce pipeline-driven batch effects. Metadata were standardized to a unified schema for donor identity, tissue site, disease state, and histologic grade. Cell type annotation was performed using a cluster-level pseudobulk correlation framework informed by Tabula Sapiens, Human Protein Atlas, and prostate-specific references.
Results: Our uniform workflow yielded ~756,000 high-quality singlets representing various cell types, including ~267,000 epithelial and ~149,000 luminal cells. Data Integration using BBKNN preserved biological structure while effectively merging studies, resolving stromal (SMC, fibroblast subtypes, endothelial, Schwann), immune (T/NK, B/plasma, myeloid), and epithelial (luminal, basal, hillock, club) compartments.
Within the luminal epithelium, we identified transcriptomic molecular subtypes consistent with canonical prostate cancer drivers. Expression-based scoring of ERG/TDRD1 and ETV1/ETV4 distinguished ERG+, ETV+, and ETS- tumor programs, where ETS fusion-positive tumors form distinct transcriptional neighborhoods. Inferred copy-number burden from RNA-based pseudobulks showed increased CNV burden in high-grade primary and metastatic CRPC relative to benign/normal tissue. In metastatic disease, we further resolved three reproducible phenotypic states, which are AR-driven adenocarcinoma, neuroendocrine PCa (NEPC), and double-negative (AR-/NE-) with occasional intra-tumoral coexistence, reflecting lineage plasticity relevant to treatment resistance. Transcriptional signature and module analysis revealed several additional facets of the different prostate cancer subtypes. This atlas establishes a unified framework for interrogating epithelial lineage states, molecular drivers, and tumor microenvironment programs across the clinical spectrum of prostate cancer.

#2689 Single-cell multiome sequencing reveals distinct transcriptional programs associated with ecDNA amplifications in medulloblastoma.

Hui Hui[1], Yan Yuen Lo[2], Jessica Wang[2], Rishaan Kenkre[3], Jon D. Larson[2], Sunita Sridhar[4], Owen Chapman[5], Lukas Chavez[6]

[1]Sanford Burnham Prebys Med. Discovery Inst., La Jolla, CA,[2]Sanford Burnham Prebys Medical Discovery Institute, San Diego, CA,[3]Sanford Childrens Health Research Center, San Diego, CA,[4]Rady Children's Hospital, San Diego, CA,[5]Nagoya City University, Nagoya, Japan,[6]Sanford Burnham Prebys Medical Discovery Institute, La Jolla, CA

Extrachromosomal DNA (ecDNA) is a key driver of intratumoral heterogeneity and has been linked to therapeutic resistance and poor patient outcomes. However, technical limitations in identifying, isolating, and analyzing ecDNA at the single-cell level have hindered our understanding of its role in tumor development and treatment response. We have previously developed a single-cell multiome(RNA + ATAC) sequencing approach that enables the simultaneous analyses of ecDNA and its gene expression profiles. Initial application of this method in a medulloblastoma tumor of the sonic hedgehog subgroup revealed distinct transcriptional signatures in ecDNA-positive compared to ecDNA-negative and non-malignant cells. Building on these findings, we performed multiome single-cell sequencing in an additional cohort of medulloblastoma specimens harboring ecDNA amplifications. Initial analyses revealed distinct functional characteristics between ecDNA-positive and ecDNA-negative tumor cells. For example, ecDNA-positive tumor cells show up-regulation of DNA replication, recombination, and damage repair pathways, while ecDNA-negative cells demonstrated increased expression of synaptic activity, cell signaling, and morphogenesis pathways. Our ongoing analysis focuses on further defining the transcriptional programs that distinguish ecDNA-positive from ecDNA-negative tumor cells, ultimately informing future functional genetic and pharmacological studies targeting transcriptional dependencies in ecDNA-driven medulloblastoma tumors.

#2690 Leveraging linked-reads to predict extrachromosomal DNA in advanced prostate cancer.

Alexander Fortuna[1], Natalie Fredriksson[1], Mital Bhakta[1], Rahul Mannan[2], Fengyun Su[2], Rui Wang[2], Dan Robinson[2], Yi-Mi Wu[2], Xuhong Cao[2], Arul M. Chinnaiyan[2], Lisa Munding[1], J. Zachary Sanborn[1]

[1]Cantata Bio, LLC, Scotts Valley, CA,[2]University of Michigan, Ann Arbor, MI

Prostate cancer is a complex disease that affects millions of men each year. Recent research has revealed that the hormone-dependent nature of prostate cancer stems from the high expression and genetic amplification of the androgen receptor *(AR)* and may be driven by extrachromosomal DNA (ecDNA). Identifying ecDNA from other modes of amplification (e.g. HSR via breakage-fusion-bridge cycles) using whole-genome sequencing (WGS) data remains challenging due to the complexity of copy number and structural variation in cancer. This is compounded in FFPE where this sample type is often at risk of nucleic acid fragmentation, DNA crosslinks, and deamination further complicating variant discovery.

In this study we investigated if structural variants and linkage patterns derived from two Dovetail linked read chemistries, LinkPrep™ (a Tn5-based method compatible with cells and fresh-frozen tissue) and Dovetail®-FFPE (an MNase-HiC-based method compatible with FFPE), could predict the presence of ecDNA. We benchmarked our approach using four cancer cell lines with known ecDNA or HSR, then applied this technique to clinical metastatic castration-resistant prostate cancer (mCRPC) cases stored in FFPE. We generated libraries at ~30x coverage and utilized BWA for alignment, Hi-C breakfinder for structural variants, DeepSomatic for SNV and InDel detection, Purple for CNVs, and an in-house script for ecDNA detection. AmpliconArchitect was used on orthogonal shotgun WGS to predict ecDNA.

By analyzing the long-range linkage from amplicons to elsewhere in the genome, our method correctly identified the presence (or absence) of ecDNAs in all four cell lines and made ecDNA predictions across the samples with *AR* amplicons among the clinical mCRPC FFPE cohort. Two analytical methods were employed to predict ecDNA presence: a novel Z-score-based method that quantifies the observed difference from expected contact distribution across the amplicon (ecDNA 5.7-fold increase vs. HSR) and a log2-ratio test comparing intra- vs. inter-chromosomal amplicon-linked contacts (ecDNA 3-fold increase vs. HSR). Both methods were found to be robust down to 5x coverage. Finally, for samples with suspected integrated amplicon(s), the percentage of all amplicons integrated at each site is estimated through site-specific vs. total amplicon linkage.

In addition to ecDNA prediction, Dovetail libraries detect variants across the full range of oncogenic driver alterations, including SNVs/InDels, copy number, and structural variants. Comparing against a fresh frozen, WGS-derived truth set for the mCRPC cohort, and Dovetail®-FFPE libraries successfully recalled homozygous *PTEN* deletions, *TMPRSS2::ERG* fusions, and oncogenic mutations to *BRCA2*, *TP53,* and *KMT2C* genes. Our findings show that Dovetail libraries provide researchers with a powerful platform for comprehensive genetic variation discovery in both fresh-frozen and FFPE tissues.

#2691 Logic-gated Switch-DARPin-based immune cell engagers guided by data-driven tumor-antigen profiling: A computational workflow for the development of cancer immunotherapies.

Albulena Toska, **Ana Maria Florescu**, Eleni Tselempi, Alexander Link, Martin Steegmaier, Marcela Guzman Ayala

Molecular Partners AG, Schlieren-Zurich, Switzerland

Precise targeting of tumor-associated antigens (TAAs) and understanding of the tumor microenvironment (TME) are essential for the development of effective and safe immunotherapies. However, the lack of highly specific, clean TAAs remains a challenge for targeted immunotherapy of solid tumors. Switch-DARPins are engineered molecules designed to conditionally activate immune cells based on co-expression of a specific combination of TAAs, enabling localized logic-gated tumor-cell killing while minimizing off-tumor toxicity.
To support the rational design of Switch-DARPins, we developed DARPin Compass, a computational workflow that integrates transcriptomic, proteomic, and structural data to identify optimal TAA pairs for dual-targeting strategies. The workflow evaluates TAA prevalence, tissue specificity, and DARPin compatibility, and identifies suitable models for preclinical validation. Additionally, it incorporates machine learning to identify candidate biomarkers for patient stratification and integrates TME profiling (including single-cell [sc] level) to assess antigen expression across TME cell compartments and evaluate therapeutic applicability. Moreover, the workflow identifies existing clinical data of the TAAs.
DARPin Compass enables us to identify clinically actionable TAA pairs and extend the Switch-DARPin concept by including co-stimulatory signals. The workflow thereby supports the development of next-generation multi-specific immune cell engagers for solid tumors with complex antigenic and microenvironmental landscapes. Our first logic-gated Switch-DARPin immune cell engager, a CD3 T cell engager (TCE) with CD2 co-stimulation, was designed to be selectively active against solid tumors which co-express mesothelin (MSLN) and EpCAM (AND-gate). We found that MSLN and EpCAM show low co-expression in healthy tissues, while both TAAs are expressed in >50 % of ovarian cancer (OC) cells from in-house curated scRNAseq patient samples.
Our DARPin Compass results captured the underlying patient heterogeneity and suggested that combinatorial targeting of both, EpCAM and MSLN, may lower the risk of on-target off-tumor toxicity compared to only targeting one of the TAAs. Our initial preclinical data validated this concept of logic-gated preferential tumor-targeting and supports further investigation.
In summary, our DARPin Compass allows to identify potential novel TAAs, profile their expression patterns and assess their safety regarding expression in healthy human cells. Used to develop our first Switch-DARPin TCE for conditional CD3/CD2 activation in OC by targeting MSLN and EpCAM, this workflow is widely applicable to discover and characterize novel TAA pairs for logic-gated immune cell engagers to treat different solid tumors lacking selective single TAAs.

#2692 EpiGuide: Tracking epigenetic plasticity in circulating tumor DNA to monitor tumor progression.

Edoardo Giuili[1], Renske Imschoot[1], Sam Kint[1], Maisa Renata Ferro dos Santos[1], Lotte Cornelli[1], Jef Haerinck[2], Joachim Taminau[2], Kathleen Schoofs[1], Ruben Van Paemel[3], Leander Meuris[4], Sofie Roelandt[1], Robin Van Belle[1], Sofie Van de Velde[1], Eva De Smet[1], Nicolas Debusschere[1], Celine Everaert[1], Geert Berx[5], Katleen De Preter[6]

[1]VIB-UGent Center for Medical Biotechnology, Gent, Belgium,[2]Center for Inflammation Research, VIB-UGent, Gent, Belgium,[3]Department of Biomolecular Medicine, Gent, Belgium,[4]Department of Biochemistry and Microbiology, University of Ghent, Gent, Belgium,[5]Center for Inflammation Research, VIB-UGent, Ghent, Belgium,[6]VIB-UGent Center for Medical Biotechnology, Ghent, Belgium

Cell state transitions such as epithelial-to-mesenchymal plasticity (EMP) play an important role in the progression of triple-negative breast cancer (TNBC) and are strongly associated with therapy resistance. These transitions are hypothesized to be largely regulated by DNA methylation (DNAm) changes, which are retained in tumor-derived plasma cell-free DNA (cfDNA). Therefore, detecting EMP-related DNAm signatures in cfDNA offers a minimally invasive strategy to monitor tumor dynamics in liquid biopsies. However, estimating the tumoral cfDNA EMP fractions is challenging because liquid biopsy samples contain a mixture of cfDNA originating from both cancer and healthy cells.

As a solution, DNAm deconvolution algorithms can be adopted to estimate tumoral cfDNA fractions in liquid biopsy samples. In the last decade a high number of DNAm deconvolution tools have been developed. However, despite the need to identify the most effective deconvolution tools for tumor fraction estimation, no benchmarking study has specifically focused on this task. Therefore, we developed DecoNFlow, an automated Nextflow pipeline including 12 DNAm deconvolution tools and 3 differential methylation analysis tools. This is the most comprehensive pipeline for DNAm deconvolution to date, which allowed us to perform a benchmarking of 12 deconvolution tools using 3.5K in silico mixtures spanning multiple tumor types, sequencing depths, marker-selection strategies and profiling technologies (paper in review). We show that CelFiE is the overall top-performing tool across multiple evaluation criteria.

In a subsequent proof-of-concept study, we assessed EMP monitoring in vivo using the MMTV-PyMT mouse model, which develops TNBC-like tumors which spontaneously undergo EMP. First, several cell lines have been derived from primary tumors of this model and characterized. These cell lines exhibited distinct EMP states (epithelial or mesenchymal) or stably co-existing EMP states. Following orthotopic injection of these cell lines into mice, we performed methylation profiling on both tumors and plasma cfDNA. Tumor EMP state fractions were estimated using CelFiE and a DNAm EMP atlas of MMTV-PyMT tumors as reference, consisting of both single-cell and bulk EMP DNAm markers. We demonstrated that EMP states can be differentially detected in cfDNA, and that mice injected with mixed cell lines show significantly higher tumoral cfDNA fractions than those injected with epithelial-only lines, suggesting that coexistence of multiple EMP states may promote higher tumor burden.

In summary, this study presents a robust analytical and computational pipeline that allows to monitor EMP in a minimally invasive way through cfDNA DNAm analysis. In future, clinical application of this approach is expected to be instrumental for timely identification of cancer patients at risk for therapy resistance through epigenetic plasticity.

#2693 Elucidating the role of specific cancer testis antigens in the progression and development of hepatocellular carcinoma.

Frida Mariana Delgadillo[1], Barbara Yang[1], Sabrina Stogoski[1], Shrikanth S. Gadad[2], Enrique I. Ramos[1]

[1]The University of Texas at El Paso, El Paso, TX,[2]The University of Texas Rio Grande Valley, McAllen, TX

Hepatocellular carcinoma (HCC) is a primary type of liver cancer and the third leading cause of cancer-related deaths. Non-resolving liver inflammation caused by a variety of etiological factors, such as viral hepatitis infections or alcohol abuse, initiates the transition from fibrosis to cirrhosis, and finally to cancer. Due to poor late-stage survival rates, novel biomarkers and therapeutic targets are desperately needed to improve HCC patient outcomes. Potential candidates include a group of Cancer Testes Antigens (CTAs), a large group of tumor-associated antigens expressed in multiple tumor types. The melanoma-associated antigen (MAGE) subfamily of CTAs is overexpressed in HCC tumors and may drive tumor progression and tumorigenesis. However, little is known about the expression patterns of these CTAs in the multiple precursor liver diseases that contribute to HCC development, such as chronic hepatitis or cirrhosis. Furthermore, the mechanisms regulating the expression of these members in liver tissue prior to and following metastatic development have not been fully elucidated. Initial Enzyme-Linked Immunosorbent Assay (ELISA) results have demonstrated an autoimmune response to these proteins as tumor-associated antigens in serum from patients with precursor liver conditions. Using computational approaches, we have evaluated the expression patterns of these CTAs in publicly available liver disease transcriptomic datasets. The analyzed samples were stratified by disease etiology to provide a comprehensive view of the spectrum of the transition from healthy to diseased liver. Wet-lab approaches, including Immunohistochemistry (IHC), were employed to validate these responses at the protein level. Our findings indicate that MAGE subfamily CTAs are potential biomarkers of HCC development, with the activation of individual members varying during the transition from diseased liver to cancer. By elucidating the molecular mechanisms and pathways by which HCC-specific CTAs function, we will be able to develop them as diagnostic markers and therapeutic targets.

#2694 Dissecting the mechanisms of drug resistance development post neoadjuvant osimertinib treatment in EGFR-mutant non-small lung cancer.

Su-Jin Choi[1], Jii Bum Lee[2], Hyuk Jee[3], Hyo Sup Shim[4], Byung Jo Park[5], Chang Young Lee[5], Min Hee Hong[2], Byoung Chul Cho[6], Sun Min Lim[2]

[1]Dept. of Research Support, Yonsei Biomedical Research Institute, Yonsei University College of Medicine, Seoul, Korea, Republic of,[2]Division of Medical Oncology, Department of Internal Medicine and Yonsei Cancer Center, Severance Ho, Yonsei University College of Medicine, Seoul, Korea, Republic of,[3]DAAN Biotherapeutics, Seoul, Korea, Republic of,[4]Department of Pathology, Yonsei University College of Medicine, Seoul, Korea, Republic of,[5]Department of Thoracic and Cardiovascular Surgery, Yonsei University College of Medicine, Seoul, Korea, Republic of,[6]Division of Medical Oncology, Department of Internal Medicine and Yonsei Cancer Center, Yonsei University College of Medicine, Seoul, Korea, Republic of

Introduction: Despite treatment with osimertinib in *EGFR*-mutant non-small cell lung cancer (NSCLC), drug-tolerant persisters (DTPs) survive through reversible adaptations. Early intervention may be an effective strategy to delay or prevent the emergence of acquired resistance to osimertinib. In this study, we characterized DTPs that survived neoadjuvant osimertinib treatment *via* single-cell RNA sequencing, and identified DTPs at an early transition stage before they acquire resistance.
Methods: Neoadjuvant osimertinib was administered daily for two 28-day cycles followed by surgical resection and adjuvant osimertinib for 3 years. We performed single-cell RNA sequencing on matched pre- and post- treatment samples from 17 patients with NSCLC harboring *EGFR* mutations (E19del, N=7; L858R, N=10). The analysis was performed based on the Python Scanpy package.
Results: Tumor epithelial cells were divided into 11 subclusters. Based on the increase in modules, signatures, and regulon activity, we subclustered and annotated them accordingly. High DTP features included the Multi Adaptive, EMT, Immune Evasion, ERS/UPR, Cycling, AT1, and Hyper Ciliated clusters. The AT2, Chromatin Accessible, Intermediate, and Detox Ciliated clusters exhibited weak DTP features. After neoadjuvant osimertinib, the proportion of Multi Adaptive, ERS/UPR, and EMT clusters were significantly increased. The Multi Adaptive cluster had the highest DTP signature whereas the Immune Evasion cluster expressed genes known for recruiting immunosuppressive cells. The ERS/UPR cluster showed increase in *XBP1* regulon activity as well as endoplasmic reticulum stress and unfolded protein response signature. The Cycling cluster was characterized by increased activity of *E2F* regulons with upregulated proliferation genes. The AT1 cluster had strong *Wnt* signaling and increased *TEAD4* regulon activity. The Hyper Ciliated cluster showed increased expression of ciliogenesis genes. Trajectory analysis revealed that EMT, Immune Evasion, Cycling, and AT1 clusters which commonly express alveolar markers, originated from AT2 and then diverge into three lineages at the Intermediate cluster. Association analysis of gene expression with pseudotime revealed that type I interferon and TGFβ pathways were significantly augmented in all lineages.
Conclusion: Our analysis shows the diversity and heterogeneity of the DTPs population and the evolutionary trajectories of DTPs after neoadjuvant osimertinib treatment in *EGFR*-mutant NSCLC. Targeting these DTPs features may potentially be applied for development of novel therapeutic strategies to overcome resistance to osimertinib.

#2695 HELP-TCR: A harmonized and explainable language processing framework for functional analysis of t-cell receptor repertoires.

Yulyana Kalesnik[1], Dawid Krawczyk[2], **Maciej Pietrzak**[3], Michal Seweryn[4]

[1]Centre for Digital Biology and Biomedical Sciences, Faculty of Biology and Environmental Protection, University of Lodz, Lodz, Poland,[2]University of Lodz Doctoral School of Exact and Natural Sciences, University of Lodz, Lodz, Poland,[3]Department of Biomedical Informatics, The Ohio State University, Columbus, OH,[4]Regional Digital Medicine Center, Copernicus Memorial Hospital and University of Lodz, Lodz, Poland

T cells are essential contributors to anti-tumor immunity, but identifying the specific T-cell receptor (TCR) features that differentiate tumor-reactive responses from background immune activity remain difficult to resolve. Tumors reshape TCR repertoires through neoantigen exposure, chronic stimulation, and immune escape, creating patterns that are biologically relevant not easily quantified with existing computational methods. Current approaches either rely on global repertoire summaries or on deep learning models with limited interpretability, which restricts their translational and clinical applications.To address this gap, we developed HELP-TCR, an explainable machine learning framework that applies concepts from natural language processing to the functional analysis of tumor-associated TCR repertoires. HELP-TCR represents TCR repertoires by the position-specific distributions of features (single amino acids and/or amino acid pairs), transforming sequences into tensor structures. To increase reproducibility, we adapt the principles of ensemble learning and proposed a series of preprocessing steps, among which a consensus grouping method is applied to merge the features with highly similar position-wise distributions opening the venue for explainable dimension reduction. A modified (to the dimensionality of the task) deep learning architecture enables accurate classification, while post-hoc analysis based on saliency map highlights the most informative features contributing to model predictions.Using a dataset of TCR sequences from non–small cell lung cancer, HELP-TCR demonstrated stable and high predictive performance (AUC ~0.96), outperforming DeepTCR (AUC 0.76) and TCR-BERT embeddings, which showed limited class separability. Post-hoc saliency analysis identified positional amino acid motifs and residue-pair interactions that contributed to tumor–normal discrimination, offering mechanistic insights potentially reflecting tumor reactivity, immune pressure, or clonal remodeling within the tumor microenvironment.HELP-TCR offers an interpretable and reproducible framework for analyzing tumor-associated TCR repertoires in settings where sequence-level information is relevant. Its representations align with emerging clinical applications of TCR profiling, such as assessing of response to immunotherapy, identification of neoantigen-reactive or tumor-enriched clonotypes and studying of immune dynamics within the tumor tissue. HELP-TCR provides a practical foundation for generating testable hypotheses and advancing translational efforts aimed at improving patient stratification and informing T-cell–based therapeutic strategies.

#2696 Unlocking novel gene-based biomarkers using an explainable deep learning framework for precision oncology.

Sydney Grant, Aritro Nath

City of Hope Comprehensive Cancer Ctr., Duarte, CA

Somatic genomic alterations are widely profiled in cancer and remain the primary indicator for personalized therapy, yet their clinical utility is limited to a small set of actionable targets benefiting only a fraction of patients. AI/ML offers a transformative path to precision oncology by leveraging large-scale genomic data, but poor interpretability, often reduced to single-gene insights, limits clinical adoption and overlooks cancer's biological complexity. We address this gap with a novel framework combining PhenoMap and PhenoSurv. PhenoMap converts gene-level alterations into a phenotypic feature map using over 9,000 pan-cancer genomes and transcriptomes, trained to emulate enrichment scores for 6,000+ pathways from MSigDB using a combined LASSO-Random Forest approach. This map serves as input to PhenoSurv, a variational autoencoder designed to predict disease-free survival. PhenoSurv employs an innovative architecture that distinctly embeds eleven phenotypes and optimizes reconstruction loss, Kullback-Leibler divergence, and Cox survival loss on the latent space. This yields survival-relevant latent features, enabling discovery of multi-phenotypic vulnerabilities and prognostic biomarkers, which we tested and validated in breast, lung, and brain cancer. PhenoMap pathways that exceeded baseline performance in internal and external validation included 3,382 for lung, 3,772 for brain, and 4,188 for breast cancer. Clustering by PhenoMap scores revealed patient subsets with shared dominant signaling pathways. Notably, PI3K and KRAS signaling-enriched clusters included patients lacking PIK3CA (54%) or KRAS (67%) mutations in breast and lung cancer, respectively, indicating PhenoMap identifies broader cohorts for targeted therapy beyond single-gene biomarkers. PhenoSurv outperformed existing AI/ML models for survival prediction across cancer types while providing multilevel explainability at phenotype, pathway, and gene levels. Using DeepSHAP, we identified key pathways driving predictions across cohorts. Over 50 pathway-level biomarkers showed significant survival differences between high- and low-signaling groups, including NOTCH1 signaling in breast cancer (TCGA: $p = 0.0098$; MSK: $p = 0.003$), the CLEC7A inflammasome pathway in lung (TCGA: $p = 0.0045$; MSK: $p = 0.041$), and inositol phosphate metabolism in brain cancer (both $p < 0.0001$). Survival declined progressively with the number of poor prognostic markers across cancer types. PhenoMap and PhenoSurv bridge a critical gap in precision oncology by delivering interpretable models based on clinical genomic data that reveal clinically actionable biomarkers. These mechanism-based insights enable biologically informed patient stratification, paving the way for more effective personalized treatment strategies.

#2697 Single-cell transcriptomic characterisation reveals pathway determinants of bipolar androgen therapy response in prostate cancer.

Rosalia Quezada Urban[1], Shivakumar Keerthikumar[2], Peter Lau[3], Georgia Cuffe[1], Linda Teng[1], Ashlee K. Clark[4], Gail P. Risbridger[5], Renea A. Taylor[4], Megan Crumbaker[6], ANTHONY JOSHUA[7], Mitchell G. Lawrence[5]

[1]Monash University, Clayton, Victoria, Australia,[2]Peter MacCallum Cancer Centre, Melbourne, Australia,[3]AGRF, Melbourne, Australia,[4]Monash University, Melbourne, Australia,[5]Monash University, Clayton, Australia,[6]Garvan Institute, Sydney, Australia,[7]St Vincents Health Australia, Melbourne, Australia

Purpose: Bipolar androgen therapy (BAT), which alternates between castrate and supraphysiological testosterone levels, represents a promising alternative to continuous androgen suppression in advanced prostate cancer. However, only a subset of patients' tumours respond. Using patient-derived models of metastatic castration-resistant prostate cancer, we aimed to identify molecular programs distinguishing BAT responders from non-responders using single-cell transcriptomics.
Experimental Procedures: We profiled over 60,000 cells from four patient-derived xenografts (PDXs) using the 10x Genomics single-cell RNA-seq platform. Mouse reads were removed with Xenocell, leaving approximately 40,000 human prostate cancer cells for downstream analysis. Samples included two complete responders, one partial responder, and one non-responder, all evaluated 24 hours after BAT exposure, with responders also assessed at a long-term (6-week) timepoint. Differential expression and gene set enrichment (GSEA) analyses were performed using Hallmark, KEGG, and Gene Ontology collections.
Results: BAT triggered robust androgen-responsive transcriptional reprogramming across models, yet the scale and persistence of pathway activation differed by response category. GSEA revealed that responders exhibited suppression of MYC target genes and stress-response pathways, alongside upregulation of metabolic and differentiation programs, including oxidative phosphorylation, cholesterol homeostasis, and cell adhesion. In contrast, the non-responder maintained MYC activation with enrichment of inflammatory, epithelial-mesenchymal transition (EMT), and cell-cycle pathways, suggesting incomplete androgen pathway re-engagement. Over time, complete responders showed reduced proliferative signalling, consistent with stable treatment adaptation.
Conclusions: Our single-cell transcriptomic analyses delineate molecular signatures underlying BAT sensitivity and resistance. MYC activity and inflammatory remodelling emerge as potential drivers of resistance, whereas metabolic and differentiation programs define durable response. These insights provide a foundation for identifying biomarkers and designing rational combination strategies to enhance BAT efficacy.

#2698 MicroRNA expression can detect canine multicentric lymphoma in golden retrievers in serum samples taken pre-diagnosis.

Heather Treleaven[1], Latasha Ludwig[2], Alicia M. Viloria-Petit[3], R. Darren Wood[1], R. Ayesha Ali[4], Geoffrey Wood[1]

[1]Department of Pathobiology, Ontario Veterinary College, University of Guelph, Guelph, ON, Canada,[2]Department of Population Medicine and Diagnostic Sciences, College of Veterinary Medicine, Cornell University, Ithaca, NY,[3]Department of Biomedical Sciences, Ontario Veterinary College, University of Guelph, Guelph, ON, Canada,[4]Department of Mathematics and Statistics, University of Guelph, Guelph, ON, Canada

Canine lymphoma (cL) is one of the most common cancers in dogs, accounting for an estimated 24% of all canine malignancies. Multicentric cL (m-cL) represents 85% of all cL cases and shares many characteristics with human non-Hodgkin's lymphoma (hNHL). Due to these similarities as well as shorter overall lifespans, shared environments, and more homogenous genetics found in purebred dogs, m-cL is a valuable spontaneous animal model for hNHL. Prognosis for m-cL is quite variable, primarily depending on immunophenotype (T or B cell origin) and stage, and has median survival times ranging from 6-12 months after CHOP chemotherapy. Unfortunately, dogs aren't often diagnosed until they have late-stage disease, and relapse following chemotherapy is very common. A biomarker for early diagnosis could help identify patients when their disease is at an earlier stage, leading to better treatment responses and longer survival times. Potential biomarkers for early detection include microRNAs (miRNAs), which are small, non-coding pieces of RNA that control gene expression and are readily isolated from blood. These molecules are dysregulated in several types of cancer, and their sequences are nearly or entirely identical between dogs and humans. This makes them good non-invasive biomarkers with cross-species applications. Given the growing body of literature showing differential expression of miRNAs at the time of diagnosis, we sought to investigate whether any of these miRNAs could detect m-cL patients in samples taken prior to the onset of clinical symptoms and diagnosis. MiRNA expression was measured by real-time quantitative PCR in serum samples from 46 m-cL dogs and 40 control dogs enrolled in the Golden Retriever Lifetime Study. Each dog had a minimum of 3 samples, taken at roughly 1-year intervals for their whole lives. For the m-cL dogs, the samples were taken anywhere from 3 weeks to 5 years prior to diagnosis, with some having a 4^{th} sample taken at the time of diagnosis. We trained 5-fold cross-validated logistic regression models to classify samples as either m-cL or controls on 2 different training data splits. The first used only the samples from each m-cL dog taken between 3 weeks and 1-year pre-diagnosis, as we anticipated this range to be the most predictive of early disease. The second model included a random selection of 2 samples from each m-cL dog, resulting in a mixed-time population. We did this to examine the differences in miRNA selection and performance when the training populations were more or less homogenous, with respect to sampling time. As m-cL has a variety of subtypes, we also repeated our analyses using only the B-cell (n=15) or T-cell (n=26) immunophenotyped patients. We achieved accuracies between 65-88% across the training sets with similar miRNAs included in all models. With further testing, miRNAs offer potential for early diagnosis in both veterinary and human patients.

#2699 Accumulation of somatic mutation and clonal architecture of fallopian tube epithelium.

Seoyihl Kim[1], Wonjune Seo[2], Soyeon Kim[3], Taekeun Park[4], Miso Kim[4], Bhumsuk Keam[5], Tae Min Kim[5], Dong-Wan Kim[5], Se Ik Kim[6], Jeonghwan Youk[4]

[1]Cancer Research Institute, Integrated Major in Innovative Medical Science, Seoul National University College of Medicine, Seoul, Korea, Republic of,[2]Cancer Research Institute, Seoul National University College of Medicine, Seoul, Korea, Republic of,[3]Cancer Research Institute, Biomedical Research Institute, Seoul National University Hospital, Seoul National University College of Medicine, Seoul, Korea, Republic of,[4]Cancer Research Institute, Seoul National University Hospital, Seoul National University College of Medicine, Seoul, Korea, Republic of,[5]Cancer Research Institute, Integrated Major in Innovative Medical Science, Seoul National University Hospital, Seoul National University College of Medicine, Seoul, Korea, Republic of,[6]Department of Obstetrics and Gynecology, Seoul National University College of Medicine, Seoul, Korea, Republic of

Background: High-grade serous ovarian carcinoma (HGSOC) is the most common subtype of epithelial ovarian cancer, characterized by somatic *TP53* mutations (≈ 96 %) and by germline or somatic *BRCA1/2* mutations in 15~20 % of cases. Mounting evidence suggests that the fallopian tube fimbria, rather than the ovary, serves as the predominant cell-of-origin for the majority of HGSOC. Despite this evidence, a direct genomic comparison between ampullary and fimbrial epithelia has been lacking. Although somatic mutations accumulate gradually, it remains poorly defined due to challenges in reconstructing clonal lineages how these processes shape clonal architecture in normal fallopian tube epithelium.

Methods: Fallopian tube epithelial organoids were derived from surgically resected tissues and cultured in 3D matrigel. We established single cell-derived clonal organoids from anatomically distinct fallopian tube epithelial regions (ampulla and fimbria) obtained from *BRCA1/2* germline mutation carriers (*BRCA1* n=3; *BRCA2* n=1) and one *BRCA* wild-type individual. Low-input DNA libraries were sequenced on the Illumina NovaSeqX (~15×) to identify somatic single-base substitutions (SBS), small insertions and deletions (indels), and structural variants (SVs), followed by mutational signature extraction and phylogenetic reconstruction to reveal clonal expansion dynamics.

Results: Across the five patients analyzed, somatic mutation burden showed only a weak and statistically imprecise correlation with age, with point estimates indicating annual increases of 7.12 SBS (95% CI, -9.6 to 23.9) and 0.04 indels (95% CI, -2.65 to 2.73). Total SBS and indels burdens were comparable between ampullary and fimbrial organoids and largely unrelated to germline *BRCA1/2* status, parity, or menopausal age, although these null associations should be interpreted cautiously given the limited sample size. No SVs were detected in either region. *BRCA1/2* germline carriers did not exhibit HRD-associated signatures, suggesting absence of somatic-level haploinsufficiency in normal epithelium. Phylogenetic analyses identified region-specific clonal dynamics: fimbrial organoids frequently showed late clonal expansion events emerging during adolescence or later. Cancer-related variants (e.g., *TP53, MET, CSMD3*) were detected in both regions, though additional clonally expanded samples will be required to evaluate region-specific enrichment.

Conclusions: Somatic mutations accumulate with age in the fallopian tube epithelium, but *BRCA* haploinsufficiency alone does not confer homologous recombination deficiency. Region-specific late clonal expansion in the fimbria, potentially influenced by its constrained, finger-like architecture, may underlie the disproportionately higher incidence of HGSOC originating from this anatomical site. Ongoing sample expansion is underway to refine evolutionary models.

#2700 SpaceMarkers 2.0: A framework for spatially aware cell-cell communication in spatial transcriptomic data.

Orian Stapleton[1], Dmitrijs Lvovs[2], Luciane Tsukamoto Kagohara[1], Elana Judith Fertig[2], Atul Deshpande[1]

[1]Johns Hopkins University, Baltimore, MD,[2]University of Maryland School of Medicine, Baltimore, MD

Background: One key limitation of single cell RNA-sequencing (scRNA-seq) is the loss of spatial resolution due to the dissociation of cells from their tissue. Despite this limitation, current computational approaches infer cell-cell interactions from scRNA-seq and often generalize findings to the tissue context. SpaceMarkers was developed to infer cell-cell communication directly in-situ using 10x Visium. SpaceMarkers 2.0 is extended to leverage both Visium and VisiumHD datasets, as illustrated using samples from colorectal cancer (CRC) patient tumor and normal adjacent tissue.

Method: SpaceMarkers uses spatially varying features as proxies for cellular activity and applies kernel-based smoothing to represent the ‘influence’ from cell populations in their vicinity. We hypothesize that two cell states interact in regions where their cellular weights and influence overlap. A Gaussian mixture model is used to separate background from enriched values to quantify ‘hotspots’ within a given tissue. Previously, SpaceMarkers inferred molecular changes due to cell-cell communication for individual genes in the transcriptome. Here, we added the ability to incorporate prior knowledge of ligand-receptors (LR) in pairs of interacting cell populations by computing ligand overexpression within a cell population under the influence of a spatially overlapping population. We also estimate receptor scores from statistical tests to identify cell type-specificity for each receptor. SpaceMarkers calculates an aggregated LR score based on the geometric mean of the ligand and receptor score enriched in the tissue-defined interaction region. We extend this by computing per-sample and grouped condition hotspot overlaps as well as applying rank statistics to identify molecular programs between cancer and normal tissue.

Results: SpaceMarkers 2.0 identified spatial hotspots where normal samples were enriched for plasma to epithelial cell signaling programs while tumor samples were enriched for stromal and plasma cell interactions. At the plasma-stromal boundary we observed a tumor specific enrichment of fibroblast growth factor (FGF) ligand signaling from plasma cells to stromal cells, with FGF23 emerging as a dominant ligand engaging FGFR4 and FGFR3 on stromal cells.

Conclusion: In CRC Visium and Visium HD datasets, this framework delineates tumor specific interaction boundaries and resolves which cell states drive LR axes in-situ across patients. Beyond CRC, the SpaceMarkers framework can be applied to additional solid tumors, enabling comparisons in cohorts of samples in matched conditions or longitudinal sampling of carcinogenesis. Overall, SpaceMarkers 2.0 proposes a central framework for leveraging spatial information and multi-sample modeling for interpreting cellular communication in the tumor microenvironment.

#2701 A transcriptomic framework to predict response and prioritize indications for p53 restoration therapy.

Hosun Lee, Seunghwan Jung, Boram Kim, Seung-Hyun Shin, Yong Ho Heo, Yu-Yon Kim, Daejin Kim, Haemin Chon, In Young Choi

Hanmi R&D Center, Hanmi Pharm. Co. Ltd., Gyeonggi-do, Korea, Republic of

Introduction: TP53 has been recognized as a promising therapeutic target because of its pivotal role in tumor suppression and the high prevalence of its functional alterations in cancer. However, sensitivity to p53 restoration varies markedly across cancer cell lines and is not determined solely by the presence or absence of intact p53. These findings suggest that additional, pathway-level factors may modulate responsiveness to p53 reactivation. In this study, focusing on p53 restoration therapy, we aimed to (1) elucidate molecular mechanism underlying variable responses, (2) build a transcriptomic prediction model capable of estimating restoration sensitivity, and (3) apply this framework to prioritize clinical indications across tumor types.
Methods: In vitro results of p53 restoration were curated from 28 cell lines (20 sensitive [S], 8 resistant [R]). Transcriptomic differences between S and R were evaluated by Gene set enrichment analysis (GSEA) and gene set variation analysis (GSVA) using p53-related gene sets from MSigDB. RNA expression data were normalized by Non-paranormal (NPN) transformation, and singscore values were computed to quantify pathway activity. A logistic regression model was trained to estimate the probability of S or R classification, with the cutoff (specificity ≥0.9) stabilized through bootstrap resampling and fixed at the median. External datasets - CCLE, TCGA, cBioPortal, and GEO (GSE271757, GSE223463, GSE169321) - were analyzed to explore appropriate clinical indications.
Results: GSEA revealed a distinct downregulation of DNA elongation and Mismatch repair pathways in the S group, indicating reduced baseline DNA repair activity in S cells. Among gene sets tested, Signature A, achieved the strongest discriminatory power between S and R (PR AUC = 0.754). For indication prioritization, integrative analysis combining Signature A-based predictions from CCLE and TCGA, together with TP53 alteration prevalence from cBioPortal, identified lung, head and neck, ovarian cancers as Tier 1 indications. By investigating the biological nature of Signature A, we observed that DNA-damaging therapies may enhance p53 restoration sensitivity. Consistently, analysis of GEO cohorts with pre- and post-treatment RNA-seq data revealed an increased fraction of S from 52% to 96% in ovarian cancer, and 85% to 92% in pancreatic cancer following DNA-damaging therapy.
Conclusion: Signature A, a transcriptomic signature, stratifies p53 restoration responsiveness across cancer types and provides a robust, reproducible framework for indication prioritization and for understanding the mechanistic context of p53 restoration during the patient treatment journey.

#2702 Integrative Computational Pipeline for Tracking Neoantigen Retention Across PDX Passages in Genitourinary Cancers.

Md Imran Khan[1], Tyler Gross[1], Christian Migliarese[2], Ian Shea[3], Jonathan F. Lovell[4], Roberto Pili[3]

[1]Genetics, Genomics and Bioinformatics, University at Buffalo, State University of New York, Buffalo, NY,[2]Pathology and Anatomical Sciences, University at Buffalo, State University of New York, Buffalo, NY,[3]Medicine, University at Buffalo, State University of New York, Buffalo, NY,[4]Biomedical Engineering, University at Buffalo, State University of New York, Buffalo, NY

Cancer neoantigens are highly attractive targets for personalized immunotherapies because they are uniquely expressed on tumor cells and absent from normal tissues. However, validating predicted neoantigens—through immunogenicity testing, HLA characterization, and expression analysis—is often limited by the small amount of tumor tissue obtainable in clinical settings. Patient-derived xenograft (PDX) models therefore serve as valuable systems for expanding tumor material and studying tumor evolution, yet the extent to which PDX models retain patient-specific neoantigens across passages remains insufficiently characterized. In this pilot study, we analyzed neoantigen prediction and retention in five (n=8) genitourinary tumors and their matched PDX passages using paired whole-exome sequencing (WES) and RNA-seq data from the NCI Patient-Derived Models Repository (PDMR). We implemented a reproducible, semi-automated Nextflow workflow combining nf-core pipelines for tumor-normal variant calling (sarek), HLA class I typing (hlatyping), transcript quantification (rnaseq), and in silico HLA-peptide binding prediction (epitopeprediction). Variant clonality was assessed with PureCN, and downstream analyses prioritized expressed, nonsynonymous variants with predicted HLA-binding affinity. Primary tumors contained 14-156 candidate neoantigens per patient. Retention in derived PDX models was generally high: initial engraftment (P0) preserved 50-89% of primary tumor neoantigens, and later passages maintained 46-95%. Although some neoantigens were lost during engraftment or propagation, most remained stable over serial passages, indicating preservation of key features of the tumor-specific immunogenic landscape. By the time of presentation, this analysis will be expanded beyond the initial five cases to include a larger PDMR cohort of genitourinary cancers. We will also incorporate our own PDX and CDX datasets to evaluate neoantigen retention or divergence across passages in an independent system. Together, these results will provide a broader assessment of neoantigen stability in patient-derived models and support the identification of robust, persistent neoantigens for personalized vaccine development.

#2703 PTMax: An AI-enabled platform integrating literature mining and multi-omics for functional interpretation of phosphorylation in cancer.

Yanling Sun, Sara S. Savage, John M. Elizarraras, Eric Jaehnig, Bing Zhang

Lester and Sue Smith Breast Center, Baylor College of Medicine, Houston, TX

Phosphorylation is a central regulator of protein function and oncogenic signaling, and advances in mass spectrometry now enable unbiased, proteome-wide identification of cancer-associated phosphosites. However, the functional relevance of most sites remains poorly understood and scattered across the literature.To address this gap, we developed PTMax, an AI-enabled resource that integrates comprehensive literature mining with systematic multi-omics data to advance functional interpretation of phosphorylation in cancer.To standardize phosphosite information reported across published studies, we enhanced our literature-mining pipeline to efficiently extract site-level evidence and associated functional information from full-text articles and pathway figures. Evidence aggregated from these sources was used to generate functional summaries, which were evaluated through both automated and manual quality assessments. PTMax additionally incorporates dozens of mass spectrometry-based phosphoproteomics datasets and multi-omics data from CPTAC cancer cohorts, including RNA, protein, phosphosite abundance, and phenotype associations. For each phosphosite, we computed two evidence scores that quantify literature-derived information richness and data-driven support, respectively. We also constructed signature sets that group phosphosites by cancer hallmarks, co-mentioned genes or diseases, and pathway figure associations, and generated a co-regulated phosphorylation network to facilitate pathway- and network-level interpretation.PTMax currently contains more than 40,000 literature-derived phosphosites extracted from over 500,000 sentences and 1,400 pathway figures, capturing ~70% of low-throughput-validated and ~80% of regulatory-annotated phosphosites in PhosphoSitePlus. Notably, over 30,000 sites lack prior regulatory evidence, underscoring the value of AI-driven literature mining. Integration with multi-omics resources adds ~200,000 unique phosphosites, including 65,000 sites with quantitative associations and 26,000 linked to cancer phenotypes. The PTMax interface enables users to query individual genes or phosphosites and retrieve comprehensive, context-rich information together with user-friendly visualizations. In addition, pathway and network-based analysis modules help translate phosphosite lists into functional and signaling insights. In summary, PTMax unifies literature and figure mining with large-scale experimental datasets to deliver a comprehensive, multi-dimensional resource that advances the functional study of phosphorylation in cancer.

#2704 NCI's childhood cancer data initiative: Advancing pediatric cancer research.

Subhashini Jagu, Jaime Guidry Auvil, Mark Cunningham, Bahar Sayoldin, Patrick Dunn, Sean Burke, Catherine Bullen, Hayley Dingerdissen, Rebecca Steck, Martin Ferguson, Johanna Lucinda Goderre, Gregory Reaman, Warren A. Kibbe

National Cancer Institute, Rockville, MD

The Childhood Cancer Data Initiative (CCDI) is a transformative effort to accelerate research and improve outcomes for children, adolescents, and young adults (AYAs) with cancer. Data are the cornerstone of cancer research, and CCDI is building a FAIR-aligned data ecosystem that functions as a multi-stakeholder interoperability platform, integrating diverse tools and services to advance pediatric cancer research. All CCDI tools and resources are accessible through the CCDI Hub, the central entry point to the ecosystem. The foundation begins with the CCDI data model, which establishes harmonized data standards to ensure consistency and interoperability across data sets, offering a framework for discovery and analysis.

Building Cohorts: The CCDI Childhood Cancer Data Catalog serves as a comprehensive inventory of pediatric and AYA cancer data resources, including registries, repositories, knowledgebases, and catalogs. It provides study-level summaries and helps users identify where specific data types and studies are located. Once users identify studies of interest, they can move to the CCDI Hub Explore Dashboard to search CCDI data sets. The dashboard indexes data at the file level to facilitate cohort building. Users can build cohorts within the Childhood Cancer Data Commons (C3DC) using clinical data, or within the National Childhood Cancer Registry (NCCR) using real-world data. Cohorts built in C3DC can be exported as manifests containing participant identifiers, which can then be uploaded to the CCDI Hub to locate associated genomic, imaging, or other data. Similarly, users can export cohorts to NCCR to access related real-world data. For cross-institutional discovery, users can query pediatric data sets across participating repositories using the CCDI Federation API, as if querying a single virtual database.All of these resources are interconnected through the CCDI Participant Index, which maps participant identifiers across studies and repositories and allows researchers to connect data from the same participant, supporting data integration and cohort expansion.

Analysis and Visualization: After cohorts are built, researchers can leverage integrated analysis and visualization platforms to further explore, interpret, and derive insights from the data. The Cancer Genomics Cloud provides a cloud-based computational environment where researchers can analyze data using custom workflows and advanced analytical tools. To make data accessible to clinicians and non-bioinformaticians, CCDI offers intuitive visualization platforms like the CCDI cBioPortal Cancer Data Explorer. Together, CCDI's many tools and resources, integrating data from thousands of participants, enable new insights that would not be possible when studied in isolation.

#2708 Revealing fibroblast-mediated impacts to therapy response through spatially resolved drug response prediction in lung cancer.

Robert F. Gruener[1], Weijie Zhang[2], Lilin Wang[2], Adam M. Lee[2], R. Stephanie Huang[3]

[1]University of Minnesota, College of Pharmacy, Minneapolis, MN,[2]University of Minnesota, Minneapolis, MN,[3]Asst. Professor, Dept. of Medicine, University of Minnesota, Minneapolis, MN

The tumor microenvironment (TME) can profoundly impact both the biology and drug sensitivity of surrounding cancer cells. There is currently no way to comprehensively evaluate the impact these interactions have on drug response across multitudes of drugs and patients. In this work, we developed a computational drug prediction approach to interrogate the effects of the TME on cancer drug response, identified fibroblast-mediated drug response associations in non-small cell lung cancer (NSCLC) patients, and validated these associations in co-culture models.

Our approach leveraged information rich single-cell *in situ* RNA sequencing data combined with our previously established single-cell drug response prediction models (scIDUC). We obtained two independent NSCLC datasets - one sequenced using NanoString CosMx (n=8 slides) and the other sequenced using 10X Xenium (n=4 slides). Given cancer-associated fibroblasts (CAFs) make up the majority of the TME and are known to impact drug response for select agents, our primary focus was to examine the influence of local fibroblast density on the drug response of cancer cells. To this end, we identified CAF-drug associations for each patient individually, aggregated the results across patients and nominated consistent findings for validation.

We used spatial windows of 100-nearest-neighbor and quantified the surrounding fibroblast density of every tumor cell. We applied scIDUC, which integrates the single-cell expression profiles with DepMap bulk expression and drug screening data to project drug response. Within each slide, we performed 100 bootstrap iterations of balanced random sampling of CAF-high and CAF-low tumor cells, predicted drug sensitivity for every tumor cell (independently for each of the 493 drugs response models), and then correlated predicted response with continuous fibroblast density. The results were then aggregated across the 100 bootstrap sampling. We observed drug-specific patterns where cancer cells were predicted to be made more sensitive, more resistant, or unchanged with increased fibroblast density. Among the most consistent results across patients were CAF-induced resistance to the HER2 inhibitor lapatinib and 5-fluorouracil as well as CAF-induced sensitization to the BRAF inhibitor dabrafenib. Experimental coculture assays using NSCLC lines (Calu-3, A549) and IMR-90 fibroblasts confirmed the predicted CAF-mediated resistance to lapatinib and 5-FU and CAF-mediated sensitization to dabrafenib.

This work demonstrates a scalable approach for generating therapeutic hypotheses directly from spatial single-cell data and reveals drug-specific, microenvironment-dependent sensitivities that may inform precision treatment strategies and guide functional investigation of tumor-stroma interactions.

#2709 PRECISE: A prognostic thyroid follicular cell-derived gene signature for papillary thyroid carcinoma.

Sophie Li[1], Chia C. Wu[1], Vicente R. Marczyk[1], Matthew A. Loberg[2], Aatish Thennavan[3], Maxime Tarabichi[4], Li Xu[1], Ying C. Henderson[1], Tuan M. Tran[3], Quanhu Sheng[5], George J. Xu[2], Eric C. Huang[6], Marie-Claude Hofmann[7], Xiao Zhao[1], Stephen Y. Lai[1], Michelle D. Williams[8], Wenyi Wang[9], Sarah Hamidi[7], Mark E. Zafereo[1], Maria E. Cabanillas[7], Nicholas E. Navin[3], Vivian L. Weiss[2], **Jennifer R. Wang**[1]

[1]Department of Head and Neck Surgery, The University of Texas MD Anderson Cancer, Houston, TX,[2]Department of Pathology, Microbiology, and Immunology, Vanderbilt University Medical Center, Nashville, TN,[3]Department of Systems Biology, The University of Texas MD Anderson Cancer, Houston, TX,[4]Institute for Interdisciplinary Research (IRIBHM) - Jacques E. Dumont, Universite Libre de Bruxelles, Brussels, Belgium,[5]Department of Biostatistics, Vanderbilt University Medical Center, Nashville, TN,[6]Department of Laboratory Medicine and Pathology, University of Washington School of Medicine, Seattle, WA,[7]Department of Endocrine Neoplasia and Hormonal Disorders, The University of Texas MD Anderson Cancer, Houston, TX,[8]Department of Pathology, The University of Texas MD Anderson Cancer, Houston, TX,[9]Department of Bioinformatics and Computational Biology, The University of Texas MD Anderson Cancer, Houston, TX

Purpose: Papillary thyroid carcinoma (PTC) exhibits heterogeneous behavior. There is a need for effective biomarkers and improved risk stratification methods in PTC. Gene signatures derived from bulk RNA sequencing capture composite transcriptional profiles that are confounded by tumor microenvironment cells. We developed a thyroid follicular cell-derived gene signature, *Prognostic RNA Expression Cell-specific Integrated SignaturE* (PRECISE), using single-cell and nucleus RNA sequencing techniques and evaluated its prognostic utility across independent cohorts.

Experimental Procedures: PRECISE was developed using a discovery cohort of PTC patients (MDACC n=109) with a median follow-up of 14 years. Within the cohort, 11 PTC tumors and 4 normal thyroid samples were successfully sequenced using single-nucleus RNA sequencing. Genes that were significantly downregulated in malignant cells compared to normal thyroid follicular cells were integrated with previously identified differentially expressed genes from single-cell RNA sequencing. Prognostic significance was assessed using bulk RNA sequencing in the discovery cohort and validated in 2 additional cohorts (VUMC n=65; TCGA n=370). A rank-based single-sample method was used for score calculation. Associations between PRECISE score and progression-free (PFS) and disease-specific survival (DSS) were evaluated using multivariate Cox proportional hazards models, and predictive models were compared using Harrell's C-statistic and ANOVA.

Results: PRECISE comprised of 41 genes downregulated in PTC tumor cells and upregulated in normal follicular cells, capturing dysregulation of thyroid function and metabolism pathways. Higher PRECISE score was significantly associated with shorter PFS across all 3 cohorts (MDACC HR=1.64, P=0.002; VUMC HR=2.54, P<0.001; TCGA HR=1.63, P=0.012) and remained significant after TNM stage adjustment in two cohorts with ≥5 years follow-up (MDACC aHR=1.42, P=0.038; VUMC aHR=2.12, P=0.024). PRECISE score was also associated with DSS in these cohorts (MDACC HR=4.16, P<0.001; VUMC HR=2.23, P=0.01), independent of TNM stage in the MDACC cohort (aHR=2.83, P=0.015). Incorporating PRECISE significantly improved predictive performance for PFS (MDACC P=0.031; VUMC P=0.024) and DSS (MDACC P=0.008) beyond stage-based models.

Conclusions: PRECISE is a thyroid epithelial gene-derived signature with independent prognostic value in PTC.

#2710 Single-nuclei multiomic profiling reveals conserved adaptive states in EGFR- and ALK-mutant lung adenocarcinoma.

Naomi Kaste Mfonfu[1], Floriane Braye[1], Galina Boldina[2], Matteo Cesaroni[2], Luc Friboulet[1], Sergey Nikolaev[1], Andrey Yurchenko[1]

[1]INSERM U981 (Gustave Roussy), Villejuif, France,[2]Translation Medicine Unit, Sanofi, Vitry-sur-seine, France

Background: Resistance to EGFR and ALK tyrosine kinase inhibitors (TKIs) in lung adenocarcinoma (LUAD) remains a major clinical challenge. Tumor persistence and relapse arise from dynamic lineage transitions and adaptive signaling rewiring, yet the molecular features defining minimal residual disease (MRD) remain incompletely understood.
Methods: We generated single-nucleus RNA and ATAC sequencing datasets from the longitudinal patient tumor biopsies at baseline, minimal residual disease (MRD), and relapse. In total, we analyzed 38 patient samples (18 baseline, 10 MRD, 10 relapse, including 6 matched samples) across both RNA-seq and ATAC-seq. Moreover, we generated six patient-derived xenograft (PDX) models harboring EGFR or/and ALK mutations, sampled at baseline and during MRD (2 baseline samples and 3-6 MRD samples per model).
Results: Transcriptomic analyses revealed consistent remodeling of regulatory programs associated with differentiation, adhesion, and stress adaptation. Across PDX models, a conserved persister signature emerged, enriched in pathways related to ciliogenesis, neuronal signaling, lipid metabolism, and senescence. In patient samples, MRD and relapse were marked by transcriptional transitions from alveolar to ciliated and neuroendocrine-like states, reflecting a lineage continuum also observed in PDXs, and this shift was supported by 127 significantly altered genes between baseline and MRD (34 downregulated and 93 upregulated), quantifying the extent of transcriptional reprogramming associated with the emergence of drug tolerant persister cells.
Conclusion: Together, these results point to shared adaptive trajectories across preclinical and clinical contexts, capturing the continuum from drug-tolerant persistence to established resistance. These findings define a conserved adaptive landscape across EGFR- and ALK-driven LUAD and lay the groundwork for identifying therapeutic strategies to eradicate residual disease and prevent relapse in TKI-treated lung cancer.

#2711 Large-scale integration of single-nuclei and spatial transcriptomics from the ETOP BEAT-meso trial reveals clinically relevant heterogeneity in malignant pleural mesothelioma.

Malignant pleural mesothelioma (MPM) is a rare, aggressive cancer of the lung lining, predominantly caused by asbestos exposure (1,2). Despite advancing therapies, 5-year survival remains poor at 10-20% (3,4). A major challenge in managing MPM is its extensive heterogeneity, which contributes to variable treatment response. Comprehensive characterisation of this heterogeneity may help guide more effective therapies. Meeting this need requires large-scale, multimodal datasets that capture the cellular, spatial and molecular landscape of MPM. We analysed FFPE tissues from 159 patients enrolled in the BEAT-meso trial (5), generating the largest multimodal MPM dataset from a single clinical trial. The dataset includes paired single-nuclei FLEX RNA-seq (snRNA-seq; 612,587 cells), spatial Xenium transcriptomics (37,949,307 cells), H&E images, and matched clinical data. We built a high-resolution snRNA-seq atlas through extensive preprocessing, reference integration, and hierarchical cell type annotations. Clinical variables were used to stratify the cohort and assess variation in cellular composition, pathway activity, and molecular patterns. Xenium data were used to contextualise the snRNA-seq-derived annotations, and transcriptomic data of malignant cells were utilised to identify clinically associated programmes. We used foundation models to learn multimodal representations across histology and transcriptomic data, and studied relationships across modalities and their associations with clinical variables.Histology-based stratification revealed differences in cell-type composition, pathway activation, and checkpoint signalling between epithelioid and non-epithelioid tumours. Foundation-model analysis identified patients with sarcomatoid-like molecular signatures, revealing heterogeneity beyond standard classification. Transcriptional programme analysis further refined malignant cell states across histologies. Integration with spatial transcriptomics confirmed the presence and localisation of all snRNA-seq-derived cell types and enabled identification of tertiary lymphoid structures. We present the most extensive multimodal resource for MPM, integrating single-nuclei, spatial and clinical data from 159 BEAT-meso patients. This multimodal framework refines molecular and histological characterisation of MPM, highlighting features associated with aggressive disease, and provides the cancer and computational biology communities with a scalable reference for benchmarking, training next-generation models, and accelerating biomarker and therapeutic discovery.

#2712 MPACT-DPD: An interpretable machine learning classifier for predicting the functional impact of *DPYD* missense variants.

Lulu Jiang[1], Ryan Jonathan Swartz[2], Lauryn Allyn Hahn[2], Brianna Bembenek[3], Hannah Marie Krause[4], Kelly Bouchonville[4], Steven M. Offer[4]

[1]Informatics, University of Iowa, Iowa City, IA,[2]Carver College of Medicine, University of Iowa, Iowa City, IA,[3]Mayo Clinic, Rochester, MN,[4]University of Iowa Holden Comprehensive Cancer Center, Iowa City, IA

5-Fluorouracil (5-FU) is a widely prescribed chemotherapy for colorectal, breast, gastric, and head and neck cancers. The drug inhibits thymidylate synthase, blocking DNA synthesis and causing cytotoxic stress that halts tumor growth. However, patients carrying deleterious variants in *DPYD*, the gene encoding the rate-limiting enzyme in 5-FU metabolism (dihydropyrimidine dehydrogenase, DPD), can experience fatal toxicity due to impaired drug clearance and accumulation of 5-FU metabolites. Current pharmacogenetic screening guidelines in the U.S. recommend testing for few of the >2,000 nonsynonymous variants that have been reported for *DPYD*, leaving patients with rare, uncharacterized mutations at risk. To interpret expanded testing, however, a means to classify *DPYD* variants of unknown significance is needed. To address this, we developed MPACT-DPD, a random-forest-based classifier that accurately predicts the functional impact of *DPYD* missense variants. Our model was trained on *in-vitro* activity of 156 variants and leveraged a feature set of biochemical, evolutionary, and AlphaFold3-derived structural features. We optimized hyperparameters using ten-fold stratified cross-validation and evaluated model performance with Matthews correlation coefficient (MCC) to account for moderate class imbalance (7:3 neutral to deleterious). It achieved exceptional performance, with a Matthews correlation coeffient (MCC) of 0.906 and an accuracy of 95.1% on an independent validation set (n=43). Furthermore, a SHAP (SHapley Additive exPlanations)-based interpretability analysis revealed cofactor proximity and residue conservation as the key drivers of predictions. MPACT-DPD showed superior performance at variant classification against other tools, including a *DPYD* gene-specific variant classifier, and has the potential to expand pre-treatment genetic screening to improve the safety of personalized 5-FU-based chemotherapy.

#2713 Ensemble machine learning using unmatched pre-treated multi-omic data can classify response to immune checkpoint inhibition in non-small cell lung cancer.

Alexander Azizi[1], Arvind Ravi[1], Natalie Vokes[2], Stephen-John Sammut[3], Petar Stojanov[4], Justin Gainor[5], Gad Getz[1]

[1]The Broad Institute of MIT and Harvard, Cambridge, MA,[2]UT MD Anderson Cancer Center, Houston, TX,[3]Institute of Cancer Research, London, United Kingdom,[4]Broad/DFCI, Cambridge, MA,[5]Massachusetts General Hospital, Charlestown, MA

Introduction: Immune checkpoint inhibitors (ICI) improve survival in non-small cell lung cancer (NSCLC), yet predictive biomarkers remain limited. Multi-omic data can improve classification, but incomplete multi-omic overlap poses challenges for integrative analysis. Ensemble methods can leverage partially overlapping multi-omic data for biological insight and predictive power. We developed an ensemble machine learning (ML) framework integrating unmatched exome and transcriptome datasets to classify ICI response, enabling model training when only a single data modality is available for a patient.
Methods: Using the SU2C-Mark Foundation NSCLC dataset (SU2C NSCLC), separate exome- (n=241) and transcriptome-based (n=84) models were trained using cross-validation, and validated via ensemble learning on overlapping multi-omic data (n=68). Models were tested in an independent SU2C NSCLC cohort (MDA), and externally validated in melanoma and urothelial datasets.
Results: In SU2C NSCLC, separate models were trained in the unmatched exome and unmatched transcriptome data, and results were blended to predict response in the 68 matched, multi-omic cases (46% responders). The baseline ensemble model using the clinically assessed PD-L1 tumor proportion score (TPS) achieved an area under the ROC curve (AUC) of 0.60. Incorporating domain knowledge and blending the two model predictions (tumor mutation burden [TMB] & *CXCL9* expression) improved AUC to 0.76, while a simple ensemble including TMB, *CXCL9*, PD-L1, first-line therapy and dual ICI reached AUC 0.80. LASSO models adding Amp5p15.33 (*TERT* locus), SBS7b COSMIC mutational signature, and clonal neoantigens achieved AUC 0.79; non-linear models (RF/XGBoost) reached 0.73. In the MDA cohort (n=22), baseline PD-L1 AUC was 0.68, domain knowledge ensemble was AUC 0.88, simple ensemble AUC was 0.82, and the previously selected test model of LASSO achieved 0.79. The domain knowledge ensemble generalized well on external data: in urothelial cancer (Mariathasan et al. *Nature* 2018; train n=105; val n=45), AUC was 0.94, and in melanoma (Freeman et al., *Cell Rep Med.* 2022; unmatched exome n=99, unmatched RNA n=98, matched multi-omic validation n=55), AUC was 0.65. Differential expression and pathway analysis in misclassified tumors highlighted stromal and histologic heterogeneity as residual error sources. *CXCL9* expression and TMB were not co-linear in TCGA, helping to explain their additive power.
Conclusion: A pragmatic ensemble ML framework can integrate unmatched exome and transcriptome data to classify ICI response in NSCLC. Blending immune (*CXCL9* expression) and genomic (TMB) features yields robust, interpretable, generalizable, and biologically meaningful models. This approach supports translation of clinically actionable, integrative biomarkers for precision immunotherapy.

#2714 Development of a novel Ikaros/Aiolos transcriptional signature and correlation with patient response in multiple myeloma patients treated with CELMoDs.

Saleh Tamim[1], Nicholas Stong[1], Yan Kai[2], Diana Jankeel[2], Bonny Gaffney[2], Antonina Kurtova[3], Alberto R. Perez[4], Celia Fontanillo[2], Tracy T. Chow[3], Patrick R. Hagner[1], Danny Jeyaraju[1], Chad C. Bjorklund[1], Michael Amatangelo[1], Kai Wang[2], Anita Gandhi[1], Maria Ortiz-Estevez[5]

[1]Bristol Myers Squibb, Summit, NJ,[2]Bristol Myers Squibb, San Diego, CA,[3]Bristol Myers Squibb, Brisbane, CA,[4]Bristol Myers Squibb, Lawrenceville, NJ,[5]Bristol Myers Squibb, Sevilla, Spain

Background: Multiple myeloma (MM) is a neoplasm characterized by the clonal proliferation of malignant plasma cells in the bone marrow. Immunomodulatory drugs and distinct CELMoD™ agents modulate Cereblon to induce the degradation of the hematologic transcription factors, Ikaros (Ik) and Aiolos (Ai), resulting in anti-proliferative and pro-apoptotic cell intrinsic effects on multiple myeloma tumor cells. While Ik/Ai degradation in MM cells can be semi-quantified using immunohistochemistry (IHC), clinical responses are not always correlated. Here, we devise a quantitative RNA-seq based Ik/Ai activity score in MM cells utilizing preclinical next-generation sequencing data and validate our approach using clinical data.
Methods: CUT&RUN and ChIP-seq experiments were performed on H929 MM cell line to identify binding targets of Ik. To refine the target list, we investigated transcriptional changes of the Ik targets when exposed to lenalidomide (LEN), pomalidomide (POM), and mezigdomide (MEZI) at 6, 24, and 48-hour timepoints, and iberdomide (IBER) at a 24-hr timepoint. Differential expression (DE) analysis between compound-treated and DMSO-treated samples was performed using DESeq2, and significantly DE genes were determined. Ik binding target results were overlapped with the DE genes to generate a high-confidence Ik regulon: 115 up-regulated and 95 down-regulated targets.
Results: Gene Set Variation Analysis was performed on Ik regulon to derive an Ik activity score. The score was first applied to RNA-seq paired samples (N=7) at screening and at cycle (C) 2 day (D) 15 from patients treated with MEZI in the CC-92480-MM-001 study. On-treatment samples had significantly lower activity score compared to screening. The Ik activity score was then applied to IBER-treated patients from the CC-220-MM-001 study, comparing RNA-seq paired samples (N=41) at screening and at C2D15. On-treatment samples, similarly, had significantly lower activity score compared to screening. Responders (R) of IBER and MEZI showed a slight trend of greater change in activity score.To determine if the change in activity score could be used as a biomarker of response with progression-free survival (PFS), the IBER dataset was investigated. Using an optimal cutpoint, significant association was observed with higher change in activity score favoring longer PFS. Association analysis using IBER IHC paired, at screening and at C2D15 samples (N=55), similarly showed significant association with higher percentage of Ik degradation also favoring longer PFS. Validation using IBER samples (N=22) having both RNA-seq and IHC data resulted in significant association between PFS and RNA-seq based and IHC based scores.
Conclusions: We compiled Ik targets and devised an RNA-seq based Ik activity score that is significantly associated with patient outcome and is comparable with the IHC score.

#2715 A comprehensive single-cell atlas of head and neck squamous cell carcinoma defines malignant cell states and enables deconvolution of legacy bulk transcriptomic cohorts.

Yuanyuan Shen, Tingyi Li, Roger Li, Xuefeng Wang, Xiaoqing Yu

Moffitt Cancer Center, Tampa, FL

Background: Head and neck squamous cell carcinoma (HNSCC) is characterized by intratumor heterogeneity driven by diverse malignant cell states and a complex tumor microenvironment influenced by HPV infection and tobacco exposure. Previous studies have used single-cell RNA sequencing (scRNAseq) to explore this complexity, none has delivered a large-scale, integrated, rigorously curated, and systematically validated atlas with high-resolution cell subtype annotation. Existing scRNAseq resources lack direct links to large legacy bulk transcriptomic cohorts that contain deep clinical characterization and long-term outcomes.
Methods: We curated, annotated,integrated scRNAseq datasets from 7 HNSCC studies, comprising 137 individuals across all disease stages. After stringent quality control and batch correction, cells were classified into major cell type and cell states. Epithelial cells were then subclustered to define transcriptional cell states and associated hallmark pathway activities. Using these atlas-derived malignant and microenvironmental states, we constructed a Bayesian model to predict cellular composition within individual cell types. This model was then applied for deconvolution of 1705 samples in 24 bulk transcriptomic HNSCC cohorts, enabling estimation of cell-state proportions and associations with HPV status, alcohol and tobacco exposure, and clinical outcomes.
Results: Clustering of 368,842 high-quality cells identified 63 cell states across 16 major cell types. Within the malignant epithelial population, we defined 12 distinct states including chromatin remodeling, cilia, E2F targets, EMT-II, cell cycle phases, and stress responses. Deconvolution of bulk cohorts using the BayesPrism approach recapitulated these altas-defined signatures and uncovered reproducible clinical association across datasets. Lower EMT-II ($p=0.02$), higher glutathione ($p=0.038$), increased cDC3 ($p=0.024$), and elevated IFN-TAM ($p=0.0153$) were associated with improved survival. HPV status demonstrated significant associations with distinct cell states including CD4 Tcm, CD8 Temra, proliferative fibroblast, G2M epithelial cells, myofibroblasts, and TNFRSF9+ Treg cells.
Conclusions: This study establishes a comprehensive single-cell atlas for HNSCC and introduces a BayesPrism-powered framework for projecting malignant and microenvironmental cell states onto heterogeneous bulk transcriptomic datasets. By linking high-resolution cellular profiles with large, clinically annotated cohorts, our work provides a scalable and robust strategy to decode the ecosystem heterogeneity of HNSCC.

#2716 Machine learning-based screening tool for multiple myeloma detection in chronic kidney disease patients with limited laboratory testing.

Wen-Chi Wu[1], Muh-Hwa Yang[1], Chih-Yu Yang[2]

[1]Department of Medical Oncology, Taipei Veterans General Hospital, Taipei, Taiwan,[2]Department of Internal Medicine, Division of Nephrology, Taipei Veterans General Hospital, Taipei, Taiwan

Background: Multiple myeloma (MM) and chronic kidney disease (CKD) share similar clinical manifestations including renal impairment and anemia, making MM diagnosis challenging in general and nephrology clinics. Many CKD patients harbor undiagnosed MM, but healthcare insurance restrictions and public health system constraints limit ordering of specialized tests (serum protein electrophoresis, free light chains, immunoglobulins). This diagnostic delay can result in irreversible renal damage and delayed treatment. We developed a machine learning model using routine laboratory parameters to identify CKD patients requiring MM-specific workup or hematology referral.

Methods: We analyzed 4,759 CKD patients (591 MM, 4,168 non-MM controls; 12.4% prevalence) from a tertiary center. Using only routine tests available in general practice, we engineered features including CBC (hemoglobin, WBC, platelets), biochemistry (total protein, albumin, calcium, LDH, creatinine), and urine studies (protein, albumin, creatinine). Three feature sets were tested: RANK1 (20 features), RANK2 (16 features), and RANK3 (4 minimal features). We compared XGBoost, Random Forest, and Logistic Regression using stratified 5-fold cross-validation. with both unbalanced and SMOTEENN-resampled data.

Results: XGBoost achieved optimal performance: accuracy 95.1%, F1-score 0.798, ROC-AUC 0.962, PR-AUC 0.889. The minimal 4-feature model (platelet, WBC, urine protein, LDH) maintained clinically useful performance (F1 0.596, PR-AUC 0.627). SHAP analysis revealed hemoglobin/WBC ratio, platelet count, albumin/total protein ratio, and total protein as top predictors, capturing MM's characteristic hematologic suppression and paraproteinemia without requiring specialized assays. Dimensionality reduction visualization (PCA, UMAP, t-SNE) demonstrated distinct clustering patterns between MM and non-MM CKD patients, confirming inherent feature space separability despite overlapping clinical presentations.

Conclusions: This ML-based screening tool demonstrates potential for identifying high-risk CKD patients warranting MM-specific testing using only routine laboratory data. However, this retrospective single-center study has limitations including potential selection bias and lack of external validation. Prospective multicenter validation studies are needed to assess real-world clinical utility, optimal decision thresholds, and impact on diagnostic timeliness before implementation in clinical practice.

#2717 Prostate cancer risk stratification by polygenic score in diabetic and non-diabetic men.

Gukjin Lee[1], Sang-Hyuk Jung[2], Jonghyun Lee[3], Ki Won Moon[4], Jae-Seung Yun[5], Dokyoon Kim[3]

[1]Bucheon St. Mary's Hospital, The Catholic University of Korea Bucheon, Seoul, Korea, Republic of,[2]Department of Medical Informatics,, Kangwon National University College of Medicine, Chuncheon, Korea, Republic of,[3]Department of Biostatistics, Epidemiology and Informatics, Perelman School of Medicine, University of Pennsylvania, Philadelphia, PA,[4]Division of Rheumatology, Department of Internal Medicine, Kangwon National University College of Medicine, Chuncheon, Korea, Republic of,[5]St. Vincent's Hospital, College of Medicine, the Catholic University of Korea, Seoul, Korea, Republic of

Background: Type 2 diabetes mellitus (T2DM) has been inversely associated with prostate cancer (PrCa) risk. However, it remains unclear whether a polygenic risk score (PRS) for PrCa can effectively stratify risk among men with T2DM. This study aimed to assess whether a PrCa PRS could predicts PrCa risk independently of T2DM status.
Methods: We analyzed data from over 140,000 men in the UK Biobank and Penn Medicine Biobank. A PrCa PRS was constructed using summary statistics from a large-scale genome-wide association study. Cox proportional hazards models were used to evaluate the association between PRS and incident PrCa, adjusting for relevant covariates and testing for interaction by T2DM status. Additionally, sex hormones and insulin-like growth factor-1 (IGF-1) levels were analyzed to explore potential mediators.
Results: T2DM was associated with a reduced incidence of PrCa. IGF-1 levels were positively associated with PrCa risk in both diabetic and non-diabetic men, while sex hormone levels showed no significant association in men with T2DM. PRS was significantly associated with PrCa risk regardless of T2DM status ($P < 0.001$). Men in the very high PRS category had the highest PrCa risk, particularly among those without T2DM. Adjusting for testosterone and IGF-1 levels did not attenuate the association between PRS and PrCa.
Conclusions: PrCa PRS effectively stratifies prostate cancer risk in men both with and without diabetes, underscoring genetic susceptibility as a robust, independent risk factor. Given the significantly lower baseline IGF-1 levels in T2DM patients, IGF-1 might partially explain the reduced PrCa risk observed in this population.

#2718 Liquid biopsy cfDNA methylation predicts lung tumor size and metastatic potential in a single assay.

Kade P. Pettie[1], Shiva Farashahi[1], Jackson Killian[1], Andrew Wong[1], Yifan Wu[1], Dorna Kashef[1], Franziska Michor[2], Jocelyn Charlton[1], Kieran Chacko[1]

[1]Data Science, Harbinger Health, Cambridge, MA,[2]Assoc. Professor, Dept. of Biostatistics & Computational Bio., Dana-Farber Cancer Institute, Boston, MA

Liquid biopsy enables noninvasive assessment of cancer severity and prognosis, informing clinical decisions across the cancer care spectrum. Estimates of the fraction of tumor-derived DNA shed into circulation (tumor content; TC) reflect disease severity, with higher TC more frequently observed in advanced stages and linked to poorer outcomes. However, TC is a product of a complex pathology and is impacted by many factors including tumor type, size, shedding rate, aggressiveness, vascularization, genotype, and metastatic state. We aim to predict two of them, size and metastatic state, using a targeted cell-free DNA (cfDNA) methylation assay.

To assess metastatic potential, we trained models for two binary prediction tasks in lung cancer: distant metastasis (Stage I/II vs IV) and late stage (Stage I/II vs III/IV). Features quantifying region-level methylation patterns were residualized with respect to sample-level TC to capture signals orthogonal to size. TC was evaluated as a single predictor in parallel. We trained on a dataset of 54 true and 324 synthetic lung cancer cfDNA samples to further emphasize size-independent, stage-related features. All models were assessed at 90% target specificity on an independent test set of 30 true cancer samples classified as lung cancer by a multiclass tissue-of-origin model to represent the end-to-end performance of the assay. For size prediction, we developed a lung-specific TC estimator, fit log-linear models linking TC to radiology-derived tumor size metrics, and generated predictions for 57 held-out test samples. All samples were from the CORE-HH clinical study (NCT05435066).

The residual methylation models identified distant metastasis with 87.5% sensitivity (14/16 Stage IV) at 83% specificity (5/6 Stage I/II) and late stage with 67% sensitivity (16/24 Stage III/IV) at 83% specificity (5/6 Stage I/II). These results substantially improved on the TC-only model (19% and 17% sensitivity, respectively, at the same specificities), indicating methylation metrics capture tumor progression-associated signal orthogonal to TC. For size prediction, restricting to Stage I-III cases with PET metrics (N = 19) yielded the strongest fits ($\log_{10}$(total volume) $R^2 > 0.5$, $p < 5\times10^{-4}$). Test set predictions showed moderate explanatory power ($R^2 = 0.24$, $p = 1.3\times10^{-4}$), consistent with factors beyond size (e.g., visceral metastasis) influencing shedding.

These findings highlight the potential for stage and size prediction models to deliver clinically actionable insights from a single blood draw. Late-stage prediction could guide workup prioritization, treatment intensity, and surveillance strategies, while size prediction may support prognosis and therapy selection. These capabilities motivate further model development for complementary prediction tasks (e.g., aggressiveness, genotype) toward a suite of tools for precision oncology.

#2719 Molecularly-informed prediction of treatment efficacy in GDSC cell line data using computational reasoning.

Robert Doczi[1], Akos Takacs[1], Anna Dirner[1], Dora Lakatos[1], Barbara Vodicska[1], Dora Gorog-Tihanyi[1], Reka Szalkai-Denes[1], Eniko Kispeter[1], Andras Makkos[2], Aniko Gorbe[2], Peter Ferdinandy[2], William T. Beck[3], Christophe Le Tourneau[4], Petak Istvan[1]

[1]Genomate Health, Cambridge, MA,[2]Semmelweis University, Budapest, Hungary,[3]University of Illinois at Chicago, Chicago, IL,[4]Gustave Roussy, Villejuif, France

The Digital Drug Assignment (DDA) system is a knowledge-graph-based computational method that automates reasoning at the patient level and scores molecularly targeted agents (MTAs) based on the full tumor genomic data. This approach was predictive of relative benefit of the agents as used in the SHIVA01 trial (DOI: 10.1038/s41698-021-00191-2). Here, we evaluated the predictive power of DDA on a larger scale by analyzing tumor genomic and drug sensitivity data from the GDSC database. Our study was based on data from 659 cell lines derived from a broad spectrum of solid tumors. Corresponding drug sensitivity data were available for 34,713 treatment datapoints involving 87 types of MTAs. All tumor genomic profiles were processed using DDA, which scores MTAs and stratifies them according to predicted efficacy. Consequently, the same MTA can receive different drug scores across tumors, depending on their individual molecular profiles. Treatments were then ranked for each tumor based on their DDA scores, resulting in 72 treatment groups defined by ranking positions (i.e., drugs ranked at the same position across tumors formed one treatment group). Sensitivity to treatment was determined using Z-scores of IC50 values, with treatments showing negative Z-scores classified as sensitive. Among the top-ranked MTAs, 54% of treatments were sensitive, with sensitivity gradually decreasing across lower-ranking groups and reaching 0% in the bottom group. A linear trend across DDA score rank groups from top to bottom was confirmed by the Cochran-Armitage trend test ($Z = -10.42$, $p = 2.08e-25$), indicating a very strong negative trend across ordered groups from the top towards the bottom. Increased confidence in the benchmark drug response classification was achieved by excluding treatments around the median with progressively larger absolute IC50 Z-score thresholds. With IC50 Z-score exclusion thresholds of absolute 1, 2, 2.5, and 3, the sensitivity of cell lines to top-ranked treatments was 59%, 67%, 74%, and 83%, respectively, while remaining 0% in the bottom groups in all cases. Thus, increasing confidence in drug response correlated with higher predictive accuracy. Although group sizes decreased with stricter thresholds - reducing statistical power - the results remained highly significant throughout, the Cochran-Armitage trend test Z-values gradually increased from -8.33 to -4.68 (all $p < 0.001$). These results demonstrate the predictive power of DDA-score-based treatment ranking across solid tumors and MTAs, with top-ranked drugs having the greatest efficacy. The findings strongly support the notion that there is a correlation between aggregated scientific evidence and drug sensitivity. DDA can potentially address challenges with complex molecular profiles in routine clinical settings and clinical trial design.

#2720 A comprehensive LLM-enabled pharmacodynamic biomarker resource to accelerate cancer drug development.

Yuntao Yang, Li Zhao, Seyedmehdi Orouji, Ying Zhu, Rebecca Johnson, David Maxwell, Kaitlyn Brickey, Bissan Al-Lazikani

Genomic Medicine, UT MD Anderson Cancer Center, Houston, TX

Introduction: A major challenge in oncology drug development is confirming target engagement of therapeutics in patient tumors. Pharmacodynamic (PD) biomarkers provide this link, enabling early assessment of target validity, drug activity and rational dose selection. However, systematic resources connecting drug targets to validated PD biomarkers remain limited. To address this, we developed a comprehensive dataset and analytic framework to identify and prioritize target-specific PD biomarkers across nine major target classes implicated in cancer biology.

Materials and Methods: We curated biomarker candidates from multiple genomic and pharmacologic resources for nine target classes: transcription factors/cofactors, kinases, phosphatases, ubiquitin ligases, deubiquitinases, acetyltransferases, deacetylases, methyltransferases, and demethylases. Source databases often apply broad definitions to functional classes such as transcription factors. To improve accuracy and reduce annotation artifacts, we cross-referenced PFAM, Enzyme Classification, and PDB databases to refine protein classifications. Using the canSAR interactome, we identified direct target-biomarker interactions supported by experimental evidence. To capture context-specific transcriptional biomarkers, we computed cohort-specific correlations using TCGA, TARGET, and GTEx datasets. Finally, we employ LLM-based fact-checking agent to extract and harmonize antibody annotations from the Antibody Registry, focusing on enzyme targets with measurable substrate modifications.

Results: From 2,900 targets and 100,000 interactions, we propose 73,000 high-confidence target-biomarker relationships involving over 2,100 potential drug targets. Of these, 67% represent transcription factor-gene interactions and 33% enzyme-substrate interactions. Commercial antibodies were identified for over 2,800 biomarker candidates, supporting experimental validation. The resulting dataset covers more than 60% of the top 20 predicted targets across 19 cancer types. We provide all the data in our canSAR platform and as a download from canSAR-PD.

Discussion: This resource provides a systematic framework for PD biomarker discovery in oncology. By integrating curated molecular interactions with LLM-derived antibody annotations, it enables robust evaluation of target engagement and drug activity. The dataset establishes a foundation for developing PD biomarkers to guide dose selection, monitor response, and accelerate cancer drug development.

#2721 Phenome-wide association study of pre-cancer diagnosis electronic health records identifies risk and protective factors in the All of Us Research Program.

Charles C. D. Rich[1], Alyssa B. Bair[2], Britton E. Richardson[1], Katelyn C. Forbes[1], Blaine A. Bates[3], Mary F. Davis[4], Matthew H. Bailey[5]

[1]Biology, Brigham Young University, Provo, UT,[2]Data Science, Brigham Young University, Provo, UT,[3]Chemical Engineering, Brigham Young University, Provo, UT,[4]Microbiology and Molecular Biology, Brigham Young University, Provo, UT,[5]Simmons Center for Cancer Research, Brigham Young University, Provo, UT

Background: The All of Us Research Program represents a rich resource for cancer epidemiology research, with over 400,000 participants with whole genome sequences linked to electronic health records (EHRs). Large cancer datasets often focus exclusively on cases without controls and neglect pre-diagnosis healthcare occurrences. Here, we perform a phenome-wide association study (PheWAS) of pre-diagnosis EHR data between cancer cases and matched controls, revealing co-occurring and mutually exclusive phenotypes that can be subsequently investigated using All of Us genomic data.
Methods: Using SNOMED CT codes, we identified 48,000+ cancer cases across 23 cancer types in All of Us version 8. To conduct PheWAS while eliminating temporal ascertainment bias, we implemented a matched truncation strategy: for each cancer case diagnosed at age X, we matched control individuals on birth year, sex, and race and truncated their EHR data at age X, ensuring equal opportunity to accrue diagnoses. We tested associations between cancer diagnosis and approximately 2,100 clinical phenotypes using logistic regression adjusted for age, sex, and EHR metrics including length of EHR and total ICD code count, with Bonferroni correction for multiple testing. For coding aspects of this study, Claude by Anthropic was used for debugging and troubleshooting.
Results: Our analysis confirmed established cancer risk factors, validating All of Us as a robust platform for cancer epidemiology research. Notably, we identified unexpected inverse associations with pain-related phenotypes: chronic pain (P-value=7.7×10^{-47}, OR=0.67) and general pain (P-value=2.9×10^{-44}, OR=0.72). Additional inverse associations included sleep disorders (P-value=2.9×10^{-27}, OR=0.79) and mood disorders (P-value=5.2×10^{-32}, OR=0.77), suggesting potentially protective relationships warranting further investigation.
Conclusions: This comprehensive PheWAS of pre-diagnosis EHR data in All of Us reveals a complex landscape of cancer-associated phenotypes extending beyond traditional risk factors. The identification of potentially protective phenotypes, combined with our rigorous approach to temporal bias elimination, establishes a foundation for hypothesis-generating research in precision cancer prevention. These findings underscore the importance of diverse biobanks and rigorous methods for identifying phenotypic relationships. Claude by Anthropic was used to revise text for grammar, clarity, and length optimization. Importantly, all scientific content, hypotheses, analyses, and conclusions remain the original work of the authors.

#2722 Integrated analysis identifies ELF3-CREB1 co-activation as a prognostic driver of high-risk pancreatic cancer.

Poorva Poorva[1], Rimpi Khurana[2], Varunkumar Krishnamoorthy[3], Sudhakar Jinka[3], Yan Guo[2], Vineet Kumar Gupta[3], Nagaraj Nagathihalli[3]

[1]Department of Surgery, University of Miami Miller School of Medicine, Miami, FL,[2]Department of Public Health Sciences, University of Miami Miller School of Medicine, Miami, FL,[3]Department of Surgery, University of Miami Miller School of Medicine, Sylvester Comprehensive Cancer Center, Miami, FL

Background: Patients diagnosed with pancreatic ductal adenocarcinoma (PDAC) face a dismal prognosis, with only about 13% surviving five years. Transcriptional factors play a vital role in PDAC survival and prognosis by defining tumor aggressiveness, therapeutic resistance, and clinical outcome. Key regulators such as CREB1 have previously been linked with tumor progression and shorter survival. While CREB1 signaling driving PDAC is known, the systematic characterization of active Transcription Factor (TF) associated with CREB1, and their clinical relevance is limited. In this study, we aimed to identify critical TF activity associated with CREB1 and assess their combinatorial prognostic impact in PDAC.
Methods: We utilized the VIPER (Virtual Inference of Protein-activity by Enriched Regulon) algorithm with high-confidence DoRothEA regulons (A-C) to infer TF activity across 182 TCGA-PAAD RNA-seq samples (178 Primary Tumors [TP] and 4 Normal Tissues [NT]). Differential Activity Analysis (DAA) using limma identified TFs dysregulated between TP and NT. Survival analyses utilized Kaplan-Meier and Cox Proportional Hazards modeling on the TP cohorts, focusing on the interaction between two key dysregulated TFs, CREB1 and ELF3 (ETS transcription factor 3). R version 4.3.0 was used for all analyses, including GSVA (v1.50.5) and VIPER (v1.36.0). Differential expression and pathway analyses were performed using the R packages limma (v3.58.1), GSVA (v1.50.5), msigdbr, gplots, and ggplot2.
Results: DAA identified 44 significantly dysregulated TFs (FDR < 0.05). The epithelial lineage regulator ELF3 showed the highest activation in tumors, while the lymphoid regulator PAX5 (paired box 5) was highly repressed. Although single-TF prognostic tests were non-significant, combinatorial analysis revealed a strong context-dependent effect. The simultaneous High CREB1 and High ELF3 activity defined a uniquely aggressive subgroup with a markedly shorter median overall survival (272 days) compared to the lowest-risk combination (492 days). Cox modeling confirmed a significant synergistic interaction between the two TFs (HR =2.31, p = 0.049).
Conclusion: This analysis reveals that the highly activated epithelial driver ELF3 acts synergistically with CREB1 to define a high-risk prognostic signature in PDAC. Our findings underscore that TF networks, rather than single factors, are crucial for patient stratification and represent compelling, context-specific therapeutic targets in PDAC.

#2723 Genomic drivers and an immune-cold microenvironment are associated with relapse in Chinese pediatric B-ALL.

Dan Yu[1], Yanni Hu[2], Xue Tang[3], Junlin Wang[1], Junwen Wang[1], Jianwen Xiao[2]

[1]Faculty of Dentistry, The University of Hong Kong, Hong Kong, Hong Kong,[2]Department of Haematology and Oncology, Children's Hospital, Chongqing Medical University, Chongqing, China,[3]Department of Hematology and Oncology, Shenzhen Children's Hospital, Affiliated to Shantou University Medical College, Shenzhen, China

Background: Relapse remains a major challenge in pediatric B-cell Acute Lymphoblastic Leukemia (B-ALL). This study aims to identify the specific genomic and cellular markers that drive treatment failure and are associated with relapse and poor Event-Free Survival (EFS) in Chinese pediatric B-ALL patients.

Methods: We performed an integrated multi-omic analysis on a cohort of 105 Chinese pediatric B-ALL patients, including 13 EFS Event (relapse plus died) cases. The cohort was profiled using ultra-deep gene panel sequencing (N=87), single-cell RNA-sequencing (scRNA-seq, N=52), and VDJ-sequencing (N=40). We integrated genomic, transcriptomic, and immune repertoire data to identify biomarkers associated with relapse and EFS. Associations were tested using Fisher's Exact Test, the Wilcoxon rank-sum test, and Cox regression.

Results: Our scRNA-seq and VDJ-seq analyses revealed the cellular landscape of relapse. We found a positive correlation between B-ALL blast proportion and BCR clonality and a negative correlation between T-cell proportion and TCR clonality ($p=0.041$). Notably, relapsed patients showed a higher BCR clonality but a highly polyclonal TCR repertoire, suggesting immune failure.

We identified that mutations in a curated panel of ALL-Drivers was significantly associated with relapse status ($p=0.033$) and a higher B-ALL blast percentage ($p=0.013$). And the higher ALL-Drivers VAF burden phenotype correlates with relapse status ($p=0.006$).

The non-relapse patients were found exhibited an “immune-hot" phenotype, characterized by significantly higher T-cell exhaustion and cytotoxicity scores ($p<0.001$). This state of active immune engagement is associated with PD-1/PD-L1 pathway. Relapse was associated with an "immune-cold" state, lacking this active T-cell engagement.

Finally, survival analysis and KM plot confirmed the prognostic significance of these findings. The presence of an ALL-Driver is significantly associated with poor Event-Free Survival ($p=0.021$).

Conclusion: Our findings reveal a biological pathway to poor prognosis. ALL-Drivers are linked to a high B-ALL blasts burden. This high-risk state is strongly correlated with patient relapse and is characterized by an "immune-cold" microenvironment, defined by the absence of the PD-L1 mediated T-cell exhaustion and cytotoxicity signature seen in non-relapsed patients.

#2724 A machine learning approach to classify breast cancer receptor subtype using genomic features.

Sandro Satta, Philip Miller, Samuel Rivero-Hinojosa, Ekaterina Kalashnikova, Angel Rodriguez, Minetta C. Liu

Natera, Austin, TX

Risk stratification, treatment course, and prognosis for patients with breast cancer presently rely upon the accurate determination of receptor subtype, ascertained through immunohistochemistry (IHC) for estrogen receptor (ER) and progesterone receptor (PR), and evaluation of HER2 expression (IHC and/or gene amplification via in situ hybridization). While IHC-based subtyping assays are informative, they require high-quality tissue samples and the technical assays can be susceptible to fixation artifacts, variability in antibody staining performance, semi-quantitative and subjective result calling. In cases of diminished sample quality, IHC-based subtype assessment may not agree with gene expression-based classification, and alternative approaches may be needed. This study aimed to develop a machine learning classifier able to predict breast cancer receptor subtypes using genomic features, without relying on immunohistochemistry or gene expression data.

This study included 19,559 patients with primary breast cancer, identified using Natera's proprietary real-world database, linked to a clinical claims database. Hormone receptor (HR) and HER2 subtype was determined from patient treatment codes. We developed a biologically-informed feature set by combining somatic mutations across 19,820 genes, using whole exome sequencing (WES) data from the SignateraTM testing workflow. Each mutation was assigned a composite mutation_score (range 1-12) based on variant class (SNV, insertion, deletion), superclass (SNP/INDEL), predicted impact (VEP annotation impact: MODIFIER to HIGH), and functional consequence (such as frameshift, stop-gain, missense, synonymous). A Random Forest classifier was trained with a stratified 75/25 train-test splitting and hyperparameter optimization.

The model was trained on features from 14,669 patients in the training cohort. In a test cohort of 4,890 patients, the model achieved 80.3% overall agreement with HR/HER2 status as inferred through medication claims data, with balanced performance across four major subtypes. Per-subtype metrics were: for HR+/HER2-, the model showed a precision of 0.935, recall 0.911, and F1 score of 0.923; for HR-/HER2+, precision was 0.714, recall was 0.753, and F1 score was 0.783; for HR+/HER2+, precision was 0.748, recall was 0.734, and F1 score was 0.741; lastly, for the TNBC subtype, precision was 0.730, recall was 0.816, and F1 score was 0.770.

Overall the genomic classifier accurately classifies breast cancer into one of the four major receptor subtypes. After definitive validation against clinically-reported HR/HER2 status, this classifier could be used to guide analyses of de-identified genomic datasets that lack complete clinical annotation.

#2725 Grade-dependent survival and co-mutation landscapes in TP53-mutant gliomas: Biological insights and therapeutic implications.

Harpreet Kaur, Kevin Camphausen, Uma Shankavaram

Radiation Oncology Branch, NIH-NCI, Bethesda, MD

Background: Gliomas display wide heterogeneity across grades, ranging from lower-grade anaplastic tumors (grades 2 and 3) to glioblastoma (GBM, grade 4). TP53 mutations occur frequently, but their prognostic significance depends strongly on co-mutation context and tumor grade. Dissecting these interactions is critical for stratification and therapy.
Methods: We analyzed somatic mutation and survival data from The Cancer Genome Atlas (TCGA) and Memorial Sloan Kettering (MSKCC) cohorts from TCGAbiolinks, and cBioPortal. Mutational profiling and co-mutation network analyses were performed using maftools, Kaplan-Meier and Cox regression models evaluated grade- and context-specific survival effects. Therapeutic associations were curated from OncoKB and NCI-MATCH.
Results: In grade 2 gliomas, TP53-mutant tumors showed a major survival advantage (40.2 vs 19.4 months in WT), enriched for co-mutations in IDH1 and ATRX. Grade-3 TP53-mutant tumors retained this advantage (32.9 vs 15.2 months) with additional mutations in MUC16 and APOB. By contrast, GBM (grade 4) showed only a modest TP53 benefit (14.8 vs 11.5 months), as protective IDH1/ATRX co-mutations were rare and proliferative drivers (EGFR, PTEN, NF1, PI3K) dominated. Within TP53-mutant gliomas, survival diverged by co-mutation profile. Favorable mutations (ATRX, IDH1, COL6A3, LAMA1, HYDIN, ADGRV1, NAV2) were linked to slower growth, immune visibility, or lower-grade biology. Mutations (PTEN, EGFR, RB1, NF1) exerted modest effects. In contrast, deleterious co-mutations (OBSCN, PRDM9, DNAH11, PTPN3) amplified genomic instability, defining a worst-prognosis subgroup.
Conclusions: The prognostic role of TP53 in gliomas is shaped by grade-specific co-mutation context. TP53-mutant tumors with IDH1/ATRX resemble lower-grade gliomas and may benefit from IDH inhibitors, whereas tumors with proliferative or instability drivers may require PI3K/mTOR inhibition or trial enrollment. This integrative framework highlights the need for co-mutation-aware stratification in both prognostication and therapeutic decision-making.

#2726 Clinicopathological and molecular significance of MUC13 in HCC.

Anupam Dhasmana[1], Swati Dhasmana[2], Rajasekhar Baru[1], Abigail Gomez[2], Iris A. Perez[2], Sheema S. Khan[2], Murali M. Yallapu[2], Subhash C. Chauhan[2]

[1]Division of Cancer Immunology and Microbiology, Medicine and Oncology Integrated Service Unit, University of Texas Rio Grande Valley, McAllen, TX,[2]University of Texas Rio Grande Valley, McAllen, TX

Background: Mucin 13 (MUC13), a cell surface glycoprotein aberrantly expressed in multiple epithelial carcinomas. Although in liver cancer MUC13 has not been comprehensively investigated. This study elucidates the clinical and molecular relevance of MUC13 expression in liver cancer samples followed by its role in liver carcinogenesis.
Methods: The significance of MUC13 and its impact on hepatocellular carcinoma (HCC) was investigated in MUC13 positive and negative subsets of HCC samples using an integrated approach combining bioinformatics and molecular biology. We performed proteomics analysis on protein samples extracted from paraffin embedded (FFPE) tissues. Differentially expressed proteins were identified by bioinformatics guided mass spectrometry and functional enrichment analyses. The MUC13 expression status was conformed in HCC tissue before samples selected for proteomics analysis. Later we performed MUC13 IHC expression analysis in HCC, MSLD, MASH, and fibrosis samples. Further, MUC13 expression in serum samples were determined by sandwich ELISA while cytokines profiling analyses were performed using cytokines arrays.
Result: Our deep data mining and bioinformatics analyses demonstrated higher expression of MUC13 in HCC samples as compared to normal liver and a similar pattern was observed in our proteomics analysis. Interestingly, in our proteomics analysis, we observed remarkable molecular level changes in MUC13+ve HCC subset as compared MUC13-ve HCC samples. Some of the key differentially expressed proteins are associated with several important pathways like PTK2 signaling, NF-KB activation, TLR signaling, MAP kinase activation, and AKT signaling. Whereas DNA repair, apoptosis, and TP53 associated pathways were depleted. IHC and ELISA analyses demonstrated strong MUC13 expression in HCC tumors/serum samples as compared to very faint or no expression in normal liver tissues/serum samples. Additionally, we observed a distinct expression pattern of several cytokine (Osteopontin, PDGFs, EMMPRIN/CD147, MIF, ICAM-1, VEGF) in HCC patients versus healthy normal serum samples.
Conclusion: This comprehensive study suggests 1) high expression of MUC13 in HCC, 2) MUC13+ve HCC patients' subset has a remarkable differential molecular profile as compared to MUC13-ve HCC patients' subset and normal liver tissues samples 3) HCC patients represent a relatively differential cytokine profile as compared to healthy normal serum samples. These intriguing findings suggest a crucial role of MUC13 in HCC and can be a useful indicator for therapy response and prognosis.

#2727 A designed live bacterial therapeutic restores responder-like microbiome profiles and improves immune checkpoint inhibitor (ICI) response in a predictive model.

Glen J. Weiss[1], Sonia Timberlake[1], Kinga Zielinska[2], Marina Santiago[3], Johannes Woehrstein[1], Christopher Weidenmaier[3]

[1]mbiomics GmbH, Munich, Germany,[2]Malopolska Centre of Biotechnology, Jagiellonian University, Krakow, Poland,[3]mbiomics Inc., Boston, MA

Background: The gut microbiome has been shown to predict response to ICI, but associations of individual species have not been statistically robust or reproducible. Fecal microbial transplant (FMT) has been reported to improve response probability in melanoma and kidney cancer, but drug development has focused on very simple microbial consortia.
Methods: We sought to replicate the therapeutic benefits of FMT for improving response to ICIs in a model, and design therapeutic microbial consortia that when added to a patient's gut microbiome could improve response rates to ICIs. We trained a machine learning model to predict response to ICI, based on gut microbiome species profiles from baseline samples in patients starting ICI therapy, and used it to evaluate candidate therapeutic consortia intended to improve response to ICI. We trained a machine learning model to predict responders (R) vs. non-responders (NR) to ICI, based on baseline gut microbiome species profiles from patients starting ICI therapy (n=418). Parameters were fixed and called NR vs. R model. We built therapeutic consortia designed around donor FMT and ICI response-related species and mechanisms. ICI patients can be NR for many reasons, so we next focused on patients where the baseline gut microbiome had good predictive value for IO response (n=257) and asked whether FMT and our therapeutic consortia would improve response probabilities.
Results: Publicly-available data from 418 NSCLC patients was analyzed. The median age was 65 years (range 24-92), 260 men, 63% were on at least 2nd line therapy. 19.4% received antibiotics near the start of ICI, and 118 of 271 had tumors with PD-L1 <50%. Our model had mean AUC 0.62 for predicting response in hold-out test sets (patients never seen by the model), and discriminated OS curves ($p<0.0001$). Focusing on patients where the gut microbiome model had good predictive value (n=257), we showed that in agreement with clinical experience, healthy donor FMT improves response rates in our model when added to baseline patient microbiomes and outcomes are exposure-dependent (i.e.modeling increasing fractions of FMT species engrafting and replacing increasing fractions of patient baseline microbiomes). We showed that our candidate therapeutic consortia improve response rates when added to baseline patient microbiomes, and outcomes are again exposure-dependent. Conclusions: Our candidate therapeutic consortia have promise for improving response rates in patients on ICI therapy. We isolated bacteria to culture these consortia, which we are developing to combine with ICI.
Conclusions: Our candidate therapeutic consortia have promise for improving response rates in patients on ICI therapy. We isolated bacteria to culture these consortia, which we are developing to combine with ICI.

#2728 The Cancer Complexity Knowledge Portal: A FAIR-aligned tool for resource discovery.

Orion Banks, Ashley Clayton, Aditi Gopalan, Amber Nelson, Verena Chung, Amy Heiser, Jay Hodgson, Aditya Nath, Adam Hindman, Milen Nikolov, Adam Taylor, Angie Bowen, Susheel Varma, Jineta Banerjee

Sage Bionetworks, Seattle, WA

Enabling discovery of interoperable data and sustainable computational tools can help maximize the value of shared resources, supporting both human- and machine-driven reuse. The Cancer Complexity Knowledge Portal (CCKP), developed by Sage Bionetworks' Multi-Consortia Coordinating (MC^2) Center with support from the NCI Division of Cancer Biology (DCB), serves as a public, NIH-supported, domain-specific repository that consolidates cancer research resources from multiple DCB consortia, including CSBC, PS-ON, TEC, CCBIR, MetNet, and PDMC. The portal provides a unified entry point for discovering and accessing datasets, computational tools, publications, and other outputs generated by the cancer research community. To support sharing and discoverability across diverse resources and data modalities, the CCKP employs versioned metadata models, which are maintained in a public GitHub repository and aligned with NIH Common Data Elements (CDEs). Metadata are curated through the Synapse platform, which functions as the backend repository supporting submission, review, and release via the CCKP. The portal aggregates metadata and links to original records, thereby accommodating materials stored in web-accessible archives. A unified search interface, clickable filters, and related resource links are available to help users navigate to relevant entries. The CCKP includes a number of resource-specific features to improve FAIRness: Croissant metadata is available for datasets, to support reuse in AI and ML contexts; the Cancer Complexity Toolkit provides auto-generated evaluation data, representing the sustainability and reusability of catalogued research software; visitors can access modularized educational resources via integration with the Cancer Complexity Education Program. As of late 2025, the CCKP indexes research outputs from over 160 NCI-funded cancer grants, encompassing 4,178 publications, 1,029 datasets, and 321 computational tools. Curated datasets represent key biological themes, including drug resistance or sensitivity (574), tumor microenvironment (563), metastasis (358), evolution (289), and epigenetics (103). These datasets span multiple species models, including human, mouse, and organoid systems, and data modalities such as sequencing, imaging, and spatial profiling. By surfacing a curated metadata database with intuitive search tools, the CCKP operationalizes FAIR-aligned discovery to amplify reuse of existing resources. This approach serves both experimental and computational research communities, enhancing transparency, interoperability, and secondary use of cancer data to accelerate mechanistic insights and therapeutic innovation. ChatGPT 5.1 was used for initial abstract drafting and refinement. *All content was evaluated and approved by the authors.*

#2729 The selective landscape of somatic mutations encodes histopathological information in breast cancer.

Gift Asefon, Nic Fisk

University of Rhode Island, Kingston, RI

Cancer effect size quantifies the strength of evolutionary selection acting on somatic mutations within tumors, providing insights into which genetic alterations are being actively selected during tumor evolution. While histopathology has long been the gold standard for cancer diagnosis and classification, the relationship between evolutionary selection pressures on specific mutations and observable tumor morphology remains unexplored. We investigated whether combinations of somatic mutations, weighted by their cancer effect sizes, could serve as genomic proxies for pathological features in breast cancer. Using deep learning-based feature extraction from pre-trained histopathology models, we extracted high-dimensional morphological representations from H&E-stained whole slide images and performed cross-modal analysis to identify which mutation-selection profiles correspond to distinct histological patterns. By identifying mutation combinations whose evolutionary selection signatures associate with specific pathological features, we tested whether these genomic profiles could contribute to classifying breast cancer molecular subtypes. Our findings reveal that evolutionary selection patterns acting on specific mutation combinations show measurable correspondence with pathological features and provide contributory predictive value for subtype classification, though they do not fully recapitulate the discriminative power of histopathological assessment. This suggests that the selective landscape of somatic mutations partially encodes morphological information, with cancer effect sizes capturing aspects of the evolutionary processes that shape tumor architecture. These results provide evidence that mutation-selection profiles can complement traditional pathology and advance our understanding of how evolutionary forces influence both the genetic and morphological characteristics of breast cancer. Moreover, because cancer effect sizes capture the directionality and strength of selective pressures, their association with histopathological assessment models may improve prediction of tumor evolutionary trajectories without -omics data, offering insights into likely progression patterns with which to inform treatment strategy.

#2731 Sylvester Data Portal: Population-level characterization of a diverse clinicogenomic cohort.

Oliver Mazariegos[1], Jeronimo Pissinis[1], Pearl Seo[2], Marcin Pilarczyk[1], Lukas Rupprecht[1], Caty Chung[1], Franklin Sotolongo[3], Marcin Blicharz[1], Piotr Smol[1], Michal Pyrkosz[1], Mateusz Jura[1], Vasileios Stathias[3], Stephan Schurer[1]

[1]Univ. of Miami Sylvester Comprehensive Cancer Ctr., Miami, FL,[2]University of Miami, Miami, FL,[3]University of Miami Miller School of Medicine, Miami, FL

The Sylvester Data Portal (SDP), developed at the University of Miami (UM) Sylvester Comprehensive Cancer Center, is an advanced cloud-based multi-omics platform that streamlines the management of real-world and research data. SDP provides an integrated framework for managing and harmonizing the center's clinicogenomic data generated by major genomic profiling vendors, including Caris Life Sciences, Foundation Medicine, NeoGenomics and Guardant Health. SDP now supports population-scale analyses that enable comparative studies across Sylvester's catchment population. To facilitate secure and role-based access to clinical and genomic data, SDP provides three structured interfaces: (1) The Clinical Dashboard, which summarizes aggregated patient demographics and data availability; (2) the Clinical Browser, which supports query and visualization of de-identified subject-level data; and (3) Clinical Collections, which integrate protected health information with next-generation sequencing data under IRB and Data broker approvals. This integrated infrastructure enables standardized and reproducible access to a large, diverse and growing clinicogenomic dataset, supporting translational research and promoting equitable representation in precision oncology. Using this framework, the demographic and molecular profiles of the Sylvester clinicogenomic cohort were systematically evaluated and compared with those of the Cancer Genome Atlas (TCGA). The Sylvester cohort includes over 30,000 samples, almost three times the number of samples reported in TCGA (11,387), and is derived primarily from targeted panel sequencing rather than whole exome sequencing. Notably, close to half of the cases, 45.9%, within this cohort are from patients that self-identify as Hispanic, vs. 3.52% in TCGA, reflecting the distinctive population from the cancer center and contributing to improved genomic representation of an underrepresented group in cancer genomics. Mutational prevalence was also compared, in particular TP53 is more often mutated in the TCGA cohort, 36.99% vs. 26.72%, whereas KRAS mutations are more prevalent in the SDP cohort 7.5% vs. 9.81%.

#2732 Florida Cancer Research (FL CARES) network and the Platform for Accelerating Collaborative Computational Cancer Research (PAC3R).

Jeronimo Pissinis[1], Michael S. Sinclair[1], Marcin Pilarczyk[1], Caty Chung[1], Dusica Vidovic[1], Lukas Rupprecht[1], Franklin Sotolongo[1], Oliver Mazariegos[1], Kathleen M. Jagodnik[1], Carlos Obregon[1], Tingyi Li[2], Ling Cen[3], Jiang Bian[4], Ji-Hyun Lee[4], Qianqian Song[4], Bikhyat Adhikari[5], Till Krenz[1], Ritik Bhandari[1], Umamaheswari Natarajan[6], Gogce C. Crynen[7], Appu Rathinavelu[6], Stuart Chalk[8], Mondal M. Ananda[5], Xuefeng Wang[3], Vasileios Stathias[1], Stephan Schurer[1]

[1]Univ. of Miami Sylvester Comprehensive Cancer Ctr., Miami, FL,[2]H. Lee Moffitt Cancer Center, Tampa, FL,[3]Moffitt Cancer Center, Tampa, FL,[4]UF Health Cancer Center, University of Florida, Gainesville, FL,[5]Florida International University, Miami, FL,[6]Rumbaugh Goodwin Institute for Cancer Research, Nova Southeastern University, Ft. Lauderdale, FL,[7]Bioinformatics and Statistics Core Facility, The Herbert Wertheim UF Scripps Institute for Biomedical Innovation & Technology, Jupiter, FL,[8]University of North Florida, Jacksonville, FL

The Florida Cancer Research (FL CARES) Network (https://floridacancernetwork.org/) is a statewide collaboration advancing cancer research and improving patient outcomes through coordinated research initiatives and a focus on understanding population-health variation across demographic categories. Funded by the State of Florida Department of Health's Bankhead-Coley Cancer Research Program, FL CARES unites six research organizations, including the state's three NCI-designated Cancer Centers. The Network has established a collaborative research consortium with unified policies, coordinated data and metadata standards, and diverse datasets and analysis tools.To accelerate computational research, FL CARES is developing the Platform for Accelerating Collaborative Computational Cancer Research (PAC3R) (https://pac3r.floridacancernetwork.org). This advanced informatics system enables FAIR (findable, accessible, interoperable, reusable) data management, including standardization, harmonization, and integration of multimodal cancer-related datasets. PAC3R is designed to support secure data sharing, deployment of scalable bioinformatics tools, and collaborative analyses across the FL CARES Network.PAC3R builds upon the Sylvester Data Portal (SDP) (https://sdp.miami.edu/), a cloud-based multi-omics platform that manages clinicogenomic and research data for the Sylvester Comprehensive Cancer Center. PAC3R integrates diverse multimodal cancer datasets to support analyses such as transcriptional perturbation signatures, cell sensitivity data, and small-molecule interactions, alongside local cancer panels from Moffitt Cancer Center and Nova Southeastern University. The platform also incorporates large-scale public genomics resources including The Cancer Genome Atlas (TCGA) and the Clinical Proteomic Tumor Analysis Consortium (CPTAC).Overall, the FL CARES Network and its advanced informatics system, the PAC3R platform, demonstrate the power of a unified semantic data model, harmonized datasets, and computational strategies to detect and understand outcome variations across Florida's populations, supporting the long-term goal of advancing effective cancer prevention, diagnosis, and treatment for all.

#2733 An interactive web platform for integrative analysis of drug responses in polyploid giant cancer cells.

Li-Ju Wang, Hsiao-Chun Chen, Chien-Hung Shih, Yuan Zhang, Huikang Ye, Ying-Ju Lai, Yushu Ma, Tiffany Habib, Hsi-Chun Wang, Yu-Chih Chen, Yu-Chiao Chiu

UPMC Hillman Cancer Center, Pittsburgh, PA

Polyploid giant cancer cells (PGCCs), typically arising from whole-genome duplication, are major drivers of therapeutic resistance and tumor recurrence. Building on our recently published high-throughput single-cell drug screening platform and ongoing efforts to profile PGCC responses across multiple cell lines representing diverse cancer lineages, we developed an interactive web-based platform that enables integrative analysis and visualization of these data. The platform integrates high-throughput PGCC drug screening results with multi-omic features curated from public cancer data resources, including somatic mutations, copy number alterations, gene expression profiles, and pathway activity scores. It supports two primary analysis modules: (1) a gene- or pathway-centric module that identifies compounds whose anti-PGCC efficacy is influenced by specific molecular features, and (2) a compound-centric module that identifies genes or pathways associated with the efficacy of a selected compound. Statistical comparisons, interactive visualizations, and annotations from external knowledgebases enable users to explore drug-feature relationships and generate new hypotheses. The platform facilitates systematic investigation of PGCC vulnerabilities through data-driven exploration. Example analyses demonstrate that compounds targeting oxidative stress response and cytoskeletal remodeling pathways preferentially suppress PGCC-enriched cell populations, consistent with their structural plasticity and adaptive signaling. Integration with baseline pharmacogenomic datasets further distinguishes PGCC-selective inhibitors from broadly cytotoxic agents, supporting the prioritization of therapeutic candidates. In summary, this interactive web resource provides an accessible and scalable framework for analyzing the molecular and pharmacologic landscape of PGCCs. By integrating our prior and ongoing high-throughput datasets with multi-omic data, it accelerates the discovery of biomarkers and therapeutic strategies to overcome treatment resistance driven by genome-doubled tumor populations.

Poster Session

#2737 Real-world usability of a clinical trial knowledge platform in a community cancer network.

Tony Kin Wai Hung[1], Shriya Amara[2], Paulette Schwartz[1], Aanshi Thumar[1], Zaid Raza[1], Elizabeth O'Brien[1], Gilad Kuperman[3], Barry Stein[1], Peter Yu[1], Jun J. Mao[4]

[1]Hartford HealthCare, Hartford, CT,[2]TeamX Health, Los Angeles, CA,[3]Columbia University, New York, NY,[4]Memorial Sloan Kettering Cancer Center, New York, NY

Background: Clinical trial participation in the United States remains suboptimal, and limited provider awareness contributes to missed opportunities for enrollment. Although public registries are comprehensive, they are not optimized for rapid use during clinical encounters. A clinical trial knowledge platform that consolidates protocol information, surfaces eligibility criteria, and generates concise AI-assisted summaries was previously evaluated at a comprehensive cancer center and demonstrated high feasibility and user engagement. We assessed real-world usability of this platform among oncology providers in a large community cancer network.
Methods: Ten oncology providers completed a standardized 30-minute guided session using the platform, followed by a 30-minute semi-structured interview and a 10-item modified Mobile Health App Usability Questionnaire (mMAUQ; Likert scale, 1-7; score ≥5 defined as favorable). During the guided session, participants were asked to complete standardized trial-search, eligibility-review, and summary-review tasks that reflect typical point-of-care use. Quantitative results were summarized descriptively. Qualitative data were analyzed using grounded-theory and interpreted through the PACMAD usability model.
Results: Usability ratings were consistently high (overall mean score, 6.8). All participants reported favorable usability and indicated willingness to recommend the tool to colleagues. Mean scores were 6.9 for ease of navigation, 6.9 for learnability, and 6.8 for usefulness in supporting trial-referral discussions. Qualitative findings mirrored quantitative results: providers identified rapid access to eligibility criteria for prescreening during time-limited visits as the most clinically valuable feature and described the tool as intuitive, easy to recall, and cognitively light, with minimal technical concerns. Suggested refinements focused on workflow integration, including interoperability with clinical systems and potential ambient support in patient encounters.
Conclusions: In a community oncology setting—where limited access to trial information can exacerbate disparities in enrollment—a clinical trial knowledge platform demonstrated excellent usability and strong perceived clinical utility. Providers reported that rapid access to eligibility criteria supported prescreening and gave them enough information to discuss trials with patients during routine care. These findings suggest that the practical integration of trial knowledge into time-limited clinical encounters—beyond trial matching alone—may be a critical determinant of whether digital clinical trial applications translate into increased participation in research. Evaluation of the platform’s effect on trial accrual and equitable access to research opportunities across diverse care environments is underway.

#2738 From chaos to columns: High-accuracy clinical data extraction with CIDER.

Mate Posta, Aida Figler, Zsofia Dobolyi, **Balazs Gyorffy**

Semmelweis University, Budapest, Hungary

The analysis of unstructured medical records represents a crucial challenge in clinical research and healthcare. Large Language Models (LLMs) offer a transformative opportunity to extract structured information from narrative text; however, their use in medical environments is limited by security, ethical, and reproducibility issues. Here we present CIDER (ClinIcal Data ExtractoR), a locally deployed, open-source LLM-based system designed for the secure analysis of medical documentation.

CIDER operates through an automated pipeline integrating vLLM-based inference, predefined data schemas, and prompt-engineered extraction rules to convert unstructured clinical text into structured variables. The system processes batch uploads, parsed reports using a fine-tuned model, and generates standardized output tables for direct analytical use. We evaluated CIDER's ability to extract structured clinical data from real-world Hungarian-language pathology and histology records. Using the Qwen3-VL-32B-FP8 model as the backbone, we analyzed 2046 pathological records and validated the model's outputs across six key clinical variables: sex, T stage, N stage, primary tumor organ, year of surgery, and tumor size. The extracted data were compared with manually mined data.

When manual data were available, extraction accuracy was very high for sex (99.4%, 1971/1982 identical), T stage (95.34%, 879/922), N stage (92.19%, 437/474), year of surgery (97.94%, 1998/2040), and primary tumor organ (95.52%, 1771/1854). The largest tumor size reached an accuracy of 77.05% (1333/1730 identical). Notably, CIDER was also capable of retrieving clinically relevant information in cases where manual annotations were missing, identifying additional instances for sex (n=64), T stage (n=780), N stage (n=213), tumor size (n=291), year of surgery (n=6), and primary tumor organ (n=15).

In summary, CIDER demonstrated strong performance across the evaluated parameters. These results show that a locally deployed, open-source LLM system can achieve near-expert level accuracy in structured data extraction from complex, non-English medical texts. By operating entirely within institutional infrastructure, CIDER ensures full data sovereignty and provides a scalable solution for automated medical record interpretation, supporting research, registry development, and clinical decision-making in multilingual healthcare environments. The CIDER platform is publicly accessible at https://llm.gyorffylab.com/cider.

#2739 Evaluation of large language models for automated clinical trial matching in oncology.

Aakash Desai, Ellen McNeeley, Sanad Alhuski, Maya Khalil, Matthew Might, Rebecca Arend, Andrew Crouse, Mehmet Akce

University of Alabama at Birmingham, Birmingham, AL

Background: Efficient patient-trial matching remains a critical challenge in oncology, complicated by heterogeneous documentation, missing data, and complex eligibility criteria. Large Language Models (LLMs) offer potential to automate eligibility screening by interpreting unstructured clinical notes and biomarker data.
Methods: We evaluated 6 models: llama3.2:3b, llama3.3:70b, medgemma_27b_text_it, deepseek-r1:8b, gpt-oss20b and gpt-oss120b for clinical trial eligibility determination across 19 key questions reflecting common eligibility criteria from oncology clinical trials. Data were extracted from patient medical records with known trial matches, and models' binary (yes/no) responses, confidence scores, and reasoning excerpts were analyzed. Concordance between models and interpretability of outputs were assessed.
Results: Both gpt-oss20b and gpt-oss120b models demonstrated high agreement on eligibility determinations for well-documented criteria such as measurable disease, ECOG status, age, and tissue availability, with confidence scores commonly above 0.90. Differences emerged in criteria requiring inference or where documentation was incomplete; gpt-oss120b showed greater confidence and nuanced reasoning in ambiguous cases. Both models flagged missing or unclear data, providing reasoning transparency that supports clinical review. Concordance metrics suggested strong reliability (Cohen's kappa >0.8) for explicit criteria, with potential to significantly reduce manual screening burden. The remaining models provided poorer quality responses in general and were unable to respond coherently at all if required to provide that response in a structured format.
Conclusions: LLMs can accurately and transparently automate critical components of oncology trial eligibility screening, augmenting manual review processes. Differences in model confidence with uncertain data underscore the need for ongoing refinement and highlight the value of explainable AI in clinical decision support. These findings support integrating LLMs into clinical trial matching workflows to improve trial access and enrollment efficiency.
Impact: Automated, interpretable LLM-based clinical trial matching represents a promising advancement toward precision oncology by scaling patient access to tailored therapies and optimizing trial throughput.

#2740 Applications of large language models to CAR-T cell therapy clinical data using Google cloud computing.

Emmanuel Contreras Guzman[1], Matthew Jankowski[1], Andre De Menezes Silva Corraes[1], Malvika Gupta[1], Monica L. Shaw[1], Madiha Iqbal[2], Talal Hilal[3], Saurabh Chhabra[4], Ricardo Daniel Parrondo[2], Jody K. Mclean[1], Kim R. Riester[1], Kayla Joseph[1], Melinda Tan[5], Holly Ross[2], Cleyonia Barnett[2], Sylvia Carter[2], Semy Girmay[2], Rachel Wolan[2], Milana Ramsey[6], Christian Downhour[6], Kristy Morgan[6], Shae Sibley[6], Erica Rushing[6], Lucy Holmes[1], Allison Burgstahler[1], Stephen M. Ansell[7], Hassan Alkhateeb[1], Matthew Hathcock[1], Ramona Bruno[1], Allison C. Rosenthal[6], Hemant Murthy[8], Patrick B. Johnston[9], Jonas Paludo[1], Yi Lin[1]

[1]Mayo Clinic, Rochester, MN,[2]Mayo Clinic Florida, Jacksonville, FL,[3]Mayo Clinic Comprehensive Cancer Center, Phoenix, AZ,[4]Mayo Clini, Phoenix, AZ,[5]Mayo Clinic Cancer Center Minnesota, Rochester, MN,[6]Mayo Clinic, Phoenix, AZ,[7]Assistant Professor, Div. of Hematology, Mayo Clinic College of Medicine, Rochester, MN,[8]Mayo Clinic, Jacksonville, FL,[9]Hematology, Mayo Clinic College of Medicine, Rochester, MN

Large Language Models (LLM) are being widely adopted into the medical field for their impressive ability to analyze and summarize large amounts of text data. These models enable clinicians and researchers to extract meaningful insights from complex datasets and may assist with decision making. Here we present our workflows and application of LLM for the interpretation and summarization of clinical data related to CAR-T cell therapy.

Using an LLM (Gemini 2.5 pro) in the Google Cloud Computing (GCP) environment, two applications were developed to analyze CAR-T cell therapy clinical data: 1) extracting and summarizing CRS and ICANS event-related data to streamline the compliance team workflow, and 2) identifying features available at time of CAR-T infusion able to classify patients into high- or low-monitoring needs 14 days post CAR-T. Patient data (vitals, labs, hematology notes, and EKGs) were extracted from the electronic medical record (EMR) using Google BigQuery into SQL tables in GCP. For each application, relevant data fields were retrieved, formatted into JSON objects, and embedded in the LLM prompt for context-aware processing. Both applications have undergone iterative prompt engineering after analyzing the LLM output against ground truth data in the EMR.

For the application extracting and summarizing CRS and ICANS events, the LLM was optimized on Mayo Clinic Rochester data. When compared to the IEC compliance database, the LLM achieved 100% accuracy and F1 score for CRS events, and 96% accuracy and 82% F1 score for ICANS events. The match rate for CRS and ICANS grades were 83% and 89% respectively. We applied the same LLM to Mayo Clinic Arizona (MCA) and Mayo Clinic Florida (MCF) cases, who document clinical notes and toxicity flowsheet differently, and achieved an accuracy (MCA: 93%, MCF:93%) and F1 score (MCA: 96%, MCF: 96%) for CRS and accuracy (MCA: 81%, MCF:82%) and F1 score (MCA: 76%, MCF: 75%) for ICANS. LLM was able to capture events missed by manual reviews. For most of the discrepancies where compliance team final adjudication is needed, LLM will be updated to flag discrepancies for review by the compliance team.

For the application related to the monitoring needs 14 days post CAR-T, the LLM identified 5 categories predictive of high or low monitoring needs post CAR-T infusion (disease status, inflammatory and tumor burden markers, hematologic status, renal function and performance status). Our model achieved a sensitivity of 85.7%, specificity of 23.8%, and F1 score of 65.5% for our first cohort, compared with data extracted by the LLM from the EMR. For our second cohort, with demographics statistically similar to cohort 1 and using the same 5 categories, the LLM achieved a sensitivity of 83.3%, a specificity of 28.6%, and F1 score of 65.4%. Our workflow and applications of LLM's provide examples and guidance to others interested in applying LLM's for clinical and research applications.

#2741 Large language model-based triage of Hematology/Oncology patient messages: Performance, safety, and clinical implications.

Dinh Nguyen, Sinjin Lee, Brett Anwar, Mason Kellogg, Ronil Synghal, Khang Nguyen

SCPMG, Pasadena, CA

Background: Patient portal messages are a major source of real-time symptom reports in Hematology/Oncology, but manual review is labor-intensive and may delay identification of urgent issues. Large language models (LLMs) can process free text at scale, yet their safety and performance for triage in cancer care are uncertain.
Methods: We conducted a retrospective study of adult patients with hematologic malignancies receiving care at a single center within Southern California Permanente Medical Group, the care delivery arm of Kaiser Permanente, from November 2024 to November 2025. All patient-initiated messages to the Hematology/Oncology clinical team were extracted from the electronic health record portal. A stratified sample of messages was annotated by clinicians for urgent and non-urgent categories. Messages labeled as urgent reflected symptoms warranting prioritized clinician review within 24-48 hours. We developed an LLM-based classifier using few-shot learning that generates a label populating the “Topic” column in the receiving clinician’s inbox. Primary outcomes included discriminative performance metrics such AUROC, sensitivity, specificity, and F1 score for classifying urgent messages.
Results: A total of 10,683 messages from 2,287 unique patients were processed by our model; 433 messages were labeled as urgent. For urgent message classification, the few-shot LLM achieved an AUROC, sensitivity, specificity, and F1 score of 91.05% (95% CI, 85.69%-96.42%), 97.62% (95% CI, 92.50%-99.89%), 84.48% (95% CI, 74.60%-93.34%), and 89.13% (95% CI, 81.82%-95.74%) respectively.
Conclusions: An LLM-based triage system reliably categorized patient messages into urgent and non-urgent categories and has the potential to facilitate timelier action for urgent symptoms within a Hematology/Oncology department. The system’s practical utility highlights its relevance for departments seeking to leverage NLP to improve message management in cancer care.

#2742 An artificial intelligence domain-specialized scalable and clinically relevant pipeline to automate standardized O-RADS stratification for imaging reports in ovarian cancer.

Asmi Agarwal[1], Min Ren[2], Jingjing Gong[3], Richard Selinfreund[4], Ruchika Goel[5], Yanhui Guo[6]

[1]SIU School of Medicine, Springfield, IL,[2]Ultrasound Department, Shanghai First Maternity and Infant Hospital, Shanghai, China,[3]Shanghai Changning Maternity and Infant Health Hospital, Shanghai, China,[4]Department of Pathology, SIU School of Medicine, Springfield, IL,[5]Department of Hematology and Oncology, Johns Hopkins University and SIU School of Medicine, Springfield, IL,[6]Department of Computer Science, University of Illinois Springfield, Springfield, IL

Purpose: Despite therapeutic advances, ovarian malignancies continue to carry a disproportionate mortality burden among women worldwide. Timely and accurate assessment of adnexal lesions is critical for improving outcomes, yet the disease is often diagnosed at an advanced stage due to subtle or misinterpreted early findings. The Ovarian-Adnexal Reporting and Data System (O-RADS) provides a standardized framework for malignancy risk stratification; however, in practice, its manual application can be time-consuming and prone to inter-observer variability, creating barriers to consistency and incorporation within clinical workflows. To address this urgent clinical need, we developed an artificial intelligence (AI) pipeline that automates O-RADS classification directly from free-text pelvic ultrasound reports.

Procedures/Methods: By integrating *Lingshu*, a multimodal *Domain-Specialized* large language model (LLM) for medical reports reasoning, with traditional machine learning classifiers, our system transforms unstructured radiology narratives into structured, high-fidelity malignancy risk assessments, eliminating the need for manual scoring. We also compared the performance of this framework with that of an equivalent pipeline using *MedGemma.*

Data/Results: We analyzed 413 de-identified pelvic ultrasound reports and extracted semantic embeddings using Lingshu. These embeddings, representing clinically meaningful linguistic patterns, were used to then train machine learning classifiers via a 5-fold cross-validation. Lingshu and a logistic regression model performed the best, achieving a mean accuracy of 0.773 ± 0.031, weighted precision of 0.777 ± 0.029, recall of 0.767 ± 0.028, F1-score of 0.765 ± 0.032, and a macro-averaged AUROC of 0.929 ± 0.019. Notably, this achieved a lower AUROC of 0.923 ± 0.027.

Conclusion: A foundation model such as Lingshu demonstrates remarkable semantic understanding. We show that this model can be safely and effectively leveraged to standardize O-RADS risk assessment directly from unstructured ultrasound reports, bridging the gap between AI capability and real-world radiology practice. Our approach establishes a *scalable and clinically impactful pathway* for integrating AI into gynecologic oncology workflows, paving the way for broader adoption of LLM-driven tools in early ovarian cancer detection and risk stratification. Importantly, this AI-driven framework is not intended to replace expert radiologic judgment but to augment it by enabling the consistent application of O-RADS criteria, supporting diagnostic confidence, and reducing variability across providers and institutions. In doing so, it has the potential to expedite early identification of high-risk adnexal lesions and ultimately improve clinical decision-making and patient outcomes.

#2743 Deploying artificial intelligence driven digital pathology for real world clinical decision-making in pancreatic cancer.

Ashish Manne[1], Alejandro Leya[1], Abdul Rehman Akbar[1], Upender Manne[2], Anne Noonan[1], Anup Kasi[3], Ashwini Esnakula[1], Ravi Paluri[4], Anil Vasdev Parwani[5], Muhammad Khalid Khan Niazi[1]

[1]The Ohio State University, Columbus, OH,[2]University of Alabama at Birmingham, Birmingham, AL,[3]The University of Kansas Cancer Center,[4]Atrium Health Wake Forest Baptist, Winston Salem, NC,[5]The Ohio State University Wexner Medical Ctr., Columbus, OH

Pancreatic ductal adenocarcinoma (PDAC) remains one of the deadliest malignancies, driven by limited therapeutic options and the absence of widely implemented, clinically actionable biomarkers. Transcriptomic subtyping, particularly the classical (CL) versus basal-like (BL) Moffitt classification, offers prognostic and predictive value: CL tumors show improved outcomes and greater sensitivity to 5 fluorouracil based regimens (e.g., FOLFIRINOX). However, BL tumors exhibit poor outcomes across treatment regimens and may benefit from clinical trial prioritization or intensified oversight. But routine use of RNA-based subtyping is hindered by cost, turnaround time, and restricted access to commercial assays such as Purity Independent Subtyping of Tumors (PurIST). To overcome these barriers, we developed a deep learning model that infers PDAC molecular subtypes directly from hematoxylin and eosin (H&E) whole slide images (WSIs) by integrating with matched RNA-sequencing data for supervised training. In this initial iteration, WSIs from 126 Pancreatic Cancer Action Network (PANCAN) patients with high-quality slides and confirmed CL or BL transcriptomic profiles were curated. Bulk RNA-seq underwent standardized preprocessing, including quality control, alignment, normalization, and quantification of Moffitt-derived gene signatures to generate high-confidence molecular labels for supervised training. These annotations served as ground truth for supervised training. Using five-fold cross-validation, the model classified PDAC tumors into CL and BL subtypes with strong performance (area under curve, AUC: 0.83; accuracy: 77%; specificity: 80%; sensitivity: 72%), comparable to existing image-based PurIST subtyping literature (AUC 0.83-0.86). Our ongoing work with larger multi-institutional datasets aims to further enhance accuracy and generalizability. This proof of concept establishes the feasibility of AI-driven digital pathology for rapid, scalable Moffitt PDAC molecular subtyping directly from WSIs of routine H&E slides. By eliminating the need for RNA-based assays, this approach offers a cost-effective and scalable alternative, particularly valuable for real-world and resource-limited clinical settings. Prospective validation studies will be crucial for refining performance, assessing clinical utility, and enabling integration into precision oncology workflows for PDAC treatment.

#2744 Automating clinical and pathological staging for breast cancer patients.

Arshad Mohammed[1], Umair Ayub[2], Pooja Advani[3], Shakeela W. Bahadur[2], Amye J. Tevaarwerk[4], Tufia C. Haddad[4], Elisabeth I. Heath[4], Brenda J. Ernst[2], Ben Zhou[5], Cui Tao[6], Sara J. Holton[4], Karthik V. Giridhar[4], Irbaz B. Riaz[2]

[1]Mayo Clinic Alix School of Medicine, Phoenix, AZ,[2]Division of Hematology/Oncology, Mayo Clinic, Phoenix, AZ,[3]Division of Hematology/Oncology, Mayo Clinic, Jacksonville, FL,[4]Division of Hematology/Oncology, Mayo Clinic, Rochester, MN,[5]Department of Computing and Augmented Intelligence ASU, Tempe, AZ,[6]Department of Artificial Intelligence and Informatics, Mayo Clinic, Jacksonville, FL

Background: Accurate staging is essential for treatment selection, prognosis assessment, and trial eligibility. While prior studies attempted automating pathological (p) staging, few address clinical (c) staging and no studies have compared LLM-derived staging with clinician staging during clinical visit and retrospective cancer registry staging.
Methods: We developed a multi-agent framework using Gemini-2.0-Flash-001 and GPT-5 to (1) identify reports (2) extract key data, and (3) apply AJCC 8th edition staging criteria. LLM staging was compared with clinician documentation and registry staging in breast cancer patients. Clinician-registry agreement served as the reference standard. Two independent breast oncologists reviewed discordant cases.
Results: We analyzed 122 randomly selected breast cancer patients across all three Mayo Clinic sites from 2018 - 2023. LLM performance matched or exceeded human inter-rater agreement for pathological staging (95-99.2% vs. 95-98.4%). Clinical staging was more challenging, with LLM concordance of 73-77.9% for cT and 87-89.3% for cN versus 87.8% and 91.0% clinician-registry agreement. Among 89 patients with clinician-registry concordance, LLM concordance was 98.9% for pT/pN, 79.8% for cT, and 91.0% for cN. Experts favored LLM staging in 27.8% (5/18) of cT and 25.0% (2/8) of cN discordances. Error analysis revealed LLM challenges in handling non-mass enhancements (6 cases), selecting radiologic measurements (2 cases), identifying discrete masses (2 cases), and miscellaneous (3 cases).
Conclusion: LLMs achieved human-level performance for pathological staging (98%), supporting human-in-the-loop deployment. For clinical staging (79.8% cT, 91.0% cN), future work must enhance multimodal reasoning and integrate physical examination data. Prospective validation is needed to assess real-world impact. With targeted refinements and oversight, automated staging can transform registry workflows while augmenting clinical decision-making.

Clinical-Pathological Staging Concordances

Comparison	pT	pN	cT	cN
LLM vs. Registry	96.7%	99.2%	73.8%	87.8%
LLM vs. Clinician	95.9%	96.7%	77.9%	89.3%
Clinician vs. Registry	95.1%	98.4%	87.8%	91.0%

#2745 Patients prefer ChatGPT to physician responses in cancer communication.

Aaron Segura, Bernard Tawfik, Ben Liem, Zoneddy Dayao, David Y. Lee, Jacklyn M. Nemunaitis, David Savage, Moises Harari-Turquie, Nicole Hill, Charles Foucar, Amy Tarnower, Dulcinea Quintana, Jude Khatib, Thomas Schroeder, Martha Mapalo, Yolanda Sanchez, Ramesh Gopal

University of New Mexico Comprehensive Cancer Center, Albuquerque, NM

Introduction
Large language models like ChatGPT (GPT) are increasingly utilized by patients and physicians yet it is unknown whether either group prefers the output of GPT compared to physician-authored content. This study evaluated how patients and physicians perceive and compare ChatGPT-generated versus physician-authored recommendations.
Methods
We surveyed 51 adult female breast cancer patients and 15 physicians at the University of New Mexico Comprehensive Cancer Center to compare their evaluations of GPT versus physician-authored responses to four cancer scenarios related to treatment, family dynamics and employment. Each scenario included two blinded, responses to the same question—one from GPT and one from a physician. Participants rated each on 7-point Likert scales for helpfulness, empathy, and informativeness and indicated their preferred response (1 = strongly agree, 7 = strongly disagree). The primary outcome was the proportion preferring GPT (binomial test vs 50%); secondary outcomes were within-subject Likert differences (Δ = GPT - physician) analyzed with Wilcoxon signed-rank tests.
Results
Among 66 participants (51 patients; 15 physicians), patients preferred GPT 71/104 (68.3%, $p = 0.00025$), while physicians preferred GPT 31/52 (59.6%, $p = 0.21$), with no significant difference between groups ($p = 0.82$). Preferences varied by scenario: patients showed no significant differences in S1 or S2 (52.6% and 58.6% preferring GPT; both $p > 0.45$), strongly favored GPT in S3 (85.7%, $p = 0.00018$), and significantly favored GPT in S4 (71.4%, $p = 0.036$). Physician preference for GPT was near equipoise for all scenarios (36.4-75.0%, all $p \geq 0.15$). Patient ratings favored GPT for helpfulness ($\Delta = -0.36$, $p = 0.009$), empathy ($\Delta = -0.46$, $p = 0.009$), and informativeness ($\Delta = -0.42$, $p = 0.013$). Physician ratings showed no significant differences for helpfulness ($\Delta = -0.10$, $p = 0.59$) or informativeness ($\Delta = +0.18$, $p = 0.57$), with a trend toward higher empathy for GPT ($\Delta = -0.44$, $p = 0.058$).
Conclusion
Patients showed a strong overall preference for GPT-generated recommendations, with scenario-specific differences. Physicians demonstrated a smaller, nonsignificant preference for GPT. While ratings were numerically close for all domains, patients consistently judged GPT responses as more helpful, empathetic, and informative, whereas physicians rated the two sources similarly. These findings suggest that physicians could combine GPT-generated responses preferred by patients with their own recommendations to improve clinical communication.

#2746 AI vs human abstraction of pain scores and analgesic trends in low-dose radiation therapy for osteoarthritis: A concordance study.

Camille Schwartz[1], Michael Anderson[2], Kelsey Moakler[2], Bradley Newby[2], David Davenport[2], Matthew Schwartz[3]

[1]University of Nevada, Las Vegas, Las Vegas, NV,[2]Comprehensive Cancer Centers of Nevada, Henderson, NV,[3]University of Nevada, Las Vegas (UNLV), Las Vegas, NV

Background / Significance:
Accurate clinical data abstraction underpins outcomes research but remains resource-intensive and variable. Artificial intelligence (AI) offers potential to streamline this process while maintaining accuracy, yet its validation in real-world oncology data is limited. This undergraduate-led study evaluated Microsoft Copilot in replicating human chart abstraction for pain and functional outcomes among osteoarthritis (OA) patients treated with low-dose radiation therapy (LDRT), emphasizing concordance, efficiency, and reproducibility.
Methods:
Clinical notes from 30 patients (55 joints) treated with LDRT (3 Gy in six 0.5 Gy fractions) between August 2024 and August 2025 were analyzed. Human reviewers manually extracted Numeric Rating Scale (NRS, 0-10) and von Pannewitz Score (VPS, 0-4) data at baseline, end-of-treatment (EOT), and one-month follow-up. Microsoft Copilot (HIPAA-compliant) independently extracted identical data. Discrepancies were classified as exact, minor (≤2-point difference), or missed. Concordance was calculated using intraclass correlation coefficient (ICC) for NRS and weighted kappa for VPS. Abstraction time per chart was recorded.
Results:
AI achieved 92 percent exact match for NRS (ICC = 0.96, 95 percent CI 0.93-0.98) and 94 percent for VPS (kappa = 0.91). No fabricated data were produced; one human omission was detected by AI. Mean abstraction time was about 2 minutes per chart versus 30 minutes for humans, a greater than 10-fold efficiency gain.
Conclusions:
AI-assisted abstraction showed near-perfect concordance with human reviewers while reducing time and labor by over 90 percent. This undergraduate-led investigation demonstrates that responsible AI implementation can enhance accuracy, reproducibility, and efficiency in radiation-oncology outcomes research and accelerate evidence generation in oncology.
Disclosure:
No external funding or conflicts of interest. Data abstraction performed using Microsoft Copilot (HIPAA-compliant); no generative AI tools were used for writing.

#2747 Source discipline matters: Guideline anchored large language model outperforms Open Evidence for decision support in acute leukemias.

Peter Palumbo[1], Connor Yost[2], Emilio Del Toro[1], Demetrios Garbis[1], Peter Odutola[3], Yash Kumar[4], Arturo Loaiza[5], Matthew Sullivan[6]

[1]Dartmouth Geisel School of Medicine, Hanover, NH,[2]Department of Internal Medicine, Creighton University School of Medicine, Phoenix, AZ,[3]Department of Molecular Biology, Harvard University, Cambridge, MA,[4]Institutional Liaquat National Medical College Hospital, Karachi, Pakistan,[5]Department of Hematology and Oncology, St. Luke's University Health Network, Bethlehem, PA,[6]Department of Hematology and Oncology, Dartmouth Hitchcock Medical Center, Lebanon, NH

Background

Acute leukemia is one of the most complex and rapidly evolving domains in hematologic oncology, where treatment selection depends on a variety of factors such as molecular subtype and performance status. The National Comprehensive Cancer Network (NCCN) provides updated, lineage-specific algorithms for Acute Myeloid Leukemia (AML) and Acute Lymphoblastic Leukemia (ALL), yet these guidelines are dense and frequently revised. Large language models (LLMs) may assist clinicians in synthesizing this data, but the reliability of their outputs depends critically on their evidence sources. This study compared an NCCN-anchored retrieval-augmented model (RAG GPT-5) with Open Evidence (OE), a model linked to journal-based sources such as *NEJM* and *JAMA*, to assess accuracy, safety, and guideline concordance in acute leukemia decision support.

Methods

Forty de-identified AML and ALL vignettes were independently evaluated by two models: Open Evidence (O_1) and an NCCN-anchored retrieval-augmented GPT-5 model (O_2).). Reviewers were blinded to model identity and rated each response using a modified Generative Performance Score (mGPS = Guideline Concordance - Hallucination Penalty; range –1.0 to + 1.0). Statistical comparison used independent-samples t-tests.

Results

The RAG model (O_2) demonstrated significantly higher overall performance (mean = 0.84, SD = 0.25) compared with Open Evidence (O_1, mean = 0.70, SD = 0.32); $t(\approx 78) = -2.17$, $p = 0.033$. Qualitative review revealed key distinctions in clinical reasoning:

- Open Evidence frequently hallucinated agents (e.g., ipilimumab), omitted prior therapy context, and failed to adjust for infection recovery or cardiac risk before chemotherapy.
- RAG GPT-5 exclusively cited NCCN recommendations, with minor rounding errors (e.g., ATRA dose), and occasionally defaulted to conservative but still guideline-concordant dosing (e.g., daunorubicin).
- Neither model fully addressed dual-tumor or BCR-ABL-positive scenarios, and both under-recognized recent updates such as *menin inhibitors* for MLL-rearranged AML, which are emerging but not yet NCCN-listed. Variance was smaller for the RAG system, indicating more consistent performance across cases.

Conclusions

In acute leukemias, evidence source materially alters LLM behavior and reliability. Guideline-anchored retrieval produced significantly more NCCN-concordant recommendations and fewer hallucinations than OE. While both systems occasionally missed nuanced treatment history or recent investigational agents, only OE introduced clinically unsafe suggestions. These findings support NCCN-anchored RAG as the safer and more consistent foundation for LLM-based decision support in acute leukemias, where precision and patient context are paramount. Future work should expand to relapse and transplant scenarios with prospective clinician validation.

#2748 Arkangel AI, OpenEvidence, ChatGPT, Medisearch: Are they objectively up to medical standards? A real-life assessment of LLMs in healthcare.

Natalia Castano -Villegas[1], Maria Camila Villa[2], Katherine Monsalve[3], Isabella Llano[2], Laura Velasquez[2], **Jose Zea**[2]

[1]Arkangel AI, Bogota, Colombia,[2]Arkangel IA, Bogota, Colombia,[3]Arcangel IA, Bogota, Colombia

Background: Large language models (LLMs) are increasingly used in healthcare, but standardized benchmarks fail to capture their validity and safety in real-world scenarios. Evaluating their quality is critical for safe integration into practice.
Methods: Four fictitious clinical vignettes were developed by independent specialists and tested in four conversational agents: ArkangelAI, OpenEvidence, ChatGPT, and Medisearch. Each vignette included four questions. Responses were evaluated by four external clinicians using an eight-criterion Likert scale: 1-2 = dissatisfaction, 3 = neutral, 4-5 = satisfaction, 6 = not applicable. The criteria considered correctness, consensus, bias, standard of care, updated information, patient safety, real sources in references, and context-awareness. Response times were measured with medians/interquartile ranges (IQR). Results were reported as frequencies. Hypothesis tests were applied ($\alpha = 0.05$).
Results: There were 128 Question-answer pairs. ArkangelAI-Deep had the highest satisfaction (92.9%), followed by OpenEvidence (83.6%), ChatGPT-Deep (80.5%), and Medisearch (71.1%). Most dissatisfaction was for the real-source-of-references criteria: GPT-Personalized 75%, GPT-Regular 97%. Conversely, ArkangelAI-Deep, ChatGPT-Deep, and OpenEvidence obtained 100% satisfaction. All performed well in correctness and agreement with the consensus. ChatGPT was the lowest-scoring in non-biased answers. The safest for patients was GPT-Personalized, followed by Arkagel AI-Deep. Medisearch had the fastest response time (18 s), while GPT-Deep (13 min) and ArkangelAI-Deep (7.4 min) were slowest, showing a trade-off between depth and usability.
Conclusions: ArkangelAI-Deep and OpenEvidence consistently outperformed others, while Medisearch and GPT-Regular had significant limitations. These results underscore the need for standardized frameworks to ensure safe use of LLMs in healthcare.

#2749 Towards a foundation model for treatment-related adverse events in cancer immunotherapy.

Bin Baek[1], Tingyi Li[1], Biwei Cao[2], Xiaqing Yu[1], Xuefeng Wang[1]

[1]Biostatistics and Bioinformatics, H.Lee Moffitt Cancer Center and Research Institute, Tampa, FL,[2]Biostatistics, H.Lee Moffitt Cancer Center and Research Institute, Tampa, FL

Background: Immune-related adverse events (irAEs) provide important clues about immune activation during checkpoint blockade, yet real-world AE reporting is often sparse and fragmented. A further challenge is that FAERS provides unstructured case-level reports, while ClinicalTrials.gov reports arm-level AE tables that differ greatly in completeness and level of detail across trials. These differences make it difficult to study toxicity patterns across data sources in a unified way. To address this gap, we developed a denoising AE foundation model that reconstructs missing Preferred Terms (PTs), learns latent AE co-occurrence structure, and generates biologically interpretable AE embeddings.

Methods: We collected ten years of FAERS reports related to immune checkpoint inhibitors (2015Q1-2025Q2) and curated a vocabulary of 200 treatment-related PTs. The model treats each AE profile as partially observed and performs PT-aware masking, case-level PT dropping, and multi-label reconstruction on a BioBERT backbone. Candidate-set validation was used to evaluate recovery of truly unobserved PTs, and mid-layer pooling was applied to improve stability across diverse AE profiles. For ClinicalTrials.gov, we harmonized arm-level AE tables by standardizing differences in reporting depth and AE granularity. We then generated pooled AE signatures for each treatment arm and evaluated whether these signatures could distinguish immunotherapy arms with known differences in clinical outcomes.

Results: The model recovered intentionally hidden AEs with strong performance (Recall@5 = 0.38; Recall@10 = 0.51). The learned embedding space separated well-known irAEs from non-immune toxicities and formed clusters that aligned with MedDRA SOC patterns. When applied to ClinicalTrials.gov treatment arms, the AE signatures reflected cancer-type-specific patterns, including dermatologic events in melanoma and hepatic or gastrointestinal patterns in hepatocellular carcinoma and GI cancers. Arm-level embedding profiles also differentiated treatment arms with superior outcomes across several ICI trials, suggesting that the representation space captures meaningful biology related to treatment response.

Conclusions: We present a foundation model that integrates FAERS and ClinicalTrials.gov AE data to denoise AE profiles, learn biologically grounded toxicity embeddings, and reveal AE patterns associated with clinical benefit. This framework provides a scalable approach for studying AE biology and may support AE-based biomarker development and arm-level prediction of immunotherapy efficacy.

#2750 Rapid curation of colon cancer cohorts using on-site peta-scale language model for MSI classification from pathology reports.

Joshua Jay Levy, Nathalie Nguyen, Minh-Khang Le, Keluo Yao, Jane Figueiredo

Cedars-Sinai Medical Center, Los Angeles, CA

Background: Pathology reports are highly heterogeneous, making it difficult to extract structured information needed for cohort curation. Earlier machine-learning models had to be trained separately for each specific task, limiting flexibility. Newer large language models (LLMs) can follow written instructions—"prompts"—to identify or summarize information directly from the text, allowing a single model to perform many tasks without retraining. These models were previously too large to run within hospital systems, but compact GPU platforms, such as NVIDIA DGX, now make state-of-the-art LLMs containing hundreds of billions of parameters feasible to deploy locally. This enables rapid prototyping of flexible extraction workflows. Here, we evaluate locally deployed LLMs for rapid cohort curation using mismatch repair (MMR) status extraction from colorectal pathology reports as an example.
Methods: A total of 82 colorectal pathology reports were collected across two study cohorts (ColoCare and SeroNet). Most reports included MLH1, MSH2, MSH6, and PMS2 staining results used to determine MSI (microsatellite instability) status. Two locally deployed LLMs (GPT-OSS 20B and 120B) classified each case as MSI, MSS, or ambiguous based on documented MMR expression or any direct MSI statement, with cases lacking clear MMR information assigned to an ambiguous category. Model predictions were compared with manual MSI annotations. For reports the model classified as ambiguous but annotators judged MSI or MSS, each model was prompted to restate and justify its decision to assess reasoning consistency.
Results: Both models performed well across the 82 reports. The 20B model achieved 96.3% accuracy, while the 120B model achieved 95.1%. For MSI, the 120B model showed higher sensitivity (87.5% vs. 77.8%) and F1 score (87.5% vs. 82.4%), with both models maintaining high precision and specificity (≥ 87.5% and ≥ 98.6%, respectively). For MSS, performance was strong for both models, with the 120B model showing slightly higher precision (97.6% vs. 95.5%) and specificity (97.4% vs. 94.6%). The 20B model perfectly identified all ambiguous cases, whereas the 120B model assigned two MSS reports to "unable to be assessed." In reviewing these discrepancies, the models remained consistent with their original classifications but differed in how they interpreted the phrase "MSI IHC low prob": the 120B model viewed it as indeterminate and returned "unknown," while the 20B model interpreted the same wording as supporting MSS in the context of intact MMR expression.
Conclusion: These findings demonstrate the practical utility of leveraging state-of-the-art LLMs within privacy constrained hospital settings. Further work will assess performance in more technically challenging scenarios and clarify how ambiguous wording impacts quality control when integrating LLMs into clinical workflows.

#2751 Large language model-derived molecular patient similarity from real-world MTB data.

Sophie Lugani[1], Oğuz Serbetci[2], Alexander Reinicke[2], Benedikt Kortum[1], Berkay Ozdin[1], Thomas Debertshauser[1], Dominik Modest[1], Ulrich Keilholz[1], Ulf Leser[2], Manuela Benary[1]

[1]Charite - Berlin University Medicine, Berlin, Germany,[2]Humboldt-Universitat zu Berlin, Berlin, Germany

Background:
Molecular tumor boards (MTBs) frequently evaluate patients with rare molecular profiles where prospective evidence is scarce. To address this challenge, we investigated whether large language models (LLMs) can structure real-world MTB documentation into analyzable representations to identify molecularly similar patients.
Methods:
MTB documentation from 2,788 patients and pathology reports from 506 patients discussed at the Charité MTB (2020-2025) were structured using NVIDIA Nemotron-49B. Textual summaries and structured features on prior targeted therapies, immunohistochemistry (IHC), and molecular alterations (MOL; CiViC-weighted) were extracted, yielding 1,736 textual, binary and numeric features. The LLM output was vector embedded using bge-multilingual-gemma2. Patient similarity was computed using cosine distance for embeddings, and Jaccard (binary) and absolute error (numeric) for structured features. Similarity rankings were ensembled via reciprocal-rank fusion and evaluated using MRR and nDCG, against BM25 and embedding baselines on raw MTB documentation. As a proxy for ground truth, MTB recommendations were structured into course of action, drug, agent class, and clinical trial elements and used as similarity targets.
Results:
LLM-based information extraction achieved F1 scores of 96% for mutation detection and 92% for IHC, evaluated against 30 manually annotated pathology reports. The ensemble similarity method - combining structured-feature similarity, summary-embedding similarity, and BM25 via reciprocal-rank fusion - showed the highest alignment with MTB recommendations (MRR@1000 = 25.8, nDCG@10 = 10.1), outperforming BM25 alone (22.8, 8.6) or text-embedding similarity of MTB documentation (22.2, 8.3), with all improvements statistically significant ($p < 0.01$). Structured features derived from MTB documentation (20.2, 9.2) outperformed those derived from pathology reports (17.9, 8.0). Together, these findings indicate that LLM-derived representation improved therapy-aligned patient similarity over text- and embedding-based baselines. Across all cases, 486 unique therapeutic entities were identified; among 290 drug entities, 163 were recommended to more than one patient, and 65% of patients shared at least one recommendation with another case.
Conclusion:
LLM-derived clinical-molecular representations enabled scalable retrieval of molecularly matched cases in real-world MTB datasets. This approach supports institutional case library formation and systematic case series generation, enhancing evidence generation in precision oncology.
[O.S. and S.L. contributed equally to this work.]

#2752 CancerSTFormer enables multi-scale analysis of spot-resolution spatial transcriptomes and dissects the gene and immune regulatory responses of targeted therapies.

Benjamin Strope[1], Dana Varghese[1], William Bowie[1], Stacy Wang[1], **Qian Zhu**[2]

[1]Lester Sue Smith Breast Center, Baylor College of Medicine, Houston, TX,[2]Lester Sue Smith Breast Center, Molecular and Human Genetics, Dan L. Duncan Cancer Center, Baylor College of Medicine, Houston, TX

Despite the success of immunotherapy, a significant number of cancer patients still do not respond to it. It is important to understand why treatment fails and to find better treatment for them. We believe that achieving the goal of increasing the efficacy of immunotherapy must start with understanding the spatial microenvironment and the mechanisms of immunosuppression, so that biology-driven treatment strategies can be developed. A growing number of studies have placed increasing importance to the concept of niche, a multicellular environment, and recognize that niches are the primary contributor of tumor phenotypes and clinical outcomes rather than individual cells or cell types. Spatial transcriptomics are adept at providing niche-level gene expression measurements. Given the importance of niches, we believe that a spatially aware foundation model for cancer ST data collections will realize the therapeutic and prognostic potential of these datasets. We propose CancerSTFormer, consisting of a pair of spatially aware transcriptomic foundation models at the 50μm-Local and 250μm-Extended scales. The models possess unique capabilities to recover ligand-target gene relationships, niche-specific differentially expressed genes, and revealing the gene and immune regulatory responses of immune-checkpoint blockade therapies, and other targeted cancer therapies, on patients' tumors given ST profiles through perturbation analysis.

In the pre-trained setting, we sought to perturb each gene encoding PD-1, PDL1, and CTLA-4 proteins, respectively PDCD1, CD274, and CTLA4, on TNBC ST profiles to simulate and understand ICB response. In silico perturbations correctly recapitulated anti-tumor immune response in both the long distance (250um Extended model), and short-range settings (50um Local model) according to GSEA. In the fine-tuned setting, we show that the tool can refine anti-PD1, ganitumab, and trebanalib treatment-resistance and sensitivity signatures. From ISPY-2 trial, we derived PD1-responsive and PD1-resistant gene sets, which served as gold standards to train a gene-classifier within for predicting response-associated genes from ST data. We next applied in silico deletion of PDCD1 using this fine-tuned model, and evaluated the results using the PD1-sensitive/resistant gene sets of the Holdout group. When compared against a fine-tuned Geneformer and a norefinement control, both Local and Extended CancerSTFormer variants consistently achieved higher accuracy in predicting resistant and sensitive genes in holdout cohorts across all 3 treatments.

Overall, this tool reuses ST data for understanding how gene perturbation impact spatial niches in cancer, while also providing ST-driven, gene-based refinement of treatment-resistance and sensitivity signatures derived from existing bulk transcriptomics.

#2753 Ontology-guided hierarchical cell typing with large language models for analyzing tumor microenvironment.

Jeongbin Park, Yuchang Seong, Hongyoon Choi

Portrai, Inc., Seoul, Korea, Republic of

Background
Due to the emergence of a vast amount of single-cell RNA sequencing (scRNA-seq) and single-cell resolution spatial transcriptomics (ST), there has been a demand for cell type annotation pipelines that are reproducible, scalable, and capable of functioning as end-to-end solutions. Reference-dependent cell typing may be compromised due to a labor-intensive preparation step for scRNA-seq data matching the data to be labeled and the algorithm. Also, reference-free pipelines couldn't provide appropriate human-interpretable labels for each deconvoluted cell type, limiting their comparison with the existing literature. Furthermore, many algorithms often overlook the hierarchical structure of cell type annotations.
Method
We developed hierarchy-aware LLM-aided cell type annotator using cell type ontology tree. LLM can be any type, but we focused on gpt-4o and gpt-oss-20b. Step 1, we first excluded cell ontologies not relevant to the context, reducing ~2,300 entries to about 400-500. Step 2, terms were processed in batches of 150 using the context and an LLM; the curated list was then reprocessed by the LLM, yielding fewer than 40 cell-type terms. Step 3, we elicited context-specific marker genes with the LLM in five independent runs and aggregated the results into a single list. Step 4, we clustered single cells using highly variable genes to obtain cluster labels, restricted the data to the Step 3 markers, and computed differentially expressed genes (DEGs). Using the top 20 DEGs for each cell, we queried the Step 2 term list to assign a cell-type label. We then retrieved the Cell Ontology tree and performed unsupervised hierarchical clustering on cluster centroids to infer relationships; aligning these with the ontology enabled hierarchical cell-type labeling for each cell.
Results
We applied the agentic workflow using LLM (gpt-oss-20b) to 40,000 lung cancer single-cell samples. A continuous hierarchy was reconstructed from "cell" (level 1) to T follicular helper cell (level 10). To assess performance, we compared Adjusted Rand Index (ARI) values between four ground-truth levels and the 10-level predicted hierarchy. We observed a maximum of 0.86 (Level 2 ground truth vs. Level 5 predicted label). Overall, the pipeline completed annotation efficiently, requiring approximately 40 minutes for ontology filtering and 20 minutes for all subsequent steps, demonstrating scalability for large-scale single-cell datasets.
Conclusion
Our pipeline provides scalable cell-type annotation to meet the recent surge of scRNA-seq data. Moreover, by leveraging the flexibility and memory capabilities of LLMs, it enables typing of minor cell types; by using existing cell-type ontology trees, it supports hierarchy-aware cell typing; and by constraining selections to the established cell ontology, it reduces hallucinations and yields human-interpretable cell typing.

#2754 VGL: Vision-Gene-Language multimodal LLM integrating histopathology and gene expression for cell type classification in lung cancer.

Haenara Shin, Dongjoo Lee, Jeongbin Park, Hongyoon Choi

Portrai, Inc., Seoul, Korea, Republic of

Background
Understanding the tumor microenvironment requires models that resolve cellular heterogeneity across molecular and spatial modalities. With the expansion of spatial transcriptomics, single-cell RNA-seq, and high-resolution histopathology imaging, there is a need for a unified foundation model that jointly interprets gene expression, spatial context, and visual tissue features. We developed a multimodal large language model (LLM) that integrates these modalities into a single adaptive framework handling heterogeneous inputs—including gene expression profiles, spatial transcriptomics spots, single-cell measurements, and histology patches—while generating harmonized outputs such as genes, cell types, and image-derived descriptors.
Method
We built a multimodal LLM within a Vision-Gene-Language (VGL) framework that integrates gene expression, histology images, and biological language representations. The model is based on MedGemma-4b-it and was fine-tuned using QLoRA for parameter-efficient training. Training used 5.2 million multimodal samples of H&E patches paired with highly variable gene expression profiles from non-small cell lung cancer, totaling 1,745,240 cells and spatial spots across scRNA-seq and spatial transcriptomics platforms (Visium, Xenium). The model was trained using multi-task learning across five canonical tasks spanning image-to-gene, gene-to-cell type, and cell type-to-gene objectives with task-specific ratio scheduling on 4 x H100 GPUs. We evaluated performance on cell type classification from gene expression profiles across 12 major immune and stromal cell types.
Results
The trained VGL model achieved 70.07% accuracy on the held-out test set (n=20,764) for predicting cell types from gene expression profiles, compared to 16.32% accuracy for the naive pre-trained model, a 4.3-fold improvement. Validation performance was similar (69.85% accuracy, n=41,529), indicating robust generalization. These gains demonstrate the value of a multimodal LLM that jointly leverages single-cell, spatial transcriptomics, and histology information. Through cross-modal learning and masking, the model learned gene and cell type embeddings that generalized across data platforms and spatial contexts and produced biologically consistent outputs even when only a subset of modalities was available.
Conclusion
We introduce a multimodal LLM-based spatial foundation model, VGL, that unifies single-cell RNA-seq, spatial transcriptomics, and histopathology imaging into a modality-agnostic framework. The improvement in cell type classification highlights the model's ability to capture and reason over cross-modal biological structure. This framework lays the groundwork for spatial AI systems that interpret heterogeneous molecular and imaging data and enable scalable tumor microenvironment profiling.

#2755 Large scale extraction of adverse events by large language models uncovers latent structure of treatment toxicity.

John Lazar[1], Divneet Mandair[2], Catherine C. Smith[2], Travis Zack[3]

[1]UCSF - University of California San Francisco, San Francisco, CA,[2]UCSF, San Francisco, CA,[3]UCSF School of Medicine, San Francisco, CA

Managing treatment toxicity is a major challenge in oncology. Large-scale data on treatment related adverse events (AEs) could help oncologists better understand and predict toxicity. However, most AE datasets are limited to small numbers or restricted types of events due to the labor-intensive manual reporting traditionally required to document AEs. Automated extraction of AEs from the electronic health record (EHR) could enable large-scale analysis but is a challenging task as information about most AEs is in diffuse, unstructured data such as clinical notes.We therefore developed and validated an agentic large language model (LLM) pipeline, *AE-Extract,* to extract and grade AEs from oncologists' progress notes. The pipeline is highly sensitive with a recall of >95% for events in the same organ system and a precision of 67% compared to manual annotation. Lower precision relative to recall reflects uncertainty in the attribution of events to treatment effects as well as design choices to prioritize higher recall over precision. To comprehensively characterize AEs during cancer therapy, we subsequently applied *AE-Extract* to a set of 84,684 progress notes from an academic cancer center. We identified 279,457 total AEs, a mean of 3.3 per note. To identify recurrent patterns of treatment toxicity, we applied non-negative matrix factorization (NMF) to the AE data and identified 85 latent factors that capture patterns of toxicities in the dataset. These latent patterns capture co-occurrence of mechanistically related events such as neuropathy and falls as well as associations in different organ systems without known mechanistic connection such as pruritus and colitis in patients receiving immunotherapy or neuropathy and nail changes in patients receiving cytotoxic chemotherapy. As the latent factors quantify core patterns of AEs, we next studied how they could be used as robust feature sets for analysis of treatment toxicity. First, we found that the latent patterns identified in the first part of a patient's treatment course can predict development of new AEs as well as worsening severity of existing AEs. We also found these patterns of treatment toxicity correlated with patient demographics and comorbidities: we recapitulated known associations such as the link between gender and cancer induced nausea/vomiting as well as novel relationships such as a link between ischemic heart disease and vestibulocochlear symptoms including tinnitus and hearing impairment.Overall, our work demonstrates a new method for accurate, high-throughput extraction of AEs from clinical notes. We show how comprehensive evaluation of treatment toxicity allows for better characterization of patterns of AEs, identifies robust associations between treatment toxicity and patient characteristics, and may serve as a starting point for building personalized models to predict treatment toxicity.

#2756 Development of an LLM framework for analysis of heterogeneous breast cancer patients genomic reports.

Krishna Rani Kalari[1], Xiaojia Tang[2], Thanmayee Boyapati[3], Tanya L. Hoskin[4], Sumathilatha Myla[4], Sumedha G. Penheiter[5], Richard M. Weinshilboum[6], Liewei Wang[5], Hamid R. Tizhoosh[7], Karthik Vikram Giridhar[2], Matthew P. Goetz[8], Judy C. Boughey[9]

[1]Biomedical Informatics, Mayo Clinic College of Medicine, Rochester, MN,[2]Mayo Clinic Cancer Center Minnesota, Rochester, MN,[3]University of Minnesota, Twin cities, Minneapolis, MN,[4]Quantitative Health Sciences, Mayo Clinic, Rochester, MN,[5]Mayo Clinic College of Medicine, Rochester, MN,[6]Professor, Dept. of Pharmacol. & Med., Mayo Clinic College of Medicine, Rochester, MN,[7]Mayo Clinic, Rochester, MN,[8]Mayo Clinic College of Medicine and Science, Rochester, MN,[9]Radiation Oncology, Mayo Clinic, Rochester, MN

Background: The increasing volume and diversity of clinical genomic reports pose a significant challenge across healthcare institutions for the interpretation and proper implementation of precision oncology research. Reports from multiple different vendors (e.g., Invitae, Ambry Genetics, Foundation Medicine) are typically PDFs and exhibit substantial heterogeneity in panel design, gene coverage, and reporting standards, which hinders efficient retrospective data mining and patient cohort identification within the electronic medical records. We sought to develop a framework to interrogate all of these reports.
Methods: We extracted genomic reports from patients with breast cancer treated with neoadjuvant chemotherapy and developed MolHarmonizer, a novel, scalable framework leveraging Python and Gemini LLMs, designed to process and harmonize genomic data from disparate multi-vendor reports. Gemini LLMs are employed explicitly for robust information extraction, normalization, and structuring of key genomic features, transforming unstructured data into a unified, queryable dataset.
Results: Our MolHarmonizer framework successfully processed 1,147 genomic reports from 1703 breast cancer patients (2006-2023) from 23 different companies, demonstrating robust capability to extract and standardize critical actionable biomarkers. Data sources included Invitae (n=554), Ambry Genetics (n=189), Natera (n=95), Mayo Clinic (n=88), Tempus (n=63), Guardant Health (n=47), and Foundation Medicine (n=37), with others contributing less than 20 reports. Of the samples, 827/1147 (72.1%) were germline (blood/saliva). A majority of the patients were tested using the panels due to a personal/family history (n=925). Overall, 413/1147 (36.0%) reports identified at least one mutation. For breast cancer, 75 reports showed BRCA1/2 mutations (37 BRCA1, 37 BRCA2, and one patient with both BRCA1 and 2). Other mutations identified included: PIK3CA (n=40), TP53 (n=96), PTEN (n=21), ESR1 (n=13) and AKT1/2 (n=8).
Conclusion: MolHarmonizer, a powerful framework leveraging Gemini LLMs, effectively addresses genomic data heterogeneity by automating biomarker extraction and harmonization. This enables rapid cohort identification and deep retrospective analyses for clinical insights, biomarker discovery, understanding disease history, facilitating novel pattern discovery, e.g., predicting BRCA1 mutations from WSI, and accelerating research within our neoadjuvant BC cohort. Future plans include expanding to include over 20,000 breast cancer patients, developing a user-friendly chatbot, and ensuring inter-institutional adaptability for a variety of complex diseases.

#2757 Scale meets Speed: A transcriptome-wide spatial analysis that runs a rapid and interactive hypothesis-driven workflow with AtoMx® SIP.

Evelyn R. Metzger[1], Patrick Danaher[1], Nicole Ortogero[1], Sayani Bhattacharjee[1], Prajan Divakar[1], Joseph M. Beechem[2]

[1]Bruker Spatial Biology, Seattle, WA,[2]Bruker Spatial Biology, Piedmont, CA

The potential of whole-transcriptome spatial analysis to answer complex biological questions is often hindered by the sheer weight of its computational and analytical demands. As the number of cells, samples, and plex increases these computational challenges are compounded resulting in bottlenecks that slow the pace of discovery. Moreover, these complex datasets often require specialist data analysis expertise that can further slow "data-to-insight". To bridge this gap, we created a new analysis paradigm that enables biologists and researchers with less analytical expertise to interact with their data directly, performing deep hypothesis-driven analysis in a rapid, conversational and accessible workflow. In this presentation we discuss three advancements arriving in the reimagined AtoMx® Spatial Informatics Platform (SIP) and in development and highlight results found in a publicly available colon adenocarcinoma FFPE WTX sample. First, we have redesigned the architecture with the goal of putting biology front and center, allowing researchers to quickly observe, hypothesize, and learn iteratively. Second, an agile computational engine, leveraging a foundational model trained on >1 billion spatially-resolved single cells, automates cell annotations, reducing analysis time from days to hours. Third, this workflow creates a carefully-curated package of summary tables, thousands of times smaller than a full dataset, but far richer than a human-generated prompt. Once an LLM ingests this package, it stands ready to answer diverse questions about the dataset, *e.g.* "what pathways are spatially variable in tumor cells?", or "what are the spatial contexts T cells inhabit in this tissue?" We applied this approach to the colon sample (412,052 cells). Our foundational model automated cell typing and spatial domain assignment, providing the basis for the analysis. We then applied the LLM chat workflow. An initial query rapidly identified the dominant pro-tumoral signatures (EGFR, TGF-β, MAPK) and reduced pro-apoptotic TRAIL pathway. A follow-up "conversational" query for molecular drivers identified a significant MIF (tumor) to CD74 (TAM) ligand-receptor interaction, providing a direct mechanistic link to the observed MAPK activity. This entire workflow from automated cell typing to mechanistic insight was completed rapidly and generated all reproducible figures, demonstrating a complete analysis-to-visualization pipeline that does not require expert coding abilities. In conclusion, the AtoMx® SIP successfully bridges the gap between complex spatial data and biological insight. This new paradigm democratizes whole-transcriptome analysis, enabling researchers to conduct rapid, iterative, hypothesis-driven discovery without deep computational expertise.

#2758 *PAX3/7::FOXO1* fusion detection and transcriptomic prediction from whole-slide images of rhabdomyosarcoma using attention-based deep learning frameworks: A multi-institutional study.

Dorsa Ziaei[1], **Hyun Jung**[1], Philip J. Lupo[2], Pagna Sok[3], Jack F. Shern[4], Corinne M. Linardic[5], Syed Abbas Bukhari[4], Hsein-Chao Chou[4], Jun S. Wei[4], Curtis Lisle[6], Uma Mudunuri[1], Javed Khan[4]

[1]Frederick National Laboratory for Cancer Research, Frederick, MD,[2]Emory University School of Medicine, Atlanta, GA,[3]Baylor College of Medicine, Houston, TX,[4]National Cancer Institute, Bethesda, MD,[5]Duke University School of Medicine, Durham, NC,[6]KnowledgeVis, LLC, Maitland, FL

Background: Rhabdomyosarcoma (RMS) is a highly malignant pediatric soft-tissue sarcoma where molecular subtyping, particularly *PAX3/7::FOXO1* fusion status, drives prognosis and treatment. However, histology-based diagnostic approaches remain limited by subjectivity and the scarcity of comprehensive molecular annotations. To overcome these challenges, we improved our previously reported convolutional neural network learning models that predict *PAX3/7::FOXO1* fusion status from whole-slide images (WSIs) while additionally trained models to infer gene expression profiles from histology, thereby linking morphology to transcriptomic signatures.**Methods:**A total of 826 independent WSIs from three sources [Children's Oncology Group (COG) biobanking protocols = 322, Kids First (KIDS) = 252, Childhood Cancer Data Initiative/Molecular Characterization Initiative (CCDI/MCI) = 252] were used to train and evaluate an Attention-Based Multiple Instance Learning (ABMIL) model using UNI2-h foundation features for fusion classification. For gene expression prediction, 135 RMS WSIs paired with bulk RNA-seq data were used to fine-tune a SEQUOIA transformer model, which was trained on TCGA UCEC/COAD datasets. Model performance was evaluated using the Matthews Correlation Coefficient (MCC), AUC, and Pearson's r correlation, with biological validation through pathway enrichment analysis.**Results:**The fusion detection model achieved robust and generalizable performance across independent test cohorts (MCC ≥ 0.80, AUC ≥ 0.94), with multi-institutional training improving external generalization (MCC up to 0.84). The gene expression model reliably predicted bulk transcriptomic profiles from WSIs (mean $r > 0.6$, $p < 0.05$), identifying biologically meaningful pathways including cell cycle and muscle development. Together, these models demonstrate the feasibility of integrating morphological imaging data to gain molecular insights that would not be possible with histology alone.**Conclusions:**This work presents the first large-scale validated deep learning framework for simultaneous molecular subtyping and transcriptomic inference in RMS. By combining digital pathology with molecular prediction, our approach offers a scalable, tissue-sparing, and generalizable tool for advancing precision oncology in RMS.

#2759 An innovative AI-based platform for antibody stability improvement and affinity optimization.

Yiran Li, Hao Peng, Xinyu Bian, Hui Zhao, Yang Li, Panpan Zhang, Jinying Ning, **Feng Hao**

Kyinno Biotechnology Co., LTD, Beijing, China

Background: Bispecific antibodies (bsAbs), which simultaneously target two distinct antigens, offer advantages in specificity, efficacy, and resistance management, making them an increasingly important modality in therapeutic antibody development. However, their complex formats impose stringent requirements on affinity and stability. Traditional affinity maturation methods, such as saturation mutagenesis and phage display, are costly, time-consuming, and limited in their ability to improve stability. To overcome these challenges, we developed an AI-based antibody engineering approach that uses deep learning to predict key mutations based on engineering objectives and integrates these predictions with high-throughput expression, enabling greatly reduced screening efforts and rapid identification of optimized antibody variants.

Methods: We developed a deep learning-based AI model to support antibody engineering by simulating antigen-antibody docking and predicting affinity changes, enabling targeted mutation design according to defined optimization goals. For antibodies with poor stability, the model proposes engineered disulfide bonds or CDR/framework mutations to adjust surface hydrophobicity while maintaining affinity. For functional enhancement, it identifies key CDR residues and generates combinatorial multi-site mutations, allowing selection of variants with preserved affinity but improved blocking or functional performance.

Results: As an example using a symmetric scFv bispecific antibody, we applied AI-driven design to generate 50 candidate variants, followed by binding-based screening to eliminate molecules with altered affinity. Then candidate molecules were expressed, purified, and subjected to stability evaluation. This approach effectively find a new mutant reduced aggregation under one-week accelerated thermal stress from 100% to less than 5%, while increasing the melting temperature (Tm) by up to ~10 °C. For functional enhancement of nanobodies, we applied single-point mutagenesis followed by three rounds of combinatorial design, generating a total of 260 variants —representing a ~1000-fold reduction compared with traditional multi-site saturation libraries (10^3-10^5). This process yielded a nine-site mutant (with at least one mutation per CDR) that demonstrated a two-fold improvement in reporter cells blocking tests.

Conclusions: We developed an AI-guided approach to design targeted antibody variants, accelerating the discovery of molecules for bispecific antibody assembly and drug development.

#2761 Large language model-derived re-contextualization reveals functional landscapes across cancers.

Yibing Guo, Yanhao Tan, Chien-Hung Shih, Li-Ju Wang, Yu-Chiao Chiu

University of Pittsburgh, Pittsburgh, PA

The vast heterogeneity of human cancer necessitates a deeper understanding of how fundamental biological pathways are functionally reconfigured across different cancer types in contrast to non-malignant diseases. Conventional pathway analyses based on static, disease-agnostic gene sets often obscure the plasticity and tumor-specific roles of pathways. We address this limitation by leveraging the knowledge integration of large language models (LLMs) to generate and embed context-aware pathway descriptions, enabling a novel framework for quantifying pathway relevance and functional variability across the oncological landscape. We applied this framework to analyze 268 KEGG pathways across 35 cancer types and 7 non-malignant diseases. We performed two complementary analyses of the LLM-generated context-aware pathway descriptions: 1) disease-level analysis by applying unsupervised clustering to the embeddings derived from the context-aware descriptions to map inter-disease functional relationships; and 2) pathway-level analysis that quantifies the functional variability of each pathway across diseases to understand their disease-specific roles. The disease-level analysis revealed a coherent functional atlas of diseases. Within cancers, lineage and cell type drove distinct yet biologically consistent groups, such as hematologic malignancies, gastrointestinal cancers, and hormonal cancers. Non-malignant conditions (e.g., neurodegenerative disorders) formed separate, distinct clusters. Pathway-level analysis showed marked functional variability. Pathways with the lowest variation across diseases mainly involved conserved cellular functions (e.g., *mitophagy, AMPK signaling*), while highly dispersed pathways captured context-specific programs (e.g., *viral carcinogenesis, transcriptional misregulation in cancer*). Independent validation using a literature-derived pathway relevance score across diseases confirmed that the top 20 most dispersed pathways had significantly higher relevance scores than the bottom 20 ($p < 0.01$). Furthermore, the continuous level of dispersion correlated positively with pathway relevance ($p < 0.01$). These observations support that the semantic heterogeneity captured by LLMs across diseases truly reflects biological specificity and functional relevance. In summary, LLM-generated context-aware pathway descriptions and their corresponding embeddings successfully capture disease-specific functional organization and reveal mechanistic coherence across cancers. This represents a significant methodological advance over traditional static approaches, providing a dynamic, biologically relevant map for understanding heterogeneous cancer mechanisms and identifying novel therapeutic strategies.

#2762 LLM-based extraction of immunotherapy toxicities reveals severity-dependent effects on overall survival.

Zeyun Lu[1], Mustafa Saleh[1], Charles Lu[2], Intae Moon[1], Razane El Hajj Chehade[1], Elio Ibrahim[1], Yevgeniy R. Semenov[2], Toni K. Choueiri[1], Alexander Gusev[1]

[1]Dana-Farber Cancer Institute, Boston, MA,[2]Massachusetts General Hospital, Boston, MA

Characterizing immune-related adverse events (irAEs) among patients with cancer receiving immunotherapy remains challenging. Traditional ICD-based identification often misses or misclassifies irAEs, and manual chart review is labor-intensive, error-prone, and not scalable. Existing large language model (LLM)-based approaches often do not fully capture irAE onset dates and severity information, frequently missing mild events and limiting their utility for time-sensitive and severity-stratified analyses.We developed a two-stage prompting strategy to extract irAE type, severity, and onset date from large volumes of unstructured clinical notes for patients receiving immunotherapy. In the first stage, the model summarizes irAE-related information from long and heterogeneous clinical documentation. In the second stage, it extracts structured irAE details. This approach improves extraction accuracy and supports more reliable identification of irAE types and onset timing.

Using expert-curated ground truth, we evaluated multiple reliable and increasingly used large language models, including ChatGPT 4o, Llama 3.1 with 70B and 450B, Llama 3.3 with 70B, and DeepSeek R1. Across models, LLM-based methods achieved higher sensitivity (0.95 vs. 0.57), higher precision (0.69 vs. 0.64), and higher F1 scores (0.77 vs. 0.55) compared with ICD-based extraction. For cases in which both LLM and ICD identified an irAE, LLMs more accurately captured event types (83% vs. 38%) and consistently identified earlier onset dates (on average 27 days earlier). This strategy is model-agnostic and will continue to improve extraction accuracy as the underlying LLM models improve.

We applied our pipeline, which incorporates ChatGPT 4o, to 340,277 notes from 8,768 patients treated with immunotherapy in the Dana-Farber Cancer Institute Profile cohort, covering 21 cancer types. 87% of patients developed at least mild irAEs within two years of treatment initiation. Consistent with prior work, CTLA-4 inhibitors were associated with higher irAE incidence (HR = 3.93; P = 1.94e-19), using Cox models that incorporate irAE onset timing, information typically unavailable in earlier studies. Survival analyses stratified by time-dependent irAE severity showed that mild irAEs were associated with reduced hazard of death (HR = 0.86; P = 5.64e-92), whereas severe irAEs were associated with an increased hazard of death (HR = 1.04; P = 1.15e-3). We also observed system-specific severe irAEs that aligned with underlying cancer type; for example, patients with non-small cell lung cancer had a higher instantaneous risk of severe respiratory irAEs (HR = 2.37; P = 1.29e-9) compared with other cancers.

These findings demonstrate that LLM-based clinical text extraction enables scalable and accurate characterization of irAEs, providing deeper insights into their prognostic implications.

#2763 Leveraging large language models to classify pathology reports into ontological hierarchies.

Brenda Fried, Ali Kamali, Cesar Colorado-Jimenez, Melissa Pulitzer, David Kim, Leonardo Boiocchi, Alexander Chan, Mariko Yabe, Mikhail Roshal, Syed Aijazuddin, Ahmet Dogan, Chad Vanderbilt, Khawaja Hassan Bilal, Gregory Goldgof

Memorial Sloan Kettering Cancer Center, New York, NY

Free-text pathology reports vary in style, terminology, and uniformity, making consistent diagnostic extraction difficult for research cohort development. This issue is amplified in large archives, where evolving classifications and intentional ambiguity hinder standardized, categorical diagnoses. Structured ontologies such as OncoTree address this by enforcing codes. While OncoTree is used here as an example, the approach generalizes to any hierarchical ontology, including current WHO classifications.
Using cutting-edge LLMs, we developed OncoPath, an application that classifies pathology reports within structured ontologies. We tested OncoPath by applying OncoTree hierarchy through a structured tree-walk, progressing from broad anatomic categories to specific subtypes. High-level categories are assessed first, then plausible child nodes, with each node's children displayed so the model can anticipate downstream options. Diagnostic paths are summarized, and the model selects the optimal code with a confidence tier (<50%, 50-90%, >90%). Multiple configurations of LLaMA 3.3 70B Instruct were evaluated. Surgical and hematopathology reports were processed separately, and accuracy was verified by pathologist review against the 10 most prevalent molecular codes, covering 49.6% of surgical and 84.9% of hematopathology cases.
The classifier mapped diagnoses to OncoTree codes with high accuracy. Heme-based coding worked well with the full report, whereas Surg-based coding performed best with a targeted summary because reports often contained multiple parts from different sites and diagnoses. Heme reports reached 90-100% accuracy; Surg codes reached 80-100%, except HGSOC (high grade serous ovarian carcinoma) at 60%, reflecting the inherent difficulty, even for pathologists, of determining the tumor's primary site of origin. Codes were stored with original reports, enabling direct reuse in research and operations. The traversal approach provided auditability, confidence levels, and automatic re-evaluation when diagnoses changed.An LLM-assisted OncoTree traversal provides a scalable method to convert diverse pathology reports into structured codes. By standardizing reports while preserving diagnostic nuance, OncoPath enables retrospective cohort development and analyses of incidence, progression, and practice patterns. This framework can readily extend to other structured disease ontologies, establishing a generalizable approach for transforming unstructured reports into standardized, reusable data.

#2764 Maximizing high-risk incidental pulmonary nodule referrals using artificial intelligence.

Ivan M. Marrufo[1], Raymond Johnson[2], Samuel Newman[3], Paras Patel[4], Kalyani Narra[5]

[1]Texas College of Osteopathic Medicine, University of North Texas Health Sciences Center, Fort Worth, TX,[2]Department of Radiology, JPS Health Network, Fort Worth, TX,[3]Office of Clinical Research, JPS Health Network, Fort Worth, TX,[4]Division of Interventional Pulmonology, JPS Health Network, Fort Worth, TX,[5]JPS Oncology and Infusion Center, JPS Health Network, Fort Worth, TX

Background: Effective lung cancer screening and pulmonary nodule (PN) management programs require timely detection and robust care coordination. We report the initial outcomes of an artificial intelligence (AI) tool for obtaining referrals to pulmonary following the detection of high-risk PN findings.

Methods: JPS Health Network created the Pulmonary Nodule Risk Score (PNRS) classification system using nationally accepted PN guidelines. AI-driven Natural Language Processing (NLP) enabled navigators to identify patients meeting the PNRS 4B criteria (Table 1), the highest risk PN category. PNRS 4B detection and referral rates were compared over 22 months, spanning 11 months pre- and post-NLP implementation. Statistical analysis used Fisher's Exact for categorical variables and Mann-Whitney U or t tests for continuous variables.

Results: From June 1, 2023-April 25, 2024 (pre-NLP), 26,393 chest CTs were performed; 23,396 were obtained post-NLP (April 26, 2024-March 20, 2025). The pre- and post-NLP periods included 76 and 106 PNRS 4B patients, respectively. Post-NLP workflow significantly improved referral within 90 days rates from 55 (72%) to 98 (93%) ($p<0.001$). Appointment completion improved from 68% to 78% ($p=0.17$). Pre- and post-NLP comparisons demonstrated no significant differences in biopsy completion (65% vs 60%), Malignancy was noted in 28 (37%) vs 38 (37%). If pre-NLP referrals had reached 93% with the same 37% malignancy rate, an estimated 6 additional patients would have been diagnosed.

Conclusion: The AI tool significantly increased referral rates and expedited malignancy detection, potentially reducing missed or delayed diagnoses in high-risk nodules.

PNRS 4B Criteria and Recommended Clinical Management Pathways

PNRS:	**Score Description:**	E**quivalent Radiology Findings:**	**Associated Recommendation(s):**
PNRS 4B	Very Suspicious	**Solid Nodule**: Single or Multiple ≥ 15 mm (≥ 1,767 mm^3) nodule(s) at baseline or new or; Growing ≥ 8 (≥ 268 mm^3) nodule. **Part Solid Nodule:** Solid component ≥ 8 mm (268 mm^3) at baseline or new or; Growing solid component ≥ 6 mm (113 mm^3) upon follow-up. **Ground Glass Nodule (GGN)**: Growing ≥ 8 mm (268 mm^3). **Perifissural or Juxtapleural Nodule**: Growing ≥ 10 mm (524 mm^3).	**Pulmonary Referral Recommended** AND **Follow-Up Diagnostic Chest CT** AND/OR; **PET/CT** AND/OR; **Tissue sampling** / **biopsy** AND/OR; **GGN Consider Resection**

#2765 Microbiome foundation modeling of cancer: MiFM-derived continuous trajectories and risk clocks for pan-cancer immunotherapy response prediction.

Hongru Shen, Yajing Bi, Yan Zong, Zhangyan Lyu, Chao Zhang, Kexin Chen, Xiangchun Li

Tianjin Medical Univ. Cancer Inst. & Hospital, Tianjin, China

Background: The human microbiome shapes cancer risk, progression and response to immunotherapy, but most existing microbiome models are task-specific and fail to generalize across cohorts and sequencing platforms. We developed MiFM (Microbiome Foundation Model), a self-supervised Transformer trained on ~2 million human, animal and environmental microbiome profiles. MiFM encodes communities as multi-level tokens (species, genus and functional pathways) and uses masked reconstruction plus contrastive learning to obtain transferable embeddings that capture taxonomic and functional structure. Here, we evaluated whether MiFM embeddings can support continuous, clinically interpretable readouts of cancer trajectories and immunotherapy response.
Methods: From MiFM embeddings we derived two continuous metrics: (1) a disease pseudotime placing each patient along a microbiome-encoded cancer progression trajectory; and (2) a microbiome cancer risk clock estimating microbiome-derived cancer risk and immunotherapy non-response at the individual level. We applied this framework to colorectal cancer (CRC) cohorts spanning normal mucosa, adenoma and carcinoma, and to 12 independent pan-cancer immune checkpoint blockade cohorts (n =1237). We additionally defined a microbiome-based aging acceleration signature and evaluated its association with disease pseudotime, the risk clock and overall survival.
Results: In CRC, disease pseudotime recapitulated the adenoma-carcinoma sequence, with median values of 0.15 (normal), 0.38 (adenoma) and 0.72 (carcinoma; $p < 0.001$), and separated disease states more clearly than conventional stage. The risk clock identified high-risk individuals within histologically normal mucosa whose microbiome embeddings resembled adenomas (AUC = 0.85) or carcinomas (AUC = 0.92), indicating a preclinical window for intervention. Across 15 CRC cohorts (n = 3739), baseline gut microbiome embeddings identified non-responders to immune checkpoint blockade with a median cross-cohort AUC of 0.84 and an AUC of 0.95 in a non-small cell lung cancer cohort. The aging acceleration signature correlated with both disease pseudotime and the risk clock and independently predicted overall survival (HR = 2.52, $p < 0.001$).
Conclusions: To our knowledge, MiFM is the first large-scale microbiome foundation model applied to oncology, yielding continuous microbiome-derived readouts of cancer progression and immunotherapy response. The disease pseudotime and microbiome cancer risk clock capture cancer trajectories beyond conventional staging, enable ultra-early identification of high-risk lesions in normal-appearing mucosa and support robust prediction of immunotherapy resistance across cohorts. This framework delivers concrete microbiome biomarkers and a scalable platform for microbiome-guided precision oncology.

#2766 Self-supervised learning defines a universal biomarker of malignancy in platelet RNA.

Hongru Shen, Yan Zong, Yajing Bi, Jilei Liu, Chen Lyu, Fangyu Shi, Yichen Yang, Meng Yang, Yang Li, Kexin Chen, Xiangchun Li

Tianjin Medical Univ. Cancer Inst. & Hospital, Tianjin, China

Background: Early detection of cancer via liquid biopsy has transformative potential for patient outcomes, yet its clinical translation is limited by the poor generalizability of machine learning models, which often overfit to cohort-specific technical or biological artifacts and fail in independent datasets. Tumor-educated platelets (TEPs) constitute a rich but underexplored source of systemic cancer signals: their RNA profiles integrate tumor-host interactions and may encode biologically generalizable disease information. Conventional supervised approaches, which depend on labeled data, are particularly prone to overfitting, leaving much of the TEP transcriptomic landscape untapped. Here, we investigate whether self-supervised learning (SSL), trained without cancer labels, can extract a robust and biologically interpretable cancer-associated representation from TEP transcriptomes that generalizes across cohorts.
Methods: An SSL framework pretrained on 22.3 million transcriptomes was applied to 2,134 TEP RNA-seq samples spanning eight cancer types across four independent cohorts generated at multiple sequencing centers. The primary output—a single SSL-derived feature—was evaluated for pan-cancer detection in discovery and external validation cohorts. Performance was compared with a conventional supervised Random Forest classifier trained on the same data. Biological interpretability was assessed using transcript-level associations and pathway enrichment analysis.
Results: The SSL feature achieved strong pan-cancer performance in the discovery cohort (AUC 0.903) and consistently generalized across external cohorts (e.g., glioblastoma AUC 0.785; non-small cell lung cancer AUC 0.803). In direct comparison, the supervised classifier demonstrated limited cross-cohort transferability (AUC 0.553 and 0.711, respectively). Across cancer types, the SSL approach yielded a median 0.23 improvement in AUC over supervised learning. At a screening-relevant threshold of 99.9% specificity, the SSL feature achieved a median sensitivity of 47.9%. In an independent colorectal cancer cohort, it detected Stage I disease with an AUC of 0.819 and retained measurable sensitivity (24.1%) at 99.9% specificity. Biological analysis indicated that the SSL feature was reproducibly associated with platelet transcripts involved in epithelial-mesenchymal transition and coagulation pathways (FDR < 1×10^{-6}), including COL6A3, FLNA, PF4, and SPARC, across all cohorts.
Conclusions: A self-supervised representation learned from large-scale transcriptomic data can extract a reproducible, biologically interpretable signal from TEPs that generalizes across cohorts and cancer types. This framework offers a technically and clinically scalable strategy for developing robust liquid biopsy biomarkers for early cancer detection.

#2770 *astril*: Automated segmentation toolkit for radiology image libraries.
Alexander L. Ling[1], C. Zoe Linke[1], Christopher M. Jannotta[1], Data Science Teamlab[2], E. Antonio Chiocca[1]

[1]Mass General Brigham, Boston, MA,[2]Break Through Cancer, Boston, MA

Volumetric tumor segmentation improves patient monitoring vs. standard radiological assessment and is often needed for extracting radiomic features. Despite this, widespread implementation of such analyses into clinical and scientific studies is hindered by the time-intensive nature of scan curation and segmentation, and by the significant computational expertise required to process large imaging datasets. To overcome these barriers, we created a python package (astril - https://github.com/Alexander-Ling/astril) that enables fully automated pre-processing, segmentation, and quantification of radiology images using simple command line arguments, starting from unprocessed DICOM directories. astril also supports the training and application of new segmentation algorithms.The first pipeline implemented in astril is for segmenting recurrent glioblastoma (GBM) MRI images, enabling users to automatically pre-process (verify integrity, parse metadata, select optimal series, de-identify, co-align, skull strip, and normalize) and segment (tumor, peritumoral edema, and necrosis) volumes, starting from raw DICOM directories and ending with tabulated volumetric statistics. The built-in CNN segmentation algorithm was trained on manually segmented images from a recurrent GBM patient cohort, enabling the algorithm to correctly handle artefacts such as resection cavities, scar tissue, and low-enhancing tumor. Automated segmentation volumes with astril are highly correlated with manual segmentations and are associated with patient clinical outcomes.This provides a robust platform for rapid, standardized, and automated processing of radiology imaging libraries, and it enables simplified training and distribution of new segmentation algorithms.

#2771 Integrating image and text-based AI improves identification of metastatic sites from whole-slide pathology images.

Yixin Chen[1], Ziyu Su[1], Muhammad Khalid Niazi[1], Anil Vasdev Parwani[2], Elshad Hasanov[1]

[1]The Ohio State University, Columbus, OH,[2]The Ohio State University Wexner Medical Ctr., Columbus, OH

Metastatic cancer accounts for most cancer-related mortality, and determining the most likely metastatic destination of a tumor is essential for prognosis and treatment planning. Although every tumor arises from a primary site, its biological behavior varies widely: some remain localized, whereas others spread to distant organs following well-recognized patterns of organ-specific tropism. In clinical practice, distinguishing these behaviors relies on whole-slide images (WSIs), immunohistochemistry, and clinical information. However, metastatic lesions often lack distinctive histological features, making it difficult to determine whether a tumor has metastasized and, if so, its site of spread—especially in poorly differentiated biopsies. We hypothesize that tumors retain subtle morphological cues—rooted in metastatic potential and organ-specific tropism—that can help distinguish localized from metastatic phenotypes and, when metastasis is present, indicate the likely site of dissemination. Leveraging computational pathology and AI-based models, these latent features can be uncovered to improve tumor stratification and metastatic site prediction. We propose a novel image-and-text-based AI model that analyzes each region within a WSI to determine metastatic status and site. Our model utilizes medically meaningful textual descriptions—textual prototypes—generated by a pre-trained pathology AI model. In our study of 3,804 metastatic cases across six clinically relevant sites, each WSI was converted into patch-level image features using a pre-trained pathology AI model. After identifying metastatic disease, the model compares each patch with concise text descriptions of metastatic patterns (e.g., lymph node metastasis). A visual-textual similarity matrix quantifies how closely each patch matches these descriptions, guiding attention toward the regions most indicative of the metastatic site. Our model achieves an AUC of 88%, an accuracy of 74%, and a macro-F1 of 60%. These findings demonstrate improved metastatic-site classification by providing metastatic-specific semantic cues that direct attention to diagnostically important regions. We believe our model can suggest the most likely metastatic site using only routine pathology slides and offers a practical, scalable strategy for AI-assisted diagnosis.

#2772 Noninvasive artificial intelligence system for prediction of lenvatinib based therapeutic regimens response and outcome in unresectable hepatocellular carcinoma.

Bo Chen[1], Yuqian Gan[1], Enguang Zou[1], Yi Wang[2], Gang Chen[3]

[1]The First Affiliated Hospital of Wenzhou Medical University, Wenzhou, China,[2]Wenzhou Medical University, Wenzhou, China,[3]The First Affiliated Hospital of Wenzhou Medical University, China

Purpose: Lenvatinib represents a first-line therapeutic option for unresectable hepatocellular carcinoma (uHCC), with four established treatment regimens utilized in clinical practice. However, treatment response rates remain suboptimal, with only a subset of patients achieving meaningful clinical benefit. We hypothesized that radiomics features reflecting tumor vascularization and microenvironmental heterogeneity could enhance treatment response prediction. This multi-center retrospective-prospective hybrid study aimed to develop and validate radiomic deep learning models (VALIANT) for personalized treatment response stratification in uHCC patients.
Methods: This study enrolled 435 uHCC patients (2018-2024) from four institutions with histologically or radiologically confirmed unresectable disease. Radiomic features were extracted from arterial and venous phases of contrast-enhanced CT imaging acquired prior to treatment initiation. Eight VALIANT models were constructed using transfer learning strategies, with performance evaluated by area under the receiver operating characteristic curve (AUC) through five-fold cross-validation and external validation cohorts. Additionally, a prospective validation cohort of 16 patients received treatment recommendations based on the highest-scoring predicted regimen, with subsequent response assessment.
Results: Partial response (PR) was achieved in 159 patients (37% response rate). The eight VALIANT models demonstrated robust performance with a mean AUC of 0.92. The arterial phase-based TPI model exhibited superior discriminative ability (training AUC 0.95; external validation AUC 0.92) with balanced classification metrics (sensitivity 0.90, specificity 0.84, accuracy 0.95), indicating excellent generalizability across institutions. All VALIANT models significantly stratified patients into distinct response/non-response groups with divergent overall survival outcomes (log-rank $P < 0.01$). In the prospective cohort, 13 of 16 patients (81.3%) achieved the predicted response category, with 87.5% concordance between AI-predicted optimal regimen and actual clinical response.
Conclusion: The integration of deep learning radiomics and tumor phenotypic features in VALIANT models significantly enhances treatment response prediction for lenvatinib-based therapy in uHCC. This clinically applicable AI system enables comparative assessment of four lenvatinib-based regimens, facilitating personalized therapeutic selection and potentially improving patient outcomes through precision medicine approaches.

#2773 Multi-regional CT-based radiomics fusion predicts pathological pollutant index associated with lung adenocarcinoma.

Yutong Li[1], Xiaoxi Pan[2], Abishek Balachandra[2], Chingyi Young[3], Maria Esther Salvatierra[4], Carmen Behrens[4], Luisa Maren Solis Soto[4], Yinyin Yuan[2], Chengyue Wu[5]

[1]UT MD Anderson Cancer Center, Houston, TX,[2]Institute for Data Science in Oncology, UT MD Anderson Cancer Center, Houston, TX,[3]Ent Data Engineering and Analytic, UT MD Anderson Cancer Center, Houston, TX,[4]Translational Molecular Pathology Department, UT MD Anderson Cancer Center, Houston, TX,[5]Department of Imaging Physics, UT MD Anderson Cancer Center, Houston, TX

Introduction: Lung adenocarcinoma (LUAD) is the most common non-small cell lung cancer, especially in never-smokers. Environmental pollution, particularly airborne particulates (PM2.5/PM5), is a critical factor driving lung cancer initiation [1]. However, reliable individual-level pollution exposure quantification is challenging. We recently introduced the lung pollutant index (LPI), an AI-derived metric quantifying tissue-resident pollutant burden from pathology images. However, pathology-based LPI is invasive and unsuitable for large-scale application. We propose a machine-learning framework to predict CT-based LPI (CT-LPI) from chest CT, enabling non-invasive pollutant burden quantification for individuals undergoing chest imaging, including high-risk smokers and never-smokers with incidental nodules.

Methods: We retrospectively investigated 153 LUAD patients who received preoperative lung CT at MD Anderson Cancer Center (IRB 2023-0114) with surgical pathology. LPI computed from digitalized H&E images [2] categorized cohorts into LPI-high (n=61) and LPI-low (n=92). Region-wise radiomics features (793 per region) were extracted from 5-mm peritumoral ring, normal lung, and whole lung, including first-order, texture, shape, Laplacian-of-Gaussian, wavelet, and habitat features. We incorporated COPD-associated radiomic markers to enhance biological interpretability. We built a multi-regional ensemble framework with features selected using mutual information and Elastic-Net. Region-specific classifiers (Ridge Logistic, Gradient Boosting, CatBoost) were trained, with final predictions via weighted-average ensemble [3].

Results: In 5-fold cross-validation, the multi-regional ensemble achieved AUC 0.719 and ACC 0.687, improving AUC by 0.048 over the best single-regional model and outperforming simple averaging (0.710), LogisticNet (0.664), and ElasticNet (0.661). Incorporating COPD-associated markers improved AUC to 0.724.

Conclusion: We developed CT-LPI, predicting tissue-resident pollutant burden from routine CT using complementary multi-regional features. This framework non-invasively quantifies individual exposure to environmental carcinogens implicated in lung cancer initiation. By enabling scalable monitoring of pollution-driven biological alterations, CT-LPI may support environmental exposure assessment and personalized risk stratification. Next steps include external validation, application to screening datasets, and integration with other biomarkers. [1] Hill W, et al. Nature. 2023. [2] Pan et al., Nature Cancer, under review. #2774 Pulmonary nodule tracking in metastatic Ewing sarcoma enables personalized predictive models.

Kevin A. Murgas[1], Shambhavi Kurup[2], Maureiq Ojwang[2], Rene Malazarte[1], Danh D. Truong[1], Heiko Enderling[2], Joseph A. Ludwig[1]

[1]Sarcoma Medical Oncology, MD Anderson Cancer Center, Houston, TX,[2]Radiation Oncology, MD Anderson Cancer Center, Houston, TX

Metastatic Ewing sarcoma (ES) is a rare, aggressive sarcoma subtype with poor outcomes, especially in the relapsed/refractory setting. Standard response evaluation, typically performed after two chemotherapy cycles, may be too delayed to effectively guide therapy for patients with rapidly progressing disease, limiting opportunities to switch to alternative regimens. Data-driven clinical tools are critically needed to provide earlier, patient-specific predictions of treatment efficacy.

We performed a retrospective analysis of patients with metastatic ES with serial CT imaging. Tracking longitudinal measurements of individual pulmonary nodules within a modified RECIST framework, we calibrated patient-specific "digital twin" models based on ordinary differential equations and predictive simulation. Each digital twin estimates nodule-specific growth and response dynamics to various therapies, providing parameters to predict disease behavior and treatment response. We also evaluated response metrics, specifically the Disease Control Rate (DCR) compared to the Overall Response Rate (ORR), as predictors of Progression-Free Survival (PFS) and Overall Survival.

Using the digital twin framework, we accurately recapitulated observed clinical trajectories, including periods of response, stability, and progression across multiple lines of therapy. Model-derived parameters, including patient-specific tumor growth rates and drug sensitivity rates, demonstrate potential as novel prognostic biomarkers for predicting time to progression and survival outcomes.

Longitudinal surveillance in metastatic ES is a valuable yet underutilized clinical resource. Here, we demonstrate a digital twin model of pulmonary nodule growth as a platform for robust response classification and prognostic prediction. These patient-specific models can adaptively forecast individual treatment responses in silico, allowing prioritization of the most effective therapies. This approach offers a framework to optimize treatment sequencing, accelerate evaluation of novel agents, and ultimately maximize therapeutic opportunities for patients with this aggressive disease.

#2775 Deep-learning CT biomarker improves early efficacy detection in simulated randomized phase II NSCLC trials.

Chiharu Sako[1], Brenda F. Kurland[1], Taly G. Schmidt[1], Dwight H. Owen[2], Arpan A. Patel[3], Nicholas C. Love[3], Olivier Gevaert[4], George R. Simon[5], Ravi B. Parikh[6], Petr Jordan[1]

[1]Onc.AI, San Carlos, CA,[2]OSU Comprehensive Cancer Center, Columbus, OH,[3]University of Rochester Medical Center, Rochester, NY,[4]Stanford University, Stanford, CA,[5]Ohio Health, Columbus, OH,[6]Emory University, Atlanta, GA

Background: Early decision-making in advanced non-small cell lung cancer (NSCLC) phase II trials is limited by the modest ability of objective response and progression-free survival (PFS) to detect early biological activity or predict overall survival (OS). Quantitative deep-learning analysis of routine CT imaging may offer a more sensitive measure that better reflects long-term benefit. We evaluated whether Serial CTRS, a fully automated CT-based deep-learning imaging biomarker, could improve early efficacy detection in simulated randomized phase II NSCLC trials.

Methods: We evaluated the utility of Serial CTRS using data from the randomized phase III trial of cetuximab plus carboplatin/paclitaxel with or without bevacizumab in advanced NSCLC, which did not meet its co-primary endpoints of PFS in patients with EGFR FISH-positive cancer and OS in the entire study population (SWOG S0819; N=1275). Serial CTRS is a convolutional-neural-network pipeline, trained on a large real-world advanced NSCLC dataset, using paired baseline and follow-up thoracic CT scans to generate a continuous imaging score without manual annotation. To quantify OS surrogacy, we repeatedly sampled 1000 pairs of random 50-patient arms from the full cohort, and correlated Serial CTRS differences at 8, 16, and 24 weeks with final OS hazard ratios (HR), comparing results with best overall response (BOR) and PFS. To simulate a positive phase II trial, we constructed a balanced subset (target OS HR≈0.50) using stratified pruning matched on randomization factors. We then simulated 1000 two-arm phase II trials (n=50/arm) with realistic staggered enrollment (averaging 1 patient/day) and interim analyses (IA) at 12-48 weeks from study start. PFS was evaluated via log-rank tests and Serial CTRS differences via Wilcoxon rank-sum tests (α=0.05). False-positive rates were evaluated through null simulations using the full dataset.

Results: Serial CTRS differences showed increasing concordance with OS HR across timepoints (R^2=0.10, 0.23, 0.35 at 8, 16, and 24 weeks), outperforming BOR (R^2 = 0.08) and PFS (R^2=0.09, 0.20, 0.28). In the simulated phase II trials, the biomarker achieved 60% (95% CI 58-62%) power and 66% (63-69%) power at 36 weeks to detect a long-term survival benefit while maintaining a 5-6% false-positive rate. BOR achieved 35% (33-37%) power, and PFS achieved 49% (46-51%) and 50% (48-52%) at the same timepoints.

Conclusions: A fully automated deep-learning CT biomarker provided earlier and more reliable efficacy readouts than BOR and PFS in simulated phase II NSCLC trials. These results suggest that quantitative CT biomarkers using the full thoracic scan can strengthen early drug-development decisions by improving power and reducing uncertainty around early activity signals. Ongoing work is focused on broader evaluation across tumor types, therapeutic modalities, and additional clinical datasets.

#2776 Prognostic value of CT radiomics in patients with *gBRCA1/2* and *PALB2* and advanced pancreas cancer.

Sonal Gandhi[1], Jayasree Chakraborty[2], Hadi Ghahremannezhad[3], Richard Do[2], Natally Horvat[1], Kenneth H. Yu[4], Wungki Park[3], Eileen M. O'Reilly[3]

[1]Medicine, University of Iowa, Iowa City, IA,[2]Memorial Sloan Kettering Cancer Center, New York City, NY,[3]Memorial Sloan Kettering Cancer Center, New York, NY,[4]Gastrointestinal Oncology Service, Memorial Sloan Kettering Cancer Center, New York, NY

Introduction: A phase II trial at Memorial Sloan Kettering Cancer Center (MSK), IRB #12-045 evaluated cisplatin/gemcitabine +/- PARP inhibitor veliparib in patients with *gBRCA*1/2 and *PALB*2 (core homologous repair deficiency; cHRD) and advanced pancreas cancer (PDAC). Although the study found no significant difference in overall survival (OS) between treatment arms, patients receiving veliparib had higher rates of stable disease (SD) or partial response (PR), suggesting heterogeneous treatment benefit within this population (RR 74.1% vs. 65.2%; P = 0.55). Leveraging this trial cohort, the present study aimed to identify CT radiomic signatures predictive of OS and to assess whether changes in radiomic features over time provide additional prognostic value.
Methods: We retrospectively analyzed contrast-enhanced CT scans of patients with cHRD and PDAC that were enrolled in the trial. A trained machine learning specialist processed baseline, 6-week, and 3-month scans using an automated pancreas segmentation workflow, and 134 radiomic features were extracted from each scan. Highly correlated features ($r > 0.9$) were removed. We performed univariate Cox proportional hazards method to identify features associated with OS. Significant top two features were integrated into multivariate Cox models to investigate their predictability using repeated 3-fold cross-validation to avoid overfitting. Kaplan-Meier analysis compared OS between radiomics-defined high- and low-risk groups.
Results: Among the 26 patients enrolled at MSK, baseline (pre-treatment) CT scans were available for 23 (88%), 6-week scans for 25, and 3-month scans for 24 (92%). Twenty-five patients received cisplatin and gemcitabine, and 16 also receiving veliparib. Radiologist-assessed treatment responses were PR (n = 21), SD (n = 2), and progressive disease (n = 3). Several radiomic features were significantly associated with OS across all three time points, with the top 2 features selected for optimal prognostic stratification. Lower gray-level non-uniformity in the baseline pancreas was associated with worse OS, indicating that increased pancreatic textural homogeneity correlates with poorer outcomes. Delta-radiomics analyses demonstrated that longitudinal changes in pancreatic texture also correlated with OS.
Conclusions: CT radiomic features demonstrate prognostic value for overall survival in patients with cHRD and advanced PDAC, supporting radiomics as a promising tool for patient stratification in future trials. Ongoing work is evaluating correlations between radiomic signatures and genomic profiles to further refine predictive models.

#2777 Automatic contrast phase classification of polyphasic CT scans.

Georgia Hughes[1], Mayank Patwari[2], Yi Wei[3], Michael Parker[4], James Parkin[4], Zhenning Zhang[5], Aleksandr Filippov[6]

[1]Astrazenca UK, Cambridge, United Kingdom,[2]Astrazeneca UK Limited, Cambridge, United Kingdom,[3]Astrazeneca UK, Cambridge, United Kingdom,[4]Norfolk and Norwich University Hospital, Norwich, United Kingdom,[5]AstraZeneca US, Gaithersburg, MD,[6]AstraZeneca Oncology, Gaithersburg, MD

Contrast phases refer to the different stages of blood vessel, tissue, or organ enhancement following the administration of an intravenous contrast agent during CT scans. Contrast phases help distinguish abnormal lesions from normal tissue, where lesions appear hypo- or hyper-vascular, depending on the disease. Therefore, selecting the appropriate phase based on the specific pathology is crucial for accurate detection, meaningful diagnostic interpretation, clinical workflows, and robust quantitative analysis. However, in many polyphasic CT scans, information about phases is missing from the metadata.

This study presents a fully automated pipeline to predict the contrast phase of CT scans, using organ-based image features. Our approach has the following novel contributions: (1) Focuses on a limited set of organs (aorta, portal vein, kidney), reducing reliance on extensive organ coverage. This is useful for scans with varying field-of-view where many organs may be absent. (2) Introduces engineered features derived from first-order PyRadiomic statistics, quantifying inter-organ relationships to capture phase-specific intensity patterns.

Our pipeline distinguishes non-contrast scans and all three major contrast phases: arterial, portal venous, delayed. Automated segmentation of the aorta, portal vein/splenic vein, and kidneys is performed using TotalSegmentator, a state-of-the-art deep learning algorithm for CT scan segmentation. For each organ mask, a comprehensive set of first-order statistical features, including mean, median, minimum, maximum, standard deviation, skewness, kurtosis, energy, and entropy, is extracted with PyRadiomics to capture intensity distributions. Engineered features reflecting the mean and maximum intensity differences between organs are created, along with the total mean intensity of all three organs, to better distinguish phases.

The model was trained and validated on the TOPAZ-1 phase 3 biliary tract cancer trial dataset. TOPAZ-1 comprised of 1418 CT baseline scans (447 portal venous, 396 arterial, 323 non-contrast, 252 delayed) annotated by a radiologist with eight years of experience. For classification, a random forest classifier was developed. Classification achieved an overall accuracy of 0.97, with weighted average precision, recall, and f1-score all at 0.97. Per-phase precision, recall and f1-score all exceed 0.93. On analysis, the engineered features indicate the arterial phase is characterized by a brighter aorta, the venous phase by a brighter portal vein, the delayed phase by increased renal intensity, and non-contrast scans by lower overall intensity relative to the other scans. These patterns align with radiologist expectations and support the model's interpretability.

By focusing on organs and features that are most indicative of phase differences, the pipeline yields a simple and interpretable model that achieves accurate polyphasic CT phase identification.

#2778 Learning spatial transcriptomic patterns from whole-slide images with a cancer-scale foundation model.

Minsoo Lee[1], Soonyoung Lee[1], Tae Hyun Hwang[2], Jongseong Jang[1]

[1]LG AI Research, Seoul, Korea, Republic of,[2]Department of Surgery, Vanderbilt University Medical Center, Nashville, TN

Background
Spatial transcriptomics (ST) provides essential insights into tumor microenvironment (TME) organization, but remains costly and limited in clinical scalability. Predicting spatial gene expression directly from routine whole-slide images (WSIs) could enable large-scale molecular phenotyping across diverse cancer types. However, existing approaches rely on self-supervised patch encoders and small gene panels, limiting biological fidelity and cross-cancer generalization.
Methods
To explicitly capture molecular variation underlying tissue morphology, we train a DINOv2-based patch encoder jointly with a spatial transcriptomics prediction head. This design aligns visual representations with gene-expression signals, addressing the morphological ambiguity often encountered in tumor pathology, where cells with similar appearance may exhibit distinct transcriptomic states relevant to tumor progression or immune activity. To model tissue-level biological organization, we introduce a masked transformer that integrates information from neighboring patches. Spatial relationships are crucial in cancer tissues, where gene expression patterns are shaped by tumor-stroma interfaces, immune niches, and gradients across the invasive front. By referencing local spatial context, the model captures these microenvironmental dependencies that conventional patch-level encoders overlook.
Results
We evaluate our framework on the HEST-benchmark, which comprises ten cancer types designed to assess ST prediction from WSIs. Without using the benchmark's training data, our foundation model already achieves comparable performance to state-of-the-art methods that were trained separately for each cancer type in the HEST-benchmark, demonstrating strong cross-cancer generalization. When further fine-tuned on each cancer cohort within the benchmark, our model surpasses prior approaches by a large margin. Qualitatively, the predicted spatial expression maps reproduce tissue features that are clinically and biologically meaningful, including localized expression changes and tumor-associated regions. These patterns closely match ground-truth ST profiles, indicating that the model captures spatial domains shaped by tissue organization.
Conclusion
Our model shows that large-scale pretraining enables reliable prediction of spatial gene expression directly from routine histology. By generating spatial gene expression maps from standard pathology slides, this approach can support biomarker assessment, enhance characterization of the tumor microenvironment, and provide value where spatial transcriptomic assays are not available. Overall, these findings highlight the potential of foundation-model-based pathology to make spatial transcriptomic insights more accessible in both clinical and research settings.

#2779 Development and evaluation of a MIRAI 5-year risk model with a breast cancer polygenic risk score.

Christopher G. Scott[1], Peter Kraft[2], Imon Banerjee[3], Ramon Correa Medero[3], Aaron D. Norman[1], Fergus J. Couch[1], Karla Kerlikowske[4], Stacey J. Winham[1], Celine M. Vachon[1]

[1]Mayo Clinic, Rochester, MN,[2]National Cancer Institute, Rockville, MD,[3]Mayo Clinic, Phoenix, AZ,[4]UCSF, San Francisco, CA

Artificial intelligence (AI)-scores estimated from digital mammograms predict future breast cancer (BC) risk. MIRAI is a deep learning BC risk model that provides a continuous 5-year risk of overall BC from four screening full field digital mammograms. Common germline genetic variation in the form of a polygenic risk score (BC-PRS) is associated with increased BC risk and may improve MIRAI's 5-year risk prediction. Our goal was to develop an updated MIRAI 5-year risk model that incorporates the BC-PRS (MIRAI+PRS) and to evaluate its discriminatory accuracy and calibration for both overall and invasive BC compared to MIRAI alone. We developed the MIRAI+PRS model by multiplying each woman's 5-year MIRAI risk estimate by their relative risk based on their BC-PRS relative to the population mean. We evaluated the models within the Mayo Clinic Biobank mammography cohort, comprised of 12,307 women without a prior history of BC; 176 invasive and 250 overall BC were diagnosed within 5 years. MIRAI was estimated on screening mammograms closest to enrollment but at least 6 months prior to BC. Discriminatory accuracy, assessed by C-statistic, was high and similar for MIRAI+PRS vs. MIRAI models, for overall BC and invasive BC (Table). Calibration assessed by observed to expected (O/E) ratios was also similar for MIRAI+PRS compared to MIRAI predictions for BC outcomes (Table), although there was improvement in decile-specific O/E ratios across the lowest risk deciles (<1.67%) for MIRAI+PRS. Calibration for invasive cancer was poor for MIRAI with or without PRS. In summary, the MIRAI+PRS risk model did not result in significant difference of discriminatory accuracy or overall calibration compared to the MIRAI model, but there was evidence for improved calibration for women with 5-year risk below 1.67%. For invasive BC, the model had poor calibration regardless of whether PRS was included, underscoring the importance of training AI models for BC outcomes that are associated with a clinical intervention.

MIRAI and MIRAI+PRS 5-year risk model performance within the Mayo Clinic Biobank mammography cohort

Model	**HR per SD (95% CI)**	**C-index (95% CI)**	**Obs/Exp Ratio (95% CI)**
Overall BC (Invasive + DCIS), N=250			
MIRAI 5 yr Risk (log)	1.69 (1.55, 1.84)	0.71 (0.68, 0.74)	0.96 (0.84, 1.09)
MIRAI+PRS 5 yr Risk (log)	1.97 (1.78, 2.19)	0.72 (0.69, 0.75)	0.93 (0.82, 1.05)
Invasive BC, N=176			
MIRAI 5 yr Risk (log)	1.68 (1.51, 1.86)	0.71 (0.67, 0.75)	0.68 (0.58, 0.78)
MIRAI+PRS 5 yr Risk (log)	1.99 (1.76, 2.24)	0.73 (0.69, 0.76)	0.66 (0.56, 0.76)

#2781 Investigating feature selection strategies with habitat-based radiomics for oropharyngeal cancer.

Oya Altinok[1], Ghulam Rasool[1], Asim Waqas[1], Matthew B. Schabath[1], Albert Guvenis[2]

[1]Moffitt Cancer Center, Tampa, FL,[2]Biomedical Engineering, Bogazici University, Istanbul, Turkey

Background: Habitat radiomics characterizes intratumoral heterogeneity by partitioning tumors into biologically meaningful and statistically distinct subregions. Because HPV-positive and HPV-negative oropharyngeal cancers (OPC) differ in morphology, intensity distribution, and texture, we evaluated different machine learning methods and habitat feature aggregation strategies to develop an HPV prediction algorithm.

Methods: Radiomic tumor habitats were generated from 192 pretreatment CT scans using a two-level unsupervised clustering approach (K=3). Tumors exhibited one to three habitats of varying prominence. Six aggregation strategies were compared: maximum, largest-volume, sum, mean, minimum, and variance. Each strategy produced a separate feature set and classifier. Support Vector Machine (SVM) models with a radial basis function kernel were trained using 7-fold nested cross-validation. Logistic regression, Gaussian process classification, random forest, naïve Bayes, and extreme gradient boosting (XGBoost) were also evaluated to benchmark model performance. HPV status was defined using p16 immunohistochemistry. SHapley Additive exPlanations (SHAP) analysis was used to interpret model behavior, and Kaplan-Meier curves were generated for the best-performing classifier.

Results: With SVM, maximum aggregation achieved the highest balanced accuracy across all strategies (training 0.906; test 0.896) and was the overall best-performing approach. Other aggregation strategies (largest-volume, sum, mean, minimum, and variance) demonstrated lower performance (test balanced accuracy range: 0.292-0.834). SVM also outperformed all other machine learning algorithms (test balanced accuracy range: 0.572-0.796). SHAP identified shape and texture features—including VolumeDensityConvexHull3D, Compactness2_3D, and InformationCorrelation1Merged3D—as major contributors to HPV-positive predictions, whereas HPV-negative tumors exhibited more heterogeneous habitats. Kaplan-Meier analysis showed that predicted HPV groups closely matched ground truth (p=0.52 HPV-; p=0.75 HPV+).

Conclusions: These results likely imply that the tumor's outcome is not determined by the average properties of its habitats, but rather by the presence and intensity of the most extreme or critical local microenvironmental condition that provides the strongest selective pressure or dictates the dominant biological process. These findings support maximum aggregation as an effective and biologically relevant strategy for HPV prediction in OPC.

#2782 Automated segmentation of hepatocellular carcinoma lesions on contrast-enhanced MRI using an AI model in patients with cirrhosis.

Emma J. Stevenson[1], Nathan Lay[1], Stephanie A. Harmon[1], Haoyue Zhang[1], Fahmida Haque[1], Peter Choyke[1], Theo Heller[2], Ross Filice[3], Baris Turkbey[1], Christine Hsu[2]

[1]Molecular Imaging Branch, National Cancer Institute (NCI), Bethesda, MD,[2]Liver Diseases Branch, National Institute of Diabetes and Digestive and Kidney Diseases (NIDDK), Bethesda, MD,[3]Radiology, MedStar Georgetown University Hospital, Bethesda, MD

Purpose: Develop an automated hepatocellular carcinoma (HCC) detection model on multi-phasic contrast-enhanced T1 MRI images. **Methods:** Multi-phase (pre-contrast, arterial, venous, and delayed phases) contrast-enhanced T1 MRIs were obtained from two institutions (Center 1: n=106; Center 2: n=87) and acquired between 2007 and 2023. An expert radiologist manually contoured 1794 focal liver lesions across 586 scans and assigned each lesion a score using the Liver Imaging Reporting and Data System (LI-RADS). Six 3D full-resolution nnU-Net models were trained on multi-phase (pre-contrast, arterial, venous, and delayed) or only arterial-phase contrast-enhanced T1 images. Lesion size (maximum lesion diameter ≥ 1 cm) and lesion score (LI-RADS ≥ 3) criteria were applied to assess the impact on the training of these nnU-Net models. Model performance was evaluated at a scan and lesion level. Performance metrics included dice similarity coefficient (DSC), sensitivity, specificity, accuracy, and positive predictive value (PPV). **Results:** The arterial phase without lesion criteria was determined to have the best overall performance among the models developed. At the scan level, the arterial phase model achieved 93% (40/43) sensitivity, 46.6% (7/15) specificity, and 81% (47/58) accuracy. At a lesion level for the arterial phase model, the performance dropped slightly, with 65.9% (126/191) sensitivity, 68.1% (126/185) PPV, and 51.8% (133/257) accuracy. In a failure analysis, it was observed that 45.2% (57/126) of true-positive lesions had a LIRADS score ≥ 4, while 9.2% (6/65) of false-negative lesions had a LIRADS score ≥ 4. **Conclusion:** An arterial phase contrast-enhanced MRI nnU-Net model was developed on multi-institutional data to detect HCC in patients with cirrhosis, producing promising results. This study indicates that AI models can improve detection in high-risk patients.

Categorization of Models based on the Inclusion of MRI Phases, Lesion Score, and Size Threshold

Model	MRI Phase(s) Used	Lesion Inclusion	Size Threshold
A	Pre-Contrast, Arterial, Venous, and Delayed	All	None
B	Arterial	All	None
C	Pre-Contrast, Arterial, Venous, and Delayed	LIRADS ≥ 3	None
D	Arterial	LIRADS ≥ 3	None
E	Pre-Contrast, Arterial, Venous, and Delayed	LIRADS ≥ 3	≥ 1.0 cm
F	Arterial	LIRADS ≥ 3	≥ 1.0 cm

#2783 Lung cancer intelligent detection (LUCID) using a universally accessible, cross-platform, AI-powered application.

Gowrishankar Palaniswamy [1], Elangovan Krishnan[2], Jansi R. Sethuraj[3], Muhammad Waqas Khan[4], Aravind Raghavan[1]

[1]MUSC Health Lancaster Medical Center, Medical University of South Carolina, Lancaster, SC,[2]AIM DOCTOR, Chennai, India,[3]The University of Texas Health Science Center at Houston, Houston, TX,[4]Medical University of South Carolina (MUSC), Lancaster, SC

Introduction: Lung cancer represents the leading cause of cancer-related mortality globally. Only 29% achieve 5-year survival, primarily due to late diagnoses. In addition, the economic burden exceeds $3.9 trillion internationally. Only one-third of all lung cancer patients are diagnosed early enough so that effective treatment can be implemented. Deep learning architectures have revolutionized diagnostic imaging, extracting complex imaging patterns beyond human capability. EfficientNetB0, a state-of-the-art convolutional neural network achieves remarkable accuracy and computational efficiency. Its application to computed tomography (CT) imaging offers unprecedented potential for early lung cancer detection and mortality reduction.

Methods: Anonymized CT images of normal, benign, and malignant lung (n = 1190) were proportioned into training (60%), validation (20%), and testing (20%) sets. Preprocessing and augmentation improved data quality and model generalizability. EfficientNetB0 was trained and optimized, with performance evaluated by accuracy, precision-recall, F1-score, F2-score, and area under the receiver operating characteristic curve (AUROC) on validation and test sets. The trained model was deployed in a universally accessible, cross-platform application for independent validation by experts globally.

Results: EfficientNetB0 demonstrated exceptional performance in distinguishing normal, benign, and malignant lung lesions. The model achieved perfect accuracy, precision, and recall for both classes, with F1-scores of 1.00 (training and validation). AUROC values of 1.00 demonstrate outstanding discriminative capacity. The confusion matrix confirmed zero misclassifications across 137 lesions (24 benign, 113 malignant). The model's exemplary performance suggests substantial potential to augment clinical decision-making and advance equitable cancer care.

Conclusion: EfficientNetB0 represents a paradigm-shifting diagnostic tool for lung cancer stratification on CT imaging, demonstrating clinical-grade accuracy that augments expert radiologist interpretation. The model's exceptional discriminative capacity, achieving high sensitivity and specificity, positions it as a transformative adjunct to conventional diagnostic workflows. Deployment via an accessible cross-platform application facilitates dissemination across resource-constrained environments, democratizing precision diagnostics. This deep learning architecture substantially augments early detection capabilities, potentially reducing mortality through timely clinical intervention. These findings establish a robust foundation for prospective validation studies and clinical integration to optimize lung cancer outcomes globally.

#2784 Integrating spatial transcriptomics with MRI reveals distinct radio-spatial genomic profile concordant with prostate cancer clonal heterogeneity.

Thineskrishna Anbarasan[1], Sandy Figiel[1], Max Beesley[2], Wencheng Yin[1], Ruth McPherson[3], Richard Colling[1], Freddie Hamdy[1], Richard J. Bryant[1], Bartlomiej Papiez[1], Alastair D. Lamb[2], Ian Mills[1]

[1]University of Oxford, Oxford, United Kingdom,[2]Barts Cancer Institute, London, United Kingdom,[3]Oxford University Hospitals, Oxford, United Kingdom

Introduction: Prostate cancer (PCa) risk stratification, to precisely identify patients at greatest risk of progression to metastatic disease remains challenging. Integrating clinical data, multiparametric MRI (mpMRI) radiomics, and spatial transcriptomics (ST) may enable identification of imaging features linked to genomic signatures of aggressive PCa.

Methods: Organ-wide spatial transcriptomics (Visium^{TM} v2, 10x Genomics) was performed on formalin-fixed paraffin-embedded prostatectomy sections and metastatic lymph nodes from patients recruited to a trial (ISRCTN10046036). A patient with Gleason 4+4 PCa and pre-operative mpMRI was included. This is a sub-study, part of a larger project mapping prostate cancer clonal dynamics in ten men using inferred clonal genomic analyses (SpatialInferCNV). Image processing involved anatomical segmentation and qualitative correlation with radiologist and pathologists. Image registration was performed using the ProsRegNet deep learning pipeline. Multiple ST sections were mapped to a common coordinate framework using SpatialStitcher (locally developed). Radiomic features were extracted using PyRadiomics.

Results: Eight ST sections representing over 85000 ST spots (55µm diameter) were mapped to T2-axial MRI. Image registration achieved a DICE similarity coefficient of 0.861 for prostate capsule. The landmark deviation for urethra and BPH nodule were 2.17mm and 2.62mm respectively. A total of 93 radiomic features were selected. First-order radiomics significantly correlated with ST spot-level histological annotation according benign vs Gleason grade group (GG2, GG3 and GG5) ($p<0.001$). Inferred clonal phylogenomic analysis revealed a region on the axial sections (X clone) with high concordance with lymph node metastasis. This region, harboured a distinct z-normalised textural (features: GLSZM, GLCM, GLDM, GLRLM, NGTDM) radiomic score compared to other tumour and benign regions ($p<0.001$). No difference in first order radiomics (visible to the eye) was observed between the X clone and other tumour clones ($p = 0.21$).

Conclusion: We show a distinct textural radiomic profile within the prostate that harbours a phylogenetic correlation with lymph node metastases. Further radio-spatial genomic profiling of the cohort and validation analyses are underway. These could offer insights into improving current MRI-based risk stratification for follow-up and lesion targeting for biopsy or focal therapy.

#2785 Assessing the risk of breast cancer recurrence with pre-treatment MRI: A transfer learning study on multicenter data.

Kanika Bhalla[1], Adrian Sanchez[1], Jose Marcio Luna[1], Tabassum Ahmad[1], Debbie L. Bennett[1], Andrew A. Davis[2], Aimilia Gastounioti[1]

[1]Radiology, Washington University School of Medicine in St. Louis, St. Louis, MO,[2]Oncology, Washington University School of Medicine in St. Louis, St. Louis, MO

Background: MRI features have demonstrated prognostic value in predicting future breast cancer recurrence. However, deep learning studies remain limited particularly those evaluating performance across tumor subtypes and different time horizons in large multicenter datasets.
Materials and Methods: We used pretreatment DCE-MRI exams from the multicenter MAMA-MIA dataset (433 breast cancer patients who underwent NAT; 115 with recurrence events, 318 recurrence-free) to evaluate a transfer-learning framework based on DenseNet121 pretrained on ImageNet. Middle tumor-containing slices were bias-field corrected, resampled, cropped to the tumor regions, and resized to 224×224 pixels. The top 10% of DenseNet121 layers were unfrozen for model fine-tuning for recurrence prediction. Five-fold stratified cross-validation preserved site distribution across data splits. Model performance was evaluated using Harrell's C-index and time-dependent AUCs at 3 and 5 year horizons. Correlated C-indices were compared using the two-sided Kang et al. test. We also assessed the added value by our deep-learning risk score to a baseline prognostic model based on the established clinical factors HR and HER2. Model performance was also assessed across tumor subtypes.
Results: Our deep learning model achieved a C-index of 0.67±0.03 with 3 and 5 year AUCs of 0.69±0.04 and 0.67±0.10, respectively. Adding our deep-learning risk score to the baseline model significantly improved performance from 0.64 to 0.71 (p=0.007). Subtype-specific evaluations (Table 1) showed variable performances with the highest performance in HER2-pure and TNBC patients.
Conclusion: Our findings highlight the potential of a transfer-learning-based DenseNet121 MRI model to predict 3 and 5 year recurrences in breast cancer patients, providing added value beyond standard clinical factors. Future optimizations will aim at improving subtype-specific performance in large multicenter datasets.

Table 1. Recurrence-free survival analysis results in multi-center MAMA-MIA dataset (N = 433).

Added prognostic value by our deep learning model			
Model	*C-index*	*p-value**	
DL model	0.67 ± 0.03	0.01	
Baseline model (HR, HER2)	0.64 ± 0.05	N/A	
Baseline + DL	0.71 ± 0.05	0.007	
* p-value for C-index differences with respect to the baseline model.			
Performance of our deep learning model by time horizon			
3-year AUC	0.69 ± 0.04		
5-year AUC	0.67 ± 0.10		
Performance of our deep learning model by breast cancer subtype			
	C-index	*3-year AUC*	*5-year AUC*
Luminal A (N = 121)	0.61±0.02	0.61±0.11	0.64±0.08
Luminal B (N = 50)	0.67±0.13	0.62±0.09	0.57±0.07
TNBC (N = 120)	0.70±0.04	0.72±0.03	0.72±0.15
HER2-enriched (N = 65)	0.65±0.16	0.59±0.19	0.68±0.28
Her2-pure (N = 56)	0.82±0.11	0.86±0.13	0.90±0.20

#2786 CorrectionNet: A lightweight residual refinement framework for improving medical image segmentation.

Antoine Azar[1], **Cally Lin**[2], Naryeong Kim[3]

[1]Computer Science, EPITECH, Paris, France,[2]Biomedical Data Science, Stanford University, Stanford, CA,[3]Biology, Stanford University, Stanford, CA

Accurate and reproducible image segmentation is crucial for oncologic imaging tasks, including tumor delineation, treatment planning, and quantitative response assessment. Despite strong baseline performance from modern deep learning frameworks such as nn-Unet, automated segmentations frequently exhibit systematic boundary errors and under-segmentation of small or infiltrative tumor regions, resulting in costly manual correction efforts. We present CorrectionNet, a lightweight and modular refinement framework designed to work on top of existing segmentation models. The method extracts patch-based regions of interest around the initial segmentation and inputs both multimodal imaging and base-model probability maps to a shallow 3D U-Net. Instead of predicting full masks, CorrectionNet learns residual connections, enabling it to fix high-confidence false positives/negatives and improve boundary regularity while preserving the global tumor structure. Training focuses on voxels where the base model is likely incorrect or uncertain, yielding efficient learning behavior and minimal computational overhead. In current quantitative evaluations, CorrectionNet maintained whole-lesion Dice performance relative to nnU-Net (ΔDice = -0.0002 ± 0.0024, $p = 0.18$) while achieving measurable improvements in boundary accuracy (ΔHD95 = -0.089 ± 0.786 mm; one-sided $p = 0.03$). Nearly half of all local voxel edits (47.7%) represented true error corrections, with the model showing a strong preference for eliminating false-positive boundary over-segmentation (FP fix precision = 81.5%). CorrectionNet hyperparameters further enable researchers or clinicians to tune the balance between false-positive removal and false-negative recovery, accommodating diverse tumor morphologies and clinical priorities. Overall, CorrectionNet provides a practical and scalable refinement layer for oncology segmentation workflows. By improving local boundary fidelity without retraining or replacing base models, it has the potential to reduce manual editing effort and enhance clinical deployment of automated segmentation.

#2787 Evaluation of imaging-based prognostication (IPRO) using artificial intelligence (AI) in stage IV colorectal cancer (CRC) patients treated with first-line (1L) systemic therapy.

Mohammed A. Alvi[1], Ronald Bridges[2], Marina Salluzzi[2], Felipe Soares Torres[3], Kartik Jhaveri[3], Natasha B. Leighl[4], John Riskas[1], Shahid Haider[1], Vignesh Sivan[1], Oleksandra Samodorova[1], Jay Hennesy[1], Duoaud Shah[1], FELIX BALDAUF-LENSCHEN[1], **Omar F. Khan**[5]

[1]Altis Labs, Inc., Toronto, ON, Canada,[2]Cumming School of Medicine, University of Calgary, Calgary, AB, Canada,[3]Department of Medical Imaging, University of Toronto Temerty School of Medicine, Toronto, ON, Canada,[4]University Health Network, Toronto, ON, Canada,[5]Department of Oncology, Univ. of Calgary Faculty of Medicine, Calgary, AB, Canada

INTRODUCTION: Accurate prognostication in stage IV CRC informs treatment decisions and stratifies patients in clinical trials. Tumor, node, metastasis (TNM) staging derived from pre-treatment computed tomography (CT) imaging classifies extent of disease but may not fully characterize prognosis. IPRO-α is an AI-generated prognostic score derived from pre-treatment CT imaging, with higher scores representing improved survival. IPRO-α was trained and validated to predict survival in advanced non-small-cell lung cancer. This study evaluates generalizability and prognostic utility of IPRO-α in real-world stage IV CRC patients receiving 1L systemic therapy, compared to TNM substage.

METHODS: We retrospectively evaluated IPRO-α and TNM substage in a real-world dataset of stage IV CRC patients treated with 1L systemic therapy between 2010-2018 at 17 cancer centers. We evaluated median overall survival (mOS) and hazard ratios (HR) using Cox proportional hazards models across stage IV substages (A, B, C) and matched relative distributions for IPRO-α.

RESULTS: 372 patients had available pre-treatment CT and known TNM substage (IVA=141, IVB=162, IVC=69). The median age was 61 years (IQR 52-69), with 32.8% (n=122) females. TNM substage IVA mOS was significantly better than IVB, with no statistically significant difference between stage IVB and IVC (Table 1). Distribution-matched IPRO-α groups showed significant survival differences across high, intermediate and low scores.

CONCLUSIONS: IPRO-α may stratify survival with greater prognostic discrimination than TNM substage in metastatic CRC patients. IPRO-α, trained on lung cancer data, learned shared prognostic features allowing generalizability of survival predictions to entirely different tumour sites. Future work will evaluate IPRO-α's ability to stratify survival in various CRC treatment subsets.

Median OS for stage IV CRC patients stratified by TNM substage and IPRO-α survival scores.

	N	mOS in months (95% CI)	HR (95% CI)	p-value
IPRO-α High	141	24.0 (19.1-29.6)	0.74 (0.58-0.93)	0.010
IPRO-α Intermediate	162	17.9 (16.2-20.9)	reference	-
IPRO-α Low	69	10.0 (7.4-13.0)	2.28 (1.70-3.06)	< 0.001
Stage IVA	141	20.8 (17.9-27.5)	0.77 (0.61-0.98)	0.032
Stage IVB	162	17.2 (14.4-20.1)	reference	-
Stage IVC	69	13.0 (10.9 - 16.0)	1.14 (0.85-1.53)	0.363

#2788 Multi-site development of automated lesion classification for comprehensive tumor burden assessment: Addressing the RECIST trial-practice disconnect.

Ella Pavlechko[1], Xi Jiang[1], Ravikumar Komandur Elayavilli[2], Eleanor McCabe[2], Jon McDunn[2], **Sean Khozin**[3]

[1]SAS Institure, Cary, NC,[2]Project Data Sphere, Cary, NC,[3]CEO Roundtable on Cancer & Project Data Sphere, Cary, NC

Background: Response Evaluation Criteria in Solid Tumors (RECIST) mandate manual selection of 2-5 target lesions with unidimensional measurements, generating inter-reader discordance beyond 30% while folding 3D tumor dynamics into categorical outcomes with limited biological interpretability. RECIST protocols are rarely used in routine practice, creating a trial-practice disconnect that undermines endpoint validity. Automated volumetric quantification of total tumor burden represents an alternative contingent on reliable autonomous model performance across diverse imaging environments.
Methods: We developed a modular dual-architecture system combining UNet segmentation with ResNet50 classification, trained on 2,464 CT scans from 1,324 patients across three continents (North/South America & Asia) acquired on heterogeneous scanner platforms (GE, Siemens, Philips, Toshiba). The 11,705-lesion dataset had a clinically representative class distribution: 2,125 malignant (18%), 193 benign (2%), and 9,387 other findings (80%). Preprocessing applied Hounsfield windowing (level: -600, width: 1500) and Lungmask segmentation. To improve classification performance and address class imbalance, we augmented minority-class images using flips, rotations, and sharpening.
Results: Segmentation training demonstrated loss reduction of 86% across epochs with parallel convergence in training and validation sets. Classification performance on held-out development data (n=1,332 lesions) yielded 86% accuracy, 91% sensitivity, 17% specificity, 94% positive predictive value (PPV), and 11% negative predictive value at 0.5 probability threshold. Precision-recall area under curve was 0.89. Model performance remained stable across scanner manufacturers without platform-specific recalibration.
Conclusions: High sensitivity (91%) with constrained specificity (17%) exhibits successful optimization for malignancy detection in imbalanced datasets. The 94% PPV confirms reliable malignancy identification, while precision-recall AUC of 0.89 supports effective minority class discrimination despite 11:1 imbalance. Stable cross-platform performance allows for multi-site training to be a viable paradigm for generalized deployment. This initial work provides the foundation for lesion-level classification within a fully autonomous system for volumetric tumor burden quantification. Our development path includes classification refinement, expansion to whole-body CT across organ systems, and integration of autonomous detection and segmentation modules. The next steps in establishing TTB as a regulatory-grade endpoint addressing RECIST's limitations require external confirmation in independent cohorts, prospective clinical-trial evidence, and correlation with clinical outcomes.

#2789 Depth prediction in superficial esophageal cancer using a foundation model from endoscopic images.

Sehun Kim[1], Sohyung Kim[1], Hyosoon Yoo[1], Hyuk Lee[2], Yang Won Min[2]

[1]Samsung Precision Genome Medicine Institute, Samsung Medical Center, Seoul, Korea, Republic of,[2]Department of Medicine, Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, Korea, Republic of

Background: For superficial esophageal cancer (SEC) without a risk of lymph node metastasis (LNM), upfront endoscopic submucosal dissection (ESD) is the preferred treatment over surgery. The representative factor for predicting LNM risk is tumor depth, but the insufficient prediction accuracy during pre-procedure evaluation frequently results in unnecessary surgery or the need for salvage surgery after ESD. Accordingly, we propose to predict SEC tumor depth using a foundation model (FM) applied to pre-procedural endoscopic images. Using a foundation model (GastroFM) that was pretrained on approximately 500,000 EGD images, we propose utilizing its knowledge gained from pre-training to provide a reliable, pre-histopathology prediction of invasion depth from endoscopic images.

Methods: We adapted a FM, which is based on a vision transformer architecture and was pretrained on approximately 500,000 upper endoscopic images, for SEC depth prediction. We propose utilizing the knowledge gained from this pre-training to provide a reliable, pre-histopathology prediction of invasion depth from endoscopic images. The model was trained and validated on a retrospective cohort of 839 ESD cases for SEC (April 2007-January 2023) using an 8:1:1 train/validation/test split. For each case, esophageal ESD expert selected tumor-displaying images (median 10, range 4-36) from pre-procedure endoscopy. We applied Attention-based Multiple Instance Learning (AbMIL) to aggregate these variable-length image sequences into a single case-level prediction score for the binary task: mucosal cancer vs submucosal cancer.

Results: The overall cohort distribution was 529 cases (63.1%) with mucosal cancer and 310 cases (36.9%) with submucosal cancer. On the test set, a FM achieved an AUC of 0.821 and an overall accuracy of 0.810. Key metrics for the binary classification were: sensitivity 0.645, specificity 0.906, F1 score 0.714, positive predictive value 0.800, and negative predictive value 0.814.

Conclusion: We developed a FM with a discriminative power for depth prediction in SEC. This model is expected to be a valuable supplementary tool in the pre-procedure workup, assisting endoscopists and surgeons in determining the optimal treatment plan for SEC.

#2790 Foundation model-based gastric cancer staging from complete, uncurated EGD image sequences.

Sehun Kim[1], Hyosoon Yoo[1], Yang Won Min[2], Hyuk Lee[2]

[1]Samsung Precision Genome Medicine Institute, Samsung Medical Center, Seoul, Korea, Republic of,[2]Department of Medicine, Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, Korea, Republic of

Background: Histopathologic assessment remains the gold standard for gastric cancer staging but creates significant treatment bottlenecks. While AI-based prediction of pathologic outcomes from endoscopic images shows promise, existing approaches rely on manually selected images, introducing selection bias and missing the case-level context essential for clinical decisions. We present GastroFM, a vision transformer-based foundation model that learns from complete esophagogastroduodenoscopy (EGD) image sequences, enabling case-level predictions aligned with clinical practice.
Methods: GastroFM is pretrained using a modified DINOv3 framework on approximately 500,000 images from 13,515 pathology-confirmed EGD cases at Samsung Medical Center (2019-2023). We then fine-tuned the pretrained model for gastric cancer staging using Attention-based Multiple Instance Learning (AbMIL), which aggregates uncurated, variable-length image sequences (1 to 105 images per case) into case-level predictions. We evaluated the model on gastric cancer staging at multiple granularities using a 75%/10%/15% train-validation-test split (8,121 cases with gastric cancer): (1) early gastric cancer (EGC) vs. advanced gastric cancer (AGC), (2) four-class T-stage (T1-T4), and (3) lymph node metastasis (N0 vs. ≥N1).
Results: On the test set, GastroFM achieved: AUC 0.93 (accuracy 0.91) for AGC classification, substantially exceeding expert endoscopic assessment (76.8% accuracy in our cohort); AUC 0.84 (overall accuracy 0.67) for 4-class T-stage classification; and AUC 0.85 (accuracy 0.87) for lymph node metastasis prediction.
Conclusion: Unlike conventional approaches that rely on manually selected images, GastroFM analyzes complete, uncurated image sequences, providing case-level predictions aligned with clinical practice workflows. Further comparative studies with existing foundation models and large-scale external validation are necessary to fully establish its superiority and clinical utility in diverse settings.

#2791 Deep learning-based survival prediction of post-operative GBM patients via multimodal radiomic phenotypes drawn from Kaniadakis vector embedding in latent space.

Roy Nasr, **Bardia Rodd**

SUNY Upstate Medical University, Syracuse, NY

Purpose: The aim of this study was to use multimodal imaging biomarkers and AI-guided personalized precision survival prediction in improving outcomes for patients with post-operative glioblastoma (GBM).
Method: A cohort of 450 de novo GBM cases from the University of Pennsylvania, each featuring the four standard multimodal MRI sequences (T1, T2, FLAIR, T1-Gadolinium), was analyzed. We extracted 354 radiomic biomarkers per modality (Pyradiomics) and reduced these high-dimensional features to a stable 11-dimensional latent space using Density-Based Isomap (PR-Isomap), with the optimal dimension determined by a gap statistic, which we developed specifically for such projection. These latent biomarkers were then normalized, fused across modalities, and projected into a risk-sensitive feature space via Kappa (Kaniadakis) Vector Embedding. The resulting multimodal features fed into a deep learning-based survival model using the log-hazard ratio, optimized via a survival loss function based on the negative log-likelihood of the Cox proportional hazards model for patient outcome prediction.
Results: The final survival-prediction model achieved a 71.7% accuracy in binary classification via a consensus of multiple machine learning classifiers with 10-fold cross-validation and a C-index of 0.5196, indicating a modest but statistically meaningful predictive capability using the imaging embeddings alone. To assess prognostic separation, a Kaplan-Meier survivorship curve was stratified by hazard-score quartiles. Distinct thresholds were established: the first quartile Q1) hazard score was -0.36 and the third quartile (Q3) score was -0.29. The median hazard score of -0.33 separated the cohort into 225 high-hazard patients and 225 low-hazard patients. The resulting stratified Kaplan-Meier curves demonstrated clear separation between these risk groups, definitively confirming the capacity of the MRI-derived embeddings to differentiate patient survival trajectories.
Conclusion: The integration of deep learning with multimodal MRI embeddings offers a powerful, objective methodology for GBM prognostication. The resulting quantitative hazard scores successfully differentiate high- and low-risk patient survival trajectories. This multimodal imaging biomarker-driven approach provides personalized risk information for post-operative GBM patients, and supporting precision neuro-oncology by informing the selection of personalized adjuvant therapies.

#2792 Leveraging PR-isometric guided deep learning to decode CT-based tumor heterogeneity and enhanced NSCLC prognosis.

Joel Thomas[1], Blake Gilbert[1], Harmen Siezen[2], Lan Ma[1], Jimmy J Azarnoosh[1], **Bardia Rodd**[3]

[1]University of Maryland at College Park, College Park, MD,[2]University of Amsterdam, Amsterdam, Netherlands,[3]SUNY Upstate Medical University, Syracuse, NY

Background: Non-small cell lung cancer (NSCLC), responsible for the majority of lung cancer-related deaths, displays prognostically meaningful intratumoral heterogeneity on CT imaging that is frequently overlooked by qualitative assessment. To advance quantitative risk stratification in precision oncology, we develop a deep learning framework to derive CT-based radiomic phenotypes in EGFR-mutated NSCLC and evaluate their association with overall survival.
Method: A cohort of 130 NSCLC patients with expert-annotated tumor masks from the Stanford Radiogenomics Dataset was analyzed. To improve radiomic stability and reduce sampling variance, 1,300 augmented 2D tumor slices were generated using controlled augmentation protocols. For each patient, slices with maximal tumor burden were selectively curated to emphasize intratumoral heterogeneity in subsequent modeling. High-level morphological descriptors were extracted through a pre-trained ResNet50, and the resulting embeddings were projected into a lower-dimensional manifold via Parzen-Rosenblatt Isometric Mapping (PR-Isomap), preserving nonlinear geometric relationships linked to heterogeneous growth dynamics. Gap statistics determined the optimal latent dimensionality. These low-dimensional vector biomarkers were then used to classify survival outcomes.
Results: PR-Isomap-derived embeddings demonstrated pronounced stratification of patient survival cohorts, underscoring the method's capacity to encode clinically salient heterogeneity within tumor phenotypes. A ResNet50 backbone was optimized over 200+ training epochs using an Adaptive Moment Estimation-based optimizer with a learning rate initialized at *10-4* 10^{-4} and adaptively decayed to ensure stable convergence. Model training employed a cross-entropy loss function to enhance discriminative capability across survival categories. The resulting classifier attained a 97% slice-level accuracy, exhibiting robust generalization across all augmentation regimes. Notably, model discrimination of survival endpoints was attributable to biologically meaningful tumor-intrinsic structural patterns, rather than extraneous anatomical noise, owing to segmentation-informed slice curation that systematically excluded non-tumoral confounders.
Conclusion: Integrating deep learning-based CT-derived heterogeneity signatures with PR-Isomap embeddings enhances survival stratification in NSCLC. These imaging-driven, low-dimensional Deepomics features provide clinically actionable prognostic biomarkers, enabling earlier identification of high-risk patients and informing precision treatment planning.

#ADV01 Patterns of lung cancer clinical trials in Latin America and their implications for patient treatment access and research equity.

Sofia Jubany

1

Patterns of lung cancer clinical trials in Latin America andtheir implications for patient treatment access and research equityThis project analyzes patterns of lung cancer clinical trialparticipation in Latin America and their impact on patient access to innovativetherapies and research equity. It examines structural barriers limitingregional participation, including the scarcity of early-phase and later-linestudies, disparities in research infrastructure, funding, and molecular testingcapacity. The work also highlights the importance of including Latin America'sdiverse population in oncology research to improve the global representativenessof evidence. Finally, it explores opportunities for patient and researchadvocates to contribute to expanding clinical trial accessibility,strengthening collaboration among stakeholders, and promoting more equitableclinical research participation across the region.

#ADV02 Transforming cancer care together: A regional collaborative model to strengthen oncology systems.
DONJETA Zeqa

Europa Donna Albania, Tirana, Albania

#ADV03 Patient engagement in research: Lessons from the ASH Research Collaborative Patient Collaboration Team.

TODD Kennedy

Advocate, Coto de Caza, CA

In December 2024 I was asked to lead a Patient Engagement Work Group for the ASH Research Collaborative (ASH RC) Multiple Myeloma Research Network. The goal was to ensure meaningful, ongoing patient engagement in core functions of the ASH RC. Under my leadership, over the course of 2025 we met our key deliverables including recruiting a diverse team of patient and care partner advocates, reviewing best practices in patient-centered research and engagement, reviewing and scoring research proposals, collaborating as active members of research teams including co-authorship on abstracts accepted by ASH, and creating a charter to serve as the foundation for a proposed, permanent “Patient Collaboration Team.” The impact of these work group deliverables led to approval by ASH RC senior leaders to approve the creation of the PCT, which I chair. This poster will describe lessons learned in the work group stage as well as plans for the PCT going forward.

#ADV04 Backfilling in early-phase oncology trials: A patient perspective on dose-finding innovation.

Kirstin Spencer

Advocate, Winchcombe, United Kingdom

Early-phase clinical trials aim to identify safe andeffective dosing strategies, balancing anti-tumour activity with acceptabletoxicity from both clinical and patient perspectives. Historically,dose-finding studies have largely focused on identifying the highest dose thatcan be safely tolerated. However, with targeted therapies and immunotherapies,the goal has increasingly shifted toward identifying doses that maintainbiological activity while keeping side effects acceptable. minimisingunnecessary toxicity and keeping side effects acceptable.“Backfilling” refers to the concurrent enrolment ofadditional patients at lower dose levels, which have already shown to be safe,while a higher dose is currently tested. This enables deeper understanding ofdrug behaviour, anti-cancer activity, and interactions with metabolic andbiological markers, supporting more confident selection of the most appropriatedose for later-phase trials. Importantly, many therapies demonstrate differentbiological effects across dose ranges, meaning that collecting data acrossmultiple dose levels may reveal activity that would not be evident ifdose-finding focused only on identifying the highest tolerated dose.Recent regulatory initiatives and guidance supporting doseoptimisation reflect this evolving approach. The United States of America Foodand Drug Administration (FDA, 2024) and the Methodology for the Development ofInnovative Cancer Therapies (MDICT) Taskforce (2022) both encourage dosefinding studies to consider broader information/evidence than toxicity aloneand highlight the value of backfilling in generating richer datasets collectingadditional information that will ultimately help selecting the optimal dose.From a patient-advocate perspective, backfilling is morethan a technical refinement. It is a practical strategy that widens recruitmentopportunities and allows additional information to be gathered earlier in drugdevelopment. This can help identify effective and tolerable dosing sooner andreduce delays caused by needing additional trials to redefine the appropriatedose. By improving understanding of how treatments behave across dose levels,backfilling may help reduce unnecessary toxicity and metabolic stress.Integrating patient perspectives into trial methodology discussions cantherefore help ensure dose-finding strategies are not only scientificallyrobust but also better aligned with tolerability and real-world patientexperience, enabling kinder, better-tolerated treatments for both current andfuture patients.

#ADV05 Analysis of trends in pancreatic cancer clinical trials and barriers to clinical trial enrollment.

Cassadie Moravek

Pancreatic Cancer Action Network, Manhattan Beach

#ADV06 Meeting people where they are: Feasibility and acceptability of an integrated cancer screening program for NYCHA residents.

TANISHA Hill

New York, NY

Cancer disparities are deeply connected to access,especially for communities facing longstanding structural barriers topreventive care. This poster will highlight a current Cancer Health ResearchCenter (CHRC) grant project I am partnering on with Dr. Jamilia Sly toinvestigate the feasibility and acceptability of an integrated cancer screeningprogram designed to better serve New York City Housing Authority (NYCHA)residents. As a co-investigator, I support the project across key phases of theresearch process, including data collection, analysis and interpretation, andknowledge dissemination. The work is grounded in community-informed engagementand is focused on understanding what screening approaches are realistic,respectful, and usable for residents, especially when it comes to trust,communication, and barriers that often prevent people from completing screeningand follow-up care. The poster will share the project's purpose,community-centered design considerations, and early insights related to feasibility(implementation realities, participation, and operational fit) andacceptability (resident perspectives, perceived value, and culturalresponsiveness). Ultimately, this project aims to generate practical evidencethat can strengthen integrated screening approaches and help move cancerprevention and early detection closer to the communities that need it most.

#ADV07 Lung cancer biomarker testing: Driving precision treatment and improved outcomes.

DAVE Bjork

Advocate, Georgetown, MA

Background: Biomarker testing has become a cornerstone ofmodern lung cancer management, enabling precise diagnosis, individualizedtherapy selection, and ongoing monitoring. Comprehensive molecular profilingnow guides treatment decisions for both non-small cell lung cancer (NSCLC) andsmall cell lung cancer (SCLC), transforming outcomes and expanding access totargeted and immune-based therapies. Objective: This poster highlights current biomarker testingstrategies in lung cancer, the clinical relevance of key genomic andimmunologic markers, and emerging technologies that are reshaping real-timedisease assessment. Content Overview: We present an overview of essentialactionable biomarkers—including EGFR, ALK, ROS1, BRAF, MET exon 14 skipping,RET, NTRK, and KRAS G12C—and their associated targeted therapies. We alsodiscuss immunotherapy-related biomarkers such as PD-L1 expression and tumormutational burden (TMB), emphasizing their role in predicting response tocheckpoint inhibitors. The poster outlines recommended testing methodologies,including tissue-based next-generation sequencing (NGS), liquid biopsy approaches(ctDNA), and reflex testing protocols that reduce diagnostic delays. Key Messages: Broad molecular testing improves detection ofactionable alterations. Immunotherapy biomarkers remain essential yet imperfectpredictors of response. Liquid biopsies provide minimally invasive options forinitial testing and resistance monitoring. Integrating multi-omics andAI-supported analytics may enhance future decision-making. Conclusion: Comprehensive biomarker testing is vital todelivering precision oncology in lung cancer. Advances in testing technologies,standardization efforts, and streamlined workflows will further improvediagnostic accuracy, clinical decision-making, and ultimately patient outcomes.

#ADV08 Patient perceptions of mammographic compression: Empowering women to improve mammography outcomes.
Vivian M. Lee

Aqua Partners, Los Altos, CA

Most women are not informed during mammogram procedures thatmammographic compression is critical to improving image quality and reducingradiation exposure. After multiple experiences of delays due to callbacks andre-imaging due to insufficient mammographic compression, I decided to initiatean advocate-led survey to assess the awareness and understanding of theclinical benefits of mammographic compression. I developed a questionnaire thatwas completed voluntarily and anonymously by 100 women undergoing routinescreening mammography about their perceptions of and tolerance for pain,anxiety, fear and discomfort associated with mammograms. Findings reveal asubstantial gap in patient awareness which may contribute to lack of compliancewith mammographic screening recommendations. My preliminary findings show thatpatient education can be effective in making women aware that they DO have thepower to improve the usefulness of their mammogram as well as minimize theirradiation exposure.

#ADV09 Early detection is power.
ETHEL Olomu

Engraced Life Foundation, Lagos, Nigeria

Since 2022, Engraced Life Foundationhas been at the forefront of restoring dignity and saving lives through thePinkRoom School Outreach — an initiative designed to introduce breast healtheducation, menstrual hygiene, and self-esteem restoration to adolescent girlsin secondary schools across Nigeria. PinkRoom creates a safe and engaging spacewhere young girls can learn about their bodies, understand early signs ofbreast changes, and access dignity kits that promote self-care and confidence.It is more than a health program — it’s a movement for awareness, compassion,and empowerment.

#ADV10 Tenacious at such a time as this.
TARAH Green

Tenaciosly Teal, Yukon, OK

Life is made of times when you must be strong because lifeoften feels hard, and also there are times, even in adversity, when life feelsreally great. Despite whether you can describe your life as good or bad at anygiven time, life always requires tenacity - even when we feel lacking. Thedefinition of tenacious is: Keeping a firm hold of something, clinging oradhering closely; determinism, possessing determination.

#ADV11 Beyond informed consent: A social work framework for authentic shared decision-making across the cancer survivorship continuum.

Nicole Normandin Rueda

Patient Empowerment Network, Kyle, TX

The Promise and Reality of Shared Decision-Making Shareddecision-making (SDM) - the process where clinicians and patients collaborateto make healthcare decisions informed by best evidence and patient values - iswidely endorsed as the gold standard for patient-centered cancer care. Yetsignificant gaps persist between SDM as an aspirational concept and SDM aslived reality for patients navigating cancer survivorship. A Social WorkPerspective on Patient Empowerment As a Licensed Master Social Worker who servedas caregiver for my father during his seven-year Stage IV pancreatic NETjourney (2005-2012), worked in pediatric oncology at Texas Children's Hospital(2014-2016), and now leads patient empowerment initiatives nationally throughPatient Empowerment Network, I have witnessed how structural barriers, powerdynamics, and psychosocial factors profoundly shape patients' capacity toparticipate meaningfully in decisions affecting their care and survival. Thisposter presents a social work framework for understanding barriers to authenticSDM across the cancer survivorship continuum and proposes research prioritiesand practice interventions that move beyond rhetoric to genuine patientempowerment.

#ADV12 Community-driven innovation to address breast cancer disparities: The AfroPink Pink Pop-Up Model and the launch of TechPink.

VINA Morris

Advocate, Bayonne, NJ

Breast cancer mortality remains disproportionately highamong Black women and medically underserved populations, often due tostructural barriers to early detection, limited access to preventive care, andlower participation in research. Community-based models that integrateculturally relevant outreach, screening access, and survivor-centered supportare critical to addressing these disparities.AfroPink, a survivor-led nonprofit organization, developedthe Pink Pop-Up Program, a community-embedded initiative that delivers breastcancer education, self-advocacy resources, and screening access directly intotrusted community settings such as churches, parks, small businesses, andcommunity centers. Through partnerships with healthcare institutions, theprogram connects participants to breast screening services, patient navigation,and follow-up care while addressing barriers related to cost, transportation,and medical mistrust.Building on the trust and engagement established throughthis model, AfroPink is launching TechPink, an initiative designed to leveragetechnology to improve survivorship outcomes and expand community participationin innovation. TechPink focuses on increasing digital literacy, expandingaccess to technology training for survivors, and exploring technology-drivenapproaches to improve health data literacy, research participation, andlong-term survivorship support.AfroPink also collaborates with research institutions andpublic health partners to support community-engaged research efforts and ensurethat the lived experiences of survivors from underserved communities informscientific discovery and cancer care innovation.This poster presents the AfroPink model as an integratedcommunity-engaged approach that combines outreach, screening access,survivorship support, and technology empowerment to improve early detection,strengthen research participation, and advance more equitable breast canceroutcomes.

#ADV13 The positive impact of one-to-one peer support on AYA cancer patients and survivors.

MARIELLE Mcleod

Cancer Hope Network, Summerville, SC

One-to-onepeer support through a trained mentor program improves patient reportedoutcomes regarding overall mental health, distress on NCI scale, and hope forthe future in adolescent and young adult cancer patients and caregivers. Whenmatching patients and caregivers in this demographic with mentors who canconnect with life circumstances and age-related issues such as working duringtreatment, caring for young children, fertility preservation, relationshipstress, and financial toxicity, patients report greater positive impact onoutlook and mental health. Methods: When a support seeker contacts ourorganization, our cancer support coordinators complete a thorough intake callwhere they assess the caller's needs and current circumstances, as well as evaluatethe support seeker's current state of mental health. They are then matched with a trained andvetted mentor who has been through a similar evaluation. Through tracking visitlogs submitted by mentors as well as survey feedback from our support seekers,we can evaluate the effectiveness and suitability of the match. If thepatient's circumstances or prognosis change, supplemental matches or outsidereferrals can be made as necessary. The program is offered in a virtualcapacity and free of cost to the participants, so it eliminates barriers tocare for our target demographic and increases participation and positiveoutcomes. Results: Between January 2023 and July 2025, 119 AYA patients orcaregivers were matched with a mentor through Cancer Hope Network. Each matchhad at least 1 phone call visit, and 75% of them completed more than one visitwith a mentor. The survey feedback from this group demonstrates significantimprovement in outlook, distress levels, hope for the future, and feelings ofisolation. Among survey respondents, 77% reported decreased levels of distresson the NCI scale. The averageself-reported score on the scale before connecting with a mentor was 8. Theaverage post-connection score was 5 as self-reported by surveyrespondents. Several respondentsreported significant decreases in distress, by as many as 6 or 7 points on thescale. AYA support seekers report discussing relationships, work or school,parenting, mental health, fertility, isolation, and lack of support with theirmentors. Numerous respondents voiced thepositive impact of mentorship including one young woman diagnosed withmetastatic disease while pregnant with her third child who shared, "My mentorhas been so helpful in giving me HOPE that even with a "poor prognosis" I maystill be around to raise my kids. She has been so kind and supportive, and Ireally appreciate having the perspective of another young mom who has gonethrough the same thing and whose priorities mirror mine. Thank you for matchingme!" These findings underscore the value of accessible, empathetic peer supporttailored to AYA patients and caregivers' life circumstances and psychosocialneeds.

#ADV14 Concept to impact: Creating a research-driven, patient informed research program.

ANGELA Timashenka Geiger

Advocate, Charleston, SC

The Medical University of South Carolina (MUSC)NCI-designated Hollings Cancer Center (HCC) Survivorship and Cancer OutcomesResearch (SCOR) Initiative was founded in 2022 to meet the needs of the growingpopulation of cancer survivors and their caregivers, SCOR provides atransdisciplinary hub for collaboration for clinicians, researchers, andpatients to improve cancer survivorship, care delivery and outcomes. To thatend, SCOR's mission is to: 1. 2. 3. 4. Deliver evidence-based, equitable,accessible and patient-centered care to cancer survivors. Foster transformativeand paradigm-changing research in cancer survivorship, outcomes and caredelivery. Establish a pipeline to inspire, train and retain the next generationof survivorship and cancer care delivery researchers. Engage the South Carolinacommunity to advance awareness of cancer survivorship. This poster will demonstrate how thisinitiative became a formal program with deliberate attention to patient/survivoradvocacy.

#ADV15 Pelotonia from community to discovery: How grassroots philanthropy amplifies Ohio State's cancer research capacity.

JOE Apgar

Pelotonia, Columbus, OH

As a cancer survivor and CEO of Pelotonia, I've witnessedfirsthand how grassroots community engagement creates sustained researchfunding to amplify institutional capacity in ways that transform both researchand outcomes. Over 18 years, Pelotonia's peer-to-peer community fundraisingmodel has raised more than $340 million directed to cancer research at The OhioState Comprehensive Cancer Center. This funding has supported the recruitmentof world-class scientists and their labs, underwritten an annual researchfellowship program, launched institutional programs including the DrugDevelopment Institute and the Pelotonia Institute for Immuno-Oncology, and manymore key research initiatives. This case study explores the history and impactof Pelotonia and how grassroots engagement creates a social movement in supportof cancer research. It also makes the case that this model, scaled andreplicated, holds the potential to transform how the world funds andaccelerates the science that will save lives.

#ADV16 Care and treatment of the LGBTQ+ community in the present hostile political environment?.

JOEL Pointon

SWOG, San Diego, CA

Historically, members of the LGBTQ+ community have facedincreased challenges in securing quality, equitable healthcare in the US. In a hostile political environment, how canwe support this community in obtaining equitable care and treatment?It takes both systemic change and individual action toprotect and advance LGBTQ+ healthcare equity, especially when facing politicalhostility. Advocacy, education, inclusive practices, and strong partnershipsare all key to ensuring that LGBTQ+ individuals receive the care they deserve.

#ADV17 Ethics and access in pediatric CAR T-cell therapy.

VICTORIA Lee

Advocate, Chapel Hill, NC

Advanced gene and cell therapies, including CAR T-celltreatments such as tisagenlecleucel (also known as Kymriah), have significantlyimproved outcomes for pediatric patients with relapsed or refractory B-cellAcute Lymphoblastic Leukemia (ALL). However, access, in the form of clinicaleligibility criteria, institutional capacity, and financial barriers, continuesto impede families and patients from pursuing these options. Currentqualifications require refractory disease or multiple relapses following theexhaustion of conventional treatment options before a patient becomes eligiblefor CAR T-cell therapy, delaying access to treatments with demonstratedefficacy. While designed to save lives, health policy implementations andprotocols limit the maximum impact of these therapies, while potentiallycontributing to disease progression for patients and higher financial burdenson families. This poster applies a bioethical approach to the currentaccessibility standards of pediatric CAR T-cell therapy, addressing the fourmain bioethical imperatives: autonomy, beneficence, non-maleficence, andjustice. From a patient advocacy perspective, this poster highlightsopportunities for improvement specifically aligned with patient-centered needsin advanced gene cell therapy development, implementation, and practice.

#ADV18 Survivorship and peer support: Outcomes from youth leadership initiatives.

Max Penzer

MIB Agents, Medford, MA

MIB Agents is a nonprofit organization dedicated toproviding support for patients and families affected by Osteosarcoma (OS), amalignancy that primarily affects children and AYAs. Over the past decade, MIBhas implemented youth-led initiatives to inform OS research, lobby forpertinent legislation, and connect with current patients affected by OS. Oneprogram, called Ambassador Agents, connects OS survivors with current patientsand families affected by OS. Another program, called the Junior Advisory Board,is a panel of AYAs who are responsible for informing OS research, lobbying forpediatric cancer legislation, and producing podcasts to spread their voiceacross the OS community. Additionally, the osTEAo podcast, run by OS survivors,aims to discuss post-treatment roadblocks that OS survivors face. One of thelargest indirect benefits of these programs is the creation of a peer supportcommunity between different OS survivors. Participation in these youth-ledinitiatives has facilitated coping among AYAs by fostering structuredopportunities for peer-to-peer connection and mutual support. Engagement inprograms such as the Ambassador Agents and Junior Advisory Board has beenassociated with reduced isolation, enhanced resilience, and a strengthened senseof identity within the osteosarcoma survivorship community.

#ADV19 From survivor to partner: integrating patient voice across the cancer research continuum.

JACQUELINE Smith

Ovarian Cancer Alliance of San Diego, Rancho Santa Fe, CA

From bench to bedside, cancer research translates scientificinnovation into patient care — yet integrating the patient voice across thatcontinuum requires a shift in research culture. For those who choose to movebeyond survivorship into advocacy, the role of *patient partner* transformslived experience into a scientific asset, amplifying impact from discovery tocare.Clinical outcomes are the cornerstone of cancer research —yet treatment carries costs that extend far beyond — physical, psychological,economic, and caregiver burden. Patient partners bring these dimensions to theforefront, ensuring research reflects the full human cost of cancer treatment.Their contributions span the research process — from study design and grantapplications to clinical trial recruitment and dissemination of findings —while extending beyond into policy and legislative advocacy and fundraising.Realizing the full potential of this partnership demandsconfronting real barriers: communication gaps, structural exclusion, anddiffering priorities. Bridging these requires shared commitment — researcherscommunicating in lay terms; patient partners deepening their understanding ofthe scientific process. Ultimately, this produces research that reflectsreal-world needs, earns public trust, and drives meaningful change for those itis meant to serve.For patient partners, this is more than contribution. It isagency. It is hope.

#ADV20 Man Up to Cancer to men facing cancer.

BILL Minh Thach

Advocate, Katy, TX

This poster presents a comprehensive mental healthinitiative addressing the critical gap in psychological support for men withcancer, who often face cultural stigma around expressing vulnerability andseeking mental health care. Through Man Up to Cancer, we have developedpeer-led support programs that create safe, judgment-free spaces where men canopenly discuss anxiety, depression, grief, identity shifts, body imageconcerns, and the emotional burden of diagnosis and treatment. The poster willoutline our multi-pronged approach: facilitated support groups that provideongoing structured peer connection, in-person meetups that foster localcommunity building and reduce isolation, and an annual retreat that brings mentogether from across regions to deepen relationships, share experiences, andbuild a sustained support network. We will present program participation data,participant testimonials on impact, and lessons learned about what language,formats, and facilitator characteristics most effectively engage men in mentalhealth conversations. Particular emphasis will be placed on addressing barriersspecific to men of color, who face compounded stigma at the intersection ofmasculinity norms and cultural attitudes toward mental health. The poster demonstrateshow community-based advocacy organizations can fill critical gaps inpsychosocial oncology services and provides a replicable model for reducingmental health disparities in cancer care.

: Advocates Poster Session 2
Poster Session

#ADV21 "What's that?" The question that saved my life and fueled "The Big See," a multi-media skin cancer awareness campaign (launched in 2019-present).

Susan Manber

Advocate, Cortlandt Manor, NY

Skin cancer is the #1 most prevalent form ofcancer, but people tend to think it's "just skin cancer" - no big deal comparedto other "more serious" cancers. Most people have no idea that more than 2people an hour die from skin cancer. As a Merkel Cell Carcinoma survivorserving as Chief Patient Officer at a major health care communications agency,together with the Skin Cancer Foundation, we crafted a pro bono campaign thatwould focus on driving early detection to save lives. Methods The campaign tapsinto critical insights from our research, including qualitative interviews withfoundation leadership, survivors, dermatologists, and clinical researchers.Co-creation workshops helped to refine the research insights into the campaignconcept and core messaging platform including television, print, outdoor,digital, and social media. Messaging platform We love the sun but we hate thedamage - we get checked when someone points out something suspicious. Whenpeople get to a dermatologist early enough to save their lives - they, or afamily member would say: "I saw something new, changing, or unusual." Thatbecame our core messaging platform. Our key human insight Cancer is the enemy,not the sun. Our tagline became the two critical words my daughter Sarina saidto me that saved my life: "What's That?" The Big See: the cancer you can see Weshot the campaign on the beach in San Diego, using a comedian hidden behind amirror to engage passersby. People would stop to look and read the engagingfacts displayed as our comedian told jokes - because laughter is the bestmedicine. We wrapped hard hitting messages in humor: · 2 people an hour die ofskin cancer · 5 year melanoma survival = 99% when caught early; drops to 20%when not · 5 sunburns doubles your risk Bringing the campaign to the communityThe campaign continues to run in national and local streaming and digital mediaand is supported by the Big See microsite and social media. We folded theFoundations'Destination Health Skin Program into the Big See brand -giving people access to free screening through a traveling skin cancerscreening program. We are grateful to the dermatologists across the country whovolunteer to help us give free skin checks. Results We were invited to launchthe campaign on the creativity stage at the Cannes Lions festival, adding toour global reach. To date, we have raised over $75 million in donated media,driving thousands of people to get checked. Through our Destination Health Skinprogram, with the help of more than 600 dermatologists, we have provided nearly34,000 free skin cancer screenings. Our volunteer dermatologists haveidentified more than 13,000 suspected skin cancers and skin precancers,including 672 suspected melanomas.65% of Destination Healthy Skin participants have never beenscreened for skin cancer before. Conclusion The program continues to bring skincancer screening to at-risk populations to help detect cases of skin cancer,saving thousands of lives all across the country. We continue to expand effortswith support from our partners to include focused screenings efforts for keypopulations including men and Hispanic people who are less likely to usesunscreen or sun-protective clothing.

#ADV22 The culture of cancer: Breaking down barriers to research.

Daniel G. Garza

Cheeky Charity, Laguna Beach, CA

This poster explores how culture, stigma, and survivorstorytelling shape access to cancer research and prevention, with a focus onanal cancer in Latine and LGBTQ+ communities. Drawing on my work with CheekyCharity and my lived experience as an anal cancer survivor, it highlights howbilingual outreach, creative media, and survivor-led initiatives can dismantlesilence and make cancer education more approachable. The poster will illustratethe interconnected circle formed by culture, religion, and social normsalongside research, studies, and outcomes. By showing how these forcesinteract, the project emphasizes the need for survivor-informed, culturallyresonant approaches that bridge communities and science, breaking down barriersto prevention and care.

#ADV23 Embedding cancer advocates as structural partners in oncology conferences: A scalable implementation model based on RISE UP for Breast Cancer and Women's Health Conference.

DIANE Heditsian

Redwood City, CA

Background: Patient, research and policy cancer advocatesare frequently included in oncology meetings, yet participation often remainssymbolic. We developed and operationalized a full-integration model at the 2026RISE UP for Breast Cancer and Women's Health conference to structurally embedadvocates across all dimensions of a scientific meeting.Methods: As Advocate Lead on the planning committee I hadthe opportunity to implement a multi-level advocate integration frameworkencompassing governance, grant support, programming, and on-site engagement.Advocacy participation included agenda development for the general meeting andindividual sessions, abstract review and speaker and poster selection. Duringthe meeting, advocates were embedded as judges alongside venture capitalists,industry representatives and medical and regulatory experts, to weigh in onpitches at the curated competition that spotlighted high-impact ideas in thewomen's health arena. In the general sessions advocates shared their storiesand their perspectives on topics ranging from pregnancy-related breast cancerto navigating menopause after a breast cancer diagnosis, to inability toconceive due to uterine fibroids. They served as presenters at poster sessions,participated in audience Q/A discussions, and hosted non-profit advocacyorganization information tables throughout the exhibit hall.Results: As a result of a targeted effort to attract adiverse group of advocates, a steeply reduced advocate registration fee, aswell as travel support scholarships, 54 advocates registered for theconference, representing 16.18% of total attendees. At RISE UP, 18 advocatesfrom six states served as speakers or judges, and an advocate presented in 100%of conference general sessions ranging from scientific to clinical to policyrelated. Advocates were integrated into 65 planning meetings over 9-months andreviewed and judged 111 abstracts. All advocate speakers were the invitedguests of RISE UP at a fundraiser awards luncheon as a show of appreciation fortheir participation in the meeting. Qualitative feedback from researchers andphysicians indicated improved discussion of patient-centered endpoints, equityconsiderations, and real-world evidence as well as increased opportunity forcollaboration. The results of the attendee satisfaction Likert Scale surveyquestion: Do you feel that the advocate stories and advocate perspectives ineach session enriched the meeting? are forthcoming.Conclusions: Structural advocate integration is feasible,scalable, and associated with measurable increases in engagement andtranslational relevance. This implementation model provides a replicableframework for oncology conferences seeking to move from symbolic inclusion toauthentic partnership with advocates.

#ADV24 How digital spacial profiling is changing the fight against lung cancer.

MICHEL Itel

Advocate, Stones Corner, Australia

Lung cancer is the leading cause of cancer death globally, and while immunotherapies and targeted therapies have been transformative, they only work in roughly 1 in 5 patients. We have not been able to reliably predict who will respond, until now. Digital Spatial Profiling allows us to read the tumour microenvironment: the complex ecosystem of immune cells, cancer cells, and supporting structures that ultimately determines whether a treatment succeeds or fails.

#ADV25 Thriving in the grey: A patient needs model to balance science and reality.

CARRIE Camino

Neuroendocrine Tumor Research Foundation, Libertyvlle, IL

This poster presents a framework for encouraging the Patient Voice and empowering Patient Agency for neuroendocrine tumor (NET) cancer patients, an uncommon cancer. Utilizing Maslow's hierarchy of needs, it defines a Patient's Matrix of Needs outlining patient education priorities, as well as medical and caregiver engagement and empowerment strategies. In socializing this model with Patients, we seek to accelerate a Patient's understanding of their diagnosis and thrivership mindset, helping Patients develop a personalized action plan towards meeting their individual needs. In socializing this model with the Research community, we help drive a holistic view of patient care and support the intersection of Patient and Researcher engagement to drive improved discovery and treatment outcomes.

NET Research Foundation and other organizations have a wealth of materials and activities that speak to Patient thrivership needs. These materials will benefit from better organization around a Needs Matrix to help Patients more quickly navigate them. Additionally, Research has medical outcome data related to treatments. The poster will include examples of linking research and thrivership educational materials, as well as highlight areas for future development to support true NET Patient Agency.

#ADV26 Henrietta Lacks House social determinants of health.

DAVID Sanders

Henrietta Lacks House of Healing, Dundalk, MD

Henrietta Lacks has been commonly known as the "invitro" miracle but there has been little effort to connect her to theSocial Determinants of Health which concept was non-existent at the time of hersecreted discovery in the era of Professional Autonomy dominated health law.Now that we are in an era of Patient/Health Equity influence on health law itis time to take a look these factors from the perspective of the science hercells helped to create and possibly descientificate the complicated for buildinghealth intelligence for all.

#ADV27 Policy and how it impacts cancer research.

LASHELLE Scott

Advocate, Houston, TX

This poster will demonstrate how policy impacts cancer research by presenting the process of a bill or budget (state or federal) and how it creates policy for researchers to create clinical trials/treatment options.

#ADV28 HEALing The Bronx: A grassroots model for cancer education, health equity, and community engagement through art and literacy.

COLETTE Smith

Advocate, Bronx, NY

HEALing The Bronx is a community-driven initiative designed to address cancer disparities in the Bronx, where outcomes for lung, breast, colorectal, and prostate cancers are disproportionately poor compared to other regions of New York State. The program integrates arts, education, and advocacy to improve health literacy and empower residents. What began with two tree beds has grown to 24 educational tree beds, including four feature beds equipped with interactive QR codes and signage providing cancer prevention and screening information. The initiative also includes outdoor art libraries, blending literacy and creative expression to foster mental well-being and health awareness. Our first art library installation is complete, and our goal is to add two new libraries annually until all 24 Bronx zip codes are represented. HEALing The Bronx demonstrates how grassroots engagement, cultural relevance, and creative strategies can drive measurable impact in underserved communities. Future plans include expanding Care Within Our Reach community events to multiple Bronx neighborhoods, reaching over 1,500 residents in 2026, and increasing participation in screening and clinical trials. This poster will showcase the program's design, outcomes to date, and its potential as a scalable model for reducing cancer disparities through community empowerment.

#ADV29 Lo que no se ve: Indigenous-centered cancer prevention and survivorship equity in California.

ISABELLA Mireles

Advocate, Goleta, CA

This poster examines how culturally grounded cancerprevention and screening programs in Indigenous Latino communities informcancer survivorship research - using California as a well-documented caseexample. California is home to one of the largest Indigenous Mexicanpopulations in the United States, estimated in the hundreds of thousands, yetIndigenous identity is rarely captured in cancer prevention, screening, orsurvivorship research. While Latino populations are often treated as culturallyhomogeneous in cancer research, Indigenous communities experience distinctlinguistic, cultural, and structural barriers that shape engagement with cancerprevention services and long-term survivorship outcomes. Drawing on astructured review of cancer prevention and screening interventions implementedamong Indigenous Mexican communities in California - with comparative insightsfrom Indigenous-focused interventions in Mexico and broader internationalevidence that demonstrate the importance of culturally grounded cancerprevention approaches - this project synthesizes evidence on how factors suchas Indigenous language access, community trust, and culturally specific healtheducation influence participation in cancer prevention and screening. Theposter highlights how survivorship outcomes commonly attributed to “Latinoculture” may depend on whether Indigenous identity is explicitly acknowledgedand centered in intervention design. By placing California-based Indigenouscancer prevention research in direct conversation with cancer survivorshipframeworks, this work identifies gaps in how protective factors and equity arecurrently conceptualized in Latino cancer research. The findings underscore theneed for survivorship research and prevention strategies that account forheterogeneity within Latino populations and offer implications for developingculturally responsive interventions that can support improved survivorshipequity both within California and in other regions with Indigenous Latinocommunities in the U.S..

#ADV30 Bridging gaps in KRAS-mutant lung cancer care: A patient perspective on clinical trial access and community support.

LISA Haines

Advocate, Rockport, MA

Despite significant advances in precision oncology, access to clinical trials remains a significant challenge for patients with KRAS-mutant lung cancer. Once considered “undruggable,” KRAS mutations now have emerging targeted therapies, making clinical trial participation increasingly important. This poster presents a patient-informed perspective from an 11-year stage IV lung cancer survivor, highlighting real-world barriers to clinical trial access and enrollment. Patients frequently encounter substantial obstacles when searching for appropriate clinical trials, including fragmented and difficult-to-interpret information, complex eligibility criteria, and limited guidance through the enrollment process. Additional barriers such as geographic distance to academic cancer centers, financial toxicity related to travel, lodging, childcare, and lost wages, as well as rigid trial schedules, further restrict participation. These challenges disproportionately limit access for many patients and contribute to reduced diversity and representativeness in clinical research. Cancer-focused support communities play a critical role in addressing these gaps by providing education, peer support, shared knowledge, compassion and patient empowerment. Such communities help patients better understand treatment options, navigate clinical trial opportunities, and advocate for themselves within complex healthcare systems. Improving patient-inclusive trial navigation, supportive services, and community engagement is essential to ensuring equitable access to clinical trials. Addressing these barriers can enhance inclusivity, strengthen the generalizability of trial findings, and support the continued advancement of precision cancer care for all patients.

#ADV31 Accelerating gastric cancer research: Programs of the Gastric Cancer Foundation.

Harriet A. Patterson

Gastric Cancer Foundation, Albany, CA

Learn about how a patient advocacy organization is workingto accelerate research and move progress forward while helping educate andsupport patients. Research impact includes creating the firstgastric cancer registry, funding seed grants to support exciting new ideas, andsupporting advanced science with multi-year grant support.

#ADV32 Quantifying patient priorities: Identifying and weighing key non-clinical factors for scalp cooling decision-making in chemotherapy-induced alopecia prevention.

Rebecca Munoz

Advocate, Austin, TX

BACKGROUND: Chemotherapy-Induced Alopecia (CIA)is consistently ranked as one of the most psychologically distressing sideeffects of cancer treatment. Scalp cooling (SC), or cold capping, remains theonly primary preventative strategy, yet its use demands a significantcommitment from the patient: added time at infusion appointments, potentialacute discomfort, and often substantial out-of-pocket financial cost.
While research exists on the clinical efficacy of SC devices and protocols(i.e., what works), there is a critical and unmet need for research focused onpatient values and decisional science (i.e., what matters). Currently, patientslack standardized tools to systematically weigh these complex clinical andnon-clinical trade-offs against their personal priorities, often leading toreliance on anecdotal information and subsequent high rates of decisionalregret when expectations are unmet. The absence of structured supportnecessitates reliance on peer groups, such as the Chemotherapy Cold Cappersnetwork.
The immediate aim of this study, titled The VALUED Study, is to pilota quantitative approach to identify and prioritize the specificpatient-determined factors (including clinical efficacy expectation,psychosocial impact, financial cost, and practical time commitment) that exertthe greatest influence on a patient's decision to utilize scalp cooling duringchemotherapy.

METHODS: This ongoing project utilizes across-sectional, mixed-methods online survey designed to capture a targetedsnapshot of the trade-offs individuals make regarding hair preservation. Thisinitial data collection phase leveraged an existing patient advocacynetwork. The survey was distributed electronically across a target populationof individuals with a history of cancer who considered or used scalpcooling. Data from this interim analysis, including ranking andweighting scores, were analyzed descriptively toestablish preliminary factor prioritization of logistics,utility, and experience. Qualitative data from open responses werereviewed using rapid thematic analysis to enrich the context of thequantitative findings.

CONCLUSION: These preliminary findings representthe foundational data regarding quantified, patient-determined decisionalpriorities currently absent from supportive care literature.The pilot data fromthis ongoing study provides an opportunity for clinicians, patient advocates,and supportive care networks to gain initial, evidence-based insight intowhat truly drives patient decisions, offering a path toward more robust shareddecision-making and reduced decisional regret.

#ADV33 Bridging the communication gap in pancreatic cancer: A stage IV PDAC survivor's perspective on improving research and biotech communication of innovation.

Elise Roth Tedeschi

Advocate, Smyrna, GA

Despite significant advances in pancreatic ductaladenocarcinoma (PDAC) research, survival rates remain low, in part due topersistent gaps in how scientific innovation is communicated to oncologists,patients, and the broader public. As a long-term Stage IV PDAC survivor,patient advisor, and participant in the AACR Scientist↔Survivor Program, I haveobserved that many promising developments, including molecularly targetedtherapies, biomarker-driven trials, and emerging diagnostic technologies,remain inconsistently translated beyond academic research settings. Incommunity oncology settings, care appropriately centers on standardof-carepathways; however, limited access to timely, practical information aboutemerging options can leave patients, particularly those with advanced disease,unaware that additional therapeutic or trial options may exist. This posterpresents a survivor-informed perspective on structural and cultural barriersthat impede effective communication among researchers, biotechnology companies,clinicians, patients, and mass media. Drawing from lived experience, patientadvisory roles, and engagement with scientific, clinical, and patientcommunities, key challenges are identified, including siloed dissemination ofresearch findings, highly technical messaging, time constraints in clinicalpractice, and the absence of trusted, patient-centered translation mechanisms.Based on these observations, the poster proposes a conceptual framework toimprove the communication of PDAC innovation that integrates survivor voicesearly and consistently across research dissemination, clinical education, andpublic engagement. Recommended strategies include concise, clinician-focusedsummaries of emerging data, co-created patient education resources, andresponsible use of mass media and digital platforms to accurately contextualizeinnovation. By positioning communication as a critical component of cancercare, rather than a downstream activity, this survivor-informed frameworkhighlights opportunities to improve awareness of emerging therapies andclinical trials, support shared decision-making, and reduce missedopportunities for patients with pancreatic cancer.

#ADV34 What survivors really need: A patient-centered model for supporting breast cancer patients through education, advocacy, and community connection.

MARSHELLE Harris

Wellness 4 Life, Gardendale, AL

This poster outlines a patient-centered support framework built around what survivors truly need during diagnosis, treatment, and life after cancer. It includes emotional support, evidence-based information, wellness tools, and culturally responsive resources. I show how my programs and advocacy training help survivors better understand treatment options, ask clearer questions, manage side effects, navigate menopause after cancer, and feel empowered in their healthcare journey.

#ADV35 Paths to research advocacy: Webinar education.

SUSUN Livingston

Powell-Drescher, Seattle, WA

The Powell-Drescher Ovarian Cancer Research Foundation is proud to introduce Paths to Research Advocacy, a quarterly educational webinar series created to inform, empower, and inspire ovarian cancer patients, survivors, and their loved ones to engage meaningfully with ovarian cancer research. Grounded in the Foundation's mission to champion collaboration between scientists and survivors, this series brings together leading researchers, clinicians, advocates, and survivor-scientists to share their unique journeys and perspectives. Each session blends personal storytelling with timely, relevant research topics, helping participants understand not only what is happening in ovarian cancer science but how they can play an active role in shaping its future. Through candid conversations and accessible education, the Paths to Research Advocacy series aims to: • Demystify the research process by offering patient-friendly explanations of emerging studies, clinical trials, and scientific innovation. • Highlight diverse advocacy pathways, showing how survivors, patients, and caregivers can contribute to research—whether through sharing experiences, participating in studies, or serving as research partners and advisors. • Strengthen the scientist-survivor partnership, fostering a two-way dialogue that elevates patient voices and accelerates impactful, human-centered research. • Build community and confidence, ensuring every participant walks away better equipped to engage in advocacy that aligns with their skills, interests, and lived experience. By illuminating the many paths to research advocacy, this webinar series empowers ovarian cancer patients and survivors to help drive the discoveries that may transform care for generations to come.

#ADV36 From silence to science: Survivor advocacy and community partnership to advance equity in cancer research.
HARJEET Kaur

Advocate, Calgary, AB, Canada

This poster explores how survivor-led, community-informedadvocacy can strengthen equity and inclusion in cancer research by addressingcultural stigma, silence, and mistrust that limit engagement amongunderrepresented populations. Drawing on lived experience as a blood cancersurvivor and patient partner, this work highlights how meaningful collaborationbetween patients, researchers, clinicians, and community networks can improveresearch relevance, participation, and knowledge translation. Focusing on SouthAsian communities, the poster examines how culturally responsive dialogue andpatient-led engagement can surface barriers to early diagnosis, clinical trialparticipation, and survivorship care that are often overlooked in traditionalresearch settings. It emphasizes the value of patient partners in translatinglived experience into actionable insights that inform research design,recruitment strategies, and communication approaches. By bridging communityadvocacy and cancer research, this work demonstrates how inclusivescientist-survivor partnerships can build trust, enhance diversity in researchparticipation, and support more equitable cancer outcomes across the carecontinuum.

#ADV37 Timely diagnosis and treatment of childhood and adolescent cancer: Challenges and opportunities.

CALLUM Mullen

Advocate, Huntsville, ON, Canada

Timely diagnosis and treatment of cancer are key tenets ofquality care, with important implications for patient outcomes and overallwellbeing. Children and adolescents are particularly vulnerable to delays incare due to patient-, clinical-, and health-system-level factors. We aimed to measure the diagnostic interval in childrendiagnosed with cancer in Québec, Canada, between 2012 and 2022, using adata-driven approach. As a complementary exploratory aim, we reviewed theliterature to identify barriers and enablers to survivorship care amongsurvivors of pediatric cancer. We identified 2927 children and adolescents with cancer inour population-based cohort and observed differences in diagnostic delay byage, cancer type, diagnosis period, and rurality. Barriers and enablers tosurvivorship care also operated at the patient, clinician, and health-systemlevels, although their relative importance likely varies across survivorship.Improving childhood cancer care requires attention not onlyto treatments, but also to the diagnostic and post-treatment phases of care.Identifying barriers across the care continuum may help guide interventions toimprove access and quality in pediatric oncology.

#ADV38 ROS1-positive lung cancer treatment access gap across Canada - A call for equitable, patient-centered care.

K. M. TAHSIN HASSAN Rahit

Advocate, Calgary, AB, Canada

Title: ROS1-Positive Lung Cancer Treatment Access Gap Across Canada - A Call for Equitable, Patient-Centred CareBackground: ROS1-positive non-small cell lung cancer (NSCLC) represents 1-2% of NSCLC cases, yet patients face significant treatment access barriers despite availability of effective targeted tyrosine kinase inhibitors (TKIs). This analysis evaluates provincial coverage disparities for ROS1 TKIs across Canada to inform patient advocacy and policy reform efforts.
Methods: We conducted a comprehensive pan-Canadian analysis of public drug coverage policies for ROS1-targeted therapies as of March 2026, examining first-line through third-line treatment access across all Canadian provinces and territories. Coverage policies, exceptional access programs, and clinical trial availability were systematically reviewed.
Results: While first-line agents (crizotinib, entrectinib) demonstrate universal coverage, profound inequities emerge in advanced-line therapy access in Canada. Second-line coverage requires case-by-case review with documented intolerance rather than progression, creating clinical and ethical challenges. Any advanced-line therapies remain virtually inaccessible through public funding across all provinces, forcing patients toward clinical trials or treatment discontinuation. Next-generation TKIs addressing resistance mutations (repotrectinib, taletrectinib, zidesamtinib) and CNS disease remain accessible only through clinical trials. Critically, coverage termination after exhaustion of first TKI line creates a "therapeutic cliff" for patients who develop resistance, despite availability of potentially effective subsequent therapies.
Conclusions: Canadian patients with ROS1-positive NSCLC face unjustifiable barriers to life-extending therapies beyond first-line treatment. The disconnect between therapeutic availability and public funding perpetuates health inequities and undermines precision oncology principles. Urgent policy reform is needed to: (1) establish consistent pan-Canadian coverage frameworks, (2) enable progression-based (not just intolerance-based) second-line access, (3) create pathways for third-line and resistance-directed therapy funding, and (4) accelerate approval timelines for next-generation TKIs. Patient-centered knowledge dissemination regarding clinical trial opportunities and exceptional access pathways remains critical until systemic coverage improvements are achieved. This analysis provides an evidence-based framework to support patient advocacy, inform healthcare provider counselling, and guide policy reform toward equitable access to ROS1-targeted therapies.

#ADV39 Addressing gaps in colorectal cancer care: Real-world impact of a national clinical navigation program.
JOHN Woerner

Advocate, Minnetonka Beach, MN

#ADV40 Disparities in access to precision oncology drugs across Canada and between Canada and the US, 2009-2025.

Sharon Batt

Advocate, Halifax, NS, Canada

In a unique funding initiative called Patient Voices inResearch, the Marathon of Hope Cancer Centres Network (MOHCCN) asked a group ofpatients from across Canada to develop themes for a research agenda and toselect the successful applicants. One theme was equity and disparities inaccess to precision medicine. I was a survivor-investigator in a study selectedto systematically document the approval process for new cancer drugs in Canadaand disparities in access between Canada and the U.S. and among provinceswithin Canada. Canadian cancer patients often hear about new oncology drugsthrough announcements that the FDA has approved a drug for use in the U.S.Because Canada has its own drug approval process, a drug approved in the U.S.may not be available in Canada. Furthermore, each Canadian province decideswhich drugs to fund under its health plan. Our research team, led by oncologistBishal Gyawali at Queen's University in Kingston Ontario, conducted aretrospective cohort study of adult solid-cancer approvals by the FDA andHealth Canada from 2009 to 2025 to identify where delays happen. Criticalvariables were time to approval, time to funding decision, and availability ofeffective anti-cancer drugs. We calculated the magnitude of clinical benefit foreach drug based on the validated ESMO-Magnitude of Clinical Benefit Scale toassess whether the delays would likely affect patient outcomes. My posterhighlights key research findings and how they can be applied to policies toaddress patients' concerns about inequities in access to cancer drugs.

Poster Session

#2796 Translating combined PD1 and LAG3 inhibition from preclinical models to patients with refractory, DNA replication repair deficient (RRD) glioblastoma: An IRRDC study.

Anirban Das[1], Vienna Mazzoli[1], Owen Crump[1], Olha Kos[1], Nuno M. Nunes[1], Lucie Stengs[1], Amanda Li[1], Adrian Levine[1], Yoshiko Nakano[1], Hope Friedman[1], Katharine O'Flaherty[1], Alexander Stein[2], Gadi Abebe-Campino[3], Annika Bronsema[2], Vanessa Bianchi[1], Melissa Edwards[1], Stergios Zacharoulis[4], Birgit Ertl-Wagner[1], Daniel A. Morgenstern[1], Trevor J. Pugh[5], Pamela Ohashi[6], Eric Bouffet[1], Cynthia E. Hawkins[7], Peter B. Dirks[1], Uri Y. Tabori[1]

[1]The Hospital for Sick Children, Toronto, ON, Canada,[2]University Hospital Hamburg-Eppendorf, Hamburg, Germany,[3]Chaim Sheba Medical center, Ramat Gan, Israel,[4]Bristol Myers-Squibb, New Brunswick, NJ,[5]UHN Princess Margaret Cancer Centre, Toronto, ON, Canada,[6]Princess Margaret Cancer Cente, Toronto, ON, Canada,[7]Staff Neuropathologist, Dept. of Pathology, The Hospital for Sick Children, Toronto, ON, Canada

Background and Aims: Glioblastoma driven by DNA Replication Repair Deficiency (RRD) account for 10% of all high-grade glioma in children and young adults, harbour high tumor mutation burden (TMB) and can respond to anti-PD1 immune-checkpoint inhibition (ICI). However, not all respond, and the majority ultimately progress, highlighting the need for combinatorial therapies for sustained immune-surveillance.
Methods: We performed transcriptomic analyses of human RRD-glioblastoma specimens for immune checkpoint expression, and accordingly, tested combined ICI in immunocompetent murine models. Based on these preclinical data, we treated refractory patients using a combination of anti-PD1+anti-LAG3 through single-patient trial/compassionate access. Complimentary immuno-genomic biomarker analyses including circulating tumor DNA (ctDNA) were performed to investigate mechanisms and track responses.
Results: Human RRD-glioblastoma (n=80) demonstrated high LAG3 expression, providing a strong rationale for therapeutic targeting. We tested combined anti-PD1+anti-LAG3 inhibition in three immunocompetent RRD-glioblastoma murine models. In the anti-PD1-responsive (Nestin-CreMSH2$^{LoxP/LoxP}$-POLE$^{S459F/+}$) model, anti-PD1+anti-LAG3 resulted in universal tumor response and superior survival to ICI-monotherapy. In the anti-PD1 resistant models (Mlh1$^{-/-}$/NestinCre+/Trp53$^{LoxP/LoxP}$ and therapy-induced hypermutant ENU/Trp53$^{-/-}$ gliomas), anti-PD1+antiLAG3 improved survival, overcoming the lack of response to ICI-monotherapy. Biologically, high LAG3 expression and immune-exhaustion observed in CD8 T-cells after treatment with anti-PD1 was ablated following the addition of anti-LAG3. Serially transplanted, post-anti-PD1 treated tumors showed response, confirming, in-vivo, that resistance to anti-PD1 could be abrogated by anti-PD1+anti-LAG3. Seven children with refractory RRD-glioblastoma who had progressed after anti-PD1 treatment were treated using anti-PD1+anti-LAG3, resulting in objective radiological responses and prolonged ongoing survival. Tolerability was better than a previous study of combined CTLA4 and PD1 inhibition for similar patients. Paired immuno-genomic tumor analyses, serial blood flow-cytometry, T-cell receptor clonotype, and CSF ctDNA analyses provided novel insights into the mechanisms of immunological invigoration and first-in-human, radiological responses.
Conclusions: LAG3 is an effective target in refractory RRD-glioblastoma. Combined inhibition with anti-PD1 inhibition demonstrated radiological response, prolonged survival and manageable toxicities in patients, and unearthered mechanisms of immune-responses. The combination will now be tested in biomarker-driven clinical trials in RRD-glioblastoma and other immune-inflamed solid tumors.

#2797 A macrophage endocytic checkpoint for PD-1 governs durable vs hyperprogressive response.

Madhubanti Mullick[1], Ella McLaren[1], Suchismita Roy[1], Brandon Biagas[1], Mahitha Anandachar[1], Vanessa Castillo[1], Samuel Williams[1], Celia Espinoza[1], Courtney Tindle[1], Gajanan Katkar[1], Saptarshi Sinha[1], Pradipta Ghosh[2]

[1]University of California, San Diego, San Diego, CA,[2]UC San Diego Health, San Diego, CA

Clinical responses to PD-1 blockade span a wide continuum, from durable regressions to hyperprogressive disease (HPD); yet the macrophage-intrinsic switches that determine these extremes responses remain undefined. Using a macrophage systems model built from >12,500 transcriptomes and calibrated with single-cell transcriptomes from >1,000 anti-PD-1-treated patients, we identified *CCDC88A* (encodes the endocytic adaptor, GIV) as a top responder-linked gene and mechanistic driver of tumor-associated macrophage (TAM)states predictive of clinical benefit versus HPD. Loss of GIV in macrophages increased cell-surface PD-1 across species and platforms (primary cell-line, and organoid co-cultures), impaired phagocytosis, and accelerated tumor progression. In syngeneic models, myeloid-specific GIV deletion converted anti-PD-1 therapy from tumor-controlling (beneficial) to tumor-accelerating (hyperprogressive), without altering T cell targeting; transcriptomic analyses of tumor-infiltrating myeloid cells confirmed a shift towards HPD-associated macrophage signatures. Mechanistically, GIV engages a TIR-like BB-loop (TILL) motif within the PD-1 cytoplasmic tail and functions as an endocytic adaptor, driving dynamin-mediated PD-1 internalization and recycling. A pharmacogenomic perturbation strategy revealed that blocking endocytic trafficking phenocopies GIV loss both *in vitro* and *in vivo*: PD-1 is trapped on the TAM surface, checkpoint blockade fails, and tumors accelerate under therapy. Conversely, preserving GIV•PD-1 coupling enhances response durability. Finally, we uncover a clinically relevant vulnerability: FDA-approved psychotropic and antiemetic drugs that impair receptor internalization (e.g., prochlorperazine) negate anti-PD-1 efficacy and induce HPD-like progression *in vivo*, consistent with pharmacoepidemiologic evidence linking such drugs to increased mortality and immune-related adverse events in patients receiving checkpoint therapy. Collectively, these findings establish GIV-dependent PD-1 routing as a macrophage-encoded checkpoint that dictates whether PD-1 blockade elicits tumor clearance or fuels malignant outgrowth. By repositioning TAMs as active arbiters of immunotherapy fate, this work exposes PD-1 trafficking, and its drug-induced derailment, as a new axis for therapeutic control and precision risk mitigation in solid tumors.

#2798 CD112 drives tumor immune evasion in HER2-positive breast cancer through sphingolipid metabolism-dependent remodeling of CD8+T cell receptor landscapeand consequent dysfunction.

YI ZHANG, Bingqiu Xiu, Jiong Wu, Qi Zhang

Fudan University Shanghai Cancer Center, Shanghai, China

Purpose: HER2-positive breast cancer (HER2+BC) features high TMB and abundant TILs, supporting immunotherapy potential. HER2-targeted therapies also engage the immune system. However, PD-1/PD-L1 inhibitors show limited efficacy, suggesting unique immunosuppressive mechanisms in this subtype.
Methods: Integrated analysis of FUSCC and validation cohorts identified key immune checkpoints. Experimental validation was performed through knockdown of candidate immune checkpoints and in vivo screening. Mouse scRNA-seq revealed CD8+ T cells as the most impaired subset. CD112-high tumor cells were characterized via stable cell lines and multi-omics analysis, with validation by spatial transcriptomics. TurboID proximity labeling identified CD112-UGCG interaction. CD8+ T cell function was assessed using conditioned medium co-culture and exogenous GlcCer supplementation. To demonstrate that CD112-driven sphingolipid metabolism exerts its function through CD112-CD112R axis, we utilized Cd112r-KO mice.
Results: We revealed that non-pCR HER2-positive patients have a comparable level of TILs but exhibited a more exhausted phenotype, and found significant upregulation of CD112 in residual tumors following HER2-targeted therapy. Moreover, while PD-L1 is highly expressed in TNBC, CD112 shows specific enrichment in HER2+BC, with predominant localization to malignant epithelial cells. These findings suggest that CD112 may hold greater therapeutic potential in HER2+BC. In addition to its canonical immunosuppressive function, our study revealed that CD112 promotes the metabolism of sphingolipid, particularly glycosphingolipid. Mechanistically, through TurboID we uncovered a previously unreported interaction between CD112 and the key enzyme UGCG in Golgi, which prevents UGCG degradation and thereby elevates glycosphingolipid level. Functional experiments demonstrated that CD112-mediated suppression of CD8+T cells is partially dependent on its regulation of sphingolipid metabolism. By altering the glycosphingolipid content of exosomal membranes, CD112-high tumor cells leads to the aberrant aggregation of CD112 key receptor-CD112R in lipid rafts of neighboring CD8+T cells, which increases CD112-CD112R interaction frequency and amplifies suppression effect. For furture in vivo translation, a combination therapy of anti-HER2, anti-CD112R, and a UGCG inhibitor is proposed.
Conclusion: We identified CD112 as a key immunosuppressive regulator in HER2+BC, surpassing PD-L1. We also revealed a metabolism-dependent mechanism of CD112-mediated immunosuppression executed through the CD112-UGCG-GlcCer axis. Inhibition of this axis may further enhances the efficacy of anti-CD112R treatment in HER2+BC, presenting a promising combination strategy.

#2799 Tumoral IL-33/ST2 signaling drives immune escape through reduced antigen presentation.

Alyssa Mauri Cornista[1], Tao Yu[2], Zhuolong Zhou[2], Niksa Roki[1], Alberto Sigler[1], David M. Suissa[1], Haniyeh Eyvani[3], George E. Sandusky[4], Rimpi Khurana[5], Yan Guo[6], Molly Dalzell[1], Shyamananda Singh Mayengbam[7], Prasenjit Dey[7], Christine Rafie[1], Erietta Stelekati[8], Jashodeep Datta[9], Saratchandra S. Khumukcham[10], Jatin Roper[10], Nivedh Paluvoi[11], Sandro Satta[12], Daniel Bilbao Cortes[12], Alejandro Villarino[8], Kevin Van der Jeught[8]

The majority (up to 85%) of colorectal cancer (CRC) patients have a microsatellite stable (MSS) tumor phenotype, which is a poor responder to immune checkpoint blockade (ICB). Therefore, there is a need to identify novel checkpoints in the tumor microenvironment, such as ST2 (Stimulation 2, IL33 receptor). We demonstrated ST2 to be prominently expressed on human tumor cells, especially MSS tumors, through multiplex immunofluorescence staining of CRC patient samples and publicly available datasets. Using CRC patient-derived organoids, we established that activation of tumoral IL33/ST2 signaling conferred tumor cell protection from T cell-mediated killing. To investigate the mechanistic basis of how tumor cells escape T cell killing, we used colonoscopy-induced, orthotopic murine tumors. We uncovered that IL33/ST2 signaling reduced antigen presentation, driven by reduced immunoproteasome activity. Removing tumoral ST2 signaling using CRISPR/Cas9-gene editing leads to significant tumor growth control and increased infiltration of T cells with a reduced terminally exhausted phenotype. Altogether, these findings indicate ST2 as a potential, novel checkpoint target on tumor cells to enlarge the pool of patients benefiting from ICB.

#2800 Understanding the mechanism by which CD4$^+$ T cells sensitize mesenchymal CD73-deficient tumors to anti-CTLA4 immune checkpoint blockade therapy.

Brian Hongtao Feng[1], Caitie Hanna Sams[1], Isabel O'Connell[1], Shiney Chandraganti[1], Anushka Dongre[2]

[1]Cornell University, Ithaca, NY,[2]Department of Biomedical Sciences, Cornell University, Ithaca, NY

Triple-Negative Breast Cancer (TNBC) is a highly aggressive disease with poor patient outcomes due to its resistance to chemotherapy and immunotherapy. Despite its efficacy in Melanoma and Lung carcinoma, immune checkpoint blockade (ICB) therapy is only effective in a small minority of TNBC patients. Epithelial-to-Mesenchymal Transition (EMT) is a key driver of malignant progression leading to greater metastatic potential and an immunosuppressive tumor microenvironment, driving resistance to therapies. Our previous results demonstrate that epithelial tumors respond to anti-CTLA4 therapy while mesenchymal tumors are resistant. Strikingly, knockout of CD73 in mesenchymal tumors results in complete sensitization to anti-CTLA4 treatment but not anti-PD1 therapy, the more clinically used treatment. Using our preclinical mouse models together with immunofluorescence staining, we observed that CD73-deficient tumors display increased infiltration of CD4$^+$ and CD8$^+$ T cells upon anti-CTLA4 treatment relative to non-responding controls. Most notably, while CD73 deficient tumors continued to respond to anti-CTLA4 treatment without CD8$^+$ T cells, they failed to respond in the absence of CD4$^+$ T cells. However, the mechanisms by which CD4$^+$ T cells facilitate the elimination of mesenchymal tumors remain unknown. Preliminary results demonstrate that cytotoxic CD4$^+$ T cells play a crucial role in potentiating the response of CD73-deficient tumors to anti-CTLA4. Moreover, tumors contain plastic CD4$^+$ T cell subsets that reduce immune suppression under anti-CTLA4 treatment while promoting immune suppression under anti-PD1 treatment. These results reveal that CD4$^+$ T cells can specifically target lethal mesenchymal cancer cells in response to anti-CTLA4 but not anti-PD1 therapy. Future work is aimed at understanding whether CD4$^+$ T cells eliminate tumors via direct interactions with cancer cells or through indirect activation of other immune cells. Given the inefficacy of anti-PD1 therapy in TNBC clinical trials, characterizing the CD4$^+$ T cell response to anti-CTLA4 provides a mechanistic basis for leveraging its therapeutic potential.

#2801 SRY-mediated upregulation of PD-L1 promotes immune evasion in hepatocellular carcinoma and contributes to sex-specific disparities in immunotherapy response.

Bingyi Ren, Kai Sheng, Yichen Yang

The First Affiliated Hospital of Xi'an Jiao Tong University, Xi'an', China

Background: The impact of sex chromosomes on the tumor microenvironment (TME) is significant, beyond hormonal effects. This study investigates the role of the sex-determining gene SRY in the immune microenvironment of hepatocellular carcinoma (HCC), focusing on how SRY regulates immune checkpoints and contributes to gender disparities in immunotherapy response.

Methods: Multiple HCC mouse models (chemically induced, hydrodynamic, orthotopic, subcutaneous) using SRY transgenic knockout (KO) or knock-in (KI) mice were employed. To eliminate hormonal effects, the mice were castrated. Flow cytometry, immunofluorescence, and ELISA assessed T cell changes in the TME. Cellular models used PCR array, CUT&Tag, qPCR, WB, and luciferase assays to explore SRY's transcriptional regulation. Clinical samples validated correlations between SRY, immune markers, and PD-L1.

Results:•In castrated male SRY-KO mice, increased $CD8^+$ T cells and elevated GZMB, TNF-α, and IFN-γ were observed in the TME.•SRY-KI in castrated males reduced $CD8^+$ T cells and functional markers.•Ectopic SRY in castrated females similarly impaired T cell infiltration and function.•PCR array in SRY-overexpressing HCC cells revealed upregulation of PD-L1.•CUT&Tag and luciferase assays confirmed SRY binds the IRF1 promoter, upregulating IRF1 expression.•IRF1 knockdown abolished PD-L1 upregulation, confirming an SRY-IRF1-PD-L1 axis.•In vivo, PD-L1 knockdown in SRY-overexpressing tumors reversed immune suppression and tumor growth.•Anti-PD-L1 treatment showed enhanced efficacy in SRY-overexpressing tumors.•Clinical HCC samples confirmed positive SRY-PD-L1 correlation and negative SRY-$CD8^+$ T cell correlation.

Conclusions: SRY, a male-specific gene, regulates the immune checkpoint PD-L1 via IRF1, suppressing $CD8^+$ T cell function in the TME. Targeting the SRY-IRF1-PD-L1 axis may improve immunotherapy outcomes, especially in male HCC patients.

#2802 *In vitro* antigen-specific T cell exhaustion model for immunomodulators evaluation.

Emilio Cosimo, **Hannah Findlay**, Robert Benson, Agapitos Patakas

RoukenBio, Motherwell, United Kingdom

The identification of novel molecular mechanisms underlying exhausted $CD8^+$ T cells (T_{EX}) represents a critical objective in advancing immunotherapeutic strategies for cancer and other diseases. Nevertheless, high-throughput analysis of *in vitro* T_{EX} remains challenging. We developed a human *in vitro* model of $CD8^+$ T cell exhaustion using antigen-specific or TCR-transgenic T cells subjected to chronic antigen stimulation. Repeated exposure to cognate peptide antigens induced hallmark exhaustion phenotypes, including co-expression of inhibitory receptors (PD-1, TIM-3 and LAG-3) and transcription factor TOX. Exhausted T cells exhibited diminished cytokine secretion (e.g. IFN-γ), reduced proliferation (e.g. Ki-67), and impaired cytotoxicity. These features closely mirror exhaustion observed in tumour-infiltrating lymphocytes and chronic infection settings. Checkpoint blockade was evaluated for functional rescue. Anti-PD-1 restored partial proliferation and modest IFN-γ production. However, neither agent fully reversed exhaustion, as other inhibitory pathways remained active. These findings align with clinical observations where monotherapy yields partial rescue. Our model thus enables quantitative assessment of exhaustion reversal and supports combinatorial checkpoint strategies. To generate sufficient antigen-specific T cells for high-throughput assays, we employed artificial antigen-presenting cells (aAPCs) derived from engineered K562 lines expressing diverse HLA alleles and co-stimulatory ligands. This platform supports expansion of rare endogenous T cells to $>10^8$ cells per donor, preserving native TCR expression. Functional validation included CMV-specific and MART-1-specific T cells, which demonstrated antigen-specific cytotoxicity and cytokine responses. This scalable and physiologically relevant assay system permits precise modelling of T cell exhaustion and facilitates systematic evaluation of immunotherapeutic interventions. It serves as a reliable platform for the quantitative screening of agents that inhibit or reverse T cell exhaustion, thereby supporting the rational development of advanced immunotherapies.

#2803 Ex vivo micro-tumor testing platform to characterize and predict patient-specific immunotherapy drug responses.

Felix M. Behr[1], Esmee Koedoot[1], Timothy J. P. Sijsenaar[1], Lea Le Large[1], Cor D. de Kroon[2], Anne van Altena[3], Farbod Khoraminia[1], Laurie C. Steinbusch[2], Christi M. Steendam[4], Dieudonne J. van der Meer[1], Willemijn Vader[1], Nelleke Ottevanger[3], Judith R. Kroep[5]

[1]VitroScan, Leiden, Netherlands,[2]Leiden University Medical Centre, Leiden, Netherlands,[3]Radboud University Medical Centre, Nijmegen, Netherlands,[4]Catharina Ziekenhuis, Eindhoven, Netherlands,[5]Dept. of Medical Oncology, K1-P, Leiden Univ. Medical Ctr., Leiden

Background. Immunotherapies have shown significant clinical benefit, but upfront identification of patients with therapy-sensitive cancers remains a major challenge. We have previously demonstrated that our ex vivo micro-tumor platform, which preserves the tumor microenvironment (TME), is predictive for clinical responses to platinum-based therapy (Koedoot et al., npj precision oncology, 2025). Here, we show that the platform also enables patient-specific profiling of drug sensitivity and immune activity for immune checkpoint inhibitors (ICIs) and bispecific T cell engagers (BiTEs).

Methods. Fresh tumor tissues were collected from colorectal cancer (CRC, N=6), non-small cell lung cancer (NSCLC, N=23) and ovarian cancer (OC, N=85) patients with primary or recurrent disease. Micro-tumors including the TME were isolated from resections, ascites or pleural fluid, embedded in hydrogel and exposed to chemotherapeutics, six ICIs and/or CD3xMUC16 BiTE ubamatamab. Drug responses were quantified by extracting morphological features from high-throughput 3D imaging. Treatment sensitivity was defined by statistically significant immune cell expansion and micro-tumor killing. Sensitivity profiles were correlated with immune cell populations. Supernatants collected after treatment were analyzed for secreted cytokines, chemokines and cytotoxic mediators using multiplex immune biomarker profiling. PD-L1 tumor proportion scoring (TPS) reported on original patient tumor tissue was used (NSCLC).

Results. Significant ex vivo ICI responses were observed in 50% of OC, 27% of early NSCLC, and 33% of metastatic NSCLC samples, with reproducible results across serial samples. Most OC samples were positive for T-cell, macrophage and NK-cell markers but not for B-cell markers. Stronger immune responses were observed in OC samples with high CD3 ($p=0.01$) or CD68 ($p=0.003$) expression. Importantly, immune sensitivity correlated with PD-L1 TPS ($p=0.13$, NSCLC). Ubamatamab induced significant immune expansion in 42% (8/19) of OC samples, half of which also showed significant tumor killing. When compared to non-responders, ubamatamab responders with effective tumor killing exhibited robust and simultaneous upregulation of T cell effector cytokines (IFN-γ, IL-2), cytotoxic mediators (Granzyme B, Perforin) and pro-inflammatory cytokines (CXCL9, CXCL11).

Conclusions. This study reports classification, characterization and prediction of autologous patient-specific sensitivity to ICIs and BiTEs by characterizing immune populations and reporting correlation with known clinical markers (PD-L1). Our ex vivo micro-tumor platform enables functional profiling of patient-specific immunotherapy responses, supporting biomarker discovery and selection of patients for emerging immunotherapies. The next step is to correlate the ex vivo sensitivity to actual clinical outcome.

#2804 Sialic acid inhibits engager-mediated T cell activation.

Johanna Nimmerfroh[1], Dinah Heiligensetzer[1], Michael Sandholzer[1], Anastasiya Borsch[2], Heinz Laubli[1]

[1]Department of Biomedicine, University Hospital and University of Basel, Basel, Switzerland,[2]Department of Biomedicine, University of Basel, Basel, Switzerland, Basel, Switzerland

Background: Although T cell-based therapies have led to a significant success in certain tumor types, a large proportion of patients receiving cancer immunotherapy still progress with the disease. Thus, there is interest in identifying and blocking alternative pathways mediating immune suppression. Beyond canonical protein-based immune checkpoints, tumor-associated glycosylation—particularly hypersialylation—has emerged as a key modulator of immune suppression. Sialic acid-containing glycans on tumor cells are recognized as glyco-immune checkpoints that engage inhibitory Siglec receptors on immune cells. While the immunosuppressive role of tumor sialylation is well established[1], new evidence indicates that sialylation of the T cells themselves[2] may also contribute to immune dysfunction, suggesting a previously underappreciated layer of glyco-regulation in the tumor microenvironment.
Methods: Human T cells were treated with pan-sialidase to enzymatically remove surface sialic acids. Desialylated T cells were then stimulated with anti-CD3/anti-CD28 or co-cultured with bispecific T cell engagers and tumor target cells, followed by flow cytometry. Primary samples from patients with chronic lymphocytic leukemia (CLL) were analyzed through single-cell RNA sequencing combined with lectin-based glycan profiling.
Results: We discovered that T cells treated with sialidase exhibited enhanced proliferation and activation. In a co-culture system with bispecific T cell engagers and target cells, we demonstrated that sialidase-treated T cells showed enhanced cytotoxicity, including increased cytokine production, T cell proliferation, and tumor cell killing. When studying T cell subsets, we observed that sialidase treatment lowered the activation threshold particularly in naïve T cells. Our findings were validated using primary samples from patients with chronic lymphocytic leukemia (CLL): sialic acid remodeling led to improved immune function.
Conclusion: Sialic acids on T cells significantly modulate their function. Enzymatic removal of these glycans enhances T cell response and may help overcome resistance mechanisms in cancer immunotherapy. Future studies will investigate whether distinct glycan signatures among T cell subtypes correlate with functional heterogeneity.[1]Dobie, C., Skropeta, D. *Br J Cancer* 2021*,124,* 76-90.[2]Edgar, L. J.; Paulson J. C *et al. ACS Cent Sci* 2021*, 7, 1508-1515.*

#2806 Myoglobin expression boosts T-cell metabolism and antitumor effector function.

Julia Werner[1], Haifeng Xu[1], Georgios Theodorakis[1], Ichiro Katahira[1], Mitrajit Ghosh[1], Michal Gorzkiewicz[1], Luisa de Sousa Santos[1], Ann Kathrin Bergmann[1], Max Anstotz[1], Anne Busch[1], Diran Herebian[1], Sascha Dietrich[1], Carsten Berndt[1], Ertan Mayatepek [1], Aleksandra Pandyra[2], Dirk Brenner[3], Philipp Lang[1]

[1]University Hospital of Dusseldorf, Dusseldorf, Germany,[2]University Hospital Bonn, Bonn, Germany,[3]University of Luxembourg, Luxembourg, Luxembourg

The tumor microenvironment is frequently hypoxic and characterized by a scarcity of nutritional resources, including limited glucose availability. As effector T cells have high energy demands, tumor metabolism can contribute to T-cell dysfunction and exhaustion. In this study, we assessed hypoxia in spleen and tumor tissue from tumor-bearing C57BL/6J mice using RT-PCR, histology, and flow cytometry. Next, $CD8^+$ T cells isolated from C57BL/6J or $P14^+$ mice were transduced with a Thy1.1 (control) or Thy1.1-myoglobin (Mb) packaging retrovirus, and Mb expression was confirmed by RT-PCR and Western blot. The metabolism of these cells was analysed using flow cytometry, TEM, FIB-SEM, Seahorse assays, metabolomics, and luminescence-based approaches. Furthermore, effector function was measured in vitro by flow cytometry. $P14^+$ $CD45.1^+$ $CD8^+$ Mb-transduced and control T cells were transferred into B16F10-gp33 or MC38-ova tumor-bearing mice and analysed by flow cytometry and histology. Finally, B16F10-gp33 tumor-bearing mice received additional treatment with an anti-PD-1 checkpoint inhibitor. Here, we demonstrate that expression of the oxygen-binding protein myoglobin in T cells can enhance their mitochondrial and glycolytic metabolic functions. Metabolites and TCA cycle intermediates were markedly increased in the presence of myoglobin and were associated with elevated ATP levels. Myoglobin-expressing T cells exhibited reduced HIF-1α expression after activation and during infiltration into the tumor microenvironment. Accordingly, myoglobin expression increased effector T-cell function against tumor cells in vitro, accompanied by reduced superoxide levels. Following adoptive transfer into tumor-bearing mice, myoglobin expression promoted greater infiltration into the tumor microenvironment. Although myoglobin-expressing T cells showed increased effector cytokine expression, PD-1 remained detectable and targetable by anti-PD-1 monoclonal antibodies, which—when combined with transfer of myoglobin-expressing T cells—achieved maximal efficacy in delaying tumor growth. Taken together, we show that expression of myoglobin in T cells enhances their metabolism, infiltration into tumor tissue, and effector function against cancer cells.

#2807 Immune cell-dependent resistance to LAG3 blockade in SMARCB1-deficient renal medullary carcinoma.

Jing Qian[1], Kai Yu[1], Deepa Bisht[1], Melinda Soeung[2], Pankaj Chauhan[1], Fei Duan[1], Menuka Karki[1], Rong He[1], Nizar M. Tanir[1], Hania Khan[3], Zilong Zhao[1], Luigi Perelli[1], Giannicola Genovese[1], Linghua Wang[1], Jianjun Gao[4], Pavlos Msaouel[5]

[1]UT MD Anderson Cancer Center, Houston, TX,[2]Dana-Farber Cancer Institute, Boston, MA,[3]UT Southwestern, Dallas, TX,[4]Medical Oncology, UT MD Anderson Cancer Center, Houston, TX,[5]Genitourinary Medical Oncology, UT MD Anderson Cancer Center, Houston, TX

Background: Renal medullary carcinoma (RMC) is an exceptionally aggressive kidney cancer of young individuals with sickle cell trait, characterized by SMARCB1 loss, rapid progression, and a median survival of ~13 months. Transcriptomic profiling shows a highly inflamed microenvironment with broad immune-checkpoint upregulation. Among these, PD-1 (log_2 fold-change 1.7; FDR = 0.008) is increased, and LAG-3 (log_2 fold-change 4.6; FDR < 0.0001) shows one of the strongest elevations relative to adjacent kidney tissue. These findings motivated an RMC-specific clinical trial testing anti-PD-1 plus high-dose anti-LAG-3 (NCT05347212), yet mechanisms underlying resistance to LAG-3 blockade remain unknown.

Study Design and Methods: To investigate RMC response to PD-1 and LAG-3 inhibition, we used a somatic-mosaic immunocompetent genetically engineered mouse model (GEMM) of RMC on a sickle-trait background. We compared anti-PD-1 and anti-LAG-3 monotherapy with isotype IgG in immunocompetent mice to assess baseline sensitivity to checkpoint inhibition. To dissect mechanisms of LAG-3 resistance, we evaluated anti-LAG-3 treatment in RAG1-knockout mice lacking mature B and T cells and examined anti-LAG-3 under $CD4^+$ T-cell depletion to identify the immune subsets driving resistance. Tumor weights were assessed at endpoint, and statistical comparisons were performed using the Mann-Whitney test.

Results: Anti-PD-1 monotherapy failed to control tumor growth, confirming intrinsic resistance to PD-1 blockade (mean tumor weight: IgG 0.58 g vs anti-PD-1 0.75 g; p = 0.6682). In contrast, anti-LAG-3 monotherapy exacerbated tumor progression (IgG 0.74 g vs anti-LAG-3 1.27 g; p = 0.0297). Loss of adaptive immunity partially reversed this phenotype: in RAG1-knockout mice, anti-LAG-3 showed a trend toward reduced tumor burden (IgG 1.415 g vs anti-LAG-3 0.61 g; p = 0.127). $CD4^+$ T-cell depletion abrogated resistance, yielding significantly lower tumor weights under anti-LAG-3 (anti-LAG-3 1.39 g vs anti-LAG-3 + CD4 depletion 0.75 g; p = 0.0291).

Conclusions: Our findings identify an immune cell-dependent mechanism limiting the efficacy of LAG-3 blockade in SMARCB1-deficient RMC. Disrupting this axis, alone or alongside PD-1/LAG-3 inhibition, emerges as a testable strategy to blunt immune checkpoint therapy-induced adaptive reprogramming and restore anti-tumor activity.

#2808 A first in class VIP receptor antagonist as an immunotherapeutic for acute myeloid leukemia.

Swapnaa Balaji[1], Antonio Ward[1], Yuou Wang[2], Jian-Ming Li[2], Srijon Sarkar[2], Sonia Mecorapaj[2], Tenzin Kalsang[3], Shuhua Wang[2], Cynthia Giver[2], Edmund Waller[1]

[1]Cambium Oncology, LLC, Atlanta, GA,[2]Emory University, Atlanta, GA,[3]Columbia University Irving Medical Center, New York, NY

Current immune checkpoint therapies targeting PD-1 and PD-L1 are ineffective in treating Acute Myeloid Leukemia (AML). Vasoactive Intestinal Peptide (VIP) is an immunosuppressive 28-amino acid neuropeptide overexpressed in nearly 30% AML patients, suggesting that some AML tumors may be using VIP expression as a mechanism to evade immune surveillance. We hypothesize that AML cells secrete VIP which signals through the VIP-R (receptor) on T cells to limit anti-cancer immunity. Therefore, targeting the VIP signaling with a VIP-R antagonist can reverse immunosuppression and potentiate anti-cancer immunity. Using *in silico* modeling, *in vitro* screening for potentiation of T cell activation, and proof-of-principle screening in mouse leukemia models, we identified a novel VIP-R antagonist, ANT308. ANT308 shows stronger binding affinity to VIP-R as compared to VIP and potentiates activation of human and mouse T cells with an EC_{50} in the range of 200-400 nM. Immunofluorescence assays show that ANT308 colocalizes with the VIP receptor, VPAC1. Co-IP and flow cytometry confirmed ANT308 binding to VPAC1. In addition, ANT308 treatment of leukemic mice induced strong T cell-mediated anti-leukemic activity. To improve the pharmacokinetics of ANT308, we have developed a novel fusion peptide combining ANT308 and Fc fragment of IgG4 named CAMV-01. In a Jurkat T-cell activation assay, CAMV-01 has an EC_{50} of 100-200 nM and reduces T cell exhaustion. Furthermore, CAMV-01 significantly improved survival in multiple murine leukemia models, including those that secrete VIP (C1498) and the VIP negative cell line P815. *In vitro* stability studies show that CAMV-01 remains stable in plasma for > 4 days, whereas the ANT308 peptide is stable for only 15 minutes. PK studies with intravenous (i.v.) or subcutaneous (s.c.) injection of 15mg/kg CAMV-01 show a half-life of 2 weeks in mice, compared to 15 minutes for the ANT308 peptide. Using Sprague-Dawley rats receiving a single i.v. or s.c injection of 5mg/kg CAMV-01, the C_{max} and $t_{1/2}$ were estimated to be 82 nM and 165 hours (i.v.) respectively and 0.7 nM and 235 hours (s.c.) respectively. In a P815 mouse model, s.c. administration of CAMV-01 induced a stronger tetramer-positive CD8+ T-cell response compared to ANT308. In conclusion, CAMV-01 is a novel, first-in-class immunotherapeutic targeting the VIP immune checkpoint, with a robust pharmacokinetic and pharmacodynamic profile and promising potential for the treatment of AML.

#2809 VIP/VPAC signaling as a phagocytosis checkpoint in TP53-mutated acute myeloid leukemia.

Zihan (Clarence) Chen[1], Tuisha Gupta[2], Fanyuan Zeng[2], Yujie Chen[3], Jian Ming Li[2], Cynthia R. Giver[4], Kiranj Chaudagar[2], Edmund K. Waller[5]

[1]College of Computing, School of Chemistry and Biochemistry, Georgia Institute of Technology, Atlanta, GA,[23]Graduate Division of Biological and Biomedical Sciences, Emory University, Atlanta, GA,[4]Hematology and Medical Oncology, Emory University, Winship Cancer Institute, Atlanta, GA,[5]Emory University School of Medicine, Atlanta, GA

Background: Acute myeloid leukemia (AML) remains one of the most lethal hematologic malignancies, especially in TP53-mutated disease where standard chemotherapy provides poor long-term survival. Immune evasion by myeloid cells in the tumor microenvironment is a major barrier to cure. We hypothesized that targeting vasoactive intestinal peptide (VIP)/VIP receptor (VPAC) signaling would overcome myeloid cell-mediated immunosuppression and enhance anti-tumor responses in AML.
Methods: RNA-seq differential expression, survival analyses, and flow cytometry of AML bone marrow and PBMC were used to profile VIP/VPAC expression and myeloid versus blast compartments in TP53-mutated and non-mutated cases. TP53-wildtype and TP53 loss-of-function human and murine AML cell lines were used to measure VIP production by ELISA and macrophage phagocytosis of VIP-producing versus low-VIP cells in M1- and M2-like co-culture assays. In vivo efficacy of the long-acting VIP receptor antagonist ANT308 and its IgG4 Fc fusion ANT308-Fc3 was evaluated in C1498 and WEHI3 AML models, including VIP, VPAC1, and VPAC2 knockout hosts.
Results: VIP expression was elevated in PBMC from ~36% of AML patients compared with healthy donors and was enriched in TP53-mutated cases. High VIP expression and TP53 loss-of-function each associated with inferior survival in cBioPortal datasets. RNA-seq showed that TP53-mutated AML is characterized by increased VIP and immunoregulatory pathway signatures together with reduced apoptosis and effector $CD8^+$ T-cell-associated genes. Secretome analysis of human leukemia cells demonstrated higher VIP secretion from TP53 loss-of-function lines than from TP53-wildtype THP-1, confirming leukemia-intrinsic VIP production. In patient samples, both $CD34^+$ blasts and $CD34^-$ myeloid cells contained VIP^+ cells, but non-blast myeloid cells accounted for most VIP^+ events, indicating they are a major VIP source in the AML microenvironment. ANT308 enhanced phagocytosis of VIP-secreting WEHI3 leukemia cells by both M1- and M2-like macrophages but did not alter phagocytosis of VIP-low C1498 cells, supporting VIP as a phagocytosis checkpoint in AML. Consistent with a host contribution, VIP-, VPAC1-, or VPAC2-knockout mice bearing C1498 leukemia showed improved survival relative to wild-type mice. In vivo treatment of wild-type C1498-bearing mice with ANT308 or the long-acting Fc fusion ANT308-Fc3 eradicated established leukemia in up to 65% of animals.
Conclusions: VIP/VPAC signaling defines a previously unrecognized phagocytosis checkpoint that reinforces myeloid immunosuppression in AML and is linked to TP53-mutated disease. VPAC antagonism with ANT308-Fc3 restores macrophage phagocytosis and produces durable leukemia control in preclinical models, supporting clinical development of VPAC-targeted immunotherapy for high-risk AML.

#2810 Anti-PD-1 efficacy is associated with a clonal trajectory composed of chronic effectors with lymph node homing capacity.

Mingshuang Wang*[1], Guanning Wang*[2], Khushboo Patel[2], Ajeya Nandi[2], Timmy Lai[2], Shira Rosenberg[2], Zhoumu Xiang[2], Stella Park[2], Tara C. Mitchell[2], Alexander C. Huang#[2]

[1]Department of Neurosurgery, Perelman School of Medicine, University of Pennsylvania, Philadelphia, PA,[2]Division of Hematology/Oncology, Department of Medicine, Perelman School of Medicine, University of Pennsylvania, Philadelphia, PA

Introduction: Immune checkpoint blockade (ICB), such as anti-CTLA-4 or anti-PD-1 (αPD-1), drives distinct patterns of T cell differentiation that ultimately influence treatment efficacy. However, it has been challenging to identify and define distinct T cell differentiation states in humans. We apply a novel algorithm *Clonotrace* (Nancy Zhang, UPenn) to define differentiation trajectories by monitoring single clones across differentiation states after αPD-1. We test the hypothesis that certain differentiation trajectories will have unique properties, including cell states and trafficking patterns, that will influence clinical efficacy.

Methods: We performed single cell RNA and paired TCR sequencing on 132,898 CD8+ T cells from 36 stage III melanoma patients treated with neoadjuvant αPD-1, including 12 patients with matched tumor, uninvolved regional lymph node, and blood samples. We applied *Clonotrace* to define differentiation trajectories by grouping clonotypes that have a similar transcriptional footprint across CD8 cell states. We then defined these differentiation trajectories in terms of cell state composition, antigen specificity, tissue distribution, gene regulation, and association with clinical outcomes.

Results: We identified 10 distinct clonal trajectories that differentiate from naïve/stem-like CD8 T cell states to exhausted and/or effector CD8 T cell states. These trajectories largely separated into two sets of clones based on antigen specificity and the expression of pathways associated with chronic stimulation. Further examination of the antigen-specific clones identified one particular trajectory (Traj 5), that was associated with clinical response. Traj 5 included clones with a unique chronic effector cell state that was able to traffic between lymph node and tumor. In contrast, Traj 1 was composed of terminally exhausted CD8 clones that were tumor-resident and associated with αPD-1 resistance.

Conclusion: We identify a unique differentiation trajectory in patients that retains effector T cell differentiation in the setting of chronic stimulation. These chronic effectors retain the ability to traffic between lymph node and tumor and are associated with the efficacy of αPD-1. These findings indicate maintaining trafficking ability is essential for the efficacy of ICB. In contrast, terminal differentiation results in CD8 T cells becoming “locked” in the tissue and terminally exhausted.

#2812 Bhlhe40 shapes distinct T cell reponses to anti PD1 and anti CTLA4 immune checkpoint therapy.

Akata Saha[1], Tomoyuki Minowa[1], Alexander S. Shavkunov[1], Avery J. Salmon[1], Sunita Keshari[1], Kristen E. Pauken[1], Kenneth H. Hu[1], Ken Chen[2], Matthew M. Gubin[1]

[1]Immunology, UT MD Anderson Cancer Center, Houston, TX,[2]Bioinformatics and Computational Biology, UT MD Anderson Cancer Center, Houston, TX

The transcriptional programs that enable CD4 and CD8 T cells to sustain anti-tumor immunity are not fully defined. We investigated the role of the transcriptional regulator Bhlhe40 in shaping CD4 and CD8 T cell responses during anti-PD-1 and anti-CTLA-4 immune checkpoint therapy (ICT). Using conditional knockout mice, we found that anti-PD-1 efficacy depends on CD8 T cell-intrinsic Bhlhe40, with potential contribution from CD4 T cells. In contrast, anti-CTLA-4 relies primarily on CD4 T cell-intrinsic Bhlhe40 and remains effective even without Bhlhe40 in CD8 T cells. Loss of Bhlhe40 skewed CD8 T cells toward TCF-1+ naïve/progenitor exhausted-like states, impairing IFNγ production, glycolysis, and mitochondrial fitness. CD8 T cell-intrinsic Bhlhe40 was also required for ICT-driven macrophage remodeling from suppressive $CX3CR1^{+}$ to $iNOS^{+}$ macrophages. Analysis of human cancer datasets showed that *BHLHE40* is enriched in tumor-reactive and activated/exhausted CD8 T cells, correlating inversely with *TCF7* (TCF-1) and positively with *TOX* and *IFNG*. Importantly, higher *BHLHE40* expression was observed in responders to ICT in a cohort of patients with basal cell cancer. Together, these findings show Bhlhe40 is a subset- and therapy-specific regulator of T cell programs, controlling effector differentiation, metabolism, and ICT efficacy, providing a mechanistic basis for the divergent modes of action of anti-PD-1 versus anti-CTLA-4.

#2813 Targeting AHR overcomes PD-L1-driven resistance to immune checkpoint blockade in triple-negative breast cancer.

Minkyoung Choi[1], Ju Hee Kim[2], Han-Byoel Lee[3], Wonshik Han[3]

[1]Seoul National University, Seoul, Korea, Republic of,[2]Center for Medical Innovation, Seoul National University Hospital, Seoul, Korea, Republic of,[3]Seoul National Univ. College of Medicine, Seoul, Korea, Republic of

Introduction: Triple-negative breast cancer (TNBC) has higher tumor immunogenicity than other subtypes, and immune checkpoint inhibitors (ICIs) targeting the PD-1/PD-L1 axis have been applied in its treatment. However, responses to immune checkpoint blockade (ICB) remain limited by intrinsic and acquired resistance, highlighting the need for predictive biomarkers and new combination strategies to improve anti-PD-L1 efficacy.The aryl hydrocarbon receptor (AHR) regulates immune responses and PD-L1 expression, promoting an immunosuppressive tumor microenvironment (TME). AHR signaling may also interfere with interferon-mediated immune activation and affect ICB response. This study aimed to examine how AHR activation contributes to anti-PD-L1 resistance in PD-L1 overexpressing TNBC and whether AHR blockade enhances therapeutic efficacy.
Methods: PD-L1-overexpressing (PD-L1 OE) and control (Ctl) 4T1 cells were generated. The AHR antagonist (CH-223191) and anti-PD-L1 antibody were applied in vitro and in vivo. Flow cytometry, western blotting, cell proliferation assay, quantitative RT-PCR, immunohistochemistry (IHC), and co-culture of macrophages and cancer cells were performed. An orthotopic syngeneic mouse model was established by injecting 4T1 Ctl or PD-L1 OE cells into the mammary fat pad. Mice were treated with CH-223191 (5 mg/kg, i.p., four times weekly) and anti-PD-L1 antibody (150 μg, i.p., twice weekly), alone or in combination.
Results: PD-L1 OE tumors showed reduced responsiveness to anti-PD-L1 therapy compared with control in vivo, confirming intrinsic resistance to ICB. AHR expression was elevated at both RNA and protein levels in PD-L1 OE tumors after anti-PD-L1 treatment. Combination therapy with CH-223191 and anti-PD-L1 antibody tended to suppress tumor growth compared with monotherapy, suggesting an ability to overcome PD-L1-driven resistance in vivo. In vitro, CH-223191 reduced 4T1 viability in a dose-dependent manner, suggesting a potential tumor-intrinsic role of AHR signaling. Co-culture of PD-L1 OE 4T1 cells with macrophages promoted M2-like polarization, supporting an immunosuppressive microenvironment. Collectively these findings suggest that AHR activation contributes to anti-PD-L1 resistance by promoting an immunosuppressive TME, and that AHR blockade could enhance anti-PD-L1 efficacy in TNBC.
Conclusions: AHR activation was linked to PD-L1-driven anti-PD-L1 resistance, and AHR inhibition enhanced responsiveness in vivo. These findings suggest that AHR mediates PD-L1 axis-driven resistance and that its inhibition may serve as a promising combination strategy in TNBC. Further studies should elucidate the mechanistic link between AHR signaling and PD-L1-mediated immune regulation and validate its therapeutic potential.

#2814 Comprehensive single-cell atlas of immune ecosystem in response to immune checkpoint blockade therapy.

Dayoung Lee[1], Ji Yoon Lee[1], Jiwon Kim[1], You Jin Song[2], Namsung Moon[1], Juyoung Lee[1], Harim Koo[3], Jason K. Sa[1]

[1]Korea University, Seoul, Korea, Republic of,[2]Korea Univ. Medical Center, Seoul,[3]National Cancer Center - Korea, Goyang, Korea, Republic of

Despite the clinical success of immune checkpoint blockade (ICB) in several malignancies, a majority of patients failed to achieve clinical response. A deeper understanding of the cellular and molecular mechanisms underlying ICB resistance is essential for advancing precision immunotherapy. In the present study, we analyzed the complex transcriptional profiles of 663,526 single cell data across eight different cancer types with clinical response to ICB therapy. Through integrative analysis, we delineated the transcriptional heterogeneity of exhausted CD8+ T cells and immunosuppressive macrophages and assessed their contribution to ICB treatment outcomes. Exhausted T cells demonstrated a wide spectrum of exhaustion states that stratified patients by clinical response. Notably, terminally exhausted T cells were particularly enriched in non-responders and exhibited high expressions of TIGIT, HAVCR2, and CTNNB1-driven WNT signaling activity, while responders were marked by activation of cytotoxic effectors and NF-κB transcriptional regulators. Immunosuppressive macrophages were functionally associated with terminal T cell exhaustion via aberrant activation of CD137 signaling axis. Transcriptional regulatory network analysis further revealed key transcriptional factors and immune checkpoint molecules that are differentially expressed across all cell states, offering new therapeutic targets. Our study provides a comprehensive single-cell atlas of immune cell states predictive of ICB response, uncovering substantial cellular and transcriptional heterogeneity and crosstalk between exhausted T cells and macrophage populations. These findings present mechanistic insights into cellular programs that can be therapeutically modulated to overcome ICB resistance.

#2815 Cytoplasmic PD-L1 levels are associated with tumor progression in small cell lung cancer.

Ji Young Lee, Anindita Das, HyeonJoo Cheon

Department of Oncology, Wayne State University, Karmanos Cancer Institute, Detroit, MI

Lung cancer is the leading cause of cancer-related mortality. Small-cell lung cancer (SCLC), accounting for about 10-15% of lung cancer diagnoses, is an exceptionally lethal subtype. Due to rapid growth, early metastasis, and resistance to therapy, SCLC often causes patient death within months. Standard first-line platinum-etoposide (PE) therapy shows significant effects and high response rates. However, recurrence is nearly inevitable, and recurrent tumors are often resistant to further treatment. Recently, combination treatments incorporating an anti-PD-L1 antibody (either atezolizumab or durvalumab) alongside PE therapy have significantly improved survival rates compared to standard PE treatment alone in SCLC patients. However, in contrast to non-small cell lung cancer (NSCLC), other immune checkpoint inhibitors (ICIs), including anti-PD-1 combined with PE, have not shown survival benefits in SCLC. The reason why only anti-PD-L1 demonstrate in SCLC remains unclear and requires further investigation. Furthermore, unlike in other cancers, the efficacy of anti-PD-L1 in SCLC is not correlated with PD-L1 expression on the cell membrane. The selective efficacy of anti-PD-L1 in SCLC suggests that it may function through a distinct mechanism of action, independent of the traditional T cell-dependent pathway. Our previous study found that PD-L1 operates in a cancer cell-intrinsic manner, independent of the interaction with PD-1. Based on these results, we hypothesize that non-membranous intracellular PD-L1 contributes to cancer cell-intrinsic PD-L1 functions and is associated with tumor progression. To test this hypothesis, we performed immunocytochemistry (IHC) and immunofluorescence (ICC) on SCLC specimens from patients at various disease stages and on SCLC cell lines. Our analyses revealed that membranous PD-L1 was rarely detected in SCLC cells in culture or in patient specimens. Instead, PD-L1 expression was predominantly found in the cytoplasm and nucleus of SCLC tumor cells. Among 72 SCLC samples, 59 cases (82%) exhibited cytoplasmic PD-L1, 10 cases (14%) displayed nuclear PD-L1, while only 6 cases (8%) showed membranous PD-L1 expression. We observed a trend toward increased cytoplasmic PD-L1 prevalence and intensity in stage II and III SCLC tumors compared with stage I tumors. In contrast, membranous PD-L1 was readily detected on the cell membrane of most NSCLC tumor cells. Despite the minimal membranous PD-L1 expression, anti-PD-L1 durvalumab significantly increased cisplatin cytotoxicity in SCLC cells independent of T cells. Our findings suggest that intracellular, rather than membranous, PD-L1 plays a key role in SCLC progression. Further studies on its functions and mechanisms may guide the development of more effective SCLC therapies.

#2816 Discovery and preclinical evaluation of novel peptide inhibitors targeting the TIGIT immune checkpoint.

Haozhe Cui, Xinyi Zhang, Wanding Wang, Francesco Zonta, **Eyad Elkord**

Xi'an Jiaotong-Liverpool University, Suzhou, China

Immune checkpoint (IC) receptors negatively regulate immune responses and play crucial roles in maintaining self-tolerance and preventing autoimmunity. However, tumor cells can exploit these pathways to evade immune recognition and destruction. TIGIT has emerged as a key immune checkpoint receptor, which exerts immunosuppressive effects through direct and indirect mechanisms. While preclinical studies with TIGIT-blocking monoclonal antibodies demonstrated encouraging antitumor activity, clinical trials of anti-TIGIT monotherapy showed disappointing outcomes, shifting attention toward alternative strategies. In this study, we identified potential peptide-based inhibitors against TIGIT. Through computational affinity maturation, starting from the anti-TIGIT antibody MG1131, we identified a library of TIGIT-inhibitory peptides. This process integrated sequence sampling, molecular dynamics, and free energy calculations, guided by Monte Carlo selection. Compared with conventional monoclonal antibodies, these peptides are expected to provide superior tissue penetration, reduced immunogenicity, and an improved safety profile. In this study, two mutant peptides (named T-M2 and T-M3) exhibited stronger inhibition of TIGIT-CD155 interactions than the wild-type peptide in hTIGIT-CHO-K1 cell-based blocking assay. Furthermore, these peptides induced higher levels of IFN-γ secretion from both human CD4+ and CD8+ T cells. This enhanced immunostimulatory activity was confirmed in a co-culture system of hTIGIT-Jurkat and hCD155-CHO-K1 cells, where the mutant peptides induced greater IL-2 secretion. The in vivo therapeutic efficacy of these peptides, either as monotherapy or in combination with immune checkpoint inhibitors, is currently being evaluated in MC38 tumor-bearing and humanized HCT116 mouse models. Tumor growth dynamics, as well as the phenotype, cytokine profile and activation status of T cells in the tumor microgovernment, tumor-draining lymph nodes, and spleens will be assessed in the treated groups and compared with control groups. Collectively, this study introduces novel TIGIT-blocking peptides as promising candidates for cancer immunotherapy, offering a potential alternative or complementary approach to antibody-based immune checkpoint blockade.

#2817 Immune checkpoint therapy induces tertiary lymphoid structures in a murine model of triple-negative breast cancer.

Zachary D. Schrank, Benjamin G. Vincent, Jonathan S. Serody

University of North Carolina School of Medicine, Chapel Hill, NC

Background: Though immune checkpoint therapy (ICT) is approved for the treatment of triple-negative breast cancer (TNBC), response rates are low and non-durable. There is thus an urgent need for improved therapeutic biomarkers and deeper understanding of TNBC antitumor immune responses to tailor improved immunotherapies. Tertiary lymphoid structures (TLS) are intra-tumoral lymphoid tissues composed of B cells and T cells that are associated with improved survival and response to ICT. Despite these associations, it is unclear what impact ICT has on these structures and whether they mediate ICT efficacy. We sought to examine if ICT may promote formation of TLS in TNBC.

Methods and Results: In this study, we show induction of TLS following immune checkpoint therapy (anti-PD-1 and anti-CTLA-4) in an orthotopic murine TNBC model. This model, T11-APOBEC, genocopies clinical TNBC and is dependent upon B cells and $CD4^+$ T cells for response to immune checkpoint therapy. Using immunofluorescence, we show that TLS formation is significantly upregulated in the periphery of T11-APOBEC tumors following ICT, whereas tumors treated with vehicle control show little to no TLS formation ($p = 0.0286$). These TLS are composed of B cells coalescing with $CD4^+$ and $CD8^+$ T cells and are also associated with pro-inflammatory macrophages and monocytes. Using spatial transcriptomics and K-nearest neighbor analysis, we show that these TLS are identified as a spatially and transcriptionally distinct niche in an unbiased manner. TLS in this model are significantly enriched for four widely used transcriptional signatures of human cancer-associated TLS, and they also significantly upregulate pathways associated with B cell activation, humoral immunity, and germinal center activity. We then further show that a signature derived from these ICT-induced TLS are focally enriched in a cohort of human TNBC samples by spatial transcriptomics, suggesting the formation of similar structures in TNBC patients.

Conclusions: These data suggest that ICT promotes the formation of TLS in TNBC, which may mediate enhanced anti-tumor adaptive immune responses. This model also provides a platform to further investigate mechanisms of formation and function of these structures in the context of ICT, which will inform predictive biomarkers and improved immunotherapy approaches for this aggressive disease.

#2818 Preclinical Characterization of ALG-094295, a highly potent and orally bioavailable small molecule PD-1/PD-L1 inhibitor targeting dimerization, internalization and degradation of PD-L1.

Heleen Roose[1], Kristina Rekstyte-Matiene[1], Sarah Stevens[2], Kusum Gupta[2], Sandra Chang[2], Nour Fayyad[1], Cheng Liu[2], Vladimir Serebryany[2], Lillian Adame[2], Kha Le[2], Antitsa Stoycheva[2], Dinah Misner[2], Lawrence M. Blatt[2], Sushmita Chanda[2], David B. Smith[2], Julian A. Symons[2], Andreas Jekle[2], **Tongfei Wu**[1]

[1]Aligos Belgium BV, Leuven, Belgium,[2]Aligos Therapeutics, Inc., South San Francisco, CA

Background: PD-1/PD-L1 antibody-based therapies have demonstrated tremendous success in the treatment of a variety of cancers. However, these antibody drugs are associated with several disadvantages, such as weak tumor penetration, immune-related adverse events and emergence of anti-drug antibodies. Here, we report the discovery and characterization of ALG-094295 as a highly potent and orally bioavailable small molecule PD-1/PD-L1 inhibitor that binds to PD-L1 and promotes PD-L1 dimerization, internalization and degradation, offering a different mechanism of action with potential advantages over PD-1/PD-L1 antibody therapeutics.
Methods: The interaction of PD-1/PD-L1 and PD-L1 dimerization were assessed by AlphaLISA®. Cellular activity was measured using PD-1 expressing Jurkat NFAT luciferase T cells and CHO-hPD-L1 cells. *In vivo* PD-L1 target engagement, tumor growth inhibition and tumor infiltration of T-cells were assessed in a humanized-PD-L1 MC38 subcutaneous tumor mouse model. *In vitro* ADME tox profile was established using standard assays. Pharmacokinetic (PK) studies were performed with rat, dog and cynomolgus monkey.
Results: ALG-094295 demonstrated inhibition of PD-1/PD-L1 interaction at sub-nanomolar concentrations and induced PD-L1 dimerization. In vitro studies showed that ALG-094295 activated T cells with approximately ten times greater potency compared to INCB086550, an orally administered small molecule PD-L1 inhibitor that has demonstrated clinical responses in a phase I trial. Furthermore, treatment of CHO-hPD-L1 cells with ALG-094295 resulted in internalization and reduction of PD-L1 protein levels. In ex vivo human PBMC assays, ALG-094295 demonstrated PD-L1 target engagement, T cell activation and immune cell mediated tumor cell killing. In a humanized PD-L1 MC38 mouse model, a single oral dose of ALG-094295 (5 mg/kg) achieved PD-L1 target engagement comparable to INCB086550 (150 mg/kg PO). Daily oral dosing of ALG-094295 (50 or 150 mg/kg) in humanized PD-L1 MC38 mice over 21 days resulted in tumor growth inhibition equivalent to twice-weekly administration of durvalumab (10 mg/kg IV), with tumor size correlating with increased $CD8^+$ T-cell infiltration. ALG-094295 demonstrated no in vitro liabilities for CYP450 inhibition or induction mediated drug-drug interactions, off target toxicity, cardiovascular safety, or genotoxicity. Preclinical *in vivo* PK data suggests once-daily oral dosing is feasible in humans.
Conclusion: ALG-094295 is a highly potent and orally bioavailable small molecule PD-1/PD-L1 inhibitor that promotes PD-L1 dimerization, internalization and degradation. ALG-094295 has the potential to overcome some limitations of antibody-based therapies due to potent PD-L1 blockade, oral delivery and novel mechanism of action.

#2819 Preclinical characterization of ALG-093940, a potent and orally bioavailable small molecule PD-1/PD-L1 inhibitor targeting PD-L1 dimerization, internalization and degradation.

Heleen Roose[1], Kristina Rekstyte-Matien[1], Sarah Stevens[2], Kusum Gupta[2], Sandra Chang[2], Nour Fayyad[1], Cheng Liu[2], Vladimir Serebryany[2], Lillian Adame[2], Kha Le[2], Antitsa Stoycheva[2], Dinah Misner[2], Lawrence M. Blatt[2], Leonid Beigelman[2], Sushmita Chanda[2], David B. Smith[2], Julian A. Symons[2], Andreas Jekle[2], **Tongfei Wu**[1]

[1]Aligos Belgium BV, Leuven, Belgium,[2]Aligos Therapeutics, Inc., South San Francisco, CA

Background: PD-1/PD-L1 antibody-based therapies have demonstrated tremendous success in the treatment of a variety of cancers. However, these antibody drugs are associated with several disadvantages, such as weak tumor penetration, immune-related adverse events and emergence of anti-drug antibodies. Here, we report the characterization of ALG-093940, a potent and orally bioavailable small molecule PD-1/PD-L1 inhibitor that binds to PD-L1 and promotes PD-L1 dimerization, internalization and degradation, offering an alternate mechanism of action with potential advantages over PD-1/PD-L1 antibody therapeutics.

Methods: The interaction of PD-1/PD-L1 and PD-L1 dimerization were assessed by AlphaLISA®. Inhibition of PD-1/PD-L1 in cell culture was measured using PD-1 expressing Jurkat NFAT luciferase T cells and CHO-hPD-L1 cells. *In vivo* PK/PD/Efficacy were assessed in a humanized-PD-L1 MC38 subcutaneous tumor mouse model. *In vitro* ADME tox profile used standard assays. Pharmacokinetic (PK) studies were performed in mice, rat, dog, and cynomolgus monkeys. Safety and tolerability were evaluated by oral administration in rats and cynomolgus monkeys.

Results: ALG-093940 inhibited PD-1/PD-L1 interaction with an IC_{50} of 0.048 nM and induced PD-L1 dimerization with an EC_{50} of 79 nM. ALG-093940 showed comparable T-cell activation potency to INCB086550 an orally dosed small molecule PD-L1 inhibitor which demonstrated clinical responses in a phase I study. Furthermore, treatment of CHO-hPD-L1 cells with ALG-093940 resulted in internalization and reduction of PD-L1 protein levels. In ex vivo human PBMC assays, ALG-093940 demonstrated PD-L1 target engagement, T cell activation and immune cell mediated tumor cell killing. In the *in vivo* humanized-PD-L1 MC38 mouse model, oral once daily dosing of ALG-093940 at 1.5, 15, 50 or 150 mg/kg demonstrated dose-dependent PD-L1 target engagement and tumor growth inhibition, where tumor size correlated with tumor-infiltration of $CD8^+$ T-cells. ALG-093940 demonstrated no in vitro liabilities for CYP-mediated drug-drug interactions, off target toxicity, cardiovascular safety, or genotoxicity. Preclinical *in vivo* PK data suggests once-daily oral dosing is feasible in humans. In addition, ALG-093940 was well tolerated when orally administered in rats for 14 days up the highest dose tested at 150 m/kg/day (up to the saturation of exposure), and in cynomolgus monkeys as a single dose up to 500 mg/kg and multiple doses for 3 days at 300 mg/kg/day.

Conclusions: ALG-093940, an orally available small molecule, is a potent PD-1/PD-L1 inhibitor targeting PD-L1 dimerization, internalization and degradation. ALG-093940 demonstrated excellent efficacy and safety, warranting further evaluation as a potential clinical candidate for the treatment of cancer.

#2820 Spatial mapping of PD1-PD-L2 interactions suggests an additional checkpoint axis in non-small cell lung cancer.

Anna Gorbunova[1], Amanda Lindberg[2], Lars Muhl[3], Ghazal Lessan Toussi[1], Hui Yu[2], Patrick Micke[2], **Carina Strell**[2]

[1]Department of Clinical Medicine, University of Bergen, Bergen, Norway,[2]Department of Immunology, Genetics and Pathology, Uppsala University, Uppsala, Sweden,[3]Department of Medicine, Huddinge, Karolinska Institutet, Stockholm, Sweden

Background: Immune checkpoint inhibitors have transformed non-small cell lung cancer (NSCLC) treatment, yet durable benefit remains limited. Current biomarkers, such as PD-L1 immunohistochemistry (IHC), measure protein abundance rather than functional PD1-ligand engagement and therefore provide limited predictive value. The second PD1 ligand, PD-L2, has often been ignored, but may influence immune regulation in the cellular context. Therefore, the activation of the PD1-PD-L1 axis is not sufficient to explain clinically relevant immune mechanisms.

Methods: We analyzed a tissue microarray of early-stage, surgically resected NSCLC (N=345), a cohort previously extensively immunoprofiled, including PD-L1 IHC and PD1-PD-L1 proximity ligation assay (PLA) [1]. We extended this work using fluorescent PLA (co-stained for CD3 and pan-cytokeratin) to visualize PD1-PD-L2 interactions across tumor, stromal, and T-cell compartments, alongside PD-L2 protein expression by IHC. Image analysis was performed in QuPath.

Results: In normal lung, PD-L2 was primarily expressed on macrophages and occasional granulocytes. Among tumors, squamous cell carcinomas (SqCC) showed higher PD-L2 expression than adenocarcinomas (AD) ($p=0.003$) and increased PD1-PD-L2 interactions ($p=0.047$), consistent with greater immune infiltration. Notably, amplification of 9p24.1, including the PD-L1 and PD-L2 locus, was also observed more frequent in SqCC. PD1-PD-L2 interactions displayed a distinct immune contexture from PD1-PD-L1. Within tumor cell compartment, PD1-PD-L2 correlated only weakly with $CD4^+$, $CD8^+$, $CD163^+$, $FoxP3^+$, PD1, and PD-L1, while PD1-PD-L1 showed strong associations with these immune populations, indicating partly distinct mechanisms of immune regulation. In the stroma, both ligands showed more similar immune-association patterns. Clinically, high PD1-PD-L1 interaction was generally associated with better prognosis. In contrast, PD1-PD-L2 interaction in SqCC showed only a trend toward better survival ($p=0.061$), whereas in AD it demonstrated a trend toward shorter survival ($p=0.092$). Also, compartment-specific PD1-PD-L2 interactions in the tumor stroma were associated with poor prognosis, particularly in SqCC with T cell-rich stroma ($p=0.033$).

Conclusion: Our findings suggest that PD1-PD-L2 represents a spatially and biologically distinct checkpoint axis in NSCLC, differing from PD1-PD-L1 in immune phenotypes and clinical associations. Including PD-L2-specific interaction analyses may enhance understanding of checkpoint biology and support refined patient stratification, particularly in SqCC, where PD-L2 co-amplification and upregulation appear to be more common.

#2821 TRIB2 regulates immune evasion in antiandrogen-resistant and neuroendocrine prostate cancer.

Sharad K. Suthar[1], Azizur Rahman[2], Sang-Yoon Lee[1], Jitender Monga[3]

[1]Department of Neuroscience, Neuroscience Research Institute, Gachon University, Incheon, Korea, Republic of,[2]Department of Surgery, Louisville University School of Medicine, Louisville, KY,[3]Department of Urology, Henry Ford Health + Michigan State University Health Sciences, Detroit, MI

Background: Enzalutamide resistance remains a major clinical challenge in advanced prostate cancer. We previously identified Tribbles homolog 2 (TRIB2) as highly upregulated in enzalutamide-resistant prostate cancer (ERPC), including neuroendocrine (NE)-type resistant tumors, where it drives tumor cell survival, lineage plasticity, and therapeutic resistance. Targeting TRIB2 suppresses the growth of resistant cells, highlighting its critical role in disease progression. Immune checkpoint molecules, including B7-H3 (CD276) and PD-L1 (CD274), are also elevated in ERPC and NE prostate tumors and contribute to impaired T cell-mediated anti-tumor immunity. These convergent findings led us to hypothesize that TRIB2 promotes immune evasion in treatment-resistant prostate cancer and that its inhibition may enhance T-cell-mediated anti-tumor immunity.

Methods: Enzalutamide-resistant (C4-2B^{ENZR} and LNCaP^{ENZR}) and NE (NCI-H660) prostate cancer cell lines were used to investigate TRIB2-dependent immune regulation. TRIB2 expression was modulated using lentiviral shRNA knockdown, plasmid-mediated overexpression, or pharmacological inhibition using the selective TRIB2 inhibitor TBI-001. B7-H3 and PD-L1 expression was measured using western blot and flow cytometry. Modified cancer cells were co-cultured with activated human CD8$^+$ T-cells, and T-cell activation, cytokine production, and cytotoxicity were evaluated using standard immunological assays.

Results: Both TRIB2 knockdown and TBI-001 treatment markedly reduced B7-H3 and PD-L1 expression in ERPC and NE prostate cancer cells, whereas TRIB2 overexpression increased immune checkpoint levels. TRIB2 inhibition enhanced CD8$^+$ T-cell activation and cytokine secretion (IFN-γ and TNF-α), and improved T cell-mediated cytotoxicity against resistant cancer cells. Conversely, cells with elevated TRIB2 levels strongly suppressed T-cell activation and cytotoxicity. Immune checkpoint blockade partially restored T-cell function against TRIB2-high cells, with combined blockade showing enhanced effects in restoring anti-tumor immunity.

Conclusion: These findings demonstrate that TRIB2 facilitates immune evasion in enzalutamide-resistant and neuroendocrine prostate cancer by upregulating immune checkpoint proteins and suppressing anti-tumor T-cell activity. This represents a dual mechanism by which TRIB2 drives treatment-resistant prostate cancer progression through both tumor-intrinsic effects and modulation of the tumor microenvironment. Therapeutic targeting of the TRIB2-immune checkpoint axis represents a rational strategy to overcome enzalutamide resistance, offering the combined benefit of inhibiting tumor growth while restoring effective anti-tumor immunity.

#2822 Serial transcriptomic analyses capture the effects of neoadjuvant immune checkpoint inhibition in resectable gastroesophageal cancer.

Blair V. Landon[1], Christopher Cherry[1], Rachel Keogh[1], Jaime Wehr[1], Gavin Pereira[1], Noushin Niknafs[1], Richard J. Battafarano[2], Stephen C. Yang[2], Stephen Broderick[2], Jinny Ha[2], Russell K. Hales[3], K. Ranh Voong[3], Kristen A. Marrone[1], Chen Hu[1], Josephine L. Feliciano[1], Ali H. Zaidi[4], Ronan J. Kelly[5], Vincent K. Lam[1], Valsamo (Elsa) K. Anagnostou[1]

[1]The Sidney Kimmel Comprehensive Cancer Center, Johns Hopkins University School of Medicine, Baltimore, MD,[2]Department of Surgery, Johns Hopkins University School of Medicine, Baltimore, MD,[3]Department of Radiation Oncology, Johns Hopkins University School of Medicine, Baltimore, MD,[4]Allegheny Health Network Cancer Institute, Allegheny Health Network, Pittsburgh, PA,[5]The Charles A. Sammons Cancer Center, Baylor University Medical Center, Dallas, TX

Introduction: Immune checkpoint inhibition (ICI) is gaining momentum as peri-operative therapy for resectable cancers, however early changes in the tumor microenvironment (TME) during and after neoadjuvant ICI have yet to be characterized.
Methods: Bulk RNA sequencing (RNAseq) was performed on 71 serial tumors sampled at baseline, post 2 cycles of neoadjuvant ICI (post-ICI), and at the time of resection, in a cohort of 32 patients with resectable gastroesophageal cancer treated with neoadjuvant nivolumab or nivolumab + relatlimab, followed by concurrent ICI and chemoradiation (NCT03044613). We performed gene set enrichment analyses (GSEA) of RNAseq data, stratified by pathological response and clinical outcomes. Complete (pCR) and major pathological response (MPR) were defined as 0% and ≤10% residual tumor at resection.
Results: GSEA revealed an upregulation of interferon alpha, interferon gamma, antigen processing and presentation, and pro-inflammatory M1 macrophage gene sets post-ICI compared to baseline (FDR-adjusted $p < 0.006$). After chemoradiation, resected tumors showed depletion of DNA repair, chromosome maintenance, cell proliferation and cell cycle progression gene sets, reflective of the cytotoxic effect of therapy (FDR-adjusted $p < 10e-06$). Notably, in the nivolumab + relatlimab arm, induction of adaptive immune response gene sets and TNFa signaling through NF-kB was noted in resected specimens (FDR-adjusted $p < 10e-05$). Among patients who attained a pCR, there was an upregulation of interferon alpha, interferon gamma, and antigen processing and presentation gene sets post-ICI (FDR adjusted $p < 10e-06$). Similarly, in those who attained an MPR there was an upregulation of inflammatory response, interferon gamma, and B cell receptor gene sets (FDR adjusted $p < 10e-09$), while cellular metabolism and oxidative phosphorylation gene sets were down regulated post-ICI (FDR adjusted $p < 0.05$). Linking transcriptomic profiles with disease recurrence, we found a downregulation of inflammatory related gene sets post-ICI in recurrent cases (FDR adjusted $p < 0.0006$). Depletion of oxidative phosphorylation, metabolism, and chromatin regulation gene sets was noted in baseline tumors of patients that attained long overall survival (FDR adjusted $p < 10e-05$). In post-ICI tumors, there was an upregulation of inflammatory and adaptive response gene sets in patients with longer overall survival (FDR adjusted $p < 10e-08$), while the oxidative phosphorylation and metabolism gene sets remained suppressed (FDR adjusted $p < 0.003$).
Conclusions: Neoadjuvant ICI induces differential inflammatory and metabolism expression programs that are reflective of pathological responses, recurrence and survival, broadening our understanding of actionable mechanisms of ICI efficacy.

#2823 Single-cell RNA-seq reveals insights into the effects of immune checkpoint inhibitors.

Junting Lu, Jinghui Xiu, **Ce Zhong**, Wentao Li, Wei Yun, Tan Pang, Jingqi Huang

Pharmacology, Pharmaron, Beijing, China

Immune checkpoint inhibitors (ICIs) have demonstrated superior clinical efficacy, significantly prolonging patient survival across various cancers. However, the mechanisms by which ICIs modulate the immune system and memory function require continued exploration. Single-cell RNA sequencing (scRNA-seq) offers a powerful tool for oncology research and development. In this study, we performed scRNA-seq following treatment with an anti-PD-1 antibody in a murine colon adenocarcinoma model. Mice were inoculated with MC38 tumor cells, treated with ICIs, and subsequently re-challenged with the same tumor cells after tumor regression. Tumor-infiltrating lymphocytes (TILs) and peripheral blood mononuclear cells (PBMCs) were isolated and analyzed using scRNA-seq alongside flow cytometry. Single-cell suspensions were processed using the 10x Genomics Chromium platform. Single-cell libraries were constructed, sequenced, and pre-processed, including demultiplexing and mapping to the reference genome. Filtered data underwent dimensionality reduction and clustering, and cells were annotated into distinct populations based on classical markers. Within the tumor microenvironment (TME), we observed notable activation of $CD4^+$ and $CD8^+$ T cells, a reduction in immunosuppressive $CD4^+$ Treg cells, and an increase in Th1 cells. Among $CD8^+$ T cells, cytotoxic effector (Teff) and memory (Tem) subsets were elevated, indicating effective T-cell activation and enhanced anti-tumor immunity. Similarly, PBMC analysis revealed increased naive T cells and Th1 cells within the $CD4^+$ population, while $CD8^+$ T cells exhibited expansion of Tem subsets with a slight increase in Teff cells. Overall, our findings demonstrate that checkpoint blockade promotes durable anti-tumor responses through expansion and differentiation of memory T cells and enhanced immune cell infiltration at both genetic and peripheral levels. Anti-PD-1 therapy directly potentiated the tumor-killing capacity of TILs, promoting a shift toward subtypes favorable to tumor clearance. Concurrently, treatment reprogrammed T-cell subsets in PBMCs, improving differentiation potential and thereby strengthening effective anti-tumor immune responses.

#2824 Intragenic rearrangement burden: A novel biomarker to predict immune checkpoint blockade response in TMB-low cancers.

Akshat Gupta[1], Selena Xiao[1], Hillary Wang[1], Rohit Bhargava[1], Adrian V. Lee[2], Adam M. Brufsky[1], **Xiaosong Wang**[1]

[1]Department of Pathology, University of Pittsburgh, Pittsburgh, PA,[2]University of Pittsburgh, Pittsburgh, PA

Background: Immune checkpoint blockade (ICB) efficacy is limited, and biomarkers like Tumor Mutation Burden (TMB) fail in TMB-low cancers (e.g., breast, ovarian) despite many being immunologically "hot". This paradox suggests an uncharacterized neoantigen source. We investigated intragenic rearrangements (IGRs)—cryptic structural mutations—as this source, hypothesizing IGR burden is a superior biomarker for T-cell inflammation and ICB benefit in these tumors.
Methods: We performed a pan-cancer WGS analysis (ICGC, n=1,033) correlating IGR burden with T-inflamed signatures. We used multivariate regression to compare IGRs against TMB, indels, fusions, and SCNA on immune infiltration, validating in TNBC (n=513), HGSC (n=33), and ESAD cohorts. Predictive power for ICB response was assessed by Kaplan-Meier, Cox regression, and ROC analysis in ESAD (durvalumab), HGSC (NACT + pembrolizumab), and mTNBC trials. We also analyzed a breast cancer immunopeptidomic dataset (n=26) to correlate IGR burden with presented neopeptides.
Results: Pan-cancer analysis showed IGR-high and TMB-high are distinct T-inflamed subsets. In TMB-low cancers, IGR burden was the most significant covariate for T-cell inflammation (p=0.0098), not TMB (p=0.224). In TNBC, IGR burden was the *only* significant genomic marker for the T-inflamed signature (p=0.008). Mechanistically, IGR burden strongly correlated with *presented* IGR-derived neopeptides (Pearson R=0.54) and showed evidence of immunoediting.In clinical trials, IGR burden predicted ICB benefit. In HGSC (NACT+Pembro), high IGR burden predicted superior OS (AUROC=0.80; 5-yr OS ~85% vs ~30%, HR=0.17, p=0.009), outperforming PD-L1 (HR=0.77, p=0.65). In ESAD (durvalumab), IGR burden (AUROC=0.74) also outperformed PD-L1 (AUROC=0.46). Critically, IGR burden was predictive, not just prognostic. High IGR burden predicted improved OS in mTNBC with chemo-IO (HR=0.18, p=0.074) but *poorer* OS with chemo-only (HR=4.29, p=0.032).
Conclusions: IGR burden is a powerful predictive biomarker for ICB response in TMB-low malignancies where TMB and PD-L1 fail. Supported by immunopeptidomic evidence of neoantigen presentation, it outperforms existing markers, distinguishes true ICB benefit from prognosis, and resolves the "hot" TMB-low tumor paradox. IGR burden represents a critical new tool for patient selection.

#2828 Paclitaxel induces colocalization of CXCL9$^+$ tumor-associated macrophages and CD8$^+$ T cells to potentiate antitumor immunity in head and neck squamous cell carcinoma.

Minsu Kwon[1], Jeong Heon Kim[1], Jisu Hong[1], Seo-Won Choi[1], Jung Min Kim[1], Hyo Jung Cho[2], Myungchan Park[3], JI-HYUN SEO[4], Jung Je Park[4]

[1]Otorhinolaryngology Head and Neck Surgery, Asan Medical Center (AMC), Seoul, Korea, Republic of,[2]Gastroenterology, Ajou University School of Medicine, Suwon, Korea, Republic of,[3]Urology, Haeundae Paik Hospital, Inje University College of Medicine, Pusan, Korea, Republic of,[4]Institute of Medical Science, Gyeongsang National University College of Medicine, Jinju, Korea, Republic of

Background: Paclitaxel is a key chemotherapeutic agent for head and neck squamous cell carcinoma (HNSCC). Recent studies have suggested the role of paclitaxel in immune responses, particularly relevant to tumor-associated macrophages (TAMs). This study explores the immunomodulatory role of paclitaxel in the tumor microenvironment (TME), focusing on its interaction with TAMs in HNSCC.
Methods: In vitro and in vivo studies were conducted on murine samples and human samples from our tertiary referral center. The in vitro experiment involved murine bone marrow-derived macrophages (BMDMs) to evaluate phagocytic functions and the expression of MHC-related genes and proteins. Our in vivo study aimed to discriminate the spatial characteristics of SPP1+/CXCL9+ TAMs and their interaction with CD8+ T cells, especially under exposure to paclitaxel, using mouse oral carcinoma (MOC) and HNSCC samples.
Results: Paclitaxel enhanced macrophage phagocytosis and upregulated antigen processing genes. In the murine HNSCC model, paclitaxel combined with anti-PD-1 significantly suppressed tumor growth, whereas either treatment alone was ineffective. This was associated with the redistribution of CXCL9+ TAMs into the tumor core. Consistently, human HNSCC samples demonstrated that paclitaxel-based neoadjuvant chemotherapy (NAC) was linked to improved survival and increased infiltration of CXCL9+ TAMs and CD8+ T cells into the tumor core, indicating a shift from an "immune-excluded" to an "inflamed" microenvironment.
Conclusion: Paclitaxel upregulates the phagocytic and antigen-presenting function of TAMs while spatially redistributing them toward the tumor core and subsequently inducing CD8+ T cell infiltration. Such features suggest that Paclitaxel may reprogram an immune-deserted TME to an anti-tumoral condition, ultimately contributing to immunotherapy responsiveness.

#2829 Afatinib exerts an inhibitory effect on T cell-mediated cytotoxicity.

Masaru Yokomura[1], Seiji Nagano[2], Hiroshi Kawamoto[2], Takahiro Asakage[3], Ryohei Katayama[1]

[1]Division of Experimental Chemotherapy, Cancer Chemotherapy Center, Japanese Foundation for Cancer Research, Tokyo, Japan,[2]Institute for Life and Medical Sciences, Kyoto University, Kyoto, Japan,[3]Department of Head and Neck Surgery, Institute of Science Tokyo, Tokyo, Japan

Immune checkpoint blockade (ICB) has become a cornerstone of cancer therapy by enhancing antitumor immunity, and combinations of targeted therapies with ICB are widely evaluated across malignancies. However, the biological determinants that predict synergistic or antagonistic effects between targeted agents and ICB remain poorly understood. To identify agents that modulate T-cell effector function, we performed an *in vitro* inhibitor library screening using WT1-specific cytotoxic T cells (CTLs) generated from induced pluripotent stem cells (iPSCs) (Maeda T et al, *Cancer Res*. 2016). WT1-specific CTLs were co-cultured with HLA class I matched cancer cells in the presence of exogenous WT1 peptide. In this screening, immunosuppressive agents such as JAK inhibitors (ruxolitinib and tofacitinib) and src inhibitor dasatinib markedly suppressed T cell-mediated killing as expected. We newly identified afatinib, a second-generation EGFR tyrosine kinase inhibitor, as a potent suppressor of T-cell effector function. Afatinib significantly reduced interferon-γ (IFN-γ) secretion and T-cell activation. Notably, this IFN-γ reduction was independent of T-cell proliferation. RNA-seq analysis revealed that afatinib downregulated the T-cell receptor (TCR) pathway signature. RT-qPCR demonstrated a dose-dependent suppression of *IFNG* mRNA expression in afatinib-treated T cells. Furthermore, afatinib impaired tumor rejection in an immunological memory mouse model which mice had been previously cured with anti-PD-L1 therapy, demonstrating functional suppression of T cell mediated antitumor immunity. Collectively, these findings identify afatinib as a negative regulator of T cell effector function and raise the possibility that EGFR-TKI-induced immunosuppression in T cells may contribute to the limited clinical efficacy of EGFR-TKI plus ICI combinations observed in EGFR-mutant NSCLC. Our screen platform provides a useful framework for predicting drug-ICI interactions and guiding rational combination strategies.

#2830 Immunomodulatory response in Dato-DXd-treated non-small cell lung cancer patient-derived organotypic tumor spheroids (pDOTS).

Satoru Yasuda[1], **Patrick Hall Lizotte**[2], Elena Ivanova[2], Zhaorong Li[2], Yui Tanaka[1], Daisuke Okajima[3], Minh Ha[2], David A. Barbie[2], Cloud P. Paweletz[2]

[1]Daiichi Sankyo Inc, Baskin Ridge, NJ,[2]Dana-Farber Cancer Institute, Boston, MA,[3]Daiichi Sankyo Co. Ltd., Tokyo, Japan

Background: Datopotamab deruxtecan (Dato-DXd, DATROWAY) is a TROP2-directed ADC with a highly potent Topo I inhibitor payload, which is approved for HR+ breast cancer and EGFR-mutated NSCLC in the US and is being investigated in several registrational phase 3 trials, including 1L NSCLC, 2L+ TNBC, and urothelial carcinoma. While the cytotoxic payload-induced apoptotic effect of DXd is well investigated, its immunomodulatory effect is less characterized. Here we analyze tumor cell-intrinsic immunological response to Dato-DXd using short-term microfluidic culture of patient-derived organotypic tumor spheroids (pDOTS) in non-small cell lung cancer (NSCLC) samples.

Methods: Four surgical NSCLC cases collected from Brigham and Women's Hospital under an IRB-approved protocol were studied. TROP2 antigen density on EpCAM+ cells was assessed by quantitative flow cytometry and immunofluorescence; baseline immune profile was assessed by flow. *Ex vivo* response to vehicle, unconjugated Datopotamab, IgG-DXd, and Dato-DXd were assessed by live/dead imaging endpoint analysis. Modulation of tumor cell immunogenicity at 24hr and 72hr was analyzed by 10x single cell RNA sequencing (scRNAseq).

Results: Four NSCLC explants with high tumor cell content and high TROP2 expression (3+ by IF) were studied. Response to drug treatment was measured by change in raw live cell area compared to control samples. Unexpectedly, EpCAM+TROP2+ tumor cells from all four samples at both timepoints exhibited negative pathway enrichment scores for Hallmark TNF-α Signaling via NFκB and Inflammatory Response when comparing Dato-DXd to control-treated. Individual gene level analysis revealed significant downregulation of myeloid-associated cytokines (IL-23a, IL-6) and chemokines (CSF1/2, CXCL1/2/3, CCL2, CCL20, IL-8), indicating possible reduced recruitment of myeloid-derived suppressor cells (MDSCs) and tumor-associated macrophages (TAMs). Investigation of tumor cell immunogenic cell death in response to Dato-DXd treatment revealed inconsistent induction of pro-inflammatory signaling.

Conclusions: Our results indicate clear and consistent immunomodulation of NSCLC tumor cells when treated with Dato-DXd, principally downregulation of myeloid-associated inflammation. Statistically significant differential expressions of CSF1/2, CXCL1/2/3, and IL-8 (CXCL8) chemokines reveal a potentially unappreciated mechanism underlying ADC therapeutic efficacy: reduced recruitment of pro-tumoral myeloid cells by tumor cells.

#2831 RAS(ON) inhibition in both cancer and immune cells by daraxonrasib drives anti-tumor immunity.

Nataliya Tovbis Shifrin[1], Mariela Moreno Ayala[1], Cristina Blaj[1], Kevin Chen[2], Felix Mbuga[1], Joaquin Pechuan Jorge[1], Rashi Raghulan[1], Rich Liang[1], Linh Tran[1], Enrico Payson[1], Alice Kumamoto[1], Alexander McNamara[1], Marie Josette Catherine Menard[1], Michael Weiss[1], Lillian Seu[1], Elsa Quintana[1]

[1]Revolution Medicines, Redwood City, CA,[2]Medicine, UCLA, Los Angeles, CA

Daraxonrasib (RMC-6236) is an orally bioavailable, RAS(ON) multi-selective, tri-complex inhibitor of oncogenic mutant and wild-type variants of N, H and KRAS, demonstrating broad activity across RAS-mutant cancers. Preclinical studies have shown that daraxonrasib not only suppresses tumor cell proliferation but also promotes a striking remodeling of the tumor microenvironment (TME), characterized by depletion of immunosuppressive myeloid cells (including M2 macrophages) and increased infiltration of T cells. Collectively these changes sensitize tumors to immune checkpoint blockade. We have reported that the combination of daraxonrasib plus pembrolizumab, with or without chemotherapy, demonstrated encouraging preliminary antitumor activity, and was generally well tolerated, in patients with 1L RAS mutant NSCLC.Given that RAS functions as a key immunosuppressive oncogene, a primary driver for the antitumor immune effects of daraxonrasib is tumor-cell intrinsic inhibition of oncogenic RAS. However, it is well established that the RAS-MAPK signaling pathway regulates critical immune processes, including maintenance of M2 macrophages and T cell receptor signaling. Here, we demonstrate that daraxonrasib has direct effects on immune cell populations and that inhibition of wild-type RAS in these cells contributes to antitumor immunity, highlighting a dual mechanism of action for this RAS(ON) multi-selective inhibitor.To determine the tumor-cell independent contributions of RAS (ON) inhibition to antitumor immunity in vivo, we used a syngeneic tumor model intrinsically resistant to daraxonrasib. Daraxonrasib treatment was initiated at the time of tumor implant. In this model, although daraxonrasib alone did not inhibit cell proliferation in vitro or affect tumor growth in vivo, it promoted favorable TME remodeling, including macrophages depletion and increased T cell infiltration. Importantly, daraxonrasib treatment – when initiated at the time of implant – sensitized these tumors to subsequent checkpoint inhibitor therapy. Together, these and earlier preclinical findings reveal that daraxonrasib acts through coordinated RAS(ON) inhibition in both tumor and immune compartments. The impact of RAS(ON) inhibition in the immune compartment includes depletion of M2 macrophages and prevention of T cell exhaustion (as suggested by in-vitro data), leading to an immune-permissive TME that enhances responsiveness to checkpoint blockade. Collectively these preclinical data support the ongoing clinical evaluation of this combination in RAS-driven cancers.

#2832 Evaluation of Natural Killer cells' contribution to Enhertu toxicity in breast cancer patient derived xenograft-derived 3D models.

Chou Fu-Ju[1], Annamaria Rapisarda[1], Veena Jagannathan[1], Marianna Zipeto[1], Michael Ritchie[1], Markus Hippich[1], Daniel Ciznadija[2], Brandon Walling[1], Stefano Cairo[3], Mara Gilardi[1], BanuPriya Sridharan[4]

[1]Champions Oncology (Rockville, MD), Rockville, MD,[2]Champions Oncology, Hackensack, NJ,[3]Champions Oncology, Inc. (Hackensack, NJ), Rockville, MD,[4]Champions Oncology, Inc. (Hackensack, NJ), Hackensack, NJ

Evaluating the impact of natural killer (NK) cells on antibody-drug conjugate (ADC) activity is essential for understanding and optimizing treatment efficacy. NK cells play a critical role in mediating antibody-dependent cellular cytotoxicity (ADCC), one of the key mechanisms through which ADCs exert their therapeutic effects. By recognizing and eliminating tumor cells via ADC Fc receptor engagement, NK cells can enhance the overall cytotoxic response and influence treatment outcomes. Assessing this interaction provides valuable insights into resistance mechanisms, guides the design of next-generation ADCs with improved immune engagement, and helps identify patient populations most likely to benefit from such therapies.

The primary objective of this study was to evaluate the contribution of NK cells to the cytotoxic activity and potential toxicity of trastuzumab deruxtecan (Enhertu) in breast cancer patient-derived xenograft organoid cultures (TumorGraft3D). A luciferase-tagged TumorGraft3D co-culture system incorporating a BioGlo luminescence endpoint was employed to enable real-time assessment of tumor cell viability and treatment response in the presence or absence of NK cells. A 3D co-culture system was established using breast cancer models that were transduced with luciferase at a multiplicity of infection (MOI) of 10 to allow quantifiable luminescence-based viability measurements. Following successful transduction, NK cells were added at predetermined ratios to the organoid cultures. Imaging and luminescence measurements were conducted at multiple time points to evaluate dynamic changes in cell viability and treatment effects. TumorGraft3D cells were seeded and transduced with luciferase. After confirming signal stability, NK cells, Enhertu or Trastuzumab were introduced into the culture system. Viability and imaging analyses were performed on Day 1 and Day 4 post-seeding, capturing both early and delayed treatment effects. Brightfield microscopy was used to visualize morphological changes, and BioGlo luminescence readings quantified cell survival and treatment response.

In the CTG-0708 model of HER2+ invasive ductal carcinoma, the addition of NK cells resulted in a slight increase in Enhertu-mediated cytotoxicity, suggesting a modest but measurable enhancement of ADC activity in the presence of NK cells. Trastuzumab efficacy demonstrated a clear correlation with antibody concentration, indicating dose-dependent ADCC activity. In contrast, Enhertu toxicity appeared independent of antibody concentration, likely due to the previously shown inefficient release of payload in vitro.

These findings suggest a potential immunomodulatory effect of NK cells on ADC efficacy, and support the use of this platform to more accurately model ADC mechanisms of action.

#2833 Amivantamab restores antitumor immunity in non-small cell lung cancer through EGFR/MET expression-dependent mechanisms.

Takamasa Ishino[1], Ryo Yoshichika[1], Fumiaki Mukohara[2], Ken Suzawa[2], Shinichi Toyooka[3], Yosuke Togashi[1]

[1]Department of Tumor Microenvironment, Okayama University, Okayama, Japan,[2]Department of General Thoracic Surgery and Breast and Endocrinological Surgery, Okayama University, Okayama, Japan,[3]Department of General Thoracic Surgery and Breast and Endocrinological Surgery, Dentistry and Pharma, Okayama University, Okayama, Japan

Introduction: Epidermal growth factor receptor (EGFR) mutations are one of the most common oncogenic drivers in non–small cell lung cancer (NSCLC). Although EGFR tyrosine kinase inhibitors (EGFR-TKIs) have demonstrated clinical benefits, acquired resistance still limits the long-term efficacy, with activation of MNNG HOS Transforming (MET) signaling serving as a representative bypass mechanism. Recently, amivantamab, a bispecific antibody against EGFR and MET, has shown clinical efficacy. However, its immunological role in human tumors has not been directly investigated.

Methods: We analyzed 40 surgically resected fresh NSCLC samples to evaluate EGFR/MET expression and their correlation with immune suppression. Tumor-infiltrating lymphocytes (TILs) were evaluated by flow cytometry and immunohistochemistry. To assess the immunomodulatory effects of amivantamab, tumor digests including viable TILs were cultured *ex vivo* under conditions with or without amivantamab.

Results: *EGFR* mutations and elevated EGFR protein expression showed a tendency for reduced infiltration of $CD8^+$ T cells and dendritic cells (DCs). *Ex vivo* exposure to amivantamab enhanced $CD8^+$ T-cell effector functions and DC maturation in TILs, particularly in tumors with high EGFR/MET expression, independent of *EGFR* mutation status.

Conclusion: This study provides the first direct evidence using fresh human NSCLC samples that amivantamab can restore antitumor immunity through $CD8^+$ T-cell activation and DC maturation. Expression levels of EGFR and MET may serve as predictive biomarkers for amivantamab monotherapy as well as for amivantamab-based combination immunotherapies.

#2834 Identification of CXCL10-CXCR3 axes as mediators of radioresistance in diffuse midline glioma (DMG).

Mostafa M. H. Ibrahim[1], Niloofar Khairkhah[1], Carl Koschmann[2], Yue Zhao[3], Stefanie Galban[1]

[1]Department of Radiology, University of Michigan Medical School, Ann Arbor, MI,[2]Department of Pediatrics, University of Michigan Health System, Ann Arbor, MI,[3]Gilbert S. Omenn Department of Computational Medicine and Bioinformatics, University of Michigan Medical School, Ann Arbor, MI

Diffuse Midline Gliomas (DMGs) are aggressive, universally fatal brain tumors with a 100% recurrence rate driven by therapeutic resistance. Many molecular therapies target epigenetically driven gene expression changes in DMG H3K27M-altered tumors, but whether they target methylation, acetylation, or downstream vulnerabilities, these treatments have failed to prevent recurrence. Since no recent therapies have prompted long-term responses, radiation remains the standard of care; however, radiotherapy often suppresses an immune response, and when tumors recur, an immune suppressive and tumor promoting microenvironment provides a niche for tumor cells to regrow uncontrollably.

In preliminary studies utilizing single-cell RNA sequencing (scRNA-seq) in a murine model of DMG, we uncovered a complex cellular tumor microenvironment that is modulated upon radiotherapy. In fact, radiation therapy significantly increased the expression of pro-tumorigenic genes in both PDGFRA+ DMG cells (e.g., Tgfa, IL133, Fgf2, Pdgfa) and tumor associated-microglial cells (e.g., IL4i1, IL33, Fgf2, Tgfbr1), suggesting a coordinated pro-tumorigenic response. Furthermore, CXCL10 dramatically increased in tumor cells (DMG) in response to radiotherapy, whereas CXCR3 was found to be predominantly expressed in T cells in these tumors. Interestingly, CXCL10 has previously been shown to be associated with macrophage infiltration and cell proliferation, and expression of the chemokine receptor/ligand pair CXCR3/CXCL10 plays an important role in the proliferation of glioma cells (Pessina et al. *Oncoimmunology* 2015). These findings suggest radiotherapy-induced immunosuppression occurs through the CXCL10-CXCR3 axis, and thus, in ongoing studies, we are evaluating whether blockade of CXCL10-CRCR3 axes can prevent radioresistance. Lastly, as previously hypothesized, we detected an increase in stemness gene expression in radiated tumors, which was prevented when mice were treated with a pan-ALDH inhibitor (CVT-10216).

In summary, we have characterized the stromal and immune tumor microenvironment in untreated and radiated DMG and have identified potential targets that may inform future therapeutic strategies to prevent recurrence.

#2835 Leveraging radiation inducible surface protein targets for tumor microenvironment reprogramming.

Courtney M. Tamaki[1], Maxwell Foisey[2], Charlotte Chen[1], Nam Woo Cho[1]

[1]Radiation Oncology, UCSF - University of California San Francisco, San Francisco, CA,[2]Microbiology & Immunology, UCSF - University of California San Francisco, San Francisco, CA

Radiation Therapy (RT) is one of the most common treatments for patients with solid tumors, administered to over 50% of patients. Failure of tumor control following RT, however, is a significant clinical challenge. In the present study, we identify a suite of novel proteins as radiation-inducible surface proteins across a variety of cancers, including breast and non-small cell lung cancers. Specific proteins characterized act as enzymes which deplete metabolic substrates, thus altering both the tumor microenvironment (TME) as well as cell intrinsic function. Using cell-surface capture mass spectrometry, bulk-RNA sequencing, fluorescence spectrometry, and cytometry by time of flight (CyTOF), we comprehensively characterize our target upregulation following RT, both as a surface protein and the enzymatic consequence of perturbation. To increase induction of surface expression, we evaluated combinatorial strategies of RT with small molecules and other soluble factors. These combinations significantly increased expression *in vitro* in both mouse and human non-small cell lung cancer cell lines. Additionally, *in vivo*, tumor-targeted RT/combination treatment significantly upregulated our protein of interest on tumor cells, as well as on a subset of macrophages and fibroblasts. Functional investigation suggests these macrophages and fibroblasts may have an immunosuppressive role within the TME. Leveraging these findings, we developed directed therapies, including antibody-drug conjugates (ADCs) and antigen-specific chimeric antigen receptor (CAR) T cells, to ablate both tumor and immunosuppressive cells with increased levels of the target, providing a more conducive combinatorial therapy to control tumors. In conclusion, we have identified and characterized a radiation-inducible therapeutic target, providing framework for reprogramming the TME and improving treatment efficacy.

#2836 Tumor-derived extracellular vesicles as key messengers of radiotherapy-induced immunogenic cell death to sensitize small cell lung cancer to immunotherapy.

Shanghai Liu[1], Kai Kang[1], Zhuoran Yao[1], Ren Luo[1], Hui Wang[1], Zichong Peng[1], Shuangsi Liao[1], Yilan Zeng[1], Ruizhan Tong[1], Jiaming Zeng[2], Weidi Xiao[2], Jianxin Xue[1], Linglu Yi[1], Chu Wang[2], You Lu[1]

[1]Division of Thoracic Tumor Multimodality Treatment, Cancer Center, West China Hospital, Sichuan University, Chengdu, China,[2]Beijing National Laboratory for Molecular Sciences, Key Laboratory of Bioorganic Chemistry and Molecular Engineering of Ministry of Education, College of Chemistry and Molecular Engineering, Peking University, Beijing, China

Background: We previously showed low-dose radiotherapy (LDRT) exerts immunostimulatory effects in both preclinical models and clinical settings for SCLC, yet its immunogenic cell death (ICD) mechanisms remain unclear. As extracellular vesicles (EVs) mediate intercellular stress signaling, we hypothesized that tumor-derived EVs play a critical role in orchestrating immunogenic signaling in the initial stages of radiotherapy response. This study tracks ICD signals from tumor to DCs via EV monitoring and elucidate their function spectrum throughout this process.

Methods: Plasma EVs from prospective extensive-stage-SCLC cohorts treated with LDRT plus chemo-immunotherapy and PDX/PDO-derived EVs post-irradiation underwent proteomic profiling. Post-irradiation cellular components - cell pellets, debris, and EVs - were used to activate DC-T axis respectively. EV inhibition and live-cell imaging confirmed radiation-induced EVs (RT-EVs) activate the axis versus non-irradiated EVs (NT-EVs). SCLC CDX and PDX models were established, and corresponding homogeneous PBMCs were collected for in vivo EV function evaluation.An ICD tracking system based on stable isotope labeling traced EV-mediated immunogenic transfer from irradiated SCLC and MC-38ova cells to DCs.

Results: Proteomic analysis identified LDRT-EVs were specifically enriched in DC activation pathways and exhibited stronger ICD hallmarks, termed “Spark-EVs”. Spark-EVs significantly enhanced DC and T cell activation more than other cellular components, with efficacy comparable to whole-cell lysates. Spark-EVs potently activated the DC-T cell axis compared to NT-EVs, whereas the EV release inhibitor reversed this effect to control levels. Live-cell imaging confirmed nearly threefold greater DC uptake of Spark-EVs than NT-EVs ($p < 0.0001$). In CDX models, Spark-EV-pulsed DCs + anti-PD-1 enhanced tumor suppression versus NT-EVs + anti-PD-1 or anti-PD-1 alone. Patient T cells primed with Spark-EV-pulsed hDCs showed enhanced stemness and cytotoxicity in vitro. Adoptive transfer of these T cells into PDX models yielded superior tumor control. EV-labeled tracing showed that Spark-EVs were enriched with increased OVA antigens, DAMPs (e.g. HSPD1), which deliver into DCs then. Additionally, Integrated multi-level proteomics and prognostic analysis identified Junction plakoglobin (JUP) as a potential key transmitter of ICD signal.

Conclusion: Using EV-based tracing, we visualized how LDRT triggers tumor cells to generate Spark-EVs, which deliver enhanced immunogenic signals to DCs. Furthermore, we delineate that radiation-responsive EV-borne proteins (e.g. JUP, HSPD1) that mediate the release, transmission, and effector functions of LDRT-induced immunogenic signaling. These findings establish Spark-EVs as key, targetable messengers of LDRT-driven ICD.

#2837 Enhanced tumor immune cell infiltration and antigen presentation after carbon ion radiotherapy correlates with curative outcomes.

Matilde Recusani[1], Sarah Meister[1], Federica Ciamarone[1], Julian Schlegel[1], Ralph Sinn[2], Carmen Klein[3], Jennifer Furkel[1], Aoife Gahlawat[1], Christel Herold-Mende[4], Max Knoll[1], Michael Breckwoldt[2], Dirk Jaeger[5], Juergen Debus[6], Amir Abdollahi[1]

[1]Translational Molecular Radiooncology, DKFZ, Heidelberg, Germany,[2]Neuroradiology Department, University Hospital Heidelberg, Heidelberg, Germany,[3]Translational Radiation Oncology, NCT, Heidelberg, Germany,[4]Neurosurgical Research, University Hospital Heidelberg, Heidelberg, Germany,[5]Dir., Dept. of Medical Onc., Heidelberg University Hospital (UKHD), Heidelberg, Germany,[6]Heidelberg Ion-Beam Therapy Center (HIT), Heidelberg, Germany

Limited immune cell infiltration and deficient presentation of neoepitopes and tumor-associated antigens (TAA) via major histocompatibility complex class I (MHC-I) represent key barriers to effective immunotherapy. This study investigates whether particle radiotherapy (RT) can modulate tumor antigen presentation and T cell recruitment. By evaluating protons, helium, carbon, and oxygen ions, we assessed how distinct biophysical properties—particularly ionization density (linear energy transfer, LET)—influence immune priming. To this end, we evaluated the induction of MHC-I expression in a comprehensive panel of human tumor cell lines (CaSki, SK-MEL-37, A549, PC3, LNCaP), as well as in B16-F1 melanoma, GL261 and 005 genetically engineered glioblastoma models in syngeneic C57BL/6 mouse. Flow cytometry revealed MHC-I upregulation is time-, dose-, and LET-dependent. The role of the cGAS-STING pathway was confirmed using isogenic STING-KO B16 cells, which exhibited reduced RT-induced MHC-I expression. In vivo, high-LET carbon ion irradiation (CIRT) resulted in enhanced tumor MHC-I expression and increased intratumoral infiltration of $CD3^+$ and CD8+ T cells. Adoptive transfer of Superparamagnetic Iron Oxide Nanoparticles (“SPION”)-labeled T cells, followed by high-field MRI tracing, confirmed enhanced intratumoral influx after fractionated (5 × 3 Gy) and single ultra-High Dose Rate (uHDR, FLASH) CIRT. Further characterization of tumor-infiltrating lymphocyte (TIL) composition and immunological memory was performed using single-cell RNA sequencing and mass cytometry (CyTOF). Collectively,
these data indicate that modulating RT quality can improve neoantigen expression, MHC-I presentation, and T cell recruitment, highlighting the potential of particle radiotherapy to reprogram the tumor immune microenvironment.

#2839 Inhibiting both Class IIb HDACs is superior to isoform-specific inhibition for improved antitumor immune response..

Satish Kumar Reddy Noonepalle[1], Manasa Suresh[1], Xintang Li[1], Sonia Sebaoui[1], Bryan Weselman[1], Marie Durr[1], Nithya Gajendran[1], Chiara Ripamonti[2], Gianluca Fossati[2], Christian Steinkuhler[2], Alejandro Villagra[1]

[1]Georgetown Lombardi Comprehensive Cancer Ctr., Washington DC, DC,[2]Italfarmaco S.p.A., Cinisello Balsamo, Italy

Class IIb histone deacetylases, including HDAC6 and HDAC10, have garnered significant interest due to their non-canonical structure, cytoplasmic localization, and their role in immunomodulatory antitumor responses. It is reported that HDAC6 inhibitors, Tubastatin A and Nexturastat A (NextA), inhibit both HDAC6 and HDAC10 isoforms with varying selectivity. In addition, HDAC6 genetic knockout models failed to recapitulate the effects observed with highly selective and isoform-specific HDAC6is, suggesting potential off-target effects. Therefore, it is crucial to discriminate the effect of inhibiting specific isoforms of Class IIb HDACs. We previously reported that dual HDAC6/10 inhibitors significantly suppressed tumor-promoting M2-like macrophage (Mφ) function and phenotype in vitro and in vivo. In this study, we report novel HDAC inhibitors, ITF3756 and ITF6475, referred to as ITF3 and ITF6, respectively, and their effects on macrophage function and phenotype using murine bone marrow-derived Mφs (BMDMs), murine RAW264.7 cells, human PBMC-isolated monocyte-derived Mφs, and Thp1 monocyte-derived human Mφs. We performed several assays, including cytotoxicity, HDAC inhibition profiling, gene expression analysis by qPCR, flow cytometry analysis of phenotypic markers, tumor cell phagocytosis, antigen cross-presentation, and T-cell activation assays to comprehensively characterize the effect of dual HDAC6/10 inhibition vs HDAC6-specific inhibition. As reference molecules, we also used NextA (dual HDAC6/10) and CPD11352 (CPD) (HDAC6-specific) inhibitors to compare the effect on Mφs. Finally, we demonstrated the therapeutic effect of ITF3 in combination with radiation therapy to suppress prostate cancer in an immunocompetent Myc-Cap murine model. The data indicated that both cytotoxicity and HDAC inhibitory activity of ITF3 were similar to NextA, and ITF6 was similar to CPD on both murine and human Mφs. Gene expression analysis of phenotypic markers by qPCR and protein levels by immunoblot indicated that ITF3 significantly suppressed M2-like Mφs, whereas ITF6 did not. In contrast, neither ITF3 nor ITF6 affected M1 Mφs. Furthermore, murine BMDM-derived M1-like Mφs treated with ITF3 and ITF6 significantly increased tumor cell phagocytosis, SIINFEKL antigen cross-presentation, and SIINFEKL-mediated activation of OT-1 CD8 T-cells. These results mirrored the effects observed in murine and human macrophages treated with NextA and CPD. Finally, a combination of ITF3 with radiation therapy significantly suppressed Myc-Cap prostate cancer tumor growth while inducing an immune-stimulatory effect, as evidenced by increased infiltration of antitumor M1 Mφs and CD8 effector T cells. Overall, we demonstrated that dual HDAC6/10 inhibition is superior to HDAC6 inhibition alone for instigating an immunomodulatory antitumor immune response in prostate cancer therapy.

#2840 Modulation of the tumor microenvironment using 5-fluorouracil to increase T cell infiltration in breast cancer bone metastases.

Galilea Chora Hernandez[1], Paloma Almeida Luna[1], Kiomy Esparza Palomares[2], Erasmo Perez Mendez[1], Samanta Jimenez[3], Ricardo Gonzalez Sanchez[3], Candice Internicola[4], Felipe Olvera[5], **Pierrick G.J. Fournier**[3]

[1]Posgrado en Ciencias de la Vida, Centro de Investigacion Cientifica y de Educacion Superior de Ensenada, Ensenada, Mexico,[2]Centro de Nanociencias y Nanotecnologia, UNAM, Ensenada, Mexico,[3]Departamento de Innovacion Biomedica, Centro de Investigacion Cientifica y de Educacion Superior de Ensenada, Ensenada, Mexico,[4]INSERM UMR 1033, Universite de Lyon, Lyon, France,[5]Departamento Biologia Molecular y Bioprocesos, Instituto de Biotecnologia, UNAM, Cuernavaca, Mexico

Bone metastases are a frequent complication of advanced breast cancer, against which immune checkpoint inhibitors are not effective. We previously identified that PD-1$^+$ T cells in a mouse model of bone metastases are inactivated, potentially because of the expansion of PD-L1$^+$ myeloid-derived suppressor cells (MDSC) in bones. 5-Fluorouracil (5-FU) can decrease MDSC in thymoma and colon cancer models. Thus, we aim to determine the efficacy of 5-FU in breast cancer bone metastases as well as its potential side effects.Balb/C mice were inoculated in the left cardiac ventricle with 4T1 breast cancer cells to cause bone metastases within 10 days. A treatment with 4 inoculations of 5-FU (50 mg/kg) prevented splenomegaly and the expansion of PMN- and M-MDSC in bones, as assessed by flow cytometry. Treatments with doses of 10 or 25 mg/kg were not as efficient against MDSC. Also, while these lower doses tended to increase T cell infiltration, 50 mg/kg decreased it, suggesting toxicity. Thus, we modulated the number of inoculations at 50 mg/kg. Two and three inoculations decreased the splenomegaly and histological damage, but also the total number of bone marrow cells. Flow cytometry confirmed these treatments decreased PMN-MDSC, while there was only a trend toward a decrease in M-MDSC in bone metastases. More interestingly, the numbers of CD4$^+$ and CD8$^+$ T cells were increased, especially naïve and central memory T cells. On radiographs, the bone destruction caused by cancer cells was also decreased. However, a single inoculation did not cause any long-lasting effects on MDSC and T cells, and the osteolysis area was not decreased. As 5-FU sharply decreased the number of bone marrow cells in bone metastases, we sought to assess potential side effects. Three inoculations of 5-FU in healthy mice decreased neutrophils, monocytes, B cells, and NK cells in bones 3 days after the last inoculation, while T cells were still increased. However, these effects were transient since a week later, the mice had recovered. We evaluated levels of hematopoietic stem cells (HSC) and myeloid and lymphocytic progenitor cells (MPC, LPC). Surprisingly, in these conditions, 5-FU transiently increased the number of HSC and LPC, which could explain the rapid recovery, while MPC remained stable. Cancer treatments can affect bones and increase the risk of fracture, so we assessed the bone 3D microarchitecture using microCT. Two and three inoculations of 5-FU did not cause any changes in the trabecular bone volume, or the thickness or number of the trabeculae. Surprisingly, histomorphometry analysis did not reveal any changes in the number of osteoclasts, the myeloid cells dedicated to bone resorption. Thus, 5-FU could be used to decrease MDSC and increase T cells in bone metastases, turning them into a hot microenvironment to increase the efficacy of immunotherapies in breast cancer patients.

#2841 PM54 reshapes the tumor microenvironment to potentiate checkpoint blockade.

Eugenio Bustos-Moran, Daniel Torralba, Ismael Fernandez-Miranda, Maria Jose Guillen, Pablo Aviles, **Marcelo L. Ribeiro**, Carmen Cuevas

Pharma Mar, S.A., Madrid, Spain

Background: PM54, a next-generation synthetic ecteinascidin, combines enhanced DNA-minor-groove binding with dual activity: direct cytotoxicity and immune modulation through immunogenic cell death and innate signalling cascades. This study aimed to characterize the immunomodulatory effects of PM54 alone and in combination with PD-1/PD-L1 blockade in in vitro and humanized tumor models.
Methods: PBMCs from healthy donor were pre-stimulated with anti-CD3/CD28 complex and coculture for 96h with MDA-MB-231 (high PD-L1) pre-treated with PM54 and IOs (anti-PD1/PD-L1). Number of resulting target cells was analysed by flow cytometry. NXG mice engrafted with human hematopoietic CD34+ cells (Hu-CD34^{+}) were xenografted with MDA-MB-231 xenografts. Randomly allocated mice (n≥4/group) were treated with placebo, PM54 (0.6 mg/kg, i.v., Days 0, 14) ± atezolizumab (10 mg/kg, i.p., twice weekly). On day 28, animals were euthanized, and tumors weighed and analyzed by multiparametric flow cytometry and RNA-seq.
Results: In vitro coculture experiments showed an increase in the immune mediated cytotoxicity of target cells upon combination of lower doses of PM54 with atezolizumab, sensitizing cells to immunotherapy. On day 28, treatments of Hu-CD34^{+} bearing MDA-MB-231 tumors induced a statistically significant tumor reduction (vs placebo: 988.4 mm^3). The median of tumor volume (mm^3) was 305.8 (p=0.0159) for PM54, 715.6 (p=0.0317) for atezolizumab and 199.7 (p=0.0286) for the combination. Of note, statistically significant tumor reduction was also recorded in the combination vs PM54 or atezolizumab (in both, p=0.0159). In humanized MDA-MB-231, PM54 + atezolizumab expanded CD3^{+} cells (32.2% vs 9.3%), increased CD8^{+} cells (44.7% vs 19.8%), reduced Tregs (10.0% vs 42.8%), modestly increased cytotoxic NK cells, and downregulated PD-L1 on tumor and immune compartments. Transcriptomics analysis demonstrated that the combination arm renders the highest number of deregulated genes (1404 up and 981 down genes vs 537 and 908 up genes or 278 and 552 down genes in PD-L1 o PM54 treatment, respectively). Among them, GSEA showed an increase upon treatment or combination in MHC genes, IFNg and IFNα response, and NK activity and TCR signaling, leading to an enhance inflammatory response. Moreover, CIBERSORT analysis of immune populations complemented cytometry evaluation with an increase in CD8 T cells, Tfh, activated DCs and NK cells and M1/M2 ratio increase upon treatment and combination.
Conclusions: PM54 is a dual action immunochemotherapeutic that drives ICD, increases allogenic immune cytotoxicity of tumoral cells and, in vivo, augments effector CD8^{+} responses, diminishes Tregs, and reprograms suppressive myeloid cells. These immunologic effects synergize with PD-1/PD-L1 blockade, supporting development of PM54-based combinations for transcriptionally driven, immune-cold malignancies.

#2842 Investigating the capability of metformin to increase the efficacy of oncolytic herpesvirus in ovarian cancer.

Emma Sielski[1], Maria C. Courreges[2], Fabian Benencia[2]

[1]Biological Sciences,, Ohio University, Athens, OH,[2]Biomedical Sciences, Ohio University, Athens, OH

Background: Ovarian cancer (OC) is common, and frequently fatal, gynecological malignancy lacking distinct symptoms, resulting in late-stage diagnosis and difficult treatment. Although direct causes of OC are unknown, an association between OC and Type Two Diabetes (T2D) exists. Individuals with T2D, characterized by chronic metabolic dysregulation, are more likely to develop cancer later in life than those without. Recently, the effects established by anti-T2D medications, traditionally used to manage hyperglycemia, have been examined within the scope of metabolically reprogramming cancer cells to sensitize them for further treatment. Metformin is a low-cost medication currently being studied as a chemotherapy adjuvant in numerous types of cancer, given its ability to manipulate cellular glucose metabolism, proliferation pathways, and promote apoptosis. Several preclinical studies have demonstrated metformin's ability to decrease inflammation in diseases other than T2D, suggesting it influences immune responses, thus creating the possibility of a novel treatment option to increase the efficacy of current immunotherapies, such as oncolytic virotherapy. Oncolytic viruses are biological anti-tumor agents capable of selectively infecting cancer cells, eliciting an anti-cancer immune response in patients. We hypothesize that metformin dysregulates glucose metabolism in OC cells, decreasing cell viability and increasing the efficacy of oncolytic virus HSV1716. This hypothesis was tested human and mouse ovarian cancer cell lines.

Methods: Mouse ovarian cancer cells (ID8, BPPNM) or human ovarian cancer cells (A2780, SKOV3) were grown in MEM 10% FBS. For some experiments, high (5 g/l) and normal (1 g/l) glucose MEM was used. Cells were treated with 50, 25, 12.5, and 6.25 mM of metformin in 2D and 3D environments. Scratch assays were used to monitor effects on cell motility. All experiments were monitored at 24-,48- and 72- hours post-treatment. Finally, metformin was administered in conjunction with HSV-1716 at varying concentrations to OC cells.

Results and Conclusions: We observed that metformin decreased cell viability and motility, and spheroid growth as determined by MTS assays, flow cytometry analysis and light microscopy. The effect of the drug was further exacerbated by virus treatment, indicating that a combination of both therapeutic strategies is feasible. Further investigations using in vivo OC mouse models will help determine the effects of metformin on immunosuppressive cell populations in the OC tumor microenvironment and its capacity to increase oncolytic efficacy in vivo.

#2843 Changes in MAVS expression and T-cell infiltration in the tumor microenvironment following platinum-based chemotherapy in high-grade serous ovarian carcinoma.

Yuki Yasui, Erika Nakatsuka, Yusaku Shimizu, Mina Sakata, Yuki Takemoto, Gaku Yamamoto, Aasa Shimizu, Mahiru Kawano, Yasuto Kinose, Kenjiro Sawada, Michiko Kodama

Gynecology, Osaka University, Suita, Japan

Background: High-grade serous ovarian carcinoma (HGSC) exhibits low sensitivity to immune checkpoint inhibitors (ICIs), partly due to limited tumor-infiltrating T cells. Type-I interferons (IFNs) from tumor cells may enhance T-cell infiltration. We investigated MAVS (mitochondrial antiviral-signaling protein) as an inducer of Type-I IFN signaling in HGSC and analyzed its association with immune-cell infiltration in relation to paclitaxel/carboplatin (TC) therapy and prognosis.
Methods: We first included advanced HGSC cases at our institution that underwent interval debulking surgery (IDS) following neoadjuvant TC therapy. Paired pre-treatment biopsies and IDS specimens were collected for immunohistochemistry to evaluate MAVS expression in cancer cells and $CD8^+$/$CD4^+$ T-cell infiltration. Changes in MAVS expression and T-cell infiltration before and after TC therapy were analyzed, along with their correlation with sensitivity to TC. Next, using human HGSC cell lines, we assessed changes in MAVS expression and T-cell infiltration following platinum administration. Finally, we established an ID8 mouse model and divided mise into a cisplatin-treated group and a control group to compare the rate of ascites production and changes in body weight. We also compared immune-cell profiles in ascites (e.g., $CD4^+$ and $CD8^+$ T cells) and MAVS expression in tumor cells between each groups.
Results: We analyzed 45 cases treated from December 1, 2019 to August 31, 2025. MAVS expression increased after TC therapy in most cases, and this increase correlated with enhanced $CD8^+$ T-cell infiltration. In prognostic analyses, decreased MAVS expression after TC therapy was associated with poor prognostic features.
In cell line experiments, MAVS expression was enhanced in platinum-treated cell lines, as demonstrated by Western blotting.
In the ID8 mouse model, the rate of ascites production was faster in the cisplatin-treated group. We also visualized the proportions of immune cells within ascites in this group. Tumor cells derived from this model likewise exhibited increased MAVS expression in the cisplatin-treated group, as demonstrated by Western blotting.
Conclusions: In HGSC, TC therapy-induced changes in MAVS expression may contribute to the induction of $CD8^+$ T-cell infiltration. In vivo, platinum administration similarly suggested potential alterations in MAVS expression and immune-cell infiltration. MAVS may serve as a biomarker for patient selection in ICI therapy for HGSC.

#2844 Cannabis smoking increases systemic inflammation and reduces immunity.

Adele Hammoudi, Mayilvanan Chinnaiyan, Sulfath Thottungal Parambil, Gautham Chengizkhan, Vengatesh Ganapathy, Lurdes Queimado

Otolaryngology, University of Oklahoma Health Sciences, Oklahoma City, OK

Introduction: Cannabis is the most used federally illegal drug in the United States with a percentage increased from 19.0% in 2021 to 22.3% in 2024 among people aged 12 or older. Smoking remains the most common mode of cannabis use, even among cancer patients. Despite the anti-inflammatory potential of certain cannabinoids, cannabis smoke contains numerous carcinogens and toxicants that can potentially disrupt immune homeostasis and heighten inflammation. Understanding these effects is crucial as inflammation and immune function shape cancer development, progression, and therapeutic response. Objective: To characterize systemic inflammation and immune alterations associated with cannabis smoking.

Methods: Following IRB approval, 44 participants were recruited via Redcap, a secure online survey. Demographics, substance use data, and blood samples were collected for a total of 24 non-users (NU) and 20 exclusive cannabis users (CAN) who smoke cannabis at least bi-weekly over the past month. Users of tobacco products, including blunts and e-cigarettes, were excluded. Product use status was biochemically verified using liquid chromatography tandem mass spectrometry (LC-MS) to quantify THC and its metabolite THC-COOH. Complete blood count (CBC) was obtained on each participant and (CBC)-derived inflammatory markers were calculated. A novel 13-antibody multiparametric flow cytometry panel was used to separate 21 immune cell subsets characterizing both myeloid and lymphoid cells. Data was analyzed using Welch's t-tests.

Results: Our CBC data show significantly higher red blood cell distribution width-standard deviation ($p=0.038$) and lower absolute number of monocytes ($p=0.038$) in CAN users compared to NU. We also observed a significant increase in platelet-to-lymphocyte ratio in CAN users vs NU ($p=0.028$). Our myeloid immune cell phenotyping data show that cannabis smokers have significantly higher number of low-density neutrophils (LDNs) than NU ($p=0.035$). Preliminary lymphoid immune cell phenotyping data suggest that cannabis smokers have significantly fewer B cells ($p= 0.014$) and activated B cells ($p= 0.016$) than NU. Our preliminary data also show a non-significant decrease in $CD8^+$ T cells. These findings indicate that cannabis smoking induces systemic inflammation (higher PLR and LDNs) and suppresses immune responses (fewer B and CD8+ T cells).

Conclusions: Our data demonstrate for the first time that cannabis smoking induces a proinflammatory and immunosuppressive state that may promote diverse human diseases, including cancer. We established the first comprehensive framework to evaluate the immunological effects of cannabis smoking. These findings reveal how cannabis use profoundly alters the immune system at both cellular and functional levels. Grant support: NIH/NCI (R01CA242168, Queimado); TSET HPRC (Queimado); PHF Bridge (Queimado); NIH/ NIGMS (U54GM104938-10)

#2845 Human serum proteomics reveals extracellular vesicle-mediated metabolic-adhesive signaling and suppression of adaptive immunity in E-cigarette users.

Rizwana Begum, Shilpa Thota, Shreya Pokharel, Biplov Sapkota, Joseph Francis

Louisiana State University, Baton Rouge, LA

Background: While the toxicological impact of combustible cigarette smoke is well characterized, the systemic biological consequences of electronic cigarette use remain poorly understood. As serum contains secreted and vesicle-associated proteins, it provides a window into early biological responses to vaping. We performed serum proteomics to determine how vaping shapes the biology of extracellular vesicles (EVs), metabolic stress pathways, and immune function in humans.
Methods: Serum from adult e-cigarette users and non-vaper controls underwent LC-MS/MS proteomics followed by Gene Set Enrichment Analysis (GSEA) across GO Biological Process (BP), Cellular Component (CC), Molecular Function (MF), KEGG, and curated MSigDB C2 secretome/EV signatures.
Results: Our results demonstrate that serum from human vapers showed increased expression of glycolytic and oxidative stress-adaptive enzymes (GPI, PKM, IDH1, SOD2), along with significant upregulation of Hypoxia up-regulated protein 1 (HYOU1), indicating engagement of a hypoxia-responsive/ER stress metabolic program. Concordantly, GSEA revealed enrichment of glycolysis, carbon metabolism, ribonucleoside metabolism, and precursor metabolite generation. Cellular component analysis identified strong enrichment of extracellular vesicle, secretory vesicle, membrane-enclosed lumen, and curated secretome signatures, accompanied by upregulation of ECM-cytoskeletal remodeling pathways, including focal adhesion, ECM-receptor interaction, and actin filament organization. These EV-linked pathways were supported by increased abundance of EV-associated adhesion molecules and immunomodulatory factors, including the Neural cell adhesion molecule L1-like protein (CHL1) and the integrins **ITGB1** and **ITGB2**, which are known to be packaged into EVs during epithelial or immune stress. In parallel, immune-related pathways, including adaptive immune response, immunoglobulin-mediated immunity, and antigen binding, were the only processes negatively enriched, indicating selective suppression of humoral immunity.
Conclusions: Chronic e-cigarette use induces a coordinated serum phenotype characterized by hypoxia/ER stress-induced metabolic reprogramming, enhanced extracellular vesicle and adhesion signaling, and downregulation of adaptive immune mechanisms. These findings suggest that metabolic stress-driven EV secretion may contribute to altered immune communication and weakened antibody-mediated responses in e-cigarette users.

#2846 Inflammasome dependent and independent dysregulation associated with periodontal disease and oral cancer risk in people with HIV.

Alejandro Yamil Odeh[1], Juliana Mary Serrano-Rodriguez[2], Jurelis Torres Reyes[1], Oscar Antonio Loperena Gonzalez[1], Jeannette L. Salgado Montilla[1], Ramon F. Gonzalez-Garcia[1], Gabriel Borges Velez[1], Josue Perez-Santiago[1]

[1]University of Puerto Rico Comprehensive Cancer Center, San Juan, PR,[2]University of Puerto Rico - Rio Piedras, San Juan, PR

Introduction: People with HIV (PWH) exhibit immune dysregulation, which can increase their susceptibility to periodontal disease (PD), elevating the risk of chronic oral inflammation, tissue damage, and oncogenesis. Persistent periodontitis may drive the development of oral squamous cell carcinoma (OSCC) through increased prevalence of pathogenic bacteria and elevated levels of inflammatory cytokines. In fact, our preliminary data show dysbiosis of the oral microbiome associated with PD. Furthermore, PD can be associated with inflammasome dysfunction, which can impact downstream production of cytokines. In PWH, these inflammatory processes may be exacerbated, fostering a pro-oncogenic microenvironment. This study aims to quantify levels of inflammasomes and inflammatory markers in PWH and evaluate their association with PD and OSCC risk.

Methods: Saliva and oral rinse samples, along with sociodemographic and clinical data, were collected from 202 virologically suppressed PWH. A comprehensive periodontal assessment was performed, and participants were categorized into four groups based on PD severity: none, mild, moderate, and severe. Protein levels of inflammasomes (NLRP3 and NLRC4) were quantified in saliva using ELISA, while cytokine concentrations (IL-1β, IL-4, IL-6, IL-8, IL-10, IL-17A, and TNF-α) were quantified using ELLA. Statistical analyses were performed using R statistical software. Median values were compared using Mann-whitney or Krukal-wallis tests with post-hoc adjustment.

Results: Participants with PD exhibited significantly higher levels of IL-1β (400 pg/mL vs 235 pg/mL, $p<0.01$), IL-6 (25.4 pg/mL vs 14.2 pg/mL, $p<0.01$), and IL-8 (798 pg/mL vs 549 pg/mL, $p=0.04$) while there was a trend for higher levels of IL-17 (2.01 pg/mL vs 1.50 pg/mL, $p=0.05$). In addition, IL-1β was significantly higher in subjects with moderate (408 pg/mL, $p=0.01$) and severe PD (378 pg/mL, $p=0.01$) when compared to no PD (235 pg/mL). On the other hand, while there was no significant difference in the levels of NLRP3 and NLRC4 by PD status, people with severe PD (3.37 ng/mL) had significantly lower levels of NLRP3 when compared to moderate (5.83 ng/mL, $p<0.01$) or no PD (5.71 ng/mL, $p=0.02$).

Conclusion: There were increased levels of inflammatory cytokines, particularly IL-1B, and alterations to inflammasome levels according to PD severity, supporting the role of pyroptosis in the pathogenesis of PD. Chronic elevation of additional pyroptosis independent inflammatory cytokines and dysbiosis of the oral microbiome may contribute to a persistent inflammatory microenvironment associated with increased OSCC risk in PWH. These results highlight the importance of monitoring oral cytokine profiles as both biomarkers of disease progression and potential indicators of cancer risk in PWH.

#2847 Sweet boost: Sucralose enhances regulatory T cell (Treg) functions *in vitro*.

Sadhana Bom[1], Jessica A. Jana[2], Kelsey M. Ertwine[2], Rachel Cumberland[3], Kristin T. Morder[2], Abigail E. Overacre-Delgoffe[2]

[1]University of Pittsburgh School of Medicine, Pittsburgh, PA,[2]Department of Immunology, University of Pittsburgh School of Medicine, Pittsburgh, PA,[3]UPMC Hillman Cancer Center, Pittsburgh, PA

Non-nutritive sweeteners (NNS) like sucralose, aspartame, and saccharin are widely used as sugar alternatives. While the FDA considers NNS safe, concerns about their long-term effects are growing. Sucralose, derived from sucrose and about 600 times sweeter, has been shown to dampen the efficacy of anti PD-1 in cancer in both mice and human. It lowers the T- cell cytotoxic function and enhances regulatory T cell (Treg) proliferation. Tregs are vital for immune tolerance but potently suppress anti-tumor immunity in the tumor microenvironment. How sucralose enhances Treg function still unknown, representing a critical gap in understanding potential dietary influences on cancer immunotherapy. Therefore, studying the sucralose -Tregs interactions is a novel approach to understand possible resistance mechanisms in cancer. We isolated Tregs from Foxp3-reporter mice and treated them with varying concentrations of sucralose *in vitro*. Cell proliferation was monitored daily via cell counting, while Tregs phenotype and function were evaluated using flow cytometry. A suppression assay was performed by coculturing Tregs (treated with 0 mM, 0.05 mM, or 0.5 mM sucralose) with CD8+ T cells. Sucralose's effect on Treg differentiation and metabolism was assessed using the naïve CD4+ T cell differentiation and Seahorse assays, respectively. Our study showed that sucralose significantly enhances proliferation, suppressive capacity, and differentiation of Treg *in vitro* while also increasing the mitochondrial spare respiratory capacity, suggesting improved metabolic fitness in these cells. These findings highlight the interactions between sucralose and Tregs, which may help us to understand how artificial sweeteners influence immune regulation and resistance mechanisms in cancer, offering insights for future *in vivo* research and informing dietary recommendations and immune modulation strategies in cancer treatment.

#2848 Harnessing SHP2-targeted signaling to reinforce anti-tumor immune responses.

Bayarbat Tsevegjav[1], Hirotake Tsukamoto[2], Osamu Kikuchi[1]

[1]Division of Clinical Pharmacology and Cancer Immunotherapy, Center for Cancer Immunotherapy and Immunobiology, Graduate School of Medicine, Kyoto University, Kyoto, Japan,[2]Division of Clinical Immunology and Cancer Immunotherapy, Center for Cancer Immunotherapy and Immunobiology, Graduate School of Medicine, Kyoto University, Kyoto, Japan

Background: SHP2, a non-receptor protein tyrosine phosphatase, regulates both immune checkpoint signaling via PD-1 and oncogenic RAS/MAPK pathways, making it a promising target for integrated anti-cancer therapy. While SHP2 inhibitors have been primarily investigated for their tumor-intrinsic effects, their immunomodulatory potential remains unclear. Therefore, we investigated whether SHP2 inhibition can simultaneously relieve PD-1-mediated T cell suppression and inhibit tumor-intrinsic MAPK signaling, a dual-action mechanism particularly for tumors driven by RAS/MAPK signaling.
Methods: Primary murine T cells and human Jurkat T cell lines were used to assess the immune cell responses. Flow cytometry was performed to characterize T cell activation, and cell viability was quantified using WST-1 and CellTiter-Glo assays. T cell-mediated cytotoxicity against cancer cells was evaluated by the LDH release assay. qPCR was conducted to analyze the gene expression profiles related to immune activation. To assess the impact on oncogenic signaling, RAS/MAPK pathway activity was measured by western blotting. For in vivo evaluation, mice bearing MC38-OVA syngeneic tumors received oral SHP2 inhibitor TNO155 (10 or 20 mg/kg, BID for 14 days).
Results: Pharmacological inhibition of SHP2 using TNO155 (1 nM-10 μM) did not affect T cell viability, indicating its suitability for in vitro immunological analysis. Despite its minimal cytotoxicity, SHP2 inhibition significantly modulated T cell activation. Flow cytometric analysis revealed the upregulation of activation markers, including CD69 and Granzyme B expression, alongside enhanced T cell-mediated cytotoxicity against tumor cells, as measured by LDH release assay (increase of 20.9% cytotoxicity at 1 μM TNO155; $P < 0.05$). In syngeneic tumor-bearing immunocompetent mice, oral administration of TNO155 (p.o. BID) led to a significant reduction in tumor volume compared to vehicle-treated controls (tumor growth inhibition: 39.6% (10 mg/kg; $P < 0.05$) and 62.4% (20 mg/kg; $P < 0.01$) on day 14. Immunohistochemical and flow cytometric analyses detected the infiltration of $CD8^+$ tumor-infiltrating lymphocytes, and qPCR revealed elevated expression of IFNγ-responsive genes, including *Cd274* (~2.2-fold induction; $P < 0.001$) in tumors. Notably, intratumoral $CD8^+$ T cells exhibited enhanced effector function, with a marked increase in Granzyme B^+ cells (control: 4.46 ± 1.86%; TNO155: 18.94 ± 12.27; $P < 0.05$) and a decrease in exhaustion markers TIM-3 and LAG-3.
Conclusions: These findings demonstrate that SHP2 inhibition enhances anti-tumor immune responses and supports its potential as a dual-function therapeutic strategy in cancer immunotherapy. This study provides a robust preclinical foundation for the translational development of SHP2-targeted approaches in precision oncology.

#2849 Endostatin and prolactin combination trigger PRLR induction and channelize CD1d signaling in TNBC.

Ritis Kumar Shyanti[1], Rajesh Singh[2], **Manoj K. Mishra**[1]

[1]Cancer Research Center, Department of Biological Sciences, Alabama State University, Montgomery, AL,[2]Microbiology, Biochemistry, and Immunology, Cancer Health Equity Institute, Morehouse School of Medicine, Atlanta, GA

Triple-negative breast cancer (TNBC) is a very aggressive breast cancer subtype and therapeutically challenging because of the absence of hormone receptors (ER, PR and HER2). TCGA datasets revealed that prolactin receptor (PRLR) was downregulated in TNBC, associated with poor overall survival. PRLR induction has been shown to reduce tumor proliferation in TNBC. However, no pharmacologically active molecule has been reported that can induce PRLR. In addition, natural killer T (NKT) cells, potent antitumorigenic immune cells activated via CD1d lipid antigen interactions, are diminished in TNBC tumors. Prior studies have demonstrated that CD1d expression is crucial for the progression of breast tumors and regulates antitumor immune responses mediated by NKT cell activation. In this study, we found that treating endostatin (2.5 μM), an anti-angiogenic protein, in combination with prolactin (2.5 nM) significantly reduced the proliferation and colony-forming potential of TNBC cells. The treatment combination was found to induce PRLR and CD1d expression (CD1d A and B isoforms) in the TNBC cell line MDA-MB-468. Further, we observed that the combination reduced epithelial-mesenchymal transition (EMT) markers and oxidative phosphorylation marker COXIV. Human NKT cells were isolated from PBMCs and co-cultured with treated TNBC cells. NKT activation was quantified by IFN-γ secretion using ELISA. Additional analyses using TNBC tissue slides are undergoing to determine PRLR and CD1d co-expression patterns. Our findings identify endostatin-mediated restoration of the PRLR as a novel strategy to restrict TNBC cell growth while simultaneously enhancing CD1d-dependent NKT cell activation, representing a promising therapeutic option for TNBC.

#2850 PHI-501, a novel pan-RAF inhibitor, enhances immunotherapy efficacy by converting cold tumors into hot tumors.

Sung Eun Kim[1], Sue Min Kim[1], Ky-Youb Nam[2], JeongHyeok Yoon[2], Sang Joon Shin[3]

[1]Yonsei University College of Medicine, Seoul, Korea, Republic of,[2]Pharos iBio Co., Ltd., Anyang, Korea, Republic of,[3]Division of Medical Oncology, Department of Internal Medicine, Yonsei Cancer Center, Seoul, Korea, Republic of

Background: Immune checkpoint blockade (ICB) has significantly improved survival outcomes in patients with melanoma; however, a substantial proportion of patients remain non-responsive. Therefore, converting “cold” tumors into “hot” tumors represents a critical therapeutic strategy to enhance responsiveness to ICB therapy. PHI-501, a novel pan-RAF inhibitor, is proposed to enhance immunotherapy responsiveness by promoting immune activation and converting “cold” tumors into “hot,” immune-inflamed tumors. In this study, we sought to characterize the immunomodulatory mechanisms by which PHI-501 primes antitumor immunity in melanoma.

Methods: RNA sequencing was performed on SK-MEL-3 ($BRAF^{V600E}$) melanoma cells treated with PHI-501 (10 μM, 48 h), followed by gene set enrichment analysis (GSEA) to identify immune-related transcriptomic alterations. To validate immune activation, SK-MEL-3 melanoma cells were treated with PHI-501 and analyzed for JAK/STAT signaling and type I interferon (IFN) response using quantitative PCR (qPCR). Additional experiments with IFN-γ (24 h) co-treatment were performed to assess MHC class I induction. Western blotting was performed on cell lysates and culture supernatants to measure intracellular immune markers and the extracellular release of HMGB1 in SK-MEL-3 and SK-MEL-29 ($BRAF^{V600E}$).

Results: GSEA of RNA-seq data from PHI-501-treated SK-MEL-3 cells revealed enrichment of the type I interferon response (NES = 1.17, p = 0.14) and the tissue-specific immune response (NES = 1.64, p = 0.01). PHI-501 treatment downregulated the expression of key MAPK pathway regulators such as DUSP6, SPRY4, ETV4, and ETV5, while upregulating canonical interferon-stimulated genes (ISGs) including IFIT1, IFIT2, IFIT3, and IRF1 ($p<0.05$). Consistent with the transcriptomic results, qPCR analysis demonstrated robust induction of immune-related genes. In SK-MEL-3, STAT2, IFNA1, and IRF1 transcripts were upregulated approximately 12-, 9-, and 7-fold, respectively. Furthermore, IFN-γ co-treatment synergistically enhanced MHC class I expression, increasing levels by more than 7-fold in SK-MEL-3 compared with controls. Additionally, extracellular HMGB1 levels increased in culture supernatants of SK-MEL-3 and SK-MEL-29 cells, accompanied by elevated IRF1 and NLRP3 protein expression in cell lysates.

Conclusion: Taken together, these findings demonstrate that PHI**-**501 activates immune-related signaling pathways, including the type I IFN and downstream JAK/STAT cascades. Overall, these results suggest that PHI-501 may serve as a promising therapeutic agent capable of enhancing ICB responsiveness when used in combination with immunotherapy.

#2851 EGFR-TKI drives the reprogramming of CD8$^+$ T cell immunity in non-small cell lung cancer.

Ssu-Pei Yu[1], Hao-Chen Chi[1], Meng-Yun Lin[1], Chao-Chi Ho[2], Geen-Dong Chang[3], Ming-Shyue Lee[4], Chun-Jung Ko[1]

[1]Graduate Institute of Immunology, National Taiwan University, Taipei City, Taiwan,[2]Department of Internal Medicine, National Taiwan University Hospital, Taipei City, Taiwan,[3]Graduate Institute of Biochemical Sciences, National Taiwan University, Taipei City, Taiwan,[4]Department of Biochemistry and Molecular Biology, National Taiwan University, Taipei City, Taiwan

Non-small cell lung cancer (NSCLC), the most common type of lung cancer, remains the leading cause of cancer-related deaths globally. Although different cancer-driving mutations have been reported in NSCLC, their prevalence varies across ethnic groups. Among Asian patients, EGFR mutations have been reported to be the most prevalent. EGFR tyrosine kinase inhibitors (EGFR-TKI) are applied to NSCLC patients carrying EGFR mutations, although EGFR-TKIs are effective treatments, their potential impact on the immune system remains largely unknown. Understanding the interactions between EGFR-TKIs and immune regulation is crucial for developing combination therapy strategies. In this study, we demonstrated that EGFR-TKI suppresses the activation, proliferation, and effector cytokine production of CD8$^+$ T cells. Moreover, in therapeutic models, EGFR-TKI treatment negatively impacts the antitumor response of CD8+ T cells. Notably, when EGFR-TKIs were combined with anti-PD-1 therapy, tumor growth was increased compared with anti-PD-1 monotherapy, indicating that EGFR-TKIs may diminish the efficacy of immune-checkpoint blockade. In parallel with our findings in mouse models, studies of NSCLC patients who underwent EGFR-TKI also showed decreased CD8$^+$ T cell activation and IFNγ production. Moreover, we identified potential EGFR-TKI-interacting targets in T cells and found that EGFR-TKIs bind to actin-interacting proteins, thereby disrupting cytoskeletal organization and compromising T-cell function. Together, these results reveal an EGFR-independent mechanism through which EGFR-TKIs attenuate CD8$^+$ T-cell antitumor activity. In conclusion, our findings not only suggest a suppression effect of EGFR-TKI on CD8$^+$ T cells but also provide crucial information on developing EGFR-TKI combination strategies with immunotherapies for NSCLC patients.

#2852 Targeting notch signaling in triple negative breast cancer with a novel adeno-associated virus-mediated therapy to enhance immunomodulation.

Mrityunjoy Biswas[1], Md. Manirujjaman[1], Yong Ran[2], Samarpan Majumder[1], Luis Del Valle[1], Jovanny Zabaleta[1], Barbara A. Osborne[3], Lucio Miele[1], Todd Golde[2], **Fokhrul Hossain**[1]

[1]LSU Health New Orleans, New Orleans, LA,[2]Emory University, Atlanta, GA,[3]University of Massachusetts, Amherst, Amherst, MA

Triple-negative breast cancer (TNBC) is a group of aggressive breast cancers with a higher mortality rate. TNBC patients have a higher rate of mortality due to metastasis or local recurrences, which are chemo- and radio-resistant. Notch signaling has emerged as an important factor in TNBC. There is strong evidence for Notch signaling involvement in TNBC. Recent studies suggest that Cancer Stem cells (CSCs) that emerge after chemotherapy or targeted agents in TNBC are often Notch-dependent. Notch inhibitors, including Gamma Secretase Inhibitors (GSIs), are quite effective in preclinical models of TNBC because they eliminate CSCs that are resistant to chemotherapy. Unfortunately, this approach has had minimal success in clinical trials due to its intestinal toxicity and adverse effects on immune cells. To avoid these toxicities, we aim to use a recombinant adeno-associated virus (r-AAV) vector encoding a soluble Notch1 decoy (r-AAV-Notch1D) to block Notch signaling intratumorally in TNBC. r-AAVs are non-replicating viruses and, therefore, are a safe platform for *in vivo* gene delivery. We found that r-AAV-GFP transduced both human and mouse TNBC cells. Our r-AAV constructs contain a C1QTNF3-derived collagen domain (CD) that facilitates the trimerization and stabilization of secreted fusion proteins. We purified these proteins using His-Tag affinity chromatography and found that they significantly reduced mammosphere growth in human TNBC cells and reduced Notch intracellular domain (NICD) expression. Intratumoral injections of the r-AAV-Notch1D virus significantly reduced syngeneic mouse TNBC tumor (C0321) growth and increased the tumor-infiltrating lymphocytes, including CD3 and CD8. Notably, the r-AAV-Notch1D virus significantly enhanced the efficacy of immunotherapy (a-PD1) in mediating the anti-tumor effect in the syngeneic TNBC mouse model. We performed RNA sequencing to identify tentative target(s) for r-AAV-Notch1D. We found that *Hmox1, Timp3, Il33, Adam8, Ero1l,* and *Saa3* genes were upregulated, on the other hand *Gm11408, Gm9844, Gm11407, Gm8430, Rnu3a, and Per1* genes were downregulated upon the treatment. From our Gene Ontology analysis, we found that r-AAV-Notch1D treatment enhanced hexosaminidase activity, carbohydrate catabolic process, covalent chromatin modification, histone modification, and histone acetylation. r-AAV-Notch1D treatment also altered several cellular pathways, including MicroRNAs in cancer, Ferroptosis, Porphyrin metabolism, Mineral absorption, and the Cytosolic DNA-sensing pathway. Given the diverse biological functions of these pathways, further study is warranted to elucidate their roles in TNBC. Overall, our findings indicate that the r-AAV-Notch1D virus is a promising approach for treating TNBC, alone or in combination with immunotherapy, and is a candidate for translational application.

#2853 VPAC antagonism as potential therapeutic for prostate cancer.

YuJie Chen, Tuisha Gupta, Kiranj Chaudagar, Edmund K. Waller

Emory University School of Medicine, Atlanta, GA

Background: Tumor-associated macrophages (TAM) within prostate cancer (PC) microenvironment correlates with poor clinical outcomes and with acquired resistance to androgen-deprivation therapy (ADT). Our preclinical work has established that macrophage phagocytosis can partially restrain PC growth at both castration-sensitive and -resistant stages; however, this response remains incomplete. We therefore hypothesized that activating phagocytosis by targeting androgen-regulated checkpoints on macrophages empowers ADT and provides a combinatorial therapeutic strategy to control PC via anti-tumor immunity.
Methods: Bone marrow-derived macrophages (BMDM) profiled using RNA sequencing and Western blot to identify androgen-regulated immune checkpoints, followed by functional validation in polarization and phagocytosis assays. In vivo anti-tumor efficacy of candidates was tested using syngeneic TrampC1, Myc-CAP, cMyc-Rb-knockout (KO) models in both wildtype (WT) and immune checkpoint-knockout mice. Treatment with androgen receptor (AR) and immune checkpoint blockade alone and the combination arms with relevant untreated controls.
Results: Transcriptomic and proteomic profiling revealed selective upregulation of VIP receptor 1 (VPAC1) on immunosuppressive M2-like BMDM vs anti-tumor M1-like. Functional assays revealed an increased IL-12 expression in BMDM following AR and VPAC co-blockade. Enzalutamide upregulated VPAC1 on both M1/M2-like BMDM. It also increased phagocytosis of PC cells in VIP-KO BMDM relative to untreated control, but not in WT, indicate that VPAC1 serves as an androgen-regulated macrophage-suppressive checkpoint. Bioinformatic analysis showed positive correlations between 1) VPAC1 and AR, and 2) VIP and synaptophysin (SYP) in prostate adenocarcinoma samples. Furthermore, degarelix improved the survival of syngeneic TrampC1 tumor (harboring both adenocarcinoma and neuroendocrine phenotypes)-bearing mice, particularly in VPAC1-KO mice, compared to VIP or VPAC2-KO and WT controls, with corresponding benefits in prostate tumor growth control. In the androgen-sensitive Myc-CAP syngeneic model, a potent VIP receptor antagonist, ANT308, increased degarelix-mediated tumor control. ANT308 treatment yielded similar effects in androgen-independent Myc-Rb-KO PC model, highlighting the synergy of co-blocking VIP/VPAC and AR pathways for controlling PC.
Conclusions: VPAC1 is an androgen-regulated macrophage checkpoint. VPAC inhibition with ANT308 leads to anti-tumor phagocytosis and enhances ADT-mediated control of prostate tumors in both adenocarcinoma and mixed adeno-neuroendocrine diseases. Further mechanistic investigation is needed to elucidate the intrinsic versus extrinsic role of VIP/VPAC at those stages, informing the design of clinical trials for ANT308 in PC patients.

#2854 Antibiotics blunt the innate immune mechanisms underlying HER2+ breast cancer therapy efficacy.

Lily J. Parker[1], Payal Mitra[1], Nofar Erlichman[1], Pavani Chalasani[2], Rong Li[1], Romina E. Araya[1]

[1]Biochemistry and Molecular Medicine, George Washington University School of Medicine and Health Sciences, Washington, DC,[2]George Washington Cancer Center, Washington, DC

Cancer patients are especially vulnerable to infections. About 20-60% of patients may receive antibiotics at some stage during their treatment, including perioperative care and neutropenic periods. Retrospective studies indicate that antibiotics can negatively affect outcomes in various cancers. HER2+ breast cancer (BC) patients often receive targeted treatments such as anti-HER2 antibodies and/or small-molecule tyrosine kinase inhibitors (TKI), which remain understudied in this context. Published work indicates that HER2+ BC patients experience more severe reductions in survival following antibiotic exposure than HER2-negative cases. Although this antibiotic effect is thought to result from host microbiota disruptions, the precise mechanisms remain unclear. To understanding how antibiotics specifically affect HER2 therapies, we examined how antibiotics influence responses to HER2-targeted therapies using an orthotopic HER2+ BC mouse model, administering an oral broad-spectrum antibiotic cocktail (ABX) to deplete the microbiota or water (H2O) as a control, and employing an anti-HER2 antibody (anti-HER2/neu) or the TKI neratinib. While antibiotic treatment alone did not influence tumor growth, it notably impaired responses to HER2 therapies. To simulate clinical scenarios, we administered oral ciprofloxacin (cipro) or amoxicillin/clavulanic acid (am/clav), common antibiotics used for cancer patients, alongside neratinib, which was most affected by ABX. Cipro reproduced the ABX effect, completely blocking neratinib response, while am/clav caused a partial impairment. Next, we characterized immune cells in tumors and the bloodstream after HER2-targeted therapy by spectral flow cytometry. In H2O mice, both HER2 therapies led to immune remodeling of the tumors, with reduced tumor-associated neutrophils and macrophages, and increased NK, CD8+, and CD4+ T cell infiltration. In contrast, NK cells were systemically decreased in untreated ABX mice compared with H2O mice and did not recover after therapy, explaining the failure to recruit these cells to the tumor site in ABX mice. To assess the role of NK cells in therapy efficacy, we depleted NK cells with an anti-asialo-GM1 antibody before and during HER2 therapies. As expected, NK cell depletion abolished the anti-HER2 response but also led to a partial reduction in neratinib efficacy, hinting that neratinib engages tumor-extrinsic innate immune mechanisms influenced by antibiotics. Overall, our findings show that antibiotic-induced disruption of the gut microbiota hampers HER2+ BC therapy by impairing the immune response both systemically and within the tumor microenvironment.

#2855 Evaluation of ^{212}Pb-PSMA radioligand therapy in an immunocompetent prostate cancer model.

Melissa Monterosso[1], Aneesha Jones[1], Kayden Kwah[2], Anna Amiss[1], Didier Boucher[1], Aimee Horsfall[1], Heather Green[1], Johannes Koehbach[1], Ralph Huebner[1], Yaowu He[2], Stephen Rose[1], Gary Li[1], Feifei Liu[1], Joana Brilhante[1], Simon Puttick[1], Anna Karmann[1], John Hooper[2], **Thomas Kryza**[1]

[1]AdvanCell Pty Ltd, Sydney, Australia,[2]Mater Research Institute, Brisbane, Australia

Introduction: Prostate cancer (PC) is the second leading cause of cancer-related death in men, and metastatic castration-resistant prostate cancer (mCRPC) remains incurable. Prostate-specific membrane antigen (PSMA) is a validated therapeutic target. Targeted alpha therapies (TAT) employing radionuclides such as lead-212 (^{212}Pb) and actinium-225 (^{225}Ac) are in development, delivering high-linear-energy-transfer radiation with potent cytotoxic and potentially immunomodulatory effects. However, currently available PSMA-positive preclinical models rely on human xenografts, which do not allow for the study of radioligand therapy-induced immune modulation.

Objective: The immunomodulatory effects of PSMA-targeted alpha therapy are believed to play a key role in the anti-tumor efficacy towards PC. However, the lack of immunocompetent *in vivo* models of PSMA-positive PC has been a major hurdle in mechanistic and translational studies. To overcome this, we established a syngeneic prostate cancer model expressing murine PSMA (mPSMA) and developed a high-affinity PSMA-directed TAT tool compound specific to mPSMA.

Methodology: Murine bone-metastatic prostate cancer cell line, RM1-BM, which recapitulates late-stage TP53-mutant disease, was engineered to express murine FOLH1 (mPSMA) using the PiggyBac transposon system. Expression of mPSMA was confirmed both *in vitro* and *in vivo* by western blotting and immunohistochemistry. The affinity and specificity of the TAT agent ^{212}Pb-PS0001 (AdvanCell) for murine and human PSMA were assessed using inhibition and cytotoxicity assays. Biodistribution and therapeutic efficacy were assessed in immunocompetent C57BL/6 mice bearing mPSMA-RM1-BM tumors. Blood and tissue samples collected from treated animals underwent multiomics analyses to characterize immune response modulation induced by ^{212}Pb-PS0001.

Results: RM1-BM-mFOLH1 cells expressed mPSMA at levels comparable to human PSMA-positive C4-2 cells. ^{212}Pb-PS0001 exhibited high-affinity, selective binding and robust tumor uptake in RM1-BM-mFOLH1 models, with minimal off-target accumulation. Therapeutic evaluation demonstrated that a single administration of ^{212}Pb-PS0001 significantly inhibited RM1-BM-mFOLH1 tumor growth in immunocompetent mice, whereas untreated controls showed progressive disease. Notably, several treated animals achieved durable tumor control, suggesting potential induction of an anti-tumor immune response.

Conclusion: By establishing a syngeneic, mPSMA-positive metastatic prostate cancer model, we enabled the evaluation of PSMA-TAT in an immunocompetent setting. Preliminary studies with ^{212}Pb-PS0001 demonstrated selective PSMA targeting, favorable pharmacokinetics, and potent anti-tumor efficacy, supporting its utility as a PSMA-TAT tool compound for investigating immune-mediated mechanisms of action in prostate cancer.

#2856 Induction of immunogenic cell stress through the inhibition of topoisomerase I.

AbbVie Inc., North Chicago, IL

When normal tissue homeostasis cannot be maintained, cells initiate distinct pathways of regulated cell death (RCD) to preserve health of the organism. Exploiting RCD pathways to induce tumor cell death is a mainstay of cancer therapy. More recently it has become appreciated that the manner in which cancer cells die can have drastic impacts on local tissue microenvironments and ultimately disease progression. Emerging preclinical and clinical data suggest certain forms of RCD can cause the release of damage-associated molecular patterns (DAMPS) to not only activate innate immunity but also generate antigen-specific adaptive immune responses, a defining feature of immunogenic cell death (ICD). In addition to bona fide ICD, it is recognized that tumor cells paralyzed in a non-replicative senescent state are also highly immunogenic through the release of immunostimulatory soluble factors, upregulation of major histocompatibility complex (MHC) molecules, and altering the array of antigens presented to T cells.
Clinical data with topoisomerase I inhibitor (TOP1i)-ADCs show responses in numerous human cancers with growing evidence that immune system engagement may contribute to their clinical activity. Therefore, we sought to determine the immunogenicity of topoisomerase I inhibition. TOP1i treatment *in vitro* induced a highly immunogenic state of murine tumor cells, which when injected to mice, acted as a cellular vaccine and resulted in the rejection of secondary live tumors. Vaccination with TOP1i treated cells required host type 1 conventional dendritic cells (cDC1) and $CD8^+$ T cells for protection. Interestingly, characterization of cell death kinetics following TOP1 inhibition reveled that the immunogenicity of TOP1i treated cells is largely derived from stressed, living cells rather than dead cells. Treatment with highly immunogenic doses of TOP1i *in vitro* revealed that tumor cells rapidly alter their physiology to exhibit multiple hallmarks of cellular senescence. Following TOP1i treatment, tumor cells were durably arrested in cell cycle (G2M), upregulated p21, exhibited heightened β-galactosidase activity and produced inflammatory senescence associated secretory phenotype (SASP) cytokines, as well as type I IFNs, and became sensitive to senolytic agents. Moreover, TOP1i treated cells were able to induce robust cDC1 activation and promote the acquisition of a mregDC like phenotype which was dependent on tumor expression of the stimulator of interferon genes (STING). Using a human antigen expressing syngeneic tumor model we demonstrated that TOP1i-ADC activity was greatly enhanced in the presence of adaptive immunity and synergizes with anti-PD1 therapy. Together these data highlight the immunogenic nature of topoisomerase I inhibition and provide new insights into the potential mechanism underlying the emerging clinical benefits of TOP1i-ADCs for the treatment of cancer.

#2857 Repeated RFA remodels the PDAC microenvironment and synergizes with CSF1R blockade and checkpoint inhibition to enhance anti-tumor immunity.

Lincoln Strickland[1], Wendao Liu[2], Casey Van Kirk[1], Shwetapadma Dash[1], MacKenzie Demmel[1], Alyssa Waller[1], Nicolette R. Mardik[3], Jesse Cox[1], Curtis J. Wray[4], Zhongming Zhao[5], Nirav Thosani[6], Jennifer Bailey-Lundberg[1]

[1]University of Nebraska Medical Center, Omaha, NE,[2]The University of Texas MD Anderson Cancer Center UTHealth Houston Graduate School of Biomedical Sciences, Houston, TX,[3]The University of Texas Health Science Center, Houston, TX,[4]Assistant Professor, Dept. of Surgery, UT Health Science Ctr. at Houston, Houston, TX,[5]Assoc. Professor, Biomedical Informatics and Cancer Bio., University of Texas Health Science Center at Houston, Houston, TX,[6]University of Texas Health Science Center at Houston, Houston, TX

Background: Pancreatic ductal adenocarcinoma (PDAC) is defined by a profoundly immunosuppressive tumor microenvironment (TME). In the majority of cases, treatment is palliative as there are few effective therapeutic options shown to improve clinical outcomes. We previously demonstrated that a single radiofrequency ablation (RFA) session is safe, induces tumor necrosis, enhances immune cell infiltration, including an abscopal effect, and synergizes with immune checkpoint blockade (ICB) to further suppress tumor growth.

Hypothesis: We proposed that repeated RFA sessions would more effectively restrain tumor progression, amplify immune cell recruitment, and enhance responsiveness to immunotherapy.

Methods: Using a bilateral tumor-bearing *Kras*^{G12D};*Trp53*$^{R172H/+}$;*Pdx1*:Cre syngeneic PDAC model, we compared tumor responses following single versus 3 repeated RFA sessions. Single-cell RNA sequencing and cytokine profiling were used to characterize TME remodeling. Given our prior findings with a single RFA session + ICB, we evaluated repeated RFA in combination with ICB and tested whether adding CSF1R blockade (PLX3397) could counteract RFA-induced myeloid immune suppression.

Results: Repeated RFA significantly reduced tumor growth rates and increased tumor necrosis in both treated and contralateral lesions compared to a single RFA session. scRNA-seq and cytokine analysis revealed that repeated RFA elevated Csf1 levels, promoting differentiation of immune suppressive Csf1r+ M2-like macrophages via the Csf1/Csf1r axis. While repeated RFA combined with ICB improved tumor control compared with either therapy alone, the addition of CSF1R inhibition further enhanced efficacy. The triple combination (repeated RFA + ICB + anti-CSF1R) produced the greatest reduction in tumor volume and weight and yielded the most pronounced remodeling of the TME.

Conclusions: Repeated RFA intensifies tumor necrosis, suppresses tumor progression, and remodels the PDAC TME, but concurrently induces a compensatory Csf1/Csf1r-driven M2-like macrophage response. Macrophage reprogramming through CSF1R blockade enhances both RFA- and ICB-mediated anti-tumor immunity. These findings support integrating repeated local ablative therapy with myeloid-targeting agents and checkpoint blockade to improve immunologic control of pancreatic cancer.

The Ohio State University, Columbus, OH

Immune checkpoint inhibitors (ICIs) are seminal advances in cancer therapeutics, yet response rates are variable. The gut microbiome is increasingly recognized as a modifiable determinant of ICI efficacy. The BEWELL trial delivered a black raspberry (BRB) nectar dietary intervention that significantly enriched the colonic microbiome with members of the *Lachnospiraceae* family. When BRB-modulated microbiomes were transferred into mice, these microbiomes enhanced ICI antitumor activity, implicating specific taxa in shaping therapeutic responsiveness.To investigate the mechanism by which *Lachnospiraceae* altered ICI effectiveness, we individually supplemented the microbiomes of mice with closely related strains enriched by BRB: *Blautia obeum*, *Blautia massiliensis*, and *Agathobacter rectalis*. In a heterotopic mouse model (1×10^6 MC38 cells injected subcutaneously into C57BL/6 mice, treated every 3 days with anti-PD1 or IgG), *B. obeum* and *B. massiliensis* improved ICI effectiveness, whereas *A. rectalis* did not. We compared the genomes of these organisms and identified 177 KEGG orthologs uniquely shared by *B. obeum* and *B. massiliensis* but absent in *A. rectalis*. KO pathway assignments and enrichment analyses were conducted using KEGGREST mapping and clusterProfiler overrepresentation testing, with all genome-encoded KOs as the background.We identified four relevant pathways associated with immunity and ICI response:**(1)** Key genes for the Wood-Ljungdahl pathway, a major route for producing acetate, shown to be a T-cell energy source (acetyl-CoA decarbonylase/synthase (K00194, K00197, K00198) and putative phosphotransacetylase (K01490));**(2)** Genes for synthesizing vitamins essential for T-cell proliferation—folate (B9) (dihydropteroate synthase (K00796), GTP cyclohydrolase I (K022391), methylenetetrahydrofolate reductase (K00297)) and cobalamin (B12) (cob(I)alamin adenosyltransferase (K019221), corrinoid adenosyltransferase (K0174), cobalamin reductase (K0175));**(3)** L-rhamnose synthesis genes whose cell-wall decorations act as microbe-associated molecular patterns, priming innate immunity (dTDP-4-dehydrorhamnose reductase (K00067) and dTDP-glucose 4,6-dehydratase (K00935)); and**(4)** Genes converting bile acids to secondary, iso-bile acids that interact with host receptors (FXR, TGR5) to regulate Th17/Treg balance (3-alpha-hydroxycholanate dehydrogenase (K0164))
Collectively, these processes align with host-relevant metabolic and signaling environments that may impact anti-tumor immunity. Our study suggests that novel food products can be developed for human testing to enhance anticancer immunotherapeutics. Furthermore, BRB-responsive *Lachnospiraceae* possess enriched metabolic and immunomodulatory gene programs that may underlie their association with improved tumor response to ICI treatment.

#2862 Dietary animal protein intake and progression-free survival (PFS) of patients (pts) with advanced urothelial cancer (UC) and renal cell carcinoma (RCC) on immune checkpoint blockade (ICB).

Timothy B. Winslow[1], Ritesh Kotecha[2], Neha Ratna[2], David Gavrilov[2], Cihan Duzgol[2], Mahnoor Akhlaq[2], Min Yuen Teo[2], Ashley M. Regazzi[2], Samuel Funt[2], David H. Aggen[2], Scot Niglio[2], Maria Carlo[2], Daniel Lage[2], Neil Shah[2], Aditi Gupta[2], Darren F. Feldman[2], Martin H. Voss[3], Robert J. Motzer[4], Jonathan E. Rosenberg[2], Gopa Iyer[2], Brendan John Guercio[1]

[1]University of Rochester Wilmot Cancer Institute, Rochester, NY,[2]Memorial Sloan Kettering Cancer Center, New York, NY,[3]Asst. Attending, Dept. of Med. Onc., Memorial Sloan Kettering Cancer Center, New York, NY,[4]Attending Physician, Ball Memorial Hospital, New York, NY

Background: Dietary fiber intake has been associated with longer PFS on ICB in observational studies, putatively due to effects of fiber on the gut microbiome. However, associations in observational studies may be due to confounding rather than causal relationships. Dietary animal protein intake impacts health and can be correlated with fiber intake. We investigated whether animal protein intake is associated with ICB outcomes in UC and RCC and whether confounding by animal protein intake might account for associations of fiber intake with ICB outcomes.
Methods: We conducted a retrospective analysis of a prospectively collected cohort, wherein baseline dietary data were collected using the Willett Food Frequency Questionnaire from pts with advanced UC or RCC initiating ICB at Memorial Sloan Kettering. Associations of diet with clinical outcomes were assessed using univariable and multivariable Cox proportional hazards regression.
Results: From 2/2021-6/2022, 86 pts eligible for this analysis were enrolled (UC n = 38; RCC n = 48; median follow-up 14.6 months). Median animal protein intake was 44 g/day (interquartile range [IQR] 31-54), below the American average of 88 g/day. Median fiber intake was 17.2 g/day (IQR 13-24), similar to the American average of 15 g/day. Intake of animal protein and fiber were correlated (Spearman's rho 0.46, $p < 0.001$). There were no statistically significant associations of animal protein intake above vs below the median with PFS in either univariable or multivariable models (Table 1). Dietary fiber intake was associated with longer PFS even after adjusting for animal protein intake and clinical covariables (Table 1).
Conclusion: Dietary animal protein intake was not associated with PFS among pts with UC and RCC on ICB. The association of dietary fiber with longer PFS could not be attributed to confounding by animal protein intake.

Hazard ratios for progression-free survival by average daily intake of animal protein and fiber

	Animal protein intake at or above the cohort median (44 g/day)		Fiber intake at or above the American average (15 g/day)	
Outcomes	HR (95% CI)	p	HR (95% CI)	p
Univariable	0.74 (0.43-1.26)	0.27	0.45 (0.26-0.77)	**0.004**
Multivariable 1*	0.94 (0.53-1.68)	0.85	0.46 (0.26-0.82)	**0.009**
Multivariable 2**	0.82 (0.45-1.50)	0.53	0.49 (0.26-0.92)	**0.026**
*Multivariable model 1 included animal protein and fiber intake simultaneously. **Multivariable model 2 further adjusted multivariable model 1 for age, performance status, cancer type, and stage (IV vs III).				

#2863 Investigating the impact of metabolic endotoxemia on breast cancer risk and progression.

Lauren M. Moulden[1], Adam S. Wilson[1], Valerie S. Payne[1], Marissa M. Howard-McNatt[2], Katherine L. Cook[1]

[1]Department of Cancer Biology, Wake Forest University School of Medicine, Winston Salem, NC,[2]Department of Surgery, Wake Forest University School of Medicine, Winston Salem, NC

Breast cancer is the most diagnosed cancer in women and the second most deadly, responsible for 670,000 deaths globally each year. Two main risk factors for breast cancer are aging and obesity, both of which are known to cause microbial dysbiosis and alterations in gut barrier function. These changes can result in chronic low levels of circulating lipopolysaccharides (LPS) in the blood, termed metabolic endotoxemia (ME). LPS interacts with toll-like receptor 4 (TLR4) resulting in the release of pro-inflammatory cytokines. Previously, our group has shown in non-cancerous postmenopausal women that obesity increases circulating LPS levels and other biomarkers of ME. However, in breast cancer patients (n=60), menopause status, not obesity, increases plasma LPS binding protein, anti-LPS IgG, and anti-LPS IgA. To investigate the impact of menopause, adiposity, and breast tumor presence on ME, we have employed a C57BL/6 murine study bearing E0771.Bo-ER+ breast tumors. Female 11-week-old C57BL/6 mice were placed on a low-fat control diet (10% kcal from fat, n=24) or a high-fat lard diet (60% kcal from fat, n=24). Subgroups of mice on each diet (n=8) underwent sham or ovariectomy (OVX) surgeries to model menopause. Additionally, we introduced fecal microbiota transplantation (FMT) groups (n=8) to examine the role of the gut microbiome. After 13 weeks of intervention, E0771.Bo-ER+ cells were injected into the mammary fat pad. We show the presence of a breast tumor (~400 mm^3 in tumor volume) significantly increases markers of ME. Furthermore, we show that a low-fat diet-derived FMT into high-fat diet consuming mice reduces breast tumor growth. LPS can vary in structure (displaying varying numbers of fatty acid chains on the lipid A toxin) and can differentially activate downstream TLR4 signaling. We show that various acylated isoforms of LPS can differentially activate NFκB and alter macrophage polarization and function. Overall, we aim to show whether the presence of breast cancer can directly influence ME and determine whether ME can impact breast cancer growth, thereby identifying a novel risk factor for breast cancer.

#2864 Prebiotic fiber supplementation mitigates the effects of maternal obesity on offspring's gut microbiome and mammary tumorigenesis.

Seema Yadav[1], Fabia Andrade[1], Melike Ozgul Onal[1], Sydney Shirk[1], Sercan Kenanogly[1], Christopher Staley[2], Leena Hilakivi-Clarke[1]

[1]The Hormel Institute, University of Minnesota, Austin, MN,[2]University of Minnesota Medical School, Minneapolis, MA

The prevalence of maternal obesity has gradually increased over successive decades, with over 50% of pre-pregnant women in the United States at present time classified as overweight or obese. Maternal obesity exerts deleterious effects on numerous pregnancy outcomes and imparts enduring negative health consequences on offspring, including elevating female offspring's susceptibility to and mortality from breast cancer. Since the gut microbiome contributes to obesity and its adverse effects, and influences breast carcinogenesis, we investigated here whether gut dysbiosis, characterized by reduced fecal short-chain fatty acid (SCFA) levels, in mouse offspring born to diet-induced obese C57BL/6 dams (OB offspring) contributed to their higher E0771 mammary tumor burden, compared with control offspring. Fecal microbiota transplant (FMT) from OB offspring increased E0771 mammary tumor burden in control offspring host, suggesting a causality between gut dysbiosis and increased mammary tumorigenesis in OB offspring. Further, levels of SCFA receptor FFAR2 in CD4+ T cells, CD8+ T cells and Foxp3+ regulatory T cells in Peyer's patches in gut and in CD8+ T cells in tumors were significantly lower in control offspring receiving FMT from OB offspring donor than from control offspring donor. To determine if increased mammary tumorigenesis in OB offspring can be reversed by increasing fecal SCFA production by dietary fiber, we employed the MMTV-PyMT mammary tumor model, in which mammary tumors develop "spontaneously" by 4 months of age. Our results indicated that MMTV-PyMT OB offspring exhibited significantly increased mammary tumor burden compared with controls. Supplementing offspring via drinking water with partially hydrolyzed guar gum (PHGG), a prebiotic fiber, exhibited significantly lower mammary tumorigenesis and higher fecal levels of SCFA propionic acid than OB offspring receiving maltodextrin (MDX) control. In contrast, control offspring receiving PHGG did not show changes in mammary tumorigenesis, although PHGG supplementation increased their fecal butyric acid levels. These results suggest that increased mammary tumorigenesis in OB offspring are linked to their gut dysbiosis. In addition, prebiotic
fiber PHGG, consumed by adult OB offspring, reverses adverse effects of maternal obesity on both their gut microbiome and mammary tumorigenesis.

#2865 Colorectal cancer-infiltrating bacteria promote the proliferation of cytotoxic lymphocyte populations endowed with antitumor properties.

Martina Villa[1], Julija Djordjevic[1], Elisa Sorrenti[2], Pedro Ventura[3], Davide Bressan[4], Antonino Cassotta[3], Caroline Junqueira[3], Fulvio Chiacchiera[4], Federica Sallusto[3], Dimitrios Christoforidis[5], Giandomenica Iezzi[2]

[1]Institute for Translational Research USI-EOC, Ente Ospedaliero Cantonale, Bellinzona, Switzerland,[2]Ente Ospedaliero Cantonale, Bellinzona, Switzerland,[3]Institute for Research in Biomedicine, Bellinzona, Switzerland,[4]Department of Cellular, Computational, and Integrative Biology, University of Trento, Trento, Italy,[5]Department of Surgery, Ente Ospedaliero Cantonale, Lugano, Switzerland

Colorectal cancer (CRC) is the second-leading cause of cancer deaths worldwide. During CRC carcinogenesis alteration of the gut epithelial barrier allows the translocation of commensal bacteria from the gut to the tumor tissue and their interaction with infiltrating immune cells. Infiltration by cytotoxic T lymphocytes is associated with improved survival, but their potential interplay with tumor-infiltrating bacteria has not been fully investigated.We previously identified a panel of bacteria whose abundance in CRC tissues correlates with the extent of lymphocytic infiltration. In this work, we have investigated the capacity of these bacteria to induce lymphocyte-mediated immune responses.Peripheral blood mononuclear cells from healthy donors or patients were cultured with cryopreserved bacteria of interest and assessed for proliferation based on CFSE dilution. Proliferating cells mostly consisted of CD4-CD8- double negative (DN) T cells expressing γδTCRs, and in particular the Vδ2 chain. CD4+ and CD8+ TCRαß+ T cells were also detected among proliferating cells. Following activation, DN Vδ2+ T cells released IFNg, TNFα, perforin, and granzymes suggesting a cytotoxic potential. Their concomitant expression of NKG2D led us to investigate whether they could mediate tumor-cell killing against CRC cell lines. In contrast to CD4+ and CD8+, bacteria-reactive DN T cells showed MHC-independent tumor cell killing.Analysis performed by large-scale flow cytometry and single-cell RNA sequencing of primary CRC samples revealed the presence of DN TCRγδ+ T cells among tumor-infiltrating lymphocytes (TILs). Interestingly, their phenotypes and transcriptomic profiles were found to partially overlap with those of bacteria-reactive DN T cells from peripheral blood. The reactivity of DN TILs to CRC-associated bacteria is currently under investigation.Bacteria-mediated activation of CRC-infiltrating DN T cells may favor a double-sided targeting of the tumor, contributing to an effective antitumor immune response.

#2866 Host-microbe-epigenetic crosstalk: Dissecting the role of microbiome, immune dysregulation, and DNA methylation in squamous cell carcinoma.

Armando G. Licata[1], Cristina Gurizzan[2], Deborah Lenoci[1], Marta Lucchetta[1], Carlo Resteghini[3], Luigi Lorini[2], Rosalba Miceli[4], Paolo Bossi[3], Loris De Cecco[1]

[1]Research department, Fondazione IRCCS Istituto Nazionale dei Tumori, Milan, Italy,[2]Department of Biomedical Sciences, IRCCS Humanitas Research Hospital, Milan, Italy,[3]Department of Biomedical Sciences, Humanitas University IRCCS Humanitas Research Hospital, Milan, Italy,[4]Unit of Biostatistics for Clinical Research, Fondazione IRCCS Istituto Nazionale dei Tumori, Milan, Italy

Squamous carcinomas of the oral cavity and head and neck share molecular, microbial, and immune features. Dysbiosis and intratumoral microbiota are increasingly implicated in epithelial transformation, with taxa such as *Fusobacterium nucleatum* linked to inflammation, hypoxia, immune evasion, and metastasis across squamous sites. Defining how host-microbe-immune interactions evolve from oral premalignant lesions to invasive tumors could reveal early biomarkers and modifiable microbial targets for prevention, risk stratification, and intervention. We analyzed samples from 66 oral potentially malignant diseases (OPMD) and 74 head and neck squamous cell carcinoma (HNSCC) using a multi-omics approach. Cohorts were profiled via RNA-seq, shotgun metagenomics, and multiplex cytokine assays. Epigenetic profiling of 20 HNC samples was performed using Nanopore sequencing to assess genome-wide DNA methylation. In OPMDs, a high-risk hypoxic subtype showed an elevated incidence of malignant transformation ($p < 0.0001$), reduced microbial diversity, and significantly elevated abundance of *Fusobacterium nucleatum* and *Leptotrichia wadei* ($Log_2FC > 1$, $FDR < 0.05$). *F. nucleatum* activity correlated strongly ($R>0.7$) with keratinocytes and pericytes. While HNSCC alpha diversity remained stable, community structure shifted (PERMANOVA $p=0.001$), marked by an enrichment of *Lactobacillus spp.* driving palmitate metabolism, whereas OPMD favored starch degradation and nitrate reduction. Immune profiling revealed a profound dysregulation within head and neck tumors. While OPMD was characterized by high levels of pro-inflammatory mediators (TNF-α, IL-6), these cytokines were markedly downregulated in HNSCC. This suggests a functional shift from an acute inflammatory response in OPMDs toward a chronic, immune-suppressive state in established carcinoma. Finally, our epigenetic analysis linked oral dysbiosis with host metabolism, revealing significant differential methylation in overweight HNC patients. Our analysis revealed significant hypomethylation affecting key oncogenic and immunomodulatory genes, including NOTCH1, STAT3, and the antigen-presenting gene HLA-DRB1. Our findings demonstrate a conserved microbial trajectory in the progression of head/neck carcinomas, characterized by the enrichment of *Fusobacterium* and a functional switch from a pro-inflammatory to an immune-evasive tumor microenvironment. These results point to a shared microbial etiology in squamous cancers, and the ongoing epigenetic analysis will provide deeper mechanistic insights into how these host-microbe interactions drive malignant transformation.

#2867 Interaction between T-cell inflamed gene expression profile score and tumor-associated microbiome on colorectal cancer mortality in a heterogeneous patient population.

Figueiredo[2], Timothy K. Thomas[7], Amanda I. Phipps[8], **Meredith A. Hullar**[1]

[1]Public Health Sciences, Fred Hutchinson Cancer Center, Seattle, WA,[2]Cedars-Sinai Medical Center, Los Angeles, CA,[3]Clinical Research Division, Fred Hutchinson Cancer Center, Seattle, WA,[4]Experimental Histopathology, Fred Hutchinson Cancer Center, Seattle, WA,[5]Ochsner Health System, New Orleans, LA,[6]Alaska Native Medical Center, Anchorage, AK,[7]Alaska Native Tribal Health Consortium, Anchorage, AK,[8]Department of Epidemiology, University of Washington, Seattle, WA

Background: The microbiome and tumor immune response are important and inter-related components that are implicated in colorectal cancer (CRC) prognosis. However, associations between these components and potential joint effects on CRC mortality remain unclear.

Methods: We included 366 participants with CRC (106 African American, 161 Alaska Native, 91 Hispanic, 8 non-Hispanic White) from the Translational Research Program in Cancer Differences across Populations (TRPCDP). 241 participants who did not die of CRC were matched to 125 participants who died of CRC during follow-up by age, sex, tumor site, tumor stage, year of diagnosis, and population group. We sequenced microbial DNA from the V4 region of the 16S rRNA bacterial gene and sequenced RNA using the Illumina TruSeq RNA Exome kit from formalin-fixed paraffin embedded (FFPE) tumor tissue. We calculated the T-cell inflamed gene expression profile (GEP) score as a weighted sum of $\log_2$-transformed transcripts per million of 18 genes: CCL5, CD27, CD274 (PD-L1), CD276 (B7-H3), CD8A, CMKLR1, CXCL9, CXCR6, HLA-DQA1, HLA-DRB1, HLA-E, IDO1, LAG3, NKG7, PDCD1LG2 (PDL2), PSMB10, STAT1, and TIGIT. We dichotomized the T-cell inflamed GEP score into high and low groups using the top tertile as a threshold. Using logistic regression, we estimated odds ratios (OR) and 95% confidence intervals (CI) for associations between bacterial presence and dichotomized T-cell inflamed GEP score, as well as interaction effects of bacteria and dichotomized T-cell inflamed GEP score on CRC-specific mortality, adjusting for matching factors.

Results: Among 48 genera tested, Anaerococcus was associated with lower odds of high T-cell inflamed GEP score (OR=0.34, 95% CI 0.20-0.58) and Leptotrichia was associated with higher odds of high T-cell inflamed GEP score (OR=2.93, 95% CI 1.66-5.22). When combined, the joint effect of tumors being Leptotrichia positive and low T-cell inflamed GEP score was associated with over four times the odds of CRC mortality (OR=4.41, 95% CI 1.86-10.83) compared to tumors that were Leptotrichia negative and high T-cell inflamed GEP score.

Conclusions: The joint effect of Leptotrichia presence and low T-cell inflamed GEP score resulted in markedly higher odds of CRC death. Understanding the influence of this immune-microbiota interaction may improve CRC prognostic stratification and enable the discovery of new treatment targets to improve CRC prognosis.

#2868 MaaT013 pooled fecal microbiotherapy improves gastrointestinal physiology and controls inflammation which delays GvHD in a proof-of-concept humanized mouse study.

Julie Reygner[1], Margaux De Seilhac[2], Cyrielle Gasc[1], Emmanuel Prestat[1], Charlotte Petitjean[1], Sophie Declomesnil[1], Carole Schwintner[1], Nathalie Corvaia[1], Sheri Simmons[1], Ernst Holler[3], Robert R. Jenq[4], **Bastien Laperrousaz**[1]

[1]MaaT Pharma, Lyon, France,[2]Immunology and New Concepts in ImmunoTherapy (INCIT), UMR 1302, University of Nantes, University of Angers, INSERM, CNRS, Nantes, France,[3]Department of Internal Medicine III (Haematology/Oncology), University Hospital Regensburg, Regensburg, Germany,[4]Department of Hematology & Hematopoietic Cell Transplantation, City of Hope, Duarte, CA

Background: Acute graft-versus-host disease (aGvHD) is a life-threatening complication of allogeneic hematopoietic stem cell transplantation (allo-HSCT), where allogeneic donor T cells recognize recipient tissues as foreign and damage them. Gut microbiota disruption following allo-HSCT has been associated with increased aGvHD incidence, severity, and mortality. The gut microbiota plays a key role in the modulation of the immune system, particularly in maintaining immune tolerance. These results prompted the development of fecal microbiotherapies to restore a healthy and diverse gut microbiota and to treat or prevent aGvHD. Growing clinical evidence supports the efficacy of fecal microbiotherapy in aGvHD mortality. MaaT013, a standardized allogeneic fecal microbiotherapy derived from pooled healthy human fecal microbiota, has demonstrated unprecedented efficacy and favorable safety profile as third-line treatment of aGvHD with gastro-intestinal (GI) involvement in the pivotal ARES trial.

Method: In this study, we combined *in vitro*, *in vivo*, metagenomics, metabolomics and transcriptomics studies to elucidate the underlying mechanisms by which MaaT013 influences GvHD.

Results: We demonstrate that MaaT013-derived metabolites control inflammation and prevent inflammation-induced gut barrier alteration in an *in vitro* leaky gut model. We also show that MaaT013 is able to modulate immunity by activating TLR and NOD sensors, stimulating DC-mediated IL-10 production and Tregs amplification *in vitro*. We further demonstrate that beneficial bacteria from MaaT013 safely engraft in the digestive tract of germ-free mice, leading to the production of anti-inflammatory metabolites and restoring healthy gut physiology and immune homeostasis. Transcriptomic analysis of colon tissue from MaaT013-treated germ-free mice provides further evidence that MaaT013 promotes gastrointestinal maturation and restores immune functions. Finally, we demonstrate that MaaT013 delays the appearance of GvHD symptoms in a humanized mouse model of aGvHD using highly immunodeficient mice engrafted with human Peripheral Blood Mononuclear Cells (PBMCs).

Conclusion: Altogether, these results support the potential of MaaT013 to mitigate aGvHD through restoration of microbial diversity, gut barrier integrity, and immune homeostasis, leading to control of inflammation.

#2869 Maternal obesity promotes gut dysbiosis, CD4⁺ T-cell reprogramming and increased prostate cancer in offspring.

Fabia de Oliveira Andrade[1], Lu Jin[1], Melike Ozgul Onal[1], Seema Yadav[1], Sercan Kenanoglu[1], Christopher Staley[2], Leena Hilakivi-Clarke[1]

[1]The Hormel Institute, University of Minnesota, Austin, MN,[2]University of Minnesota Medical School, Minneapolis, MA

Maternal obesity (MO) is a growing global concern linked to long-term disease risk in offspring and may also increase prostate cancer susceptibility, although the mechanisms remain unclear. We tested whether MO-induced gut dysbiosis promotes prostate cancer in male offspring and reprograms immune function. Using a TRAMP-C1 allograft model, we evaluated male offspring from dams fed a control diet or an obesity-inducing diet (OID). Gut microbiota was assessed by 16S rRNA sequencing and SCFA profiling. Causality was tested using antibiotic ablation and fecal microbiota transplantation (FMT), and microbiota modulation was further examined using a prebiotic intervention with partially hydrolyzed guar gum (PHGG). Activated splenic T cells were analyzed with paired RNA-seq and ATAC-seq. MO increased prostate tumor burden in adult offspring and induced gut dysbiosis marked by reduced α-diversity and significantly lower fecal butyric acid. Gut microbiota ablation reversed the MO-induced increase in tumor growth, whereas FMT from MO offspring transferred the pro-tumor phenotype to control mice. MO induced profound immune reprogramming that was specific to CD4⁺ T cells and not observed in CD8⁺ T cells. RNA-seq data revealed activation of Th2 and pro-inflammatory pathways, including Th17 differentiation (NES 1.96, p.adj 0.009) and JAK-STAT signaling (NES 2.1, p.adj 0.0009). We also observed reduced antigen-presentation (NES -2.24, p.adj 0.0007) and interferon-signaling programs (NES -3.4, p.adj 8.39E-06), indicating impaired IFN-driven activation.Twenty-one loci exhibited concordant chromatin (ATACseq) and transcriptional remodeling, including repression of *Zbtb10* and *Ifrd1*, regulators of Th1 differentiation. These molecular changes manifested in vivo as increased Th2 (GATA3⁺) and Th17 (RORγ⁺) cells and reduced Th1 (Tbet⁺) cells in spleen, and impaired CD8⁺IFNγ⁺ cytotoxicity in tumors. Antibiotic ablation partially normalized inflammatory signatures, indicating that gut dysbiosis contributes to—but does not fully explain—MO-driven immune remodeling. These findings suggest a combined effect of long-lasting epigenetic alterations and microbiome-driven signals. Prebiotic PHGG, which increases SCFA production, reduced tumor growth in MO offspring, demonstrating that microbiome-targeted interventions can mitigate MO-induced cancer susceptibility. Overall, our data indicates that MO is associated with a microbiota-dependent increase in prostate cancer risk in offspring, alongside a durable and epigenetically imprinted CD4⁺ T-cell program.

#2870 Amino acid metabolic reprogramming drives doramectin-enhanced CD8⁺ T cell immunity and tumor control.

Sedigheh Taghinezhad-S[1], Amirhossein Mohseni[2], Vincenzo Casolaro[3], Zhongwei Lv[4], Dan Li[5]

[1]Department of Hematology-Oncology, Henry Ford Health, Detroit, MI,[2]Division of Gynecologic Oncology, Department of Women's Health Services, Henry Ford Health, Detroit, MI,[3]Department of Medicine, Surgery and Dentistry "Scuola Medica Salernitana", University of Salerno, Baronissi, Salerno, Italy,[4]Department of Nuclear Medicine, Shanghai Tenth People's Hospital, Tongji University School of Medici, Shanghai, China,[5]Department of Nuclear Medicine, Sun Yat-sen Memorial Hospital, Sun Yat-sen University, Guangzhou, China

CD8⁺ T-cell metabolic programming is a pivotal determinant of antitumor immunity, yet strategies to therapeutically activate these pathways remain limited. Here, we show that doramectin, a clinically available macrocyclic lactone, enhances antitumor immunity by reprogramming amino acid metabolism in CD8⁺ T-cells. In tumor-bearing mice, doramectin promoted amino acid-dependent metabolic engagement, strengthened effector function, supported memory differentiation, and increased CD8⁺ T-cell infiltration into the tumor microenvironment, collectively resulting in durable tumor control. These findings suggest that doramectin induces a metabolically reinforced T-cell state capable of sustaining immunosurveillance. Mechanistically, doramectin enhanced amino acid-linked bioenergetic and biosynthetic pathways, consistent with elevated metabolic fitness and immune competence. A critical requirement for this metabolic reprogramming was revealed through the role of the gut microbiota. Doramectin treatment led to a selective microbial shift, with specific taxa trafficking to lymphoid tissues where they delivered signals required for CD8⁺ T-cell metabolic engagement. When these microbial signals were disrupted, the metabolic reprogramming and corresponding antitumor effects failed to manifest, indicating that the microbiota acts as a permissive metabolic cofactor rather than an autonomous initiator of immunity. Together, these results define a metabolism-centered mechanism by which doramectin enhances antitumor immunity through microbiota-enabled amino acid metabolic reprogramming of CD8⁺ T-cells. This work highlights the therapeutic potential of targeting amino acid metabolism, supported by microbial cues, to improve T-cell mediated immunotherapy in solid tumors and underscores the importance of host-microbe metabolic crosstalk in shaping antitumor immune responses.

#2873 Neurotensin suppresses anti-tumor immunity and is associated with poor prognosis in colorectal cancer.

Haoming Wu, Yang Wang, Dana Napier, Hong Jiang, Dong Li, Jing Li, B. Mark Evers

Markey Cancer Center, University of Kentucky, Lexington, KY

Introduction. Colorectal cancer (CRC) is a leading cause of cancer-related deaths worldwide with substantial heterogeneity in patient outcomes. Neurotensin (NTS) and its high-affinity receptor (NTSR1) have been implicated in CRC progression, particularly in modulating tumor metabolism and immune responses. NTS secretion increases under psychological stress and high-fat intake. Given the widespread expression of NTSR1 on immune cells, we hypothesized that NTS modulates anti-tumor immunity in CRC. The purpose of our current study was to integrate clinical, *in vivo*, and functional evidence to delineate the impact of NTS on immune responses and patient outcomes.

Methods. (i) Clinical survival: Overall survival (OS) was analyzed in a single-institution CRC cohort (University of Kentucky; n=196) stratified by tumor NTS expression, and findings were validated using KMplot (n=1,061). (ii) Transcriptomic correlation: Correlations between NTS and immunosuppressive genes (e.g., IL10, ENTPD1) were assessed utilizing publicly available datasets (GEPIA/TCGA). (iii) *In vivo*: Murine CRC cells (MC38) were implanted subcutaneously into NTS wild-type (NTSWT) and NTS knockout (NTSKO) mice to compare tumor growth. Tumor-infiltrating immune cells and granzyme B (GZMB) expression were quantified by immunohistochemistry (IHC) and flow cytometry. (iv) *In vitro* cytotoxicity: MC38 cells were co-cultured with spleen-derived CD8+ T cells from MC38-primed mice, with or without NTS treatment, and cytotoxicity was measured by LDH release.

Results. (i) High NTS expression was associated with shorter OS in the institutional cohort ($P<0.05$) and was validated in the KMplot dataset (n=1,061; $P<0.001$). (ii) NTS expression showed significant positive correlations with multiple immunosuppressive genes, including IL10 ($P=0.0038$) and ENTPD1 ($P=0.046$). (iii) *In vivo*, NTSKO mice exhibited markedly slower tumor growth, with increased immune-cell infiltration and higher intratumoral GZMB expression. (iv) *In vitro*, NTS treatment significantly reduced CD8+ T-cell cytotoxicity against MC38 cells, as indicated by decreased LDH release, supporting a direct suppressive effect of NTS on effector T-cell function.

Conclusions. High NTS expression identifies CRC patients with poorer prognosis and functionally suppresses anti-tumor immunity by limiting CD8+ T-cell infiltration and cytotoxic activity. Interventions that lower NTS (e.g., stress reduction and dietary optimization) may improve responses to immunotherapy and clinical outcomes. These findings provide a biological rationale for targeting the NTS/NTSR1 axis in combination with immunotherapeutic strategies.

#2874 PPARδ overexpression in villin-positive gastric progenitor cells drive gastric tumorigenesis independent of helicobacter infection in mice.

Daoyan Wei[1], Yi Liu[1], James C. Yao[1], Imad Shureiqi[2], Xiangsheng Zuo[1]

[1]UT MD Anderson Cancer Center, Houston, TX,[2]University of Michigan, Ann Arbor, MI

Background Overexpression of the single gene PPARδ in villin-positive gastric progenitor cells (VGPCs) has been shown to induce gastric adenocarcinoma (GAC) in villin-PPARδ mice. However, PPARδ overexpression alone in colonic epithelial cells or pancreatic progenitor cells in mice fails to initiate tumorigenesis but dramatically accelerated tumor development in the colon and pancreas. These findings raise the question of whether additional factors cooperate with PPARδ to drive GAC. *H. pylori* infection is a strong risk factor for human GAC. In modified SPF barrier where villin-PPARδ mice are housed, *helicobacter* species is not excluded and presumed to be endemic. Whether such *helicobacter* infection contributes to PPARδ-driven GAC remains unknown.

Methods A new villin-PPARδ mouse line was generated via *in vitro* fertilization using frozen sperm of villin-PPARδ mice and housed in helicobacter-free barrier. At 4 weeks of age, half of the mice remained in helicobacter-free barrier (villin-PPARδ-L1), while the other half were transferred to modified SPF barrier, where *helicobacter* species is commonly detected in the gastrointestinal tract of housed mice (villin-PPARδ-L2). These mice, along with the previous villin-PPARδ mouse line that had been maintained in modified SPF barrier for years (villin-PPARδ-L3), were followed for 25, 35, and 55 weeks (n =10-12 mice per group). Wild type (WT) littermates from each line were served as controls. All mice were evaluated for tumor multiplicity and subjected to histologic examination. *Helicobacter* species was assessed by detecting 16S rRNA genes from genomic DNA extracted in mouse stomach contents and stools using qPCR/PCR.

Results *Helicobacter* species was not detectable in villin-PPARδ-L1 mice at all ages and villin-PPARδ-L2 mice at 10 and 25 weeks but were detected in villin-PPARδ-L2 mice at 35 and 55 weeks and villin-PPARδ-L3 mice at all ages. Longitudinal follow-up revealed that gastric tumorigenesis progressed in an age-dependent manner. Gross lesions were initially found in the lesser curvature of the gastric corpus at 25 weeks and eventually expanded to occupy the whole gastric corpus at 55 weeks. All mice examined at ≥ 25 weeks developed at least gastric hyperplasia. At 35 weeks, approximately 60% of mice developed low-grade or high-grade gastric dysplasia, and by 55 weeks, around 70% developed GACs, including 30% with large, locally invasive GACs. Chronic inflammation was present in gastric lesions and positively correlated with tumor progression. No significant differences in gastric inflammation and tumorigenesis were observed among three villin-PPARδ mouse lines. None of WT controls developed gastric tumors.

Conclusions PPARδ overexpression in VGPCs drive gastric tumorigenesis independent of helicobacter infection in mice, suggesting that PPARδ may be a potential therapeutic target for GAC.

#2875 Toll-like receptor 4 deletion promotes bacterial burden and cutaneous tumorigenesis in mice lacking one *Ikkα* allele in keratinocytes.

Deep Kumari Yadav, Amit Kumar Singh, Debra Tross, Yinling Hu

National Cancer Institute Frederick, Frederick, MD

Toll-like receptor 4 (TLR4) is an extracellular pathogen recognition receptor (PRR) that identifies a variety of pathogens and damage-associated molecular patterns. Analysis of human TCGA database reveals many mutations of the *Toll-Like Receptor 4* (*TLR4*) gene in human skin cancers. The exact function of PRRs in response to elevated ambient and commensal bacteria for carcinogenesis is still unknown. Recently, we found a low number of spontaneous skin squamous cell carcinomas (SCCs) in 1-year-old $Ikka^{f/+}$K5 Cre mice with specific *Ikka* reduction in keratinocytes. Interestingly, ablation of *Tlr4* enhanced SCC numbers and sizes but reduced the latency of SCC development in $Ikkα^{\Delta KC/+}; Tlr4^{-/-}$ mice compared to $Ikka^{\Delta KC/+}$ mice. Both spontaneous skin SCCs obtained from $Ikka^{\Delta KC/+}$ and $Ikka^{\Delta KC/+}; Tlr4^{-/-}$ mice showed loss of wild-type (WT) *Ikka* allele. Thus, we hypothesize that *Ikka* reduction in keratinocytes alters skin microbes and *Tlr4* deletion promote this condition, which lead to increased spontaneous skin SCCs. Indeed, the bacterial burden were increased in the skin of $Ikka^{\Delta KC/+}$ and $Ikka^{\Delta KC/+}; Tlr4^{-/-}$ mice compared to the skin of WT and $Tlr4^{-/-}$ mice predominately Gram (+) firmicutes. Further, we explore the interactions between bacteria and their hosts using skin organoids derived from these mice. Organoids are three dimensional structures recapitulating the organ's epithelial layer, linking the gap between *in vitro* and *in vivo* models. Skin organoids infected with heat killed gram positive bacteria reveals more DNA damage in the $Ikka^{\Delta KC/+}; Tlr4^{-/-}$ along with impaired bacteria clearance in these mice. Together, these findings suggest that increased bacteria cause genomic instability which leads to DNA damage. Additionally, we are investigating which bacterial pathways compromise the integrity of the skin genome through Ikka reduction or Ikka reduction/Tlr4 deletion, as well as whether Tlr4 deletion affects immune cell function in combat against bacterial infections.

#2877 The role of oral microbiota in pre-metastatic niche preparation in the brain.

Rene Nicolas Rico, Sarah B. Johnson, Vivian R. Orellana, Ashish V. Damania, Matthew C. Wong, Bharat B. Singh, Lon W. R. Fong, Brenda Melendez, Nadim J. Ajami, Jennifer A. Wargo, Golnaz Morad

UT MD Anderson Cancer Center, Houston, TX

Background: The oral microbiota plays a critical role in maintaining oral health and immune homeostasis. Emerging evidence suggests a link between oral microbiota and the brain, particularly in the context of brain development and neurological diseases. However, its contribution to brain tumors is underexplored. In this study, we investigated the role of oral microbiota dysbiosis (OMD) in brain metastasis (BrM) development. We hypothesized that OMD may alter the brain's physiological state in ways that favor premetastatic niche (PMN) preparation, thereby creating conditions conducive to BrM development.
Methods: Mice with subcutaneous BP melanoma tumors, with no intracranial tumors, were used to model the PMN preparation stage in the brain during melanoma development. To induce OMD, 5 days after primary tumor injection, mice were treated with chlorhexidine gluconate mouthwashes every 12 hours for 10 days. Saliva and stool samples were collected longitudinally and analyzed via 16S rRNA amplicon sequencing. Primary melanoma tumors were measured using a caliper. Brain samples were analyzed by mass spectrometry and immunohistochemistry. Digital spatial profiling was used to determine immune composition and transcriptional signatures in both brain and melanoma samples.
Results: Chlorhexidine treatment led to OMD, as verified by a reduction in alpha diversity and alterations in bacterial composition of the oral microbiota. The gut microbiota remained unchanged. Mice with OMD demonstrated a significant increase in primary tumor growth compared to controls ($p=0.039$), associated with lower immune infiltration. In the brain, OMD resulted in upregulation of proteins associated with acute inflammation and a reduction in peri-vascular extracellular matrix and adhesion proteins, suggestive of blood-brain barrier remodeling.
Conclusion: Our investigation suggests oral microbial imbalance is associated with alterations of the peri-vascular niche and may contribute to PMN preparation in the brain. Ongoing studies in our group investigate the impact of these OMD-induced alterations on BrM development, providing insights for microbiota-targeted translational applications.

#2879 Intra-tumoral microbiota and host genotype cooperatively shape neutrophil antitumor activity in colorectal cancer.

Colorectal cancer (CRC) represents a major cause of cancer related death worldwide. Defined genetic alterations are known to underlie CRC oncogenesis. However, in the last decades a critical role of the composition of tumor microenvironment has also been recognized. While tumor infiltration by T lymphocytes has been consistently recognized to predict improved clinical outcome, the role of tumor-associated neutrophils (TANs) in CRC is still debated.CRC develops in a microbiota-rich environment, and barrier dysfunction allows bacterial translocation into the mucosa. Neutrophils, as first responders to bacteria, may interact with tumor-infiltrating bacteria. However, the functional outcome and prognostic relevance of these interactions have not been thoroughly investigated. Here we unravel that TAN recruitment and functions are modulated by intra-tumoral microbiota and only defined bacterial species are able to unleash TANs' antitumor potential. Fusobacterium nucleatum (Fn) promotes expression of neutrophil-recruiting chemokines in tumor cells and enhances neutrophil migration more efficiently than Bacteroides fragilis (Bf). Importantly, Fn, but not Bf, triggers neutrophils to release cytotoxic proteins showing tumoricidal activity in vitro and in xenograft models. Mechanistically, these antitumor effects are elicited upon Fn binding to an activatory receptor (R-a) expressed on neutrophils but are impaired upon R-a blockade or in neutrophils from donors carrying a R-a loss-of-function polymorphism. Supporting these findings, in human CRCs, elevated Fn loads, high TANs densities, and expression of wild-type, but not polymorphic, R-a allele, correlate with improved patient survival. Our findings identify microbiota composition and host genetic background as critical determinants of TAN functional profiles and offer insights into neutrophil-targeted therapeutic strategies in CRC.

#2880 Antibiotic driven microbiota disruption impairs HER2 targeted therapy efficacy.

Romina Elizabeth Araya[1], Lily Parker[1], Payal Mitra[2], Nofar Erlichman[1], Pavani Chalasani[3], Rong Li[2]

[1]Biochemistry and Molecular Medicine-SMHS, George Washington University, Washington, DC,[2]The George Washington University, Washington,[3]Division of Hematology and Oncology, George Washington Cancer Center- George Washington University, Washington, DC

Up to 60% of cancer patients require antibiotics during therapy, yet retrospective studies indicate that antibiotic exposure can worsen outcomes across cancers. In breast cancer (BC), HER2+ patients show notably reduced survival after antibiotic use, an effect attributed to microbiota disruption, though mechanisms remain unclear. Our previous work demonstrated the role of microbiota signaling in chemo and immunotherapy efficacy. But HER2+ BC relies on targeted therapies, thus the impact of antibiotics on these agents requires further investigation. To address this, we used 16S rRNA sequencing of cecal content from mice bearing HER2+ TUBO tumors to assess whether an anti-HER2 antibody or neratinib, a HER2 tyrosine kinase inhibitor, each induces distinct microbiota shifts. Anti-HER2 increased *Oscillospiraceae*, *Rikenellaceae*, *Ruminococcaceae*, and *Lachnospiraceae*, whereas neratinib increased only the latter two Families. However, alpha diversity metrics remained unchanged. To study how these microbes contribute to treatment, we first depleted the gut microbiota using a broad-spectrum antibiotic cocktail (ABX). We observed the partial and complete loss of anti-HER2 and neratinib efficacy, respectively, on TUBO tumors. A clinically relevant antibiotic, such as ciprofloxacin (cipro), also fully halted neratinib response, whereas amoxicillin/clavulanate (am/clav) caused partial impairment. Because both antibiotics and neratinib were administered orally, we quantified plasma neratinib by LC-MRM mass spectrometry and ruled out antibiotic-induced blockade of neratinib absorption. Cipro and am/clav significantly reduced alpha diversity to a lesser extent than ABX, with cipro showing the most dramatic effect. Families enriched by HER2 therapies, including *Lachnospiraceae* and *Ruminococcaceae,* were targeted by cipro and am/clav. Notably, both antibiotics increased *Akkermansia*, a Family previously linked to favorable immunotherapy outcomes, suggesting that HER2-targeted therapies may rely on microbiota features, like *Lachnospiraceae* or *Ruminococcaceae*, distinct from those supporting checkpoint blockade. Spectral flow cytometry analysis of the tumor immune infiltration revealed that HER2 therapies triggered NK, CD8+, and CD4+ T cell infiltration. Antibiotic-treated tumors showed enrichment of pro-tumor macrophages and neutrophils with no significant NK cell recruitment. Microbiota alpha diversity was positively correlated with tumor NK and CD8+ T cell content, which, in turn, were associated with treatment outcomes. Overall, our findings demonstrate that antibiotic-driven disruption of gut microbiota composition and diversity impairs immune mechanisms linked to the efficacy of HER2+ BC therapy. These results highlight the potential of microbiota-based strategies to mitigate antibiotic-associated therapeutic resistance in HER2+ BC.

#2881 Interleukin-1 upregulates dual oxidase 2 expression and ROS production in human pancreatic cancer cells in a STAT1/STAT3-dependent manner.

David J. Mallick[1], Yongzhong Wu[2], Mariam M. Konate[1], Becky A. Diebold[2], Smitha Antony[1], Jennifer L. Meitzler[2], Goujian Jiang[2], Jiamo Lu[2], Krishnendu K. Roy[1], James H. Doroshow[1]

[1]NCI Division of Cancer Treatment and Diagnosis, Bethesda, MD,[2]NCI Developmental Therapeutics Branch, Bethesda, MD

Chronic pancreatitis and sustained pancreatic inflammation increase the risk of pancreatic ductal adenocarcinoma (PDAC), in part through the release of pro-inflammatory cytokines and excessive generation of reactive oxygen species (ROS). Interleukin-1 (IL-1), a major upstream cytokine secreted by malignant or microenvironmental cells, promotes pancreatic inflammation, tumorigenesis, invasiveness, and intratumoral heterogeneity. Previously, our laboratory has established that dual oxidase 2 (DUOX2), one of seven NADPH oxidase (NOX) family members, plays a critical role in H2O2-mediated host defense and chronic inflammation in the gastrointestinal tract. DUOX2 is upregulated and expressed along with its maturation factor, DUOXA2, in several human pancreatic cancer cell lines following exposure to various pro-inflammatory cytokines, including IFN-γ, IL-4, and IL-17A. In the present study, we show that IL-1α and IL-1β robustly upregulate DUOX2/DUOXA2 mRNA and protein expression in a panel of human PDAC cell lines and patient-derived PDAC organoids. IL-1 exposure triggers transient activation of STAT1 and STAT3, followed by sustained induction of DUOX2/DUOXA2, without increasing expression of other NOX family members. Activation of canonical IL-1 signaling in PDAC cell lines was supported by the observation of IL-1-related upregulation of IL-8 (CXCL8) mRNA, a chemokine essential for neutrophil recruitment and a potent promoter of angiogenesis, in IL-1-treated PDAC cells. Co-administration of Anakinra, an IL-1 receptor antagonist, markedly suppresses IL-1-induced DUOX2/DUOXA2 and CXCL8 expression *in vitro*. Knocking out DUOX2 in BxPC-3 cells established DUOX2 as the predominant source of IL-1-mediated ROS production. Targeted siRNA knockdown of proximal IL-1 pathway nodes, such as IL-1R1, MYD88 and IRAK1/2, significantly decreased expression of DUOX2/DUOXA2 and of CXCL8. We also found that STAT1 and STAT3, two transcription factors involved in downstream transcription in the IL-1 pathway, are crucial for the regulation of DUOX2/DUOXA2 in pancreatic cancer. Collectively, these findings define an IL-1-STAT1/STAT3 axis that drives DUOX2-dependent ROS production in PDAC, reinforcing a pro-oxidant, pro-inflammatory microenvironment.

#2882 The impact of high fat diet on tumor growth is dependent on fatty acid composition and tumor type.

Rebecca C. Simpson[1], Freya E. R. Edge[2], Jordan W. Conway[1], Hsin-Yi Tseng[3], Mirei Okada[2], Inah Camaya[1], Laura Smith[1], Akshaya Ramanathan[1], Oliver K. Fuller[2], Stewart W. C. Masson[2], Jessamy Tiffen[3], Georgina V. Long[1], Erin R. Shanahan[2]

[1]Melanoma Institute Australia, The University of Sydney, Sydney, Australia,[2]School of Life and Environmental Science, The University of Sydney, Sydney, Australia,[3]Centenary Institute, The University of Sydney, Sydney, Australia

Diet is a key factor that shapes the gut microbiome, systemic metabolism and immune function. However, how specific macronutrients alter host physiology and tumor-immune interactions relevant to tumor progression and response to immune checkpoint inhibitor (ICI) immunotherapy remains unclear. We therefore sought to investigate how high fat diets (HFDs) varying in macronutrient source and composition influence metabolism, the gut microbiome and anti-tumor immunity. C57BL/6 mice were fed either a standard chow (CD), high fat (HF)/high sugar (HS)-Copha or HF-Lard diet for 2 or 7 weeks prior to inoculation with a syngeneic cancer cell line. These diets notably have differing fatty acid compositions; the copha-based (plant) HFD has more MCFAs compared to the lard-based (animal) HFD that is dominated by LCFAs. Mice on HF-Lard exhibited impaired glucose tolerance and reduced insulin sensitivity compared to CD and HF/HS-Copha after 2 and 7 weeks on diets. However, only mice on HF-Lard longer term had both elevated fasting glucose and insulin. Profiling the gut microbiomes of mice revealed both HFDs rapidly induced gut dysbiosis characterized by reduced diversity, although HF/HS-Copha compared to HF-Lard were enriched with metabolically beneficial species *Blautia coccoides*, *Parabacteroides merdae* and *Bacteroides acidifaciens*. Notably, HF-Lard accelerated the growth of B16-F10 and YUMM3.3-UVR melanomas while both HFDs accelerated the growth of MC38 colorectal adenocarcinomas. Similar results were observed in the short-term study except for B16-F10 where no differences between diets were observed. This suggests the acceleration is independent of obesity though may be influenced by the immunogenicity or intrinsic insulin sensitivity of the tumor. Spectral flow analysis of immune cells across the mesenteric lymph nodes (MLN), spleen, tumor draining LN (tdLN) and tumor revealed divergent immune profiles across diets. Both HFDs had lower plasma cells, cDC1s and CD8 T cells in the tdLN compared to CD. However, HF-Lard mice had higher frequencies of monocytes, and both Th17 cells and RORgt+ Tregs, indicating polarization towards suppressive phenotypes in addition to impaired anti-tumor priming. This was accompanied by enhanced exhaustion across CD8 T cells in the tumors of HF-Lard mice.Together this suggests that HFDs dominated by LCFAs are associated with metabolic dysfunction, and altered microbiome and immune phenotypes, which could contribute to accelerated tumor growth for melanoma. It also highlights that tumor type/genetics are important factors in how the diet-gut axis influences tumor growth. Ongoing work will focus on understanding how specific fat sources and diet durations impact ICI treatment and ultimately inform the design of more specific dietary interventions to enhance the efficacy of treatment.

#2883 Divergent gut microbial communities are linked to differences in baseline immune profiles, tumor features and ICI outcomes in melanoma.

Rebecca C. Simpson[1], Ines Pires Da Silva[1], Jayden Beckwith[1], Irene L. M. Reijers[2], Judith M. Versluis[2], Camelia Quek[1], Alexander M. Menzies[1], Gonzalez Maria[1], James S. Wilmott[1], Christian U. Blank[2], Richard A. Scolyer[1], Erin R. Shanahan[3], Georgina V. Long[1]

[1]Melanoma Institute Australia, The University of Sydney, Sydney, Australia,[2]Netherlands Cancer Institute, Amsterdam, Netherlands,[3]School of Life and Environmental Science, The University of Sydney, Sydney, Australia

We have previously identified links between gut microbial community assemblages, defined by the ratio of *Ruminococcaceae* to *Bacteroidaceae,* and response to immune checkpoint inhibitor (ICI) immunotherapy, suggesting microbiome-immune interactions may prime patients for treatment outcomes. To investigate how these microbial states shape baseline immune tone and anti-tumor immunity we profiled peripheral immune and tumor-intrinsic features across these stratified patient groups. In 129 Australian and Dutch stage III melanoma patients treated on trial with neo-adjuvant anti-PD-1/anti-CTLA-4 immunotherapy (OpACIN-neo/PRADO), pre-treatment stool (microbiome; 16S rRNA gene sequencing) and PBMCs (immune profiles; mass cytometry) were analyzed. Tumor biopsies were subject to DNA/RNA sequencing, with tumor mutation burden (TMB) and IFN-γ score assessed. Clear differences in baseline peripheral immune profiles were observed upon stratifying patients by microbial community types. *Ruminococcaceae* (Ru)-dominated gut microbiomes were associated with higher ICI response rates, had greater frequencies of circulating memory B and T cell subsets (CD27+ B cells, CD8+ Tem (CD45RA-CCR7-)) and higher ICOS+ Tregs. *Bacteroidaceae* (Ba)-dominated patients had higher frequencies of total B cells and a more naïve immune profile. Further, the pre-treatment tumors of Ru-dominated patients were enriched with pathways involved with immune signalling and antigen presentation while Ba-dominated patient tumors were enriched with pathways associated with dysregulated metabolism and cell proliferation. The distribution of tumor TMB and IFN-γ groups between responders (R) and non-responders (NR) within each microbial community type was also significantly different; 81% of Ba-R had high TMB, compared to only 54% of Ru-R, and 72% of Ba-dominated patients belonged to the IFN-γ low group compared to 48% of Ru-dominated patients, with all Ba-NR being IFN-γ low. Gene ontology enrichment analysis further revealed distinct biological programs associated with response within each microbial community type. Ru-R were enriched for T, B and NK cell differentiation and cytotoxicity, while Ba-R showed enrichment for extracellular matrix remodelling. Together this demonstrates that different microbial community types are associated with altered baseline peripheral immune tone and tumor features. Furthermore, it suggests that ICI response within each microbial community type may be characterised by divergent predictive markers and mechanisms of response. This is highly relevant to optimally targeting the gut microbiome in the clinic and identifying patients who will benefit most from microbiome-modifying interventions.

#2884 Defined bacterial consortium highlights the impact of carcinogenic bacteria on DNA methylation and tumorigenesis.

Siddhi Chitre[1], Claudia Mercado-Rodriguez[1], Anthony Pompetti[2], Pyounghwa Park[2], Raad Z. Gharaibeh[1], Jean-Pierre Issa[2], Christian Jobin[3]

[1]University of Florida, Gainesville, FL,[2]Coriell Institute for Medical Research, Camden, NJ,[3]University of Florida College of Medicine, Gainesville, FL

BACKGROUND: Colorectal cancer (CRC) is second leading cause of deaths in the USA. Bacteria like *E. coli* harboring the carcinogenic island *pks* promote CRC in preclinical models. However, the impact of carcinogenic bacterial DNA methylation and CRC development is unknown.

METHODS: A defined consortia of 13 bacterial isolates (C13) containing either *E. coli* low pks (C13-DSMZ) or *E. coli* high pks (C13-UM149) were used in the study. Mice were administered 10^8 CFU of the bacterial consortia via oral gavage. 2 weeks later, they received 2% Dextran sodium sulfate (DSS) for one week, and tissues were collected at week 7 for analysis. Stools, colonic tumors and matched normal mucosa were collected. Stool samples were subjected to 16S rRNA sequencing. Tumors and normal mucosa were subjected to reduced representation of bisulfite sequencing (RRBS) and RNA-seq analysis for methylation and gene expression analysis respectively. Western Blot (WB) and Immunofluorescence (IF) analysis were used to determine DNA damage and cell proliferation in IEC-6 cells. Immunohistochemistry (IHC) was performed on colonic tissues.

RESULTS: IEC-6 cells exposed to *E. coli* DSMZ exhibited lower DNA damage (γH2AX expression), whereas cells treated with *E. coli* UM149 showed elevated γH2AX. Mice colonized with C13-UM149 developed significantly more tumors than those with C13-DSMZ ($p = 0.046$). IHC of colonic tissues showed that C13-UM149 exhibited higher Ki-67 (cell proliferation), β-catenin (oncogenic signaling), and γH2AX compared with C13-DSMZ ($p < 0.05$). Genome-wide methylation analysis showed broader CpG alterations in C13-DSMZ tumors (247,797 CpGs) than C13-UM149 mice (172,727 CpGs). Compared to C13-DSMZ, C13-UM149 tumors had 70,650 hyper and 65,024 hypomethylated CpGs, and 192 hyper and 220 hypomethylated promoters. These changes were associated with upregulation of *Il5ra* (inflammation), *Galr1* (tumor growth), and *Minar1* (tissue remodeling), and downregulation of *Tmed6* (protein trafficking) and *Pcdhb19* (adhesion) in C13-UM149 tumors. In normal mucosa, C13-UM149 altered 28,316 hyper and 59,780 hypomethylated CpGs with increased *Aldoart1* (glycolysis) and *Palm3* (immune signaling) expression. C13-UM149 tumors also showed promoter hypomethylation driving increased expression of *Sema4c* (tumor invasion) and promoter hypermethylation accompanied by increased *Mmp9* expression (matrix remodeling). C13-DSMZ tumors exhibited promoter hypermethylation with elevated expression of *Mecom* (tumor progression) and promoter hypomethylation with increased *Wnt7b* (oncogenic signaling).

CONCLUSION: Distinct *pks* activities differentially modulate DNA methylation and influence gene expression and tumor development. Our findings suggest that the methylome can shift in two directions depending on the bacterial context, with predominant hypermethylation in tumors and hypomethylation in normal tissues.

#2885 Intron retention marks a myeloid-skewed immune desert and nominates an ICI nonresponse marker in *H. pylori*-positive gastric cancer.

Daisuke Takayanagi[1], Junya Kitadani[2], Masahiro Katsuda[2], Toshiyasu ojima[2], Keiji Hayata[2], Manabu Kawai[2], Sinichi Hashimoto[3], Kazuhiko Tagawa[4], Toru Sugino[4], Satoshi Wada[5], Hiroki Yamaue[6], Takuya Tsunoda[7]

[1]Division of Medical Oncology, Showa Medical University, Tokyo, Japan,[2]Second Department of Surgery, Wakayama Medical University, Wakayama, Japan,[3]Wakayama Medical University, Wakayama, Japan,[4]Zenick.lab Corporation, Tokyo, Japan,[5]Showa Medical University, Tokyo, Japan,[6]Pancreatic Cancer Center, Division of Gastroenterological & General Surgery, Department of Surgery, Showa Medical University, Tokyo, Japan,[7]President & CEO, Showa University, Tokyo, Japan

Background: The benefits of immune checkpoint inhibitors (ICIs) in gastric cancer (GC) vary according to the *Helicobacter pylori* (Hp) status. While profiling transcriptomes, intron retention (IR) emerged as a major distinguishing feature in Hp-positive disease, but its immunologic significance remains unclear.
Methods: We analyzed 66 RNA-seq tumor samples (39 Hp-positive and 27 Hp-negative) from 24 patients. Alternative splicing (AS) were quantified USING PSIsigma, rMATS. AS-derived neoantigens were predicted (SNAF; strict filters), and a quality-weighted neoantigen burden was calculated. Antigen-presentation machinery (APM) was summarized using a purity-adjusted APM score. Tumor microenvironment (TME) features were profiled using ESTIMATE, Hallmark GSEA, ssGSEA, CIBERSORTx, and a four-class subtype (desert/immune-enriched [IE]/IE fibrotic/fibrotic). High IR was defined as three or more IR events. Statistical analysis was performed using the Mann-Whitney test and Spearman correlation, with BH-FDR correction.
Results: Across Hp infection status, Hp-positive tumors harbored more IR/AS events and a higher total neoantigen burden under strict filters; however, IR-specific and quality-weighted burdens were not significantly higher. In Hpnegative tumors, higherquality neoantigen burden correlated with intrinsic APM capacity ($\rho \approx 0.41$, $p=0.034$), indicating preserved antigen-APM coupling. Within Hp-positive tumors, IRhigh (n=12) versus IRlow (n=27) tumors showed higher neoantigen metrics (IRderived 4 vs 1, $p=4.6\times10^{-7}$; weighted 24.1 vs 12.2, $p=3.9\times10^{-4}$), enrichment of G2M/E2F/MYC/mitotic spindle programs (FDR<0.05), higher tumor purity (p=0.022), lower ImmuneScore (p=0.0156) and StromalScore (p=0.017), and uniform classification as the Desert subtype (12/12). NMD and splicing signatures were significantly elevated (p=0.014/0.034), CD8/IFN signatures were reduced (p=0.034), and the APM score favored IRlow tumors (p=0.050). A Myeloid/mastcell-skewed pattern was also evident (MDSC signature, p = 0.037; activated mast cells, p=0.0077; resting mast cells, p=0.0027). In Hp-positive tumors overall, quality-weighted neoantigen burden correlated positively with NMD/splicing ($\rho \approx 0.63$, $p=1.9\times10^{-5}$; $\rho \approx 0.67$, $p=3.7\times10^{-6}$), while IR burden correlated negatively with CD8/IFN activity ($\rho \approx -0.44$, p=0.0056). IR events were not enriched in core APM genes.
Conclusions: In Hp-positive GC, high IR defines a proliferative, NMD/splicing-stressed, myeloid/mastcell-skewed immunedesert microenvironment characterized by neoantigen-APM uncoupling. This phenotype aligns with limited ICI benefit, identifying high IR as a potential predictive marker of ICI nonresponse, supporting prospective validation and hypothesis-driven evaluation of ICI-based regimens that reprogram myeloid-rich TMEs or modulate splicing/NMD pathways.

#2886 Microbiota-driven modulation of tumor growth in Li-Fraumeni Syndrome: Evidence for bile acids as a key mediator.

Noel W. Y. Ong[1], Camilla Giovino[2], Nicholas Fischer[2], Paula Rosanna Quaglietta[2], Ashby Kissoondoyal[2], David Malkin[2]

[1]Medical Biophysics, University of Toronto, Toronto, ON, Canada,[2]The Hospital for Sick Children, Toronto, ON, Canada

Li-Fraumeni Syndrome (LFS) is caused by a germline mutation in *TP53,* which greatly increases the risk of earlier onset malignancies. Microbial communities can regulate the host inflammation and metabolism, linking them to p53 biology. However, we do not fully understand how gut microbiome contributes to this risk. In this study, we looked at how depleting microbiota impacts tumor development in a mouse model of LFS. *Trp53*$^{R172H/WT}$ (LFS) mice and their wildtype (WT) littermates received a broad-spectrum antibiotic cocktail to deplete the gut microbiota. After four days of treatment, mice were injected subcutaneously with MC38 colon adenocarcinoma cells and continued the antibiotic treatment until study endpoint. LFS mice that received antibiotics developed significantly smaller tumors compared to untreated LFS controls, while the tumor growth in WT mice did not change. This suggests that microbial activity promotes tumor growth in mutant p53 mice. To interrogate if microbial metabolites, rather than live organisms, caused this effect, we transferred filtered fecal matter from LFS mice to WT recipients. These filtrates increased tumor size, showing that soluble microbial products can mimic the tumor-promoting effect. Faecal filtrate was analyzed with LC-MS and untreated LFS mice showed higher levels of fecal bile acids compared to WT animals. The presence of these bile acids also positively correlated with subcutaneous tumor mass, and antibiotic treatment reduced bile acid presence. We observed increased NF-κB levels in the intestines of untreated LFS mice. ELISAs further confirmed elevated intestinal pro-inflammatory cytokines expression, including IL-6, TNF-α, IFN-γ, and IL-17A, which decreased after microbiota depletion. In addition to these intestinal changes, untreated LFS mice had higher total levels of circulating plasma pro-inflammatory cytokines, which slightly decreased after antibiotic treatment. FITC-dextran assays demonstrated increased gut permeability in untreated LFS mice, returning to normal after treatment with antibiotics. Mutant p53 has been reported to enhance the mevalonate pathway, leading to increased cholesterol synthesis and an expanded pool of primary bile acids. These bile acids can then be converted by gut microbiota into secondary bile acids that have known inflammatory and NF-κB-activating effects. This combined metabolic and microbial pathway may explain the elevated bile acids and inflammatory signaling seen in LFS mice. Taken together, these data broaden the current understanding of LFS biology by revealing that tumor susceptibility is shaped not only by cell-intrinsic mutant p53 functions but also by microbiota-driven metabolic and inflammatory cues. This integrated view opens new avenues for therapeutic intervention beyond traditional surveillance-based care.

Poster Session

#2891 Specificity and timing of TREM-1 blockade initiation impact its therapeutic efficacy in cancer.

Alexander B. Sigalov

SignaBlok, Inc., Shrewsbury, MA

Overexpression of triggering receptor expressed on myeloid cells 1 (TREM-1) is associated with the immune-suppressive tumor microenvironment (TME) and unfavorable prognosis in pan-cancer. TREM-1 is mainly expressed on neutrophils, monocytes, and macrophages including monocyte-derived macrophages. These cells can play different or even opposite roles in the pathogenesis of cancer. Despite more than two decades of intensive research in the field, the question whether specificity of TREM-1 inhibitor can impact its antitumor efficacy has never been addressed mostly, due to the lack of cell-restricted approaches to TREM-1 blockade. This study aims to determine whether broad or macrophage-specific TREM-1 blockade demonstrates distinct therapeutic efficacy and superior outcomes in cancer models. Ligand-independent TREM-1 inhibitory peptides GF9 and GA31 (the latter in a form of macrophage-targeted lipopeptide complexes, GA31-LPC) were evaluated in animal models of pancreatic cancer. GF9 inhibits TREM-1 on all TREM-1-expressing cells, while GA31-LPC targets TREM-1 predominantly on macrophages. In the Kras (G12D)/Trp53 null/Pdx1-cre (KPC) mouse allograft tumor model established in fully immunocompetent C57BL/6 mice, GF9 and GA31-LPC alone significantly inhibited pancreatic cancer progression. In combination with anti-PD-L1 therapy, GA31-LPC, but not GF9, overcame cancer resistance to PD-L1 checkpoint blockade and synergized with immunotherapy. In PANC-1 xenograft-bearing athymic nude mice with intact innate immunity but lacking T cells, both GF9 and GA31-LPC increased complete response rate and survival when combined with chemotherapy. The effectiveness of these agents was dependent on the timing of TREM-1 blockade initiation relative to chemotherapy. GF9 was effective only when given with but not after chemotherapy. In contrast, GA31-LPC was effective only when given after but not together with chemotherapy. Unexpectedly, GF9 and GA31-LPC alone or combined with anti-PD-L1 and chemotherapy did not exhibit significant antitumor effects in the orthotopic Pan02 syngeneic pancreas tumor allograft model established in C57BL/6 mice. This suggests that selecting the appropriate animal model is critical when developing antitumor agents that target TME. The detailed mechanisms of this paradoxical finding require further investigation for their potential contribution to the long-standing debate whether to activate or inhibit TREM-1 in cancer. In summary, these findings for the first time demonstrate that both inhibitor specificity and timing of treatment initiation are crucial for therapeutic TREM-1 inhibition. This has significant implications for clinical strategies targeting TREM-1, particularly informing tailored treatment approaches for not only pancreatic cancer but also other hard-to-treat tumors.

#2892 Safety and activity of cLRRC15-IFNa, a conditionally active biologic targeting IFNa specifically to LRRC15+ CAFs.

Justin Killebrew, Linda Liang, Shannon Okada, Aelish Guinn, Alton Etheridge, Brett Robison, David Colby, David Jurchen, Jacqueline Pham, Jamie Nguyen, John Skonier, Kendyl Daniels, Kerri Thomas, Laura Carlucci, Lynn Amon, Megan Sprague, Meri Galindo, Remington Lance, Sam Wrenn, Sandra Notonier, Shannon Fallen, Shea McClain, Wendy Curtis, Zane Kraft, John Mulligan, Diane Hollenbaugh

Bonum Therapeutics, Seattle, WA

While cancer-associated fibroblasts (CAFs) have emerged as a key cell type capable of influencing malignant cell growth, this axis of cancer biology has not yet been exploited for therapeutic benefit. CAFs enable tumor growth through multiple mechanisms including deposition of extracellular matrix, production of soluble factors, and inhibition of the immune response. Recent advancements have revealed how distinct CAF populations correlate with patient prognosis and response to therapies across many solid tumor types. Amongst these CAF subsets, LRRC15 expression has been shown to identify a myofibroblast population with a central functional role in supporting tumor cell growth and inhibiting anti-tumor immune responses. Approaches to reprogram or reduce this LRRC15+ population of CAFs may provide therapeutic benefit in multiple solid tumor indications.

IFN-α signaling directly on tumor-supporting CAFs drives reprogramming, countering the TGF-β signal on which the phenotype depends. IFN-α also effectively promotes both innate and adaptive immune responses, including dendritic cell maturation, repolarization of suppressive myeloid cells, and CD8+ T cell activation. However, the use of systemic IFN-α therapy has been limited by significant dose-limiting toxicities.

We have generated a conditionally active cLRRC15-IFNα therapeutic that targets IFN-α activity to LRRC15+ cells while remaining largely inactive on other cells. Our approach uses a novel dual-binding antibody (DBA) mechanism that takes advantage of the ability of an antibody to bind specifically and competitively to two distinct antigens. With this technology, IFN-α is bound and inactive in circulation and only becomes active when the therapeutic binds to LRRC15.

Once localized to the surface of an LRRC15+ CAF, cLRRC15-IFNα exerts anti-tumor activity both by direct cis-signaling of IFN-α on CAFs and by trans-signaling to adjacent immune cells. In vitro, reporter cell and receptor binding assays demonstrate that cLRRC15-IFNα has >100-fold preferential IFN-α activity in the presence of LRRC15. In primary cells, cLRRC15-IFNα preferentially induces IFN-α signaling in LRRC15-expressing activated human fibroblasts. cLRRC15-IFNα inhibits tumor growth in mouse syngeneic tumor models, avoids clinical signs of IFN-α-mediated toxicity, and demonstrates robust combinatorial activity with anti-PD-1. In the TME, cLRRC15-IFNα drives the activation of CD8+ T cells. Collectively, these results demonstrate the potential of the DBA platform and support the clinical development of cLRRC15-IFNα.

#2893 Selective inhibition of eIF4A targets tumor-associated macrophages to restore lymphoma-specific immunity.

Haley Lynn Klimaszewski[1], A. Douglas Kinghorn[2], Michael R. Grever[3], Robert A. Baiocchi[3], John T. Patton[3]

[1]College of Medicine, The Ohio State University, Columbus, OH,[2]Division of Medicinal Chemistry and Pharmacognosy, College of Pharmacy, The Ohio State University, Columbus, OH,[3]Department of Internal Medicine, Division of Hematology, The Ohio State University, Columbus, OH

Background: Silvestrol is an antineoplastic translation inhibitor targeting eukaryotic translation initiation factor 4 subunit A (eIF4A). Silvestrol's antineoplastic effects are well characterized, with our group reporting anti-tumor activity in Epstein-Barr Virus (EBV)-associated lymphoma. While the direct anti-tumor effect in EBV-associated lymphoma was modest, silvestrol mediated indirect tumor control by preserving $CD8^+$ T-cell viability and cytotoxicity. However, silvestrol's impact on the myeloid compartment remains poorly understood. We hypothesize that silvestrol supports anti-tumor immune activity by suppressing tumor-associated macrophage (TAM) growth in the tumor microenvironment (TME).

Methods: Co-cultures (co-cx) of EBV-transformed lymphoblastoid cell lines (LCL) and autologous peripheral blood mononuclear cells (PBMC) were used to model the lymphoma TME. LCLs were transformed by native virus in SCID mice before ex vivo culturing. Flow cytometry was used to profile immune population frequency and phenotype. Cell proliferation was monitored via MTS assay. Cytokine arrays and trans-well assays were used to explore soluble and contact-dependent features of the model. Magnet bead separation was used to deplete or enrich immune populations. Transcription was analyzed with AmpliSeq.

Results: Depletion of $CD8^+$ T-cells from co-cx led to LCL expansion, whereas $CD14^+$ depletion improved LCL control. Cytokine arrays showed co-cx media (CM) was enriched for cytokines linked to recruitment, differentiation, and activity of immunosuppressive macrophages. Silvestrol-treated co-cx showed reduced $CD14^+$ and $CD206^+$ populations by flow and decreased CCL2, CCL8, CCL7, IL-8 by cytokine array. To assess silvestrol's direct effect on myeloid subsets, $CD14^+$ cells were isolated and incubated in CM. $CD14^+$ cells in CM showed increased proliferation and expression of TAM markers CD206 and CD163. CM-driven proliferation required LCL-PBMC contact and presence of T-cells in initial co-cx. CM-polarized $CD14^+$ cells inhibited proliferation of activated T-cells. Silvestrol treatment of CM-cultured $CD14^+$ cells reduced proliferation, CD206 and PD-L1 expression, and down regulated M2 and TAM transcriptional signatures.

Conclusions: Our co-cx replicates features of a lymphoma TME, exhibiting monocyte polarization toward immunosuppressive TAMs. Silvestrol suppresses TAM proliferation and polarization in co-cx and in monocytes incubated in CM. Planned experiments include Ribo-seq to identify deferentially translated transcripts in silvestrol-treated monocytes, murine studies of silvestrol's effects on TAMs, and synergy studies with other immunotherapies. Overall, these findings, along with previously reported immune effector sparing qualities, support eIF4A inhibition as a therapeutic strategy to target immune escape mechanisms in the lymphoma TME.

#2894 Alphavirus replicon expressing IL-12 reprograms tumor-associated macrophages and neutrophils and induces anti-tumor immunity.

Forrest Bowling[1], Momoko Ishikawa[1], Dhanya Nambiar[2], Jayalaxmi Sastri[1], Keiko Ishimoto[1], Fumiya Tao[1], Koyo Takahashi[1], Ivan Stepanek[2], Hongbin Cao[2], Davis Leitner[1], Kenta Matsuda[1], Fred Baik[2], John Sunwoo[2], Quynh Thu Le[2], Jonathan Smith[1], Wataru Akahata[1]

[1]VLP Therapeutics, Inc., Gaithersburg, MD,[2]Stanford University, Stanford, CA

Immunosuppressive myeloid cells such as tumor-associated macrophages (TAMs) and neutrophils (TANs) contribute to resistance against immune checkpoint therapies by fostering a suppressive tumor microenvironment (TME). To overcome this barrier, we developed a single-cycle alphavirus replicon particle (VRP) vector encapsulating self-amplifying RNA (saRNA) encoding interleukin-12 (IL-12) for intratumoral delivery, leveraging the natural tropism of alphaviruses for myeloid cells. The VRP was engineered with a capsid nuclear localization signal mutation to enhance transgene expression and reduce host cell toxicity. In preclinical studies, single-cell RNA sequencing of treated mouse 4T1 breast carcinoma tumors and draining lymph nodes revealed that IL12-VRP preferentially transduced M2-like TAMs and TANs, reprogramming them toward pro-inflammatory phenotypes via interferon signaling. This effect was further amplified by IL-12 expression, leading to expansion of pro-inflammatory $Nos2^{+}$ macrophage and neutrophil populations. IL12-VRP also activated cytotoxic NK and T cells, inducing IFN-γ expression and enhancing anti-tumor immunity. Compared to lipid nanoparticle-based delivery of the same saRNA replicon, IL12-VRP achieved superior tumor control in the MC38 colorectal model with ~1000-fold lower RNA gene copies in the dose. IL12-VRP suppressed MOC2 head and neck model tumor growth, prevented nodal and lung metastases, and remodeled immune landscapes in both tumors and lymphoid tissues. CT26 colorectal carcinoma model mice treated with IL12-VRP exhibited tumor reduction, durable systemic immune memory and rejected subsequent tumor rechallenge. These findings establish IL12-VRP as a potent immunomodulatory platform capable of reprogramming myeloid cells and enhancing adaptive immunity. This approach may improve outcomes in myeloid-dominant TMEs and augment current immunotherapies. Ongoing clinical evaluation (NCT06736379) will determine its translational potential.

#2895 JAK inhibition enhances virotherapy in gliomas by modulating interferon-driven resistance.

Andres R. Lopez-Rivas[1], Andrew Gregg Gillard[1], Akhila Parthasarathy[1], Dong Ho Shin[1], Angelis Morales-Rivera[1], Claudia Solbes-Godina[1], Alejandra Duran[1], Joy Gumin[1], Christopher A. Alvarez-Breckenridge[1], Marta M Alonso[2], Frederick F. Lang[1], Juan Fueyo[1], Candelaria Gomez-Manzano[1]

[1]MD Anderson Cancer Center, Houston, TX,[2]Universidad de Navarra, Navarra, Spain

Background: Treating glioblastoma remains a therapeutic challenge in oncology. Our laboratory developed an oncolytic adenovirus, termed Delta-24-RGD, which has been tested in clinical trials for recurrent glioblastoma patients with encouraging results (NCT00805376, NCT02798406). Here, we aim to further improve the efficacy of Delta-24-RGD by targeting factors that maintain the immunosuppressive characteristics of gliomas.

Methods: We performed bulk RNA-sequencing of murine gliomas treated with Delta-24-RGD or control (PBS) and analyzed the upstream regulators using Ingenuity Pathway Analysis. A correlation plot of IFNγ and IDO1 transcript levels from 38 glioblastoma patient samples was obtained from the Delta-24-RGD plus Pembrolizumab clinical trial (NCT02798406) and analyzed in R Studio. Western blots, qPCR, and ELISA in glioma cells validated the IFNγ-induced IDO1 expression. To study macrophage polarization, bone marrow-derived macrophages (BMDMs) were stimulated with IFNγ or IL-4 in the presence or absence of JAK inhibitors, and gene expression of immunosuppressive markers was assessed by qPCR. Therapeutic efficacy in vivo was assessed by quantifying brain-infiltrating leukocytes using flow cytometry and evaluating tumor growth and survival.

Results: RNA sequencing revealed IFNγ as the top upstream regulator in murine tumors treated with an oncolytic virus. In addition, we observed upregulation of the tryptophan metabolism and immunoregulator IDO1 network in these treated tumors. We found a significant and positive correlation between IFNγ and IDO1 in glioblastoma tumor biopsies from the clinical trial. In vitro studies demonstrated that IFNγ treatment of glioma cells increased JAKs/STATs phosphorylation levels, IDO1 expression, and the Kyn/Trp metabolite ratio, which were abrogated by concomitant treatment with JAK inhibitors. Additionally, we observed that the JAK inhibitors reduced the expression of anti-inflammatory genes (Retnla, Arg1, Ido1, and Cd274) in polarized BMDMs. In syngeneic glioma models, we demonstrated that combination therapy with Delta-24-RGD and Baricitinib (a JAK inhibitor) yielded better tumor control when compared to monotherapy controls. Moreover, we observed that combination therapy reprograms the myeloid compartment of the tumor microenvironment towards an immunostimulatory phenotype.

Conclusions: Our study highlights the dual role of IFNγ in gliomas treated with oncolytic virotherapy: while it promotes antitumor immunity, it also induces immunosuppressive pathways such as IDO1 activation and tryptophan metabolism. These findings underscore the complexity of immune regulation in the tumor microenvironment and support the therapeutic potential of JAK inhibition in combination with oncolytic viruses for cancer treatment.

#2896 Therapeutic targeting of TGR5 abrogates bile acid driven myeloid cell immunosuppression in cholangiocarcinoma.

Enis Hikmet Ozmert[1], Binbin Li[2], Jingchun Yang[2], Hannah Elizabeth Stumpf[3], Jessica R. Willhite[1], Danielle Carlson[1], Jennifer L. Tomlinson[4], Jon Covel[5], Raghuveer Ramachandra[5], Steven Olson[5], Rory L. Smoot[6], Sumera Ilyas[2]

[1]Gastroenterology and Hepatology, Mayo Clinic, Rochester, MN,[2]Mayo Clinic, Rochester, MN,[3]Mayo Clinic College of Medicine and Science, Rochester, MN,[4]Mayo Clinic Hospital-Rochester, Rochester, MN,[5]Sanford Burnham Prebys, La Jolla, CA,[6]Surgery, Mayo Clinic, Rochester, MN

Background: Cholangiocarcinoma (CCA) is an aggressive hepatobiliary malignancy with limited treatment options. CCA exhibits a distinct desmoplastic and tolerogenic tumor immune microenvironment (TIME) characterized by elevated bile acid concentrations resulting from obstructive cholestasis and dysregulated bile acid metabolism. TGR5 is an essential component of bile acid signaling. We hypothesize that bile acids promote CCA progression by establishing an immunosuppressive TIME through TGR5 signaling, which can be therapeutically targeted using SBI-364, a novel potent small molecule TGR5 inhibitor.

Methods: Single-cell RNA sequencing (scRNA-seq) of immune cells from human intrahepatic (iCCA) and perihilar (pCCA) CCA tumors were conducted. Therapeutic studies were performed using syngeneic murine models of iCCA (PMID: 38458319), a novel syngeneic model of pCCA, and patient-derived xenograft (PDX) models. In collaboration with Sanford Burnham Prebys, SBI-364, a first in-class competitive TGR5 antagonist, was assessed in vivo. Additionally, we performed co-culture experiments with bile acid +/- SBI-364-treated murine bone marrow-derived monocytic myeloid-derived suppressor cells (M-MDSCs) and $CD8^+$ T cells to assess functional immunosuppressive effects.

Results: Human scRNA-seq revealed significantly increased TGR5 (GPBAR1) expression predominantly in myeloid cell populations within the CCA TIME. SBI-364 treatment significantly reduced tumor burden in both syngeneic orthotopic iCCA models and a novel pCCA model that recapitulates the anatomic characteristics of perihilar CCA. In contrast, NOD/SCID mice bearing PDX535 (predicted sensitive) and PDX136 (predicted resistant), SBI-364 treatment did not achieve tumor reduction, suggesting that TGR5 inhibition predominantly attenuates tumor progression through modulation of bile acid-immune cell interactions. SBI-364 treated murine tumors had a significant reduction in immunosuppressive macrophages expressing interleukin-10 and M-MDSCs compared to vehicle treated tumors. Furthermore, bile acid-treated M-MDSCs exhibited enhanced suppression of $CD8^+$ T cell proliferation and function, an effect that was abrogated by SBI-364 co-treatment.

Conclusion: We demonstrate that TGR5 inhibition represents a promising therapeutic strategy across multiple immunocompetent preclinical CCA models. We demonstrate that the bile-acid TGR5 axis promotes CCA progression via immunosuppressive myeloid cells. Specifically, TGR5 signaling potentiates the immunosuppressive capacity of M-MDSCs, contributing to an immunosuppressive niche that facilitates tumor progression. These results establish TGR5 as a rational therapeutic target for overcoming immune evasion in cholangiocarcinoma.

#2897 A patient-derived fragmented tumor assay for detailed evaluation of drug response in the tumor microenvironment (TME) using scRNAseq.

Daniel C. Rabe, Daniel J. Gorski, Shiyuan Zheng, Mary Flaherty, Tommy Trieu, A'Riane Branch, Terykah Hollis, Lovepreet Singh Chahal, Brian Roberts, Richard A. Klinghoffer, Sonal Khare

Tempus AI, Inc., Chicago, IL

Background: Many platforms exist for evaluating drug response in patient-derived tumor models. However, they are limited by their ability to recapitulate the multitude of cell types present in the TME. Additionally, they don't represent physiological ratios of tumor to immune cells and lack many secreted factors present in the TME. Each of these characteristics can have a profound impact on the efficacy of TME-targeting therapeutics. To overcome these limitations, we investigated the use of a fragmented tumor assay to interrogate TME alterations following treatment.

Methods: We developed a method of processing fresh patient tumor specimens into drug penetrable (~1mm^3) fragments, allowing short duration (4 to 48h) drug exposure and evaluation of therapeutic response by measuring cytokine/chemokine secretion using multiplexed ELISA and alterations in cell populations via single cell RNAseq (scRNAseq). To determine how therapies broadly affect the TME, we treated samples with either the multikinase inhibitor, Lenvatinib, immune checkpoint inhibitors (ICIs) Pembrolizumab/Nivolumab, or STING agonist cGAMP.

Results: Endothelial cells of the tumor vasculature are one of the most difficult TME cell components to evaluate by conventional bulk analysis methods. To evaluate responsiveness of endothelial cells we exposed endometrial cancer specimens to Lenvatinib. Following drug exposure, tumor fragments were processed for scRNAseq. Well-defined and expected cell clusters were resolved including endothelial, tumor epithelial, stromal, and multiple immune cell populations. Analysis revealed differential expression across these diverse cell populations in response to drug treatments. Specifically in endothelial cells we observed significant dose-dependent downregulation of transcripts involved in angiogenesis.

To examine immune perturbations, we treated tumor fragments with STING activators and ICIs. We observed activation of Type I Interferon genes and Interferon Stimulated Genes (ISGs), consistent with T-cell activation and proliferation through both ELISA and scRNAseq. Transcriptional changes in macrophages indicated activation of IFNγ and PI3K, consistent with changes from an immune-repressive to immune-activating state. Epithelial cells showed increased MYC and PI3K signatures and decreased signatures involved in hypoxic responses as well as NFκB signaling.

Conclusions: Our results demonstrate that TME-dependent cell-specific responses to drug exposure are observable by combining tumor fragmentation and scRNAseq. This allows the platform to be used for the characterization of responses to new investigational agents, particularly those that target the non-tumor cell components of the TME, evaluate mechanism of action in detail, and assess the promise of such agents for treating solid tumor malignancies.

#2898 Aging-related morphological change in regional lymph nodes promotes an immunosuppressive microenvironment in colorectal cancer.

Kosuke Kanemitsu[1], Rin Yamada[2], Daiki Yoshii[2], Yukio Fujiwara[2], Yoshiyuki Tagayasu[1], Teruki Sako[1], Kota Arima[1], Kohei Yamashita[1], Kazuto Harada[1], Norihisa Hanada[3], Yoshihiro Komohara[2], Masaaki Iwatsuki[1]

[1]Department of Gastroenterological Surgery, Kumamoto University Hospital, Kumamoto, Japan,[2]Department of Cell Pathology, Kumamoto University Hospital, Kumamoto, Japan,[3]Department of Surgery, Izumi General Medical Center, Kagoshima, Japan

Background: Lymph nodes (LNs) play a central role in anti-cancer immunity, yet the influence of aging on LN morphology and function in cancer remains largely unexplored. This study aimed to elucidate the relationship between aging-related LN alterations and the tumor immune microenvironment in colorectal cancer (CRC).
Methods: Mesenteric LNs from 160 CRC patients who underwent curative resection were histologically examined. LN ectasia—defined as sinusoidal dilation with loss of sinus macrophages—was quantified and correlated with clinicopathological factors, systemic inflammatory markers, and immune cell infiltration in the primary tumor (CD3, CD8, Foxp3, Iba1, CD163 by IHC).
Results: LN ectasia was significantly more frequent in elderly patients (≥70 years) and in right-sided colon cancers (p=0.002). Patients with marked LN ectasia showed lower serum albumin and leukocyte counts, indicating systemic immunosenescence. Immunohistochemical analysis revealed significantly reduced infiltration of $CD8^+$ cytotoxic T cells and $Iba1^+/CD163^+$ macrophages in tumors from patients with high LN ectasia, representing a “cold” immune microenvironment. However, LN ectasia was not directly associated with prognosis.
Conclusions: Aging-related LN ectasia reflects functional decline of regional lymphoid structures and correlates with attenuation of local anti-tumor immune activity in CRC. LN ectasia may serve as a histopathological biomarker of LN senescence and systemic immunosuppression in elderly cancer patients.

#2899 Oncolytic virus-chemotherapy combination improves control of PDAC growth and spread.

Biplov Sapkota[1], Naveen Chintala Ramulu[1], Shreya Pokharel[1], Mohammed T. Hussain[2], Brent Stanfield[2], Konstantin Kousoulas[2], Joseph Francis[1]

[1]Department of Comparative Biomedical Sciences, Louisiana State University, Baton Rouge, LA,[2]Department of Pathobiological Sciences, Louisiana State University, Baton Rouge, LA

Pancreatic ductal adenocarcinoma (PDAC) remains one of the deadliest solid tumors. Its progression is driven by KRAS-dependent signaling, a dense desmoplastic stroma, early metastatic spread, and an immunologically ‘cold’ tumor microenvironment (TME). Therapies that combine direct cytotoxic activity with TME reprogramming may improve treatment response. Oncolytic virotherapy offers such a dual mechanism.We hypothesize that a genetically engineered herpes simplex virus (HSV-1) strain, HSV-1(VC2), engineered to express murine GM-CSF, can synergize with gemcitabine by modulating tumor-intrinsic signaling and initiating early steps toward a more immune-responsive TME. *In vitro* studies using murine $KRAS^{G12D}$ $TP53^{R172H}$ Cre (KPC) cells demonstrated a strong synergistic interaction between the proposed oncolytic virus (oV) and gemcitabine, as supported by ZIP synergy modeling. qPCR analysis showed that gemcitabine increased EMT-associated transcripts (TGF-β, fibronectin, TAZ) as well as pro-survival/pro-migratory transcripts (CAV1, AKT, CTNNB1, PI3K). The oV alone activated STING-associated innate immune pathways. The combination treatment suppressed gemcitabine-induced EMT and proliferative signaling while maintaining antiviral and immunostimulatory gene expression, indicating coordinated transcriptional modulation consistent with enhanced cytotoxic and immunogenic activity.To evaluate in vivo relevance, we used an orthotopic immunocompetent PDAC model in which 10^4 KPC cells were surgically implanted into the pancreas of WT C57BL/6 mice. This model reflects PDAC growth kinetics and metastatic behavior. In preliminary studies, oncolytic virotherapy alone did not reduce tumor size but markedly reduced liver metastasis, with 1 of 4 mice showing liver involvement compared to 4 of 4 in the control group at day 38. In another study, the same OV application schedule (administered on days 10 and 24 after tumor implantation) was used together with gemcitabine (given weekly starting on day 11 at 100 mg/kg). This combination further decreased primary tumor burden compared with either monotherapy at the 38-day endpoint (n=8 mice/group). A Panc-1 xenograft model showed similar patterns in primary tumor reduction and metastatic spread.Ongoing work includes flow cytometry, targeted transcriptomics, and proteomic profiling to define immune and molecular contributors to synergy. Additionally, in vitro studies using human PDAC and pancreatic stellate cell 3D co-cultures, as well as human PDAC organoids, are in progress. Together, these findings position HSV-1(VC2) GM-CSF as a clinically relevant partner for gemcitabine and a potential strategy to improve PDAC responsiveness through both cytotoxic and immune-mediated effects.

#2900 Activation of the cGAS-STING signaling pathway as an immunotherapeutic approach to glioblastoma.

Louise Leparc, Judit Sanchez Gil, **Hiroaki Wakimoto**

Massachusetts General Hospital, Boston, MA

Glioblastoma (GBM) is the most aggressive primary brain tumor, characterized by rapid progression, resistance to therapy, and a highly immunosuppressive tumor microenvironment (TME). By sensing and reacting to cytosolic DNA, the cGAS-STING signaling pathway plays a critical role in innate immune defense, producing type I interferons and pro-inflammatory cytokines. In GBM, STING expression is frequently downregulated, contributing to tumor immune evasion. We set out to evaluate the potential of stimulating cGAS-STING signaling as a strategy to modulate the TME and provoke anti-tumor immunity in preclinical models of GBM based on murine GBM stem-like cell lines (005, NF53, C3, RIG) that are driven by TP53 loss and HrasV12. We found heterogeneous baseline expression levels of cGAS-STING components in these murine GBM cells, analogous to our observation in human patient-derived GBM cells. Despite this variability, murine GBM cells consistently responded to exposure to STING agonist ADU-S100 with transient IRF3 phosphorylation and robust induction of type I interferons (IFN-β) and chemokines (CXCL10, CCL5). *In vivo*, intratumoral injection of ADU-S100 (50 micrograms) mediated therapeutic efficacy against murine orthotopic GBM in C57BL/6 mice as it resulted in significant survival extension including long-term survival. This was achieved despite apparent ADU-S100-elicited, acute and transient body weight loss. Rechallenge of the same GBM cells in the contralateral hemisphere in long-term survivors was rejected, indicative of immune memory. These findings support pharmacological cGAS-STING activation as a strategy to counter GBM-driven immune suppression and a promising immunotherapeutic approach to this deadly brain tumor.

#2901 Integrated spatial, single-cell, and in vivo dissection of matrix CAF-driven immune exclusion in colorectal cancer.

Yuki Nakanishi[1], Kosuke Iwane[1], Yu Muta[1], Kento Yasumura[1], Mayuki Omatsu[1], Naoki Aoyama[1], Munehiro Ikeda[1], Yoko Masui[1], Go Yamakawa[1], Yasuhiro Fukui[2], Hiroaki Kasashima[2], Akihisa Fukuda[1], Hiroshi Seno[1]

[1]Kyoto University, Kyoto, Japan,[2]Osaka Metropolitan University Graduate Scholl of Medicine, Osaka, Japan

Background:
Fibrotic colorectal cancers (CRCs) are largely microsatellite stable and characterized by desmoplastic stroma that excludes cytotoxic T cells. Cancer-associated fibroblasts (CAFs) are major stromal constituents, yet how specific CAF subsets regulate immune exclusion remains poorly understood.

Methods:
We integrated orthotopic in vivo tumor models with spatial and single-cell transcriptomic analyses of human and murine CRCs to elucidate the mechanisms by which matrix CAFs modulate the tumor immune microenvironment.

Results:
Matrix CAFs highly expressed *THBS2*, a matricellular protein enriched at the invasive tumor front. In vivo, global or fibroblast-specific *Thbs2* deletion disrupted the fibrotic barrier and markedly increased intratumoral $CD8^+$ T-cell infiltration. Mechanistically, THBS2 restrained CXCL9/10 production by dendritic cells and macrophages, limiting recruitment of $CXCR3^+$ $CD8^+$ T cells. Neutralization of CXCL9/10 or blockade of CXCR3 reversed these effects, confirming the central role of the CXCL9/10-CXCR3 chemokine axis in CAF-mediated immune exclusion. Spatial transcriptomic profiling of human CRC further demonstrated that loss of THBS2 in matrix CAF-rich regions correlated with increased proximity between $CD8^+$ T cells and myeloid cells and elevated chemokine expression. Despite enhanced infiltration, these $CD8^+$ T cells displayed features of exhaustion, rendering tumors more responsive to immune checkpoint blockade.

Conclusion:
This integrated spatial, single-cell, and in vivo dissection reveals that matrix CAF-derived THBS2 orchestrates immune exclusion in fibrotic CRC via suppression of the CXCL9/10-CXCR3 axis. Targeting THBS2 or its downstream stromal pathways may represent a promising therapeutic strategy to overcome stromal-driven immunotherapy resistance in microsatellite-stable colorectal cancer.

#2902 Deciphering the function of lipid-associated macrophages in immunotherapy resistance of hepatocellular carcinoma.

Xiaohang Long[1], Yaxian Wang[1], Siyuan HUANG[1], Joaquim Si Long VONG[1], Joseph Jao-Yiu Sung[2], Lam, Stephen CHAN[3], Alfred Sze-Lok Cheng[1]

[1]School of Biomedical Sciences, The Chinese University of Hong Kong, Hong Kong, Hong Kong,[2]Lee Kong Chian School of Medicine, Nanyang Technological University, Singapore, Singapore, Singapore,[3]Department of Clinical Oncology, The Chinese University of Hong Kong, Hong Kong, Hong Kong

Background: Hepatocellular carcinoma (HCC) is a leading cause of cancer-related mortality globally. While immune-checkpoint blockade (ICB) has transformed oncology, its efficacy in HCC is limited by an immunosuppressive tumor microenvironment (TME) and diverse disease etiologies, yielding response rates below 30%. Our prior work identified several key transcriptional and epigenetic drivers of immune exclusion and myeloid-mediated immunosuppression underlying ICB resistance in preclinical models (*Gut* 2018, 2020, 2023, *Sci Transl Med* 2021). To develop precise immunotherapies, it is critical to identify the central regulatory nodes within the TME of ICB-resistant patients.
Methods: We applied single-cell RNA sequencing (scRNA-seq), single-cell Assay for Transposase-Accessible Chromatin using sequencing (scATAC-seq), and spatial transcriptomics to investigate the TME of HCC patients resistant to ICBs (from trial NCT05873244), with treatment-naïve patients serving as controls.
Results: Multi-omics analysis uncovered a subcluster of tumor-associated macrophages (TAMs) characterized by high levels of lipid-associated genes. Bioinformatics analysis of open chromatin regions identified a transcription factor (MTF) that was significantly up-regulated in TAMs from ICB-resistant HCCs but not in treatment-naïve tumors. Spatial transcriptomic profiling and multiplex immunohistochemistry confirmed the co-localization of MTF with the lipid-associated macrophages (LAMs) in patient tumors. Chromatin immunoprecipitation-sequencing in THP-1 cells revealed that MTF binding was enriched in phagocytosis-related genes. Functional studies in macrophage cell lines demonstrated that knockdown or overexpression of MTF modulated phagocytic capacity. Integrated RNA sequencing and Cut&Tag analysis further delineated its downstream targets and involvement in phagocytic pathways.
Conclusions: This study identifies a novel key transcriptional regulator and provides mechanistic evidence for its role in modulating macrophage phagocytosis and lipid metabolism in HCC ICB resistance. Our findings uncover critical epigenetic and transcriptional alterations within the immunosuppressive myeloid landscape and highlight promising therapeutic targets to overcome ICB resistance. These insights lay the groundwork for targeting the immunometabolic axis as a new strategy to counteract ICB resistance in HCC.
Acknowledgment: This study is supported by the General Research Fund (14120621, 14119023 and 14112525) CUHK Research Committee-Direct Grants (504643107) and the Li Ka Shing Foundation.

#2903 Modulating the tumor microenvironment (TME) to enhance anti tumor immunity using metabolic inhibitors.

Takeshi Ito[1], Shun Kishimoto[1], Kazutoshi Yamamoto[2], Jeffrey Brender[2], Frank Echtenkamp[1], Daniel Crooks[1], Murali Cherukuri Krishna[2], William Marston Linehan[1]

[1]Urologic Oncology Branch, National Institutes of Health, Bethesda, MD,[2]Molecular Imaging Branch, National Institutes of Health, Bethesda, MD

The tumor microenvironment (TME) presents a challenging setting for anti-tumor immunity due to its extreme metabolic features: nutrient deprivation, metabolite accumulation, acidity and hypoxia. Immune cells become dysfunctional under these unfavorable conditions resulting in diminished anti-tumor activity. Thus, strategies to address immunosuppressive conditions in the TME are warranted. We utilized metabolic inhibitors to modulate the TME and enhance anti-tumor immune responses. Neuroendocrine tumors (NETs) and chimeric antigen receptor (CAR)-T cells for somatostatin receptor 2 (SSTR2), a potential therapeutic target for NETs, were utilized as our experimental model. SSTR2 CAR-T cells were prepared from $CD8^+$ T cells of healthy donors. To recapitulate T cell dysfunction in TME, CAR-T cells were cultured under unfavorable metabolic situations: acidic, hypoxic and low glucose conditions. The CAR-T cells exhibited dysfunctional phenotypes including decreased proliferation and viability and impaired cytotoxicity and cytokine production capacity. Additionally, exhaustion-related markers were significantly upregulated on CAR-T cells especially under acidic conditions. To modulate metabolism of NETs, we utilized inhibitors targeting lactate dehydrogenase A (LDHA) and mitochondrial complex I. LDH inhibitor NCI-006 reduced glucose consumption and lactate (Lac) production from NETs by inhibiting lactate fermentation, resulting in reduced extracellular acidification. However, NETs exhibited metabolic rewiring to oxidative phosphorylation (OXPHOS) after NCI-006 treatment. In contrast, Complex I inhibitor IACS-010759 treatment induced OXPHOS inhibition and rewiring to aerobic glycolysis. Combined treatment with these inhibitors successfully interrupted metabolic rewiring of NETs by blocking both aerobic glycolysis and OXPHOS. Hyperpolarized magnetic resonance imaging (HP-MRI) with 1-13C pyruvate (Pyr) and electron paramagnetic resonance (EPR) pO2 imaging were conducted to monitor in vivo metabolic activities in NET-derived xenograft tumors. Consistent to our in vitro findings, NCI-006 suppressed Lac production from Pyr, and IACS-010759 treatment resulted in elevated pO2 level in xenograft tumors. However, metabolic rewiring was also observed in xenograft model; NCI-006 treatment exacerbated hypoxia and IACS-010759 promoted Lac production from Pyr. To overcome the metabolic rewiring, we attempted combination treatment with NCI-006 and IACS-010759 on xenograft mice. The combination treatment effectively abrogated metabolic flexibility of NET-derived xenograft tumors. Metabolic stress resulted in CAR-T cell dysfunction, while NCI-006 and IACS-010759 showed potential to improve the extracellular environment of the TME. Further studies are warranted to test the feasibility and efficacy of metabolic inhibitors in combination with CAR-T therapy.

#2904 Infectious bursal disease virus (IBDV) as a novel virotherapy for stimulating innate and adaptive immune responses in different cancer models.

Vicent Tur Planells[1], Yonina Bykov[1], Gloria Dawodu[1], Leticia Perez Rodriguez[2], Noemi Garcia Romero[3], Angel Ayuso Sacido[3], Jordi Cano Ochando[4], Daniel Lozano Ojalvo[5], Adolfo Garcia Sastre[1], Estanislao Nistal Villan[6], Sara Cuadrado Castano[7]

[1]Microbiology, Icahn School of Medicine at Mount Sinai, New York, NY,[2]Precision Immunology Institute (PRIISM), Icahn School of Medicine at Mount Sinai, New York, NY,[3]Experimental Sciences, Francisco de Vitoria University (UFV), Madrid, Spain,[4]Microbiology, National Center of Microbiology Health Insitute Carlos III, Madrid, Spain,[5]Immunology, Center for Research in Food Sciences CSIC-UAM, Madrid, Spain,[6]Pharmaceutical Sciences, CEU San Pablo University, Madrid, Spain,[7]Microbiology, Ichan School of Medicine at Mount Sinai, New York, NY

Within cancer immunotherapy, oncolytic viruses (OVs) are recognized as a promising and robust treatment approach. This study presents the potential of Infectious Bursal Disease Virus (IBDV), an avian-specific pathogen with no known human zoonosis, as a novel therapeutic agent. We assessed IBDV's efficacy against several cancer types, including glioblastoma (CT-2A, patient-derived glioblastoma stem cells), melanoma (B16-F10), colorectal carcinoma (CT-26), and B-cell lymphoma (A20). We have evaluated the infectivity, cytotoxicity, replication kinetics, and analyzed the expression of pro-inflammatory and anti-viral (IFN-I/IFN-III) cytokine responses in all tumoral models following viral infection, in comparison to those elicited by a very well-known OV, Newcastle disease virus (NDV). We further evaluated IBDV's anti-tumor effects in preclinical glioblastoma, colon, melanoma, and B-cell lymphoma models using immunocompetent mice. Immunological responses to IBDV virotherapy were analyzed locally, in the tumor microenvironment (TME) and systemically (in tumor-draining and distal lymph nodes) via spectral flow cytometry. Results demonstrate that IBDV significantly exhibits oncolytic activity both in vitro and in vivo, effectively infecting, replicating in, and killing all cancer models, while inducing type-I/III IFN responses and enhancing pro-inflammatory (IL-1β and IL-6) responses. Notably, in melanoma (B16-F10) and glioblastoma (CT-2A) in vivo models, IBDV treatment delayed tumor growth and improved overall survival compared to PBS-treated mice, while complete tumor elimination was achieved in 30% of colorectal carcinoma (CT-26) and 60% of B-cell lymphoma (A20) engrafted mice. In the A20 lymphoma model, a bilateral tumor setup was also used to assess abscopal effects. IBDV was injected in only one tumor, and delayed growth was observed in the contralateral, untreated tumor, indicating partial systemic immune activation. Overall, IBDV virotherapy elicited robust innate and adaptive immune responses within the TME, disrupting tumor immunotolerance. This was evidenced by the elevated ratios of M1/M2 and CD8+/Treg immune cell populations upon IBDV treatment compared to PBS-treated mice. In melanoma and colorectal carcinoma models, there was an upregulation of immunosuppressive markers on both CD4+ and CD8+ T cells in the TME and tumor-draining lymph nodes. Conversely, in the A20 lymphoma model, IBDV treatment resulted in a marked reduction of immunosuppressive features, characterized by decreased M2-like monocyte/macrophage populations and reduced expression of immunosuppressive markers on both CD4+ and CD8+ T cells. These findings highlight IBDV’s potential as a robust OV and suggest combining IBDV treatment with therapies targeting co-inhibitory markers to enhance efficacy.

#2905 Pancreatic adenocarcinoma immune tumor microenvironment is shaped by differential miRNA expression.

Maksymilian Jan Pilecki, Shannon M. Wallet, Robert Maile, Gerik Tushoski- Aleman, Song Han, Steven J. Hughes

Department of Surgery, University of Florida College of Medicine, Gainesville, FL

Introduction: Pancreatic ductal adenocarcinoma (PDAC) is a malignancy with poor prognosis and advanced stage at diagnosis. The tumor microenvironment (TME) plays a role in driving aggressive, treatment-resistant PDAC subtypes. This study explores miRNAs' role in modulating the immune cell composition of the PDAC TME.
Methods: The Database of Differentially Expressed microRNAs in Cancer was queried for miRNAs with log2 fold-change ≥3.5 or ≤-3.5 between PDAC and normal pancreas. miRNA and predicted target mRNA expression in neoadjuvant-treated PDAC samples was profiled using Nanostring nCounter. Patient and disease characteristics, miRNA target prediction, biologic pathways, immune infiltration, and survival were analyzed to identify associations with aggressive, treatment-resistant disease.
Results: Differentially expressed miRNAs were analyzed using Nanostring nCounter. Principal component analysis revealed two sample clusters: one with younger patients, high nodal stage, frequent positive surgical margins, and poor neoadjuvant treatment response; the other with less advanced disease features and better neoadjuvant treatment response. 14 differentially expressed miRNAs and 31 mRNA targets were identified. These were predicted to activate cytokine signaling, neutrophil degranulation, phagosome formation, IL-27 signaling, and tumor microenvironment pathways on Qiagen Ingenuity Pathway Analysis. Survival-congruent expression, defined by inverse hazard ratio between miRNAs and target mRNAs, was observed for miR-148a-3p (targets: SLC2A1, ITGA5) and mir-193a/b-5p (target: RORC). Low miR-148a-3p levels and high miR-193a/b-5p levels were linked to short overall survival. TIMER 2.0 analysis demonstrated positive correlation between ITGA5 expression and cancer-associated fibroblasts, M2 macrophages, and regulatory T cell infiltration; global suppressive effect of SLC2A1 on immune cell infiltration; and a mixed effect of RORC on immune cell infiltration, characterized by positive correlation with neutrophil and type 1 macrophages and negative correlation with CAF, natural killer cell, and dendritic cells.
Conclusion: Distinct miRNA expression profiles in neoadjuvant-treated PDAC are linked to increased inflammatory signaling and immunosuppressed TME via effect on predicted mRNA targets. A subset of miRNAs differentially expressed between advanced, treatment-resistant PDAC and treatment-responsive PDAC is predicted to influence the PDAC TME via upregulation of immune pathway signaling and effects on the TME composition. Particularly, we demonstrated that low miR-148a-3p expression in treatment-resistant PDAC facilitates ITGA5-mediated immunosuppressive cell infiltration and predicts worse survival. Together, these findings highlight miRNAs' role as critical modulators of the PDAC immune TME and clinical outcomes in PDAC.

#2906 The iRGD peptide reprograms the tumor microenvironment and potentiates immunotherapy in an advanced humanized PDAC mouse model..

Norio Miyamura[1], Yukihito Kuroda[1], Kodai Suzuki[1], Yuki Kunisada[1], Hotaka Kawai[2], Henri Havia[3], Tero Jarvinen[3], Moriya Tsuji[4], Kazuki N. Sugahara[1]

[1]Columbia Univ. Vagelos College of Physicians & Surgeons, New York, NY,[2]Okayama University, Okayama, Japan,[3]Tampere University, Tampere, Finland,[4]Columbia University, New York, NY

Pancreatic ductal adenocarcinoma (PDAC) presents a desmoplastic, poorly perfused, and immunosuppressive tumor microenvironment (TME) that limits immunotherapy. We recently discovered that the tumor-penetrating peptide iRGD, which binds αv integrins and neuropilin-1 (NRP-1), reprograms this hostile TME by targeting tumor-infiltrating regulatory T cells (Tregs) and inhibiting transforming growth factor-β (TGF-β), a key driver of fibrosis, vascular collapse, and immune suppression. Here, we show that iRGD elicits similar effects in humanized PDAC mice reconstituted with functional human immune cells. PDAC-infiltrating Tregs expressed αvβ5 integrin in addition to NRP-1, enabling iRGD-mediated targeting and depletion in transgenic and syngeneic PDAC models. In contrast, splenic Tregs lacked αvβ5 and remained unaffected. αvβ5$^+$ Tregs represented a highly suppressive CCR8$^+$ Treg subset. These αvβ5$^+$ Tregs were also identified in human PDAC tissue and could be induced from human CD4$^+$ T cells. Beyond Tregs, αvβ5 was broadly expressed on cancer cells, fibroblasts, and endothelial cells in PDAC. Our recent studies showed that the αvβ5-rich TME facilitates integrin-dependent TGF-β activation, which is effectively antagonized by iRGD. Owing to its tumor-penetrating activity, systemic iRGD monotherapy broadly inhibited TGF-β signaling in syngeneic PDAC tumors, improving vascular perfusion, reducing stromal fiber density, and enabling deep infiltration of CD8$^+$ T cells. iRGD also significantly enhanced the response to immune checkpoint blockade. In humanized PDAC mice, iRGD reproduced these TME-modifying effects: it reduced vascular collapse and hypoxia, increased pericyte coverage, decreased stromal fibers, improved the CD8/Treg ratio, and activated human cytotoxic T cells. Early data further suggest that combining iRGD with checkpoint blockade prolongs survival in these mice. These findings indicate that the biological activity of iRGD is preserved across species despite potential differences in its target proteins. Collectively, iRGD orchestrates a coordinated reprogramming of the PDAC TME through αvβ5-dependent Treg targeting and TGF-β suppression, resulting in enhanced anti-tumor immunity in both mouse and humanized models. These results strongly support further clinical development of iRGD-based immunotherapies and highlight αvβ5 as a promising, mechanistically defined target for treating PDAC and other desmoplastic, TGF-β-rich tumors.

#2907 Characterization of tumor microenvironment phenotypes as potential biomarkers for immune infiltration.

Iqra A. Arif, Ruchi Shah, Katherine A. Johnson, Cheri A. Pasch, Dustin Deming

McArdle Laboratory for Cancer Research, Madison, WI

Background: Improved biomarkers are needed to identify immune permissive tumor microenvironment (TME) phenotypes that correlate with tumor infiltrating CD8+ T cells (TILs) and immunotherapy response. Myofibroblastic and inflammatory cancer-associated fibroblasts (myCAFs and iCAFs) are CAF subtypes involved in remodeling extracellular matrix and immunomodulation. Versican (VCAN), a matrix proteoglycan, and its proteolysis product, versikine (Vkine), regulate immune infiltration in the CRC TME. Here, we evaluate VCAN proteolysis and CAF phenotypes together as potential biomarkers for immune infiltration.
Methods: Immunohistochemistry was performed to evaluate the below CAF markers, as well as VCAN and Vkine, in 636 primary and metastatic patient tumor samples. CD8+ TILs were quantified per high-powered field (HPF). All other stains were scored on a scale of 0-3 based on stromal abundance and intensity. MyCAF (αSMA and TAGLN) and iCAF marker (PDPN and ICAM1) scores were averaged and categorized as previous. VCAN status was categorized as previous.
Results: Of the VCAN proteolytic weak (VPW) cancers, 25.9% were myCAF high, 9.6% were iCAF high, 31.9% were neither high, and 32.7% were both high. Of the VCAN proteolytic predominant (VPP) cancers, 31.9% were myCAF high, 16% were iCAF high, and 30.3% were both high. Of the VCAN/Vkine low (VVL) cancers, 18.5% were myCAF high, 14.1% were iCAF high, and 14.1% were both high. In VPW cancers, the mean CD8+ TILs/HPF were relatively low across all CAF phenotypes with the neither high phenotype having the greatest TILs (5.7/HPF). In VVL cancers, the mean CD8+ TILs/HPF in the both high (3.2) and myCAF high (4.5) phenotypes were less than that observed with the iCAF high (7.7) and neither high (12.5) phenotpyes. For VPP cancers, the mean CD8+ TILs/HPF in myCAF high cancers (10) is significantly lower ($p=0.045$) than in all other phenotypes (neither high 24.2, iCAF high 16.5, both high 23.4).
Conclusion: The absence of CAFs or the presence of high iCAF correlates with enhanced T-cell infiltration in VVL and VPW metastatic cancers. For VPP cancers, the presence of a high myCAF phenotype does not suppress T-cell infiltration, though it is reduced relative to cancers with an absence of CAFs or presence of iCAFs. The combination of CAF phenotype and versican status should be further assessed as a biomarker for immune therapy response.

#2908 SR-A antagonism remodels the myeloid population of tumor immune microenvironment, expands CD8-positive T cells, and enhances antitumor efficacy in vivo.

Steven R. Post[1], Fariba Jousheghany[1], Thomas J. Kelly[1], Charles M. Quick[1], **Behjatolah M. Karbassi**[2]

[1]Pathology, University of Arkansas for Medical Sciences, Little Rock, AR,[2]University of Arkansas for Medical Sciences, Little Rock, AR

Introduction: Tumor-associated macrophages (TAMs) are key regulators of the tumor immune microenvironment (TIME). Macrophage class A scavenger receptors (SR-A) modulate macrophage activation and polarization, and increased SR-A-positive TAMs are associated with poor outcomes in several cancers, including breast cancer. We previously showed that SR-A engagement skews macrophages toward an immunosuppressive phenotype, suggesting that SR-A blockade may reprogram the TIME and enhance antitumor immunity. In this study, we tested whether SR-A blockade reprograms the TIME and limits tumor progression in tumor-bearing mice.

Methods: EO771 cancer cells were injected into mammary fat pads of syngeneic mice to establish breast tumors. Tumor-bearing mice were treated with an SR-A antagonist or a control, and then $CD45^+$ tumor-infiltrating cells were isolated for single-cell RNA sequencing. In separate cohorts, SR-A blockade was combined with CD137-targeted activation, and mice were euthanized when tumors reached the predefined tumor endpoint (volume ≥ 1.5 cm^3). In parallel, mice were treated with the appropriate controls for both SR-A antagonist and CD137 activation. Tumor volume, time to the tumor endpoint, and the presence of lung metastases were determined. Mice showing complete tumor regression were rechallenged by assessing tumor growth following the injection of EO771 cells into the contralateral mammary fat pad.

Results: Monotherapy with the SR-A antagonist did not significantly alter primary tumor growth. However, single-cell RNA-seq of $CD45^+$ tumor-infiltrating cells indicated a shift in the polarization of tumor-associated macrophages toward an immunostimulatory, antigen-presenting phenotype, characterized by the upregulation of MHC class II molecules. Further, there was an increase in a cytotoxic T-cell subset characterized by high expression of the CD137 co-stimulatory receptor. Extending these results, we evaluated the effect of combining the SR-A antagonist with targeted CD137 activation. Treating tumor-bearing mice with the combination of SR-A antagonist and CD137 activation significantly inhibited both tumor growth and the proportion of mice that developed lung metastases compared to control-treated mice. Moreover, a subset of treated mice achieved complete tumor regression and rejected subsequent tumor rechallenge, consistent with the generation of durable systemic antitumor immune memory.

Conclusions: Inhibiting SR-A-dependent interactions reprograms macrophages toward a tumor-hostile, antigen-presenting phenotype, enhances cytotoxic T-cell responses, and synergizes with CD137-targeted activation. Thus, SR-A-blocking strategies may improve the efficacy of co-stimulatory receptor agonists by conditioning the TIME.

#2909 Targeting USP22 reprograms the tumor microenvironment and sensitizes KRAS-mutant, TP53-Null Lung cancer to immunotherapy.

Keqiang Zhang, Ching Ouyang, jinhui Wang, Wendong Li, Walter Tsark, Yuanyuan Gao, Mingxiao Yang, Aimin Li, Colt Egelston, Crystal Marconett, Dan Raz

City of Hope National Medical Center, Duarte, CA

Ubiquitin-specific peptidase 22 (USP22), a deubiquitinase and component of the “Death-By-Cancer” gene signature, is overexpressed in many cancers and associated with recurrence, therapy resistance, and poor prognosis. Although USP22 has recently been implicated in tumor immune evasion, its role in KRAS-driven lung cancer and antitumor immunity has remained unclear. Here, we aimed to investigate the role of USP22 in tumor progression and antitumor immunity in KRAS-driven lung cancer.
By immunohistochemistry analysis, USP22 was found to be highly expressed in nearly all human KRAS-mutant lung adenocarcinomas and in early-stage KRAS-induced mouse tumors, where its strong correlation with the proliferation marker Ki67 highlights USP22 as a potentially important mediator of KRAS-driven tumor biology and reinforces its promise as a therapeutic target.
To define USP22’s role in tumor progression and immune regulation, we generated a conditional Usp22 knockout (Usp22-KO) model in $KRAS^{G12D}$; $Tp53^{-/-}$ (KP) mice. Usp22 loss significantly suppressed tumor growth, prolonged survival, and promoted tumor differentiation, accompanied by reduced KRAS pathway activity and partial restoration of p53 signaling. Spatial transcriptomics, RNA sequencing, and multiplex immunofluorescence revealed that Usp22 deletion reprogrammed the tumor microenvironment by decreasing $CD206^{+}$ M2 macrophages, reducing TGF-β1 levels, limiting angiogenesis, increasing $CD8^{+}$ T cell infiltration, and diminishing $FOXP3^{+}$ regulatory T cells. Mechanistically, Usp22-KO altered gene expression and protein stability, reducing c-Myc, PD-L1, TGF-β1, and secreted protein acidic and rich in cysteine (SPARC); disruption of the TGF-β1-SPARC axis led to a marked depletion of immunosuppressive PD-L1^+ M2 macrophages. Functionally, Usp22 deletion substantially enhanced sensitivity to anti-PD-L1 immune checkpoint blockade in KP lung cancer. Collectively, these findings reveal USP22 as a critical driver of tumor progression and immunosuppression in KRAS-mutant, TP53-deficient lung cancer and demonstrate that targeting USP22 has significant therapeutic potential for overcoming resistance to immune checkpoint inhibitor therapy.

#2910 GRN deficiency loosens stromal barriers and enhances MHC-II signaling yet reduces MHC-I driven cytotoxic immunity.

Feng Guo, Boping Jing, Tadahito Yasuda, Mayu Yasuda, Hudie Li, Fabio N. de Mello, Alan Y. Wang

Brown Center for Immunotherapy, Indiana University School of Medicine, Indianapolis, IN

Progranulin (GRN) is a multifunctional regulator of tissue remodeling and myeloid biology. Although neuroprotective in the CNS, increasing evidence indicates that GRN supports a fibrotic and immune suppressive tumor microenvironment.We investigated whether host GRN restrains anti-tumor immunity and whether its inhibition could be therapeutically leveraged. Using C57BL/6J Grn-/- mice across three syngeneic models (KPC pancreatic ductal adenocarcinoma, B16-F10 melanoma, MC38 colorectal carcinoma), GRN loss consistently delayed tumor growth, with the most pronounced effect in KPC subcutaneous tumors, indicating a substantive but incomplete contribution of host GRN to tumor control.Single-cell RNA-seq and cell-cell interaction analyses of KPC tumors revealed coordinated rewiring of antigen presentation and stromal programs in Grn-/- hosts: MHC-II signaling predominantly B to T was increased, whereas MHC-I inputs decreased. Cancer-associated fibroblasts exhibited downregulation of chemokine/GPCR sensing, ER-phagosome and complement pathways. CAF composition shifted toward iCAF expansion with mCAF/vCAF reduction, and fibroblast→tumor ECM adhesion pairs (COL/FN1/LAM→CD44/SDC) were diminished, consistent with a loosened stromal matrix.In T cells, $CD4^+$/$CD8^+$ central or resident memory compartments expanded, while cytotoxic and exhausted $CD8^+$ populations declined; pseudotime analyses demonstrated attenuated progression from memory toward cytotoxic or exhausted endpoints.Collectively, these data indicate that host GRN sustains a myeloid-CAF program that strengthens stromal tension and supports MHC-I driven T-cell terminal differentiation. GRN loss relaxes this circuit, reducing MHC-I availability while enhancing B-T MHC-II engagement, which shifts T cells toward memory states and limits cytotoxic output. These findings identify GRN blockade as a TME reprogramming strategy that should be paired with agents restoring $CD8^+$ signal-1 (MHC-I) to convert enlarged memory pools into durable cytotoxic control in PDAC.

#2911 Versican expression and proteolysis as a biomarker for CD8+ T cell infiltration across cancer types and molecular profiles.

Ruchi Shah[1], Elizabeth L. Field[1], Cheri Pasch[1], Dustin A. Deming[2]

[1]Univ. of Wisconsin Madison Sch. of Med. & Public Health, Madison, WI,[2]University of Wisconsin Carbone Cancer Center, Madison, WI

Background: Current biomarkers for immune checkpoint inhibitor (ICI) response, including tumor mutation burden (TMB) and microsatellite instability (MSI), do not completely identify responsive patient populations. Versican (VCAN), a matrix proteoglycan found in the tumor microenvironment (TME), and its proteolysis product, versikine (Vkine), can regulate immune infiltration. Here we evaluate VCAN status as a biomarker for CD8+ T cell infiltration across cancer types and molecular profiles.

Methods: Patients (n=123) were identified and consented as part of an IRB-approved protocol. Patient characteristics were collected for all patients, and *PIK3CA*, *KRAS*, *TP53*, *BRAF*, *BRCA1/2*, *PTEN*, and *CDKN2A* mutation status were identified in a subset of 45 patients. Cancer samples were collected prior to ICI treatment, and were stained for VCAN, Vkine, and CD8. VCAN and Vkine staining was scored 0-3 based on stromal abundance and intensity. CD8+ tumor infiltrating lymphocytes (TILs) were quantified per high powered field (HPF). Cancers were assigned a VCAN status as previously.

Results: Clinical characteristics: 28 Colorectal , 8 Bladder, 44 Lung, 16 Skin, 6 Esophageal, and 21 other pan-cancer patients. Median CD8+ TIL abundance was higher in MSI-high (MSI-H) cancers (11.33) than in microsatellite stable (MSS) cancers (7.67; p=0.05). A weak positive correlation between TMB and CD8+ TIL abundance was observed (spearman's 0.201). A trend of elevated CD8+ TILs/HPF were observed in VCAN proteolytic predominant (VPP, percent of cancers 5%, mean CD8+ TILs/HPF 13) and VCAN/Vkine low (VVL, 37%, 15) cancers relative to VCAN proteolytic weak (VPW, 58%, 10). This relationship was preserved independent of MSI status, though MSI-H cancers had higher CD8+TIL abundance in VPP (MSI-H median CD8+ TILs/HPF 20, MSS 9), VVL (15, 11), and VPW (10, 5, p = 0.02) cancers compared to MSS cancers. VVL and VPW cancers were most prevalent across mutation profiles. Those cancers that are KRAS mutant were more likely to be VVL. A trend towards increased CD8+ TILs/HPF in VVL/VPP cancers relative to VPW cancers was observed generally across the mutation profile. However, CD8+ TILs/HPF were similar across VPP/VVL and VPW for *KRAS*-mutant cancers.

Conclusion: While TMB and MSI-H status correlate moderately with CD8+ T cell infiltration, VCAN status predicts CD8+ TIL abundance across several cancer types and mutation profiles. Further studies to investigate the impact of VCAN proteolysis on immune infiltration and ICI response are necessary to better identify patient populations which could receive benefit from ICIs.

#2912 SECN-15: Antisense oligonucleotide-mediated Neuropilin-1 suppression enhances anti-tumor immunity and overcomes checkpoint inhibitor resistance in solid tumors.

Andre Maaske, Sven Michel, Anne Sadewasser, Julia Festag, Monika Schell, Janani Sekar, Stefanie Raith, Frank Jaschinski, **Richard Klar**

Secarna Pharmaceuticals GmbH & Co. KG, Planegg, Germany

Background:Immune checkpoint inhibitors (ICIs) have transformed cancer therapy, but their efficacy remains limited in many solid tumors due to suppressive features of the tumor microenvironment (TME). Neuropilin-1 (NRP1), a multifunctional co-receptor, promotes tumor progression through immunosuppressive mechanisms and neoangiogenesis. High NRP1 expression correlates with poor prognosis and ICI resistance in different solid tumors, including gastric cancer. SECN-15 is a locked nucleic acid (LNA)-modified antisense oligonucleotide (ASO) designed to selectively downregulate NRP1 and counteract its protumorigenic functions.
Methods: NRP1-specific ASOs were generated using the OligoCreator™ platform and evaluated *in vitro* and *in vivo* in syngeneic murine tumor models as monotherapy or in combination with anti-PD-(L)1 antibodies. NRP1 knockdown was assessed at RNA and protein levels, including soluble NRP1 as a target engagement biomarker. Tumor cell composition and transcriptomic profiles were analyzed by flow cytometry and RNA sequencing. In silico analyses of publicly available bulk and single-cell RNA-seq datasets from cancer patients informed indication selection for the upcoming Phase I/II clinical trial and elucidated NRP1 biology in human tumors.
Results: Systemic SECN-15 treatment of tumor-bearing mice induced robust NRP1 knockdown in macrophages, T cells, and endothelial cells, leading to tumor growth delay and complete regressions in a subset of animals, both as monotherapy and in combination with anti-PD-1 treatment. Transcriptomic profiling revealed upregulation of pro-inflammatory pathways and downregulation of extracellular matrix and epithelial-to-mesenchymal transition (EMT) genes. Analysis of single-cell RNA-seq datasets from patients with gastric cancer identified endothelial cells and macrophages as major NRP1-expressing populations. NRP1high endothelial cells exhibited activation of TGF-β signaling, while NRP1high macrophages showed an upregulation of hypoxia and EMT pathways and suppressed allograft rejection signatures, in comparison with their NRP1low counterparts. These findings suggest that NRP1 promotes an immunoregulatory, pro-angiogenic TME in gastric cancer, further supporting its selection as a lead indication.
Conclusion: SECN-15 represents a promising therapeutic strategy to enhance anti-tumor immunity and overcome ICI resistance. Integration of preclinical and single-cell data highlights NRP1's role in sustaining an immunosuppressive TME which is currently further investigated in *in vitro* models. IND-enabling studies are underway to advance SECN-15 into clinical development.

#2913 Type I interferon reprograms neutrophil-T cell interactions to enhance antitumor immunity and informs a combinatorial strategy for esophageal cancer.

Tingxuan Gu[1], Kun Yu[1], Zigang Dong[2]

[1]Tianjian Laboratory of Advanced Biomedical Sciences, Academy of Medical Sciences, Zhengzhou University, Zhengzhou, China,[2]Zhengzhou University Medical College, Zhengzhou, Henan, China

Background: Type I interferons (IFN-I) integrate antiviral and antitumor responses by coordinating innate and adaptive immunity. Although their canonical function involves dendritic-cell (DC)-mediated antigen presentation, we identified a DC-independent mechanism whereby IFN-I directly reprograms neutrophils and reshapes the tumor immune microenvironment (TME) in esophageal squamous cell carcinoma (ESCC). This study pursued three aims: (1) to define the cellular compartments required for IFN-I signaling; (2) to dissect how IFN-I-reprogrammed neutrophils potentiate T-cell antitumor function; and (3) to evaluate translational strategies combining IFN-I agonism, TGF-β and PD-1 blockade.

Methods: Differentiated neutrophil-like cells were stimulated with IFN-α or IFN-I inducers (RIG-I-2CARD, STING-CTD ± c-di-GMP). N1/N2 polarization markers (CD54/ICAM-1, CD86, SELL, ARG1) were analyzed by flow cytometry and Western blot. Co-cultures of neutrophils, T cells, and KYSE esophageal carcinoma cells quantified T-cell cytotoxicity. Mechanistic assays used ICAM-1/LFA-1 blockade, metabolic inhibitors (nor-NOHA, DPI, NAC), and Transwell tests. For *in-vivo* validation, Ifnar1 fl/fl with CD4-Cre, Itgax-Cre, and S100a8-CreERT2 mice restricted IFN-I signaling to T cells, DCs, or neutrophils. MC38 tumor (C57BL/6) and KYSE450 xenograft (HSC-NSG) were established. IFN-I activation used Ad5-IFNA4 (10^7-10^8 PFU i.v., weekly) or c-di-GMP (20 μg i.p., q3d). Combination arms received TGF-β-trap and/or anti-PD-1 (10 mg/kg i.p.). Tumor growth, N1/N2 ratio, and $CD8^+$ Teff infiltration were assessed by flow cytometry.

Results: IFN-I signaling acted as the dominant upstream regulator of neutrophil-dependent tumor control. IFN-α and IFN-I inducers consistently polarized neutrophils toward an N1-like phenotype. Only neutrophils pretreated with IFN-α enhanced T-cell-mediated tumor killing; untreated cells failed. Direct addition of IFN-α to the culture had no effect, confirming that neutrophil priming by IFN-I is required. Blocking ICAM-1/LFA-1 or separating cells by Transwell reduced T-cell killing, indicating contact dependence. In vivo, Ad5-IFNA4 and c-di-GMP were well tolerated and increased intratumoral $CD54^+$ N1-like neutrophils. Ongoing studies in Ifnar1 conditional and HSC-NSG models are testing whether sustained IFN-I activation synergizes with PD-1 and TGF-β blockade to enhance $CD8^+$ Teff infiltration and antitumor efficacy.

Conclusions: Type I interferon signaling links neutrophil reprogramming to T-cell activation. IFN-I drives N1 polarization, promotes ICAM-1/LFA-1-dependent contact, and may relieve ARG1/NOX2-mediated suppression to restore T-cell cytotoxicity.These findings support a therapeutic framework combining IFN-I agonists with TGF-β and PD-1 blockade for durable antitumor immunity in ESCC.

#2914 Modulating the tumor microenvironmentwith an engineered oncolytic herpesvirus facilitates potent antitumor response.

Joseph Najjar[1], Geetanjali Geetanjali[2], Chase Kangas[2], Vk Gadi[3], Bin He[2]

[1]Biomedical Engineering, University of Illinois Chicago College of Medicine, Chicago, IL,[2]Microbiology and Immunology, University of Illinois Chicago College of Medicine, Chicago, IL,[3]University of Illinois at Chicago, Chicago, IL

Oncolytic viruses (OV) are a promising approach to cancer treatment, whereby attenuated viruses selectively infect and kill tumors, while sparing healthy cells. Tumor antigens and cytokines released from infected cells prime and activate the immune system to generate durable antitumor responses. This inflames the tumor microenvironment and may complement immune checkpoint inhibitor (ICI) therapy. However, this synergy is yet to be demonstrated: in a randomized, double blind, phase III trial, the HSV based talimogene laherparepvec (TVEC) in combination with anti-PD1 ICI therapy failed to improve both progression free survival and overall survival relative to anti-PD1 therapy alone. This may be attributable to viral factors that promote tumor selective replication in part by suppressing antitumor immune elements. Consequently, there is an unmet need for OVs that overcome the limitations of current therapies. We previously developed a novel oncolytic HSV, DN146, optimized for maximum immune stimulation without compromising tumor selective replication. Re-engineering of the γ_1 34.5 gene in DN146 permits efficient viral replication and tumor cell killing, while robustly activating STING and RIG-I. *In vivo*, DN146 exhibits strong immune stimulation and dendritic cell maturation, and robust clearance of metastatic lesions as compared to clinical analogues in a mouse model of triple negative breast cancer. We armed DN146 with an engineered high affinity SIRPα to further potentiate its antitumor effects by blocking the SIRPα-CD47 immune checkpoint. Antagonists of this checkpoint improve macrophage phagocytosis and T-cell recruitment to the TME. Further, CD47 blockade can improve cross presentation of tumor antigens to CD8+ T-cells. Together, these effects should cooperate with STING activation from DN146 to broadly reprogram the tumor microenvironment. When tested in a bilateral, murine colorectal cancer model, this virus achieves clearance of both locally injected and distal un-injected tumors, indicating strong local and systemic antitumor effects.

#2915 Tumor-intrinsic METTL5 restricts T cell-induced ferroptosis by impairing ATF4 translation in ovarian cancer.

Jiakai Hou[1], Cheng-wei Ju[2], Nicholas A. Egan[1], Yanjun Wei[3], Yunfei Wang[4], Minghao Dang[5], Tianyi Zhou[1], Leilei Shi[6], Ningbo Zheng[1], Si Chen[1], Ashley Guerrero[1], Xiaofang Liang[1], Wanfu Wu[1], Areej Akhtar[1], Chitra Dhiman[1], Debanwita Roy Burman[1], Andro Gerges[1], Mason D. [1]Biology and Biochemistry, University of Houston, Houston, TX,[2]The University of Chicago, Chicago, IL,[3]Bioinformatics and Computational Biology, The University of Texas MD Anderson Cancer Center, Houston, TX,[4]Clinical Science Lab, H. Lee Moffitt Cancer Center & Research Institute, Tampa, FL,[5]Lymphoma and Myeloma, The University of Texas MD Anderson Cancer Center, Houston, TX,[6]Epigenetics and Molecular Carcinogenesis, The University of Texas MD Anderson Cancer Center, Houston, TX,[7]Netherlands Cancer Institute, Amsterdam, Netherlands,[8]Neurology, Johns Hopkins University School of Medicine, Baltimore, MD,[9]Genomic Medicine, The University of Texas MD Anderson Cancer Center, Houston, TX,[10]Gynecologic Oncology and Reproductive Medicine, The University of Texas MD Anderson Cancer Center, Houston, TX,[11]Cleveland Clinic, Cleveland, OH

To systematically define tumor-intrinsic mechanisms driving immune resistance in ovarian cancer (OC), we integrated an *in vitro* genome-wide CRISPR immune screen, *in vivo* targeted immune screens, and analysis of 16 published ICB patient cohorts. From this pipeline, 693 candidate genes were shortlisted, and METTL5 emerged as a key regulator of tumor-intrinsic immune evasion. Pan-cancer TCGA analysis revealed significant METTL5 upregulation across multiple cancer types, with OC showing the second-highest expression among 34 malignancies. Although METTL5 expression did not correlate with OC stage or overall survival, higher expression was strongly associated with reduced cytolytic activity scores, suggesting suppressed antitumor immunity. In the MDACC HGSOC cohort (NCT03026062), patients with elevated METTL5 expression in baseline tumor samples exhibited significantly poorer responses and shorter overall survival after ICB therapy, supporting its clinical relevance. Mechanistically, METTL5 loss in OC models specifically reduced m^6A methylation at A1832 of 18S rRNA, disrupting helix 44 structure and impairing ribosomal scanning and translation. RiboLace-based active ribosome profiling demonstrated that METTL5 knockout reprograms translation, notably downregulating genes enriched in the “Response of EIF2AK1 to Heme Deficiency” pathway, consistent with defective integrated stress response (ISR). Translation of ATF4 was markedly reduced, accompanied by decreased expression of downstream targets SLC7A11 and SLC3A2, key components of the cystine/glutamate antiporter that suppress lipid peroxidation and ferroptosis. As a result, METTL5-deficient OC cells displayed increased lipid peroxidation and heightened sensitivity to T cell-mediated ferroptosis *in vitro* and *in vivo*. Reintroduction of ATF4 restored SLC7A11/SLC3A2 expression and reversed ferroptosis sensitivity, while pharmacologic inhibition of ferroptosis produced similar effects. These findings identify METTL5 as a central regulator of ATF4 translation, oxidative stress control, and immune resistance in OC. Elevated METTL5 expression may serve as a biomarker for poor ICB response. Therapeutically, METTL5 inhibition, ATF4 translation suppression or ferroptosis induction represent potential strategies to enhance immunotherapy efficacy. This study establishes the METTL5-ATF4-ferroptosis axis as a critical tumor-intrinsic mechanism of immune evasion and provides a generalizable framework for decoding cancer-immune interactions.

#2916 Tumor-intrinsic IRE1α signaling drives immune evasion and resistance to immune checkpoint inhibitor in lung cancer by upregulating PD-L1 and remodeling the tumor microenvironment.

Youngjoo Jeon[1], Hyun Kyung Ahn[1], Hongsoon Kim[1], Sung-Yup Cho[2], Jaemoon Koh[3], Yoon Kyung Jeon[4]

[1]Cancer Research Institute, Seoul National University, Seoul, Korea, Republic of,[2]Seoul National University Cancer Research Institute, Seoul, Korea, Republic of,[3]Seoul National University Hospital, Seoul, Korea, Republic of,[4]Department of Pathology, Seoul National University College of Medicine, Seoul, Korea, Republic of

Tumor cells exploit endoplasmic reticulum (ER) stress pathways for survival. While the role of the unfolded protein response in tumorigenesis is well-established, its specific effect on the tumor microenvironment (TME) and therapeutic resistance in non-small cell lung cancer (NSCLC), particularly via IRE1α signaling, remains poorly understood. Here, we demonstrate that high IRE1α activity correlates with poor prognosis and resistance to immune checkpoint inhibitors in NSCLC patients. IRE1α activation was associated with an immunosuppressive TME, characterized by enriched regulatory T-cell (Treg) and M2-like tumor-associated macrophage (TAM) signatures in patient cohorts. Consistently, genetic ablation of tumor-intrinsic IRE1α (*ERN1* KO) in immunocompetent mice significantly attenuated tumor growth and enhanced CD8+ T-cell infiltration. Mechanistically, IRE1α promoted the expression and secretion of key chemokines, specifically CCL20, which in turn drove M2-like macrophage differentiation in vitro. Notably, this pro-tumorigenic secretome was abrogated by the IRE1α inhibitor MKC8866. Concurrently, IRE1α-XBP1s signaling synergized with IFNγ to directly upregulate tumor-intrinsic PD-L1 expression. This process was mediated by the activation of the RIG-I-IRF1 axis, sustained STAT1 phosphorylation, and direct XBP1s binding to the *CD274* promoter. Collectively, tumor-intrinsic IRE1α orchestrates immune evasion in NSCLC by amplifying tumor-intrinsic PD-L1 expression through the IFNγ-STAT1-XBP1s-IRF1 axis and remodeling the TME via chemokines such as CCL20 that recruit immunosuppressive cell populations. The combination of an IRE1α inhibitor and anti-PD-1 antibody represents a promising strategy to enhance the efficacy of immunotherapy for NSCLC.

#2917 Novel strategies for targeting B7-H3 to empower precision oncology.

Di Zhao

UT MD Anderson Cancer Center, Houston, TX

Immune checkpoint B7-H3 (encoded by CD276) is an emerging immunotherapy target across diverse cancer types. However, our limited understanding of B7-H3 biology, its dysregulation, and its role in modulating immune and stromal components of the tumor microenvironment (TME) hinders the clinical application of B7-H3-targeting therapy. By leveraging genetically engineered mouse models and multi-omics approaches with single-cell resolution, we identified B7-H3 as one of the most promising checkpoint immunotherapy targets in cancers containing *PTEN* and *TP53* defects. In addition to suppressing T cells, we identified non-canonical dual functions of B7-H3 in modulating myeloid and stromal cells in the TME, thereby promoting cancer progression and therapy resistance. In this study, we answered long-standing questions regarding B7-H3 signaling and its cellular counterpart in the TME, uncovered the cellular and molecular basis of resistance to B7-H3 immunotherapy in cancer treatment, and developed innovative biomarker-driven, combinatorial strategies for B7-H3-targeted immunotherapy in malignancies.

#2918 Agonist activation of RIG-I^{+}tumor associated macrophages enhances anti-tumor immunity and therapeutic response in glioblastoma.

Han Xu[1], Sungwoon Lee[1], Felipe Saceanu Leser[2], Olga Federova[3], Peiwen Lu[4], Eric Song[5], Anne Eichmann[2], Akiko Iwasaki[4], Anna Anna Marie Pyle[3], Jean-Leon Thomas[1]

[1]Neurology, Yale School of Medicine, New Haven, CT,[2]Cardiovascular Research Center, Department of Internal Medicine, Yale School of Medicine, New Haven, CT,[3]Molecular, Cellular and Developmental Biology, Yale School of Medicine, New Haven, CT,[4]Immunobiology, Yale School of Medicine, New Haven, CT,[5]Ophthalmology and Visual Science, Yale School of Medicine, New Haven, CT

Glioblastoma (GBM), the most frequent and aggressive primary tumor of the brain, escapes all standard-of-care treatments that are provided after resection, including chemotherapy, radiotherapy or immunotherapy. The GBM tumor microenvironment is regulated by immunosuppressive mechanisms of the innate immune system, thereby contributing to the lack of anti-tumor adaptive immunity. We found that tumor associated macrophages (TAMs) can be repolarized into a M1 anti-tumor phenotype via agonist stimulation of the retinoic acid-inducible gene I (RIG-I), a cytosolic double-stranded RNA pattern recognition receptor (PRR). Innate immunity is governed by PRRs, which act as sensors of foreign and danger-associated molecular patterns and initiate the innate immune response. In silico analysis of adult GBM datasets available in the public domain revealed that *RIGI-I* expression by a subset of activated M1 TAMs positively correlated with patient survival. Studies in syngenic mouse models of GBM showed that intratumoral delivery of stem-loop RNA 14 (SLR14), a RIG-I agonist, improved the efficacy of all standard anti-GBM treatments, beyond the effects of other nuclei acid sensor agonists. We found that the combined activation of M1 TAMs and priming of functional cytotoxic CD8^{+} T lymphocytes and NK cells were accounting for the anti-GBM effect of SLR14, opening a significant new avenue for adult GBM treatment.

#2919 A little STING spices up tertiary lymphoid structures: Therapeutic induction of mature TLS by STING and lymphotoxin-β receptor activation confers immune protection against cancer metastasis.

Yasuhiro Kikuchi, Maxwell Duah, Fumiaki Kanamori, **Masanobu Komatsu**

Johns Hopkins All Children's Hospital, St. Petersburg, FL

Significant clinical evidence demonstrates an association of tertiary lymphoid structure (TLS) formation with cancer survival. Clinically translatable pharmacologic/biologic agents that induce TLS-rich tumor immune environment could provide a breakthrough strategy to treat therapy-resistant cancers. Here, we show that simultaneous activation of innate immune effectors, STING and lymphotoxin-β receptor (LTβR), by their agonists induces the formation of multiple TLS in TLS-free tumors in a manner dependent on $CD4^+$ and $CD8^+$ T cells. Using this approach, functional TLS were induced in all treated mice, in different tumor types and anatomical sites—TLS developed in adenocarcinomas and sarcomas in the pancreas, mammary gland, skeletal muscle, and subcutaneous tissues. TLS also developed in the brain harboring gliomas. STING activation alone was insufficient for inducing B cell-containing TLS or eliciting long-term therapeutic effects. However, when combined with LTβR activation, it improved the fitness of TLS with B cell expansion and maturation to IgG-producing long-lived plasma cells and memory cells, exhibiting lymph node follicle-like germinal center responses within tumors. In addition, the treatment induced high endothelial venule formation, increased $CD4^+$ T cell recruitment, memory $CD8^+$ T cell expansion, and the accumulation of $TCF1^+$ stem-like $CD8^+$ T cells around TLS. These immune responses resulted in strong suppression of tumor growth and metastasis, with excellent survival benefit, demonstrating that the treatment successfully immunized mice against tumor cells. The STING/LTβR combination therapy also substantially improved the efficacy of anti-PD-1 immune checkpoint blockade in resistant tumors. The immediate early response to the combination therapy was mediated mainly by $CD8^+$ T cells. The delayed but prolonged response was mediated by humoral immunity of B cells, which exerted a lasting anti-tumor effect together with the cellular immunity of $CD8^+$ T cells and NK cells. Our finding establishes a foundation for the therapeutic induction of TLS in cancer. Unlike other reported strategies, TLS induction by this method does not require viral antigens or artificial genetic manipulations to boost immune response, making it feasible for clinical applications. The high-affinity tumor-specific IgG-producing long-lived plasma cells and memory B and T cells generated in these TLS could provide lifelong protection against tumor recurrence and metastases. Effective tumor immunization by this strategy is expected to improve other cancer immunotherapies and suggests broad therapeutic applications in cancer. Since STING agonists are clinically available and humanized agonistic antibodies to LTβR can be developed, this strategy is readily translatable to clinical use for cancer treatment.

#2920 Metabolic reprogramming of hepatic macrophages restores CD8⁺ T cell immunity in T cell-desert hepatocellular carcinoma.

Liangliang Ji[1], Delaney Bessel[1], Sophia Brosnan[1], Isha Malik[1], Zijian Xu[1], Jiaxin Li[1], Peng Li[1], Xian Zhang[1], Jing Zhang[1], Ting-Wei Tsu[1], Shengyu Gao[1], Amaia Lujambio[2], Ming Li[1]

[1]Immunology Program, Memorial Sloan Kettering Cancer Center, New York, NY,[2]Icahn School of Medicine at Mount Sinai, New York, NY

CD8⁺ T cell-mediated immunosurveillance relies heavily on the functional integrity of antigen-presenting cells (APCs), particularly dendritic cells (DCs) that prime and activate T cells in secondary lymphoid organs. However, DCs are often defective in certain pathological contexts, such as β-catenin-mutated cancers, disrupting the cancer-immunity cycle and giving rise to “T cell-desert” tumor immunotypes that resist immunotherapy. Besides DCs, macrophages can also act as APCs and modulate CD8⁺ T cell activation, but their antigen-presenting function remains less well understood. Using genetic mouse models, we systematically characterized mice with macrophage-specific deletion of the mTORC1 suppressor *Tsc1* and found a striking increase of CD8⁺ T cells in the liver-but not in other tissues. This tissue specificity likely reflects the unique intravascular niche in which Kupffer cells interact directly with circulating CD8⁺ T cells. Notably, this CD8⁺ T cell expansion occurs independently of DC compartments. In a MYC/β-catenin-driven “T cell-desert” hepatocellular carcinoma (HCC) model, TSC1-deficient hepatic macrophages (hMϕs) reinvigorated antigen-specific CD8⁺ T cell responses and suppressed HCC progression, also in a DC-independent manner. hMϕs from wild-type mice predominantly express T-cell immunoglobulin and mucin domain-containing 4 (TIM-4), while TSC1-deficient hMϕs consist of both TIM-4⁺ and TIM-4⁻ subsets, with the TIM-4⁻ population driving CD8⁺ T cell expansion. Moreover, TSC1-deficient hMϕs exhibited enhanced tumor antigen acquisition and presentation capacity. Combining TSC1 deficiency in hMϕs with anti-PD-L1 immunotherapy significantly improved outcomes in murine “T cell-desert” HCC. Metabolic profiling revealed markedly increased mitochondrial activity in TSC1-deficient hMϕs, and their enhanced APC and anti-tumor functions required malate-aspartate shuttle-mediated oxidative phosphorylation. Together, these preclinical studies reveal a DC-independent role for hMϕs in orchestrating CD8⁺ T cell immunity and suggest that metabolic reprogramming of macrophages may offer a promising strategy to overcome immune evasion in “T cell-desert” tumors caused by defective DC function.

#2924 ζ-Stat inhibits glioblastoma multiforme progression by targeting PKC-ζ/Cx43 signaling and inducing senescence.

Grazielly Teodoro, Shreejana Rimal, Wishrawana S. Ratnayake, Abigail Olatunji, Mildred Acevedo-Duncan

University of South Florida, Tampa, FL

Glioblastoma multiforme (GBM) is a grade IV astrocytic tumor and the most aggressive form of brain cancer, marked by poor prognosis, complex vascular networks, and genomic heterogeneity. PI3K/AKT (Phosphoinositide 3-kinase/Protein Kinase B) signaling and the atypical protein kinase C isoform PKC-ζ, play essential roles in GBM cell proliferation, migration, and resistance to therapy. In addition, PKC-ζ regulates Connexin 43 (Cx43), a gap junction protein that influences cell communication, cytoskeletal organization, and tumor cell motility. This study investigated the effects of ζ-Stat (8-hydroxy-1,3,6-naphthalenetrisulfonic acid), a selective PKC-ζ inhibitor, on GBM cell lines. Treatment with ζ-Stat significantly reduced proliferation by approximately 40% in T98G cells (80 μM) and 30% in U87MG cells (40 μM) ($p \leq 0.001$). Co-immunoprecipitation confirmed a strong association between PKC-ζ and Cx43 in both cell lines. Western blot analysis demonstrated that treatment with ζ-Stat reduced the levels of PKC-ζ and Cx43. As a result of PKC-ζ/Cx43 inhibition, PI3K/AKT signaling was downregulated in T98G cells. In addition, ζ-Stat induced cell cycle arrest, with increased expression of p21, p27, and PTEN, while inducing cellular senescence, as indicated by elevated β-galactosidase activity. Furthermore, ζ-Stat affected epithelial-mesenchymal transition (EMT), reducing the migratory potential of the cells through inhibition of vimentin expression. These findings highlight ζ-Stat as a promising therapeutic candidate for overcoming chemoresistance and improving treatment outcomes in glioblastoma.

#2925 Monzosertib, a selective CDC7 inhibitor, induces cell death via premature mitosis promoted by the FOXM1-cyclinB1 axis.

Hiroko Endo[1], Yu Nishioka[1], Mariko Hatakeyama[1], Youichi Tajima[2], Sayuri Ito[2], Akinori Arimura[3], Hisao Masai[2], Masaaki Sawa[1]

[1]Carna Biosciences, Inc., Kobe, Japan,[2]Department of Basic Medical Sciences, Tokyo Metropolitan Institute of Medical Science, Setagaya, Japan,[3]CarnaBio USA, Inc., South San Francisco, CA

Introduction: Cell division cycle 7 (CDC7) is a highly conserved serine/threonine kinase that plays a critical role in initiation of DNA replication and in replication stress checkpoint. Aberrant CDC7 expression has been implicated in various malignancies, highlighting its potential as a therapeutic target in cancer treatment. Consequently, CDC7 inhibitors are being explored as a novel class of anticancer agents. However, the mechanisms underlying cancer cell death induced by CDC7 inhibition are not fully elucidated. Monzosertib (AS-0141) is a potent, selective, and orally bioavailable CDC7 inhibitor, currently undergoing Phase I clinical trials in patients with solid and hematologic malignancies. In this study, we investigated the mechanisms of cell death induced by monzosertib in human cervical cancer cell lines by comparing cell lines with differential sensitivity to CDC7 inhibition.
Method: Six human cervical cancer cell lines (HeLa, CaSki, ME-180, SKG-I, SKG-IIIa, and C33-A) were used to evaluate their sensitivity to CDC7 inhibitors including monzosertib and simurosertib (TAK-931). Cell viability was assessed by the resazurin assay. Cell cycle distribution and apoptosis were analyzed by flow cytometry. Protein and gene expression levels related to CDC7 and cell cycle regulation were analyzed by Western blotting and real-time PCR, respectively. FOXM1 knockdown was performed by introducing shRNA via lentiviral transduction.
Result: We evaluated the antiproliferative activity of CDC7 inhibitors in six human cervical cancer cell lines. Among tested cell lines, HeLa cells were the most sensitive to CDC7 inhibition, whereas SKG-I cells exhibited the highest resistance. Treatment with monzosertib led to an increase in the sub-G1 population in these cell lines, depending on their sensitivity. Monzosertib increased the expression of the G2 and M-phase marker, cyclin B1 and phospho-CDK1 in HeLa cells in a dose-dependent manner, but not in SKG-I cells. Cell cycle analysis revealed that monzosertib induced cyclin B1 expression during the S-phase, which is characteristic of premature mitosis. These findings indicate that monzosertib-induced cell death appears to result from impaired mitotic progression. Since cyclin B1 expression was found to be elevated, we next examined the role of FOXM1, a transcription factor which regulates cyclin B1 gene expression. Treatment with monzosertib significantly increased FOXM1 expression in HeLa cells, whereas only a mild increase was observed in SKG-I cells. Knockdown of FOXM1 in HeLa cells resulted in reduced cyclin B1 expression and decreased sensitivity to CDC7 inhibition.
Conclusion: We found that the FOXM1- cyclin B1 axis contributes to cell death in cervical cancer cells induced by the selective CDC7 inhibitor, monzosertib.

#2926 Sonrotoclax (BGB-11417), a selective Bcl-2 inhibitor, demonstrates better efficacy than Venetoclax (Ven) and Lisaftoclax (APG-2575) in hematological cancer cells, xenografts, and human bloods.

Haitao Wang[1], Lin Li[1], Yiwen Wang[1], Hao Wang[1], Weiwei Song[1], Shuang Peng[1], Sijia Zhai[1], Ziyu Jia[1], Peng Chi[1], Xiaoyu Feng[2], Teiko Sumiyoshi[3], Wei Jin[1], Zhirong Shen[2]

[1]BeOne Medicine (Beijing) Co., Ltd., Beijing, China,[2]BeOne Medicines (Shanghai) Co., Ltd., Shanghai, China,[3]BeOne Medicines USA, Inc., San Carlos, CA

Background: Bcl-2 overexpression, a hallmark of hematologic malignancies, is associated with cell death evasion and drug resistance. Bcl-2 inhibitors such as Ven counteract this by disrupting Bcl-2 interaction with pro-apoptotic proteins (e.g., BIM), thereby restoring apoptosis. Despite Ven's clinical success, limitations like tumor lysis syndrome and suboptimal complete remission (CR) rates in CLL (chronic lymphocytic leukemia), underscore the need for improved inhibitors. Lisaftoclax (Lisa) and sonrotoclax (Son), are other two Bcl-2 inhibitors at late-stage of development. However, how are the three Bcl-2 inhibitors different from each other is unknown. This study investigates the difference of Ven, Lisa, and Son in different model systems.

Methods: RS4;11- and KMS-12-PE- Bcl-2-G101V cells were generated by ENU mutagenesis. OCI-LY10 expressing BTK-WT and mutations were engineered using lentiviral transduction. *In vitro* cytotoxicity was assessed via CellTiter-Glo (CTG) assay. Bcl-2:BIM complex disruption were examined by MSD assay.

Results: *In vitro* cytotoxicity assay revealed higher potency of Son compared to Ven and Lisa in Bcl-2-dependent cell lines across different indications. In Bcl-2-G101V mutant cells—a mutation presented in ~30% of Ven-relapsed CLL patients—Son retained >10-fold higher potency than Ven and Lisa. Moreover, Son also presented better efficacy than Ven and Lisa in different xenografts in vivo. Given Bcl-2 inhibitors are often used with/after BTK inhibitors in treating B cell lymphoma like CLL, MCL (mantle cell lymphoma), where BTK mutations contributing to resistance, Bcl-2 inhibitors were also profiled on B lymphoma cancer cells expressing BTK mutations. Intriguingly, Son maintained similar activity in OCI-LY10 cells expressing wildtype BTK as in BTK mutations (C481S, T474I, L528W, A428D), where Ven and Lisa exhibited less potent activity. Mechanistically, Son induced stronger Bcl-2:BIM disruption and caspase-3 activation in cancer cells, consistent with enhanced apoptosis. In human, Bcl-2 inhibitor effect is confounded by plasma protein binding (PPB). To understand potential difference in human under PPB, human whole blood from healthy donors was treated with Son, Ven, Lisa, the Bcl-2:BIM protein complex disruption—the very proximal and direct effect of Bcl-2 inhibitors—was then examined. Human whole blood assays also demonstrated that Son has >10-fold lower IC90 than Ven and Lisa in disrupting Bcl-2:BIM.

Conclusions: Son demonstrates significant advantage over Ven and Lisa in preclinical studies, including better efficacy in Bcl-2-dependent cancers, against Bcl-2-G101V and BTK resistance mutations, and enhanced target engagement in human whole blood. These highlight Son's great potential in addressing unmet needs in hematologic malignancies.

#2927 Synthetic lethality of G6PD deficiency and asparaginase for colorectal cancer therapy.

Yun-Cheol Chae[1], Alan Wong[2], Su Hyun Lee[1], Anais Barthe[3], Meaghan McGuinness[3], Samantha Fitzgerald[4], Sima Jeha[1], Seth Karol[1], Kimmie Ng[4], Marios Giannakis[4], Naama Kanarek[2], Alejandro Gutierrez[1]

[1]St. Jude Children's Research Hospital, Memphis, TN,[2]Boston Children's Hosptal, Boston, MA,[3]Boston Children's Hospital, Boston, MA,[4]Dana-Farber Cancer Institute, Boston, MA

Asparaginase, an enzyme therapeutic that deaminates asparagine to produce aspartate and ammonia, is among the most effective treatments for several cancers. However, the molecular determinants governing asparaginase response and resistance remain poorly defined, limiting its therapeutic potential. We previously demonstrated that asparaginase has potent activity in R-spondin fusion colorectal cancer (CRC), whereas APC-mutant CRCs are resistant (Hinze et al., Cancer Discovery, 2020). To elucidate mechanisms of asparaginase resistance in APC-mutant CRC, we conducted an unbiased genome-wide loss-of-function CRISPR/Cas9 screen, which revealed that loss of G6PD confers marked asparaginase sensitivity. This finding was validated using independent CRISPR/Cas9 and shRNA approaches in multiple human CRC cell lines and mouse intestinal organoid models ($P < 0.0001$ for all comparisons). G6PD, the rate-limiting enzyme of the pentose phosphate pathway (PPP), was found to mediate asparaginase resistance through maintenance of NADPH production, whereas other PPP functions, such as ROS detoxification or ribonucleotide biosynthesis, were not implicated. Untargeted metabolomics indicated that G6PD loss impairs the urea cycle, and we found that G6PD inactivation selectively sensitized cells to ammonia toxicity but not to asparagine deprivation ($P < 0.0001$ for ammonia; P = n.s. for asparagine-free media). In G6PD-deficient cells, the toxicity of asparaginase was rescued by small molecules that enhance ammonia detoxification ($P < 0.0001$) or by knockdown of NMRAL1, a redox sensor that inhibits the urea cycle enzyme ASS under NADPH-limiting conditions ($P < 0.05$). To assess whether G6PD deficiency influences asparaginase toxicity in humans, we analyzed a cohort of 586 children with acute lymphoblastic leukemia (ALL) treated with asparaginase and with available assessments of erythrocyte G6PD activity. Seventeen patients had functional evidence of G6PD deficiency, and we observed no increase in grade ≥3 asparaginase-related toxicities among G6PD-deficient patients, either individually or in combination (P = n.s.). Finally, genetic inhibition of G6PD enhanced asparaginase efficacy in vivo in mouse CRC models ($P < 0.01$ and $P < 0.05$), and a tool G6PD inhibitor induced profound asparaginase sensitivity in patient-derived CRC organoids ($P < 0.0001$). Together, these findings reveal that G6PD deficiency unmasks a tumor-selective vulnerability to ammonia toxicity, which can be therapeutically exploited using asparaginase. This work provides a rationale for clinical testing of asparaginase in G6PD-deficient CRC and for the development of clinical G6PD inhibitors as combination partners for asparaginase therapy.

#2928 KRAS inhibition-induced GSDME-mediated pyroptosis and its augmentation by LAT1 inhibition in KRAS-mutant lung cancer.

Kenji Morimoto, Ju Hwan Cho, Po-Lan Su, Peiran Xu, Andrew Barnes, Rahul Shivahare, Jacob Kaufman, Zihai Li, David Paul Carbone, Kai He

The Ohio State University James Comprehensive Cancer Center and Pelotonia Institute for Immuno-Oncology, Columbus, OH

Introduction: KRAS mutations are the most common oncogenic alterations in non-small cell lung cancer (NSCLC) globally. Although KRAS inhibitors (KRASi) show clinical benefit, their efficacy remains limited. This underscores the need to better understand KRASi-induced cell death mechanisms and to identify rational combination strategies that enhance antitumor activity. Pyroptosis, an inflammatory form of programmed cell death mediated by gasdermin (GSDM) pore-forming proteins, has emerged as a potential key mechanism to enhance therapeutic response and antitumor immunity. Whether KRASi induces pyroptosis in KRAS-mutant NSCLC has not been established. Here, we identify KRASi-induced pyroptosis, define its molecular mechanisms, and explore approaches to potentiate this process.
Methods: Murine and human KRAS G12C or G12D mutant NSCLC cell lines (H23, A427, KXP885, 2695L and others) were treated with mutation-specific KRASi. Pyroptosis and associated mechanisms were evaluated by LDH release, live-cell microscopy, Western blotting, and various siRNA knockdowns. LAT1 involvement was assessed using the LAT1 inhibitor JPH203 and rescue with spermidine.
Results: Mutation-specific KRASi induced pyroptosis in KRAS G12C and G12D mutant NSCLC cell lines, as evidenced by LDH release, characteristic pyroptotic morphology, and GSDM cleavage. This process required GSDME, but not GSDMD, as confirmed by GSDME knockdown. Mechanistically, KRASi activated two complementary GSDME-dependent pathways. First, KRASi triggered mitochondrial apoptosis, resulting in caspase-9 and caspase-3 activation and cleavage of GSDME into its pore-forming active N-terminal fragment (GSDME-NT). Second, KRASi stabilized GSDME-NT by suppressing its degradation. Previous research has shown that LAT1-mediated methionine uptake promotes GSDME-NT degradation. Consistent with this, we found that KRASi reduced c-MYC expression and downregulated its transcriptional target LAT1, the major transporter of methionine, thereby decreasing methionine-dependent GSDME-NT turnover and stabilizing the active fragment. Pharmacologic LAT1 inhibition with JPH203 further enhanced KRASi-induced pyroptosis, and this augmentation was reversed by the methionine-derived metabolite spermidine.
Conclusions: We identify GSDME-mediated pyroptosis as a previously unrecognized mechanism of KRASi-induced cell death in KRAS-mutant NSCLC. KRASi promotes both the generation and stabilization of GSDME-NT, while LAT1 inhibition amplifies this process by increasing metabolic stress and reducing GSDME-NT degradation. These findings support metabolic modulation, specifically LAT1 inhibition, as a promising combination strategy to enhance KRAS-targeted therapy and potentially improve immunogenic tumor cell death in KRAS-mutant NSCLC.

#2929 Immune and pharmacodynamic effects of sotorasib plus panitumumab in *KRAS* G12C-mutant colorectal cancer: Paired biopsy results from CodeBreaK 101.

David Hong[1], Lata Mukundan[2], Abraham Anderson[3], Emily Chan[3], Dorothy French[2], Linnea Haeggblom[2], Daniel Lu[2], Toshiki Masuishi[4], Rona Yaeger[5], Yuliya Katlinskaya[3]

[1]UT MD Anderson Cancer Center, Houston, TX,[2]Amgen Inc., San Francisco, CA,[3]Amgen Inc., Thousand Oaks, CA,[4]Aichi Cancer Center Hospital, Nagoya, Japan,[5]Memorial Sloan Kettering Cancer Center, New York, NY

Background: Sotorasib, a *KRAS* G12C inhibitor, plus panitumumab is approved for use in chemorefractory metastatic colorectal cancer (mCRC) . Yet, early effects on the tumor microenvironment (TME) in clinical samples are not well understood. In preclinical models, sotorasib potently suppresses MAPK signaling and promotes a pro-inflammatory TME characterized by $CD8^+$ T cell infiltration and increased IFN-γ activity, implicating adaptive immunity in tumor control. We investigated if these pharmacodynamic and immunologic effects are observed clinically in patients (pts) treated with sotorasib plus panitumumab.

Methods: Paired biopsies before and after 3-4 weeks of sotorasib plus panitumumab treatment were available from 12 pts in Cohort A of CodeBreaK 101 (NCT04185883). We performed whole-transcriptome RNA sequencing (n=12), pERK immunohistochemistry (n=8), spatial analysis of H&E-stained sections using digital pathology (n=10), and single-cell spatial transcriptomics (n=2). Analyses were primarily descriptive, and Wilcoxon signed-rank tests and summary statistics were used to characterize differences between paired biopsies.

Results: Transcriptomic profiling revealed robust suppression of MAPK signaling, shown by an approximate 4-fold reduction in median MAPK Pathway Activity Score with consistent downregulation of cell cycle-related genes. Key MAPK targets were downregulated, including *ETV4* (–6.9-fold), *EPHA2* (–2.8-fold), and *DUSP6* (–2.0-fold), while *EPHA4* was largely unchanged. pERK immunohistochemistry showed an approximately 1.8-fold reduction in H-score and a 2.0-fold decrease in proportion of $pERK^+$ tumor nuclei among profiled pts, consistent with effective MAPK pathway inhibition. Immune activation was reflected by a 1.9-fold increase in the Tumor Inflammation Signature score and upregulation of chemokines and antigen-presentation genes (CXCL9, CCL5, HLA-DPA1). Digital pathology analysis of H&E images showed increased immune cell clustering in the TME, mirroring immune remodeling observed in RNA-seq data. Single-cell spatial confirmed presence of $CXCR6^+$ $CD8^+$ T cells and macrophage derived CXCL10 in the tumor and associated stroma suggesting cytotoxic T cell recruitment and activation. Comprehensive pathway analysis showed upregulation of PI3K-AKT, HER2, and TGFβ signaling in some pts, suggesting compensatory survival mechanisms and a potential rationale for combinatorial strategies.

Conclusion: Paired biopsy analysis revealed potent MAPK inhibition and immune remodeling, providing mechanistic insight into the role of the immune TME in early response to sotorasib plus panitumumab and underscoring opportunities for rational combination strategies in mCRC.

#2930 Unraveling determinants of drug response: PRISM viability profiling of hundreds of oncology therapeutics reveals mediators of selectivity and mechanism.

Matthew G. Rees, Mustafa Kocak, Matthew J. Emmett, Colleen T. Harrington, Li Wang, Anthony Fazio, Alvin Kalathungal, Dennie T. Frederick, Aydin Golabi, Rachael Barry, Emily Reeves, John Davis, Melissa M. Ronan, Laura Doherty, Jillian N. Eskra, William R. Sellers, Jennifer A. Roth

Broad Institute, Cambridge, MA

Incomplete understanding of drug mechanism, selectivity, and polypharmacology can contribute to failed clinical trials. Drug candidates are generally characterized with limited pre-clinical tools and a narrow indication focus based on expected target biology. Using approaches such as large-scale PRISM profiling of 900 cell lines that have been genomically profiled in the Dependency Map coupled with machine learning analysis can provide a more thorough and agnostic understanding of oncology drugs. Here, we demonstrate that systematic characterization of an Oncology Reference library of over 250 oncology drugs, encompassing biologics (e.g., cytokines, antibody-drug conjugates), targeted protein degraders, and small molecules, of which two-thirds have never been tested with large-scale cell line profiling, enables better understanding of on-target and off-target effects. We developed models to quantify selectivity, on-target activity, and polypharmacology. Surprisingly, in some instances, these measures of cellular specificity can anticipate differential outcomes in clinical trials. Among unexpected findings, we identified a recurrent viability signature predictive of compound lysosomal accumulation, a phenomenon associated with phospholipidosis. In addition, CDK4-selective inhibition emerged as a potential therapeutic vulnerability across a diverse range of cancer types, including CDK6-deficient or CDK4-altered cancer. Our findings establish the Oncology Reference dataset and PRISM as a benchmark for evaluating current and emerging cancer therapies: combining large-scale systematic cell line profiling, genomic characterization, and machine learning analysis enables comprehensive characterization of oncology drugs with potential to inform clinical development.

#2931 RC108, a c-Met-targeting ADC, exhibits differential cytotoxicity between cMet-high and HGF-dependent tumor cells compared with Teliso-V, suggesting a potential safety advantage.

Jiayue Geng, Zhanjiao Yu, Haiqing Zhong, Qingbo Wang, Xiao Lv, Tongyu Xiao, Kailin Wang, Xiaoping Zhang, Xiaoli He, Lili Wang, Ying Jiang, Jianing Liu, Yinghao Xin, Jianmin Fang, **Yuanhao Li**

RemeGen Co., Ltd. (Yantai), Yantai, China

Telisotuzumab vedotin (Teliso-V) is the first c-MET-targeting ADC approved by FDA in May 2025 for the treatment of locally advanced or metastatic non-squamous NSCLC with high c-MET protein expression in patients who have received prior systemic therapy. Aberrant c-MET signaling is frequently observed in lung cancer and many other malignancies. Both c-MET overexpression and its ligand HGF contribute to hyperactivated c-MET signaling, promoting tumor proliferation, metastasis, and therapeutic resistance. Consequently, c-MET-targeted therapies employing various modalities have been actively pursued. RC108 is a novel c-MET-targeting ADC developed by RemeGen. It comprises a humanized antibody linked via a cleavable valine-citrulline/PABC linker to the cytotoxic payload monomethyl auristatin E (MMAE). Comparative in vitro studies were performed to evaluate RC108 versus Teliso-V, focusing on binding characteristics and cytotoxicity profiles. Both antibodies recognize distinct epitopes (bins) on the c-MET protein, and although their antigen-binding affinities and cell-binding properties are broadly comparable, RC108 exhibits faster and more efficient endocytosis than Teliso-V. For cytotoxicity assessment, a panel of cancer cell lines-particularly lung carcinoma cells-was characterized for c-MET signaling status using Western blotting to distinguish HGF-dependent versus HGF-independent (c-MET overexpression-driven) activation. The results revealed a clear pattern that RC108 demonstrated equal or superior potency to Teliso-V in c-MET-overexpressing tumor cells, but showed markedly weaker cytotoxicity in HGF-dependent cells. Although the underlying mechanism is under further investigation, clinical observations with RC108 support the hypothesis that this differential activity may confer a potential safety advantage. Since HGF-dependent c-MET signaling is commonly utilized by normal tissues in physiological repair and homeostasis, the lower cytotoxicity of RC108 in HGF-driven cells may indicate reduced interference with normal tissue signaling while maintaining strong activity against tumors driven by c-MET overexpression. Clinically, RC108 has shown a favorable and manageable safety profile in early monotherapy trials, characterized by a low incidence of TRAEs. In contrast, Teliso-V exhibited notable toxicity in earlier studies, with a relatively high discontinuation rate due to TRAEs. Importantly, RC108 was associated with low rates of peripheral neuropathy, a markedly lower incidence of interstitial lung disease (ILD), and no observed ocular toxicity. In summary, RC108 is a c-MET-targeted ADC with distinct properties to be recognized in further studies and may have potentially improved safety margin.

#2932 Combination of miRNA-379-5p and miRNA-125a-3p for the treatment of platinum resistant ovarian cancer.

Serenade Trevino, Trey Zepeda, Sue Anne Chew

Health & Biomedical Sciences, The University of Texas Rio Grande Valley, Brownsville, TX

Ovarian cancer (OC) is the second most common gynecologic cancer and the leading cause of death from cancers of the female reproductive system. The development of resistance to first-line platinum chemotherapy (e.g., cisplatin, carboplatin) contributes to high recurrence and lethality of OC, with over 50% of patients with advanced-stage OC relapsing due to drug resistance within two years of remission. Therefore, there is a need for alternative methods to treat platinum-resistant OC (PROC). Among several mechanisms, resistance to platinum-based therapy has been linked to upregulation of focal adhesion kinase (FAK), which activates signaling pathways that promote cell migration, invasion, adhesion, proliferation, and survival, and its overexpression is an accurate predictor of poor survival. Because FAK inhibitors have been unsuccessful when tested as single agents, combining them with other therapeutic agents may be more effective. Combination therapies are promising as they can improve treatment response while minimizing resistance and adverse side effects. Furthermore, cancer is often driven by multiple molecular pathways, and thus, a single therapy may not be sufficient. miRNA-379-5p has been shown to act as a tumor suppressor by directly targeting FAK and is downregulated in several OC cell lines and patient tumor samples. Additionally, overexpression of miRNA-125a-3p has been shown to inhibit cell invasion, migration, and proliferation, and induce apoptosis and cell cycle arrest in OC cells. BCL2-related ovarian killer (BOK) is a direct downstream target of miRNA-125a-3p, which acts as a pro-apoptotic regulator, and its protein levels can be increased by miRNA-125a-3p. The objective of this study was to investigate the dual delivery of miRNA-379-5p and miRNA-125a-3p for the treatment of PROC. OVCAR3 cells (i.e., adenocarcinoma ovarian cells shown to be platinum resistant) were transfected with each miRNA individually or in combination using Lipofectamine RNAiMAX, and cell viability was assessed using an MTT assay after 48 and 72 hours. After 48 hours, miRNA-379-5p, miRNA-125a-3p, and a combination of these miRNAs reduced cell viability by ~5, 14, and 21%, respectively, compared to the negative control. After 72 hours of exposure, both individual miRNA treatments significantly reduced cell viability by ~13%, while the treatment with both miRNAs reduced cell viability by ~28% compared to the negative control. The treatment of OVCAR3 with the combination of miRNA-379-5p and miRNA-125a-3p was able to significantly reduce cell viability compared to the treatment with each miRNA alone, suggesting a possible additive effect on cell death. Future studies will evaluate the mechanisms underlying reduced cell viability by investigating protein levels of markers for apoptosis, proliferation, and invasion.

#2933 Itareparib: A potent, selective and non-trapper PARP1 inhibitor for combination therapy with DNA damaging agents in solid tumors.

Alessandro Galbiati[1], Gianluca Papeo[1], Nilla Avanzi[1], Fabio Gasparri[1], Claudia Perrera[1], Gemma Texido[1], Lisa Mahnke[2], Shiho Nakano[3], Kang Jin Jeong[4], Gordon B. Mills[4], Junko Murai[3], **Alessia Montagnoli**[1]

[1]Nerviano Medical Sciences, Nerviano, Italy,[2]Nerviano Medical Sciences, Cambridge, MA,[3]Ehime University, Ehime, Japan,[4]OHSU Knight Cancer Institute, Portland, OR

BACKGROUND: The poly(ADP-ribose) polymerase-1 (PARP1) enzyme is critical to DNA Damage Response. Multiple first generation non-selective, trapping PARP1/2 inhibitors have been successful as single agent cancer treatments in homologous recombination (HR)-deficient malignancies; on the other hand, first-generation PARPi such as olaparib (a strong PARP1 trapper), or veliparib (a PARP1 trapper with medium potency), have not been successful in combination with chemotherapy due to a poor therapeutic window. Recently, second generation trapper PARP1-selective inhibitors (e.g. saruparib, M9466, SNV1521 and palacaparib) have entered clinical development, based on preclinical evidence that PARP2 inhibition is associated with anemia and dispensable for anti-tumor efficacy. However, emerging clinical data suggest that these drugs display hematological effects similar to the first generation PARPi. Indeed, all these inhibitors trap PARP1 on DNA lesions, causing hematological adverse effects that are overlapping with those caused by chemotherapy agents such as temozolomide (TMZ) and topoisomerase I inhibitors (TOP1i), thus limiting their combination potential.
METHODS: We used biochemical and cellular assays to evaluate itareparib potency and selectivity. Additionally, we performed cellular proliferation assays and mechanistic assays such as DNA damage markers assessment by high-content imaging and DNA combing assays, to evaluate itareparib activity in combination with DNA damaging agents (DDA). Finally, we performed in vivo experiments in tumor bearing mice and tumor free rats to assess the combination effects of itareparib plus TMZ on tumor growth inhibition and on the bone marrow.
RESULTS: Itareparib is a non-trapper PARPi and showed synergistic activity in combination with TMZ and TOP1i or Antibody Drug Conjugates (ADCs) with TOP1i payloads on DNA damage markers and in proliferation assays in vitro. The combination efficacy with temozolomide was confirmed in vivo in a small cell lung cancer xenografts model. Additionally, the comparative data with trapper-PARPi suggests that the combination efficacy with TMZ and TOP1i is not dependent on the trapping potency. Importantly, itareparib combination with DDA had lower impact on bone marrow precursors both *in vitro* and *in vivo* compared to PARP1-trapping inhibitors. Consistently with literature data, in vitro studies identify SLFN11 expression as a sensitivity biomarker to the combination of itareparib with chemotherapy.
CONCLUSIONS: Itareparib features are designed to expand the application of PARP1i through combination with chemotherapy, ADCs and radionuclides addressing the unmet need of patients with both HR-deficient and HR-proficient tumors. Itareparib is currently in Phase I/II clinical trials in combination with DNA-damaging agents in brain (high grade gliomas), lung and ovarian cancer.

#2934 Characterizing response to PARP inhibitor treatment combinations in advanced prostate cancer.

Bryan Correa Gonzalez[1], Akshaya Karthikeyan[1], Love A. Moore[1], Ethan Sandoval[1], Anamitra Bhuamik[1], Marion Hardy[2], Alan P. Lombard[1]

[1]UC Davis Comprehensive Cancer Center, Sacramento, CA,[2]UC Davis, Sacramento, CA

Background: Combining poly (ADP-ribose) polymerase inhibitors (PARPi) with androgen receptor pathway inhibitors (ARPi) has improved advanced prostate cancer management but questions remain including 1) where in the clinical treatment paradigm will these combinations fare best? 2) what underlies the efficacy of these combinations? and 3) what else may be more effective in combination with a PARPi? Here, we address these questions to advance the utility of PARP inhibition.
Methods: LNCaP (CSPC), C4-2B (CRPC), MDVR (enzalutamide-resistant C4-2B derivative), and AbiR (abiraterone-resistant C4-2B derivative) served as models of different advanced prostate cancer indications. Viability assays, microscopy, western blots and RNA-sequencing were used to investigate response to treatment.
Results: Data suggest prior exposure to an ARPi does not preclude benefit from combination treatment, but that the effect is greatest in ARPi-naïve cells. Despite a decrease in cellular viability, morphology of treated cells reveals a largely cytostatic response. Transcriptomic analysis and western blots suggest current hypotheses explaining the mechanism of combination efficacy may be incomplete, as findings do not support that ARPis induce significant BRCAness nor that PARPis reduce AR activity. Given that PARPi and ARPi combination may be less effective post ARPi exposure, we sought an alternative which may be more effective in this setting. Our work suggests that PARPis induce a robust, ATM-driven DNA damage response, and that co-targeting ATM elicits a synergistic reduction in cellular viability. Co-inhibition of ATM and PARP is much more effective than ARPi containing combinations in models of ARPi-resistant CRPC.
Conclusions: Current results suggest that 1) PARPi and ARPi combinations may be most effective earlier in the treatment paradigm, 2) more work is needed to understand PARPi and ARPi combination efficacy, and 3) ATM inhibition may be better in combination with a PARPi in more advanced settings. Future efforts will be directed at better understanding how these drugs work together and when best to administer them given the rapidly evolving prostate cancer treatment landscape.

#2935 Establishment of experimental model for measuring antibody-drug conjugate (ADC) bystander effects in breast cancer.

Hyunmyoung Yun[1], Won-Ji Ryu[1], Hyein Jung[1], Tae Yeong Kim[1], Cheol-Hwa Hong[1], Yumi Hwang[1], Hyun Ju Han[1], Geon-Uk Kim[1], Seo Young Lee[1], Kyoo Hyun Kim[2], Min Hwan Kim[2], Gun Min Kim[2], Joo Hyuk Sohn[2]

[1]Avison Biomedical Research Center, Yonsei University College of Medicine SBSI, Seoul, Korea, Republic of,[2]Department of Internal Medicine, Yonsei University College of Medicine SBSI, Seoul, Korea, Republic of

Antibody-drug conjugates (ADCs) targeting HER2 and TROP2 are now a mainstay of breast cancer therapeutics. ADCs equipped with cleavable linker-payload systems can kill non-target-expressing cancer cells through a bystander effect, which is influenced by antibody internalization and lysosomal degradation of the linker-payload complex. We first evaluated the IC_{50} values of the HER2-targeting ADC trastuzumab deruxtecan (T-DXd) across a panel of breast cancer cell lines. HER2 protein expression levels correlated well with sensitivity to T-DXd, confirming that HER2 target expression is a major determinant of individual response. We next assessed the presence of bystander effect by co-culturing of MCF7 (low-HER2) with SK-BR-3 (HER2+) cells in culture. T-DXd successfully induced caspase-3 activation in MCF7. Leveraging observation in the co-culture experiment, we established a quantitative co-culture model to measure the magnitude of ADC-mediated bystander activity. In this model, we engineered the TNBC cell line MDA-MB-231 (HER2-null) to stably express EGFP to be co-cultured with SK-BR3 (HER2+). T-DXd was labeled with pHrodo Red to visualize lysosome-ADC contact in breast cancer cells, and DNA damage was assessed by γ-H2AX staining. We observed internalization and co-localization to lysosome of T-DXd in selectively in SK-BR-3 cells, but not in MDA-MB-231 cells. Whereas, γ-H2AX activation were detected in EGFP-tagged MDA-MB-231 cells, suggesting propagation of payload DXd via bystander effect. Finally, we performed genomic analyses to identify genetic factors potentially associated with bystander activity in 50 breast cancer patients treated with ADCs using targeted-panel NGS data. Alterations in NOTCH1, NOTCH2, and NF1 were associated with poor progression-free survival under ADC treatment by Cox regression analysis, and these genes are implicated in lysosomal and autophagy regulation. Collectively, these findings highlight that the anticancer efficacy of ADCs is substantially influenced by the bystander effect and underscore the need for deeper investigation into how genetic factors modulate this process.

#2936 NAMPT inhibition enhances the efficacy of standard chemotherapies and immunomodulation in pancreatic ductal adenocarcinoma.

Purnachandra Nagaraju Ganji[1], Sujith Sarvesh[2], Dhana Sekhar Reddy Bandi[2], Husain Yar Khan[3], Irfana Muqbil[4], Amro Aboukameel[4], Sahar Bannoura[4], Khalil Choucair[4], Walid Sukkari[4], Sunil Jaiman[4], Rafic Beydoun[4], Gergory Dyson[4], Yang Shi[4], N. Vaishampayan[5], Eliza W. Bael[4], Miguel Tobon[4], Steve Kim[4], Herbert Chen[1], Muhammad W. Saif[4], Anthony Frank Shields[6], Philip A. [1]Hematology and Oncology, University of Alabama at Birmingham, Birmingham, AL,[2]University of Alabama at Birmingham, Birmingham, AL,[3]Barbara Ann Karmanos Cancer Institute, Detroit, MI,[4]Wayne State University, Dearborn, MI,[5]Hematology and Oncology, Karmanos Cancer Institute, Detroit, MI,[6]Associate Director for Clinical Research, Barbara Ann Karmanos Cancer Institute, Detroit, MI,[7]Remedy Plan Therapeutics, Gaithersburg, MD,[8]Karmanos Cancer Institute, Detroit, MI

Background: Pancreatic ductal adenocarcinoma (PDAC) is characterized by high metabolic demand and dependency on NAD salvage pathways. NAMPT, the rate-limiting enzyme in NAD biosynthesis, is upregulated in PDAC and supports tumor survival under therapeutic stress. We investigated the preclinical activity of a novel hyperbolic NAMPT inhibitor (NAMPTi) in combination with standard-of-care (SOC) chemotherapy regimens including gemcitabine, paclitaxel, 5-FU, oxaliplatin, hydroxychloroquine, and paricalcitol to determine whether NAMPT blockade enhances cytotoxic and immunomodulatory responses.
Methods: Human and murine PDAC cell lines (PANC-1, MIA PaCa-2, KPC-Luc, and patient-derived 2838c) were treated with NAMPTi (5 μM) alone or with SOC agents at clinically relevant doses. Synergy was assessed in 2D viability and 3D spheroid assays. Olaparib combinations were also tested in BRCA-related models. In vivo, KPC allografts received NAMPTi (20 mg/kg, 5×/week) with gemcitabine, paclitaxel, hydroxychloroquine, 5-FU, oxaliplatin, or paricalcitol for three weeks. Immune infiltrates (CD45+, CD8+, CD4+ subsets), functional markers (GZMB, CD107a, IFNγ, TNFα), and fibroblast subtypes (apCAF, myCAF, iCAF) were quantified by flow cytometry.
Results: Across all PDAC models, NAMPTi alone produced modest growth inhibition, while combination treatment consistently outperformed monotherapies. NAMPTi synergized with gemcitabine-paclitaxel-hydroxychloroquine and gemcitabine-paclitaxel regimens, significantly reducing cell viability in both human and KPC-derived lines. In vivo, NAMPTi combinations markedly suppressed KPC tumor growth compared to SOC alone and reduced metastatic burden to liver and lung (e.g., GPH+NAMPTi: 60% metastasis-negative vs. 20-40% in monotherapy groups). Dual treatment increased CD8+ T-cell infiltration and effector phenotypes, enhanced cytotoxic function (GZMB+, CD107a+), and elevated IFNγ and TNFα production. NAMPTi also shifted fibroblast composition, with significant reductions in myCAFs and apCAFs, suggesting stromal remodeling. In FO and GPH regimens, combining NAMPTi produced superior tumor control, decreased immunosuppressive cell populations, and improved effector memory T-cell signatures.
Conclusions: NAMPT inhibition robustly enhances SOC chemotherapy efficacy in PDAC by simultaneously amplifying cytotoxic responses, remodeling the tumor immune microenvironment, and reducing metastatic spread. These findings support NAMPTi-based combinations as a promising therapeutic strategy and justify further translational development, including biomarker-driven clinical evaluation in PDAC.

#2937 Imipridones ONC201, ONC206, and ONC212 show potent killing and colony arrest of small-cell lung cancer cell lines.

Audrey Y. Su, Connor Purcell, Shengliang Zhang, Lanlan Zhou, Ashley S. Uruchurtu, Wafik S. El-Deiry

Brown University, Providence, RI

Introduction: Small cell lung cancer (SCLC) represents about 15% of all lung cancers, with an estimated 5-year survival rate of only 7%. While most SCLC cases initially respond to chemotherapy, a majority (70-80%) of cases recur and become resistant to first-line treatments. As such, further investigation of novel therapeutics is heavily warranted. Imipridones are a class of selective anti-cancer drugs that activate integrated stress response and increase TRAIL expression to lead to cancer cell death. While ONC201 (dordaviprone) has been investigated in small-cell and various other cancers, its derivatives ONC206 and ONC212 have not yet been explored within SCLC. As such, the present study compares ONC201, ONC206, and ONC212 within the context of SCLC.
Methods: Three SCLC cell lines were used: H526, H1048, H1882. For viability assays, cells were plated at 1000 cells/well in a 96-well plate and allowed to adhere overnight before treatment. Viability was assessed 72h after imipridone treatment by Cell-TiterGlo® assay to yield each drug's IC50. Western Blots (WBs) were performed across cell lines at 24h, 48h, and 72h following equitoxic treatments with each imipridone (IC25, IC50, IC75). Colony formation assays (CFAs) were also performed in triplicate for two cell lines (H1048, H1882) after three-day treatment with equitoxic doses of each drug followed by fourteen days of drug-free incubation.
Results: Across cell lines, ONC212 exhibited the lowest IC50, followed by ONC206 and ONC201. By WB, changes in ATF4, cPARP, and ClpX differed by drug, with ONC212 generally inducing the earliest and most significant changes in expression. CFA showed that ONC212 resulted in the greatest decrease in colony formation after 72 hours of treatment, followed by ONC206 and then ONC201.
Conclusions: The present findings suggest that SCLC may be highly sensitive to imipridones, particularly ONC212. Future works will aim to explore combination therapies and potential mechanisms including senescence induction, cell cycle alterations that may lead to reproductive arrest, metabolic changes, and alterations in growth and survival pathways in order to further characterize sensitivity and the colony arrest phenotype.

#2938 KRAS and ERK5 signaling pathways in cancer: Implications for targeted therapy.

Christophe Marcireau[1], Frederic Lacroix[1], Fatima Amor[1], Karine Dobrazix[1], Guillaume Nurit[1], Veronique Jean-Baptiste[1], Eiwen Yang[2], Donald Jackson[2], Colette Dib[1], Gaelle Muzard[1], Franck Slowinski[1], Laurent Debussche[1], Pawel K. Mazur[3]

[1]Sanofi, Paris, France,[2]Sanofi, Boston, MA,[3]PostDoc, UT MD Anderson Cancer Center, Houston, TX

KRAS Signaling in Cancer: KRAS functions as a small GTPase that serves as a molecular switch in cellular signaling, orchestrating proliferation, differentiation, and survival mechanisms. As the central node of the RTK-RAS-RAF-MEK-ERK signaling cascade, KRAS mutations represent the most frequent oncogenic events across human cancers, particularly in pancreatic, colorectal, and lung malignancies. These mutations drive constitutive pathway activation, promoting uncontrolled cellular growth. In lung cancer, KRAS G12C mutations are especially prevalent, leading to the development and approval of targeted therapies such as Sotorasib and Adagrasib. The clinical success of these KRAS G12C inhibitors has established a promising foundation for developing additional molecules targeting various K/N/H RAS isoforms.

ERK5 Signaling and Cancer Progression: ERK5, another member of the MAPK family, is activated by MEK5 in response to mitogenic and stress signals. The MEK5-ERK5 pathway regulates critical physiological and pathological processes, including cell survival and proliferation. Additionally, this signaling axis plays significant roles in metastatic progression and immune modulation within tumor microenvironments. Notably, inhibition of the RAS pathway frequently triggers compensatory upregulation of MEK5-ERK5 signaling, enabling cancer cells to maintain oncogenic signaling despite targeted intervention.

Research Focus: In this investigation, we will establish an ERK5 transcriptional gene signature and demonstrate how broad RAS pathway inhibition leads to ERK5 signaling overactivation through multiple experimental approaches.

#2939 Extrachromosomal DNA plasticity enables novel trajectories of cancer adaptation to drug treatments.

Jingting Chen[1], Joseph M. Dahl[2], Poorya Behnamie[3], Elizabeth Brunk[4]

[1]Department of Biochemistry and Biophysics, University of North Carolina at Chapel Hill, Chapel Hill, NC,[2]Bioskryb Genomics, Inc., Durham, NC,[3]Integrative Program for Biological and Genome Sciences, University of North Carolina at Chapel Hill, Chapel Hill, NC,[4]Department of Pharmacology, University of North Carolina at Chapel Hill, Chapel Hill, NC

Acquired resistance of cancer arises from continual evolution induced by therapeutic pressure. Breaking conventional evolutionary barriers, extrachromosomal DNA (ecDNA) recently emerged as a powerful driver of tumor adaptability and therapeutic failure. Studying ecDNA-driven evolution has largely focused on ecDNA copy number dynamics. However, this perspective overlooks the adaptive potential of ecDNA structural changes. A key mechanism of structural adaptation is ecDNA reintegration into chromosomes to form homogeneously staining regions (HSRs), elongated stretches of chromosomes that store oncogene copies. Prevalent in resistant malignancies, ecDNA-HSR transition is increasingly suspected to underlie therapeutic evasion. Yet how ecDNA reintegration occurs, how it varies across treatment conditions or cell types, and how it enables adaptation and resistance remain unclear. Addressing these gaps will greatly improve our ability to predict resistance progression and counteract ecDNA-driven malignancies, and this requires systematic characterization of ecDNA and HSRs.To fill these gaps, this work provides a systematic, high-resolution characterization of ecDNA drug responses using state-of-the-art single-cell multi-omics sequencing, imaging, and machine learning. We demonstrate that during drug exposure, ecDNA produces distinct adaptive responses in a cell population through complex genomic alterations. First, we consistently see significant ecDNA reduction in the cells that survived treatments. This is tightly correlated with gene expression changes in the same single cells, evidence that ecDNA is subject to selection. Intriguingly, imaging results have uncovered a previously unrecognized type of ecDNA that may represent an intermediate state bridging ecDNA-HSR transition. This observation challenges the traditional two-state view of ecDNA reintegration, suggesting instead a dynamic continuum that may underlie graded adaptation. To dissect this continuum at the functional levels, we are measuring ecDNA, intermediate, HSRs, RNA, and protein configurations in single cells across diverse adaptation models.Integrating innovative single-cell technology development with mechanistic discovery, our findings underscore the remarkable plasticity of ecDNA implicated in resistance acquisition. We show that rather than solely relying on pre-existing pro-survival traits, cancer cells may additionally exploit ecDNA to fast-track genomic changes that enable a wider range of adaptation. Such genomic plasticity may explain the quick relapse after selective therapies, offering new insights into actionable biomarkers that can reverse ecDNA-driven resistance.

#2940 Tumor-selective dimeric and monomeric RAF targeting with a next-generation Type 1 RAF inhibitor.

Mathieu Desaunay[1], Tara L. Peters[2], Evangelia Matenoglou[3], Beau Baars[1], Bijaya Gaire[1], Ana Orive-Ramos[1], Li Ren[2], Joseph P. Lyssikatos[2], Michael R. Burkard[2], Dalton Dacus[2], Matthew J. Sale[4], Stuart A. Aaronson[5], Frank McCormick[6], Evripidis Gavathiotis[7], Stefan D. Gross[2], Poulikos I. Poulikakos[1]

[1]Oncological Sciences, The Tisch Cancer Institute, Icahn School of Medicine at Mount Sinai, New York, NY,[2]Enliven Therapeutics, Boulder, CO,[3]Department of Biochemistry, Albert Einstein College of Medicine, Bronx, NY,[4]UCSF - University of California San Francisco, San Francisco, CA,[5]Icahn School of Medicine at Mount Sinai, New York, NY,[6]UCSF Helen Diller Family Comprehensive Cancer Ctr., San Francisco, CA,[7]Albert Einstein College of Medicine, Bronx, NY

Therapeutically silencing the RAS/MAPK signaling cascade, an oncogenic driver in more than one-third of human cancers, is constrained by a fundamental trade-off: potent pathway inhibition in tumors versus dose-limiting toxicities in normal tissues. BRAF-mutant (BRAF-MUT) cancers are a notable exception, where current clinical RAF inhibitors (RAFis) (Type 1.5 - αC-OUT/DFG-IN) selectively inhibit monomeric BRAF(V600X), while paradoxically activating MAPK signaling pathway in settings where RAF signals as a dimer, including wild-type and RAS-Mutant (RAS-MUT) contexts. While this paradoxical activation limits the broader applicability to BRAF-MUT tumors, it has been therapeutically exploited in vertical MAPK-targeting combinations with MEK or EGFR inhibitors, enhancing antitumor efficacy while restoring physiological MAPK signaling in normal tissues, achieving an improved therapeutic window and enhancing tolerability.To target dimeric RAF-driven tumors, including RAS-MUT tumors, Type 2 (αC-IN/DFG-OUT) RAFis were developed to engage both RAF monomers and dimers. However, as single agents, Type 2 RAFis showed only modest activity. Combining them with MEK inhibitors improved efficacy but also exacerbated toxicities due to MAPK pathway suppression in normal tissues, limiting dosing and ultimately constraining therapeutic benefit.Here, we characterized ELV-3111, a next-generation, highly potent and selective Type 1 RAFi with broad activity across BRAF class I/II/III, CRAF, and RAS-MUT models, including contexts resistant to current MAPK-targeted therapies. Unlike Type 2 RAFis, ELV-3111 induces robust paradoxical MAPK hyperactivation selectively in normal tissues - a phenomenon we successfully modeled in cells. Using complementary biochemical and live-cell assays, alongside molecular dynamics simulations, we demonstrate that this MAPK hyperactivation occurs via a RAS-dependent allosteric mechanism distinct from the paradoxical activation described for Type 1.5 RAFis. This unique property can be therapeutically exploited. Combining ELV-3111 with a MEK inhibitor overcomes the therapeutic ceiling of MAPK pathway targeting by creating a pharmacologically complementary interaction: additive suppression in tumors, where both agents inhibit MAPK signaling, and opposing effects in normal tissues, where MEK inhibition counteracts RAFi-driven hyperactivation. This configuration produced profound and durable regressions across RAS- and BRAF-MUT models, including a RAS-MUT model refractory to current therapies, while maintaining favorable tolerability. This tumor-selective mechanism, previously exploited in BRAF-MUT cancers, can now be extended to RAS-MUT and other dimeric RAF-driven tumors, offering a renewed therapeutic opportunity and the potential to reshape combination strategies across a broader spectrum of MAPK-driven cancers.

#2941 Pharmacologic ascorbate exerts anticancer activity through ROS-dependent metabolic vulnerability in MYCN-amplified neuroblastoma.

Tasfia Farah, Qi Chen

Pharmacology, Toxicology & Therapeutics, KUMC, Kansas City, KS

Background: Neuroblastoma (NB) is an aggressive pediatric cancer with poor prognosis, particularly in patients with MYCN amplification (MNA). MYCN-driven metabolic plasticity allows NB cell survival even under therapeutic stress. Pharmacologic ascorbate (Asc) has emerged as a potential low-toxicity anticancer agent that generates hydrogen peroxide (H_2O_2) and induces oxidative stress, selectively killing cancer cells. This study investigated the ROS-mediated metabolic vulnerability of MYCN-amplified and non-amplified NB cells in response to ascorbate.

Method: Patient-derived MYCN-amplified (MNA) (COG-N-415) and non-amplified (COG-N-618) neuroblastoma cells were treated with 0-20 mM ascorbate for 24 hours. Cell viability was measured using the CellTiter-Glo® assay. Intracellular ATP levels were quantified by HPLC. H_2O_2 and catalase were used to assess ROS dependence. Mitochondrial respiration and glycolytic activity were assessed by Seahorse XF analysis after 1-10 mM ascorbate treatment.

Result: Ascorbate induced a dose-dependent decrease in cell viability in both MNA and non-MNA neuroblastoma cells, with approximately 90% cell death at 10 mM. COG-N-618 (non-MNA) cells exhibited greater sensitivity than COG-N-415 (MNA), showing significant viability loss at 5 mM ascorbate. ATP levels decreased in both cells upon 5 mM ascorbate treatment. Catalase rescued ascorbate-induced ATP depletion, confirming an H_2O_2-mediated mechanism. Seahorse analysis demonstrated progressive inhibition in mitochondrial respiration and glycolysis, with COG-N-618 cells showing dose dependent Oxidative Phosphorylation (OCR) and Glycolysis (ECAR) inhibition at 1-10 mM. For the COG-N-415 cells (MNA), both OCR and ECAR decreased at 1 mM of ascorbate, but 5 mM and 10 mM did not cause further decrease, indicating an adaptive mechanism in the MYCN-amplified cells.

Conclusion: Pharmacologic ascorbate induces cytotoxicity in neuroblastoma cells and triggers ROS-dependent metabolic disruption and MYCN downregulation.

#2942 Inhibition of stearoyl-CoA desaturase 1 (SCD1) by SSI-4 as a therapeutic strategy in non-small cell lung cancer.

Valeria Romina Salerno Gonzales[1], Lauren Antal[2], Tamiel Nichole Turley[3], John A. Copland III[4]

[1]Mayo Clinic Graduate School of Biomedical Sciences, Mayo Clinic, Jacksonville, FL,[2]Research, Mayo Clinic, Jacksonville, FL,[3]Mayo Clinic, Rochester, MN,[4]Mayo Clinic, Jacksonville, FL

Lipid metabolism plays an important role in lung cancer growth, survival, and therapeutic resistance. Stearoyl-CoA desaturase 1 (SCD1), the enzyme that converts saturated fatty acids (SFAs) into monounsaturated fatty acids (MUFAs), represents a metabolic vulnerability since cancer cells depend on MUFAs for membrane biosynthesis, ER homeostasis, and alternative energy to glucose. SSI-4 (a.k.a MTI-301) is a selective SCD1 inhibitor currently in Phase I clinical evaluation for metastatic, unresectable, or refractory solid cancers, but its activity in non-small cell lung cancer (NSCLC) has not yet been characterized. To evaluate how NSCLC models respond to SCD1 blockade, we performed an initial screen of a panel of 17 human non-small cell lung cancer cell lines treated with 100 nM SSI-4 under defined serum conditions. Cell viability assays identified 9 responding cell lines, and dose-response studies confirmed IC50 values ranging from approximately 0.65 to 45.5 nM. Rescue experiments showed that adding oleic acid, an SCD1 regulated MUFA, reversed SSI-4-mediated growth inhibition, confirming mechanistically that this effect occurs through SCD1 blockade. Western blot analysis confirmed that SSI-4 treatment increased markers of endoplasmic reticulum (ER) stress and apoptosis in sensitive lines, consistent with disruption of lipid homeostasis. In contrast, non-responsive lines exhibited minimal induction of these stress pathways and retained viability despite treatment. Soft agar assays further showed that SSI-4 reduced anchorage-independent colony formation in responsive lines, indicating that SCD1 inhibition suppresses a key malignant growth property in these NSCLC models. Collectively, these findings demonstrate that SSI-4 selectively inhibits proliferation in a subset of NSCLC cells through an SCD1-dependent mechanism by reducing MUFA availability and activating stress and apoptotic signaling. This work establishes a framework for subsequent in vivo studies and lays the foundation for exploring SCD1 inhibition as a potential therapeutic strategy for patients with limited treatment options in NSCLC, while also advancing understanding of the mechanisms by which SCD1 supports tumor survival.

#2943 Antitumor effect of TROP2-targeted antibody drug conjugate, datopotamab deruxtecan (Dato-DXd), in association with DNA damage response in breast cancer cell lines.

Seohyeon Lim[1], **Sujin Ham**[1], Hae Min Hwang[1], Youlim Noh[1], Jiwon Koh[2], Chaeyoung Lee[1], Minyoung Jeong[1], Yu-Jin Kim[3], Minyoung Lee[4], Sohyeon Kim[4], Changhee Park[5], Dae-Won Lee[5], Kyung-Hun Lee[5], Seock-Ah Im[5]

[1]Cancer Biology, Graduate School of Interdisciplinary Graduate Program & Cancer Research Institute, Seoul National University, Seoul, Korea, Republic of,[2]Department of Pathology & Cancer Research Institute, Seoul National University Hospital & Seoul National University, Seoul, Korea, Republic of,[3]Cancer Research Institute, Seoul National University, Seoul, Korea, Republic of,[4]Cancer Biology, Graduate School of Interdisciplinary Graduate Program, Seoul National University, Seoul, Korea, Republic of,[5]Department of Internal Medicine & Cancer Research Institute, Seoul National University Hospital & Seoul National University, Seoul, Korea, Republic of

Background: Trophoblast cell surface antigen-2 (TROP2), Tumor-associated calcium signal transducer 2 (TACSTD2) is a transmembrane glycoprotein expressed in various cancer types. Datopotamab deruxtecan (Dato-DXd) is an antibody-drug conjugate (ADC) composed of an anti-TROP2 antibody (Datopotamab) linked via a cleavable peptide linker to DXd, a Topoisomerase-I inhibitor. Topoisomerase-I maintains DNA topological stress by resolving DNA supercoils during replication and transcription. We sought to determine whether this DNA damage mechanism classically induced by topoisomerase I inhibitors emerges when delivered through an ADC, and to further elucidate the previously uncharacterized molecular mechanisms of DNA damage response (DDR) and cell death by Dato-DXd.

Methods: Five established human breast cancer cell lines and one patient-derived breast cancer (PDC) cell line (SNU-3171) were used in this study. MCF7 and SNU-3171 were luminal breast cancer cell lines, and the others were triple-negative breast cancer (TNBC) cell lines. Sensitivity of each cell to Dato-DXd was assessed by colony formation assay (CFA) for 14 days (0.25-5 nM). Internalization and cell cycle analysis were performed by flow cytometry. Apoptosis was detected by Annexin V assay. The protein expression of TROP2, DNA damage, and repair molecules was analyzed by Western blotting and immunofluorescence.

Results: Based on CFA results, HCC1806, HCC70, and SNU-3171 were identified as sensitive cells (IC_{50}<0.5 nM), whereas MCF7, MDA-MB-157, and HCC1395 as less sensitive cells (IC_{50}>2.5 nM) to Dato-DXd. Dato-DXd was internalized within 2 hours in TROP2-positive cells. Following internalization, topoisomerase-I cleavage complexes (Top1ccs) were formed in all TROP2-positive cells; however, co-localization of Top1ccs and ɣ-H2AX was observed only in sensitive cells. Dato-DXd induced G2/M arrest in all TROP2-positive cells. In sensitive cells, the expression of TDP1, XRCC1, DNA Ligase III, and PNKP was decreased, while phospho-Chk1 (S345) and ɣ-H2AX were increased, indicating a reduction in single-strand DNA damage repair capacity and activation of DDR. Moreover, increased doses of Dato-DXd were associated with higher number of Annexin V-positive cells and sub-G1 populations, as well as higher expression of cleaved PARP, caspase-3, and caspase-7 in sensitive cells.

Conclusion: Dato-DXd demonstrated efficient internalization in TROP2-positive breast cancer cells including PDC, and impaired DNA single-strand break (SSB) repair, which consequently induce apoptosis in sensitive breast cancer cells. In particular, formation of Top1ccs and G2/M phase accumulation are induced in most of TROP2-positive cells. Further experiments are required to elucidate how impaired SSB repair contributes to the induction of DNA double-strand breaks and apoptosis.

#2944 Uncovering the zinc-dependent pathways of response and resistance to THZ1 in clear cell ovarian cancer.

Maya Modak[1], Soledad Ochoa[2], Forough Abbasi[3], Dandi Huang[3], Robbin Nameki[3], BJ Rimel[4], Kate Lawrenson[2]

[1]Center for Inherited Oncogenesis, Cedars-Sinai Health Sciences University/ University of Texas at San Antonio, Los Angeles/ San Antonio, CA,[2]Center for Inherited Oncogenesis, University of Texas at San Antonio, San Antonio, TX,[3]Cedars-Sinai Health Sciences University, Los Angeles, CA,[4]University of Washington, Seattle, WA

Ovarian cancer (OC) ranks as the fifth most lethal form of cancer for women and in the US causes the most deaths of any reproductive system malignancies. The current lack of clinical tools for effective early detection results in predominantly late-stage diagnosis. Clear cell ovarian cancer (CCOC), one of the five subtypes of OC, has low rates amongst Western demographics but makes up 25-30% of all cases of OC in Eastern countries such as Japan. A key characteristic of CCOC is its high rates of resistance to standard platinum therapy, with only 20-50% of patients showing response. Thus there is an urgent need for new treatment options for CCOC that can elicit sustained responses. An exciting new area of cancer therapeutics is focused on targeting the epigenetic drivers of cancer. New epigenetic cancer therapies include drugs that target transcription-associated cyclin dependent kinases (CDKs), CDK7/12/13, which promote transcription initiation and elongation by RNA polymerase II (RNAp2). Drugs targeting these proteins, such as THZ1, induce preferential depletion of key transcripts controlling cell survival and oncogenic pathways, and therefore have potent anticancer activity. However the efficacy of targeting transcriptional CDKs in CCOC, and the pathways involved is currently unknown. CCOC lines are sensitive to THZ1 in vitro. In high-grade serous tumor cell lines, transcriptional responses to THZ1 could be largely explained by downregulated expression of master transcription factors (MTFs) SOX17 and PAX8. However, downregulation of CCOC MTFs PAX8, HNF1B and ETS2 did not explain transcriptional responses to THZ1 in the CCOC models. Instead, exposing CCOC cell line RMG1 to THZ1 showed differential enrichment of pathways related to causes and consequences of modified intracellular zinc levels. Previous findings in OC connect intracellular zinc levels with oncogenic processes including metastasis and epithelial-to-mesenchymal transition. However, the role of zinc homeostasis in response to epigenetic drugs in OC is completely novel. Treating CCOC models with zinc chelator TPEN reduced intracellular free zinc by 63-70%. Co-treating CCOC cells with TPEN and THZ1 showed a significant 23% increase in sensitivity to THZ1. THZ1 resistant CCOC models were developed by exposing CCOC lines to increasing doses of THZ1 over a period of 300 days. Surprisingly, pharmacologic reduction of intracellular zinc increased growth of THZ1-resistant cells in the presence of THZ1, suggesting that fine-tuned control of free intracellular zinc dictates cellular responses to THZ1. In addition, THZ1-resistant lines had a 25% reduction in intracellular zinc compared to THZ1-sensitive parental lines. Our ongoing work is focussed on dissecting the impact of zinc on the activity of RNAp2 in the presence of THZ1, and will define the genes and regulatory elements involved in zinc-dependent responses to THZ1.

#2945 Target actin-microtubule network integrity to enhance taxane drug-target engagement and chemosensitivity in prostate cancer.

Felipe Carvolho[1], Tanvi Desai[2], Keira Ly[3], Joubin Jebelli[3], Ajay Bommareddy[1], Jianning Wei[3], **Michael L. Lu**[2]

[1]Biomedical Sciences, Florida Atlantic University, Boca Raton, FL,[2]Florida Atlantic University, Boca Raton, FL,[3]BioMedical Sciences, Florida Atlantic University, Boca Raton, FL

Taxanes exert anticancer activity by binding beta-tubulin on the luminal surface of microtubules, stabilizing protofilaments, suppressing GTP hydrolysis, and thereby promoting drug-target engagement (DTE) and apoptotic cell death. Access of taxanes to luminal binding sites depends on protofilament organization and microtubule lattice integrity, including entry via plus-end openings, small lattice pores, and stress-induced lattice defects. Because microtubules are tightly coupled to the actin cytoskeleton through crosslinking and mechanical support, we hypothesized that kinases controlling actin-microtubule architecture modulate taxane DTE and sensitivity. We investigated the PAK6-LIMK1 signaling axis in human prostate cancer PC3 and DU145 cells using CRISPR/Cas9 PAK6 knockout and small-molecule inhibitors of PAK6 or LIMK1. Taxane chemosensitivity was quantified by cell viability assays, and cytoskeletal organization and DTE were assessed by immunofluorescence microscopy of F-actin, alpha-tubulin, and the +TIP protein CLIP170. Consistent with prior shRNA data, genetic ablation of PAK6 markedly increased taxane sensitivity in both cell lines. PAK6 loss or pharmacologic inhibition produced concordant, distinctive remodeling of the actin-microtubule network, characterized by loss of dorsal, ventral, and transverse stress fibers and the emergence of crooked, banded microtubule cables, indicating compromised cytoskeletal integrity. These structural changes were accompanied by enhanced taxane-induced microtubule bundling and a robust increase in CLIP170 comet number and size, identifying a novel cytoskeletal signature associated with heightened taxane responsiveness. Similar phenotypes and chemosensitization were observed following LIMK1 inhibition, supporting a shared PAK6-LIMK1 pathway that dually regulates actin and microtubule dynamics. Together, these data suggest that disruption of PAK6-LIMK1 signaling weakens cytoskeletal resilience, facilitates taxane access to intraluminal binding sites, and thereby amplifies DTE and cell killing in prostate cancer cells, nominating this axis as a tractable target to overcome taxane resistance in advanced disease.

#2946 RQ43: A quinoline derivative that inhibits pancreatic cancer cell EMT and migration.

Sreyoshi Das, Qi Chen

Pharmacology, Toxicology and Therapeutics, The University of Kansas Medical Center, Kansas City, KS

Background: Pancreatic ductal adenocarcinoma (PDAC) is one of the deadliest cancers due to early metastasis and therapeutic resistance. The epithelial-to-mesenchymal transition (EMT) drives PDAC invasiveness and poor prognosis. RQ-43, a novel quinoline derivative, has shown antiproliferative activity in other cancer models previously with unclear mechanisms. This study investigated its cytotoxic, anti-migratory/invasive effects, and mechanisms of action in PDAC.
Methods: Human (PANC1) and murine (PAN02) PDAC cell lines were treated with RQ-43 (0.625-20 µM) for 48 h, and cell viability measured by MTT assay. Migration and invasion were assessed using wound-healing and Boyden chamber assays at sub-cytotoxic drug concentrations. EMT-related genes and transcription factors were assessed by qPCR. A syngeneic orthotopic PDAC mouse model was used to assess the in vivo effects of RQ-43 in C57/BL/6 mice.
Results: RQ-43 selectively decreased PDAC cell viability in a dose-dependent manner with IC_{50} values of 3.61 µM (PANC1) and 8.24 µM (PAN02). At concentrations of 2.5 µM for PANC1 and 5-20 µM for PAN02, RQ-43 significantly inhibited migration, reducing wound closure by 27.5% in PANC1 and 78% in PAN02 ($p < 0.05$ compared to controls). Invasion through Matrigel-coated Boyden chamber was also significantly suppressed in both cell lines ($p < 0.01$). EMT-related transcription factors Snail and B-catenin were downregulated ($p < 0.05$). In the orthotopic model, RQ-43 treatment (80 mg/kg, daily IP) significantly reduced tumour weight by 62.95% compared with controls. Metastasis rate was 80% in the control group and 25% in the treated group.
Conclusions: RQ-43 demonstrates cytotoxic, anti-migratory/invasive effects in vitro and effectively reduces tumour growth and metastasis in vivo. EMT-related transcription factors were downregulated. Further efficacy and mechanistic evaluation are warranted.

#2947 Inhibition of NRF2 driven antioxidant defence and EMT underlies brusatol induced cytotoxicity in cervical cancer cells.

Gunjan Dagar[1], Mohd Umar Rehmani[1], Teena Haritwal[1], Ajaz A. Bhat[2], Mayank Singh[3]

[1]Medical Oncology, All India Institute of Medical Sciences (AIIMS), New Delhi, India,[2]Translational Medicine, Sidra Medicine, Doha, Qatar,[3]All India Institute of Medical Sciences (AIIMS) New Delhi, New Delhi, India

Cervical cancer remains a major global health burden, and its therapeutic resistance is strongly influenced by redox adaptation, epithelial-mesenchymal transition (EMT), and metabolic reprogramming. Brusatol, a natural quassinoid compound, is known for its ability to suppress NRF2-driven antioxidant defense mechanisms. However, its mechanistic impact on cervical cancer has not been fully characterized.In this study, we first employed quantitative proteomic profiling to obtain an unbiased overview of Brusatol-induced molecular alterations. Proteomics analysis revealed extensive downregulation of proteins associated with antioxidant defense, glycolysis, cytoskeletal organization, and EMT regulation. Conversely, proteins linked to oxidative stress responses, mitochondrial dysfunction, and apoptotic signalling were significantly upregulated. Pathway enrichment analysis confirmed inhibition of glycolytic and redox-regulatory pathways, suppression of cell motility networks, and activation of oxidative stress driven cytotoxic processes.These global proteomic signatures were further substantiated through western blot validation, which demonstrated reduced expression of key components involved in antioxidant defense and EMT regulation following Brusatol treatment. Western blot analysis also showed suppression of glycolytic markers, supporting the proteomics-predicted metabolic disruption.Functionally, Brusatol significantly reduced proliferation, induced apoptosis, suppressed migration, and reversed EMT characteristics in cervical cancer cell lines. Treated cells exhibited decreased mesenchymal marker expression, restoration of epithelial traits, reduced glucose uptake, and impaired glycolytic activity. Importantly, a non-tumorigenic epithelial cell line showed substantially lower sensitivity, indicating selective cytotoxicity toward cancer cells.

Together, these findings demonstrate that Brusatol exerts potent anti-tumor effects in cervical cancer by initiating widespread proteomic reprogramming, suppressing NRF2-linked antioxidant pathways, reversing EMT, and disrupting glycolytic metabolism. The integration of proteomic profiling with biochemical validation and functional assays provides strong mechanistic evidence supporting brusatol as a promising therapeutic candidate for overcoming treatment resistance in cervical cancer.

#2948 A spatial-trapping mechanism of RAF by RAF/MEK glue enables full-dose combination with a pan-RAF inhibitor and drives potent, RAS-mutant tumor-selective MAPK and growth inhibition.

Bijaya Gaire[1], Ana Orive-Ramos[1], Christos Adamopoulos[1], Beau Baars[1], Mathieu Desaunay[1], Evangelia Matenoglou[2], Silvia Coma[3], Nayeli Gutierrez-Trejo[1], Kevin Mohammed[1], Stuart A. Aaronson[1], Jian Jin[1], Tiphaine Martin[1], Ernesto Guccione[1], Evripidis Gavathiotis[4], Jonathan A. Pachter[3], Poulikos I. Poulikakos[1]

[1]The Tisch Cancer Institute, Icahn School of Medicine at Mount Sinai, New York, NY,[2]Albert Einstein College of Medicine, New York, NY,[3]Verastem Oncology, Needham, MA,[4]Albert Einstein College of Medicine, Bronx, NY

The therapeutic benefits of MAPK pathway inhibitors depend on achieving more potent pathway inhibition in tumors over normal tissues, maintaining a broad therapeutic index. In BRAF-mutant cancers, selective BRAF inhibitors (BRAFi) achieve this balance, and their combination with MEK inhibitors (MEKi) at full doses resulted in significant clinical benefit. In contrast, next-generation Type 2 dimeric RAF, also known as pan-RAF inhibitors (pan-RAFi), which target wild-type BRAF and CRAF and demonstrate single-agent activity in RAS-mutant (RAS-MUT) tumors, have failed to achieve comparable therapeutic impact in combination with MEKi, owing to toxicity-driven dose reductions that constrain clinical efficacy. In preclinical and clinical studies, these combinations have reached a therapeutic ceiling, yielding predominantly stable disease and only rare tumor regressions. We show that dose-limiting toxicity in pan-RAFi + MEKi combinations stems from relief of negative feedback by MEK inhibition, which amplifies RAF activation and pan-RAFi engagement in normal tissues, oversuppressing MAPK signaling and limiting the therapeutic index. RAF/MEK glues constitute a distinct category of MEK inhibitors that stabilize RAF-MEK complexes and functionally suppress RAF. Although structural studies have captured these glues bound to both active and inactive RAF conformations, we show that their inhibitory activity stems from a spatial-trapping mechanism: we found that MEK is constitutively cytosolic, RAF/MEK glues sequester RAF in the cytosol, blocking its membrane recruitment and dimerization, steps essential for activation. In line with this mechanism, the RAF/MEK glue avutometinib, when combined with a pan-RAFi, was well tolerated at full dose and, critically, drove tumor regressions across multiple RAS-MUT models, achieving a 90% ORR compared with 0% using a conventional pan-RAFi + MEKi regimen in an insensitive RAS-MUT model. Tumor regressions corresponded with deeper MAPK pathway suppression by both pharmacodynamic and transcriptional metrics, without increased toxicity. Together, these findings reveal an unrecognized mechanism of RAF inactivation by RAF/MEK glues and show that substituting the MEKi with a RAF/MEK glue can overcome the therapeutic ceiling of current MAPK-targeting regimens, shifting outcomes from mostly stable disease to frequent tumor regressions. More broadly, this work establishes drug-induced proximity as a means to increase tumor selectivity by reprogramming the spatial and biochemical state of wild-type signaling effectors, thereby widening the therapeutic window for oncogenic pathway inhibition and providing a new paradigm for precision oncology.

#2949 Palazestrant, a CERAN, in combination with OP-3136, a KAT6 inhibitor, synergistically downregulates cell proliferation and metastasis related gene signatures.

Susanna A. Barratt, Gopinath S. Palanisamy, Azita Ghodssi, Chelsea Hope, Guadelupe Pena, Srinivasan Jayaraman, Raymond A. Ng, David C. Myles

Olema Oncology, San Francisco, CA

Histone lysine acetyltransferases KAT6A and KAT6B are epigenetic enzymes involved in regulating transcription of oncogenic genes, including ERα, MYC, and cell cycle drivers. We previously reported that OP-3136, a KAT6 inhibitor, shows enhanced efficacy in vitro and in vivo in ER+/HER2– breast cancer models when combined with the complete estrogen receptor antagonist (CERAN) palazestrant (OP-1250) (Palanisamy et al., 2024). Here, we further investigate the mechanisms of this synergy by characterizing treatment-dependent transcriptional changes.We used T47D, an ER+/HER2– ESR1–wild-type breast cancer cell line overexpressing KAT6A, as an in vivo xenograft model. We evaluated the impact of OP-3136, palazestrant, and the combination in comparison to monotherapy and OP-3136 combination with the approved antiestrogen, fulvestrant. Xenografts were treated for 28 days, and bulk RNA sequencing was performed on isolated tumors.Palazestrant and OP-3136 combination resulted in greater suppression of genes associated with cell proliferation and cell-cycle progression (Hallmark E2F and G2M gene sets) than monotherapy treatment. While the fulvestrant–OP-3136 combination also reduced these gene sets, the palazestrant combination caused stronger downregulation, consistent with observed efficacy responses. The palazestrant-OP-3136 combination also showed the most potent suppression of key transcriptional regulators of ER+ breast cancer, including PGR, E2F1, MYC, GATA3, and FOXA1.Palazestrant plus OP-3136 further suppressed expression of MTORC1 and TNF-α via NFκB signaling pathways. These pathways were also downregulated by the fulvestrant–OP-3136 combination but to a lesser extent. The observed effects exceeded expected additive responses, indicating that CERAN plus KAT6 inhibition synergistically regulate these pathways at the transcriptional level. Because inhibition of the PI3K/mTOR/AKT axis mitigates endocrine resistance and TNF-α/NFκB signaling promotes metastasis and invasion, these findings suggest that combining a KAT6 inhibitor with palazestrant may represent a promising strategy to overcome resistance in metastatic ER+ breast cancer.Collectively, these data demonstrate that palazestrant and OP-3136 synergize to suppress genes associated with proliferation, survival, and metastasis. The transcriptional changes align with enhanced anti-tumor efficacy and establish a mechanistic rationale for this combination over fulvestrant in ER+ breast cancer. The palazestrant–OP-3136 combination is currently being evaluated in a phase I clinical trial in ER+/HER2– metastatic breast cancer patients.

#2950 Palazestrant directly recruits the corepressor protein NCoR1 *in vitro* leading to complete antagonism of estrogen receptor alpha.

Susanna A. Barratt, Guadelupe Pena, Chelsea Hope, Gopinath S. Palanisamy, Raymond A. Ng, David C. Myles

Olema Oncology, San Francisco, CA

The estrogen receptor (ER) is a well-established driver of breast cancer with approximately 80% of patients presenting as ER-positive (ER+). The current treatment paradigm relies on endocrine therapies; however, there are pharmacokinetic, efficacy and tolerability issues with approved agents indicating a clear unmet need for better treatments for patients. Palazestrant, a complete estrogen receptor antagonist (CERAN), has demonstrated favorable tolerability and efficacy in a heavily pre-treated patient population and is currently being evaluated in two Phase III clinical trials (OPERA-01 and OPERA-02) for the treatment of ER+/HER2-metastatic breast cancer. We previously described preclinical characterization of this molecule (Parisan et al., 2023; Ng et al., 2025) where we demonstrated that palazestrant is a novel, orally bioavailable complete ER antagonist and selective ER degrader that completely blocks estrogen-induced transcriptional activity and demonstrates impressive in vitro and in vivo antitumor activity. As a CERAN, palazestrant can inactivate both the AF-2 and AF-1 domains of ER-alpha resulting in complete antagonism that does not demonstrate any agonist activity. Here we show for the first time that palazestrant and other CERANs completely and potently recruit the corepressor protein NCoR1 to ERα as part of their mechanism of action. Contrarily, selective estrogen receptor modulators (SERMs) such as 4-OH-tamoxifen and vepdegestrant either do not induce recruitment or are incomplete recruiters, in line with previous data indicating that SERMs are not complete antagonists. At the transcriptional level, palazestrant more potently suppresses the transcription of key E2 and cell cycle related genes such as PGR and GREB1 in ER+ breast cancer models as compared to 4-OH-tamoxifen, with strong downregulation observed at concentrations of 5 nM and lower. CERAN molecules palazestrant and fulvestrant consistently demonstrate greater suppression of GREB1 and PGR as compared to SERMs in both ESR1 wildtype and mutant ER+ breast cancer models.Functionally, treatment with palazestrant leads to antiproliferative activity in ER+ breast cancer models comparable or superior to investigational and approved anti-estrogens. All molecules that demonstrate complete antagonism of ER demonstrate a greater total inhibition of proliferation (Emax %). Importantly, in the CAMA-1 ER+/HER2 model, palazestrant demonstrates a complete suppression of cell proliferation where tamoxifen does not. When cells are not stimulated with E2, SERMs like tamoxifen demonstrate induction of cell proliferation where CERANs do not. Palazestrant is a promising therapeutic strategy for treating ER+/HER2- breast cancer patients and is being evaluated clinically, both as monotherapy and combination.

#2951 Adaptive and acquired mechanisms underlying RAS-mutant tumor response to mutant and state selective RAS inhibitors.

Ziyue Kou, Bijaya Gaire, Beau Baars, Mathieu Desaunay, Poulikos I. Poulikakos

Icahn School of Medicine at Mount Sinai, New York, NY

RAS mutations drive over 20% of human cancers and often correlate with poor clinical outcomes. Mutant RAS (RAS-MUT) maintains elevated GTP binding, biasing the protein toward its active (ON) state and driving hyperactivated signaling through effector pathways (MAPK and PI3K, among others), leading to uncontrolled cell growth and resistance to apoptosis. Thus, targeting RAS with small-molecule inhibitors presents a promising therapeutic strategy for RAS-MUT cancers. Recent advances in drug discovery have enabled the development of the pan-RAS(ON) inhibitor RMC6236, which uses a tricomplex strategy, as well as several KRAS-MUT-specific inhibitors (such as Adagrasib, Sotorasib, and MRTX1133) that target the OFF state. However, the antitumor efficacy of these direct RAS inhibitors varies across cancer types and is limited by a “therapeutic ceiling,” marked by stable disease and transient responses for most patients. Thus, a deeper understanding of mechanisms underlying variability in response and development of acquired resistance in RAS-MUT cancers is urgently needed. By analyzing signaling and cell growth inhibition in response to distinct direct RAS inhibitors, we observed similar sensitivity patterns across cell line models, suggesting that the antitumor activity of these drugs is largely confined to a shared subset of RAS-MUT cancers. Notably, we found that a subset of insensitive cells could regain sensitivity to direct RAS inhibitors through serum starvation or cotreatment with an SHP2 inhibitor, indicating hyperactive upstream Receptor Tyrosine Kinase (RTK) signaling contributing to RAS inhibitor resistance. Moreover, we found that resistant cell lines show a greater contribution of wild-type RAS (RAS-WT) to overall RAS activity than sensitive lines, suggesting that resistance may arise from RAS-WT-dependent compensation upon RAS-MUT inhibition. To model acquired resistance, we exposed KRAS-MUT cell line models to high concentrations of various RAS inhibitors individually and derived resistant models that displayed markedly reduced sensitivity compared with parental lines. No evidence of acquired secondary KRAS mutations was observed. However, we detected upregulation of the RTK-RAS-MAPK pathway along with elevated KRAS-MUT protein expression in resistant models. This increased RAS-MUT expression reduced inhibitor effectiveness and impaired suppression of RAS-GTP cycling. We also identified multiple cross-resistance patterns across different direct RAS inhibitors, highlighting the need for better mechanistic understanding to optimize RAS-inhibitor treatments for maximal therapeutic benefit. Together, our results provide mechanistic insight into resistance to direct RAS inhibitors in RAS-MUT cancers and emphasize the urgent need for improved strategies to treat patients who do not respond to current RAS-targeted therapies.

: Drug Resistance 1: Antibodies and ADCs
Poster Session

#2955 Systematic mechanistic profiling of ADC-resistant cancer cell lines.

Tingting Yuan, Yanqiu Bai, Lehua Cheng, **Yanan Xu**, Wenzhang Chen, Yan Gao, Zhuo Wen, Qiangqiang Fan, Zhengang Peng

WuXi AppTec Co., Ltd., Shanghai, China

In recent years, antibody–drug conjugate (ADC) discovery has become one of the hottest areas for targeted therapy development of diverse cancer types. Regardless of its superiority to other therapeutic modalities, resistance remains one of the major and most common challenges, thereby severely hindering its clinical efficacy. ADC-resistant cell lines have been well demonstrated to be valuable and reliable models to help interrogate ADC-relevant resistance, hence facilitating development of therapies overcoming resistance. To this end, we have successfully developed over a dozen of ADC-resistant cancer cell lines by chronically challenging parental cancer cells with escalating dosages of ADCs for several months. We validated such a gain of resistance by a full-dosage drug sensitivity profiling at the endpoint, demonstrating >10 fold of drug IC50 increase in most of the established resistant cell models compared to their respective parental counterparts. To further unravel the underlying drug resistance mechanisms, we applied RNA-Seq and global proteomics profiling on several resistant models paired with their parental controls, including HCC1954 and NCI-N87 Enhertu-resistant, HCC1806 and Colo-205 Trodelvy-resistant cells. Promisingly, we observed that HER2 expression was dramatically and concordantly (~30-fold) reduced at both mRNA and protein levels according to RNA-Seq and global proteomics profiling, which was further validated by flowcytometry and Western blot analysis. Subsequent cross-drug sensitivity profiling revealed that HCC1954 Enhertu-resistant cells were resistant to the other two HER2-targeting ADCs, T-DM1 and RC48 rather than their respective payloads, which further consolidated that reduction of HER2 expression other than any adaptive resistance to payload plays a pivotal role in the HCC1954 Enhertu-resistant model. Interestingly, we didn’t observe any robust reduction of antibody target expression in the other three ADC resistant models, implying diverse resistance mechanisms across different ADCs and cancer cell lines. We will continue to do datamining and validation on these models in the near future, aiming to shed light on more ADC resistance mechanisms.

#2956 Determinants of sacituzumab govitecan therapeutic response in breast cancer models.

Carson J. Walker[1], Nina Dashti-Gibson[1], Julia E. Altman[2], Rachel K. Myrick[2], Emily K. Zboril[1], Oniya M. Smith[2], David C. Boyd[2], Bin Hu[1], Mikhail G. Dozmorov[3], Joshua C. Harrell[4]

[1]VCU Massey Comprehensive Cancer Center, Richmond, VA,[2]Virginia Commonwealth University, Richmond, VA,[3]Biostatistics, Virginia Commonwealth University, Richmond, VA,[4]Pathology, Virginia Commonwealth University, Richmond, VA

This study identifies markers of Sacituzumab Govitecan (SG) response in triple-negative breast cancer (TNBC) models and introduces new SG acquired resistance patient derived xenografts (PDXs) that can serve as examples of patient-acquired mutations or gene regulation changes that confer resistance to this targeted therapy. SG is an antibody drug conjugate (ADC) that has been approved for treating TNBC and estrogen receptor positive breast cancers that have progressed on initial treatments. SG binds to TROP2 and delivers SN-38 as its payload; resistance to SG could be due to inefficient antibody internalization or lack of payload efficacy. We hypothesize that individual intrinsic and acquired SG resistance mechanisms will uncover features that can be targeted to extend the duration of response to SG. Using a linear mixed effects model, we mapped PDX responses to SG *in vivo* to their RNA expression in order to identify differences in gene expression that stratify SG response; developing an initial SG response predictor in this process. By administering suboptimal and continuous SG treatments to formerly SG-sensitive PDXs, we created acquired SG resistant (SGR) models. We then compared the RNA expression between these syngeneic pairs of PDXs to identify acquired resistance mechanisms and common pathways of resistance in patients. Performing antibody internalization assays on the paired sets allowed us to investigate if antibody or encapsulation mediated resistance was responsible for the continued tumor growth. Short-term SN38 testing was used to define the extent of payload resistance in paired models. Through these efforts, we identified 9 SG-sensitive and 3 intrinsically resistant TNBC PDXs whose differential expression led us to focus on 13 genes that predict SG response. Three of the most sensitive models were used to create acquired resistance models and analysis is underway to compare these to the intrinsic resistance models utilizing bulk and single-cell RNA-sequencing, proteomics, and cytotoxic compound screens. RNA sequencing of PDXs with innate SG resistance defined differences in gene expression related to extracellular matrix, angiogenesis, and metal ion trafficking. Conversely, acquired resistance models show diversity in resistance mechanisms including notably heightened extracellular matrix protein synthesis. Ongoing studies aim to define these mechanisms so that candidate therapeutics can be prioritized to overcome SG resistance. In conclusion, a preliminary SG resistance signature has been developed, which we will refine for clinical selection of patients to be treated with SG. Additionally, several biological processes are activated during acquired SG resistance and may be targetable.

#2957 Retinoic acid pathway regulates NECTIN4 expression and enhances NECTIN4-directed chimeric antigen receptor (CAR) T and antibody-drug conjugate therapies in bladder cancer.

Tamilla Nechiporuk[1], Sha Zhu[1], Yuxin Yang[1], Shivani Saxena[2], Jun Zhu[3], Rosalie Nolley[3], Imene Boukhalfa Ep Hanafi[3], Rhea Master[1], Elizabeth Yip[2], Kevin Chang[1], William Dougherty[2], Terence Friedlander[3], Vadim S. Koshkin[1], David Quigley[4], Jonathan Chou[2], Carissa E. Chu[1]

[1]Urology, University of California at San Francisco, San Francisco, CA,[2]Division of Hematology/Oncology, Department of Medicine, University of California at San Francisco, San Francisco, CA,[3]Radiation Oncology, University of California at San Francisco, San Francisco, CA,[4]Urology, Epidemiology and Biostatistics, University of California at San Francisco, San Francisco, CA

Urothelial carcinoma (UC) is the sixth most common malignancy in the United States, with 83,000 new cases and 17,000 deaths annually. Prognosis for metastatic UC remains poor, underscoring the need for new targeted therapies. NECTIN4, a cell adhesion molecule highly expressed in UC, is a target of an FDA-approved antibody-drug conjugate (ADC) enfortumab vedotin (EV) with 40% response rates. NECTIN4 genomic amplifications and expression levels correlate with response to NECTIN4-targeted therapies like EV, but regulators of NECTIN4 remain poorly defined. To identify regulators of NECTIN4 surface expression, we performed a CRISPR interference (CRISPRi) FACS-based screen in bladder cancer cell lines, followed by validation across multiple UC models and use of pharmacological modulators of genetic hits to assess effects on NECTIN4 expression and sensitivity to NECTIN4-directed ADCs and CAR T cells. Our screen revealed both positive and negative regulators of NECTIN4 expression, especially factors linked to luminal differentiation and epithelial-to-mesenchymal transition (EMT), which exert opposing effects. We found that activating retinoic acid (RA) signaling, alone or with PPARγ modulation, transcriptionally induces NECTIN4 as part of the luminal program. Pharmacologic RA activation increased NECTIN4 surface levels and sensitized bladder cancer cells to both EV and NECTIN4-targeted CAR T cells. This RA-driven regulation reinforces luminal identity, acting alongside PPARγ and counteracting EMT-driven therapeutic escape. Modulating RA signaling offers a promising strategy to overcome both, primary resistance due to low NECTIN4 levels and acquired resistance from NECTIN4 downregulation.

#2958 P-glycoprotein (ABCB1) overexpression confers resistance to the antibody-drug conjugate Enfortumab vedotin in EV-resistant organoid and PDX models.

Emilie Decaup[1], Claire Beraud[1], Isabelle Bernard-Pierrot[2], Guerric Gilbert[2], Clementine Krucker[2], Xavier Game[3], Philippe Lluel[1], **Nadege Bidan**[1]

[1]Urosphere, Toulouse, France,[2]Institut Curie, Paris, France,[3]CHU Toulouse, Paris, France

Background: Resistance to Enfortumab vedotin (EV) remains a major clinical challenge in bladder cancer (BC). The resistance can emerge through diverse mechanisms such as alterations in Nectin-4 expression, defects in ADC internalization and trafficking, or changes in downstream processing and payload response. We previously developed EV-resistant BC PDX and organoid models (poster 50, AACR 2025), providing validated preclinical tools to investigate the molecular basis of EV resistance. These models were designed both to elucidate resistance mechanisms and to enable direct comparison with patterns of resistance observed in the clinic.
Methods: F659 PDX model was selected based on its high Nectin-4 mRNA expression and its strong response to EV treatment. Acquired resistance was generated by repeated EV administrations until tumors ceased to regress. From the resulting EV-resistant PDX (F659rP2), a matched organoid model was subsequently established. Both resistant and parental models were profiled using whole-exome sequencing, RNA-sequencing, and immunohistochemistry (IHC), and functionally characterized to assess EV activity and identify resistance mechanisms. Validation of these mechanisms was performed using pharmacological inhibition assays.
Results: Resistance to EV was confirmed in both organoid and PDX models, as evidenced by a marked loss of sensitivity compared with their parental counterparts. Then, Nectin-4 expression was evaluated in resistant and parental models to investigate the underlying mechanisms, Flow cytometry and IHC analyses revealed a decreased cell surface expression of Nectin-4 in resistant models. Transcriptomic profiling identified significant changes in the expression of drug efflux transporters, FGFR3 and PPARγ pathways. Notably, the ABCB1 gene was markedly upregulated in resistant models, and corresponding P-glycoprotein (P-gp) overexpression was confirmed by flow cytometry and IHC.Given that ABC transporters promote drug efflux, reducing intracellular drug accumulation and therapeutic efficacy, we assessed the impact of P-gp inhibition. Our results demonstrate that co-treatment with the P-gp inhibitor tariquidar (XR9576) partially restored EV sensitivity in both resistant organoid and PDX models.
Conclusion: We successfully generated paired in vitro and in vivo EV resistant models. Our findings highlight the role of ABC transporter upregulation in EV resistance associated with a reduction of Nectin4 expression consistent with clinical observations. Other pathways seem to be involved and will need further investigations. Importantly, these EV-resistant preclinical models provide powerful tools for evaluating innovative therapeutic strategies against resistant tumors.

#2959 Improving the efficacy of B7-H3 targeting antibody-drug conjugates in TP53-deficient prostate cancer.

Javier Leo, Di Zhao

UT MD Anderson Cancer Center, Houston, TX

Prostate cancer is the most diagnosed malignancy and the second leading cause of cancer-related death among men in the United States. Treatment options for advanced prostate cancers remain limited, and *TP53* alterations occur in approximately 60% of prostate cancer cases and are associated with higher metastasis rates and worse overall outcomes. Effective therapies are urgently needed for advanced prostate cancers with TP53 defects. Immune checkpoint B7H3 is overexpressed in prostate cancer, and its overexpression correlates with increased risks of clinical recurrence and disease spread. DS-7300a is one of the most advanced B7H3-targeting antibody-drug conjugates (ADC) and has demonstrated clinical activity across multiple refractory malignancies. DS-7300a comprises a humanized anti-B7H3 monoclonal antibody warhead with topoisomerase I inhibitor, Dxd. In this study, we evaluated the efficacy of DS-7300a in prostate cancer that contains TP53 defects. Our results showed that the anti-tumor efficacy of DS-7300a is highly dependent on functional p53 in prostate cancer cells. Mechanistically, we found that DS-7300a and its payload Dxd induce DNA damage and activate the ATM/ATR/CHK signaling cascade, leading to p53 stabilization and transcriptional activation of pro-apoptotic and senescence-associated genes. In contrast, *TP53*-deficient cells fail to sense DNA damage adequately and exhibit a high proliferation rate and low levels of apoptosis and senescence, leading to resistance to DS-7300a. Ferroptosis is an iron-dependent form of regulated cell death triggered by lipid peroxidation. Interestingly, we found that DS-7300a treatment induces lipid peroxidation as well as the expression of glutathione peroxidase 4 (GPX4), an antioxidant that mitigates lipid peroxidation, in TP53-deficient cancer cells. Taking advantage of our isogeneic xenograft models and a newly developed humanized B7H3 mouse model, we demonstrate that inducing ferroptosis by pharmacological inhibition of GPX4 enhanced the anti-tumor effects of DS-7300a in *TP53*-deficient prostate cancer. Collectively, our studies indicate that p53 status dictates anti-tumor responses to DS-7300a in prostate cancer, and ferroptosis induction represents a promising therapeutic approach to overcome resistance to Dxd-based ADCs in malignancies harboring TP53 defects. Our studies will accelerate the development of effective therapies for prostate cancer patients with TP53 defects and provide a strong rationale for using TP53 status as a molecular biomarker to guide patient selection for clinical application of DS-7300a. This novel biomarker-driven combination strategy will also provide insights into the clinical trial design of Dxd-based ADCs and ferroptosis inducers in advanced prostate cancer and other malignancies.

#2960 Overcoming acquired and intrinsic resistance with an integrated ADC platform.

Jie Wen[1], Hao Cheng[2], Cheng Zhang[2], Bingrui Han[2]

[1]Oncology Pharmacology, PharmaLegacy Laboratories, Shanghai, China,[2]PharmaLegacy Laboratories, Shanghai, China

Antibody-drug conjugates (ADCs) emerged as a transformative class of targeted therapeutics, reforming the treatment landscape for a growing number of malignancies by integrating benefits from the specificity of antibodies and the potent cytotoxicity of payloads. Despite the remarkable clinical successes, development of acquired and intrinsic resistance poses a fundamental challenge limiting the long-term potential in a considerable proportion of patients. Various mechanisms have been reported to cause ADC resistance, including alterations in target antigen, impaired ADC internalization, efflux of the cytotoxic payload, dysregulation of lysosomal function and insensitivity to payload *etc.* Elucidating this complex biology is crucial for developing novel ADCs, identifying biomarkers for patient stratification and exploring strategies to overcome resistance. This is not only a scientific need but also an important clinical imperative.
The current study describes an integrated platform recapitulating different clinical scenarios of ADC resistance. Models with acquired resistance were developed by either long-term *in vivo* induction on responsive CDX models or by establishing PDX from post-treatment relapsed patient tumors. Models with intrinsic resistance were first identified by screening ADC responses across a panel of target-positive models, followed by subsequent mechanism studies, such as PD examination, sequencing and *ex vivo* analysis. An Her2- and Trop2-positive gastric PDX shown clear resistance (TGI < 10%) to trastuzumab deruxtecan and sacituzumab govitecan, two clinically used Her2 and Trop2 ADCs respectively, limited response (TGI 10-30%) to Herceptin and no response to Dxd treatment. This result suggests its intrinsic resistance is largely due to the unresponsiveness to payload end. Further study on double-humanized PDX (PDX established on humanized mice) shown significant tumor growth inhibition (TGI > 65%) when treated with anti-PD1 antibody, implicating the clinical benefit of combining immune checkpoint inhibitors with ADCs.
In addition to *in vivo* models featuring ADC resistance, multiple *in vitro* platforms were established to enable rapid assessment of ADC in terms of sensitivity and toxicity. A tissue culture assay using clinical samples allows ADC evaluation and comparative screening of combination strategies over a panel of patient tumors. In addition, the well-known ocular toxicity associated with multiple clinically used ADCs can be recapitulated by a cell-based assay using human corneal epithelial cells. On this platform, belantamab mafodotin, trodelvy and T-DM1 demonstrated consistent high, medium and low cytotoxicity respectively.
The integration of above-mentioned platforms facilitates a deep understanding of resistance mechanisms and promotes the development of ADCs that are better aligned with clinical needs, with the ultimate goal of overcoming resistance.

#2961 Developing ADC-resistant tumor models for efficacy evaluation of next-generation anticancer therapies.

Jian Feng, Fuyin Zhao, Xinlong Dong, Aaron Li Hua, Chenpan Nie, Dorrith Verstegen, Caitlyn Hulsebosch, Wubin Qian, Sheng Guo, Jessie (Jingjing) Wang, Lenno Krenning, Marrit Putker, Ludovic Bourre, Peng Wang, Jun Zhou

Crown Bioscience, Inc., San Diego, CA, United States, San Diego, CA

Introduction: Antibody-drug conjugates (ADCs) pair monoclonal antibodies with cytotoxic payloads. Trastuzumab deruxtecan (DS8201) targets HER2, and datopotamab deruxtecan (DS1062) targets TROP2. Both use a topoisomerase I inhibitor (Dxd) via a cleavable linker. After target-mediated internalization, proteases release the payload, causing DNA damage, apoptosis, and bystander killing. However, resistance may stem from antigen loss, altered internalization, impaired payload release, efflux pumps, or apoptosis regulation. We developed ADC-resistant cell and organoid models via chronic dosing, lentivirus transduction, and Cas9 mediated knock out.

Methods: First, efflux pump proteins (ABCB1, ABCG2) were introduced into HER2+ HCC1954 cells via lentiviral transduction (HCC1954-ABCB1, HCC1954-ABCG2); overexpression was confirmed by Western blot. Cytotoxicity to Dxd/ADC was evaluated by CellTiterGlo (CTG)--assay. Second, chronic *in vitro* exposure generated HCC1954-DS8201R and HCC1954-DxdR. HER2 expression was assessed by flow cytometry (FACS), and ADC binding/internalization by IncuCyte imaging. RNA-seq investigates the resistance mechanisms. Finally, TROP2 was knocked out using CRISPR in two DS1062 responsive organoids. Loss of TROP2 was confirmed using immunofluorescence, and ADC sensitivity was tested using CTG assay. Xenograft models of ADC-resistant cells are in development for further *in vivo* studies.

Results: HCC1954-ABCB1 showed remarkable resistance to MMAE (IC_{50}: 85.8 nM vs 0.3 nM parental) but showed no change to Dxd. While, HCC1954-ABCG2 is resistant to Dxd (IC_{50}: >10 µM vs 0.509 µM parental), with minimal MMAE impact. The RC48 (Her2-targeting ADC with MMAE) and DS8201 are confirmed payload-based resistances. HCC1954-ABCB1 is resistant to RC48 (IC_{50}: >100 nM vs 0.288 nM parental), while HCC1954-ABCG2 is resistant to DS8201 (IC_{50}: >100 nM vs 5.2434 nM parental). These findings suggest that efflux pump proteins preferentially transport distinct cytotoxic payloads. Chronic exposure to Dxd generated HCC1954-DxdR cells reduced sensitivity to both Dxd (IC_{50}: >10 µM vs 0.2023 µM parental) and DS8201 (IC_{50}: >100 nM vs 2.1695 nM). Similarly, chronic exposure to DS8201 produced the HCC1954-DS8201R, showing significant resistance (IC_{50}: >70 nM vs 2.1695 nM). In HCC1954-DS8201R with reduced HER2, confirmed by FACS and RNA seq, showed a decrease in HER2 binding/internalization, whereas HCC1954-DxdR exhibited ABCG2 amplification. TROP2 KO efficiency was 30% (LU11786B) and 5% (BR9465B). Cytoxicity of TROP2 KO models resistant to DS1062. with loss of DS1062 uptake and absence of the DNA damage marker yH2AX. Xenograft models of ADC-resistant cells are able to grow *in vivo*.

Conclusion: We developed a panel of ADC-resistant tumor models to study mechanisms of acquired resistance. These models provide a valuable preclinical platform for advancing ADC therapy.

#2962 HER2 ADC resistance driven by IL-17 signaling and ROR1 upregulation: Overcoming DS-8201 resistance with BRY812 and BR111.

Qianqian Tao[1], Qinqin Zhuang[1], Qizhe Wu[1], Lei Nie[1], Gang Chen[2], Haibin Wang[1], Jingtao Lu[1]

[1]Bioray Pharmaceutical Co., Ltd.,, Hangzhou, China,[2]Bioray Pharmaceutical Corp., San Diego, CA

DS-8201 (Trastuzumab Deruxtecan), a milestone antibody-drug conjugate, has demonstrated reputable efficacy in various solid tumors, particularly in patients with HER2-low and HER2-ultralow expression. However, its widespread application has been accompanied by increasingly prominent drug resistance. To investigate the resistance mechanism towards DS-8201, we successfully established DS-8201-resistant cell lines in breast cancer and in lung cancer, and performed mechanistic investigations on HER2 expression change, DS-8201 internalization efficiency, cross-resistance to DXd as well as ABC transporters expression. Results revealed that these mechanism were observed in both resistant cell lines expect for DXd-resistance, which was only found in breast cancer. Furthermore, we selected lung cancer resistant cell line to perform RNA-seq analysis and found IL-17 signaling as major contributing pathway, with CXCL1 and LCN2 being the mostly affected genes. Literature research revealed possible mechanism includes tumor microenvironment remodeling, enhanced cell survival, and immune evasion.BRY812 (an anti-LIV1 ADC conjugated to MMAE) and BR111 (an anti-ROR1 ADC conjugated to eribulin) are novel ADCs that have shown potent antitumor activity in various solid tumors. Ours studies with both resistant cell lines and corresponding CDX models demonstrated that both BRY812 and BR111 can effectively overcome DS-8201 resistance. Further investigation revealed that treatment with HER2-targeting ADCs (DS-8201 and T-DM1) dose-dependently upregulated ROR1 expression, providing a potential mechanism for BR111's efficacy in this resistant setting. In conclusion, our research findings collectively revealed DS-8201 resistance mechanism and provided evidence that BRY812 and BR111 can overcome DS-8201 resistance.

#2963 Development and characterization of a novel *in vivo* JIMT-1 DS8201a resistant model and its efficacy evaluation.

Qikuan Chen, Longyun Zhang, Ya Xu, Jingjing Zhang, Li Li, Greg Liang, Mingqi Shao, Fan Feng, Yinfei Yin

Shanghai ChemPartner Co., Ltd., Shanghai, China

Trastuzumab deruxtecan, marketed as Enhertu (DS-8201a) is a next generation HER-2 targeted Antibody-Drug Conjugate (ADC), that releases a topoisomerase inhibitor payload. As the Deruxtecan is membrane permeable it exhibits a strong bystander effect as it can diffuse into neighboring cells, killing antigen negative cells. Despite clinical success and reinvigorating ADC interest, acquired and primary resistance driven by tumor heterogeneity and genomic alterations remain a major consideration. To investigate tumor resistance mechanisms, we have established in house a DS8201a resistant JIMT-1 cell line and the corresponding *in vivo* tumor model. We have also acquired a primary resistant gastric cancer PDX model (GAX227M), and we have derived an organoid model (PDXO) from this PDX. Based on *in vitro* and *in vivo* screening, we have demonstrated significant resistance to DS8201a in all models. Furthermore, we have comprehensive whole-exome sequencing (WES) and RNA sequencing (RNA-seq) for the JIMT-1 DS8201a-resistant model that is currently undergoing bioinformatic analysis. Our preclinical toolbox is designed to help decipher resistance mechanisms and guide rational strategies to overcome ADC resistance. These insights will inform the development of next-generation ADC's and improve outcomes in HER-2 positive heterogenous tumors.

#2964 Identification of synergistic dual payload combinations for antibody-drug conjugates to overcome resistance through resistance modeling.

Lili Chai, Yue Zhai, Yan Zhang, Ying Bi, Xue Yang, Zhengtai Li, **Tiejun Bing**

ICE Bioscience, Beijing, China

Background: Antibody-Drug Conjugates (ADCs) are potent cancer therapeutics, but resistance to ADCs or their single payloads remains a critical clinical barrier. Dual payload ADCs—co-delivering two distinct payloads via a single antibody—offer a promising solution by leveraging complementary mechanisms. Clinical progress and pipeline candidates validate this approach. However, a systematic framework to identify resistance-tailored synergistic payload combinations and decipher their mechanisms is underdeveloped.
Methods: We established 10+ drug-resistant cell lines against clinical ADCs/payloads via long-term selection. To elucidate resistance mechanisms and predict synergistic combinations, we performed RNA-seq and WES on resistant/parental pairs, followed by pathway enrichment and synthetic lethality prediction. We screened 100+ dual payload combinations (resistant/parental cell panel, viability assay) to identify hits. Mechanisms of hit combinations were investigated via bioinformatics analysis and validated by Western blotting/immunofluorescence (DDR markers and cell cycle markers).
Results: bioinformatics analysis identified key resistance mechanisms including elevated P-gp transporter and reduced antigen expression. We screened 100+ combinations (TOPO1 inhibitors paired with DDR inhibitors, CDK inhibitors, TYR kinase inhibitors, toxins) and identified three synergistic hits including TOPO1 inhibitor combined with DDR related targets and cell cycle targets. All hits showed significant synergistic effect (IC50 shifts >3 folds and CI<0.9) in resistant cells, while single payloads had minimal efficacy. Bioinformatics implicated enhanced DNA damage and cell cycle dysregulation as core mechanisms, validated by pathway assays.
Conclusions: Our study establishes a systematic framework (resistance modeling, bioinformatics, high-throughput screening) to identify synergistic dual payload combinations for ADCs. The three TOPO1-based hit combinations potently overcome resistance via validated DDR/cell cycle mechanisms. This work provides a rational basis for next-generation dual-payload ADC development and a generalizable strategy to accelerate resistance-overcoming regimen discovery across cancer therapies

#2965 Identification of TROP2 as an adaptive resistance mechanism in KRAS G12C inhibition and its therapeutic targeting.

Masahiro Kashima[1], Hidenori Kitai[1], Yukiko Yoshida[1], Yuriko Ishida[1], Yuma Sato[1], Daisuke Morinaga[1], Kosuke Tsuji[1], Shotaro Ito[1], Kanako C. Hatanaka[2], Takuma Kobayashi[3], Yoshiki Shinomiya[2], Teppei Konishi[3], Yutaka Hatanaka[2], Jun Sakakibara-Konishi[1], Satoshi Konno[1]

[1]Department of Respiratory Medicine, Faculty of Medicine, Hokkaido University, Sapporo, Japan,[2]Center for Development of Advanced Diagnostics, Hokkaido University Hospital, Sapporo, Japan,[3]Biomy Inc., Tokyo, Japan

Background: KRAS mutations occur in up to 30% of non-small cell lung cancer (NSCLC), predominantly at codons 12 and 13. KRAS G12C, the most frequent variant, accounts for approximately 40% of KRAS-mutated NSCLC. The KRAS G12C inhibitors sotorasib and adagrasib have been introduced into clinical practice for KRAS G12C-mutated NSCLC, but their clinical benefit remains limited. One important mechanism for this limited efficacy is adaptive resistance, linked to activation of membrane-associated signaling molecules such as receptor tyrosine kinases, which in turn reactivate KRAS downstream signaling and reduce drug durability. Identifying factors driving adaptive resistance is critical for developing effective combination strategies.
Objective: To identify molecular targets mediating adaptive resistance to KRAS G12C inhibitors in NSCLC and evaluate novel therapeutic approaches to overcome resistance.
Methods and Results: To elucidate the mechanism of adaptive resistance to KRAS G12C inhibitors, we performed RNA sequencing after short-term sotorasib exposure in H1373 cells and found TACSTD2 (TROP2) was a gene with early upregulation of its mRNA expression. To test its functional relevance, we silenced TROP2 by siRNA in H358, H2122, and H1373 cells and found that TROP2 knockdown increased sotorasib-induced apoptosis by flow cytometry and enhanced suppression of PI3K-AKT signaling. Consistent with the in vitro findings, sotorasib increased TROP2 expression in H1373 xenograft tumors. Furthermore, TROP2 suppression by shRNA enhanced the antitumor effect of sotorasib in vivo. In addition, in LU65 xenograft model, the combination of sotorasib with the anti-TROP2 antibody-drug conjugate datopotamab deruxtecan achieved more durable tumor shrinkage compared with sotorasib monotherapy. Finally, we utilized an artificial intelligence (AI) model to analyze TROP2 immunohistochemistry scores in clinical specimens from patients with non-small cell lung cancer (NSCLC) and investigated the association with prognosis.
Conclusion: TROP2-targeted therapy represents a promising strategy to overcome adaptive resistance to KRAS G12C inhibitors in NSCLC and warrants further clinical investigation.

#2966 Zongertinib-tolerant cells enhanced sensitivity to Topo1 inhibition in Her2-positive NCSLC.

Kohei Maruyama, Ryohei Katayama

Japanese Foundation for Cancer Research, Tokyo, Japan

Her2 aberration is found in approximately 2-4% of patients with non-small cell lung cancer (NSCLC). For the treatment of Her2 mutated/amplified NSCLC, the antibody-drug conjugate Trastuzumab deruxtecan, several Her2-selective inhibitors, such as zongertinib and sevabertinib, have shown beneficial efficacy in clinical settings. Although these Her2 inhibitors have exhibited durable clinical benefits, drug resistance is not inevitable, and tumor eventually relapse. To date, numerous resistance mechanisms to pan-ERBB family inhibitors have been identified, and combination strategies to overcome the resistance have been proposed. However, resistance mechanisms to Her2-selective inhibitor zongertinib have not been fully elucidated. In this study, we established zongertinib-tolerant Her2-positive NSCLC cells (zongerR) and investigated their therapeutic vulnerability. To establish the zongerR cells in vitro, Her2-amplified or Her2-mutated patient-derived cells were sequentially cultured with 100 nM zongertinib for 9 days, followed by a drug holiday. After 2-4 cycles, established zongerR cells demonstrated a more than 2-fold increase in cell viability at 100 nM zongertinib in vitro. Immunoblot analysis revealed that zongertinib suppressed Her2 phosphorylation, indicating that resistance mechanisms were related to bypass signaling. To assess the activating bypass signaling in zongerR cells, we performed inhibitor library screening with or without zongertinib. Drug screening revealed that zongerR cells exhibited sensitivity to the multi-tyrosine kinase inhibitor ponatinib and foretinib. Additionally, PI3K/AKT pathway inhibitors (PI3Ki) such as GDC0941 and mTOR inhibitor PP242 also markedly suppressed the survival of zongerR cells in combination with zongertinib. Notably, we identified a single treatment with the TopoI inhibitor SN38 suppressed cell viability in a zongerR cell derived from Her2-amplified H2170 cells (H2170zongerR), compared with H2170 parental cells. From the analysis of immunoblot and cell cycle, TopoI inhibitors induce DNA damage, leading to G2/M arrest and apoptosis, in H2170zongerR. These findings suggested that sequential treatment with zongertinib, followed by T-Dxd, might have been effective. Therefore, we evaluated the treatment efficacy in vivo. In a preliminary result, administration of zongertinib regressed tumor growth for several weeks, whereas tumor regrowth was observed. Subsequently, T-Dxd treatment showed tumor regression in contrast to the continuous treatment of the zongertinib group. Currently, zongertinib and T-Dxd have been approved for Her2-positive NSCLC, whereas treatment strategies to prolong the durable response have not been well-established. Further investigations were needed, but our findings suggested that T-DXd treatment after zongertinib may be a potential therapeutic strategy in a subset of Her2-positive NSCLC.

#2967 Evolution of TOP1 variants under selective pressure from topoisomerase-based therapeutics.

Tejaswini Reddy[1], Lei Kang[2], Hung Le[2], Senthil Damodaran[3], Kanwal Pratap Singh Raghav[2], Scott Kopetz[3], Jordi Rodon Ahnert[3], Ecaterina Elena Dumbrava[3], Timothy A. Yap[3], Stephen Williams[2], Mark J. Routbort[2], Keyur P. Patel[2], Funda Meric-Bernstam[3]

[1]Baylor College of Medicine, Houston, TX,[2]The University of Texas MD Anderson Cancer Center, Houston, TX,[3]UT MD Anderson Cancer Center, Houston, TX

Background: Antibody-drug conjugates (ADCs) that incorporate topoisomerase I inhibitor payloads, including sacituzumab govitecan (SG) and trastuzumab deruxtecan (T-DXd), have demonstrated activity across multiple solid tumors. SG is approved for previously treated triple-negative and hormone receptor-positive breast cancers, while T-DXd is approved for HER2-expressing malignancies. Despite broad clinical use, the mechanisms underlying resistance to topoisomerase-based ADCs remain insufficiently defined. Recent reports indicate that acquired TOP1 mutations may contribute to therapeutic failure. We evaluated the frequency and characteristics of *TOP1* alterations in patients who progressed on ADCs carrying topoisomerase payloads or on camptothecin-based chemotherapy.

Methods: We reviewed 17,092 solid tumor samples profiled by tumor and/or liquid biopsy next-generation sequencing (NGS) through the MDA MAPP platform at The University of Texas MD Anderson Cancer Center from January 2019 to January 2025. Patients exposed to topoisomerase inhibitor-based ADCs (SG, T-DXd, or datopotamab deruxtecan [Dato-DXd]) or irinotecan/topotecan-containing chemotherapy were identified (n = 1,807). Those with available paired pre- and post-treatment NGS formed the analytic cohort (n = 343). We assessed the emergence of *TOP1* variants at progression, changes in variant allele frequency (VAF), and annotated mutations using ClinVar, InterVar, and literature review.

Results: *TOP1* mutations were detected in 160 of 17,092 patients (0.94%). This included 14 of 2,040 patients (0.68%) with liquid-biopsy NGS only, 18 of 1,324 (1.35%) with both liquid biopsy and tumor NGS, and 128 of 13,728 (0.93%) with tumor-only NGS. Nine unique *TOP1* variants, *G363S*, *G365V*, *G365S*, *R364C*, *K333fs*, *R434Q*, *R84K*, *A670G*, and *R364H*, arose at progression. Emergent alterations occurred in 3.4% (5/145) of patients treated with topoisomerase-payload ADCs and 2.1% (4/193) of those receiving irinotecan-based chemotherapy. *G365S* and *R364H* were previously described as pathogenic variants associated with camptothecin resistance, with *R364H* also linked to ADC resistance. One SG-treated breast cancer patient developed three concurrent alterations, *G365V* (VAF 23%), *G365S* (12%), and *R364C* (8%), at progression. Four colorectal cancer patients receiving FOLFIRI plus bevacizumab or panitumumab exhibited distinct emergent *TOP1* mutations at disease progression.

Conclusions: *TOP1* alterations can appear after exposure to topoisomerase-payload ADCs or irinotecan-containing regimens, suggesting a potential resistance mechanism in a subset of patients. The functional impact of these variants and their relevance to therapeutic response remain undefined, warranting further mechanistic and clinical investigation.

#2968 EGFR S442 mutation confers cetuximab resistance that can be overcome by ERBB2 blockade by trastuzumab-deruxtecan.

Neeraj Joshi[1], Sarah J. Harmych[2], Hidenori Tanaka[1], Galina Bogatcheva[1], Marisol A. Ramirez[1], Ramona Graves-Deal[1], Claiborne W. Tydings[2], Claudia C. Wahoski[2], Chelsie K. Sievers[1], Maria Johnson Irudayam[1], James N. Higginbotham[1], Frank L. Revetta[1], Zhiguo Zhao[1], Jeffrey L. Franklin[1], Binyam Yilma[3], Tina M. O'Grady[3], Stamatina Fragkogianni[3], Metamia Ciampricotti[3], M Kay Washington[1], Xingyi Guo[1], Allison S. Walker[2], Jens Meiler[2], Qi Liu[1], Robert J. Coffey[1], Eben L. [1]Vanderbilt University Medical Center, Nashville, TN,[2]Vanderbilt University, Nashville, TN,[3]Tempus AI Inc, Chicago, IL,[4]Professor of Surgery, Vanderbilt University School of Medicine, Nashville, TN

Epidermal growth factor receptor (EGFR) is a critical oncogenic driver in multiple cancers and a therapeutic target of tyrosine kinase inhibitors and neutralizing monoclonal antibodies. However, resistance to EGFR-targeted therapies, particularly the anti-EGFR antibody cetuximab, remains a clinical challenge in colorectal (CRC) and head and neck (HNSCC) cancers. To investigate cetuximab resistance mechanisms, we cultured the cetuximab-sensitive CRC cell line DiFi in 3D in type I collagen with cetuximab, generating cetuximab-resistant derivatives (DiFi-CR). Genomic and transcriptomic profiling revealed that DiFi-CR cells have a mutation of the S442 residue in the EGFR extracellular domain. Patient samples revealed EGFR S442 mutations following anti-EGFR therapy, indicating S442 as a potential resistance hotspot. For an in-depth mechanistic analysis, we reconstituted the EGFR S442I mutation, using a doxycycline-inducible system, and showed that it was necessary and sufficient to induce cetuximab resistance in CRC and HNSCC cells using *in vitro* (2D and 3D) cultures and *in vivo* mouse experiments. *In silico* structural studies, live-cell binding assays, and antibody enrichment in nude mice xenografts revealed that the S442I mutation leads to weaker EGFR-cetuximab binding. Weaker cetuximab binding was also predicted *in silico* for other S442 patient mutations. Importantly, we found that mutant EGFR-driven cetuximab resistance could be overcome by targeting EGFR family member ERBB2 with trastuzumab-deruxtecan. Notably, this combinatorial response was contingent upon a physical interaction between EGFR and ERBB2, as determined by co-immunoprecipitation. Overall, our study establishes EGFR S442 mutations as drivers of cetuximab resistance and highlights co-targeting ERBB2 as a promising therapeutic strategy to restore anti-EGFR efficacy.

#2969 B836: A novel bispecific antibody-drug conjugate (ADC) as a clinical candidate to overcome trastuzumab deruxtecan resistance.

Yi Zhao, Huahua Hao, Xin Yang, Weiwei Pan, XinxinLiang, Quanai Zhang, Xiaoxia Liu, Jingting Cui, Elizabeth Wu, **Zhican Qu**

Nanolattix, Taiyuan, China

Resistance to single-antigen HER2-targeted ADCs, such as Enhertu (trastuzumab deruxtecan, DS-8201) and Kadcyla (trastuzumab emtansine, T-DM1), poses a significant challenge in HER2-positive cancers, often due to tumor heterogeneity and antigen downregulation. To address this unmet medical need, we developed B836, a first-in-class bispecific ADC leveraging the Nanolattix Biolattix technology platform. B836 is engineered to target both HER2 and Tissue Factor (TF). TF is an attractive therapeutic target and is overexpressed in various tumor types. Results from in vitro experiments demonstrated that B836 achieved significantly enhanced cancer cell binding and internalization compared to single-target ADCs. In vivo studies of B836 showed superior anti-tumor efficacy over Enhertu, particularly in animal models characterized by low HER2 expression, suggesting its potential for overcoming primary or acquired resistance mechanisms. GLP safety and toxicokinetic (TK) studies were conducted in cynomolgus monkeys. No drug-related ocular toxicity or abnormalities in body temperature, blood pressure, or electrocardiogram (ECG) were observed. Furthermore, no systemic toxicity was detected at doses up to 5 mg/kg. These collective findings support the continued clinical development of B836, promising therapeutic potential in oncology.

#2970 Limited efficacy of HER3-DXd in colorectal cancer PDX models reveals molecular resistance mechanisms and informs rational combinatorial strategies.

Preeti Kanikarla[1], Alexey Sorokin[2], Alisha Bent[1], Kelly Gale[1], Fengqin Gao[1], Zhensheng Liu[1], Kanwal Pratap Singh Raghav[1], Scott Kopetz[1]

[1]UT MD Anderson Cancer Center, Houston, TX,[2]GI Medical Oncology, UT MD Anderson Cancer Center, Houston, TX

HER3 (ERBB3), a member of the EGFR family, activates PI3K/AKT signaling through dimerization with other ERBB receptors and is frequently implicated in resistance to targeted therapies. Patritumab deruxtecan, a HER3-directed antibody-drug conjugate (ADC), has shown clinical activity in non-small cell lung and breast cancers, and has been recently evaluated in metastatic colorectal cancer (mCRC). Despite frequent HER3 expression in mCRC, its therapeutic relevance in chemotherapy-refractory disease is not well defined. We evaluated HER3-DXd in a panel of 17 molecularly characterized mCRC patient-derived xenograft (PDX) models, the majority of which were derived from patients previously treated with and resistant to irinotecan. Tumor growth inhibition was used to assess response. Molecular profiling (including whole-exome sequencing, RNA sequencing, and Reverse Phase Protein Array) was conducted to elucidate resistance mechanisms and direct rational combination strategies. Single-agent HER3-DXd showed variable activity across models, with limited responses in those exhibiting irinotecan resistance. HER3 expression did not consistently predict response. Interpretation of this association might be limited by the absence of a standardized cutoff for HER3 positivity. The results of the relative weight analysis indicated that 86% of the response was attributable to the payload sensitivity, while only 13% was associated with HER3 expression as determined by IHC. Molecular analyses revealed persistent PI3K/AKT and MAPK signaling in non-responders, along with upregulated receptor tyrosine kinase (RTK) signaling and a correlation with increased expression of drug efflux transporters. Functional studies demonstrated that combining HER3-DXd with MEK, WEE1, or PLK1 inhibitors produced synergistic antitumor effects. Phospho-proteomic data supported adaptive pathway rewiring following HER3 blockade. These findings highlight the complexity of HER3 signaling in chemotherapy-refractory mCRC and support the development of biomarker-driven combination strategies to enhance therapeutic efficacy of HER3-targeted ADCs (and conceivably other ADCs with topoisomerase inhibitor payload) in this setting.

#2971 In-depth profiling of SCLC models of acquired chemoresistance reveals SLFN11-dependent antibody-drug conjugate payload sensitivity and ATR inhibitor synergy.

Buesra Ernhofer[1], Lisa Glatt[1], Benjamin Morris[2], Beata Szeitz[3], Zsolt Megyesfalvi[1], Abigail Deloria[1], Diana Piesel[1], Laura Schnell[1], Kristiina Boettiger[1], Amirali Karimi[2], Monique Nilsson[2], Melinda Rezeli[4], Simon Heeke[2], John Victor Heymach[2], Clemens Aigner[1], Balazs Dome[1], Karin Schelch[1]

[1]Department of Thoracic Surgery, Comprehensive Cancer Center, Medical University of Vienna, Vienna, Austria,[2]Department of Thoracic and Head and Neck Medical Oncology, MD Anderson Cancer Center, Houston, TX,[3]Department of Biochemistry & Molecular Pharmacology, New York University Grossman School of Medicine, New York, NY,[4]Department of Biomedical Engineering, Lund University, Lund, Sweden

Introduction: Small cell lung cancer (SCLC) represents an aggressive malignancy that initially responds well to frontline platinum-based chemotherapy. However, most patients relapse quickly due to rapid development of chemoresistance, emphasizing the urgent need for novel therapeutic strategies to achieve durable clinical benefit.

Methods: To elucidate the mechanisms driving treatment failure, we established *in vitro* SCLC models that acquired cisplatin resistance across distinct molecular subtypes. These models were characterized by proliferation, cell cycle, and proteomic assays. Drug screens were conducted to identify therapeutic vulnerabilities, including responses to unconjugated antibody-drug conjugate (ADC) payloads and targeted pathway inhibitors.

Results: Cisplatin-resistant (CR) SCLC models exhibited broad cross-resistance to clinically relevant cytotoxic drugs such as carboplatin, lurbinectedin, and topoisomerase I and II (TOP1 and TOP2) inhibitors. Resistance was associated with diminished intracellular platinum accumulation, reduced proliferation, and altered cell cycle distribution with G2/M arrest or senescent-like features compared to the corresponding sensitive parental lines. Proteomic analysis of CR models, together with patient-derived samples at treatment relapse, revealed extensive metabolic reprogramming and downregulation of DNA repair and checkpoint control pathways, highlighting shared adaptive signatures. Screening of unconjugated ADC payloads uncovered mechanism-specific vulnerabilities. While CR models were resistant to DNA-damaging payloads such as calicheamicin, microtubule-disrupting ADC payloads (MMAE and DM1) retained sensitivity across all CR models. Responses to TOP1-directed ADC payloads varied and were associated with SLFN11 expression levels. Importantly, inhibition of ATR with ceralasertib synergized with DNA-damaging ADC payloads, re-sensitizing SLFN11-low resistant models by increasing DNA damage and inducing apoptosis.

Conclusion: Our findings demonstrate shared adaptive mechanisms of acquired cisplatin resistance in SCLC, including checkpoint rewiring and metabolic flexibility. SLFN11 was identified as a key determinant of TOP1-directed ADC efficacy. Combining ATR inhibition with DNA-damaging ADC payloads represents a promising strategy to restore DNA damage-induced cell death in resistant SCLC. These insights provide a translational framework for developing rational ADC-based combination therapies to overcome chemoresistance in relapsed SCLC.

#2972 TROP2 upregulation and interaction with HER2 mediate trastuzumab resistance.

Yuan-Liang Wang, Chi-Huan Lu, Cheng-Yen Wei, Jye-Yu Huang, Woan-Eng Chan, Lu-Tzu Chen, Ya-Chi Chen

Biological Discovery, OBI Pharma, Inc, Taipei City, Taiwan

Trastuzumab (Herceptin) remains a cornerstone therapy for HER2-positive gastric cancer, yet acquired resistance severely limits its long-term efficacy. Identifying resistance mechanisms is critical for developing next-generation treatment strategies. We investigated the role of TROP2, a known oncogenic protein, in mediating resistance to trastuzumab. Trastuzumab-resistant HER2-positive gastric cancer (GC) cell lines were developed, characterized, and compared to parental cells. The functional impact of TROP2 on sensitivity was assessed using cytotoxicity assays following genetic knockdown (siRNA) of TROP2. The molecular interaction between TROP2 and HER2 was definitively evaluated using several assays, including co-immunoprecipitation (Co-IP), immunofluorescence (IF) co-localization, blue native PAGE (BN-PAGE), and label transfer binding assays. To define the specific heterodimer interface, site-directed mutagenesis was performed targeting predicted residues.

Trastuzumab-resistant gastric cancer cells exhibited a significant increase in IC_{50} (>5-fold) and displayed markedly higher TROP2 expression compared to sensitive parental cells. Knockdown of TROP2 expression transiently can restore trastuzumab sensitivity in resistant cell lines, confirming TROP2's direct role as a mediator of therapy evasion. HER2/TROP2 heterodimerization was confirmed by Co-IP (co-immunoprecipitation), IF (immunofluorescence), and BN-PAGE provided strong evidence for the direct interaction of HER2 and TROP2 heterodimerization. Binding Interface determination in mutagenesis targeting TROP2-Asp99 and the HER2-Val308/Lys333 interface successfully disrupted the physical interaction between HER2 and TROP2.

TROP2 upregulation and its subsequent physical heterodimerization with HER2 constitutes targetable mechanism of acquired resistance to trastuzumab in HER2-positive gastric cancer. This interaction suggests that TROP2 may sustain critical oncogenic signaling even when HER2 is pharmacologically inhibited. These findings provide a strong molecular rationale for developing strategies aimed at disrupting the TROP2-HER2 complex to enhance and restore therapeutic efficacy.

#2974 The anticancer effect of TROP2-targeted antibody-drug conjugates (ADC) is potentially attenuated by dysregulated cholesterol metabolism in cancer cells.

Kimio Yonesaka[1], Yusuke Kawanaka[1], Takashi Kurosaki[1], Satomi Watanabe[1], Junko Tanizaki[1], Kazuko Sakai[2], Takeshi Teramura[3], Kazuto Nishio[2], Hidetoshi Hayashi[1]

[1]Medical Oncology, Kindai University Faculty of Medicine, Sakai, Osaka, Japan,[2]Genome Biology, Kindai University Faculty of Medicine, Sakai, Osaka, Japan,[3]Cell Biology for Regenerative Medicine, Kindai University Faculty of Medicine, Sakai, Osaka, Japan

Background: Trop-2 is a widely expressed glycoprotein on a variety of different tumors. Datopotamab deruxtecan (Dato-DXd) is a Trop-2-targeted ADC that has demonstrated anticancer efficacy in patients with *EGFR*-mutated non-small cell lung cancer (NSCLC). However, their efficacy is inconsistent. In cancer cells, cholesterol synthesis is promoted, and cholesterol localizes to the cell membrane, playing a crucial role in the endocytosis of various receptors on the cell membrane. The current study aimed to explore the mechanisms underlying the limited efficacy of Dato-DXd using *EGFR*-mutated NSCLC cells.

Materials and methods: We established a Dato-DXd-resistant PC9DR cell line by long-term exposure of *EGFR*-mutated NSCLC PC9 cells to Dato-DXd. A colony formation assay was performed to evaluate anticancer effects. Trop-2 expression on the cell membrane was measured immunologically. Intracellular uptake of Dato-DXd was measured using a pH-Rhod method. Microarray data were analyzed using Transcriptome Analysis Console Software to examine differentially expressed genes and related-pathways.

Result: According to the colony formation assay, 1μg/mL Dato-DXd inhibited 89% colony formation in PC9 cells, but inhibited 5% colony formation in PC9DR cells. In PC9DR cells, cell surface Trop-2 expression was greater than PC9 cells (434,338 vs 400,722 molecules per cell, $p = 0.0012$). However, intracellular uptake of Dato-DXd was significantly reduced in PC9DR cells compared to PC9 cells (two-way ANOVA, $p < 0.0001$). These results suggested that reduced internalization of Trop-2 protein on the cell membrane is hypothetically associated with resistance to Dato-DXd. Second, pathway analysis revealed that the cholesterol metabolism pathway showed the most significant change in PC9DR cells compared to PC9 cells. Specifically, compared to PC9 cells, PC9DR cells showed a marked decrease in the expression of cholesterol synthesis-related enzymes, including HMGCR, MVD, and SQLE, while conversely exhibiting increased expression of the cholesterol transporter ABCA1 (ANOVA $p<0.001$, greater than two-fold change). Therefore, we hypothesized that impaired cholesterol metabolism cause resistance to Dato-DXd. Finally, we exposed the Dato-DXd-sensitive cells including PC9 and HCC827 to the HMGCoA reductase inhibitor, 1μM mevastatin, and evaluated anticancer effect of 1μg/mL Dato-DXd using a colony formation assay. In PC9 cells, Dato-DXd potently inhibited colony formation (relative colony formation area, Control; 100%, Dato-DXd; 3.6%). However, PC9 cells treated with mevastatin, Dato-DXd minimally inhibited colony formation (Control; 100%, Dato-DXd; 77.4%). Similar trend was observed in HCC827 cells.

Conclusion: These results suggest that impaired cholesterol metabolism may cause resistance to Dato-DXd in *EGFR*-mutated NSCLC.

#2975 Q702 enhances trastuzumab efficacy for HER2 + gastric cancer cells.

Mi Young Kim[1], Yoonji Lee[2], Kiyean Nam[2], **Jin-Soo Kim**[1]

[1]Seoul Metropolitan Government Seoul National University Boramae Medical Center, Seoul, Korea, Republic of,[2]Qurient Co., Ltd., Seongnam, Korea, Republic of

Background: Trastuzumab (Tmab) is an effective monoclonal antibody against advanced esophago-gastric cancers (GCs) with HER2 amplification. Unfortunately, the efficacy of Tmab is limited due to primary and acquired resistance to this agent. Q702 is a novel, orally available small molecule that selectively inhibits three receptor tyrosine kinases: Axl, Mer, and CSF1R. Here, we describe a therapeutic synergism between Tmab and Q702 in HER2+ GC cells.
Material and Methods: After screening 37 GC cell lines (J-S Kim et al Int. J. Mol. Sci. 2024, 25(11), 5975), the following GC cells were evaluated: HER2 amplification -positive (HER2+) and Tmab-sensitive NCI-N87 and OE19, HER2+ Tmab-resistant OE33, ESO26, SNU-216, MKN7, YCC19, YCC33, and YCC38 and HER2 negative AGS and SNU638. We assessed the cytotoxic response of these GC cells to trastuzumab alone or in combination with Q702 by 3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium (MTT) assay, and clonogenic cell survival assays. Western blots were performed to assess biochemical changes, especially those related with HER2 signaling components. The statistical significance of differences of colony numbers were determined by using the Kruskal-Wallis test.
Results: HER2+ Tmab-resistant GC cells showed relatively higher expression of AXL than HER2+ Tmab-sensitive GC cells. Q702 significantly decreased the number of colonies in clonogenc assays and exerted dose-dependent effects in HER2+ GC cells. Additionally, we observed that treatment with trastuzumab in combination with Q702 induced a statistically significant decrease of the colonies in HER2 + GC cells, both Tmab-sensitive and Tmab-resistant. Combination with Q702 resulted in decreased phosphorylation of HER2 and its downstream targets, AKT and ERK, in Tmab-resistant HER2+ cells. No growth inhibition was detected in HER2-GC cells treated with Tmab alone or combination.
Conclusion: Collectively, these data support that Q702 could overcome primary resistance to Tmab in HER2+ GC cells.

#2979 MAPK driven kinetochore instability as a biomarker and therapeutic vulnerability in glioblastoma.

Jennifer DeLuca[1], **Patrick J. Paddison**[2]

[1]Colorado State University, Fort Collins, CO,[2]Fred Hutchinson Cancer Center, Seattle, WA

Chromosome segregation fidelity relies on stable attachments between kinetochores (KTs) and spindle microtubules during mitosis. We recently identified a previously unrecognized form of KT dysfunction that is prevalent in human glioblastoma (GBM) isolates and is triggered by aberrant activation of mitogen-activated protein kinase (MAPK) signaling during mitosis. This phenotype—termed MAPK-stressed kinetochores (MaSKs)—arises when hyperactive Ras-Raf-MEK-ERK signaling drives excessive phosphorylation of KT components by a network of KT-associated kinases. As a result, MT-binding affinity is reduced and KT-MT turnover becomes abnormally high, producing a lethal mitotic stress state. MaSKs provide a direct mechanistic link between oncogenic Ras/MAPK pathway activity and the generation of chromosome instability, filling a key gap in our understanding of how mitogenic oncogenes disrupt mitosis. Notably, MaSKs appear to be restricted to cancer and transformed cells, where they create unique genetic and molecular dependencies. MaSK-positive cells rely specifically on two non-essential domains of the mitotic checkpoint protein BubR1/BUB1B to recruit PP2A phosphatase and suppress MaSK-induced KT-MT instability. These dependencies suggest new opportunities for tumor-selective therapeutic targeting. In this presentation, we will describe the molecular basis of MaSK formation, the assays enabling their discovery, and evidence supporting their utility as biomarkers for a subset of MAPK-driven tumors. We further discuss how MaSKs can be exploited to identify novel therapeutic strategies and define a patient responder population.

#2980 SMARCA2 and SMARCA4 expression in cancer: A tissue microarray study on 14,966 tumors from 134 different tumor types.

Nina Schraps[1], Anne Menz[1], Florian Lutz[1], Viktoria Chirico[1], Florian Viehweger[1], David Dum[1], Ria Schlichter[1], Andrea Hinsch[1], Fiete Gehrisch[1], Christoph Fraune[1], Christian Bernreuther[1], Seyma Buyucek[1], Martina Kluth[1], Claudia Hube-Magg[1], Katharina Moller[1], Viktor Reiswich[1], Andreas M. Luebke[1], Patrick Lebok[1], Baris Mercanoglu[2], Nathaniel Melling[2], Thilo Hackert[2], Guido Sauter[1], Maximilian Lennartz[1], Till S. Cauditz[1], Andreas H Marx[1], Ronald Simon[1], Stefan Steurer[1], Eike Burandt[1], Natalia Gorbokon[1], Maria Christina Tsourlakis[1], Sarah Minner[1], Till Krech[1], Morton Freytag[1]

[1]Institute of Pathology, University Medical Center Hamburg-Eppendorf, Hamburg, Germany,[2]General, Visceral and Thoracic Surgery Department and Clinic, University Medical Center Hamburg-Eppendorf, Hamburg, Germany

The two mutually exchangeable ATPases SMARCA2 and SMARCA4 form the two catalytic subunits of a polymorphic family of SWI/SNF complexes. In both normal and malignant cells, they play a regulatory role in numerous essential cellular processes. For example, SWI/SNF affects the regulation of cell differentiation, programmed cell death, DNA repair, chromosome stability, signaling pathway crosstalk and cell metabolism. Topical interest in SMARCA4/SMARCA2 is due to the observation of their synthetic lethal relationship, potentially offering new therapeutic approaches. Targeting SMARCA4 deficient cancer cells with SMARCA2 inhibitors or degraders has resulted in significant growth inhibition in experimental systems and further agents are being tested in early clinical trials. To determine the prevalence of SMARCA2/SMARCA4 expression in cancer, a tissue microarray containing 14,966 samples from 134 different tumor entities and 608 samples of 76 different normal tissue types was analyzed by immunohistochemistry. SMARCA2 immunostaining was absent in 6.9%, weak in 8.0%, moderate in 18.3%, and strong in 66.8% of 12,253 interpretable tumors. SMARCA4 staining was absent in 0.7%, weak in 1.9%, moderate in 5.9%, and strong in 91.5% of 13,093 interpretable tumors. Remarkably, losses of SMARCA2 and SMARCA4 were strongly correlated. Of 91 SMARCA4 deficient tumors for which SMARCA2 data were also available, 28 (30.8%) did also show a complete loss of SMARCA2 expression. SMARCA2 deficiency was most commonly seen in Burkitt lymphoma (66.7%), endometrial carcinomas (up to 57.1%), rhabdoid tumors (50.0%) and ovarian carcinomas (up to 37.8%). SMARCA4 staining was predominantly lost in in neuroendocrine carcinomas (up to 25.0%), endometrioid carcinomas (up to 7.7%) and adenocarcinomas of the lung (7.5%). Absent or low SMARCA2 expression was significantly linked to unfavorable tumor phenotype in clear cell renal cell carcinoma, bladder cancer, and breast cancer while weak or absent SMARCA4 staining was linked to unfavorable tumor features in colorectal and clear cell renal cell carcinoma ($p \leq 0.05$). It is concluded, that SMARCA4 deficiency is a rather rare event in tumors, whereas SMARCA2 deficiency is much more common in many different tumor entities and is associated with unfavourable cancer characteristics in several tumor types. The frequent co-deficiency of SMARCA2 and SMARCA4 challenges the concept of a synthetic lethal relationship of these proteins in vivo.

#2981 PM54 targets oncogenic transcriptional networks across multiple cancer types.

Ismael Fernandez-Miranda, Javier Robles, Maria Jose Guillen, Pablo Aviles, **Marcelo L. Ribeiro**, Carmen Cuevas

Pharma Mar, S.A., Madrid, Spain

Background: PM54, a synthetic ecteinascidin analog derived from lurbinectedin, binds GC-rich promoter regions to block transcription, induce DNA double-strand breaks, and trigger S-phase arrest and apoptosis. We aimed to define PM54 transcriptional mechanisms across tumor types and to identify transcriptomic features associated with heightened sensitivity.
Methods: Comprehensive transcriptomic profiling (RNA-seq) was performed following acute PM54 exposure (50 nM, 6 h) in a panel of 32 cancer cell lines representing six tumor types: 12 small-cell lung cancers (SCLC), 8 gastric cancers, 6 prostate cancers, 4 breast cancers, 1 ovarian cancer, and 1 melanoma. Hierarchical clustering, differential expression, GSEA, and GO analyses were used to define temporal transcriptional response clusters. In vivo validation was conducted in four CDX models (SCLC DMS-53, ovarian A2780, melanoma WM-266-4, and TNBC MDA-MB-231) after a single PM54 dose, with RNA-seq performed on day 7.
Results: PM54 induced a rapid, broad transcriptional repression in all models, with >2,000 downregulated genes per line and a conserved core of 1,170 commonly repressed genes (versus 226 commonly induced). Repressed programs included cell cycle, RNA Pol II transcription, chromatin organization, DNA repair and MYC targets; early upregulated signatures implicated metabolism, PARP signaling and stress responses. Unsupervised clustering based on PM54 transcriptional effect identified a “primed” responder cluster (characterized by high baseline transcription and rapid transcriptional shutdown after treatment) and an “adaptive” responder cluster. Curiously, all three POU2F3 SCLC lines and prostate cancer models were into the primed responder cluster. Consistently, in vivo transcriptomic analyses recapitulated these clusters, demonstrating enhanced transcriptional repression, MYC/mTOR signaling suppression, and markedly improved survival outcomes in primed (+192%, +345% and +412% in ovarian, melanoma and SCLC, respectively) compared to adaptive responders (+185% in breast cancer and +240% in gastric cancer).
Conclusions: PM54 rapidly suppresses proliferative/MYC-driven programs and elicits adaptive metabolic/immune responses. Baseline transcriptional state predicts response and may guide patient selection and combination strategies.

#2982 Role of high mobility group nucleosome-binding domain-containing protein 3 (HMGN3) in prostate cancer progression a novel target for therapeutic intervention.

Vikkram Venkatesan[1], Jeffrey Mathew[2], Janani Harikrishnan[1], Gnanasekar Munirathinam[1]

[1]Biomedical Sciences, University of Illinois College of Medicine (Rockford), Rockford, IL,[2]Biology, John Hopkins University, Baltimore, MD

Prostate cancer (PCa) accounts for more than one million new cases globally each year. Standard therapeutic approaches such as chemotherapy, radiotherapy, prostatectomy, and androgen deprivation therapy often yield only temporary benefits and are associated with substantial toxicity. Neuroendocrine prostate cancer (NEPC) represents a rare, highly aggressive subtype of PCa that may develop de novo or emerge as a treatment-resistant form of adenocarcinoma. NEPC is particularly challenging to manage because it is androgen receptor (AR) independent and responds poorly to conventional therapies. Chromatin modulators such as EZH2, BRD4, and NKX2-1 have been shown to promote the development of NEPC. One such novel chromatin regulator namely High Mobility Group Nucleosome-Binding Domain-Containing Protein 3 (HMGN3), a member of the HMGN protein family, binds nucleosomes and modulates chromatin structure, thereby influencing transcription, replication, and DNA repair may also have a role in the progression of NEPC. Previous research has demonstrated that HMGN3 promotes metastasis in cholangiocarcinoma by binding to the transcription factor SNAI2 and interacting with histone deacetylases (HDACs), leading to repression of epithelial-regulatory genes and induction of epithelial-mesenchymal transition (EMT). However, its role in PCa has not been previously explored. Bioinformatic analyses using PCA Tools and Betastasis indicate that AR-negative and neuroendocrine cell lines—such as NCI-H660 and LASCPC—exhibit the highest mRNA expression levels of HMGN3. This suggests that HMGN3 may contribute to EMT-associated metastatic pathways in PCa. To explore this, western blotting and RT-PCR were performed to analyze HMGN3 protein and mRNA levels in NEPC cell lines. Both NCI-H660 and LASCPC showed high protein expression, with LASCPC displaying the highest mRNA expression. Functional assays were carried out by treating BPH-1 cells with *r*HMGN3 in colony formation assays (CFA), while TRAMP-C1 cells were used for wound healing and Transwell migration assays. In these assays, treated groups demonstrated increased colony formation, accelerated wound closure, and higher migratory activity compared to controls. Additionally, a preliminary MTT cell viability assay performed in NCI-H660 cells treated with varying concentrations of monoclonal antibody targeted to HMGN3 showed reduced cell viability relative to untreated controls. Collectively, these findings suggest that HMGN3 as a significant enhancer of tumor growth and metastatic spread, being especially abundantly expressed in aggressive NEPC. In conclusion, our data supports that targeting HMGN3 could serve as an innovative therapeutic approach for advanced, treatment-resistant forms of PCa.

#2983 Genome-wide CRISPRi screen identifies RPS27 as a novel synthetic lethal target for TP53 mutant cancers.

Stephen Paik, Yi Yu, Ashley H. Choi, Samuel R. Meier, Shangtao Liu, Binzhang Shen, Shanchuan Zhao, Xuewen Pan, Jannik N. Andersen, **Teng Teng**

Tango Therapeutics, Boston, MA

TP53 is a master tumor suppressor that regulates diverse cellular functions, including cell cycle progression, apoptosis, DNA damage repair and genome stability. Due to its critical role, TP53 is the most frequently mutated gene across human cancer and its loss often represent an early event in tumorigenesis. However, therapeutic strategies that specifically target TP53-mutant cancers remain limited. To identify novel synthetic lethal targets for TP53 mutant cancers, we engineered and validated isogenic cell lines differing only in TP53 status and performed a genome wide CRISPR interference (CRISPRi) screen in paired A549 cells. The screen identified the small ribosome subunit protein RPS27 as the top dependency unique to TP53 knockout cells. Interestingly, this dependency was specific to the CRISPRi platform, as RPS27 did not score in a parallel CRISPR knockout (CRISPRko) screen. Further examination revealed that most CRISPRko gRNAs targeting RPS27 have multiple off-target sites with less than 3 mismatches. This likely causes general DNA-cutting-induced cytotoxicity that confounds true gene dependencies, which is avoided with the CRISPRi platform. Supporting this conclusion, re-analysis of the public DepMap/Achilles dataset showed that a single mismatch-free gRNA also demonstrate RPS27 dependency in TP53 mutant cell lines. Mechanistically, TP53 drives the expression of RPS27L, a close paralog of RPS27. While TP53 wildtype cells express both RPS27L and RPS27, allowing for functional redundancy in ribosome assembly, TP53 mutant cells lack RPS27L expression and become largely dependent on RPS27 for ribosomal integrity and survival. Single gene validation confirmed that TP53 KO A549 cells are exquisitely sensitive to RPS27 knockdown and this dependency can be rescued by re-expression of either TP53, RPS27 or RPS27L. Together, these findings identify RPS27 as a novel synthetic lethal target for TP53 mutant cancers, revealing a previously unrecognized paralog-dependency within the ribosome and highlighting a potential therapeutic vulnerability.

#2984 *In situ* and functional analysis of Integrin-alpha 5 reveals its role in tumor progression in non-small cell lung cancer.

Mirei Ka[1], Takahiro Ando[2], Munetoshi Hinata[3], Kousuke Watanabe[4], Akiko Kunita[4], Masanori Kawakami[2], Masaaki Sato[5], Hiroyuki Okada[6], Hironori Hojo[7], Tetsuo Ushiku[3], Cecilia C. Krona[8], Patrick Micke[8], Katsutoshi Oda[1], Hidenori Kage[2]

[1]Division of Integrative Genomics, Graduate School of Medicine, The University of Tokyo, Bunkyo City, Japan,[2]Department of Respiratory Medicine, Graduate School of Medicine, The University of Tokyo, Bunkyo City, Japan,[3]Department of Pathology, Graduate School of Medicine, The University of Tokyo, Bunkyo City, Japan,[4]Next-Generation Precision Medicine Development Laboratory, Graduate School of Medicine, The University of Tokyo, Bunkyo City, Japan,[5]Department of Thoracic Surgery, Graduate School of Medicine, The University of Tokyo, Bunkyo City, Japan,[6]Center for Disease Biology and Integrative Medicine, Graduate School of Medicine, The University of Tokyo, Bunkyo City, Japan,[7]Bioinformatics Research Unit, Graduate School of Dentistry, The University of Osaka, Suita City, Japan,[8]Department of Immunology, Genetics, and Pathology, Uppsala University, Uppsala, Sweden

[Background] Integrins are transmembrane receptors that mediate cell adhesion to adjacent cells and the extracellular matrix, thereby regulating fundamental cellular processes. Abnormal integrin expression has been linked to tumor progression and metastasis across multiple cancer types, primarily through their interactions with components of the tumor microenvironment. Integrin alpha-5 (ITGA5) typically forms a heterodimer with the commonly shared beta-1 subunit and functions as a receptor for fibronectin and fibrinogen. This study aimed to investigate the clinical and biological significance of ITGA5 in non-small cell lung cancer (NSCLC).
[Methods] Survival analysis was based on RNA-seq data sets from NSCLC patient cohorts of the University of Tokyo Hospital (n = 100) and The Cancer Genome Atlas (TCGA; n = 986). Protein expression was analyzed by immunohistochemistry (IHC) in diagnostic tissue samples from NSCLC patients from The University of Tokyo Hospital (n = 20) and from the Uppsala University Hospital (Sweden; n = 312), which also included extensive mutation data. The biological relevance of ITGA5 was experimentally evaluated in a xenograft model with Calu-1 cells using an ITGA5 inhibitor (GLPG0187), and the effect of ITGA5 knockdown derived from the same cell line was analyzed by bulk RNA-seq analysis.
[Results] Both RNA and protein-level survival analyses consistently revealed that high ITGA5 expression was associated with shorter survival across multiple cohorts (TCGA RNA: p=0.011; University of Tokyo Hospital RNA: p=0.025; University of Tokyo Hospital protein: p=0.038; Uppsala University Hospital protein: p=0.013). Notably, protein IHC analysis indicated a greater impact of ITGA5 in tumors than in stromal cells. ITGA5 inhibition suppressed tumor growth in vivo compared to controls. Bulk-RNA seq data showed that ITGA5 knockdown altered the expression of genes involved in integrin-mediated signaling. Genes such as FERMT2, SEMA7A, and CCN1/CCN2 showed decreased expression following knockdown, consistent with their roles in integrin activation, ECM remodeling, and pro-invasive signaling. In addition, this analysis showed downregulation of pathways related to inflammation and tumor immunity (e.g., CSF3, CXCL8, IL6ST), EMT (e.g., TGFBR1, CDH2, PXN), and mTOR signaling (e.g., PIK3R2, STAT3, HRAS).
[Conclusion] Our study provides a comprehensive analysis of ITGA5 expression on RNA and protein levels in the clinical context. The results indicate an essential role of ITGA5 in promoting tumor progression and poor prognosis in lung cancer, providing the rationale for further studying ITGA5 as a target with biomarker and therapeutic potential for NSCLC patients with elevated ITGA5 expression.

#2985 TRIB2 as a therapeutic vulnerability in ALK-rearranged non-small cell lung cancer.

Jitender Monga[1], Sudha Sadasivan[2], Sang-Yoon Lee[3], Sharad K. Suthar[3], Craig Rogers[1], Shirish Gadgeel[2]

[1]Department of Urology, Henry Ford Health + Michigan State University Health Sciences, Detroit, MI,[2]Division of Hematology & Oncology, Henry Ford Health + Michigan State University Health Sciences, Detroit, MI,[3]Department of Neuroscience, Neuroscience Research Institute, Gachon University, Incheon, Korea, Republic of

Background: Lung cancer remains the leading cause of cancer-related deaths worldwide. Among its molecularly defined subsets, EML4-ALK rearranged non-small cell lung cancer (NSCLC) is a distinct subtype (3-5% of NSCLC), occurring disproportionately in younger, non-smoking patients. Despite the clinical success of next-generation ALK tyrosine kinase inhibitors (TKIs), including alectinib and lorlatinib, most patients eventually experience disease relapse due to adaptive signaling and bypass mechanisms. The prognosis of relapsed ALK-positive NSCLC is poor, underscoring the critical need to identify novel therapeutic targets that drive tumor growth and survival. We have previously demonstrated that TRIB2, a pseudokinase, promotes tumor growth and therapy resistance in tumors treated with targeted therapy. We therefore evaluated TRIB2 expression in ALK-rearranged lung cancer cell lines and assessed the effects of TRIB2 downregulation on tumor cell growth and viability.
Methods: TRIB2 expression was assessed, and its functional role was tested using shRNA and CRISPR-Cas9-mediated depletion, and pharmacologic inhibition approaches. Cell viability, apoptosis, and downstream signaling changes were analyzed in vitro, while xenograft studies evaluated tumor growth *in vivo*. Synergy studies were performed combining TRIB2 inhibition with ALK inhibitors.
Results: TRIB2 was found to be highly expressed in ALK-positive cell lines and lung tumors. Genetic inhibition of TRIB2 using shRNA significantly suppressed proliferation and induced apoptosis in ALK-positive NSCLC cells. *In vivo*, Dox-induced CRISPR-Cas9-mediated depletion of TRIB2 resulted in significant tumor regression in xenograft models, highlighting its critical role in tumor maintenance. Combination studies revealed that TRIB2 inhibition synergized with ALK-TKIs such as alectinib or lorlatinib to more effectively suppress cancer cell growth than either approach alone. Mechanistic studies demonstrated that TRIB2 loss attenuated ALK signaling, reducing phosphorylation of key survival effectors including STAT3, thereby impairing downstream pathways essential for cell survival and tumor progression.
Conclusions: This study identifies TRIB2 as a critical survival factor in ALK-rearranged NSCLC and establishes its inhibition as a promising therapeutic strategy. TRIB2 targeting not only disrupts tumor maintenance but also enhances sensitivity to ALK TKIs, offering a potential approach to extend the durability of therapeutic responses. These findings provide strong translational rationale for developing TRIB2-targeted therapies to improve outcomes for patients with ALK-positive lung cancer.

#2986 Vertical inhibition of the autophagy pathway promotes growth arrest and apoptotic cell death in pancreatic ductal adenocarcinoma.

Mallory K. Roach[1], Jonathan M. DeLiberty[1], Seamus Degan[2], Lily M. Pita[2], Elyse G. Schechter[2], Noah L. Pieper[2], Runying Yang[2], Mariaelena Pieronon[3], Clint A. Stalnecker[2], Emanuel Frank Petricoin[3], Kirsten L. Bryant[2]

[1]Department of Pharmacology, University of North Carolina at Chapel Hill, Chapel Hill, NC,[2]Lineberger Comprehensive Cancer Center, University of North Carolina at Chapel Hill, Chapel Hill, NC,[3]Center for Applied Proteomics and Molecular Medicine, George Mason University, Manassas, VA

Pancreatic ductal adenocarcinoma (PDAC) is dependent on autophagy for growth. The sole FDA approved inhibitor of autophagy, chloroquine/hydroxychloroquine (CQ/HCQ), inhibited the growth of multiple preclinical models of PDAC. However, clinical trials using CQ alone or in combination with standards of care have shown that CQ has limited clinical efficacy. To identify genes to target as sensitizers to CQ treatment, we performed a CQ-anchored CRISPR-Cas9 mediated loss-of-function screen. We identified multiple autophagy-related genes. This result led us to hypothesize that concurrent inhibition of two nodes (i.e. vertical inhibition) of the autophagy pathway is a more effective method of inhibiting cell growth. Specifically, loss of *PIK3C3*, the gene that encodes VPS34, a protein essential for autophagosome nucleation, sensitized PDAC cells to CQ treatment. We validated this finding via both genetic depletion and pharmacological inhibition with the compound SAR405. Additionally, pharmacological inhibition of ULK1/2, the serine/threonine kinases critical for autophagy initiation, further reduced CQ-mediated anti-proliferative effects. We recently demonstrated that inhibition of the lipid kinase PIKfyve with apilimod potently suppressed autophagy in PDAC. We found that both ULK1/2 and VPS34 inhibitor treatment sensitized cells to PIKfyve inhibition.To elucidate the mechanisms driving decreased cellular proliferation following combination treatment, we explored both autophagy-dependent and -independent pathways using reverse phase protein array (RPPA) based protein pathway activation mapping. We determined that vertical autophagy inhibition resulted in metabolic rewiring including enhanced receptor tyrosine kinase and PI3K-AKT-mTORC1 signaling. Furthermore, by monitoring levels of the autophagy-related protein LC3B following CQ or apilimod treatment alone or in combination with ULK1/2 inhibition, we demonstrated that vertical autophagy inhibition impairs both autophagosome formation and autophagosome processing, simultaneously. We also found that cleaved caspases accumulated more in the presence of two autophagy inhibitors. We validated this finding using Annexin V apoptosis assays and demonstrated that growth suppression was due in part to enhanced apoptotic cell death. In summary, our findings demonstrate that vertical inhibition of the autophagy pathway more effectively suppresses autophagy and increases cell death in PDAC and provides rationale for a vertical inhibition strategy to enhance the therapeutic efficacy of autophagy inhibition.

#2987 Cordycepin inhibits Intrahepatic cholangiocarcinoma progression by targeting NAT10-mediated ac4C RNA modification of VCAN.

Yuting Zhao[1], Yinzhao Chen[1], Yuhan Fang[1], Kai Luo[2], Jialin Qu[3], Dong Shang[3], **Caiming Xu**[4], Guixin Zhang[2]

[1]Dalian Medical University, Dalian, China,[2]The Second Hospital of Dalian Medical University, Dalian, China,[3]The First Affiliated Hospital of Dalian Medical University, Dalian, China,[4]Beckman Research Institute of The City of Hope, Monrovia, CA

Background: Intrahepatic cholangiocarcinoma (ICC) is an aggressive malignancy with poor prognosis. Among RNA modifications that drive tumor progression, N4-acetylcytidine (ac4C) mediated by NAT10 is crucial for RNA stability and translation. Cordycepin, a bioactive compound from Cordyceps sinensis, has known antitumor activity, yet its impact on ICC via RNA-modification pathways remains unclear. This study examines how cordycepin targets the NAT10-ac4C axis to inhibit ICC, providing mechanistic support for RNA-modification-based therapy.

Methods: The antiproliferative effects of cordycepin on HUCCT1 and RBE cells were quantified using CCK-8 assays to determine IC_{50} values. Western blotting was employed to profile RNA-modifying enzymes and identify ac4C/NAT10 as potential targets. The effects of cordycepin on cellular phenotypes were systematically assessed via CCK-8, EdU incorporation, colony formation, flow cytometry, Transwell migration and invasion, and wound-healing assays. Direct cordycepin-NAT10 interaction was validated by molecular docking, cellular thermal shift assay (CETSA) and drug affinity responsive target stability (DARTS) analysis. Global ac4C levels were examined by dot blotting. RNA-seq combined with acRIP-seq was used to define downstream ac4C-regulated genes. Antitumor efficacy was further evaluated in C57BL/6 mouse subcutaneous ICC xenograft models.

Results: Cordycepin exhibited IC_{50} values of 67.18 μM in HUCCT1 cells and 75.50 μM in RBE cells. It markedly suppressed proliferation, migration, and invasion while inducing apoptosis in a dose-dependent manner ($P < 0.05$). Cordycepin significantly reduced NAT10 protein abundance and global ac4C modification levels ($P < 0.05$). Docking analysis predicted a binding energy of −7.0 kcal/mol, and CETSA together with DARTS confirmed direct target engagement. Integrative RNA-seq and acRIP-seq analyses identified VCAN, an extracellular matrix-associated gene, as a principal ac4C-regulated downstream effector. Cordycepin decreased both ac4C enrichment and expression of VCAN, whereas NAT10 overexpression reversed these effects. In vivo, cordycepin substantially suppressed tumor growth, reflected by reduced tumor volume and weight ($P < 0.05$). Correspondingly, NAT10 and VCAN expression in tumor tissues were significantly downregulated.

Conclusion: This study demonstrates that cordycepin directly targets NAT10, attenuating its expression and global ac4C modification, thereby suppressing the downstream oncogenic effector VCAN and restraining ICC progression. These findings underscore the central role of the NAT10-ac4C axis in cordycepin's antitumor activity and identify this pathway as a promising therapeutic target in ICC.

#2988 A druggable genome screen identifies b-catenin transcription targets as desmoid cell vulnerabilities.

Jia Hu[1], Tianjie Pu[1], Vladislav Tsiperson[1], Lakshana Senthilkumar[1], Katherine Prendergast[2], Narasimhan P. Agaram[1], Marco Russo[1], Sameul Singer[1], Ralph Garippa[1], Meera Hameed[1], Aimee Crago[1]

[1]Memorial Sloan Kettering Cancer Center, New York, NY,[2]NYU Langone Health, New York, NY

Background: Desmoid-type fibromatosis (DT) is a rare mesenchymal neoplasm associated with *CTNNB1* activating. DT have variable biologic behavior not explained by secondary genomic events, and in aggressive tumors, local progression can cause significant morbidity. We performed a druggable genome screen to better understand β-catenin function in DT and nominate potential therapies for DT treatment.

Experimental design: A lentiviral shRNA screen (LT3GEPIR backbone) was performed in a primary DT cell line overexpressing TERT (DES9525T). Cell proliferation, cell cycle, gene expression and protein accumulation/localization after pharmacologic inhibition or gene silencing were assessed by CyQuant, Guava Cell Cycle reagent, RNA-seq, and immunoblot in whole cells or after subcellular fractionation (NE-PER extraction), respectively.

Results: 75 significantly enriched and 20 significantly depleted genes were identified in DT cells. Among the genes that had the most significant effects on proliferation were *MDM2*, *BRD4* ($p<0.001$, FC=0.25, 0.31) and *XPO1* (encoding exportin-1; $p<0.002$, FC=0.26) while shRNA targeting *TP53* and *CDKN1A* induced proliferation. Inhibition of exportin-1 with selinexor or shRNA directed at *XPO1* inhibited proliferation (by 51%, $p<0.05$), but failed to affect β-catenin subcellular localization as in other systems. It did have canonical effects on p53/p21 signaling with increased protein levels observed in treated DT cells. Inhibition of MDM2 with milademetan or shRNA similarly increased p53 and p21 and reduced proliferation (by 60%, $p<0.05$). In both cases, p53 induction was associated with G_1 cell cycle arrest. BRD4 inhibition via shRNA or treatment with birabresib reduced proliferation (85%, $p<0.01$) but did not affect p53/p21 signaling. Instead BRD4 inhibition decreased transcription of genes indirectly regulated by β-catenin including potential oncogenes *TNC*, *TGFBI*, and *PITX2*. RNA-seq, ChIP-seq and ChIP-PCR showed that *BRD4* transcription was directly regulated by β-catenin binding to the gene. *MDM2* transcription was also directly modulated by β-catenin, but in its case β-catenin binding to the gene appeared to result in transcriptional repression.

Conclusion: BRD4, MDM2 and XPO1 were identified as potential therapeutic targets in DT with gene products modulating p53/p21 or β-catenin activity. Both *BRD4* and *MDM2* represent direct transcriptional targets of β-catenin though negative regulation of *MDM2* in the context of DT cell dependency on its protein product suggest secondary genetic events or environmental signaling may be necessary to counteract this potential tumor suppressive effect of β-catenin.

#2989 ONCO Prime platform enables discovery of synthetic lethal targets for genetically stratified cancers.

Andrzej Mazan[1], Eliza Zimolag[1], Joanna Szuszkiewicz[1], Marcin Serocki[1], Oleksii Bryzghalov[1], Izabella Wieckowska[1], Marcelina Chmiel[1], Katarzyna Sarad[1], Julia Wirkijowska[1], Wiktoria Luczak[1], Szymon Woroszylo[1], Dariusz Klonski[1], Kamil Kus[1], Andrew Thomason[1], Michal Mikula[2], Rafal Dziadziuszko[3], Krzysztof Brzozka[1]

[1]Ryvu Therapeutics, Krakow, Poland,[2]Maria Skłodowska-Curie Institute of Oncology, Warsaw, Poland,[3]Medical University of Gdansk, Gdansk, Poland

Colorectal cancer (CRC) remains a leading cause of cancer mortality, underscoring the need for new, mechanism-based therapeutic strategies. Using the ONCO Prime discovery and validation platform, based on genome wide CRISPR/Cas9 screenings across clinically relevant models, we identified novel treatment options for genetically stratified CRC patients The ONCO Prime platform integrates healthy human intestinal stem cells (hISCs), isogenic CRC models carrying key driver mutations (*APC*, *KRAS*), and patient-derived primary cultures. All types of models can be genetically manipulated or used in the high-throughput setting for the drug testing. Transcriptomic and machine learning analyses confirmed that these models faithfully recapitulate CRC molecular diversity and clinical behavior. Systematic CRISPR/Cas9 loss-of-function screenings revealed multiple synthetic lethal (SL) interactions, uncovering target genes with first-in-class therapeutic potential. Additionally, using a clinical grade drug that is FDA-approved in other indications, we achieved proof of concept in genetically stratified CRC models, demonstrating strong efficacy as monotherapy in vitro. These data validate ONCO Prime's translational capability to uncover clinically actionable vulnerabilities and deliver tangible therapeutic candidates. This work provides a robust foundation for drug discovery programs and strategic partnerships built on ONCO Prime's ability to bridge functional genomics with therapeutic development. Our first proof of concept establishes ONCO Prime as a scalable platform to drive the next generation of precision, first-in-class oncology therapies.

#2990 PSMA expression in neoplastic cells and tumor-associated vasculature: A tissue microarray study evaluating 12,409 cancers from 135 different tumor types.

Fiete Gehrisch[1], Alexandra Malinowski[1], Anne Menz[1], Florian Lutz[1], Viktoria Chirico[1], Florian Viehweger[1], David Dum[1], Ria Schlichter[1], Andrea Hinsch[1], Christoph Fraune[1], Christian Bernreuther[1], Seyma Buyucek[1], Martina Kluth[1], Claudia Hube-Magg[1], Georgia Makrypidi-Fraune[1], Nina Schraps[1], Katharina Moller[1], Andreas M. Luebke[1], Patrick Lebok[1], Guido Sauter[1], Maximilian Lennartz[1], Frank Jacobsen[1], Till S. Clauditz[1], Andreas H. Marx[2], Ronald Simon[1], Stefan Steurer[1], Eike Burandt[1], Nathalia Gorbokon[1], Maria C. Tsourlakis[1], Sarah Minner[1], Till Krech[1], Morton Freytag[1], Viktor Reiswich[1]

[1]Institute of Pathology, University Medical Center Hamburg-Eppendorf, Hamburg, Germany,[2]Department of Pathology, Academic Hospital Fuerth, Fuerth, Germany

Prostate-specific membrane antigen (PSMA) is a transmembraneous glycoprotein that serves as a diagnostic and therapeutic target in prostate cancer. Beyond prostate malignancies, PSMA expression can also be detected in tumor cells and in endothelial cells (ECs) of newly formed, tumor-associated blood vessels across various other malignancies. To evaluate the prevalence of PSMA expression in both tumor cells and tumor-associated neovasculature, 12,409 tumors from 135 different tumor types, were analyzed by immunohistochemistry in a tissue microarray format. PSMA positivity in tumor cells was detected in 46 tumor entities, including 13 with at least one strongly positive case. Tumor cell PSMA positivity was frequently observed in prostatic adenocarcinoma (84.2-98.7%), granular cell tumor (76.5%), basal cell adenoma of the salivary gland (64.3%), as well as in endometrial (up to 60.7%) and ovarian carcinomas (up to 13.8%). In prostate cancer, PSMA expression was higher in Gleason 4+4 and 5+5 cancers (96.4-98.7%) compared to Gleason 3+3 cancers (94.7%), while it was lowest in recurrent cancers after hormonal therapy (84.2%; p<0.0001). In breast cancer of no special type, PSMA positivity was linked to high grade (p=0.0451), ER- (p=0.0279), and PR-negativity (p=0.0135). PSMA positivity in ECs of tumor-associated vasculature occurred in 4,888 of 10,658 (45.9%) tumors. 123 tumor entities had at least one case with PSMA positive ECs, 106 included at least one sample with many PSMA-positive vessels and 102 had at least one case with strong vessel positivity. EC PSMA positivity was most frequent in renal cell carcinoma (RCC) (88.7-88.9%), adenocarcinoma of the uterine cervix (82.4%) endometrioid endometrial carcinoma (76.7%), colorectal adenocarcinoma (70.5%), cholangiocarcinoma (66.7%), chondrosarcoma (63.5%), HCC (62.5%), and squamous cell carcinomas from different sites (up to 88.2%). The number of positive vessels tightly correlated with their staining intensity (<0.0001) and both parameters were often associated with features of cancer aggressiveness. PSMA staining quantity and intensity in vessels were associated with tumor stage (p=0.0343), tumor grade (p<0.0001), ER- (p=0.0002) and PR-negativity (p=0.0351) in invasive breast carcinoma, multiple grading and staging systems (p=0.0022-0.0388) in clear cell RCC, Fuhrman grade (p=0.0091) and metastatic disease (p=0.0175) in papillary RCC, pT stage (p<0.0001) in urothelial carcinoma, pT stage (p=0.0459), nodal positivity (p=0.0089) and lymphatic invasion (p=0.0023), mismatch repair (MMR) deficiency (p=0.0178) and *BRAF* mutations (p=0.0026) in colorectal adenocarcinoma, and MMR deficiency (p=0.0089) in gastric adenocarcinoma. It is concluded that PSMA expression in tumor cells is largely limited to few cancer entities while EC positivity is common in a broad range of cancer types.

#2991 Superior detection of NTRK fusions across Chinese solid tumors using amplicon-based DNA and RNA NGS co-detection compared with hybrid-capture DNA-NGS.

Mingqian Lu

Yichang Central People's Hospital, Yichang City, China

Background: NTRK fusions are clinically actionable drivers across many solid tumors, with several tumor-agnostic targeted therapies approved. Traditional DNA-based assays often lack sensitivity for NTRK rearrangements. Although RNA-NGS improves fusion detection, the relative performance of amplicon-based DNA+RNA NGS co-detection versus hybrid-capture DNA-NGS for identifying NTRK fusions in pan-solid tumors remains unclear.
Methods: This study analyzed NTRK fusion detection across 16,546 tumors using a 35-gene amplicon-based DNA+RNA NGS co-detection and 4,709 tumors using hybrid-capture DNA-NGS. Tumor types included BRCA, COAD, HNSC, melanoma, NSCLC, PAAD, SARC, THCA, BTC, and STAD. Specifically, the co-detection cohort consisted of BRCA (27), COAD (3,839), HNSC (39), melanoma (111), NSCLC (11,242), PAAD (89), SARC (61), THCA (62), BTC (310), and STAD (766), whereas the DNA-NGS cohort included BRCA (126), COAD (857), HNSC (79), melanoma (42), NSCLC (2,504), PAAD (184), SARC (67), THCA (62), BTC (398), and STAD (446).
Results: Amplicon-based DNA+RNA NGS co-detection demonstrated higher NTRK fusion positivity across multiple solid tumors, including BRCA (2/27, 7.41%), COAD (7/3,839, 0.19%), HNSC (1/39, 2.56%), melanoma (1/111, 0.90%), NSCLC (18/11,242, 0.16%), PAAD (2/89, 2.25%), SARC (1/61, 1.64%), and THCA (1/62, 1.61%), with no NTRK fusions detected in BTC or STAD. All 33 fusions detected by Amplicon-based DNA+RNA NGS were classical 5′-3′ events, with predominant fusion partners including TPM3-NTRK1(42.42%), SQSTM1-NTRK3(12.12%), CD74-NTRK1(9.09%), and several rare forms involving LMNA-NTRK1(3.03%), KIF5B-NTRK2(3.03%), ETV6-NTRK3(21.21%), AKAP13-NTRK3(3.03%), CD74-NTRK3(3.03%), EML4-NTRK3(3.03%). In contrast, hybrid-capture DNA-NGS showed generally lower detection rates across the same tumor types, identifying only sporadic NTRK-positive cases in COAD (1/857, 0.12%), NSCLC (4/2,504, 0.16%), BTC (1/398, 0.25%, NTRK1), and STAD (1/446, 0.22%), and none in BRCA, HNSC, melanoma, PAAD, SARC, or THCA. Among the fusions detected by hybrid-capture DNA-NGS, all but one were classical 5′-3′ rearrangements; a single NSCLC case harbored a non-canonical 5′-5′ ETV6-NTRK3 fusion. Fusion partners detected by this method included PIGR-NTRK1, NTRK1-RHBG, NTRK1-HAPLN2, NTRK1-S100A12, NTRK2-TMPRSS2, and ETV6-NTRK3. Collectively, co-detection demonstrated a markedly broader fusion spectrum and substantially improved sensitivity, particularly in BRCA, COAD, HNSC, and PAAD.
Conclusion: Amplicon-based DNA+RNA NGS outperformed hybrid-capture DNA-NGS in sensitivity and fusion-partner breadth, highlighting the importance of RNA analysis in routine testing for NTRK-guided tumor-agnostic therapy.

#2992 The role of FOXD1 in the anaplastic transformation of thyroid cancer.

Aki Inase[1], Mitsuyoshi Hirokawa[2], Miyoko Higuchi[2], Naoyoshi Onoda[3], Takuya Higashiyama[3], Taiji Koyama[1], Shiro Kimbara[1], Masanori Teshima[4], Hironobu Minami[1], Ken-Ichi Nibu[4], Mitch A. Phelps[5], Naomi Kiyota[1]

[1]Department of Medical Oncology and Hematology, Kobe University Graduate School of Medicine, Kobe, Japan,[2]Department of Diagnostic Pathology and Cytology, Kuma Hospital, Kobe, Japan,[3]Department of Surgery, Kuma Hospital, Kobe, Japan,[4]Department of Otorhinolaryngology-Head and Neck Surgery, Kobe University Graduate School of Medicine,, Kobe, Japan,[5]Ohio State University College of Pharmacy, Columbus, OH

Background: Anaplastic thyroid carcinoma (ATC) is a rare and highly aggressive malignancy. ATC can occur *de novo*, but accumulating pathological and genomic evidence suggests that a subset may arise through progressive dedifferentiation of pre-existing differentiated thyroid carcinoma (DTC), most commonly papillary thyroid carcinoma (PTC). Supporting this concept, coexistent PTC has been reported in approximately 20-30% of ATC cases, and genomic studies indicate that additional somatic alterations—such as TERT promoter and TP53 mutations—may drive this transition. However, the molecular mechanisms underlying this dedifferentiation process remain poorly understood. To address this gap, we compared gene expression profiles between well-differentiated PTC regions and undifferentiated ATC regions within the same tumors.
Methods: RNA was extracted from well-differentiated and undifferentiated regions of the same tumor specimens (FFPE) obtained from six ATC cases. After RNA extraction, RNA libraries were prepared and sequenced using the Illumina NovaSeq 6000 platform, and comparative gene expression analysis was performed. To evaluate the impact of FOXD1 (Forkhead Box D1) on chemosensitivity, siRNA-mediated knockdown was performed, and cell viability after doxorubicin or paclitaxel treatment was assessed using the CCK-8 assay in two ATC cell lines (OCUT-1C and OCUT-1F). To investigate the regulatory mechanism of FOXD1 expression, methylation analysis of the FOXD1 promoter region was performed by bisulfite sequencing in a PTC cell line (KTC-1), OCUT-1C, and OCUT-1F.
Results: Gene expression and KEGG pathway analyses showed EMT activation in ATC. Among transcription factors upregulated in the undifferentiated regions, FOXD1 was consistently overexpressed and therefore selected for further investigation. TGF-β-induced EMT of KTC-1 cells increased the expression of FOXD1 and the EMT-related transcription factors SNAI1 and SNAI2. qRT-PCR analysis revealed that siRNA suppression of FOXD1 altered the expression of EMT-related genes (CDH1, CDH2, SNAI1, SNAI2), whereas knockdown of SNAI1/2 did not affect FOXD1 expression. In both OCUT-1C and OCUT-1F cell lines, FOXD1 suppression restored sensitivity to doxorubicin and paclitaxel. Bisulfite sequencing revealed that the FOXD1 promoter was demethylated in OCUT-1C and OCUT-1F compared to KTC-1.
Conclusions: These findings suggest that FOXD1 contributes to the dedifferentiation process from PTC to ATC. Moreover, restoration of chemosensitivity upon FOXD1 knockdown indicates that FOXD1 could be a promising therapeutic target for ATC. Future studies will further validate FOXD1 expression in additional clinical samples and perform functional analyses using FOXD1-knockout cell lines.

#2993 Deciphering the key role of the glycosyltransferase GALNT14 in osteosarcoma tumorigenesis.

D. Isabel Petrescu[1], Tajhal D. Patel[2], Shoshana Leeds[3], Jeffrey Ritzenthaler[4], Heath Bradley[4], Juan Dou[4], Jason T. Yustein[4]

[1]Graduate Program in Genetics and Molecular Biology, Emory University, Atlanta, GA,[2]Dept of Pediatric Oncology, Baylor College of Medicine, Houston, TX,[3]College of Arts and Sciences, Emory University, Atlanta, GA,[4]Aflac Cancer and Blood Disorders Center, Emory University, Atlanta, GA

Osteosarcoma (OS) is the most common primary malignant bone tumor with bimodal incidence by predominantly affecting adolescents and adults 60 years of age and older. Current treatment of OS commonly involves surgical resection and neoadjuvant and adjuvant chemotherapy, which remains insufficient to improve survival for patients with refractory or relapsed OS. We have identified the glycosyltransferase GALNT14 as a potential therapeutic target for OS by incorporating gene expression data from the NIH TARGET database and transcriptomic analysis of institutional patient-derived xenografts (PDXs) from patient tumors demonstrating chemoresistance. High expression of *GALNT14* in patient tumors is associated with reduced survival likelihood and chemosensitivity compared to patient tumors with low *GALNT14* expression. By comparing samples based on percent necrosis, we determined that *GALNT14* is significantly upregulated in patient samples with low (<90%) necrosis, which is associated with reduced overall and relapse-free survival. To gain further insights into the role of *GALNT14* in OS tumorigenesis and chemosensitivity, we have established *in vitro* and *in vivo* OS models of altered *GALNT14* expression either by knock-out (KO) models in high-expressing *GALNT14* OS cell lines or *GALNT14* overexpression (OE) models in low-expressing *GALNT14* OS cell lines. KO models were established by using CRISPR-Cas9 gRNA targets against *GALNT14* in human OS cell lines. OE models were established using lentiviral transduction of human OS cell lines using a vector expressing *GALNT14*. *In vitro* studies demonstrated that loss of *GALNT14* increased chemosensitivity and decreased metastatic potential, assessed through transwell invasion and migration assays. Furthermore, sarcosphere assays demonstrated decreased stem cell properties in our *GALNT14* KO models. We observed reverse effects by *in vitro* studies of cell lines with overexpression of *GALNT14*, suggesting a specific role for *GALNT14* in OS tumorigenesis. In addition, orthotopic *in vivo* studies using immunodeficient mice injected with *GALNT14* KO cell lines displayed decreased tumor growth and metastasis. RNA sequencing comparing *GALNT14* KO and OE models revealed gene signatures and biological pathways related to immune function, leading us to develop syngeneic models of *GALNT14* OE in murine OS cell lines derived from genetically-engineering murine models (GEMMs). We have validated these models at the protein level and are currently assessing their *in vitro* and *in vivo* characteristics. Our results suggest a role for *GALNT14* in contributing to OS tumorigenesis by mechanisms related to therapeutic resistance, metastatic potential, stem cell properties, and/or immune function. Further studies are ongoing to strengthen our mechanistic understanding of the downstream effects dependent on *GALNT14* expression.

#2994 Integrative pathway analysis of I-SPY2 HER2+ breast cancers reveals drug-repurposing opportunities.

Kingsley V. Chow[1], Tam Binh Bui[1], Denise M. Wolf[2], Annuska Glas[3], Zheyun Xu[4], Gillian L. Hirst[5], I-SPY2 investigators, Amy Clark[6], Julia Wulfkhule[7], Angie DeMichele[8], Emanuel Frank Petricoin[7], Laura J. Esserman[5], Jennifer Rosenbluth[9], Laura van 't Veer[1], Rosalyn W. Sayaman[1]

[1]UCSF - University of California San Francisco, San Francisco, CA,[2]UCSF - University of California San Francisco, Berkeley, CA,[3]Quantum Leap Healthcare Collaborative, San Francisco, CA,[4]Yale University, New Haven, CT,[5]UCSF Helen Diller Family Comprehensive Cancer Ctr., San Francisco, CA,[6]University of Pennsylvania-Penn Presbyterian, Philadelphia, PA,[7]George Mason University, Manassas, VA,[8]University of Pennsylvania, Philadelphia, PA,[9]UCSF - University of California San Francisco, Boston, MA

Background: HER2-positive breast cancer (HER2+) accounts for approximately 20% of all breast cancers. Major advances in HER2-targeted therapy have improved outcomes; however, substantial room for response improvement remains. Molecular subtyping by BluePrint (BP) stratifies HER2+ disease into HER2 and Luminal types. While BP-HER2 tumors achieve up to 78% pathologic complete response (pCR) with standard therapy, BP-Luminal tumors exhibit persistently low pCR rates (<15%). To address this unmet need, we profiled pretreatment molecular features distinguishing responders from non-responders across all HER2+ tumors and within BP subtypes to identify druggable pathways for rational combination or repurposing strategies.
Methods: Baseline microarray profiles from 305 pretreatment HER2+ tumors (87 BP-Luminal, 218 BP-HER2) enrolled across five investigational agents or standard of care in the I-SPY2 trial were analyzed using Gene Set Variation Analysis (GSVA) across 2,265 canonical pathway gene sets. Differential pathway enrichment was assessed using linear models adjusting for treatment arm and false-discovery rate. Two comparisons were performed: (1) pCR vs. no pCR overall and within subtypes, and (2) BP-HER2 vs. BP-Luminal. Shared response- and subtype-specific pathways were grouped by functional similarity and cross-referenced with drug-target databases to identify FDA-approved or investigational compounds.
Results: Across HER2+ tumors and within BP-HER2, we identified 42 pathways enriched in non-responders that were also elevated in BP-Luminal relative to BP-HER2, suggesting a luminal-linked resistance program even in non-luminal tumors. These pathways converged into eight metabolic and signaling themes. Growth-factor/RTK bypass (PI3K/AKT) and DNA repair & oxidative stress defense were strongly upregulated in non-responders within BP-HER2, revealing actionable nodes involving PI3K/AKT (alpelisib, capivasertib), IGF1R (linsitinib), MET (crizotinib, capmatinib), and DNA repair (PARP inhibitors). Notably, metabolic rewiring and lipid homeostasis—targetable by vismodegib and sonidegib—were upregulated in non-responders across both BP subtypes, reflecting a shared metabolic vulnerability.
Conclusions: Luminal biology-linked transcriptional programs may persist within the HER2+ BP-HER2 subtype and contribute to resistance. BP-HER2 non-responders exhibit coordinated activation of RTK-bypass and DNA repair pathways, exposing therapeutic vulnerabilities targetable by existing agents. Furthermore, targeting lipid metabolic reprogramming alongside anti-HER2 therapy may enhance efficacy and overcome resistance across both BP subtypes. Our future directions include testing these drug combinations in patient-derived HER2+ organoid models.

#2995 ATRX in-frame fusions promote endogenous chemoresistance programs but yield immunotherapeutic vulnerabilities in neuroblastoma.

Mohammad Ali Mohammad Nezhady[1], Sheetal Bhatara[1], Siarhei Hladyshau[1], Estevez Prado Daniel[1], Vernon Ebegboni[1], Alja Kozulic-Pirher[2], Arnav Barpujari[3], Bo Wang[1], Yuan Feng[1], Qiqi Jin[1], Xueying Liu[1], Paul Geeleher[1], Xiaotu Ma[1], Jiyang Yu[1], Emily Bernstein[2], Kelly Goldsmith[3], Hunter Jonus[3], Adam D. Durbin[1]

[1]St. Jude Children's Research Hospital, Memphis, TN,[2]Icahn School of Medicine at Mount Sinai, New York, NY,[3]Emory University, Atlanta, GA

High-risk Neuroblastomas (NB) carrying in-frame fusion mutations in the ATRX chromatin remodeler("ATRX-IFF") are chemoresistant, and children with these mutations display poor overall survival. There are no specific agents to target these tumors, and the mechanisms driving chemoresistance remain unknown. To gain insight into the mechanisms of chemoresistance, we used scRNAseq in combination with cisplatin to study if cellular plasticity drives chemoresistance. In contrast to non-ATRX-IFF-bearing NBs, *ATRX*-IFF NBs did not appear to display transcriptionally plastic subpopulations, suggesting that the *ATRX*-IFF promotes an inherent chemoresistance program. To this end, CRISPR-mediated engineering of *ATRX*-IFF into the endogenous locus in wildtype cells, results in enhanced chemoresistance to multiple clinically-used agents. Next, to identify potential targetable proteins directly regulated by the ATRX-IFF, we combined chromatin binding assays with cell surface proteomics. Using cell lines and orthotopic PDXs, we identified that the ATRX-IFF binds to, and nucleates a super-enhancer at the *PTK7* locus, thereby driving extremely high level cell surface expression of PTK7. PTK7 is a pseudokinase receptor that is targeted by experimental CAR-T cell therapies in active preclinical development. Ongoing work is aimed at understanding the dependency of PTK7 on the ATRX-IFF, and using preclinical CAR-T cell models to target PTK7 in *ATRX*-IFF NB.

#2996 Internalization of B7-H3 is enhanced by cholesterol disruption in esophageal cancer cells.

Takashi Imajima, Kenji Tsuchihashi, Takafumi Kitazono, Wataru Kusano, Eishi Baba

Kyushu University, Fukuoka, Japan

B7-H3, a member of the B7-family protein, is highly expressed on cancer cells. An antibody-drug conjugate (ADC) targeting B7-H3 showed potential efficacy in early-phase clinical trials. As endocytosis and subsequent degradation of the ADC drugs are the key processes to release the payload and demonstrate cellular toxicity, alteration in the endocytosis pathway could play a role in the resistance mechanisms or synergistic therapeutic effects. As for HER2-targeted ADCs, one of the most developed ADC targets, some preclinical trials reported a synergistic effect of HER2-targeted ADCs and modulators on the dynamics of HER2 on the cellular membrane, such as membrane cholesterol and HSP90. However, such machinery for B7-H3 and the targeting antibody remains unclear. Thus, we hypothesized that modulating the stability of the membrane B7-H3 could have a synergistic effect with B7-H3 ADC. Using flow cytometry, we evaluated the decrease of surface expression of the targeted antigens as a surrogate marker of their internalization efficacy in TE4, an esophageal squamous cell carcinoma cell line, which showed high expression of both B7-H3 and HER2. Trastuzumab and enoblituzumab, anti-HER2 and -B7-H3 antibodies, respectively, were used to induce endocytosis of target antigens. We validated that there was no epitope interference between therapeutic antibodies, trastuzumab or enoblituzumab, and fluorescent-labelled antibody to detect HER2 or B7-H3. Internalization efficacy was evaluated by comparing surface expression of HER2/B7-H3, between trastuzumab/enoblituzumab and an isotype antibody. The stability at the membrane was modulated by two drugs, pimitespib, an inhibitor of HSP90, and methyl-beta-cyclodextrin (MbCD), a cholesterol disruptor. In flow cytometry analysis, neither pimitespib nor MbCD did not affect the cell surface expression of HER2 and B7-H3. While the pimitespib enhanced trastuzumab-mediated HER2 internalization, enoblituzumab-mediated B7-H3 internalization was not affected. Under MbCD treatment, surface expression of both HER2 and B7-H3 was markedly decreased after administration of targeted antibodies. Additionally, fluorescent immunocytochemistry showed the enhanced internalization of HER2 and B7-H3 molecules at the cell membrane into the cytoplasm. These results suggest that membrane cholesterol, rather than HSP90, might affect the stability of B7-H3 on the cell membrane. In conclusion, membrane cholesterol disruption could enhance the internalization efficacy of HER2 and B7-H3 molecules.

#2997 LTA4H promotes intrahepatic cholangiocarcinoma progression via mTOR activation and T-cell exhaustion.

Ganglian Lin[1], Jinhui Wang[1], Yizhuo He[2], Fangkai Feng[2], **Chongming Zheng**[2], Yi Wang[2]

[1]The First Affiliated Hospital of Wenzhou Medical University, Wenzhou, China,[2]Wenzhou Medical University, Wenzhou, China

Introduction: Intrahepatic cholangiocarcinoma (ICC) is a highly aggressive liver cancer with a poor prognosis. Immune evasion plays a critical role in ICC progression. Leukotriene A4 hydrolase (LTA4H), a key enzyme in eicosanoid metabolism, is overexpressed in multiple cancer types; however, its role and mechanism in ICC remain entirely unexplored.

Methods: LTA4H expression and its prognostic significance were assessed in two independent ICC cohorts (n=130) and cell lines using bioinformatics, immunohistochemistry (IHC), and western blot (WB). LTA4H was genetically modulated in ICC cell lines via lentiviral transduction. Functional impacts on proliferation, migration, and invasion were evaluated by colony formation, real-time cellular analysis, wound healing, and Transwell assays. Spontaneous ICC was modeled in mice via hydrodynamic tail vein injection of a plasmid combination comprising pT3-EF1α-myr-AKT, pT3-EF1α-myr-NICD, and pCMV-SB. Mechanistic insights were investigated through RNA sequencing, metabolomics, and WB. Tumor immune microenvironment was profiled by flow cytometry. The therapeutic efficacy of the LTA4H-specific inhibitor LYS006 was tested in vivo and in patient-derived organoids.

Results: LTA4H was significantly overexpressed in ICC tissues and correlated with poor patient survival. LTA4H overexpression enhanced ICC cell proliferation, migration, and invasion in vitro, and accelerated tumor progression in vivo. Conversely, LTA4H knockdown suppressed these malignant phenotypes. Mechanistically, LTA4H activated the mTOR signaling pathway and induced T-cell exhaustion in the tumor microenvironment. Therapeutic inhibition of LTA4H with LYS006 significantly suppressed tumor growth in mouse models and organoids.

Conclusions: Our study identifies LTA4H as a novel oncoprotein in ICC that drives tumor progression by activating the mTOR pathway and fostering an immunosuppressive microenvironment via T-cell exhaustion. Targeting LTA4H represents a promising therapeutic strategy for ICC.

Clinical Significance: This work unveils the dual pro-tumorigenic functions of LTA4H in ICC and provides a strong rationale for targeting LTA4H, potentially alone or in combination with immunotherapy, for the treatment of this lethal disease.

#2998 Disrupted clock pathway during lineage plasticity and prostate cancer progression.

Nishat Manzar, Himisha Beltran

Department of Medical Oncology, Dana-Farber Cancer Institute, Boston, MA

Most treatment resistant prostate cancers are driven by androgen receptor (AR) signaling. However, AR-negative prostate cancer has been increasingly recognized as the mechanism of resistance, particularly as potent AR-targeted therapies have been introduced earlier in the treatment paradigm. Lineage plasticity and histologic transformation of AR-driven prostate adenocarcinoma to AR-negative neuroendocrine prostate cancer (NEPC) represents one of the most lethal forms of prostate cancer. Here, we explored how the circadian clock pathway changes occur during lineage plasticity and prostate cancer progression. We identified loss of rhythmicity in the expression of clock regulated genes. Clock pathway regulators RORα, BMAL1, and CLOCK are highly expressed in NEPC compared to prostate adenocarcinoma. *RORA* displays marked upregulation in prostate tumors after AR targeted therapy relative to matched pre-therapy tumors. *RORA* overexpression in prostate adenocarcinoma models led to increased cell proliferation and enriched cell cycle pathway. Importantly, we noted that clock pathway is reprogrammed differently in AR-dependent and AR-independent prostate tumors. For instance, *RORA* overexpression in AR-dependent adenocarcinoma cells resulted in enriched androgen response and enhanced sensitivity towards AR-targeted pathway inhibitors. *RORA* knockout in AR-independent models resulted in increased expression of mitochondrial genes and increased sensitivity towards oxidative phosphorylation (OXPHOS) inhibitors. Moreover, targeting RORα in NEPC patient-derived organoids and mouse xenograft models abrogated tumor growth and downregulated the NEPC phenotype. Altogether, our findings point to a mechanistic regulation of clock genes including RORα during prostate cancer progression and nominates potential new strategies to target lineage plasticity.

#2999 Targeting cholesterol pathways in p53 deficient head and neck cancers.

Jovanka Gencel-Augusto[1], Nuo Tian[1], Akshat Singhal[2], Hua Li[3], Liam Woerner[3], Arthur Goldberg[1], Daniel E. Johnson[4], Jennifer Rubin Grandis[5]

[1]Otolaryngology - Head and Neck Surgery, UCSF - University of California San Francisco, San Francisco, CA,[2]UCSD Medical Ctr., San Diego, CA,[3]The University of California, San Francisco, San Francisco, CA,[4]Associate Professor, Dept. of Med. & Pharmacology, UCSF Helen Diller Family Comp. Cancer Center, San Francisco, CA,[5]UCSF - University of California San Francisco, San Francisco, CA

Loss of p53 function is a major driver of poor outcomes in HNSCC, with over 70% of tumors harboring deactivating *TP53* mutations. Despite decades of effort, mutant p53 remains “undruggable”. Cholesterol is essential for membrane integrity and oncogenic signaling, and elevated cholesterol levels correlate with aggressiveness across many cancers. In HNSCC, patients whose tumors express high levels of cholesterol-upregulating genes have a 50% higher risk of death, highlighting this pathway as a clinically relevant therapeutic target. We previously showed that HPV+ HNSCC cells retain wild-type (WT) p53 activity and that p53 transcriptionally regulates multiple metabolic pathways, including cholesterol-regulating genes. These observations led us to investigate how p53 loss rewires cholesterol metabolism and whether this metabolic shift creates a targetable vulnerability in p53-deficient HNSCC. Silencing WT p53 in HPV+ HNSCC cells (siRNA or CRISPRi) increased intracellular cholesterol and proliferation - an effect reversed by cholesterol deprivation. This p53 deficiency also elevated expression and maturation of SREBP1/2, master transcriptional regulators of cholesterol metabolism, along with multiple downstream SREBP targets. Elevated cholesterol and activated SREBP1/2 were similarly observed in HPV-negative p53-mutant HNSCC lines, indicating that p53-dependent cholesterol metabolism is a broader function independent of HPV status. In HNSCC patient-derived xenografts (PDXs), p53-mutant tumors exhibited higher expression and preferential nuclear localization of SREBP1 compared to p53-WT tumors, confirming cholesterol pathway reprogramming *in vivo*. To test pathway dependency, we examined the effects of SREBP1 genetic ablation (via siRNA or in CRISPR knock-out datasets) in HNSCC and other squamous carcinoma lines. SREBP1 loss selectively reduced viability in p53-deficient cells compared with WT counterparts. Pharmacologic inhibition of SREBP1/2 with the small molecule fatostatin also produced an average 2.7-fold greater cytotoxic response in p53-deficient versus p53-proficient HNSCC lines. In isogenic cell line-derived xenograft (CDX) models, fatostatin treatment (315 mg/kg over 32 days) significantly suppressed growth of p53-deficient tumors. A pan-cancer pharmacogenomic screen of >900 cell lines further identified p53 deficiency as a determinant of fatostatin sensitivity. Together, these findings demonstrate that p53 loss confers dependency on SREBP-driven cholesterol metabolism and support therapeutic targeting of this pathway in a genomically defined subset of HNSCC.

#3000 Tumor Treating Fields (TTFields) may weaken glioblastoma network connectivity, with implications for malignancy.

Julius Beichert[1], Jonas A. Kretz[2], Jena Kim[1], Xiaoyu Ma[3], Daniel Dominguez Azorin[2], Andreas E. Moor[2], Haikun Liu[3], **Miriam Ratliff**[1]

[1]Department of Neurosurgery, University Hospital Mannheim, Medical Faculty Mannheim, University of Heidelberg and German Cancer Research Center (DKFZ), Mannheim, Heidelberg, Germany,[2]Department of Biosystems Science and Engineering, ETH Zurich, Basel, Switzerland,[3]Molecular Neurogenetics, German Cancer Research Center (DKFZ), Heidelberg, Germany

Background: Glioblastoma malignancy is strongly driven by the formation of tumor microtubes (TMs), which promote intercellular connectivity and calcium (Ca^{2+}) wave propagation. The mechanisms by which Tumor Treating Fields (TTFields) influence these TM-mediated processes remain incompletely understood.
This study aims to elucidate the effects of TTFields on the structural and functional organization of tumor cell networks and to assess potential frequency-dependent modulation of signaling pathways, including NF-κB.
Methods: A comprehensive set of biological model systems is being utilized, including 2D glioblastoma cell monolayers, 3D brain organoids, and *in vivo*, awake, head-fixed mouse models with chronic cranial windows for longitudinal imaging. Live-cell imaging with confocal and multiphoton microscopy enables real-time observation of morphological and functional tumor dynamics. Quantification of Ca^{2+} signaling is being performed using Cellpose-based segmentation and custom Python analysis pipelines. Immunohistochemistry and spatial transcriptomics (Visium HD) are currently employed to dissect molecular mechanisms; COMET-based immunofluorescence and RNAscope FISH are planned to enable spatially resolved multi-omics.
Results: TTFields induced a marked disruption of glioblastoma network architecture and function. Specifically, treatment resulted in >50% reduction in global GCaMP8s-mediated Ca^{2+} activity, a decrease in pacemaker-like cell populations, and significant reductions in synchronization and Ca^{2+} co-activity within S24 glioblastoma cells in both 2D and 3D models.
Conclusion & Outlook: TTFields disrupt glioblastoma network integrity and Ca^{2+} signaling, potentially reducing tumor aggressiveness. Preliminary data from 3D brain tumor organoids and *in vivo* models support our previous *in vitro* results regarding TTFields-induced activity changes. Parallel studies in patient-derived organoids explore frequency-dependent signaling effects - including NF-κB and MAPK pathways - via spatial transcriptomic profiling. Together, these efforts aim to further elucidate the mechanistic underpinnings of TTFields action and their impact on glioblastoma plasticity and network organization.

#3001 Therapeutic inhibition of oncogenic miR-181a processing for cancer therapy.

Grace McIntyre[1], Jessica Mathew[2], Zoe Jackson[3], Meghana Choragudi[4], Madison Uyemura[1], Aaron Robida[5], Renju Jacob[5], Jose Colina[1], Jiaming Yao[6], Hang Yang Wong[7], Rachel Offenheim[8], Mark Kunkel[9], Sriram Chandrasekaran[3], Peter Toogood[7], Analisa DiFeo[1]

[1]Department of Pathology, University of Michigan, Ann Arbor, MI,[2]Chemistry, College of Literature, Science, and the Arts, University of Michigan, Ann Arbor, MI,[3]Biomedical Engineering, University of Michigan, Ann Arbor, MI,[4]School of Public Health, University of Michigan, Ann Arbor, MI,[5]Center for Chemical Genomics, University of Michigan, Ann Arbor, MI,[6]College of Literature, Science, and the Arts, University of Michigan, Ann Arbor, MI,[7]College of Pharmacy, University of Michigan, Ann Arbor, MI,[8]Medical School, Queens University, Kingston, ON, Canada,[9]Frederick National Laboratory of Cancer Research, National Cancer Institute, Frederick, MD

Background: Oncogenic microRNA-181a (miR-181a) is a master regulator of tumor pathogenesis, driving cancer initiation, progression, metastasis, and immune evasion across diverse cancer lineages by suppressing critical pathways such as STING, WNT, and TGFβ signaling. While genetic ablation of miR-181a is potently anti-tumorigenic and well tolerated, no therapies currently exist targeting miR-181a, presenting a critical therapeutic gap. Targeting miR-181a offers a promising strategy as it regulates multiple oncogenic pathways simultaneously, unlike existing therapies that act on a single target. Nucleotide-based miRNA-targeting therapies have made significant advances with more than 1,300 clinical trials having been conducted to target miRNAs; yet challenges remain in bioavailability, stability, and effective delivery. Therefore, a small molecule pharmacological strategy targeting miR-181a processing represents an attractive alternative with superior pharmacokinetic properties, improved stability, and enhanced delivery potential. Here, we report the discovery and characterization of SMIR-181s (Small Molecule Inhibitors of miR-181a), a novel class of compounds that alter miR-181a biogenesis and suppress cancer properties.

Results: Using a high-throughput biosensor-based screening platform in miR-181a dependent cancer lines, we identified a novel small molecule inhibitor of miR-181a biogenesis. Screening identified a class of seven SMIR-181s, that impair miR-181a maturation, resulting in the accumulation of precursor miR-181a accumulation and depletion of mature. Mechanistic studies reveal that SMIR-181s mediate this depletion by inducing degradation of TARBP2 (Trans-Activating Responsive Binding Protein 2), an RNA-binding protein that acts as a rheostat for stress-induced miRNAs such as miR-181a. Importantly, SMIR-181s display broad cytotoxicity across the NCI-60 cancer cell line panel, with enhanced efficacy in miR-181a high tumor cells while sparing normal cells. Furthermore, these compounds trigger apoptosis and exhibit a novel mechanism of action distinct from all known agents in the NCI-60 database.

Conclusions: Collectively, this work emphasizes miR-181a's potential as a predictive biomarker, establishes proof-of-concept for small molecules that target miRNA processing, and nominates the SMIR-181 class as first-in-class candidates for the treatment of a broad spectrum of miR-181a-driven malignancies.

#3002 Aneuploidy as a metabolic liability: Exploiting novel therapeutic targets in squamous cell carcinomas.

Nadja Zhakula[1], Sejal Jain[2], Zeinab Amini-Farsani[1], Jiankang Zhang[1], Mari Nakamura[1], Laura Byron[3], Joan J. Castellano-Perez[1], Tannishtha Reya[1], Matthew L. Meyerson[2], Alison M. Taylor[4]

[1]Columbia University Irving Medical Center, New York, NY,[2]Dana-Farber Cancer Institute, Boston, MA,[3]Rutgers University, New Brunswick, NJ,[4]Columbia University, New York, NY

Squamous cell carcinomas (SCCs) across epithelial tissues of the lung, head and neck, and esophagus lack canonical oncogenic mutations and urgently require therapeutic strategies. Aneuploidy—chromosomal gains or losses, is detrimental in normal cells yet occurs in >90% of solid tumors in tissue-specific patterns. SCCs exhibit near-universal chromosome 3q gain, which associates with progression, metastasis, and therapy resistance; however, the mechanisms linking aneuploidies to tumorigenesis remain unclear. To investigate aneuploidy-driven dependencies, we engineered isogenic human lung epithelial cells modeling chromosome 3 disomy and 3q gain and performed genome-wide CRISPRi and drug-repurposing screens. Both screens converged on a lipid metabolism dependency specific to 3q gain, with heightened sensitivity to disruption of the sterol regulatory element-binding protein (SREBP) pathway. *SREBF1* emerged as the top genetic hit, while statins (HMGCR inhibitors), were the strongest chemical hits and preferentially induced apoptosis in 3q gain cells. Rescue with mevalonate confirmed on-target effects and additional cholesterol-lowering drugs also induced increased cytotoxicity. Transcriptomic and lipidomic profiling revealed altered cholesterol and fatty acid biosynthesis programs and distinct lipid composition in 3q gain cells. Protein and immunofluorescence analyses further demonstrated impaired SREBP1 activation in 3q gain cells. To identify potential causal gene drivers, we performed a chromosome 3q-focused CRISPRi screen alongside SREBP/HMGCR inhibition. This screen revealed multiple gene candidates—including *TFG*, *SEC62*, *SERP1*, and *RAB43*—whose knockdown rescued drug-induced loss of viability, implicating ER-to-Golgi transport and cellular stress pathways in altered SREBP1 activation. Ongoing studies are determining whether these mechanisms directly explain reduced pathway activation in 3q gain cells. To assess translational relevance, we validated these dependencies in isogenic organoids and SCC cell lines. *In vivo* xenograft studies demonstrated that 3q gain SCC tumors exhibit increased sensitivity to suppression of SREBF1 and HMGCR, leading to reduced tumor volume and weight. These findings support chromosome 3q gain as a biomarker of pathway inhibitor response. Together, our results define an aneuploidy-driven, targetable metabolic vulnerability in SCC. Chromosome 3q gain imposes a metabolic cost that creates actionable therapeutic dependencies, nominating lipid metabolism and mevalonate pathway regulators as precision therapy targets for aneuploid SCC.

#3003 Impact of sequencing technology on actionable fusion detection in precision oncology for lung cancer.

Gabriel Bandeira do Carmo[1], Rafael Canfield Brianese[1], Karina Miranda Santiago[1], Adriano Bonaldi[2], Marina De Brot Andrade[3], Giovana Tardin Torrezan[1], Dirce Maria Carraro[1]

[1]Clinical and Functional Genomics Group, A.C.Camargo Cancer Center, Sao Paulo, Brazil,[2]Laboratory of Genomic Diagnostics, A.C.Camargo Cancer Center, Sao Paulo, Brazil,[3]Department of Anatomic Pathology, A.C.Camargo Cancer Center, Sao Paulo, Brazil

Precision oncology has transformed the management of non-small cell lung cancer (NSCLC), where identifying targetable genomic alterations is central to selecting targeted therapies and improving outcomes. Among these relevant biomarkers, gene fusions represent key actionable events in NSCLC. Because many fusions generate chimeric transcripts rather than recurrent DNA-level breakpoints, RNA-based next-generation sequencing (NGS) has become essential in the molecular evaluation of lung cancer. These assays may differ substantially in gene content and sequencing technology, factors that influence fusion detection and the identification of clinically actionable biomarkers. Understanding how sequencing strategies affect diagnostic yield is therefore crucial for implementing precision oncology in NSCLC. This study compared two RNA-based NGS assays, TruSight Oncology 500 (TSO-500)-RNA (Illumina) and Oncomine Focus Assay (OFA)-RNA (Thermo Fisher), to evaluate their performance in detecting actionable fusions in NSCLC. RNA extracted from 35 NSCLC tumors (IRB: 2496/18) was analyzed in both platforms. TSO-500-RNA uses a hybrid-capture strategy, interrogating 55 genes and enabling the detection of both known and novel partners, requiring at least 80 ng of RNA input. OFA-RNA employs AmpliSeq amplicon-based technology, targeting 23 predefined genes and requiring only 10 ng of RNA. Fifteen fusions were identified in 13 of 35 tumors (37.2%): thirteen were identified uniquely by TSO-500-RNA, while two (*CD74::ROS1* and *KIF5B::RET*) were detected by both panels. Among the 23 genes included in both assays, one actionable fusion (*TRIM33::RET*) was exclusively detected by TSO-500-RNA. Overall, OFA-RNA detected actionable events in 6% of tumors, whereas TSO-500-RNA detected 9%. Most discrepancies were a result of hybrid-capture's greater flexibility to detect novel or noncanonical fusion partners. TSO-500-RNA also detected *YAP1::KMT2A*, an oncogenic fusion with approved therapies in other cancer types, but outside OFA-RNA's target list. Importantly, no discordances were observed when both assays covered the same gene regions, demonstrating technical robustness of both assays within their designed scope. In conclusion, the sequencing strategy is a major determinant of fusion detection in NSCLC. The hybrid-capture-based TSO-500-RNA enables broader gene coverage and discovery of novel fusion partners, resulting in a higher detection rate. Conversely, the amplicon-based OFA-RNA offers reliable detection of predefined fusions with lower RNA input, a critical advantage when working with limited tumor samples. Both features, comprehensive fusion discovery and compatibility with low-input, are essential to fully support precision oncology. Therefore, panel selection should balance tissue availability with the need for broad fusion detection to guide therapeutic decisions in NSCLC.

#3004 OXTR targeted local therapy could be a promising strategy for pleural mesothelioma.

Ichidai Tanaka[1], Hideyuki Itoigawa[1], Kazumi Hori[1], Shoichiro Fukuda[2], Heng Huang[1], Haruka Takata[2], Taketo Kato[1], Mitsuo Sato[1], Yoshitaka Sekido[3], Shinobu Shimizu[1], Tatsuhiro Ishida[2], Toyofumi Fengshi Yoshikawa[1], Makoto Ishii[1]

[1]Nagoya University Graduate School of Medicine, Nagoya, Japan,[2]Tokushima University, Tokushima, Japan,[3]Aichi Cancer Center, Nagoya, Japan

Introduction

Mesothelioma is one of the most aggressive neoplasms worldwide and has an extremely poor prognosis. We have previously discovered that oxytocin receptors (OXTR) are highly expressed in mesothelioma and *OXTR* knockdown significantly decreases the proliferation of mesothelioma cells with high-*OXTR* expression by disturbing the tumor cell cycle. Furthermore, the OXTR inhibitor, cligosiban, demonstrated antitumor efficacy in vivo. However, systemic administration required high doses, raising concerns about systemic toxicity. Therefore, we explored a local treatment strategy using intrathoracic drug delivery, and developed a dissolved formulation of cligosiban to enhance drug accumulation.

Methods

To establish a treatment method for localized control via trans-thoracic administration against pleural mesothelioma, the antitumor effect of a dissolved cligosiban in levulinic acid was evaluated in several mesothelioma cell lines. For *in vivo* analysis, an intrathoracic mesothelioma xenograft model was established with nude mice, and the therapeutic efficacy of intrathoracic administration of the dissolved cligosiban was examined.

Results

In vitro, dose-response experiments in two mesothelioma cell lines with high-*OXTR* expression demonstrated significant concentration-dependent changes in cell viability at micromolar concentrations. In parallel, the dissolved cligosiban significantly decreased the expression of cell-cycle-regulatory genes, including *Cyclin-dependent kinase 1* and *Cyclin E2* in the two mesothelioma cell lines with *OXTR*-high expression. In an orthotopic Y-MESO-27 model established by intrathoracic injection of mesothelioma cells with high-*OXTR* expression into nude mice, intrathoracic administration of the dissolved cligosiban at 50-400 µM was performed. Administration at 100 µM every other day clearly suppressed tumor growth and demonstrated a statistically significant prolongation of survival. Similar trends were observed in an intrathoracic MSTO-211H model, which is mesothelioma cells with low-*OXTR* expression. Next, we implanted the Alzet osmotic pump into the mice subcutaneous tissue and continuously administered total 400 µL (100 µM) of the dissolved cligosiban into the mice thoracic cavity. With injection rate at 1µl/hr, the dissolved cligosiban significantly prolonged mice survival.

Conclusion

Intrathoracic administration of the dissolved cligosiban effectively suppresses mesothelioma progression, representing the first demonstration of OXTR-targeted local therapy as a promising strategy for pleural mesothelioma.

#3005 *Ex vivo* trial of ODM-212, a novel pan-TEAD inhibitor, in patients with primary and metastatic solid tumors.

Juha K. Rantala[1], Eetu Valimaki[2], Janne Suhonen[1], Reetta Riikonen[3], Anu-Maarit Moilanen[3]

[1]Orion Corporation, Espoo, Finland,[2]Misvik Biology, Turku, Finland,[3]Orion Corporation, Turku, Finland

BACKGROUND: The Hippo signaling pathway is a highly conserved signaling cascade that controls the activation or inactivation of YAP/TAZ proteins. In cancer cells, genomic alterations can result in deactivation of the Hippo pathway and consequent hyperactivation of the YAP/TAZ to promote oncogenesis. Since YAP/TAZ induce the oncogenic effects by binding to TEAD transcription factors, TEAD targeting has emerged as a therapeutic opportunity in various solid cancers. ODM-212 is a novel small molecule that binds specifically to all TEAD/TEF transcription factors (TEAD1-4). ODM-212 effectively inhibits growth and viability of patient-derived solid tumor models with or without hippo pathway genetic alterations. Here we present pan-cancer *ex vivo* efficacy and biomarker discovery results of ODM-212 in primary and advanced solid tumors.

METHODS: Parallel to an ongoing multi-site, open-label, first-in-human study of ODM-212 in advanced solid tumor (TEADES, NCT06725758), ODM-212 therapy efficacy was studied using *ex vivo* drug screening in patient-derived functional tumor models. Vital tumor cells dissociated from excess tissues obtained in context of patients´ standard therapy were used to assess ODM-212 and 150 other therapies while DNA sequencing was used for exploratory biomarker evaluation. To assess predictive value of *ex vivo* drug screening, the results will be correlated with observed responses in eligible patients upon completion of the TEADES study.

RESULTS: 395 (n=46 solid cancer types) patient-derived tumor samples were included in the *ex vivo* study of ODM-212 efficacy. 83/395 samples were derived from primary untreated tumors and rest from recurrent metastatic tumors. Largest individual indications included, bladder cancer (n=45), brain tumors (n=61), HNSCC (n=93), lung cancer (n=20), melanoma (n=21) and sarcoma (n=27). ODM-212 demonstrated potent anti-tumor activity in select patient samples across all included main anatomical sites supporting genomic medicine approaches for patient stratification. Highest therapeutic efficacy was seen in Hippo pathway altered, KRAS and YAP driven solid tumors.

CONCLUSIONS: ODM-212 shows potent pan-cancer *ex vivo* efficacy in both primary untreated and heavily pre-treated metastatic tumors. Single agent efficacy correlates with Hippo pathway alterations while encouraging anti-tumor activity is seen also in select patient samples with no known Hippo alterations. This confirms ODM-212 as a potent novel therapeutic to target TEAD transcription factors in solid tumors supporting further clinical development.

#3006 Genomic determinants of PIK3CA mutation driven breast cancer initiation.

Snehal B. Bhandare[1], Ruizhong Wang[1], Poornima Bhat-Nakshatri[1], Stephanie Adama[2], Sarah R. Spivak[1], Farzaneh Behzadnia[3], Cihat Erdogan[3], Hongyu Gao[3], Yunlong Liu[3], Lylah H. Hutson[4], Xin Dauterman[4], George Sandusky[4], Harikrishna Nakshatri[1]

[1]Surgery, Indiana University School of Medicine, Indianapolis, IN,[2]Translational Cancer Biology, Indiana University School of Medicine, Indianapolis, IN,[3]Medical & Molecular Genetics, Indiana University School of Medicine, Indianapolis, IN,[4]Pathology and Laboratory Medicine, Indiana University School of Medicine, Indianapolis, IN

PIK3CA is the second most mutated and/or amplified gene in breast cancer after *p53*. The PIK3CA-specific inhibitor Alpelisib is an FDA approved treatment for breast cancer. Toxicity and rapid development of resistance limit its clinical utility. Mutations in PIK3CA are found in many normal organs including the breast suggesting that additional genomic aberrations are needed for mutant PIK3CA to initiate breast cancer, and those aberrations can be exploited for therapy. Consistent with this possibility, our previous studies have demonstrated that immortalized breast epithelial cells derived from *BRCA1/2* mutation carriers are susceptible to transformation by the *PIK3CA* mutant, whereas transformation of immortalized breast epithelial cells from healthy donors required combinations of mutant *PIK3CA* and SV40-T/t antigens. These results suggest that transformation of breast epithelial cells by *PIK3CA* mutants requires additional genomic aberrations like those induced by SV40-T/t antigens or *BRCA1/2* mutations. To decipher genomic aberrations required for *PIK3CA* mutant driven breast epithelial transformation, we used model system of immortalized breast luminal epithelial cell lines from healthy donors. We show that mutations that activate MEK/ERK pathway such as NF-1 mutation in parallel with *PIK3CA* mutations initiate ductal carcinoma- *in situ* (DCIS)-like breast tumors with accompanying reduction in BRCA2 protein, whereas mutant PIK3CA plus SV40-T/t antigens generate invasive ductal adenocarcinoma (IDC). DCIS and IDC cells differed significantly in the expression of extracellular matrix components including reduced expression of LAMC2 and COL17A1 and upregulation of drivers of aneuploidy in IDC cells. Consistent with the possibility of mutant PIK3CA and MEK/ERK pathway collaboration in breast cancer initiation, Estrogen Receptor-positive/*PIK3CA* mutation-positive breast tumors contained higher levels of activated ERK compared to Estrogen Receptor-positive/PIK3CA-wild type breast cancers.

Significance: To our knowledge, this is the first study to generate DCIS like lesions from breast epithelial cells from healthy women using combinations of breast cancer-enriched genomic aberrations and without the use of viral proteins such as SV40-T/t antigens or HPV E6. In this process, we have developed an isogenic DCIS and IDC model to study breast cancer progression. These results also suggest that mutant PIK3CA is a weaker oncogene and the effective therapy for mutant PIK3CA driven breast cancers needs to include inhibitors of PIK3CA as well as drugs that target genomic aberrations that cooperate with mutant PIK3CA.

#3010 LIN-T (lipid integrated tag): An optimized tag-lipid nanoparticle design for targeted therapeutic mRNA delivery.

Tommy Lidstrom[1], Alexandros Kostakis[2], Rosanne Veerman[3], Venera Emruli[3], Safia Guleed[3], Tina Furebring[3], Jonas A. Nilsson[1], Sara Mangsbo[2]

[1]Umea University, Umea, Sweden,[2]Uppsala University, Uppsala, Sweden,[3]Strike Pharma AB, Lund, Sweden

Background: Lipid nanoparticles (LNPs) are the leading platform for mRNA delivery, but targeted delivery remains challenging. Factors such as lipid composition, particle size, charge, and ionizable lipid selection influence biodistribution, cellular uptake, and mRNA translation. Antibody-decorated LNPs offer a strategy to expand therapeutic applications.
Approach: Conventional antibody decoration methods, such as post-formulation conjugation (click or maleimide chemistry), fusion proteins, or site-specific lipid conjugation, require chemical modification of antibodies. Modifications that can compromise stability and increase aggregation risk. To address this, we developed a modular system using a short peptide tag integrated into the LNP surface, enabling rapid antibody attachment via a bispecific antibody design without chemical conjugation.
Innovation: Our 9-amino-acid tag (optimized in our recent Nature com. publication: PMID 39500897) binds an scFv (single-chain variable fragment) domain with picomolar affinity. The tag shows minimal immunogenicity risk in vitro and in vivo, likely as the tag is shielded upon binding. We demonstrate two complementary strategies for tag incorporation on the LNP:
1. Protein-based: Recombinant inert ApoE (ApoEi)-fusion tag for rapid coating of preformed LNPs.2. Synthetic lipid-based: DSPE-PEG-tag conjugate integrated during LNP assembly.
Both approaches preserve tag accessibility and enable efficient antibody decoration. The ApoEi-tag design uniquely also blocks ApoE-LDL receptor interactions, and we can display that this reduces liver tropism.
Results: Using this platform, we achieved targeted mRNA delivery and translation in Her2+, CD40+, CD3+, and CD20+ cells. The synthetic DSPE-PEG-tag supports scalable, GMP-compatible production, and the ApoEi-based method enables a rapid tool for research purposes. Our human scFv can be formatted into a classical Morrison bispecific design and expressed in CHO cells at titers >8 g/L.
Conclusion: These strategies provide a versatile framework for precision-targeted mRNA delivery, supporting customizable LNP therapeutics within for example oncology and autoimmune diseases.

#3011 A STING-boosted lipid nanoparticle mRNA vaccine for therapeutic cancer vaccination.

Alessia Marrocu[1], Osama W. M. Hassuneh[2], Victor M. Moreno Zafra[2], Alaa Zam[2], Emre Demirel[1], Meriem Bahri[1], Adam Walters[2], James N. Arnold[1], Khuloud T. Al-Jamal[2]

[1]School of Cancer and Pharmaceutical Sciences, Faculty of Life Sciences and Medicine, King's College London, London, United Kingdom,[2]Institute of Pharmaceutical Sciences, Faculty of Life Sciences and Medicine, King's College London, London, United Kingdom

Despite the success of immunotherapies and preventative vaccines in virus-associated cancers, the translation of therapeutic vaccination has been limited, often by limited immunogenicity and inability to overcome the immunosuppressive ‘cold’ tumor microenvironment. Recent advances in mRNA vectors for viral immunization, and optimized nanoparticle delivery, have renewed promise for cancer vaccination. In this study, we developed an ionizable stable nucleic acid lipid nanoparticle (SNALP) nanovaccine for the delivery of mRNA-encoded model antigen, ovalbumin (OVA). To counter tumor-associated immunosuppression, we harnessed the innate anti-viral stimulator of interferon genes (STING) pathway by co-encapsulating cyclic dinucleotide STING agonist 2’3’-cGAMP. SNALP formulations were optimized for biocompatibility and cell uptake, with small particle size, near-neutral surface charge, and high encapsulation efficiency of both mRNA and 2’3’-cGAMP within a single platform. SNALP-mediated co-delivery achieved effective mRNA transfection and antigen presentation in primary dendritic cells (DCs) *in vitro*, whilst addition of 2’3’-cGAMP enhanced DC maturation and activation, noted by increased co-stimulatory (CD80, CD86) and MHC-I (H-2Db, H-2Kb) marker expression. Nanovaccine-activated DCs efficiently primed naïve primary $CD8^+$ T cells to elicit effector function and replicate in co-culture. *In vivo*, immunization with 2’3’-cGAMP-boosted OVA-SNALPs elicited a robust immunological T cell response, evidenced by circulating antigen-specific $CD8^+$ T cell populations with central memory phenotypes, and effector splenic $CD8^+$ T cells capable of TCR-mediated cytokine production upon challenge. Therapeutic relevance of 2’3’-cGAMP-OVA-SNALPs was assessed in murine models of melanoma expressing OVA (B16F10-OVA) under different vaccination protocols. The nanovaccine consistently delayed tumor onset and extended survival, completely preventing tumor formation when given prophylactically, or driving total tumor regression when given therapeutically by local (intra-tumoral) or systemic (intra-muscular) routes, in a subset of animals, which was not found in non-adjuvanted controls. Some tumor control was also noted upon therapeutic administration of SNALPs containing irrelevant mRNA, highlighting potentially beneficial innate adjuvancy of the platform itself. Altogether, this work shows that SNALP-based nanovaccines are a versatile and translatable platform for next-generation cancer immunotherapy. The nanovaccine showed potential as a monotherapy, converting immunologically ‘cold’ tumors into responsive microenvironments. This adaptable system enables co-delivery of antigens and immune modulators to target immunosuppressive and induce durable anti-tumor responses. Future studies will explore combining it with additional immunotherapies to improve clinical efficacy.

#3012 Lipid nanoparticles enable high efficiency CRISPR HDR mediated gene insertions in primary human T cells.

Reka Geczy[1], Meenakshi Swaminathan[1], Hannah Ly[1], Mana Novin[1], Bernice Thommandru[2], **Sijo Chemmannur**[1], Sadik Kassim[3], Samuel Clarke[1]

[1]Cytiva, Vancouver, BC, Canada,[2]Integrated DNA Technologies, Coralville, IA,[3]Danaher Corporation, Washington, DC

Stable gene insertion using non-viral delivery is essential to unlocking the next generation of safe and accessible cell and gene therapies. Currently, viral vectors carry high manufacturing costs and insertional mutagenesis concerns, while electroporation (EP) affects cell yield and viability. Lipid nanoparticles (LNPs) can be a promising alternative option for engineering cells for persistent expression of target genes, as they offer a favorable safety profile and are both cost-effective and scalable. In this work, we mapped out the critical parameters governing homology-directed repair (HDR) in primary T cells using LNP-mediated cargo delivery. Cas9 mRNA, a chemically synthesized guide RNA (sgRNA), and an ~100 nt single-stranded donor oligonucleotide (ssODN) were encapsulated within a novel LNP composition using a scalable production platform. A haemagglutinin (HA) epitope tag was knocked in at the CD5 locus as an easily quantified read-out for parameter optimization. CD3+ primary T cells from healthy donors were cultured in well-plates and the CRISPR LNPs added to the media in a one-step process, without further cell manipulation. Various parameters were identified and systematically varied, including (and not limited to) the length of cell activation, cell density, nucleic acid dose and the RNA/DNA molar ratios. Through multiple rounds of optimization, LNPs achieved on average 31 ± 7% HDR in n=5 T cell donors, detected through dual CD5/HA flow cytometry 4 days post-LNP administration. Viability of the cells remained high at 96 ± 5% at the time of HDR detection, relative to untreated controls. The aforementioned results reflect no added enhancers; however, when we tested various small molecules, such as NHEJ inhibitors, HDR rates further improved to over 50% in primary T cells. Finally, we compared the optimized LNP protocol to EP which resulted in similar HA+ frequencies. However, most notably, the yield of viable edited cells by LNP was an order of magnitude higher than EP owing to improved cell viability and proliferation. All together, this data demonstrates how LNPs can achieve clinically relevant knock-in frequencies and showcases the benefits of LNPs as a non-viral alternative for gene insertion. This approach for parameter optimization is applicable for a diverse set of therapeutic loci, providing a framework for the rapid application of LNPs to enable the next generation of T cell therapies.

#3013 Biomimetic exosome-delivered STAT3 inhibitor for radiosensitization in oral squamous cell carcinoma cells.

Kehua Hu[1], Sisi Yan[1], Xiaowan Guo[1], Rurui Xue[1], Yunli Mo[1], Hui Qiu[1], Linlin Bu[2], **Qiuji Wu**[1]

[1]Zhongnan Hospital of Wuhan University, Wuhan, China,[2]Hospital of Stomatology, Wuhan University, Wuhan, China

Background: Signal transducer and activator of transcription 3 (STAT3) is a key driver of resistance to radiotherapy in advanced oral squamous cell carcinoma (OSCC), promoting an immunosuppressive microenvironment via upregulation of immune checkpoints including PD-L1. Although STAT3 inhibition represents a promising radiosensitizing strategy, its clinical application is limited by poor drug delivery. Exosomes, as natural nanocarriers, present an ideal solution with their excellent biocompatibility, low immunogenicity, and inherent targeting capabilities. This study aimed to develop an exosome-based targeted delivery system for a STAT3 inhibitor to improve the efficacy of radiotherapy in OSCC.

Methods: We constructed a biomimetic delivery system (Exo@S3I-201) by loading the STAT3 inhibitor (S3I-201) into exosomes derived from mouse oral squamous cell carcinoma (MOC2) cells via sonication. The system was characterized by transmission electron microscopy (TEM), nanoparticle tracking analysis (NTA), and Western Blot. Drug loading efficiency and pH-dependent release profile were determined by ultraviolet spectroscopy. Cellular uptake and targeting were visualized by fluorescence microscopy. The radiosensitizing effect of Exo@S3I-201 on MOC2 cells were evaluated in vitro through CCK-8 assay, colony formation assay, flow cytometry, live-dead staining.

Results: The successfully constructed Exo@S3I-201 exhibited similar size, dispersion, and stability to plain exosomes. UV absorption confirmed that Exo@S3I-201 retained the characteristic absorption peak of S3I-201, exhibited high drug loading efficiency, and displayed pH-responsive drug release behavior, with maximal release under acidic conditions (pH=5.5) mimicking the tumor microenvironment. Fluorescence microscopy revealed efficient cellular uptake of Exo@S3I-201 into MOC2 cells. Western Blot analysis revealed that Exo@S3I-201 combined with radiotherapy more effectively suppressed STAT3 phosphorylation and expression of its downstream target genes, compared with free S3I-201. Functionally, compared to radiotherapy alone or free S3I-201, the combined treatment markedly inhibited MOC2 cell proliferation and colony-forming ability and induced higher levels of cellular apoptosis.

Conclusion: Our study presented an autologous exosome-based system for targeted STAT3 inhibitor delivery. Exo@S3I-201 significantly enhanced radiosensitivity in OSCC by inhibiting the STAT3 pathway, demonstrating its potential as a novel combination therapy to overcome radioresistance.

#3014 Targeting PLXND1 using RNA bioengineering technologies and customized lipid nanoparticles in advanced prostate cancer.

Huan Qu[1], Menghuan Tang[2], Qiufang Zong[2], Sohaib Mahri[2], Pengfei Xu[1], Joy C. Yang[1], Fan Wei[1], Junwei Zhao[2], Meijuan Tu[2], Neelu Bartra[2], Leyi Wang[1], Allen C. Gao[3], Kit Lam[2], Marc A. Dall'Era[1], Aiming Yu[4], Yuanpei Li[2], Chengfei Liu[3]

[1]Urologic Surgery, UC Davis, Sacramento, CA,[2]UC Davis Comprehensive Cancer Center, Sacramento, CA,[3]Urologic Surgery, UC Davis Comprehensive Cancer Center, Sacramento, CA,[4]UC Davis, Sacramento, CA

Background: PLXND1 (Plexin D1) is a transmembrane receptor that plays critical roles in promoting neural lineage plasticity and driving resistance to enzalutamide therapy in prostate cancer. Despite its significance, PLXND1 has been considered "undruggable." siRNA-based therapeutics offer a strategy to silence disease-driving genes like PLXND1 but face limitations, including instability, poor cellular uptake, and off-target effects.
Methods: We employed an RNA bioengineering approach using a tRNA/pre-miRNA-mir-34a scaffold to stabilize and express siRNAs targeting PLXND1 (BioRNA-siPLXND1). BioRNA/PLXND1-siRNA expression plasmids were constructed via molecular cloning, and the resulting BioRNA was purified and analyzed for quality, yield, and endotoxin levels. We tested BioRNA-siPLXND1 function in vitro and formulated it into lipid nanoparticles (LNPs) using two lipid components: DOPE and DOTAP. The stability, transfection efficiency, and safety of each formulation were evaluated in vitro and in vivo using prostate cancer cell lines and neuroendocrine prostate cancer (NEPC) patient-derived xenograft (PDX) organoids.
Results: BioRNA-siPLXND1 achieved high yield and purity with low endotoxin levels. It efficiently silenced PLXND1 at the mRNA and protein levels, significantly inhibiting cell proliferation, colony formation, and organoid growth in vitro. Among the LNP formulations, LNP-DOTAP demonstrated higher transfection efficiency but greater cytotoxicity in normal cells, whereas LNP-DOPE showed a favorable safety profile and effective delivery. LNP-DOPE-loaded BioRNA-siPLXND1 remained stable for at least 7 days in vitro and suppressed tumor growth in NEPC PDX organoids. In vivo, LNP-DOPE accumulated in tumors within 2 hours, persisted for up to 4 days, and was predominantly retained in tumor tissue by day 7.
Conclusions: Our study demonstrates the feasibility and therapeutic potential of a tRNA-based BioRNA platform for delivering PLXND1-targeting siRNAs in prostate cancer. LNP-DOPE serves as a safe and effective delivery system, offering a promising strategy for targeting "undruggable" oncogenes like PLXND1 in therapy-resistant prostate cancer.
Financial support: This work was supported in part by grants from NIH/NCI R37CA249108 (Liu), R01CA251253 (Liu), R21CA277171 (Liu), Department of Defense HT9425-23-1-0144 (Liu), HT9425-23-1-0325 (Liu), HT9425-23-1-0324 (Dall'Era), and UC Davis Comprehensive Cancer Center Support Grant (CCSG) awarded by the National Cancer Institute (NCI P30CA093373).

#3015 Advancing mRNA therapeutics towards immuno-oncology applications: Lipid nanoparticles demonstrate favorable safety and efficacy profile with repeated mRNA administration in normal and tumor-bearing mice.

Sams MA Sadat[1], **Avisek Deyati**[1], Leanna Yee[1], Zhengyu Chen[1], Kalyan Golla[1], Tony Wu[1], Richard Jiang[1], Jay Paquette[1], Malathi Anantha[1], Noorjahan Aibani[1], Nikita Jain[1], Anitha Thomas[2]

[1]Cytiva, Vancouver, BC, Canada,[2]Cytiva, Marlborough, MA

Lipid nanoparticles (LNPs) have revolutionized mRNA delivery, offering a promising approach for advancing cancer immunotherapy. Effective and safe delivery of tumor antigen-encoding mRNA can stimulate robust anti-tumor immune responses. Here, we developed LNP formulations for immuno-oncology applications and tested its fit-for-use by delivering ovalbumin (OVA)-encoded mRNA as a surrogate payload and evaluated the safety, efficacy, and therapeutic potential in the B16-F10-OVA xenograft melanoma mouse model.Novel ionizable lipids were selected for formulating LNPs by rational screening of pKa, encapsulation efficiency, hydrodynamic size, and biodistribution properties. OVA-encoded mRNA was encapsulated in LNPs using NxGen™ microfluidic mixing technology on the NanoAssemblr™ platform. The LNPs were characterized for hydrodynamic size, polydispersity index (PDI), loading, and encapsulation efficiency. To assess long-term safety and stability, healthy mice received multiple intramuscular (IM) injections of the LNP formulations at 21-day intervals. Physicochemical stability and toxicity were evaluated through the standard assays and clinical observations. Following this series, B16-F10-OVA tumor-bearing mice were vaccinated intramuscularly with OVA mRNA-loaded LNPs. Clinical symptoms and survival outcomes were monitored and compared to untreated controls.OVA mRNA-loaded LNPs were in the desired size range of 60 to 80 nm with a PDI value below 0.2 and an encapsulation efficiency greater than 95%. Long-term stability studies indicated retention of critical quality attributes (CQAs). Repeated IM administration of the proprietary LNPs over an extended period demonstrated stability and tolerability with no detectable toxicity or adverse effects observed in treated animals. Treatment with the OVA mRNA-LNP vaccine improved survival in tumor-bearing mice, significantly extending median survival compared to controls.By retaining the CQAs of the drug products, our novel LNP platform efficiently delivers OVA mRNA as a model for delivering therapeutic or immune modulating nucleic acid payloads. Additionally, repeated IM administrations of these LNPs over an extended period resulted in no detectable adverse events and OVA mRNA LNPs induced potent anti-tumor effects in the B16-F10-OVA model. This favorable safety profile and stability upon repeated dosing underscore LNP suitability for long-term immune modulation or therapeutic strategies for immuno-oncology applications.

#3016 Enhancing CX-5461 therapy in TNBC through liposomal delivery and ATR inhibitor combination.

Henos S. Negash[1], Rachel K. Myrick[2], Sandro R.P. da Rocha[2], J. Chuck Harrell[2]

[1]Virginia Commonwealth University - VCU, Richmond, VA,[2]Virginia Commonwealth University, Richmond, VA

Background: Breast cancer (BC) is the second leading cause of cancer death in women. Triple-negative breast cancers (TNBCs), an aggressive subtype, account for 15-20% of cases and disproportionately contribute to BC mortality. For patients with metastatic TNBC, the current standard of care is chemotherapy; although initially effective, overall survival remains poor. Thus, novel therapeutic strategies are urgently needed to improve TNBC outcomes.

Aims: We aim to evaluate the novel DNA-damaging agent CX-5461 (Pidnarulex), which has shown promising preclinical activity in TNBC patient-derived xenograft (PDX) models with homologous recombination deficiency (HRD), derived from metastatic patients resistant to standard-of-care chemotherapy. CX-5461 is currently in clinical trial and holds FDA Fast Track designation for breast and ovarian cancers with HRD. To enhance efficacy and improve survival, we are exploring liposomal delivery and rational combination with the ATR inhibitor, Berzosertib. As CX-5461 is most effective in DNA repair-deficient backgrounds, we focused on models with HR or other DNA repair pathway deficiencies.

Methods: Human TNBC cell lines and PDX-derived cultures were screened in vitro for single-agent CX-5461 activity. PDX models with $IC_{50} \leq 5$ μM were prioritized for in vivo testing to determine sensitivity (defined as ≥50% tumor volume reduction compared to control). One PDX model (BCM-3887) has been tested in vivo to date. CX-5461 liposomes were prepared using thin-film hydration method with copper complexation-based gradient loading. In vitro responsive cell lines and BCM-3887 were screened for single-agent activity of Berzosertib. Cell lines and BCM-3887 with $IC_{50} \leq 10$ μM for Berzosertib were selected for in vitro combination studies to evaluate synergistic interactions with CX-5461.

Results: CX-5461 has demonstrated potent in vitro single-agent activity. In a pilot in vivo study using BCM-3887 model, strong tumor growth inhibition was observed. Liposomes were prepared with favorable physical characteristics. In vitro combination studies with Berzosertib showed synergy.

Conclusion: CX-5461 is a promising agent for DNA repair-deficient TNBC, with strong single-agent activity demonstrated in vitro and in vivo. Preliminary combination studies with Berzosertib revealed synergistic potential. Future in vivo studies will evaluate whether liposomal delivery and combination therapy can improve survival in TNBC.

#3017 Combination effect of vinorelbine and doxorubicin in free solutions and liposomes in a multicellular spheroids model.

Yong Zhu, Zizhao Xu, Yifan Lu, Shen Zhao, Md Delowar Hossain, Xin Guo

Department of Pharmaceutics & Medicinal Chemistry, University of the Pacific, Stockton, CA

Purpose: Combination drug therapy is a cornerstone approach to treat cancers, yet strategies of delivering drug combinations, including optimal drug ratios and drug formulations, remain challenging. Doxorubicin (DOX) and vinorelbine (VNR) are well established anticancer drugs that inhibit different phases of cell division, thus making them promising candidates for combination therapy. This study evaluated the combination effect of DOX and VNR in various formulations (free solution, pH-sensitive liposomes, and non-pH-sensitive liposomes) at various drug ratios against multicellular spheroids (MCSs) of A549 cells (NSCLC) by cell viability assay and mathematical modeling.

Methods: Non-pH-sensitive liposomes (NonFlip) are composed of cholesterol, POPC and PEG-Ceramide. pH sensitive liposomes (Flip) are composed of POPC, PEG-Ceramide and lipids with a pH-sensitive conformational switch (flipids). A549 MCSs were constructed in 96-well ultra-low attachment microplates with RPMI-1640 and 0.3% collagen. MCSs (~500 μm) were treated with free or formulated DOX, VNR, or DOX:VNR combinations at various ratios. Cell viability was assessed using CellTiter-Glo 3D assay. The effects of drug combination were evaluated by three mathematical models (Greco's, unified theory, and Bliss independent) using the GraphPad Prism 10.6.0 software.

Results: For individual drugs, free DOX, NonFlip DOX, and Flip DOX exhibited similar IC50 values around 5 μM. Free VNR and Flip VNR showed IC50 around 44 μM, while NonFlip VNR displayed IC50 exceeding 200 μM. For combinations, DOX:VNR ratios of 5:1, 1:1, and 1:5 yielded IC50 values of approximately 5, 8, and 16 μM, respectively, in free drug and Flip groups. NonFlip groups at 5:1 and 1:1 showed IC50 values of approximately 5 and 8 μM, but the IC50 of NonFlip DOX:VNR 1:5 exceeded 200 μM. Compared to individual drugs, most of the DOX:VNR combinations in Free drug solution, Flip formulations, and NonFlip formulations demonstrated synergism in Greco's and unified theory models (R^2>0.95). To optimize the synergism, Greco's model favored the DOX:VNR ratio of 5:1 while unified theory favored 1:5. In contrast, the Bliss independent model fitted the cell viability data poorly (R^2<0.9) and did not show synergistic effects.

Conclusions: Greco's and unified theory modeling of the dose dependent cell viability data demonstrated the synergistic effect of combining DOX and VNR in various formulations. The poor fitting of the cell viability data by the Bliss independent model suggests DOX and VNR may not suppress the cancer cell growth independently. Further studies are needed to confirm these findings.

#3018 Lipopolymer-mediated delivery of fusion oncogene-targeting siRNAs attenuates leukemia burden and improves survival in preclinical models of hematologic malignancies.

Mohammad Nasrullah[1], Remant KC[2], Spencer B. Gibson[3], Xiaoyan Jiang[4], Olaf Heidenreich[5], Joseph Brandwein[6], Hasan Uludag[2]

[1]Pharmacy & Pharmaceutical Sciences, University of Alberta, Edmonton, AB, Canada,[2]Chemical & Materials Engineering, University of Alberta, Edmonton, AB, Canada,[3]University of Alberta, Edmonton, AB, Canada,[4]BC Cancer, part of the Provincial Health Services Authority, Vancouver, BC, Canada,[5]Princess Maxima Center for Pediatric Oncology, Utrecht, Netherlands,[6]Faculty of Medicine & Dentistry - Medicine Dept, University of Alberta, Edmonton, AB, Canada

Hematologic malignancies are genetically heterogeneous cancers marked by a range of chromosomal translocations, among which fusion oncogenes, e.g., *KMT2A::AFF1* in acute lymphoblastic leukemia (ALL), *KMT2A::MLLT3* in acute myeloid leukemia (AML), and *BCR::ABL1* in chronic myeloid leukemia (CML), are particularly aggressive and clinically intractable. These fusion-driven hematologic malignancies are associated with poor prognosis and resistance to conventional therapies, emphasizing the need for fusion targeted, personalized treatment strategies. Small interfering RNAs (siRNAs) offer a promising approach due to their capacity for precise gene silencing. However, clinical translation is hindered by delivery challenges, including rapid degradation, off-target effects, hepatic accumulation, and inefficient uptake by hematopoietic cells, largely due to their negative charge, size, and the limited cytoplasmic volume of blood cells.

To address these limitations, we developed a novel lipopolymer-based siRNA delivery platform by conjugating aliphatic lipids onto low-molecular-weight polyethyleneimine (PEI, 1.2 kDa). This modification yielded a series of lipopolymers capable of forming stable nanocomplexes with siRNAs, colloquially known as lipopolymer/siRNA nanoparticles (LPNPs). These LPNPs leverage the cationic nature of PEI for siRNA binding and lipid-mediated mechanisms to enhance cellular uptake. We evaluated the efficacy of LPNPs in delivering siRNAs targeting *KMT2A::AFF1*, *KMT2A::MLLT3*, and *BCR::ABL1* in preclinical models of ALL, AML, and CML, respectively. LPNP-mediated delivery attained efficient intracellular siRNA uptake and robust gene silencing in all three forms of leukemia cell lines, which resulted significant downregulation of fusion oncogene expression. This silencing induced apoptosis and markedly reduced colony-forming potential *in vitro*. *In vivo* biodistribution studies demonstrated enhanced biodistribution of LPNPs in leukemia-accompanying tissues, including bone marrow and spleen, with reduced hepatic sequestration. Particularly, systemic administration of LPNPs led to a substantial reduction in leukemia burden and significantly improved survival in xenograft models of ALL, AML, and CML.

Our findings highlight the therapeutic potential of lipopolymer-mediated siRNA delivery for targeting fusion oncogenes in hematologic malignancies. This platform offers a promising strategy for overcoming current delivery barriers and advancing RNA interference-based therapies toward clinical application.

#3019 The first coacervate based delivery system for efficient and safe genetic engineering in stem cells.

Peipei Zhu[1], Manman Lu[2], Qing Zhang[1], Renxia Zhang[1], Lihong Jiang[2], Xiaowen Fei[2], Xiaofei Gao[1]

[1]Westlake University, Hangzhou, China,[2]Nanoportal Biotech, Hangzhou, China

Stem cell biology, which orchestrates embryogenesis, influences aging, and holds promise for revolutionary therapies, represents a central thread in human health. This underscores the pressing need for advanced delivery technologies to facilitate both research progress and clinical translation. Here, we harness coacervates-regarded as protocells during evolution-to develop a pioneering delivery platform. We identified a mammalian endogenous protein that encapsulates diverse nucleic acids through liquid-liquid phase separation (LLPS), forming protein-based coacervates. These coacervates exhibit superior mRNA encapsulation capacity, efficient cellular internalization, robust cytoplasmic cargo release, and broad compatibility across multiple cell types -including primary immune cells and stem cells. The resulting platform, named ProteanFect, supports diverse genetic cargoes for versatile gene manipulation strategies. ProteanFect demonstrated high versatility and efficiency across key stem cell types, including hematopoietic stem cells (HSCs), human embryonic stem cells (ESCs), and induced pluripotent stem cells (iPSCs) derived from diverse somatic sources such as PBMCs, urine, and adipocytes. It efficiently enabled gene overexpression and knockout through the delivery of mRNA or Cas9 RNP complexes. In a key demonstration of its therapeutic potential for hematological disorders, ProteanFect achieved approximately 80% allele modification at the *BCL11A* locus in HSCs, a strategy aimed at reactivating fetal hemoglobin to treat hemoglobinopathies, with no detectable off-target editing. Furthermore, the platform facilitated precise genetic correction by delivering prime editing tools into PBMC-derived iPSCs, achieving approximately 55% precise base substitution with high cell viability. In summary, ProteanFect constitutes a versatile, safe, and efficient non-viral platform that operates without synthetic lipids or electroporation. By enabling robust transient expression of reprogramming and gene-editing cargo without genomic integration, it provides a safer and more controllable pathway for cellular reprogramming, iPSC generation, and the development of next-generation cell therapies.

#3020 Lymphocyte-mimetic drug carriers enable targeted therapeutic delivery to lymph nodes for enhanced immunomodulation.

Michael J. Donzanti[1], Luisa A. Fink[2], Bahar Bahramimeimandi[2], Kayla Katz[2], Dylan T. Ngo[2], Ana Obradovic[2], Ryan Zurakowski[1], Jason P. Gleghorn[1]

[1]Navicyte Biotechnologies LLC, Newark, DE,[2]University of Delaware, Newark, DE

Introduction: Immunotherapy efficacy in solid tumors is often limited by immune tolerance within tumor-draining lymph nodes (TDLNs), where antigen presentation and T-cell priming originate. Immune activators, such as STING agonists, are capable of reversing local immunosuppression, however their clinical translation has been hindered by rapid systemic clearance, dose-limiting toxicity, and poor lymph node bioavailability. Effective targeting of TDLNs could overcome these translational barriers by reprogramming local immune environments and amplifying durable antitumor immunity. To address this, we have developed a novel delivery platform T-Lymphocyte Mimetic Membrane-wrapped Microparticles (T3MPs).

Methods: T3MPs were fabricated using a flow-focusing microfluidic device to generate uniform, cell-sized alginate microparticles (10-20 μm). Multiple payloads, including cyclic-di-GMP (STING agonist) and cisplatin, were encapsulated within the alginate matrix during particle formation. Drug-loaded T3MPs were cloaked with allogenic T-cell membranes to preserve trafficking proteins, confirmed via flow cytometry. Drug encapsulation and release kinetics were quantified via spectrofluorometry. *In vitro* payload functionality was assessed with THP-1 culture, and *in vivo* biodistribution and efficacy were evaluated following intravenous administration in BALB/c mice.

Results: T3MPs exhibited uniform size distribution and retained key lymphocyte surface proteins (L-selectin, LFA-1) critical for LN trafficking and demonstrated tunable, sustained drug release, achieving ~50% release over 10 days *in vitro*. Following intravenous administration, drug-loaded T3MPs achieved ~700% greater LN-specific delivery than free drug controls and extended the therapeutic index >500-fold by reducing systemic exposure. Delivery of c-di-GMP via T3MPs induced potent activation of lymph node resident antigen presenting cells (elevated IFN-β and IL-12), while co-delivery of c-di-GMP and model tumor antigen (SIINFEKL) enhanced antigen-specific $CD8^+$ T-cell priming.

Conclusions: T3MPs represent a novel lymphocyte-mimetic platform that overcomes pharmacological barriers to lymph node drug delivery, enabling safe, localized immunomodulation for reprogramming immune niches. By combining lymphocyte-inspired targeting with tunable release, this technology offers a broadly applicable strategy to enhance the efficacy of immunotherapies and vaccines. Ongoing work through Navicyte Biotechnologies is advancing the T3MP platform toward IND-enabling studies and strategic pharmaceutical partnerships.

#3021 ONM-421, a pH-responsive polymer-drug conjugate nanoparticle, delivers MMAE to solid tumors and shows antigen-independent antitumor efficacy in mice.

Jason B. Miller, Stephen Gutowski, Qingtai Su, Bhargavi Allu, Austin Burcham, Zirong Chen, Ruolan Han, Tian Zhao

OncoNano Medicine, Inc., Dallas, TX

Introduction: Strategies that enable precise tumor delivery of cytotoxic agents such as monomethyl auristatin E (MMAE) and reduce off-tumor toxicity would profoundly improve cancer treatment outcomes. Though antibody-drug conjugates (ADCs) have been approved for several indications, the efficacy of ADCs can be limited by multiple factors including heterogenous antigen expression and target downregulation which restrict effective treatment in many patients. We have developed ON-BOARD™, an ultra-pH sensitive nanoparticle technology, which shields payloads from systemic exposure during circulation but responds to the acidic tumor microenvironment (TME), to deliver therapeutics in an antigen-independent and histology-independent manner. Herein, we report the preclinical characterization of ONM-421, an ON-BOARD™ polymer-drug conjugate covalently linked to MMAE via a protease-cleavable linker, showing favorable tolerability and anti-tumor efficacy in multiple xenograft models.
Methods: Properties and storage stability of ONM-421 were characterized by dynamic light scattering and HPLC. Linker cleavage was investigated *in vitro* while cytotoxicity assays were performed in human cancer cell lines and primary cells (keratinocytes, corneal epithelial cells) with free MMAE and MMAE-ADCs. Efficacy and tolerability of ONM-421 was studied *in vivo* in multiple human xenograft models, HT-29, HCT-116, and FaDu compared to docetaxel (DTX) and a tissue factor targeting MMAE-ADC tisotumab vedotin (TV).
Results: ONM-421 showed stable uniformly distributed size (D_h<50nm), <1% free MMAE, and consistent pH-responsiveness over a 6-month ongoing storage stability study. ONM-421 showed >1,000-fold payload protection compared to free MMAE *in vitro*, while MMAE payload activity was confirmed after cathepsin B enzymatic cleavage from ONM-421. Incubation of ONM-421 in mouse plasma showed improved stability compared to TV as measured by LC-MS and a cancer cell cytotoxicity assay. ONM-421 also showed markedly reduced toxicity compared to free MMAE and TV in human primary corneal epithelial cell and keratinocytes. In repeat-dose studies, ONM-421 demonstrated potent antitumor efficacy in multiple xenograft models in an antigen independent manner with significantly improved tolerability compared to DTX in all models. ONM-421 resulted in 100% tumor free survival in HT-29 and FaDu, and 82% TGI in HCT-116 while TV was only efficacious in TF^{Hi} FaDu (100% tumor free) but not in TF^{Lo} HCT-116 (20% TGI). ONM-421 also showed better tumor inhibition than TV in large established FaDu and HCT-116 xenografts after a single injection.
Conclusion: ONM-421 demonstrated potent antigen-independent antitumor efficacy in multiple xenograft tumors with good tolerability in mice. The data justifies further development of ONM-421 towards IND-enabling studies.

#3022 A peptide-based drug delivery system to target metastatic prostate cancer.

Yukihito Kuroda[1], Norio Miyamura[1], Chisato M. Yamazaki[2], Erkki Ruoslahti[3], Tambet Teesalu[4], Kazuki Sugahara[1]

[1]Columbia Univ. Vagelos College of Physicians & Surgeons, New York, NY,[2]The University of Texas Health Center at Houston, Houston, TX,[3]Distinguished Professor, Sanford Burnham Prebys Medical Discovery Institute, La Jolla, CA,[4]Univ. of Tartu, Tartu, Estonia

While effective treatments for prostate cancer (PC) such as androgen deprivation therapy (ADT) have been developed, it is still a challenge to treat advanced PC, which has become resistant to ADT or has metastasized. Lately, therapeutic agents that selectively target PCs such as [177Lu]Lu-PSMA-617 have shown promise, suggesting that tumor-specific drug delivery may greatly improve the management of metastatic castration-resistant PC. Here, we report a novel peptide, MHP1 (metastasis homing peptide 1), which effectively homes to metastatic PC in vivo.MHP1 was identified by phage display using experimental metastasis mouse models using the androgen-independent PC-3 human cancer cell line. The mouse models were prepared by either directly injecting the cells into the tibia and/or the brain or through intracardiac or intravenous injections to produce disseminated tumors. Phage display was performed using a cyclic CX7C peptide library expressed on T7 phage. To enrich for peptides that effectively home to metastatic PCs, the phage display was performed in mice by first performing 1 round of ex vivo phage panning using cell suspensions prepared from PC-3 tibia xenografts, followed by 3-4 rounds of in vivo selections in disseminated metastasis mice. DNA sequencing of the enriched phage clones yielded 150 candidate peptides. Phage clones that expressed each peptide on the coat protein were then mixed at an equimolar ratio to produce champion phage pools. “Play-off” in vivo phage display studies were performed by systemically injecting the phage pools into disseminated PC-3 tumor mice. A phage clone that expressed the MHP1 peptide showed the highest tumor-specificity by homing to tumors in various organs without accumulating into corresponding normal tissues. The MHP1 peptide chemically synthesized with a fluorescent tag (FAM-MHP1) effectively homed to tibia and brain xenograft PC-3 tumors. It also homed to disseminated metastatic PC-3 tumors in various organs, such as the jaw, femur, lymph nodes, and eye. Of note, in a spontaneous metastasis model prepared with 22Rv1 human PC cells, FAM-MHP1 homed more effectively to metastatic tumors than to the primary tumor. To identify the receptor of MHP1, affinity chromatography was performed by passing tissue lysates of PC-3 tibia tumors over MHP1-coated beads. A protein was eluted with the MHP1 peptide (but not by a control peptide). Mass spectrometry analysis revealed a list of candidate proteins. Preliminary data suggest that one of the candidates appears promising for being highly expressed in PC tissues. Interestingly, while the protein is intracellular in normal cells, it is misplaced onto the surface of some PC cells making it available for affinity-based targeting. These results suggest that the MHP1 peptide may serve as a promising platform to target metastatic PC. Characterization of the receptor may also lead to additional PC-specific therapies and deeper understanding of PC biology.

#3023 Capsaicin nanoparticles display robust growth-inhibitory activity in human NSCLC.

Kushal Jignesh Modi, Reagan S. Light, Kaitlyn B. Conley, Sarah L. Miles, Piyali Dasgupta

Joan C. Edwards School of Medicine, Huntington, WV

Purpose of the study: The dietary compound Capsaicin is the hot and pungent ingredient of chili peppers. Preliminary data in our laboratory have found that capsaicin displays robust growth-inhibitory activity in human lung cancers. However, the clinical applications of capsaicin as a viable anti-cancer drug are hindered by its adverse side effects, such as gastric irritation, nausea, stomach cramps and a burning sensation in the gut. Clinical trials which explored the pain-relieving activity of capsaicin found that patients who orally ingested capsaicin discontinued taking the drug due to its unpleasant side effects. One strategy to circumvent this drawback is to encapsulate capsaicin in long-acting formulations (like polymeric nanoparticles). Once capsaicin is entrapped in these polymeric nanoparticles, it is released at a very slow rate, so it does not produce any “heat-sensation” and adverse side effects in patients
Experimental procedures: Capsaicin [poly(lactic-co-glycolic acid)] nanoparticles (hereby called CAP-PLGA-NPs] were custom synthesized by a biotech company. The physicochemical properties of these nanoparticles were provided by the vendor. We tested the pro-apoptotic activity of these CAP-PLGA-NPs in a panel of human NSCLC cell lines. We also measured the impact of these CAP-PLGA-NPs on the growth of normal human lung, liver and kidney cells. We also performed soft agar assays to evaluate the ability of CAP-PLGA-NP to inhibit anchorage independent-growth on soft agar. Finally, we tested the anti-neoplastic activity of CAP-PLGA-NPs in SCID mice xenografted with human NSCLC tumors.
Results: The CAP-PLGA-NP displayed greater pro-apoptotic activity than capsaicin in human NSCLCs. CAP-PLGA-NP inhibited colony-formation in soft agar assays. Most interestingly, CAP-PLGA-NP did not impact the growth of normal human lung, liver and kidney cells. The intravenous administration of CAP-PLGA-NPs decreased the rate of human NSCLC tumors xenografted in SCID mice
Conclusions: The long-acting capsaicin drug formulation, namely CAP-PLGA-NP, may be a promising nutrition-based drug in human NSCLCs.

This study was supported in part by the West Virginia IDeA Network of Biomedical Research Excellence (WV-INBRE) grant (NIH grant P20GM103434; PI: Dr. G. Rankin), the National Institute of General Medical Sciences of the National Institutes of Health under the award number P30GM122733.

#3024 Enhancing targeted delivery in multiple myeloma via novel NCI-H929 lipid-extracted-modified nanoliposomes.

Kenny D. Pham, Shivmani Barve, Robert B. Campbell

School of Pharmacy, Department of Pharmaceutical Sciences, Massachusetts College of Pharmacy & Health Sciences, Worcester, MA

Background: Multiple myeloma (MM) is an incurable hematological malignancy characterized by the aberrant proliferation of plasma cells in the bone marrow. Current first line goals of therapy for newly diagnosed symptomatic MM aim to achieve minimal residual disease prior to transplant, a key predictor of overall survival. However, toxicities remain a rate limiting step during induction therapy. Cell membrane lipid-extracted nanoliposomes (CLENs) are a novel drug delivery system that can be optimized to preferentially target MM cells. Prior research involving the use of the multiple myeloma cell line, RPMI-8226, supports the use of lipid extracts (LE) to enhance targeting. This study aims to evaluate whether the inclusion of LE derived from an additional MM cell line, NCI-H929, will also enhance targeting, while decreasing nanoliposome uptake by model off-target and non-target cells.
Methods: The MM (target) cell line explored in this study was NCI-H929. K562-GFP was used as the non-target cell line, and normal healthy peripheral blood mononuclear cells (PBMCs) served as the off-target cell control. Cells were seeded at a concentration of 20,000 cells/mL in vented centrifuge tubes and exposed for 1 hour to varying compositions of nanoliposome preparations including: DOPC, NCI-H929 lipid extract (LE), cholesterol (Chol), and DPPE-rhodamine for fluorescence studies. Nanoliposomes were prepared using a modified thin film method. Relative fluorescence intensity was determined using a fluorescence microplate reader.
Results: Mean liposome diameters (± deviation) for DOPC formulations containing NCI-H929 LE were: DOPC (100%)- 188.6 ± 2 nm, DOPC/LE- 95/5 212.3 ± 2 nm, 90/10- 230.4 ± 2 nm, 85/15- 200 ± 4 nm, and 80/20- 142 ± 1 nm. For formulations including cholesterol, diameters were: DOPC/Chol 90/10- 235 ± 2 nm and DOPC/Chol/LE 80/10/10- 227.4 ± 2 nm. Following 1 hour exposure of the target cell line to different concentrations of DOPC/LE, a statistically significant increase in uptake was observed in DOPC/LE preparations compared to DOPC alone: 95/5 and 90/10 ($p < 0.0001$), 85/15 ($p < 0.001$), and 80/20 ($p < 0.05$), with the highest uptake observed for 90/10. The addition of cholesterol did not further enhance uptake, and no significant uptake was observed in non-target or off-target cells compared to controls.
Conclusions: Our preliminary findings support that cellular uptake in MM cells may be increased via NCI-H929-LE modified nanoliposomes, with diminished uptake by non-target and off-target cell populations. Confirmation studies are currently underway, including cytotoxicity studies comparing conventional chemotherapy against NCI-H929 LE-modified nanoliposomal formulations.

#3025 Self-synergizing mutual prodrug liposomes co-targeting redox homeostasis and PIN1 for cancer therapy.

Nuri Kim, Dongwon Lee

Jeonbuk National Univ., Jeonju-si, Korea, Republic of

PIN1 is a prolyl isomerase that catalyzes the cis-trans isomerization of phosphorylated Ser/Thr-Pro motifs and is overexpressed in various cancer types, where it functions as a key regulator that amplifies oncogenic signaling. PIN1 promotes cancer cell proliferation, survival, and metastasis by stabilizing diverse oncoproteins and disrupting tumor-suppressive pathways such as p53, and its activity is highly sensitive to the intracellular redox state, becoming inactivated in a redox-dependent manner in response to changes in oxidative stress levels. In this study, we developed a mutual prodrug in which all-trans retinoic acid (atRA) is integrated into a single molecule with a quinone methide (QM) precursor that amplifies oxidative stress via glutathione (GSH) depletion, to simultaneously maximize atRA-mediated PIN1 inhibition and reactive oxygen species (ROS)-mediated anticancer activity. We first evaluated the synergistic cytotoxicity of atRA and the QM precursor in MCF-7 breast cancer cells by calculating the combination index and assessing changes in PIN1 and its downstream effector cyclin D1 by Western blotting. To exploit this synergy, we designed and synthesized a mutual prodrug in which atRA is covalently linked to the QM precursor, and confirmed its structure by ^{1}H NMR and LC-MS/MS analysis. Owing to its amphiphilic molecular structure, the mutual prodrug could be stably incorporated into the lipid bilayer at a high loading (~40%) together with DPPC, which enabled the formulation of prodrug-based liposomes. The liposomal surface was subsequently coated with γ-poly(glutamic acid) (γPGA) targeting γ-glutamyl transferase (GGT), yielding particles with a mean diameter of approximately 150 nm. We then examined esterase-triggered release of atRA and QM and evaluated intracellular GSH depletion and ROS amplification, as well as mitochondrial dysfunction, in MCF-7 cells. We further analyzed redox-responsive, PIN1-related, and apoptosis-related signaling by qPCR and Western blotting. Targeting and in vivo antitumor efficacy of the γPGA-coated prodrug liposomes were assessed in an MCF-7 xenograft mouse model, and additional biosafety evaluation revealed no apparent systematic toxicity. Collectively, the mutual prodrug liposomal formulation integrating atRA and the QM precursor disrupted intracellular redox homeostasis and suppressed PIN1-dependent oncogenic signaling, resulting in enhanced anticancer efficacy and reduced systematic toxicity. Thus, this platform offers a next-generation precision nanomedicine candidate that unifies high drug loading, tumor-selective delivery, and self-synergistic mechanisms within a single, clinically translatable system.

#3026 A polymer-drug conjugate platform for tumor specific drug delivery: Advancement of a clinically validated ultra pH-sensitive micelle technology.

Qingtai Su, Stephen Gutowski, Bhargavi Allu, Austin Burcham, Zirong Chen, Ruolan Han, Jason B. Miller, Tian Zhao

OncoNano Medicine, Inc., Dallas, TX

Background: Antibody-drug conjugates (ADCs) have been developed to deliver anti-tumor therapeutics directly to tumors, and have demonstrated some impressive clinical benefits. Challenges with ADCs, however, persist, including necessary identification of exclusively or highly expressed tumor targets, emergence of resistance due to target downregulation, and systemic toxicities from both off-tumor/on-target deployment of payload or unplanned payload release. Herein, we report a polymer-drug conjugate (PDC) platform based on a clinically-validated, ultra-pH sensitive micelle technology - ON-BOARD™. This novel technology enables delivery of cytotoxic compounds through targeting the acidic tumor microenvironment (TME), independent of tumor target expression, offering a differentiated approach from existing therapeutics.

Methods: A pilot library of pH sensitive ON-BOARD™ PDCs was synthesized, connecting clinically utilized warheads (DM1, MMAE, SN-38) via cleavable or non-cleavable linkers. Purity and drug-to-polymer ratio (DPR) were characterized by HPLC and ^{1}H NMR. PDC micelles were characterized for purity, particle size, and pH-responsiveness. Linker reactivities were confirmed by treating formulations under cleavage-inducing conditions. *In vitro* cytotoxicity was evaluated by incubation with different cancer cell lines. *In vivo* anti-tumor efficacy and tolerability were demonstrated in mice bearing human colon cancer xenografts (HCT-116, HT-29) and compared with a standard chemotherapy and/or the corresponding free drug.

Results: The PDC polymers were synthesized with high purities (>95%) and DPR ranging from 2 to 4. The formulated micelles showed sharp pH responsiveness with particle size < 60 nm and an expected > 1,000 drug per micelle ratio. *In vitro* treatment of the cleavable PDC micelles confirmed the reactivity according to their respective linker cleavage mechanisms. Cytotoxicity assays in multiple cancer cell lines showed directed payload release with PDCs containing certain cleavable linkers showing strong potency upon triggering of drug release. DM1 and SN38 PDCs with a cleavable linker demonstrated stronger antitumor activity compared to the ones with a non-cleavable linker in HCT-116 and HT-29 tumors in mice, respectively, while a cleavable SN-38 PDC showed superior efficacy to irinotecan (76% vs 48% TGI) at 21-fold lower SN-38 equivalent dose. MMAE PDCs with cleavable linkers achieved strong efficacy in HT-29 model (99% TGI, 88-100% tumor free) with favorable tolerability compared to the docetaxel control.

Conclusion: A variety of PDCs with different linker drug combinations were generated with ON-BOARD™ pH sensitive micelle technology. The resultant formulations demonstrated strong potency *in vitro* and *in vivo*, offering a promising platform for delivery of therapeutics to the TME with high specificity.

#3027 Cellular uptake of nanoliposomes with optimized cholesterol concentration and lipid extract derived from a model low grade serous ovarian carcinoma cell line.

Sofia Orlando, Krishna Panchal, Heer Patel, Robert B. Campbell

Massachusetts College of Pharmacy and Health Sciences, Worcester, MA

Introduction: Low-grade serous ovarian carcinoma (LGSOC) represents a rare subtype of epithelial ovarian cancer, accounting for less than 10% of all cases and typically diagnosed in younger women. The disease is characterized by tumor growth driven by activating mutations in the MAPK pathway, including *KRAS*, *BRAF*, and *NRAS*. Despite its slow progression, LGSOC remains challenging to treat due to limited responsiveness to conventional chemotherapy. The objective of this study was to isolate cellular lipid extract (LE) material from a model LGSOC cell line, and to utilize the newly acquired LE material to develop a relatively target specific nanoliposomal system. Early formulation and in vitro studies include optimization for cholesterol and LE content.
Methods: Low-grade serous ovarian carcinoma cell line (PM-LGSOC-01, Cytion) was cultured and expanded in EMEM growth medium supplemented with 10% FBS. The PM-LGSOC-01-lipid extract (LE) material was extracted from PM-LGSOC-01 when the cells reached ~90% confluency. Lipid extraction was performed as described previously (Alharbi & Campbell, AAPS Open, number: 5(2018)). Nanoliposomal preparations consisted of DOPC, cholesterol, and LE at various ratios and wereformed by thin film method using a Buchi R-80 rotary evaporator. DPPE-Rhodamine was included in the preparations for cellular studies. Following sonication, particle size and zeta potential values weredetermined using ZetaPals. Fluorescence detection was performed using a fluorescence microplate reader.
Results: Three preparations (1) DOPC (100%), (2) DOPC/Chol (95/5), and (3) DOPC/Chol (90/10) wereprepared with an average particle size of 221 ± 3 nm, 250 ± 5 nm, and 139 ± 0.3 nm, respectively. Preliminary results suggest that the additional inclusion of cholesterol in the nanoliposomal preparations increased their uptake by the target (PM-LGSOC-01) cells. Studies investigating the influence of PM-LGSOC-01-LE on the uptake of nanoliposomes by the target cells are currently underway.
Conclusion: To date, the influence of cholesterol on the uptake of nanoliposomes by LGSOC cells has been investigated. Future studies will evaluate the effect of optimized cholesterol and LE contenton targeting low-grade serous ovarian carcinoma.

#3028 Investigating phosphatidylcholine and phosphoethanolamine phospholipids in conventional and novel cationic nanoliposomes for interactions with chronic myeloid leukemia cells *in vitro*.

Shivmani Y. Barve, Robert B. Campbell

Department of Pharmaceutical Sciences, Massachusetts College of Pharmacy & Health Sciences, Worcester, MA

Background: Lipid Nanoparticles (LNPs) have been established as excellent vehicles for drug/nucleotide delivery for Chronic Myeloid Leukemia (CML). The optimization of lipid ratios of cationic and helper lipids, such as phosphatidylcholine (PC) and phosphoethanolamine (PE)- based lipids, governs the selectivity of LNPs. Furthermore, the incorporation of LE (lipid extracts) derived from target cell membranes has been used to develop CLENs (cell membrane lipid-extracted nanoliposomes) for superior targeting. However, the behavior of PE- and PC-based lipids in the presence of LE is not well understood. In this study, we investigate the cellular interactions of LNPs consisting of PE or PC phospholipids employed in different combinations of cationic lipids and/or lipid extract ingredients using a model CML (K562-GFP) cell line.
Methods: The K562-GFP human CML cell line (CCL-243-GFP) was cultured in RPMI-1640 medium supplemented with 10% fetal bovine serum (FBS). LNPs were prepared using the thin film hydration method and characterized for size and zeta potential. Phase I of the study compared the cellular uptake of LNPs, substituting four cationic lipids (DOTAP, EPC, DOTMA, DODMA) at varying concentrations (0-50 mol%) with the helper lipid DOPC. Phase II involved comparing the PC versus PE helper lipid at a fixed cationic lipid concentration determined in Phase I. Phase III of the study aims to investigate the cellular uptake of LNPs after the inclusion of LE at various concentrations by target and non-target cell lines.
Results: We identified the cellular uptake to be about 250% higher for LNPs containing 25 mol% of DOTAP or EPC compared to the control (DOPC 100 mol%) from Phase I. Phase II revealed that LNPs with helper lipid DOPC performed significantly better at all time points (0 to 120 min) with an increase in cellular uptake compared to helper lipid DOPE. In phase III, the inclusion of LE derived from the target cell in the cationic LNPs led to a selective uptake by the target cell line and decreased uptake by the non-target cell lines.
Conclusion: Results to date revealed that the cellular uptake of LNPs depends largely on the optimum ratio of the cationic lipid to the helper lipid type employed in the development of the nanoparticles, and that inclusion of LE leads to superior targeting.

#3029 A modular lipid-based oral drug delivery system for precision combination chemotherapy in breast cancer.

Shailvi Soni[1], Terrick Andey[2]

[1]Department of Pharmaceutical Science, Massachusetts College of Pharmacy & Health Sciences, Boston, MA,[2]Department of Pharmaceutical Science, Massachusetts College of Pharmacy and Health Science, Worcester, MA

Breast cancer is the third leading cause of cancer-related deaths among women in the United States. Treatment options often include chemotherapy, which involves the use of highly potent but toxic medications that can cause severe adverse reactions, further worsening the patient's condition and, in some cases, leading to fatal outcomes. Additionally, oral delivery of chemotherapeutic agents is limited by poor bioavailability, arising from the harsh acidic and enzymatic environment of the gastrointestinal tract, low oral absorption, and extensive hepatic first pass metabolism, which contribute to the significant toxicity and reduce therapeutic efficiency associated with conventional chemotherapies. This study aimed to develop and evaluate a mannosamine modified, freeze-dried self-emulsifying drug delivery system (SEDDS) capable of co-delivering chemotherapeutic agents to enhance oral absorption and improve targeted delivery for breast cancer treatment

Methods: Four SEDDS formulations were optimized and prepared using varying ratios of Labrasol, Capryol 90, Labrafac PG, and Gellucire 44/14. Primary water-in-oil emulsions containing doxorubicin and ellipticine were dispersed into an external aqueous phase containing mannosamine to form water-in-oil-in-water double emulsions under passive mixing. Formulations were subsequently freeze dried to yield solid, dispersible SEDDS. The formulations were characterized for particle size, polydispersity index, stability, and morphology (SEM). Thermal behavior (DSC, XRD), drug release profile (In vitro Dissolution), permeation (MDCK cell line), and cellular uptake (MDA MB-231 and MDA MB-468 cell lines) were also assessed.

Results: Optimized surfactant-to-oil ratios (1:9 and 2:8 aqueous: oil phase ratios) produced stable primary and double emulsions suitable for SEDDS development. Microscopy confirmed triphasic w/o/w structures with internal aqueous droplets encapsulated within a lipid phase and surrounded by an external aqueous phase. SEDDS demonstrated particle sizes between 190-587 nm and PDI values of 0.005-0.336. Thermal analyses of freeze dried SEDDS indicated the formation of amorphous mixtures with sustained release kinetics. Fluorescence imaging showed efficient cellular uptake of the dual drug loaded formulations.

Conclusion: A mannosamine modified SEDDS was successfully developed, enabling dual loading of doxorubicin and ellipticine with favorable stability, sustained release, and efficient cellular uptake. This work demonstrates the potential of this lipid-based, modular oral delivery platform to enable mono and combination chemotherapy with improved bioavailability and reduced toxicity. By integrating innovative formulation science with targeted drug delivery, this work contributes to broader efforts at designing safe and effective treatments for cancer.

#3030 SU-CCS-1 lipid extract-modified nanoliposomes and characteristic growth profile of a model clear cell sarcoma target cell line.

Ashley Silva[1], **Abigail Chan**[1], Simoun Banoud[1], Charloote Bouchard[1], Robert B. Campbell[2]

[1]Pharmacy, Massachusetts College of Pharmacy & Health Sciences, Worcester, MA,[2]Massachusetts College of Pharmacy & Health Sci., Worcester, MA

Background: Sarcomas account for approximately 1% of adult cancers and 15% of childhood cancers in the United States. Conventional treatment strategies are somewhat effective during early disease, but once metastasized, treatment success significantly declines. Nanomedicine presents an alternative approach to increase current treatment efficacy and prolong survival. Optimization of liposomal preparations is essential to ensure the most selective targeting. The objective of the study was to develop a novel nanoliposomal drug delivery system using a cellular model of human clear cell sarcoma in vitro.
Methods: The SU-CCS-1 cell line was selected as the cellular model for clear cell sarcoma and used for the drug selectivity studies. SU-CCS-1 cells were cultured and expanded in vitro for cellular extraction purposes. Cellular lipid extract (LE) material was derived from a clear cell sarcoma target (SU-CCS-1) cell line. Nanoliposomes were optimized for LE and cholesterol content. DPPE-Rhodamine (used as a fluorescence indicator) for cellular uptake studies, and a fluorescence microplate reader was used to assess relative fluorescence intensity values. Phase I of evaluation included characterization of cells and cellular uptake properties of nanoliposomal preparations of DOPC and cholesterol consisting of 0, 5, and 10 mol% cholesterol content. To characterize the cellular growth characteristics, separate flasks were prepared with either 100% adherent or 100% suspension cells acquired from a mature mixed cell population. The percentage of adherent and suspension cells was determined on Day 0 and Day 5.
Results: An evaluation of growth profile characteristics of the SU-CCS-1 target cell line revealed a substantial transformation of suspension cells to adherent cells over time. While the flask of 100% adherent cells remained 72% adherent after 5 days, the flask of 100% suspension cells transformed to become 59% adherent after 5 days. The particle size for nanoliposomes containing 0, 5, and 10 mol% cholesterol was 283 nm, 139.9 nm, and 247 nm, respectively. Additionally, the inclusion of 10 mol% SU-CCS-1-LE increased uptake of nanoliposomes compared to 0% LE control preparations (without SU-CCS-1-LE).
Conclusion: Preliminary findings suggest that the DOPC:cholesterol ratio affects nanoliposome uptake by SU-CCS-1 cells. The inclusion of SU-CCS-1-LE in nanoliposomes enhances their targeting efficiency. Ongoing studies will investigate the effect of dual incorporation of optimized cholesterol and SU-CCS-1-LE content on the targeting of clear cell sarcoma.

#3031 Enhanced delivery of doxorubicin via milk-derived extracellular vesicles in lung cancer cells.

Cayden Xuanzhang Xia[1], Elise Copeland[2], Akhil Srivastava[3]

[1]Emory University, Atlanta, GA,[2]College of Arts & Sciences, Department of Chemistry, Georgia State University, Atlanta, GA,[3]Departments of Pathology and Anatomical Sciences, Ellis Fischel Cancer Center, University of Missouri School of Medicine, Columbia, MO

Introduction:
Extracellular vesicles (EVs) are nano-sized particles that mediate intercellular communication by transporting proteins, lipids, and nucleic acids. Due to their natural origin and biocompatibility, EVs have gained attention as potential drug delivery systems. However, their clinical use has been limited by low delivery efficiency and potential cytotoxicity. Milk-derived EVs, especially from skim milk and milk powder, offer advantages such as resistance to digestive enzymes and minimal toxicity. Our previous studies demonstrated their effective encapsulation and delivery of doxorubicin, a widely used chemotherapeutic agent.
Materials and Methods:
EVs were isolated from skim milk and milk powder and characterized using nanoparticle tracking analysis (NTA) for size and concentration, and protein content was measured via BCA assay. Doxorubicin was loaded into EVs, and the EV-doxorubicin formulation was tested in A549 and H1299 lung cancer cell lines. Cells were treated with either free doxorubicin or EV-doxorubicin, and apoptosis and viability were assessed at 24, 48, and 72 hours. Apoptosis-related proteins PARP-1, Caspase-9, and Caspase-3 were analyzed using Western blotting.
Results:
The EV-doxorubicin complex demonstrated superior uptake and significantly reduced cell viability in both cell lines compared to free doxorubicin. Apoptosis levels were consistently higher in the EV-doxorubicin-treated groups across all time points. Western blot analysis revealed reduced levels of total PARP-1, Caspase-9, and Caspase-3, supporting enhanced apoptotic activity. EVs alone did not exhibit cytotoxic effects, confirming their safety.
Discussion:
Milk-derived EVs can efficiently encapsulate and deliver doxorubicin, enhancing its therapeutic effects in lung cancer cells while minimizing toxicity. These results highlight the potential of milk EVs as safe and effective drug delivery vehicles for chemotherapeutics.

#3032 Electroporation-enhanced targeted bleomycin delivery for the treatment of canine perianal tumors.

Sergio Fernando Salgado[1], Josmell David Mestanza[2], Andrea Hatsumi Bazan[2], Micaela Vizquerra[2], Mitzi Westreicher[2], Nandi Ken Candela[2]

[1]Universidad Peruana Cayetano Heredia, Lima, Peru,[2]Creo Vet, Lima, Peru

Introduction: Perianal tumors are common in middle-aged to older male dogs. Treatment of these tumors remains a clinical challenge due to the complex anatomy of the region and limited surgical margins, which increase the risk of local recurrence. In this context, electrochemotherapy (ECT) emerges as a promising non-surgical alternative that combines chemotherapeutic agents, such as bleomycin, with high-intensity and short-duration electric pulses, enhancing cell membrane permeability and potentiating the antitumor effect. The objective of this study was to evaluate the efficacy and safety of ECT as a non-surgical treatment for perianal tumors.

Materials and methods: Medical records of dogs of various breeds diagnosed with perianal neoplasms confirmed by histopathology were reviewed. Both benign and malignant lesions of variable size and number were included, excluding apocrine gland anal sac carcinomas. For each patient, the number of treatment sessions, type of clinical response, and recurrence were recorded. All animals underwent ECT consisting of eight monophasic pulses at 5 kHz and an electric field strength of 1,000 V/cm using a long needle electrode. The first pulse was delivered 8 minutes after the administration of intravenous bleomycin (15,000 IU/m2).

Results and discussion: Thirty-three dogs with perianal tumors were treated with ECT. The most frequent diagnoses were adenocarcinoma (57.6%), adenoma (36.4%), and hemangiosarcoma (6.1%). Most lesions were solitary (75.8%) and varied in size: <1cm (30.3%), 1-3 cm (48.5%), and >3cm (30.3%). A single ECT session was sufficient in 87.9% of cases, while 12.1% required two sessions. A complete response (CR) was achieved in 87.9% of patients, and a partial response (PR) was 12.1%. No cases of progressive or stable disease were reported in this study. Regarding tumor type, adenomas showed a 90.9% complete response rate, adenocaricnomas 84.2%, and hemangiosarcomas 100%. The recurrence rate was low (9.1%) with an overall treatment efficacy of 90.9%. Adverse effects were mild and self-limiting, consisting mainly of local inflammation (100%) and transient pain. However, one case presented with mild post-procedural constriction and constipation.

Conclusions: Electrochemotherapy represents an effective option for managing canine perianal tumors, particularly when complete surgical excision is not feasible or when preservation of anal function is desired.

#3033 Electrochemotherapy for rectal adenocarcinoma: Advancing drug delivery through electroporation.

Sergio Fernando Salgado[1], Josmell David Mestanza[2], Micaela Vizquerra[2], Mitzi Westreicher[2], Nandi Ken Candela[2], Andrea Hatsumi Bazan[2]

[1]Universidad Peruana Cayetano Heredia, Lima, Peru,[2]Creo Vet, Lima, Peru

Introduction: Rectal adenocarcinoma is the most common tumor of the lower digestive tract of the dogs, affecting the quality of life. Electrochemotherapy (ECT) is a novel drug delivery system that enhances the intracellular delivery of low-permeability cytostatic drug through the transient permeabilization of the cell membrane. This study aimed to evaluate ECT as a treatment for colorectal adenocarcinoma in dogs

Experimental procedure: Twelve dogs diagnosed with rectal adenocarcinoma were included. For each patient, data recorded included, breed, sex, tumor size, number of treatment sessions, clinical response, recurrence, disease-free interval and post treatment complications. The therapeutic protocol consisted in intravenous administration of Bleomycin (15,000 IU/m2). Traction points were placed in the rectal mucosa to facilitate exposure of the lesion to be treated. Eight minutes after drug administration, electric pulses were delivered using a Biotex EPV200 electroporator (Argentina). A train of eight monophasic pulses (1000V/cm, 5000Hz) was applied using needle and plate electrodes.

Results: This is the first study in dogs evaluating ECT for rectal adenocarcinoma. Most tumors were pedunculated and smaller than 1cm (9/12).; the remaining were broad-based, with one case involving nearly the entire rectal circumference. All lesions were located within 3cm of the anus. All dogs (12/12) underwent a single treatment session, achieving a 100% complete response rate. Ten of twelve dogs remained disease-free at the end of the study; one died of unrelated causes after two years, and two showed local recurrence (at 308 and 688 days, respectively), the latter successfully retreated and disease-free to date, with survival exceeding 1350 days. Observed complications included local inflammation and tenesmus; pain and constipation were reported in two cases.

Conclusion: Bleomycin delivered by electroporation for rectal adenocarcinoma in dogs proved to be effective and can be considered a first-line alternative to surgery. A comprehensive medical management plan is recommended to address post treatment complications.

#3034 Feasibility and safety of electroporation-enhanced bleomycin delivery for the treatment of parenchymal tumors in dogs and cats.

Sergio Fernando Salgado[1], Andrea Hatsumi Bazan[2], Josmell David Mestanza[2], Nandi Ken Candela[2], Mitzi Westreicher[2], Micaela Vizquerra[2]

[1]Universidad Peruana Cayetano Heredia, Lima, Peru,[2]Creo Vet, Lima, Peru

Introduction: Cancer affecting parenchymal organs in dogs and cats present a therapeutic challenge, particularly in cases of multiple lesions or locally advanced disease where surgery is not indicated and medical therapies offer limited response. Electrochemotherapy (ECT) facilitates bleomycin entry into cells through the formation of transient membrane pores, providing a precise drug delivery that enhances cytotoxic efficacy. The aim of this study was to report the safety and feasibility of ECT for the management of parenchymal tumors in both species.

Materials and methods: Five patients (four dogs and one cat) diagnosed with hepatic or pancreatic cancer, for whom no therapeutic option was feasible, were included. Recorded variables included diagnosed pathology, clinical presentation, treatment duration, clinical response, and short-and long-term adverse effects. Bleomycin (15,000 IU/m2) was administered intravenously, followed by electric pulse application using a Biotex EPV200 electroporator (Argentina). Electric pulses (eight pulses of 100 µs, 1.000 V/cm, 5 kHz) were delivered to all lesions, planned preoperatively via computer tomography. Response was evaluated by ultrasonography at 30 and 60 days post-treatment.

Results: Among the four dogs, three were diagnosed with multifocal hepatocellular carcinoma and one with insulinoma. Additionally, a cat was diagnosed with pancreatic adenocarcinoma. All cases were treated. Hepatic lesions were ≤3 cm, located in different lobes, with 2-3 nodules treated per patient. The insulinoma (2.66 x 0.88 cm) was located in the right pancreatic lobe, and the feline adenocarcinoma (2.15 x 1.63 x 1.89cm) was found i the pancreatic body in contact with the duodenum and the pancreaticoduodenal vein. All treatments were performed via laparotomy. A foldable needle electrode was used for hepatic lesions due to deeper access, while plate electrodes were selected for pancreatic tumors to ensure complete coverage. The mean treatment duration was 15 minutes from bleomycin infusion, with longer times for hepatic cases. All patients achieved a complete response: hepatic tumors by day 60, the feline pancreatic tumor showed a partial response at day 30, and a complete response by 6 months. Among hepatic cases, one showed transient liver enzyme elevation, and another case showed normalization of liver enzymes. For pancreatic cases, the specific pancreatic lipase was elevated post-treatment. All animals experienced mild to moderate pain, slightly prolonged in the cat. The dog with insulinoma resolved hypoglycemia but later developed diabetes mellitus requiring medical management, the only long-term adverse outcome observed.

Conclusions: Electroporation-mediated bleomycin delivery represents a viable and safe option for the treatment of malignant parenchymal tumors. Further studies are needed to confirm these preliminary findings.

#3035 Electrochemotherapy as an innovative drug delivery modality for local control of canine acanthomatous ameloblastoma.

Sergio Fernando Salgado[1], Andrea Hatsumi Bazan[2], Josmell David Mestanza[2], Micaela Vizquerra[2], Nandi Ken Candela[2], Mitzi Westreicher[2]

[1]Universidad Peruana Cayetano Heredia, Lima, Peru,[2]Creo Vet, Lima, Peru

Introduction: Acanthomatous ameloblastoma is the most common odontogenic epithelial tumor in dogs. Block excision is the treatment of choice since marginal removal has a recurrence rate exceeding 90% within one year. Electrochemotherapy (ECT) enables intracellular delivery of bleomycin, inducing apoptotic cell death. The aim of this study was to evaluate efficacy, response and complications of ECT in canine ameloblastomas.

Materials and Methods: Twelve dogs with histopathologically confirmed oral ameloblastoma were included. Of the lesions analyzed, nine were smaller than 2 cm and three were larger than 2 cm. All patients were treated with ECT in one or two sessions. In 11 of 12 cases, tooth extraction was required to optimize tumor access. Treatment was performed using an EPV-200 electroporator (Biotex, Argentina) with needle electrodes. Bleomycin was administered intravenously at a dose of 15000 IU/m^2, eight minutes prior to delivering the electric pulses (train of eight 100 µs pulses, 1000 V/cm, 5000 Hz). Tumor response, recurrence and post treatment complications were recorded.

Results: Seventy-five percent (9/12) of the lesions were smaller than 2 cm. A single ECT session was performed in 10 patients (8.3.3%), while the remaining two required a second session- one at 30 days and another at 95 days- based on the initial treatment response. Smaller lesion (<2cm) showed better response when the entire tumor was covered by the electric field. In 11 of 12 cases (91.6%) partial tooth removal was necessary to ensure complete exposure of the tumor and its origin. Clinical responses were complete in 83.3% (10/12), partial in 8.3% (1/12), and stable disease in 8.3% (1/12), with no cases of tumor progression during the follow- up. The main postoperative complications were local inflammation (100%) and mild to moderate pain (33.3%), both managed successfully with analgesic and anti-inflammatory therapy.

Conclusions: Electrochemotherapy represents an effective and safe therapeutic alternative for the conservative management of canine ameloblastoma. Early detection and treatment are associated with higher complete response rates. Extraction of adjacent teeth improves treatment efficacy by enhancing electric field contact with the tumor tissue. Post treatment pain and inflammation control are essential to minimize complications and optimize recovery.

#3036 Intellipulse platform for efficient and effective delivery of therapeutics to solid tumors.

Richard Heller[1], Loree Heller[2], Jody Synowiec[2], Julie Singh[2], Alex Otten[2], Mark J. Jaroszeski[2]

[1]USF Health Morsani College of Medicine, Tampa, FL,[2]University of South Florida, Tampa, FL

The Intellipulse® system is a next generation user-friendly platform for safe and controlled delivery of therapeutics to solid tumors. One issue with delivering therapeutics is being able to get the agent where it is needed without unwanted adverse effects related to clearance of a carrier or off-target events. The second issue with any nucleic acid delivery is having confidence that delivery has occurred. We have demonstrated the utility of this platform by delivering two plasmids encoding immune modifiers directly to melanoma tumors to induce a robust immune response. We previously demonstrated that the intratumor delivery of a plasmid encoding interleukin-12 (pIL-12) resulted in a significant increase in T effector cells and a reduction in T regulatory cells and myeloid derived suppressor cells within the TME, inducing a robust systemic immune response that was amplified when combined with ICIs. The key to make this an effective therapy is to deliver these agents in a manner that has minimal adverse and off target effects while still inducing the desired response. We have designed a novel approach to efficiently deliver multiple plasmids directly to solid tumors. The rationale was based on the premise that by performing intratumor delivery, stimulation would be directed against the specific antigens within the TME to produce an effective local response while stimulating a systemic response, resulting in an abscopal effect. This delivery utilizes a next generation electrotransfer device that enables the use of significantly reduced voltages and includes a means to monitor when successful delivery has occurred. We tested this concept in the B16.F10 mouse melanoma model. Intratumor delivery of pIL-12 resulted in effective control of the treated tumor in over 90% of the mice and generated resistance to challenge. To fully test this approach, we next evaluated a combination therapy delivering both pIL-12 combined with a plasmid encoding the extracellular domain of the PD1 protein, as an alternative form of checkpoint inhibitor. The therapy was tested in a multi-tumor model which included a subcutaneous tumor and intraperitoneal injection of tumor cells. The plasmids were delivered to the subcutaneous tumor; tumors generated by intraperitoneal injection were untreated. Peritoneal tumor growth was not affected by single plasmid delivery or when both plasmids were delivered using other delivery approaches or older electrotransfer technology. Delivery of the plasmids with the Intellipulse® platform resulted in two significant results. Binding of the expressed PD1 peptide to PDL1 on tumor cells was observed by immunohistochemistry and flow cytometry. In addition, complete regression in 90% of the treated mice of the subcutaneous tumor and blockage of peritoneal tumor growth as assessed via in vivo imaging was observed. Work is continuing to explore the treatment of other tumor types.

#3037 Investigating the therapeutic potential of a nanocrystal PRMT5 inhibitor in pancreatic ductal adenocarcinoma.

Faranak Alipourgivi[1], Zhongyue (Claire) Yuan[2], Rahaf Habboub[3], Yoon Yeo[4], Tao Lu[5]

[1]Translational Cancer Biology, Indiana University Melvin and Bren Simon Comprehensive Cancer Center, Indianapolis, IN,[2]Department of Industrial and Molecular Pharmaceutics, Purdue University, West Lafayette, IN,[3]Biochemistry, Molecular Biology and Pharmacology, Indiana University School of Medicine, Indianapolis, IN,[4]Industrial and Molecular Pharmaceutics, Purdue University, West Lafayette, IN,[5]Department of Biochemistry, Molecular Biology and Pharmacology, Indiana University School of Medicine, Indianapolis, IN

Persistent inflammation is a defining feature of pancreatic ductal adenocarcinoma (PDAC), largely driven by sustained activation of the NF-κB signaling pathway. Disruption of NF-κB regulatory mechanisms contributes significantly to this chronic activation. Protein arginine methyltransferase 5 (PRMT5), a known promoter of tumorigenesis in several cancers, including PDAC, colorectal, and breast, has emerged as a promising therapeutic target. Clinical data reveal that PDAC patients with high PRMT5 expression have significantly shorter median survival, underscoring its prognostic and therapeutic relevance. Our lab has been developing small-molecule inhibitors targeting PRMT5. Among these, our patented compound, PR5-LL-CM01 (CM01), has shown superior anti-tumor efficacy and reduced toxicity in PDAC models compared to the commercially available PRMT5 inhibitor EPZ015666. However, CM01's poor water solubility poses a challenge for clinical translation. To address this, we aim to enhance its water dispersibility and bioavailability by formulating CM01 as an albumin-coated nanocrystal (NC) (Abxtal). Preliminary studies confirmed successful production and physicochemical characterization of CM01 NCs, which have an optimized particle size (Z-average ~87 nm) and can be stored at -20ºC as lyophilized solid for at least three months. In this project, we assess the therapeutic potential of CM01 NC in vitro and in vivo. We hypothesize that CM01 NC more effectively inhibits PRMT5-mediated NF-κB signaling and associated oncogenic processes than unformulated CM01, and that it synergizes with gemcitabine (Gem) to suppress PDAC progression. Supporting this hypothesis, CM01 NC showed equal or greater inhibition of PDAC PANC1 and MIA PaCa2 cell growth compared to CM01, and more effectively suppressed 3D spheroid growth and cell migration in vitro. CM01 NC also outperformed CM01 in reducing NF-κB transcriptional activity, with comparable reductions in NF-κB target genes (TNF-α and IL-8) per qPCR assays. Additionally, Chou-Talalay analysis demonstrated that CM01 NC exhibits synergistic activity with Gem. We are now transitioning to in vivo studies to evaluate the pharmacokinetics and therapeutic efficacy of CM01 NC, both as a monotherapy and in combination with Gem, using PDAC models. This study may establish CM01 NC, alone or with Gem, as a promising therapeutic strategy, and could lay the foundation for clinical development of CM01 NC-based treatments for PDAC.

Poster Session

#3040 FOXM1 as a drug target in NF1-associated malignant peripheral nerve sheath tumors.

Ellen M. Voigt[1], Quinn Hanigan[2], Joshua J. Lingo[2], Altay Koyas[2], Rebecca D. Dodd[3], Benjamin W. Darbro[4], Dragana Kopanja[5], Sung Hoon Kim[6], Benita S. Katzenellenbogen[7], John A. Katzenellenbogen[6], Dawn E. Quelle[2]

[1]Medical Scientist Training Program, University of Iowa, Iowa City, IA,[2]Neuroscience and Pharmacology, University of Iowa, Iowa City, IA,[3]University of Iowa College of Medicine, Iowa City, IA,[4]Pediatrics, University of Iowa, Iowa City, IA,[5]Biochemistry & Molec. Genetics, University of Illinois at Chicago, Chicago, IL,[6]Dept. of Chemistry, University of Illinois at Urbana-Champaign, Urbana, IL,[7]Dept of Physiology and Cancer Center, University of Illinois at Urbana-Champaign, Urbana, IL

Purpose: Malignant peripheral nerve sheath tumors (MPNSTs) are deadly sarcomas that arise spontaneously or via transformation of benign tumors, called plexiform neurofibromas (PNFs) and atypical neurofibromatous neoplasms of uncertain biologic potential (ANNUBPs), in patients with Neurofibromatosis Type 1 (NF1). Understanding molecular events that cooperate to promote malignancy is a priority in the field. One putative driver, FOXM1, is a powerful transcription factor that heightens the activities of kinases, MEK and CDK4/6, known to drive MPNST growth. We sought to understand the role of FOXM1 in these deadly sarcomas and *hypothesized it is a new druggable target that is essential for MPNST pathogenesis.*
Methods: FOXM1 mRNA and protein expression were evaluated in patient-matched PNFs, ANNUBPs, and MPNSTs via RNA-Seq and IHC. For *in vitro* studies, knockdown (KD) of FOXM1 was performed in MPNST cell lines (S462, sNF96.2, JH2-002). Proliferation, survival, and cell cycle progression were measured in response to FOXM1 inhibitors, including newly developed NB-55, NB-73 and NB-115 drugs. To directly test the *in vivo* role of FOXM1 in MPNST initiation and progression, *de novo* MPNSTs were initiated by *Nf1/Ink4a/Arf* editing in the sciatic nerve of $Nf1^{+/-}$, DhhCre, *Foxm1* floxed mice relative to $Nf1^{+/-}$;DhhCre controls.
Results: In patient-matched tumor sets, *FOXM1* mRNA was significantly elevated in MPNSTs relative to PNF/ANNUBP precursor lesions. FOXM1 protein expression rose dramatically in a stepwise manner from normal nerve to PNFs, ANNUBPs, and MPNSTs. FOXM1 KD slowed MPNST cell growth. FOXM1 inhibitors (thiostrepton, FDI-6, and multiple NB drugs) effectively inhibited MPNST proliferation and induced apoptosis. Synergistic killing of MPNST cells was obtained by combining thiostrepton with a MEK inhibitor (mirdametinib), CDK4/6 inhibitor (palbociclib), or EGFR inhibitor (gefitinib), while NB drugs synergized best with gefitinib. Excitingly, targeted *in vivo* deletion of *Foxm1* in the sciatic nerve significantly slowed tumor progression.
Conclusion: Our data demonstrate FOXM1 is an important driver of MPNST pathogenesis. FOXM1 expression and transcriptional activity are greatly increased in MPNSTs compared to benign precursors from the same patients. In agreement, genetic and therapeutic inactivation of FOXM1 promoted MPNST cell arrest and death. Synergistic killing of MPNSTs was achieved by combined inhibition of FOXM1 with MEK, CDK4/6, or EGFR while *Foxm1* ablation in the sciatic nerve significantly slowed tumor progression *in vivo*. Together, these findings reveal that FOXM1 inhibition in specific combination therapies represents a new treatment strategy for MPNST patients.

#3041 Selective PARP2 inhibitor disrupting PARP2-FOXA1 interaction to inhibit androgen receptor signaling in prostate cancer.

Fu Gui[1], Wenfei Hu[2], Qi Miao[3], Zhi Tan[4], Mingxing Teng[3], Adam S. Kibel[1], Wei Zhang[2], Li Jia[1]

[1]Department of Urology, Brigham and Women's Hospital, Harvard Medical School, Boston, MA,[2]Department of Chemistry, University of Massachusetts Boston, Boston, MA,[3]Department of Pathology & Immunology, Center for Drug Discovery, Baylor College of Medicine, Huston, TX,[4]Department of Pharmacology & Chemical Biology, Center for Drug Discovery, Baylor College of Medicine, Huston, TX

Currently targeting androgen receptor (AR) pathways is the primary treatments for advanced prostate cancer (PCa). However, resistance to AR pathway inhibitors and emergence of castration-resistant prostate cancer (CRPC) remain a significant clinical challenge. We previously found that PARP2 interacts with FOXA1 to facilitate the recruitment of AR to genome-wide prostate-specific enhancer regions. Selective disruption of the PARP2-FOXA1 interaction inhibited AR signaling and PCa growth. However, lack of selectivity and potency of existing PARP2/FOXA1-targeting agents and uncertainty of the functional importance of PARP2-FOXA1 binding have limited our study. To address these gaps, we developed a potent small molecule inhibitor UMB-J17 that disrupts PARP2-FOXA1 interaction. In this study, we demonstrated that UMB-J17 competes with FOXA1 for the same PARP2 binding sites, and significantly suppresses AR signaling and PCa cell growth without involving AR-ligand binding. Preclinical studies demonstrated that UMB-J17 exerts potent anti-tumor effects in both in vitro and in vivo CRPC models. UMB-17 also exhibits potent synthetic effect with AR pathway inhibitors in enzalutamide-resistant CRPC models. Furthermore, UMB-J17 enhanced the synthetic lethality of PARP inhibition through AR signaling suppression in PCa. These findings identify UMB-J17 as a promising therapeutic agent that targets PARP2/FOXA1/AR axis for AR signaling inhibition, which is urgently needed to improve CRPC patient outcomes.

#3042 Inhibition of *de novo* purine biosynthesis via PPAT targeting by cucurbitacin B restrains esophageal squamous cell carcinoma growth.

Mengqiu Song[1], Jing Guo[1], Huajie Jia[1], Jie Tian[2], Pan Li[2], Zigang Dong[3]

[1]Department of Pathophysiology, School of Basic Medical Sciences, Henan Medical College, Zhengzhou University, Zhengzhou, China,[2]China-US (Henan) Hormel Cancer Institute, Zhengzhou, China,[3]Henan Medical College, Zhengzhou University, Zhengzhou, China

Background: The *de novo* purine biosynthesis (DNPB) pathway plays a critical role in the malignant progression of tumors. However, its specific contribution to esophageal squamous cell carcinoma (ESCC) growth, radioresistance, and response to targeted therapies remains poorly understood.
Methods: In this study, the underlying metabolic change of ESCC were analyzed by untargeted metabolomics and single-cell RNA sequencing data analyses. The expression and function of PPAT were further evaluated through immunohistochemistry (IHC) and lentivirus-mediated gene manipulation. Additionally, patient-derived xenograft (PDX) and cell-derived xenograft (CDX) models were utilized to assess the role of PPAT and its inhibitor in ESCC tumor growth and radioresistance.
Results: In this study, we identified phosphoribosyl pyrophosphate amidotransferase (PPAT), a key rate-limiting enzyme in the DNPB pathway, as a critical modulator of ESCC malignancy. We demonstrated that PPAT promotes the production of energy-related nucleotides, including AMP, GMP, ADP, GDP, ATP, and GTP, thereby fueling ESCC tumor growth in vitro and in vivo. Moreover, we found that Cucurbitacin B (CuB) specifically targets PPAT and induces its polyubiquitin-mediated degradation via the E3 ligase TRIM38, leading to suppression of the DNPB pathway and inhibition of tumor growth. Importantly, CuB also functions as a radiosensitizer, significantly enhancing the therapeutic efficacy of radiotherapy in ESCC.
Conclusions: Our findings reveal that targeting PPAT represents a promising therapeutic strategy to suppress ESCC progression and enhance the efficacy of radiotherapy.

#3043 CKAP2 modulation with a novel small molecule results in excellent *in-vitro* and *in-vivo* anti tumor activity.

Deepa M. Sridharan, Vignesh Viswanathan, Dmitry Kuchenov, Quynh Mai, Yerem Yeghiazarians, Kurosh Ameri

Soley Therapeutics, South San Francisco, CA

Cytoskeleton-Associated Protein 2 (CKAP2) is an intrinsically disordered protein, considered undruggable, and the most potent microtubule growth factor identified to date. It is associated with malignant progression, modulating multiple cancer-associated processes including cell proliferation, migration, metastasis and angiogenesis, and may act as a functional oncogene by targeting FAK-ERK2 signaling pathway. CKAP2 has been reported to be an important prognostic marker and potential therapeutic target in certain cancers (e.g. non-small cell lung cancer). We have discovered and are developing an oral CKAP2 small molecule modulator as a potential treatment for cancer. Bioinformatics analysis of a 300 tumor cell line panel treated with the CKAP2 modulator demonstrated a strong correlation between CKAP2 protein abundance and drug sensitivity across cancer types, with large B cell lymphoma and acute myeloid leukemia showing the highest drug sensitivity. Additionally, analysis in the TCGA cohort indicated that CKAP2 RNA expression was significantly elevated in patient tumors compared to normal tissues and strongly correlated with their predicted sensitivity to the CKAP2 modulator. Protein array analysis revealed that proteins associated with predicted sensitivity are involved in downstream pathways of CKAP2 such as cell migration and focal adhesion signaling. Functional studies indicated down-stream pathways of CKAP2 to be affected upon treatment. Treatment of cells with either the CKAP2 modulator, or with CKAP2 targeting siRNA, similarly decreased FAK protein level, reduced migration and diminished cell viability/count. Immunofluorescence-based assays confirmed altered CKAP2 phenotype and disruption of microtubule network upon treatment, resulting in G2/M cell cycle arrest. Furthermore, CKAP2 modulation significantly inhibited angiogenesis in tube formation assays using HUVECs and maintained activity in hypoxia, which is a driver of angiogenesis and associated with resistance to many therapies. In-vivo efficacy was demonstrated in a mouse xenograft model of non-small cell lung cancer and three different models of colon cancer with up to 79% tumor volume reduction noted at the highest dose tested and was well tolerated. In conclusion, we have discovered a first-in-class, oral small molecule which modulates CKAP2 and its downstream pathways indicating very good anti-tumor activity both in-vitro and in-vivo. This novel therapy is being considered as a promising therapeutic candidate for the treatment of CKAP2 expressing cancers.

#3044 PKMYT1 inhibition is synthetically lethal with CCNE1 overexpression and synergizes with standard of care chemotherapy.

Natalie Hill, Jeremy Fournier, Srijita Bhowmik, Jenny Zhu, Saranya Chandrasekar, Ester Fernandez-Salas, **Samantha S. Hodge**

Arcus Biosciences, Inc., Hayward, CA

BACKGROUND: CCNE1 is frequently overexpressed in ovarian, endometrial, and colorectal cancers due to gene amplification, reduced degradation (via FBXW7 mut/del), or increased gene transcription. High levels of CCNE1 dysregulate the G1/S checkpoint, increase replication stress, and amplify dependence on the G2/M checkpoint to ensure proper DNA damage repair before mitosis. Additionally, high CCNE1 levels are associated with poor prognosis and response to therapy, highlighting the need for improved treatments for CCNE1 high cancers. PKMYT1 is a protein kinase that regulates the G2/M checkpoint. The data presented here demonstrate that PKMYT1 inhibition, which inactivates the G2/M checkpoint and pushes cells into mitosis, is both synthetically lethal in CCNE1-high cancer cells and synergizes with standard of care chemotherapy *in vitro* and *in vivo*.
METHODS: CCNE1-high cell lines were selected based on CCNE1 gene amplification or FBXW7 LOF. Sensitivity of CCNE1-high cell lines to single agent PKMYT1 inhibition was assessed by measuring the cell cycle, DNA damage, apoptosis, and cell viability. CCNE1-high cancer cell viability was also measured after combined treatment of PKMYT1 inhibition and standard of care chemotherapy. Bliss synergy scores were used to determine synergy. *In vivo* efficacy of PKMYT1 inhibition alone and in combination with chemotherapy was assessed using CCNE1-high human xenograft models.
RESULTS: In CCNE1-high cancer cells, PKMYT1 inhibition disrupts the cell cycle by increasing entry into mitosis, thereby inducing DNA damage and apoptosis. Non-tumorigenic cells are insensitive to PKMYT1 inhibition. In CCNE1-high xenograft models, PKMYT1 inhibition exhibits significant single agent tumor growth inhibition, and its efficacy correlates with increased mitotic entry. Importantly, PKMYT1 inhibition synergizes with standard of care chemotherapies, namely those targeting the S and G2 phases of the cell cycle, in CCNE1-high cancers both *in vitro* and *in vivo*.
CONCLUSION: The data presented here strongly support targeting CCNE1-high cancer cells with a combination of PKMYT1 inhibition and chemotherapy. CCNE1-high cancer cells, which accumulate DNA damage in S phase due to a dysregulated G1/S checkpoint, are highly susceptible to PKMYT1 inhibition due to the propagation of this increased DNA damage into mitosis. Additionally, chemotherapies targeting S/G2 phases, including nucleoside analogs and topoisomerase inhibitors, combine with PKMYT1 inhibition by further enhancing replication stress. Importantly, non-tumorigenic cells are insensitive to PKMYT1 inhibition due to intact G1/S checkpoint and DNA damage repair pathways. In summary, these data highlight PKMYT1 inhibition as a promising approach to selectivity target CCNE1-high cancer cells and enhance the effectiveness of standard of care chemotherapies while sparing non-tumorigenic cells.

#3045 TM4SF20 scaffolds DDR1-IRS4 signaling to drive PDAC metastasis and represents a druggable therapeutic target.

Xinyue Liu[1], Weishuai Liu[2], Antao Chang[1], Jihui Hao[1]

[1]Department of Pancreatic Cancer, Tianjin Medical University Cancer Institute and Hospital, National Clinical Research Center for Cancer, State Key Laboratory of Draggability Evaluation and Systematic Translational Medicine, Tianjin, China,[2]Department of Pain Management, Tianjin Medical University Cancer Institute & Hospital, National Clinical Research Center for Cancer, Tianjin Key Laboratory of Digestive Cancer, Tianjin's Clinical Research Center for Cancer, Tianjin, China

Pancreatic ductal adenocarcinoma (PDAC) exhibits an exceptionally high propensity for liver metastasis, which critically contributes to its poor clinical outcomes. However, therapeutic strategies specifically targeting metastatic progression remain limited. In this study, we investigated the molecular mechanisms driving PDAC liver metastasis and explored therapeutic approaches capable of suppressing metastatic dissemination. Leveraging single-cell sequencing data from pancreatic cancer samples collected at our center, we identified transmembrane 4 L six family member 20 (TM4SF20), a tetraspanin-like transmembrane protein, as a previously unrecognized driver of metastatic progression. TM4SF20 is markedly upregulated in PDAC and highly enriched within liver metastatic lesions. Through integrative analyses combining clinical pathological data, TM4SF20-knockout mouse models, organoid systems, and multiple experimental platforms—including small-animal PET-CT, ultrasonography, immunoprecipitation-mass spectrometry, and in vitro kinase assays—we systematically validated the functional role of TM4SF20 in promoting PDAC liver metastasis. Mechanistically, TM4SF20 acts as a membrane “bridge molecule”: its extracellular domain binds discoidin domain receptor 1 (DDR1), while its intracellular domain interacts with insulin receptor substrate 4 (IRS4). This scaffolding enables DDR1-dependent phosphorylation of IRS4 at T208, thereby activating the AKT signaling cascade and enhancing invasive and metastatic phenotypes. Therapeutic blockade of TM4SF20 with a monoclonal antibody (αTM4SF20) disrupted DDR1-IRS4 complex formation, suppressed downstream signaling, and attenuated PDAC cell migration and invasion. Guided by this mechanistic insight, we developed a TM4SF20-directed antibody-drug conjugate (TM4SF20-ADC) by conjugating αTM4SF20 with the topoisomerase I inhibitor deruxtecan (DXD). TM4SF20-ADC retained high target specificity and exhibited potent antitumor activity, inducing apoptosis, depleting metastatic TM4SF20-positive cells, and markedly inhibiting tumor growth and liver metastasis. In orthotopic PDAC models with established liver metastases, TM4SF20-ADC simultaneously eliminated primary and metastatic lesions, significantly reducing tumor burden and extending survival without detectable systemic toxicity. Collectively, this study identifies TM4SF20 as a key metastatic driver and establishes TM4SF20-targeted ADC therapy as a promising translational strategy for PDAC liver metastasis.

#3046 Robust and durable antitumor activity of a novel PDE10 inhibitor, ADT-030, that enhances the efficacy of chemotherapy and immunotherapy by blocking RAS and β-catenin signaling and overcoming resistance to RAS-selective inhibitors.

Gary A. Piazza[1], Dhana Sekhar Reddy Bandi[2], Veronica Ramirez Alcantara[3], Ganji Purnachandra Nagaraju[2], Junwei Wang[1], Sindhu Ramesh[1], Kristy Berry[1], Khalda Fadlalla[1], Elmar Nurmemmedov[4], Ivan Babic[4], Md Yeashin Gazi[5], Xi Chen[1], Jeremy B Foote[2], Adam B Keeton[1], Yulia Y. Maxuitenko[1], Donald Buchsbaum[2], Fokhrul Hossain[6], Gang Zhou[5], Bassel F. El-Rayes[2]

[1]Auburn University, Auburn, AL,[2]University of Alabama at Birmingham, Birmingham, AL,[3]University of South Alabama, Mobile, AL,[4]CellarisBio LLC, San Diego, CA,[5]Augusta University Medical Center, Augusta, GA,[6]Louisiana State University Health Sciences Center, New Orleans, LA

Resistance to mutant or isoform-specific KRAS inhibitors from compensatory activation of MAPK/AKT signaling by unchecked non-mutant RAS isoforms supports the development of pan-RAS inhibitors. However, secondary mutations or aberrant activation of other oncogenic pathways (e.g., Wnt/APC/β-catenin) may cause resistance to pan-RAS inhibitors. We and others have reported that the cyclic nucleotide-phosphodiesterase 10A (PDE10) isozyme is overexpressed in cancer cell lines and tumors but has low expression and no known function in tissues outside the CNS. PDE10-specific inhibitors and gene silencing were found to selectively inhibit the growth of cancer cells. PDE10 inhibitors developed to treat CNS disorders achieve high brain levels but low levels in peripheral tissues. Thus, we designed a novel, orally bioavailable PDE10 inhibitor, ADT-030, that achieves high systemic levels exceeding those required to inhibit recombinant PDE10 but lacks the major side effect (sedation) caused by conventional PDE10 inhibitors. ADT-030 bound to PDE10 and activated protein kinase G in cancer cells within the same concentration range that inhibited proliferation and induced apoptosis of a large panel of histologically diverse cancer cell lines. These effects also occurred within the same concentration range at which ADT-030 inhibited RAS-mediated MAPK/AKT signaling and selectively degraded the oncogenic (transcriptionally active) pool of β-catenin. Notably, cancer cell lines that developed resistance to pan-RAS, pan-KRAS, or mutant-specific KRAS inhibitors retained full sensitivity to ADT-030. ADT-030 strongly inhibited tumor growth in mouse models of colon, lung, breast, and pancreatic cancer at dosages that were well tolerated. Pancreatic cancer models were particularly sensitive to ADT-030, resulting in tumor regression, inhibition of metastasis, and prolonged survival. ADT-030 also increased survival and inhibited metastasis in mouse models of lung cancer with a durable response that persisted well beyond the treatment period, resulting in cures. ADT-030 also enhanced the antitumor activity of chemotherapy (paclitaxel) and immune checkpoint inhibitors in mouse models of lung, colon, and breast cancer. Deep immunophenotyping studies revealed a significant impact of ADT-030 treatment on the tumor immune microenvironment, characterized by the selective induction of apoptosis in myeloid-derived suppressor cells (MDSC), while increasing tumor infiltration by CD8+ T cells and natural killer cells. These results show that ADT-030 has potential advantages over direct-acting RAS inhibitors, supporting clinical trials of ADT-030 as a monotherapy or in combination with chemotherapy or immunotherapy for a broad range of RAS-driven cancers.

#3047 A small molecule inhibitor of NVL suppresses tumor growth by blocking ribosome biogenesis.

Arin B. Aurora[1], Holly H. Guo[1], Ye Tao[1], Victor E. Cruz[2], Min Fang[1], Vlshal Khivansara[1], Shanhai Xie[1], Ashley Leach[1], Divya Reddy[1], Johann Peterson[1], Jiwoong Kim[3], Noelle S. Williams[4], Jan P. Erzberger[2], Jef K. De Brabander[1], Deepak Nijhawan[1]

[1]Department of Radiation Oncology, Section in Molecular Medicine, UT Southwestern Medical Center, Dallas, TX,[2]Department of Biophysics, UT Southwestern Medical Center, Dallas, TX,[3]Quantitative Biomedical Research Center, Department of Clinical Sciences, UT Southwestern Medical Center, Dallas, TX,[4]Department of Biochemistry, UT Southwestern Medical Center, Dallas, TX

Our research program integrates phenotypic screening with a tunable forward-genetics platform engineered to identify anticancer small molecules and their novel molecular targets. Using this approach, we identified nuclear valosin-containing protein-like (NVL), a hexameric AAA+ ATPase required for large ribosomal subunit (60S) assembly, as the target of a dibenzothiazepinone, MM17. Cryo-EM reconstructions of NVL bound to a substrate analog mimic reveal two MM17 docking sites within the hexameric assembly, with resistance mutations clustering around the ligand binding site. NVL inhibition disrupts 60S biogenesis and stabilizes p53 through MDM2, leading to cell cycle arrest or apoptosis, in the absence of DNA damage. Cancer cells upregulate ribosome production to sustain the high protein synthesis demands of unchecked proliferation, making ribosome biogenesis an attractive therapeutic target. Notably, inhibition of ribosome biogenesis—rather than induction of DNA damage—has recently been identified as a major mechanism underlying widely used chemotherapies such as 5-FU and oxaliplatin. To assess the therapeutic potential of selectively targeting ribosome biogenesis by blocking NVL, we engineered a degron system (NVL-AID) in which administration of 5-Phenyl-indole-3-acetic acid (Ph-IAA) dose dependently degrades the endogenous NVL protein in a colorectal cancer cell line. Degradation of NVL phenocopied the effects of MM17 treatment on the induction of p53, the blockade of ribosome assembly, and on the inhibition of cell growth. Moreover, daily Ph-IAA administration for two weeks effectively suppressed the growth of established NVL-AID xenograft tumors. A more potent and bioavailable MM17 analog, MM927, suppressed tumor growth in mouse models of colorectal cancer through direct NVL targeting, supporting the pharmacological inhibition of ribosome assembly as a cancer vulnerability. Together, these findings validate NVL as a therapeutic target and set a benchmark for the efficacy of small-molecule NVL inhibitors. Current efforts are focused on lead optimization to nominate advanced, orally bioavailable NVL inhibitors that are tested head-to-head with target degradation (NVL-AID) to maximize efficacy. To characterize the on-target toxicities of candidate leads, we developed a CRISPR-engineered, compound-resistant mouse model. Collectively, these tools will enable us to characterize the consequences of inhibiting this novel cancer target in normal tissues and to establish the therapeutic index of optimized NVL inhibitors to support their clinical development.

#3048 Nesuparib enhances anti-tumor efficacy with gemcitabine and nab-paclitaxel in BRCA wild type pancreatic cancer xenograft model.

Banyoon Cheon, Jung-young Shin, Geon Kang, Dae In Park, John Kim, Hyunju Cha

Onconic Therapeutics Inc., Seoul, Korea, Republic of

Pancreatic ductal adenocarcinoma is one of the most aggressive and fatal cancer with limited treatment options. The combination of gemcitabine and nab-paclitaxel (GnP) is the first-line treatment for pancreatic cancer, but the median overall survival remains less than a year, and high toxicity limits its use.
To address this limitation, we explored whether Nesuparib, a dual inhibitor for poly-ADP-ribosyl transferase 1/2 and tankyrase 1/2, enhances anti-tumor efficacy with GnP in BRCA wild-type pancreatic preclinical models.
We first conducted a cell viability assay in BRCA wild-type Mia Paca-2 cells to determine whether Nesuparib increases the cytotoxicity of gemcitabine-based chemotherapy. Combination of Nesuparib with GnP decreased viability by more than 70% compared to GnP treatment alone. In Mia Paca-2 *in vivo* xenograft model, GnP treatment resulted in 31% tumor growth inhibition (TGI) compared to the control group, while Nesuparib with GnP elicited TGI by 79%. At the end of the *in vivo* experiment, changes in various molecules at protein levels were investigated in the separated tumors to characterize plausible mechanisms underlying the significant tumor reduction in Nesuparib with GnP-treated group compared to other treatment groups. Interestingly, c-Myc and MYBL2 levels were increased in the GnP treated one compared to the vehicle control speculating that compensatory mechanisms might be activated after the drug treatment, while these upregulations were restrained by Nesuparib with GnP treatment. We also observed that cyclinD1, β-Catenin, and RAD51 were decreased in Nesuparib with GnP treatment compared to the control or GnP treatment. Collectively, the data suggests that those molecular modulations are closely associated with the tankyrase inhibition by Nesuparib in BRCA wild-type model, and that combining Nesuparib with the standard chemotherapy further reduces cell proliferation and delays DNA repair compared to chemotherapy alone.
Overall, our results suggest that combination with Nesuparib with GnP chemotherapy could be a novel and rational therapeutic option for pancreatic cancer treatment.

#3049 Atamparib: First-in-class PARP7 inhibitor for treatment of NSCLC adenocarcinoma in monotherapy and in combination with standards of care.

Genny Degani[1], Federica Carbone[1], Patrizia Banfi[1], Laura Gianellini[1], Nilla Avanzi[1], Elena Casale[1], Marina Fasolini[1], Laura Riva[1], Gianluca Papeo[1], Francesca Quartieri[1], Fabio Gasparri[1], Michael O. Hottiger[2], Claudia Perrera[1], Alessia Montagnoli[1]

[1]Nerviano Medical Sciences, Nerviano, Italy,[2]Department of Molecular Mechanisms of Disease, University of Zurich, Zurich, Switzerland

PARP7 is a relevant target in cancer cells and is involved in several cellular processes, including type I interferon (IFN-I), aryl hydrocarbon receptor, estrogen receptor, and androgen receptor signaling, and stabilization of the oncogenic RAS-MAPK effector FRA1. Atamparib is the first PARP7 inhibitor in the clinic, with high potency and selectivity. It is orally bioavailable, with favorable safety profile in PhI/II trials both as single agent and in combination with anti-PD1 antibodies. Recent better understanding of PARP7 biology shed light on a unique atamparib dual mechanism of action, that combines direct cancer cell killing with innate immune activation via restoration of IFN-I signaling to assist adaptive response. This insight, along with new preclinical and clinical data, points to new indications and opportunity for combination.

Atamparib biochemical and cellular characterization was conducted by HTRF, SPR and Nanobret. PARP7 crystal structure was determined by X-ray crystallography. In investigating atamparib antiproliferative activity, cancer cell lines from multiple indications have been treated with 0-10 µM of atamparib single agent for 144 hours. Combination with various standards of cares approved in each setting have been evaluated in 7x7 or 7x11 matrix.

Atamparib subnamolar potency and long residence time on PARP7, selectivity versus other members of PARP family, and PARP7 target engagement in cell, were corroborated using biochemical and biophysical assays. The unprecedented crystal structure of PARP7 bound to atamparib was solved by X-ray crystallography at 2 Å resolution, confirming the proposed binding mode. Atamparib was proven to be efficacious in multiple high-unmet-need indications, demonstrating a remarkable anti-tumor activity in NSCLC adenocarcinoma at clinically achievable concentrations, particularly when oncogenic pathways are activated, due to KRAS or other oncogene drivers' mutations. These findings were validated through both *in vitro* and *in vivo* studies. Interestingly, atamparib sensitivity in NSCLC adenocarcinoma KRAS mutant is observed irrespective of the specific KRAS mutation involved. These data support the mechanistic link that connect PARP7 to RAS-MAPK pathway through FRA1, a potent oncogene frequently overexpressed in tumors, where it promotes proliferation, survival, and immune evasion. By inhibiting PARP7, atamparib induces FRA1 degradation, reactivates IFN-I signaling, and triggers tumor cell death and immune-mediated tumor clearance. Moreover, atamparib increases the activity of several standards of care and targeted drugs in late development in NSCLC when combined with them.

Overall, our data shed light on a PARP7 dependency in NSCLC adenocarcinoma context and support atamparib development in this setting, both in monotherapy and in combination with multiple standards of care.

#3050 RPT1G, a novel hyperbolic NAMPT inhibitor, effectively synergizes with PARP inhibitors in solid tumors *in vitro* and in a xenograft breast cancer model.

Michael Schelle, Min Wu, Francis Roushar, Banumathi Cole, Dennise A. De Jesus-Diaz, Gregory Thomas Crimmins

Remedy Plan Therapeutics, Gaithersburg, MD

Background: Poly-ADP ribose polymerase (PARP) inhibitors are key drugs in treating solid tumor patients with defects in homologous DNA repair (HR) pathways. The substrate for PARP enzyme activity, nicotinamide adenine dinucleotide (NAD), is regulated by nicotinamide phosphoribosyltransferase (NAMPT), the rate limiting enzyme in NAD recycling. NAMPT is upregulated in many cancers, in part to supply the NAD consumed by PARP enzymes. RPT1G is a novel hyperbolic NAMPT inhibitor that eliminates NAD in cancer cells while allowing NAD production in healthy tissues. The safety, tolerability, and NAMPT inhibition of RPT1G was recently demonstrated in a first-in-human Phase 1 study (NCT06667765, Crimmins et al., ASH 2025). Here we show that RPT1G synergizes with PARP inhibitors in solid tumor cells and in a xenograft breast cancer model.
Methods: Cells were incubated with RPT1G, olaparib, or in combination for 96 hours then assessed for viability using CellTiter Glo. MDA-MB-436 mouse xenograft studies testing RTP1G, olaparib, or combination were initiated when the average tumor size reached 150-200 mm^3.
Results: RPT1G in combination with the PARP inhibitor olaparib was synergistic across a spectrum of solid tumor cell lines, including breast, pancreatic, and ovarian cancers. Several solid tumor cell lines that are resistant to either RPT1G or olaparib monotherapy showed increased sensitivity to RPT1G and olaparib combinations, including Cal51 (breast) and Mia Paca-2 (pancreatic). Similarly, the MDA-MB-436 triple negative HR-deficient breast cancer xenograft model was insensitive to RPT1G monotherapy, while combination of RPT1G with olaparib synergistically inhibited tumor growth, with complete tumor elimination in 40% of the mice versus <15% with olaparib monotherapy. Furthermore, 80% of mice treated with olaparib monotherapy rebounded despite continuous treatment, compared with <40% of mice showing tumor rebound when treated with RPT1G and olaparib.
Conclusion: Therapeutic inhibition of NAD synthesis with NAMPT inhibitors has been challenging to achieve clinically due to severe on-target toxicity stemming from the critical role of NAD in living systems. RPT1G is the first NAMPT inhibitor that is well-tolerated in people. The high tolerability of RPT1G is especially critical when combining with PARP inhibitors that have known toxicities. We demonstrate that RPT1G in combination with olaparib is efficacious and synergistic in breast, pancreatic, and ovarian solid tumors *in vitro*, and enhances the extent and duration of efficacy in an HR-deficient mouse xenograft breast cancer model. Thus, we present a novel combination strategy to overcome the challenges seen with approved monotherapies in solid tumors.

#3051 Enhancing matchmaking in targeted therapy (TT) for cancer (ca): Beyond the 'arranged' criteria.

Farah Mazahreh, Liyan Mazahreh, Ahmad Mazin Safar

University of Arkansas for Medical Sciences, Little Rock, AR

Cancer is a unique cellular condition marked by constant activation of oncogenes. Heritable DNA changes (mutations, translocations and copy number alterations) can produce this 'constant' state. Theoretically, however, static changes are not limited to DNA alterations in the gene body, but can result from DNA amplification of oncogene's transcription factors (TF) or ligands (for receptor Oncogenes), at a minimum. Constant activation depends on identifying clonal events in oncogenes, but may be also inferred from functional activation of oncogenic pathways in multiple sites of a biopsy as a maneuver to identify the pivotal cancer driver for therapeutic targeting. Targeted therapies have produced major therapeutic benefits especially when drugging pivotal oncogenes. Accordingly, efforts to identify such targets are rational, justifiable and desirable. Standard oncology practice includes next generation sequencing (NGS) for this very purpose. NGS criteria are almost entirely based on DNA variance in the gene body of an expanded lists of cancer genes. NGS, as reported in the literature, identifies targets only in 25% of cases sequenced. We hypothesized that extending DNA criteria to assess TF/Ligand amplification of an extended set of oncogenes will identify rational, but hitherto unrecognized targets increasing the ability to match tumors with relevant Targeted Therapies.
Methods: We examined 1,731 tumor samples in The Cancer Genome Atlas agnostic to histology or stage using an extensive list of wild-type (WT) but over-expressed (2 fold) proto-oncogenes. We recorded amplification of canonical TFs, or ligands (for receptor oncogenes). We also assessed the transcriptional activity of the oncogenes examined. The genes identified are used routinely in a major commercial vendor for NGS.
Results: 31.7% of cases show gene amplification of ligands or TFs of the list of wild type Oncogenes; 4.7% harbor TF/ligand mutations. ~60%of cases demonstrate activation of an oncogenic signaling pathways (without DNA changes) despite wild type oncogenes reflected by transcriptional activity at z-score >2.
Conclusions: Our method outperforms NGS identifying 'targets' to pair tumors with effective Therapies. Many druggable oncogenes are potential targets in unexpected histologies (e.g., Abl in breast cancer). Our method should be integrated in future diagnostic interrogation of cancers. Additionally, the algorithms should change to 'call' these TFs and ligands events as 'actionable'. In doing so, we will be extending beyond the classic oncogene-specific NGS. Assessment of translocations and extrachromosomal DNA mechanisms (among many other proposals) may provide further answers for the remaining cases that cannot be classified using the above. This would allow oncologists to introduce Targeted Therapies to a many patients who currently won't receive such effective and desperately needed treatments.

#3052 RK-582, a tankyrase inhibitor, attacks Wnt-driven colorectal cancer cells with short-type APC mutations and high β-catenin expression.

Hiroyuki Seimiya[1], Mingjue Chen[1], Taichi Oishi[1], Yukiko Muramatsu[1], Manabu Takamatsu[2], Naomi Kawata[1], Ayane Nakamura[1], Saori Inaba[1], Satoshi Nagayama[3], Ryohei Katayama[4], Kensei Yamaguchi[5], Fumiyuki Shirai[6], Tetsuo Mashima[1]

[1]Division of Molecular Biotherapy, Cancer Chemotherapy Center, Japanese Foundation for Cancer Research, Tokyo, Japan,[2]Division of Pathology, The Cancer Institute, Japanese Foundation for Cancer Research, Tokyo, Japan,[3]Gastroenterological Surgery, Cancer Institute Hospital, Japanese Foundation for Cancer Research, Tokyo, Japan,[4]Division of Experimental Chemotherapy, Cancer Chemotherapy Center, Japanese Foundation for Cancer Research, Tokyo, Japan,[5]Gastroenterological Chemotherapy, Cancer Institute Hospital, Japanese Foundation for Cancer Research, Tokyo, Japan,[6]Drug Discovery Chemistry Platform Unit, RIKEN Center for Sustainable Resource Science, Saitama, Japan

Colorectal cancer (CRC) is one of the three major cancers, causing over 90,000 deaths worldwide annually. For unresectable metastatic CRC, cytotoxic, targeted, and immuno-oncology drugs are used, but these therapies only extend survival by about 30 months or less. Approximately 80% of CRCs carry *APC* mutations that upregulate Wnt/β-catenin signaling, yet this pathway has long been considered difficult to target due to the lack of druggable molecules. Tankyrase poly(ADP-ribosyl)ates (PARylates) AXIN, a negative regulator of β-catenin, promoting its ubiquitin-dependent degradation and β-catenin accumulation. Accordingly, tankyrase inhibitors have been proposed as potential therapeutics for Wnt-driven cancer. To establish a targeted therapy for Wnt-driven CRC, we developed an orally available tankyrase inhibitor, RK-582, and investigated its predictive biomarkers. In *APC*-mutated CRC cells, RK-582 inhibited tankyrase-mediated AXIN PARylation, resulting in AXIN accumulation and β-catenin degradation. RK-582 exhibited excellent bioavailability and suppressed Wnt-driven CRC growth in mouse xenograft models. Under approval of the JFCR Institutional Review Board and with patients' informed consent, *APC*-mutated CRC patient-derived cells were analyzed, revealing that *APC* mutations lacking all seven 20-amino acid repeat domains and β-catenin accumulation are predictive biomarkers for sensitivity to tankyrase inhibitors. In original tumor tissues of inhibitor-sensitive cells, β-catenin expression was significantly higher than in inhibitor-resistant cells. Analysis of primary tumor location indicated that left-sided tumors were more common in the inhibitor-sensitive group, with elevated β-catenin levels. Ectopic expression of a gain-of-function *CTNNB1* allele conferred resistance in drug-sensitive CRC cells. *PIK3CA* gain-of-function mutations were associated with inhibitor resistance, whereas *KRAS*, *BRAF*, or *TP53* mutations were not. GLP-compliant toxicity studies, safety pharmacology assessments, and drug metabolism/pharmacokinetic evaluations were completed to generate the preclinical dataset required for clinical trials. Additionally, a large-scale synthesis method for RK-582 was developed, and a GMP-grade active pharmaceutical ingredient was produced, subsequently used to prepare the capsule formulation for the clinical trial. In summary, RK-582 targets the Wnt/β-catenin pathway, a key cancer pathway previously considered undruggable. An investigator-initiated first-in-human clinical trial of this drug is currently ongoing, and these findings are expected to contribute to the development of an innovative therapy for unresectable advanced and recurrent CRC.

#3053 Combination of the MDM2 antagonist ASTX295 and Olaparib as a novel treatment option for *BRCA2* mutant, *TP53* wild-type solid tumors.

Antonio Morales[1], Joanna Obacz[1], Bryn Hardwick[1], Adam Jackson[1], Liam Davis[1], Zoe Haines[1], Patrick Herr[1], Paula Martinez Sanz[2], Violetta Serra[2], Judit Espana-Agusti[3], Gianni Chessari[3], Maria Ahn[3], John F. Lyons[4], Amy Emery[1], **Sarah Holt**[1], Stephen Shuttleworth[1], Barry R. Davies[1]

[1]Mosaic Therapeutics, Cambridge, United Kingdom,[2]VHIO, Barcelona, Spain,[3]Astex Therapeutics Ltd., Cambridge, United Kingdom,[4]Astex Therapeutics Ltd., Cambridge

p53, encoded by the TP53 tumor suppressor gene, is a critical regulator of the cellular response to stress such as DNA damage and oncogenic signaling. p53 triggers the transcriptional program that dictates cell-fate decisions, including cell cycle checkpoint activation, senescence, and apoptosis. In tumors with functional p53, reactivation of TP53 transcriptional activity has emerged as an attractive therapeutic approach to promote cancer cell death. Therefore, inhibition of MDM2, the key negative regulator of p53, has been an attractive target to achieve this strategy. ASTX295 is a selective small molecule antagonist of the p53/MDM2 interaction, resulting in p53 stabilisation. Whilst the efficacy of MDM2 antagonists as monotherapy has been modest, there is a strong rationale for MDM2-combination therapies blocking DNA repair or inducing DNA damage to potentiate p53-mediated apoptosis. We identified components of DNA repair pathways including PARP1 as strong sensitizers to ASTX295 in a genome-wide drug-CRISPR screen. PARP inhibition results in DNA damage when single strand breaks are converted into double strand breaks during S-phase, leading to the accumulation of unresolved DNA damage and triggering checkpoint activation. PARP inhibitors have been shown to induce p53 activation and, in turn, promote p21-mediated cell cycle arrest. In the presence of an MDM2 antagonist, this excessive genotoxic stress combined with sustained p53 activation leads to increased apoptosis, offering a more durable response than PARP inhibition alone. We demonstrated the combinatorial interaction of ASTX295 with Olaparib in drug combination screens, and our proprietary biomarker discovery pipeline, PRIME, identified significantly enriched combination synergy and reduced viability in BRCA2-mutant solid tumor cell lines. We established that synergistic cell death is driven by elevated p53 activity for the combinatorial administration of ASTX295 with Olaparib, particularly in BRCA2-mutant/TP53-wild-type solid cancer cell lines. In vivo, using both cell line- and patient-derived BRCA2-mutant/TP53 wild-type xenograft models, we showed superior anti-tumor activity for the combination compared to single agents, resulting in prolonged control of tumor growth and regressions at well tolerated doses. Taken together, our data provide a strong rationale for combining ASTX295 with PARP inhibitors such as Olaparib in patients with TP53-wild-type/BRCA2-mutant solid tumors.

#3054 Inhibition of ARNT suppresses growth of primary human kidney cancer cells.

Shengchen Su, Yanping Wang, Yanchun Zhang, Patrick Tamukong, Hyung L. Kim

Urology, Cedars-Sinai Medical Center, Los Angeles, CA

Background: Hypoxia-inducible factor (HIF) signaling drives clear cell renal cell carcinoma (ccRCC). ARNT (HIF-1β) dimerizes with HIF-1α and HIF-2α to enable gene transcription. Belzutifan is a small-molecule drug that blocks HIF-2α, which is approved for clinical use. It's been proposed that increased signaling through HIF-1α represents a belzutifan-resistance mechanism. Blocking ARNT should attenuate both HIF programs. We assessed an ARNT-selective small-molecule inhibitor (ARNTi) in renal cancer models.
Methods: 786-O cells were cultured under hypoxia. Cells received belzutifan, ARNTi, or vehicle control (DMSO). After treatment, cells were fixed, and the interaction between HIF-2α and ARNT was quantified using a proximity ligation assay. Primary cultures were generated from patients who underwent nephrectomy. Under hypoxia, both normal and ccRCC primary cell cultures were exposed to ARNTi or vehicle and then processed for proliferation assessment and qPCR of HIF target genes. Primary papillary renal cell carcinoma cultures were evaluated using the same workflow.
Results: ARNTi lowered the proximity ligation signal between HIF-2α and ARNT. The extent of inhibition matched the effect of belzutifan. In patient-derived ccRCC cultures (n=5), ARNTi produced significant growth inhibition under hypoxia compared with vehicle. The magnitude of the effect was similar to belzutifan. Expression of hypoxia-responsive target genes, such as GLUT1, NDRG1, and VEGFa, decreased after ARNTi treatment. ARNTi also suppressed growth in papillary renal cell carcinoma cultures (n=3), indicating activity across histologic subtypes.
Conclusions: Inhibition of ARNT reduces the formation of the HIF-2α and ARNT complex and suppresses proliferation in primary human kidney cancer cells. These effects coincide with reduced expression of HIF target genes under hypoxia. These results support the development of ARNT-directed candidates for the treatment of kidney cancer.

#3055 Targeting the MKK3/MYC protein-protein interaction to overcome drug resistance in MYC-driven cancers.

Payton Fleming, Elsa Bildtsen, Zhen Chen, Eric J. Miller, Yuhong Du, Shi-Yong Sun, Haian Fu, Andrey A. Ivanov

Emory University, Atlanta, GA

MYC is a central oncogenic transcription factor that drives tumor progression in multiple cancer types, including triple-negative breast cancer (TNBC) and non-small cell lung cancer (NSCLC). However, direct MYC inhibition remains highly challenging due to its intrinsically disordered structure and lack of defined drug-binding pockets. We uncovered a novel mechanism of MYC activation through a direct protein-protein interaction (PPI) with mitogen-activated protein kinase kinase 3 (MKK3). Integrative bioinformatics analyses using our AVERON platform revealed that elevated levels of the MKK3/MYC complex significantly correlate with poor clinical outcomes in TNBC and lung cancer, particularly in patient subsets with high MYC dependency.

To define the functional consequences of the PPI, we combined genetic perturbation, chemical biology, and clinical genomics analyses. MKK3 silencing reduced the viability of TNBC and NSCLC cells, and these effects were recapitulated with small-molecule MKK3/MYC PPI inhibitors (MMPins), identified through our TR-FRET ultra-high-throughput screening campaign. Disruption of the MKK3/MYC PPI destabilized MYC and suppressed MYC-driven transcriptional programs. Furthermore, MKK3/MYC PPI inhibition is correlated with the downregulation of lactate dehydrogenase A (LDHA), a key mediator of glycolytic reprogramming and a well-established driver of drug resistance. In TNBC models, MKK3/MYC PPI inhibition reduced LDHA expression and blocked the glycolytic flux that fuels MYC-dependent growth. In NSCLC, MMPins restored apoptotic sensitivity in EGFR TKI-resistant cells and, when combined with osimertinib, significantly suppressed tumor growth in vivo.

Together, these findings define the MKK3/MYC PPI as a mechanistic driver of LDHA-mediated metabolic adaptation and drug resistance. Pharmacological disruption of this interaction offers a promising therapeutic strategy to suppress MYC-dependent oncogenic networks, reverse resistance phenotypes, and improve outcomes in MYC-driven cancers.

We thank the Emory University Undergraduate Research Program in Biology.

#3056 Inhibition of oncogenic phenotypes by hexanoate in triple-negative breast cancer.

Nahara Yupe-Muniz[1], **Samira B.F. Abdullah-Vargas**[2], Oscar A. Loperena-Gonzalez[1], Ariana S. Garcia- Lopez[1], Gabriel Borges-Velez[1], Josue Perez-Santiago[1]

[1]University of Puerto Rico Comprehensive Cancer Center, San Juan, PR,[2]University of Puerto Rico, Rio Piedras Campus, San Juan, PR

Background: Triple-Negative Breast Cancer (TNBC) is an invasive molecular subtype of breast cancer defined by the lack of estrogen and progesterone receptors, and the absence of HER2 amplification. This molecular profile limits current treatment options contributing to poor patient outcomes. Recent evidence features the microbiome as a key factor in cancer biology, modulating tumor progression through metabolites and bacterial products. Among these products, medium-chain fatty acids (MCFAs), such as hexanoate, are produced by microbial fermentation within the microbiome. Previous studies from our laboratory demonstrated that hexanoate reduces the viability and proliferative capacity in oral cancer cells, which may suggest hexanoate as a promising candidate target for alternative cancer treatments. Therefore, the aim of this study was to evaluate the impact of hexanoate on oncogenic phenotypes including cell viability, proliferation, and migration of the TNBC cell line MDA-MB-231.
Methods: MDA-MB-231 cells were cultured at 37°C, 5% CO_2 in RPMI-media. Cell viability was measured using AlamarBlue after 24, 48 and 72 hours (h) of treatment with sodium hexanoate at 9 different concentrations starting at 800mM (1:2 serial dilution) to measure the half-minimal inhibitory concentration (IC50). Cell proliferation was measured by seeding 100,000 cells per well and counting with TrypanBlue the change in cell number after treatment with hexanoate at 5mM for 24h, 48h and 72h. Cell migration was evaluated using a scratch assay; after inflicting a wound, its width was measured at 0h, 24h, and 48h to calculate the percentage of wound closure.
Results: Hexanoate reduced cell viability at 24h, 48h, and 72h with a consistent IC50 of 29mM. Additionally, no significant effects on the proliferation rate were observed at 24h and 48h when treated with hexanoate, whereas it decreased significantly at 72h ($p=0.004$). Furthermore, hexanoate showed a decreased percentage of wound closure at both time points, showing significance at 48h ($p = 0.002$).
Conclusions: Overall, hexanoate exhibited inhibitory effects on viability, proliferation, and migration in TNBC cells. As a microbiome-associated compound, hexanoate may modulate cancer cell behavior in a time-dependent manner and represent a potential alternative target for TNBC treatment, although additional studies are required for validation.

#3058 A first-in-class orally bioavailable small molecule tumor suppressor activator for the treatment of a wide range of cancers.

Hee-Sung Park, Chakrapani Subramanyam, Kyu-kwang Cho, Se Hee Hyun, Yeonjee Kahm

Promedigen, Daejeon, Korea, Republic of

Novel therapeutic agents capable of restoring the function of key tumor suppressors, frequently inactivated across a wide spectrum of cancers, represent a powerful strategy to address the limitations of current treatments and mitigate resistance to existing therapies. Using colorectal cancer (CRC) as a primary indication, we developed an orally bioavailable small-molecule agent, PMG-A9, that restores the activity of a key tumor suppressor and suppresses the oncogenic transcription factor FoxM1, a major driver of therapeutic resistance. Notably, 5-fluorouracil (5-FU), a widely used first-line CRC therapy, is known to induce substantial upregulation of FoxM1. In this study, we demonstrate that PMG-A9 induces a robust, dose-dependent reduction of 5-FU-driven FoxM1 expression in colorectal cancer cells. Exposure of 5-FU-treated cells to PMG-A9 promotes apoptosis through pro-apoptotic mediators, including PUMA. In preclinical CRC xenograft models, PMG-A9 exhibits robust single-agent antitumor efficacy and shows pronounced synergy when combined with multiple chemotherapeutic agents, including 5-FU, while effectively downregulating FoxM1 in vivo. These findings highlight tumor-suppressor reactivation as a promising, broadly applicable therapeutic strategy to improve treatment outcomes for CRC and, potentially, overcome drug resistance across diverse tumor types.

#3059 Targeting metabolic dependencies in MYC-driven osteosarcoma through Lp-PLA2 inhibition.

Katherine Shelmidine[1], Juan Dou[1], Tajhal Patel[2], Jason Yustein[1]

[1]School of Medicine Pediatrics, Emory University, Atlanta, GA,[2]Pediatrics, Baylor College of Medicine, Houston, TX

Osteosarcoma (OS) is the most prevalent pediatric bone cancer and treatment outcomes and survival rates have remained largely unchanged for decades. Patients with metastatic or relapsed/refractory disease face five-year survival rates below 30%, with no salvage therapies available after standard of care failure. Overexpression of the oncogene MYC contributes to aggressive tumor progression, therapeutic resistance, and metabolic reprogramming in OS, yet direct targeting of MYC remains challenging. Lipoprotein-associated phospholipase A2 (Lp-PLA2), an inflammatory enzyme, regulates phospholipid remodeling and inflammatory lipid signaling that may be exploited by MYC-high tumors. Targeting this pathway with the small-molecule Lp-PLA2 inhibitor Darapladib could reveal metabolic dependencies on phospholipid and fatty acid metabolism that supports growth and survival in MYC-driven OS. A 3D spheroid high-throughput drug screen of 2,036 FDA-approved and bioactive compounds was performed on a high-MYC patient-derived xenograft (PDX) OS cell line and a murine Myc knock-in OS cell line. Darapladib was identified as a candidate compound and IC_{50} values were determined in both 2D and 3D models. High MYC-expressing PDX and murine OS cells were treated in 2D for 72 hours based on IC_{50} values, followed by spheroid formation assays post-treatment. CellTiter-Glo viability was assessed after a 72-hour growth period. Migration capacity was examined via wound healing assays using the same treatment strategy. *In vivo* efficacy of Darapladib was evaluated in NSG mice using two high MYC-expressing PDX models. Darapladib exhibited IC_{50} values below 5 µM in both PDX and murine OS lines, indicating sensitivity to Lp-PLA2 inhibition. Low-MYC expressing OS lines showed relatively higher IC_{50} values compared to high-MYC lines. In 3D spheroids, Darapladib pre-treatment decreased cellular ATP levels and demonstrated significant spheroid size reduction. Darapladib-treated cells exhibited impaired migration in wound healing assays. *In vivo* studies revealed decreased average primary tumor volume in both high-MYC PDX models. Darapladib demonstrates *in vitro* and *in vivo* efficacy in high-MYC OS models, establishing Lp-PLA2 as a novel therapeutic target that potentially exploits MYC-dependent metabolic vulnerabilities. The selective sensitivity of high-MYC expressing lines to Darapladib suggests that MYC status may serve as a predictive biomarker. As Darapladib has an established safety profile from previous cardiovascular clinical trials, these findings support its clinical translation for high-risk OS patients lacking effective therapies. Further studies are warranted to elucidate mechanisms by which Lp-PLA2 inhibition disrupts MYC-driven lipid metabolism and evaluate Darapladib in combination with other targeted therapies.

#3060 Periplocin restores HTR1E signaling by CTCF to inhibit proliferation and dissemination of ovarian cancer.

Rong Xiang, Haojie Chen, Yi Shi, Huimin Liu, Kejia Xu

Nankai University, Tianjin, China

Ovarian cancer (OC) is one of the three malignant tumors threatening women's health, ranking third in incidence and second in mortality among all the gynaecological malignancies. The high mortality of OC is due to the lack of typical symptoms and effective early screening methods in the early stage. In the rapid progression of ovarian cancer, a risk factor that cannot be ignored and is currently a hot topic of cancer research is psychological stress. It is largely unknown about the key and robust factors directly linking psychological stress to the dissemination of cancer cells, causing the lack of effective intervening method. The dysregulation of the neurotransmitter 5-Hydroxytryptamine (5-HT) and its receptor HTR1E-mediated dissemination-suppressing function played an essential role in the growth and peritoneal dissemination of OC, indicating HTR1E to be a potential target for the prevention of the malignant progression of OC. In a previous systematic study screening Periplocin as monomer molecule isolated from the traditional Chinese medicine, it can effectivly restore the HTR1E expression and its anti-tumor signaling against the malignant growth and peritoneal disseminated metastasis of OC. We next found CTCF as insulator enforces TAD boundary between HTR1E and ZNF292 in cancer. CTCF is released from the boundary through competitive binding by Periplocin. In summary, we the first time identified Periplocin to be an effective natural small molecule that was able to restore the HTR1E expression and its anti-tumor signaling against the malignant growth and peritoneal disseminated metastasis of OC. We also clarified the molecular mechanism of the anti-tumor effects of Periplocin. This provides new evidence for the clinical treatment of ovarian cancer.

#3061 CS231295, a novel AURKB-biased multi-kinase inhibitor, demonstrates synthetic lethality in RB1-deficient tumors and potent intracranial efficacy.

You Zhou, Qianjiao Yang, Qinyi Xia, Yu Zhang, **Zhijian Li**, Desi Pan, Song Shan

Shenzhen Chipscreen Bioscience Co.,Ltd., Shenzhen, China

Background: The clinical development of multi-kinase inhibitors targeting Aurora kinase B (AURKB) is often limited by dose-limiting toxicities from concurrent VEGFR inhibition, preventing optimal AURKB target suppression. CS231295 was designed as an AURKB-biased inhibitor to overcome this challenge.
Methods: Kinase profiling was performed using biochemical and cellular assays. RB1 biomarker validation employed an isogenic NCI-H1048-tet-on-RB1 model. In vivo efficacy and pharmacokinetics were assessed in RB1-deficient SCLC cell-derived and patient-derived xenograft models. Brain penetration and intracranial efficacy were evaluated in orthotopic brain tumor models.
Results: CS231295 potently inhibits AURKB (IC_{50} = 1.32 nM) with a balanced multi-kinase profile. Crucially, its direct antitumor activity—evidenced by caspase-3/9 cleavage at 0.3-3 μM—occurs at concentrations overlapping with or below those needed for anti-angiogenic effects (HUVEC tube inhibition at 3-6 μM), indicating a potential synergistic therapeutic window. CS231295 also demonstrated a synthetic lethal relationship with RB1 deficiency, exhibiting heightened cytotoxicity in RB1-deficient compared to RB1-wildtype small cell lung cancer (SCLC) cells. RB1 overexpression in NCI-H1048 cells increased the IC_{50} from 0.671 μM to 8.389 μM, confirming RB1 deficiency as a key sensitivity marker. Oral administration induced significant tumor regression in RB1-deficient SCLC models. Prominent brain penetration (brain-to-plasma ratio ≈1) correlated with robust efficacy in an intracranial tumor model.
Conclusion: CS231295 achieves effective AURKB inhibition at doses concurrently modulating angiogenesis, overcoming a key limitation of prior agents. Its synthetic lethality with RB1 deficiency and marked intracranial efficacy support its therapeutic potential for RB1-deficient malignancies and brain-involved tumors. IND approvals have been obtained in China and the U.S., facilitating global clinical development.

#3062 TRIM7 inhibition blocks RTK/RAS pathway driven tumor proliferation independent of mutation and in the setting of KRASi resistance.

Yuhui Chen[1], Marc Morra[1], Haru Kato[2], Kevin Li[3], Ulhas Bhatt[3], Kevin Gayler[4], Grace Elliott-Fromm[2], Nathan Oien[2], Julio Medina[3], Taylor H. Schreiber[5], **George Fromm**[1]

[1]Kayak Therapeutics, Inc., Durham, NC,[2]Shattuck Labs, Inc., Durham, NC,[3]R2M Pharma, Inc., South San Francisco, CA,[4]R2M Pharma, Inc., South San Fransico, CA,[5]Shattuck Labs, Durham, NC

Most cancer patients experiencing clinical benefit from targeted therapies in RTK-KRAS driven cancers develop acquired resistance (AR) and relapse. The mechanism of resistance in patients who initially respond to monoallelic KRAS G12C/G12D inhibitors is dominated by the accumulation of new mutations in KRAS itself, followed by mutations downstream in the MAP kinase pathway. Therapeutics that more broadly target this pathway, like the multi-KRAS isoform inhibitor daraxonrasib, offer promise in less common mutations (e.g., KRAS G12X/Q61X). However, the tolerability of KRASi combinations has been a concern, and it is unclear whether similar resistance mechanisms will arise in multi-KRASi treated patients, as has been seen in monoallelic-KRASi treated patients. To identify novel approaches for complex or resistant RTK-KRAS driven cancers, we generated a murine CRC KRAS(G12D) AR model and through transcriptional/proteomic analysis, identified the E3 ubiquitin ligase TRIM7 as a putative driver of resistance. TRIM7 is downstream in the RTK-KRAS pathway and is upregulated in KRAS mutant and MSI-high tumors, resulting in (1) aberrant cell proliferation through ubiquitination and stabilization of RACO-1 and activated cJun/AP1 transcription, and (2) dysregulated IFN responsiveness through ubiquitination and degradation of MAVS and STING. TRIM7 is not a known mutated oncogene; rather, its hyperactivation is a byproduct of increased RTK-KRAS signaling due to upstream amplifications or mutations. We developed a highly potent and selective TRIM7 small-molecule inhibitor (KT-300) and showed it directly disrupts the ubiquitination and stability of RACO-1, resulting in decreased phosphorylation of cJun and STAT3, and altered transcription of cJun/AP1 targets. KT-300 reduced ubiquitination of MAVS, resulting in MAVS accumulation, and restored STING signaling in tumor cells where STING was impaired due to TRIM7 overexpression. KT-300 induced significant TGI in a range of KRAS/NRAS mutant tumor models (G12X, G13X, and Q61X) and in cell lines with amplification or mutation of EGFR or MAP kinase. TRIM7 specificity was confirmed using inactive enantiomers, which did not induce TGI. *In vivo*, monotherapy KT-300 delayed the growth of human KRAS-mutant NSCLC, CRC, and PDAC tumor xenograft and PDX models. TRIM7i-induced anti-tumor activity was enhanced in combination with concurrent KRAS inhibition, and KT-300 monotherapy delayed tumor growth in mice that developed resistance and progressed on KRAS inhibitors. TRIM7 inhibition via KT-300 may offer broad, mutation-agnostic activity in RTK-KRAS driven cancers. This represents a novel “pan-RTK-KRAS pathway inhibition” strategy that could extend efficacy to complex mutational backgrounds not addressed by current KRAS inhibitors, including in patients who have developed resistance to existing RTK-KRAS targeted therapies.

#3063 Selective cytotoxicity of butyrate highlights its potential as a targeted anti-cancer agent.

Nahara Yupe-Muniz[1], Josue Perez-Santiago[1], Gabriel Borges-Velez[1], Esther A. Peterson-Peguero[2], Ariana Garcia-Lopez[1], Amanda Prats-Marrero[2], Samira B.F. Abdullah-Vargas[2]

[1]University of Puerto Rico Comprehensive Cancer Center, San Juan, PR,[2]University of Puerto Rico Rio Piedras campus, San Juan, PR

Background: Within the marked heterogeneity of breast cancer, the triple-negative subtype stands out for its highly aggressive nature. Its absence of hormonal receptors prevents the use of targeted treatments, pointing the need to uncover improved therapeutic strategies. Nevertheless, recent studies have recognized butyrate as a potential agent for intervention. Butyrate is a microbial-derived short chain fatty acid that exerts anti-cancer effects. Our preliminary data showed that butyrate treatment can significantly reduce cell viability, migration, and proliferation at concentrations of 5 mM in the triple-negative cell line MDA-MB-231. While butyrate has proven its potential as a treatment option, its safety towards healthy mammary cells remains unclear. Therefore, in this study, we evaluated the effects of butyrate in a non-tumorigenic mammary epithelial cell model (MCF10A).
Methods: Cells were cultured in 1:1 DMEM/F12 supplemented with 20ng/mL EGF, 0.5 ug/mL hydrocortisone, 10ug/mL insulin, 100ng/mL cholera toxin, and 5% horse serum. Cell viability was measured using AlamarBlue assay, and butyrate treatment was given in serial dilutions (1:2) starting at 800 mM for 24, 48, and 72 hours. The half-minimal inhibitory values (IC-50) were assessed via fluorescence (590nm). Cell proliferation was evaluated by treating MCF10A with 5mM of butyrate and then quantifying for 24, 48, and 72 hours using an automated cell counter.
Results: No IC-50 was reached, yet there was a reduction in cell viability with concentrations from 100 mM and higher. In fact, MCF10A cells continued to be viable at 24, 48, and 72 hours at 5mM. There was no significant change in cell proliferation at 5mM in all time points.
Conclusions: These results suggest that butyrate reduced viability in triple-negative breast cancer cells while having no meaningful effect on the viability of MCF10A cell line, indicating a selective cytotoxic response. Proliferation results show that MCF10A presents no significant change in cell growth upon butyrate exposure in comparison to untreated controls. These results show the potential of butyrate as a selective anti-cancer agent and raise interest in the mechanism of which butyrate modulates cancer cell behavior.

#3064 Synergistic combinations of novel small molecule CtBP inhibitors with DR5 agonists or BH3-mimetic PROTACs targeting chemoresistant high grade serous ovarian carcinoma.

Kranthi Kumar Chougoni[1], Nicholette St. Martin[2], Diana T. Dcona[3], Nari Kim[3], Boxiao Ding[4], Ronny I. Drapkin[5], Keith C. Ellis[2], Steven R. Grossman[1]

[1]Hoag Memorial Hospital Presbyterian, Newport Beach, CA,[2]Department of Medicinal Chemistry, School of Pharmacy, Virginia Commonwealth University, Richmond, VA,[3]USC Norris Comprehensive Cancer Center, University of Southern California, Los Angeles, CA,[4]Virginia Commonwealth University, Richmond, VA,[5]University of Pennsylvania, Merion Station, PA

Background: High Grade Serous Ovarian Carcinoma (HGSOC) is especially lethal due to frequent diagnosis at advanced stage and development of chemoresistance. The oncogenic transcription factors C-terminal binding proteins 1 and 2 (CtBP1/2; or “CtBP”) are transcriptional scaffolds/coregulators that drive tumor progression and metastasis in many solid tumors and are amplified in ~10% of HGSOC, with their frequent protein overexpression correlated with poor prognosis.

Results: We have previously reported that CtBP transcriptionally represses the proapoptotic Death Receptors (DR) 4/5 in HGSOC cells, preventing activation of caspase 8-dependent apoptosis. Aside from its role as an oncogenic dependency in HGSOC, CtBP is a therapeutic target encoding an NAD-dependent dehydrogenase domain against which we have developed small molecule CtBP inhibitors (CtBPi) which exhibit significant anti-tumor activity in various solid tumor models without toxicity. Our current lead CtBPi’s, NAS-2-133/134, which are naphthyl derivatives of the 1st generation CtBP inhibitor scaffold 2-hydroxyimino-3-phenylpropanoic acid, exhibit IC_{50} values of 4-17 µM in multiple HGSOC cell lines, while A2780 cells with homozygous deletion of CtBP1/2 (A2780/DKO) were resistant to NAS-2-134 relative to parental A2780 cells (IC_{50}s = >>25 µM [beyond titration] vs. 20 µM, respectively), demonstrating that NAS-2-134 exhibits potent on target cytotoxic selectivity. In addition, NAS-2-134 induced caspase-8 dependent apoptosis in HGSOC cells via upregulation of DR5 and exhibited synergistic cytotoxicity when combined with the DR5 agonists MD5.1 or Biomyifi using Bliss methodology (Bliss synergy scores: MD5.1=15.8, BIOYMIFI=15.3). Further mechanistic studies revealed NAS-2-134 decreased Bcl-2 levels, which prompted evaluation of potential synergy of NAS-2-134 with BH3-mimetics venetoclax (ABT-199) and navitoclax (ABT-263), which target Bcl-2 and Bcl-2/X_L, respectively. Though NAS-2-134 and ABT-199 did not exhibit synergistic cell killing in HGSOC cells, NAS-2-134 and ABT-263 exhibited strong synergy with a Bliss score of 47. Importantly, both NAS-2-134 and the closely related CtBPi NAS-2-133 demonstrated potent in vivo antitumor activity, abrogating growth of OVCAR3 xenografts in immune deficient mice.

Conclusion: We demonstrate that NAS-2-134 exhibits target selective cytotoxicity in HGSOC cells via induction of caspase-8/DR5 dependent apoptosis *in vitro* and both NAS-2-134 and NAS-2-133 exhibit potent anti-HGSOC tumor activity *in vivo;* and 2) concerted targeting of CtBP and DR5 or Bcl-2/X_L is synergistically cytotoxic in HGSOC cells and this strategy may lead to a future low toxicity precision therapy for chemoresistant HGSOC.

#3065 Therapeutic efficacy of CK2 inhibitor in patient-derived lung metastatic model of Ewing sarcoma.

Muhammad Danial[1], Chandrika Gowda[1], Rajesh Rajaiah[1], Marudhu Pandiyan Shanmugam[1], Upendar Golla[1], Sholler Chloe[1], Jeremey Hengst[1], Abhinav Beeravally Nagulapally[1], Yasin Uzun[1], Hannah Valensi[2], Matthew Lanza[1], Giselle L. Saulnier Sholler[1]

[1]Penn State College of Medicine, HERSHEY, PA,[2]Penn State College of Medicine, Hershey, PA

Introduction: Metastatic Ewing sarcoma (ES), a highly aggressive bone cancer, has an extremely poor 5-year overall survival rate of <25%. EWS-FLI oncogenic fusion protein drives tumor progression in nearly all cases. Casein kinase II (CK2) is a serine/threonine kinase that is essential for normal cellular processes and is overactive in cancer. CK2 high-expressing ES patients have a high relapse rate and worse 5-year overall survival. CX-4945 (silmitasertib) is an orally bioavailable, CK2-selective small molecule inhibitor in clinical trial for the treatment of pediatric cancers.

Methods: Patient-derived xenograft (PDX) cell lines derived from relapsed refractory metastatic EWS-FLI1 fusion-positive ES (n=15) were treated with CX-4945 and analyzed. We generated metastatic models of EWS-FLI fusion-positive ES following subcutaneous implant in athymic nude mice. After 4 weeks of treatment with CX-4945, mice were analyzed for the presence of lung and bone metastasis using histology, immunohistochemistry (IHC), and pathology review. We scored the lung metastasis burden. The number and area of tumor cell foci within the lung tissue were noted. Tumor cells and inflammatory cells in the extra-parenchymal space and tumor cells circulating within the blood vessels were confirmed using IHC. Using flow cytometry with a human CD99 antibody, we confirmed tumor cells in the lung tissue. Tumor size and survival (time to reach endpoint) were noted. We then assess the effect of CX-4945 treatment on the occurrence and severity of lung metastasis.

Results: Four weeks of treatment with CX-4945 alone showed slow tumor progression and significantly prolonged survival in two xenograft models. More importantly, treated mice showed significantly less tumor burden in lungs and bone marrow.

Conclusions: These results support further preclinical characterization and mechanistic investigation of CX-4945 for treating ES. A phase 1 clinical trial is evaluating the safety of CX-4945 in pediatric solid tumors, including ES (NCT06541262). Patient derived lung metastasis model of Ewing sarcoma development and assessment for effect of treatment is feasible and essential to determine clinically meaningful therapeutic effect of anti-cancer agent.

#3066 A novel class of allosteric CDK8/19 inhibitors induces synthetic lethality through concurrent mTOR and c-MYC suppression and activation of p53-mediated G2/M arrest.

Hui Chen, Zihan Xu, Erpei Wang, Jason Rivera, Judith Varner

UCSD, San Diego, CA

Cancer cells exhibit dysregulated signal transduction and cell cycle control pathways that drive unchecked proliferation. Both uncontrolled tumor cell growth and the expansion of immunosuppressive macrophages contribute to tumor progression. Although PI3K and MEK inhibitors can initially suppress tumor growth, resistance frequently develops through compensatory activation of alternative signaling pathways. We have identified a novel class of allosteric tyrosine kinase receptor inhibitors that induce synthetic lethality in acute myeloid leukemia (AML), lung carcinoma, pancreatic carcinoma, and other cancers. These compounds target both tumor cells and proliferating macrophages in vitro and in vivo by concurrently inhibiting c-Myc and mTOR, while activating the stress-activated kinase JNK, leading to p53-mediated G2/M cell cycle arrest. Mechanistically, selective inhibitors containing a uniquely positioned single side chain suppress CDK8/19 activation, resulting in Myc degradation, mTOR inhibition, and phosphorylation of JNK and p38. JNK activation drives sustained ATF-2 and c-Jun signaling, leading to activation of p53, Chk1/Chk2, G2/M arrest, and apoptosis. These compounds markedly suppress tumor growth in vivo by blocking both tumor and macrophage proliferation and exhibit strong synergy with anti-PD-1 and anti-CTLA-4 immunotherapies, resulting in tumor eradication and durable immunological memory. Collectively, these findings define a new class of allosteric CDK8/19 inhibitors with potent, synthetically lethal, and immunologically synergistic anti-tumor activity, revealing a promising therapeutic avenue for overcoming resistance in cancer treatment.

#3067 Short-chain fatty acids suppress invasion and clonogenic survival in triple-negative breast cancer cells.

Amanda Prats-Marrero[1], Ariana S. Garcia-Lopez[2], Liah M. Roman-Calderon[2], Samira B. F. Abdullah-Vargas[1], Gabriel Borges-Velez[2], Esther Peterson-Peguero[2], Josue Perez-Santiago[2]

[1]University of Puerto Rico, Rio Piedras Campus, San Juan, PR,[2]University of Puerto Rico Comprehensive Cancer Center, San Juan, PR

Background: Triple-negative breast cancer (TNBC) accounts for 15-20% of all breast cancers. Defined by the absence of estrogen receptors, progesterone receptors, and HER2 expression, this subtype is highly aggressive and has limited therapeutic options, resulting in a five-year survival rate of 78% compared to over 90% for other subtypes. Previous data from our laboratory demonstrated that short-chain fatty acids (SCFAs), microbiota derived metabolites, reduce TNBC cell viability, proliferation, and migration, with butyrate showing the strongest inhibitory effects. However, the impact of SCFAs on invasion and long-term survival remains unclear.
Objective: This study aimed to investigate the effects of SCFAs on invasion and clonogenic potential in a TNBC cell line (MDA-MB-231) as indicators of metastatic behavior and sustained proliferative capacity.
Methods: MDA-MB-231 cells were treated with SCFAs butyrate, acetate, and propionate at 5 mM and invasion was assessed using Boyden chambers coated with Matrigel. Cells were seeded in the upper chamber in serum-free medium, while the lower chamber contained complete medium as a chemoattractant. After 24 hours, cells that passed through the Matrigel layer were fixed, stained, and quantified using ImageJ. To evaluate long-term proliferative potential, clonogenic assays were performed with butyrate-treated cells, chosen for its strong inhibitory effects on TNBC growth and migration. MDA-MB-231 cells were seeded at a density of 1,000 cells per well of a six-well plate and treated with butyrate at 1 mM and 5 mM for 9-10 days. Colonies were fixed, stained, photographed, and quantified using ImageJ.
Results: Butyrate and propionate treatment significantly suppressed invasion compared to control ($p<0.0001$ and $p=0.0031$, respectively), while acetate had no significant effect in invasion ($p=0.4084$). Clonogenic assays showed complete inhibition of colony formation in cells treated with 1 mM and 5 mM butyrate, while control cells formed a mean of 429 colonies per well. Morphologically, treated cells displayed loss of adherence and rounded shapes consistent with cytotoxicity.
Conclusion: Butyrate and propionate significantly inhibited invasion of MDA-MB-231 cells, while butyrate also completely suppressed clonogenic survival. These findings align with our previous transcriptomic data indicating SCFA modulation of pathways involved in oncogenic processes such as migration and cell adhesion. SCFAs demonstrate potent inhibitory effects on metastatic behavior and long-term proliferation, supporting further investigation into their therapeutic potential.

#3068 Targeting ornithine aminotransferase as a promising therapeutic strategy for hepatocellular carcinoma.

Wenan Qiang[1], Yi Yang[2], Tommy Ouyang[2], Vivian Chen[2], Alice Qiu[2], Richard B. Silverman[3]

[1]Chemistry of Life Processes Institute, Department of Obstetrics and Gynecology, Pathology, Northwestern University, Evanston, IL,[2]Chemistry of Life Processes Institute, Northwestern University, Evanston, IL,[3]Department of Chemistry, Northwestern University, Evanston, IL

Comprising 90% of all liver cancers, hepatocellular carcinoma (HCC) is the second leading cause of cancer-related death worldwide. Despite decades of research, prognosis remains poor: approximately 800,000 people are diagnosed with HCC each year, and ~80% die within five years. Therapeutically, there is a critical unmet need for more effective treatments. Resistance to sorafenib, the current first-line multi-target tyrosine kinase inhibitor, has become increasingly common. Moreover, more than 150 clinical trials evaluating targeted agents, immunotherapies, and combination regimens have failed due to insufficient efficacy, underscoring the urgent need for novel, mechanism-based therapeutic strategies. Emerging evidence highlights the central role of metabolic reprogramming in carcinogenesis, treatment resistance, and recurrence across multiple cancers, including HCC. Ornithine aminotransferase (OAT) is a key enzyme in this process, linking amino acid metabolism, particularly glutamine and proline, to polyamine biosynthesis and cancer cell proliferation. OAT is overexpressed in HCC and validated as a therapeutic target in preclinical models. We previously demonstrated that the OAT inactivator LHJ-2-79 effectively inhibits tumor growth in HepG2 and Hep3B xenografts and significantly suppresses alpha-fetoprotein (AFP) secretion, a key HCC biomarker, in Hep3B and HepG2 cells. However, no OAT inactivators have yet advanced to clinical trials. To address this gap, our laboratory recently synthesized SS-1-148, a novel OAT inactivator. Here, we report the effects of SS-1-148 on HCC using IC50 profiling, enzyme expression assays, xenograft survival studies, RNA-seq analysis, and metabolomic data. Our findings reveal cell line-dependent differences in SS-1-148 potency, OAT activity inhibition, tumor growth suppression, metabolic gene expression, and alterations in proline and polyamine levels. In vivo, SS-1-148 inhibited Huh-7 xenograft growth but not Huh-6 tumors. Metabolomic analyses of LHJ-2-79 and SS-1-148 in Huh-6 and Huh-7 cells further demonstrated distinct effects on proline and putrescine levels, suggesting different mechanisms of action between the two inactivators. Collectively, these results support OAT as a promising therapeutic target in HCC and lay the foundation for further development of OAT-based treatment strategies.

#3069 Involvement of ROS species in amiloride derivative-induced lysosome-dependent cell death in triple-negative breast cancer cells.

Noemi Castro[1], Michelle Hu[1], Anastasia Berg[1], Ruiwu Liu[2], KIT LAM[2], Kermit Carraway III[2]

[1]Biochemistry and Molecular Medicine, UC Davis, Davis, CA,[2]UC Davis, Sacramento, CA

Drug resistance leading to cancer recurrence poses a particularly challenging barrier to clinical disease management. Since tumor cells commonly activate anti-apoptotic pathways that cause caspase-dependent pathways to malfunction, cellular resistance to apoptosis is perhaps the most critical factor contributing to the therapeutic failure of conventional and targeted therapeutic agents. Consequently, subpopulations of apoptosis-resistant cells, such as cancer stem cells (CSCs), persist after therapy to seed primary tumor recurrence and metastatic lesions, even after complete remission. The overarching goal of this project is to develop novel drugs that exploit the process of lysosome-dependent cell death, a programmed necrotic cell death mechanism, in suppressing CSC-mediated triple-negative breast cancer. We have previously observed that hexamethylene amiloride (HMA), a derivative of the FDA-approved diuretic amiloride, is cytotoxic in vitro and ex vivo toward cultured cells from a variety of tumor types but not non-transformed cells. HMA also suppresses primary and metastatic tumor outgrowth in vivo. HMA acts on breast tumor cells regardless of subtype, proliferative status, or species of origin. It engages a potent caspase- and autophagy-independent programmed necrotic death mechanism in tumor cells that alters lysosome structure, dysregulates lipid synthesis, leads to lysosomal membrane permeabilization, and acts efficiently toward therapy-resistant CSC-related subpopulations. Although some specifics of the mechanism remain unknown, we examine how the formation of reactive oxygen species is crucial to the induction of necrosis and the potency of HMA and other amiloride derivatives.

#3073 Dickkopf1 as a potential therapeutic target in highly aggressive breast cancers.

Mohd Mughees[1], Jian Wang[2], Wendy A. Woodward[3], Megumi Kai[1], MDACC IBC Team[1], Sharon H. Giordano[1], Chandra Bartholomeusz[1]

[1]UT MD Anderson Cancer Center, Houston, TX,[2]Biostatistics, UT MD Anderson Cancer Center, Houston, TX,[3]Associate Professor, Radiation Oncology, UT MD Anderson Cancer Center, Houston, TX

Background: Triple-negative breast cancer (TNBC) and inflammatory breast cancer (IBC) are aggressive and lethal breast cancer subtypes, largely due to the absence of targeted therapies and insufficient understanding of the mechanisms driving metastasis and immune evasion. The glycoprotein Dickkopf-1 (DKK1) inhibits the WNT pathway and has been reported to enhance angiogenesis, metastasis, and invasion in breast cancer. We hypothesized that elevated serum DKK1 expression in IBC patients correlates with poor patient outcomes and that inhibiting DKK1 expression reduces proliferation and stemness in breast cancer cell lines.
Methods: We used the GOBO online tool (http://co.bmc.lu.se/gobo) to analyze gene expressions in breast cancer patients and performed a western blot to check the expression of DKK1 in a panel of TNBC and IBC cell lines. Next, as DKK1 is a secreted protein, we quantified its levels in serum samples from 176 IBC patients from MD Anderson using ELISA. To investigate DKK1's biological role in TNBC and IBC, we performed in vitro cell viability, clonogenic, mammosphere formation, $CD44^{+}/CD24^{-/low}$ flow cytometry, and Western blot analyses.
Results: Using the GOBO datasets, we retrospectively analyzed DKK1 expression in breast tumors and observed that the mean *DKK1* expression was higher in basal tumors (most likely to be TNBC) and HER2+ subtypes than in the other subtypes or normal tissue and cell lines. The DKK1 expression was higher in most of the TNBC and IBC cell lines as compared to the normal breast MCF-7 cells. For serum samples, the median age of patients was 52.5 years (range, 23-78 years), 75.0% were non-TNBC, and 25.0% were TNBC. The disease stage was III in 71.6% and IV in 28.4%, and the nuclear grade was 1 or 2 in 30.5% and 3 in 69.5%. High DKK1-expressing patients (categorized using median expression) showed a high risk of developing metastases (p=0.039), breast cancer-specific mortality (p=0.0183), and shorter overall survival (p=0.0267) compared to low DKK1-expressing patients, confirming literature findings and suggesting that DKK1 is likely to act as a metastasis or tumor promoter in breast cancer. shRNA- and CRISPR-based knockdown/knockout of DKK1 significantly reduced viability, clonogenic capability, mammosphere formation capability, and $CD44^{+}$ and $CD24^{-/low}$ subpopulations in the MDA-MB-231 and SUM149 TNBC/IBC cell lines. DKK1 knockout showed loss of AKT S473 phosphorylation but no effect on beta-catenin expression in SUM149 IBC cells, suggesting beta-catenin-independent signaling.
Conclusions and future prospects: DKK1 could be a clinically significant biomarker with implications for diagnosis and therapeutic targeting in TNBC and IBC. We are now assessing DKK1 inhibition in a high DKK1-expressing genetically engineered mouse model. Additional studies may clarify how DKK1 regulates stemness and metastasis in TNBC and IBC at the molecular level.

#3074 A first-in-class ER stress modulator selectively induces regulated cell death of STK11/TP53-deficient cancer cells.

Ying-Jie Wang[1], Xiaobing Zhang[1], Wei Jia[1], Bo Kang[2], Zhao Xu[1], Mingxing Yin[1], Hongban Zhong[1]

[1]Nain Biotech Co., Ltd., Hangzhou, China,[2]First Affiliated Hospital, School of Medicine, Zhejiang University, Hangzhou, China

Background: The tumor suppressor gene STK11 encodes LKB1 kinase that is a key regulator for cell metabolism, and TP53 gene encoding p53, a transcription factor known as the “Guardian of the genome”, critically protects the DNA integrity of the cell. STK11/TP53-deficient cancers are vulnerable to metabolic stress, redox stress, etc. and resistant to most therapies including immunotherapy, but there is no therapy so far that can specifically target this population of cancer patients. Notably, somatic mutations in KRAS, TP53 etc. are the major drivers, while germline mutations in STK11 and TP53 are the major inherited risk factors for pancreatic cancer that has no efficacious therapies yet.

Methods: The IC50s of our first-in-class PDIA6/IRE1 modulator NAI003, singly or in combination with a variety of marketed anticancer drugs, against multiple cancer cell lines and patient-derived primary cancer cells, were determined by CCK-8 cell viability assay or CellTiter-Glo® luminescent cell viability assay.

Results: NAI003 series compounds selectively kill or inhibit the proliferation of 20 out of 170 human cancer cell lines (with at least one compound having IC50 < 10 μM) via regulated cell death, 11 and 16 out of the 20 cells harbor STK11 and TP53 genetic and functional defects, respectively, and 8 out of the 20 cells carry defects of both genes. Further, NAI003 series compounds, particularly NAI003-7 (that dually targets PDIA6/IRE1 and HDACs), potently kill patient-derived primary cancer cells harboring STK11/TP53 genetic and functional defects. For patient-derived primary pancreatic cancer cells in vitro, NAI003-7 outperformed the current standard of care (SOC) therapy. In contrast, up to a concentration of 50 μM, NAI003 compounds exhibit no cytotoxicity to normal human cells (PBMCs, Jurkat T cells, HCerEpiC cells, etc.), consistent with their good in vivo safety profiles. Their in vivo efficacies in PDX models are currently under investigation.

Conclusion: PDIA6/IRE1-regulated ER stress is a target of vulnerability in STK11/TP53-deficient cancers, and NAI003 is a potential first-in-class small-molecule ER stress modulator that can specifically treat cancer patients harboring STK11/TP53 genetic and functional defects. This compound holds great promise in tackling hard-to-treat cancers such as pancreatic cancer, and in overcoming cancer drug resistance by various mechanisms.

#3075 FGFR2b is a highly prevalent and actionable cell surface target in intrahepatic cholangiocarcinoma.

Nakul M. Shah, Beatriz Alvarado-Hernandez, Xinyue Chen, Quentin Kimana, Felicity Namayanja, Wei Lu, Khaja B Khan, Juan Gallegos, Sangeeta Goswami, Lawrence N. Kwong, Luisa M. Solis Soto, Milind M. Javle, Sachet A. Shukla

The University of Texas MD Anderson Cancer Center, Houston, TX

Intrahepatic cholangiocarcinoma (iCCA) is an aggressive type of biliary tract cancer (BTC) with a rising incidence and limited treatment options. Previously established cell-surface targets of antibody-based therapies are not common in iCCA; for example, HER2 amplification occurs in <5% of patients. Knowledge of targetable membrane-bound proteins is a critical bottleneck in the field. Here, we performed a proteogenomic analysis that revealed FGFR2b as a dominant cell-surface isoform in iCCA and explored the association of its expression with genomic alterations, expression pathways, and splicing regulation.

We developed a comprehensive end-to-end platform to search for cell surface targets, including alternative splicing variants. Briefly, we perform *de novo* assembly of RNA-sequencing data from BTC samples (n=79), the majority iCCA (n=67), to include unannotated alternative isoforms using *stringtie*. Using *fragpipe*, we searched for novel proteins from *in silico* translation of these assembled transcripts in cell surface protein enriched mass spectrometry data from 15 cancer cell lines. Splice junction expression from detected isoforms was normalized and compared. Using *recount3*, we also assessed expression of these splice junctions across 10,415 TCGA samples and 19,081 GTEx samples. An optimized IHC protocol was established using the Roche anti-FGFR2b mouse monoclonal antibody (FPR2-D).

A unique glycosylated peptide from a FGFR2 alternative transcript was detected in the cell-surface mass spectrometry data, and we identified this alternative isoform to be FGFR2b. In our institutional cohort of 79 BTC samples, FGFR2b was the predominant FGFR2 isoform for 88.6% (70/79) of patients, which was further confirmed in 34 BTC samples from TCGA (88.2%; 30/34). Across 33 TCGA tumor types, BTC had the highest average expression of FGFR2b. FGFR2b had limited expression in normal tissues from GTEx. Patients with FGFR2 fusions had significantly higher FGFR2b expression than FGFR2c (p=0.025). FGFR2b expression negatively correlated with epithelial-to-mesenchymal transition and positively correlated with the epithelial splicing factor ESRP1, suggesting that ESRP1-driven FGFR2b expression is a hallmark of a more differentiated subtype of iCCA. In our institutional iCCA samples, 31.6% (6/19) of patients had >10% 2+/3+ staining. Strikingly, all patients with FGFR2 fusions (4/4; 100%) were positive for FGFR2b.

These results indicate that FGFR2b is highly expressed in iCCA, especially in patients with FGFR2 fusions, and highlight it as a compelling therapeutic target. Notably, the positivity rate of 31.6% is higher than that reported for gastric cancer (~16%), a setting in which multiple FGFRb-targeted therapeutic campaigns are currently underway. Our findings provide a strong rationale for the repurposing and evaluation of these FGFR2b-targeting agents in iCCA in prospective clinical trials.

#3076 Development of a SIX1-specific PROTAC for the treatment of esophageal adenocarcinoma.

Asad Faili, Vic Scharfenberger, Ellen Weber, Samaneh Heydarzadeh, Reinhard Buettner, Tristan Lerbs

Pathology, University Hospital of Cologne, Cologne, Germany

Esophageal adenocarcinoma belong to the cancer entities with a sharply increasing incidence. Though multimodal therapies have improved outcomes, prognoses remain poor in advanced stages and the 5-year survival rate is only between 20 to 25%. For this purpose, new therapeutic options are urgently necessary. In this context, this project investigated a SIX1-specific PROTAC (ELX19) in EAC - including potential adverse effects on the immune system. SIX1 is an embryonic transcription factor, which is required during embryogenesis for the development of various organs and tissues. In contrast, it is no longer or only weakly expressed in adult tissue. However, many cancers show a reactivation of cancer, which leads to different pro-tumorigenic features, making SIX1 a potentially therapeutic target. We first tested the efficiency of ELX19 in degrading SIX1 via WB and ELISA. Thereby, a higher SIX1 expression correlated with a better degradation efficiency, leading to a DC50 of below 1 µM in FLO-1 cells. ELX19 also reduced proliferation and increased apoptosis in FLO-1 cells. Importantly, ELX19 did not affect proliferation and apoptosis in a cell line with low SIX1 expression (OE19) suggesting that the effects caused by ELX19 are SIX1-specific. As adverse effects on the immune system can be a major impediment for further clinical development, we tested the effect of ELX19 on primary T helper and cytotoxic T cells. Thereby, unspecific effects only started 3 µM which is common for VHL-based PROTACs. In conclusion, these preliminary results show the potential of a SIX1-targeting PROTAC for the treatment of esophageal adenocarcinoma.

#3077 A novel MMP-targeting peptide suppresses glioblastoma metastasis by reducing MSI1 activity.

Xian Liu, Liang-Ting Lin

Department of Health Technology and Informatics, The Hong Kong Polytechnic University, Hong Kong, Hong Kong

Glioblastoma (GBM) remains the most lethal primary brain tumor, with a median survival of under 15 months, underscoring the critical need for novel therapies. The RNA-binding protein Musashi-1 (MSI1) is a pivotal oncoprotein that drives tumorigenesis and is associated with a poor prognosis. However, direct targeting of MSI1 is hampered by its high homology with MSI2, a lack of specific inhibitors, and the biochemical challenges posed by its C-terminal intrinsically disordered region (IDR), which has obscured key regulatory mechanisms. We employed a comprehensive strategy using GBM cell lines, orthotopic mouse models, and patient-derived tissues. A custom phospho-specific antibody detected MSI1 phosphorylation at Serine 347 (pS347). Functional roles were delineated using tetracycline-inducible shRNA and site-directed mutagenesis. Metastatic potential was assessed via multiplex immunohistochemistry, gelatin zymography for MMP activity, and invasion assays. A cell-penetrating decoy peptide was synthesized by fusing the S347-mimic sequence to the TAT protein transduction domain. We identified Serine 347 as a novel, functionally critical phosphorylation switch within the C-terminal IDR of MSI1. Clinically, pS347-MSI1 levels were significantly elevated in GBM patient samples and correlated with reduced survival in preclinical models. Mechanistically, preventing S347 phosphorylation via the S347A mutation profoundly suppressed GBM tumor formation and invasive potential. For the signaling axis, phosphorylation at S347 is essential for the expression and pericellular localization of key metalloproteinases MMP-2 and MMP-9 in vivo. The subsequent MMP activity drives an Epithelial-Mesenchymal Transition (EMT), as evidenced by the upregulation of vimentin, Twist, Slug, and Snail, which in turn facilitates the F-actin reorganization necessary for effective motility. Based on this mechanism, we engineered a strategic, cell-penetrating decoy peptide that mimics the S347 epitope. This peptide acts as a highly specific competitive inhibitor, selectively reducing MSI1 phosphorylation because MSI2 lacks a homologous serine. Treatment with this decoy peptide successfully recapitulated the anti-tumor effects of genetic dephosphorylation, significantly reducing MMP-2/9 levels, suppressing EMT markers, inducing disruptive morphological changes, and potently inhibiting cellular invasion. Our work establishes MSI1-S347 phosphorylation as a previously unrecognized druggable master switch that drives GBM metastasis via an MMP-EMT signaling axis. The development of a first-in-class MSI1-S347 decoy peptide that effectively neutralizes this switch and curbs invasion offers a highly specific, mechanistically grounded therapeutic strategy with significant potential to combat GBM progression.

#3078 Targeting the non-canonical neddylation of TGRBR2 suppresses the metastatic potentials of oral squamous cell carcinoma.

Yuan-Feng Lin

Taipei Medical University, Taipei, Taiwan

Background: Oral squamous cell carcinoma (OSCC) is the most common malignant tumor in the head and neck region and is characterized by rapid growth, strong invasiveness, early cervical lymph node metastasis, and a high overall metastatic rate. Primary surgery followed by adjuvant concurrent chemoradiotherapy is currently the preferred treatment strategy for most patients with advanced OSCC. Cetuximab, an epidermal growth factor receptor (EGFR) tyrosine kinase inhibitor (TKI), in combination with radiotherapy, has recently been approved by the U.S. Food and Drug Administration (FDA) for the treatment of recurrent or metastatic OSCC. However, TKI resistance mediated by alternative activation of the transforming growth factor-β (TGF-β) signaling axis has been reported in non-small cell lung cancer. Therefore, elucidating the crosstalk between TGF-β receptor signaling and EGFR-mediated signal transduction may be critical for the future precision management of OSCC.
Methods: Gene set enrichment analysis (GSEA) was applied to predict the potential mechanisms through which the protein neddylation inhibitor MLN4924 (Pevonedistat) suppresses cellular migration and lymph node metastasis in OSCC. Site-directed mutagenesis was performed to confirm the requirement of TGFBR2 neddylation in promoting OSCC metastatic potential. A pulldown assay was used to validate TGFBR2 neddylation, and a cycloheximide chase assay was employed to evaluate TGFBR2 protein degradation upon MLN4924 treatment in HSC3 cells.
Results: We found that MLN4924 treatment effectively suppresses the metastatic potential of OSCC cells both in vitro and in vivo. Site-directed mutagenesis targeting residues K1667 and K1700 (Lys→Arg) confirmed that TGFBR2 neddylation is essential for OSCC metastatic progression. GSEA predicted that MLN4924 mainly suppresses the TGF-β signaling axis in treated cells. Pulldown assays further demonstrated that MLN4924 markedly reduces neddylated TGFBR2 levels in HSC3 cells. Consistently, MLN4924 treatment accelerated TGFBR2 degradation, as shown by cycloheximide chase analysis. In rescue experiments, re-expression of wild-type TGFBR2—but not the K1667R/K1700R neddylation-defective mutant—significantly restored migration in TGFBR2-silenced HSC3 cells. Moreover, knockdown of the E3 ligase c-Cbl substantially decreased TGFBR2 neddylation and impaired cell migration.
Conclusion: This study is the first to demonstrate that non-canonical c-Cbl-mediated neddylation of TGFBR2 plays a decisive role in driving OSCC metastatic progression.

#3079 Discovery of a novel, covalent and heterobifunctional thioredoxin reductase inhibitor with antitumor activity.

Yanyan Han, Nicholas Blazanin, Sasi Kotagiri, Md Qudratullah, Xiaobing Liang, **Yonathan Lissanu**

The University of Texas MD Anderson Cancer Center, Houston, TX

Reactive oxygen species (ROS) play a central role in cellular signaling and homeostasis. However, imbalances in ROS levels contribute to various pathologies, including cancer. Tumor cells often upregulate antioxidant systems, such as the thioredoxin reductase (TrxR) and glutathione (GSH) pathways, to buffer against oxidative stress. The identification of aberrant metabolism and ROS has generated excitement and promise as a hallmark targetable vulnerability of tumors. Unfortunately, despite tremendous academic and industry efforts, this promise remains unfulfilled. Here, we report the discovery of YS207, a first-in-class covalent heterobifunctional inhibitor of TrxR1 using the deubiquitinase-targeting chimera (DUBTAC) technology. YS207 is composed of TrxR1 recruiting moiety coupled to deubiquitinase recruiting moiety via a novel chemical linker resulting in stabilization of covalently inhibited TrxR1 for profound generation of therapeutic levels of ROS. YS207 treatment potently inhibited TrxR1 enzymatic activity in vitro and in vivo (IC_{50} of 40nM & 700nM respectively). Mechanistically, YS207 elevated ROS levels, induced lipid peroxidation, and decreased intracellular GSH. Additionally, we observed profound alterations of the mitochondria including swelling, loss of cristae, increased electron density and prominent mitophagy, all characteristic of oxidative damage by using transmission electron microscopy (TEM). Rescue experiments with the ROS scavenger N-acetyl cysteine (NAC) confirmed that YS207-induced cell death was ROS-dependent. Large-scale PRISM profiling across 885 cancer cell lines revealed that sensitivity to YS207 strongly correlates with TrxR1 dependency, NADPH metabolism, and selenoprotein biosynthesis pathways. Notably, dual knockout of TrxR1 and GPX4 partially rescued YS207-induced cytotoxicity, underscoring a cooperative role in redox regulation. Further, we showed promising anti-tumor growth inhibitory activity of YS207 in xenograft models of lung cancer. Taken together, our results demonstrate that YS207 is a potent ROS modulator with potential antitumor activities through novel mechanism of action. We aim to pursue further development of this class of molecules in tumors with enhanced vulnerability to redox imbalance.

#3080 Site-specific conjugation of CPL976H-MMAE enables stable and selective dual targeting of PD-L1 and AXL.

Delfina Popiel[1], Filip Mitula[1], Anna Jablonska[1], Krzysztof Lacek[1], Natalia Czerwinska[1], Tomasz Kornatowski[1], Magdalena Langowska[1], Sylwia Wieczorek[1], Bartosz Wiernicki[1], Damian Kolakowski[1], Adam Zmyslowski[1], Tomasz Banach[1], Joanna Deshayes[1], Michal Mroczkiewicz[2], Marcin Zagozda[2], Joanna Hucz-Kalitowska[1], Emilia Mroz[1], Malgorzata Choros[1], Maciej Wieczorek[3], Olga Abramczyk[1]

[1]Preclinical Research Department, Celon Pharma S.A., Lomianki, Poland,[2]Medicinal Chemistry Department, Celon Pharma S.A., Lomianki, Poland,[3]Clinical Development Department, Celon Pharma S.A., Lomianki, Poland

Background: Combining immune checkpoint blockade with cytotoxic chemotherapy has improved survival in multiple solid tumors; however, systemic toxicity and limited response durability remain key limitations. To overcome these barriers, we developed CPL976H-MMAE, a next-generation bispecific antibody-drug conjugate (ADC) that simultaneously targets PD-L1 and AXL. This dual-target approach aims to suppress immune escape and tumor progression pathways while ensuring efficient and precise delivery of Monomethyl Auristatin E (MMAE) directly to the cancer cells.
Materials and Methods: CPL976H-MMAE was created with Fc-glycan remodeling and click-chemistry conjugation, resulting in an enhanced molecular stability and a standardized drug-to-antibody ratio (DAR). Target binding and stability of CPL975H-MMAE in serum were assessed by Surface Plasmon Resonance (SPR) after incubation in human, cynomolgus, mouse, and rat sera (7 days at 37°C). Pharmacokinetic and biodistribution studies were performed in MDA-MB-231 cell line xenograft models using LC-MS. Efficacy of CPL976H-MMAE was validated ex vivo in patient-derived xenografts (PDX) representing distinct PD-L1/AXL expression profiles. Potential binding to red-blood-cells (RBCs), MMAE release and its partitioning to RBCs were quantified by LC-MS in rat and cynomolgus species.
Results: CPL976H-MMAE retained strong and stable dual-target binding across different species sera, showing highest stability in human and cynomolgus, moderate in mouse, and lowest, but still satisfactory, in rat. ADC binding and MMAE level in RBCs of mouse and cynomolgus species was negligible, even though free MMAE exhibits partial association, further indicating conjugate stability in circulation. Pharmacokinetic analyses revealed a favorable plasma clearance profile and evident, dose-dependent tumor accumulation at 0.8-6 mg/kg, with minimal off-target MMAE exposure. Ex vivo studies confirmed potent cytotoxic activity of CPL976H-MAME in PDXs expressing both high and moderate PD-L1/AXL levels.
Conclusions: CPL976H-MMAE effectively merges immune checkpoint blockade with targeted cytotoxicity, addressing both primary and acquired resistance to PD-1/PD-L1 therapies. High serum stability, sustained tumor accumulation, and limited systemic exposure presents CPL976H-MMAE as a formidable and robust bifunctional ADC. Presented data highlight CPL976H-MMAE translational potential for future therapies, especially for patients unresponsive to current immunotherapies.
This study was supported by The National Centre for Research and Development (POIR.01.01.01-00-0429/19)

#3081 TEAD inhibition by IAG933 as a novel therapeutic strategy for cholangiocarcinoma.

Hidemi Nishi[1], Erik Jessen[2], Danielle M. Carlson[1], Amro M. Abdelrahman[1], Enis H. Ozmert[1], J. Pedro Fincatto Safi[1], Brandon A. Wilbanks[1], Shelby K. Yee[1], Jack W. Sample[1], Nathan W. Werneburg[1], Rory L. Smoot[1]

[1]Surgery, Mayo Clinic, Rochester, MN,[2]Biochemistry and Molecular Biology, Mayo Clinic, Rochester, MN

Background: Cholangiocarcinoma (CCA) is an aggressive hepatobiliary malignancy with marked molecular heterogeneity, limited systemic treatment options, and poor prognosis. Chemoresistance and KRAS mutations remain major therapeutic challenges. Dysregulation of the Hippo pathway, particularly YAP/TAZ hyperactivation, drives CCA progression and resistance. TEAD, the essential transcriptional partner of YAP/TAZ, represents a promising target. IAG933 is a novel oral pan-TEAD inhibitor designed to disrupt YAP/TAZ-TEAD interactions. RMC-6236, a pan-KRAS inhibitor, has also gained attention. Combined TEAD and KRAS inhibition may overcome resistance and improve efficacy in CCA.

Methods: We evaluated IAG933 in human (HuCCT1, RBE) and murine (SB1, FAC) CCA cell lines. Cells were treated with IAG933 alone or in combination with GemCis or RMC-6236. Cell viability assays were used to determine IC_{50} values and calculate combination *indexes* (CI). TEAD activity was assessed by luciferase reporter and qRT-PCR of YAP/TAZ target genes (CTGF, CYR61, NUAK2). Transcriptomic alterations were analyzed by RNA sequencing. In vivo efficacy was evaluated in syngeneic orthotopic and patient-derived xenograft (PDX) models.

Results: IAG933 suppressed TEAD-dependent transcription ($IC_{50} \approx 500$ nM) and downregulated YAP/TAZ target genes. Combination with GemCis or RMC-6236 produced synergistic effects ($CI < 1$) in all CCA lines. Transcriptomic analysis revealed activation of oxidative stress response pathways, particularly SOD2 upregulation. MitoSOX staining confirmed increased mitochondrial ROS after treatment. In vivo, IAG933 monotherapy suppressed tumor growth similarly to GemCis. Dual TEAD and KRAS inhibition achieved marked tumor regression and significantly delayed tumor regrowth after treatment cessation in KRAS-mutant PDX models.

Conclusion: IAG933 effectively suppresses YAP/TAZ-TEAD signaling and inhibits CCA growth. While the combination with GemCis showed limited additional benefit due to strong single-agent efficacy, synergy with RMC-6236 produced durable antitumor effects, particularly in run-out studies, delaying regrowth in KRAS-mutant models. These findings highlight IAG933 as a promising therapeutic candidate targeting the Hippo-TEAD pathway, with potential benefit in KRAS-mutant CCA.

#3082 A novel iNOS inhibitor as a targeted therapeutic approach for inflammatory breast cancer.

Karina Ortega Martinez[1], Maria Florencia Chervo[1], Feng Li[1], Jenying Deng[1], Liliana Guzman-Rojas[1], Wei Qian[2], Jianying Zhou[2], Recep Bayraktar[1], Aireana Phillips[1], Ivonne Uzair[1], Mailin Li[1], Aijun Zhang[1], Spencer Hankins[1], Dale Hamilton[1], Zhonglin Liu[1], Christopher Lincoln[1], Christoforos Thomas[3], Jenny C. Chang[4]

[1]Houston Methodist Research Institute, Houston, TX,[2]Houston Methodist Research Institute, houston, TX,[3]Houston Methodist Research Institute, Houston, Houston, TX,[4]Houston Methodist Hospital, Houston, TX

Nitric oxide (NO), generated by inducible nitric oxide synthase (iNOS), has been implicated in tumor progression, metastasis, and therapy resistance. Our completed phase Ib/II clinical trial in metastatic and locally advanced triple negative breast cancer showed that combination therapy with the pan NOS inhibitor LNMMA and standard chemotherapy elicits potent antitumor activity. Mechanistically, LNMMA targets the breast cancer stem cell (BCSCs) population enhancing their susceptibility to chemotherapy. We have developed a new iNOS inhibitor TDIMER co formulated with a calcium channel antagonist to mitigate the hemodynamic effects associated with systemic iNOS inhibition. We hypothesize that TDIMER can be effective for the treatment of inflammatory breast cancer (IBC), a rare and highly aggressive subtype with high recurrence rates and poor prognosis. In vitro studies were performed using SUM149 IBC cells. iNOS expression was confirmed by RT-qPCR and western blot. TDIMER efficacy was assessed, alone or with docetaxel, and compared to LNMMA, through cell proliferation, apoptosis and cell migration assays. BCSCs ($CD44^{+}/CD24^{-/low}$) were identified by flow cytometry after treatment with TDIMER or LNMMA in combination with docetaxel. In vivo studies using non-tumor bearing NSG mice were conducted to determine TDIMER dose toxicity and effect on blood pressure (BP). Mice received TDIMER (40 mg/kg oral gavage on day 1, 20 mg/kg oral gavage on days 2-5) or in combination with the calcium channel blocker amlodipine (10 mg/kg IP injection on days 1-5). Mice treated with PBS were used as control. BP was measured daily with BP-2000 (Visitech Systems). Animals were euthanized on day 5 for histopathological analysis and assessment of biochemical markers (ALT, AST, BUN) in serum samples. TDIMER treatment demonstrated superior efficacy over LNMMA, with a markedly lower IC_{50} in SUM149 cells. TDIMER more effectively reduced cell viability, and delayed migration relative to LNMMA. Combination therapy with TDIMER and docetaxel induced the highest levels of apoptosis and reduced BCSCs, suggesting potent activity against chemo resistant tumor-initiating cells. In vivo toxicity studies demonstrated that TDIMER treatment did not produce histopathological alterations or significant elevations in serum ALT, AST, or BUN levels, confirming a favorable safety profile. Furthermore, no significant changes in BP were observed across experimental groups, underscoring TDIMER's advantage in achieving potent iNOS inhibition without the need for coadministration of antihypertensive agents. Ongoing studies are aimed to elucidate the antitumor efficacy of TDIMER in xenograft mouse models of IBC. Overall, our findings support continued preclinical development of TDIMER as a novel iNOS targeted therapy for IBC patients.

#3083 YT-DP: A glyco-conjugation-based dual-payloads ADC platform.

Yi Yang, Zhentao Song, Rui Yu, Jiangping Hu, Zhouyang Qian, Xinyue He, Guoli Yang, Ji Chen, Juntao Yu

Glyco-therapy Biotechnology Co. Ltd., Hangzhou, China

Dual-payloads antibody-drug conjugates (ADCs) represent a promising next-generation modality to enhance antitumor efficacy, achieve synergistic effects, and overcome tumor heterogeneity and therapeutic resistance. However, their development faces several key challenges, including: (i) identifying payload combinations that maintain efficacy within a shared safety window without single-agent dominance; (ii) achieving precise and efficient assembly of distinct payloads into antibodies with controlled drug-to-antibody ratios (DARs); and (iii) ensuring robust stability, in vivo efficacy, and favorable safety profiles. To address these challenges, we developed YT-DP, a glyco-conjugation-based dual-payloads ADC platform that enables the incorporation of two distinct mechanism-of-action (MOA) payloads into a single antibody molecule through a one-step glyco-conjugation strategy. This system allows flexible DAR configurations (e.g., DAR 2+2 or DAR 2+4). The YT-DP platform integrates our proprietary cleavable-linker-topoisomerase I inhibitor payload (CLTp) technology (YT-CLTp) with a microtubule inhibitor (MTI) via the YTConju glyco-conjugation system. The YT-CLTp series comprises tunable payload candidates with adjustable target and bystander killing activities, demonstrating superior anti-tumor potency compared with “GGFG-Dxd” in multiple CDX models when conjugated to antibodies. We generated trastuzumab-based dual-payloads ADCs (Tras-DPs) containing an MTI and distinct CLTps at different DARs (DAR 2+2 and DAR 2+4). Tras-DPs exhibited high homogeneity, excellent thermal and plasma stability, and potent synergistic antitumor activity with strong by-stander effects. Notably, Tras-DPs demonstrated markedly superior antitumor activity compared with DS-8201, as well as the corresponding single-payload ADCs or their combinations, in CDX models. In addition, the dual-payloads ADCs showed favorable pharmacokinetic (PK) properties and safety profiles in rat studies. In summary, the YT-DP platform provides a robust and versatile strategy for constructing homogeneous, stable, and synergistic dual-payloads ADCs with tunable DARs. Its broad compatibility with various antibody formats, including Fc-containing bispecific antibodies, underscores its potential to enable next-generation ADCs with an enhanced therapeutic index.

#3084 Network-based discovery of tumor-checkpoint inverter drugs targeting pancreatic ductal adenocarcinoma cell states and macrophage reprogramming.

Yining Chen[1], Alvaro Curiel-Garcia[1], Alex Piacentini[2], Zhouzerui Liu[2], Tim Olsen[2], Richard Yau[3], Praveer Sharma[3], Liz Murray[3], Gaetano Viscido[1], Ken Olive[1], Andrea Califano[1]

[1]Herbert Irving Comprehensive Cancer Ctr., New York, NY,[2]Chan Zuckerberg Biohub, New York, NY,[3]Cellanome, Foster City, CA

Pancreatic ductal adenocarcinoma (PDAC) remains one of the most lethal malignancies, driven by extreme tumor heterogeneity and a profoundly immunosuppressive tumor microenvironment (TME). Distinct PDAC cell states—Gastrointestinal-like (GLS), Morphogenic (MOS), and Primitive (PLS)—coexist within individual tumors and are further stratified by MAPK activity (M^+/M^-), reflecting dynamic transcriptional programs sustained by Master Regulator (MR) proteins. These cell states are hypothesized to differentially modulate the tumor-associated macrophages in the TME. To investigate this, we established a co-culture system of THP-1-derived macrophages with PDAC cell lines representing each state and profiled macrophage transcriptional reprogramming. Macrophages co-cultured with distinct PDAC states exhibited differential activation of M2-like and $TREM2^+/APOE^+/C1Q^+$ immunosuppressive phenotype, suggesting that PDAC cell states may uniquely influence macrophage phenotypes and immune evasion.To identify compounds capable of reprogramming these malignant states, we applied a network-based systems biology framework integrating ARACNe and VIPER to infer MR activity across PDAC states, OncoMatch to identify representative cell line models, and OncoTreat to predict small molecules capable of inverting tumor checkpoint-module activity. Cross-model validation identified state-specific candidate drugs, including Leuprolide, Vinblastine, and Mercaptopurine for GLS; Vindesine, Gossypol, and Binimetinib for MOS; and AT9283, Crizotinib, and Afatinib for PLS. Predicted MR-inversion scores correlated with experimental dose-response profiles in cell lines selected via OncoMatch.Together, these results establish a mechanistic link between tumor-intrinsic transcriptional states and macrophage immunosuppression, while identifying mutation-agnostic, state-specific drugs capable of reprogramming both tumor and immune compartments. This work provides a generalizable framework for network-based drug repurposing to overcome transcriptional plasticity and immune resistance in PDAC.

#3085 Molecular characterization of inhibition of the DNA repair protein RAD51 by the small molecule JKYN-1.

Peter Ferguson[1], Mark Vincent[1], Yousef Najajreh[2], Morgan Black[3], Sweta Sharma Saha[4], Melissa Thomas[5], Olivier Lord[6], Stephen Ritter[7], Jean-Yves Masson[5], Brian Shilton[7], James Koropatnick[7]

[1]London Health Sciences Centre, London, ON, Canada,[2]Faculty of Pharmacy, Al-Quds University, Abu-Dies, Jerusalem, Palestinian Territory,[3]London Health Sciences Ctr., London, ON, Canada,[4]Teesside University, Middlesbrough, United Kingdom,[5]CHU de Quebec-Universite Laval, Quebec, QC, Canada,[6]Universite Laval, Quebec, QC, Canada,[7]Western University, London, ON, Canada

The ability of cancer cells to form large tumors and rapidly adapt to changing environmental conditions results from inherent genetic instability that also confers upon them sensitivity to cytotoxic agents. Cancer cells rely heavily on the action of the protein RAD51, overexpressed in many tumors, to survive DNA damage and replication stress (RS) (Cells 12: 1169-1189, 2023. https://doi.org/10.3390/cells12081169). The IBR-family RAD51 inhibitors not only inhibit tumor cell proliferation as single agents at low micromolar concentrations, but also work synergistically with a variety of established anticancer agents to stop growth and induce cell death (J Pharmacol Expt Ther, 364: 46-54, 2018. doi.org/10.1124/jpet.117.241661). To better understand the synergistic interaction and help improve selectivity against cancer cells, and thus potential for clinical use, we have characterized the activity of IBR2, IBR120, and JKYN-1 using a variety of methods. JKYN-1, the structure of which is a modification of IBR120, is 5-fold stronger as a single-agent inhibitor of proliferation. As demonstrated previously for IBR2 and IBR120, JKYN-1 synergistically inhibited proliferation of cell lines representative of numerous tumor sources in combination with established anticancer drugs. In hydroxyurea-treated human breast carcinoma MCF-7 cells, B02, an established RAD51 inhibitor (Mol Cancer Ther 20:1257-1269, 2021. doi: 10.1158/1535-7163.MCT-20-0252), and JKYN-1 markedly suppressed formation of RAD51 foci while increasing pRPA foci formation, a marker of RS. In human osteosarcoma U2OS cells exposed to ionizing radiation, JKYN-1 alone reduced RAD51 foci formation. Mechanistically, JKYN-1 impaired RAD51-dependent D-loop formation. JKYN-1 inhibited multimerization of RAD51 as well as its ATPase activity, responsible for normal dissociation of RAD51 from DNA following completion of repair. Therefore, JKYN-1 acts as expected in inhibiting RAD51 function. How this contributes to the synergy observed with anticancer agents is being investigated. Derivatives of JKYN-1 are currently being studied for improvements to pharmacokinetic properties. *Funded by Sarissa, Inc., Breast Cancer Canada, and London Health Sciences Foundation.*

#3086 ART1 as an immune modulating therapeutic target in EGFR-mutated lung cancer.

Mimansa .[1], Rajika Jindani[1], Mukherjee Sumit[1], Jorge Quintero[1], Naresh Regmi[1], Grace Ha[1], Justin Olivera[1], Justin Rosario[1], Melissa Tracy[1], Brendan Mullaley[1], Victor Gray[2], Erik Wennerberg[2], Lindsay M. LaFave[1], Brendon Stiles[3]

[1]Albert Einstein College of Medicine, Bronx, NY,[2]The Institute of Cancer Research, London, United Kingdom,[3]Montefiore Einstein Comprehensive Cancer Center, The Bronx, NY

Purpose: Epidermal growth factor receptor (EGFR) mutations drive non-small cell lung cancer (NSCLC). Tyrosine kinase inhibitors (TKIs) provide clinical benefit but are limited by resistance. We investigated the role of mono-ADP-ribosyltransferase-1 (ART1) in mediating EGFR signaling, immune suppression, and therapeutic resistance.
Methods: ART1 expression was assessed in a human tissue microarray. ART1 function was assessed in vitro in HCC827 and other EGFRmu lines using immunoprecipitation, immunofluorescence, and RNA-seq to define MARylation events and transcriptional changes. In vivo studies tested ART1 blockade with the fully humanized anti-ART1 monoclonal antibody, 22C12, alone or in combination with osimertinib in EGFR-mutant NSCLC GEMMs. These approaches enabled integrated assessment of ART1's biochemical, transcriptional, and immunologic functions.
Results: ART1 protein expression was higher in EGFRmu than EGFRwt human tumors. In vitro, ART1 was increased by osimertinib treatment. ART1 enhanced EGFR signaling through NAD^+-dependent mono-ADP-ribosylation (MARylation). ART1 blockade with 22C12 abrogated EGFR MARylation and reduced downstream oncogenic signaling. RNA-seq revealed ART1-dependent regulation of EGFR-related transcriptional programs. In vivo, 22C12 osimertinib and 22C12 each demonstrated single agent efficacy, however small tumors persisted in GEMM models. However, combination therapy with Osimertinib and 22C12 reduced macrophage infiltration, increased tumor-infiltrating $CD8^+$ tissue-resident memory (TRM) T cells, and rendered treated mice tumor-free. This synergy highlighted complementary tumor-intrinsic and immune-modulatory roles of ART1. These dual tumor-intrinsic and immune-modulatory effects identify ART1 as a driver of therapeutic resistance and potential therapeutic target.
Conclusions: ART1 promotes EGFR pathway activation and suppresses antitumor immunity in EGFR-mutant NSCLC. Targeting ART1 enhances efficacy of TKIs while decreasing macrophage infiltration and reinvigorating $CD8^+$ T-cell responses. ART1 inhibition represents a promising therapeutic strategy for overcoming resistance, warranting further investigation including ADP-ribosylome mapping and studies on ART1 blockade in modulating receptor signaling and bispecific antibody or antibody-drug conjugate interactions. Overall, these results support ART1 as a targetable mediator of EGFR-driven tumor progression and immune dysfunction in EGFR-mutant lung cancer. 22C12 is being developed to enter phase 1 clinical trials across multiple tumor types.

#3087 Targeting AURKA and TRIP13 exploits mitotic vulnerability and enhances antitumor immunity in Rb-deficient immunocompetent lung cancer models.

Soma Ghosh[1], Jennifer L. Anderson[2], Andrew G. Sikora[3], Faye M. Johnson[1]

[1]UT MD Anderson Cancer Center, Houston, TX,[2]The University of Texas MD Anderson Cancer Center, Texas, TX,[3]Department of Head and Neck Surgery, The University of Texas MD Anderson Cancer Center, Texas, TX

Rb loss is a common event in multiple cancers and creates vulnerabilities that can be therapeutically exploited. We previously reported that HPV-positive, Rb-deficient cancers depend on two mitotic checkpoint regulators, Aurora kinase A (AURKA) and TRIP13, for proper mitotic exit. Dual inhibition of these proteins induces mitotic catastrophe and cell death. To determine whether this dependency extends beyond HPV-driven tumors and affects the tumor immune microenvironment, we evaluated the combination of AURKA and TRIP13 inhibition in Rb-deficient lung cancer models. To test the combination, we used the TRIP13 inhibitor DCZ0415 and the AURKA inhibitor alisertib. We first assessed the ability of DCZ0415 to inhibit TRIP13. Consistent with previous reports, DCZ0415 binds to TRIP13 as confirmed by CETSA and affinity chromatography assays. Treatment of cancer cells with 10μM DCZ0415 reduced MAD2 association with CDC20 in pull-down assays, indicating that DCZ0415 selectively interferes with TRIP13-mediated MAD2 conversion. TRIP13 ATPase activity was largely unaffected, suggesting a kinase-independent inhibitory mechanism. The IC_{50} values for DCZ0415 in murine non-small cell lung cancer (NSCLC) cell lines were 20μM for 344SQ and 16μM for 344P, as determined by CellTiter-Glo assays. In apoptosis assays (Annexin V), DCZ0415 alone did not induce measurable cell death, while alisertib (200 nM) resulted in ~25% apoptosis after 72 hours. In contrast, the combination treatment produced significantly greater apoptosis. In 344SQ cells, the combination induced ~40% cell death, compared with 4.6% for DCZ0415 and 25% for alisertib alone. Similar findings were observed in 344P cells, with combination treatment inducing ~55% apoptosis. We next evaluated the combination in a PD1-resistant, Rb-deficient immunocompetent mouse model. The combination produced a marked reduction in tumor growth compared with either agent, with significant differences apparent by day 14. Preliminary immunoprofiling of tumor-infiltrating immune cells (TILs) revealed several combination-specific effects. Dendritic cell abundance increased, suggesting enhanced antigen presentation within the tumor. The combination also reduced myeloid-derived suppressor cell (MDSC) levels in the tumor, indicating a shift toward a less suppressive tumor immune microenvironment. Additionally, TIL analysis showed increased overall T-cell infiltration, with both $CD4^+$ and $CD8^+$ T-cell populations elevated relative to single agents. T-cell polyfunctionality was also enhanced, as indicated by higher frequencies of $GZMB^+$ and $IFN\gamma^+$ effector T cells. Together, these findings identify combined AURKA and TRIP13 inhibition as a promising therapeutic approach for Rb-deficient cancers and provide the first *in vivo* evidence of its efficacy and immune-modulating potential in NSCLC.

#3088 Targeting NONO as a therapeutic strategy for metastatic castration-resistant prostate cancer (mCRPC).

Brian McEllin, **Gaelle Mercenne**, Daniele Canzani, Gavin Hirst, Lindsay Pino, Alexander Joel Federation

Talus Bio, Seattle, WA

Prostate cancer is among the most prevalent cancers among men, with approximately 300,000 new cases diagnosed annually. While androgen deprivation therapy (ADT) is effective in controlling early-stage prostate cancer, treatment options are limited once the disease advances to metastatic castration-resistant prostate cancer (mCRPC). This progression underscores the critical need for innovative therapeutic strategies to address this difficult-to-treat stage. Resistance to ADT arises when androgen receptor (AR) signaling becomes active even in the absence of ligands. This resistance is often driven by mutations in the ligand-binding domain (LBD) of AR or the expression of AR variants (AR-Vs) that lack the LBD. Uncovering new strategies to inhibit these constitutively active AR-Vs could provide significant clinical benefit for patients with mCRPC.

Talus Bio has developed a groundbreaking technology, TF-Scan, the first cell-based global screening platform specifically designed to target transcription factors (TF) and other regulome proteins. TF-Scan integrates functional proteomics, automated cell processing, and machine learning to evaluate a drug's ability to modulate the activity of DNA-bound proteins in live human cells. This is an ideal system to identify and optimize compounds that suppress AR through direct or indirect mechanisms.

Building on this mechanistic insight, we applied TF-Scan to systematically identify covalent modulators of NONO (non-POU domain-containing octamer-binding protein) that disrupt AR expression and protein binding. We then initiated an iterative hit-to-lead optimization campaign leveraging TF-Scan to optimize NONO binding, AR disruption and proteome-wide selectivity.. Our chemical series engages NONO at C145 with high selectivity in intact prostate cancer cells and produces a consistent reduction in chromatin-bound AR. Lead compounds suppress both full-length AR and AR-V7 protein levels, downregulate multiple downstream AR/AR-V target genes, and achieve sub-micromolar EC50 values for blocking the accumulation of AR mRNA isoforms. These effects translate into concordant anti-proliferative activity in AR-dependent prostate cancer models. Several advanced analogs exhibit improved solubility, enhanced microsomal stability, and overall favorable ADME/PK profiles. Based on these results, we are advancing our most promising candidates into proof-of-concept in vivo efficacy studies to evaluate their potential as first-in-class NONO/AR-targeting therapeutics for mCRPC.

#3089 Characterization of a novel inhibitor of asparagine synthetase that activates the integrated stress response.

Nicholas T. Walda[1], Lucciano A. Pearce[2], Nigel Richards[3], Wen Zhu[2], Yuichiro Takagi[1], Ronald C. Wek[1], **Kirk A. Staschke**[1]

[1]Biochemistry, Molecular Biology, and Pharmacology, Indiana University School of Medicine, Indianapolis, IN,[2]Chemistry and Biochemistry, Florida State University, Tallahassee, FL,[3]Foundation for Applied Molecular Evolution (FfAME), Alachua, FL

Asparagine synthetase (ASNS) catalyzes the biosynthesis of L-asparagine (L-Asn) from L-aspartate, L-glutamine, and ATP, and plays a central role in anticancer therapies such as L-asparaginase treatment of acute lymphoblastic leukemia. In response to L-Asn depletion, ASNS induction is a key effector of the GCN2-ATF4 arm of the integrated stress response (ISR), enabling tumor cells to maintain amino acid homeostasis under limiting nutrient conditions. However, direct ASNS targeting has long been hindered by the poor cellular potency of existing inhibitors. Here, we delineate the molecular and cellular mechanism of ASX-173, a cell-penetrant ASNS inhibitor with potent biochemical and cellular activity with the potential to starve tumors of asparagine and enhance the impact of combination therapies targeting tumor metabolism.

Using HEK293A cells cultured without exogenous L-Asn, ASX-173 markedly reduced intracellular L-Asn levels, activated the ISR, and stimulated ATF4 transcriptional activity. ISR induction was reversed by physiological levels of L-Asn, confirming on-target activity. Deletion of GCN2 lowered basal ASNS expression, impaired ATF4 induction, and sensitized cells to ASX-173. Similarly, the GCN2 inhibitor GCN2iB suppressed ASX-173-induced ATF4 transcriptional activity and synergized to inhibit the growth of multiple cancer lines, including renal (RENCA) and prostate (Myc-CaP) models. Cell-based thermal protein profiling experiments confirmed direct ASNS binding, shifting its melting temperature from 45 °C to 54 °C. Using recombinant ASNS, ASX-173 inhibited L-Asn production without affecting L-glutamate and showed reduced activity at the Km for Mg^{2+}-ATP. Differential scanning fluorimetry experiments demonstrated that binding of ASX-173 to ASNS requires Mg^{2+}-ATP. Moreover, a 2.58 Å cryo-EM structure revealed ASX-173 bound in the C-terminal synthetase subdomain alongside AMP, PPi, and two Mg^{2+} ions, stabilized by hydrophobic, π-interactions, and hydrogen bonding with AMP to form a composite pocket. The structure indicates that ASX-173 promotes ATP hydrolysis and blocks ammonia transfer, supporting an uncompetitive mechanism.

These findings establish ASX-173 as a potent ASNS inhibitor with strong cellular target engagement and ISR-inducing activity. The heightened sensitivity of GCN2-deficient cells and the synergy with GCN2 inhibition highlight the therapeutic potential of dual ISR targeting and support ASNS inhibition—alone or in combination with ISR-modulating strategies—as a promising approach for cancers dependent on asparagine metabolism.

#3090 VRK1 inhibition leverages paralog synthetic lethality to selectively target VRK2-deficient cancer cells.

Kiera M. Vassallo, Kevin M. Cottrell, Katarzyna B. Handing, Mu-Sen Liu, Alvin Lu, Alice Tsai, Maria Dam Ferdinez, Patrick McCarren, Sirimas Sudsakorn, Jannik N. Andersen, **Kimberly J. Briggs**

Tango Therapeutics, Inc., Boston, MA

Vaccinia-related kinases (VRKs) are a family of serine/threonine kinases involved in a variety of cellular processes, including cell signaling, chromatin modification, nuclear envelope dynamics, and cell cycle progression. More than 60% of glioblastomas and nearly all neuroblastomas have low expression of the *VRK2* gene resulting in deficient VRK2 activity. VRK1 has been identified as a paralog synthetic lethal target in these VRK2-deficient cancers, with the potential for indication expansion into additional cancer types. Here, we show that inhibition of VRK1 leads to a concomitant loss of Barrier to Autointegration Nuclear Assembly Factor 1 (BANF1 or BAF) phosphorylation leading to aberrant nuclear envelope formation and downstream loss of cellular viability. As a target, VRK1 is both tractable and structurally-enabled, with chemical series capable of achieving >4000-fold biochemical selectivity against its paralog VRK2 and >70-fold viability selectivity in VRK2 isogenic cell line pairs. Compounds show strong correlations between biochemical, cellular target engagement, pharmacodynamic, and functional viability assays. Furthermore, in vivo tolerability studies suggest that VRK1 inhibitors are well-tolerated in immunocompromised mice. Preclinical validation studies support the development of VRK1 inhibitors for the treatment of patients with VRK2-deficient tumors such as glioblastoma and neuroblastoma.

#3091 Exploring the anti-tumor potential of HLA-G-targeted therapeutics through diverse preclinical approaches.

Hyeonju Kang, **Inyoung Lee**, Sungyeon Park, Yoo jin Kim, Kyueun Cho, Hongjai Lee, Yiyoung Choi, Jiyeon Hong, Chihye Park, Chungmin Lee, Gyongsik Ha

IMBiologics Corp., Suwon, Korea, Republic of

HLA-G, a non-classical MHC class I molecule with potent immunosuppressive properties, is aberrantly expressed in various solid tumors and plays a critical role in immune evasion. This immune suppression is primarily mediated through its interaction with inhibitory receptors such as ILT-2 on immune cells, which dampens anti-tumor responses and facilitates tumor progression. As such, HLA-G functions as an immune checkpoint molecule, making it a promising target for cancer immunotherapy. Monoclonal antibodies and CAR-T therapies targeting HLA-G have been previously explored; however, further optimization of therapeutic formats, incorporation of novel modalities such as antibody-drug conjugates (ADCs) and multi-specific antibodies, and preclinical validation are needed to advance their clinical potential. In this study, we present a preclinical evaluation of HLA-G-targeting biologics, including ADCs and bispecific antibodies, with emphasis on pharmacokinetics, efficacy, and biomarker-guided tumor selectivity. Notably, in a choriocarcinoma xenograft model, one complete response was observed following ADC monotherapy, suggesting the therapeutic potential of HLA-G-targeted ADCs in specific tumor contexts. To further assess clinical relevance, MiniPDX platforms derived from patient tumors were employed for target validation and biomarker correlation. These studies indicate HLA-G expression may serve as a predictive marker for therapeutic response and revealed differential efficacy across tumor types. In parallel, bispecific antibodies targeting HLA-G and co-expressed tumor antigens were evaluated for binding affinity and cytotoxicity. Bispecific formats demonstrated enhanced tumor cell engagement and potent anti-tumor activity, suggesting their utility in overcoming antigen heterogeneity and resistance mechanisms. Collectively, these findings provide preclinical evidence supporting the development of HLA-G-targeting therapeutics using diverse modalities. ADCs are particularly appealing as they can enhance potency through cytotoxic payloads while minimizing off-target toxicity due to the tumor-specific antigen nature of HLA-G. In addition, bispecific antibodies may offer further tumor selectivity and augment immune activation. This study presents additional efficacy data from in vivo xenograft and MiniPDX models, contributing to the ongoing preclinical evaluation of HLA-G-targeting strategies. Importantly, HLA-G has emerged as a potential therapeutic target capable of delivering robust efficacy through diverse therapeutic modalities and may serve as a predictive biomarker. These findings underscore the potential of HLA-G-targeted therapeutics, particularly ADCs and bispecific formats, as investigational treatment options for cancers with limited effective therapies, such as ovarian cancer.

#3092 Epiregulin and amphiregulin as dual targets in colorectal cancer.

Cara Biddle-Guernsey[1], Joan Jacob[2], Zhengdong Liang[1], Kendra S. Carmon[1]

[1]Center for Translational Cancer Research, The Brown Foundation Institute for Molecular Medicine, University of Texas Health Science Center at Houston, Houston, TX,[2]Pediatrics Oncology-AICT, Baylor College of Medicine, Houston, TX

Advanced-stage metastatic colorectal cancer is associated with high mortality. Current therapies have shown limited survival benefit and are often constrained by dose-limiting toxicity or drug resistance, including constitutively activating mutations (i.e., *KRAS*) limiting epidermal growth factor receptor (EGFR)-targeted therapy efficacy. Thus, novel targeted therapeutic strategies are needed. Antibody-drug conjugates (ADCs) act as guided missiles where a monoclonal antibody (mAb) conjugated to cytotoxic payloads binds its tumor-specific target, internalizes, and traffics to lysosomes for payload release, inducing tumor cell death while sparing normal tissues. We previously developed ADCs targeting the EGFR ligand epiregulin (EREG), which is overexpressed in *KRAS* wildtype and mutant (MUT) colorectal tumors, that were effective at inhibiting tumor growth in CRC cell line- and patient-derived xenograft models. Yet, tumor regrowth was observed upon treatment termination, and residual tumors showed target downregulation as a potential mechanism of ADC resistance. This indicates EREG ADC monotherapy may not be sufficient to eliminate colorectal tumors. Co-targeting of additional cell-surface antigens may enhance intratumoral payload delivery and address potential resistance mechanisms. Previous studies and our analyses of RNA-seq expression data from The Cancer Genome Atlas (TCGA) colorectal adenocarcinoma cohort show EREG is often co-overexpressed with the related EGFR ligand amphiregulin (AREG) in CRC patients, with their expression predominant of all seven EGFR ligands, suggesting potential functional importance. Therefore, we hypothesize that targeting EREG and AREG with ADCs simultaneously will inhibit tumor growth and enhance ADC efficacy compared to single-target ADC monotherapy. We generated EREG knockout (KO), *KRAS*-MUT CRC cell lines via lentiviral transduction using CRISPR-Cas9, which show significantly reduced proliferation and tumor growth compared to the parental and vector cells. These results indicate that EREG actively promotes CRC growth, despite oncogenic mutations downstream of EGFR. We are also generating AREG KO and EREG/AREG-double KOs using CRISPR-Cas9 for characterization. Additionally, we have cloned, produced, and purified human AREG-targeted mAbs for the development of novel AREG-targeted ADCs. AREG overexpression cell lines were generated for mAb validation. Our data demonstrate the AREG mAbs bind AREG with high specificity and promote internalization and lysosomal trafficking in CRC cells. These results suggest AREG to be a suitable therapeutic target in CRC, and we are currently in the process of generating AREG-targeted ADCs. Future work will test whether co-targeting EREG and AREG provides additional therapeutic benefit.

#3093 *SLC25A28* is a synthetic lethal target in nucleotide excision repair-deficient cancer.

Nan Yang[1], Vijai Joseph[1], Lisa Hoeg[2], Xuechun Bai[1], Sizhi Gao[1], Ouathek Ouerfelli[1], David B. Solit[1], Jian Carrot-Zhang[1], Gopa Iyer[1], Daniel Durocher[2], Kent W. Mouw[3], Kenneth Offit[1], Steven M. Lipkin[4]

[1]Memorial Sloan Kettering Cancer Center, New York, NY,[2]Lunenfeld-Tanenbaum Research Institute, Toronto, ON, Canada,[3]Radiation Oncology, Dana Farber Cancer Institute, Boston, MA,[4]Weill Cornell Medical College, New York, NY

Background: Nucleotide excision repair-deficient (NER-D) cancers comprise approximately 10% of bladder urinary tract and uterine cancers. Platinum-based chemotherapy is the current standard of care for NER-D cancers; however, its nephrotoxicity limits applicability in patients with compromised renal function. No druggable targets have been identified for NER-D tumors. Genome-wide CRISPR screening offers a powerful strategy to identify synthetic lethal interactions. We performed a genome-wide screen to identify potential synthetic lethal targets in NER-deficient cells.

Methods: An RT112/84 *ERCC4* knockout (*ERCC4*$^{-/-}$) cell line was generated. ERCC4 status was examined by Sanger sequencing and Western blotting, and nucleotide excision repair activity was assessed using the Host Cell Reactivation Assay (HCRA). A genome-wide CRISPR screen was performed in RT112/84 wild-type (WT) and *ERCC4*$^{-/-}$ cells to identify candidate synthetic lethal targets. Colony formation assays validated candidate interactions, and *SLC25A28* was further tested for synthetic lethality with *ERCC2*, *ERCC3*, and *ERCC5*. RNA sequencing was conducted to investigate the mechanism underlying *SLC25A28-ERCC4* synthetic lethality.

Results: Sanger sequencing and Western blot confirmed *ERCC4* knockout in RT112/84 cells. HCRA demonstrated markedly reduced NER activity in *ERCC4*$^{-/-}$ cells. Genome-wide CRISPR screening identified *SLC25A28* as a top synthetic lethal candidate with *ERCC4*. Colony assays validated the synthetic lethality between *SLC25A28* and *ERCC2*, *ERCC3*, *ERCC4* and *ERCC5*.

Conclusions: Our findings identify *SLC25A28* as a novel synthetic lethal target in NER-deficient cancers, suggesting that inhibition of *SLC25A28* may represent a potential therapeutic strategy for tumors harboring NER pathway mutations. This study was supported by STTR 1 R41 CA275627-01, the Niehaus Center for Inherited Cancer Genomics, and the Breast Cancer Research Foundation.

#3094 Targeting TUBB2B: Exploiting brain metastatic vulnerabilities in triple-negative breast cancer.

Qingling He[1], Jianyang Hu[1], Gary M. Tse[2], Julia Y. Tsang[2], Pui-Chi Lo[1], C Geoffrey Lau[3], **Y Rebecca Chin**[4]

[1]City University of Hong Kong, City University of Hong Kong Shenzhen Futian Research Institute, Hong Kong, Hong Kong,[2]Department of Anatomical and Cellular Pathology, Prince of Wales Hospital, The Chinese University of Hong Kong, Hong Kong, Hong Kong,[3]Department of Neuroscience, City University of Hong Kong, Hong Kong, Hong Kong,[4]Dept Biomedical Sciences and Tung Bio Sci Centre, Dept Precision Diagnostic and Therapeutic Tech, City University of Hong Kong, City University of Hong Kong Shenzhen Futian Research Institute, Hong Kong, Hong Kong

Breast cancer remains a leading cause of cancer-related mortality, with brain metastasis contributing significantly to poor outcomes. Triple-negative breast cancer (TNBC) exhibits aggressive behavior, a high incidence of brain metastasis, and limited therapeutic options, underscoring the urgent need for novel strategies targeting brain metastatic vulnerabilities.

We recently established an in vivo brain metastasis model using an optimized intracarotid injection method and integrated bioinformatics to identify drivers of metastatic colonization. TUBB2B, a β-tubulin isoform involved in axon guidance during neural development, was identified as a novel TNBC gene promoting brain metastatic outgrowth (He et. al. J Exp & Clin Can Res, 2025). In line with its neural-related functions, TUBB2B overexpression in TNBC cells activates astrocytes, which in turn upregulate TUBB2B in tumor cells, suggesting a feed-forward interaction that promotes brain metastatic colonization. Here, we further evaluated the therapeutic potential of targeting TUBB2B and investigated its role in mediating TNBC-stromal cell interactions in the brain niche.

Methods: Patient-derived organoid (PDO) models were established to evaluate TUBB2B knockdown effects on tumor growth and survival. 3D co-culture models were employed to examine carcinoma-astrocyte/neuron gap junctions and dye transfer assays were used to assess intercellular communication. Preclinical studies were performed to test the effect of TUBB2B inhibition alone and in combination with the brain-penetrant Akt inhibitor (Akti) GDC-0068 (Ipatasertib), currently in Phase 3 trials.

Results: TUBB2B knockdown significantly inhibited PDO growth in two independent models and reduced dye transfer between TNBC cells and astrocytes, suggesting impaired gap junction communication. Combining TUBB2B depletion with Akti markedly reduced TNBC cell viability compared to single-agent treatment. Ongoing studies are testing the combination effects of siTUBB2B-gold nanoparticles with Akti (GDC-0068 and Capivasertib) in preclinical animal models.

Conclusions: TUBB2B plays a critical role in TNBC brain metastasis and represents a promising therapeutic target, particularly in combination with Akt pathway inhibition. These findings may inform future clinical strategies for TNBC patients with brain metastases.

#3095 Optimizing targeting molecule density on drug carriers to improve cellular uptake.

Maria Lambros, Manjot Kaur

Biotechnology and Pharmaceutical Sciences, Western University of Health Sciences, Pomona, CA

Purpose: The purpose of this work is to determine whether the number of targeting molecules on a carrier correlates with improved cell uptake. The xCT transporter is a cell-surface facilitative transporter that imports cystine into the cell and exports glutamate. Using liposomes as the carrier, we conjugated varying amounts of cystine, the targeting agent, to their surfaces to harness the xCT transporter. We evaluated the cellular uptake of liposomal formulations with different levels of the targeting molecule conjugated to the liposomal surface (A: medium, B: low, C: high) in several cell lines.
Methods: Liposomes with different levels of the targeting molecule were formulated, and sulforhodamine B (SRB), a fluorescent dye, was encapsulated in the liposomes. The formulations tested were: three targeted formulations with varying levels of the targeting molecule (A: medium, B: low, C: high), one non-targeted formulation (NT), and an untreated control. These formulations were incubated for 6 hours with five human cancer cell lines (BxPC-3, MIA PaCa-2, A549, OVCAR-8, and PANC-1). After incubation, the cell lines were washed three times, and liposome uptake was quantified by measuring the mean fluorescence intensity of SRB using flow cytometry (Attune NxT, Acoustic Focusing Cytometer, Thermo Fisher Scientific, MA).
Results: Targeted liposomes consistently demonstrated significantly higher uptake than the non-targeted formulation across all five cell lines tested. However, the correlation between targeting-molecule density and uptake was cell-line-dependent. The formulation with the highest targeting molecule density (Formulation C) showed the highest uptake in three of the five cell lines (BxPC-3, MIA PaCa-2, and A549). In contrast, varying the targeting molecule density did not result in a statistically significant difference in uptake among the targeted formulations in the OVCAR-8 and PANC-1 cell lines.
Conclusion: The data suggest that cells' ability to internalize liposomes depends on whether the liposomes carry a targeting molecule. However, the extent of internalization is cell line dependent.

#3096 The anti-cancer effects of silibinin through the modulation of JAK1/STAT3 signaling and inhibition of MMPs levels in triple-negative breast cancer cells.

Shubham D. Mishra, Patricia Mendonca, Sukhmandeep Kaur, **Karam F. a. Soliman**

Pharmaceutical Sciences, Florida A&M University College of Pharmacy & Pharmaceutical Sciences, Tallahassee, FL

Breast cancer is the second most common type of cancer in US women. The most aggressive subtype is triple-negative breast cancer, which corresponds to 10% and 20% and affects African American women disproportionally. Various natural compounds have been identified as having potential therapeutic applications in breast cancer by targeting the tumor microenvironment. Among these compounds, silibinin, a natural compound found in Silybum marianum, has been shown to exhibit anticancer properties against several cancer types. This work examined the anticancer activity of silibinin in MDA-MB-231 (Caucasian) and MDA-MB-468 (African American) TNBC cells by targeting the JAK/STAT signaling pathways and by measuring matrix metalloproteinase (MMP) levels. The approaches included cytotoxicity analyses, 2D and 3D cell culture assays, RT-PCR, Western analyses, and ELISA to evaluate MMP-2 and MMP-9 protein levels in IFN-γ- and TNF-α-stimulated TNBC cells. Silibinin (0.78-400 μM) caused a decrease in cell viability in both cells, with higher sensitivity in MDA-MB-231 cells (IC_{50} = 154.23 ± 4.15 μM) compared to MDA-MB-468 cells (IC_{50} = 175.43 ± 5.87 μM). Antiproliferative activity was observed in both cell lines, with MDA-MB-468 cells exhibiting greater sensitivity over time. Additionally, 3D cellular assays demonstrated silibinin's potency in inhibiting spheroid growth and viability, consistent with the cytotoxicity observed in 2D culture. RT-PCR results show reduced levels of JAK1 mRNA after 6, 12, or 24 hours of silibinin treatment in both cell lines. STAT3 mRNA levels were decreased only in MDA-MB-231 cells (after 6 hours), with no effect in MDA-MB-468 cells. Reduced levels of phosphorylated JAK1 and STAT3 proteins were observed in both cell types. Moreover, using ELISA assays, silibinin significantly reduced TNF-α-induced MMP-2 and MMP-9 protein levels in MDA-MB-231 and MDA-MB-468 cells. In conclusion, the data demonstrate that silibinin exerts anticancer activity against TNBC cells by inhibiting the JAK/STAT signaling pathway and reducing MMP-2 and MMP-9 levels, which play pivotal roles in tumor growth, invasion, and metastasis. Notably, this study underscores differences among distinct TNBC cellular lines with distinct genetic backgrounds, reinforcing silibinin's role as a promising adjuvant treatment for aggressive forms of human breast cancer.

#3097 Preclinical characterization of MBS309, a PD-1-targeted and α-biased IL-2, demonstrating robust anti-tumor activity and a favorable safety profile.

Jiangmei Li[1], Guangzhong Lin[1], Lunfeng Zhang[2], Shuo Huang[2], Shuang Qing[1], Feng Li[1], Mingze Sun[1], Hong Chen[1]

[1]Beijing Mabworks Biotech Co Ltd, Beijing, China,[2]Beijing Mabworks Biotech Co. Ltd, Beijing, China

The clinical impact of PD-1/PD-L1 inhibitors remains limited, as the vastmajority of cancer patients ultimately experience relapse or lack a durable response.Conversely, the therapeutic potential of IL-2, a pioneering immunotherapy cytokine,has been historically overshadowed by its severe toxicity and narrow therapeuticwindow. While past efforts to develop safer IL-2 variants with reduced Treg bias(non-α IL-2) have seen scant clinical success, they have spurred the development of anew class of PD-1/IL-2 bispecific molecules. These agents are engineered to achievecis-engagement and deliver α biased IL-2 signal specifically to PD-1-high andCD25-high CD8+ T cells within the tumor microenvironment.MBS309 was engineered to enhance the safety of IL-2 in cancers relapsed orresistant to PD-1/PD-L1 therapy. It consists of an α-biased IL-2 variant fused to theC-terminus of pembrolizumab (Keytruda). This design retains IL-2's binding toIL-2Rα while significantly reducing its interaction with IL-2Rβγ. In vitro studiesdemonstrated that MBS309 exhibits activity restricted to PD-1 targets. As amonotherapy, MBS309 elicited robust anti-tumor responses across a range ofpreclinical xenograft models, regardless of their intrinsic sensitivity to PD-1 inhibition.In mice, MBS309 showed a favorable safety profile, characterized by a longerhalf-life compared to a clinical-stage benchmark and significantly reduced systemictoxicity. At a dose of 20 mg/kg, it exhibited less toxicity. Pharmacodynamic
investigations revealed the mechanistic basis for this improved therapeutic window:MBS309 induced dampened T cell activation in normal tissues while achieving potentintra-tumoral CD8+ T cell expansion comparable to the benchmark.The compelling preclinical profile of MBS309, characterized by robustanti-tumor efficacy and a favorable safety window, warrants its further clinicalinvestigation as a promising therapeutic candidate for oncology.Disclosures: All the authors are employees from Beijing Mabworks Biotech Co. Ltd

#3098 Discovery of the RAD51 inhibitor JKYN-1 and characterization of its anticancer activity in preclinical models of non-small cell lung cancer.

Yifan Yu[1], Morgan Black[2], Nikolina Radulovich[1], Peter Ferguson[2], James Koropatnick[3], Ming Sound Tsao[1], Mark D. Vincent[3], Geoffrey Liu[1], Samir H. Barghout[1]

[1]Princess Margaret Cancer Center, Toronto, ON, Canada,[2]London Health Sciences Center, London, ON, Canada,[3]Western University, London, ON, Canada

BACKGROUND: RAD51 is a recombinase that plays a central role in homologous recombination-mediated double-strand DNA break repair and is required for the maintenance of genome stability. In addition to this canonical function, RAD51 contributes to the tolerance of replication stress, a phenotype frequently observed in tumor cells, thereby establishing RAD51 as a potential pharmacologic target in multiple malignancies including non-small cell lung cancer (NSCLC). The development of direct small-molecule RAD51 inhibitors has been limited by suboptimal potency and solubility. Here, we report the discovery of JKYN-1, an optimized RAD51 inhibitor, and the characterization of its single-agent and combinatorial antitumor activity in preclinical models of NSCLC.
METHODS: Using molecular docking, JKYN-1 was discovered through virtual chemical modifications of the previously reported RAD51 inhibitor IBR120. Target engagement in cells was evaluated by the cellular thermal shift assay (CETSA) and immunoblotting. CellTiter-Glo assay was used to measure cytotoxicity in cell lines and patient-derived organoids (PDOs) of NSCLC after 6-day treatment.
RESULTS: JKYN-1 (patent application # CA3204011A1) is a derivative of IBR120, with improved solubility and potency. As assessed by CETSA, JKYN-1 bound to and destabilized RAD51 in H1975. Using immunoblotting, we demonstrated downregulation of RAD51 in response to JKYN-1 treatment in a concentration-dependent manner. Compared to the classical RAD51 inhibitor B02, JKYN-1 demonstrated higher cytotoxicity in A549 and H1975 cell lines with over 50% reduction in the IC_{50} values (H1975, 3.2 vs 8.3 μM; A549, 4.9 vs >10 μM). In a panel of 8 *EGFR*-mutated NSCLC PDOs, JKYN-1 and its more soluble mesylate salt displayed sub-micromolar IC_{50} values (0.1-0.88 μM) as opposed to B02 (2.4 to >10 μM). We subsequently evaluated the synergistic potential of JKYN-1 in combination with the EGFR inhibitor osimertinib in osimertinib-resistant models. Combination with JKYN-1 resulted in > 4-fold reduction in the IC_{50} of osimertinib in the laboratory-evolved osimertinib-resistant H1975 cells, and > 2-fold reduction in the LPTO357 PDO. Mechanistically, both JKYN-1 and osimertinib induced downregulation of RAD51 in cell lines and PDOs in a concentration-dependent manner as assessed by immunoblotting, explaining in part the synergistic combinatorial activity.
CONCLUSIONS: Our data identify JKYN-1 and its mesylate salt as promising RAD51 inhibitors with superior anticancer activity compared to existing inhibitors in preclinical models of NSCLC. Moreover, JKYN-1 can potentially overcome resistance to osimertinib in a subset of NSCLC models.

#3099 Selective CDK2 inhibition with ECI830: preclinical characterization, efficacy, and on-target mechanism supported by biomarker and gene signature analysis.

Ophelia Maertens[1], Bradley French[1], Eric Fang[2], Imad Hanna[3], Ying Huang[1], Sajan Joseph[1], Fallon Lin[1], Neil Umbreit[1], Anna Uvarova[1], Vivek Rauniyar[1], Samuel Ho[1]

Dysregulation of the cell cycle pathway is a hallmark of many human cancers, enabling uncontrolled cell growth. Cyclin-dependent kinases, exemplified by CDK2, CDK4, and CDK6, play crucial roles in regulating cell cycle progression. While CDK4/6 inhibitors such as ribociclib have transformed the treatment landscape for HR+/HER2− breast cancer, selectively targeting CDK2 has remained challenging due to the high degree of structural similarity to other essential CDK family members, such as CDK1. Genetic and pharmacological studies have shown that CCNE1-amplified cancer models have a dependency on CDK2 and that combined inhibition of CDK2 and CDK4 enhances tumor suppression in HR+/HER2− breast cancer models. Here, we describe the preclinical activity of ECI830, an orally bioavailable and potent adenosine triphosphate-competitive CDK2 inhibitor with high selectivity over other CDK family members. ECI830 demonstrated substantial antiproliferative activity in CCNE1-amplified ovarian (OVCAR3) and lung (H810) cancer cell lines. In an HR+/HER2− breast cancer cell line (MCF7) and several patient-derived xenograft models resistant to standard-of-care treatment, the combination of ECI830 and ribociclib resulted in synergistic activity with deeper pathway suppression, enhanced biomarker modulation, and stronger tumor growth inhibition compared with either agent alone. Mechanistic studies demonstrated that the activity of ECI830, alone or in combination with ribociclib, was on-target. Moreover, ECI830 showed a favorable pharmacokinetics and tolerability profile in preclinical mouse models. Taken together, these promising preclinical data support ECI830 as a selective and potent CDK2 inhibitor for the treatment of HR+/HER2- breast cancer and other CCNE1-dysregulated advanced solid tumors, which is currently being investigated in clinical trials.

: Overcoming Chemotherapy Resistance
Poster Session

#3101 Identification and characterization of novel peptide binders against platinum resistant epithelial ovarian cancer.

Pritha Ray[1], Sreyashi Nath[1], Pranita Uttamrao Patil[2], Parijat Das[2], Prasenjit Bhaumik[2]

[1]Imaging Cell Signalling and Therapeutics Lab, ACTREC, Tata Memorial Centre, Navi Mumbai, India,[2]BioScience and Bioengineering, IIT Bombay, Mumbai, India

Background: Acquirement of Platinum-resistance leads to recurrence and poor survival outcomes in epithelial ovarian cancer (EOC) patients with inadequate second-line treatment options. Moreover, the current therapeutic strategies lack the precision to target the chemoresistant cells *in vivo* limiting treatment efficacy. Identification and validation of unique targeting moieties are critical to develop effective therapeutic strategies for this dreadful disease.
Methods: Phage Display peptide library screening, ELISA and FACS were used to identify novel peptide binders using platinum resistant EOC cells (both intrinsic and acquired). MTT, cell cycle analysis, confocal microscopy, scratch assay and adhesion assays used to delineate the peptide properties. Clinical relevance was determined using primary tumor cells derived from high grade serous ovarian cancer (HGSOC) patients and subsequent PDX models. In-silico analysis and molecular docking were employed to identify the putative receptor/s.
Results: Two novel heptapeptides (A and B) exhibiting higher binding capabilities to platinum-resistant cells were identified by phage peptide display screening and further validated using multiple EOC cell lines, primary cells isolated from malignant ascites of high-grade serous ovarian cancer patients, and patient-derived xenograft (PDX) models. Peptide A showed ~2-fold increased binding in intrinsically cisplatin-resistant cells (TOV112D, OVCAR3) while peptide B demonstrated ~3 fold higher binding to $A2780^{Ptres}$ cells compared to platinum-sensitive A2780 cells. Peptide A showed a 5-fold increased binding in chemoresistant patient-derived cells and a 3-fold higher binding towards chemoresistant PDX models compared to chemonaïve counterparts, suggesting the presence of unique surface receptor(s) enriched in resistant populations. Peptide A did not induce toxicity, cell cycle alteration or proliferation but reduced adhesion and invasion of the resistant cells. Intraperitoneal injection of peptide A led to reduced secondary metastasis in platinum-resistant PDX mice. In silico docking identified GPCR proteins, particularly Endothelin Type A/B receptors (ETAR/ETBR), as putative receptors for peptide A. Functional characterization and receptor identification for peptide B are in progress.
Conclusions: With higher affinity towards platinum-resistant cells and ability to impede adhesion, these novel peptide/s have promising potential to be developed as scaffolds for imaging or as therapeutic conjugates for the targeted treatment of platinum-resistant ovarian cancer cells.

#3102 YB-1 small-molecule inhibitor improves chemotherapy success in treating high-grade serous ovarian carcinoma.

Dhanir Tailor[1], Fernando J. Garcia-Marques[2], Abel Bermudez[2], Wenqi Li[3], Annah Rolig[4], Chia-Feng Tsai[5], Tao Liu[5], Tanja Pejovic[6], Sharon Pitteri[7], Sanjay V. Malhotra[1]

[1]Knight Cancer Institute, Oregon Health & Science University, Portland, OR,[2]Stanford University, Stanford, CA,[3]Oregon Health & Science University, Portland, OR,[4]OHSU Knight Cancer Institute, Portland, OR,[5]Pacific Northwest National Laboratory, Richland, WA,[6]Providence OB/GYN Health Center, Medford, OR,[7]Stanford University, Palo Alto, CA

Ovarian cancer is the most lethal gynecological malignancy. The primary treatment regimen—surgery followed by platinum- or taxane-based chemotherapy—offers limited long-term success, as 85-90% of women diagnosed with late-stage disease will recur post adjuvant combination chemotherapy, an unfortunate outcome largely driven by treatment resistance. Thus, once ovarian cancer recurs, available treatments are palliative only. Clinically, the lack of treatment options for these patients is a critical unmet need, which we propose can be addressed with a novel therapeutic approach that directly addresses treatment resistance—therapeutic inhibition of Y-Box Binding Protein 1 (YB-1), a stress-responsive, multifunctional protein. To test this hypothesis, we collected tumor samples and nearby normal tissues from patients whose high grade serous ovarian cancer (HGSOC) relapsed after four to six treatments. These samples underwent proteomic analysis and were used to develop HGSOC treatment-resistant patient-derived xenograft (PDX) models. Using proteomics to profile these samples revealed that, in comparison to nearby normal tissue, malignant tissues significantly overexpressed YB-1 along with the related mRNA-processing pathways. Similar proteomic profiling of mouse HGSC cells exposed to SU056 confirmed that inhibiting YB-1 activated mRNA processing pathways, consistent with the findings from patient tissues. We subsequently employed mouse studies using PDX models from the HGSOC patient samples to determine whether inhibiting YB-1 with the small molecule SU056 significantly delayed tumor progression. These studies demonstrated that HGSOC tumors are susceptible to YB-1 inhibition. To test whether YB-1 inhibition additionally sensitizes tumors to chemotherapy, we combined SU056 with cisplatin and paclitaxel in the HGSC syngeneic mouse model (HGS1) and the treatment-resistant PDX model, finding that SU056 enhanced chemotherapeutic efficacy and extended overall survival. Proteomic analysis performed on mouse cell lines and tumors from syngeneic and PDX studies indicated that SU056 treatment significantly suppresses YB-1 and mRNA processing pathways in both *in vitro* and *in vivo* settings. Overall, these studies indicate that combining a YB-1 inhibitor with chemotherapy could overcome treatment resistance to improve responses in HGSC patients.

#3103 Spatial proteomics reveals vasculature and immune modulation for overcoming doxorubicin resistance in breast cancer.

Gautami Gaidhani, Juraj Jakubik, Leoni Moldaner, Yishu Xu, Zuzana Tatarova

German Cancer Consortium (DKTK), Heidelberg, Germany

Therapeutic resistance hinders the efficacy of single-agent cancer treatments, often mediated by the tumor microenvironment. Significant endothelial cell enrichment following local doxorubicin treatment has been proposed as a resistance mechanism in breast cancer. Here, we apply the tumor vasculature normalization principle using an anti-angiogenic drug combination delivered locally using the high-throughput multiplex implantable microdevice assay in mouse models of breast cancer. Spatial single-cell proteomic profiling paired with unsupervised learning methods confirmed doxorubicin-mediated pro-angiogenic changes, including pericyte detachment and sprouting angiogenesis. A combination with cabozantinib depleted endothelial cells and increased tumor antigenicity by inducing immunogenic cell death with recruitment of leukocytes including neutrophils, and T cells. Leveraging this immune modulatory activity, we tested a systemic triple combination with anti-PD1 immunotherapy, which led to a significant and complete tumor regression. Our study demonstrates a rational drug combination that improves doxorubicin efficacy to overcome microenvironment-driven resistance for long-term breast cancer control.

#3104 Characterization of high plasticity cell states in cutaneous squamous cell carcinoma in response to chemotherapy and immune checkpoint inhibitor treatments.

Ramin Farhad[1], Di Wu[1], Mark A. Taylor[1], Allan Balmain[2], Rosemary J. Akhurst[3]

[1]Helen Diller Family Comprehensive Cancer Center, University of California, San Francisco, San Francisco, CA,[2]Department of Biochemistry and Biophysics, University of California, San Francisco, San Francisco, CA,[3]Department of Anatomy, University of California, San Francisco, San Francisco, CA

Therapeutic resistance and cancer recurrence in cutaneous squamous cell carcinoma (cSCC) are strongly driven by genetic heterogeneity and phenotypic plasticity. Tumor cells that enter high-plasticity, low-proliferative states often evade cytotoxic therapies, including mitotic-targeting chemotherapeutics, yet the molecular mechanisms enabling these transitions and maintaining these states under therapeutic pressure remain poorly defined. Here, we seek to identify, characterize, and ultimately destabilize these therapy-refractory cell states across multiple treatment modalities.

We developed a chemically induced cSCC model in FVB mice using a single initiating dose of DMBA followed by 20 weeks of biweekly TPA promotion. Once tumors reached approximately one cubic centimeter, cohorts were assigned to distinct therapeutic regimens, including anti-PD1 immune checkpoint blockade, cisplatin, paclitaxel, and combination strategies incorporating the Pp2a inhibitor LB100 to test whether pharmacologic perturbation can drive mitotically silent tumor cells back into a proliferative, therapy-responsive state.

Normal skin, papillomas, lymph nodes, and carcinomas were collected and approximately 900,000 cells were profiled using the 10x Genomics single-cell RNA-sequencing platform to map the full spectrum of malignant, stromal, and immune programs across various treatment groups. Ongoing analysis aims to resolve transcriptional signatures associated with high-plasticity states, identify treatment-induced and treatment-specific state transitions, and define potential therapy-evading intermediates that arise under drug pressure. A major focus is the discovery of metagene signatures that correlate with high-plasticity phenotypes and the evaluation of whether these molecular programs can be modulated or therapeutically targeted to re-sensitize tumors to conventional or immune-based therapies. In parallel, we are also examining how immune cell abundance, activation states, and lineage-specific gene expression profiles shift across treatment arms, particularly in response to anti-PD1 therapy, to uncover how the tumor immune microenvironment contributes to or counteracts the emergence of resistant high-plasticity cell states.

This work seeks to establish a unified mechanistic framework describing how plasticity-driven resistance emerges in cSCC and to identify points of therapeutic vulnerability that may improve responses to chemotherapy and immunotherapy both within and beyond this disease context.

#3105 MalforminA1 reverts cisplatin resistance by modulating oncogenic signaling pathways in ovarian cancer.

Yahya Tamimi[1], Aikou Okamoto[2], Ikram Burney[3]

[1]Biochemistry, SQU, Muscat, Oman,[2]Associate Professor, Dept. of Ob/Gyn, Jikei Univ. School of Medicine, Tokyo, Japan,[3]Sultan Qaboos Comprehensive Cancer Care and Research Centre (SQCCCRC), Muscat, Oman

Ovarian cancer is a highly lethal gynecological malignancy, largely due to its late-stage diagnosis, frequent recurrence, and the development of chemoresistance. Standard treatment typically involves surgical debulking followed by chemotherapy, most commonly with platinum-based agents such as cisplatin. Unfortunately, many patients eventually develop resistance to these therapies, reducing treatment effectiveness and contributing to poor overall survival. These clinical challenges underscore the urgent need for novel therapeutic strategies that can overcome or prevent chemoresistance. Marine-derived compounds have recently emerged as a valuable source of potential anticancer agents, with several demonstrating potent biological activity. In our previous work, we identified multiple marine-derived molecules with promising anti-cancer properties, including Malformin A1 (MA1). MA1, a cyclic pentapeptide isolated from the marine fungus *Aspergillus niger*, exhibits cytotoxic activity against both cisplatin-sensitive (A2780S) and cisplatin-resistant (A2780CP) ovarian cancer cell lines. Building on these findings, the present study sought to elucidate the molecular pathways through which MA1 may reverse cisplatin resistance in ovarian cancer. In this study, we assessed the molecular pathways through which MA1 modulates cisplatin resistance in A2780CP cells, using the cisplatin-sensitive A2780S cell line as a reference. The expression of key cancer-related proteins, including ERK1/2 and NF-κβ, was analyzed by Western blot to evaluate the modulatory effects of MA1 on these signaling pathways. MA1 treatment resulted in a significant reduction of total MEK1/2, ERK1/2, and NF-κβ protein levels in A2780S cells, whereas in A2780CP cells, only NF-κβ expression was increased. Furthermore, phosphorylated ERK1/2 and NF-κβ levels were elevated, particularly in A2780CP cells, indicating activation of ERK1/2 and NF-κβ pathways, which play central roles in regulating cell survival and apoptosis. The cytotoxic effects of MA1 were more pronounced in cisplatin-resistant A2780CP cells, supporting the compound’s potential role in reversing cisplatin resistance. Activation of these signaling pathways following MA1 treatment may resensitize resistant cells to apoptosis or other cytotoxic mechanisms, thereby contributing to the overcoming of chemoresistance.In conclusion, our findings demonstrate that MA1 can reverse cisplatin resistance through the modulation of key oncogenic signaling pathways, highlighting its promise as a therapeutic candidate to improve treatment outcomes in ovarian cancer.

#3106 OC201 and OC202e, an AI-driven drug combination, enhance the susceptibility of pancreatic cancer to FOLFIRINOX by modulating HIF-1α.

Yongjin Kim, Sewon Kim, Dong Sub Jung, So Jung Sung, Yenny Kim, Ki Sung Song, Hyemin Won, Yi Rang Kim, **Jihoon Kang**

Oncocross Co., Ltd, Seoul, Korea, Republic of

Objective: Pancreatic cancer remains highly lethal, with a five-year survival rate of ~13%, largely due to late-stage diagnosis, aggressive progression, and resistance to standard therapies. Although FOLFIRINOX is the current first-line regimen, therapeutic resistance limits its durability. Our previous work showed that the AI-derived combination OC201 and OC202e suppresses EMT and metastasis. This study investigated whether OC201/OC202e enhances the response to FOLFIRINOX by modulating multidrug-resistance mechanisms.
Methods: Panc-1 and MIA PaCa-2 cells were treated with OC201 and/or OC202e followed by FOLFIRINOX. Cell viability and clonogenic potential were assessed using MTT and colony-formation assays. Multidrug-resistance determinants—including hypoxia, extracellular matrix factors, dysregulated signaling, genetic alterations, stemness, and ABC transporters were analyzed by Western blotting and RT-qPCR. Stemness was further evaluated using sphere-formation assays. An in vivo hepatic metastasis model was established via intrasplenic injection of Panc-1 cells, followed by 10 weeks of treatment with OC201, OC202e, and/or FOLFIRINOX beginning two weeks post-injection. Metastatic burden was quantified histologically.
Results: OC201/OC202e significantly enhanced FOLFIRINOX efficacy, as shown by reduced colony formation in both cell lines, while MTT assays indicated limited short-term synergy, suggesting a primarily long-term effect. In vivo, the combination further reduced hepatic metastatic lesions compared with FOLFIRINOX alone. Mechanistic analyses revealed decreased HIF-1α and stemness markers (CD44, Flotillin2) following combination treatment. HIF-1α expression correlated with stemness and FOLFIRINOX responsiveness, supporting its role in resistance. These findings align with the known EMT-stemness link and provide mechanistic insight into the observed synergy.
Conclusion: The AI-derived OC201/OC202e combination enhances sensitivity to FOLFIRINOX and suppresses metastasis by targeting HIF-1α and the EMT-stemness axis. Reductions in clonogenicity and resistance-related markers highlight its potential as an adjuvant to standard chemotherapy and underscore the promise of AI-guided strategies for developing synergistic therapeutic combinations.

#3107 CWH43 emerges as a novel therapeutic target linked to chemoresistance in colorectal cancer.

Yu-Jia Chang[1], Chien-Yu Huang[2], Po-Li Wei[3], Cheng-Chin Lee[4]

[1]Graduate Institute of Clinical Medicine, Taipei Medical University, Taipei, Taiwan,[2]School of Medicine, National Tsing Hua University, Hsinchu, Taiwan,[3]Department of Surgery, School of Medicine, College of Medicine, Taipei Medical University,, Taipei, Taiwan,[4]Graduate Institute of Clinical Medicine, College of Medicine, Taipei Medical University, Taipei, Taiwan

Background: Chemoresistance remains a key barrier to effective colorectal cancer (CRC) treatment. CWH43, a regulator of membrane-associated protein processing, has been implicated in CRC progression, but its relevance to therapy response and ferroptosis-related vulnerability is unclear.
Methods: Public CRC datasets were analyzed to examine associations between CWH43 expression, treatment response patterns, and patient outcomes. CRC cell models with altered CWH43 expression were used to assess responses to chemotherapeutic agents and oxidative-stress-related phenotypes. Enrichment analyses were performed to explore biological processes linked to CWH43 dysregulation.
Results: High CWH43 expression correlated with reduced sensitivity to standard chemotherapy and poorer outcomes in advanced CRC. In vitro, CWH43 overexpression promoted a resistant phenotype accompanied by changes in oxidative-stress handling and ferroptosis-associated features. Reducing CWH43 expression increased susceptibility to chemotherapeutic challenge.
Conclusions: CWH43 may serve as a previously unrecognized contributor to chemoresistance in CRC, potentially through modulation of redox and ferroptosis-related processes. These findings support CWH43 as a candidate biomarker of therapeutic response and a target for future mechanistic investigation.

#3108 LEDGF/p75 drives chemoresistance in CML via JAK/STAT pathway modulation.

Thatcher Akele[1], Cecilia Iglesias-Herrero[2], Frauke Christ[1], Zeger Debyser[1]

[1]Catholic Univ. of Leuven Faculty of Medicine, Leuven, Belgium,[2]Laboratory for Molecular Virology and Gene Therapy, Department of Pharmaceutical and Pharmacological, KU Leuven, Leuven, Belgium

Lens Epithelium Derived Growth Factor/p75 (LEDGF/p75,PSIP1) is a H3K36me2/3 reader implicated in several malignancies. Within the MLL/KMT2A fusion complex, it tethers the fusion protein to chromatin. KMT2A rearrangement (KMT2A-r) occurs in ~10% of acute leukemia patients and is associated with poor prognosis due to relapse and chemoresistance. Our lab has shown that LEDGF/p75 is essential for KMT2A-r leukemogenesis but dispensable for hematopoiesis. High LEDGF/p75 levels have been linked to drug resistance in AML blasts, prostate and breast cancer. As a dependency factor in KMT2A-r leukemia, LEDGF/p75 is an attractive therapeutic target and a potential component of combinatorial strategies for LEDGF/p75 driven chemoresistance cancers. However, the leukemic subtypes dependent on LEDGF/p75 remains unclear. We previously showed that LEDGF/p75 depletion sensitizes KMT2A-r AML cells to cytarabine via the sphingosine-1 pathway. Here, we aimed to assess the role of LEDGF/p75 in therapy resistance across multiple leukemia models. Stable LEDGF/p75 knockdown (LEDGF/p75 KD) cell lines were generated using miRNA-expressing vectors, and more than ten leukemia cell lines were screened for LEDGF/p75 dependent chemoresistance. In KMT2A-wild-type (WT) AML cell lines U-937 and Kasumi-1, LEDGF/p75 depletion did not alter cytarabine sensitivity and the same trend was observed in WT T-ALL cell lines Jurkat and SupT-1. However, in the KMT2A-r T-ALL cell line, Karpas-45, LEDGF/p75 KD significantly sensitized the cells to cytarabine (IC_{50} Karpas Mock/KD: 76.32 ± 8.32 µM / 53.75 ± 12.46 µM). Unexpectedly, LEDGF/p75 KD in SEM cells (B-ALL, KMT2A-AF4) increased proliferation and reduced apoptosis upon cytarabine treatment (IC_{50} SEM Mock/KD: 0.12 ± 0.02 µM / 0.53 ± 0.06 µM). The latter was accompanied by a lower level of caspase3. Interestingly, LEDGF/p75 KD in two WT KMT2A CML cell lines, K-562 and JUR-MK1, led to a significant reduction in proliferation upon vincristine treatment (IC_{50} K-562 Mock/KD: 2.61 ± 0.10 nM / 0.81 ± 0.09 nM and IC_{50} JUR-MK1 Mock/KD: 3.93 ± 0.35 nM / 2.37 ± 0.30 nM) and increased apoptosis with elevated caspase3. Treatment of K-562 cells with BCR-ABL inhibitors Imatinib and Ponatinib also showed decreased proliferation upon LEDGF/p75 depletion. RNA-seq analysis of LEDGF/p75 KD K-562 and JUR-MK1 cells showed that LEDGF/p75 loss affects pathways associated with hematopoietic cell differentiation and immune response regulation. Anti apoptotic genes such as BCL-XL and BCL2A1 were downregulated, along with STAT5 and STAT2, key players in the JAK/STAT pathway. Western blotting confirmed reduced total and activated STAT5 in LEDGF/p75 depleted CML cells. Taken together, our result indicates that the role of LEDGF/p75 in therapy resistance is context dependent and varies across leukemic subtypes. We identify a previously unknown function of LEDGF/p75 in mediating drug resistance in CML cells acting through the JAK/STAT Pathway.

#3109 Extracellular matrix glycan signatures predict chemotherapy response in ovarian cancer.

Erica J. Peterson[1], Ryan J. Weiss[2], James D. Hampton[1], Ava R. S. Beaudin[1], Thomas M. Clausen[3], Joseph B. M. Turner[1], Amrita Basu[2], Bin Hu[1], Jennifer E. Koblenski[1], Nicholas P. Farrell[1], Larisa Litovchick[1]

[1]Virginia Commonwealth University, Richmond, VA,[2]University of Georgia, Athens, GA,[3]University of Hawaii, Honolulu, HI

Background: Ovarian cancer (OC) is a highly lethal gynecologic malignancy, most often diagnosed at advanced stages and prone to recurrence after platinum-based chemotherapy. Nearly 30% of patients exhibit platinum-resistant or refractory disease, with aggressive tumors recurring within six months. Emerging evidence implicates glycosaminoglycans (GAGs) as regulators of tumor progression and treatment response, yet their structural complexity limits accurate assessment by transcriptomic or proteomic methods alone.
Methods: To define how GAGs influence OC biology and platinum sensitivity, we analyzed single-cell RNA sequencing and spatial transcriptomic datasets from normal ovary, primary ovarian/fallopian tube tumors, and metastatic abdominal and colonic lesions. CRISPR/Cas9 XYLT1/2 knockout was used to deplete GAGs in ovarian cancer cells, which were evaluated for morphology, proliferation, migration/invasion, and in vivo tumor behavior. To directly quantify tumor GAG composition, glycan reductive isotope labeling mass spectrometry was performed on OC patient-derived xenografts (with known carboplatin response profiles. Complementary pharmacology studies evaluated efficacy and drug distribution of carboplatin and Triplatin, a GAG-targeting platinum agent.
Results: Single-cell analysis revealed that fibroblasts are the predominant source of proteoglycan gene expression within the tumor microenvironment. Spatial transcriptomics analysis of precursor and invasive lesions showed these changes occur in the later stages of ovarian cancer development. XYLT1/2 knockout cells showed a shift from mesenchymal to epithelial morphology, decreased migration/invasion potential, reduced tumor dissemination and absence of ascites, and increased sensitivity to carboplatin associated with higher drug penetration into the tumor. GRIL-MS profiling of four OC PDX models identified chondroitin-4-sulfate (C4S) as the dominant tumor-associated GAG motif, with high C4S strongly correlating with carboplatin resistance. Importantly, elevated C4S reduced carboplatin efficacy but enhanced Triplatin uptake and antitumor activity. A C4S expression threshold stratified tumors by predicted response, and analysis of patient tissue microarrays showed that 40-83% of OC tumors exceed this cut-off depending on subtype.
Conclusions: GAGs play a central role in ovarian cancer progression, dissemination, and platinum resistance. C4S is a mechanistically grounded biomarker capable of predicting differential sensitivity to carboplatin and Triplatin, supporting its integration into precision-medicine strategies and the clinical evaluation of Triplatin for patients with C4S-high, platinum-resistant ovarian cancer.

#3110 Targeting LIF/LIFR signaling with EC359 overcomes chemoresistance and enhances chemotherapy efficacy in ovarian cancer.

Sonal R. Chaudhari[1], Baskaran Subramani[2], Gaurav Sharma[3], William Cole Arnold[1], Durga Meenakshi Panneerdoss[1], Edward R. Kost[1], Bindhu Santhamma[4], Hareesh B. Nair[4], Suryavathi Viswanadhapalli[2], Ratna K. Vadlamudi[1]

[1]ObGyn, UTHSA, San Antonio, TX,[2]UTHSA, San Antonio, TX,[3]ObGyn, UT Health Science Center at San Antonio, San Antonio, TX,[4]Evestra, San Antonio, TX

Background: Ovarian cancer (OCa) is the deadliest gynecologic malignancy, with nearly 90% of patients experiencing disease recurrence following standard treatments. Leukemia inhibitory factor (LIF) and its receptor (LIFR) are implicated in OCa progression, chemoresistance, and recurrence. The TCGA data indicated a negative correlation between the expression of LIFR and LIF and the survival of OCa. Elevated expressions of LIF and LIFR in recurrent OCa underscores the need for innovative therapeutic strategies targeting this pathway. In this study, we tested the hypothesis that the progression of OCa to therapy resistance is dependent on LIF/LIFR signaling and that the standard of care interventions will be enhanced by the disruption of LIF/LIFR signaling with the small molecule inhibitor EC359.

Methods: The effectiveness of the LIFR inhibitor EC359, in combination with paclitaxel and/or carboplatin, was evaluated in both established and chemotherapy-resistant OCa cell lines, as well as in patient-derived xenograft (PDX) models. Paclitaxel-resistant cell lines were developed and characterized through RNA sequencing. To assess therapeutic impact, cell viability, colony formation, and apoptosis were measured using MTT assays, colony formation assays, and apoptosis assays, respectively. Mechanistic insights into the combination therapy were obtained via Western blot analysis to identify modulated signaling pathways. Additionally, 3D organoids derived from xenografts were employed to examine the *ex vivo* effects of EC359 combined with chemotherapy. The efficacy of the combination treatment was further validated *in vivo* using both CDX and PDX models.

Results: Utilizing long term culture of OCa cells with increasing concentrations of chemotherapy, we have successfully established several chemotherapy-resistant OCa model cell lines. EC359 significantly enhanced the anti-tumor efficacy of chemotherapy in reducing cell viability and suppressing colony formation in clonogenicity assays. Further, EC359 treatment enhanced apoptosis in OCa cells by promoting ferroptosis pathway. Remarkably, the combination therapy demonstrated increased effectiveness of chemotherapy in paclitaxel-resistant and carboplatin-resistant OCa cells, underscoring its potential to overcome chemotherapy resistance. The results from the CDX model demonstrated the effectiveness of EC359 as a monotherapy for resistant OCa. Further, the results from PDX model studies demonstrated the efficacy of EC359 in conjunction with carboplatin and as a maintenance therapy for OCa. These findings suggest EC359 as a potent combination agent with chemotherapy for improved therapeutic outcomes in OCa.

Conclusions: These findings provide compelling preclinical evidence that LIFR inhibition with EC359 is a promising strategy to enhance chemotherapy efficacy in OCa. Supported by NIH R01 CA266970.

#3111 Pancreatic cancer cells elevate NAD+production in response to nutrient limitation and chemotherapeutic stress.

Faith Nakazzi[1], Mehrdad Zarei[2], Mariana Lopes[3], Hallie J. Graor[2], William C. Beegan[1], Eric Gu[1], Sakineh Rezaei[1], Peder J. Lund[3], Jordan M. Winter[4]

[1]Biochemistry, Case Western Reserve University, Cleveland, OH,[2]Surgery, Case Western Reserve University, Cleveland, OH,[3]Nutrition, Case Western Reserve University, Cleveland, OH,[4]UH Cleveland Medical Center, Cleveland, OH

Introduction: Pancreatic cancer (PC) cells are consistently in a state of aneuploidy, nutrient deficiency, and hypoxia-induced stress, which may necessitate increased NAD^+ levels to maintain critical survival functions such as antioxidant defense, mitochondrial activity, and DNA repair. Therefore, we hypothesized that PC cells adapt to chemotherapy and nutrient deprivation in their microenvironment by elevating NAD+ levels.

Methods: We used liquid chromatography-mass spectrometry (LC-MS) to measure NAD^+ and its precursors in cancer versus non-cancer cells under stress (nutrient deprivation and chemotherapy). Western blot and qPCR were used to assess enzyme expression in NAD+ synthesis pathways following chemotherapy. Athymic nude mice and C57BL/6 mice were injected with MIA PaCa-2, respectively. Once palpable tumors formed, the mice received treatments with either vehicle or oxaliplatin (5 mg/kg, administered twice weekly) for 21 days, and tumors were collected and tested for NAD+ and its precursors.

Results: Baseline intracellular NAD^+ and NAM levels were higher in PC cells (PANC-1, MIA PaCa-2, and BxPC-3) compared to non-cancer cells (HPDE and HPNE) and stayed elevated after 72 hours of treatment with complete media. During increased cellular stress, such as glucose limitation, NAD^+ and NAM levels rose more significantly in MIA PaCa-2 cells than in HPNE cells, demonstrating pancreatic cancer cells' ability to adapt to the increased NAD^+ demand required to counteract oxidative and energy stress caused by glucose withdrawal. Intracellular NAD^+ levels consistently remained higher in PANC-1 and MIA PaCa-2 cells than in HPNE cells during four days of growth. Interestingly, NAM concentrations in the media declined by ~ 40% over 72 hours across all cell lines, regardless of glucose level, indicating strong utilization of external NAD+ precursors. Both Oxaliplatin and 5-fluorouracil (5FU) significantly increased NAD^+ and NAM levels in MIA PaCa-2 and PANC-1 cells, supporting the model that NAD^+ is necessary for fueling survival mechanisms under stress. Oxaliplatin treatment increased mRNA levels of NMNAT1 and protein levels of NAPRT, NRK, and NMNAT1, the main enzymes in the Preiss-Handler and NAD^+ salvage pathways. Although chemotherapy did not change intracellular NAMPT (iNAMPT) mRNA levels, it increased iNAMPT protein levels, whereas extracellular NAMPT (eNAMPT) protein levels remained unchanged. Chemotherapy also increased NAD+ levels in both MIA PaCa-2 and KPC mouse xenograft models in vivo.

Conclusion: These findings suggest that PC cells actively prioritize NAD^+ synthesis as an adaptive mechanism to survive the harsh microenvironment and develop chemoresistance. Therefore, targeting NAD+ synthesis pathways offers a therapeutic vulnerability to enhance chemotherapy susceptibility in pancreatic cancer.

#3112 Targeting chemoresistance in ovarian cancer.

Dhanamjai Penta[1], Vishal Chandra[1], Lauren Dockery[2], Rajani Rai[1]

[1]OUHSC, Oklahoma, OK,[2]Obstetrics and Gynecology, OU Health Stephenson Cancer Center Gynecologic Cancer Clinic, Oklahoma, OK

Introduction: Ovarian cancer (OvCa) is a highly aggressive malignancy characterized by frequent relapse and metastasis, both of which contribute to its high mortality rate. Although most patients initially respond to platinum-based chemotherapy, up to 80% eventually develop resistance, rendering OvCa largely incurable. Therefore, there is an urgent need to identify new therapeutic targets and develop strategies to overcome chemoresistance. This study identifies integrin β4 (ITGB4) as a key molecular driver associated with cisplatin resistance and explores its potential as a therapeutic target in ovarian cancer.
Methods: Transcriptomic profiling of cisplatin-sensitive (WT) and cisplatin-resistant (CPR) OVCAR8 OvCa spheroids was performed using RNA sequencing to identify differentially expressed genes associated with chemoresistance. Selected candidates were validated by qRT-PCR, and western blotting. The clinical significance of ITGB4 was assessed using publicly available datasets (GSE133859, TCGA-OV) and immunofluorescence analysis of tissue microarray from primary and recurrent OvCa patient samples. Functional roles of ITGB4 were examined using genetic manipulations (overexpression and CRISPR-mediated knockout) followed by migration, invasion, and cisplatin sensitivity assays. Co-immunoprecipitation (Co-IP) was performed to examine the interaction between ITGB4 and TGFβ receptor 2 (TGFβR2).
Results: Transcriptomic profiling revealed ITGB4 overexpression and SERPINB2 downregulation in CPR spheroids, findings that were consistent with GEO, TCGA-OV datasets as well as TMA analysis of patient samples. High ITGB4 expression in platinum-resistant OvCa patients was significantly associated with worse overall and progression-free survival. Functionally, ITGB4 overexpression enhanced cell invasion, migration, and cisplatin resistance, while ITGB4 knockout resensitized resistant cells to cisplatin and suppressed their invasive phenotype. Mechanistically, ITGB4 activated FAK and TGFβ/SMAD signaling pathways, both of which are known mediators of EMT and chemoresistance. CO-IP assays demonstrated a direct interaction between ITGB4 and TGFβR, supporting a cooperative role in promoting SMAD3 activation.
Conclusion: This study identifies ITGB4 as a central regulator of cisplatin resistance and aggressiveness in ovarian cancer and highlights ITGB4 as a promising therapeutic target to overcome chemoresistance and improve treatment outcomes in OvCa patients.
Acknowledgment of Funding: The work is supported by COBRE P20GM135009, SCC CT Pilot Grant, PHF-Seed and PHF CTGA Grant Program.

#3113 Chronic type 1 interferon exposure phenocopies chronic cisplatin exposure in high grade serous ovarian cancer.

Ashlyn Conant[1], Kiera McGivney[2], Tise Suzuki[3], Sharon Asariah[4], Brigitte Vazquez[1], Jay Deng[5], HyeonJoo Cheon[6], Juli Unternaehrer[1]

[1]Loma Linda University, Loma Linda, CA,[2]Whitworth University, Spokane, WA,[3]Southern Adventist University, Collegedale, TN,[4]California University of Science and Medicine , Colton, CA,[5]University of Redlands, Redlands, CA,[6]Wayne State University, Detroit, MI

Despite initial response to platinum-based therapeutics, high grade serous ovarian carcinoma (HGSOC) remains one of the deadliest gynecologic malignancies, due to high molecular and genetic heterogeneity that contributes to acquired drug resistance mechanisms and rapid recurrence. Frontline treatment for the disease has remained largely unchanged for 30 years, with CA125 serving as the only established biomarker for the past 4 decades and PARP inhibitors representing one of the few available targeted therapies. There is an urgent need for improved understanding of factors that may predict therapy response and tumor aggression, thus contributing to recurrence and resistance. We previously published on the dissociation of stemness and therapy resistance in an isogenic pair of therapy sensitive and resistant patient-derived HGSOC cells. RNA sequencing revealed enrichment of JAK/STAT signaling and an upregulation of gene signatures associated with type 1 interferon production and signaling in the chemo-resistant (CR) cells. We hypothesize that chronic, low-level IFN-1 signaling promotes the development of therapy resistance in HGSOC, via the priming of a DNA damage associated IFN-1 response. RT-qPCR and flow cytometry were used to validate the pathways and targets of interest. IFN-1 and pro-tumor interferon-related DNA damage signature (IRDS) genes were found to be significantly upregulated in the CR cells. Acute cisplatin treatment enriched IFN-1-related protein expression in all cells. CR and SE cells exhibited different temporal expression patterns of IFN-1 and IRDS RNA in response to acute cisplatin exposure, with SE cells displaying an acute IFN-1 response to cisplatin and CR cells responding with delayed IFN-1 induction. To determine if IFN-β is a driving factor in the development of resistance, cells were treated with chronic, low-level IFN-β for several weeks. Chronic, low-level IFN-β did not induce anti-viral ISG expression when compared to high dose cytokine after 24 hours. However, after 6 passages the treatment blunted ISG expression in both CR and SE cells. IFN-β treatment phenocopied several aspects of chronic cisplatin exposure: increased resistance to cisplatin, epithelial-like morphology changes, and reduced proliferation. Despite these changes, IFN response was dampened. Future studies aim to explore strategies for surmounting chemotherapy resistance by impacting IFN-I signaling.

#3115 RTF2 drives oxaliplatin resistance in colorectal cancer by promoting phase separation-mediated homologous recombination repair.

Yiran Bie, Chong Chen, Haiqin Jiang, Zhizhong Xiong, Bin Zhong, Haoyang Xv, Yufeng Chen, Lei Lian, Xiaojian Wu, Peishan Hu

The Sixth Affiliated Hospital of Sun Yat-sen University, Guangzhou, China

Colorectal cancer (CRC) is one of the most common malignant tumors worldwide. Current treatment options for CRC include surgery, chemotherapy, and radiotherapy. Chemoresistance is a major factor contributing to poor prognosis in CRC patients. Oxaliplatin is recommended as a first-line chemotherapeutic agent for CRC, and overcoming oxaliplatin resistance holds great clinical significance. In this study, multi-omics cohort analysis using the ARGO database revealed for the first time that Replication Termination Factor 2 (RTF2) exhibits high-frequency mutations in CRC and shows elevated RNA and protein expression levels. We established 42 CRC organoids and performed sequencing and drug-sensitivity assays; RTF2 expression was markedly higher in the oxaliplatin-resistant organoid cohort. As a conserved replication-termination factor, RTF2 prevents DNA degradation during replication-fork stalling, maintains genome stability, and plays a critical role in replication-fork restart. Its high expression is significantly correlated with poor patient prognosis. We found that RTF2 is substantially upregulated in CRC cells compared with normal intestinal epithelial cells, and its expression is also elevated in oxaliplatin-resistant cell lines. Therefore, we generated RTF2-overexpression and RTF2-knockdown CRC cell models, as well as a subcutaneous xenograft nude-mouse model. Using the RTF2 inhibitor Aphidicolin in combination with oxaliplatin, we verified that targeting RTF2 enhances the cytotoxic effect of oxaliplatin on CRC cells. In recent years, increasing evidence has shown that many transcription factors exert biological functions through phase separation. RTF2, which contains an intrinsically disordered region (IDR), may also possess this property. We observed that fluorescently tagged RTF2 formed liquid-like droplets in the nucleus, suggesting potential phase separation, which was further confirmed by FRAP assays. Treatment of CRC cells with the phase-separation inhibitor 1,6-hexanediol reduced their oxaliplatin resistance. Results from comet assays and γH2AX immunofluorescence indicated that the mechanism by which RTF2 regulates resistance may be related to DNA double-strand break repair. Using DR-GFP and EJ5-GFP reporter systems, we found that 1,6-hexanediol significantly inhibited homologous recombination (HR) repair efficiency. These findings suggest that in CRC, RTF2 may enhance oxaliplatin resistance by undergoing phase separation and promoting HR-mediated DNA damage repair. In summary, our study reveals for the first time that RTF2 enhances oxaliplatin resistance in colorectal cancer by undergoing phase separation and promoting HR-mediated DNA repair. This discovery provides new mechanistic insights and potential therapeutic targets for overcoming chemoresistance and improving patient prognosis in CRC.

#3116 CDK4/6 inhibition overcomes 5-FU resistance by suppressing TYMS-driven R-loop-associated DNA damage in colorectal cancer.

Lingling Xu[1], jiabei zhu[1], Jinghua Sun[2], Man Li[2], Ajay Goel[3]

[1]Beckman Research Institute of City of Hope, Monrovia, CA,[2]The Second Affiliated Hospital of Dalian Medical University, Dalian, China,[3]City of Hope, Duarte, CA

Background: Resistance to 5-fluorouracil (5-FU) remains a significant obstacle in colorectal cancer (CRC) therapy. As an antimetabolite, 5-FU induces cytotoxicity by inhibiting thymidylate synthase (TYMS), thereby impairing DNA synthesis and repair. However, CRC cells frequently adapt through TYMS upregulation, thereby strengthening their DNA repair capacity and reducing the efficacy of drugs. R-loops, three-stranded nucleic acid structures formed by hybridization of RNA to its DNA template, are key contributors to replication stress and DNA damage. Since TYMS regulates nucleotide synthesis, it may influence R-loop-associated DNA damage. Cyclin-dependent kinases 4 and 6 (CDK4/6), which control G1-S cell cycle progression via E2F activation, also regulate TYMS transcription. Therefore, we hypothesized that CDK4/6 inhibition may downregulate TYMS and enhance R-loop-related DNA damage, restoring 5-FU sensitivity.

Methods: We established 5-FU-resistant CRC cell lines (HCT116-5FUR and SW480-5FUR). Cell viability was assessed using the MTT assay, and protein and mRNA levels were quantified by Western blot and RT-PCR, respectively. Flow cytometry was used for cell cycle profiling. DNA damage was assessed by γH2AX immunofluorescence, and R-loop formation was detected via S9.6 and anti-nucleolin immunostaining. A luciferase reporter assay was used to monitor the efficiency of double-strand break (DSB) repair. Synergistic effects of 5-FU and the CDK4/6 inhibitor abemaciclib were also evaluated.

Results: TYMS expression was markedly upregulated in HCT116 5FUR ($p<0.001$) and SW480 5FUR ($p<0.01$) compared to parental lines. CDK4 expression was upregulated in HCT116 5FUR and SW480 5FUR ($p<0.01$) compared to parental lines. CDK6 expression was also upregulated in HCT116 5FUR and SW480 5FUR ($p<0.01$) compared to their parental cell lines. Abemaciclib downregulated TYMS expression in HCT116 5 FUR ($p = 0.011$) and SW480 5FUR ($p = 0.0002$) compared to untreated 5-FU-resistant CRC cell lines. TYMS downregulation promoted R-loop-associated DNA damage, indicating a mechanistic link between nucleotide metabolism and genomic instability. Combination treatment with 5-FU and abemaciclib synergistically reduced the viability of resistant cells by inducing G1 arrest and enhancing DNA damage. Abemaciclib alone induced R-loop formation and DNA damage signaling, consistent with TYMS suppression and the amplification of replication stress.

Conclusions: TYMS modulates R-loop-associated DNA damage, contributing to 5-FU resistance in CRC. CDK4/6 inhibition restores chemosensitivity by repressing TYMS and enhancing R-loop-driven genomic stress. Combining CDK4/6 inhibitors with 5-FU represents a promising therapeutic strategy to overcome drug resistance in colorectal cancer.

#3117 Defining the role of nucleolar stress in mediating DDB2 induced oxaliplatin resistance in colorectal cancer.

Vinod Kumar[1], Dennis Hsu[2], Orlando D. Scharer[1], Matthew A. Schaich[1], Katherine E. Helfrich[3], Simon C. Watkins[3], Bennett Van Houten[1]

[1]Pharmacology and Chemical Biology, University of Pittsburgh School of Medicine, Pittsburgh, PA,[2]Medicine, UPMC-Hillman Cancer Center, Pittsburgh, Pennsylvania, Pittsburgh, PA,[3]Center for Biologic Imaging, University of Pittsburgh, Pittsburgh, PA

Background: Colorectal cancer (CRC) is the second most common cause of cancer deaths in the USA. Oxaliplatin containing regimens are generally considered first line therapy for fit patients, either in the form of FOLFIRINOX or NALIRIFOX. However, acquired resistance is inevitable and a significant percentage of patients treated with adjuvant FOLFOX (5-FU/leucovorin/oxaliplatin) fail to respond. Furthermore, oxaliplatin treatment has toxic side effects. Recent studies have shown that oxaliplatin kill cells by inducing stress to nucleolus. We and others have shown that oxaliplatin, but not cisplatin resistance in tumor cells is dependent upon the levels of DDB2, a DNA repair protein involved in damage recognition in chromatin during global genome nucleotide excision repair (GG-NER). However, the role of DDB2 in suppressing oxaliplatin induced nucleolar stress is not known. Therefore, defining the molecular roles of DDB2 in oxaliplatin response, to assess CRC response rates correlate with low DDB2 levels and the mechanisms of how DDB2 acts to remove these DNA lesions will fill an urgent gap in our knowledge.
Methods: DDB2 protein levels were measured by western blot and IHC assay in CRC tissue microarrays. The IC50s for oxaliplatin and cisplatin was obtained by performing cell titer glo (CTG) cell viability and clonogenic assay. The accumulation of DDB2 in nucleolus after oxaliplatin treatment was imaged by confocal microscopy. We used our newly developed SMADNE assay to calculate DDB2 binding kinetics and equilibrium dissociation constant (KD).
Results: We found that high DDB2 expressing CRC cell lines have higher IC50 for oxaliplatin and DDB2 KO cells are more sensitive to oxaliplatin than cisplatin therapy. Our IHC data suggests that DDB2 is differentially expressed in CRC patient's tumor. Interestingly, single molecule analysis by C-trap, reveals that DDB2 binds to oxaliplatin and cisplatin adducts with similar affinities, indicating that while DDB2 recognizes cisplatin lesions loss of DDB2 does not increase cisplatin sensitivity. Confocal microscopic imaging demonstrates that oxaliplatin treatment dramatically facilitated DDB2 accumulation in nucleolus with mutual colocalization of NPM1 (a marker for nucleolar stress). The combination of DDB2 inhibitors (NAEi or CSN5i-3) and oxaliplatin kills HCT116 CRC cells synergistically.
Conclusions: Our studies demonstrate that DDB2 is a potential biomarker for response to oxaliplatin and a new clinically targetable protein in the treatment of CRC. These studies will lay the foundation for clinical trials of combination therapy of Pevonedistat or CSN5i with oxaliplatin and 5FU.

#3118 Dichloroacetate reprograms metabolism and disrupts ROS adaptation, attenuating stemness to reverse chemoresistance in ovarian cancer.

Yen Thi Do[1], **Seungmee Lee**[2], Shin-Wha Lee[3], Eun Ji Nam[4], Jin-Young Kim[5], Sojin Shin[2], Ji Hae Seo[6]

[1]1Department of Gynecology and Obstetrics and Institute for Cancer Research, Keimyung University School of Medicine, Daegu, Korea, Republic of,[2]Gynecologic Oncology, Keimyung University School of Medicine, Daegu, Korea, Republic of,[3]Asan Medical Center, University of Ulsan, Seoul, Korea, Republic of,[4]Yonsei University College of Medicine, Seoul, Korea, Republic of,[5]Department of Internal Medicine, Keimyung University School of Medicine, Daegu, Korea, Republic of,[6]Department of Biochemistry, Keimyung University School of Medicine, Daegu, Korea, Republic of

Chemotherapy resistance and the associated high rates of relapse represent critical barriers in the effective management of ovarian cancer, contributing significantly to poor patient prognosis and mortality. In this study, we investigated the therapeutic potential of Dichloroacetate (DCA), a pan-pyruvate dehydrogenase kinase (PDK) inhibitor, as a strategy to overcome Cisplatin (CP) resistance. We initially identified that CP-resistant ovarian cancer cells exhibit elevated phosphorylation of pyruvate dehydrogenase (pPDH). Treatment with DCA effectively blocked pPDH, leading to a marked suppression of cell migration and invasion through the reversion of motile mesenchymal phenotypes to epithelial characteristics. Furthermore, DCA treatment significantly attenuated stem cell-like properties, as evidenced by reduced sphere formation capacity. When combined with CP, DCA exerted a synergistic anti-proliferative effect by triggering apoptosis in chemoresistant cells. Mechanistic investigations revealed a distinct metabolic adaptation: while CP induces cell death via Reactive Oxygen Species (ROS) generation in sensitive cells, resistant cells display high basal ROS levels and fail to generate further ROS upon CP exposure. Crucially, DCA treatment disrupted this ROS adaptation, inducing a lethal accumulation of ROS specifically in the resistant cells. Collectively, our findings indicate that DCA restores CP sensitivity by targeting ROS metabolism and inhibiting stemness, suggesting it is a promising therapeutic candidate for treating refractory ovarian cancer.

#3119 Modeling chemotherapy persistence in colorectal cancer using patient-derived organoids.

Yasmine Abouleila, Timo Voskuilen, Mayke Doorn, Roel Verkerk, Jasmin Pourfarzad, Joris Maas, Robert G. J. Vries, **Sylvia F. Boj**

HUB Organoids B.V., Utrecht, Netherlands

Therapy resistance in colorectal cancer remains a major clinical challenge. Despite standard-of-care chemotherapies such as FOLFOX and FOLFIRI, tumors frequently develop resistance, leading to treatment failure. A growing body of research implicates drug-tolerant persister (DTP) cells—a reversible, slow-growing population that survives initial therapy—as a critical step in resistance development. These persister cells create a window for cancer to acquire additional adaptations—such as mutations and alternative signaling pathway activation—ultimately leading to irreversible resistance. Understanding this transition from persistence to full resistance is essential for developing therapies that can prevent relapse. To investigate these mechanisms in a clinically relevant context, we developed patient-derived organoid (PDO) models of colorectal cancer capable of surviving FOLFOX or FOLFIRI treatment. These organoids retain the heterogeneity and architecture of the original tumors, providing a physiologically faithful system to study persistence. Because chemotherapy impact varies by mechanism of action, standard assays may not fully capture response diversity. We therefore optimized viability readouts to measure treatment effects across the entire organoid population, capturing both cytotoxicity and partial survival. Using these persistent PDOs, we performed whole-exome sequencing alongside bulk and single-cell RNA sequencing to map the molecular features associated with the DTP state and subsequent resistance. This approach revealed pathways and cellular programs that enable tumor cells to tolerate chemotherapy, highlighting potential targets for overcoming resistance. By modeling clinically relevant persistence, these PDOs offer a platform to test interventions that eliminate persister populations before they evolve into fully resistant tumors.

#3120 Using genome wide CRISPR screening to identify synthetic lethal targets for overcoming chemoresistance in rhabdomyosarcoma.

Aqsa Mazhar[1], Qian Wang[1], Satyanarayana Gadde[1], Daenikka Ravindraraja[1], Belamy B. Cheung[1], Glenn Marshall[2]

[1]Faculty of Medicine and Health, School of Clinical Medicine, Children's Cancer Institute Australia, Children's Cancer Institute, UNSW Sydney, Australia,[2]Kids Cancer Centre, Sydney Children's Hospital, Children's Cancer Institute, UNSW, New South Wales, Australia

Chemotherapy resistance in Rhabdomyosarcoma (RMS), the most common pediatric soft tissue sarcoma, remains a major obstacle to improve survival outcomes, particularly in high-risk alveolar RMS (ARMS), which accounts for approximately one-third of all RMS cases and is clinically more aggressive due to its strong propensity for metastasis, with survival rates fall below 24% after relapse. Drug resistance is a primary driver of treatment failure, contributing to nearly 80-90% of cancer-related mortality. Although irinotecan remains one of the most effective chemotherapeutic agents in RMS, the emergence of irinotecan-related chemoresistance highlights the urgent need to develop rational combination therapies to target the genetic robustness and functional redundancy of RMS cells. To overcome the stagnation in survival outcomes and intrinsic drug resistance, a genome wide Clustered Regularly Interspaced Short Palindromic Repeats (CRISPR) Knockout screening was performed to develop and identify novel therapeutic vulnerabilities and effective combination strategies specifically tailored to overcome irinotecan resistance in ARMS cells. For the first time, our study identified 47 candidate prognostic genes whose deletion potentially sensitizes RMS cells to irinotecan treatment. Along with several druggable targets, pathway enrichment analysis revealed that the DNA damage repair pathway is the most significantly downregulated in irinotecan-resistance in RMS cells, suggesting that targeting this pathway could induce a synthetic lethal interaction with irinotecan. Among the top hits, we validated FGFR4 and PARP1 as key modulators of resistance, and siRNA-mediated silencing of these genes sensitizes RMS cells to irinotecan treatment. Most importantly, FGFR4 was significantly enriched as a gene dependency in ARMS. In addition, pharmacological inhibition of these genes using available small-molecule inhibitors markedly enhanced irinotecan sensitivity and further reduced cell viability, both as single agents and in combination, with a favorable therapeutic window, supporting their potential for clinical translation. We are currently investigating the mechanistic basis and *in vivo* efficacy of these drug combinations in RMS models. This study provides a promising framework for developing personalized and targeted therapeutic strategies to improve outcomes for RMS patients.

#3121 METTL7B-driven m6A RNA methylation promotes gemcitabine resistance and tumor progression in pancreatic ductal adenocarcinoma.

Tung-Wei Hsu[1], Wan-Yu Wang[1], Yen-Hao Su[1], Chih-Ming Su[1], Po-Chen Tseng[2], Hsin-An Chen[1]

[1]Department of Surgery, Division of General Surgery, Taipei Medical University-Shuang Ho Hospital, Ministry of Health and Welfare, New Taipei City, Taiwan,[2]Department of Ophthalmology, Taipei City Hospital, Renai Branch, Taipei, Taiwan

Pancreatic ductal adenocarcinoma (PDAC) remains one of the most lethal malignancies, with a five-year survival rate below 12%, primarily due to rapid development of chemoresistance. To identify molecular drivers of drug resistance, we performed integrated transcriptomic, proteomic, and methylation analyses on gemcitabine-resistant PANC-1 GR cells. We identified the methyltransferase-like protein METTL7B as a novel regulator of RNA methylation-mediated resistance in PDAC. Global m6A profiling revealed hypermethylation in resistant cells that correlated with elevated METTL7B expression. Analysis of TCGA and UALCAN datasets confirmed METTL7B upregulation in PDAC tissues, particularly in KRAS-mutant tumors, and its association with poor overall and disease-free survival. Functional assays demonstrated that METTL7B knockdown suppressed proliferation, migration, invasion, and colony formation while restoring gemcitabine sensitivity. Mechanistically, m6A-seq and RNA-seq analyses revealed that METTL7B methylates oncogenic transcripts such as CSF2, CDKN1A, and FoxM1, enhancing their mRNA stability and translation to promote cell-cycle progression and stress adaptation. Network and pathway analyses further linked METTL7B activity to activation of KRAS and STAT3 signaling, indicating its role in PDAC aggressiveness. Collectively, these results identify METTL7B as a key epitranscriptomic regulator of gemcitabine resistance through m6A-dependent stabilization of oncogenic mRNAs and activation of pro-survival pathways. Targeting METTL7B-mediated RNA methylation offers a promising therapeutic strategy to overcome chemoresistance and improve clinical outcomes in PDAC.

#3122 Integrative multi-omic investigation of gene regulatory networks associated with chemotherapy response in acute lymphoblastic leukemia.

Kelly R. Barnett, Robert J. Mobley, Wenjian Yang, Landon Choi, Kami Chauncy, Kristine R. Crews, Samuel W. Brady, Jun J. Yang, **Daniel Savic**

St. Jude Children's Research Hospital, Memphis, TN

Acute lymphoblastic leukemia (ALL) is the most common pediatric cancer. While treatment outcomes have improved, drug resistance remains a major clinical concern and the primary cause of relapse in patients, with relapsed patient survival rates at approximately 40%. Although changes in gene expression are known to impact drug resistance in ALL, the gene regulatory elements that control and modulate these genes are frequently undefined, and the role of these elements in anti-leukemic drug resistance remains largely unknown. As a result, a more comprehensive epigenetic effort is needed to profile and validate gene regulatory networks linked to anti-leukemic drug response in ALL. We therefore generated matched B-cell origin ALL patient chromatin accessibility and *ex vivo* drug sensitivity (pharmacotyping) datasets covering 16 anti-leukemia drugs in primary ALL cells from over 150 patients to generate a compendium of gene regulatory elements associated with *ex vivo* chemotherapy response. Importantly, *ex vivo* measurements of chemotherapy response are known to associate with clinical outcomes in ALL patients. We further integrated these data with transcriptomics, tumor-normal whole genome sequencing and three-dimensional chromatin conformation results obtained from a subset of these patient biospecimens. We identified 74,307 drug response elements (DREs) and 2,854 drug response genes (DRGs) using a combination of linear modeling and feature selection techniques (p-adj < 0.05, s-value < 0.005). For this analysis, LC50 drug sensitivity was modeled in both continuous and categorical modes against chromatin accessibility and transcriptomic sequence counts. Although many DREs were specific to a singular drug or common drug family, a subset was associated with response to multiple drugs. DREs harbored 868 somatic mutations, many of which overlapped transcription factor (TF) footprints, with PU.1 among the most common overlapping TF sites. TF footprinting identified 148,732 TF binding events associated with drug response. Common TF footprints that correlated with drug response included EBF family TFs for inotuzumab ozogamicin response and STAT family TFs for trametinib response. On average, 74% of these drug response TF footprints mapped to DREs. Subsequent multi-omic integration of gene expression, chromatin accessibility and TF footprinting with three-dimensional chromatin conformation maps identified over 9000 gene regulatory networks linked to altered drug response. Collectively, this work represents the largest study of chromatin accessibility and TF occupancy impacting ALL chemotherapy drug response and supports an important functional role for many DREs in anti-leukemic drug resistance.

#3123 Metabolic reprogramming via statin repurposing: A strategy to reverse the Warburg effect and overcome gemcitabine resistance in pancreatic ductal adenocarcinoma.

Takayuki Noma[1], Mitsuo Shimada[2], Ajay Goel[3]

[1]Beckman Research Institute of The City of Hope, Duarte, CA,[2]Dept. of Surgery, University of Tokushima, Tokushima, Japan,[3]City of Hope, Duarte, CA

Background: Pancreatic ductal adenocarcinoma (PDAC) remains among the deadliest cancers, with mortality projected to rank second in cancer-related deaths by 2030. Gemcitabine is a first-line chemotherapy, but resistance frequently develops, leading to poor prognosis. Metabolic reprogramming, particularly enhanced glycolysis driven by hypoxia and HIF-1α activation, is a key mechanism of gemcitabine resistance. Statins, commonly used cholesterol-lowering drugs that inhibit HMG-CoA reductase, have demonstrated potential metabolic and anti-cancer effects with an established safety profile. This study investigated whether statins could overcome gemcitabine resistance in PDAC by targeting glycolytic adaptation.
Methods: Gemcitabine-resistant PDAC cell lines (MIA PaCa-2 and BxPC-3) and patient-derived 3D organoids were treated with simvastatin alone or combined with gemcitabine. Outcomes included cell viability, apoptosis, migration, invasion, and glycolytic activity (measured by extracellular acidification rate [ECAR] and lactate production). Expression of glycolysis-related genes HIF-1α, HK2, and LDHA was measured by RT-qPCR and Western blotting. Pharmacological modulation of HIF-1α was used to validate the mechanism. Clinical significance was assessed via EUS-FNA samples from 50 patients with PDAC treated with Gemcitabine and transcriptomic data from The Cancer Genome Atlas (TCGA).
Results: Simvastatin reduced the viability of Gemcitabine-resistant PDAC cells compared with parental cell lines (IC50: 20-21 μM vs. 37-39 μM in parental cells; $p<0.01$) and showed synergy with Gemcitabine (Bliss scores: 5.5 and 4.29) and markedly enhanced anti-tumor activity, reducing viability by 41.7% and 44.4%, respectively. The combination significantly suppressed migration and invasion and increased apoptosis ($p<0.001$), accompanied by increased cleaved PARP and caspase-3. Resistant cells exhibited elevated glycolysis, and simvastatin, especially in combination with Gemcitabine, reduced lactate, ECAR, and expression of HIF-1α, HK2, and LDHA at both mRNA and protein levels ($p<0.01$), mimicking HIF-1α inhibition. In two PDAC organoids, combination therapy disrupted structure and reduced viability while downregulating glycolytic genes. Clinically, high HIF-1α/HK2/LDHA expression correlated with Gemcitabine nonresponse and worse PFS/OS in both our gemcitabine-treated cohort and TCGA dataset.
Conclusion: Statins restore gemcitabine sensitivity in PDAC by suppressing HIF-1α-driven glycolytic reprogramming, reversing the metabolic adaptations responsible for chemoresistance. With their proven safety, affordability, and wide availability, statins offer a promising, immediately translatable approach to improve outcomes in gemcitabine-resistant PDAC.

#3124 SRSF1 orchestrates splicing-directed dual-engine glucose metabolism driving chemoresistance in diabetes-associated pancreatic cancer.

Zu-Wei Wang[1], Yi-Ting Chen[2], Jin-Peng Lu[3], Shun-Can Zhu[3], Hong-Yi Lin[1], Yin-Hao Chen[3], Hao-Xiang Zhang[1], Shi Chen[1]

[1]Department of Hepatobiliary Pancreatic Surgery, Fuzhou University Affiliated Provincial Hospital, Fuzhou, China,[2]Fuzhou University, Fuzhou, China,[3]Fujian Medical University, Fuzhou, China

Background: Pancreatic ductal adenocarcinoma (PDAC) patients with concurrent type 2 diabetes mellitus (T2DM) exhibit significantly worse treatment responses and shorter survival rates. However, the molecular mechanisms underlying diabetes-driven chemoresistance and immune suppression remain poorly understood. This study aims to elucidate how the diabetic microenvironment promotes PDAC chemoresistance through the splicing-metabolism axis.
Methods: We investigated SRSF1-mediated splicing regulation using clinical samples from 28 advanced PDAC patients receiving AG chemotherapy, T2DM-associated PDAC mouse models (KPC, KPSC), patient-derived organoids, and multiple in vivo models. Mechanistic studies included scRNA-seq, eCLIP-seq, ATAC-seq, RIP, ChIP-qPCR, and metabolic flux analysis.
Results: This study revealed that pancreatic cancer with concurrent diabetes is prone to chemoresistance, accompanied by SRSF1-driven elevated back-splicing ratios and altered pyruvate metabolism. Mechanistic investigation found that lactate accumulation in the diabetic microenvironment induced K48 lactylation of SRSF1 protein, enhancing its stability and promoting back-splicing events. SRSF1 regulated the linear-to-back splicing conversion of PSMA3-AS1 to circ-PSMA3-AS1, ultimately promoting transcriptional upregulation of metabolic enzymes DLAT and LDHA. DLAT/LDHA provided metabolic resilience through enhanced mitochondrial fusion and glycolysis, enabling cells to activate both TCA cycle and glycolytic energy-producing systems to acquire chemoresistance. Additionally, this metabolic remodeling profoundly impacted the tumor immune microenvironment through upregulated PD-L1 and sustained lactate production, causing immune evasion, suppressing CD8+ T cell function, and promoting Treg expansion. This process constituted a self-reinforcing positive feedback loop, resulting in the intractability of diabetes-associated pancreatic cancer. Based on these mechanistic discoveries, we developed a triple combination therapy (Berberine + anti-PD1 + AG) targeting SRSF1, DLAT, and LDHA while reducing glucose and tumor lactate levels, significantly improving treatment efficacy in diabetic PDAC models.
Conclusions: This study reveals the mechanistic framework underlying poor outcomes in diabetes-associated PDAC and provides a clinically translatable therapeutic strategy. The discovery of the splicing-metabolism-immunity axis opens new avenues for targeting metabolic vulnerabilities in cancer treatment, with particular significance for the growing population of diabetic cancer patients.

#3125 Transcriptomic analysis of glycosylation genes in chemotherapeutic-resistant glioma cells.

Vi P. Dang, Nicole S. Lav, Alan Y. L. Jiang, Jaclyn N. Hanamoto, Daniela A. Bota, Lisa A. Flanagan

University of California, Irvine, Irvine, CA

The purpose of this study was to characterize the glycosylation gene signature of chemotherapeutic-resistant glioma cells derived from dielectrophoresis-based sorting. Glioblastoma, astrocytoma, and oligodendroglioma comprise a class of aggressive and deadly brain tumors called diffuse gliomas. Around 20,000 glioma cases are diagnosed yearly in the US alone. The current standard chemotherapy treatment, temozolomide (TMZ), is insufficient as the 5-year survival rate of glioblastoma patients is as low as 8%. This is due to the presence of TMZ-resistant cells within tumors that lead to chemotherapeutic resistance and tumor recurrence. Thus, it is critical to characterize the molecular profile of TMZ-resistant cells to determine means of targeting them for more effective treatment. Preliminary data from our lab show that glycosylation could be an important dynamic regulator of TMZ resistance. Glycosylation, the post-translational addition of glycans (sugars) to proteins and lipids, regulates the function of many membrane proteins including drug transporters, growth factor receptors, and adhesion proteins. Our lab has developed an innovative dielectrophoresis-based method to sort cells based on electrophysiological membrane properties that are influenced by glycosylation. We used this method to successfully enrich TMZ-resistant populations from various glioma types and patient-derived tumors for downstream transcriptomic characterization using glycosylation gene microarrays, qRT-PCR, and single-cell and bulk RNA sequencing. Our study concluded that TMZ-resistant glioma cells exhibit transcriptomic differences in glycosylation genes, suggesting that these cell-surface sugars may serve as novel biomarkers or targets for glioma treatment. These results could enable the development of effective treatment strategies through targeting glioma cell glycosylation to ultimately improve patient outcomes.

#3127 Overcoming chemoresistance: Restoring doxorubicin sensitivity and natural killer cell immunity in resistant DLBCL cells through reduction of endoplasmic reticulum stress.

Yi-Cheng Lin[1], Chih-Chi Andrew Hu[2], Chih-Hang A. Tang[2], Chun-Yu Cheryl Chuang[1], Chiung-Tong Chen[3]

[1]National Tsing Hua University, Hsinchu, Taiwan,[2]Houston Methodist Research Institute, Houston, TX,[3]National Health Research Institutes, Miaoli, Taiwan

The recurrence of diffuse large B-cell lymphoma (DLBCL) is commonly attributed to its resistance to doxorubicin (DOX), which presents a significant therapeutic challenge and contributes to poor prognosis. Endoplasmic reticulum (ER) stress, pivotal in DOX resistance, is governed by regulating the survival of tumor cells and immune evasion. This study developed DOX-resistant DLBCL cell lines using murine xenografts to investigate the underlying mechanisms and potential therapeutic strategies. Comprehensive analyses were performed, focusing on stress-response pathways, oncogene-driven immunomodulatory signaling, and the cytotoxic activity of natural killer (NK) cells. Resistant cells exhibited elevated IRE1-XBP1s activation and c-MYC expression, which compromised NK cell-mediated tumor killing and reinforced immune evasion. Inhibition of XBP1s through ER stress inhibitor BI09 effectively dismantled this compensatory resistance strategy, reinstated NK cell sensitivity, and substantially increased tumor cell apoptosis. Notably, the combination of BI09 with DOX resulted in substantial anti-lymphoma activity at reduced DOX concentrations, thereby overcoming chemoresistance. These findings indicated that BI09 operated through a dual approach, simultaneously restoring chemosensitivity in refractory DLBCL and counteracting c-MYC-mediated immune evasion. Consequently, this study underscored the IRE1-XBP1s-c-MYC axis as a pivotal pathway in chemoresistance and immune suppression in DLBCL cells, and identified BI09 as a viable therapeutic candidate capable of disrupting chemoresistance and enhancing the efficacy of immunochemotherapy in aggressive lymphoma.

#3128 IDH1 inhibition potentiates gemcitabine efficacy in pancreatic ductal adenocarcinoma.

Yuan Li[1], Wenhao Weng[2], Ajay Goel[1]

[1]Beckman Research Institute of City of Hope, Monrovia, CA,[2]Shanghai Children's Hospital, School of Medicine, Shanghai, China

Background: Pancreatic ductal adenocarcinoma (PDAC) is the most aggressive cancers, with a 5-year survival rate of approximately 13%. Gemcitabine remains standard first-line chemotherapy, over 80% of patients develop resistance, limiting its clinical benefit. Wild-type isocitrate dehydrogenase 1 (wt-IDH1) is highly expressed in PDAC, catalyzing the conversion of isocitrate to α-ketoglutarate and NADPH to support mitochondrial metabolism. Ivosidenib (AG-120) is an FDA-approved oral allosteric inhibitor originally developed for mutant IDH1, but it also effectively inhibits wt-IDH1 under nutrient-deprived and low-magnesium conditions typical of PDAC. This inhibition reduces NADPH, increases chemotherapy-induced reactive oxygen species (ROS), and markedly impairs the survival of resistant cells, providing a mechanistic rationale for combining AG-120 with gemcitabine to overcome chemoresistance.
Methods: The synergistic effect of AG-120 and gemcitabine was evaluated in gemcitabine-resistant PDAC cell lines (MIA PaCa-2 and BxPC-3) using the PicoGreen dsDNA assay. Optimal drug doses were applied in functional assays, including wound healing, migration/invasion, and colony formation, to evaluate effects on cell growth and motility. Mechanistically, wt-IDH1 inhibition reduces NADPH and impairs mitochondrial metabolism, intracellular ROS levels were measured following treatment to evaluate oxidative stress. Mitochondrial function was further examined using Seahorse assays. Transcriptomic profiling via RNA sequencing, combined with qRT-PCR and Western blot validation, was performed to identify key pathways driving the synergistic response. The efficacy of the combination therapy was further confirmed in vivo using a PDAC xenograft model.
Results: The combination of AG-120 and gemcitabine exhibited synergistic anticancer effects on cell proliferation, migration, invasion, and colony formation in gemcitabine-resistant PDAC cell lines. Transcriptomic analysis of genes downregulated by IDH1 inhibition revealed significant enrichment of OXPHOS pathways (enrich score = 2.32, $P<0.01$), supported by Seahorse assays showing suppression of mitochondrial OXPHOS. Mechanistically, gemcitabine-resistant cells exhibited a marked upregulation of the magnesium influx transporter TRPM7, an essential regulator of magnesium homeostasis in mammalian cells, suggesting increased sensitivity and dependency on magnesium. These findings suggest that low-magnesium conditions enhance the responsiveness of resistant PDAC cells to wt-IDH1 inhibition, contributing to the observed synergistic anticancer effect of the combination therapy.
Conclusion: This study provides mechanistic insight into how AG-120 overcomes gemcitabine resistance in PDAC cells by targeting wt-IDH1 and modulating the OXPHOS pathway, highlighting a potential therapeutic strategy to improve treatment outcomes.

#3129 Proteasome-associated DUB inhibition by VLX1570 targets UCHL5/USP14 and enhances cisplatin efficacy in neuroblastoma.

Yi Ju Kao[1], Kuan-Lin Kuo[2], Chen-Hsun Hsu[3], Shih-Ming Liao[3], Po-Ming Chow[3], Kuo-How Huang[3]

[1]National Taiwan University Hospital and National Taiwan University College of Medicine, Taipei, Taiwan,[2]National Taiwan University College of Medicine, Taipei, Taiwan,[3]National Taiwan University Hospital, Taipei, Taiwan

Neuroblastoma is the most common extracranial solid tumor in children, and high-risk disease still carries an unfavorable prognosis despite intensive multimodality therapy. Deubiquitinating enzymes (DUBs) associated with the 19S proteasome, such as ubiquitin C-terminal hydrolase L5 (UCHL5) and ubiquitin-specific protease 14 (USP14), are key regulators of protein homeostasis and have attracted interest as potential therapeutic targets. In this study, we examined UCHL5 and USP14 expression in clinical neuroblastoma specimens compared with normal peripheral nerve tissue by immunohistochemistry, and investigated the effects of pharmacologic inhibition of proteasome-associated DUB activity using the small-molecule inhibitor VLX1570 in a panel of human neuroblastoma cell lines by assessing cell viability, cell-cycle distribution, apoptosis, clonogenic growth, and markers of proteasome stress, endoplasmic reticulum stress, and autophagy, as well as in a xenograft mouse model. Cisplatin remains a cornerstone of induction and consolidation chemotherapy for high-risk neuroblastoma, and resistance or intolerance to cisplatin-based regimens represents a major barrier to cure; therefore, we specifically evaluated whether VLX1570 could potentiate cisplatin-induced cytotoxicity in vitro and in vivo. UCHL5 and USP14 were markedly upregulated in neuroblastoma tissues relative to normal peripheral nerve, and VLX1570 treatment significantly reduced neuroblastoma cell growth, induced G2/M arrest and caspase-dependent apoptosis, promoted accumulation of polyubiquitinated proteins, activated unfolded protein response signaling, and modulated autophagy-related proteins. Notably, combining VLX1570 with cisplatin produced greater suppression of cell viability and clonogenic survival, and enhanced apoptotic signaling, than either treatment alone in vitro. Consistently, VLX1570 significantly suppressed tumor growth in xenograft models, while co-treatment with cisplatin further delayed tumor progression and reduced proliferative indices without overt systemic toxicity. Taken together, these data demonstrate that UCHL5 and USP14 are overexpressed in neuroblastoma and that pharmacologic inhibition of proteasome-associated DUB activity with VLX1570 exerts antitumor effects and enhances the efficacy of cisplatin, supporting further evaluation of DUB inhibitor-cisplatin combination strategies in neuroblastoma.

: Pharmacogenomics and Translational Biomarkers for Precision Cancer Therapy
Poster Session

#3133 A pharmacogenetic interaction analysis of second-line chemotherapy with bevacizumab in metastatic colorectal cancer patients: Results from the randomized BEBYP trial.

Arianna Bandini[1], Paola Orlandi[2], Marco Scalese[3], Gianluca Masi[4], Federica Marmorino[1], Chiara Cremolini[5], Guido Bocci[1]

[1]Department of Translational Research and New Technologies in Medicine and Surgery, University of Pisa, Pisa, Italy,[2]Department of Clinical and Experimental Medicine, University of Pisa, Pisa, Italy,[3]Institute of Clinical Physiology, Italian National Research Council - CNR, Pisa, Italy,[4]Department of Translational Research and New Technologies in Medicine and Surgery, University Of Pisa, Pisa, Italy,[5]Polo Oncologico - AOUP, Pisa, Italy

Metastatic colorectal cancer (mCRC) remains a major therapeutic challenge, and although bevacizumab combined with chemotherapy has demonstrated clinical benefit, validated predictive biomarkers of its activity are still missing. Moreover, pharmacogenetic analyses of angiogenesis-related genes in mCRC patients have failed to predict treatment efficacy and survival outcomes. Based on this rationale, we conducted a pharmacogenetic study on a different approach, investigating the potential combined effect of *EPAS-1, IL-8, VEGF-A,* and *VEGFR-2* single nucleotide polymorphisms (SNPs) on progression-free survival (PFS) and overall survival (OS) in mCRC patients treated with second-line mFOLFOX-6 or FOLFIRI (CHT) with or without bevacizumab. Germline DNA was obtained from peripheral blood samples, and SNPs were genotyped by Real-Time PCR. Pharmacogenetic interaction analysis was performed using the Multifactor Dimensionality Reduction (MDR) approach to explore potential statistical interactions between SNPs associated with treatment outcomes. This analysis included mCRC patients enrolled in the randomized phase III BEBYP trial (clinicaltrials.gov: NCT00720512) at the University Hospital of Pisa, who received second-line mFOLFOX-6 or FOLFIRI with (n=66) or without (n=66) bevacizumab. In the bevacizumab+CHT group, the MDR analysis identified two pharmacogenetic interaction profiles based on specific combinations of *VEGF-A* rs1570360 and *VEGFR-2* rs11133360 genotypes. Patients carrying the favorable genetic profile showed a median PFS of 8.89 months compared with 5.23 months for those with the unfavorable profile (p=0.001), with a multivariable Cox hazard ratio (HR) of 0.49 (95% CI, 0.25-0.96; p=0.039). Median OS was 20.69 vs. 9.28 months (p=0.04) for favorable vs. unfavorable profiles, respectively, with an adjusted HR of 0.54 (95% CI, 0.3-0.98; p=0.042). In contrast, among patients treated with CHT alone, no significant differences were observed in PFS (5.52 vs. 4.85 months, p=0.642) or OS (16.31 vs. 16.34 months, p=0.969) between the two genetic profiles. Overall, the interaction between *VEGF-A* rs1570360 and *VEGFR-2* rs11133360 genotypes identified a favorable pharmacogenetic profile associated with improved PFS and OS in patients receiving bevacizumab, whereas no association was observed in the CHT-alone group. These findings suggest that MDR analysis of angiogenesis-related genes identifies patients who benefit from bevacizumab-based therapy and strengthens the rationale for a pharmacogenetic selection of candidate patients for anti-angiogenic strategies in mCRC.

#3135 Comparative analysis of phenotypic markers of DPD activity as biomarkers of 5-FU toxicity.

Brianna Bembenek[1], Kelly Bouchonville[2], Carlo Largiader[3], Steven M. Offer[2]

[1]Molecular Pharmacology and Experimental Therapeutics, Mayo Clinic Graduate School of Biomedical Sciences, Rochester, MN,[2]Pathology, Carver College of Medicine, University of Iowa, Iowa City, IA,[3]Clinical Chemistry, University of Bern, Bern Center for Precision Medicine, Bern, Switzerland

Nearly 300,000 cancer patients are treated with fluoropyrimidine chemotherapy in the U.S. annually. Approximately one-third of patients experience severe and life-threatening toxicities, which can result in death. Deleterious genetic variants in *DPYD*, which encodes the rate-limiting enzyme of fluoropyrimidine catabolism (dihydropyrimidine dehydrogenase, DPD), have been correlated with severe toxicity in clinical studies. However, these variants explain only 10-30% of toxicity cases. Phenotypic measures of DPD function are attractive biomarkers of fluoropyrimidine toxicity risk with the potential to identify unknown causes of DPD deficiency. In this study, we compared two measures of DPD enzyme activity, blood plasma dihydrouracil to uracil ratio (UH_2:U) and direct measurement of DPD activity in peripheral blood mononuclear cells (PBMCs) using 204 subjects with comprehensive *DPYD* genotype data. DPD PBMC measurements showed higher overall inter-individual variation compared to UH_2:U ratios. Low correlation between UH_2:U and PBMC measurements were noted for matched samples taken from the same subject. As expected, DPD metabolites (U and UH_2) correlated with UH_2:U ratio; however, no correlation was noted between U or UH_2 levels and the PBMC DPD activity. Furthermore, when data were analyzed by genotype, no correlations were noted between UH_2:U and PBMC DPD activity. We observed the expected decrease in UH_2:U ratio for carriers of the four clinically tested *DPYD* variants and identified two novel variants associated with a significantly decreased UH_2:U ratio. To further investigate the impact of rare genotypes and previously identified *DPYD* haplotypes on the UH_2:U ratio, additional cohorts of 1994 and 500 subjects, enriched for specific genotypes, were utilized. Our results suggest that phenotyping may have limited validity as a single test when predicting DPD deficiency at an individual level and call into question the often-reported belief that PBMC DPD activity represents the "gold standard" for identifying DPD deficiency. Additional studies are needed to investigate correlations between phenotypic measures and 5-FU toxicity in patients, potentially as secondary biomarkers in conjunction with genetic tests.

#3136 Pharmacogenetic assays for personalized cancer treatment.

Abhishek Chadha[1], Jarvis Law[2], Zhiwei Wang[1], Max Mamroth[1], Zhenhua Shen[2], Khairuzzaman Bashar Mullah[2], Alexandre Vlassov[1], Anna Chikova[1]

[1]One Lambda Inc., part of Thermo Fisher Scientific, Canoga Park, CA,[2]Life Sciences Solutions, Thermo Fisher Scientific, Pleasanton, CA

Pharmacogenomics is increasingly utilized in various areas of medicine for personalization of drug selection and dosing. Nevertheless, the cost of large pharmacogenomic panels may be prohibitive for some practices due to reimbursement and utility limitations. Smaller, cancer treatment-specific pharmacogenetic panels that are currently available as services provide a limited number of gene targets and do not include important HLA alleles associated in published studies with adverse effects for specific cancer drugs (note that this work does not establish diagnostic capability). We evaluated the feasibility of developing a targeted pharmacogenetic test for cancer related drugs, which includes HLA along with other critical gene targets not captured by commonly available panels. The number of individual qPCR reactions in a given reaction mix is known as the plex level. Standard genotyping assays are designed as 2-plex mixtures, which are provided as an array of multiple reactions per sample present on a single qPCR plate. Increasing the qPCR plex level reduces the number of reactions required per sample, potentially reducing operational cost, reducing operator error rates and improving turn-around time for pharmacogenetic testing. We evaluated the feasibility of implementing maximal multiplexing in our targeted pharmacogenetic panel. We have designed 50 individual qPCR assays and optimized multiplex mixes into fewer than 8 individual reactions. Our assay targets include single nucleotide polymorphisms (SNPs) in HLA-A, HLA-B, HLA-DRB1, HLA-DQA1, UGT1A1, DPYD and CYP2C9. Based on multiple publications, certain polymorphisms in these genes are associated with increased risk of adverse effects for specific cancer drugs. Our new data analysis method allows derivation of genotyping results from up to 9-plex qPCR reactions performed on a standard qPCR instrument. Assays were tested using a combination of synthetic DNAs and human DNA samples, from Terasaki collection of well-characterized DNA samples and the Coriell repository. Our multiplex reactions included assays for detection of HLA and non-HLA alleles in single reactions using a combination of standard qPCR dyes (i.e; ABY, JUN, etc.) as well as FRET and long-stoke shift dyes. Future development of such pharmacogenetic panels may contribute to further advancement in precision medicine.

#3137 Partial alternative splicing in carriers of *DPYD* rs75017182 explains modest association with severe 5-FU toxicity to 5-FU.

Lauryn Allyn Hahn[1], Ryan Schwartz[1], Hannah Marie Krause[2], Lulu Jiang[1], Brianna Bembenek[3], Kelly Bouchonville[1], Steven M. Offer[1]

[1]Carver College of Medicine, University of Iowa, Iowa City, IA,[2]University of Iowa Holden Comprehensive Cancer Center, Iowa City, IA,[3]Mayo Clinic, Rochester, MN

Dihydropyrimidine dehydrogenase (DPD, encoded by the *DPYD* gene) is the rate-limiting enzyme in the catabolism of the widely used chemotherapeutic drug 5-fluorouracil (5-FU). Genetic variations in *DPYD* are predictive biomarkers of 5-FU toxicity. One such biomarker, rs75017182 (the causal allele linked to the “HapB3” haplotype), has been suggested to promote alternative splicing of *DPYD*, leading to expression of an inactive proteoform. However, carriers of rs75017182 exhibit only moderately increased risk of 5-FU toxicity and modestly decreased *ex vivo* DPD activity compared to carriers of another well-studied splice variant, rs3918290 (**2A*). We hypothesized that, unlike *2A, the rs75017182 variant does not cause obligate alternative splicing but instead promotes partial alternative splicing. To test this, we generated dual-fluorescent minigene reporter constructs containing either the G (wildtype) or C (variant) allele. In our minigene system, alternative splicing was elevated in cells transfected with C-containing vectors via flow cytometry, though levels were lower than those observed in a parallel *2A model. To investigate contributions of other variants in LD with rs75017182, we expanded the reporter to include additional relevant genomic regions. The analyses were complemented by the study of *in vivo* splicing in cells engineered to harbor various combinations of variants and in lymphoblastoid lines carrying specific genotype combinations. Overall, our findings demonstrate that rs75017182-C promotes only partial alternative splicing, eliciting a modest decrease in DPD activity and explaining its comparatively weak association with severe 5-FU toxicity. Additional variants in LD have a minimal impact on splicing and 5-FU sensitivity.

#3138 CellMiner Cross-Database (CellMinerCDB) for Exploration of Patient-Derived Cancer Cell Line Pharmacogenomics.

Fathi Elloumi[1], William C. Reinhold[2], Sudhir Varma[3], Yanghsin Wang[1], Meric Kinali[4], Yashuhiro Arakawa[5], Yoshitaka Inoue[6], Mirit Aladjem[1], Yves Pommier[1], Augustin Luna[7]

[1]National Cancer Institute, Bethesda, MD,[2]National Cancer Institute, Rockville, MD,[3]HiThru Analytics LLC, Princeton, NJ,[4]University of Massachusetts-Boston, Boston, MA,[5]Jikei University, Tokyo, Japan,[6]National Library of Medicine,, Bethesda, MD,[7]National Library of Medicine, Bethesda, MD

CellMiner Cross-Database (CellMinerCDB) (https://discover.nci.nih.gov/cellminercdb/) is an established interactive application providing direct access and enabling exploration of cancer cell line pharmacogenomics without extensive programming experience. Data are compiled from many sources, including the National Cancer Institute (NCI), Broad Institute DepMap, Sanger/MGH GDSC, MD Anderson Cancer Center (MDACC) MCLP, and National Center for Advancing Translational Sciences (NCATS) cell line projects. In the version 2.2 update, our collection has expanded to pharmacogenomics data for 1,916 cancer cell lines and over 25,000 drugs. Drug screening data include many additional compounds for potential drug repurposing from the Broad PRISM, NCATS, and NCI. The user interface facilitates uncovering specific samples of interest and identifying drug and cell lines across databases. We also expanded the annotations for cross-referencing other databases and downloading our data for further cancer biology and drug discovery studies. Herein, we provide use cases for CellMinerCDB including (i) data reproducibility given overlaps of cell lines, genes, and drugs across databases; (ii) candidate biomarker discovery; and (iii) cross-dataset analyses.

#3139 drGT: Attention-guided gene assessment of drug response utilizing a drug-cell-gene heterogeneous network.

Yoshitaka Inoue[1], Hunmin Lee[2], Tianfan Fu[3], Rui Kuang[2], **Augustin Luna**[4]

[1]National Library of Medicine, Bethesda, MD,[2]University of Minnesota, Minneapolis, MN,[3]Nanjing University, Nanjing, China,[4]National Library of Medicine, Rockville, MD

Background: Accurate drug response prediction alone is insufficient for translational impact; computational models must also generate biologically plausible hypotheses. We present drGT, a heterogeneous graph neural network (GNN) model over drugs, genes, and cell lines that couples prediction with mechanism-oriented interpretability via attention coefficients (ACs).
Results: drGT encodes a drug-gene-cell line graph and uses ACs to describe drug-gene associations. We assess both predictive generalization (random, unseen-drug, unseen-cell, and zero-shot splits) and biological credibility (text-mined PubMed co-mentions and comparison to a structure-based DTI predictor) on GDSC1, GDSC2, NCI60, and CTRP datasets. Here, we evaluate both regression (IC50 values) and binary classification (cell-line sensitivity) settings to reflect typical pharmacogenomic experiments; we report R^2 for regression and AUROC for classification tasks. Across benchmarks, drGT consistently delivers top regression performance while maintaining competitive classification accuracy. Under random 5-fold cross-validation, where 20% of samples are randomly masked for testing in each fold, drGT attains an R^2 of up to 0.690 (1st overall against similar methods) and an AUROC of up to 0.945 (3rd overall). In leave-one-out generalization tests, where either all samples from one cell line or all samples of one drug are excluded during training, drGT achieves R^2 values of 0.692 (1st) and 0.022 (1st) and AUROCs of 0.706 (3rd) and 0.844 (2nd), respectively. In the zero-shot prediction test, trained on GDSC1 and evaluated on GDSC2, drGT achieves an R^2 of 0.334 (1st) and an AUROC of 0.786 (1st), both of which represent the highest scores among all models. For interpretability, AC-derived drug-gene links recover known biology: among 976 drugs from the NCI60 dataset with known DTIs, 36.9% of predicted links match established DTIs, and 63.7% are supported by either PubMed abstracts or a state-of-the-art (SOTA) structure-based DTI prediction model. Moreover, an over-representation analysis of AC-ranked genes identifies mechanism of action (MoA)-consistent pathways, such as KRAS signaling, for relevant kinase inhibitors, providing pathway-level explanations for the model predictions.
Conclusions: drGT advances predictive generalization and mechanism-centered interpretability with AC-derived drug-gene links, offering SOTA regression accuracy and literature-supported biological hypotheses, demonstrating how interpretable graph learning can bridge AI prediction and biological discovery. Code: https://github.com/sciluna/drGT

#3140 Characterizing the critical role of enhancer-gene regulation in 5-fluorouracil toxicity and resistance.

Hannah Marie Krause[1], Julia Magee[2], Kelly Bouchonville[1], Lauryn Allyn Hahn[1], Ryan Jonathan Swartz[1], Brianna Bembenek[3], Lulu Jiang[1], Steven M. Offer[1]

[1]University of Iowa Carver College of Medicine, Iowa City, IA,[2]University of Iowa, Iowa City, IA,[3]Mayo Clinic, Rochester, MN

5-Fluorouracil (5FU)-based chemotherapy remains a front-line treatment for most patients with colorectal cancer. However, approximately 30% of patients who receive 5FU experience severe, life-threatening toxicity. Dihydropyrimidine dehydrogenase (DPD, *DPYD* gene) mediates the rate determining step in 5FU catabolism. Deleterious genetic variations in *DPYD* have been associated with elevated concentrations of circulating 5FU and significantly increased risk for 5FU toxicity. Five deleterious variants in *DPYD* have been identified as clinical biomarkers of toxicity and have led to prospective genotyping and differential dosing recommendations for carriers of these variants, as noted on recent updates to the FDA label for the 5-FU prodrug capecitabine. Our previous studies also established the importance of epigenetic control of DPD expression. In this study, we used existing epigenetic repositories to identify candidate enhancer elements for *DPYD*. We selected 20 novel high-priority putative enhancers for further study using a combination of reporter assays and CRISPRi applied across multiple cell models. Further studies will investigate means to target these regulatory mechanisms as a means to increase localized efficacy of 5-FU-based therapies in colorectal cancer.

#3141 Integrative genomic analysis reveals pharmacogenomic determinants of chemotherapy response.

Djuraev Farrukh[1], yashodhara Bhattacharya[2], Mohan Uttarwar[2], Sandhya Iyer[2], Hrishita Kothavade[2], Mina Darooei[3], Madhura Basavalingegowda[2], Hetakshi Kurani[3], Bharat Bhosale[4], Aarthi Ramesh[2], Gowhar Shafi[3]

Background: Pharmacogenomic (PGx)markers are critical in understanding patient responses to chemotherapeutic agents. They influence how patients metabolize popular chemotherapeutic agents like fluoropyrimidines and irinotecan, thereby impacting efficacy and risk of severe toxicity. Although PGx testing significance is well established, their genomic profiling and clinical interpretation involves challenges including limited clinical evidence for many variants, incomplete capture of pharmacogenomic-relevant regions, tumor heterogeneity and sampling bias, and variant interpretation. Many cohort studies among the Uzbek population have also highlighted the challenges including the one among 99 Uzbek cancer patients (breast, gastric, colorectal) identified the clinically significant DPYD IVS14+1G>A splice-site variant, also known as the DPYD *2A allele in a significant fraction of individuals indicating that DPD-related 5-FU risk is present in the population and merits pretreatment consideration. Our current study presents the significance of a comprehensive genomic profiling (CGP) and interpretation of pharmacogenomic markers for effective chemotherapeutic performance in clinical scenario.

Methods: A total of 124 patients who were genomically profiled using our CGP assay was retrospectively investigated for pharmacogenomic variants. The cohort included cancer types including breast, colon, lung, melanoma, pancreatic, stomach, ovarian, rectal, and hepatobiliary tract. CGP was performed on these patients using next-generation sequencing (NGS) with the OncoIndx® panel.

Results: From the CGP results of the 124 profiled patients, three critical pharmacogenomic markers were detected. The DPYD wildtype genotype was detected in 92% (n=114) of patients which was interpreted to be associated with reduced risk of adverse events when treated with 5-FU/ fluoropyrimidine-based chemotherapy. Another 2.4% (n=3) of patients were detected with DPYD c.1129-5923C (HapB3) variant which was interpreted to impact DPYD function and can affect treatment outcomes leading to increased toxicity when treated with standard dosage of 5- FU / fluoropyrimidine-based- based chemotherapy. Further, 4% (n=5) were detected with wildtype genotype of TYMS, and 0.8% (n=1) heterozygous, and 4.8% (n=6) patients detected with 6bp deletion interpreted to cause increased toxicity/ADR. In addition, 9.7% (n=12) of patients were detected with UGT1A1 wildtype which determines response o irinotecan-based chemotherapy.

Conclusion: This study, highlights the significance of profiling and effective interpretation of a patient's PGx phenotype from the profiled genotype as a critical measure to lower risk of debilitating adverse events and guide towards safer, more effective dosing of chemotherapy.

#3142 Genomic determinants of response to the Wnt/Beta-catenin condensate modulator DPTX3186 in gastric cancer PDX models and implications for clinical development.

Francis Carpenter[1], Kip West[2], Doug Baumann[2], Adam Talbot[2], Thomas Durand-Reville[1], Karl Hsu[1], Ann Boija[1], **Isaac Klein**[1]

[1]Dewpoint Therapeutics, Inc., Boston, MA,[2]Dewpoint Therapeutics, Boston, MA

DPTX3186 is a first-in-class small molecule oral condensate modulator (c-mod) designed to disrupt oncogenic wnt/beta-catenin signaling in tumors selectively. DPTX3186 forces beta-catenin to concentrate within an inactive condensate inside tumor cells, resulting in malignant cell death *in vitro* and robust single-agent anti-tumor activity in wnt-driven tumor models *in vivo*. DPTX3186 has an open IND, has been granted Orphan Drug and Fast Track Designations, and is being tested in a combined Phase 1/2 trial focused on gastric cancer. To assess the therapeutic potential of DPTX3186 across gastric cancer and identify biomarkers predictive of high response, we tested DPTX3186 in a diverse panel of well-characterized gastric cancer patient-derived xenograft (PDX) models. Mice implanted with PDX-based tumors were treated with either DPTX3186 or vehicle, with tumor volume and body weight measured for up to 70 days following treatment initiation. Across models, treatment with DPTX3186 resulted in a statistically significant decrease in tumor volume growth, including stasis and regression (as measured by tumor growth inhibition, TGI), and a statistically significant increase in survival, without affecting body weight. Each of the PDX models implanted were characterized in terms of the patients' clinical, genomic, and transcriptomic profiles, enabling analysis of biomarkers that were predictive of increased TGI or survival when comparing DPTX3186 treated mice to vehicle mice. Through these analyses, we identify prevalent and clinically actionable genomic characteristics that predict an increased response to DPTX3186. Specifically, mutations in oncogenes that are associated with greater beta-catenin activity confer greater response to DPTX3186, reinforcing the specificity of the condensate mechanism for wnt-driven tumors. These results demonstrate the promising therapeutic potential of DPTX3186 in gastric cancer, outline our patient selection strategy for the ongoing clinical trial, and provide a roadmap for the clinical selection of high responders to condensate-modulating anti-cancer agents.

#3143 Co-targeting of two distinct androgen receptor-regulated signaling pathways as a therapeutic approach in prostate cancer.

Min-Yu Ko, Rachid Safi, Suzanne E. Wardell, Paige Watkinson, Isabel Jones, Brianna Richardson, John D. Norris, Donald P. McDonnell

Duke University School of Medicine, Durham, NC

Prostate cancer (PCa) is the most frequently diagnosed cancer in men and the second leading cause of cancer-related deaths in the United States. Androgen deprivation therapy (ADT) is initially effective; however, most patients eventually relapse and progress to castration-resistant prostate cancer (CRPC), where tumor growth persists despite being exposed to extremely low levels of androgens. In probing the molecular determinants of androgen receptor (AR) pharmacology in PCa, we made the unexpected observation that PCa cells can recognize and respond differently to different levels of androgens. Notably, we demonstrated that low levels of androgens, functioning through an AR monomer, facilitate a non-genomic activation of the mammalian target of rapamycin (mTOR) signaling pathway to drive proliferation. Conversely, we found that eugonadal levels of androgens (high dose; HD) promote AR dimer formation, which actively suppress c-MYC expression, inhibit proliferation, and drive a transcriptional program associated with a differentiated phenotype.

To elucidate the mechanism(s) by which AR activates mTOR signaling, we dissected the molecular events initiated by androgens in validated cellular models of PCa. These studies revealed that androgens, acting through AR, induce AKT phosphorylation at S473, an early and previously unrecognized regulatory node in AR-driven pathways. Prior studies have established that AKT S473 phosphorylation is mediated by mTOR complex 2 (mTORC2) and can be stimulated by insulin-like growth factor-1 (IGF-1). Indeed, we demonstrated that IGF-1 signaling was absolutely required for androgen-dependent mTOR activation and cell proliferation. These results suggest that androgens/AR act upstream of mTOR to amplify the activity of the IGF-1-AKT signaling axis rather than directly engaging mTOR pathway components.

While we have established that AR-driven mTOR activation occurs through the IGF-1-AKT axis, our data also revealed a distinct AR-regulated growth program centered on c-MYC. Notably, inhibition of the IGF-1-AKT-mTOR pathway suppresses PCa cell proliferation *in vitro* but fails to reduce c-MYC expression, indicating that targeting this axis alone is unlikely to achieve durable control of the disease. It is significant, therefore, that we determined that HD androgens downregulate c-MYC expression while maintaining mTOR activation. Leveraging these insights, we evaluated the utility of combining AKT inhibition with HD androgen treatment in a xenograft model of PCa. This combination strategy was superior to either treatment alone, resulting in robust suppression of tumor growth. Together, these findings establish a mechanistic framework for the dose-dependent effects of androgens on PCa biology and highlight the potential clinical utility of dual-targeting approaches to overcome resistance to standard of care treatments in PCa.

#3144 Targeting AR-SREBP crosstalk in prostate adenocarcinoma.

Sirisha Devarakonda, Prashanth Parupathi, Ekniel Francois, Avinash Kumar

Long Island University, Brooklyn, NY

Androgen receptor (AR) is a well-studied nuclear transcription factor responsible for the progression of prostate cancer. Prostate Cancer (PCa) is the most commonly diagnosed cancer and the second leading cause of cancer-related deaths among men in the United States, despite the availability of advanced AR inhibitors. Hence, there is an urgent need to identify alternative therapeutic targets and agents to supplement AR-based therapy. Sterol regulatory element-binding proteins (SREBPs) are a family of transcription factors, consisting of SREBP-1 and SREBP-2, that are responsible for de novo lipogenesis and cholesterol biosynthesis. Recent studies show that crosstalk between AR and SREBP promotes PCa progression. Consistent with this, we have observed that SREBP is overexpressed in the presence of AR. Therefore, we hypothesized that pharmacological inhibition of SREBPs might be a promising therapeutic approach in androgen receptor-positive PCa. In our study, we evaluated the anticancer activity of fatostatin, an SREBP inhibitor, in AR-positive PCa cell lines (LNCaP and C4) and AR-negative PCa cell lines (PC3 and Du145). We observed inhibition of viability, proliferation, migration, and invasion in all PCa cell lines. Additionally, we observed decreased protein and mRNA expression of SREBPs and AR in the fatostatin treatment group. Notably, fatostatin showed significantly more potent inhibition in AR-positive PCa cell lines compared to AR-negative PCa cell lines. To further understand the molecular mechanism of fatostatin in AR-positive PCa cell lines, we performed RNA-Seq, which revealed inhibition of AR signaling and cholesterol homeostasis. It was also observed that genes involved in mitotic spindle assembly and the mTORC1 pathway have been downregulated. Altogether, our data show that pharmacological inhibition of SREBP may be a potential therapeutic target in AR-positive prostate cancer.

#3145 Pharmacologic inhibition of SREBP-driven lipogenesis suppresses metastatic progression in prostate cancer.

Prashanth Reddy Parupathi[1], Sirisha Devarakonda[2], Ekniel Francois[3], Avinash Kumar[3]

[1]Department of Pharmaceutical Sciences, Long Island University, Greenvale, NY,[2]Long Island University, Greenvale, NY,[3]Long Island University, Brooklyn, NY

Prostate cancer (PCa) progression is increasingly recognized as a metabolically driven process, particularly through alterations in lipid metabolism. Sterol regulatory element-binding proteins (SREBPs) are master transcription factors that regulate genes involved in lipogenesis and are often upregulated in advanced prostate cancer, leading to aberrant lipid accumulation, and are associated with poor prognosis and disease progression. Despite advances in characterizing the metabolic phenotype of PCa, a critical gap remains in understanding how SREBP-driven lipid remodeling mechanistically contributes to the metastatic dissemination of PCa. Our analysis of publicly available patient datasets revealed increased gene expression of SREBPs in prostate tumors compared to normal prostate tissue. Furthermore, we observed substantially higher SREBP gene expression in metastatic samples compared to primary tumors. We also found notably higher levels of SREBPs in the more invasive PC3M and C4-2B cell lines than in their less invasive counterparts, PC3 and LNCaP. Based on these findings, we hypothesize that inhibition of SREBPs by fatostatin could be an effective therapeutic strategy against lethal metastatic prostate cancer. We found that fatostatin inhibited the viability, proliferation, clonogenic survival, migration, and invasion of the more invasive PCa cell lines, with significantly greater potency than in less invasive lines. Immunoblotting confirmed that fatostatin inhibited both SREBPs and their downstream targets more effectively in more invasive PCa cell lines than in less invasive ones. We then performed RNA-Seq and pathway analysis on all cell lines treated with fatostatin. We found that pathways related to EMT and mTORC1 are significantly downregulated in the more invasive prostate cancer cell lines compared to their less invasive counterparts. Overall, our results demonstrate that SREBP-driven lipid metabolism mechanistically contributes to PCa invasiveness and pharmacological inhibition of SREBPs may improve outcomes in lethal metastatic prostate cancer.

#3146 Targeting KMT2D enhances sensitivity to AKT inhibition in treatment resistant prostate cancer.

Abbas Jawadwala[1], Remi M. Adelaiye-Ogala[1], Surendra Gulla[1], Tej K. Sharma[2], Ephraim Jeremiah Gardner[1], Maddie Aust[2]

[1]University at Buffalo, State University of New York, Buffalo, NY,[2]University at Buffalo, Buffalo, NY

Prostate cancer (PCa) is the leading cause of cancer-related deaths in men, with over 299,000 new cases expected in the U.S. in 2024 alone. A loss-of-function mutation in the PTEN gene activates the PI3K-Akt-mTOR pathway, driving increased cell proliferation and metastasis. Prior studies from our group and others have shown that the AKT signaling pathway remains an attractive target in advanced prostate cancers and other solid tumors. In breast cancer, inhibition of the PI3K pathway has been shown to activate KMT2D, a histone lysine dimethyltransferase. Activation of KMT2D enhanced hormone-regulated gene expression and, in turn, enhanced the response to hormone-targeted therapies. We modified treatment-resistant human PCa cell lines (C4-2B ER, LREX) to suppress AKT isoforms using shRNAs. Using these models, we observed increased KMT2D expression and activity, as indicated by increased H3K4 dimethylation, with suppression of AKT2 and AKT3, but not AKT1, isoforms. In addition, we observed increased androgen receptor (AR) expression. Conversely, knocking down KMT2D in the C42B cell line resulted in a significant decrease in proliferation and increased sensitivity to the Akt inhibitor (Ipatasertib). Although preliminary, these findings suggest that KMT2D may be involved in cross-talk with the PI3K-AKT signaling pathway with implications for AR signaling.

#3147 Pinostilbene exhibits anticancer activity in advanced prostate cancer.

Ekniel Francois[1], Prashanth Reddy Parupathi[1], Sirisha Devarakonda[1], Avinash Kumar[2]

[1]Long Island University, Greenvale, NY,[2]Long Island University, Brooklyn, NY

Prostate cancer is the foremost incident cancer and the second major cause of cancer-associated mortality among men in the U.S. Although current therapies, involving androgen receptor (AR) pathway inhibitors have improved survival rates, advanced prostate cancer remains a lethal disease. Therefore, new therapeutic approaches should continue to be investigated. Previous studies from our group as well as others have widely demonstrated the anticancer activity of resveratrol and its analogs. However, pinostilbene, a monomethylated resveratrol analog, is less well studied and reports on its anticancer activity in prostate cancer is limited. In this study, we investigated the anticancer activity of pinostilbene in prostate cancer. We found that pinostilbene inhibited the viability, proliferation, and metastatic potential of all prostate cancer cell lines tested. Of note, pinostilbene exhibited significantly higher potency as an anticancer agent in more invasive compared to less invasive prostate cancer cell lines. Overall, our results demonstrate that pinostilbene shows tremendous potential as an anticancer agent for improved management of prostate cancer.

#3148 Human blood micronucleated reticulocytes: Application as a pharmacodynamic biomarker for DNA double strand breaks in oncology drug development.

Jeffrey C. Bemis[1], Colette Baxter[2], Gillian Langford[2], Timothy A. Yap[3], Susanna Varkey Ulahannan[4], Nehal Lakhani[5], Babar Bashir[6], Kathleen N. Moore[7], Payal Shah[8], Svetlana Avlasevich[1], Dorothea Torous[1], Stephen Dertinger[1]

[1]Litron Laboratories, Rochester, NY,[2]Artios Pharma Limited, Cambridge, United Kingdom,[3]UT MD Anderson Cancer Center, Houston, TX,[4]University of Oklahoma Health Sciences Center, OKC, OK,[5]START Midwest, Grand Rapids, MI,[6]Thomas Jefferson University Hospital, Philadelphia, PA,[7]OU Health Stephenson Cancer Center, Oklahoma City, OK,[8]Perelman Center for Advanced Medicine, Philadelphia, PA

Introduction: Micronucleated reticulocytes (MN-RET) are a well-established biomarker of chromosomal damage, and their assessment is traditionally included as part of regulatory-based, product safety testing during preclinical development. Adaptation of the methodology to high-throughput flow cytometric analysis broadened the utility of the assay and enabled practical translation to human subjects. Most recently, this methodology has been used to demonstrate target engagement via the induction of MN-RET as a biomarker of efficacy during the development of therapies targeting DNA double strand break-repair pathways.
Methods: To support this application, we have conducted studies in clinical models to define basic methodological parameters. In an effort to better understand baseline values over time/between subjects and reproducibility, we evaluated technical replicate variability in MN-RET frequencies based on blood specimens from 14 subjects. Intra-subject variability was based on serial blood draws from 6 subjects, and inter-subject variation was based on up to 344 subjects age 0 to 73 years.
Results: Human models demonstrate increased MN-RET frequencies following exposure to known DNA damaging agents. Inter-subject variation (≥77%) was much greater than intra-subject and technical replicate variability. The relatively large inter-subject variation is apparent from mean and standard deviation values for MN-RET (0.15 ± 0.10%). Neither age nor sex affected inter-subject variation of the MN-RET frequency. In a clinical setting, patients treated with PARP inhibitors at a labelled dose showed elevated MN-RETs, demonstrating the increased unrepaired DNA damage as an indicator of target engagement induced by treatment.
Summary: This translational biomarker of chromosomal damage represents a unique and powerful tool for use in the development of cancer therapies that elicit DNA double strand breaks.

#3149 Micronuclei (MN) dynamics in preclinical models and in patient reticulocytes as a pharmacodynamic biomarker for the first in class DNA polymerase theta (PolΘ) inhibitor ART6043.

Colette L. Baxter[1], Timothy A. Yap[2], Susanna V. Ulahannan[3], Nehal Lakhani[4], Minal Barve[5], Erika P. Hamilton[6], Babar Bashir[7], Helen M. R. Robinson[1], Jayesh B. Majithiya[1], Paula Costales[1], Sarah V. Holt[1], Samantha C. Skelton[1], Marina Roy-Luzarraga[1], Jeff C. Bemis[8], Dorothea Torous[8], Svetlana Avlasevich[8], Susana Barriga[1], Bryony Harrop[1], Gillian A. Langford[1], Ian Smith[1], Graeme C. M. Smith[1]

[1]Artios Pharma Ltd, Cambridge, United Kingdom,[2]UT MD Anderson Cancer Center, Houston, TX,[3]University of Oklahoma Health Sciences Center, OKC, OK,[4]START Midwest, Grand Rapids, MI,[5]SCRI at Mary Crowley, Dallas, TX,[6]Sarah Cannon Research Institute, Brentwood, TN,[7]Thomas Jefferson University Hospital, Philadelphia, PA,[8]Litron Laboratories, Rochester, NY

Introduction: ART6043 is a first in class, potent and selective polymerase domain inhibitor of DNA Polθ, a central mediator of the microhomology-mediated end joining (MMEJ) DNA double strand break (DSB) repair pathway. Novel biomarkers are important to demonstrate target engagement of ART6043. Polθ knock out mouse studies highlighted increased levels of MN in mouse reticulocytes (RETs) and normochromatic erythrocytes since MN are a common hallmark of genome instability. Here we describe the utility of an assay designed to monitor MN induction in reticulocytes from both preclinical models and patient samples to evaluate Polθ inhibition.
Methods: This analysis builds on the MN-RETs assay, which is traditionally used as a preclinical toxicology assessment (Tometsko et al., 1995). This assay involves fixing whole blood, isolating reticulocytes (specifically in the human assay), and labelling them for nucleic acids to stain any MN. High throughput flow cytometry is then used to quantify the number of reticulocytes with MN.
Results: These data demonstrated the utility of MN-RET as a target engagement biomarker for ART6043 in preclinical studies and in the subsequent clinical study (NCT05898399). In preclinical xenograft models ART6043 monotherapy and ART6043 in combination with olaparib induces MN-RET at doses where tumor regressions occurred. The MN-RET data evaluated in the phase 1 trial of ART6043 mirrored the preclinical data. Patients treated with the highest dose of ART6043 evaluated as monotherapy had elevated MN-RETs, while patients treated with ART6043 in combination with olaparib had statistically higher MN-RET levels. This suggests that the combination of two DNA repair pathway inhibitors, targeting separate mechanisms, leads to a synergistic increase in DNA damage.
Summary: The increase in MN-RETs observed in patients dosed with ART6043 has demonstrated target engagement of a Polθ inhibitor for the first time in humans. MN-RETs has demonstrated potential utility as a mechanism of action target engagement biomarker for a range of therapeutics targeting different DNA damage repair pathways.

#3150 InVEST44™ is a cost-effective *in vitro* safety panel that identifies off-target effects in early-stage drug discovery.

Julian R. Wooltorton, Afsara Ahona, Nicole Barbacane, Alex D'Andrea, Justin Lansberry, Cindy Lay, Paige Miller, John Ries, Jamin Steffen, Patricia Valentine

Reaction Biology Corporation, Malvern, PA

Drug development costs exceed $172m and increase to over $500m when clinical trial failures are considered (Sertkaya 2024, DOI: 10.1001/jamanetworkopen.2024.15445). It can take 20 years to bring a drug to market so it is critical to identify safety liabilities early in the discovery process to ensure valuable time and money are not invested in preclinical and clinical trials. In vitro safety panels, such as InVEST44™, can identify potential toxicities of drugs cost-effectively during early-stage drug development. This is particularly relevant as, between 2006 and 2023, the proportion of venture capital investments in early-stage drug discovery has decreased from 50% to 16% while increasing for later stage from 20 to 54% (*The Biopharma Industry Investment Report 2015*. Biotechnology Innovation Organization; Larka 2024, *Trends in Venture Capital Funding for Biopharma Startups*. GlobalData). This highlights a trend towards expensive, high-risk but potentially lucrative, clinical trials and away from early drug discovery. The goal is to demonstrate that early-stage in vitro safety panels are fiscally and scientifically critical steps in drug development to identify off-target effects before advancing drugs to animal testing and clinical trials. InVEST44™ is an in vitro safety panel designed to identify off-target effects of lead compounds for oncology and other therapeutic areas in early-stage drug development, ensuring a more efficient path from discovery to clinical trials. It comprises 44 industry standard, high risk targets based on Bowes et al. (2012; DOI: 10.1038/nrd3845), including GPCRs, transporters, ion channels, nuclear receptors and enzymes. Various assay types are utilized, including radioligand binding, fluorescence polarization, enzymatic activity, cell reporter, calcium mobilization and electrophysiology assays. We identified 20 drug candidates from 17 failed clinical oncology trials between 2001 and 2025, all terminated because of reported severe adverse effects (clinicaltrials.org). These were screened at 10 µM in InVEST44™: 17 drugs elicited >50% effect on at least 1 target, including 8 with 4+ target interactions and one interacting with 15 safety targets. This study demonstrates the importance of in vitro safety panels, such as InVEST44™, by identifying off-targets effect of lead compounds before pursuing time-consuming and expensive animal testing and potentially failed clinical trials. Data from such panels are increasingly being provided to enhance IND applications (Scott, 2022, DOI: 10.1016/j.vascn.2022.107205). In summary, by providing cost-efficient, early-stage identification of off-target effects by lead compounds, in vitro safety panels, such as InVEST44™, have become integral components of drug discovery and warrant increased early-stage consideration and investment in the future.

#3151 High-throughput high-plex proteomic profiling of hepatocyte toxicity to oncologic drug compounds: A platform for toxicity assessment, immune risk prediction, and drug development acceleration.

Nicole Paul, Alyssa Rosenbloom, Nathaniel Robichaud, Kiran Edwardson, **Nathan Chang**, Narges Rashidi, Milad Dagher

Nomic Bio Inc, Montreal, QC, Canada

The rapid and necessary expansion of cancer drug development requires accessible and scalable strategies for early toxicity screening and immune risk profiling. Liver plays a central role in drug metabolism, detoxification, and immune modulation. Robust detection of liver-specific responses to oncologic therapeutics is essential to identify and mitigate hepatotoxicity and immune-related adverse events (irAEs) which could limit clinical development. Here, we demonstrate a high-throughput, high-plex proteomic platform as a powerful approach to evaluate functional perturbations of hepatocytes across a spectrum of cancer drugs.Utilizing the novel Omni 1000 proteomic solution, based on nELISA technology, we profiled 1,000 proteins in >6500 samples of primary human hepatocytes following exposure to a diverse panel of over 550 distinct drug compounds at 3 doses per compound. Omni 1000 protein target content enables simultaneous quantification of stress response markers, inflammatory cytokines, metabolic enzymes, and signaling pathway effectors. This allows for evaluation of both cytotoxic and immunomodulatory signatures. Perturbation with tripolide, doxorubicin, and cobimetinib resulted in dose dependent cell toxicity, detected via increased levels of intracellular proteins such as GAPDH and Casp3 released into the supernatant, consistent with clinically observed hepatotoxicity. We also detect increased Galectin-3, Galectin-1, and VEGFA at non-toxic perturbation doses, indicative of cell stress and potential toxicity at higher doses. In addition, we concurrently observe loss of proteins associated with protection against apoptosis, such as ST6GAL1, a potent inhibitor of FAS-mediated apoptosis. Across the 510 compounds screened, 68 showed similar signs of toxicity, including compounds with dose-limiting liver toxicity in the clinic. Of particular note is PHA-793887, a potential therapeutic candidate, which failed clinically due to unexpected hepatotoxicity, which here was captured in a pre-clinical *in vitro* model.We further demonstrated the platform's ability to identify likely irAEs through detection of dose dependent increases in key cytokines. Hepatocytes perturbed with Imatinib and Pomalidomide demonstrated increases in IL-6, IL-10, and IL-2, indicative of potential irAE and consistent with published literature for these drugs.High-throughput high-plex proteomic analysis of hepatocyte responses offers a significant advance in preclinical toxicology and immune safety, and enables an early stage indication of drug-induced liver injury (DILI) risk and immunotoxic potential, two major barriers in oncology drug development.

#3152 Development of iPSC-derived human liver organoids for preclinical drug testing and toxicology studies.

Fong Cheng Pan[1], Mahi Rahman[1], David Austin[2], Stephan Krieg[3], Luisa Marie A. Pfeifer[3], Anthony Saporita[1], Philip Hewitt[4], Steven Johnston[5], Laura Braeuninger-Weimer[4], Willem Kools[6], Vi Chu[1]

[1]MIlliporeSigma, Temecula, CA,[2]R&D, MIlliporeSigma, Temecula, CA,[3]Discovery Toxicology, Merck KGaA Darmstadt, Darmstadt, Germany,[4]Merck KGaA Darmstadt, Darmstadt, Germany,[5]Merck KGaA Darmstadt, Tempe, AZ,[6]MIlliporeSigma, Burlington, MA

Background and Purpose: Over 90% of drug candidates fail during clinical trials, often due to insufficient efficacy and unmanageable toxicity. Drug-induced liver injury (DILI) is frequently missed in preclinical testing due to a lack of robust and predictive liver models. We report the de novo development of iPSC-derived human liver organoids as scalable, reliable, and physiologically relevant preclinical toxicology models.

Methods: Using an efficient and reproducible iPSC-differentiation protocol, we generated long term expandable, cryopreservable bipotential 3dGRO^{TM} Human iPSC-derived Liver Progenitor Organoids, which differentiate into mature liver organoids (MLOs) containing multiple liver cell types.

Results: The iPSC-derived mature liver organoids display long-term stability, secrete albumin and urea, and express key biomarkers of mature hepatocytes (albumin, CYP3A4, HNF4a, PCK2) and cholangiocytes (Sox17, Sox9, CK7, MRP2). They also exhibit functional Phase I/II liver enzymes (CYP3A4, CYP2C9, CYP1A2, ALT, AST, GST) and active bile salt/drug transporters. Compared to primary hepatocytes, our 3dGRO^{TM} Human iPSC-derived Mature Liver Organoids demonstrate comparable functionality and outperform HepG2 cells and liver spheroids. In DILI assays, MLOs responded to drug treatment with elevated liver enzymes, confirming their potential for toxicology screening.

Conclusion: These liver organoids represent a powerful tool for high-throughput drug screening, DMPK and toxicological studies, with future applications including disease modeling of hepatocellular carcinoma, MASLD, and NASH.

#3153 An integrated *in vitro* profiling platform for the simultaneous assessment of anti cancer efficacy and multi organ toxicity.

Xia Tu, Hao Wen, Dawei Yan, Jingna Ren, Qin Guo, **Peichuan Zhang**, Haiheng Dong

WuXi AppTec, Shanghai, China

The high attrition rate of oncology drug candidates is frequently driven by an insufficient understanding of a compound's therapeutic index early in development. Many promising molecules advance based on potent efficacy, only to fail later due to unanticipated safety concerns. To address this, there is a critical need for a comprehensive *in vitro* strategy that can simultaneously and systematically evaluate anti-cancer activity and organ-specific toxicity risks in the preclinical phase, enabling more informed and de-risked candidate selection.

To address this gap, we developed an integrated *in vitro* profiling platform that synergizes a robust Efficacy & Mechanism Module with an extensive Early Safety & Toxicity Module. The efficacy module delivers a multi-faceted assessment of anti-tumor potential, beginning with high-throughput viability screening across a diverse panel of human cancer cell lines to determine potency and selectivity. It can be further implemented by functional phenotyping assays including angiogenesis, migration, and invasion to evaluate anti-metastatic potential. Furthermore, downstream molecular investigations via qPCR and Western Blot analysis elucidate mechanisms of action and target engagement. The safety module employs a battery of specialized assays in relevant normal cell models to proactively identify a broad spectrum of adverse effects, encompassing organ-specific toxicities such as hepatotoxicity, nephrotoxicity, cardiotoxicity, and neurotoxicity, alongside general toxicological concerns including mitochondrial toxicity, genotoxicity, and phototoxicity. By integrating these rich datasets, our platform empowering the selection of safer and more effective lead compounds for successful translational development.

#3154 Novel inhibitors of BCRP and P-gp found among drugs used in the treatment of cancer.

Martina Timonen, Feng Deng, Mikko Niemi

Clinical Pharmacology, University of Helsinki, Helsinki, Finland

Breast cancer resistance protein (BCRP) and P-glycoprotein (P-gp) are ATP-binding cassette transporters involved in clinically relevant drug-drug interactions (DDI). This study aimed to identify new BCRP and P-gp inhibitors among used in the treatment of cancer, as the inhibition by many commonly used anticancer and supportive care drugs remains unclear. A total of 133 drugs were screened at 50 µM for inhibition of BCRP and P-gp using a transport assay with BCRP or P-gp-expressing membrane vesicles. Following initial screening, 50% inhibitory concentrations (IC_{50}) were predicted, and the most potent inhibitors were selected for experimental IC_{50} determination. The risks of intestinal and systemic inhibition of BCRP and P-gp were assessed by comparing the estimated intestinal concentration (I_2; dose/250 ml) and maximum plasma concentration (I_1) to the IC_{50} values. If the I_2/IC_{50} ratio surpassed 10 or the I_1/IC_{50} ratio exceeded 0.1, in vivo inhibition was considered possible. Mechanistic static modelling was then utilized to assess the risk of a pharmacokinetic DDI in humans. Following initial screening, 24 and 23 drugs were selected for the determination of IC_{50} values for BCRP and P-gp, respectively. Of the investigated compounds, cabozantinib (IC_{50} of 0.65 µM), midostaurin (0.69 µM), and entrectinib (5.8 µM) showed the strongest inhibition of BCRP. Nilotinib (1.0 µM), osimertinib (2.0 µM), and abemaciclib (2.4 µM) showed the strongest inhibition of the P-gp. The highest I_2/IC_{50} ratios for BCRP were observed for mitotane (6190), cabozantinib (1730), and abiraterone (831). For P-gp, the highest I_2/IC_{50} ratios were observed for nilotinib (2880), pazopanib (1580), and mitotane (1480). These compounds might therefore inhibit BCRP or P-gp in the intestine. The highest I_1/IC_{50} ratios for BCRP were observed for doxorubicin (8.2), etoposide (2.8), and fosaprepitant (0.84). For P-gp, the highest I_1/IC_{50} ratios were observed for amscarine (1.6), vinorelbine (0.55), and fosaprepitant (0.50). These compounds might therefore inhibit systemic BCRP or P-gp. Mechanistic static model for BCRP inhibitors suggested that cabozantinib, midostaurin, and apalutamide could almost fully inhibit intestinal BCRP, increasing the exposure to concomitantly administered rosuvastatin by 94%, 89%, and 83%, respectively. Similarly, mechanistic static model for P-gp inhibitors suggested that sorafenib, cabozantinib, and nilotinib could almost fully inhibit intestinal P-gp, increasing the exposure to concomitantly administered dabigatran etexilate by 124%, 123%, and 115%, respectively. Our findings identified multiple novel BCRP and P-gp inhibitors, which may cause transporter-mediated DDIs in cancer treatment. Clinical DDI studies are warranted to investigate the potential interactions in humans.

#3155 Pharmacokinetic/pharmacodynamic correlation and biodistribution of Re (CO)3-phenformin compared with phenformin in murine PDAC model following equimolar intravenous dosing.

Amir Mohammad Gholizadeh[1], Fatima Dagher[1], Mikayla Skillman[1], Airong Li[1], Chun Li[2], Diana S-L Chow[1]

[1]University of Houston, Houston, TX,[2]UT MD Anderson Cancer Center, Houston, TX

Re (CO)3-phenformin (Re-phen) is a newly synthesized rhenium biguanide complex recently reported and structurally characterized as a potential anticancer agent. However, a comprehensive evaluation of its *in vivo* pharmacokinetics (PK), biodistribution (BD), metabolic fate, and PK/pharmacodynamic (PK/PD) properties has not yet been characterized. In this study, we conducted an integrated PK, BD, and PK/PD analysis of Re-phen compared with Phenformin (Phen) following three consecutive equimolar intravenous doses (26.26 µmol/kg per dose) in PDAC-bearing mice, with additional quantification of *in vivo* biotransformation of Re-phen to Phen to support parent metabolite exposure modeling. Blood collected after the final dose and major organs (tumor, pancreas, liver, kidney, spleen, lung) were analyzed using a rigorously validated LC-MS/MS assay. Re-phen achieved markedly higher tissue deposition than Phen across all organs, including tumor (3.05 ± 1.86 vs 0.05 ± 0.02 nmol/g, **p<0.01), pancreas (61.64 ± 36.24 vs 0.08 ± 0.05 nmol/g, **p<0.01), liver (38.27 ± 20.08 vs 0.16 ± 0.06 nmol/g, ***p<0.001), kidney (22.27 ± 5.80 vs 0.08 ± 0.03 nmol/g, ****p<0.0001), spleen (4.60 ± 1.36 vs 0.29 ± 0.07 nmol/g, ****p<0.0001), and lung (4.51 ± 1.40 vs 0.13 ± 0.04 nmol/g, ****p<0.0001), demonstrating extensive distribution and preferential tissue retention. Re-phen also exhibited measurable *in vivo* conversion to Phen, with a fraction metabolized (Fm) of ~11% and an AUC Ratio (Phen/Re-phen) of 0.22, indicating that both the parent compound and its converted Phen contribute to systemic exposure. 3D PK/PD analysis demonstrated a statistically significant inverse correlation between the AUCs of Re-Phen and its metabolite Phenformin and terminal tumor weight. By comparison, Phenformin exhibited only a moderate, non-significant 2D correlation with tumor weight ($r = -0.800$, $p = 0.1333$), supporting the superior antitumor efficacy of Re-Phen. These results indicate that Re-phen displayed a clear exposure-efficacy relationship and that systemic exposure is a key driver of its anti-tumor response. Collectively, this study provides the first comprehensive *in vivo* evidence defining the PK, biodistribution, metabolic conversion, and PK/PD behavior of Re-phen, highlighting its superior tumor delivery, measurable parent-metabolite interplay, and strong exposure-driven antitumor effect. These findings support further development of Re-phen as a rhenium-based therapeutic and as a core component of the Re/99mTc-phen theranostic platform for pancreatic cancer.

#3156 Pharmacokinetics of a series of anticancer agents in immunodeficient female NOD scid gamma mice.

Mohd Beshr Chama[1], Emily J. Koubek[2], Sarah A. Buhrow[3], Renee A. Schoon[1], Joel M. Reid[3]

[1]Oncology Department, Division of Oncology Research, Mayo Clinic, Rochester, MN,[2]University of Michigan, Ann Arbor, MI,[3]Mayo Clinic, Rochester, MN

Introduction: We aimed to characterize the preclinical pharmacokinetics (PK) of a series of 20 anticancer agents in highly immunodeficient female NOD scid gamma (NSG) mice to provide clearance and exposure data for agents under investigation by the NCI PDX Development and Trial Centers Research Network (PDXNet).
Methods: The series of 20 anticancer agents (inhibitors of CDK4/6, PI3K-β/PI3K-δ, ATR, MEK1/2, PI3K, microtubule, EZH2, BCL-2, PARP, histone deacetylase, γ-secretase, FGFR, SHP2, and ERK1/2, as well as a SMAC mimetic) were administered to female NSG mice via IV, PO, or IP routes to characterize plasma exposures under conditions used for PDX efficacy testing. Serial plasma samples were collected 15, 30, 60, 120, 240, 360, 480, and 1440 minutes after dosing. Drug concentrations were quantified using validated LC-MS/MS assays. PK parameters were calculated using non-compartmental analysis.
Results: The PK for each agent was determined, and the clearance and half-life values are listed in the table below. The PK metrics for Navitoclax could not be calculated. Due to higher metabolic rates, mice show faster PK processes. They generally had shorter half-lives and higher weight-normalized clearance than humans. Copanlisib, Navitoclax, and Trametinib were exceptions.
Conclusion: These PK data are critical for understanding the antitumor activities of agents studied by the PDXNet and will aid investigators in developing new approach methodologies for preclinical safety studies in preparation for human clinical trials.

Pharmacokinetic Analysis

Agent	Clearance (L/hr*kg)	Half-life (Hours)
abemaciclib	1.32	10.99
AZD8186	4	2.42
BAY-1895344	1.77	4.72
birinapant	4.19	8.47

RO4929097	1.01	4.2
rogaratinib	0.46	3.86
romidepsin	6.2	14.38
selumetinib	0.77	5.91
SHP099	0.35	55.12
talozoparib	0.295	4.26
trametinib	0.31	37.47
ulixertinib	0.32	2.48

#3157 Pharmacokinetic/pharmacodynamic correlation and biodistribution of paclitaxel and cyclopamine from M-CPA/PTX in HCC mice following multiple dosing.

Emanuel R. Baltrip[1], Lu Dai[2], Qiu-Xu Teng[3], Defeng Deng[3], Guodong Zhang[3], Chun Li[3], Diana S.-L. Chow[2]

[1]Pharmacological and Pharmaceutical Sciences, University of Houston, Houston, TX,[2]University of Houston, Houston, TX,[3]UT MD Anderson Cancer Center, Houston, TX

Hepatocellular Carcinoma (HCC) is the most common form of liver cancer, highly aggressive and heterogenous. Due to lack of effective diagnostic techniques, HCC is often detected when surgical and chemotherapeutic interventions are inadequate. To address this, we developed a polymeric micelle containing Paclitaxel (PTX), a microtubule-stabilizer, and Cyclopamine (CPA), a Hedgehog pathway inhibitor, termed M-CPA/PTX. The M-CPA/PTX contained 2.5 mg each of PTX and CPA, with size of 70.6 ± 3.4 nm, PDI of 0.12 ± 0.04 (n = 3), and encapsulation efficiency of ≥ 80% for both agents. The biodistribution (BD) of PTX and CPA in tumor, liver, lung, spleen and kidney were characterized following IV dosing of 5 mg/kg M-CPA/PTX in C-MYC expressing transgenic mice which were randomized into four groups: vehicle (n = 10), 1 dose (n = 8), 2 doses (n = 7), and 3 doses (n = 9). ANOVA with Tukey's post hoc test was for statistical analysis with p-value < 0.05 for significance. The BD data were compiled in Table 1. The blood concentrations for each agent were substantially lower than those in tumor and organs at 24 hours post the last dose. The BD patterns were distinct between PTX and CPA. The PTX concentrations were the highest in tumor, 369-443 ng/g, followed by liver >> lungs> kidney >> spleen, 11-15 ng/g. The CPA concentrations were high in lungs, 537-751 ng/g, and kidney, 305-339 ng/g, followed by tumor, 218-300 ng/g, and liver, 206-328 ng/g. The BD levels were not significantly altered among the dosing groups. The 3D PK/PD correlation was established for tumor growth inhibition (%), with tumor concentrations of PTX and CPA in individual mice. In conclusion, the biodistributions of PTX and CPA following multiple IV dosing in an HCC mouse model were characterized, and a 3D PK/PD correlation was established with PX and CPA uptakes in tumor, potentially enabling future efficacy projection.Table 1: Biodistribution of PTX and CPA from M-CPA/PTX

#3158 Pharmacokinetic and biodistribution evaluation of nebivolol and dasatinib in the 4T1 triple-negative breast cancer model: Implications for drug-drug interaction.

Airong Li[1], Mikayla Skillman[2], Junhyoung Park[3], Fatima Dagher[2], Amir M. Gholizadeh[2], Emanuel Baltrip[2], Meghana Trivedi[2], Benny A. Kaipparettu[3], Diana S.-L. Chow[2]

[1]College of Pharmacy, University of Houston, Houston, TX,[2]University of Houston, College of Pharmacy, Houston, TX,[3]Department of Molecular and Human Genetics, Baylor College of Medicine, Houston, TX

Background: In our recent *in-vitro* study, nebivolol (NEB) and dasatinib (DAS) synergistically inhibited the growth of 4T1 cell line, which is a murine mammary carcinoma cell line used to study triple-negative breast cancer (TNBC). However, the in vivo disposition and potential for drug-drug interactions (DDI) are not well defined. This study aimed to characterize the pharmacokinetics (PK) and biodistribution of NEB and DAS in 4T1 tumor-bearing mice and evaluate whether co-administration modifies plasma or tissue concentrations.

Methods: Female BALB/c mice (7-8 weeks) were implanted with 4T1 cells orthotopically and treated with NEB (n=5), DAS (n=5), or NEB+DAS (n=6). The regimen was NEB 10 mg/kg once a day and DAS 20 mg/kg twice a day, 5 days/week for 3 weeks. After the last dose, blood was collected at multiple time points and tissues (tumor, liver, kidney, lung, spleen, heart, pancreas, and brain) were harvested at the end. Drug concentration was quantified using a validated LC-MS/MS method. PK parameters were generated by Phoenix (8.5.1) and GraphPad 10 was used to generate the PK profile and statistical analysis.

Results: Co-administration significantly increased NEB exposure in blood, of which the area under curve (AUC normalized by dose) was 229.45±150.98 hr*ng/mL/(mg/kg), compared to 44.51±10.21 hr*ng/mL/(mg/kg) in the NEB alone group ($p<0.05$). The NEB clearance was decreased from 24.06±7.13 to 5.59±2.88 L/(kg*hr) ($p<0.05$). DAS concentration and parameters were not changed significantly in combination group vs. DAS alone group. Biodistribution analysis modified tissue partitioning in the combination group. NEB concentrations in all tissues were higher in combination group than NEB alone group ($p>0.05$ due to the large variance). Tissue-to-blood (T/B) ratios interpreted the tissue uptake of drugs. T/B ratios of both drugs in tumor, liver, lung, spleen, kidney and pancreas were over 1, indicating preferential tissue accumulation. Even though the T/B ratios in tumor were higher in NEB (32.27±61.87) and DAS (99.45±179.53) alone groups than the combination group (2.53±2.25, 3.73±2.41, respectively), no significant difference was observed due to the large variance, suggesting that co-administration can influence intratumoral delivery. The ratio (T/B) of DAS in the kidney was significantly elevated under combination dosing compared with DAS alone, which indicated more DAS accumulation in combination treatment.

Conclusions: Combination dosing led to a higher exposure of NEB in blood with a lower clearance, and an increased renal distribution of DAS. Distribution shifts indicated a drug-drug interaction. These findings provide a foundational framework for mechanistic PK/PD modeling and support further investigation of NEB+DAS combination for TNBC treatment.

#3160 Synergistic preclinical activity of dual CDK4/6 and mTORC1 inhibition in translocation renal cell carcinoma.

Shikha Gupta[1], Prateek Khanna[1], Eddy Saad[1], Renee Maria Saliby[2], Shatha AbuHammad[3], Jiao Li[1], Bingchen Li[1], Prathyusha Konda[1], Usman Ali Ahmed[1], Ananthan Sadagopan[1], Qingru Xu[1], Ziad El Bakouny[4], Wenxin Xu[1], Ramaprasad Srinivasan[5], Toni K. Choueiri[1], Srinivas R. Viswanathan[1]

[1]Department of Medical Oncology, Dana Farber Cancer Institute, Boston, MA,[2]Yale University, New Haven, CT,[3]Krantz Family Center for Cancer Research, Mass General Hospital, Boston, MA,[4]Memorial Sloan Kettering Cancer Center, New York, NY,[5]National Cancer Institute, Bethesda, MD

Background- Translocation renal cell carcinoma (tRCC) is an aggressive subtype of RCC driven by a gene fusion involving a transcription factor in the MiT/TFE gene family, most commonly TFE3. There are currently no approved therapeutic agents specific to tRCC and this subtype of kidney cancer represents a major unmet medical need.
Methods- We utilized integrative genomic approaches associated with activation of the cyclin- dependent kinase 4/6 (CDK4/6) and mammalian target of rapamycin complex 1 (mTORC1) signaling in tRCC. We tested the activity of CDK4/6 inhibitors (CDK4/6i), alone or in combination with mTORC1-selective inhibition, using *in vitro* and *in vivo* models of tRCC.
Results- Our work shows that tRCC tumors harbor multiple genomic and transcriptional features associated with activation of the CDK4/6 and mTORC1 signaling pathways. Pharmacological inhibition of CDK4/6 activity using palbociclib or abemaciclib, causes cell cycle arrest which was also recapitulated upon genetic knockout of CDK4/6 using CRISPR-Cas9. This was further accompanied by impaired cell growth in long-term culture in presence of palbociclib with a rapid cell regrowth observed upon drug withdrawal. CDK4/6 proteins regulate G1-S cell cycle progression by combining with CyclinD1, the expression of which is significantly reduced upon treatment with mTORC1-selective inhibitor, RMC-5552. Combined treatment with the CDK4/6 inhibitor, palbociclib, and RMC-5552 resulted in synergistic suppression of tRCC cell viability and increased markers of apoptosis *in vitro*. The combination of palbociclib and RMC-5552 in a tRCC xenograft model showed greater efficacy than either single agent while also being well-tolerated.
Conclusions- Our work suggests that combined inhibition of CDK4/6 and mTORC1 activity has therapeutic potential in tRCC. This work may offer rationale for molecularly directed therapies in tRCC, which currently lacks any standard of care.

#3162 Assessing statin sensitivity and hypoxia regulation in aggressive metastatic cancers.

Jimin Kim[1], Shannon Shams[1], Diana Vaca[1], Junhui Hu[1], Moe Ishihara[1], Khiara Threets[2], Robert Damoiseaux[1], Lily Wu[1]

[1]UCLA, Los Angeles, CA,[2]Clark Atlanta University, Atlanta, GA

Statins are a class of small molecule, FDA approved drugs that are widely used to combat cardiovascular disease due to their cholesterol lowering effects. Traditionally, they are competitive inhibitors of HMG-CoA Reductase (HMGCR), a critical enzyme involved in cholesterol synthesis. Previous studies in our lab highlighted that various kinds of statins can effectively kill metastasis-driving clear cell renal cell carcinoma (ccRCC) cells that are von Hippel-Lindau gene (VHL) negative, hypoxia inducible factor (HIF)-1α dominant, while sparing the less aggressive VHL positive, HIF-2α dominant cells. Similar to this metastasis driving ccRCC subpopulation, other aggressive cancers such as triple negative breast cancer (TNBC), and neuroendocrine prostate cancer (NEPC) share the same features of HIF-1α dominance and statin sensitivity. While statins' cytotoxicity for cancer is well documented, there is still no consensus on their mechanism of action nor is there a rationale explaining why statins are better at killing aggressive cancers. Our findings suggest that HIF-1α could be the target in statin metastasis-blocking mechanism, rather than its known cholesterol-lowering action. This project uses a multi-pronged approach involving qRT-PCR, western blot, and Clustered Regularly Interspaced Short Palindromic Repeats (CRISPR) knockouts to rule out the role of HMGCR and the cholesterol pathway in statin cytotoxicity in all three cancer models (ccRCC, TNBC, and NEPC). By understanding the possible role that the HIF-1α proteins play in mediating statin sensitivity, we aim to further clarify their mechanism of action in aggressive metastatic cancers and make a step forward in developing a new safe and effective drug that can both prevent and treat these cancers.

: Targeting Cell Surface Vulnerabilities to Overcome Therapeutic Resistance
Poster Session

#3166 TKI adaptive resistance in HER2-driven non-small cell lung cancer at minimal residual disease stage can be targeted using cell surface-directed therapies.

Manale El Kharbili[1], Daniel Wilkinson[2], Lauren Giesy[3], Sharon R. Pine[4], Peter Fecci[2], Kyle Concannon[1]

[1]Medical Oncology, The University of Colorado Anschutz Medical Campus, Aurora, CO,[2]Neurosurgery, The University of Colorado Anschutz Medical Campus, Aurora, CO,[3]University of Colorado Anschutz Medical Campus, Aurora, CO,[4]University of Colorado-Anschutz Medical Campus, Aurora, CO

Background: HER2 mutations drive 1-2% of non-small cell lung cancers (NSCLCs), and recent HER2-directed antibody-drug conjugates and tyrosine kinase inhibitors (TKIs) such as trastuzumab-deruxtecan and zongertinib have significantly improved outcomes. However, these approaches remain non-curative, and nearly all patients develop progressive disease. Novel strategies capable of eliminating minimal residual disease (MRD) are urgently needed. Generating cell-surface-directed therapies that recognize cell membrane proteins present or upregulated upon TKI adaptation remain underdeveloped in the HER2 space due to lack of cell surface dynamic characterization.
Methods: HER2-mutant NSCLC cell lines were treated with zongertinib at varying doses to establish sensitivity values (CellTiter-Glo). A HER2-mutant, zongertinib-insensitive small cell lung cancer line (H446) served as a negative control. Total and cell surface expression of targetable receptors and markers amplified in lung cancers were quantified by western blot and flow cytometry in both, TKI-naïve and TKI-tolerant states (IC50 and IC90 zongertinib exposure). HER2-driven (TKI sensitive and resistant) and control lines were then treated with cell-surface-directed therapies for 24 hours and evaluated for their toxicity.
Results: We demonstrate that HER2-mutant NSCLC cell lines retained demonstrated dynamic changes in cell surface protein expression in treatment-naïve versus zongertinib-induced MRD states. TKI-sensitive and TKI-resistant HER2-driven lines demonstrated high sensitivity to therapies targeting surface proteins, which correlated with their level of expression.
Conclusions: HER2-driven NSCLC cell lines present dynamic changes in cell surface proteins when undergoing TKI treatment. These proteins can be successfully targeted to eradicate residual NSCLC after TKI treatment, supporting this avenue as a rational therapeutic strategy for eradicating MRD and preventing relapse in HER2-mutant NSCLC. Ongoing studies will inform advancement toward early-phase clinical trials with curative intent.

#3167 Preclinical efficacy of a first-in-class anti-ALCAM ADC in hard-to-treat solid and hematologic malignancies.

Qinhong Ma, Daizong Li, Kewei Zhao, Mary Q. Xu, Mason Lu

MedAbome, Inc., Fremont, CA

ALCAM (CD166) is a type I transmembrane glycoprotein that mediates cell-cell adhesion through homophilic ALCAM-ALCAM and heterophilic ALCAM-CD6 interactions. ALCAM is aberrantly overexpressed across a variety of solid and hematologic malignancies. Using our proprietary live-cell immunization (LC-I) and high-throughput screening (LC-HTS) platforms, we developed MAb52-29.1, an anti-ALCAM monoclonal antibody that selectively recognizes a tumor-restricted conformational epitope of ALCAM, exhibiting minimal or no cross-reactivity with normal cells or tissues. Both the chimeric and humanized versions of MAb52-29.1 exhibited high binding affinities to recombinant ALCAM-ECD ($K_D \approx 1.1$ nM). MAb52-29.1 cAb, containing two point-mutations in each Fc, was conjugated to MMAE through an MC-Vc-PAB linker to produce MAb52-29.1-ADC (DAR4). MAb52-29.1-ADC demonstrated potent antiproliferative effects *in vitro*, with cytotoxicity correlating with its high antibody internalization efficiency in various cancer cell lines. Anti-tumor efficacy was demonstrated by a single intraperitoneal (*i.p.*) dose of MAb52-29.1-ADC at 4, 7, or 10 mg/kg using cell line-derived xenograft (CDX) mouse models of triple-negative breast cancer (TNBC), non-small cell lung cancer (NSCLC), gastric cancer (GC), and other tumor types, with subcutaneously inoculated tumors disappearing within 27~30 days after treatment. Preliminary toxicology studies indicated that MAb52-29.1-ADC did not raise any safety concerns. These findings support MAb52-29.1-ADC as a promising therapeutic candidate for treating solid and hematologic malignancies, and potentially mitigating toxicity concerns. Ongoing studies aiming to support further clinical investigation include MAb52-29.1-ADC in patient-derived xenograft (PDX) gastrointestinal (GI) cancer models, along with retrospective analyses of its target expression in clinical tumor samples.

#3168 Fully human anti-HER-2 antibodies to HER-2 domains distinct from trastuzumab as antibody drug conjugates for tumor growth inhibition.

Ginette Serrero[1], Jianping Dong[2], Jun Hayashi[3]

[1]A&G Pharmaceutical, Inc., Columbia, MD,[2]A&G Pharmaceutical, Columbia, MD,[3]Precision Antibody, A&G Pharmaceutical, Columbia, MD

HER2 is a receptor overexpressed in several cancers with prognostic and predictive implications as it is associated with shorter disease-free and overall survivals, resistance to hormonal agents and increased risk of brain metastasis. Trastuzumab is a humanized anti-HER2 neutralizing monoclonal antibody binding to domain IV of HER2 extracellular region. While first FDA approved as a naked antibody, it is at the basis of the development of several antibody drug conjugates bearing different linker and payloads such Ado-Trastuzumab-Emtansine (Kadcyla) and fam-trastuzumab-deruxtecan-nhki (Enhertu). Thus, it would be interesting to develop antibodies to different domains of Her2 which could be used as ADCs as an alternative or even potentiators of trastuzumab based ADCs. We are reporting here the development of fully human internalizing anti-Her2 antibodies that bind to HER2 domain distinct from domain IV, the trastuzumab binding site. These antibodies have been developed by immunizing humanized transgenic mice with recombinant Her2 protein. The screening process included inhibition of binding of trastuzumab to Her2 by enzyme linked immunoassay and by Octet epitope binning as well as internalization assay. Several internalizing antibodies not competing with trastuzumab and with high affinity (Kd ranging from 10^{-9} M to 10^{-12} M) were selected. Their applications as antibody drug conjugates were examined with several HER2 overexpressing breast and gastric cancer cells. Two trastuzumab noncompeting antibodies were further characterized for their ability to inhibit proliferation in vitro and in vivo in mouse xenografts studies and to potentiate trastuzumab effect. Our data also demonstrates that the use of fully human mice constitutes a powerful approach to develop fully human monoclonal antibodies against cancer targets allowing to by-pass the need for humanization and affinity maturation of antibodies.

#3169 Development of conformation selective ITGB6 ADC.

Xiaofei Zhou, Huijie Zhao, Liuge Gu, Guoping Jiang, Wenkai Zhao, Jiangbo Song, Teddy Yang, Ying Lei, Li Tong, **Fei Peng**

Hongcheng Biopharma, Shanghai, China

Integrin β6 (ITGB6), an epithelial receptor upregulated in fibrotic diseases and epithelial-derived cancers, drives tumor progression by regulating immunosuppression, therapeutic resistance, and metastatic processes. Conventional antibodies lack conformational specificity, often resulting in on-target, off-tumor toxicity. To address this, we developed HC029, a novel activation-state-selective anti-ITGB6 monoclonal antibody and antibody-drug conjugate (ADC) designed to specifically target disease-specific ITGB6 conformation while sparing physiological state ITGB6 unaffected. HC029 binds to a unique conformational epitope exposed on activated ITGB6, achieving 100-fold selectivity for disease-specific ITGB6. Binding affinity increases proportionally with disease severity, as demonstrated by enhanced HC029 ITGB6 engagement in the presence of cancer associated fibroblast (CAF) and latency-associated peptide (LAP) predominantly present in tumor microenvironment. HC029 demonstrated weak and partial inhibition on pathological ITGB6 signaling pathway while preserving physiological ITGB6 function. Furthermore, HC029 incorporates an Fc-silenced human IgG1 which further mitigates off target toxicity. HC029 conjugated with camptothecin derivatives (HC029-CPT) retains ITGB6 conformation-dependent binding, selectively kills cancer cells in the presence of CAF and LAP while sparing cells under physiological conditions. In vivo, HC029-CPT demonstrated potent antitumor activity across multiple PDX and CDX *in vivo* models including NSCLC, HNSCC, and BLCA, with no significant weight loss or severe toxicity observed. Exploratory pharmacokinetic and toxicology studies in non-human primate demonstrated that HC029-CPT has a maximum tolerated dose (MTD) exceeding 60 mg/kg, with no drug-related mortality observed. Comprehensive evaluations revealed no significant hematological, biochemical, coagulation, or histopathological abnormalities in potential target organs. HC029-CPT exhibited typical ADC pharmacokinetics in cynomolgus monkeys, with dose-proportional exposure of the intact ADC, total antibody, and payload. The linker-payload was highly stable in both *in vitro* and *in vivo* studies, with minimal payload release (<0.0001%) from the ADC in plasma. Combining ITGB6 disease state selectivity, unique conformational epitope, effector null Fc, extra stable linker payload and safety profile, HC029-CPT expects to achieve a much broader therapeutic window compared to conventional ITGB6 ADC targeting therapeutics.

#3170 Combination of CDK4/6 inhibitory and anti-hypoxia miRNA-6883 lipid nanoparticles with ferroptosis inducers or MEK inhibitors in preclinical breast and colorectal cancer models.

Connor Purcell[1], Leiqing Zhang[1], Maryam Ghandali[1], Shulan Holmes-Farley[1], Audrey Yimin Su[1], Anais Sidonia[1], Ameen Raissi[1], Mackenzie Barrette[1], Emile Youssef[2], Theresa M. Raimondo[1], Wafik S. El-Deiry[1]

[1]Brown University, Providence, RI,[2]SMURF Therpeutics, Providence, RI

Introduction

MicroRNA 6883-5p (miR-6883) inhibits cancer proliferation and hypoxia signaling by silencing the cyclin-dependent kinases CDK4/6, inducing downstream degradation of Hypoxia-Inducible Factor 1α (HIF1α). Prior work demonstrated that CDK4/6 inhibition (CDK4/6i) induces HIF1α degradation through a VHL-independent mechanism via the E3 ubiquitin ligase SMURF2. Notably, several preclinical studies have reported synergy between CDK4/6i and MEK inhibition (MEKi). Others have reported that CDK4/6i sensitizes cancer cells to ferroptosis inducing agents, though this observation is not unequivocally supported and may be context-dependent. Here, we investigate combinations of miR-6883 lipid nanoparticles (LNPs) with MEKi or ferroptosis inducers using in vitro assays and in vivo murine xenograft models.

Methods

A hypoxia response element (HRE)-driven reporter (Addgene #118706) was transduced into HCT116 colorectal carcinoma and SK-BR-3 HER2+ breast cancer (BC) cells. For in vivo experiments, 2 million HCT116-HRE cells were injected subcutaneously into nude mice and tumors ≥150mm3 were treated with 0, 1, or 10μg LNP-encapsulated miRNA. For viability assays, 4,000 cells/well were plated and allowed to adhere overnight. 48-72h after treatment, viability was assessed by CellTiter-Glo®. In vitro hypoxia experiments were conducted in a 0.5% O2 hypoxia workstation.

Results

As a single agent, miR-6883 LNPs significantly attenuated HIF signal in the HCT116-HRE xenograft model, with a 94.3% reduction in luminescence observed 3 days post-treatment with 1μg miR-6883 compared to baseline. Ki67 was significantly reduced with a 10μg dose, supporting the antiproliferative activity of miR-6883. In vitro, the SK-BR-3-HRE model demonstrated a significant reduction in HIF activity with miR-6883 treatment under 0.5% O_2, suggesting that the anti-hypoxia effect of miR-6883 extends to BC. In vitro viability assays were conducted in HCT116 (colorectal), SK-BR-3 (HER2+), MCF-7 (ER+), MDA-MB-231 (triple-negative), and MDA-MB-468 (triple-negative). Combination of small-molecule CDK4/6i and ferroptosis inducers (RSL3 or erastin) or MEKi (trametinib) revealed largely positive synergy scores. Accordingly, miR-6883 LNPs sensitized cells to doses of RSL3, erastin, or trametinib that were ineffective as monotherapies.

Conclusions

Our data support the anti-hypoxia and antiproliferative activity of miR-6883, and provide a basis for combination therapies with ferroptosis inducers or MEKi. Future experiments will employ BC xenografts and assess long-term tumor growth inhibition of combination therapies.

#3171 Multitargeted kinase inhibitor LCI139 overcomes chemotherapy resistance in patient-derived non small cell lung cancer organoids by harnessing intrinsic and extrinsic apoptosis.

Anna Ivanina Foureau[1], Nadeem Wajih[2], Cody C. McHale[3], Hailey L. Dryden[4], Sara Muhiczukic[2], Dhananjaya Pal[1], Bharath Yada[1], David Foureau[1], Fei Guo[1], Raj Dhupar[5], Donald Durden[1], Konstantinos Votanopoulos[4], Shay Soker[6], Eleftherios Markis[2], Kathryn Mileham[3]

[1]Atrium Health, Charlotte, NC,[2]Wake Forest Organoid Research Center, Wake Forest Institute of Regenerative Medicine, Wake Forest School of Medicine, Winston Salem, NC,[3]Levine Cancer Institute, Charlotte, NC,[4]Wake Forest University, Winston-Salem, NC,[5]Wake Forest Institute of Regenerative Medicine, Wake Forest School of Medicine, Winston Salem, NC,[6]Wake Forest Organoid Research Center, Wake Forest Institute of Regenerative Medicine,, Wake Forest School of Medicine, Winston Salem, NC

Introduction: In-silico designed multitarget inhibitor LCI139 (PI3K-CDK4/6-CDK9-AURKA/B) was engineered to overcome resistance inherent to single-target agents by simultaneously targeting tumor metabolism and inducing robust apoptosis. This compound demonstrated nanomolar potency against NSCLC in vitro. We evaluated efficacy in NSCLC cell lines and patient-derived tumor organoids (PTOs)—biofabricated spherical constructs recapitulating cellular matrix of native tumor tissue.
Methods: NSCLC cell lines (NCI-H1703, NCI-H1781) and PTOs generated from unsorted lung tumor suspensions in PEPGEL matrix (n=7) were utilized under IRB-approved protocol. Treatments included LCI139 (0.25-1μM), chemotherapeutics (carboplatin, gemcitabine, pemetrexed, cisplatin), and single-agent inhibitors: PI3K (Buparlisib), CDK4/6 (Ribociclib), CDK9 (AZD4573), AURKA (Barasertib), AURKB (Alisertib). Cell lines were co-treated with inhibitors of (carbenoxolone), Caspase (Casp)-8 (Z-IETD-FMK), Casp-9 (Z-LEHD-FMK), or AMPK activator (PF-06409577). Viability (propidium iodide, CellTiter-Glo), cell cycle (DNA dye) and apoptosis (Annexin-V/7-AAD, Casp-3/7/8/9 activity) were measured. Target inhibition was evaluated immunoblotting for pAkt, pRb, pRNA Pol II, MCL-1, pAMPK, pFOXO3, and p53.
Results: LCI139 achieved nanomolar IC_{50} against H1703 cells (48hr) and demonstrated dose-dependent PTO cytotoxicity: 49% reduction at 0.25μM, 62% at 0.5μM, 78.4% at 1μM (all $p<0.0001$). By comparison, 1 μM single-agent inhibitors reduced PTO viability by: AURKA (34%), AURKB (24%), PI3K (29%), CDK9 (50.9%) all $p<0.0001$; CDK4/6 (6.9%, $p=0.43$). LCI139 overcame significant carboplatin resistance (IC_{50}: 10.25-11.69μM) and outperformed standard chemotherapeutics: gemcitabine (29.2%), cisplatin (28.2%), pemetrexed (no activity). LCI139 activated caspases 8, 9, 3/7 in cells and PTOs. Selective Casp-8 or Casp-9 inhibition diminished but didn't abrogate cytotoxicity. Western blotting confirmed dose-dependent target inhibition: decreased pAKT, pRb, MCL-1, pRNAPol II, and p53 modulation. LCI139 induced metabolic stress via pAMPK-pFoxO3 activation. FoxO3 inhibition diminished LCI139 potency against sensitive H1703 cells. AMPK activation enhanced potency in p53-proficient H1703 and sensitized p53-deficient H1781 cells.
Conclusions: LCI139 demonstrates superior anti-tumor activity versus standard chemotherapeutics in resistant NSCLC through dual activation of intrinsic (cell cycle arrest-induced) and extrinsic (metabolic stress-induced) apoptotic pathways. Efficacy in both cell lines and PTOs validates this micro-physiological platform for drug development, supporting translational potential of multitargeted kinase inhibition for overcoming therapeutic resistance, as aligned with FDA guidance.

#3172 XYD-8006: A novel ADAM9-targeting dual-payload ADC demonstrates superior preclinical efficacy in gastrointestinal and lung cancer models.

Weng Hang Ho, Pengfei Rong, Mengrui Zhao, Jun Li, Xidong Zhang, Hui Ding, Fangxing Ouyang

FDC Biotech, Kunshan, China

Background: A Disintegrin And Metalloproteinase 9 (ADAM9) is a cell surface protease implicated in growth factor shedding, integrin binding, and cell migration, processes critical for tumor progression, metastasis, and neovascularization. Its overexpression is correlated with poor prognosis in multiple solid tumors, and overexpressed in GI and lung cancers but limited in normal tissues, highlighting its potential as a therapeutic target. While Antibody-Drug Conjugates (ADCs) represent a transformative oncology modality, single-payload ADCs face limitations including, tumor heterogenecity, the emergence of payload resistance such as DXD/SN38. To address this, we developed XYD-8006, a ADAM9-targeting ADC equipped with dual-payload platform designed to enhance efficacy and overcome tumor heterogenecity and DXD/SN38 resistance.
Methods: XYD-8006, a humanized anti-ADAM9 IgG1 monoclonal antibody conjugated with high hydrophilic linker to two distinct potent payloads: a microtubule inhibitor and a topoisomerase I inhibitor, with a controlled and specific Drug-to-Antibody Ratio (DAR). The molecule was evaluated for specificity, internalization efficiency, and in vitro/in vivo efficacy across a panel of ADAM9-high, -medium, and -low expressing tumor models.
Results: XYD-8006 exhibited high specificity for ADAM9 with no observed cross-reactivity to paralog family members and demonstrated superior internalization efficiency. In vitro and in vivo study showed, XYD-8006 induced potent, synergistic tumor cell killing, significantly outperforming single-payload ADC controls. Notably, it achieved robust tumor growth inhibition and regression not only in ADAM9-high models but also in models with medium and low ADAM9 expression. XYD-8006 exhibited potent ADAM9-targeted cytotoxicity and tumor suppression, with a favorable pharmacokinetic and safety profile.
Conclusion: XYD-8006 was designed to overcome key limitations of current ADC therapies. Its promising preclinical efficacy across gastrointestinal and lung cancers supports its further development, with an expected entry into clinical study in 2026.

#3173 XYD-295 and XYD-338: Novel hydrophilic site specific linker platform enables next generation dual payload ADCs with enhanced efficacy and safety.

Weng Hang HO[1], Pengfei Rong[1], Mengrui Zhao[1], Jun Li[1], Xidong Zhang[1], Hui Ding[1], Fangxing Ouyang[1], Jun Wang[2], Jiangcheng Xu[2], Yang Liu[2], Jiawang Liu[2], Kyoungwoo Lee[2]

[1]FDC Biotech, Kunshan, China,[2]Beijing Hanmi Pharm. Co., Ltd., Beijing, China

Background: The therapeutic potential of Antibody-Drug Conjugates (ADCs) is often limited by linker technology. Conventional hydrophobic linkers usually lead to ADC aggregation, rapid plasma clearance, and undesired cleavage in blood and normal tissues. We have developed a novel linker platform to overcome these challenges, enabling the construction of more stable, homogenous, and efficacious ADCs, including dual-payload formats.

Methods: Our ADC platform was designed to have: 1) High stability to minimize undesired payload release; 2) High hydrophilicity to improve solubility, and reduce the formation of aggregates; and 3) Efficient enzymatic cleavage and release of potent payload within the tumor. This linker was site-specifically conjugated to antibodies targeting diverse antigens (including DLL3, PD-L1, ADAM9, B7H3, EGFR, and cMET) and equipped with potent payloads such as microtubule inhibitor and a topoisomerase I inhibitor, individually or in dual-payload formats.

Results: ADCs generated with this novel linker demonstrated superior stability in plasma and significantly slower clearance rates compared with ADCs with conventional linkers. These improved pharmacokinetic profiles were translated into stronger anti-tumor efficacy in multiple animal models. XYD-295 with TOP1 inhibitor payload, XYD-338 with microtubule inhibitor payload and the dual-payload format, all showed enhanced and synergistic tumor killing in vitro and in vivo. Furthermore, this designed linker supported a higher drug load with reduced aggregation, and improved safety profile in preclinical studies, suggesting a higher therapeutic index. Several ADCs based on XYD-295, XYD-338 and the dual-payload format were expected entry into clinical study in 2026.

Conclusion: XYD-295 and XYD-338 facilitates the construction of more stable, homogenous, and efficacious ADCs, including dual-payload formats

#3174 Nuvisertib (TP-3654) and Dordaviprone (ONC201) synergize to reduce renal cell carcinoma cell viability.

Kimberly S. Meza[1], Sheldon L. Holder[2], Wafik S. Deiry[1]

[1]Legorreta Cancer Center, Brown University, Providence, RI,[2]Hematology/Oncology, Trinity Health Grand Rapids, Grand Rapids, MI

The Incidence of renal cell carcinoma (RCC) continues to increase in the United States, ranking among the ten most frequently diagnosed cancers in men and women. Unfortunately, resistance to existing treatments remain a major obstacle, driving the need for identification of clinically relevant biomarkers and therapeutic targets. TNF-related apoptosis inducing ligand (TRAIL) is a promising cancer therapy that selectively induces apoptosis in malignant cells while sparing normal cells. TRAIL exerts its cytotoxic effects through binding death receptors DR4 and DR5, initiating caspase dependent programmed cell death. However, intrinsic and acquired resistance mechanisms have limited TRAIL's efficacy as anti-cancer strategy. We have identified a link between the overexpression of oncogenic PIM kinases and regulation of DR5 expression and sensitivity to TRAIL apoptosis in RCC. PIM1 is emerging as a clinically relevant biomarker and therapeutic target in RCC. Nuvisertib (TP-3654) is a selective PIM1 kinase inhibitor currently being evaluated in Phase 1/2 clinical trials for patients with myelofibrosis and has received FDA fast track designation. We find that treatment of RCC cells with low dose (2.5 μM) of Nuvisertinib over 24 hours induces a 5.75-fold ($p<0.01$) increased mean membrane expression of DR5 compared to vehicle control assessed by flow cytometry. We also investigated synergism between Nuvisertib and Dordaviprone, a newly FDA approved imipridone and TRAIL inducer. We evaluated combinations of Nuvisertib and Dordaviprone via Cell Titer Glo in RCC cells and find that combination indices indicate synergism which significantly reduce RCC cell viability more potently than either agent alone. Our findings highlight actionable novel candidate targets and strategies for therapeutic intervention in RCC. Ongoing studies are aimed to uncover mechanistic insights of these treatments in RCC and guide the development of optimal treatment strategies.

#3175 Comparative efficacy of MUC1-C (XYA02) and MUC1-N (PankoMab, DS-3939a analog) antibody-drug conjugates in preclinical NSCLC.

Surender Kharbanda[1], Rehan Ahmad[1], Changchuin Mao[1], Sourav Choudhary[2], Brian Lawney[1], Govind Panchamoorthy[1], Ravi Jasuja[1]

[1]R&D, Xyone Therapeutics Inc., Canton, MA,[2]Birla Institute of Technology and Science, Hyderabad, India

Background: Aberrant glycosylation and elevated expression of MUC1 are common in non-small cell lung cancer (NSCLC), in which the two domains of the MUC1 heterodimer—MUC1-N, the shed extracellular subunit, and MUC1-C, the membrane-anchored oncogenic subunit—serve as therapeutically relevant yet biologically distinct targets. PankoMab-Dxd (DS-3939a analog) is an antibody-drug conjugate (ADC) directed against MUC1-N glycoepitopes, whereas XYA02 is a next-generation ADC targeting the transmembrane MUC1-C subunit that remains tumor anchored and is involved in numerous tumor survival signaling pathways. A direct comparison of these two targeting strategies reveals unique insights into the relative potency of drugs aimed at different MUC1 domains.
Methods: We assessed antigen density, internalization, in vitro cytotoxicity and in-vivo antitumor efficacy of NSCLC cell lines. ADCs (XYA02 and DS-3939a analog) were evaluated using proliferation assays, apoptosis induction, and in vivo tumor growth inhibition studies. Safety of XYA02 in nude mice was assessed by monitoring the body weight, CBC, hematologic parameters and vital organ histology.
Results: High-affinity binding of anti-MUC1-C monoclonal antibody (MAb)* was observed across multiple NSCLC cell lines endogenously expressing MUC1. At 4°C, robust cell-surface binding was detected, and shifting to 37°C resulted in efficient receptor internalization, consistent with productive ADC trafficking. Incubation of NSCLC cell lines with increasing concentrations of the MUC1-C-targeting ADC (XYA02) produced potent, dose-dependent cytotoxicity with low-nanomolar IC_{50} values. In contrast, treatment of the same models with a DS-3939a analog, which targets the shed MUC1-N subunit, resulted in markedly higher IC_{50} values.In vivo, XYA02 achieved durable tumor regressions in both NSCLC CDX and PDX models, whereas the DS-3939a analog produced variable responses. Both ADCs were well tolerated; however, XYA02 demonstrated a superior therapeutic index, with greater efficacy at comparable administered doses.
Conclusions: Our findings demonstrate that targeting the membrane-tethered MUC1-C subunit with XYA02 provides superior antitumor efficacy compared with MUC1-N-directed DS-3939a analog in preclinical NSCLC models. Enhanced efficacy appears to be driven by uniform antigen binding and potential avoidance of MUC1-N-mediated antigen sink effects. These data support prioritizing MUC1-C-selective ADCs for clinical development in NSCLC and other MUC1-driven malignancies.*

#3176 Tumor-selective regression through MUC16-guided DR5 (TNFRSF10B) clustering by the bispecific anti-MUC16×anti-DR5 antibody IMV-M™.

Iosif M. Gershteyn[1], Viktor Goldmakher[2]

[1]ImmuVia Inc., Cambridge, MA,[2]

Background

IMV-M, a bispecific anti-MUC16×anti-DR5 antibody, previously showed potent MUC16-selective antitumor activity *in vitro* and in xenograft models without requiring secondary crosslinking. In a pilot non-human-primate study, repeated 10 and 20 mg/kg dosing produced no detectable toxicity. Here, we demonstrate that IMV-M induces clustering of death receptor 5 (DR5; TNFRSF10B) through a novel MUC16-dependent mechanism: assembly of multiple IMV-M molecules on a single MUC16 molecule. IMV-M also lacked cytotoxicity toward hepatic cell lines.

Methods

Three bispecific antibodies sharing identical anti-DR5 arms were generated: Sofituzumab (h5A3)×Lexatumumab scFv, 11D10/DR5×Lexatumumab scFv, and (anti-fluorescein)×Lexatumumab scFv. Sofituzumab recognizes multiple tandem repeats within human MUC16, whereas 11D10 binds a single non-repetitive epitope. The anti-fluorescein construct, which does not bind human cells, served as a negative control. Binding to MUC16 was evaluated by (i) ELISA with shed MUC16 and (ii) flow cytometry using MUC16-positive cells. Cytotoxicity was assessed by CellTiter-Glo after 48h exposure.

Results

IMV-M bound shed MUC16 ≈11-fold and cell-surface MUC16 ≈8-fold more strongly than 11D10/DR5 at saturation, while apparent affinities were similar. Only IMV-M induced cytotoxicity in MUC16-positive PK-59 cells, demonstrating that MUC16-mediated clustering of DR5 is required for apoptosis. In hepatocyte-derived HepG2 and Hep3B cells ($MUC16^{-}/DR5^{+}$), IMV-M showed no cytotoxicity, whereas $MUC16^{+}/DR5^{+}$ OVCAR-3 cells were highly sensitive across all concentrations. Secondary crosslinking did not elicit killing in MUC16-negative cells. These findings indicate a low risk of off-target hepatic toxicity, consistent with the benign safety profile of earlier anti-DR5 antibodies.

Conclusions

Effective DR5 agonism by bispecific antibodies requires high-order receptor clustering. IMV-M achieves this through MUC16-mediated assembly of multiple antibody molecules on a single MUC16 molecule, enabling potent, tumor-selective apoptosis without hepatotoxicity.

#3177 JM.

Jeong-Yeon Mun[1], Chang Shu[1], Emily Hsia[2], Mike-Andrew Westhoff[3], Georg Karpel-Massler[4], Markus David Siegelin[1]

[1]Department of Pathology and Cell Biology, Columbia University Irving Medical Center, New York, NY,[2]The Cooper Union for the Advancement of Science and Art, New York, NY,[3]Department of Pediatrics and Adolescent Medicine, Ulm University Medical Center, Ulm, Germany,[4]Department of Neurosurgery, Ulm University Medical Center, Ulm, Germany

Background: Resistance to mitochondrial apoptosis contributes to treatment failure in IDH-wildtype glioblastoma (GBM). Cyclin-dependent kinase 12 (CDK12) regulates transcriptional programs that sustain tumor survival, but its role in apoptotic control is largely unclear.
Methods: CDK12 was inhibited in GBM patient-derived xenografts, stem-like cells, and established lines by genetic depletion or the small-molecule SR-4835. Bcl-xL was targeted using the BH3 mimetic ABT-263 (navitoclax). Viability, apoptosis, and mechanistic endpoints were assessed by combination index analysis, caspase activity, immunoblotting, and gene silencing.
Results: Co-treatment with SR-4835 and ABT-263 produced a synergistic loss of viability across GBM models (combination index <0.5), whereas either agent alone had minimal effects. This synergy was associated with enhanced cleavage of initiator and effector caspases and was fully rescued by the pan-caspase inhibitor zVAD-fmk, confirming caspase-dependent apoptosis. Mechanistically, CDK12 blockade downregulated the anti-apoptotic protein Mcl-1 and induced the pro-apoptotic BH3-only protein Noxa through activation of an ATF4-driven integrated stress response (ISR). Silencing ATF4 blunted SR-4835-induced Noxa expression, and Noxa knockdown significantly reduced apoptosis triggered by the combination, demonstrating its essential role in the response.
Conclusions: CDK12 inhibition activates an ISR-ATF4-Noxa signaling axis that lowers the apoptotic threshold and sensitizes GBM cells to Bcl-xL inhibition. Dual targeting of CDK12 and Bcl-xL represents a mechanistically defined strategy to overcome apoptosis resistance in GBM and may have broader therapeutic relevance across malignancies driven by Mcl-1-mediated survival.

#3178 Antifolate ADCs, a novel linker-drug platform for targeted therapy with a clear differentiating mechanism of action.

Ronald C. Elgersma, Renier C. Heijkants, Eline M. Loosveld, Noortje Veen, Chiel A. J. van der Horst, Iris van de Wetering, Arne J. Bramer, Erik Swiers, Tijl Huijbregts, Mike M. Ruth, Monique van der Vleuten, Gerard J. A. Rouwendal, Miranda M. C. Van der Lee, Benno Ingelse, Patrick H. Beusker, **Wim H. A. Dokter**

Byondis B.V., Nijmegen, Netherlands

Background: Clinical resistance to dominant ADC payloads - topoisomerase-I inhibitors and tubulin inhibitors - is increasing, underscoring the need for novel payloads with a differentiated mechanism of action (MoA). Methotrexate (MTX), a pioneering antifolate, revolutionized oncology and autoimmune disease treatment but suffers from poor tumor selectivity and systemic toxicity. Despite its clinical validation, MTX and related antifolates have not been successfully adapted into targeted therapies. Byondis revisited the class of antifolates and optimized these to a proprietary novel linker-drug platform currently in IND-enabling studies.
Results: Byondis developed a first-in-class antifolate linker-drug platform, featuring optimized payloads with a low- to sub-nanomolar potency and suitable for linker coupling. The resulting optimized payload demonstrates potent inhibition of dihydrofolate reductase (DHFR), *in vitro* cytotoxicity in a broad panel of cell lines, minimal affinity for resistance-associated transporters (BCRP, PGP), and favorable physicochemical properties allowing for the ongoing GMP-scale up of the linker-drug (LD) and good ADC manufacturability. The selected optimized linker contains a glucuronide moiety with the aim to improve the therapeutic index. The PhysChem properties of the LD demonstrates / ensures minimal impact on ADC hydrophobicity after conjugation and perfectly allows its use in a future dual payload approach. The Byondis' lead antifolate ADC is based on the novel antifolate LD platform. This antifolate ADC is based on a yet undisclosed tumor antigen targeting antibody. It shows strong *in vitro* cytotoxicity across a broad tumor cell-line panel and in a deruxtecan insensitive cell-line. Robust *in vivo* efficacy in NSCLC and HNSCC patient-derived xenograft models is demonstrated, with no significant toxicity at doses resulting in tumor regressions. The antifolate ADC delivers optimal pharmacokinetics and anti-tumor activity. GMP manufacturing of the linker-drug is underway.
Conclusions: The antifolate platform reintroduces a clinically validated MoA into the ADC landscape with enhanced selectivity, potency, and manufacturability. Its orthogonal MoA offers potential across different tumor types including an advantage in overcoming resistance to existing ADCs and supports sequential ADC therapy. With broad applicability across tumor types, antifolate-based ADCs are poised to address unmet clinical needs and are ready for clinical translation.

#3179 Rationale for the development of a differentiated Trop2 ADC in solid tumors of the bladder, lung, and breast.

Satyajit K. Mitra[1], Mastewal Abuhay[1], Mary Do[2]

[1]Akari Therapeutics, Tampa, FL,[2]Mercor, San Francisco, CA

Background: Trop2 is a transmembrane protein that is overexpressed in several solid tumor cancers and is a validated target. Trop2 ADCs are approved in TNBC, Her2- HR+ metastatic breast cancer, and 2nd line EGFR-mutated NSCLC in US, China, or Japan. PH1 is a unique immunomodulatory payload targeting the spliceosome and has been used as a platform to generate a Trop2 PH1 ADC and other pipeline ADCs with differentiated preclinical efficacy and safety profiles[1,2,3]. Following significant characterization and derisking of the Akari Trop2 ADC program, the clinical candidate, AKTX-101, is progressing for IND-enabling studies.

Results: Previously, a 75-cell line screen was performed and Trop2 PH1 ADC demonstrated single digit nanomolar (nM) IC50 potency in 8 solid tumor indications *in vitro*[2]. In follow-up experiments, AKTX-101 was tested alongside first-in-class approved Trop2 ADCs and compared with Standard-of-care targeted therapy in these models to identify an advantageous niche for the clinical development of AKTX-101 (Table 1). As AKTX-101 exhibited nM IC50 potency in all urothelial models tested (5/5), and since the PH1 payload is known to synergize with anti-PD-1, the ADC was tested plus/ minus checkpoint inhibitor in a syngeneic MB49 mouse model of urothelial cancer overexpressing human Trop2. Sequential dosing of ADC followed by mPD-1 demonstrated synergy whereas concomitant dosing was associated with additive anti-tumor efficacy.

Conclusion: Our results support the clinical development of AKTX-101 in bladder cancer and in other solid tumor niches. These niches will be explored further in planned translational studies.

#3180 ATL-024, a novel topoisomerase I-based ADC targeting the tumor-specific glycopepitope CA242 (CanAg), demonstrates potent activity in colorectal and pancreatic cancer models, and excellent safety profile.

Warren Viricel, Edouard Leroy

Antelope Therapeutics, Lyon, France

CA242 (also known as CanAg) is a tumor-associated carbohydrate antigen that is aberrantly expressed by gastrointestinal solid tumors but is virtually absent from normal tissue. In particular, this glycopepitope is highly expressed in colorectal, pancreatic and gastric tumors (high prevalence and elevated number of copies per tumor cell). Previous clinical trials in the early 2000s showed that CA242 can be safely targeted with an antibody-drug conjugate (ADC), as no significant CA242-related off-tumor toxicities were reported. The modest clinical benefit seen with microtubule inhibitor payloads indicates that alternative payloads, such as topoisomerase-I inhibitors, may enhance therapeutic outcomes in CA242-positive tumors.To exploit CA242 differential expression, we developed a novel CA242-targeting ADC called ATL-024, which is comprised of an anti-CA242 humanized Fc-silenced monoclonal antibody conjugated to the topoisomerase I inhibitor exatecan via a dipeptide cleavable linker. This ADC is a homogeneous construct with a drug-to-antibody ratio (DAR) of 4.ATL-024 demonstrated potent antitumor efficacy in multiple colorectal and pancreatic cancer PDX models showing homogeneous or heterogeneous CA242 expression patterns (as determined by IHC), being effective at doses as low as 3-6mg/kg. Compared to previous cantuzumab-DM4 based ADC (microtubule inhibitor payload), ATL-024 exhibits significantly stronger in vivo anti-tumor activity in colorectal PDX models.In a pilot toxicology study in cynomolgus monkeys, ATL-024 was well tolerated up to 80 mg/kg (Q3W), which was established as the highest non-severely toxic dose (HNSTD). At this dose, findings were limited to mild and reversible hematologic changes in one animal, with normal clinical chemistry parameters, no severe clinical signs and no observed organ toxicities. Pharmacokinetic profiling showed linear dose-dependent exposure and is consistent with systemic stability of the conjugate.Overall, the preclinical characterization of ATL-024 shows a very favorable therapeutic index and support human clinical evaluation for patients with CA242-expressing gastrointestinal tumors such as colorectal or pancreatic tumors. ATL-024 is currently undergoing IND-enabling development.

#3181 Mutant p53-specific TAZ/TEAD pathway dependency as a therapeutic opportunity for triple-negative breast cancer.

Lydia Sakala, Yining Zhang, Jin G. Park, Joshua LaBaer

Arizona State University, Tempe, AZ

Background: Missense mutations in the TP53 tumor suppressor gene lead to gain-of-function (GOF) properties that affect differently tumor growth, metastasis, and resistance to therapies, but targeting mutant p53 is still a major clinical challenge. Using MCF10A cells expressing 10 prevalent TP53 mutations, we performed integrated phenotypic and molecular analyses to identify targetable genes and pathways in Triple-Negative Breast Cancer (TNBC) harboring specific p53 mutations and discovered TAZ/TEAD dysregulation as the key determinants of cell invasion and drug resistance.
Methods: Based on our previous findings, we measured activation status of TEAD in drug-sensitive and resistant mutant p53-expressing cells and evaluated the differential drug response against single or combination treatment of the TEAD inhibitor GNE-7883 and the standard-of-care, doxorubicin. The TEAD activity was verified with a luciferase reporter, and cell viability was measured with phosphatase assays.
Results: The TEAD-luciferase reporter assay showed that p53 G245S and R273H mutants but not R175H or Y163C had elevated activity of the Hippo pathway effector, TEAD. Treatment of GNE-7883 robustly inhibited the hyper-activation of TEAD specifically in the G245S and R273H cells. In viability assays, these "TEAD-addicted" cells uniquely displayed sensitivity to high dose of GNE-7883 monotherapy (IC_{50} ~2.5 μM). Moreover, they also showed hypersensitivity to doxorubicin (IC_{50} = 14 nM), compared to the cells with wild-type p53 (IC_{50} = 250 nM). We were able to develop a synergistic, low-dose combination regimen (3.5 nM doxorubicin + 0.625-1.25 μM GNE-7883) that was cytotoxic for the cells with G245S and R273H mutants yet had minimal to no activity in the wild-type cells. In contrast, R175H and Y163C mutants were resistant to TEAD inhibition, requiring higher doses of GNE-7883 to observe an anti-cancer activity, emphasizing the selectivity of this vulnerability.
Conclusion: We have established a synthetic lethal interaction between TEAD inhibition for a defined chemo-sensitive subgroup of GOF p53 mutants, G245S and R273H, for which the Hippo/TEAD pathway states appear to be a key dependency. We propose a precision approach to therapeutic strategy of combining low, non-toxic dose doxorubicin with TEAD inhibition to increase efficacy while decreasing toxicity. Our ongoing work is to validate these findings in more physiologically relevant models.

#3182 The FLT3 inhibitor quizartinib suppresses the WT1-driven activation of the KIT-STAT5-PIM signaling pathway and induces apoptosis in FLT3-wild type HL-60 cells.

Background: WT1 (Wilms' tumor 1) is a key transcription factor regulating hematopoietic stem cell self-renewal and differentiation. In acute myeloid leukemia (AML), WT1 overexpression promotes leukemogenesis by blocking differentiation and conferring apoptosis resistance. Although several WT1 targets (*BCL2, c-MYC, IGF2, VEGF*) have been identified, its downstream mechanisms remain unclear. Interestingly, although parental HL-60 cells are FLT3-unmutated and resistant to the FLT3 inhibitor quizartinib, WT1-overexpressing HL-60 cells (HL-60/WT1) exhibited increased sensitivity, suggesting that WT1-induced KIT expression may mediate this effect.

Methods: HL-60/WT1 cells were generated via lentiviral transduction, resulting in a 7.5-fold increase in WT1 mRNA expression compared with parental HL-60 cells. To evaluate drug sensitivity, two complementary assays were employed: apoptosis was assessed after quizartinib treatment (700 nM, 48 h) using Annexin V/PI flow cytometry, while dose-dependent cytotoxicity was quantified by XTT assay following 72-hour exposure to graded concentrations of quizartinib. Expression of *KIT* was measured by RT-PCR, and RNA sequencing was performed to obtain transcriptome-wide profiles and fold-change-based comparisons across conditions, enabling identification of WT1-dependent signaling alterations.

Results: Cell growth was comparable between HL-60 and HL-60/WT1 cells (doubling times: 27.3 h and 23.9 h, respectively). HL-60 cells were unresponsive to quizartinib (IC_{50}, not reached), whereas HL-60/WT1 cells exhibited increased sensitivity (IC_{50} = 665 nM). RT-PCR confirmed KIT expression in HL-60/WT1 but not in parental cells, supporting WT1-driven activation of a *KIT*-mediated signaling pathway. Quizartinib markedly increased apoptosis in HL-60/WT1 cells (30.0 ± 10.1%) but not in parental HL-60 cells (7.0 ± 1.6%; Mann-Whitney U, $p < 0.05$). RNA-seq analysis using fold change revealed that WT1 overexpression increased the expression of KIT (1.2-fold), AKT1 (1.4-fold), STAT5A (5.0-fold), and PIM1 (6.2-fold). Notably, quizartinib treatment reduced these transcripts in HL-60/WT1 cells, indicating suppression of a WT1-induced, KIT-driven survival program independent of FLT3.

Conclusion: These findings demonstrate that WT1 overexpression establishes a previously unrecognized KIT-STAT5-PIM signaling pathway that promotes AML cell survival. Importantly, this pathway creates a therapeutically exploitable vulnerability: HL-60 cells that are normally resistant to quizartinib become sensitized through WT1-induced *KIT* activation. Our study provides mechanistic insight into WT1-mediated leukemogenesis and suggests that KIT-targeted strategies may be effective in subsets of WT1-high, FLT3-unmutated AML.

#3183 NEK7 overexpression contributes to stemness of hepatocellular carcinoma.

Hepatocellular carcinoma (HCC) is one of the cancers with the highest mortality rates worldwide, being the sixth most commonly diagnosed cancer globally and the third leading cause of cancer-related deaths. Growing evidence suggests that tumor initiation can be driven by a cancer stem cell (CSC) subset, which is responsible for tumor persistence, relapse, metastasis, chemo-resistance, and radio-resistance, establishing CSCs as important therapeutic targets. Identification and characterization of functional pathways and biomarkers associated with CSC biology will provide useful information for developing novel treatment strategies against HCC. NIMA Related Kinase 7 (NEK7) is a serine/threonine kinase that plays an important role in regulating gene transcription or protein expression of the NLRP3 inflammasome signaling pathway. We have observed that the expression level of NEK7 is significantly elevated in HCC tissues compared to surrounding normal tissues, therefore, we initially investigated whether NEK7 targeting could suppress HCC proliferation. As expected, siRNA silencing of NEK7 effectively inhibited the growth of HCC cell lines such as Huh7, HepG2, and PLC/PRF/5. Based on the previous report that the treatment of vitamin D suppressed stemness of $CD133^{+}/CD44^{+}$ CSCs by reducing NLRP3 expression in triple-negative breast cancer, we next determined to observe if targeting of NEK7 could suppress the metastatic potential of HCC as well. Inhibition of NEK7 expression reduced the abilities of migration, invasion, and sphere formation of both parental HCC cell populations (of Huh7, HepG2, and PLC/PRF/5) and $CD133^{+}$ liver CSCs (isolated from PLC/PRF/5). Our findings suggest that NEK7 contributes HCC stemness, indicating its potential as a therapeutic target for treating primary HCC and preventing metastasis and/or recurrence.

#3184 HMGB1 mediates chemoresistance and tumor progression in glioblastoma: Implications for targeted therapy.
